Preface

The *Handbook of Global Bioethics* is published at the right time for the progressive development of bioethics. Started as a discourse critical of medical professional ethics, the new discipline of bioethics emerged in the 1970s primarily in western countries. Concerns about the potential impacts of new scientific and technological advances were dominant. The main challenge was how to empower patients and citizens in light of the new diagnostic and therapeutic powers of medical practice and the sheer endless technological possibilities to improve health, eliminate disease, and extend life.

However, since the turn of the millennium, bioethics has entered a new, more expansive stage. Due to international cooperation, new information technologies, and transnational economic activities, bioethical issues have also been globalized. Bioethical challenges are now experienced in almost all countries. Yet the major questions facing global bioethics today are no longer related to the power of science and technology. Nowadays the most important bioethical questions are related to money and socio-economic conditions. Many people in a large number of countries do not even have access to the benefits of scientific and technological progress. They have treatable diseases but medication is not available. They need surgery but sanitary facilities are far away. They need medical care but cannot afford to pay. They cannot take care of their sick children because they have to work long hours away from home. They cannot properly feed themselves and their family. Thus the processes of globalization have called into existence a truly global bioethics, but at the same time the neoliberal market ideology has particularly created multiple new bioethical issues.

A landmark in the early stage of global bioethics was the Universal Declaration of Bioethics and Human Rights, adopted by all member states of UNESCO (United Nations Educational Scientific and Cultural Organization), in 2005. This political and legal document presents the first general framework of ethical principles for global bioethics that covers all cultures and countries. It has been used as the major reference document for this Handbook.

The Handbook aims to provide a geographic and systematic overview of global bioethics. Volumes 1 and 2 discuss many of the existing and emerging topics in the field. Volumes 3 and 4 present the current state of bioethics in a large variety of countries throughout the world. It is obvious that the Handbook can only give an early picture of the state of global bioethics, a discipline that will undoubtedly go

through a long process of maturation. Many issues will need to be more thoroughly addressed and new unexpected issues will arise. Therefore, this first edition of the Handbook will certainly need continuous updating. In this way it aims to orientate the reader in the ongoing developments within the new discipline of global bioethics.

A work of this magnitude could not have been accomplished without the support of many. First of all, we would like to thank our bioethics colleagues who were willing to spend time and intellectual effort in contributing. But we also thank all those who assisted in the development, reviewing, and processing of the content of this title. Particular thanks go to Aimee Zellers, Barbara Postol, and Jillian Walsh, graduate assistants, and Glory Smith, academic advisor in the Center for Healthcare Ethics in Pittsburgh.

About the Editors

Henk A. M. J. ten Have studied medicine and philosophy at Leiden University in Netherlands. He received his medical degree in 1976 from Leiden University and his philosophy degree in 1983. Dr. ten Have worked as a researcher in the Pathology Laboratory, University of Leiden (1976–1977), as a practising physician in the Municipal Health Services, City of Rotterdam (1978–1979), and as a Professor of Philosophy in the Faculty of Medicine and Faculty of Health Sciences, University of Limburg, Maastricht (1982–1991). From 1991 he was a Professor of Medical Ethics and the Director of the Department of Ethics, Philosophy, and History of Medicine in the University Medical Centre Nijmegen in Netherlands. In September 2003 Dr. ten Have joined UNESCO as Director of the Division of Ethics of Science and Technology. Since July 2010 he has been Director of the Center for Healthcare Ethics at Duquesne University in Pittsburgh, USA.

Dr. ten Have is involved in many public debates concerning palliative care, euthanasia, drug addiction, genetics, choices in health care, and resource allocation. His research has focused on ethical issues in end-of-life care. Dr. ten Have was the coordinator of the European Commission funded project, 'Palliative Care Ethics'. Over the last decade, he has been particularly involved in debates on global bioethics, emphasizing the need to create bioethics infrastructure (teaching programs, ethics committees, and legislation) in developing countries.

Dr. ten Have serves on numerous editorial boards. He is editor-in-chief of *Medicine*, *Health Care and Philosophy*. He was co-founder and secretary of the European Society for Philosophy of Medicine and Health Care. Dr. ten Have published *Medische Ethiek* (1998; 3rd revised edition 2009), a textbook for medical curricula (also translated in Lithuanian) used in most medical schools in Netherlands. His other books include *Palliative Care in Europe*. *Concepts and Policies* (IOS Press, Amsterdam, Netherlands, 2001), *Bioethics in a European Perspective* (Kluwer Academic Publishers, Dordrecht, Netherlands, 2001), *The Ethics of Palliative Care*: *European Perspectives* (Open University Press, Buckingham, UK, 2002), *Ethics and Alzheimer Disease* (Johns Hopkins University Press, Baltimore, 2004), and *Death and Medical Power*. *An Ethical Analysis of Dutch Euthanasia Practice* (Open University Press, 2005). In UNESCO Dr. ten Have has been involved in a wide range of international activities in bioethics, such as capacity building on the basis of the Universal Declaration of Bioethics and Human Rights, particularly the establishment of national bioethics committees and the promotion of ethics teaching (with a current priority for Africa and the Arab region). With UNESCO he published *Environmental Ethics and International Policy* (Paris, 2006), *Nanotechnologies*, *Ethics and Politics* (Paris, 2007), and *The UNESCO Universal Declaration on Bioethics and Human Rights*: *Background*, *Principles and Application* (Paris, 2009). In 2011, Dr. ten Have published as editor together with Ruth Chadwick and Eric Meslin *The Sage Handbook of Health Care Ethics*: *Core and Emerging Issues* (Sage Handbook Series, Sage, London). In the same year his book in Dutch, *Bioethiek zonder grenzen*: *Mondialisering van gezondheid*, *ethiek en wetenschap* (*Bioethics without Borders*: *Globalisation of Health*, *Ethics*, *and Science*), was published by Valkhof Pers in Nijmegen, Netherlands.

Dr. ten Have is a member of the Real Academia Nacional de Medicina (in Madrid, Spain) as well as of the Royal Dutch Academy of Science (in Amsterdam, Netherlands). From 2007 to 2010 he was an Honorary Research Professor in the School of Philosophy, University of Tasmania, Australia. In March 2008, Dr. ten Have was awarded the title of Doctor Honoris Causa by the Medical University of Pleven in Bulgaria. In September 2008 he received the Oscar M. Ruebhausen Visiting Professorship in the Department of Bioethics, Case Western Reserve University, in Cleveland, USA. In September 2008 Dr. ten Have was also awarded the Ethos Prize for Bioethics sponsored by Calouste Gulbenkian Foundation in Lisbon, Portugal.

Bert Gordijn is Professor and Director of the Institute of Ethics at Dublin City University in Ireland. He studied Philosophy and History in Utrecht, Strasbourg, and Freiburg in Breisgau. In 1995 Bert was awarded a doctorate in Philosophy from the Albert-Ludwigs-Universität Freiburg, followed by a doctorate in Bioethics from the Radboud University Nijmegen in 2003. He has been a Visiting Professor at Lancaster University (UK), Georgetown University (USA), the National University of Singapore, and the Fondation Brocher (Switzerland).

Bert has served on Advisory Panels and Expert Committees of the European Chemical Industry Council, the European Patent Organisation, the Irish Department of Health, and UNESCO. He is Secretary of the European Society for Philosophy of Medicine and Healthcare, and President-Elect of the International Association of Education in Ethics.

Bert is Editor-in-Chief of two book series—*The International Library of Ethics*, *Law and Technology* and *Advances in Global Bioethics*—as well as a peer reviewed journal, *Medicine*, *Health Care and Philosophy*, all published by Springer. His latest published books are *Biobanks and Tissue Research*: *The Public*, *the Patient and the Regulation*, published by Springer in 2011; *Scientific and Philosophical Perspectives in Neuroethics*, published by Cambridge University Press in 2010; and *Ethik in Klinik und Pflegeeinrichtung – ein Arbeitsbuch* (Third Edition) by Hermann Luchterhand Verlag in 2010. Bert's forthcoming books are *In Pursuit of NanoEthics* and *Disaster Bioethics*: *Normative Issues when Nothing is Normal*, both to be published by Springer.

Section I

Introduction

Global Bioethics

1

Henk A. M. J. ten Have and Bert Gordijn

Introduction

Bioethics is often regarded as a typically Western phenomenon. According to this view, its development began some forty plus years ago in North America and shortly later in Western Europe in response to emerging scientific and technological advances. It is strongly based on Western values and ethical principles. And, recently bioethics has been "exported to increasing numbers of developing countries" in an almost missionary effort to bring "salvation" to other parts of the world (Myser, 2011, p. xix). This view of today's bioethics is often advocated by anthropologists and sociologists interested in the cultural values and traditions of specific countries (De Vries & Rott, 2011). But it is also defended by some researchers, philosophers, and healthcare professionals in developing countries, arguing that Western bioethics has been imported in their countries without sufficiently taking into account the indigenous and traditional value systems (Chattopadhyay, 2011). This view on the development of bioethics will be called the "story of exportation." According to this story bioethics has originated in Western culture. It is nowadays being exported to other countries, thus imposing Western values on non-Western cultures in the process. Accordingly, bioethics is regarded as an exponent and promoter of "moral colonialism." Therefore, it is appropriate to talk about the "globalization of bioethics" or "globalizing bioethics" as a phenomenon that can be studied, analyzed, and explained as an interesting subject by anthropologists, sociologists, historians, and political scientists who pursue empirical studies and are interested in transformations of value systems, cultural and intellectual imperialism, and so forth. According to this view, any talk about "global bioethics" is suspect because it implies unsubstantiated claims of normative universality that basically amount to imperialistically exporting and

imposing a dominant Western ethics upon other approaches in ethics in other cultures and traditions.

This view on bioethics is closely related to a particular view on its origin, i.e., the "story of invention." This view centers around the claim that modern bioethics is in fact an American invention. In *The Birth of Bioethics*, bioethicist Albert Jonsen describes how bioethics emerged in the 1960s in the United States. Jonsen's historic sketch of the transformation of the old medical ethics into the new bioethics reflects his own story. Like many other early bioethicists he had been drawn from theological and philosophical backgrounds to the new ethical discourse around medicine, healthcare, life science, and medical technologies. Those pioneers have developed bioethics as a new discipline, crafting the theoretical framework and core notions and principles, as well as developing a public discourse, bringing ethical debate and reflection to hospitals wards, classrooms, courtrooms, and television studios. But first of all, this history demonstrates how bioethics was first born in the United States. Dan Callahan, another founding father of bioethics cited in Jonsen's history of bioethics, has said it this way: "Bioethics is a native grown American product" (Jonsen, 1998, p. 377). From this point of view, bioethics in other countries came only later; there simply was no bioethics prior to its American invention. Naturally this later development makes bioethics in other countries less relevant and interesting. Thus, in his 431 page book Jonsen touches on developments outside the USA in only one chapter, entitled "Bioethics – American and elsewhere" (29 pages). In this chapter actually not less than 5 pages are devoted to bioethics outside the USA.

Jonsen extensively elaborates on the question of why bioethics has, and perhaps only could have developed in his country. At first sight, there might be historical reasons: critique of medical paternalism, the citizen's rights movement, the emergence of new technologies, liberalism with its emphasis on individual freedom, and the market ideology. However, according to Jonsen, the real explanation for the invention of bioethics should be sought at a deeper level: the American ethos. In Jonsen's view, this is a way of thinking about ethics that is difficult to understand if one has not lived through the American experience. It is obvious that from the perspective of this interpretation of bioethics it is difficult to conceive of a genuine global bioethics. It can only imagine globalization of bioethics as an extension of the bioethics that has been invented in the USA. However, that extension is intrinsically somewhat difficult because bioethics is so tightly connected to the American ethos. Thus, in this perspective bioethics in other parts of the world is indeed the result of importing US values and adapting them to the idiosyncrasies of non-US countries.

Both the story of exportation and the story of invention are in fact two sides of the same coin. They articulate the outsider and insider views, respectively. More important is that they both lead to similar conclusions. Protagonists of both stories will primarily articulate the differences between forms of bioethics: Asian bioethics and European bioethics, and also Mediterranean bioethics, French bioethics, and perhaps even Burgundian bioethics. They will point out the enormous cultural diversity. In the perspective of diversity, bioethics will be focused on differences

rather than commonalities. Global bioethics in this perspective will primarily address different traditions, religions, and cultures but is less interested in the question what they have in common. They can hardly promote any universally shared values that might make sense of global bioethics. For believers in the story of exportation this would be offensive as, from their point of view, such a conception of global bioethics can only be driven by an agenda that advances Western values to the detriment of non-Western traditions. It disregards other cultures and lacks respect for cultural diversity. For believers in the story of invention promoting universal values is irrelevant and hardly interesting as an essentially US derived bioethics will have to be modified according to local and regional specifics of other cultures in order to be successfully incorporated elsewhere.

Thus, for believers of the stories of exportation and invention, global ethics as based on universal values is either undesirable or impossible: it is either abusive or futile. Bioethics must always have a local origin and a local field of application. It cannot overcome its specific, localized origin. It must always remain characterized by its local nature. Thus, both stories lead to the same conclusion. If bioethics is indeed a Western product it should not and, in fact, cannot be disseminated in other countries, at least not in an unaltered state. Nowadays nobody wants to be regarded as an imperialist and neocolonialist, certainly not bioethicists.

This Handbook of Global Bioethics will follow another approach. Surely, bioethics has an important origin in the West. That being said, however, more historic research may be required to sketch a complete picture of bioethics' origins. Whatever the precise historic origins of bioethics, currently, it has turned into a truly global phenomenon. It has significance around the world, because people are not merely European or Asian, but citizens of the world and members of a global moral community. Bioethics is important for everybody everywhere, not because it is imported or imposed, but because it provides a universal framework to interpret and manage the ongoing changes, in which currently all countries and cultures are involved. However, the interpretation and application of this framework must always be informed by local circumstances. Thus, present-day bioethics must be conceived as characterized by both its global nature as well as its local characteristics. On this view, local traits and origins as such do not preclude universal validity. Whatever one might find out through historical research about the precise origins of the ideas that slavery and racial discrimination are wrong, these finding are not going to have any influence on the universality of these norms. The origin of norms does not affect their universality or lack thereof.

The Coining of "Bioethics"

The word "bioethics" was introduced in the intellectual discourse in the early 1970s. Warren Reich (1994) concluded that it had a "bilocated" birth, the word being coined more or less at the same time by Van Rensselaer Potter in his publications and by Andre Hellegers in the initial name of the Kennedy Institute.

It is clear, however, that Potter had already used the term in a journal publication in autumn 1970, months before his book *Bioethics: Bridge to the Future* was published (Potter, 1971). The book again preceded the opening of the Kennedy Institute with a half year. The term "bioethics" became quickly adopted and widely used. In 1973, for example, Dan Callahan published "Bioethics as a discipline" (Callahan, 1973). In fact it was an ideal term to designate a new movement, away from the traditional medical ethics, and referring to an innovative discipline that was open for experts from a broad range of other disciplines. The recent claim that the term "bioethics" was in fact coined long before the emergence of bioethics as a discipline is interesting, because it embarrasses the view that bioethics is an American invention. The German pastor Fritz Jahr introduced the term "Bio-Ethik" in a publication in 1927 (Sass, 2008). His concept of bioethics is broad, based on respect for both human beings as well as other living organisms in the universe, similar to the respect for life advocated by his contemporary Albert Schweitzer. However, calling him the founder of bioethics is exaggerated. After all, his work had been largely forgotten and the term he used had no impact at all. But at least he is forerunner, indicating that a new idea always has a long history as Jahr himself acknowledged that his view was rooted in the ideas of others (Goldim, 2009).

Van Rensselaer Potter (1911–2001) worked for more than 50 years as Professor of Oncology at the McArdle Laboratory for Cancer Research at the University of Wisconsin in Madison in the USA. Potter was an enthusiastic scientific researcher. Oncology, for Potter was essentially interdisciplinary; it cannot merely focus on individual and medical perspectives. In explaining cancer, it is necessary to go beyond the level of individual persons and beyond the medical perspective, since cancer is often associated with life style and environmental influences. In the 1960s, Potter started to publish on issues outside his initial scope of cancer research, such as on the concept of human progress, the interrelation between science and society, and the role of the individual in modern society. These publications are included as chapters in his first book on bioethics (Potter, 1971). This broadening of scope was due to limitations of the range of research in which he was fully engaged; studying cell mutations only provides a limited view of the complex problem of cancer. Potter noted that progress had been made but he was also aware that the goal of eliminating cancer was far away. He argued that we must be content with "small victories" without expecting a breakthrough anytime soon. There will be some limited progress at the individual level (in terms of alleviation of suffering and improved treatment) but much more can be accomplished at the level of populations (in terms of prevention of cancer, for example, through restrictions on smoking).

However, Potter pointed out that his long-term preoccupation with cancer research prevented him from realizing that there were more important problems. He acknowledged that it took a long time before he started to look around and take interest in "the major problems of our time" (Potter, 1971, p. 150). Although Potter did not systematically discuss them, he listed the priority problems as: population, war, pollution, poverty, politics, and the negative side effects of progress. He regarded these problems as jeopardizing the survival of humankind, and their

urgency induced in him a growing concern regarding the future. What was necessary, therefore, according to Potter, was a new science of survival, a new discipline that he called "bioethics."

In an interview in 1992, Potter indicates that the word "bioethics" just came to him, like a Eureka feeling (Reich, 1994). Interestingly, Potter himself had previously analyzed the Eureka feeling (Potter, 1975). When a new idea, concept, insight, action plan, or experimental approach is formed subconsciously and then erupts into our consciousness, the result is called a Eureka feeling. This feeling has three properties: (a) suddenness: it cannot be willed and it is unpredictable whether or when it will occur; (b) euphoria: it is accompanied by a feeling of elation, which invites action; and (c) fallibility: it has the inherent possibility of error – the new idea may be useful and survive or may be erroneous and will disappear. On the basis of his consideration of these properties Potter developed ". . .the idea of humility with responsibility as the basic bioethic" (Potter, 1975, p. 2304). This basic bioethics is nowhere more appropriate than for oncologists because of the multidisciplinary character of oncological problems. However, it has a broader validity for scientist and professionals in general. Because there is always the possibility of error, one ought not to assume that one's own area of expertise will provide all the answers. In order to make recommendations for public policy, one should develop a realistic understanding of biological knowledge, trying to steer a course between optimistic and pessimistic evaluations so that the most feasible policy will result. It is also necessary to be continuously aware of the limitations of such knowledge since there are always built-in error tendencies.

A New Discipline

For Potter, "bioethics" was the name of a new discipline that would combine science and philosophy. The goal of this discipline would be wisdom. Already in his first publication on bioethics, he defined wisdom as "knowledge of how to use knowledge" for human survival and for improvement of the quality of life (Potter, 1970, p.127). The knowledge to be brought together was, on the one hand, biological knowledge or the science of living systems (hence "bio"), and on the other hand knowledge of human value systems (hence "ethics"). Wisdom is action-oriented; it is a guide for action. When there are competing possible policy decisions and when it is uncertain what to do or what has priority, biological knowledge must be combined with value judgments. In these circumstances, one can only proceed with humility. But at the same time cautiousness requires assessment mechanisms and feedback so that one learns from experiences. Bioethics is a science (the science of survival) because it is using the scientific approach of testing ideas, i.e., confronting them in peer groups, in experiments, and with what has been learned from previous investigation. Ideas should be tested and verified. They can no longer be based on introspection or logic alone. What is new in bioethics is the interdisciplinarity of this approach. We should cross the boundaries between disciplines in order to look for ideas "that are susceptible to objective verification

in terms of the future survival of man and improvement in the quality of life for future generations," as Potter formulates the mission of bioethics (Potter, 1970, p. 132).

Already in the opening sentence of the Preface of his first book on bioethics Potter emphasized that he wanted to contribute to the future of the human species. He observed that part of the reason why the future was in danger was that the two cultures of modern society, viz., the sciences and the humanities, were not communicating. This idea had already been developed by the British physicist and novelist Charles Percy Snow in his widely read and discussed lecture "The two cultures" (1959). According to Snow, a common culture had been lost in modern Western society. This had made it difficult to solve the problems people were facing especially with regard to the future. With his book Potter intended to give a reply to this challenge. The creation of the new discipline of bioethics could provide a bridge between the two cultures.

Bioethics on the Wrong Track

Potter himself was positively surprised how quickly the word "bioethics" was disseminated in the ethical but also public discourse. However, he also saw that it was used to demarcate the activities of ethics experts from the traditional discourse of medical ethics without incorporating a really new approach as he had advocated. He complained that, although using the word "bioethics" suggested innovation, the ethical practice remained business as usual. Already a few years after he introduced the term "bioethics," Potter began to make a distinction between "medical bioethics" and "environmental bioethics" (Potter, 1975). The first term signified the bioethics movement as it was rapidly developing since 1970 under the leadership of the Kennedy Institute at Georgetown University. The orientation of this movement was completely at odds with Potter's original conception of bioethics. As an "outgrowth of medical ethics," it was focused on medical issues and medical technology (Potter, 1988, p.1). First, it was primarily concerned with the perspective of patients: how can their lives be enhanced, maintained, and prolonged through the application of medical technologies? Second, it was exclusively interested in the short-term consequences of medical and technological interventions as well as the prolongation of our current individual existence. Third, it was unrelated to social, cultural, and political environmental determinants of human life. In contrast, "environmental bioethics" was characterized by a long-term view and a concern with the continued existence of the human species. In addition, it was developing without any connection to medicine and healthcare (Potter, 1988).

Potter conceded that medical bioethics had a somewhat broader approach than traditional medical ethics. It focused, for example, on new technologies, particularly in the field of reproductive medicine, which generated intricate ethical questions. But it was still too narrow to address what were, in his view, the basic and urgent ethical problems of humankind today, for example, environmental pollution, overpopulation, poverty, violence, and war. He regarded these problems as threats

to the survival of humankind, and their urgency induced a growing concern regarding the future. In order to adequately address these problems, according to Potter, a much broader vision was necessary. That is why he had initially introduced the new term "bioethics." But now that this term was used in the conventional medical way, it did no longer evoke the need for a broader and more inclusive approach. Because bioethics, as it did not go beyond the medical perspective, was not generating new perspectives and new syntheses, Potter wanted to reemphasize the concern for the future of the human species by qualifying the terminology. According to Potter, medical bioethics needed to be combined with ecological bioethics, and other forms of ethics related to human life such as agricultural ethics. All these approaches in bioethics should be merged in a new synthetic and interdisciplinary approach called "global bioethics" (Potter, 1988).

The Coining of "Global Bioethics"

In the second part of the 1980s, Potter started to use the new term: "global bioethics." It aimed at bringing together the different approaches in bioethics in a unified, broad approach (Potter, 1987). His ideas were published in 1988 in his second bioethics book: *Global bioethics – Building on the Leopold legacy* (Potter, 1988). In this book, he strongly emphasized the ecological perspective in bioethics, inspired by his former university colleague Aldo Leopold, an American pioneer in wildlife conservation. Leopold had suggested that there are three stages in the development of ethics. In the first stage, ethics concerns the relations between individuals, in the second stage it focuses on the relations between individual and society, and the third stage, which does not yet exist, ethics would deal with the relations of human beings with their environment, i.e., land, animals, and plants. Potter was convinced that the rise of global bioethics heralded the emergence of Leopold's third stage of ethics.

In connecting bioethics with a global perspective Potter was in fact using ideas of Pierre Teilhard de Chardin (1881–1955), French Jesuit philosopher, geologist, and palaeontologist. In his early publications, Potter made references to Teilhard's work, explaining that he started to study his philosophy in 1964. He also published an article exclusively focused on Teilhard (Potter, 1968), which was later included in his 1971 monograph.

Teilhard anticipated what nowadays is called "globalisation." One of his main ideas was that humanity will develop into a global community. Teilhard devoted his life to reflection on the place of human beings in the universe and the grand scheme of evolution. Due to processes of "planetary compression" (intensified communication, travel, exchanges through economic networks) and "psychic interpenetration" (increased interconnectedness and a growing sense of universal solidarity) humankind will be involved in an irresistible process of unification, according to Teilhard de Chardin (2004). The emergence of a global community will occur, or so Teilhard argues, not because human beings will accept one single truth or will desire one single thing, but because they increasingly recognize their interdependency and their

common destiny. Shortly after the Second World War Teilhard wrote that even incidental recurrences of racism and nationalism lack importance in the overall process of cultural and social evolution of the planet; they are disastrous for individuals but compel us sooner or later to come together on the basis of human solidarity. This is what he has called the "planetization of Mankind" (Teilhard de Chardin, 2004, p. 108).

The challenge for Teilhard is to outline a new vision of the world that emerges from the accomplishments of science and that takes into account the role of human beings. For Teilhard the notion of evolution is the starting-point for such an endeavor. This notion is no longer only relevant for biology but it can clarify all dimensions of the human condition: matter, life, and mind. Furthermore, evolution is an ongoing process. It progresses through humankind, not in the sense that there will be a new biological species of super-humans but in that it creates more complexity and consciousness among human beings, an "ultra-human" phase. In Teilhard's view, humanity was becoming more unified, more interdependent, and increasingly cooperative. Humankind would evolve into a coherent whole, a cosmopolitan community. Nowadays, human beings have significant means at their disposal to facilitate communication, distances can be easily overcome, and borders between nations are becoming futile. As a result it has never been so easy to get to know other people. Growing unification within complex diversities and an increasing feeling of solidarity between human beings are stages in the process of evolution that will lead to a moral community of citizens of the world. The world population is growing while the surface of the earth remains the same; therefore, people are obliged to cooperate even more intensely: "We can progress only by uniting" (Teilhard de Chardin, 2004, p. 66).

Potter recognized that Teilhard, like him, was interested in the problem of human progress and the survival of humankind. They share the view that human progress is the goal of the universe, that we should try to bring about the best possible future and that the best way to do this is to combine the science of biology with human values. Given these concurring views it is remarkable that in Potter's first bioethics book there is no explicit mentioning either of the global scope of problems or the global nature of the search of solutions, the more so since the need for a global perspective in ethics had also been emphasized by Leopold. However, it is obvious that the global dimension had always been implicitly assumed by Potter. Bioethics' basic problems such as overpopulation and poverty are necessarily affecting the whole of humankind. Bioethics' goal of survival is global since what is at stake is the survival of humanity. Bioethics' methods are global in the sense that they combine all available intellectual resources for long-term approaches. Global bioethics in the vision of Potter unites two meanings of the word "global" (Potter, 1988). First, it is a system of ethics that is worldwide in scope. Second, it is unified and comprehensive.

Global Bioethics Today

Nowadays, Potter's vision remains in full force. Global bioethics is truly worldwide in that it goes beyond international bioethics. It is not merely a matter of crossing

borders, but it concerns the planet as a whole. Bioethical discourse is not limited to transnational territories (e.g., the European Union) but has become supra-territorial. Bioethics nowadays is relevant to all countries and takes into account the concerns of all human beings wherever they are. While bioethics may have primarily originated in Western countries, its reach and relevance are now planetary. On the one hand, the traditional issues of bioethics are confronted with new challenges. With the introduction of clinical trials in developing countries the concept of informed consent is confronted with different cultural traditions in which individual decision making is an unusual concept. On the other hand, the existence of global markets has created new problems such as organ trade, medical tourism, corruption, and bioterrorism. Even if such problems exist only in few countries, the way they are addressed will have consequences for other countries. Usually the transactions and interconnections between developed and developing countries can either exacerbate or diminish the impact of such problems on society and culture. Often national legislation or regulation will not be sufficient but international cooperation and action will be required. Problems like pandemics, malnutrition, hunger, and climate change require coordinated global policies and actions. Even if the moral values in specific countries and regions differ, a common ground has to be found as a world community.

Potter's second meaning of "global" refers to bioethics as more encompassing and comprehensive, combining traditional professional (medical and nursing) ethics with ecological concerns and the larger problems of society. This implies more than simply declaring that today's problems are global and affect everyone. First, it requires interdisciplinary cooperation. Global problems as poverty, climate change, and inequities in healthcare can only be addressed by obtaining and applying different types of knowledge. It is unavoidable to bridge the gap between science and humanities. Secondly, it requires that diverse perspectives must be used to explain and understand complex phenomena. Global problems can no longer be approached only from an exclusively Western or Eastern perspective. Healthcare will not be improved by simply importing and applying Western medication; we need to understand the existing value systems. Various methods and theories will therefore be used in global bioethics. It also needs input from empirical studies as well as philosophical analysis.

A Transcultural Moral Framework?

Both characteristics of global bioethics will probably not be disputed: bioethics has become worldwide and comprehensive. It has an interdisciplinary approach and applies a mixture of methods. Also, there are many new ethical issues on the agenda. Controversial, however, are the following questions: should global bioethics advance a transcultural framework of ethical values and principles? Are there any global values and principles in the sense that they are commonly shared among all human beings?

Warren Reich has pointed out that global bioethics utilizes a "comprehensive vision of methods" (Reich, 1995, p. 24). The global perspective of bioethics is not

a matter of geographical expansion, but rather, it refers to phenomena that have a global dimension – i.e., they are no longer dependent on the specifics of a particular culture or society – and that require global answers and remedies. Of course, this is not the same as arguing that there is an international set of fundamental values that is used everywhere. That we have similar bioethical problems in different countries does not imply that we follow the same ethical approach everywhere. The global dimension, however, invites us to rethink our usual approaches and ethical frameworks that are often connected to domestic values. It makes us aware of the "locality" of our own moral views, while challenging us to search for moral views that will be shared globally. As a result bioethics is increasingly connected with international law, particularly human rights law, which has a similar global vision.

Universal ethical theories that can transcend cultural differences are looked upon with suspicion. They incite some colleagues in developing countries to breathe new life into the "story of exportation" and advance accusations of "moral neo-colonialism." Other bioethicists doubt whether universal theories can ever do justice to cultural diversity (Verkerk & Lindemann, 2011; Widdows, 2007). Of course, there should be a theoretical debate about the question of whether a common framework of values and principles is possible or desirable as a basis for global bioethics. Apart from this debate, however, we are witnessing the fast development of global bioethics as an exponent of globalization. Globalization refers to a movement toward greater interdependence and integration, or "planetization" in the words of Teilhard.

Since the globalization of bioethics is only one component of a more encompassing process, it would be wrong to suggest that bioethics became globalized as an independent entity. The ongoing globalization of bioethics is inextricably bound up with the ceaseless globalization of medical research and healthcare. As soon as humanitarian aid programs are introduced or international clinical trials undertaken bioethical discourse automatically appears as well. This does not mean that a global bioethics is "imposed." After all, any international or global moral framework that is introduced in a new local context usually immediately engages with the ethical discourse at local level. This observation follows from current globalization studies demonstrating that there is a dialectics between global and local (see, e.g., Kirby, 2006). Many local events are shaped by events far away, while global events are often influenced by the local context and conditions. Globalization, therefore, is not simply a process in which one global culture gets to dominate local cultures. There is no antithesis between the global and the local. In contrast, they increasingly seem to gain access to each other. Instead of generating oppression of the local sphere, the emergence of a global space for moral frameworks and ethical discourse has created opportunities for local cultures to find universal expression. Many indigenous groups, for example, disadvantaged within their own countries, have been able to reframe their position with an appeal to human rights on a global platform (Kearney, 1995). The idea that global bioethics is a "colonizing" force does not take into account the interaction between global and local. In addition, it underestimates the power of existing local value systems.

This interpretation of global bioethics therefore depends on how we view globalization. If globalization is considered as an irresistible process that "reshapes, mutilates, and overturns the local," we would indeed be subject to external forces, hard to identify and control, and making our cultures homogeneous and transforming our specific identities and values. Globalization would therefore be primarily passively endured (Burawoy, 2001). In this view, global bioethics would present values and principles as "universal" in order to dominate local value systems.

In contrast, if one takes the dialectics of global and local levels seriously, much of globalization is "globalization from below." In this view, everybody takes part in globalization: "What we understand to be "global" is itself constituted within the local" (Burawoy, 2001, p. 150). Globalization is therefore not only experienced passively but in many cases actively produced by groups of citizens, agencies, and institutions at the local level. In this view, global bioethics does not refer to ethical values and principles that are transcending various cultures or are imposed on them from outside, but global values are produced in interactions with local value systems. The global ethical framework is emanating from the fast growing manifold interconnections between people worldwide.

Universal Principles and Local Traditions

In the debate on globalization of ethics, Kymlicka (2007) has suggested that global ethics is a two-level phenomenon: at one level there is a self-standing international human rights discourse defining a minimum set of standards agreeable to all. At a second level, there is a multiplicity of different ethical traditions. These "local" traditions define what is ethically required beyond and above human rights. The same distinction can be used for global bioethics. On the one hand, there is a set of minimum standards on which traditions and cultures agree; this is expressed in international human rights language and elaborated into specific bioethics principles. On the other hand, there are many efforts to articulate more specific bioethics standards in the context of specific religious and cultural traditions. Members of these traditions also bring their views in the global debate through constructive dialogues and sometimes negotiations, so that the dialectic of global and local also helps to construct and produce global bioethics. Thus, the universal principles of global bioethics are the result of continuous and multilateral articulation, deliberation, and production.

The way in which a shared global bioethical discourse can be established is demonstrated, for example, in the activities of the Parliament of the World's Religions. In 1993, approximately 200 leaders from more than 40 religious and spiritual traditions signed the statement "Toward a Global Ethics." This statement drafted by German theologian Hans Küng, declares that all traditions share common values such as respect for life, solidarity, tolerance, and equal rights (Küng, 1997). The document emphasizes that it is important to show what world religions have in common rather than to point out how they differ. Another example

is the Universal Declaration on Bioethics and Human Rights adopted by UNESCO member states in 2005 (Ten Have, Henk & Jean, 2009). The request to develop a common framework of ethical principles was explicitly made by developing countries. They were afraid that with the rapid evolution and globalization of medical science and research they would insufficiently benefit from the advances and suffer too many harms and risks. A major concern was that international medical research and healthcare endeavors would proceed along double standards so that people in developing countries would receive substandard care and be involved in clinical trials without the ethical protection that exists in developed countries. This call from developing countries to develop a global normative framework demonstrates that global bioethics principles are not necessarily imposed by rich and powerful countries on the rest of the world. Their development might very well be triggered and driven by less powerful countries instead. The 191 member states negotiated 2 years to reach consensus on the text of the Declaration. Many activities took place in very different countries. Expert conferences have been organized in countries such as Lithuania, Turkey, Indonesia, and Argentina. Regional conferences were convened on Latin America, the Arab region, and Africa. Experts from many countries filled out questionnaires or wrote commentaries and suggestions (Ten Have, Henk & Jean, 2009). Some issues remained highly contested. For example, it turned out to be impossible to reach consensus on certain specific ethical issues as abortion, euthanasia and stem cell research consensus. The solution was found with the above mentioned two-level approach. In the end official representatives of states but also of cultures, traditions, and religions could agree on 15 ethical principles of global bioethics. These principles include the four principles of Beauchamp and Childress but also other principles that seemed to play a more significant role in non-Western countries, such as solidarity, social responsibility, and benefit sharing.

One of the principles is that of respect for cultural diversity. This is the only principle that can never overrule any of the other principles. In other words: a healthcare practice that is violating human dignity can never be justified by referring to the principle of respect for cultural diversity. Let us clarify this by focusing on the debate about informed consent. Although there is wide consensus that informed consent is a fundamental principle, it is also argued that in different cultures informed consent takes shape in different ways. For example, in many African countries, a communitarian approach underlines the importance of the group or tribe. Thus, in healthcare and research decisions a group discusses the issue and the community leader takes the lead in decision making. In many Arab countries the head of the family tends to be crucial, and husbands are used to take important decisions rather than their wives. Nonetheless, the principle of informed consent requires that in the end the concerned individual needs to provide informed consent whatever the specific cultural context. According to the Declaration nobody is allowed to violate the principle of informed consent on the basis of the principle of respect for cultural diversity. However, differences can occur in the application of informed consent in specific contexts where "local" values and norms play a major role. For example, informed consent in North America requires

a lot of bureaucracy. Patients have to sign extensive documentation, while in certain other countries, specifically in the Arab region and Africa, a word is a word, and asking a signature a sign of distrust.

A Global Moral Community

The establishment of a global bioethical framework marks the beginning of a "global moral community." This is also demonstrated in debates on the new principle of protecting future generations and on intergenerational justice. The UNESCO Declaration on the Responsibilities of the Present Generations toward Future Generations (UNESCO, 1997) connects our responsibilities to posterity with the need to ensure the future existence of humankind. These are the same concerns as those advocated in Potter's conception of global bioethics. The notion of the global moral community is furthermore introduced in global bioethics through the principle of benefit sharing. This novel principle is important in the context of bioprospecting, i.e., the search and collection of natural substances that might be used for the development of new drugs. Natural resources are abundantly available in developing countries with rich biodiversity such as Brazil and Indonesia. In many developing countries, traditional medicine is based on such natural resources. These resources and the traditional knowledge of indigenous populations are increasingly being appropriated ("biopiracy") by Western companies to fabricate new profitable drugs without any compensation to the indigenous communities. Against this backdrop the principle of benefit sharing has been advanced in order to counteract this injustice.

These new debates in fact refer to a more fundamental discourse around the notions of "global community" and "world moral community." In this discourse, two interrelated claims are now gaining ground (Agius, 2005). One claim states that the global community includes not only human beings but the totality of biological nature, broadening up the traditional concept of community so as to include nonhuman species as well. After all, we all share dependency and vulnerability. In fact, this is Potter's view. He argues that ethics should extend the idea of community from human community to a community that includes soils, waters, plants, and animals. Humankind coexists with ecosystems; together they constitute the "entire biological community" (Potter, 1988, p. 78). The second claim is that the earth is not the possession of one particular generation; each generation inherits it and should not bequeath it in an irreversibly damaged state to future generations. Because of the interdependence of human life and the fragility of our planet, we need a new vision of community that encompasses past, present, and future generations.

Apart from its members, who are increasingly connected and related due to processes of globalization, the global moral community contains content as well: global values and responsibilities as well as global traditions and institutions. An example is the concept of the "common heritage of humankind." Introduced in international law in the late 1960s to regulate common material resources, such as

the ocean bed and outer space, the concept was expanded in the 1970s to include cultural heritage. This has led to the construction of a new global geography of symbols indicating that humanity itself can be regarded as a community. Cultural heritage is no longer only representative of a particular culture but of human culture in general. Labeling some cultural products as a world heritage produces a global grammar, in which diverse and local phenomena receive a universal significance and require global management. Such heritage is the expression of human identity at a global level. It is part of the quest of citizens of the world. It becomes an indicator of world culture. Regarding and categorizing cultural property as world heritage implies a global civilization project that seeks to create a new global community representing humanity as a whole, enable the identification of world citizens, and evoke a sense of global solidarity and responsibility. This process of creating the global community as a moral community was further promoted through the application of the concept of "common heritage" in global bioethics, first in the late 1990s in the field of genetics and promoted by researchers in genetics, followed in the 2000s by the adoption of Universal Declaration on Bioethics and Human Rights by almost all countries in the world (Ten Have, Henk & Jean, 2009). With such a universal framework global bioethics can now claim to represent a global geography of moral values, closely associated to universal human rights discourse. It enables humanity itself to be regarded as a moral community. It implies that citizens of high-income countries can no longer be indifferent to obscure clinical research practices or organ trade in low-income countries, since the same moral values and standards apply within the global community, although the application of principles is always modified according to local circumstances and local communities. Membership in the global community furthermore draws on a growing number of global institutions and movements (e.g., Doctors without Borders, Oxfam, fair trade, UNESCO). Thus, we are witnessing the rise of a global community of shared values. These values are the product of intensive and continuous negotiation, deliberation, and dialogue. They are reflected in a universal framework of ethical principles that will continuously be challenged, interpreted, and coproduced in local settings influenced by specific religions and cultural traditions. The dialectics between the universal and local normative frameworks will enrich and reinforce global bioethics.

Conclusion

This chapter has presented and criticized "the story of exportation" and "the story of invention," which regard global ethics as either undesirable or as futile. Instead, a more favorable and optimistic account of global bioethics has been advanced. Against the backdrop of Potter's original conception of global bioethics and along the lines of Kymlicka's conception of global ethics an account of global bioethics as a two-level phenomenon has been presented. On an abstract level, there is a set of minimum standards, on which different traditions and cultures agree. On a more contextualized level, there are efforts to articulate more specific bioethics standards in

the context of specific religious and cultural traditions. In addition, local specifics of cultures and traditions are important for the interpretation and application of universal standards. The two levels are interacting along bottom up and top down lines of communication. Global platforms and local contexts mutually help each other to construct and produce global bioethics. Thus, global bioethics is the result of continuous and multilateral articulation, deliberation, and production. It is both a herald and a witness of the rise of a global community of shared values, as revealed in this Handbook.

History of Global Bioethics

2

Diego Gracia

Introduction

Globalization is a new term coined to express one of the most outstanding characteristics of human life in the end of the twentieth century and the beginning of the twenty-first. For the first time in the history of mankind, people are aware and know what is happening all over the world, no matter the distance or the differences of any kind. This phenomenon has been the consequence of the progress in telecommunications and the new capacity of managing and exchanging information through the world, due to new computer technology. This first technological and informational globalization made possible another one in the fields of economy and finances. The problems arising in many countries in the wake of the economic crisis that began in 2007 made many people aware of the need, going ahead in this process, to look for new ways of globalizing politics. This was also the moment in which the necessity of focusing on moral problems with a global perspective became evident. New terms, like "global ethic" and "global bioethics," appeared. These are not only new and specific fields of analysis and debate, but questions that affect the core of ethics, making it necessary to rethink and reconstruct the entire discipline.

Globalization, A Linguistic Novelty

"Globalization" is a new term. It proceeds from *globus*, the Latin translation of the Greek word *sphaîra*, round body, ball, sphere, or globe. The word was frequently used by scientists and in philosophical writings in antiquity, but without any moral connotation. On the contrary, the word *kósmos*, whose primary meaning was "order," and also "world order" or "universe," acquired in late antiquity the meaning of the realm of sin and death, as opposed to the spiritual kingdom of holiness and life (John. 12:31; 14:30; 17:9,16; 18:36. Eph. 2:2; 6:12.

DOI 10.1007/978-94-007-2512-6_64,

New International Version). This moral meaning was even more evident in the words *mundanus*, mundane, and *mundanitas*, which in Medieval Latin meant *vanitas*, vanity, or *mundi amor*, mundane or worldly love. This negative moral meaning came to Western languages, giving in English the word "worldly," secular, sophisticated, or not spiritual. This is perhaps the reason why it was necessary to coin a new word with a more descriptive and positive meaning, deriving it from "globe" and not from "world"; the result being the term *global*. This word was frequently used in classical English. But the abstract noun *globalization* is new in the English language. It appeared for the first time in the third decade of the twentieth century, and it began to be generally used during the 1960s and 1970s. From English, it entered into other languages as *Globalisierung*, *globalisation*, *globalización*, etc. The French language has also the word *mondialisation*, and the same happens in Spanish, *mundialización*. In any case, the word globalization has today a specific meaning, different from that of *mondialisation* or *mundialización*. This meaning, completely new, appeared during the last decades, as a consequence of some important changes happened in science and technology, and also in the political and economic life of the societies.

The Global Village

The possibility of knowing in "real time" the things happening in other territories or on different continents has been remote during the major part of the human history. Only recently, due to the development of telecommunication, has the entire world become an integrated electronic network in which everyone is connected with all others. Human beings are now interconnected in a web of interdependency with changes and developments on one side of the world affecting the other. This revolutionary phenomenon was called by Marshall McLuhan "the global village." For the first time in history, the world has become one big village, in which all things are present and inextricably interconnected. McLuhan remembered that George Washington, two centuries ago, once remarked, "We haven't heard from Benjamin Franklin in Paris this year. We should write him a letter" (McLuhan & Powers, 1989, 80). In the information era, he stresses, the "real" world of things has been substituted by another that is "virtual," the world of information.

Globalization of Economy

The first globalization, prompted by the development of telecommunications, opened the door to other types that are more subtle. The second has happened in the field of economics and finance, with the integration of national economies into international or global ones, through trade, foreign direct investment, and capital flows. After World War II, Western politicians adopted Keynesianism as the way of building the new welfare state. It reigned, especially in Europe, until the crisis

of 1973. This crisis was interpreted by many as the death knell of the welfare state. As an alternative, many returned to the theories of the neoclassical school, lead in this movement by the economists of the Chicago school, based on monetarism, economic liberalism, little government intervention, and free markets. These ideas were implemented by politicians during the 1980s, when Margaret Thatcher (UK prime minister, 1979–1990) and Ronald Reagan (US president, 1981–1989) came to power. They also became the core principles of the main economic international agencies located in Washington (the International Monetary Fund, the World Bank, and the US Treasury Department) during the 1990s. After 1989, this economic ideology became generally known as the "Washington Consensus," an expression coined by John Williamson, an economist from the Institute for International Economics based in Washington. As a consequence, the General Agreement on Tariffs and Trade (GATT), and its successor, the World Trade Organization (WTO), promoted international agreements in order to lower the barriers to international free trade, facilitating the flow of goods, capital, services, and labor. Thus, the entire world has become, for the first time in history, a global free market.

This second process of globalization has also had a negative side. The economic collapse of the years 2007–2012 has generally been interpreted as the consequence of the drastic distinction by the neoclassical school between economy as a science and applied economy, in an attempt to make of Economics a value-free science, centered only on the so-called economic "facts," without any "value" compromise. Milton Friedman said in 1970 that the only social responsibility of business is to increase its profits; profit is the sole value to be taken into account. This oversimplification is seen as one the causes of the economic crisis, interpreted by many as a crisis of values (i.e., a moral crisis).

Today, it seems evident that in trying to be value-free, economics chose a value option, perhaps one that was not the most beneficial. There is no possibility of making human decisions without values. In avoiding value questions, economists transmitted to the public opinion the wrong idea that there is only one important value, the economic one – profit. This is what George Soros calls "market fundamentalism," most frequently seen during the last decades in Western countries. "The functions that cannot and should not be governed purely by market forces include many of the most important things in human life, ranging from moral values to family relationships to aesthetic and intellectual achievements. Yet market fundamentalism is constantly attempting to extend its sway into these regions, in a form of ideological imperialism. According to market fundamentalism, all social activities and human interactions should be looked at as transactional, contract-based relationships and valued in terms of a single common denominator, money. Activities should be regulated, as far as possible, by nothing more intrusive than the invisible hand of profit-maximizing competition. The incursions of market ideology into fields far outside business and economics are having destructive and demoralizing social effects. But market fundamentalism has become so powerful that any political forces that dare to resist it are branded as sentimental, illogical, and naive." (Soros, 1998, xxvi).

The theorists of the neoclassic school stressed that value questions do not pertain to scientific economics, but to another branch they call applied or normative economics, which is the realm of politicians and managers. But politicians were obliged by the same ideological bias to focus all their work around the economy and the economic problems of their societies, the main goal being to increase incomes and the welfare of their states. Hence, the essential role played by economics in the new politics, both national and international. To manage the economy of the new global situation, the politicians of the six major economies created in 1975 the so-called G6 (Group of Six), which became G7 in 1976, G8 in 1997, and G20 in 2009. It has been the main economic council of wealthy nations, but not a global economic forum. As a consequence, some anti-globalization movements appeared, in an attempt to avoid the negative consequences of the economic process of globalization. They have organized riots during the summits of the G6 and G20 (Mittelman, 2000).

As politicians are the agents of public policies, managers are the leaders of private corporations. Management has also been frequently conceived as a "value-free" activity. Some managers, on the contrary, have stressed the importance of values in the promotion of quality and excellence in organizations. Hence, the importance of value questions in some new business theories. Terms like *virtue*, *quality*, *excellence*, *stakeholders*, *good citizenship*, *corporate social responsibility*, and so on are beginning to play a new role in business ethics. Trying to promote these practices, the United Nations launched in 2000 the UN Corporate Social Responsibility Global Compact program, seeking to mainstream ten moral principles in business activities around the world in the time of globalization. The importance of the Global Compact is due to the fact that, today, most important private industrial corporations are transnational and, to some extent, global, unlike the governments, which are by definition national. This means that the economic power of industries is in some cases greater than that of nations and governments.

Lack of a Global Polity

In the globalization era, economies are inextricably interconnected, surpassing the national borders and territories in which politicians and governments can take decisions. The consequence is that the globalization process has shown problems that can only be managed and perhaps solved in the international arena. This means that the globalization of trade and the economy demand another more difficult process, the political one. This is, perhaps, the biggest issue of humanity's present situation, in which the global economy coexists with a political system based on an old idea of nationality.

There is a general consensus that politics must find new ways of managing global problems, first because international bodies have been, up to now, subordinate to national interests, and, second, due to the fact that there is neither a real, nor perhaps desirable, global government. An intermediate solution may be the so-called "global governance," a novelty that appeared after the fall of the national

security model prior to the collapse of the Soviet Union in 1991. Global governance tries to manage global processes through institutions such as intergovernmental organizations (IGOs), non-governmental organizations (NGOs), and private entities. The question is whether bodies like these are capable of limiting the individual power of states in a positive way, going beyond market laissez-faire and private economic interests, and then solving the collective problems of mankind. In any case, global governance remains weak relative to pressing current needs for global public policy. Some theorists try to avoid these problems through the promulgation of a Global Constitution as the basis of global governance. Going beyond the traditional Westphalian system, states should share part of their sovereignty with institutions and bodies at other territorial levels, and they must begin a major process to deepen democracy, making their organization more responsible. The main goal of the Global Constitution should be to make possible the convergence of the unsustainable development of developed countries and the unsustainable underdevelopment of the underdeveloped countries into "sustainable development."

Some political theorists think that political globalization is coming through the triumph of Western patterns of life. Francis Fukuyama, a supporter of the Reagan doctrine during the 1980s, published in 1992 a book entitled, *The End of History and the Last Man*. He argued in it that the triumph of Western culture is complete after the struggle of ideologies during the Cold War, the fall of the Berlin Wall, and the collapse of Marxism. Political and economic liberalism, he stresses, is the only theory with a future. Big confrontations will no longer be possible, making possible a new era he calls the "end of history." "What we may be witnessing is not just the end of the Cold War, or the passing of a particular period of post-war history, but the end of history as such: that is, the end point of mankind's ideological evolution and the universalization of Western liberal democracy as the final form of human government" (Fukuyama, 1989, 3).

A year later, the political scientist Samuel P. Huntington published an article titled, "The Clash of Civilizations" in response to Francis Fukuyama's vision. Three years later, in 1996, he expanded this theory in the book, *The Clash of Civilizations and the Remaking of World Order*. The question is, once more, how to conceived a global politic after the Cold War era. Fukuyama's answer is that human rights, liberal democracy, and a free market economy will be the pillars of the process of political globalization. Huntington, on the contrary, thinks that after the time of ideologies, only cultures and religions have the values capable of conducting the life of societies. These are, for the same reason, the true sources of social and political conflicts. Therefore, the fundamental source of conflict in this new world will not be primarily ideological or economic, but cultural. "Nation states will remain the most powerful actors in world affairs, but the principal conflicts of global politics will occur between nations and groups of different civilizations. The clash of civilizations will dominate global politics. The fault lines between civilizations will be the battle lines of the future" (Huntington, 1993).

One important source of conflict is religion, especially between those religions that defend the existence of an absolute truth, one only in the hands of its believers,

who have the duty of extend their message to the whole world as the only way of salvation. This is the case of Christianity, most common in Western civilization, and of Islam. Both messages and pretensions are incompatible and will lead to a violent confrontation between them. That is what Hizb ut-Tahrir has called "the Inevitability of the Clash of Civilisations."

Others think that these predictions are completely biased, because they focus the analysis on the extreme points of view of fundamentalisms, either political or religious. Hence, the importance of promoting respect and tolerance between different cultures and religions. Some proposals have been developed in this way by religious leaders, like the declaration promoted by the Parliament of the World's Religions on peace and global ethics in 1993; others include the Dialogue Among Civilizations promoted by the former Iranian president Mohammad Khatami, which was the basis of the declaration by the United Nations in 2001 as the Year of Dialogue among Civilizations, and the Alliance of Civilizations proposed at the 59th General Assembly of the United Nations in 2005 by the president of the Spanish government, José Luis Rodríguez Zapatero, and co-sponsored by the Turkish prime minister Recep Tayyip Erdogan.

Philosophers have made their own proposals, following, especially in Europe, the Kantian tradition of "cosmopolitanism" (Held, 1995). One of the most prominent defenders of this idea has been Jürgen Habermas, who translated the Kantian cosmopolitanism into a more pragmatic global constitutionalism (Habermas, 2008, 312–352). Human beings are living now in a "multilevel system" (with "states," "transnational" regimes such as the European Union, and "supranational" organizations like the United Nations) that establishes "a politically constituted world society without a world government" (Habermas, 2008, 316). In this situation, public action should be based on "negative duties of a universalistic morality of justice," legitimated by a thin "worldwide background consensus." Habermas thinks that this ideal is expressed today, at least, in the "shared moral indignation" of people in response to "egregious human rights violations and manifest acts of aggression [that] gradually produce[s] traces of cosmopolitan solidarity" (Habermas, 2008, 344).

Need for an Ethical Globalization

Political globalization cannot become real without an established "Global Civic Culture" (Boulding, 1988) or a "Global Civil Society" (Oliveira & Tandon, 1994). On the front line of this social movement is the "third sector" (Florini, 2000), which is nonprofit but at the same time neither governmental nor religious, and then a veritable "global associational revolution," "a massive upsurge of organized private, voluntary activity in virtually every region of the world" (Florini, 2000, 1). It tries to construct a society different from the purely economic one of the free market. In the words of the French Prime Minister Lionel Jospin, "Yes to a market economy, no to a market society." The third sector is the upsurge of a new culture

and a new set of values, beyond the economic profit, from one side, and the religious charity, from the other. And now the question is what kind of values are these?

There are, at least, two strictly different types of values, called "intrinsic" and "instrumental" (Gracia, 2011, 89–133). These are the most accessible today to human beings. The most important instrumental value by-and-large is the economic one. Money is only one instrument to achieve different things people value. In other words, money is a value-mean, not a value-end. It has no value by itself, but by the other things that can be achieved with it, which are appreciated by themselves, for instance, the beauty of a picture, or the friendship in a person. In fact, only instrumental values can be measured in monetary units; friendship or beauty are priceless.

The problem is that economic globalization has grown with the idea that economic profit is the only important value, and that priceless means worthless. This is the public opinion today, and is also prevalent in politics. "Elected representatives also frequently put their personal interests ahead of the common interest. Instead of standing for certain intrinsic values, political leaders want to be elected at all costs - and under the prevailing ideology of market fundamentalism, or untrammeled individualism, this is regarded as a natural, rational, and even perhaps desirable way for politicians to behave [. . .] The contradiction between politicians' personal and public interests was, of course, always present, but it has been greatly aggravated by prevailing attitudes that put success as measured by money ahead of intrinsic values such as honesty" (Soros, 1998, xxvi).

Money is the measure of all instrumental values. But some values, the most important in human life, are not instrumental. They are called intrinsic, because they are valuable by themselves, like friendship, love, justice, peace, pleasure, wellbeing, solidarity, life, and health. When one of them is lost, something valuable by itself vanishes. It cannot be imagined a true human world without love, or without beauty, or any other of these values. Technical instruments, like cars, phones, or pharmaceuticals, are needed, but only for the intrinsic values they are related to. A pill is a way of curing a headache. If the pill could not improve health, it could be said that it is completely useless, or worthless. Health is an intrinsic value, and the value of drugs is only instrumental.

The duty of all human beings is always the same, to add value, that is, to promote or implement values, to increase values or to do things more valuably. Ethics deals with all kinds of values, but especially with the intrinsic ones, because they are ends by themselves, the true ends of human life.

The Long Run to Moral Globalization

Human beings have always been aware that they have moral duties not only to themselves, promoting, for instance, their perfection and happiness, but also, and perhaps primarily, to others. But what they have understood by others, from a moral point of view, has been changing through history. In ancient times, it can be imagined that the moral world of human beings was reduced to families and

relatives; at the most, to their segmentary or tribal society. Outsiders were by definition strangers, rivals, and enemies, with which the only moral duty they had was to kill them or make them slaves.

The Greek perspective was to some extent similar. Only Greeks were endowed with the *logos* or reason needed to develop a fruitful moral life. All others were "barbarians," incapable of developing their lives as true human beings. Only in the *polis*, and not in the other minor social structures, was deliberation, the right method of moral thinking, considered possible. And in the *polis*, only some people were endowed with a true deliberative capacity, "for the slave has no deliberative faculty at all; the woman has, but it is without authority, and the child has, but it is immature" (Aristotle, Pol. 1260 a 12-14. Aristotle 1984, 53). The consequence was that there were some people entitled to take moral decisions, the true moral agents, while the others were by nature moral patients, that is, people only capable of obedience.

The first consequence of this historical analysis is that humankind has never understood all human beings as moral agents. On the contrary, it has been thought that only a small number of people were endowed with the true moral condition. The only moral virtue of all others was obedience, that is, moral slavery. Even during the Middle Ages, this moral slavery did not disappear; it was interpreted then in theological terms. The cause of this new spiritual slavery, as discriminatory as the old one, was sin (John 8: 34f; Rom. 6: 16). Sinners were degraded to the level of slaves, and deprived of nearly all human rights, in some cases even the right to life, while grace was taken as the way of liberation from the sinners' slavery, entering to a new one. "But you have been set free from sin and have become slaves of God" (Rom 6: 22). In this new slavery, people were not endowed with the capacity of deliberating about moral things, but reduced to the role of moral patients instead of moral agents, and obliged to blind obedience.

Only in modern times was moral agency asserted as an intrinsic propriety of all rational beings. This was the origin of the so-called "principle of universalization," coined by Kant. All human beings are by nature autonomous agents, and therefore slavery is always inhuman, either social or moral. There are two different and opposite sets in the world, the one with all rational beings and the other with all the other things. The first is called the "moral world" and the other the "natural world." The Kantian universalization covers, therefore, human beings but not the things of nature.

From the end of the eighteenth century, the time in which Kant coined the so-called moral principle of universalization to today, many things have happened. By "all human beings" Kant could only understand the "actual" people living on earth in a certain period of time. But there was little capacity to take into account the actual situation of people all over the world in Kantian times. The Kantian world covered little more than Europe. Only during the last decades, and due to the accelerated development of telecommunication, has it been possible to know what really happens anywhere and anytime. This is the first difference between the old "universalization" and the new "globalization." What Kant called "the kingdom of ends," the set of human beings, covers today for the first time all

human beings actually existing on earth. People's moral decisions must take into account all of them in order to think they are right.

From Ethical Universalization to Moral Globalization

But this is not the only way in which globalization goes beyond universalization. One of the most important consequences of scientific development is the increase in one's capacity of foresight. This foresight embraces not only the future of present human beings, but also the life of all others possible, that is, future generations. Future generations are only "virtual," not actual, but mankind is now aware, perhaps for the first time in history, that there are moral duties to them, making possible its existence with a quality of life at least equal to the one people enjoy today. The problem is to determine whether these duties are perfect or imperfect, that is, duties of justice or duties of beneficence. In the first case, these virtual human beings should be entitled to human rights, and therefore included in the moral set, the set of human beings. This is what has happened lately, with the development in the theory of human rights of the so-called "rights of future generations." In the second case, if they were not entitled with rights, one's moral duties would only be imperfect, or private duties of good will and beneficence. Things are currently going in the first direction more than in the second, and therefore moral globalization is taking into account not only all actual human beings but also the virtual ones, that is, future generations. They are human beings, although right now only virtual.

Globalization, therefore, differs from universalization at least in two points. First, it covers all human beings actually existing, and second, future human generations. But it also covers non-human nature. This is also the consequence of scientific development. During the last decades of nineteeth century, ecology appeared as a new discipline. Its main idea is that living organisms are inseparable of their surroundings. A living organism alone is an abstraction without reality. This is one of the consequences of the theory of evolution, defined broadly by Darwin in 1859. Therefore, it is necessary to think of human beings in their environments, without which they are not real.

An important consequence of this new approach is that things can no longer be divided in two opposite sets, one with human beings and the other with all other things. Human beings cannot be taken alone, without their environment. And if they are ends by themselves, natural things must participate in this condition at some extent. Therefore, they are not pure means, as supposed previously. Kant said that human beings are means and *not only* ends, which means that, in addition to their condition of ends, they are also means, like all other things. If this is so, then the opposite should be also possible, that is, that natural things are at some extent ends, and *not only* means. Natural things should be included, at least partially, in the same set of human beings. They are also, in some way, ends, and therefore subject to rights. This is the origin of the so-called animal and environmental rights.

Animal and environmental rights can be justified in ways different from the Kantian one. Many thinkers do not accept the application of the category of "end by themselves" to animals and things to any extent, due to the fact that they are neither rational nor adequate subjects of morality and rights. The only thing that can be said is that they have "value." This is another approach, more pragmatic and intuitive than the first. The more enforcing language of rights is substituted here with the language of values. Natural things are valuable only by the fact of being or existing, and living organisms more so. The simple fact of being is an intrinsic value, the value of being instead of not being, and the fact of being a living organism is another important intrinsic value. Kant said that human beings are endowed with an intrinsic value called dignity. But this is not the only one. There are many other intrinsic values, not only in human beings but also in pure natural things and living organisms. And due to the fact that these are endowed with intrinsic value, the defenders of this second approach think that human beings have the moral duty of respecting these values and promoting them as much as possible. Such duties are respective to intrinsic values inherent to these things, and then it can be said that these things are entitled to the right be respected, in order to safe their values. Another way of explaining that is saying that these non-human beings are endowed with rights that are respective to one's duties. This is, therefore, a different form of justifying the so-called animal and environmental rights. They have rights because they are entitled with intrinsic values.

There is another way, a third, of approaching the problems raised by the new ecological ethics. If the first approach was the Kantian, and the second one the axiological, this third is strictly utilitarian. It is necessary to take into account animals and nature in moral considerations due to the negative consequences of doing the opposite. Taking care of nature is also taking care of ourselves. Both are members of the same world, with a common future (U.N. World Commission on Environment and Development, 1987).

A consequence of these new approaches is that the classic Kantian categorical imperative – "Act so that you can will that the maxim of your action be made the principle of a universal law" – is now inconsistent, because it must be formulated in broader terms. Hans Jonas proposed these four alternative formulations: "Act so that the effects of your action are compatible with the permanence of genuine human life"; or expressed negatively: "Act so that the effects of your action are not destructive of the future possibility of such life"; or simply: "Do not compromise the conditions for an indefinite continuation of humanity on earth"; or, again turned positive: "In your present choices, include the future wholeness of Man among the objects of your will" (Jonas, 1984, 10–11).

One problem with this wide and totalizing approach is the impossibility that human minds can take into account in their moral deliberation process things so vague and indefinite as "the permanence of genuine human life through time," or "the indefinite continuation of humanity on earth," etc. Edward Norton Lorenz described the "butterfly effect" in 1969, and the impossibility of forecasting non-linear phenomena or predicting the future in chaotic systems. The most astonishing example of this is the inaccuracy of weather forecasting from more than

about a week out. In the era of non-linear phenomena and the chaotic approach to reality, what does "the indefinite continuation of human life on earth" mean?

Science is a system of prevision. In fact, these new problems are the consequence of one's better understanding of natural laws. This new capacity of foreseeing the future have many scientific and technological consequences, and also may influence in a definite way one's moral thinking. Now it is necessary to take into account in moral judgments the foreseeable consequences of one's actions. The problem is that natural systems are extremely complex, influenced by so many factors that human beings are incapable of taking control of all of them. Here certainty is very rare, and there is the need of working only with probabilities. This is the reason why in this field it is not possible to reach a lineal and determined conclusion, but only to choose a course of action that seems better than the others, in the balance of risks and benefits. This means that in this field the only thing that can be intended is to make wise, reasonable, or prudent decisions. A sage decision can be wrong, and time can also show that an unwise decision would have avoided many risks or harms. But the moral duty of human beings is to make wise and responsible decisions, not the avoidance of any mistakes. The opposite could be highly unwise and imprudent.

Towards a Global Ethics

The expression "global ethics" has, at least, two different meanings. In its first meaning, global ethics includes also virtual ethics and environmental or ecological ethics. This is the meaning in which the expression global ethics is frequently used. But it has another meaning. The question is whether it is possible to define some moral content that all human beings could agree upon. Anthropologists are aware of the diversity of moral norms in different cultural and religious traditions. They assume generally as a postulate the so-called "cultural relativism" also in the moral domain. Disagreement seems to be the norm in moral matters, which is why Huntington (1993) thinks that the clash between the major cultures and religions is unavoidable. Could it be possible, then, to formulate some universal moral principles? Are there some moral contents that can be called global?

The first attempt to answer to this question in a positive way came from the Parliament of the World's Religions in 1993, immediately after Huntington's proclamation. On 4 September 1993, the Parliament passed a "Declaration toward a Global Ethic," in which people of very different religious backgrounds for the first time agreed on a minimum of irrevocable directives that they were already affirming in their own traditions. The promoter of the Declaration was the Catholic theologian Hans Küng, who previously, in 1990, published a book entitled *Project Weltethos*. The German expression *Weltethos* means "global ethos" and not "global ethics," which in German would be said *Weltethik*. The difference is important, because the goal of the *Weltethos* movement is not to define specific duties or to construct an ethic, but to promote a basic attitude, a fundamental moral option that the world's religions have in common, drawing up a minimal code of

rules of behavior everyone can accept. The idea of Küng is that the new "world society" does not need a single unified religion or ideology, but "does need some norms, values, ideals and goals to bring it together and to be binding on it" (Küng, 1991). Some statements in the book have become famous: "There will be peace on earth when there is peace among the world religions," and "No world peace without peace among religions; no peace among religions without dialog between religions" (Küng & Kuschel, 1993).

The Declaration of 1993 was the origin of a wide international movement, organized around the *Global Ethic Foundation*, which appeared in 1995. The Parliament of World's Religions developed the content of the Declaration in its meeting of 1999 in Cape Town, South Africa, with the document *A Call to Our Guiding Institutions*. And Pope John Paul II gave the official Catholic judgment about globalization and global ethic in his address to the Pontifical Academy of Social Sciences on 27 April 2001. On the other hand, the core ideas of global ethic have been applied to specific fields, like science, education, politics, and economics. Promoted by Hans Küng, in 2009 a group of people signed at the United Nations the *Manifesto Global Economic Ethic: Consequences and Challenges for Global Businesses*.

In a secularized society and in a post-metaphysical era, other ways of justifying globalization that are alternative or complementary to the religious justifications appeared immediately. The main characteristic is that they do not look for "substantial" agreements but only for "procedural" consensus. Two of the most outstanding representatives of this trend are John Rawls in America and Jürgen Habermas in Europe. The first has developed a procedural way of reaching a rational consensus between all human beings on the basic content of the idea of justice. Although this procedure is strictly secular, religious "tolerance" is an essential precondition in order to achieve the agreement (Rawls, 1971, 180–181). Therefore, this secular approach to global ethics cannot be seen as opposed to the religious one, but complementary to it.

The perspective of Habermas is similar. The procedural way of reaching a global ethic is, in this case, through the symmetrical dialogue between all the people affected by the norm or decision at stake. And, as in the previous case, one of the presuppositions of this dialogue is tolerance, especially in religious matters (Habermas, 2008, 306). A secular and post-metaphysical global ethics cannot be indifferent in religious matters, but it needs to be tolerant. Without tolerance, the communicative ideal discourse becomes impossible.

All these questions have political consequences, and thus the importance of politicians in this debate. More than 30 of them, former heads of state or government, are trying to promote universal ethical standards in national and international politics, through the *InterAction Council*. This body develops proposals for action for government leaders, national decision-makers, heads of international organizations, and influential individuals around the world. In 1997, they proposed to the U.N., as a complement to the Universal Declaration of Human Rights (1948), a *Universal Declaration of Human Responsibilities*. At the same time, UNESCO promoted another *Declaration of Human Duties and Responsibilities*, proclaimed

in 1998, to commemorate the 50th anniversary of the Universal Declaration of Human Rights in the city of Valencia. Finally, the U.N. approved, on the 50th anniversary, a *Declaration on the Right and Responsibility of Individuals, Groups and Organs of Society to Promote and Protect Universally Recognized Human Rights and Fundamental Freedoms* (53/144, 9 December 1998).

There is a growing amount of literature and documentation on global ethics. To collect it, UNESCO began and supports the Global Ethics Observatory (GEObs), a system of six databases with worldwide coverage.

Globalization and Bioethics

"Bioethics" is a recent movement. It appeared as such half a century ago. As Warren T. Reich has stressed, it had a "bilocated birth," in Madison, at the University of Wisconsin with Van Rensselaer Potter, and in Washington, DC, at Georgetown University, with André Hellegers. Potter gave to the word *bioethics* an environmental and global significance, whereas Hellegers understood it more narrowly as the ethics of medicine and biomedical research. The Hellegers/Georgetown approach came to be the more widely accepted, while Potter's idea of bioethics remained largely marginalized (Reich, 1995). In any case, it was into Potter's tradition that the concept of "global bioethics" appeared. Eighteen years after coining the word *bioethics*, Potter (1988) introduced the term *global bioethics* as a way of unifying medical and ecological ethical issues in the one, more inclusive field (Reich, 1995, 25).

In 1971, Potter published a book entitled *Bioethics: The Bridge to the Future*. The metaphor of the bridge is important, because Potter conceived bioethics as the way of balancing new scientific facts, especially in the life sciences, with reflection about the values at stake. The goal of bioethics is to make up these two types of knowledge in a wider vision, reaching a way a new wisdom (Potter, 1971, 2). Only this new wisdom can assure, in the Potter's view, the survival of humankind, which is why he defines also bioethics as "the science of survival" (Potter, 1971, 1).

Because bioethics was born and developed during its first decades in the United States, many people assumed that the "four bioethical principles" of the Georgetown model could be asserted as "global," and therefore exportable to the rest of the world. But critical voices began to appear. Sociologists (Fox & Swazey, 2008) and anthropologists (Turner, 2003) denounced this attempt at globalization as disrespectful with the values of other cultures (Schroeder, 2005). "Moral pluralism and cultural difference have not been central topics of concern in the first decades of American academic bioethics [...] Bioethics has only concerned itself with issues of cultural pluralism quite recently" (Marshall & Koenig, 2004, 253).

There have been two different agencies of the United Nations interested in the promotion of dialogue between different cultures in order to make bioethics into a true global discipline. One is the World Health Organization (WHO), which in 2002 established an Ethics and Health Unit, expanded in 2003 to foster the

development of programs on ethical issues in biomedicine and science in both clinical and research setting worldwide, particularly in resource-poor nations. It is also part of the international consortium that supports the Global Forum on Bioethics, promoted by the Fogarty International Center at the National Institutes of Health of the United States.

The second large international agency engaged in the development and promotion of global bioethics is UNESCO, through its Unit on Ethics in Science and Technology, and more specifically through the International Bioethics Committee (IBC). This committee approved in 2003 a Report on the Possibility of Elaborating a Universal Instrument on Bioethics. Two years later, the Universal Declaration on Bioethics and Human Rights was adopted by UNESCO's General Conference. The aim of the Declaration is "to provide a universal framework of principles and procedures to guide States in the formulation of their legislation, policies or other instruments in the field of bioethics." The sixteen principles are declared as universal, and the procedures are related to the establishment of independent, multidisciplinary, and pluralistic ethics committees at institutional and/or local, regional, national, and international levels.

This Declaration tries to be an extension of the Universal Declaration of Human Rights of 1948. And, as in those days, criticism immediately appeared, due to the difficulty of determining moral principles as "universal." For some authors, this is once more the attempt to extend the Western moral tradition to other places with different cultures and values. One of the most outstanding critics has been the American bioethicist H. Tristram Engelhardt, Jr. (2006). His libertarian thesis is that in the postmodern world a general consensus about values is impossible. (Engelhardt, 2006, 3, 6) Another strong criticism came from the British bioethicist John Harris. He questions the wisdom and utility of a declaration that neither distinguishes moral judgments from judgments about moral issues, nor provides any evidence that consensus was informed consensus (Harris, 2008).

The Declaration has had opponents and defenders. Some other authors looked for ways of articulating universal principles with cultural particularities (Finkler, 2008), using especial methodologies to solve the antinomy (Zieler, 2009), and stressing the need of deepen the way opened by the Declaration in the future (Williams, 2005).

In all these cases, "global bioethics" is understood as a set of universal or global moral principles. But there are other meanings of the expression. One is less theoretical and more operational. The question is whether bioethics has become a global field of inquiry, or, on the contrary, whether it is in a phase previous to the actual constitution of a global scientific domain. This has been the topic analyzed by Søren Holm and Bryn Williams-Jones in their paper "Global bioethics: myth or reality?" (Holm & Williams-Jones, 2006). The conclusion reached is that moral globalization is in the process of being real, but it is not yet (Borry, Schotsmans, & Dierickx, 2006). Therefore, global bioethics is still a topic in process of becoming a discipline. Bioethics is a young product of the Western culture, requiring time and dedication to become a true global body of knowledge and practices.

Concluding Remarks

Globalization is a recent phenomenon and is far from being completed. It began with the revolutionary changes in telecommunications that happened during the second half of the twentieth century and continued with the globalization of the financial and commercial markets in the beginning of the 1980s. The great economic crisis experienced by the Western world since 2007, without any precedent in the history of mankind, is generally interpreted as the consequence of the achievement of a global market, without the counterweight of an effective political and moral globalization. The ideology of profit as the main goal, or the only one, in human actions, is one of the causes, perhaps the most important, of the present disaster. There are two types of human values, some intrinsic and others instrumentals. The first are the most important in human lives, and these cannot be measured in monetary units. Ethics deals primarily with these intrinsic values, and then the importance of its culture. When, on the contrary, only the instrumental values are at stake, or when they take precedence, then what Habermas calls "strategic action" or "instrumental rationality" comes forward. That is, perhaps, what is happening at present.

Structure of the Compendium

3

Henk A. M. J. ten Have and Bert Gordijn

Introduction

This Compendium of Global Bioethics, as volume of the *Handbook of Global Bioethics*, is the first comprehensive systematic treatment of the major normative issues in contemporary global bioethics to date. The global issues, problems, and principles addressed in this work represent a genuinely new stage in the development of bioethics, especially since they are pertinent to developing and developed countries. This new stage in bioethics is furthermore promoted through the ethical framework presented in the *Universal Declaration on Bioethics and Human Rights*. This declaration is the first political statement in the field of bioethics, adopted unanimously by all member states of UNESCO in 2005. The declaration is distinct from other international documents such as the Declaration of Helsinki in formulating a commitment of governments. Being part of international law (though not binding as a convention), it presents a universal framework of ethical principles for the further evolution of bioethics at a global level. This chapter explores the roots and the development of the Universal Declaration. In addition, it shows how its principles inform the structure of the compendium. This may help to understand and comprehend the approach that is followed in most of the chapters of the compendium.

The Growth of Global Bioethics

Most developing countries still have a limited infrastructure in bioethics, lacking expertise, educational programs, bioethics committees, and legal frameworks. Due to the global nature of science and technology, however, there are similar bioethical questions emerging as in developed countries where bioethics has already existed

for a long time. As a result, developing countries endeavor to develop and apply bioethics principles that are coherent with their own value system. They recognize the importance of bioethics but do neither have the capacity nor the facilities to fully engage in it. At the same time, they aim to have a bioethics framework in their country that would not be regarded as extraneous but would be considered as suitable for their own country and culture. For this reason, they have appealed to UNESCO as an impartial global organization to set universal ethical benchmarks for the analysis and assessment of the issues within bioethics. They wanted to work together in this international political platform toward identifying basic principles and shared values regarding science, technology, and health care to be put to use in the global bioethics conversation.

When the United Nations Educational, Scientific and Cultural Organization (UNESCO) was established more than 60 years ago, its constitution declared that peace must be founded upon the intellectual and moral solidarity of humanity. Julian Huxley, the first director general, pointed out that, in order to make science contribute to peace, security, and human welfare, it was necessary to relate the applications of science to a scale of values. Guiding the development of science for the benefit of humanity therefore implied "the quest for a restatement of morality [. . .] in harmony with modern knowledge" (Huxley, 1946, p. 41).

Since its foundation, UNESCO has been concerned with moral issues in relation to science. From the 1970s onward, the emergence of the life sciences, in particular, has led to the international examination of bioethical questions. In order to match the increasingly global scope of the bioethics debate, UNESCO established the International Bioethics Committee (IBC) with a work program and budget for international activities in 1993. The program was expanded in 1998 with the foundation by UNESCO of the World Commission on the Ethics of Scientific Knowledge and Technology (COMEST), which addresses other areas of applied ethics such as environmental ethics, science ethics, and technology ethics. Since 2002, UNESCO has been coordinating the activities of several international bodies in the area of bioethics through the Inter-Agency Committee on Bioethics of the United Nations (with, among others, FAO, OECD, and WHO). In the same year, the 191 member states decided that ethics should be one of the five priorities of the organization.

Against this backdrop, it is hardly surprising that UNESCO was considered by states to be the most appropriate international forum for the elaboration of a framework of bioethical principles, the more so since the organization has demonstrated its ability to fulfill a constructive standard-setting role in the field of bioethics. Over the past two decades, UNESCO, being the only specialized instance within the United Nations system that combines education, culture, science and social sciences in its field of competence, has developed a bioethics program that reflects the multidisciplinary and transcultural dimension of the discipline. UNESCO has been engaged in carrying out actions to involve countries around the world in order to bring out fundamental principles acceptable to all, without loosing sight of respect for cultural diversity. The success of the Universal Declaration on the Human Genome and Human Rights, adopted in 1997 (and furthermore adopted by the General Assembly of the United Nations 1 year later), and the International Declaration on Human

Genetic Data, adopted in 2003, has reinforced UNESCO in its standard-setting action in the field of bioethics and has convinced states to place confidence in the organization's capability to develop a more general bioethics declaration.

Constructing Consensus

In October 2001, the general conference (the general meeting of all member states), supported by the Round Table of Ministers of Science, invited the director general of UNESCO to examine the possibility of developing "a universal instrument on bioethics." The feasibility study drafted by the International Bioethics Committee (IBC) concluded that it might be possible to find common ground in divergent bioethical positions by focusing on basic principles (Ten Have & Jean, 2009). Some of these principles had already been identified in previous declarations. The study also stressed the necessity to develop a universal instrument because of rapidly developing scientific practices increasingly extending beyond national borders. Consequently, it was deemed desirable that developed and developing countries alike achieve a consistent set of principles informing their regulations and policies.

Two years later, in October 2003, the general conference provided a mandate to submit a draft declaration within 2 years. In the meeting, then French President, Jacques Chirac, made a vigorous plea for a universal normative framework, preferably a convention, to guide the progress of the life sciences and to protect the integrity and dignity of human beings. Taking into account the short time frame, the variety of cultures and traditions to be take into account, and the controversial nature of many bioethical issues, the subsequent process of drafting, entrusted to the IBC, was based on extensive consultations with many organizations (e.g., FAO, WHO, WIPO, Council of Europe, National Bioethics Committees, and international bioethics societies). Throughout the process of elaborating the text, several drafts were published on the website of UNESCO. The work of the IBC drafting group was conducted in as public a way as possible in order to facilitate consensus formation and early identification of any dissenting views.

Dealing with bioethics in an intergovernmental organization such as UNESCO implies a linkage between science and politics. Each normative instrument needs to reflect the scientific and ethical state of the art. But in the end, every draft is submitted for approval to the member states which then decide if they wish to adopt it. Thus, the draft text developed by the independent scientific experts of the IBC was subjected to political negotiations among the experts who represented the various governments of the UNESCO member states. As a result, the cogency of the final text may have been diminished, in some respects, due to textual adaptations to create maximum adherence by all of the governments involved. In order to facilitate the opportunities for compromise, the work of the independent IBC was connected at an early stage with that of governmental experts. Several amendments to the IBC text were made by the governmental experts. The Declaration, as adopted, represents the IBC draft as so amended. After 2 years of intense work, the members states adopted, unanimously and by acclamation on 19 October 2005, the Universal Declaration on Bioethics and

Human Rights, thus solemnly affirming the commitment of the international community to respect a certain number of universal principles for humanity in the development and application of science and technology.

Universal Declaration on Bioethics and Human Rights

The Universal Declaration aims to define the universally acceptable norms, principles, and procedures in the field of bioethics, in conformity with human rights as ensured by international law. It is thus conceived as a group of general provisions and principles that allow for a better evaluation of the implication of ethical issues at stake and to provide assistance in decision-making in this field. It does not pretend to resolve all the bioethical issues. In order to achieve its goals, the Universal Declaration incorporates a linkage to international human rights law as is reflected in its full title. Thus, it anchors its ethical principles in the international rules that govern respect for human dignity, human rights, and fundamental freedoms. By drawing on the 1948 Universal Declaration of Human Rights, it clearly enshrines bioethics in international human rights law thus applying human rights discourse to the specific domain of bioethics.

One of the contentious issues in the elaboration process was the scope of bioethics. At least three views were advanced stating that bioethics had to do with (1) medicine and health care as well as associated technologies; (2) the social context, such as access to health, solidarity, and justice; and (3) the environment. In different parts of the world, different conceptions, definitions, and histories of bioethics were prevalent.

The scope of the adopted text of the Declaration is an obvious compromise between these views. It addresses "ethical issues related to medicine, life sciences and associated technologies as applied to human beings, taking into account their social, legal and environmental dimensions" (Art. 1a).

The aims of the Declaration are multiple. However, the most important aim is to provide "a universal framework of principles and procedures to guide states in the formulation of their legislation, policies or other instruments in the field of bioethics" (Art. 2i). One characteristic of present-day bioethics is that it is not merely an academic discipline; it is also a subject of public policy. This is why the Declaration primarily addresses states. But at the same time, since the bioethical principles identified are founded on human rights and fundamental freedoms, the Declaration also aims "to guide the actions of individuals, groups, communities, institutions and corporations, public and private" (Art. 2). The ethical principles that should guide governments cannot be different from the ones guiding professional conduct.

Ethical Framework for Global Bioethics

The heart of the Declaration is to be found in the 15 principles that are listed. The principles express the different obligations and responsibilities of the moral subject

("moral agent") in relation to different categories of moral objects ("moral patients"). The principles are arranged according to a gradual widening of the range of moral objects: the individual human being itself (human dignity, benefit and harm, autonomy), other human beings (consent, privacy, equality), human communities (respect for cultural diversity), humankind as a whole (solidarity, social responsibility, sharing of benefits), and all living beings and their environment (protecting future generations and protection of the environment, the biosphere, and the biodiversity).

Fundamental ethical principles in the UNESCO Declaration:

1. Human dignity and human rights
2. Benefit and harm
3. Autonomy and individual responsibility
4. Consent
5. Persons without the capacity to consent
6. Respect for human vulnerability and personal integrity
7. Privacy and confidentiality
8. Equality, justice, and equity
9. Nondiscrimination and non-stigmatization
10. Respect for cultural diversity and pluralism
11. Solidarity and cooperation
12. Social responsibility and health
13. Sharing of benefits
14. Protecting future generations
15. Protection of the environment, the biosphere, and the biodiversity

Some of the principles are already widely accepted (e.g., autonomy and consent). Other principles have been endorsed in previous declarations (e.g., sharing of benefits). Innovative within the set of principles in the Universal Declaration on Bioethics and Human Rights is the balance struck between individualist and communitarian moral perspectives. The Declaration recognizes the principle of autonomy (Art. 5) as well as the principle of solidarity (Art. 13). It emphasizes the principle of social responsibility and health (Art. 14), which aims at reorienting bioethical decision-making toward issues urgent to many countries (such as access to quality health care and essential medicines especially for women and children, adequate nutrition and water, reduction of poverty and illiteracy, improvement of living conditions and the environment). Finally, the Declaration anchors the bioethical principles firmly in the standards governing human dignity, human rights, and fundamental freedoms.

The section on the application of the principles (Arts. 18–21) is also innovative because it addresses the spirit in which the principles ought to be applied. It calls for professionalism, honesty, integrity, and transparency in the decision-making process; the setting up of ethics committees; appropriate assessment and management of risk; and ethical transnational practices that help in avoiding exploitation of countries that do not yet have an ethical infrastructure. The Universal Declaration thus opens perspectives for future action and reiterates the need to place bioethics within the context of reflection open to the political and social world. Today,

bioethics goes far beyond the code of ethics of the various professional practices concerned. In addition, it involves and promotes reflection, as advocated by Potter, on the future of humankind and on the evolution of society and science (see ▶ Chap. 1 on "Global Bioethics" in this volume). The Universal Declaration paves the way for a new agenda of bioethics at the global level.

Rationale of the Compendium

Although the Universal Declaration constitutes a nonbinding instrument in the eyes of international law, its value and its strength are in no way diminished. For the first time in the history of bioethics, all states of the international community are solemnly committed to respect and implement the basic principles of bioethics, set forth within a single text. Also through the Universal Declaration, bioethics finds its place on the agenda of states. Furthermore, characterized by the transparency and active participation of all the actors concerned, the elaboration process of the Universal Declaration, involving extensive consultations, has already largely contributed to the renown of the text and its general acceptance. The innovative dimension of the Declaration is that it constitutes for the first time a commitment of governments to a set of bioethical principles. Previous international declarations, although sometimes very influential, such as the Declaration of Helsinki, have been adopted by professional organizations (such as the World Medical Association).

The Universal Declaration on Bioethics and Human Rights should therefore not be seen as the fruit of the reflection of just a few but as the result of a long and sustained common effort in which numerous actors have been involved, representing a wide range of countries in the world. It should also be regarded as the beginning of a long process implementing and applying the principles stated in the Declaration. First, it is important to make sure that scientists, healthcare professionals, and policy-makers all over the world are informed about the existence and the contents of the Declaration. Second, it is necessary to exchange experiences about possible ways of application of the principles in different settings. These aspirations have determined the structure of the Compendium for Global Bioethics. Taking the ethical principles of the Declaration as guides, the contributions in the compendium will explore how these principles are interacting with cultural and religious traditions and how they are helpful in analyzing many of the new issues on the agenda of today's global bioethics.

Structure of the Compendium of Global Bioethics

The first section of this compendium presents an introduction into global bioethics as well as an overview of its history. These chapters not only explain what is involved in using the terms "bioethics" and "global bioethics" but they also locate today's emerging global bioethics issues and discussions within an historical context.

The second section elaborates the 15 ethical principles adopted by UNESCO. These principles can be seen as foundational for global bioethics. It goes without saying that, in a global context, they are to be interpreted and applied differently according to the specifics of the manifold social and cultural local contexts. Against this backdrop, the authors in Section 2 proceed in roughly the same way: they explain the principle, present the various arguments pro and con, discuss the practical possibilities and problems in applications, and sketch the interrelations with other ethical principles. In this way, each of the ethical principles is explained in a similar manner, allowing a comparative assessment of strengths and weaknesses.

The third section presents the most significant cultural perspectives on the problems and practices of global bioethics. These perspectives influence the way in which ethical principles are specified and weighed. Application of the ethical principles always takes place within specific contexts that are influenced by culture and religion. The authors in this section discuss how the framework of ethical principles presented in Section 2 can be regarded and worked with from the specific perspectives of African, Arab, Asian, European, Latin-American, North-American, and Pacific cultures.

Section four focuses on religious perspectives. It follows the same methodological approach as the previous section. Only this time, the ethical principles are addressed from the perspectives of the world's major religions: Buddhism, Catholicism, Confucianism, Hinduism, Judaism, Orthodox Christianity, Protestantism, Islam, and Taoism.

The fifth section of the compendium presents the major ethical issues and challenges of current global bioethics. The emergence and significance of these issues have primarily been triggered by the globalization of science, research, technology, and health care. The authors use the framework of ethical principles, presented in Section 2, in order to analyze and discuss the specific issue at stake thereby demonstrating the practical use of the principles. Naturally, often, only a selection of the Declaration's principles will apply to the moral issue or dilemma at hand. Sometimes, the analysis is also still rather tentative, since a fair number of issues, such as bio-piracy, corruption, disasters, indigenous medicine, immigrants and displaced persons, malnutrition, and hunger, are rather new in bioethics as a topic of scholarly research.

The compendium concludes with an outlook focused on the future of global bioethics. Since global bioethics is a relatively young field, many issues and questions are still open for analysis and debate. Also, the debate will be enriched by the experiences with bioethics in an increasing number of countries. This section will outline the priorities for future research and development of global bioethics.

Conclusion

This chapter has presented the rationale for the Compendium of Global Bioethics. It has argued that present-day global bioethics is characterized by a common

framework of ethical principles defined in the UNESCO Universal Declaration on Bioethics and Human Rights. The various sections of this compendium are elaborating the ethical principles, examining the principles in various cultural and religious contexts, and applying the principles of topical issues in contemporary bioethical debate.

Section II

Principles of Global Bioethics

Human Dignity and Human Rights

4

Roberto Andorno

Introduction

"Dignity" is defined as "the state of being worthy of honor or respect" (Oxford Encyclopedic English Dictionary). When this concept is associated with the adjective *human*, it is used to denote that all human beings possess equal and inherent worth and therefore ought to be accorded the highest respect and care, regardless of age, sex, socioeconomic status, health condition, ethnic origin, political ideas, or religion.

Inherent human dignity should be distinguished from *moral dignity*, which is a synonym of "honor." While the former plays a central role in the legal instruments relating to bioethics, the latter has less relevance in this field. On the one hand, the inherent dignity, as it is inseparable from the human condition, is the same for all, cannot be gained or lost, and does not allow for any degree (Spiegelberg, 1970). Even the worst criminal cannot be stripped of his or her inherent dignity and has therefore the right not be subjected to inhuman or degrading treatments or punishments.

On the other hand, moral dignity does not relate to the *existence* itself of persons but to their *behavior*; it is the result of a virtuous life, that is, of a life lived in accordance with moral principles. This is why moral dignity is not possessed by all individuals to the same degree (e.g., an honest citizen has more dignity than a pickpocket). While this is a kind of dignity that people may occasionally exhibit, lack, or lose, the dignity in which all humans are said to be equal is a characteristic that belongs permanently and inherently to every human as such (Gewirth, 1982, p. 27).

The concept of intrinsic human dignity operates in modern times as the bedrock of the international human rights system that emerged in the aftermath of the Second World War. It plays also a key role in the international policy documents relating to bioethics that have been adopted since the end of the 1990s. Human dignity can be characterized as the "shaping principle" of international bioethics

(Lenoir & Mathieu, 2004) or as the "overarching principle" of the global norms governing biomedical issues (Andorno, 2009). Far from representing a shift merely in style, the higher profile accorded to human dignity in bioethics is seen as a true shift in substance that deserves to be carefully considered (Beyleveld & Brownsword, 2002, p. 29).

This chapter aims, first, to briefly present how the notion of human dignity has been conceptualized over centuries of philosophical thought; second, to stress the foundational role it currently plays in international human rights law; third, to emphasize its even more crucial role in the international policy documents relating to bioethics; fourth, to present the reasons for the recourse to human rights in the formulation of global bioethical standards; and finally, to briefly address the challenge to the universality of human dignity and human rights posed by cultural diversity.

Human Dignity in the History of Philosophical Thought

The notion of human dignity has been the subject of many centuries of philosophical inquiry. Most of the explanations emphasize the rational capacities and the free will that characterize human beings and make of them something absolutely unique among living beings. Ancient Greek philosophers, in particular Plato and Aristotle, came to the conclusion that the core of every human individual is not just pure matter, but a *spiritual principle*, which they called *soul (anima, psyché)*. They argued that, since human beings are capable of spiritual activities (understanding, self-understanding, loving, self-determining by judging and choosing, expressing themselves through arts, etc.), they are essentially *spiritual beings* (Aristotle, *On the Soul, III*). Precisely thanks to their spiritual component, human beings were regarded as radically unique among living beings and were thought to share in the divine nature (Plato, Laws, V; Timaeus, 90). The modern idea of human dignity was nevertheless not yet clearly present in ancient Greek philosophy, which justified slavery, a rigid hierarchical social order and a sharp distinction between Greeks and other peoples. However, its thoughtful reflections on the spiritual dimension of human beings provided an invaluable basis for the later developments of Stoic and Christian philosophy and theology, which adopted a *universal* perspective.

Stoicism insisted particularly on rationality as the constitutive element of human dignity, because the human person is the only living being who is able to live according to nature through its reason, which means living a virtuous life. Virtue is possible because human reason shares in the divine reason that governs all things and in this way is able to know the natural law. Roman Stoic philosophers seem to have been the first to use the term dignity (*dignitas*) to indicate the intrinsic and universal worthiness of human beings. Cicero explicitly employs it to refer to the excellence and dignity (*excellentia et dignitas*) that all human beings possess by the simple fact of sharing in the common rational nature (*On duties*, I, 105).

Similarly, Christian thinkers stressed the special dignity of all human beings on the grounds of their spiritual soul, which is the seat of intellect and free will.

Certainly, in this tradition, the intrinsic worth of all human individuals is ultimately a consequence of their being an "image of God" (Gen. 1, 26) and of the belief in the redemption by Jesus Christ of every single human being. But these theological explanations of human worthiness presuppose that the ultimate internal principle of every human being is *spiritual* and not merely corporeal. This philosophical assumption is explicit in the thinking of theologians, according to whom the likeness to God is to be found mainly at the level of the soul, not of the body, because God is a purely spiritual being (Thomas Aquinas, *Summa Theologica*, I, 93). However, the Christian tradition, following Aristotle, holds that every individual has an integrated bodily and spiritual nature. This implies that, although the soul is the core of every human being, it is connaturally related to the body, with which it makes up the substantial unity of the person.

During the Renaissance humanism, the emphasis on human dignity became more persistent, more exclusive, and ultimately more systematic than it had ever been during the preceding centuries. Italian Renaissance philosophers such as Marsilio Ficino and Giovanni Pico della Mirandola, based on both ancient Greek philosophy and on biblical sources, insisted on the intrinsic moral worth of human beings on grounds of the spirituality and immortality of the soul, on its central position in the cosmos, and on man's freedom and creativity capacities. Pico della Mirandola's *Oration on the Dignity of Man* (1486) describes the moment of the creation of the human being, following both the biblical and Platonic accounts. He claims that when the creation of the universe had been completed, God decided to add a being capable of meditating on the reasons of the world, loving its beauty, and admiring its greatness. Thus, he undertook the creation of the human being. But, since all gifts had already been distributed among the other creatures, he decided that the being for which nothing had been left as its peculiar property might in turn have a share of all the gifts that had first been assigned singly to the other living beings. Hence, according to Pico della Mirandola, human persons have no clearly determined essence or nature. They are neither celestial nor earthly, neither mortal nor immortal. On the contrary, they are free to choose good or evil, to develop or not the capacities they are endowed with. They may live like a plant, an animal, a celestial being, or may even be united with God himself. For this reason, the human person can be metaphorically described as a "chameleon." Human dignity consists in the freedom of choice that characterizes the human being in comparison to other living beings because the different possibilities open to the human person include the highest one.

At the end of the eighteenth century, Immanuel Kant developed one of the most influential accounts of human dignity in the history of philosophy. For the German philosopher, the intrinsic human worthiness is grounded on the capacity for practical rationality, especially the capacity for autonomous self-legislation under the categorical imperative: "Autonomy is then the ground of the dignity of human nature and of every rational nature" (*Groundwork of the Metaphysics of Morals*, 1996, p. 85). The Kantian approach puts the emphasis on the freedom to conceive and follow the moral law, which is a specific capacity of human beings. Kant holds that it is only from this *moral* perspective, and not on *ontological* terms, that human

dignity can be justified. Having maintained that there is nothing in the world that "could be considered good without limitation except a good will" (p. 49), he points out that the value of the good will cannot be grounded empirically, that is, it cannot depend upon its having good effects or being oriented to attain certain purposes. The value of the good will, to be really unconditional, must be contained *within it*. This is only possible insofar as the moral action is oriented by a purely formal imperative, which can only consist in acting for the sake of *duty alone* (i.e., from respect of the moral law). This imperative must have a categorical nature, which means that it should represent certain actions as rationally required in themselves for everybody and without reference to any further end or goal. Therefore, the categorical imperative must be purely formal. Kant concludes that there is only one categorical imperative and it is this: "Act only in accordance with that maxim through which you can at the same time will that it become a universal law" (p. 73). In his view, the only way to make sense of the human will as a ground of a universal moral law is to conceive human beings as *ends in themselves*. This idea is expressed in the second formulation of the categorical imperative: "So act that you use humanity, whether in your own person or in the person of any other, always at the *same time as an end*, never merely as a means" (p. 80). Kant presents "dignity" as exactly the opposite of "price": while "price" is the kind of value for which there can be an equivalent, "dignity" makes a person irreplaceable. Therefore, the notion of human dignity expresses a requirement of *non-instrumentalization* of persons.

Although the concept of human dignity has been especially developed in the Western world, it is important to note that it is not strange to other cultural traditions. For instance, according to Chinese scholars, it has a correlate in the teachings of Confucianism (Zhang, 2000). The great Confucian philosopher Xunzi (third century BC) said that "Water and fire have essences (Qi), but not life; herbs and trees have life, but no knowledge; birds and beasts have knowledge, but no sense of justice (*Yi*). Man has an essence, life, knowledge and, in addition, a sense of justice; thus he is the noblest on earth" (*Kingly Government*, Ch. IX, cited in Zhang, 2000, p. 309). Xunzi believed that, although people are not innately good, they are all born with the *capacity* to *become* good (a "kingly person"), and this is what makes of each individual something special. Another great Confucian philosopher, Mencius (fourth century BC), developed a theory of human nature, claiming that the uniqueness of human beings lies not in their bodies, which they share with animals, but in their moral faculties assembled in their heart-mind (*Xin*). In this way, Confucianism has given substantive content to the notion of dignity in classic Chinese philosophy by establishing the moral ideals of humanity (*Ren*) and righteousness (*Yi*), as exemplified in the moral character of the Confucian gentleman (*junzi*), the prototype of the virtuous man (Zhang, 2000).

Also the Islamic tradition emphasizes the very special place of human beings on earth. According to the Qur'an, the sacred text of Islam, God gave to the human being the best shape and form (95:4), breathed into him his spirit (15:29; 38:72), gave him intellect and freedom (16:78; 23:78), bestowed dignity on the progeny of Adam (17:70), placed him even above his angels (2:31), and made him his *Khalifah* (representative) on earth (2:30; 33:72). Because of this, it is commonly interpreted

that the sacred text of Islam assigns dignity to all human beings, regardless of color, sex, race, or religion. Dignity arises from the mere fact of sharing in the human condition and is not restricted to those who believe in Islam (Hashim Kamali, 2002; Sachedina, 2009).

Human Dignity in International Human Rights Law

Immediately after the horrors of the Second World War, the international community felt it necessary to strongly emphasize the notion of human dignity in order to prevent "barbarous acts which have outraged the conscience of mankind" from ever happening again (Preamble of the Universal Declaration of Human Rights of 1948, thereafter UDHR). Three years before the UDHR, the United Nations Charter, which is the foundational treaty of this major intergovernmental body, had already reaffirmed the member states' "faith (. . .) in the dignity and worth of the human person" (Preamble). The UDHR served as the cornerstone of the new international human rights system, which was grounded on the "recognition of the inherent dignity and of the equal and inalienable rights of all members of the human family" (Preamble). From the very beginning, the declaration puts forward that "all human beings are born free and equal in dignity and rights" (Article 1).

According to international law, the relationship between human dignity and human rights is the one between a foundational principle of equal respect for every human being and the concrete norms that are needed to flesh out that principle in social life. Human dignity is the foundation of human rights; rights *derive* from human dignity. Human dignity is not a kind of super-right, or a collective term to refer to rights, but rather the ultimate source of all rights. The notion of human dignity attempts to respond to the question, "why do human beings have rights?" And the answer is that they are entitled to rights precisely because they possess intrinsic worth.

At present, the entire international human rights system is based on the assumption that people do really have inherent dignity. In modern political thought, the state's raison d'être is precisely to promote and secure respect for dignity and rights. The validity of human dignity and human rights is thought of as not conditional upon their explicit recognition by states. Rather, both the international community and individual states are *obliged* to recognize that people do have basic rights (i.e., that they have equally valid claims to basic goods) because these latter derive from the dignity which is inherent in every human being. Hence, it can be said that, ultimately, the notion of human dignity points to a requirement of *justice* toward every individual. In the words of Rawls, this requirement presupposes that "each person possesses an inviolability founded on justice that even the welfare of society as a whole cannot override" (Rawls, 1971, p. 3).

Certainly, the practical efficacy of promoting human rights is significantly aided by their legal recognition by states. But the ultimate validity of basic rights is characteristically thought of as not *conditional* upon such recognition (Nickel, 1987). In other words, legal systems do not present the notion of human dignity

as a merely theoretical hypothesis or as a legal fiction but as the *indispensable basis for the fair functioning of human society*.

It is noteworthy that human dignity is not explicitly defined by international law. Rather, its meaning is "left to intuitive understanding, conditioned in large measure by cultural factors" (Schachter, 1983, p. 849). This is not surprising given the foundational nature of this notion, as well as the extreme difficulty of finding a precise definition of such a basic concept that satisfies everyone, especially in a transcultural context. This is also explained by the fact that lawmakers are reluctant to provide rigid definitions, which may lead to unsolvable difficulties in the implementation of legal norms. In this regard, they prefer to follow the old Roman dictum: *omnis definitio in iure periculosa est* ("every definition in law is perilous").

Despite this lack of definition, international law offers a helpful guidance for a better understanding of the notion of dignity when it provides, first, that dignity is "*inherent*. . . to all members of the human family" (UDHR, Preamble); second, that all human beings are "free and *equal* in dignity and rights" (UDHR, Article 1); and third, that "these rights *derive* from the inherent dignity of the human person" (1966 International Covenants on Civil and Political Rights, and on Economic, Social, and Cultural Rights, Preambles):

(a) The term "inherent" means "involved in the constitution, or essential character of something," "intrinsic," "permanent or characteristic attribute of something." The idea expressed in this term, when it is accompanied by the adjective "human," is that dignity is *inseparable from the human condition*. Thus, dignity is not an accidental quality of some human beings or a value derived from some particular personal circumstances such as the fact of being young or old, man or woman, and healthy or sick but rather something that all human beings possess *by the mere fact of being human*.
(b) The second important consequence of the meaning that "human dignity" has in international law is that basic rights are *equal* for all: if human dignity is the same for all and the ground of human rights, then all human beings possess equal basic rights. This is the reason why discrimination, that is, the unjust distinction in the treatment of different categories of people is directly contrary to human dignity.
(c) The third statement of international law stressing that rights *derive* from human dignity has also an important practical consequence: if basic rights are not given by authority, but are preexisting values which are inherent in every human being, then they cannot be legitimately taken away by government (Schachter, 1983, p. 853).

Human Dignity in International Norms Relating to Bioethics

Having been firmly established since 1948 as the bedrock of international human rights law, the notion of human dignity began gradually also to play an important role in the field of bioethics. Interestingly, the emphasis on human dignity in

modern bioethics is closely related to the same dramatic events that led to the development of international human rights law. The drafting work of the UDHR was indeed largely inspired by the discovery of the horror of concentration camps, including the revelation that prisoners were used for brutal medical experiments (Baker, 2001). The Second World War was "the crucible in which both human rights and bioethics were forged, and they have been related by blood ever since" (Annas, 2005, p. 160).

The increasing recourse to human dignity in bioethics can be schematically divided into three stages. The first stage, which took place immediately after the end of the Second World War, was focused on issues relating to medical research on human subjects, in particular, the requirement of free and informed consent of participants. This trend crystallized in 1947 in the famous Nuremberg Code formulated by the trial that condemned the Nazi physicians. Although the principles included in the Nuremberg Code do not explicitly refer to human dignity, it is clear that they are immediately inspired on this notion. The *nonnegotiable* nature of the code principles puts in evidence that the idea of an unconditional human worthiness was in the mind of the judges that formulated them. In this respect, it has been stressed that "never before in the history of human experimentation, and never since, has any code or any regulation of research declared in such relentless and uncompromising fashion that the psychological integrity of research subjects must be protected *absolutely*" (Katz, 1992, p. 227). According to Principle 1, "voluntary consent of the human subject is absolutely essential," and "the person involved should have legal capacity to give consent; should be so situated as to be able to exercise free power of choice (…); and should have sufficient knowledge and comprehension of the elements of the subject matter involved as to enable him to make an understanding and enlightened decision." The code also requires that research "should be so conducted as to avoid all unnecessary physical and mental suffering and injury" (Principle 4), that it should not be conducted "where there is an a priori reason to believe that death or disabling injury will occur" (Principle 5), and that "the degree of risk to be taken should never exceed that determined by the humanitarian importance of the problem to be solved by the experiment" (Principle 6). Consistent with the focus on medical research during this first period, the only provision of the International Covenant on Civil and Political Rights of 1966 which directly relates to bioethics states that "no one shall be subjected without his free consent to medical or scientific experimentation" (Article 7). Twenty years after the Nuremberg Code, this article is still like an echo of that historical trial decision.

The second stage in the recourse to human dignity in the field of biomedicine started in the end of the 1970s. It went beyond the domain of medical research and began to cover very different medical practices and techniques that operate at the edges of life, both at the very beginning (assisted reproductive technologies, preimplantation genetic diagnosis, embryo research, etc.) and at the very end (futile treatments, assisted suicide, euthanasia). Human dignity began also to be invoked to criticize some practices that are regarded as new forms of commodification of the human body, like organ selling and surrogate motherhood. In this varied context, it is not surprising if the term "dignity" was sometimes used to support different and

even opposed views (such as in the debate on assisted suicide). This broader and multifaceted function of human dignity is visible in the intergovernmental instruments adopted since the end of the 1990s. Two of the most important ones from a global perspective are the Universal Declaration on the Human Genome and Human Rights and the Universal Declaration of Human Rights and Bioethics, which were adopted by representatives of virtually all countries at the UNESCO General Conference in 1997 and 2005, respectively. The latter one is probably the best example of the key and multifaceted role that human dignity plays in bioethics. The promotion of respect for human dignity is the main purpose of the declaration (Article 2.c); the first principle governing the whole field of biomedicine (Article 3); the main argument every form of against discrimination, including, for instance, genetic discrimination (Article 11); the framework within which cultural diversity is to be respected (Article 12); and the highest interpretive principle of all the provisions of the declaration (Article 28).

The Council of Europe's Convention on Human Rights and Biomedicine of 1997 is another good example of the central and overarching role that human dignity is beginning to play in the biomedical field. According to its Explanatory Report, "the concept of human dignity . . .constitutes the essential value to be upheld. It is at the basis of most of the values emphasized in the Convention" (Paragraph 9). The Preamble refers three times to dignity: the first, when it recognizes "the importance of ensuring the dignity of the human being"; the second, when it recalls that "the misuse of biology and medicine may lead to acts endangering human dignity"; and the third, when it underlines the need to take the necessary measures "to safeguard human dignity and the fundamental rights and freedoms of the individual with regard to the application of biology and medicine." The purpose itself of the convention is defined by appealing to the notion of human dignity (Article 1). Although this is a regional, not a global instrument, its potential impact on a global scale should not be overlooked as it is the only intergovernmental legally binding instrument that comprehensively addresses the linkage between human rights and biomedicine.

Certainly, even with the formal recognition of human dignity as a fundamental principle, there is not always unanimity between countries, and within countries, about the concrete implications of this notion, especially regarding those medical practices that operate at the edges of life. Nevertheless, this does not necessarily mean that a universal conception of dignity does not exist but suggest only that a universal understanding of dignity does not exist *at the margins* (McCrudden, 2008, p. 711).

The third stage in the increasing recourse to human dignity in bioethics started at the end of the 1990s and marked a significant shift in comparison to the previous ones. The notion of human dignity began also to be invoked to articulate concerns about biotechnological developments that may impact on humanity as a whole. What is at stake in this new context is not only the dignity of existing *individuals* but also the value attached to the existence and integrity of the human species as such. It is important to note that a purely human rights approach is powerless to face these new challenges because rights are only enjoyed by *existing* individuals, not by humankind as a whole or by future generations. This is why the new instruments

relating to bioethics directly appeal to the notion of human dignity, and not to human rights, when they condemn practices such as human reproductive cloning or human genetic engineering. Three examples illustrate this trend: the Universal Declaration on the Human Genome and Human Rights of 1997, which emphasizes the need to preserve the human genome as a "heritage of humanity" (Article 1) and expressly labels human reproductive cloning and germline interventions as "contrary to human dignity" (Articles 11 and 24, respectively); the UN Declaration on Human Cloning of 2005, which calls on member states "to prohibit all forms of human cloning inasmuch as they are incompatible with human dignity and the protection of human life" (Paragraph d); the Council of Europe's Convention on Human Rights and Biomedicine of 1997, which prohibits germline interventions on the ground that "they may endanger not only the individual but the species itself" (Explanatory Report to the Convention, Paragraph 89); and the 1998 Additional Protocol to the same convention, which bans human reproductive cloning on the grounds that it is "contrary to human dignity" (Preamble).

The Recourse to Human Rights in Global Bioethics

The emerging global instruments relating to bioethics combine the recourse to human dignity as an overarching principle with the integration of the new commonly adopted standards into a human rights framework. Moreover, these instruments present themselves as an extension of international human rights law into the specific field of biomedicine. Several reasons explain this strategy.

One reason is that, since biomedical activities are directly related to the most basic human rights such as the right to life and to physical integrity, it is logical to have recourse to the umbrella of human rights norms to ensure their protection. In spite of all its evident weaknesses, the existing human rights system, with its extensive body of international standards and wide range of mechanisms and international courts, is an invaluable tool for promoting respect for the most fundamental human goods *also* in the biomedical field.

A second advantage for appealing to a human rights framework in this field is that it facilitates the formulation of universal standards, because international human rights law is based on the principle that basic rights transcend cultural diversity and political borders. Human rights are conceived as entitlements that people have simply by virtue of their humanity and not by any particular condition or circumstance. In other words, human rights are held to be universal in the sense that "all people have and should enjoy them, and to be independent in the sense that they exist and are available as standards of justification and criticism whether or not they are recognized and implemented by the legal system or officials of a country" (Nickel, 1987, p. 561). In such a sensitive field as bioethics, where diverse sociocultural, philosophical, and religious traditions come into play, the universalistic nature of human rights is of crucial importance.

A third reason for the recourse to human rights in bioethics is that the notion of human dignity, which is the cornerstone of global bioethical norms, is unable alone

to provide concrete responses to most challenges raised by biomedical advances. Human dignity is not a magic word that, when uttered, will immediately solve all the complex dilemmas posed by medical technology. This is why the abstract principle of human dignity normally operates through other much more concrete notions (informed consent, bodily integrity, nondiscrimination, privacy, confidentiality, etc.), which are usually formulated using the terminology of "rights."

A more pragmatic reason for casting the bioethical standards into human rights terms is that there are few, if any, mechanisms available other than human rights to function as a global normative foundation in biomedicine (Thomasma, 2001). Moreover, the human rights framework provides "a more useful approach for analyzing and responding to modern public health challenges than any framework thus far available within the biomedical tradition" (Mann, 1996, p. 924). The human rights strategy allows "a well-tested and long-established common language, rhetoric and institutional practice to be applied in order to achieve consensus both on the nature of the problem and, ideally, on the form of possible solutions to it" (Ashcroft, 2010, p. 644).

This increasing use of a human rights framework to deal with bioethical issues does not mean that "human rights will subsume bioethics" (Faunce, 2005) or render bioethical discussions at the academic and professional level useless. Insofar as bioethics is a part of the ethics, it cannot and will never be entirely encapsulated in legal form. Though ethics and law interact in various ways and may significantly overlap with one another, they will always remain as two different normative systems. Legal instruments only attempt to establish a minimal ethics, inasmuch as it is necessary to ensure respect for the most basic human goods. In doing so, the law leaves a broad range of issues open for discussion and to the prudential judgment of the various stakeholders involved in medical practice and research controversies.

Human Dignity, Human Rights, and Cultural Diversity

A common objection to the very idea of human dignity and human rights applying universally is that they embody a Western liberal-individualistic perspective and are therefore alien to other cultures. Attempting to impose respect for human rights standards on non-Western countries would be tantamount to cultural imperialism. This objection can be overcome by considering that, although the current notion of human dignity was systematically developed in the West, it has close correlates in non-Western cultures, as it was mentioned above.

Understandably, each culture articulates the idea of intrinsic human worth using its own conceptual tools, but the crucial point is that this notion is present, in some way or another, in all of them. Concerning the much more modern notion of "human rights," it is a fact that it has its immediate origins in the insights of the European Enlightenment philosophers and in the political revolutions of the end of the eighteenth century, notably, the American and French Revolutions. Nevertheless, this historical circumstance is not a good enough reason to discard the idea that

people have inherent dignity and, as a consequence, equal rights. The relevant question is whether or not this idea deserves to be promoted, no matter where it was conceptually developed for the first time. Merely pointing to moral diversity and the presumed integrity of individual cultures does not, by itself, provide a philosophical justification for cultural relativism nor a sufficient critique of universalism.

It may happen that certain practices that could be seen as cultural traditions of a particular society enter in conflict with human rights principles: lapidation, female genital mutilation, child labor, the "honor killing" of women who are regarded as having brought dishonor upon the family, discrimination against people of lower castes, etc., are the most known examples. These practices, even if accepted by large part of a particular community, are regarded by the international community as incompatible with basic human rights and therefore do not deserve to be given due regard on the ground that they reflect the cultural specificities of a society. In such cases of clear conflict between the supposed cultural values of a society and human rights principles, these latter should prevail. In this regard, the 2005 Universal Declaration on Bioethics and Human Rights, while recognizing that cultural diversity should be given "due regard," makes it clear that such respect is subjected to the condition that it is not "contrary to human dignity, human rights and fundamental freedoms" (Article 12).

In addition, it is a historical fact that international human rights law was developed by representatives of the most diverse countries and cultures. Thus, it is hard to claim that it intends to impose one *cultural* standard. Rather, it can be said that it seeks to promote a minimum legal standard of protection for all human beings, regardless of their specific cultural background. Certainly, in many Western nations, there has been an excessive emphasis on rights and freedoms for the *individual*, sometimes to the detriment of duties and of family and community values, which are of paramount importance to most non-Western (mainly Asian and African) societies. However, it would be equally fair to say that international law has made substantial efforts over the last decades to be more attuned to the communal and collective basis of many non-Western countries. This was done, in particular, through the development of the "second generation of rights" that are included in the abovementioned International Covenant on Economic, Social, and Cultural Rights of 1966, which emphasizes the notion that the individual has not only "rights" but also "duties to other individuals and to the community to which he belongs" (Preamble). The protection of the family, which is recognized as "the natural and fundamental group unit of society" (Article 10), the special protection awarded to children and young persons, the promotion of just and favorable working conditions, and the improvement of education and of public health, have a special place in this document. This tendency toward a broader understanding of human rights has been even further developed in the last few decades through the so-called rights of solidarity, which include the right to development, to peace, to self-determination, and to a healthy environment.

Hence, although human rights remain philosophically grounded within an individualist moral doctrine, it must be acknowledged that serious attempts have been made by the international community to adequately apply them to more

communally oriented societies. This more socially oriented tendency can also be found in the intergovernmental instruments dealing with bioethics. For instance, the 2005 Universal Declaration on Bioethics and Human Rights insists on the importance of developing "new approaches to social responsibility to ensure that progress in science and technology contributes to justice, equity and to the interest of humanity" (Preamble); of taking into account "the special needs of developing countries, indigenous communities and vulnerable populations" (idem); of promoting "solidarity and cooperation" (Article 13); and of fostering the sharing of benefits resulting from scientific research within each society and between societies (Article 15).

In sum, human dignity and human rights, which are by definition universal, are not necessarily in conflict with respect for cultural diversity. This is also valid in the field of bioethics. The circumstance that bioethical issues are closely linked to the deepest sociocultural and religious values of every society is not an obstacle to the formulation of universal norms but, quite to the contrary, can be regarded as a valuable asset in the efforts to develop global bioethical principles. Precisely because bioethics is close to the most cherished aspirations of people, and people are essentially the same everywhere, the development of some minimal common standards in this area is feasible. Human dignity plays in this regard a unifying role by reminding that all human beings are entitled to basic goods and have therefore equal basic rights. From this perspective, human dignity plays the role of a precious bridge between cultures.

Conclusion

Since 1948, the notion of human dignity operates as a central organizing principle of the international human rights system. It also plays a crucial role in the emerging global norms relating to bioethics, which present themselves as an extension of international human rights law into the field of biomedicine. The recourse to dignity in this specific area reflects a real concern about the need to promote respect for the intrinsic worth of human beings and the urgency to preserve the identity and integrity of the human species against potentially harmful biotechnological developments.

However, human dignity alone cannot solve most of the dilemmas posed by biomedical advances. This explains why international norms addressing bioethical issues combine, on the one hand, the appeal to human dignity as an overarching principle with, on the other hand, the recourse to human rights, which provide an effective and practical way forward for dealing with bioethical issues at a global level.

Benefit and Harm

5

Donald Evans

Introduction

Article 4 of the Universal Declaration on Bioethics and Human Rights (UNESCO, 2005) states that:

> In applying and advancing scientific knowledge, medical practice and associated technologies, direct and indirect benefits to patients, research participants, and other affected individuals should be maximized and any possible harm to such individuals should be minimized.

There are two layers of difficulty involved in any attempt to apply this article in either research or practice in health care. The first concerns the fundamental problem of identifying precisely what should count as a benefit or harm in a given situation. The second is to identify the ethical limits of the injunction to maximize the potential benefits and to minimize the potential harms involved in each of these enterprises. In each of these contexts, it is important to identify the relationship between this article and others in the declaration.

What is a Health Benefit?

Let us first consider the former problem by asking the question "What is a health benefit?"

At first glance, it does not seem to be problematic to identify health benefits. We are all only too familiar with the common reasons we have for going to see our doctor. Perhaps we have an unexplained pain, or we are short of breath, or we simply feel dreadful and find we have no energy to do anything. We expect the doctor to diagnose some kind of problem associated with disease, either trivial or serious. We are told that we have an infection or that our condition demands further investigations which will involve sophisticated detective work to determine

whether we are developing a malignant tumor, or rheumatic joints, or a stomach ulcer, or whatever. There is an orthodox nosology to which doctors refer when conducting these investigations. It is tempting, therefore, to conclude that to be healthy is to be free from any of the diseases detailed in that list and being unhealthy is to suffer from one or more of them.

Once we have determined the disease state of a person, then it seems we have also identified their health needs. Absence of disease means no health needs and, therefore, no possibility of health benefits; presence of disease means there is a need for treatment, if there is one, leading to either the cure or the palliation of the effects of the disease each of which counts as a health benefit.

A Narrow Concept of Health

Attractive though the above story is, it is only part of the truth. A cursory glance at the practice of medicine will show that health benefits are available to people who do not presently suffer from any disease. These are provided by prophylactic treatments or disease prevention programs such as vaccination against whooping cough. To be protected from the onset of a disease clearly constitutes a health benefit. Indeed, it has been argued by health economists that these are the cheapest forms of health benefits to achieve. Most people would also prefer that their health practitioners enable them to avoid suffering diseases rather than have to treat those diseases when they occur. However, conceding this point does not move us far from the disease model of health in that the range of health benefits is still exhausted by either the treatment or the avoidance of disease.

If we look more closely at health care delivery, we will see that non-disease conditions are also part of the remit of medicine and surgery. The most obvious treatments which go beyond the disease-related conditions are bodily dysfunctions arising from traumas such as broken legs and brain injuries. Restoring proper physical functioning by treating the results of non-disease events is clearly part of the remit of health care provision. But the practice of health care professionals might go way beyond restoring normal bodily functions in the face of such events. When such restoration is impossible, health care professionals might still have a role in providing health benefits to those who suffer impairments of function. For example, the provision of prostheses to people who have suffered the loss of arms or legs in accidents is doing nothing to restore normal bodily functioning nor to treat or ameliorate the affects of disease. It is to treat a social dysfunction insofar as the new limb enables its wearer to engage in a wider range of social activity and the affairs of life than would otherwise be possible. No one would hold that this was not to provide a health benefit. Such an extension of the definition of health benefits demonstrates that simply widening the disease model of health to one related to physiological function is also inadequate. Here, the social context of a physical condition becomes significant.

Further reflection will soon bring us to a consideration of mental health problems. There are very few people who would assert that such problems always

originate from or are explicable in terms of physiological functioning. Even though there has been vigorous debate among psychiatrists and philosophers about the application of terms like illness to mental conditions, it is generally accepted that many behaviors and psychological phenomena fall under the umbrella of health (Szasz, 1961). Indeed, mental health is a major segment of health care delivery. While there are some advocates for physiological explanations of mental problems, including genetic determinists, most practitioners disagree. Indeed, to take an extreme example, even personality disorders which figure in the Diagnostic and Statistical Manual of Mental Disorders (DSM IV) are not so explained. If, for example, an apparent psychopathy can be explained by the existence of a brain lesion, a physiological explanation, then it is described as a pseudo-psychopathy (Walton, 1973).

The WHO Definition

Given the apparently limitless extension of the boundaries of health and consequently of needs and benefits indicated above, can we find some kind of general description which would secure a manageable range of benefits which health care should aim for? The World Health Organization, fully aware of the dangers of imposing narrow limits on the notion of health, has provided a definition which has been influential for many years. It is as follows: "Health is a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity" (World Health Organisation [WHO], 1946).

This definition certainly takes account of the extensions of health beyond the boundaries imposed by disease-related and physiological dysfunction-related conceptions. It takes the psychological and social dimensions of people's conditions seriously. Insofar as this is the case, the definition is valuable. However, it is limited in its usefulness by the sheer immensity of the range of circumstances and conditions for which, by implication, health authorities should be regarded as responsible. These would include the benefits of the provision of adequate defense capabilities to provide for the security of the population of a country and for the benefits of the provision of education to a population. A later suggested amendment includes "the ability to lead a socially and economically productive life" (ACT Health, 2009). However, the amended definition merely tempers the criticism at the ethical cost of discounting the interests of a large group of potential patients, viz., those who will never be able to live an economically productive life, from the cohort of possible recipients of the benefits of health care and research. In addition, the amended definition might tempt us to consider that there are universal objective measures of health and consequently of health benefits. This would oversimplify the task of identifying and measuring health benefits.

So how do we proceed when we want to identify a health benefit? It seems that the general definitions of health tend to be either too wide or too narrow to fit all cases. It might, therefore, be helpful to look at the arguments that have been made for and against the identification of a particular condition as a candidate for being

a health need and for the identification of the relevant concomitant health benefits which attach to the treatment of that condition by means of the application of a new biotechnology.

The Case of Infertility

Is infertility a health need? (Evans, 1996) Are the benefits afforded by infertility treatment health benefits? Should scarce health funds be used for providing treatments for infertility?

For centuries, the inability of couples to produce their own children was blamed on the female partner who was described as barren. We now know that in at least half of the cases of infertility, the problem lies with the male partner rather than the female and is usually connected to an inadequate production of sperm. This knowledge has come as a great relief to many women who suffered misplaced guilt, anxiety, and social disapproval for not being able to become mothers. But such a relief is a small comfort to them when nothing can be done to address the issue of their childlessness.

In limited numbers of cases, women with disease conditions which caused their infertility could be treated for those diseases, or the results of them, and their fertility could be restored. Tubal surgery is still performed for this purpose. Such treatments enjoy limited success. But they also leave unhelped couples whose infertility is not explained and those whose infertility is due to their male partner's physiological problems. The technological breakthrough of in vitro fertilization (IVF) in the late 1970s afforded clinical hope for these couples. Professor Robert Edwards has reported that by the year 2002 more than a million children had been born as a result of the use of this technology and that by 2012 he estimates that ten million people will be alive who were born by these means (personal conversation, October 22–24, 2002). But the provision of these services has been the subject of continued dispute among health care providers in numerous parts of the world (Evans, 1995).

The problems can be seen to arise from the difficulties presented by the temptation to assume that health is fundamentally constituted by the absence of disease. This is clearly demonstrated in a research paper which compared the behavior of a number of health providing authorities in the United Kingdom (Redmayne & Klein, 1993). Half of them refused to purchase IVF treatments while the other half did purchase them. The reasons for their choices are illuminating. The predominant reason given by the non-purchasers of IVF services was that couples with unexplained infertility were not ill and that their infertility was not a disease. Even some of the purchasers gave reasons which also embodied the assumption of the need to relate the treatment to disease in that they purchased the services as a prophylactic designed to ward off the onset of stress and mental illnesses which often arise from infertility.

Others paid lip service to the importance of social aspects of the condition but in such a way as to bar it from treatment. The view was that the condition of

childlessness constituted a social need rather than a health need. It is the case that the use of IVF does not really constitute a treatment of infertility as such but rather that of childlessness. This is because the treatment leaves the couple as infertile as they were before that condition was circumvented to achieve a pregnancy. But to disengage such physiological conditions from the context in which they occur, as these non-purchasers did, is a sure way to misidentify health needs and benefits.

It is not difficult to make a case for regarding infertility as a health need in certain circumstances and, hence, to regard its clinical circumvention as a health benefit. It is acknowledged by all that the condition is a source of much unhappiness and stress causing suffering for many couples. It is also clear that it constitutes a physiological dysfunction. The function of procreation is a fundamental physiological function at the species level. But it is also an extremely important function at the personal level for the vast majority of people for whom living in and rearing families is a major constituent of emotional well-being. For the infertile couple who long for a child, the dysfunction is socially debilitating. We have already noted that other dysfunctions such as the loss of limbs are standardly treated by health care professionals because of their socially significant consequences. So why not infertility or, rather, childlessness? Until the advent of IVF and the subsequent research on the early stages of human development and reproduction, there was little that could be done to address the condition for most couples. Thus, they could not then be said to have any need for clinical treatment. But now that we do have clinical means to circumvent their infertility and enable them to achieve a pregnancy in many cases, they can be said to have a clinical need. This is tantamount to saying that they have a health need and that the successful bringing to birth of a child constitutes a health gain.

It now begins to look as though the amended WHO definition of health does, after all, serve the purpose of identifying what shall count as a health benefit; if we add the rider that where a clinical intervention can achieve the possibility of a socially productive life, then it achieves a health benefit. However, this is not quite so. One might be tempted to read it as suggesting that wherever infertility is found, then it represents a physiological dysfunction which calls for treatment. But this would be a mistake. It is possible to argue that no physiological condition in itself constitutes a health need. That is, until the condition is cast in the context of the life of the person or persons concerned, we cannot know whether it is a health need or not. This is easily demonstrated in the case of infertility or childlessness. It is ironic that in many areas where IVF services are not accessible to patients, contraceptive and sterilization services are available. Of course, in some cases, sterilization, for example, is thought to be an important clinical treatment to avoid the possibility of diseases unrelated to reproduction. But in most cases, it is offered in order to produce a desirable biological dysfunction for the patient concerned. For those patients, their fertility is seen as constituting a health need and the state of childlessness, whether temporary or permanent, is seen to be a desirable condition. Thus, in the process of identifying possible health benefits, it is important to consider the particular circumstances of each patient in question in order to see whether the apparently general rule in fact applies.

Above All, Do No Harm

It will not be surprising to learn that the task of identifying harms in health care delivery suffers from the same difficulties as the identification of benefits. The conclusions reached in the use of reproductive technology above apply equally to the following case of identifying harms. Let us imagine that a surgical procedure to remove an ovarian cyst is carried out successfully on a patient. In the course of the procedure, one of her fallopian tubes is inadvertently damaged and scarred. This damage results in infertility. Has a harm been visited upon that patient? The answer to this question is that it all depends on the patient. If the patient considers that she has completed her family and that she will not want any further children, then the inability to conceive will not constitute a harm for her. Of course, it might turn out that she will change her mind about this given the possible circumstances which could develop in her life. In such an event, she would come to consider that the surgical error did harm her. In other words, we are obliged to consider the context of the surgical mistake in the life of the patient before we can determine whether it was harmful or not.

We have seen that the application of a general rule for identifying a health need crucially masks the variety of possible perceptions of harm and benefit. Some situations are even more complex and demanding of the clinician than those we have considered. Indeed, this variety can sometimes challenge the most basic assumptions about what constitutes a health care intervention and a lack of imagination or willingness in a health professional; to contemplate such challenges can vitiate the critical determination of what treatment is indicated for a given patient.

The juxtaposition of three recorded clinical cases each involving what might be naively considered as the same intervention graphically illustrates this point (Evans, 2008). The intervention which was either contemplated or executed in each case was the amputation of a limb, viz., a leg.

C was a paranoid schizophrenic patient who was detained in Broadmoor Special Hospital following his arrest on the charge of attempting to murder his fiancée and his subsequent diagnosis. After some 30 years of detainment there, he developed a gangrenous foot which was diagnosed as life threatening. The hospital authorities wished to proceed with an amputation but this was challenged by the patient. A delusion that he was an important surgeon might well have clouded the issue of whether he was competent to determine whether he should be so treated. Such a condition would lead one to think that he mistakenly thought that the clinical decision was flawed. However, when asked by the court why he did not want the amputation, he declared that he would rather be dead with two feet than alive with one. In other words, he considered that the procedure would so undermine his dignity that his subsequent life would be undesirable. This had nothing to do with the likely outcome of the procedure in clinical terms. That is, it was not a question of his being correct or mistaken. Thus, Judge Thorpe declared that he was competent to decide for himself. C's decision was based on his perception of what was an acceptable life. On this, the court considered him to be the authority (Re C, 1994).

The one-legged man was a combatant in the trenches in Northern France in the 1914–1918 War. He was the victim of shell fire which so seriously injured his leg

that it was amputated in a field hospital following which he was repatriated to England. He has been immortalized in a short poem entitled "The one-legged man" (Sassoon, 1961). Now living in the English countryside in peacetime, he reflects on the loss of his limb:

> Safe with his wound, a citizen of life,
> He hobbled blithely through the garden gate,
> And thought: 'Thank God they had to amputate!

Life was sweet and highly desirable. He would, without doubt, prefer to be alive in his own land with one foot than dead in the trenches of Northern France with two.

Now how much sense is there in asking which of the two, the old soldier or C, was correct? The answer is plain; there would be no sense in it. This was not a matter of the calculation of empirical odds for them. It was rather a matter of fundamental differences in their valuation of a certain kind of existence. One would need to know more about each of them than their clinical conditions as diseased or injured men in order to understand whether the procedure was indicated for them or not.

The significance of the absence of a general rule for determining what constitutes a harm or a benefit to individual patients might go even deeper in determining what is an indicated treatment for a patient. Consider the case of a proposed amputation for a patient whose leg was neither diseased nor injured.

From the age of 8 years, Kevin Wright had felt that his healthy left leg was not part of him. This unease resulted in considerable emotional pain and distress which defied treatment by medications or behavioral therapy. In desperation, he sought the amputation of the limb. This request seemed to be totally unacceptable to a number of surgeons who were approached. Robert Smith, a Scottish surgeon, thought more carefully about the case. He was able to reject some descriptions of the motivations for requesting the procedure by examining his medical record and engaging in extensive conversations with him. He concluded that the patient's desire was not motivated by some sexual deviation, by a desire to be dependent, nor by a tendency to self-mutilate for gratification. He embraced the diagnosis of body dysmorphic disorder (BDD) in the case and proceeded with the amputation. Following the procedure, the patient claimed that the surgeon had made him complete (Taylor, 2000).

The Balance Between Benefit and Harm

There remain some interesting issues to consider around the question of identifying and avoiding harms in health care. If the hippocratic oath which asserts the primum non nocere (above all do no harm) principle is to be adhered to in practice, how can any surgical procedure be attempted or indeed any medication be prescribed when we can never know with certainty what the effects in total of that intervention will be in a given patient? In another context, the wound inflicted by the surgeon in an abdominal operation would constitute a grievous bodily harm. Similarly, the

administration of cytotoxic drugs in other situations than in treatments of malignant disease would constitute poisoning. What justifies them in surgery and chemotherapy is the net balance of benefit over the harm which the treatments inevitably involve. Indeed, any clinical intervention has to be undertaken only after the completion of a risk of harm/benefit calculation. If a patient does not stand the chance of benefiting overall from an intervention, then that intervention is not indicated for him. That is, where the risk of harm outweighs possible benefit, the treatment is not indicated.

These calculations are often very difficult to make for, not only will the variety of perceptions of harm and benefit mentioned earlier come into play, but also the empirical and conceptual uncertainties of the possible outcomes will confound the procedure.

With respect to the former uncertainty, it has been said that every administration of a drug is an experiment. How one patient will react will not always be a reliable guide to how another will react. One patient with the same disease as another might respond well to a drug whereas the other will remain unhelped. Or one might suffer unpleasant adverse events whereas the other will tolerate the medication well. While there is hope that the new technology of pharmacogenomics will increase our levels of confidence in matching medicines to patients and remove much of the trial and error element of prescribing, it will never eliminate uncertainty.

With respect to conceptual uncertainty, we might consider the difficulties of making risk of harm/benefit calculations in withdrawing or continuing intensive care treatments. In such circumstances, it is often difficult to distinguish between whether it is of benefit to a patient to withdraw life prolonging treatment as to ask whether it is harmful to continue life support where it precludes the possibility of a death with dignity. In such situations, we might be tempted to describe any choice equally as being beneficial or harmful.

Acute and Elective Procedures

Another context in which harms and benefits have to be recognized and weighed is in the classification of clinical cases as acute or elective. No health service is able to treat all patients as soon as they present themselves with a health problem. Access to services is managed by means of a distinction between acute and elective treatments. These classes are defined in terms of the possible harms which are likely to result from not treating the patient immediately. There are two categories of harm involved in the distinction. The first is that failure to treat as soon as possible could result in death. The second is that failure to treat immediately could lead to irreparable damage. Thus, it makes no sense to place a case of the rupture of an aortic aneurism on a waiting list as time is of the essence if that life is to be saved, whereas treatment of a standard abdominal rupture could be delayed without risk. Similarly, it is dangerous to delay treating a patient suffering from septic arthritis whereas treating a case of osteoarthritis could be delayed beyond the immediate future. There might be graded waiting times also depending on the rate at which

gross damage could occur. Thus, for example, one might distinguish between immediate, urgent, semi-urgent, and routine cases where septic arthritis would rank as immediate, seropositive RA as urgent, inflammatory polyarthritis as semi-urgent, and osteoarthritis as routine. This possibility of ranking certain conditions will be examined in more detail in the next section.

Once again, there will be difficult cases arising in these categorizations. For example, some might regard any cancer diagnosis as potentially life threatening and, therefore, as an acute condition. However, it is known that whereas some cancers are aggressive and the earliest intervention offers the only chance of recovery, others are more gradual. Yet even in these cases, postponement of the provision of care beyond a short time frame is dangerous because of the possibility of the development of systemic problems and secondary metastases. Certainly, in the mind of the sufferer, delays will appear to be grossly neglectful and the possibilities of good outcomes become more and more remote.

In contrast, chronic diseases which involve joint damage such as hemophilia and rheumatoid arthritis might not be threatening in the way that malignant tumors are but, nevertheless, they can result more or less quickly in catastrophic disability. Protection against the deterioration of joints by the avoidance of bleeds through the prescription of Factor 8 or steroids and antimetabolites to counteract connective tissue disease is also called for promptly. Insofar as these kinds of classification are feasible, it is possible to grade degrees of harm and benefit. However, we have to be careful not to be too ambitious in scoring relative harms and benefits. The temptation to extend the process is often demanded by attempts to manage resource allocation and access to health services. This runs up against both empirical and conceptual difficulties.

Maximizing Benefit and Minimizing Harm

Let us now turn to the second feature of Article 4 (UNESCO, 2005), which enjoins us to maximize benefit and minimize harm insofar as they can be identified.

It is plausible to claim that in times of scarcity of health care resources, one ought always to seek to achieve the maximum benefit from the investment of every health dollar. It seems that any other approach will applaud the achievement of less benefit than was possible and result in the denial of care to some patients (Mooney, 1986). This view is in line with many of the approaches of health economists who operate on a utilitarian model of determining correct allocation decisions (Mill, 1910). Mill's guiding principle is often called the greatest happiness principle in that it asserts that whatever action achieves the greatest happiness of the greatest number of people is the right action to perform. Any other action is less than optimal in terms of its rightness as it fails to achieve the maximization of happiness. Before we apply this theoretical structure to the health care setting, it is important to note that Mill himself recognized problems in its application. They were largely concerned with making the calculations called for to determine which action would maximize happiness. We shall see that this problem is more than an empirical

difficulty. It is a conceptual problem attaching to the nature of goods or benefits which are the measure of the rightness of an action and to the correlative harms. This is a problem which we have earlier discussed in the health care setting.

The search for one measure of goodness was designed to facilitate the utilitarian calculations. Happiness was his choice. But he recognized that different people have different views as to what happiness is. The tongue-in-cheek proposal of convening a committee of experts in happiness to adjudicate the matter is amusing. These experts, having experienced all the pleasures, would be in an authoritative position to tell us which were the best pleasures. Of course, such a proposal is nonsense. Some pleasures are antithetical to others such that they cannot all be experienced by the same person. There are no experts in happiness and the view of such a committee would be a view from nowhere.

But this lesson has not been learned in health care management where efforts are still made to find a single measure in terms of which to cast health needs and to rank them. Concepts such as the restoration of normal ranges of opportunity have been candidates for this role (Daniels, 1985). The truth is, however, that these are also views from nowhere. Both the identification of health goods or benefits and the aggregation of health benefits to discover the maximal outcome from health expenditure are not simply difficult to achieve, they are misconceived. We have seen the problem of finding a universal identifier of health benefits and harms, so let us now consider the problem of trying the aggregate health benefits and harms. Even if we agree on the identification of health benefits, how can we perform the calculations needed to tell us which is the most efficient way to spend health resources in order to maximize outcomes?

Two kinds of calculations have been designed to assist in the task. One is misleading, the other is useful. The misleading concept is of horizontal aggregation. This consists in attempts to find a common measure, such as the one mentioned above, in terms of which one might cash any given health condition and, hence, use this common currency to compare the outcomes of given investments. But the endeavor fails to recognize the incommensurability of harms and, consequently, of benefits in health. It is not difficult to illustrate the impossibility of achieving such a goal. Imagine trying to ranking the following five conditions in terms of their worseness – that is, endeavor to answer the question which condition would you least like to suffer from and which next and so on. Here is the list: blindness, a grossly disfiguring facial disease, the shortening of one's life by 25 years, serious mental illness, and constant intractable and intense physical pain. It is simply not possible to think of a currency in terms of which we could form such preferences. How much more difficult would it be to decide between the value of one person's blindness, another's mental illness, and another's shortening of life? Health managers have to make macro-decisions about expenditure in all these fields. But it is dangerous to pretend that we can put a management tool in their hand to make definitive determinations of relative need between such patients. Thus, there is a conceptual problem in aggregating or ranking all health conditions.

Yet if we want to achieve equity in health care provision by treating people according to their degree of need, then we must to be able to compare the needs of

some persons to those of others. This is possible using the second model of aggregation, viz., vertical aggregation. It embodies the principles involved in the previous example of arthritis. While ranking is not possible across conditions which are dissimilar, save in respect of the acute/elective kind of distinction, it is possible within specific health services such as surgical intervention for hernias, varicose veins, Dupuytren's contracture, cataracts, and so on enabling clinicians to compare the severity of the condition of one patient with that of another and to perform a fair calculation of relative health needs between them. While this is not an exact science, some contrasts are clear. For example, where a patient's vision is so defective that reading is impossible and even leading an independent life is ruled out by the condition, the need will be seen as greater than that of patients who do not need to live independently and for whom reading is not an important activity. The social limitations imposed on the sufferers by their condition such as the ability to continue employment or carry out weighty family duties can also be built into this assessment. In these ways, patients who do not count as acute cases might still be ranked above other patients on the basis of their degree of need for an intervention.

Clinicians have worked hard in many disciplines to produce reliable tools for ranking their patients within the confines of specific conditions in this manner in order to inject more equity of access to services than is afforded by crude waiting list systems (Derrett, Devlin, Hansen, & Herbison, 2003). It is, therefore, important to note that measurements of need and, consequently, of harm and benefit are possible when related to individual patient narratives. But this does not involve the maximization of benefit. On this model, less benefit might be achieved overall from a given investment of resources but the allocation will be better insofar as it is fairer (Evans, 2008). Maximization models discriminate against minority groups, the chronically ill, the dying, the mentally ill, and the elderly among others, insofar as all calculations employing measures which involve multipliers such as the degree and duration of benefit militate against the interests of both those whose health problems afford less prospect of extremely good outcomes and those whose longevity is compromised.

Interrelation of Article 4 with Other Articles in the Declaration

While we have noted that maximization of benefit as such is an ethically questionable goal in the allocation of health care provision, there are important senses in which maximizing the provision of benefit and minimizing the occurrence of harm is an ethical requirement. Article 4 does not in any way throw doubt on this claim. It is rather concerned to describe the intent of clinicians, researchers, and institutions in the area of health to aim for a proper balance of benefit over harm in the clinical encounter. It is not so much concerned with the issue of who should be afforded the privilege of such an encounter as with the predominant motivation of clinicians vis-à-vis their relationship with each individual patient for whom they are providing care. The wording is clear in its application to patients where

it specifies that in *applying* scientific knowledge in medical practice and associated technologies, direct and indirect benefits to patients should be maximized and any possible harm to such *individuals* should be minimized. We have already noted that the notion of an "indicated treatment" is based on such individual calculations.

However, the article has wider connotations related to the issues of maximization of benefit and minimization of harm which become clearer when we see its relationship to other articles in the declaration.

The article mentions the concepts in relation to the conduct of research in health care. Here, we need to be precise for it might appear that the wording enjoins that research participants as such are to enjoy the maximization of benefit and the minimization of harm. The latter idea is the sine qua non of good research involving human participants (Nicholson, 1986; Evans 2012). However, the former idea, viz., that research procedures should maximize health benefit to participants is incoherent. Research protocols are designed to determine whether a novel treatment is safe and, then, whether it is effective. No benefit can be promised to research participants for the very research question being posed in a trial is whether the novel procedure can count as a treatment at all. Until this question is answered, no promises of benefit can accompany the administration of the novel drug or the execution of the novel procedure which is being researched.

However, there is an important sense in which the maximization of benefit is applicable to the research enterprise. This sense becomes clear when the relation between Article 4 and other articles in the declaration are recognized. For example, Article 15 deals with the issue of the sharing of the benefits of research (UNESCO, 2005).

> Benefits resulting from any type of scientific research and its application should be shared with society as a whole and within the international community, in particular with developing countries.

This extension of as wide a range as possible treatments to as many people as possible is not a maximization policy in terms of who shall be refused treatments (as resource allocation models are), but rather a response to the fundamental needs of as wide a group of sufferers as possible, vast numbers of whom are not even candidates for their health needs to be addressed at all at present. These needs will in turn also have to be graded between individuals for their application, but until they are recognized and addressed, for example, in relevant research, no allocation decisions are even called for.

This is a program of the maximization of benefit if it is anything. It can take a number of forms. For example, special consideration should be given to those who participate in the research. In the past, some groups, especially from developing countries, who have participated in the research phase of the development of drugs, have been denied access to those drugs when they have been marketed. Such barriers should be removed. In addition, maximization of the benefits of research also entails the provision of quality care on the widest basis including access to diagnostics and novel therapeutic modalities and the sharing of expertise and

knowledge. These are but part of the declaration's intent to link ethical behavior in health care practice and research to human rights. There are further elaborations on the theme in Article 14 on social responsibility and health (UNESCO, 2005).

> Taking into account that the enjoyment of the highest attainable standard of health is one of the fundamental rights of every human being without distinction of race, religion, political belief, economic or social condition, progress in science and technology should advance access to quality health care and essential medicines, especially for the health of women and children, because health is essential to life itself and must be considered to be a social and human good.

While the ethical encouragement to provide the benefits of research to as many citizens of the world as possible is laudable, there are major obstacles to its achievement. These obstacles include national interests and the interests of investors in health research. Article 15, as we have noted, strongly suggests that these barriers are not justified insofar as they deny fundamental human rights to large proportions of the world's population. This is not to say that these interests are improper. It is, however, to say that though they are justifiable and even essential, there should be room for accommodation of the interests of humanity in general in programs of health care research and delivery. This can be illustrated in the role which university research plays in health research (Evans 2012).

Researchers have always been jealous of their discoveries and have wished to protect them from misappropriation. Isaac Newton so feared that his methods and results in his enunciation of the Laws of Motion would be copied that he slept in his laboratory at Cambridge to watch over them. He later accused Leibniz of plagiarizing them. Similarly, there was a dispute over whether Louis Pasteur plagiarized the results of Bechamp's research in his discovery of the germ theory of disease. Preserving due credit for research results is an ethical enterprise. However, things have moved beyond that in the academy where such protections have been hardened into intellectual property rights (IPRs) which effectively privatize the knowledge so providing funds for the University by licensing the use of this property by other researchers and practitioners in exchange for royalty payments. The owners of the knowledge can make the knowledge available to those who are both willing and able to pay for it and deny it to the rest. The academy has met the market. This is far from a maximization of the benefits of the research though it is a maximization of the profits of the owners of the knowledge.

If this is true of the university which has traditionally been much involved in public good research, then what hope is there of maximizing the benefits of that knowledge discovered and patented by multinational companies? There is need for the establishment of ethical guidelines in business to ensure that room is left for the exploitation of the products to meet the dire needs of vast numbers of human beings in the developing world. The 10/90 gap identified by the Global Forum for Health Research has shown that only 10 % of the monies invested in health research are related to the health needs of 90 % of the world's population. Consider the graphic example of the likely developments of nanotechnology as discussed by Singer, Salamanca-Buentello, and Daar (2005).

The authors consider the question of the likely future direction of the development of the technology in the context of the rival pressures of the market, on the one hand, and the fundamental needs of vast numbers of citizens of developing world on the other hand.

The needs involved are overwhelming. Eighty percent of the diseases in the developing world are water related. 1.5 billion people currently lack access to clean water. It has been estimated that 3.4 million deaths per annum result from the use of water contaminated by bacteria, viruses, oil, and heavy metals. Nanotechnology offers solutions to this contamination. Singer et al. (2005) list three possible tools nanotechnology might offer to achieve this highly desirable extension to the benefits of progress in science.

1. Intelligent membranes can be produced to make affordable and portable filter systems which will remove most contaminants including bacteria and viruses. These materials are 10,000 times more capable of binding bacteria and toxins than activated carbon.
2. Nanomagnets with various coatings can be designed to deal with specific contaminants, including oil, from water. Such dustlike preparations could be spread over wide areas and gathered up affording almost 100 % effectiveness. These nanomachines could be recycled and used over and over.
3. Magnetite nanoparticles combined with citric acid could remove heavy metals from water.

But will the development of this technology move in this direction under pressure from the desperate needs of so many human beings or will it succumb to the pressures of the marketplace? Singer et al. (2005) starkly pose the question.

> Will nanotechnology produce the nanodivide? Resources might be directed primarily to nanosunscreens, nanotrousers, and space elevators to benefit the 600 million people in rich countries, but that path is not predetermined. Nanotechnology could soon be applied to address the critical food, water, and energy needs of the five billion people in the developing world.

Conclusion

The identification of health benefits and harms is crucial in the delivery of effective health care services; though it is a complex activity. It is also crucial in the allocation of those services to patients. However, it is important to remain aware of the limitations which attach to this activity both in clinical practice and health care management. Maximization of benefits as a tool for the rationing of health care offends the ethical principle of equity (Article 10). However, to ignore the responsibility to maximize the use of medical and technological innovations also offends against the fundamental right of human beings to the enjoyment of the highest attainable standard of health without distinction of race, religion, political belief, economic, or social condition (Article 14). Actions are called for to temper obstacles to the sharing of medical and technological knowledge as demanded by Article 13 and 14 of the declaration. Solidarity among human beings and international cooperation toward that end are to be encouraged.

Autonomy and Individual Responsibility

6

O. Carter Snead and Kelli Mulder-Westrate

Introduction

The Universal Declaration on Bioethics and Human Rights is an extraordinarily ambitious document. It seeks to "provide a universal framework of principles and procedures to guide States in the formulation of their legislation, policies or other instruments in the field of bioethics" (Universal Declaration, Art. 2(a), 2005). Few, if any, intergovernmental instruments match its breadth in terms of subject matter covered ("ethical issues related to medicine, life sciences and associated technologies as applied to human beings, taking into account their social, legal and environmental dimensions") (Universal Declaration, Art. 1, 2005). It is also notable for the unusually vast audience to whom it is addressed. Not only is it meant to offer advice to member states but also "to guide the actions of individuals, groups, communities, institutions and corporations, public and private" (Universal Declaration, Art. 2(b), 2005). The Declaration has received some attention from scholars and policy makers, both positive and negative. UNESCO itself has taken steps to circulate and promote it, including by publishing commentaries on its various provisions, authored by invited contributors, including the International Bioethics Committee itself. But one aspect of the Declaration has not yet received the attention it deserves, namely, its treatment of autonomy as an ethical principle. Whereas autonomy has been accorded pride of place as the dominant ethical principle in mainstream bioethics for decades, the Declaration offers a strikingly different approach. That is, it subordinates autonomy to other goods such as human dignity, solidarity, and protection of the vulnerable. In this way, the Declaration recovers and restores the original key animating good for public bioethics that gave rise to this new species of law and policy in the first instance. It marks an important return to the foundational principle of respect for persons.

This chapter will elaborate on this countercultural feature of the Declaration and offer an argument that it is a salutary development for public bioethics. To that end, it will proceed in the following manner. First, it will supply a necessarily

compressed account of the shift from respect for persons to respect for autonomy as the dominant ethical norm in public bioethics. Next, it will argue that this singular emphasis on autonomy has impoverished public bioethics as a form of governance (and a field of inquiry). This chapter will then explain how the Declaration represents a turnaway from this approach, toward the embrace of a suite of goods squarely situated within the concept of respect for persons, richly understood.

Brief History: From "Respect for Persons" to "Respect for Autonomy"

The origins of bioethics in its scholarly and public forms are complicated and contested (Jonsen, 2003, offering a compelling account of this history; Snead, 2010, offering an extended discussion). As a field of interdisciplinary scholarly inquiry, bioethics seems to have emerged in the middle of the twentieth century (late 1960s) in large part as a reaction to the simultaneous increase in technical skills on the part of physicians (enabled by extraordinary advances in biomedical science) and *decline* in the humanistic dimension of medical practice. As doctors became more technically proficient, they also became (or were widely perceived as becoming) more humanly distant from their patients. The almost priestly role of the physician (who had historically ministered to the whole person and her family) gave way to a narrowed emphasis on the technical mastery of interventions aimed at correcting clinical pathologies. As a result, patients increasingly felt neglected as participants in their treatment. Worries about paternalism proliferated. In response, an interdisciplinary array of physicians, theologians, philosophers, legal scholars, and social scientists convened meetings and founded centers to explore these and related matters. These events, according to Albert Jonsen (and other commentators) marked the beginning of bioethics as a field of scholarly inquiry (Jonsen, 2003).

The birth of *public* bioethics (i.e., the *governance* of medicine, science, and biotechnology in the name of ethical goods), however, emerged in response to a very different series of events. Unlike the scholars and commentators described above, public officials charged with making, enforcing, and interpreting the law were not "driven by a desire to tame the imperialism and arrogance of medicine" (Schneider, 1994b, p. 1076, describing the theoretical foundations of bioethics and the role of autonomy as its dominant norm). Instead, they were moved to action in the face of a series of grave abuses of the weak and vulnerable by scientific researchers. Such abuses occurred at the hands of Nazi scientists in concentration camps (later prosecuted for crimes against humanity in a trial that culminated in the publication of the Nuremberg Code), by researchers who (from 1963 to 1966) deliberately injected children at the Willowbrook School for "mentally defective persons" with the hepatitis virus, by investigators who (in 1963) intentionally and without consent injected living cancer cells into patients at New York City's Jewish Chronic Disease Hospital, and by researchers in 22 separate clinical studies whose unethical practices were documented by Harvard's Dr. Henry K. Beecher in his groundbreaking 1966 article in the *New England Journal of Medicine* (Davis, 2008).

But two events in particular prompted members of the United States Congress to convene hearings in 1973. First, lawmakers in Congress were spurred to respond by reports of the Tuskegee Syphilis Study, in which scientists from the US Public Health Service enrolled 399 poor black men suffering from syphilis in a research project aimed at studying the progress of the disease in its untreated form. For 40 years, the researchers systematically deceived these men and their families about the nature and purpose of the project. Worse still, the researchers did not administer antibiotics to the subjects, even after the drug became established as an effective treatment for the disease in 1947 – 15 years after the study began. Second, lawmakers in Congress were animated by reports of experimentation on unborn children slated for abortion in protocols that involved temporary life support followed by direct killing in especially gruesome and painful fashion (Jonsen, 2003, pp. 94–95). Jonsen quotes one researcher as saying "I don't think it is unethical. It's not possible to make this fetus into a child, therefore, we can consider it as nothing more than a piece of tissue."

It is notable that in all of the aforementioned instances of abuse – from Nuremberg forward – the researchers involved attempted to defend their actions on the grounds that they had not created the underlying tragic circumstances facing the various subjects, nor would their interventions materially harm them further. The subjects were already destined to suffer from dread diseases or to be killed in any event. By their lights, the researchers were merely trying to salvage something useful from an unfortunate circumstance. Understandably, these arguments have been widely rejected and criticized. It is one thing to accept the unavoidable death or suffering of another. It is another thing entirely to appropriate and instrumentalize the circumstances and (as in the cases of some of the researchers described above) intentionally infect or even kill the otherwise doomed subject for the sake of research.

In response to these two particularly troubling examples of unethical and abusive conduct by researchers, Congress passed the National Research Act of 1974, which, among other things, established the National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research (Pub. Law No. 93–348). This development marked the first time an organ of government was created with explicit charge to "do bioethics" in the name of the state.

Given the constellation of research scandals to which the National Commission was a response, it is not surprising that an anchoring norm of its iconic 1979 *Belmont Report* was the principle of "respect for persons." This principle entailed a twofold protection for persons in the context of biomedical and behavioral research. First, the Commission asserted that respect for persons includes respect for their autonomy and self-determination (to be realized through legal mechanisms such as informed consent). Second, it claimed that respect for persons imposes an obligation "to protect those with diminished autonomy," including persons who are "immature and the incapacitated" (National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research, 1979; Lysaught, 2004, pp. 665–680). Thus, while the National Commission proposed a principle for public policy that protected self-determination (in a way that aligned with the

aforementioned concerns about medical paternalism), it likewise attended to worries about the vulnerable class of persons whose diminished cognitive abilities render them unable to defend their own interests. In this way, the Commission cast an admirably wide net of protection for people in a domain where the risks of extraordinary forms of abuse had already been tragically demonstrated.

In short order, however, prominent and influential voices moved to constrict the circle of protection constructed by the National Commission. As both M. Therese Lysaught and F. Daniel Davis have shown, in a series of high-profile commentaries and textbooks, the principle of respect for persons was replaced by a new, more limited principle – respect for autonomy (Davis, 2008; Lysaught, 2004). Lysaught details how this change of course emerged in particular in Beauchamp and Childress's first edition of *Principles of Biomedical Ethics* (1983).

Beauchamp and Childress's *Principles of Biomedical Ethics* has perhaps become the single most influential work on bioethics and departs significantly from the *Belmont Report*. Beauchamp and Childress restyled *Belmont*'s "respect for persons" simply as the principle of autonomy or *respect* for *autonomy*. Whereas the *Belmont Report* presupposed an inverse relationship between autonomy and protection, Beauchamp and Childress took the opposite view. In the framework set forth by the *Belmont Report*, the moral imperative to protect individuals from harm increases as their autonomy diminishes: "Respect for the immature and incapacitated may require protecting them as they mature or while they are incapacitated. *Some persons are in need of extensive protection, even to the point of excluding them from activities which may harm them*" (Lysaught, 2004, p. 669 quoting the *Belmont Report* 1979, p. B.1 3, emphasis added). Moreover, in the *Belmont Report*, the obligation to protect the vulnerable extends to all human beings, not merely those capable of individualized choice (Lysaught, 2004, p. 678). By contrast, Beauchamp and Childress distinguish autonomous and nonautonomous individuals, privileging only the former as full "persons" entitled to robust care and protection (Lysaught, p. 676). For Beauchamp and Childress, "respect" thus becomes something like "noninterference" and is defined almost solely by informed consent (Lysaught, p. 676). This form of respect is not due "to persons who are not in a position to act in a sufficiently autonomous manner" (Beauchamp & Childress, 1983, p. 64). The *Belmont Report*'s framework for protecting the vulnerable under the heading of "respect for persons" drops from consideration altogether.

Moreover, with the rise of autonomy to pride of place among bioethical principles, the concept of "personhood" itself became truncated to include only those human beings capable of rational choice. Ruth Macklin confirmed as much when she famously equated "human dignity" with autonomy. She argues that dignity (and the respect and protections that it entails) is owed only to those whose actions and thoughts are "chosen, organized and guided in a way that makes sense from a distinctly individual point of view" (Macklin, 2003, pp. 1490–30 quoting the Nuffield Council on Bioethics, Genetics and Human Behaviour). In a similar vein, Steven Pinker has argued that human dignity is "stupid," "a mess," dangerous, and should be abandoned in favor of a single-minded focus on respect for autonomy (Pinker, 2008).

This startling shift from respect for persons to the narrower respect for autonomy seems to emerge, in part, from a desire to push the boundaries of scientific research, especially with regard to abortion and embryo research. Lysaught argues persuasively that the shift to autonomy alone was meant to enable the endorsement of activities that "traditionally would have been strong candidates for violating 'respect' – for example, destroying embryos, creating embryos for research, creating embryos through cloning, and creating chimeras" as "morally licit" pursuits (Lysaught, 2004, p. 667 discussing National Bioethics Advisory Commission, 1999, internal citations omitted). The shift to autonomy likewise seems to be driven by the aspiration to identify an ethically "thin" principle that would command broad appeal in a pluralistic culture and thus provide a suitable basis for public policy.

The Consequences of the Hegemony of Autonomy in Public Bioethics

The consequences of this shift to autonomy as the singular lodestar of public bioethics have been profoundly deleterious. As Carl Schneider points out in his article, *Bioethics with a Human Face*, the notion of autonomy alone does not capture the whole truth of what it means to be human. He argues, "A powerfully stated and too-often simple autonomy paradigm has become the central feature of bioethical thought and law. Yet, despite the undoubted and true importance of that paradigm, its reiteration has become stale, flat, and unprofitable, and its simplicities have become too costly" (Schneider, 1994b, p. 1076).

The inadequacy of autonomy as the sole normative paradigm for bioethics becomes particularly apparent when one considers the profound vulnerability of patients in the clinical setting (Lysaught, 2004, p. 678). Patients seeking care surely desire information and the opportunity to give consent to treatment. But, first and foremost, they are asking for help. To entrench autonomy as the only normative polestar in this domain threatens to reorient the doctor-patient relationship itself. Carl Schneider warns that:

> If doctors and patients meet clad in the armor of their rights, both of them will lose as well as gain: 'The physician who is now instructed to obey the 'informed consent' of his patient, no matter how harmful he feels that action to be for the patient, is not only permitted but positively enjoined to separate himself from his patient, to respect his patient's "autonomy" by suppressing his own identifications, his self-confusions, with that patient.' (Schneider, 1994a, pp. 16–22 quoting Burt, 1977, p. 32)

As Charles Bosk writes, "The dark side of patient autonomy [is] patient abandonment" (Schneider, 1994a, pp. 16–22 quoting Bosk, 1992, p. 158). A simplistic emphasis on autonomy alone is "particularly injurious in bioethics, a field that treats people in their least rational moments, in their most emotional travails, in their most contextual complexity" (Schneider, 1994a, pp. 16–22 quoting Bosk, 1992, p. 158).

Further, the narrowed definition of "person" that results from a sole focus on autonomy radically constricts the circle of protection for the weakest and most vulnerable members of the human family. As Gilbert Meilaender has correctly

observed (quoting Philip Abbott): "There are very few general laws of social science but we can offer one that has a deserved claim: the restriction of the concept of humanity in any sphere never enhances respect for human life" (Meilaender, 1998, pp. 108–109). The very victims whose plight motivated public officials to intervene in the practice of medicine and scientific research in the first instance – the unborn, the socially marginalized, the cognitively disabled, the elderly suffering from dementia – are deemed "sub-personal" under the autonomy-only paradigm of public bioethics. It is a paradigm that stands humankind's best moral traditions their heads – perversely privileging the claims of the strongest over those of the weakest.

Even aside from the grave concerns about the weak and vulnerable, the autonomy paradigm reflects an impoverished moral anthropology even for those capable of robust free choice. It conceives of persons as radically individualistic disembodied wills whose activities are reducible to bargained-for exchanges with other wills. Left ignored are bonds of kinship, community, and the *unchosen* obligations that characterize such relationships. The human good of solidarity is missing from this framework.

Restoration and Retrieval in the Universal Declaration on Bioethics and Human Rights

One of the signature achievements of the Universal Declaration on Bioethics and Human Rights is a turnaway from this inhumane paradigm, back toward a richer conception of human beings and their obligations to one another. The Declaration is grounded in a humanly robust moral anthropology – one of human dignity and solidarity – and situates autonomy within this framework. It rejects that conception of personhood that over time has become conflated with autonomy and decouples these notions. It recognizes that persons are not simply autonomous beings. In fact, the Declaration eschews the term "person" as an exclusionary category; rather, it uses the term "human beings" to orient the document and then uses "persons" in an expansive fashion. Furthermore, the Declaration mentions "persons" incapable of autonomous decision-making, so the cognitively impaired and cognitively immature are included in the Declaration's notion of personhood.

Most obviously, Article 5 ("Autonomy and Individual Responsibility") signals a return to the original conception of autonomy (as a subsidiary good), found in the *Belmont Report*. It urges respect for autonomy but reminds the reader that individuals bear responsibility for the choices they make and must pay due regard for the good of others. More importantly, Article 5 restores the injunction to protect "persons not capable of exercising autonomy," by ensuring that "special measures be taken to protect their rights and interests."

By acknowledging that there are "persons" who lack the capacity to exercise autonomy, Article 5 also strikes a blow against the use of "personhood" as a term of exclusion, about which Meilaender cautioned above. Likewise, Article 6 ("Persons without the Capacity to Consent") calls for special protections for "persons who do not have the capacity to consent." Thus, on their face, these provisions reject the

notion that the capacity to exercise autonomy or to give consent is a necessary prerequisite to membership in the community of persons. By extension, all of the attendant protections of human dignity and human rights accorded to "human beings" in the Declaration are equally applicable to persons lacking the capacity for intentional, self-aware action.

A related virtue of the Declaration is its global use of the phrase "human beings" to describe the principal focus of its protections. By opting for this term, the Declaration offers its protections to the widest possible array of subjects and strengthens its human life-affirming provision even further. And these protections are significant. First, the preamble recognizes that human beings have a responsibility to protect one another. Additionally, the preamble provides that "all human beings, without distinction, should benefit from the same high ethical standards in medicine and life science research." Article 10 ("Equality, Justice and Equity") affirms explicitly the principle that "all human beings" are equal in dignity and rights and are to be treated justly and equitably. Article 8 ("Respect for Human Vulnerability and Personal Integrity") declares that in the development and application of science, technology, and medicine, "individuals and groups of special vulnerability should be protected and the personal integrity of such individuals respected." Finally, protection of future generations is declared to be an explicit aim of the instrument. This is made more concrete by Article 16 ("Protection of Future Generations"), which provides that "the impact of life sciences on future generations, including on their genetic constitution, should be given due regard."

Human dignity – not autonomy – is the most prominent ethical principle featured throughout the Declaration. The Declaration includes many provisions that serve to elevate the importance of human dignity and highlight the respect for human life. First, the preamble establishes human dignity as the very lens through which science and technology should be understood. It provides that "advances in science and their technological applications should be examined with due respect" for human dignity. The first "aim" of the Declaration relating to the development of ethical principles (Article 2[c]) declares that the purpose of the instrument is to "promote respect for human dignity." Similarly, the very first "principle" of the Declaration (Article 3), titled "Human Dignity and Human Rights," provides that "Human dignity, human rights and fundamental freedoms are to be fully respected." The Declaration forcefully asserts in several of its provisions that human dignity may not be ignored or transgressed. Indeed, the Declaration makes clear that full regard for human dignity is itself an explicit limitation on the application of other worthy principles. For example, the preamble recognizes the importance of "the freedom of science and research" and affirms the benefits that flow from "scientific and technological developments," but firmly reminds the reader that such activities should take place in a context that gives proper recognition to human dignity. Similarly, Article 12 ("Respect for Cultural Diversity and Pluralism") celebrates the virtues of diversity and pluralism but explicitly notes, "Such considerations are not to be invoked to infringe upon human dignity." Finally, the Declaration concludes (in Article 28) with the following injunction: "Nothing in this Declaration may be interpreted as implying for any State, group or

person any claim to engage in any activity or to perform any act contrary to … human dignity." Simply put, the concept of human dignity infuses the entire Declaration. The instrument literally begins and ends with statements underscoring its importance. There is no principle that animates the Declaration to the same extent.

The Declaration also strongly affirms the centrality and importance of respect for human life. Most obviously, it is tremendously significant that an explicit aim of the Declaration is "to promote respect for human dignity and protect human rights, by ensuring respect for the life of human beings, and fundamental freedoms, consistent with international human rights law" (Universal Declaration, Art. 2(c), 2005).

Conclusion

The Universal Declaration on Bioethics and Human is anchored in the concepts of human dignity and solidarity and affirms the central importance of basic obligations of human beings to one another in virtue of their shared humanity. Although the Declaration is by no means perfect, its provisions reject the notion that respect for autonomy should remain the key animating principle in bioethics. In this way, the Declaration signals a vital recovery and return to the foundational anchoring norm of respect for persons.

Persons Without the Capacity to Consent

7

Eugenijus Gefenas and E. Tuzaite

Introduction

Implementation of the doctrine of Informed Consent (IC) into the practice of health care has been one of the major ethical and legal shifts in the history of twentieth century medicine. The essence of this shift has been the replacement of the paternalistic ethos of the doctor-patient relationship with respect to personal autonomy based health care decision making. As a result, the principle of IC has become a basic rule to be followed in all health care related interventions with competent patients. Although there are still many problematic issues related to the implementation of IC into health care practice with capable persons (Stanton-Jean, Doucet, & Leroux, 2012), a particularly complex situation may arise when health care decision making involves persons without the capacity to consent, such as minors, people with learning disabilities, or those suffering from severe mental disorders. The complexity of this field of decision making can be attributed to the need to harmonize the traditional approach of protecting the best interest of this particularly vulnerable group of patients with the paradigm of health care based on the principle of personal autonomy and self-determination. The major international guidelines and legal instruments reflect the importance of this issue. The Universal Declaration on Bioethics and Human Rights (UDBHR) by UNESCO devotes a separate Article 7 to set general principles protecting the rights and interest of persons without the capacity to consent (UNESCO, 2005). Similarly, at the European level, the Council of Europe Convention on Human Rights and Biomedicine (The Oviedo Convention) provides an even more elaborated normative framework aiming at the protection of persons not able to consent (Council of Europe, 1997a). This instrument provides separate guiding principles with respect to different categories of incapable persons: those suffering from mental disorders, being in emergency situations, and, what is very important for this discussion, those who had their wishes expressed in the past before becoming incapable (previously expressed wishes). This chapter aims at

analyzing the general framework of decision making with regard to persons unable to consent as well as presenting some areas of practice, where decisions are particularly complex.

Conceptual Framework of Decision Making and Incapable Persons

The concept of capacity or incapacity is closely linked to the concept of competence. In health care context being competent means the capacity to make autonomous health care decisions. A person loses his or her competence and becomes incapacitated when s/he loses such a capacity and is unable to (1) posses a set of values and goals; (2) communicate and understand information, and (3) reason and deliberate about one's choices (US President's Commission for the Study of Ethical Problems in Medicine and Biomedical and Behavioral Research, 1982). Two different meaning of a loss of competence can be distinguished. First, a narrow legal definition means a loss in court of a person's legal right to function in a particular area. Second, a broader and more common clinical use of the term means that a person can still have a legal right but is unable to make their health care decisions (Wettstein, 2005). This broader definition of competence is very important for this discussion because rather often the decisions with regard to persons unable to consent are made without their legal capacity being removed.

Different Meanings of Personal Autonomy and Protection of Incapable Persons

The system of protection of incapable persons has been recently developed within the new paradigm of medical ethics based on the principle of respect for personal autonomy. However, within the bioethics literature some interpretations of this principle have been criticized as providing insufficient background for complex health care related decisions. This criticism has been mostly directed toward a so-called minimalist-libertarian account of personal autonomy, which limits the relationship between the care giver and the cared person to noninterference rather than promoting and facilitating the decision making of the person concerned. This interpretation of personal autonomy can be criticized as reducing the relationship between health care providers and patients to simple contractual relationship of two "strangers." As such, this model neglects the caring attitude of health care provider, which is crucial when dealing with vulnerable patients.

Therefore, the alternative interpretation of personal autonomy going beyond the minimalistic-libertarian approach seems to be more relevant in many health care situations, particularly when incapable persons or other vulnerable patients are involved. This account of autonomy is emphasizing authenticity of a decision-making process (Welie, 1998). Autonomy as authenticity is implemented when decision making is based on the values and life story of the person. This is

especially relevant when people who are close to the patient and familiar with his or her personality can make choices that are congruent with the patient's values and life story. This helps to base important decisions not only on the rational and explicitly stated information but also on motivation and signs, which are not explicitly expressed by the incapable person. This component of decision making becomes increasingly important in the course of decreasing cognitive capacities of the person.

The modern system of legal protection of incapable persons has been developed following the broader interpretation of personal autonomy rather than the minimalist-libertarian one. The authenticity based account of personal autonomy allows developing a more flexible set of measures assisting a person who is starting to lose decisional capacity. Such a system of legal protection is elaborated in some international recommendations based on a set of principles to be followed when it is necessary to organize protective measures for an incapable person (Council of Europe, 1999). First, the protection provided for a person concerned should be based on respect for the wishes and feelings, including previously expressed wishes, which is of paramount important when decision-making capacity of the person is getting increasingly compromised by the disease. Second, prominence should be given to the welfare and interest of the person to counteract the sometimes existing tendencies to use assets of the person to benefit other parties. Third, the principle of subsidiary or minimum necessary intervention should be followed, which means that protection has to be established, if and only if it is unavoidable in the circumstances. It also means that preference should be given for any less formal arrangements that might be used rather than formal ones, and for any assistance that might be provided by family members. Finally, the proportionality of the measure to be applied means that protection needed should correspond to the degree of capacity of the person concerned and tailored to the individual circumstances of the case (Council of Europe, 1999). All the mentioned principles are important to understand the limits of the traditional system of protection. The problem is that some countries still have a rather traditional approach toward the protection of incapable persons. This approach can be characterized as rather rigid. In this traditional system, the measure applied deprives a person concerned of almost all legal capacity to make decisions and is coupled with the appointment of the guardian who is supposed to represent the incapable person in all the matters of life. As a result, it is mainly based on deprivation of legal capacity rather on the attempt to involve the incapacitated person into his or her own care-related decision making, which is a key feature of the alternative modern approach based on a broader concept of personal autonomy (Gefenas, 2004).

Normative Principles of Protecting Incapable Persons in Health Care Context

There have also been some more specific principles developed with regard to medical interventions on persons not able to consent. In the European context,

the Oviedo Convention provides a rather comprehensive framework for these principles summarized in its Article 7 (Council of Europe, 1997a). References will be made to this and other legal instruments and guidelines to make this framework explicit.

First of all, another person or a body substituting the decision making of the incapable person should be introduced when such a necessity arises following the subsidiary rule mentioned above. It means that the authority to consent is being transferred to somebody who represents the interests of the person unable to consent. For example, the intervention on the minor may only be carried out with the consent of his or her parents. In cases of incapable adults, the substituted decision makers should be legal representatives or any person or body provided for by law. It should also be noted that before making a decision, the representative should get the same information that would have been given to the person concerned if s/he was capable.

Second, the guidelines require to involve the person himself, as far as possible, into the process of his or her health care decision making. This principle is relevant to both minors as well as adults whose capacity starts to diminish due to a mental disorder. In case of minors, it helps to ensure that their opinion is to be regarded as an increasingly determining factor in proportion to their age and capacity for discernment. This means that in certain situations and depending on the nature and seriousness of the intervention as well as the minor's age and ability to understand, the minor's opinion should increasingly carry more weight in the final decision. This principle is also enforced by the Article 12 of the United Nations Convention on the Rights of the Child (United Nations [UN], 1989). The involvement of the person who has lost or is losing the decision making capacity in respect to health care can also be achieved by referring to his or her previously expressed wishes, life goals and values. This is an especially important issue in the context of this discussion and it will be addressed in a separate section.

Third, the general framework also usually specifies the type of intervention to be authorized in terms of risk/benefit ratio. For example, according to the Oviedo Convention the only interventions to be authorized on behalf of incapable persons are those that are supposed to bring them direct benefit. In general, the higher the benefits of the intervention, the more stringent capacity criteria are required from the person whose capacity is being questioned to refuse such an intervention, for example, in case of refusing potentially life-prolonging interventions. This tendency has been called "sliding scale" of competence evaluation (Wettstein, 1995).

Complexity of Implementation and Remaining Controversies

Although a consensus has been achieved with regard to the general principles mentioned above at the international level, this general framework is not always easily applied in practice. The difficulties arise because sometimes these principles can contradict each other or because their interpretation contains some level of unavoidable ambiguity. For example, the requirement to take into account

previously expressed wishes can come into conflict with the views of representatives or medical staff with regard to the best interest of the person concerned. In other cases, such as decisions on reproductive choices of minors, it is not always clear if the representative should have a final word on the issue or the teenager can make her own choice. The following most controversial areas of decision making will be analyzed in this chapter:

- Recent tendencies to implement previously expressed wishes in practice
- Complex reproductive choices by minors and people with learning difficulties
- Compulsory hospitalization and treatment of people with mental disorders
- Research on incapable persons

Previously Expressed Wishes

As has already been noted, previously expressed wishes are one of the most basic means to implement the principle of respect to personal autonomy in the field of health care with regard to people unable to consent. This is why the concept of previously expressed wishes is included into the international ethical and legal guidelines presented in this chapter. Article 7 of the UDBHR by UNESCO does not explicitly mentions this concept; however, it refers to the need to involve a person concerned to a greatest extent possible in the decision-making process. At the same time the Article 9 of the Oviedo Convention makes it explicit that "[t]he previously expressed wishes relating to a medical intervention by a patient who is not, at the time of the intervention, in a state to express his or her wishes shall be taken into account" (Council of Europe, 1997a).

Advance Directives

The concepts of "document of prior instructions" or "advance directives" have been used to refer to implementation instruments of previously expressed wishes of incompetent patients (Council of Europe, 2011). This section will only focus on the advance directives which deal with those health care and treatment options that the person would like to receive while s/he is still alive and will not deal with the decisions about the use of body and organs after death.

Two major models (or their combination) of advance directives can be distinguished in this context. These are living wills and continuing powers of attorney (World Health Organization [WHO], 2004). Living wills are written legal documents which allow people to convey their wishes about the life-sustaining procedures ahead of time. They usually include instructions on withholding or withdrawing the treatment. For example, a person can express his/her wishes by signing the, "do not resuscitate" (or DNR) order when admitted to the hospital. However, living wills are not limited to treatment refusals. They can also be used to advance a wish that a particular type of treatment will be continued (Council of Europe, 2011).

On the other hand, the model of continuing powers of attorney is based on the choice of a person who is supposed to make health care decisions on behalf of someone who loses the ability to do so. Usually attorneys are relatives or close friends and it can be argued that this model has a significant advantage comparing to the living will because it can provide a "personal voice" clarifying the patient's preferences. This is especially important in those cases when written instructions are ambiguous, or there are unexpected developments in the situation that have not been addressed by the patient (Council of Europe Steering Committee on Bioethics (CDBI) [CDBI], 2008). It can also be noted that this model provides the granter an opportunity to appoint one more person to supervise how the attorney performs his/hers duties (Council of Europe, 2009).

The increasing importance given to advance directives in both legal instruments and academic literature is related not only to the changing paradigms of health care provider – patient relationship, where the paternalistic culture has been gradually replaced by the value of personal autonomy and the practice of informed consent. The importance of integrating previously expressed wishes into the clinical decision making and the need to introduce the practice of advance directives also reflect intensive technological advancements of modern medicine and life-sustaining technologies. These developments not only help to save human lives. They can also contribute to the continuation of physical survival of patients for prolonged periods of time without their capacity to make decisions about their own health care for the rest of their lives.

Implementation Difficulties

It should be noted, however, that the changes in ethical and legal paradigms have not yet been fully implemented in many countries in the world. In this respect, the situation is somewhat better in the USA, where the percentage of people with an advanced directive is far higher than in European countries, where only a tiny minority of the Council of Europe's 800 million citizens actually have advance directives (Council of Europe, 2011). For example, in the USA the advance directives have been expressed by around 22 % of all patients (raging from 32.1 % of surgery patients vs. 17.7 % of medicine patients), living wills being the most frequently chosen type of advance directives (Morrell et al., 2008).

In many European countries, it is still unusual to base clinical decision making on previously expressed wishes. Many states are just starting to recognize the importance of advance directives. For example, in some countries such as Austria, Belgium, Finland, Germany, Hungary, the Netherlands, Spain, Switzerland, and the United Kingdom advance directives are made legally binding. More specifically, in Austria it is obligatory to take the advance directives into account if a few criteria are met: the physician's consultation has been provided, the procedure of advanced directive has been supervised by a lawyer, the refused treatment is described in detail, and the document has been signed not more than 5 years ago (CDBI, 2008). However, in many other European countries specific provisions concerning the

advance directives are not legally binding or there is a lack of laws on this particular matter. It is argued, that the reason for such a slow integration of previously expressed wishes into the legislation of some European countries has been the advisory character of the provision of the Article 9 of the Oviedo Convention, which only states that patient's "wishes shall be taken into account" rather than being followed. In other words, according to this article European countries are not required to assign the advance directives a legally binding status (CDBI, 2008). More details on the advisory nature of this provision are provided in the Explanatory Report of the Oviedo Convention, which states that "[. . .] taking previously expressed wishes into account does not mean that they should necessarily be followed.[. . .] when, for example, they were expressed long time before the intervention or medical technology made a significant progress since the time when the advance directive was signed" (Council of Europe, 1997b).

There can also be other obstacles to build an efficient system of advance directives. For example, in some countries patient autonomy is taken more seriously, while in the other countries the paternalistic model of decision making still prevails. Furthermore, the economic situation in the country can also play an important role. This is especially the case when the most basic health care services are hardly available for the country's population. For example, it has been argued that in transition European countries, like Ukraine, interest in this kind of arrangements is very limited due to the fact that people are mostly preoccupied with access to basic services in the context of severe scarcity of health care services available (Council of Europe, 2011).

Previously Expressed Wishes in the End of Life Care

The importance of advance directives should be particularly emphasized in end of life care situations with persons unable to consent. Here there are two interrelated issues to be discussed: first, involvement of patients and their relatives in particular medical end of life decisions (MELDs) that might have a life-shortening effect; second, controversy of associating the advance directives with euthanasia.

According to the EURELD study conducted in six European countries, rather often MELDs are shared neither with patients nor with their relatives. For example, in Italy and Sweden, countries representing culturally rather different regions of Europe, MELDs were not discussed with the patient or with the relative in more than 50 % of cases (van der Heide, Deliens et al., 2003). It should be stressed that these figures applied to both competent and incompetent patients and showed how important advance directives can be in these highly sensitive and stressful situations. The reason why the doctors try to escape from communicating and sharing their decisions with relatives or patients can be their reluctance to overburden relatives (in case of incompetent patients) or the consideration that even competent patients would not be able to fully comprehend the situation. The advance directives seems to be a relevant solution to overcome both of the mentioned obstacles as this would make possible a decision making respectful to personal autonomy of the patient.

The association between advance directives and euthanasia should also be addressed. It has been pointed out that this association is unfortunate because active termination of life is forbidden in the vast majority of European countries (Council of Europe, 2011). In addition, as has been shown by the EURELD study, administering, supplying or prescribing drugs with the explicit intent to hasten the death on patient's explicit request (which are the most common criteria of active voluntary euthanasia), appeared to be also one of the least frequent types of decision. It occupied a very small portion of MELDs as reported in the studies available, e.g., 1 % of deaths or less in Denmark, Italy, Sweden, and Switzerland as compared to nontreatment decisions such as withdrawing or withholding medication (or forgoing hydration and/or nutrition), which in some countries (e.g., Switzerland) reached as much as 28 % of all death cases (van der Heide et al., 2003). Therefore, the introduction of advance directives can help to ensure that no form of unconsented medical end of life treatment decision is taking place, which is still the existing practice in many countries as shown above. It can also enable a person to explicitly express the wish to not take or omit some actions with the intention to shorten his or her life.

There have been important recent European developments that can bring positive changes in this field. First, the Council of Europe Committee of Ministers issued a special Recommendation CR/Rec (2009)11 on the principles concerning continuing powers of attorney and advance directives for incapacity. This document laid down basic principles on the role of attorney, the procedure of her/his appointment and the circumstances when her/his rights come into force (Council of Europe, 2009). Second, and more specific to this discussion on advance directives in the field of health care, the Council of Europe is adopting a Resolution and Recommendation on "Protecting Human Rights and Dignity by taking into Account Previously expressed Wishes of Patients" (Council of Europe, 2012). Hopefully, this can be an important impetus to further encourage the European countries to take steps in this field.

Reproductive Issues in Minors and People with Learning Difficulties

As has been already shown in the previous sections of the chapter, it is currently accepted that minors and people with learning difficulties should be involved in the decision making about their health care as much as this is possible in the circumstances. However, the involvement of people unable to consent in the decision making on their reproductive health issues can be more complicated because of societal taboos surrounding the sexuality of the intellectually disabled. As has been noted, due to this reason even studies concerning their contraception and moreover their sterilization may be difficult to carry out and when carried out, biased by low participation rates (Servais et al., 2004). However, the denial of the problem does not eliminate it. On the contrary, if the issue of reproductive choices fell beyond the scope of legal regulations and public discourse, nobody can guarantee that the best interests of the incapable people are really served and their rights are protected.

Use of Contraception and Termination of Pregnancy in Minors

The complexity of reproductive health policies in relation to minors arises predominantly because of the tension between the rights of the minors and those of their legal representatives. According to Article 16 of the United Nations Convention on the Rights of the Child every child has the right to privacy (UN, 1989). This right can also justify those cases when legal representatives are not asked for authorization of the minor's decision and the practice of teenage contraception seems to be particularly relevant case to be discussed in this context. For example, the issue of prescribing contraceptives without authorization of legal representatives became widely discussed in the UK in the 1980s when Mrs Gillick wrote to her area health authorities forbidding medical staff to give contraceptive or abortive advice or treatment to any of her four teenage daughters without her consent. This case culminated in the well-known Gillick judgment of 1985 when the House of Lords ruled (by the narrowest of majorities) that doctors can in certain cases prescribe contraceptives for girls under 16 without parental consent (Dyer, 1985).

The supporters of Mrs. Gillick position usually argue that the policy of confidential counseling allows teenagers to engage in risk taking behavior and insist that information about the use of contraceptives should be disclosed to the parents because the minor's ability to give a valid informed consent can be compromised by the minor's immaturity and the lack of life experience. This may make minors vulnerable to exploitation and external coercion and therefore decision making in such a sensitive field should be overtaken by legal representatives who are believed to act according to the best interests of the minors.

The opponents of this position may respond that the involvement of parents into the counseling procedure do not necessarily increase the welfare of the minor. For example, if the family relations are complicated and parents or guardians are informed about their child's request for contraception, this can make teenagers life in the family unbearable due to excessive control exercised upon the social environment of the child. Furthermore, it seems that confidential consultations have the potential to reduce the unintended pregnancy and abortion rates because some surveys have shown that as many as 59 % of teenagers would discontinue use of specific sexual health care services if their parents were informed that they were seeking prescribed contraceptives (Reddy, Fleming, & Swain, 2002).

The role of health care professionals seems to be very important in this context because they can act as moderators between teenagers and their parents in this complex and controversial area of personal relationships. In fact, sensitive and professional counseling can resolve raising tensions and encourage communication between the parties involved. Due to this, physicians are strongly recommended to help adolescences to see the potential advantages of improved communication with their parents (Ford, English, & Sigman, 2004).

However, despite the importance attributed to the confidentiality issue in health care provider – minor relationship, the health care providers do not necessarily share the same opinion. In some countries, physicians do not regard the confidentiality as the issue of utmost importance in the field of adolescences' medicine.

The study carried out among Swiss doctors revealed that maintaining minors' confidentiality was ranked considerably lower than such issues as psychosomatic/functional symptoms, eating disorders, or depression-anxiety and was not considered to be a priority topic in adolescent medicine training (Kraus, Stronski, & Michaud, 2003). Furthermore, a resent Lithuanian study in this field showed that when consulting on general sexual issues, more than 70 % of the Lithuanian general practitioners stated that they would respect their minor patients' confidentiality. However, nearly the same percentage said they would inform parents in cases of sexually transmitted infections or pregnancy (Jeruseviciene et al., 2011).

The termination of teenagers pregnancy is probably the most sensitive and controversial issue in this discussion. Whose decision must be followed in case of disagreement between the pregnant minor and her parents? A tendency to give priority to the opinion of the minor has been observed in many European countries and the USA. However, there are opposing views expressed toward this prevalent tendency as well. For example, in Britain teenage girls are allowed to have an abortion without their parents consent, however, some time ago a mother whose daughter secretly had a chemical abortion publicly criticized this law claiming that if she had known what was happening she would have been able to change her 14 years old daughter mind (Mother angry at secret abortion, 2004). On a state level some countries, such as Slovakia, enforced the legislation to require parental or guardian consent in case of termination of pregnancy in minors. This shows a fundamental and hardly commensurable disagreement between the worldviews of those who hold different positions on this matter (Gefenas, 2012).

Sterilization of People with Learning Difficulties

Policies to regulate reproductive choices of incapable adults have a long and controversial history. The racial hygiene politics and eugenics movement in Nazi Germany is probably the best known, but not the only example of such a policy in the twentieth century. In fact, during the whole post–World War II period till about the 1980s, the sterilization laws were in force in many countries of the world. For example, in 1997, one of the most influential Swedish newspapers disclosed information about a sterilization program carried out between 1935 and 1975 leaving more than 60,000 Swedes being sterilized including people with learning difficulties. The sterilization law existed in Denmark as well. From 1934, when this particular law was adopted, until 1968, 5,579 mentally disabled people were sterilized in this country (Broberg & Roll-Hansen, 2005).These policies were largely associated with eugenic intentions to reduce the incidence of learning disability in general population, which appeared to be based on a mistaken belief that this goal can be achieved by eliminating the opportunities for intellectually disable people to reproduce (Howard & Hendy, 2004). Even though the understanding of mental disability has undergone significant changes in recent years, the issues concerning the reproductive health of incapable people remain controversial and difficult to handle.

In many countries, women with learning difficulties are still rarely involved in decisions about their contraception arguing that these issues are too complex for them to understand. In this situation, the reproductive questions have been dealt with in a paternalistic manner and contraception presented as a preventive measure to assure that in the case of the sexual assault the unintended pregnancy is avoided. Sterilization of mentally disabled people is regarded to be the most reliable method of contraception. Although it is regarded as the last measure which should be taken only if the more conservative methods of birth control do not work, it is rather widespread and mainly applied to sexually active women. Although it is difficult to single out a concrete disability which could increase the possibility of sterilization, people with Down syndrome seems to be the group most often exposed to contraceptive sterilization. This is probably due to the fact that this genetic condition can be transmitted to the offspring with 50 % of probability. In addition, women with Down syndrome are commonly considered as very social and affectionate, which also make them more vulnerable in intimate relationship (Servais et al., 2004). However, the level of capacity of people having this syndrome can be very diverse, which makes the decision on their sterilization sensitive.

The comparison of sterilization rates of people living in social care institutions versus those staying with their family members in the community helps to reveal some prevalent tendencies in this field. It might seem that opportunities to control fertility of people living in institutions are more favorable than for incapable people staying in the community. This feature can be explained by the fact that nowadays intellectually disabled people are more integrated into the society which provides them with more opportunities to start sexual activities. At the same time, however, this makes them more vulnerable to sexual offenses. It can be predicted therefore that sterilization rates should be higher for noninstitutionalized population of incapable people. However, the Belgian study revealed the opposite tendency where living in an institution was associated with an increased probability to be sterilized (Servais et al., 2004). This tendency seems to point to the need to revise the existing institutional policies as they might better serve the interests of the institutional employees rather than the interests of the incapable persons themselves.

Compulsory Hospitalization and Treatment of People with Mental Disorders

Coercive measures applied to people suffering from mental disorders are another ethically sensitive issue to be addressed. Images of chaining psychiatric patients to the walls of the asylums or medicating political dissidents with high doses of neuroleptics can hopefully be regarded as historical examples not to be repeated in modern psychiatry. Indeed, methods of treatment and the models of patient-doctor relationships showed in the Oscar wining movie “One Flew Over the Cuckoo’s Nest” are hardly imaginable in contemporary society. Nowadays, it is universally accepted that people with mental disorders, including those unable to consent to particular health care interventions, are entitled to the same civil, social,

political, and cultural rights as the rest of the population. However, even in the twenty-first century, reports on keeping psychiatric patients in net beds or just chaining them to their beds are published (Sailas & Wahlbeck, 2005; WHO, 2008). There is still disagreement among different representatives of the society and professionals about the proper use of restraints and coercive measures in general. Therefore, this section surveys the most important principles guiding coercive measures to be applied to psychiatric patients with limited capacity.

Basic Normative Framework

The major changes in the field have been brought by integrating psychiatric practice with basic human rights principles in the second half of the twentieth century. The Universal Declaration of Human Rights (UN, 1948) can be considered to be the first international human rights instrument paving the way to more specific documents enforcing the rights of people with mental disorders, such as Convention on the Rights of Persons with Disabilities (UN, 2008) or the Council of Europe Recommendation Rec(2004)10 concerning the protection of the human rights and dignity of persons with mental disorder (Council of Europe, 2004a). The latter document provides a detailed normative framework on involuntary measures applied in the field of psychiatry. According to this document two basic conditions should be satisfied in order to apply coercive measures, such as involuntary hospitalization, with regard to people with mental disorders. First, involuntary hospitalization is only justified when the existence of mental disorders is recognized or its assessment is required to determine whether a mental disorder is present. Second, it must be very likely that mental disorders can cause a risk or a serious danger to the person concerned or a serious danger to other persons (Article 17, part i & ii). In addition, the Council of Europe Recommendation (Article 17, part iii) also emphasizes that the intention of the involuntary placement should always include a therapeutic purpose. Two specific distinctions are important in this context, namely, the distinction between involuntary hospitalization and involuntary treatment, as well as the distinction between formal versus informal involuntary hospitalization.

Distinction Between Involuntary Hospitalization and Involuntary Treatment

Although it is often thought that the need of compulsory hospitalization also includes mandatory treatment, the forced hospitalization does not necessarily imply the involuntary medication. A person involuntarily admitted to the institution should be provided with several treatment choices and should be free to choose any of them. Among these choices and despite being forcibly admitted to the hospital the person should retain the right to refuse the medical treatment proposed. The Explanatory Memorandum to Recommendation Rec(2004)10 (Article 17, paragraph 133) states that “therapeutic purpose” of hospitalization should not be equated with medical

treatment. For example, a person diagnosed with schizophrenia can choose to experience hallucinations (such as hearing voices) instead of taking medications because of their short and long-term side effects (Council of Europe, 2004b).

The distinction between forced placement and forced medical treatment has not been made until the late 1970s. Due to the human rights movement in psychiatry this approach has remarkably changed in the USA and Europe leading to a clear separation between involuntary hospitalization and involuntary treatment. It should be noted, however, that some European countries still do not define in their laws involuntary placement and treatment as separate modalities, which seems to also imply that in these countries the decision of forced hospitalization means an approval for forced medication of psychiatric patients against their expressed resistance (Dressing & Salize, 2004).

Formal Versus Informal Involuntary Hospitalization

One more issue to be addressed here is the inconsistency between legal regulations for involuntary placement and application of these regulations in practice. This inconsistency can be analyzed as a distinction between formal involuntary hospitalization and so-called informal involuntarily hospitalization, where patients sign the admission forms for voluntary hospitalization, however, cannot leave the institution whenever they want. This can be demonstrated by remarkable variation between frequency of compulsory admissions into psychiatric institutions in the European Union countries. The frequency of involuntary hospitalizations can vary from 218 involuntary placements per 100 000 population in Finland, 175 in Austria, 114 in Sweden to 11 in France or just 6 in Portugal (Salize & Dressing, 2004). Due to the fact that the ratio of persons with mental disorders in population in Europe cannot be so different, one possible explanation of this phenomenon is that admissions to the hospital are formalized in a significantly different way. Health care providers can avoid compulsory admission due to complex legal procedures, such as obligatory court's hearing or search for patient's representative. Scarce personnel and financial recourses at the health care institution can also be the reason of escaping the formalities of mandatory hospitalization. The problem is that these tendencies raise a question about the safeguards to protect patients' rights in these complex situations because de facto involuntary patients are left without the safeguards, which should be provided for them in the institutions for mentally disordered people unable to consent (European Committee for the Prevention of Torture and Inhuman or Degrading Treatment or Punishment (CPT) Standards & CPT/Inf/E [CPT], 2011).

Research on Incapable People

Conducting research activities on participants who are not capable to understand and consent to these activities is nowadays regarded as one of the most complex and controversial areas of research ethics. After all, modern history of research ethics

has emphasized the fundamental importance of informed consent. This principle has been placed on the top of the list of ten requirements of the Nuremberg Code – the first international instrument condemning the Nazi experiments and paving the way for the development of research ethics. In addition, as has been already shown above, the principle of informed consent has replaced traditional paternalism and marked a paradigm shift in the history of medical ethics and health care provider-patient relationship.

The problem is that research on persons unable to consent has to actually "bypass" this basic research ethics benchmark, which since the Nuremberg Code has been incorporated into the most important research ethics guidelines and legal instruments. Therefore, some alternative mechanisms of protecting incapable research subjects had to be developed. The historical overview of the evolution of these alternative models of protection reveals some complex features of establishing what is nowadays regarded as widely accepted ethical and legal algorithm to conduct research on incapable persons. The Article 7 part B of the UDBHR by UNESCO is a good example of this algorithm. It is important to note that this framework of research on incapable persons is also enforced by other important international instruments such as Article 17 of the Oviedo Convention and the Guideline 9 of the International Ethical Guidelines for Biomedical Research Involving Human Subjects (CIOMS). Although there exist some differences between the mentioned documents, the convergence of the main provisions is remarkable as compared to the regulations in some other areas of health care on persons unable to consent presented in this chapter.

It can be useful to briefly explain this two-step model of involving incapable persons into research project. As the first step, the guidelines require to limit research to only those projects where:

- The results of the research have the potential to produce real and direct benefit to the health of incapable research participant.
- Research of comparable effectiveness cannot be carried out on individuals capable of giving consent.
- The necessary authorization has been given specifically and in writing.

In case it is not possible to comply with the first step criteria, the second step of the framework is formulated as an exceptional scenario for research that does not have the potential to produce results of direct benefit to the health of the person concerned. Such a research can only be allowed if the following additional conditions are met:

- The research has the aim of contributing, through significant improvement in the scientific understanding of the individual's condition, disease, or disorder, to the person concerned or to other persons in the same category of disease or disorder.
- The research entails only minimal risk and minimal burden for the individual concerned.

In all circumstances the person concerned must not object to the participation in the project.

Two important features of developing the current ethical framework of research on incapable persons will be discussed. First, the liberalization tendency in the post-Nuremberg evolution of the research ethics codes: after an earlier absolute ban of

research on persons unable to consent, there are now provisions of research without the direct benefit. Second, a possible explanation will be provided for the emergence of the current ethical framework of research on incapable persons by referring to balancing or rather compensating the inability to get informed consent with other ethical principles and safeguards (Gefenas, 2007).

Two Steps of Liberalization

It can be claimed that modern research ethics started as a reaction to the horrors of Nazi human experiments, where adults and children became involuntary victims of activities, to which they would have never consented. The Nuremberg code responded to these atrocities in a radical way – it only legitimized research on those who were able to give informed consent. Paradoxically, this would have stopped the development of treatment and diagnostic interventions for many categories of patients unable to consent. That is why the Declaration of Helsinki made a step toward the softening of this very strict position in 1964 and introduced a distinction between so-called therapeutic research and nontherapeutic research (World Medical Association, 1975). This distinction made it possible to conduct so-called therapeutic research or research with the direct benefit for incapable people assuming that authorization from their representative was secured.

This was not, however, a sufficient condition allowing conducting early phase research where benefits for individual research participants can only be very limited. Therefore, the second step toward the liberalization of this type of research was introduced in the 1990s when research without direct benefit to the persons concerned was allowed by international codes and legal instruments under strict protective conditions described above.

Balancing Approach

The first liberalization tendency was followed by the attempt to "compensate" the impossibility to apply the principle of informed consent with other ethical principles and values involved in ethical decision making. Careful consideration of the risk and benefit ratio has been the most important one for this discussion: there is always a correlation between the capacity to consent and a justifiable risk/benefit ratio in the documents presented in this chapter.

For example, the level of risk that is tolerated in research on capable persons is higher than that allowed in research on incapable or other vulnerable groups: The Oviedo Convention only allows research with "real and direct benefit" on incapable people, while allows a higher level of risk by introducing the concept of "acceptable risk" in nontherapeutic research on capable persons. Similarly, the CIOMS Guidelines say that the risk presented by such intervention must be reasonable in relation to the knowledge to be gained (see Guideline 8). However, the CIOMS guideline 9 requires following the "low-risk" standard with incapable research participants.

Minimal risk or low-risk standard is probably one of the most important and complex principles to be followed in the field of research on incapable persons because it reveals both the conceptual differences between different definitions as well as variations in applying these definitions in different societies. For example, according to Article 17 of the Oviedo Convention the "minimal risk" standard is defined as "a very slight and temporary negative impact on the health of a person concerned." Paragraph 100 of the Explanatory Report to the AP to the Oviedo Convention provides examples of the interventions that might be considered as those not exceeding the minimal risk standard. These examples are among others: taking saliva, urine; taking small additional tissue samples during operation; taking a blood sample (capillary, peripheral vein); sonographic examinations, one X-ray exposure, or one exposure using magnetic imaging without a contrast medium.

The CIOMS guidelines introduce even more complex and liberal scale of balancing. Guideline 9 refers to the "low-risk standard": the risk that should not exceed the risk attached to routine medical or psychological examination of incapable persons. However, CIOMS Guideline 9 also provides a more liberal standard, the so-called slight or minor increase above such risk when there is (a) overriding scientific and medical rationale for such an increase and (b) research ethics committee's (REC) approval. The Commentary to Guideline 9 explains that there is no agreed definition of what the "slight or minor increase" is. However, it says that its meaning is inferred from the RECs' reports that provide such examples as, additional lumbar punctures or bone-marrow transplantation.

There are also other complexities that arise when conducting research on persons unable to consent. For example, the requirement to take into account the objection of the person concerned can beg the question what type of objection should be considered as a sufficient ground to stop or not to start participation in the research project. Research in emergency situations can also be mentioned as raising additional concerns. First, because in the emergency situations it can be very difficult to find a representative (e.g., a family member) who is supposed to authorize the involvement of the person in the research project. Second, because emergency medicine research also raises discussion on the alternative models of consent replacing the "real time" IC procedure. For example, different options have been proposed for these "modified" forms of consent in the emergency medicine research. One option can be "advance" consent given before the intervention when the person is still capable to make decisions. Another and more practicable option can be "retrospective" consent, which is given when a person regains the decision making capacity. However, this type of consent also raises serious concerns because it is given after a person has already started or completed participation in the research project.

Concluding Remarks

It should be acknowledged that since the second half of the twentieth century, there has been a significant progress in the protection of rights of persons unable to consent to medical interventions. Massive sterilization campaigns including among

others people with mental disorders or learning disabilities, chaining psychiatric patients as a means of restraint, "treating" political dissidents with damaging doses of psychotropic medications and sticking them the label of "sluggish schizophrenia" – all these will hopefully remain sad historical medical practices and will never return to the field of medicine.

The positive changes in attitudes and practices with regard to people unable to consent have been mainly achieved in the process of developing international and national regulations based on fundamental human rights instruments adopted in the post–World War II period. In some areas, such as research on incapable persons or the involuntary measures in the field of psychiatry, these regulations reached a remarkable level of convergence. It should be noted, however, that despite the mentioned positive developments, there are still many problematic open question. Many countries are still rather slow to follow with the implementation of some important internationally established principles. For example, respect for previously expressed wishes and advance directives have not yet been implemented in the national regulations of many countries. In addition, despite the presence of relevant regulations, there are still some controversial practices going on, such as the use of coercive measures in psychiatry or sterilization of some groups of population, which should attract more attention and studies in order to develop strategies of how to better protect the interests of the most vulnerable group of people – persons without or in a process of losing their decisional capacities.

Respect for Human Vulnerability and Personal Integrity

8

Sheila A. M. McLean

Introduction

Article 8 of the UNESCO Declaration on Bioethics and Human Rights (2005) reads as follows:

> In applying and advancing scientific knowledge, medical practice and associated technologies, human vulnerability should be taken into account. Individuals and groups of special vulnerability should be protected and the personal integrity of such individuals respected.

This article, therefore, is concerned with two concepts – special vulnerability (seemingly, an effort to distinguish "mere" vulnerability from a higher level of vulnerability), and respect for personal integrity (which is often used almost interchangeably with the concept of human dignity). In 2011, UNESCO's International Bioethics Committee (IBC) issued a report on this article.

As the IBC puts it:

> The specific task of this Article is to address special vulnerabilities that occur, whether as a consequence of personal disability, environmental burdens or social injustice, in the contexts of health care, research and the application of emerging technologies in the biomedical sciences. Article 8 enjoins everyone to exercise vigilance in protecting the well-being of individuals and groups in these contexts. As the Declaration (taken as a whole) confirms, every human being has a claim to our care that must be respected. (para 5)

Importantly, Article 8 of the Declaration, ". . . .entails both a 'negative' duty to refrain from doing something and a 'positive' duty to promote solidarity and to share the benefits of scientific progress. There is an integral relationship between respect for the integrity and dignity of persons on the one hand and the vulnerability of persons on the other." (para 3) This is, therefore, a dynamic article of the Declaration, encouraging action to fulfill its aims, specifically in the context of healthcare delivery, even when that action might be construed as failing to do something. However, arguably, the concepts at the heart of Article 8 are not

unproblematic, and it is necessary, therefore, before going further to spend a little time considering precisely what is meant by both "vulnerability" and "personal integrity."

Vulnerability

While its meaning may seem self-evident, in fact, various efforts have been made to define what is meant by the concept of vulnerability, and no consensus on its precise content has emerged from the wealth of literature and commentary associated with these efforts. However, despite this, it is sometimes easy to identify situations in which people are vulnerable. Schroeder and Gefenas (2009), for example, offer one relatively straightforward example where vulnerability seems evident: the old lady walking with difficulty, followed by a group of drunken youths bent on trouble. Unless the old lady is a black belt, or armed with a lethal weapon (and perhaps even then!), it is easy to identify her as vulnerable in this setting. She is weaker and less able to defend herself from imminent attack and lacks the ability to escape from this potentially dangerous situation. She is, therefore, vulnerable both as a result of personal attributes (her difficulty in walking) and her situation (that is, the context in which she finds herself).

However, not all attempts to describe vulnerability are quite so straightforward. While vulnerability as a concept appears in a number of international reports and guidelines, its precise ambit remains unclear. The International Ethical Guidelines for Biomedical Research Involving Human Subjects Prepared by the Council for International Organizations of Medical Sciences (CIOMS) in collaboration with the World Health Organization (WHO), for example, refer to vulnerable people in the context of human subject research in guideline 13. In the commentary on this guideline, vulnerability is described in the following way:

> Vulnerable persons are those who are relatively (or absolutely) incapable of protecting their own interests. More formally, they may have insufficient power, intelligence, education, resources, strength, or other needed attributes to protect their own interests. (Council for International Organizations of Medical Sciences [CIOMS], 2002, available at: http://www.cioms.ch/publications/guidelines/guidelines_nov_2002_blurb.htm)

The most recent (2008) version of the World Medical Association's Declaration of Helsinki also refers to vulnerable individuals and populations, indicating that certain groups or populations who are potential research subjects may be "particularly vulnerable": for example "those who cannot give or refuse consent for themselves and those who may be vulnerable to coercion or undue influence." (Article 9) For Merry, "the conception of vulnerability hinges on the idea of agency. The vulnerable person is one who has little choice or capacity to escape pain and injury" (Merry, 2007, p. 195)

Although the concept may be difficult to describe in detail or to place boundaries around – and clearly other examples either within or outside of the research context could be found – there is an apparent consensus that vulnerable individuals, groups, and populations (however defined) are worthy of special protections. Whatever the source or cause of vulnerability, its presence demands the highest standards of care

and protection of human rights. This requirement is strengthened when individuals or groups are regarded as being especially vulnerable, and it is with these people that Article 8 of the UNESCO Declaration is specifically concerned. Of course, if defining vulnerability itself is problematic, ex hypothesi defining "special vulnerability" is every bit as challenging.

Interestingly, unlike some of the commentaries and guidelines already discussed, the IBC specifically declined to attempt a definition of vulnerability, or special vulnerability, preferring instead to provide examples of situations within the healthcare enterprise in which "special" vulnerability can be clearly identified. As the report says, "attempts to define vulnerability in general risk drawing the concept too widely or too narrowly, thereby triggering disputes rather than resolving them. . .." (para 7). This approach has the benefit of not focusing on the minutiae of definitional specifics, but rather concentrating on the concrete (but by no means exhaustive) examples the report describes. States and other agents/organizations can use these examples as templates for triggering appropriate responses and assisting in devising the protections that, it seems universally to be agreed, need to be put in place in certain circumstances and for specific individuals/groups/populations.

Personal Integrity

As has been seen, Article 8 specifically rolls together two concepts, the second of which is respect for the personal integrity of those who fall into the category of "special vulnerability." Unfortunately, perhaps, while widely used in human rights instruments and bioethical literature, this concept also can present definitional problems. Indeed, it is common to see the concept of "personal integrity" subsumed within, or accepted as a necessary facet of, human dignity. Both concepts recur in human rights instruments, and the literature that focuses on them. Indeed, Article 1 of the (UN) Universal Declaration of Human Rights says "All human beings are born free and equal in dignity and rights. . .," and Sulmasy (2008) reports that dignity is mentioned five times in the Universal Declaration. However, the Declaration does not explain what dignity actually is. Like vulnerability, however, it is a concept that seems to attain form and content by experience and implicit understanding. Just as there are obvious situations in which people would be widely recognized as vulnerable, so too the conclusion to Article 1, that exhorts people to "act towards one another in a spirit of brotherhood," serves to put some flesh on the bones of the concept, by emphasizing the importance of respect, equality, and solidarity.

Merely by belonging to the human species, people are entitled to respect, and it is this that triggers the attribution of human rights; perhaps the most significant political tool of the twentieth and twenty-first centuries. Definitional difficulties aside, as Sulmasy argues, "People do not have dignity because they have rights; they have rights because they have dignity. . .. All human rights depend upon the concept of dignity" (Sulmasy, 2008, p. 25) As one important aspect of human dignity, respect for personal integrity is integral to the attribution of human rights,

thereby offering the protection of "negative" rights, such as freedom from discrimination and exploitation, as well as "positive" rights, such as the right to self-determine.

Vulnerability Revisited

As has been noted, attempts to define vulnerability have proved problematic, yet as a concept it is in widespread use. Indeed, as Coleman says, "Even if there is no consensus on what vulnerability actually means, calls for 'protecting the vulnerable' seem to have an intuitive ethical appeal, and are therefore likely to continue" (Coleman, 2009, p. 14) Although, in Fox's words, the concept can be described as "plastic," nonetheless, it can serve as a trigger for important and sometimes essential protections (Fox, 2002). The International Bioethics Committee's decision not to focus on definition, but rather to provide relevant (albeit not exhaustive) examples, arguably successfully navigates the choppy definitional waters and provides a practical template for the implementation of Article 8. Focusing on outcome rather than definition allows for attention to be paid to the fundamental underpinnings of respect for persons in general and for the vulnerable in particular. Running the two concepts together, according to the IBC report, ". . ..reinforces this commitment by linking it to respect for personal integrity and the need to protect vulnerable individuals and groups" (International Bioethics Committee [IBC], 2011, para 1).

It is widely accepted that vulnerability is universal. At some time in life, everyone is vulnerable, irrespective of social status, intelligence, authority, or economic power. However, for many, the state of vulnerability is transient or contextual rather than inherent. While not unimportant, such states can often be overcome, or at least they pass in time. However, it is to those individuals, groups, or communities for whom vulnerability is not a transient state that attention is particularly important. It was to address the isolation, discrimination, and powerlessness of these individuals and groups that the IBC document was drafted, and it is to these individuals and groups in particular that the responsibility of seeking to rectify wrongs and obviate harms is owed.

Importantly also, people must be vulnerable *to* something. Vulnerability, then, is not merely a passive, but also an active, notion; political systems, socioeconomic or health-related circumstances to name but a few can individually or collectively conspire to attack or constrain capacities, life choices, and experiences. People are then, for example, vulnerable *to* disrespect, discrimination, stigmatization, and lack of agency.

While each and every person may be vulnerable at some time(s), some commentators have preferred to identify vulnerability by group characteristics. Thus, it is often claimed, for example, that children, pregnant women, the elderly, and people with disabilities are all ex hypothesi to be thought of as vulnerable. To be sure, this categorization may reflect both historical and contemporary realities. There is little doubt that women are disproportionately

disenfranchised, even in modern times, in some cultures and countries. Children all too often are at risk of exploitation – sadly, even by their own parents. The treatment of the elderly in some societies leaves much to be desired in terms of respecting them, and people with disabilities often identify disrespectful treatment in healthcare settings.

However, when commentaries, international statements, and guidelines direct special attention to groups or populations, the potential downside is the temptation to characterize all members of a discrete group as necessarily vulnerable. This is by no means uncontroversial, of course. Grady, for example, notes that:

> . . ..current concepts of vulnerability are usually applied to whole groups of people, without distinguishing between individuals in a group who might truly have a compromised capacity to protect their own interests from those who do not. Considering all poor people, pregnant women, members of ethnic or racial minorities, and people with terminal illness as inherently vulnerable in research has been particularly controversial. (Grady, 2009, p. 19)

While Grady's comment was made in specific reference to the healthcare research context, it resonates throughout life and transcends the clinical or research setting.

Thus, while there may be cases where all members of a group are vulnerable (perhaps, for example, in human population, genetic research on poor and isolated communities), it is important that the concept is sufficiently nuanced to ensure that the protections triggered by it are targeted appropriately and not indiscriminately merely because a person is a member of a group. This goes back to the question of definition, since it might be thought that it is the ability to describe those encapsulated by the concept that allows for strategic interventions to be made. However, problems emerge from this effort. Hurst expresses the impact of this definitional deficit concisely and clearly:

> Broadly, we agree that the vulnerable should be afforded some kind of special attention, or protection. Defining vulnerable persons or populations, however, has proved more difficult than we would like. This is both a theoretical and a practical problem. On a theoretical level, uncertainty as to what we mean by vulnerability is unsatisfactory because although we agree that this notion has a strong pull, we cannot account for this pull, justify it, or define its limits. On a practical level, we cannot know who should be afforded the protection due to vulnerable persons, or what form this protection should take. Contradictory definitions can lead to confusion for those who are supposed to protect the vulnerable, and wrong definitions may be acted upon. (Hurst, 2008, p. 191)

It is evident from this that translating aspiration into practice can be as challenging as finding a definition of vulnerability itself, and ultimately it is the imperative actually to *provide* the appropriate protections that is, or should be, at the heart of national and international endeavors. While, however, it may be difficult concisely and definitively to describe just *who* is vulnerable, it may be more straightforward to describe *when and where* people are vulnerable and what they are vulnerable to. One situation in which people may be thought of as especially vulnerable, and where their right to respect for personal integrity may be challenged, is in the provision of healthcare and its associated technologies.

Vulnerability in Healthcare, Research, and Technological Advances

The IBC report specifically divided the provision of healthcare into three discrete, albeit sometimes overlapping, areas: the routine clinical relationship, the research setting, and biotechnological advances. For ease, this essay will follow that pattern in what follows. However, it should be noted that special vulnerability and threats to personal integrity or human dignity can arise outside of the healthcare setting as well as within it.

The Clinical Context

People who are, or perceive themselves to be, unwell are dependent on healthcare professionals for diagnosis, prognosis, and – where appropriate – treatment. Irrespective of context, the sick person is vulnerable. That vulnerability has far-reaching consequences for his/her ability to self-determine. For this reason, laws have been developed over centuries that seek to secure protection of the individual's right to respect by focusing on the responsibility of healthcare providers to ensure that individual patients are well-informed, and ideally active, participants in any decisions made about their treatment and care. These laws, underpinned by the concepts of autonomy and respect for personal integrity, are intended to redress, to the extent possible, the imbalance between the healthcare professional and the patient, an imbalance based on characteristics such as context, knowledge, and authority. In combination with the law, professional guidelines increasingly stress the need to respect patients and their decisions, and to take care in ensuring that the dignity and rights of patients are respected.

If "average" patients can be described as vulnerable in their interaction with healthcare, there are others who can be described as being especially vulnerable and for whom the basic rules of law and professional guidelines offer insufficient protection. Although it has been argued to be inappropriate to make generalized assumptions about people simply because of their membership of a group, advocates, for example, for the elderly and people with disabilities, often argue that there is systemic disrespect within healthcare systems for these particular groups of people who are often regarded as inherently vulnerable. Inadequate funding may be routed into their care in general, they may be treated as "second-class citizens" even when care is available, and their specific needs may be neither adequately identified nor met. The principles articulated in Article 8 reinforce the need for action in such cases and, because they are directed at individuals as well as states, reinforce the obligations of solidarity and compassion that are owed to those who are especially vulnerable.

The dependent role of the patient in respect of healthcare providers seems self-evident. Irrespective of economic status, intellect, or any other characteristic, in a very real sense, individuals surrender something of themselves to the authority of healthcare professionals when they are, or believe themselves to be, ill. They are,

therefore, vulnerable to being ill informed, misled, or becoming passive recipients of, rather than active participants in, healthcare decisions that affect them. However, although it is clear that people can be described as vulnerable even in the standard therapeutic interaction, it is on the area of research that much commentary and activity has been focused, not least because in this setting the traditional, beneficent relationship between healthcare professional and patient is fractured by the very nature of human subject research. The primary aim in research is to identify potentially beneficial treatments for future patients, even if the individual research subject may also benefit. The research protocol, in order to be scientifically valid, must to some extent distance the researcher from the subject in a manner that does not exist in a good therapeutic relationship.

The Research Context

The need to undertake human subject research is generally accepted. Without it, medicine would not progress; novel treatments and technologies would not emerge, to the detriment of human health. While the law of consent also applies to the research context, and may even require that more information needs to be provided in this setting, concern remains that people invited to participate in human subject research are particularly vulnerable. Striking an appropriate balance between individual interests and rights and those of the wider society – current or future – is a challenge whose significance cannot be underestimated. Yet it is also a balance that is difficult to achieve. The importance of potential benefits may obfuscate the fact that research subjects may be exploited in the name of the greater good, even if that exploitation poses minimal risks to the subject.

There are a number of factors that may generate special vulnerability in the research context. These may be individual to the research subject or patient themselves; they may relate to the quality of the information provided by researchers; they may be socioeconomic or specific to the kind of research being proposed. These factors, according to Grady, may be more important than the subjects' identification with a specific group, reinforcing the claim that simple categorization as belonging to a particular community may be insufficiently nuanced to act as a rule of thumb for triggering special protections. Indeed, one consequence of such thoughtless homogenization has historically been not the inclusion, but rather the exclusion, of certain groups from engagement in the research enterprise. For example, particularly in the aftermath of the thalidomide case, pregnant women were routinely deemed unsuitable for involvement as research subjects, even though they too are entitled to the benefits of medical research. The International Ethical Guidelines for Biomedical Research Involving Human Subjects devised by the Council for International Organizations of Medical Sciences (CIOMS) in collaboration with the World Health Organization (WHO) declare in Guideline 13 that "Special justification is required for inviting vulnerable individuals to serve as research subjects and, if they are selected, the means of protecting their rights and welfare must be strictly applied." However, it must also

be borne in mind that people can also be rendered vulnerable by their *exclusion* from research.

It has already been indicated that the law in many jurisdictions has developed so as to attempt to provide protection for patients, primarily through the law of consent. Naturally, consent is also an important feature in medical research. However, it can be questioned to what extent the law of consent is able to offer the most appropriate level of protection to those who are especially vulnerable in the research setting. It is the nature of research that an hypothesis is being tested; by definition, the outcome is not known. This makes it more difficult for an open, full, and honest discussion of possible harms and benefits of the research to be undertaken, and requires a level of trust between research subject and researcher that is arguably even greater than in the standard clinical setting.

Yet, for some individuals and groups, the apparent protections of the law of consent may be more apparent than real and the necessary trust may not exist. Sadly, examples of research misconduct do exist and have been reported on; more than basic legal rules is, therefore, required. Broadly speaking, the additional protections recommended for vulnerable groups lie in, and are dependent on, procedural requirements. For example, the Declaration of Helsinki says that:

> Medical research involving a disadvantaged or vulnerable population or community is only justified if the research is responsive to the health needs and priorities of this population or community and if there is a reasonable likelihood that this population or community stands to benefit from the results of the research. (Article 17)

These additional criteria are designed to add another level to the protection ostensibly afforded by laws on consent. Of course, however, they are not always applied, nor are they always easy to apply. For example, in the case of human population genetic research which has been referred to already, the research is neither generally designed to benefit the specific population nor is it the case that the community will benefit without a genuine commitment to benefit sharing. The subjects of this research may agree to participate based on misconceptions, pressure, or lack of awareness of the implications of participation. Given the nature of the targeted populations, they may be poor, ill educated, and isolated; in other words, they are especially vulnerable. Lack of education, lack of healthcare resources, and poor understanding of the research enterprise as a whole, coupled with ancient cultural traditions, may mean that even the most scrupulously designed research project fails to protect the personal integrity of these vulnerable groups. Their vulnerability may stem from a wide range of sources, not least that their lack of authority in the face of the global research enterprise may cause them to engage in a particular project without fully understanding what may be lost by their involvement, or because they simply feel powerless to refuse. As Grady argues, "Individuals may have difficulty rejecting unfair offers and protecting their own interests if they do not recognize the offer as unfair, if they accept an unfair offer as better than nothing, or they feel as if they cannot refuse" (Grady, 2009, p. 21). In addition, and in apparent contrast to the requirements of the Declaration of Helsinki referred to above, there may be no benefit for the group or its individual

members; indeed, there may be no intention or expectation that any such benefit will flow from their involvement.

Outside of what might be seen as a somewhat extreme example, the research context requires careful attention to the actual or potential vulnerability of research subjects and to respect for their personal integrity. The fact that research will generally be conducted in an effort to benefit future (albeit sometimes current) patients should not be permitted to obfuscate the possibility that subjects are exploited. Nor is this risk necessarily affected by the *nature* of the research. For example, while invasive research with potentially limited benefits might trigger careful consideration and mandate special protections by way, for example, of strict adherence to a high level of information sharing and additional requirements imposed by ethical review bodies, less intrusive research might be treated more casually, especially where the potential benefits are significant.

Research design must be sensitive to the fact that any intrusion – physical or emotional – can be harmful. Every protocol, therefore, must pay special attention not just to the possible vulnerability of the subject but also to the impact of the research itself on the respect to which each person is entitled. Sacrificing this for the greater good, while it may sometimes be tempting, disregards the commitments contained in Article 8.

Equally, it may be that potential benefits may override respect for personal integrity and ignore or minimize human vulnerability where the situation seems urgent. Again, the greater good may be used as a justification for circumventing some of the requirements of best medical research. For example, in situations where certain diseases are prevalent, it may be tempting for researchers and/or companies to test developing vaccines in protocols that, for one reason or another, have not been, or would not be, approved by the relevant ethical review committee in the country leading the research. Very often, as is the case with population genetic research, the researchers will come from a developed country and the subjects will be from one that is developing, creating additional levels of vulnerability in the target group to those which exist in any case because of disease prevalence.

Of course, medicine is expected, and needs, to progress and research is an integral part of that. Nor is it intended to imply that the vast majority of research is not conducted both for good reasons and also in clear, respectful, and scientifically valid protocols. However, there is an obligation on researchers, and those who authorize the project, to bear in mind not just the scientific validity of the project, but also any special vulnerability of the target individuals and/or groups, and ensure that special attention is paid to the need to ensure that their rights are respected.

Technological Advances

Over the course of the last century and a half, medicine and its potential have developed almost beyond recognition. The development of anesthesia and antibiotics, for example, has saved uncounted millions of lives. More recently, advances

in assisted reproduction and human genetics have changed the face of medicine yet again. While for the moment, these developments have more relevance for the developed world than elsewhere, the issues raised by them are emblematic of the problems that can be generated by scientific advances and their applications. Medicine is now capable of doing more than palliating or curing; it can circumvent established problems, as well as use the human body – particularly its genetic components – as a source of information of potentially wide-ranging importance and effect.

For many individuals and couples, the ability to reproduce – to establish a family – is a fundamentally important desire. As the causes of infertility became better established, and as the number of people reporting themselves as having fertility problems continued to rise, the devastating individual effects of the inability to conceive or carry a pregnancy to term became clearly identifiable both in individual terms and – sometimes – in community terms. While in some parts of the world, overpopulation is a serious threat to well-being, in (mostly) western countries, the inability to found a family is seen by some as a personal and social evil, or at least as the thwarting of a powerful desire. While arguments historically abounded about whether or not satisfying the desire to have a child was the proper business of medicine, that debate seems largely to have been resolved. The advances in assisted reproduction and associated technologies (ARTs) have placed this aspect of fertility control firmly within the medical domain.

For largely psychological, and sometimes social, reasons, people who find themselves in need of assistance to found a family feel themselves disadvantaged. In some communities, they may even be stigmatized. Two primary sources of vulnerability emerge from this. From the perspective of some feminist writers, women become vulnerable to pressure to conform by having children and are victims of social norms that prevent them either from coming to terms with childlessness or seeing themselves as "full" members of the community if they fail to breed (Sherwin, 1992; Corea, 1988; Rowland, 1992). Proponents of this school of thought would maintain that medicine's focus on facilitating women's reproductive role is a male-driven conspiracy to keep women within the constraints of their traditional role as carers and home makers, making their full integration into social, economic and political life more difficult. Not only are they vulnerable to this pressure, but they are also disrespected by the coercion to take advantage of ARTs that arises from societal expectations.

On the other hand, those who require assistance to reproduce may see themselves as vulnerable in a very different way. The availability of the technology to facilitate reproduction may be limited by state regulation regarding "fitness to parent" or by financial constraints. For these people, the inability to participate on an equal footing with those who do not need assistance is what renders them vulnerable and disrespects their dignity.

In this situation, women are rendered vulnerable by virtue of their overwhelming desire – some would say need – to have access to the technology that allows them to become a parent. With the best will in the world, this leaves open the opportunity for exploitation – that is, it may encourage women to engage in practices that they

would otherwise not agree to. For example, schemes have been developed that allow women to circumvent the restrictions on availability of ARTs, which may be seen as ethically problematic. In some situations, women who are unable to afford the services they seek may be given free treatment if they volunteer to share their eggs with other infertile women. This may result in the stranger becoming pregnant, but the egg donor remaining childless, with all of the psychological sequelae that may flow from this. For those for whom having a child is an overriding goal, it is *prima facie* unlikely that they would willingly give away some of the opportunities they may have to do so. Yet they may see themselves as having no option but to do this, given that the alternative is no treatment – no chance at all of becoming a parent. While affecting a relatively small number of women, a variation on this scenario was regarded as sufficiently important to be used as one of the examples proffered in the IBC's report on Article 8.

Not mentioned in the report, but arguably of additional concern, is the question whether or not the assisted reproduction revolution is also implicated in the creation of a new group of vulnerable people – namely, the children born as a result of its application. While there is no evidence to support their claims, opponents of assisted reproduction often use these children as a reason to limit its availability. The argument is that children born into unconventional families, which assisted reproduction now permits, will necessarily suffer psychologically, and may also be stigmatized, for example, by being born into a same sex family or as the result of a surrogacy arrangement.

The other so-called medical revolution that raises issues about vulnerability and respect for personal integrity – perhaps even more acutely – arises from the rapidly developing area of human genetics. While advances in this area have the potential to explain the causes of ill health or disability, to develop treatment and perhaps ultimately cures for these conditions and to prevent the birth of children destined to suffer, as yet, it must be said, the much vaunted benefits have yet to emerge in significant numbers. Nonetheless, healthcare professionals, scientists, researchers, and multinational companies continue to press ahead with research and development. There are, obviously, both medical and financial benefits to be obtained.

While awaiting the therapies and cures that were so confidently predicted at the beginning of this revolution, vast amounts of genetic information are stored either for anonymized research purposes (such as in so-called biobanks) or in medical records. At a general level, the mere possession of this information is argued to render people vulnerable. Since it is now known just how many conditions have a genetic basis, and predictions can be made about future health status, inappropriate disclosure of the information may lead to stigmatization and discrimination. On the other hand, there is a lobby suggesting that disclosure of this kind of information in certain contexts is not inappropriate, but is rather entirely relevant.

For example, it can be, and has been, argued that employers and insurers have a right to information about the actual or potential health status of those whom they employ or are invited to insure. In terms of employment, it is argued, employers would be able to make more informed decisions about who to employ or retain based on predictable health-related information. Of course, this makes the

assumption – often not accurate – that genetic information is predictive rather than probabilistic. Certainly, in some cases, genetic information can predict with some certainty that disease will eventuate – for example, in the case of Huntington's disease – but more often than not all it conveys is a possibility or probability that a condition will emerge. Even in cases such as Huntington's disease, the mere presence of the disease gene does not predict the time of onset of the condition, yet this information may be used negatively in employment decisions.

For insurers, it might also seem to make sense that they are informed about genetic predispositions. After all, health-related information is routinely required for health and life insurance, and, it may be argued, genetic information is merely another type of medical information. In addition, family histories are also generally taken in these situations and this too allows insurers to identify patterns of illness which may be inherited. This kind of argument raised early fears of the creation of a "genetic underclass" of people who would be uninsurable (and possibly also unemployable). Should this eventuate, these would become the "new vulnerable": unable to participate fully in the life of a modern society and their privacy rights ignored.

Admittedly, such fears have not become a widespread reality, but it is arguable that the potential remains. Even if no underclass emerges, individuals may feel themselves challenged psychologically by the mere fact that genetic information exists in their respect. With whom will that information be shared? To whom might they have an obligation to disclose it? Do people have an obligation to their families and/or future generations to seek this information in the first place? These are realistic situations which may compel people to discover information about themselves that they would otherwise not wish to have, in breach of what has been termed a "right not to know," or to have information shared with relevant third parties that they would prefer to maintain in privacy.

Conclusion

Despite the relative vagueness of the concepts of vulnerability, special vulnerability, and personal integrity, Article 8 of the UNESCO Declaration nonetheless moves some way toward serious reflection of the national and international obligation to protect those who are in a weak position in the healthcare setting, either as a result of personal characteristics, socioeconomic factors, or any other indicator of disadvantage. This is important, not because there is an assumption that healthcare professionals, scientists, researchers, or even global corporations necessarily act in bad faith or for impure motives; rather, its significance lies in the explicit recognition that the very nature of the enterprise predicts a power imbalance between "consumer" and "provider" that is institutional. The responsibility, therefore, lies on providers, agencies, companies, and states to ensure that – to the extent possible – protections are built into the system. Where the vulnerability is special, the obligation is greater, and specific consideration needs to be made as to how to minimize or obviate vulnerability and ensure that people's rights are respected. The Article

emphasizes that everyone is vulnerable at some times and in some situations, but focuses specifically on those whose position is particularly in need of protection. In tandem with the IBC's report on this article, this is a clarion call to action to protect rather than exploit those whose agency is diminished by their life experiences and the lethargy or lack of respect from third parties and/or organizations such as the state that create or increase their inability to self-determine.

Privacy and Confidentiality

9

Jean F. Martin

Introduction: The context

Regarding the themes of this chapter, there have been, under the auspices of several organizations, developments that constitute a substantial background. To quote some:

The UNESCO Universal Declaration on Bioethics and Human Rights. This Declaration (UDBHR), adopted in 2005 by the UNESCO General Conference, is of particular importance (UNESCO, 2005b; ten Have and Jean, 2009). It says:

> ***Article 9: Privacy and confidentiality***
> *The privacy of the persons concerned and the confidentiality of their personal information should be respected. To the greatest extent possible, such information should not be used or disclosed for purposes other than those for which it was collected or consented to, consistent with international law, in particular international human rights law.*

An Early Effort: The Declaration on the Promotion of Patients' Rights in Europe (1994). This Declaration was elaborated under the auspices of the WHO Regional Office for Europe in collaboration with governments and interested bodies. In the resulting publication, Dr. J.E. Asvall, Regional Director, writes: "Well informed patients are beginning to assert rights in their private dealings with professionals in the health field. Until the beginning of the 1970s, the health professional-patient relationship was defined primarily by the rules of medical ethics. During the last two decades, the relationship was gradually redefined in terms of a contract (. . .) It has been demonstrated that well informed patients make better partners in their care, and have quicker and more complete recoveries (. . .) Patients' rights are a reflection of the importance of human rights" (WHO, 1995, p. 8).

H.A.M.J. ten Have, B. Gordijn (eds.), *Handbook of Global Bioethics*,
DOI 10.1007/978-94-007-2512-6_72,

The set of principles set forth in the Declaration include

> In the section "Human Rights and Values in Health Care": the right to respect of the patient's person as a human being; the right to respect for his or her privacy; the right of patients to be fully informed about their health status, including the medical facts about their conditions and alternatives to the proposed procedures. It further said that information may only be withheld from patients exceptionally, that patients have the right not to be informed at their explicit request, and to choose who, if anyone, should be informed on their behalf (WHO, 1995, pp. 38–39).
>
> In the section "Confidentiality and privacy": All information about a patient's health and all other information of a personal kind must be kept confidential, even after death; confidential information can only be disclosed if the patient gives explicit consent or if the law expressly provides for this; consent may be presumed where disclosure is to other health care providers involved in that patient's treatment; all identifiable patient data must be protected; patients have the right to access their medical files and technical records, such access excluding data concerning third parties; patients have the right to humane terminal care and to die in dignity (WHO, 1995, p. 41 and 43).

The Council of Europe Convention on Human Rights and Biomedicine (The so-called Oviedo Convention) was adopted in 1997. It includes in particular:

> ***Article 10: Private life and right to information***
> *Everyone has the right to respect for private life in relation to information about his or her health.*
>
> *Everyone is entitled to know any information collected about his or her health. However, the wishes of individuals not to be so informed shall be observed.*
>
> *In exceptional cases, restrictions may be placed by law on the exercise of the rights contained in paragraph 2 in the interests of the patient.*

> ***Article 2:***
> *"Primacy of the human being," of the same Convention, is worth noting as well: "The interests and welfare of the human being shall prevail over the sole interest of society or science." Article 2, paragraph 2, of the UDBHR has, with minor editorial changes, the same content.*

Privacy

Privacy is a major feature of medical care, particularly in the Western World, with roots in the Hippocratic Oath as it has arrived to us. Today, the right to privacy is, among other things, a consequence of the autonomy attributed to (adult, normally competent) individuals, their right to conduct their lives as they see fit.

Regarding the already-mentioned UDBHR, this issue is described as follows in a Memorandum of the International Bioethics Committee that developed it (Stiennon, 2009, p. 166): "A right to privacy restricts access to personal and medical information and provides a claim of non-interference in various private

spheres (. . .) Confidentiality refers to a special and often fiduciary relationship, such as that between researcher and research subject, or doctor and patient, and provides that the shared information shall not be disclosed to third persons, unless a strictly defined, compelling interest justifies disclosure." It goes on to mention international legal instruments that have recognized the importance of privacy.

Groups Whose Privacy Is Not Protected in Their Own Society

In Ancient Rome, to take a historical example, only a minority were Roman citizens and could participate in decisions of a political nature. The Roman *pater familias* exerted a right of life and death on members of his household (wife, children, and slaves). The latter had thus no autonomy or real power over their own lives, including as regards privacy. Similar situations are numerous today still; it is necessary to recall how often the autonomy and right to privacy of entire groups are not recognized and much less guaranteed. This is especially true for women (in past centuries their testimony was not accepted in courts or did not have the same weight as that of men). In fact, they remained *legal minors* in several respects (civically, politically) in European countries until the twentieth century and, in a number of regions, remain so today.

One point is of particular importance in medical ethics and bioethics: because of their inferior social status, formally or informally, women encounter significant difficulties in exercising their autonomy and privacy in matters of sexuality; their right/freedom to choose when and with whom to have sexual relationships, when and in which circumstances to bear children, is not at all universally accepted. This makes them vulnerable to various types of pressures and to violence. Moreover, contraceptive needs often include an element of urgency for the woman who might thus be, in various ways, at the mercy of the care provider and/or of others.

The Cultural Dimension

It is important to recognize how in different societies traditional rules interfere with privacy as understood elsewhere. UNESCO's International Bioethics Committee, in its *Report on Consent* – discussing Articles 6 and 7 of the UDBHR – says under the title "Communal and individual consent": "In many societies, the community is the entity in terms of which the individual is identified. The leaders make decisions on behalf of the community and its members and these are not questioned (. . .) There is a difficulty in aligning the autonomy of individual as embodied in Article 5 of the Declaration with certain cultural settings. The expression of individual wish that goes against these decisions can be difficult or impossible (. . .) The distribution of responsibilities and the decisional hierarchy in the family unit are such that the choice to be treated or not is not necessarily made by the person concerned. Health professionals must ensure that individuals should

not be subjected to coercive treatment, involuntary exclusion from available treatment or unwilling participation in research." (IBC, 2008, pp. 35–36).

Further, the Report says: "One of the most complex situations arises in societies where communal forms of decisionmaking may prevail. Seeking consent from an individual is indispensable even if his/her community is consulted [respectively informed, as regards privacy] (...) although it is important to observe and respect values of different cultures, these values should not infringe on fundamental freedoms." (IBC, 2008, p. 49).

Respect of Privacy by the Health Care Provider

Over the centuries, health care has been marked by a strong tradition of paternalism by care providers. In many societies, the priesthood and medicine were fulfilled by the same persons or were closely related functions. To be noted, however: paternalism is not always authoritarian or rigid, it may be benevolent and empathetic; admittedly there is, within limits, some reasonable use of paternalism.

One should know that the principle of patient autonomy is absent in Hippocratic writings. It is mostly since the emergence of modern bioethics, in the l960s and1970s and in Anglo Saxon countries first, that the diseased person has been seen as the *subject* of health care rather than its *object*. In the former quite asymmetrical state of affairs, privacy was not much of a concern. A few decades ago, in hospitals in Europe and elsewhere, even in university ones, it was customary to see consulting rooms with lines of patients queuing to be seen by the doctor at the end of the line, who would ask questions in front of others; adopting often in the conversation the "tu" when addressing them (in Latin and German languages, "tu" is the "you" used when talking to a child or person of inferior status). These manners were seriously encroaching on the privacy of the patients, and indeed on their dignity. Quoting from the above-mentioned WHO European Office Declaration on patient's rights: "Patients admitted to health care establishments have the right to expect physical facilities which ensure privacy, particularly when health care providers are offering them personal care" (WHO, 1995, p. 42).

Such behavior might not have been basically ill-meant but corresponded to a power/authority relationship in medical care. The spontaneous provision of sufficient and understandable information to patients and the requirement of their informed consent, which are pillars of today's bioethics, were not given much attention – at best they were envisaged at the free, arbitrary, judgment of the physician. Things are changing, not always as rapidly as one would wish, however. There is a major need, in the training of all health personnel as well as in their practice, to underline the importance of attentive and tactful respect of patient privacy – and especially of his or her modesty.

This is an essential component of adequate care today, as expressed, for example, in the above-mentioned WHO Declaration on the Promotion of the Rights of Patients in Europe: "There can be no intrusion into a patient's private or family

life unless and only if, in addition to the patient consenting to it, it can be justified as necessary to the diagnosis, treatment and care. Medical interventions may only be carried out when there is proper respect shown for the privacy of the individual. A given intervention may be carried out only in the presence of those persons who are necessary for it" (WHO, 1995 p. 41).

It is important here to mention the issue of sexually suggestive or loaded behaviors by care providers, which is rightly receiving more and more attention. It is a fact that, due to the singular encounter situation, there might be temptation to express inadequate words or gestures, especially sexual in nature. Contrary to the autonomy of the patient, which does not appear in it, the prohibition of such inappropriate contact is expressly mentioned in the Hippocratic Oath**:** "In every house where I come I will enter only for the good of my patients, keeping myself far from all intentional ill-doing and all seduction and especially from the pleasures of love with women or with men" (English translation of the original by Michael North, National Library of Medicine – in Wikipedia, January 2012).

Such abuse of the care situation is strictly unacceptable. A number of professional bodies have included relevant dispositions in their deontological codes. For example, the Québec College of Physicians Code of Deontology:

> ***Article 22:***
> A physician must refrain from taking advantage of the professional relationship established with the person to whom he is providing services.

More specifically, the physician must, for the duration of the professional relationship established with the person to whom he is providing services, refrain from having sexual relations with that person or making improper gestures or remarks of a sexual nature (www.cmq.org – January 2012).

The deontological Code of the Swiss Medical Association says at article 4: In his professional activity, the physician does not exploit the dependence of the patient; it is particularly prohibited to misuse his authority on the patient, emotionally, sexually or materially" (www.fmh.ch – January 2012).

Of course, what is said here of sexually connoted behaviors holds true as well for any gestures or words that might be demeaning, insulting, scornful, or racist.

Finally, let us mention special needs, for example, when there is a particular risk of violence or escape by people under police custody or imprisoned. All efforts have to be made nevertheless to ensure maximum possible privacy and respect of the patient's dignity.

Privacy of the Care Provider

The professional is entitled to respect of his or her own privacy. Physicians and others, however, have a professional duty to be physically and mentally fit for their tasks.

None of them should drink alcohol when working; surgeons should not have any difficulty that might alter their dexterity. The author of this chapter had in his official capacity to ask two psychiatrists with serious bipolar syndrome to stop their practice.

An increasingly important issue is whistle-blowing. "Traditionally health care professionals have been reluctant to blow the whistle on an incapacitated colleague. This may have been out of misguided loyalty or fear of repercussions for themselves. Even when a colleague's infractions are serious, reporting such behaviours will not necessarily find peer support," writes in 1996 a practicing physician involved in medical ethics (Hébert, 1996 p. 62). Yet there is today no excuse for covering up inadequate abilities or professionalism. In the jurisdiction where this author worked, a legal provision, adopted in 2002, says that health professionals are obliged to inform the health authority of facts raising suspicion of abuse or malpractice by other professionals (Vaud, 2002).

In a recently published Casebook by the UNESCO Ethics Education Programme (UNESCO, 2011a), two situations regarding physician privacy are discussed (Cases 1 and 2 – the book describes real situations). The first case is about an accidentally cut obstetrics/gynecology resident, in whom immediate blood testing shows HIV seropositivity. Several hundreds of hospital patients had been involved with this doctor during their treatment. The question is to evaluate whether this physician's colleagues and patients have to be informed of his status and how. The second story is of a gynecologist who did not disclose to a patient that he was suffering from epilepsy. The disease, however, was adequately medicated and kept under control.

Such situations usually are delicate, do not have ready-made answers and need to be considered in depth under their various facets, by the professional concerned, by responsible deontological and public authorities, by the employers.

Privacy and Research

The rules and principles within a research endeavor are basically the same as those for the provision of health care. Any element touching on the participant's privacy has to be carefully explained. Any invasion of privacy, as the case may be, should be agreed upon by participants and strictly limited to what is imperative for the study purposes. There must be assurances that the participants may withdraw at any time from the research, without having to give motives. Also all research projects should be submitted to appropriate ethical review.

Relevant articles of the World Medical Association Declaration of Helsinki on ethical principles for medical research involving human subjects (1964, amended last in Seoul, Korea, in October 2008):

> ***Article 11:*** *It is the duty of physicians who participate in medical research to protect the life, health, dignity, integrity, right to self-determination, privacy, and confidentiality of personal information of research subjects.*

Article 23: *Every precaution must be taken to protect the privacy of research subjects and the confidentiality of their personal information and to minimize the impact of the study on their physical, mental and social integrity.*

A Particular Ethical Issue in Research with Data Anonymization

A delicate situation is raised in research in which (with the consent of the participants) data are anonymized: "Even after rendered anonymous or encrypted, data related to samples might still be associated to the ethnic or geographical origin, socio-economic level and lifestyles of specific populations" (Stiennon, 2009, p. 169). Furthermore, in some studies, it appears ethically necessary to be able to go back to the provider of (anonymized) samples, when, for example, the sample examination uncovers information of major importance for him. However, if such "back-tracking" is possible for a reasonable, well-meaning purpose, concerned professionals and institutions should make all necessary efforts to prevent that it may be unduly used.

Confidentiality

Medical Confidentiality

The notion of confidentiality in medical care goes back in the West to the *Hippocratic Oath*: "All that may come to my knowledge in the exercise of my profession or in daily commerce with men, which ought not to be spread abroad, I will keep secret and will never reveal" (English translation of the original by Michael North, National Library of Medicine – in Wikipedia, January 2012). Said oath regained visibility and vigor in eighteenth century Europe. During the Middle Ages, European medicine was hardly organized and there is no clear indication of a confidentiality duty then, although such a duty was present in Islamic and Jewish medicine (Morais, 2001, p. 725).

In Anglo-Saxon societies, confidentiality is mainly a deontological rule without legal protection (British common law gives a right to professional confidentiality to the barrister only). This flexible conception has been influenced by eighteenth century medical personalities such as J. Gregory and T. Percival. The latter said, "confidentiality must be strictly observed when circumstances demand it", but, if called to testify, "the physician must tell the truth, all the truth and only the truth" (Morais, 2001, p. 725).

This is very different from the French approach: in France, the 1810 Napoleon Code provides a basis to the "secret médical," imposed to any person who by virtue of his or her profession is depository of secrets entrusted to him or her. The Québec legal disposition is of the same vein. Medical confidentiality is more than a moral duty, it is a legal obligation. It is considered an element relevant to "public order"

and its violation is sanctioned by the Criminal Code. Several authors think that this particularly stringent definition is due to some assimilation of the "secret médical" to the Catholic confession confidentiality – "secret de la confession" (Hoerni & Bénézech, 1996). In Switzerland, the "secret médical/professionnel" is also ruled by the Criminal Code but the faculty of being lawfully freed from the obligation to keep confidentiality is more easily obtained, and in more circumstances, than in France (Martin & Guillod, 2000).

Medical confidentiality has in modern times followed three different routes: one, as said above, is *deontological* (professional ethics). One of its expressions is the Geneva Declaration (1948), the forerunner of today's Helsinki Declaration. The second one is the *legal* one (the French model). One might note that deontological texts, elaborated and applied by a professional body, do not have the democratic legitimacy law has – today an increasing number of rules linked to bioethical issues are inscribed in public law and regulations.

Since the 1970s and the emergence of modern bioethics, confidentiality tends to follow a third route, the *human rights* one – similar to major evolutions in public and community health thinking. Below, we mention that the late Jonathan Mann, then head of the WHO AIDS program, championed the importance of human rights in the struggle to contain the epidemics. Would all concerned human beings be free to exercise their rights (especially autonomy, capacity to refuse unwanted relations), the spread of HIV/AIDS would not have been the same.

Goal of the Confidentiality/Secrecy

Fundamentally, the overarching objective of medical confidentiality is the *protection of the patient's interests* (and not the protection of the provider's – see below). It exists to protect the sick person from undue curiosity from a variety of others.

It is considered a cornerstone of good therapeutic rapport between the person cared for and the caring one. Louis Portes, a French physician who was (in the mid-twentieth century) president of the *Ordre national des médecins*, had the famous sentence: "There is no medicine without trust, no trust without confidence and no confidence without secret" (Hoerni & Bénézech, 1996, p. 12). The French doctrine insists strongly on the notion that, would patients not be fully confident about the strict secrecy of what happens in the therapeutic encounter (*colloque singulier*), they would not readily come for treatment anymore.

In principle, the doctor and other professionals have to be released from the confidentiality obligation *before they can talk to any other person* about the patient health condition. This holds true also for the patient's loved ones, wife/husband, partner, or children. The recognition of that principle has become more effective in recent decades. The consent of the patient needed before informing others usually does not require a formal procedure like a signature. Instead, it might be governed by common sense – as many things ideally should be in the relations between care givers and patients. In routine situations (fracture, appendectomy, common cold…), one

can often assume a tacit agreement that the provider informs family and loved ones. Yet, every time that there might be an unwelcome breach of the patient's privacy (information allowing to deduct questionable contacts or behaviors, e.g., sexually transmitted disease; this is an issue also in psychiatric care), the provider has to ensure that the patient gives clear and explicit consent, or mandate, to inform others. These aspects have been very significant, during the first decades of the AIDS epidemic.

Secret of the Doctor or "Secret of the Patient"

This is a significant terminological question. In German-speaking regions, one speaks today of the secret of the patient ("Patientengeheimnis"), which comes closer to the actual meaning of medical confidentiality, that is, to protect the person's privacy and data.

Over the last decades, a major evolution in a number of countries has been the recognition, and inclusion in the laws, of patients' rights. These imply the duty for the provider to inform the patient, spontaneously, without delay, and in a sufficiently complete fashion, about the medical observations made, laboratory and other para-clinical exam (imaging, etc.) results, about diagnosis and the various possible therapeutic avenues with their advantages and disadvantages, and about prognosis. This information is a *sine qua non* condition in order to obtain a valid informed consent from the person. Another patient's right is access to the medical file (in principle, to all that is in the file).

In this modern context, it is said that "the patient is the master of the confidentiality/secret," the health professional being the one who maintains it and stores it. Doctors who would refuse to their patients access to their medical data arguing that they are entitled to deny access "based on the medical confidentiality" would be grossly perverting the legal and deontological principle. After all, the patients should decide about the secret and its keeping or opening. Regarding their own medical data, they are to say to whom it may be given/transmitted, how and when. Case study 3 of a UNESCO Casebook in ethics education (UNESCO, 2011a) presents an actual example.

The Particular Situation of Teenagers Having Competency, the Capacity to Consent/Judge

Different systems have here different ethical and legal provisions. In several countries where the legal age of majority is 18 or 20, it is considered that teenagers have, some years before that age, the ability – the "strictly personal right" as the Swiss Civil Code has it – to request, accept, or refuse medical care, even without information being given to their parents or legal guardians, or against the will of their parents/legal guardians (see Martin, 2009). This allows, in Switzerland, for example, a 15-year-old girl to consult on her own a gynecologist to request

a contraceptive prescription, or even an interruption of pregnancy, without information of the concerned adults or against their will. Case 7 of the UNESCO Casebook on Benefit and Harm (UNESCO, 2011b) deals with that issue: the law, in the actual situation described, does not recognize any rule of absolute parental authority until a fixed age.

That "psychological/social age of competency" is not fixed by law, in general, it is a matter of appreciation by the care provider, in view of his or her professional experience. Understandably, it depends of the specific situation and in particular its severity.

The above has much to do with the principle of autonomy but is fully relevant regarding confidentiality. While for younger children the care provider has to thoroughly inform the parents, the provider has to be careful to protect the youth's privacy. By the same token (see preceding section), the youth is the one who decides about "secrecy" regarding their own medical data and the provider must have the patient's consent before informing others.

Shared Confidentiality Among Members of the Care Team

The need to share data among a variety of persons involved in the patient's treatment (the care team) is undisputable and now well recognized. The realization of this need required a change in mores and habits among the professions over the second half of the twentieth century. Physicians has been earlier rather possessive of the information they had ("information is power"...).

Stiennon notes, "Scientific and technical development has resulted in the need to accommodate the imprescriptible duty of confidentiality. Indeed, confidentiality is complicated by the fact that the flow of information is in the very interest of the patient. New confidentiality problems have also arisen from the computerisation of health administration. In the management of health problems and the prevention of diseases, government can intervene in the confidentiality domain" (Stiennon, 2009, p. 168).

In a time of high sensitivity to appropriate protection of personal private data (medical data are particularly sensitive), the desirable practice of "shared secrecy" has limits to be observed. The main one it that each member of the team has access only to the information needed in order to fulfill adequately his/her role/mission in the diseased person's treatment. Shared confidentiality shall not mean that everybody on the team can peruse any part of the file. This represents challenges and demands strict measures (passwords, etc.) in an age of computerized medical documents – see also what is said above of the respect of patient privacy by care providers.

Waiving Confidentiality When Others' Interests Are Seriously at Stake

There are situations where it appears desirable or necessary, as the case may be, to give others information covered by medical confidentiality. Flowing from the principle that

the patient is the master of the secret, the golden rule is to first obtain consent before the data is forwarded to others who have a significant interest in being informed.

Both the public authorities (health authority especially) as well as private individuals might have such an interest. The following examples are meant to illustrate this point:

- A number of communicable diseases need to be brought to the attention of the health authority in order to take appropriate treatment, control, or prevention measures.
- It is today generally considered necessary that violence and ill-treatment of persons, especially minors and others who are under the responsibility, rule, or pressure from others (including parents and close ones) and not in a position to adequately defend themselves and their interests, should be reported to an appropriate service or authority.
- The patient might be a danger for himself/herself but also for others, especially in psychiatric situations. In most countries there are legal texts allowing hospitalizing (committing) persons even without their consent.
- There might be cases where the declarations or behavior of a patient raise the fear that he might seriously harm others. The care provider has then to judge to what extent the danger is such that information should be conveyed to persons or offices concerned.
- There are countries where by law physicians or other care providers have to report to the appropriate authorities, if they come to know of a crime (in others, and by analogy with the confidentiality duty of ecclesiastic persons, this is not the case).

From an ethical point of view, one should generally oppose a duty of health professionals to denounce persons having committed a delict or crime (while the professional keeps the faculty, if they deems it necessary, to be freed – according to the relevant legal or deontological rules – from the confidentiality duty in order to give information to concerned third parties). In 1832, the famous French surgeon Dupuytren, asked by the police to give the names of rioters, answered famously "I don't know rioters in my wards, I see only wounded persons."

This issue is similar to the one raised by the ethical principle that physicians should not participate in any way, in acts of torture or other harsh and inhuman treatments, including the death penalty.

Confidentiality and Public Health: The Balance to be Struck Between the Individual's Interest and Privacy and Possible Community Interest and Wellbeing

In a book providing explanations about the UNESCO Universal Declaration on Bioethics and Human Rights, aimed at worldwide understanding and application of its principles, Jeanine-Anne Stiennon writes, "In practice, the rights and freedom of individuals are in conflict with the exigencies of the 'common good' and with the potentialities of information technology. Examples are : screening of pathogenic

agents or diseases, genetic or immunological typing, identification of potential offenders, codes of public health, interdependent social situations (social services, social insurance, preventive medicine, hygiene, and psychiatry) The interests of certain economic sectors linked to the exploitation of data are also involved" (Stiennon, 2009, p. 167).

In the future, deciding when medical confidentiality (may) have to be opened to others, private or public, will present many questions and challenges. They are to be dealt with by considering carefully the private and public interests concerned. The next sections provide illustrations.

Practical Issues and Examples in Today's World

A Major Challenge: Confidentiality and AIDS at the Outset

AIDS was described in 1981, first as a medical rarity and enigma, and became a worldwide public health problem around 1985. Public health authorities had then to ponder a number of difficult ethical questions, as it became apparent that it was an infectious disease, transmitted mainly through quite private behaviors (sexual intercourse, intravenous drug use), which raised alarms in the public.

There were demands for the promulgation of certain legal obligations in order to limit the spread of the disease. There were discussions in the 1980s and early 1990s about compulsory and universal testing (for HIV seropositivity) in the population, of exclusion of seropositive children from kindergartens or schools, of limitation of the freedom of persons living with AIDS to move around and even of their internment in closed institutions or camps. Several countries (including the United States) required an HIV test before delivering a visa! The problems were made more acute as medicine remained practically helpless for several years. There were many fears that one could catch that terrible disease unknowingly ("without deserving it").

With society faced with a dangerous communicable disease, it was logical that professionals were required to report whether they had seen cases, how many, in which types of patients (in order to advance epidemiological research, among other things). But did public health surveillance require that the names of the patients be known? With the possible exception of particular situations, the answer is no.

Medical confidentiality was at stake from another perspective, too: what was the physician to do about the (most reasonable) wish to make sure that partners of a person with HIV seropositivity be informed of that fact – at a time when full-blown AIDS killed in 1 or 2 years. The French medical profession never admitted that it was understandable, and in a way morally compulsory, to inform at least the regular partner (entitled to expect that his/her consort not be sexually nomadic), and that medical secrecy had to be waived. French physicians went on with a rigid legal view of confidentiality, arguing that if giving such a information, even to a directly endangered person, was accepted, then the seropositive patient

would lose all trust in the health system and not seek care anymore. That might very well be true, argued others, but what about intentionally letting another person be at a mortal risk? In Switzerland, ways were devised to achieve the goal of informing regular partners; first through efforts to convince the patient to allow information to be given, then if necessary by asking the relevant authority to waive medical confidentiality.

In the UNESCO Casebook on Benefit and Harm (UNESCO, 2011b), cases 27, 28, and 30 focus on situations that went before courts in relations with HIV seropositivity having been hidden, either from the patient or from an interested third party, or on the contrary disclosed to others without the consent of the patient.

It was not easy thus for public health professionals and decision-makers to strike the right balance in a novel situation, with a number of unknowns regarding the spread of the disease. As forceful intrusions in the private sphere of individuals were talked about, one had to evaluate when and to what extent it was legitimate to invade privacy. Should there be compulsory testing? If so, of the whole population? Or, in certain groups like children in school? What about patients entering hospitals, as clinicians also were afraid? Should it be routine in persons with multiple sexual partners, in IV drugs users? In retrospect, one may say that, thanks to courageous positions by the WHO (including the late Jonathan Mann, a great advocate of human rights issues in AIDS and in public health in general), by National AIDS and Bioethics Commissions and other bodies, and by public health professionals, one could in most places avoid unjustified authoritarian measures which would have seriously jeopardized privacy and confidentiality.

Privacy and Genetic Testing

Progress in medicine, especially in genetics, poses new challenges, for example in respect to Huntington disease (known as Woody Guthrie's disease in the US), a dominant hereditary disease leading to early dementia (in the forties) and death, for which there is no therapy. Today, it is possible from childhood on to know whether a person carries the responsible gene, which represents a first ethical difficulty: may one propose to young persons that they be tested when, should the result be positive, it would mean a terrible burden for the rest of their (rather short) life. For these reasons, it is considered unethical to propose testing before the legal age of consent. In any case, prior enlightened and tactful genetic counseling is indispensable, after which the decision to test or not is taken in all liberty by the person.

Confidentiality – or disclosure – comes into play in relation with the children of a person tested positive. Should they be informed that one of their parents is a carrier, is going to die prematurely with dementia, and might have passed on to them the Huntington disease gene, which they might later on transmit to their own offspring? The person tested positive has the right to refuse that their close relations be informed but one readily sees that this opens serious questions. Similarly, one would have to ponder these questions in relation to the fiancé of a young person who has tested positive.

Similar challenges and difficulties are encountered as a result of other current advances in genetics. In the recently published UNESCO Casebook on Benefit and Harm (UNESCO, 2011b), case 26 describes a situation of a woman found with a genetically transferable disease where physicians did not take measures to have her threatened children informed.

In 1997, UNESCO adopted the Universal Declaration on the Human Genome and Human Rights (UNESCO, 1997). Articles related to privacy and confidentiality include:

> *Everyone has a right to respect for their dignity and for their rights regardless of their genetic characteristics.*
>
> *The right of each individual to decide whether or not to be informed of the results of genetic examination and the resulting consequences should be respected.*
>
> *Genetic data associated with an identifiable person and stored or processed for the purposes of research or any other purpose must be held confidential in the conditions set by law.*
>
> *In order to protect human rights and fundamental freedoms, limitations to the principles of consent and confidentiality may only be prescribed by law, for compelling reasons within the bounds of public international laws and human rights.*

Medical Confidentiality and Daily Life

Other questions are common and may touch everybody's existence. Thus, employers have a (legitimate, per se) interest to have employees who enjoy good health. Should they be allowed to get information out of the medical file of applicants for a job? No, in principle. According to the above-mentioned golden rule, job applicants have the right to ask their doctors to inform any others, including a prospective employer, but one is well advised to be careful here; one would want to be sure that there is no undue pressure involved. Is the employer even allowed *to ask* health-related questions (about physical or mental conditions) to the candidate? This is much debated.

On the other hand, there are cases where such queries are logical: one very much wants a bus driver or a pilot to have good vision. One may understand as well that, before offering an expensive additional training to a collaborator, the employer wishes to have a reasonable assurance that the person will not in the short term be limited by medical conditions. Yet, there is here a contradiction with the notion of equal chances for all which we would like to maintain and promote.

Medical Confidentiality and Health Insurance

In countries with universal social security and/or health coverage mandated by law, it is unacceptable that risk factors linked to health or disease be invoked to reduce or

diminish what the legal mandate fixes. But the situation is very different where there is no such coverage, as well as regarding complementary insurance on a private basis: in many countries those who can afford it contract additional coverage to get better than basic care. Then the insurer may ask questions – and demand answers – before agreeing to an insurance policy. In fact, in that private industry (including life insurance), the name of the game, the researched goal is to propose to the customers the most advantageous premium, as figured on the basis of the risks they represent – or not – to get sick or die prematurely. Insurers are advised to learn as much as they can about an applicant, in order to offer a low premium to good risks and high premiums – or offer a refusal – to bad risks. There is no consideration here of social solidarity, which is in principle the rule for universal coverage. Applicants may of course refuse to provide information or allow their physician to transmit medical data, but in that case they will most probably not have any proposal by the insurance.

Such situations have been frequent, and difficult, in respect to HIV/AIDS. When effective anti-retroviral therapies were introduced, a number of young seropositive persons were able to pursue professional careers, in which they often needed to contract life insurance, for example, to get loans from banks. In those circumstances, physicians faced serious dilemmas when answering insurers' questionnaires.

Medical Confidentiality and Duties of the Public Hand

Within any health care system today, there are strong pressures to contain the cost of care. Authorities and bodies supervising insurance programs ask for medical data justifying the prescriptions and acts performed, aiming at ensuring that money is efficiently used, and for the purposes it is supposed to serve. The goal is to eliminate unnecessary procedures, redundancy, and waste, wherever they may be. From a social ethics point of view, this is legitimate; we all have an interest in the relevant and economical use of means made available by the community. Confidentiality should certainly not serve to hide any wasteful use of resources. On the other hand, this objective should not allow excessive curiosity by others, which would be contrary to the interest of a patient and their treatment. A reasonable balance is to be found between what the insurer might ask and undue breach in the privacy of the care relationship.

There are requests for medical data that are justified by other tasks of the State, where one expects the authority to take adequate measures. For example the control of the driving capacity: there is a clear public interest in reducing the number of dangerous drivers on the road – be they dangerous because of drinking, some physical or mental problem, or other reasons. The right to privacy and confidentiality of the individual is thus superseded by the desirable security in traffic. Either one agrees to be medically examined and the conclusions are transmitted to those in charge of road safety or one should accept not to drive anymore.

In summary on this point: confidentiality is established to protect/preserve the privacy and interests of the patient. However, there are situations that make it necessary to waive the confidentiality when others' or the community's interests are seriously endangered.

Privacy and Confidentiality Are Threatened by Difficulties in Communication and Integration

It is increasingly recognized, all over, that persons living in an area where they were not born, and of which they do not know the socio-cultural mores and language, are for that reason quite vulnerable. They are migrant workers who, legally or not, moved to the new country, or refugees and asylum seekers, or people displaced within their own country. They are at a much greater risk of not being able to explain what their health problem is nor to understand recommendations of health personnel, and consequently not to be treated adequately. In the UNESCO Casebook on Benefit and Harm (UNESCO, 2011b), case 3 describes difficulties rising from such misunderstanding.

These situations demand the collaboration of interpreters, or cultural mediators when the problem is to understand the way things work in the new residence. In several countries there are valuable efforts in this direction. As regards our topic, one should be aware of a potential side effect of this basically useful development, that is, the threat to the patient's privacy through the presence and intervention of a third person. The interpreter or mediator, though knowing the person's language and culture, might be reluctant to render exactly declarations which he or she finds awkward or even offensive (because "these are things which are not said or done in our original culture"). Also, a woman might very well not be willing to talk of a gynecological problem through a male interpreter. An adult might not accept translation by a youth. Interpreters must be aware of and respect the confidential character of what happens in the care relationship. They must understand that they have to transmit the message neutrally, without modifying it. Furthermore, the translation might simply be inaccurate or the health provider might misunderstand. There are here growing challenges in today's increasingly diverse and mobile societies.

Confidentiality and the Health Status of Persons Assuming High Office or Other VIPs

On several recent occasions, there have been rumors, concerns, and questions around the health of elected officials, including heads of State (e.g., President Georges Pompidou in France in the 1970s). The issue is to evaluate whether there is a *public interest* of the concerned citizens to be informed when a person with major political duties is hampered in his or her capacity to carry out the responsibilities they have been elected to. Does the public have a right to know, and if yes, to what extent? The main opinion today is that there is such a right. How rapidly it should be done and with which degree of detail should be evaluated in the particular case. Whether the same might hold true too for members of the "people crowd," movie stars, singers, writers is of less momentous importance. There, the potential unfortunate consequences of not knowing appear more related to the fans' sorrow or of a commercial nature. Contrary to the situation of major political decision makers, the reasons to request a "right to know" do not appear compelling at all in these cases.

To What Extent Is the Intervention of the State Legitimate in Highly Private Situations, for Example, at the End of Life?

There is an ongoing and necessary ethical debate about the extent to which the public authority is entitled to take compulsory measures vis-à-vis certain diseased persons (e.g., with psychiatric or addictive conditions). When, how, and in which circumstances might the State pretend to know better than the individual what is good for him or her? This is an important issue regarding the individual's right to privacy.

Until a few years ago, France had a law mandating premarital medical examination. As a measure ordered by the State, it came to be considered an inappropriate intrusion in the private life of individuals and was abolished. Needless to say, engaged people who freely decide to undergo a premarital examination show responsibility and are perfectly welcome. But, then, they are well advised to agree beforehand that the physician(s) are authorized to transmit possible pathological information both to the person concerned and to his or her partner. Case 30 of the UNESCO Casebook on Benefit and Harm describes the unfortunate consequences of a situation where the sick member of the couple did not inform his partner of the finding and where the doctor had not been given the mandate to inform her (UNESCO, 2011b).

Suicidality presents another illustration. Health care providers and society generally, have a general "mandate" to prevent suicide. However, putting an end to one's own life is also, in a way, a right. Almost all countries that earlier criminalized suicide (attempts) have abrogated such laws. Further, there is agreement that some suicides are understandable, "reasonable," given heavy and painful life circumstances – with a high degree of dependence, despondency, and no hope for recovery. One may talk of "stock-taking suicide," In some states in the US and in several European countries (Belgium, Luxemburg, Netherlands, and Switzerland), people with intractable suffering have the right to seek assistance for a suicide (though no right to require that it be given), and such assistance by third parties is not punished. The need there is to define a reasonable balance between the measures that public health might take to prevent suicide (e.g., of young persons under the effect of transitory stress or misfortune) and possibly undue and authoritarian limitations of the right of persons to decide over their own lives – their privacy.

About the Right Not to Know

Sigmund Freud is said to have told his physician, when the latter announced that he had diagnosed a cancer of the tongue, "Who authorized you to tell me that?" The right not to know is a generally recognized right. It follows from the principles of autonomy of the person, of consent (or refusal) and is linked to privacy. The patient is free to say, "Doctor, I trust you to do the best for me, whatever the diagnosis and available treatments, but I don't want to be informed" (especially, one assumes, in the case the findings and prognosis are severe). There are, however, cases where this raises questions. As mentioned above, the AIDS epidemic,

particularly when no therapy was available, generated much discussed ethical dilemmas. One is confronted with comparable issues in relation with less symbolically loaded communicable diseases as well as with hereditary conditions.

There might be other dilemmas for the physician and care team: suppose the discovery of a severe condition with bad prognosis in a young 40-year-old entrepreneur full of perspectives and projects. It is this patient's right not to be informed; yet he might have wife and children and the consequences of an announced death may be less devastating in several respects than if unannounced. Not knowing the threat to his life, he might engage in new investments that might become wasted; his business might lose much of its worth would he insist on managing it with a severely altered health. While the care provider's mission is not to take responsibility for all aspects of the patient's life, he is concerned with his general wellbeing.

Summarizing: patients are entitled not to know and to leave their close ones in ignorance but, in situations like the one described, for the professional to think of ways to discuss the possible consequences of deliberate ignorance is at least legitimate.

And After Death?

An important point is that the requirement for medical confidentiality is not cancelled by the death of the patient. Ethical and legal provisions remain the same, as well as the possibilities to be released from it – as mandated by law or if specific circumstances demand it (with no possibility then to follow the above-mentioned "golden rule" of the patient's consent as he or she is no longer in a position to give it).

Conclusion and Perspectives

The whole domain of privacy and confidentiality in health care and research has been marked in recent decades by the emphasis put on human rights. First, with the emergence of charters and laws about patients' rights, whereby the former deontological rules, elaborated and applied (arbitrarily as the case may be) by a profession, were replaced by public law – with therefore a democratic legitimacy.

Future challenges are, in particular, at the interface between traditional confidentiality, with the primary goal to protect the patient's interests, and the consideration of the interests of third parties. In some cases, these third parties are family members and close ones, in others cases they are persons the patient comes into contact with – in areas as diverse as communicable diseases, ill-treatment and battering of others, especially children, or traffic safety – or the community at large (public health problems).

There are delicate questions around the right not to know and whether to hide from concerned close ones information that is of importance for their own lives.

With increased emphasis on the respective rights and duties of patients and care providers, the latter might now more than in the past insist on protecting their own privacy. On the other hand, whistle blowing about incompetent professionals is now asked for. Others whose privacy is in jeopardy (unwillingly or sometimes willingly) are persons in very visible and looked upon positions: elected officials, people of the business or media worlds. For some of them, a legitimate public interest to know may be invoked.

In research, the widespread use of computerized banks, including biobanks, results in storage of ever larger amounts of data and samples of many sorts. This poses challenges in terms of informed consent for their use – when, for example, a new study is envisaged, which was not foreseen when they were collected, as well as questions in terms of privacy. Use of anonymized material has its own delicate issues.

Non-discrimination and Stigmatization

10

Nouzha Guessous

Introduction

Justice and equality are two founding principles of universal human rights. Any attempt to infringe these principles is considered as an infringement of human dignity.

The equality principle implies the duty of equal treatment of any individual or group irrespectively of their particular characteristics. Based on the uniqueness of every human being and the duty of respect for human diversity, the nondiscrimination principle aims to ensure that no criteria or situation produce effects, which systematically disadvantage persons or groups possessing those characteristics or living under those situations. Historically speaking, slavery and all kinds of racism and xenophobia demonstrated dramatically the possible harms of discrimination.

Thus, the principle of nondiscrimination has been introduced from the very beginning of international attempts to institutionalize the human rights philosophy at a universal scale.

Obviously, as bioethics is an extension of human rights philosophy to the field of medicine, life sciences, and associated technologies, the nondiscrimination and nonstigmatization principles have been affirmed and considered as guiding principles in all discussions, documents, and legislations.

UNESCO has called on the nondiscrimination and nonstigmatization principle in almost all documents related to bioethics including the Universal Declaration on Bioethics and Human Rights (UDBHR) adopted in 2005.

Article 11 of the UDBHR states: "No individual or group should be discriminated against or stigmatized on any grounds, in violation of human dignity, human rights and fundamental freedoms."

This article addresses two issues: discrimination and stigmatization. Both deal with infringement of the equality principle and are considered as violations of human dignity, human rights, and fundamental freedom.

DOI 10.1007/978-94-007-2512-6_74,

The application of this article either in research or healthcare practice will have to deal with a major difficulty related to the fundamental problem of identifying precisely what is to be considered as discrimination. Some practices can be perceived differently from one context and culture to another. Thus, this article in the UDBHR is closely related to Article 12 on respect for cultural diversity, and the main concern is to identify ethical limits so that this article could not be invoked to justify any discrimination and stigmatization of persons or groups.

Finally, in each of these contexts, it is important to identify the relationship between Article 11 and others in the declaration.

Some Definitions

Discrimination

The word "discrimination" comes from the Latin "discriminare" which means to "distinguish between."

To discriminate socially is to make a distinction between people on the basis of class or category or individual character without regard to individual merit, which is an infringement of the ethical theory of egalitarianism based on social equality.

Distinction between people based on individual merit (such as personal achievement, skill, or ability) is generally not considered socially discriminatory.

In contrary, distinctions between people based on race, social class or caste, nationality, ethnicity, religion, sex, sexual orientation, height, age, social conditions, physical or mental disability, diseases or genetic characteristics, or any other ground are generally considered in the whole corpus of human rights law as discriminatory and as a violation of human dignity, human rights, and fundamental freedoms.

Nondiscrimination

The concept of nondiscrimination is a social as well as a legal concept of long standing within human rights law. It requires the equal treatment of an individual or group irrespective of their particular characteristics. It is used to define and legally prohibit any criteria that may produce effects which systematically disadvantage persons possessing those characteristics.

The general aim of this principle is that in any decision or practice, no one shall be subjected to discrimination based on any grounds, including physical, mental, or social conditions, diseases or genetic characteristics, nor shall such conditions or characteristics be invoked or used to stigmatize an individual, a family, or a group.

Positive or Reverse Discrimination

There are several examples of discriminatory policies or acts that benefit a historically and sociopolitically nondominant group (typically women and minorities but sometimes majorities), at the expense of a historically and sociopolitically dominant group (typically men and majority races). Originally called "positive or reverse discrimination," international bodies are now used to call it "affirmative action policies." Such actions can be in any field to facilitate the access of vulnerable people to their rights including those related to health.

However, whether a given example of discrimination is positive or negative is often a subjective judgment.

Stigmatization

The word "stigmatization" is related to the word "stigma." Among other definitions (Rivard, 2009), stigmatization is defined by the Oxford English Dictionary Online as a "distinguishing mark or characteristic (of bad or objectionable kind)." The verb "to stigmatize" is defined as to "call by a disgraceful or a reproachful name; to characterize by a term implying severe censure or condemnation."

The concept of "stigmatization" is a social rather than a legal concept.

According to the *Encyclopedia Britannica*, "stigmatization" is a discrediting process which strikes an individual who is considered as "abnormal" or "deviant." He or she is reduced to this single characteristic in other people's eyes or opinions for whom this "label" justifies a range of social discriminations and even exclusion. The social impact of stigmatization shows a number of negative behaviors toward stigmatized people that can end in real discrimination as regards, for example, access to social services such as healthcare and education, employment and professional advancement, income level, and domestic life.

In the field of health, the concept of stigmatization has been frequently used in the work of WHO, especially in relation to HIV and AIDS, but also in contexts like mental health, genetic characteristics, diseases, or any other situation where a single physical or biological or a health character may be looked at as "bad" with a range of social and even legal negative impacts.

In the field of bioethics, UNESCO recognizes stigmatization as a distinguished kind of discrimination that may have a serious impact on the right to health and benefit of scientific research. It refers to any characteristics that may interfere negatively with a person or a group and infringe his/her/their right to access and benefit from the progress of "medicine, life sciences and associated technologies." In this perspective, stigmatization is a violation of human dignity, human rights, and fundamental freedom.

For some authors, the concept of stigmatization amounts to limited or indirect kind of discrimination but not as understood in international law (Rivard, 2009).

International Human Rights Instruments on Discrimination and Stigmatization

The *Universal Declaration of Human Rights* (1948) clearly stated the equality among humans by proclaiming in Article 1 that "All human beings are born free and equal in dignity and rights." Equality is therefore the basic fundamental principle of human rights philosophy. The same declaration stated in Article 2 that "Everyone is entitled to all the rights and freedoms set forth in this Declaration, without distinction of any kind," thus starting the concept of nondiscrimination among humans in any issue.

Article 7 specifically addresses the issue of discrimination "All are equal before the law and are entitled without any discrimination to equal protection of the law. All are entitled to equal protection against any discrimination in violation of this Declaration and against any incitement to discrimination."

The recognition of this principle was historically extended to all kind of domains and rights including socioeconomic and political rights. It is stated in many national constitution laws as well as in several regional and international instruments approved via intergovernmental organizations.

Many other conventions have further addressed discrimination in socioeconomic, political, and cultural rights, and others addressed issues of discrimination based on specific grounds: racial, sex and age. The *International Convention on the Elimination of All Forms of Racial Discrimination* of 21 December 1965 and the *Convention on the Elimination of All Forms of Discrimination against Women* of 18 December 1979 are the two major examples.

Without any attempt to create new human rights with new grounds of discrimination, or to duplicate the entirety of established international law, every specific instrument of bioethics has been embedded within this larger body of international human rights law.

Discrimination and Stigmatization in International Instruments on Bioethics

The twentieth century is sadly full of examples of harmful practices in the field of health and medical and scientific research based on several grounds of discrimination. The most famous drama occurred during the Holocaust and gave birth to the Nuremberg Code (1948) followed by several other professional, national, regional, or international instruments.

Within its mandate as defined by its constitution, UNESCO has been engaged in the ongoing global debates under the broad rubric of bioethics, beside a number of other international and regional organizations such as the World Health Organization, the World Intellectual Property Organization, the World Medical Association, and the Council of Europe. UNESCO aims mainly to provide guidance to member states for the elaboration of their laws and regulations.

UNESCO's work in the field of bioethics called on the established standard-setting corpus and other international human rights instruments adopted by the United Nations and specialized agencies of the United Nations system as well as the other international and regional instruments, international and national legislation, regulations, codes of conduct, guidelines, and other ethical texts in the field of science and technology.

The concept of stigmatization could appear as a label of the UNESCO input. It was added as a principle to the general body of international human rights law as UNESCO declarations in the field of bioethics were the first international instruments related to human rights to use this concept.

Nevertheless, UNESCO consider that "questions of bioethics, which necessarily have an international dimension, should be treated as a whole, drawing on the principles already stated in the Universal Declaration on the Human Genome and Human Rights and the International Declaration on Human Genetic Data and taking account not only of the current scientific context but also of future developments" (10th paragraph of the preamble of the UDBHR).

Nondiscrimination and Stigmatization in UNESCO Declarations

To date, UNESCO produced three declarations that dealt with bioethical issues:

1. The *Universal Declaration on the Human Genome and Human Rights* (UDHGHR) adopted by the General Conference of UNESCO in November 1997
2. The *International Declaration on Human Genetic Data (IDHGD)* adopted by the General Conference of UNESCO in October 2003
3. The *Universal Declaration on Bioethics and Human Rights (*UDBHR) adopted by the General Conference of UNESCO in October 2005

The preambles of the three declarations endorse the main related international, regional, and professional instruments of bioethics and human rights.

- *The UDHGHR* dealt with discrimination in Article 6: "No one shall be subjected to discrimination based on genetic characteristics that is intended to infringe or has the effect of infringing human rights, fundamental freedoms and human dignity."

Article 2 makes a direct link between genetic data and the risks of discrimination by proclaiming that

> "(a) Everyone has a right to respect for their dignity and for their rights regardless of their genetic characteristics.
> (b) That dignity makes it imperative not to reduce individuals to their genetic characteristics and to respect their uniqueness and diversity."

However, the UDHGHR did not call on the concept of stigmatization.

- *The IDHGD* dealt with the two concepts of discrimination and stigmatization in paragraph (a) *of* Article 7: "Every effort should be made to ensure that human genetic data and human proteomic data should not be used for purposes that discriminate in a way that is intended to infringe, or has the effect of infringing

human rights, fundamental freedoms or human dignity of an individual or for purposes that lead to the stigmatization of an individual, a family, a group or communities."

The paragraph 6 of the preamble recognizes that genetic characters may clearly expose an individual or a group to discriminatory actions both in their general life and in the issues of health and life sciences. They also may be cause of stigmatization: "Human genetic data have a special status on account of their sensitive nature since they can be predictive of genetic predispositions concerning individuals and that the power of predictability can be stronger than assessed at the time of deriving the data; they may have a significant impact on the family, including offspring, extending over generations, and in some instances on the whole group; they may contain information the significance of which is not necessarily known at the time of the collection of biological samples; and they may have cultural significance for persons or groups."

Thus, Article 3 on "person's identity" states: "Each individual has a characteristic genetic make-up. Nevertheless, a person's identity should not be reduced to genetic characteristics, since it involves complex educational, environmental and personal factors and emotional, social, spiritual and cultural bonds with others and implies a dimension of freedom."

- *The UDBHR* went further to proclaim nondiscrimination and nonstigmatization as universal principles of bioethics and human rights in Article 11.
- *Additional UNESCO documents* dealt with nondiscrimination and nonstigmatization. Further to the adoption of the UDBHR, the UNESCO Division of Ethics of Science and Technology has published a Bioethics Core Curriculum set out to introduce the bioethical principles of the Universal Declaration on Bioethics and Human Rights to university students. The primary target group of the core curriculum is medical students. Available on the UNESCO website, the core curriculum consists of two sections.

Section 1 provides the core contents with objectives, syllabus, and teacher manual for each unit of the curriculum.

Section 2 contains the proposed study materials for each unit of the curriculum.

The core curriculum is organized in units. Unit 11 is dedicated to the nondiscrimination and nonstigmatization principle.

Grounds of Discrimination and Stigmatization in Bioethics

In the field of healthcare and bioethics, some groups need more protection such as infants and elderly people, AIDS patients, psychiatric patients, and depressed patients.

The list of grounds of discrimination differs markedly from an international human rights instrument to another, starting from the UDHR. Arguably, the drafters of the UDBHR declined the proposal of identifying major grounds that are pertinent to the field of bioethics, in favor of a wording that makes it clearly embedded within

the established international law of human rights. This is why the enumeration of specific grounds has been dropped from the fourth draft of the declaration. This was based on the fact that any list would either be incomplete or even be seen as a way of creating new grounds of discrimination (Rivard, 2009).

This implies that the identification of the most pertinent grounds to the field of bioethics will be up to the implementation step and according to specific contexts of UNESCO member states.

1. Poor and vulnerable individuals and groups may be discriminated in the sense of suffering of deep inequalities in their right to access to healthcare services. A common argument in favor of positive actions toward those vulnerable persons is that it can correct some of these inequalities, while some opponents claim that it can create dependence and a sense of entitlement. Nevertheless, it can create a sense of discrimination for those who are excluded from the programs.

Case Study: Positive Discrimination for Poor Minorities
In a poor multiethnic country with limited health and economic resources, the government decided to give priority for primary healthcare to poor nomads of the desert minorities. For instance, specific funds will be allocated for the prevention, diagnosis, and care of trachoma and infantile diarrheal diseases.
(From Nouzha Guessous experience)

2. Advances in medical technology have the potential to create disproportionate disadvantages for some social groups, either by being applied in ways that harm members of these groups directly or by encouraging the adoption of social policies that discriminate unfairly against them with significant individual, social, and legal consequences.

For instance, reproductive medicine has developed techniques that enable parents to choose the sex of their child which raises the concern of discrimination against girls and women in societies where male children are valued more highly than female children. Similar concerns have been raised about the increasing use of abortion as a method of birth control in overpopulated countries where there is considerable social and legal pressure to limit family size. On the basis of cultural and/or socioeconomic background, in several parts of the world, there is a strong preference for male children. Prenatal diagnosis (PD) through chorionic villus sampling and direct fetal sexing or early ultrasonography are means to determine the fetal sex allowing couples to abort a fetus of a nondesired gender. PGD technology is used for this purpose as well, although only by a small elite that can financially afford it. According to the European Society of Human Reproduction and Embryology (ESHRE) 2002 Report, 70 % of the participating centers oppose the idea of embryo sexing and authoritative clinical geneticists have made a plea to limit PGD to medical indications.

In the 2003 report on preimplantation genetic diagnosis (PIGD), the UNESCO-IBC concluded as follows: "It is recommended that PGD be limited to medical indications. Therefore sex gender selection for non-medical reasons is considered to be unethical" (IBC-UNESCO, 2003).

Sex Selection in India

Prenatal testing and termination is the main problem in India, where its use has led to the ratio of girls to boys declining to 927 girls to 1,000 boys in 2001. In some regions, the ratio is as low as 800 per 1,000.

Sex selection is the exercise of sexism at the most profound level, choosing who gets born, and which types of lives are acceptable. In traditional patriarchal societies, such as in India and China, the preference for boys has led to huge imbalances in the sex ratio in the population. Worldwide, there are estimated to be 100 million missing women as the result of sex selection. Indian communities in the USA and the UK are now being targeted by clinics which have no scruples about exploiting these traditional prejudices for profit. In Western countries, there seems to currently be a preference among the majority white communities for girls, but the choices that are being made are still based on rigid, sexist, gender roles. Even in the case of "family balancing" (where a family has one or more child of one sex and wants a child of the opposite sex), which the HFEA views as relatively acceptable, rigid gender expectations are clearly operating. In how many cases where parents are "desperate for a girl" will they be hoping for a loud tomboy that grows up to be an engineer? Society must continue to fight sexist gender, not allow them to dictate who is born.

(From http://www.hgalert.org/sexselection.PDF)

3. Gender discrimination extends to many other areas both in the access to healthcare and to benefit from research. As women live longer in many parts of the world, elderly women might find themselves abandoned by their families, subject to inadequate healthcare, and disregarded by society. The prevalence of some diseases among mid-aged women may induce national positive actions to the exposed population.

Case Study: Positive Discrimination of Low-Income and Uninsured Women to Prevent Breast and Cervical Cancer

The national program for early detection of breast and cervical cancer in country A was designed to reduce disparities in mortality due to cancer by targeting primarily low-income and uninsured women.

The program has delivered notable improvements in access to screening for low-income women minority groups that could not benefit from the diagnosis campaigns in the 2000s with an emphasis on overrepresentation of women originating from rural areas.

This result was obtained at the expense of an underrepresentation of other women.

(From Nouzha Guessous experience)

4. Dominant moral and cultural habits and even legal dispositions may deprive adult women their personal authority to make important life and healthcare decisions.

Case Study: Discrimination and Stigmatization on Cultural-Based Grounds

MZ, aged 20, has come to Dr. NG for testing of her status for pregnancy and for sexually transmitted infections. She explains that her brother's friend has been sexually abusing her 1 week before. She further explains that, when she complained to her parents, they angrily denied the possibility and accused her of flirting and being sexually provocative. MZ lives with her family in a small village where the community is religiously devout, so any sexual scandal involving police or other authorities would be very stigmatizing. MZ asked for a prescription of an emergency postcoital contraception. She was very scared and asked that her parents not be informed of her visit because this would confirm their suspicions of her immorality.

(From Nouzha Guessous experience)

It may also deprive women from their right to equal access to healthcare services.

Case Study: Discrimination on Moral Grounds

In community A, any sex outside marriage is very strongly condemned, particularly for women. Furthermore, this community lives in a village with very limited health resources and is both poorly staffed and equipped in hospitals and delivery facilities. One evening, two women, Ms. KW and Mrs. MZ, came for delivery, with Ms. KW arriving shortly before. Ms. KW was known in the village as a sex worker and that she was pregnant as a single mother meaning that the father of her child was unknown.

Given the lack of resources, the administrators of the delivery hospital decided to give priority to Mrs. MZ as she was legally married and to refer Ms. KW to another maternity ward, approximately 2 h drive on non-asphalted road from village A.

(From Nouzha Guessous experience)

5. Migration and situations of war or civil conflicts also affect women especially. They are often vulnerable to abuse and to be deprived from their right to be part of the process for conflict resolution and reconciliation. The report of IBC on the principle of respect for human vulnerability and

personal integrity (IBC-UNESCO, 2011) provides an account of the principle of respect for personal integrity (Article 8 of the UDBHR) and the need to protect those who are especially vulnerable. As one of the most important examples of special vulnerabilities, IBC more specifically deals with the position of women, in particular migrant women and women affected by war who are especially vulnerable to the risk of being unwanted, uncared for, abused, and rejected (IBC-UNESCO).

6. In the field of genetics, the use of relatively simple tests for determining a patient's susceptibility to certain genetically transmitted diseases has led to concerns that the results of such tests, if not properly safeguarded, could be used in unfair ways by health insurance companies, employers, and government agencies. In addition, through genetic counseling, prospective parents can be informed about the chances that their offspring will inherit a certain genetic disease or disorder; this will enable them to make more informed decisions about reproduction. This is viewed by some bioethicists and some NGOs as contributing to a social atmosphere considerably less tolerant of disability than it ought to be. The same criticism has been leveled against the practice of diagnosing, and in some cases treating, congenital defects in unborn children.

Genetics Privacy and US Legislation

In 2008, the "Genetic Information Nondiscrimination Act" (GINA) passed by the US Senate prohibits US insurance companies and employers from discriminating on the basis of information derived from genetic tests. GINA protects Americans from discrimination based on information derived from genetic tests. It forbids insurance companies from discriminating through reduced coverage or pricing and prohibits employers from making adverse employment decisions based on a person's genetic code. In addition, insurers and employers are not allowed under the law to request or demand a genetic test.

(From http://www.ornl.gov/sci/techresources/Human_Genome/elsi/legislat.shtml)

Special attention should be paid to the so-called research on the genetic bases of behavior. It is controversial though it is still in its infancy because of its potential to encourage the adoption of crude models of genetic determinism in the development of social policies, especially in the areas of education and crime prevention. Such policies, it is claimed, could result in unfair discrimination against large numbers of people judged to be genetically disposed to "undesirable" forms of behavior, such as aggression or violence.

7. Medical research in general is also a domain where groups of population or patients may be subject to discrimination. The Tuskegee experiment is one of the most famous cases.

Case Study: The Tuskegee Experiment

In 1932, the US federal government of Alabama launched into a medical study called "The Tuskegee Study" of untreated men with syphilis. At that time, penicillin was proved as an efficient treatment. The study selected 412 poor African Americans men infected with the disease and faked long-term treatment, while really only giving them placebos and liniments. The premise of the action was to determine if blacks reacted similar to whites to the overall effects of the disease. The experiment lasted 40 years and was only discontinued in 1972 when a Senate investigation was initiated. The survivors of the study did receive treatment and financial compensation after the Senate investigation.

(Based on the true story of the decades – long Tuskegee experiment, a movie, Miss Evers' Boys (Director: Joseph Sargent), was adapted from the 1992 stage play written by David Feldshuh).

Limitations of the Principle of Nondiscrimination and Stigmatization

Article 26 of the UDBHR specifies the general framework of these limitations. "The Declaration is to be understood as a whole and the principles should be understood as complementary and interrelated." This implies that if a bioethical issue or problem emerges, it is usually the case that several principles are relevant to the issue or problem and need to be balanced in order to reach a justified conclusion about what to do.

Article 27 specifies the limitations on the application of the principles. It mentions several conditions in which application may be limited by law:

- "in the interests of public safety,
- for the investigation, detection and prosecution of criminal offences,
- for the protection of public health,
- for the protection of the rights and freedoms of others.
- Any such law need to be consistent with international human rights law."

Therefore, when public health is at risk, exceptions or restrictions to the nondiscrimination principle can be necessary either by "affirmative" actions in favor of some key persons or groups or by "negative" actions that may infringe upon individual rights. These exceptions must be publicly discussed and applied with transparency and according to the national law. They also must be subject to revision according to developments of the situation and scientific knowledge.

Interrelation of Article 11 with Other Articles in the Declaration

As with the entire Declaration on Bioethics and Human Rights, the understanding and the implementation of this article requires to be built in the context of the entire instrument, as stated in Article 26 above mentioned.

The provisions of Article 1 pertaining to the scope of the declaration cover those of Article 11 on nondiscrimination and nonstigmatization.

The injunction against discrimination and stigmatization is in reference to the resolution of "ethical issues related to medicine, life sciences and associated technologies as applied to human beings" with consideration of "social, legal and environmental dimensions." It applies to states, individuals, and organizations.

To be coherent with the declaration, Article 11 is to be read and implemented as a theoretical and practical continuation of Articles 3 (human dignity and human rights) and Article 10 (equality, justice, and equity). Whatever it may be built on, discrimination is against human dignity and human rights in general, and it infringes the principles of equality of all humans and of their right to justice and equity.

Article 12 (respect for cultural diversity and pluralism) is closely related to the issue and risks of discrimination and stigmatization based on cultural considerations, rules, and habits. Therefore, it clearly affirms that "such considerations should not be invoked to infringe upon human rights and fundamental freedoms."

Stigmatization on cultural grounds: Circumcision of girls

In some communities, a girl who is not "circumcised" may be stigmatized.

Mothers usually maintain such tradition under the justification that if they do not circumcise their daughter, these later will be considered negatively by members of her wider family and by her young peers and that she will not be eligible for marriage. This is facilitated by the fact that there are usually no legal prohibitions in the jurisdiction that ban the practice in the communities where the circumcision is practiced.

Because of the risks of such intervention, some mothers bring their daughter to medical doctors. They argue that if the medical doctor does not agree to perform the circumcision, the grandmother or a traditional birth attendant will undertake the procedure herself by customary unsafe and risky means responsible of severe bleeding and infection.

Finally, the duties of nondiscrimination and nonstigmatization are necessary for the comprehension and implementation of the principles of solidarity and cooperation (Article 13), social responsibility (Article 14), and sharing benefits among humans (Article 15).

Conclusion

In bioethics like in human rights philosophy, the principle of nondiscrimination is based on the understanding that discrimination is socially constructed rather than "natural." This recognizes the need and paves the way for concerted action against inequality and the institutional mechanisms which perpetuate it. It also aims to fight against any discrediting process which stigmatizes an individual or a group who is reduced to a single characteristic in other people's eyes or opinions for whom this

"label" considered as "abnormal" or "deviant" justifies a range of social discriminations and even exclusion.

This is to be understood, implemented, protected, and promoted, at national and international level, in accordance with the whole set of principles in the UNESCO Universal Declaration on Bioethics and Human Rights.

Respect for Cultural Diversity and Pluralism

11

Ruth Macklin

Introduction

Our world is culturally, politically, and ethically pluralistic. Several major world religions, with numerous adherents, exist side by side in many countries, along with numerous smaller religious groups. Ethnic and cultural groups abound, with a wide variety of norms and customs. Countries – and even states or provinces within countries – have different political and economic systems, each with its own structure of laws and regulations. But it is not only in these respects that our world is pluralistic. Pluralism refers also to the ways different nations order the relations between state, religion, and citizens. Some nations, such as the United States of America, have a constitutionally protected separation between church and state. Others, such as Iran and Israel, have an official state religion, with formally recognized, state-supported religious laws and institutions, observances, and parochial education. The growth of multicultural societies and an increasingly globalized world have prompted a call for cultural sensitivity and respect for different traditions. With vastly increased immigration from developing to industrialized countries, nations that were predominantly homogeneous in the past have had an influx of immigrants from Africa and Asia. It is, therefore, uncontroversial to urge respect for cultural diversity and recognition of pluralism in a globalized world.

All cultures comprise members who adhere to their norms and practices to a greater or lesser extent, and individuals may have overlapping cultural identities. They may be members of an ethnic minority within a religious majority in a population. Alternatively, individuals may be members of an ethnic or a racial majority but a religious minority. The fundamental ethical principle, "respect for persons," implies that such respect includes recognition of the beliefs people hold and the actions they perform in conformity with their membership in a culture.

Several paragraphs in this chapter are extracted from my book, *Against Relativism: Cultural Diversity and the Search for Ethical Universals in Medicine*. New York: Oxford University Press, 1999.

The UNESCO Universal Declaration on Bioethics and Human Rights makes reference to cultural diversity in Article 12, entitled "Respect for cultural diversity and pluralism." Article 12 states: "The importance of cultural diversity and pluralism should be given due regard. However, such considerations are not to be invoked to infringe upon human dignity, human rights and fundamental freedoms, nor upon the principles set out in this Declaration, nor to limit their scope." The caveat in this last sentence sets out the task for anyone seeking to comply with the UNESCO Declaration and at the same time express respect for cultural diversity. It requires determining which cultural norms and practices related to human health and medicine in our diverse world do not deserve respect or adherence because they violate human rights or universal ethical principles.

Several contexts related to bioethics exist where respect for cultural diversity may arise. The first is within a multicultural country or city characterized by large numbers of recent immigrants from other countries or cultures. Clinicians and biomedical researchers residing in the city or country face an immigrant population with values, beliefs, and practices that medical personnel may not have encountered previously. One example is the prohibition in some traditional cultures for a woman to undergo a medical examination by a male physician. A second context is that of multinational research, in which the sponsor is typically from an industrialized country or the pharmaceutical industry and the research participants are from a developing country with different cultural norms or values. A third context is that in which physicians from industrialized countries bring medical students or residents to a developing country to provide humanitarian aid and often at the same time, education and training for the students in a different cultural setting. Similar dilemmas or quandaries of cross-cultural conflict may arise in all three settings, and some situations may be unique to one or the other context.

Culture, Ethical Principles, and Moral Rules

Despite a very general understanding of the concept of "culture," it remains ambiguous and often means different things to different people. One critic of the sloppy use of the term writes that "most of the time, *culture* is a lazy, trendy substitute for a more specific word." The anthropological use of the term "refers to the total way of life of a discrete society, its traditions, habits, beliefs, and art. . ." (Clausen, 1996, p. 2). A culture, in this sense, is defined by certain features that differentiate it from other cultures.

Although it is indisputable that different nations, cultures, religious, or ethnic groups adhere to different norms of behavior, it is possible to provide an ethical analysis of social practices by seeing how they conform to fundamental ethical principles such as those embodied in the UNESCO Universal Declaration and to human rights provisions in United Nations treaties and covenants. However, this is no easy or straightforward task. Ethical principles require interpretation in their applications to specific actions or practices. The same is true for human rights provisions. Moreover, ethical principles and human rights are not the only features

that require interpretation in an ethical analysis of respect for cultural diversity. The very notion of what constitutes an ethical principle may be open to debate. Here are two illustrations.

The well-known "four principles" of bioethics – respect for persons, nonmaleficence, beneficence, and justice (Beauchamp & Childress, 2008) – are widely known in bioethics outside of "Western" countries, although they have been given various interpretations in different cultural settings. Yet, debates can arise over what should count as an ethical principle. For example, on occasion, one hears reference to the phrase, "respect for tradition," implying that it is an ethical principle. Does "respect for tradition" qualify as an ethical principle? If it does, is it on a par as a fundamental principle with "respect for persons" or the ethical imperative to strive to bring about more benefits than harms? "Maintain respect for tradition" is a customary norm in many societies and operates as a conservative force for maintaining the status quo. It also functions as a practical and possibly also a moral maxim for anthropologists conducting fieldwork. It is evident that "respect for tradition" can conflict with one or more of the well-known four principles, especially respect for autonomy.

Some traditions are ethically neutral yet are intimately bound in cultural practices. These include ceremonies of various sorts at weddings and funerals; nonharmful rituals that may include prayers, dancing, chanting, and rites of passage; and adhering to dietary laws like kosher and halal. Most of the time, these sorts of activities are ethically neutral; that is, they do not give rise to harms or wrongs to those involved. Ethics deals with how people treat one another, how governments or nongovernmental institutions treat people, and whether human beings are harmed or wronged by these treatments. Adherence to a cultural tradition may be neutral; it may harm people or it may benefit them; it may support human rights or violate them. But "respect for tradition" as a norm does not by itself constitute an ethical principle.

A second illustration of a debate over what constitutes an ethical principle is an ongoing contrast between so-called "Western" and "Eastern" principles. The guest editors of a journal issue devoted to a discussion of this pair of principles wrote: "Much has been made of the fact that the so-called Western principles of 'autonomy, nonmaleficience [sic], beneficence, justice' do not address 'compassion' and professional 'competence' as has been the case in all healing traditions for centuries" (Sass & Zhai, 2011, p. 1). Presumably, the principle that embodies the concept of compassion goes as follows: "physicians should treat their patients with compassion." If that is a moral principle, it does not seem to be uniquely "Eastern." Physicians everywhere and throughout history have been enjoined to behave compassionately (as the authors of the article acknowledge). An article that appeared in an online publication of the American College of Physicians is entitled "Why compassion is such an important part of practice." The first sentence of the article states: "Amid the daily demands of teaching and practice, it's sometimes easy to lose sight of our primary purpose as physicians: providing compassionate care to our patients" (American College of Physicians, 2011). Nevertheless, "treat patients with compassion" cannot properly be considered a general ethical

principle. It is, rather, a norm of medical practice, a moral rule for physicians in caring for patients. Arguably, it is a specific example of a rule that falls under the general ethical principle, *respect for persons*. In any case, it is no more Eastern than it is Western. Alternatively, as one author notes, "compassion is more of a virtue than a principle to Confucianism" (Cheng-Tek Tai, 2011, p. 25).

The other example of a so-called "Eastern" principle that these same authors refer to is "physician competence." This can also be cast as a moral rule: "Physicians should be competent in the practice of medicine and not exceed the skills they can competently exercise in treating patients." Arguably, this moral rule falls under the principle of beneficence: "Act so as to maximize benefits and minimize harms (to patients)." An incompetent physician is unlikely to maximize benefits but is perhaps equally likely to maximize harms. Nothing peculiarly "Eastern" or "Western" characterizes this moral rule. In any case, like "compassion," it is not a general ethical principle but rather, a moral rule subsumed under a more general principle (Beauchamp & Childress, 2008). It would be difficult to find a so-called Eastern ethical *principle* that does not have an equivalent "Western" formulation, or else is better construed as a moral rule that can be subsumed under a more general principle.

According to one position, a rigid categorization of "Eastern" and "Western" values fails to accord with the realities of today's globalized world (Joseph, 2011). A fusion of ethical principles is one possibility, leading to greater harmony. But uncertainty or even occasional harm can occur when respect for autonomy is conjoined with cultural sensitivity. The case of a Hindu woman seeking a cesarean section is illustrative. The woman, a devout Hindu, asked her obstetrician for an elective cesarean section so the baby could be born on an auspicious day in the Hindu calendar. This required that the C-section be performed earlier than at the time of a full-term pregnancy. In many traditional societies even today, physicians make the decisions and patients willingly comply (this was, of course, also true in Europe and North America for most of medical history). But in this case, adhering to the principle of "respect for persons" and at the same time showing cultural sensitivity, the obstetrician acceded to the patient's request based on her faith-based reasons. The operation was performed at 35 weeks and resulted in harms: the baby had immature lungs, required a prolonged stay in the hospital, and at great financial cost to the parents (Joseph, 2011).

Increasingly, scholars in bioethics question whether "Eastern" and "Western" principles of ethics are mutually exclusive or even readily identifiable as such (Widdows, 2011). For example, a "Western" view in bioethics not unlike the "Eastern" value that put individuals in the context of family or community is the idea of "relational autonomy" in feminist theory. The difference between these values seems to be more one of emphasis than of radically different ethical principles.

Pluralism

Just as the concept of culture can be vague or ambiguous, so too does confusion exist regarding ethical "pluralism." According to one author: "What we might call

'social pluralism' is the view that diverse and often mutually inconsistent ethical outlooks should be respected and that there may not be any single moral principle or set of principles, however basic, that all moral agents must acknowledge. Human rights, for example, may be widely acknowledged in the West, but not in other parts of the world; hence, from a social pluralist's point of view, for Western governments to try to impose standards of human rights upon non-western societies is inappropriate" (Callicot, 1995, p. 685). This author is mistaken in claiming that non-Western governments do not recognize human rights. The difference between acknowledgment of human rights by Western governments and some others lies in *which* human rights they recognize and acknowledge, not whether they recognize human rights at all.

A somewhat different concept of pluralism has been proposed in the context of multinational research. The authors of an article in the second edition of the *Encyclopedia of Bioethics* contrast ethical universalism and ethical pluralism: "Some contend that all research, wherever it is conducted, should be justified according to universally applicable standards. Those opposed to this position, while sometimes accepting certain standards as generally applicable, argue that most standards must be adapted to accommodate the mores of particular cultures; they argue for ethical pluralism. Pluralists commonly refer to the universalist position as 'ethical imperialism,' while universalists often call that of their opponents 'ethical relativism'" (Christakis & Levine, 1995, p. 1781). Although intended to be helpful in distinguishing two widely held views regarding ethics in the conduct of multinational research, this paragraph is rife with confusion. It refers to "universally applicable standards" and to "the mores of particular cultures." Nowhere are ethical principles mentioned. Are "universally applicable standards" ethical principles? If so, do pluralists reject one or more of the well-known ethical principles that govern research? And if so, do they propose to replace ethical principles with the mores of particular cultures? Do they maintain that cultural mores are on a par with general ethical principles? Without knowing what the "ethical standards" are, which mores, in particular, might override such standards, and where ethical principles enter the picture (if at all), we cannot understand what the pluralists will or will not endorse.

This conceptual confusion calls for clarification in what is meant by "ethical standards." Are all ethical aspects of research with human subjects properly considered *standards*? Should standards be universally applicable or are variations permissible according to economic, political, or cultural differences among nations? When different ethical standards exist and are potentially applicable, which ones should researchers adhere to? It is useful to distinguish between *substantive* and *procedural* ethical requirements in research. Substantive ethical requirements are those embodied in the fundamental principles of bioethics: respect for persons, beneficence, and justice. These substantive requirements are the ones that constitute ethical *standards* and should be applied universally. Examples are the requirement to obtain informed consent individually from each adult participant and the need to disclose complete information about the research maneuvers to be performed and the expected risks of those interventions. Procedural requirements,

on the other hand, may vary according to cultural and other differences in multinational research. Examples are the requirement that informed consent documents be signed and the composition of ethical review committees and their rules of procedure. Attention to the distinction between substantive and procedural ethical requirements shows that the same ethical standards can be applied across national borders, while permitting differences in specific procedures in order to respect cultural variations.

Even more problematic than confusion over the meaning of "ethical standards" is the use of the terms "ethical imperialism" and "ethical relativism" by the authors of the encyclopedia article. The charge of ethical imperialism is clearly a condemnation; it implies that the perpetrator is acting like a colonial power in imposing a governmental system or way of life on a conquered or subordinate state or population. "Ethical relativism," when used in this context, refers to a philosophical doctrine: the view that whatever a culture *believes* is ethically right *is*, therefore, ethically right for that culture. One application of ethical relativism holds that rules governing research practices may vary according to the cultural norms accepted in the country in which the research is carried out. Respect for diversity underlies this form of ethical relativism, which rejects the notion that a single set of ethical standards for research should prevail in our culturally diverse world. Ethical relativism has defenders and critics. However, no one is likely to come to the defense of "ethical imperialism," since the very concept of imperialism is one of denigration.

These same authors are clearer when they provide examples of the contrast they intend between universalists and pluralists. Again, addressing multinational research, they invoke the *Declaration of Helsinki*: "Pluralists call attention to the fact that the *Declaration of Helsinki* reflects a uniquely Western configuration of a number of key ethical points; in particular, the declaration has a largely Western view of the nature of the person and, as such, it does not adequately guide investigators to show respect for persons in non-Western settings" (Christakis & Levine, 1995, p. 1782). Much of the discussion that follows in the article rehearses the oft-repeated arguments about how different cultures have different concepts of what constitutes a person, with implications for informed consent to research. Not only the *Declaration of Helsinki* (World Medical Association, 2008), but every other document that addresses research with human beings requires that individuals provide their informed consent to be enrolled as research subjects except in cases where they lack capacity or have diminished autonomy. Cultural norms that might militate against this requirement exist in cultures in which adult women are not permitted to make health-care decisions or participate in research on their own. In some Islamic societies and other traditional groups, women's behavior is controlled by their husbands or other male guardians. If the so-called pluralists come to the defense of cultural mores such as this, they are not only in violation of international ethical standards for research, such as the *Declaration of Helsinki*, but they also transgress the most basic provisions of human rights treaties and covenants.

Human Rights

The most relevant human rights document with respect to cultural practices regarding women is the *Convention on the Elimination of all Forms of Discrimination Against Women* (United Nations, 1979). Article 2 of the Convention says:

States Parties condemn discrimination against women in all its forms, agree to pursue by all appropriate means and without delay a policy of eliminating discrimination against women and, to this end, undertake:... To establish legal protection of the rights of women on an equal basis with men and to ensure through competent national tribunals and other public institutions the effective protection of women against any act of discrimination; [and]... To take all appropriate measures, including legislation, to modify or abolish existing laws, regulations, customs and practices which constitute discrimination against women (United Nations, 1979).

Several articles in the UNESCO *Universal Declaration on Bioethics and Human Rights* (2005) are relevant, as well. Article 5, "Autonomy and individual responsibility," states: "The autonomy of persons to make decisions, while taking responsibility for those decisions and respecting the autonomy of others, is to be respected. For persons who are not capable of exercising autonomy, special measures are to be taken to protect their rights and interests." Article 6, on consent, is even more explicit in both the treatment and research contexts: "Any preventive, diagnostic and therapeutic medical intervention is only to be carried out with the prior, free and informed consent of the person concerned, based on adequate information"; and "Scientific research should only be carried out with the prior, free, express and informed consent of the person concerned"; and further: "In no case should a collective community agreement or the consent of a community leader or other authority substitute for an individual's informed consent." One can only assume that the defenders of pluralism would say the same things about the UNESCO Universal Declaration that they have said about the *Declaration of Helsinki* – that it reflects a uniquely Western view of what constitutes a person.

It does not require a deep philosophical inquiry to conclude that in the context of medical practice and research, a *person* is the human being whose body may be harmed or benefited by the proposed intervention. The individual whose body may be harmed or benefited is the *person*, and that person should be the only one to decide whether or not to accept the proposed intervention. Of course, nothing in so-called Western medical practice or research precludes a person from consulting with one or more family members about a course of treatment or whether to participate in research. Informed consent documents for research frequently encourage potential participants to do just that. Those cultures that locate the *person* as an interconnected unit within the family or the community are not conflating the individual human being with the larger group. When the individual dies, only that person is mourned and buried – not the whole family or the community. That some non-Western cultures locate the individual human being as more essentially connected to the family or community than is true of European or North American societies does not mean they hold a different concept of "the nature of the person,"

to quote the sloppy formulation of the authors cited above. This conceptual confusion runs through the bioethics literature on ethical and cultural relativism, and it is time that some clarity is introduced to dispel the conceptual errors.

Skepticism about the concept of human rights and its universal application typically invokes the facts of cultural diversity. An anthropologist writing about female genital cutting asked: "Are there universal human rights that can be applied without cultural imposition? How is it to be determined what constitutes a violation of these rights?" (Slack, 1988, p. 473). In support of her contention that these are difficult questions to answer, the anthropologist cited a "Statement on Human Rights" published 40 years earlier in a scholarly journal in her field: "...what is held to be a human right in one society may be regarded as anti-social by another people, or by the same people in a different period of their history" (American Anthropologist, 1947, p. 542). Cultural anthropologists face great difficulty in reconciling the existence of human rights with the dictum in their profession to avoid making value judgments about beliefs and practices of the groups they study. In the case of female genital cutting, the World Health Organization – the United Nations global public health agency – has determined that the practice is a human rights violation.

The biomedical research enterprise today is global in scope. Can a coherent argument be made that because different countries or cultures have varying customs and traditions, different ethical standards based on those customs and traditions can be justified? To argue that different ethical standards are permissible because research in any culture is acceptable so long as it follows the customs and norms of that culture is either to sanction violations of human rights in the countries where those violations occur or else to deny that there are any fundamental human rights. Either view embodies a form of ethical relativism that comes down in the end to the position that "whatever is, is right."

Violence, Culture, and Subordination of Women

If "respect for cultural diversity" requires an acceptance of deeply rooted traditions, it is important to see what some of these cultural traditions allow or even require. It is almost always the case that no culture is monolithic, and almost every country in today's world includes members of different religions, ethnic groups, and subpopulations. It should not come as a surprise that some of the people who are harmed the most and whose human rights are most frequently violated are women. As UN Women (the newly established United Nations organization devoted to women's concerns) points out: "Women throughout the world may be exposed to a wide range of 'harmful practices' across their life cycle, including prenatal sex selection and female infanticide, child marriage, dowry-related violence, female genital mutilation, so-called 'honour' crimes, maltreatment of widows, inciting women to commit suicide, dedication of young girls to temples, restrictions on a second daughter's right to marry, dietary restrictions for pregnant women, forced feeding and nutritional taboos, marriage to a deceased husband's brother, and witch hunts" (UN Women, 2010).

While it is true that many cultural practices are not located within medical practice or research, they may still be relevant to bioethical inquiry. To cite one situation, physicians and other health personnel from North America or Europe provide humanitarian assistance and conduct research in places where harmful traditional practices are prevalent. How should they react when they witness or are called upon to treat victims of these practices? Does respect for cultural diversity require that they remain silent in the face of evident violations of human rights? In the context of research, studies in population health today focus at least as much on social determinants of health as they do on the provision of health care by physicians and other health practitioners. Research on the social determinants of health has mainly centered on disparities in wealth and income both within countries and between industrialized and developing countries. That focus has tended to obscure health inequities between women and men, especially as those inequities exist in developing countries. These latter inequities typically stem from adherence to cultural traditions of one sort or another rather than from differences in wealth or income between women and men.

Although major causes of women's health inequalities compared to men are related to women's inability to access reproductive health services or the availability only of poor quality health services where they do exist, other inequalities are unrelated to health care services. While the circumstances that give rise to these latter inequalities may not be among the most statistically prevalent causes of women's mortality and morbidity, they are nevertheless symptomatic of the enduring widespread subjugation of and discrimination against women. Leading the list is sexual violence against women, due to the prevalence of this factor. Every country in the world experiences civilian rape in varying degrees. However, in South Africa, one in four men admitted to having committed rape, and many confessed to attacking more than one victim (Jewkes, Sikweyiya, Morrell, & Dunkle, 2010). This astounding statistic is hard to believe and leads to speculation that perhaps men in the study who reported this result were exaggerating their exploits. But if that is true, it would hardly be comforting. If men find it appropriate to boast about their violent behavior toward women, it indicates the value they place on domination and subjugation of women.

Physical violence against women occurs everywhere. A WHO study covering 15 countries reported that between 20 % and 64 % percent of women experienced violence by men. Some of the women admitted that before being interviewed for the study, they thought being beaten by their husband was "natural" (World Health Organization, 2005).

As is true of poor women in industrialized countries who suffer from intimate partner violence, abused women in developing countries remain with their husbands because they have no other source of income. But in most developing countries, police and other authorities do not intervene in domestic disputes, no shelters exist for battered women, and courts do not issue orders of protection. Another difference lies in the training of medical professionals in democratic countries committed to gender equality. Where intimate partner violence is openly criticized and condemned, medical associations make recognition of such episodes

part of the training of physicians. Where husbands may beat their wives with impunity, physicians look the other way. Would European or North American physicians working in such places fail to respect cultural diversity if they questioned women patients whom they suspected had been beaten?

Culturally sanctioned violence is an undeniable source of harm to women in many parts of the world (Niaz, 2003). It is beyond doubt that some customs and traditions are not only harmful to women, but violate their human rights as well as existing laws. Consider the following examples. In India, the dowry system continues to give rise to bride burning by husbands or members of the husband's family if the bride's family provides too little dowry money. India passed the Dowry Prohibition Act back in 1961, making dowry a punishable offense. Yet, the practice has continued five decades later despite the law. When such cases are reported to the authorities, the husband or his family claims that the stove exploded and that is why the woman was burned. Corrupt officials and loopholes in the law have mostly favored offenders (Vindhya, 2000). This is a clear example of an existing law that is not enforced.

A different custom that remains surprisingly frequent in some cultures is honor killings. Women are killed by male family members for reasons including their refusal to enter into an arranged marriage, seeking a divorce – even from an abusive husband and allegedly committing adultery (the allegation is made but is typically not followed by an evidence-based inquiry). Perhaps, most egregious is the practice of family members killing a woman after she has been the victim of a sexual assault. The cultural value of maintaining honor and avoiding shame to the family extends to situations in which a female member of the family has engaged in sex outside of marriage, even if the sexual act was coerced.

The United Nations Commission on Human Rights reports that honor killings have occurred in Bangladesh, Great Britain, Brazil, Ecuador, Egypt, India, Israel, Italy, Jordan, Pakistan, Morocco, Sweden, Turkey, and Uganda (Mayell, 2010). In the developed countries, the killings take place in immigrant communities. India has seen a rise in the past several years of honor killings of young people who seek to marry outside their caste (Yardley, 2010). Such killings have included men as well as women, since both members of the couple are viewed as transgressors. Although many people in India claim to have abandoned the caste system, and the government has required that the legislature include members from the "lower" castes, adherence to traditional attitudes and practices remains, mostly in the northern states of the country. An uncle of a slain couple justified the killing, saying: "What is wrong in it? Murder is wrong, but this is socially the best thing that has been done." Five sets of couples were killed in 1 week in India in June 2010 (Yardley, 2010). Here again, the situation reveals the strength of the cultural value of family honor. Parents feel they have to act against their own children – most often daughters – to save the family's reputation. A spate of honor killings in 2010 resulted in the Indian government convening a cabinet-level meeting to discuss imposing a harsher punishment than now exists. It remains an open question whether this could be a successful deterrent, especially in a country that has failed to enforce its laws against dowry.

Still another practice harmful to women is early marriage. In traditional societies where marriages are arranged by families, the age at which girls are married can be as low as 13 or even younger. Being a child or even a young teen is a condition of vulnerability because of physical and emotional immaturity and limited worldly experience. Furthermore, children and teens are not granted decision-making autonomy in most societies, especially in traditional cultures. In almost all such cases, they cannot refuse to enter the marital arrangement. More often than not, in family-arranged marriages, the young girl is wed to an older man, who will exercise power and authority over her decisions and actions.

Being thrust into marriage at a young age places adolescents at physical risk. When girls have reached puberty but their bodies are not fully mature, pregnancy and childbirth can be hazardous. A frequent consequence of pregnancy in very young women is obstructed labor, an actual physical harm. In resource-poor settings and most rural areas where performing a cesarean section is not possible, the result is sometimes the death of the woman; more often, the woman survives but with an obstetrical fistula – an opening between the vagina and the bladder, which results in constant leaking of urine. The women become foul-smelling, are ejected from their marriage by their husbands, and even their own families will not take them back. Unless medical repair of the fistula is available and a woman has access to it, her condition will continue to render her an outcast for her lifetime. According to the World Health Organization, "It is estimated that more than two million young women live with untreated obstetric fistula in Asia and sub-Saharan Africa. Obstetric fistula is preventable; it can largely be avoided by delaying the age of first pregnancy, the cessation of harmful traditional practices, and timely access to obstetric care" (World Health Organization, 2011a). Although some medical practitioners in countries where obstetrical fistula exists are capable of making repairs, many more women remain untreated. Since obstetrical fistula is virtually unknown in industrialized countries, physicians from those parts of the world lack the knowledge and skills to provide medical assistance.

Early marriage, along with the cultural tradition of arranged marriages, violates human rights related to reproductive health. According to the World Health Organization, men and women have the right "to be informed of and to have access to safe, effective, affordable and acceptable methods of fertility regulation of their choice, and the right of access to appropriate health care services that will enable women to go safely through pregnancy and childbirth and provide couples with the best chance of having a healthy infant" (World Health Organization, 2011b). This reproductive right has its basis in several articles of the United Nations Women's Convention (United Nations, 1979). All countries that have signed and ratified the women's convention are therefore obligated to abide by its human rights precepts. Those countries include many in which forced early marriage continues to place adolescent girls at risk of obstructed labor, obstetrical fistula, and even death. The relevant article in the UNESCO Universal Declaration is Article 8: respect for human vulnerability and personal integrity. That article states: "In applying and advancing scientific knowledge, medical practice and associated technologies, human vulnerability should be taken into account. Individuals and groups of special

vulnerability should be protected and the personal integrity of such individuals respected." Although the article refers explicitly to scientific knowledge and medical practice, it also can apply more broadly to those contexts in which obligations of public health are the responsibilities of governments.

Son preference, still very common in China and India, is based on customs and traditions in these countries and persists despite economic development and modernization in other aspects of society. The preference for male children has harmful physical consequences, as well as social consequences for girls and for women who do not bear sons. In poor families, girls may be malnourished as boys are fed first, and girls may be denied medical care as well as education, resulting in fewer opportunities open to them in the future. The single most important cause of the excess mortality rate among females in these Asian countries is thought to be systematic neglect of the health and nutrition needs of girls and women, especially among girls from birth to 4 years of age (Cohen, 2000, p. 1369). The imbalance in the sex ratio in India is attributable to female infanticide, better food and health care for boys, maternal death at childbirth, as well as prenatal sex determination and the abortion of female fetuses in the past 20 years. Selective abortion of female fetuses is believed to result in about half a million "missing" female births each year (Jha et al., 2006). Despite the passage of laws in India that prohibit prenatal sex determination, both the value and the practice of son preference have shown no sign of abating.

The cultural traditions and practices just described are clear violations of the UNESCO Universal Declaration's Article 11: non-discrimination and non-stigmatization. The Article says: "No individual or group should be discriminated against or stigmatized on any grounds, in violation of human dignity, human rights and fundamental freedoms." It would belabor the point to specify the details of the discrimination, stigmatization, violations of human dignity, human rights, and fundamental freedoms embedded in these cultural traditions and practices. Improving public health interventions alone can do nothing to prevent the types of violence against women stemming from custom, culture, and tradition. All governments that have ratified the International Covenant on Civil and Political Rights have an obligation to respect, protect, and fulfill the human rights of the many women in their countries who are killed, maimed, raped, disfigured, or rendered disabled. Injustice in women's health inequalities can be remedied only by gaining control of the social factors that are causally responsible. It can be done, but it requires courage and political will in those countries in which women suffer the greatest health inequalities.

Globalization and Transformations of Values

Cultures are not static. Although harmful traditional practices remain prominent in some societies, in others, they have begun to change or even been altogether eliminated. Numerous examples exist in which harmful traditional practices are condemned by members of societies in which they are practiced. For example,

a transformation has been occurring in Senegal, in which a movement against the practice of female genital mutilation (FGM) has been gaining ground. Not only have individual women – older as well as from the younger generation – abandoned the practice for their daughters, but also, some religious figures have begun spreading the word that FGM is not a religious requirement in Islam (Dugger, 2011). Why the practice of FGM has begun to be abandoned in Senegal but not in Somalia or Sudan, among other places, requires further study.

Governments are accountable for some harmful traditional practices by failing either to enact laws or to enforce existing ones. As noted earlier, India is a case in point with regard to violence against women in the form of bride burning and dowry deaths. One example where the rule of law to honor killings is applied is Kurdistan. The prime minister of the Kurdistan Regional Government (KRG) in Iraq took the initiative in a campaign to eliminate the practice. One step was to establish a Commission on Violence Against Women in 2007. The initiative included calls for open debate, reforms in the law, education and training, and greater support. In this situation, as in many others, the first steps were taken by women's nongovernmental organizations (NGOs), which start their campaigns by raising awareness. Kurdistan saw a rise in honor killings in the past two decades. How much real progress has been made, however, is open to question. In response to a query about why some perpetrators of honor killings received only short prison sentences in spite of an amended law in 2002, a women's rights activist replied: "Reform takes time. The judicial systems, even in progressive countries like the UK, are based on patriarchy and often fail to protect women. . .. Honour killing is deeply rooted in a traditional mentality and requires changes to the law, strict implementation of the law and awareness-raising programmes for the judiciary and the police, and for the public through the education and cultural systems, as well as the media" (KRG.org, 2008). It is hard to say whether good news about reform of the laws here, as elsewhere, will give rise to even better news that these laws will be successfully implemented and will yield judicial reform. The more difficult challenge is to change the cultural views of a public that adheres to traditional norms and beliefs.

As noted above, a preference for sons remains strong in India and China, with serious health consequences for female infants and children. However, what has occurred in South Korea signals that change is possible. After decades of widening increase in the sex ratio in South Korea, a country with the same basic cultural and historical traditions as those of China and India, a reversal has now occurred. A report issued in 2007 by the World Bank Development Research Group (Chung & Das Gupta, 2007) documents these changes in South Korea and suggests implications for China and India as well regarding the still robust preference for sons and imbalanced sex ratio in those countries. Unlike China and India, a reversal began in the mid-1990s, with the sex ratio beginning to approximate that of European and North American countries. The authors of the World Bank report argue that this reversal came about as a result of changes at the societal level rather than the individual level. The explanation is that ideational change occurred, based on alterations in the economic and social conditions in the country.

Conclusion

The role that social determinants play in the health of individuals, as well as that of economically disadvantaged groups, women, and children, is undeniable. When poor health of such individuals and groups is a consequence of low economic status, governments have a clear obligation to seek ways of changing social and economic factors to improve the health of the public. When the social determinants of poor health, deliberate injury, and death are cultural factors, governments are often reluctant to act for fear of offending traditional religions or cultures. However, since governments play the predominant role in respecting, protecting, and fulfilling the human rights of all people who reside in their countries, the state above all has a responsibility to act. Respect for cultural diversity, whether within a multicultural society or across national borders, must give way when cultural practices violate the human rights of any segment of the population.

Solidarity and Cooperation

12

Volnei Garrafa

Introduction

The terms "solidarity" and "cooperation" seem to have a certain closeness and complementariness, so much so that they appear together in Article 13 of UNESCO's Universal Declaration on Bioethics and Human Rights: "Solidarity among human beings and international cooperation towards that end are to be encouraged" (UNESCO, 2005). However, in practice, these two expressions receive a variety of interpretations, which makes it necessary to undertake a more detailed analysis on them, and especially on the concept of solidarity, in order to achieve better comprehension of their real meanings and the possible repercussions from applying them. As well as being the main constituents of this article, these two expressions are present in several other articles of the Declaration, either directly or indirectly crossing through them.

From the outset, in the first item of the Prologue of the Declaration, cooperation between human beings is recognized as a "moral expression of ethics itself," which is also unfailingly a form of solidarity, as will be seen further on. International cooperation in bioethics, in turn, is justified in Article 15, which deals specifically with research on human beings, through the commitment to take into consideration the "specific needs of developing countries, indigenous communities and vulnerable populations." While solidarity appears in Article 13 as the moral value of legitimation for international cooperation practices, Article 15 establishes examples for putting into effect the sharing of benefits from investigations developed within the field of science.

The theme of cooperation and solidarity is also indirectly referred to in Article 21, under the title "Transnational Practices," in which the Declaration holds states, public and private institutions, and the professionals involved in transnational research responsible for fulfillment of the specific needs of host countries and addressing the problems that affect overall health around the world. In turn, Article

24 indicates specific obligations of cooperation and solidarity between the states that promoted the Declaration, namely: (a) to promote dissemination of scientific information and stimulate free circulation of knowledge, (b) to stimulate cultural and scientific cooperation established through bilateral and multilateral agreements that aim to strengthen the research capacity of developing countries, and (c) to promote solidarity between states, individuals, families, groups, and communities, especially those that have become vulnerable through any individual, social, or environmental condition, and individuals with more limited resources.

However, there is no doubt that there are very many situations and examples, in which actions of solidarity are seen to be actions of goodwill, based solely on compassion or even just on a pious intention of replacing the state in which, at the same time as proving some help to improve people's lives, they also contribute toward maintaining deep social differences.

This chapter has the purpose of serving as support for countries, organizations, institutions, or groups of people who intend to develop some kind of reflection or study relating to the duo of solidarity and cooperation, conducted critically and constructively toward diminishing the acute socioeconomic disparities that are evident in today's world.

Origin and Brief History of Solidarity

In analyzing the origin of the word "solidarity," two terms derived from Latin are found: *solidum* (totality, security, or total) and *solidus* (solid, massive, or entire). Among other interpretations relating to solidarity that have been recorded, the following can be cited, which may serve as a matter for discussion in the present study: a state or condition of two or more people who equally share the responsibilities for an action, company, or business, and are answerable all for one and one for all; a mutual tie or bond between two or more things among which one depends on the others; a commitment in which people are each placed under an obligation by the others and each of them has an obligation toward all of them; a group condition resulting from communion of attitudes and sentiments such that a solid group unit capable of resisting external forces, and even becoming more resolute when faced with opposition from outside, is constituted (Weiszflog, 2004); mutual dependence between people; a feeling that leads people to mutually assist each other; a mutual relationship between dependent things; and a commitment through which people put obligations on each other (Ferreira, 1999).

All these expressions of solidarity are thus presented through mutual actions that take place solely among people who are within the same environment and have shared interests, in a kind of "social corporatism" in which all those involved have a relationship of interdependence. These interpretations probably derive from the words of Aristotle, *apud* Avelino (2005), who placed the foundations of solidarity (although he would have used other terms at that time) in a position that is

antagonistic to individualism. In this, a position of solidarity refers to the assemblage that makes group life better, while individualism is a position in which individuals place esteem on themselves, while regarding society with different eyes:

> Domestic societies and individuals are not more than integral parts of the *polis*: all subordinated to the whole body, all with distinct powers and functions and all rendered useless when disjointed, like hands and feet, which once separated from the body, only maintain their names and appearance, but without reality, as if made of stone. The same occurs with the members of the *polis*: none of them can be enough on their own. A person who does not need other men or cannot become settled with them is either a god or a brute. Thus, natural inclination leads men to this kind of society (Avelino, 2005, p. 228).

Within this context, no matter how much humans seek autonomy and respect for diversity, there would always be a need to form part of the universe known as society, albeit fragmented into family, work, nation, and so on, in which one component depends on another for protection, survival, and preservation of the species. Living in this society envisaged by Aristotle therefore signifies respecting others and accepting that the group is stronger than the individual. This makes it necessary to have rules for living together so that a satisfactory balance can be achieved, because without such rules, collective life would not exist.

With a variety of focuses, solidarity has been receiving attention and reports of different nature since ancient times (Hudson, 1999). In Egypt, there were moral codes based on social justice, through which individuals were stimulated to help others without demanding anything in return. The process was named "voluntary work." One example that makes it easier to comprehend this type of activity is that individuals who owned boats were expected to transport poor people to the other side of the river if they needed this. From the earliest times onward, there have also been reports of members of families who became responsible for caring for a sick, orphaned, widowed, handicapped, or elderly member of the family, in situations in which such individuals were found for some reason to be alone and/or destitute. Although this specific example could be described with other words or expressions, it is common to find such situations correlated with solidarity in the literature, as will be seen further on.

It is well known that with the historical development of cities over time and the resultant rural exodus, individuals started to become separated from their families and needed to become closer to each other living collectively in large megacities, helping each other with the aim of making it possible to better live together within society and thereby avoid isolation. A new form of living together socially termed "social assistance" thus gradually emerged. The Christian churches in particular helped poor, sick, and destitute individuals through support funds maintained by means of donations made by their members. These people also helped others by means of donations and voluntary work or service; philanthropic hospitals (named *santa casa* in Portuguese, i.e., "holy house") were created and maintained through donations for the sake of commiseration and charity, terms that are usually confounded with solidarity. Continuing today, voluntary service is interpreted as a non-remunerated activity provided by an individual to a public entity of any nature,

or to a private not-for-profit institution, which has civic, cultural, educational, scientific, recreational, or social assistance aims, including mutuality (Brasil, 1998).

In 1893, Durkheim (1967) analyzed society following the process of urbanization and industrialization, and expressed uneasiness regarding the transformation of individuals into autonomous and individualistic beings. He thus questioned how, within this context, so-called social cohesion could be maintained. He took this society to be a model in which norms ensuring interactions between individuals would be incorporated, thereby making it easier for people to live together, in an attempt to minimize social risks such that people would not suppress others or deny others' rights of citizenship, cultural diversity would be respected, and collective solidarity would be motivated. This response came through differentiation with other factors (economic, cultural, juridical, scientific, religious, and so on), from which the division of labor made individuals become interdependent, thereby further solidifying social cohesion through creation of social ties.

Through this analysis, Durkheim differentiated two types of solidarity. The first, mechanical solidarity, comes from traditional society that provides similar lifestyles for people (physical, social, and cultural) and thus provides the motive for people to unite toward the objective of maintaining equality and preserving and perpetuating the group. The second, organic solidarity, is based on modern society, which has become increasingly differentiated and interdependent because of the division of labor, thus requiring greater interrelation and cooperation between individuals, and causing the collective conscience to be placed above the individual conscience. However, Durkheim stated in his work that organic solidarity may be responsible for problems and pathological conditions consequent to the division of labor, when there is no coordination and fairness in labor relations does not prevail, which may even lead to revolt and breakage of the social ties that had previously been constructed.

However, in today's reality, even though relationships within society have developed basically along the lines of reflection indicated so far, and have a certain historical interface with the concept of solidarity, this is not the type of solidarity that occurs and that is of interest in the present study. On the contrary, the solidarity expressed in UNESCO's Bioethics Declaration requires a different view (bilateral and, at the same time, horizontal) between individuals, groups, or sectors that are in different historical and social situations, in which some of them become capacitated to support others in a disinterested manner, without concern regarding any material return or any of other nature. When this solidarity occurs between different countries, in which a stronger and better organized country supports another one without interest other than providing real help in the light of a situation of temporary or continuing weakness, this is a state of true, real cooperation. Nevertheless, unfortunately, reports have constantly been made both in ancient and in modern history, in which humanitarian actions undertaken in solidarity by certain nations have only given rise to different forms of exploitation and derived advantage over the long term, thereby further weakening these people in need whom such nations had supposedly been willing to "aid."

Expressions Confounded with Solidarity

There are several terms that are often confounded with solidarity, which makes it pertinent to comprehend them adequately in order to avoid misinterpretation and confusion. In the following, a brief conceptual and critical presentation is made on some of these – charity, compassion, fraternity, and philanthropy – to make it easier for readers to differentiate them from each other, and especially from solidarity.

Charity

Charity originates from the Latin word *caritas*, which means love toward one's neighbors. Charity is generally regarded within society as a noble, honorable, and welcoming virtue that strengthens the group's actions of solidarity. With the passage of time, this word gradually acquired a certain religious connotation, in the strict sense of material aid for other people who are in greater need. The Catholic Church and its followers base the practice of charity on the idea of brotherly love, with provision of immediate assistance to the poor and needy, and concerned only with serving one's fellow men without interest in material recompense (Kisnerman, 1983). According to the Catholic Church's Decree on Missionary Activity (Vaticano, 1966), published in 1966 as a result of the Second Vatican Council, charity should be understood as an act of love for one's neighbors. The document said that the presence of Christians in human groupings is heartened by the charity through which God loves us, and through which He wishes that we should also love each other. And therefore affirm just as God loves us with freely bestowed love, so too the faithful, though their charity, will be sought by men, and will love them with the same zeal with which God came to seek the faithful.

Charity, according to Christianity, is not limited to alms, but encompasses all the relationships with one's fellows, whether these are hierarchically lower than the person making the act, or equal, or even higher. Through charity, Christianity guides its followers to be lenient, and forbids humiliation of those who have suffered misfortune, contrary to what often happens in the real world.

However, many people with religious concerns end up doing charitable acts that primarily have the function of "relieving the weight of their own consciences," i.e., acting generously only with the aim of trying to make amends for a bad act committed in the past and imagining that through this compensatory act done during their lifetimes, they will achieve "divine forgiveness and eternal salvation." Bruckner (1996) goes further in his criticism in affirming that:

> The ontological scandal of charity (and of philanthropy) is the inequality between the donor and the beneficiary, who through incapacity to save himself by himself, can only receive and thank, without responding. Loving this person solely for this reason signifies placing on him not the nobleness of our souls but, rather, our desire for power. (Bruckner, p. 261)

Nevertheless, the concept of charity is central to the social behavior of pious people who follow Kardecist spiritism, summarized in the word "generosity,"

which represents constant growth or evolution of the being in seeking to live well, without becoming worn down through feelings of egoism, unhappiness, and hate (Kardek, 2009). In this context, generosity becomes the result from the charity-giver's spiritual maturation, thereby acquiring a meaning of love that is not inert and does not have imposed rules, but which acquires a connotation of experience, acceptance, and comprehension. In other words, this is an act of psychological balance and comprehension of the external world from inside each person. For Spiritists, charity does not have a label, i.e., it is universal (Gomes, 2012).

Charity is also sometimes confounded with "social work," which is not necessarily linked to religious meaning, but to reparation of social injustice that is generally perpetrated within the collective environment and which unfailingly has a sociopolitical basis.

However, there are authors like Nietzsche who have demolished the notion of charity arguing that the ethics of charity, and also of compassion, is no more than a strategy for power that, in promising aid and assistance, concomitantly multiplies the mechanisms of coercion and submission. According to Nietzsche (1981), people who make donations are thinking much more about themselves than about the people that they want to help.

Compassion

The word compassion comes from the Latin *compassio*, which means comprehension of the emotional state of the other person or desire to alleviate the other person's distress. Having compassion does not mean feeling pity for the other person; it means putting oneself at someone's side without judgment, with the intention of only providing relief from the situation of turbulence and distress that the other person is experiencing. In relation to compassion, Hume (2009) stated in his work "Treatise of human nature" that no one is so insensitive that they cannot perceive another person's happiness or unhappiness. Nevertheless, there are some who think that while solidarity makes it plain that some wrong exists, since it signifies that accepting or tolerating actions that belittle or violate people cannot be accepted, compassion runs the risk of trivializing such actions, since it is restricted only to stimulating tolerance up to the limit of what is intolerable (Caponi, 2000). This critical vision of the compassion is very diffuse in some countries of Latin America, especially in Brazil.

In turn, the Dalai Lama has conceptualized compassion as concern for other people, because all human beings have the right to be happy. In his view, the sentiment of compassion is attained by starting from this understanding, thus differing from the feeling of pity, which becomes a barrier against understanding the full essence of other people. Compassion cannot just be among relatives and fields, since this would be affection, rather than compassion. True compassion occurs in situations of thinking about voluntarily alleviating other people's problems. Pious people also say that practicing compassion brings benefits to physical and spiritual health, and that people who are compassionate are healthier than egoists. According to the Dalai Lama, while modern societies show concern for

educating their children in order to attain better intellectual and economic development, they forget to guide their children toward compassionate gestures and leave this responsibility to religions, which all encourage compassion (Dalai-Lama, 1989).

However, pious but immoral personal attitudes can be seen in day-to-day life, in responses to the force of compassion that produce highly illegitimate, albeit legalized coercion over individuals who have suffered misfortune. In this author's view, such attitudes legitimize situations such as internment and isolation of mentally ill individuals in places that should never be called "recovery centers," or removal of homeless people living on the streets, against their will, to put them in public shelters that are often dangerous and unhealthy (Caponi, 2000). This author's full reflections are, however, based on the hypothesis that there is no absolute rupture between care policies based on compassion ethics and those proposed by classical utilitarianism but, rather, continuity, solidarity, and complementariness. According to this idea, it is essential to rethink care policies from a perspective differing both from diffuse utilitarianism and from pious compassion that sustains and perpetuates charity.

In a general manner, compassion is very close to commiseration, another word that is sometimes confounded with solidarity. However, because of the etymological roots of the word commiseration, it always has a direct relationship with misery, which is not necessarily seen in relation to compassion, which may also be directed toward people who have other types of needs, such as physical or emotional needs.

Fraternity

The word fraternity derives from the Latin *fraternitas* (brotherhood, set of brothers, or affection between brothers). In speaking of fraternity, there is an idea of close family, consanguineous ties of kinship with the same genealogy. Over time, this expression has become used to describe relationships with people who have the same convictions, which could be religious, political, economic, or cultural, or even with people performing similar functions. Aristotle stated that citizens join together in groups, to create political communities, an act that he named "political friendship." In "Nicomachean Ethics," he stated that friendship is above justice, since "where friendship exists, justice is present." In his view, equity between people is only consolidated when mutual trust exists, i.e., when one depends on the other, which makes them equal (Aristóteles, 2009).

During the French Revolution, the three-word motto "Liberty, Equality, Fraternity" was adopted. These words are rooted in masonry and Christianity, and they seek a brotherly dimension, i.e., community life without prejudice, under similar conditions, thereby establishing a kind of citizenship between men who would be able to live in a free and dignified manner (Silva, 2006).

In the preamble of the Universal Declaration of Human Rights of 1948, it is recognized that all men are members of the same family: the human family (ONU, 1948). This context of the human family forms the focus for the present reflection on the word fraternity. It is configured from the observed relationship between

people and the dissemination of the concept of equality among human beings, taking all of them to have equal rights. Thus, this interpretation diverges from the concept proposed by Aristotle. According to Aquino (2008):

> Fraternity originates a kind of behavior: a relationship that should be established with other human beings, with action "by some in relation to others", which also implies a dimension of reciprocity. In this sense, fraternity is more than another principle standing alongside liberty and equality: it seems to be the one that is capable of making these principles effective (p. 137).

Based on these ideas, fraternity starts from the principle that all human beings have certain duties in relation to their fellow men, thus maintaining a sentiment of reciprocity, i.e., having a sense of solidarity between themselves. In this manner, fraternity would be the basis for attaining equality and liberty among men, thus closing the triangle proposed by the French revolutionaries.

However, differing from the above interpretations, another author stated that fraternity can only be attained through dialogue, which they considered to be a tool for bringing men together, because in this way, some are forced to hear the others (Simões, 2008).

Philanthropy

The word philanthropy has a Greek origin and means "love of humanity." In its broader meaning, it is understood in the context of present-day society as humanitarian organizations of communities, companies, public bodies, private bodies, or even groups of individuals with the objective of helping other people through donations, without profit-making aims. Organizations with the specific purpose of helping human beings and other living beings to improve their lives are taken to be philanthropic institutions.

Philanthropy is action related to support or donations of financial or other nature, for the benefit of institutions or individuals who develop activities that are considered meritorious and that produce social stimulus. It is understood by many people to be a private form of support for development of activities that might generate transformations in the structure of life of needy groups, without resorting to state intervention. In many countries, philanthropy is now considered to be a significant source of funding, particularly for humanitarian and cultural issues. In some countries, philanthropic actions even take on an important role in supporting scientific research and funding universities and academic institutions.

Although philanthropic activities have also been criticized, in the same way as charity and compassion, its original meaning has a historical sense, through reports of individuals and/or families with a solid financial situation who decide to make part of their resources available for supporting entities or causes that have the capacity to improve the social structure or people's lives, to stimulate the arts and improve libraries, or even to support scientific research in universities, among other initiatives.

Undertaking philanthropy has also been pointed out to be a stimulus for development of so-called social responsibility, developed especially by private

companies. This concept has been gaining greater visibility over recent years. The difference between philanthropy itself and social responsibility is that the former is always motivated by humanitarian reasons and by social actions, even if managed by private companies, while although the latter is also a social action, it is defined from a sporadic or regular active commitment by the company that already forms part of a formal predefined strategic plan.

In all forms of philanthropy, just like the other expressions analyzed in this chapter, there cannot be any confusion with solidarity, since philanthropy does not in practice express the dialectical and dynamic actions that are proposed for the indispensable interchanges, bilaterality, or exchanges of benefits and experiences. Gomberg (2002) went so far as to state that philanthropic actions promote a type of "political silence," which conceals the institutional causes of poverty (especially capitalism) from attention. Such actions would therefore divert the responsibility of institutions that promote them, away from seeking radical alternatives for solving such problems. Other authors have stated that philanthropy "undermines true political change" (Singer, 2010, p. 34).

Contemporary Forms of Solidarity

The theoretical interpretations relating to solidarity vary between different authors. In any event, it is especially important to differentiate it from the terms dealt with above: charity, compassion, fraternity, and philanthropy. Some authors have been more accommodating, interpreting solidarity as an action that is always viscerally linked to virtuous action or even to the so-called ethics of virtues. However, others have taken a sharper view and have deepened the concept by politicizing it and providing it with a more concrete shape, with transformational visibility. The Latin American Dictionary of Bioethics states that solidarity is a social value created from the conscience of a community of interests and is therefore humanitarian in itself. Consequently, it incorporates the moral need to help, assist, and support other people, as part of personal responsibility (Vergés, 2008). In the following, three contemporary ways of interpreting solidarity are explored, thereby seeking to provide a broader and more dialectical view of this topic: voluntary-action solidarity, critical solidarity, and radical solidarity.

Voluntary-Action Solidarity

Voluntary-action solidarity is the most traditional skewing of the concept of solidarity. This type of action in solidarity, for which Brazilian critics have coined the term *assistencialismo*, meaning "handout culture," is based on the volunteer or donor and not on the other person who, in addition to requiring help, needs a way out from his current situation. The antithesis of a handout culture is a commitment toward the other person (Garrafa, 1987).

The handout-culture model therefore consists of action that only maintains the status quo, without contributing toward effective transformational changes in its beneficiaries' lives. Instead of being subjects of an assistance process, such individuals merely become passive spectators of the act of solidarity. This action may even resolve a transitory situation of inequity or necessity, but it does not effectively take these individuals out of the situation that was encountered previously. Instead, it just contributes toward maintaining and perpetuating the situation, because there is no new and transformative element that might alter the structure of the existing relationship between the provider of the help and the person helped (Garrafa, 1989).

Thus, voluntary-action solidarity may have several connotations. One of the best known can be seen through the passive unilateral handout-culture voluntary actions that are provided, for example, by so-called service clubs. These are often organized in peripheral countries based on background reference points that are somewhat unclear, and are established from the so-called central countries, through associations like the Lions' Club or others of similar origin. These groups, generally with the support from private companies interested in a certain line of business, promote special days of help for groups of needy people, usually with certain pathological conditions, thereby seeking visibility and public recognition. This naturally results in dividends of political and other natures for the donor group and its partners.

In this context, it is common to create false expectations in the communities that receive such assistance, given that the activities proposed are implemented episodically, starting from some urgent specific need detected, or even from artificially defined calendars, which are governed by temporality and discontinuity of scheduling (Garrafa, 1987, 1989).

The word "assistencialismo" (handout culture) is erroneously considered to be a synonym for assistance, thus causing aversion among people who are in favor of true and genuine assistance of disinterested nature and free from secondary intentions. Assistance as a social and rights policy is of great importance when carried out responsibly on an emergency basis in situations of natural catastrophe, for example. However, this differs from handout cultures implemented by some populist governments as a way of manipulating their citizens, thereby impeding individuals' emancipation and leading them to depend on public actions for their subsistence (Marx & Engels, 1977).

Some countries have already defined in their constitutional charters that the state has a commitment to provide certain basic rights for its citizens, such as: housing, healthcare, special programs to promote access to school for children and family subsistence programs, among others. On the one hand, these programs may bring real benefits over the medium and long terms, when there is a commitment toward true social change. On the other hand, depending on how they are proposed and implemented, they may create a continual process of submission among the presumed beneficiaries. Handout cultures are no more than concealed paternalism with the aim of achieving social control, implemented in such a way as to maintain a false equilibrium between those who are vulnerable and the elite (Vieira, 1995).

As stated by Alayón (1995), violence and criminality are at best lessened through public and private handout cultures.

In Durkheim's view (1967), societies are only constructed through social cohesion, i.e., from socialization of individuals, through acceptance of norms and social values, and also through creation of awareness that individual actions should reflect actions that have been defined collectively. For this reason, Durkheim defined solidarity as a consensus among the individuals of a given group, thereby defining the existence of two types of solidarity (mechanical and organic), as presented earlier. Today, organic solidarity predominates, at least in most developed countries, since its pillars are based on social reference points that are determined from norms established through rights.

Critical Solidarity

Critical solidarity is taken to be the agent's capacity for discernment, i.e., possession of criteria that are capable of helping him to discriminate among the social and political dimensions that are inseparably present in relationships of solidarity. In this manner, solidarity does not become exhausted as a typical relationship of civil society. On the contrary, it has a political element that has the state as its reference point (Selli & Garrafa, 2011). A capacity to understand this expanded dimension, relating to citizenship and the possibility of intervening actively in defining public policies, also characterizes this critical dimension of solidarity (Bobbio, Pasquino, & Mateutti, 1995).

The identity of critical solidarity is centered on commitment toward the subject, in actions and interventions that fundamentally favor respect for moral pluralism and construction of inclusive social transformations. It is centered on a dialectical commitment toward the subject, in organic actions and interventions that aim to provide the other person with attainment of autonomy, free from paternalism or any other form of handout culture and authoritarianism. Its historical expression is given concrete shape through wielding individual liberty, as set forth in the Universal Declaration of Human Rights. This epistemological proposition also proposes to replace the word autonomy with the words "empowerment" and "liberation," terms that give greater strength to the idea of subjects who are free from any bindings and able to make their own decisions (Nascimento & Garrafa, 2011). In this sense, facing up to social problems presumes that a linkage exists between government disposition and social initiatives, between institutional resources and community dynamics, between technical competence and human skills. The proposition that solidarity can be a value-guiding association in voluntary practices comprises this aggregating factor of civil, political, and social forces (Selli & Garrafa, 2005).

Studies on critical solidarity are based on people's democratic participation in society, without concern for their own benefit or simply for "helping one's fellow men," but with a concern for providing other people with concrete tools to enable them to effectively find a way out from their situation of vulnerability. This would

place such people, in traditional interpretations of solidarity, as the passive and unilateral receptors and beneficiaries of an act of solidarity (Selli & Garrafa, 2005). In other words, critical solidarity suggests voluntary actions that are related mainly to public policies directed toward social organization, with the aim of minimizing social inequalities. The participative process between society and state is constructed cooperatively and may help in scientific and educational training within society, thereby enabling discovery and strengthening of moral and ethical values. This type of cooperation promotes social and economic development, since it stimulates the participants' self-confidence, brings dignity to the people involved, and mobilizes social groups. In essence, in the concept of critical solidarity, the word donation is replaced by cooperation.

The solidarity that is sought to comprehend and propose as the central motivation for voluntary action by organizations within civil society is a value linked to the way in which modern society is itself organized. This manner of organization, by definition, does not derive from political or religious doctrines, which by their nature are partial. However, this is a central value and it serves as a motivator for voluntary associations that have the main objective of providing real benefits for people in need (Selli & Garrafa, 2006). In its ethical dimension, it designates a value that is immanent to the human condition, which results from the fact that human beings live in communities and therefore in interdependent relationships.

Interest in the proposal of critical solidarity as a value for guiding organic voluntary service is motivated by social realities and other reference points based on personal experiences, among other justifications. Use of the adjective "critical" refers to the agent's capacity to note the social dimensions (which are also political dimensions) of the relationship of solidarity. The capacity to understand this dimension, which relates to citizenship and the possibility of intervening actively in defining public policies, also characterizes this critical dimension. In turn, the correlated concept at the foundations of critical solidarity, named organic voluntary action, was constructed as an analogy to the concept of organic intellectual action that was developed by Gramsci (1979). It can be understood as active participation of individuals who develop voluntary activity to construct the conditions needs for effective democratization of the state, in all its dimensions.

Exercising of the proposed critical solidarity, when done democratically and bilaterally, promotes citizenship. It thus differs from handout-culture solidarity, which suffocates autonomy, thereby causing dependence and low self-esteem. On the contrary, its interventions minimize social inequalities through organic voluntary action, with politicized and committed participation by society, with expansion of the individual and collective rights that have already been achieved.

Radical Solidarity

To develop the topic of radical solidarity, studies by the Australian philosopher Peter Singer will be used as reference points. Although this author has frequently used the word "radical," he has not mentioned the expression "solidarity," but has

preferred to use expressions such as "humanitarian help," "donation," or even "charity." Nonetheless, the concept of solidarity formulated in the present chapter, in the critical sense of exercising responsible solidarity, is consonant with some of Singer's ideas. His reflections led the subject studied here preferentially toward the field of personal and individual obligations, dealing rigorously and directly with the topic and placing responsibility for the poverty that exists around the world on all people who have an excess of resources for maintaining their lives, yet are unwilling to help those in need (Singer, 1998).

According to Singer, "helping is not, as is commonly thought, a worthy act of charity to perform, but from which it would not be wrong to be exempted; it is something that should be done by everyone" (Singer, 1998, pp. 241–2). In his view, the wealth of the inhabitants of rich countries makes it possible for them to have income that they could relinquish without this depriving them of the basic necessities of life, and which could be used to diminish absolute poverty in the world: "The amount that we feel obliged to give is going to depend on what we judge to be of moral importance, in comparison with the poverty that we could avoid: expensive clothes and dinners, a second car, vacations abroad. . ." (Singer, 1998, p. 243).

Singer also advocates that because a person is close to us, this does not imply that one should have greater concern for this person than for other people who, by chance, are distant from our eyes and lives. In his view, moral duty should be impartial. In this sense, he advocated that if one agrees with the principles of universality, equality, or impartiality, one cannot disparage someone just because he is not close by. He considered that one of the problems of modern societies is that one always feels less guilty if one is able to point to other people who, in the same situation, would also do nothing. In such contexts, one is influenced by what people around them do and expect that one does.

In reading Singer's work, it can be seen that his affirmations do not relate to the public responsibility of governments, but particularly to each individual who has the economic possibility of doing something to improve the situation of poverty that is observed around the world, yet does not do anything. In such cases, despite the vertical individuality of the proposal, its radicalism is stunning: "If letting someone die is not intrinsically different from killing someone, the impression that remains is that we are all murderers" (Singer, 1998, p. 234). In his view, the lack of an identifiable victim does not have moral importance, even though this may have an important role in explaining our attitudes: "The idea that we are directly responsible for those who we kill, but not for those who we fail to help, results from a very questionable notion of responsibility. . ." (Singer, 1998, p. 239).

Singer stated that if it is within one's reach to stop something bad happening, without having to sacrifice anything of comparable moral importance in so doing, then this is what one should do. Within a context that he called "indisputable principles," he went as far as to propose a "radical" version (as he himself termed it), to impede bad events. This radical version requires that people should stop bad things from happening, unless something of comparable moral significance is being sacrificed in so doing, thereby reducing such action to a level that he called "marginal usefulness" (Singer, 2002). He confessed that he ended up

advocating a more moderate version that recommended preventing bad events unless one had to sacrifice something that was morally significant in so doing, but he finished by stating: "... the radical version seems to me to be more correct" (Singer, 2002, p. 150). He also emphasized that although the idea of charity is thought of as part of people's individual responses, a broader idea of justice seems to be more appropriate, because charity does not simply encompass what individuals do in relation to each other, but also includes the structures and general relationships that exist, or ought to exist, in a society.

Cooperation

The word cooperation comes from the Latin *co* + *operare*, which can be interpreted as "working together" or "working in collaboration." This last word also originates from Latin, *co* + *labore*, and likewise refers to the notion of shared work (Ferreira, 1999).

In different fields of knowledge, understanding of the significance of cooperation presupposes that there are benefits or mutual advantages in interactions between countries, institutions, organizations, groups, or individuals. In studying environmental ethics, for example, cooperation consists of a harmonic, interspecific, and facultative relationship in which individuals obtain mutual benefits without any vital dependence between them. This differs from mutualism, in which a harmonic interspecific relationship is generally mandatory (Instituto Brasileiro De Geografia E Estatística [IBGE], 2004).

As a political and economic doctrine, cooperation was initially formulated within so-called cooperative socialism (Singer, 2001), a proposal that emerged in the nineteenth century as an alternative to the polarization that was then seen between capitalism and communism. One of the authors of this doctrine, John Stuart Mill, advocated that social problems relating to inequality and exploitation of labor would be overcome through cooperative processes involving free associations between workers and other workers and between workers and capitalists. Mill believed that gradual replacement of capitalist companies with cooperatives would result in fairer distribution of the wealth produced by society (Mill, 2001). In diplomatic practice, cooperation signifies political dialogue and assistance between friendly countries, both bilaterally and multilaterally, in opposition to the idea of confrontation (Ceolin, 2011).

Whether as a moral principle of ethics, a natural biological fact, a concept of political science, or even a diplomatic practice, cooperation did not appear as a concept within the discourse of bioethics until the publication of the UNESCO Declaration in 2005. Likewise, there are no indications of specific references to the term "cooperation" in any of the editions of the Encyclopedia of Bioethics (Reich, 1978, 1995; Post, 2004), in the single edition of the Latin American Dictionary of Bioethics (Tealdi, 2008), or even in a systematic search of the literature that was conducted using the BIREME platform of PAHO/WHO in 2008 (Santana & Garrafa, 2012). It can therefore be argued that the Universal Declaration on

Bioethics and Human Rights was the first document that officially incorporated the principle of cooperation in the lexicon of bioethics, with the topic of solidarity alongside it.

Discussing the Relationship Between Solidarity and Cooperation

Until the last decades of the twentieth century, solidarity was still regarded as a markedly individual or group activity, and only rarely as a public initiative by governments. However, the establishment of its relationship with the topic of cooperation came to provide the possibility of new, expanded, and bilateral focuses, with greater social commitment. These focuses came to serve as a conceptual tool with the capacity to contribute toward diminishing the acute inequalities that are observed among individuals and peoples in the contemporary world.

Today, solidarity is a theme that is increasingly born in mind by international organizations, the media, and even governments. Many countries have already gone so far as to include it in their constitutional charters, taking the view that it is a social principle relating to construction of freer and fairer societies. Some constitutional texts, like the Brazilian one, suggest that social change can come through participation with a sense of solidarity, with the state working in conjunction with society toward the objective of creating new values aimed at citizens themselves and citizenship (Rocha, 2011).

In this context, a social group acting through a sense of solidarity comes to be seen as part of a sociopolitical-cultural organization that respects and stimulates equality and social justice. The relationship between state and society comes to be configured with equal values, thus characterizing a relationship of effective cooperation, and no longer one of inequality. Decisions are constructed based on justice, thus creating greater social cohesion. This model may generate good results because it contributes toward diminishing the poverty, violence, and injustice rates, thereby creating greater credibility and security, as well as ensuring better quality of life. This is solidarity delineated from equal rights, with responsibilities that are also shared.

The construction of an ethics of solidarity may start from different motivations, with special emphasis in the present study on so-called critical solidarity, for preferentially public initiative and also individual and private initiatives that have the real intension of diminishing the differences and improving the quality of life among different social segments. In this case, for an appropriate interpretation to be made, it is essential to have a critical differential view between compassion and utilitarianism as distinct forms of social behavior that, at the same time, are complementary. These strengthen the struggle for emancipation of vulnerable classes through charitable or philanthropic actions, but they may equally determine domination by the most favored individuals with the same form of solidarity as the strategy (Caponi, 2000).

According to Freire (2002), exercising solidarity requires a minimum degree of authenticity among its agents, which necessarily includes attainment of democracy

and respect for plurality of ideas and cultures. This author took the view that, more than an isolated act or action, solidarity is an inalienable commitment by each individual, each human being, and states themselves toward people in greater need, with the aim that they should find a way out of their current situation of exclusion and marginality.

Conclusion

As can be seen from the above, there are clear differences between the three angles of solidarity presented here. While voluntary-action solidarity, through unilateral actions centered on promoters of assistance, does not have any continual commitment to the people who are assisted, radical solidarity represents an advance in the sense that real and concrete humanitarian aid is provided to individuals and communities that are in need. Nevertheless, although the latter attains evocation of the principle of justice, rather than individual assistance, it does not go so far as to provide needy and marginal individuals and groups with effective empowerment and liberation mechanisms for them to be able to make future decisions regarding their lives that are truly free and unpressured. Meanwhile, critical solidarity signifies more than a donation, act of help, or act of charity: It is an organic and collective planned act that is carried out starting from bilateral sociopolitical commitment among the players in the donation and reception process. Differing from the other two types of solidarity, it proposes actions to transform the status quo of the people who are on the more fragile side of the equation, which could contribute in a concrete manner toward improving these people's lives and help them to effectively become free from the bonds that keep them marginalized from the worldwide development of society.

Taking the present reflection into the field of the solidarity and cooperation agreements that are often signed between different countries, for these to be considered ethical, it is essential for the activities to consist of real cooperative practices, and not exploitative practices, in which more powerful nations end up being the beneficiaries. This reasoning may be perfectly applicable to research on human beings, in which it is common to conduct multicenter clinical studies on new medications in peripheral nations in which the disease studied has minimal epidemiological impact, such that the study unilaterally serves the interests of the sponsoring company, which has its headquarters in a developed nation.

Article 15 of the Universal Declaration on Bioethics and Human Rights may be highlighted as a normative reference point for conducting cooperative studies, with a sense of solidarity, that result in fair sharing of the benefits, thereby avoiding exploitation. This article postulates that the benefits derived from research should be shared with the entire international community, and especially with poorer countries, even if the development of the assets has taken place only in richer countries. To consolidate an international system of cooperative nonexploitative research done with a sense of solidarity, it has been suggested that an international funding source destined for supporting and applying research and public policies in

poorer countries and communities should be created (Garrafa, Solbakk, Vidal, & Lorenzo, 2010): in other words, a proposal drawn up on a truly horizontal basis, involving solidarity and cooperation.

Social Responsibility and Health

13

Stefano Semplici

Introduction

The expression "social responsibility" has become widespread only recently, boosted first and foremost by the growing success of the so-called "business ethics" and as one of its flagships. In a very broad sense, the term is meant to imply a change or at least an enlargement of perspective in the strategies and aims of companies and institutions. This enlargement entails two main aspects. First, the concept of the obligation that economic actors should be responsible for is reshaped and integrated. Of course, they are supposed to comply with all the requirements and constraints that are legally binding and establish the rules for any profit-oriented strategy. They are at the same time, however, called upon to meet other and more encompassing duties stemming from a commitment to improve the welfare of the societies they are rooted in and prevent them from suffering the consequences of negative "externalities" resulting from their activity, such as pollution, urban crowding, etc. Many of these "social" responsibilities correspond to *moral* rather than legal obligations, because of the lack of justiciability (people who do not comply with them can be blamed, but not put on trial). Yet, it could never be said that the values involved are something "private" or less important. Thus, we come to the second essential feature. W. Evan and E. Freeman published in 1988 the article entitled *A Stakeholder Theory of the Modern Corporation*: *Kantian Capitalism*. This was the starting point of the new stakeholder approach that looks at the management's responsibility toward not only the property and the perfectly legitimate interest in profit for the stockholders but also the many individuals and organizations that are in many ways targeted by and/or involved in the activity of a corporation or an institution. In other words, the idea of social responsibility widens the scope of the subjects that ought to be involved in the process of decision-making (not only the stockholders and managers) as well as that of the aims (not only profit). It also goes without saying that the idea of social responsibility applies to both private and public sectors, inasmuch as the latter

shares the same scope of activities and produces analogous effects. What is at stake, following a comprehensive and telling definition by R.E. Freeman, is a new need "for theories and strategies for dealing with particular groups and issues, and the need for processes for integration across issues and groups." This new need was triggered by "shifts in traditional relationships with external groups such as suppliers, customers, owners and employees, as well as the emergence and renewed importance of government, foreign competition, environmentalists, consumer advocates, special interests groups, media and others" (Freeman 2010, p. 27).

Responsibility Toward Stakeholders, Responsibility for Health

Social responsibility implies what has been defined as a holistic perspective. An illustrative example is provided by ISO 26000 that has been worked out by the International Standard Organization with the purpose of giving guidance on this new approach. Seven "core subjects" are identified: organizational governance, human rights, labor practices, the environment, fair operating practices, consumer issues, and community involvement and development. It is neither about the idea of immediately widening the reach of legal constraints nor about setting a strict management system standard. On the website of the organization, it is explicitly asserted that ISO 26000 aims solely at boosting "voluntary guidance" and is therefore "not intended or appropriate for certification purposes or regulatory or contractual use." The goal is rather to boost a *shared* commitment, and the addressees are therefore "organizations of all types, in both public and private sectors, in developed and developing countries, as well as in economies in transition." A wide range of goals to pursue and initiatives and tools to improve is underpinned, because of the fact that the decisions, procedures, and deeds of whoever acts within the market of producing and trading commodities and services impinge upon the life of individuals and societies in manifold ways. Sometimes even at the global level, as it unquestionably happens in the case of multinational companies or other institutions whose decisions affect millions of people at one time.

One of the main topics that social responsibility refers to is undoubtedly the protection and promotion of health. In ISO 26000 itself, health is explicitly mentioned as one of the main issues directly related to the core subjects of labor practices, consumer issues, and community involvement and development, but its relevance for the others as well is also quite obvious. This observation corresponds with the awareness that everyone's health depends very much on the conditions in which people are born, live, work, and age. The World Health Organization established in 2005 a Commission on Social Determinants of Health that produced its final report in 2008. The importance of various social, economic, and environmental factors was stressed, together with individual genetic characteristics and behaviors. This is where the concrete opportunity to enjoy "the highest attainable standard of health" that had already been recognized in 1946 in the WHO Constitution as "one of the fundamental rights of every human being without distinction of race, religion, political belief, economic, or social condition" is at stake.

This is where we have to acknowledge the existence of huge, growing inequalities. It is vis-à-vis these inequalities that WHO calls on us to share an ambitious commitment to "closing the gap in a generation" and complying with three overarching recommendations: (a) improve daily living conditions; (b) tackle the inequitable distribution of power, money, and resources; (c) measure and understand the problem and assess the impact of action (WHO 2008, p. 10).

Article 14 of the *Universal Declaration on Bioethics and Human Rights*, adopted by UNESCO in 2005, offers a telling summary both of the social determinants that need addressing and of the "sharing" of responsibility that is required to perform the task effectively. A list of the main targets of this commitment is clearly bulleted in the second paragraph: access to quality health care, access to adequate nutrition and water, improvement of living conditions and the environment, elimination of marginalization and exclusion on any grounds, reduction of poverty and illiteracy. The premise is the traditional underlining of the enjoyment of the highest attainable standard of health as one of the fundamental rights of every human being. It is in the concise wording of the first paragraph, however, that the two pillars of the conceptual link between social responsibility and health are unmistakably stated: "The promotion of health and social development for their people is a central purpose of governments that all sectors of society share." On the one hand, this statement implies the awareness that no actual promotion of health for people is possible without making development of the whole society a pivotal issue. On the other hand, "all sectors" of the latter are called upon to share this responsibility that is unquestionably and in the first place a responsibility of governments, but can in no way be considered a responsibility *just* of governments, lest the goal of promoting health be missed.

The standard of health and health care that is actually available not only for the wealthiest part of the population, as indicated by the figure of life expectancy at birth, is one of the variables that build up the Human Development Index, together with educational attainments and income. The *Annual Report*, an independent publication commissioned by the United Nations Development Programme, offers strong evidence of the impossibility of leading the ranking concerning health while remaining at the bottom of the list as regards the other factors. If we look at the 2011 report, we are still confronted with the brutal fact of a world where the people of some countries enjoy a life expectancy beyond 80 years and many others cannot expect to live beyond 50. The interdependence of the variables is hardly deniable. Only 3 among the 20 countries with the lowest general index are able to offer their citizens a life expectancy of more than 60 years, whereas only 3 among the first 20 countries ranked fall below 80 years. The "inequality adjusted" Index underlines the figures of this deep fault even *within* and not just *between* the different States. Poor people living in less developed countries appear to "share" a doubly burdened life expectancy: greater inequalities in terms of the opportunity to have access to quality health care and greater inequalities in terms of education and income. Better health and a longer life rely on greater and comprehensive human development.

Other benchmarks of development are easy to add. *Health in all policies*, the *Adelaide Statement* adopted in 2010 by the participants at a meeting promoted by the government of South Australia together with WHO, points to many examples of

joined-up government action to promote health across all sectors of government and at the same time engage the health sector in contributing to others: economy and employment; security and justice; education and early life; agriculture and food; infrastructure, planning, and transport; environment and sustainability; housing and community services; land and culture. Once again, it is easy to see how tightly interwoven all these issues are, although education (culture) and income (wealth) directly or indirectly affect most of them and contribute in the most important way to shaping general living and working conditions and thereby the conditions of health. In any case, this is the point explicitly made in Article 14 of the UNESCO *Declaration* of 2005; this unavoidable political challenge turns into a matter of *social* responsibility as soon as we acknowledge that efficiency and effectiveness in the action of governments is not enough, even if supported by a great amount of resources.

Looking at economic actors, whose social responsibility is first underscored, it goes without saying that their role is and will remain crucial, starting with the manufacturing sector. Industry – together with health care, research, and education – is one of the "special areas of focus" identified in the Report of the International Bioethics Committee of UNESCO on Article 14, published in 2010: "Work conditions can be harmful for people. Pollution can damage the environment and jeopardize the well-being of the population. Marketing strategies are often used to boost unhealthy behavior related to food and lifestyles. Research itself may serve profit-oriented activities more than interests and needs of individuals and society" (UNESCO 2010, § 64). Two specific aspects need addressing, however, in comparison with the more general commitment to include goals other than profit, constraints other than law, and respondents other than stockholders in the definition of a corporation's strategy. Health, that is, a fundamental human right, is what we are talking about. Therefore, at least in this context, it is difficult to make a sharp distinction between the term "stakeholder" and the term "citizen." We are all legitimate stakeholders with regard to the responsibility for health. The other specification refers to the concept and context of sharing. The idea of a threshold of sharing, for example, in the sense of the protection of intellectual property, is in principle consistent with an effective, sincere commitment to social responsibility. Can this be the case with the right to enjoy the benefits of scientific development when life itself is at stake? Not surprisingly, in the *Universal Declaration on Bioethics and Human Rights*, the article devoted to the principle of benefit sharing comes immediately after that on social responsibility, repeating almost verbatim the same list of core subjects.

Why Social Responsibility Is Required

There may be many and very different reasons for a profit-oriented company to improve its reputation as a socially responsible one. A producer of detergent could devolve part of the price paid by purchasers to promoting a campaign for the vaccination of newborns in a developing country: not under the table, but as

the pivotal message of an advertising strategy. A bank could donate part of the commission paid by its account holders to a charity which helps to provide health care, medicines, and housing for the poorest in times of financial crisis: a poster in full view at the entrance of every single branch could illustrate all the details of the operation. An industry could pledge to establish a zero-emission plant just outside a town: it is perfectly aware of the steady determination of the inhabitants to protest against the project otherwise. The list can easily be extended. The unavoidable conclusion seems to be that in many circumstances, the protection and promotion of health are the means to obtain something else (approval, trust, readiness to buy, and loyalty in doing that) much more than a goal as such. All the same, even the most instrumental application of the practices stemming from the principle of social responsibility – in terms of "cause-related" marketing or "strategic philanthropy" – is not a justification to dismiss the principle. On the contrary, it underlines its importance and the potential pervasiveness of its effects.

The commitment to improve everyone's standard of health seems to come up against the traditional *weakness argument* applied to all *social* rights. When we look, for example, at the *International Covenant on Economic, Social, and Cultural Rights* that was adopted by the General Assembly of the United Nations on December 16, 1966, in one and the same resolution with the *Covenant on Civil and Political Rights*, the insurmountable difference between the "civil and political rights" on the one hand and the "economic, social, and cultural rights" on the other is conspicuous. Article 1 reads the same in both documents: it is about the right of every individual and people to self-determination and to freely dispose of their natural wealth and resources, according to the principle of mutual benefit and international law. The instruments suggested in Article 2 to respect, protect, and fulfill the rights that the two covenants referred to are quite divergent, however. In the case of civil and political rights, each State is called upon to adopt "such laws or other measures" as may be necessary to ensure "that any person whose rights or freedoms as herein recognized are violated shall have an effective remedy" and that such a remedy is to be guaranteed by "competent judicial, administrative, or legislative authorities." In the case of economic, social, and cultural rights – including, according to the standard definition, the right to "the enjoyment of the highest attainable standard of physical and mental health" (Art. 12) – we cannot always and immediately rely on the force of public coercion. Each State party's commitment can but be to take steps "to the maximum of its available resources." Legislative measures are just part of a broader strategy, aiming "to achieving progressively the full realization of the rights." Needless to say, a progressive achievement can be easily criticized as simply a way to put off the concrete realization of a less unjust society and cannot, in any case, be as effective as a judicial remedy. This is exactly the point at which social responsibility steps in, however, before, beyond, around the law.

A social right is a *positive* right. The word means that it is not enough in order to realize the right, to refrain from doing something, for example, from doing harm to someone else, and to have laws that ensure that every violation is prosecuted and punished. It is necessary to do something actively, as it happens every time that

a new treatment against a disease is made available or a new school is built. Resources are therefore needed, especially when the right to enjoy such benefits as those related to health care and education is recognized independently of any differences in economic condition. Knowledge is also a limit: by enlarging it, we steadily widen the scope of what it is actually possible to achieve. In other words, a positive right is necessarily confronted with the issue of *attainability* and is to be considered, at least to some extent, as a context-related right. There is no reason, however, to understand this observation solely in terms of the difference between what is legally mandatory and what remains an imperfect duty (see below), not only because of the observation that legislative measures may contribute decisively to the progressive realization of social rights. In acknowledging this difference, by the same token, we are looking at the unavoidable and possibly fruitful permeability of the two spheres, besides addressing the specific complexity of the obligation entailed in every social right. Social responsibility boosts this dynamic, thus helping to move forward the limit of what remains – so far and, it is to be hoped, only so far – unattainable.

This statement can be explained by the well-known distinction proposed by Immanuel Kant in the *Metaphysics of Morals*. Kant distinguished, among the duties of virtue, the duty to respect from the duty to love. The former implies an obligation to refrain from intruding on one another's freedom as well as from doing harm to someone else and from treating other human beings as mere instruments. In this sense, the duty to respect sets a distance between individuals, each of them remaining free to pursue their own goals. The duty to love, on the other hand, brings the same individuals closer to one another, looks for the good of one's neighbor, and implies a commitment to doing something actively. It is the duty to enhance everyone's capabilities, as well as to help them in their needs in order to promote their happiness. Only the duty to respect is a strict one, however, and is therefore likely to become a legal duty, secured by the coercive force of the law, and we can consequently call it a *perfect* duty. The duty to love remains a wide, and thus *imperfect*, duty, in relation to both its content and its context. By assuming something as a purpose of social responsibility, we can say that we avoid the temptation to reduce the content to just a matter of private deeds and the context to that described merely in terms of a two-subject game: the State and its law on the one side and the individuals on the other. Kant himself paves the way for such an interpretation by assuming an ethical community besides the juridical one.

A very telling example of this overlap of perspectives has been offered by Amartya Sen in his book *The Idea of Justice*. Taking his cue from a very old distinction in Sanskrit literature, he describes a difference between two roots of this idea: we can speak of justice either in terms of *niti*, that is, in terms of "organizational property and behavioral correctness" related to "the institutions or rules we happen to have," or in terms of *nyaya* that "stands for a comprehensive concept of realized justice." In the real world – this is the very heart of the argument – we cannot be satisfied with performing the task of a sort of perfectionistic, transcendental institutionalism. In the first place, because there may be circumstances where the decision to abide strictly by the law could imply the risk of intolerable

consequences, owing to the overlap of very complex chains of determinants and effects: it is the Weberian call for an ethics of responsibility against the inflexible application of the principle that justice always has to be done, even though the world might perish. Second – and this is for us the most relevant clarification – because good institutions are insufficient in any case to achieve many meaningful human goals and especially to fully realize a social human right. This is also the answer to the "institutionalization critique," that relies on the belief that "real rights must involve an exact correspondence with precisely formulated correlate duties" and – simply because of the inevitable lack of strict juridification – social rights would therefore necessarily fall prey to rhetorical declamations. Reliance on institutions for the realization of "welfare rights" is out of the question. Yet, it is precisely the ethical significance of these rights that widens the scope: "helping to generate greater awareness of the seriousness of the problem" and pressing for changes in "social attitudes" may be as important as serious commitment to producing changes in institutions (Sen 2010, pp. 20–21 and 382–383).

Social responsibility for health works along the edge that separates and at the same time links *niti* and *nyaya*. The commitment to making it possible for every human being to enjoy the highest attainable standard of health is to be conceived as a universal obligation independent of any specific condition and capacity. What is at stake is the first and most important of all *basic* goods. Therefore, albeit we have to acknowledge that there are limits that no institutional framework can overcome, we cannot be satisfied with reshaping just our good will. John Rawls, who possibly produced the most influential example of a political-institutional and yet flexible theory of justice, has no doubt that basic health care for all citizens is one of the principles that all liberal conceptions ought to share, if the goal is to offer to all citizens the essential means to make effective use of their freedom. In meeting the challenge, however, social attitudes are equally important. To assess whether or not the right to X is realized, Thomas Pogge suggests to evaluate not only the fundamental legal texts and the functioning of the judicial system but also any social institution whose action (or inaction) impinges upon the enjoyment of that right. In the end, the pervasiveness of social attitudes may result in a change of the legal system itself. What happens, for example, when a patient dies, in a country where a free public health-care system is not provided, from a disease that required an expensive medical treatment that she/he could not afford? The lack of a strict legal obligation does not justify dismissing the right or even the *duty* to indignation: "a valid complaint against our social institution can be presented by all those whose physical integrity is not sufficiently secure, not by all those who happen to suffer an assault." Good and inclusive nonlegal practices, "such as a culture of solidarity among friends, relatives, neighbors, compatriots," may anticipate or implement what is legally binding (Pogge 2008, p. 53), in the sense of a social responsibility before, beyond, around the law. Even in the case of philanthropy for the sake of profit, it is only because certain behaviors and procedures are appreciated by the public that they may happen to be included in a self-interested strategy.

The difference between legal and social responsibility requires and at the same time strengthens the bonding role of *solidarity*. We find here three main

conceptions, once we accept the principle that it is the standard of health of every human being that ought to be maximized. Solidarity has often been interpreted as a group concept, based on a shared experience of life and events, on a shared narrative identity. In this case, the bond and the obligation we feel and recognize as stronger are toward only some people with the exclusion of others and the coherent conclusion had already been drawn by Adam Smith in the sixth part of his *Theory of Moral Sentiments*: "the state or sovereignty in which we have been born and educated, and under the protection of which we continue to live, is, in ordinary cases, the greatest society upon whose happiness or misery, our good or bad conduct can have much influence," whereas the administration of the great system of the universe and the care for universal happiness are to be considered as "the business of God and not of man" (Smith 1759, VI.II 27 and VI.II.49). According to a second conception, respectful of the comprehensive framework set by the modern tradition of universal human rights and proposed by Michael Sandel in the ninth chapter of his book *Justice*, published in 2009, we should distinguish three different categories of responsibility: (a) natural duties that we owe to human beings as such; (b) voluntary obligations, such as contracts; (c) obligations of solidarity that involve responsibilities we owe to those with whom we share and *feel* we share a particular history or identity. Justice, in the case of a fundamental right such as that to health care, should not be predicated on solidarity, inasmuch as the latter produces asymmetries of commitment: equality is supposed to be the benchmark. It is easy to see, however, that these asymmetries are the standard not only of most practices but also of most normative statements at the international level: the States' first and primary obligation is to their own people, and, although the principle of some kind of responsibility for other, poorer, countries is by now widely accepted, this duty is a very loose one and the States in the end retain their freedom to choose what to do. This is why, for example, the *Report of the International Bioethics Committee on social responsibility and health*, published in 2010, looks at an idea of solidarity that "requires more than that, thus involving an idea of justice." We can call it cosmopolitan solidarity that boosts the awareness of a "shared life or destiny" not only within each person's group but also in the direction of a "profound and active acceptance of our interconnectedness," that turns social responsibility into "a principle that defines and celebrates our common humanity." In this perspective, it is solidarity itself that underpins the conviction that the limits of attainability, the constraints of a progressive and only progressive realization, and the lack of legally binding instruments in the transnational context do not allow us to dismiss the principle that "the maximum of equality remains the ultimate goal when everyone's right to life is at stake" (UNESCO 2010, §§ 41, 101 and 40).

Frameworks for Action

Governments are obviously the first addressees of a call for responsibility for health. They do indeed have at their disposal the most powerful means – taxation and legislation – to collect the resources that are needed and to set the rules

concerning both the access to health care and the protection of their people from the consequences of unhealthy or even hazardous living conditions. Most international documents now distinguish these two clusters of care/assistance and prevention/protection obligations. The *European Social Charter*, revised in 1996, provides – among others – an illustrative example. On the one hand, the States undertake to ensure that any person who is without adequate resources is granted adequate assistance and, in case of sickness, the care necessitated by his or her condition. On the other hand, the States undertake (a) to remove as far as possible the causes of ill-health, (b) to provide advisory and educational facilities for the promotion of health and the encouragement of individual responsibility in matters of health, (c) to prevent as far as possible epidemic, endemic, or other diseases, as well as accidents. The provision to ensure the "care necessitated" has unavoidably to face – as I have already underscored – not only the limits of attainability that applies to all human beings because of the limits of knowledge itself but also the limit of attainability that is the consequence of a lack of resources. Owing to the former, more and more appropriate and effective means to fight diseases are made available only progressively. Owing to the latter, what is readily available for some peoples or some individuals remains unaffordable for others. Nonetheless, it is up to the States to avoid new faults of inequality worsening the situation *within* the countries they are responsible for. This is why we still have to speak here of a responsibility that is, at least in the first place, *political* rather than social.

Of course, a determined and comprehensive action by governments and States is also decisive in addressing the broad social determinants of health, thus improving its standard together with the other figures of human development. Working conditions largely depend on legislation, as well as the control of production and trade of hazardous substances. Food and drugs safety is manifestly crucial for health, and in order to guarantee it, the regulation of a long chain of activities is required. The necessity of such a regulation has long since been accepted with regard to research on new medicines, especially when it involves human subjects, but there is increasing awareness that healthy food is as much a goal, starting with sustainable agricultural practices and ending with clear, exhaustive information for the consumer. Urban and infrastructure planning are also a competence that governments can never dismiss. Think of the impact of the lack of an adequate transport network and of devastating nonrenewable resources on daily life and the environment. Housing may be considered another private matter of public interest: enforceable laws are probably the best instrument to prevent people from building houses in dangerous places or not respecting the security standard required to withstand natural disasters like earthquakes. The whole span of the competences entrusted to public institutions is involved: regulation and standard setting, enforcement and coercion, financing. This, however, is a responsibility that must be shared with other public and private organizations and associations as well as individuals. The best-designed system of disease surveillance, for example, relies on people reporting disease even if they are afraid it could be a very contagious one. There are some thresholds respecting privacy that it may be inappropriate or difficult to cross: everyone should be fully informed about the huge risks of smoking,

and many States have now adopted legislation to prohibit it in every public space, but turning it into a crime still appears to be overzealous. Calling for social responsibility for health entails the commitment to be loyal to the law, at the same time increasing the effectiveness of the principles that cannot be realized only by means of existing law and efficiency in the action of governments and administrative machinery. In this perspective, some contexts of shared responsibility seem to be particularly worth focusing on.

Education and Lifestyle

Illiteracy, together with poverty, is a factor that undermines individuals' capacity to cope with the natural vulnerability to diseases that humankind is heir to, making it at the same time more difficult for them to protect themselves from the risks spread in their living and working environment. By establishing quality educational infrastructure and especially by encouraging scientific learning and education, governments may strongly contribute to improving the health of their people. Health literacy refers to the degree to which individuals are able to obtain, understand, and make use of at least basic information about what can directly or indirectly impinge upon their health. This may be essential if we are not to miss the symptoms of disease at a very early stage, thus missing the opportunity to treat it in the best possible way, as much as to detect the presence of risks, such as those related to hazardous chemicals, that are not immediately perceivable. Health literacy is also the irreplaceable premise of the capacity to make decisions according to the principle of free, informed consent. Indeed, the beneficial effects of higher levels of education go far beyond it. They help to enlarge the number of professionals and the application of the most advanced results of scientific research. They foster the awareness that the standard of health that people enjoy is not a matter of destiny, but of fundamental rights and corresponding obligations, thus boosting the will to claim those rights and to criticize lack of respect of those obligations. The overlap of poor educational systems, weak and often corrupt institutions, deep social inequalities, and poor health is not a chance circumstance.

At the same time, individuals cannot call themselves outside their own responsibility. It is up to them, once they have sound information about the likely causes of many diseases, like lung cancer or cardiovascular problems owed to binge eating, to steer their lifestyle accordingly: appropriate behaviors and commitment to sharing them are nowadays one of the most powerful means of prevention. This is all the more reason for not behaving in such a way that others could suffer harm: sexually transmissible diseases need to be coped with through full awareness of one's personal condition and of the means to check it, together with the decision not to conceal the risk to one's partner; the most severe laws are not sufficient to prevent people from dying and being killed in accidents, as long as too many drivers do not take their responsibility for other people's lives, as well as their own, seriously enough.

Media and Information

The media play a decisive role in knowledge dissemination. They have become one of the most important – for many people, the only – source of information. Therefore, professionals in this sector can help a lot to improve people's sensitivity to health-related issues, trigger serious debate about the most relevant challenges, and give to experts and scientific institutions a wider opportunity to explain to citizens the main outcomes of research that may have an impact upon their daily life or offer concrete hope against disease. This role is crucial when there are valid reasons to fear that an epidemic could break out or some other widespread threat against public health is to be thwarted. The media, however, can fall easy prey to an audience-oriented approach, which is analogous to the profit-oriented strategy of an entrepreneur who is therefore not considered socially responsible. This is the case when they run after scoops and sensationalism by all means, either announcing prematurely revolutionary findings that are not validated by the scientific community or, conversely, raising unjustified alarm that causes confusion and increases pressure upon the authorities to take expensive and perhaps unnecessary measures.

The transparency and reliability of information are the indispensable premise and guarantee for decision-making procedures that are contended with trade-offs more and more difficult to cope with. The costs of making available to the largest number of people what science has made possible are growing: health care needs resources, and resources are limited, even in the richest countries. We therefore need reasonable criteria for their *fair* allocation and priority setting, together with an open-minded willingness to revise and update decisions in the light of new elements of knowledge and discussion among stakeholders. This role of the media, besides the internet and all kinds of social networks, is even more important when civil society and political institutions face the challenge of developing laws on very controversial matters, as often happens in the context of health-related issues.

Professionals and Research

Health-related business is a legitimate economic activity. Notwithstanding, it deals with the very first of all human rights and is therefore exposed not just to the risk of a conflict of interests but to the risk of jeopardizing life itself. Focus on the care and well-being of patients is the crucial calling of all physicians according to their conduct codes, if not the law. It means therefore that medicine is to be considered as a very special kind of profession, where a practice is exerted whose possible commoditization should always be thought of as a means to improve protection of health, without predicating protection on the capacity to pay. This awareness affects many aspects of the activity of all professionals involved in the health-care sector: how they participate in decision-making procedures on priority setting, their relationships with profit-oriented bodies such as pharmaceutical industries and medical equipment firms, and the promotion of their own expertise, which cannot be subject to commercial advertising. No trade activity should in principle stimulate

wanton consumption of goods, but in the case of medicine, this limit ought to be seen as imperative: the target is the actual needs of people, without profiting from the insurmountable asymmetry of competence and in the most cost-effective way.

Research aiming at new treatments and drugs shares this responsibility. There are two main aspects to be considered here, and both are related to the observation that nowadays a substantial amount of applied research is carried out by the private sector. The first one is the possibility that scientific development is driven by the interest in potential financial reward more than potential social benefits. This is a fault of inequality that is not likely to be overcome by any legal instrument. The telling example is that of research on ailments, such as tropical diseases, that affect the poor much more than the rich and entail both high costs and small or even no profit and thus remain largely neglected. The second, crucial, issue is that of sharing of benefits and intellectual property, whose impact cannot be overestimated, especially at the global level. The *Doha Declaration on the TRIPS Agreement and Public Health* of 2001 explicitly acknowledged that "flexibility" is unavoidable, given "the gravity of the public health problems afflicting many developing and least-developed countries." Social responsibility draws on this flexibility and widens its reach and content, neither with the aim of simply dismissing the system of patents that retains in many circumstances its valuable function nor eluding the challenge of financing and rewarding research. Some promising initiatives are already being carried out: a number of charities and nongovernmental and international organizations are addressing specific health problems related to poverty and exacerbated by it. Of course, the results would be significantly improved if the governments of the wealthiest countries agreed to share this approach. At the same time, the agenda of priorities should be reshaped by involving all stakeholders who are relevant, besides empowering people to set it by themselves.

Global Market

The concept of social responsibility was first introduced to strengthen the accountability of economic actors. The premise is the impossibility of thinking of the economy as a monadic and thus exclusively self-oriented activity. Companies themselves – according to Joseph Stiglitz – are communities of people working together with a common purpose and "as they work together, they care about each other, the communities in which they work, and the broader community, the world, in which we all live." For sure, this concept has helped to develop a more careful awareness of the full consequences of what happens in the market. It has also brought about, in many countries, some change "in the mind-set of many corporations and of the individuals who work for them." As "in a world of ruthless competition incentives often work against even those with the best of intentions," however, corporate social responsibility is often compelled eventually to turn itself into a claim for legislation, lest complying with it would depend only on the payoff of good reputation against bad (possibly hidden) behavior. Stronger, legal regulations protect those who are really serious about higher standards "from those who

do not adhere to the same standards. Regulations will help prevent a race to the bottom" (Stiglitz 2006, pp. 198–199). This is not to dismiss the importance of corporate social responsibility but to underline its role as the cultural background of a complex society determined not to elude its obligations in terms of justice and fairness and, at the same time, fully aware of the constraints of efficiency and competition in a globalized market of workers, goods, and financial resources.

Therefore, it is no surprise that in the final report of the WHO Commission on Social Determinants of Health, the responsibilities of the private sector and those of governments largely overlap. The former is trusted, among others, to ensure fair employment and working conditions for men and women, reduce and eradicate child labor, and ensure compliance with health and safety standards. It is up to the governments to implement *regulatory* mechanisms to promote and enforce fair employment and decent work standards for all workers. The risk of a clash of obligations stemming from the duty to aim at the highest standard without accepting any compromise when the most fundamental human right is at stake against the constraints of a pitiless, iron-hearted competition is manifestly much higher when legislation makes the difference. This is why the global market is the arena where the tasks of social responsibility are at the same time the most important to proclaim and, very often, the most difficult to perform. Economic actors are called upon not to profit from double standard opportunities, that is, from the chance not to abide by the same rules in different contexts and with different people when a significant harm or risk to health is likely to result, first and foremost considering working conditions and the protection of the environment. The golden standard set by the most advanced legislations, the best practices, and the most demanding international codes and agreements, even if not legally binding, should be applied.

International Cooperation

The cosmopolitan version of the concept of solidarity, rooted in the experience of living in one and the same world, is presupposed by the principle of sharing the benefits of scientific development as expressed in Article 15 of the *Universal Declaration on Bioethics and Human Rights*, even though this assumption does not and cannot claim that all differences and inequalities can be tackled overnight. The range of the benefits we are looking at is indeed very broad: access to quality health care, provision of new diagnostic and therapeutic modalities, support for health services, access to scientific and technological knowledge, and capacity-building facilities for research purposes. Science, together with market and some cultural mainstreams, is a powerful determinant of globalization. The challenge of a *global* social responsibility for health, however, entails much more than the refusal to predicate the right to share the life-saving benefits of scientific research on participation in research itself, as I have already underscored.

To take seriously the universality of the principles of economic justice implies the willingness to improve the sharing of resources, standards of education,

and policies oriented to ameliorating the poorer statistics of social determinants of health. Sharing of resources does not refer exclusively to income. It entails, for example, the capacity to reverse the brain drain of highly skilled professionals from low-income countries to the richest ones. Sharing of education is made possible by establishing networks organized on the principle of open access and taking advantage of new technologies to connect people from all around the world, thus minimizing the costs of globalization of knowledge. Sharing of policies requires strong determination to support those international institutions whose mission is to assess and reshape the rules of the game that many people reject because all too often, they are set according to the one and only principle that might be right.

This is equally true when there are risks rather than benefits to share. Pollution is probably the most telling example of a potential harm to health that cannot be effectively tackled only by single States or groups of States, both because the one polluter who would still act as a free rider could gain decisive competitive advantage and because the consequences of pollution will inevitably spread worldwide. At the same time, we are today increasingly confronted with new responsibilities that arise in almost every area of medicine and life sciences and could determine a growing delocalization of dangerous practices. Genetics and bioengineering, nanotechnologies and neurosciences, may easily produce unprecedented situations of discrimination, special vulnerability, and multiple standards of respect and protection that cannot be addressed without an agreement on new rules and priorities at the international level, as well as the capacity to foster the feeling that we are all stakeholders in terms of the decisive challenges to the future of humankind.

Conclusion

The right to enjoy the highest attainable standard of health is a social right. Consequently, its realization relies not only on appropriate legislation but also on willingness to strengthen the pillars of education and civil society that contribute to ensure that this right be effectively acknowledged as something that is worth active effort and investment in terms of both individual and collective behaviors. Laws concerning social human rights can but be formulated in a program-type manner, even when they entail some binding obligation and/or prohibition. To let the program become reality, to the furthest extent of what is actually attainable, all individuals and sectors of society, together with governments, ought to do their best to improve the different factors that are requisite for the flourishing of human life: on the one hand, minimizing discrimination on any ground as well as the consequences of inequality of resources, environmental risks, and unhealthy personal behaviors, on the other hand, promoting concrete solidarity, sharing of knowledge, and capacity-building. The right to health is not just about the conditions of access to quality health care that obviously remains the cornerstone of political responsibility for health. It is about boosting awareness of the right and consequently the availability and affordability of the means to prevent diseases and suffering and to deal with them better.

The looser the legal coercion, the more important is the role of social responsibility, not as a weak substitute, but as a front-runner of the effort to dismiss every double standard of human dignity. Global bioethics is at the crossroads of many crucial issues stemming thereof. The idea of a worldwide-shared commitment to provide every human being with the best opportunity to live long and be free to pursue their goals gives perhaps the best unquestionable evidence of the solidity and reasons of the vocabulary of human rights.

Sharing of Benefits

14

Doris Schroeder

Introduction

Benefit sharing is a legal term used in the context of access to and utilization of biological resources. The term describes an exchange between those who grant access to a particular resource and those who provide compensation or rewards for its utilization. For instance, in 2000, a US-based biotech corporation (Diversa) signed an agreement with a South African research institute (CSIR) to obtain access to South African microorganisms. In return for such access, Diversa supports the CSIR's bioprospecting activities and pays royalties on any successfully developed products. The above exchange is typical for a benefit-sharing agreement as governed by the UN Convention on Biological Diversity (CBD, 1992).

On a broader understanding of benefit sharing, results from scientific research should be shared with society as a whole and not only with those who provide access to resources. This more aspirational meaning of benefit sharing is expressed, for instance, in the UNESCO's Universal Declaration on Bioethics and Human Rights (2005). The main governance instruments for benefit sharing are listed in Table 14.1. The Declaration of Helsinki, the Convention on Biological Diversity, and the UNESCO Universal Declaration on Bioethics and Human Rights will be discussed in more detail in this chapter.

This chapter examines both aspects of benefit sharing and aligns them with different conceptions of justice. The access and benefit-sharing requirements of the CBD – which covers plants, animals, microorganisms, and traditional knowledge – will be described as a justice-in-exchange mechanism. The same applies to the benefit-sharing provisions for human biological resources through post-study access to successfully tested medical interventions or alternative benefits. The distributive justice and human rights aspects of benefit sharing will be examined using the above mentioned UNESCO declaration. Four case studies are added to illustrate the challenges occurring in all areas of benefit sharing.

Three Benefit-Sharing Instruments

The Convention on Biological Diversity

In 1992, a UN conference of unprecedented size and scope was held in Rio de Janeiro. What became known as the "Earth Summit" provided a platform for discussing the ongoing destruction of global biodiversity. Almost 10,000 on-site journalists covered the summit, and its main output was the Convention on Biological Diversity (CBD). The CBD recognized that the conservation of biodiversity is a "common concern of humankind."

The legally binding convention has 193 Parties (the world minus the United States of America (USA) and Andorra). It has three major objectives:
The conservation of biological diversity
The sustainable use of its components and
The fair and equitable sharing of benefits from the use of genetic resources

The first objective relates to the common interest of humankind, namely, to deal with the serious loss of biodiversity and its potential implications for ecological functions as well as future technoscientific uses. The twentieth and twenty-first century witnessed the disappearance of species at 50–100 times the natural rate. The figure had risen to 100–1,000 times the natural rate in 2010 and may accelerate to 1,000 or 10,000 times by 2020. The second objective relates to user requirements for the long-term availability of resources, for instance, in scientific or commercial endeavors or to support human livelihoods. The third objective summarizes the demands made by developing countries since the 1970s, namely, to require users to share benefits with resource providers in order to avert exploitation. The Convention on Biological Diversity covers plants, animals, microorganisms, and related traditional knowledge.

To understand the established legal meaning of benefit sharing, it is important to consider why resource use can be exploitative (see Box 14.1 for a definition of exploitation).

Box 14.1: Exploitation
Exploitation is a failure to benefit others as some norm of fairness requires leading to wrongful gain on the one hand and undeserved loss on the other (Mayer, 2007). Three forms of exploitation can be distinguished:

In type 1 exploitation, exploiters fail to benefit other parties *at all* even though they ought to. For instance, public transport users who "dodge" fares are exploiters type 1 or free-riders.

In type 2 exploitation, exploiters do not benefit others *sufficiently*. In this case of exploitation, an exchange takes place, but it does not benefit both parties fairly. One party gains disproportionately, while the other loses out. For instance, a landlord might exploit a recent immigrant's ignorance of local rents and overcharge her.

In type 3 exploitation, exploiters do not benefit others *authentically*. Exploiters might give others what they want and at a fair price, but the exchange does not genuinely benefit them. For instance, the purchase of heroin might be what buyers want and it might be sold at a competitive market price, but they would nevertheless be harmed by the exchange when judged from a neutral standpoint.

Why should a European researcher who uses an African plant in product development be hampered by access and benefit-sharing requirements of a legally binding international convention? Why not assume that the resulting product, for instance, a new medical drug, will benefit humanity as a whole and leave scientists unencumbered by costly bureaucracy?

Indeed, prior to the adoption of the CBD, nonhuman biological resources and traditional knowledge were frequently regarded as the common heritage of humankind. Bioprospectors were able to take resources out of their natural habitat or make use of traditional knowledge to develop commercial products without sharing benefits with states or local communities. This approach was justified on the premise that the planet's biodiversity ought to be shared among humankind rather than being fenced in by individual states.

The idea of the common heritage of humankind entered the canon of international law in the 1970s and 1980s with the conclusion of two UN brokered international treaties: the Agreement Governing the Activities of States on the Moon and Other Celestial Bodies (1979) and the Convention on the Law of the Sea (1982). These treaties declared that the seabed, the ocean floor, its subsoil, as well as the surface and subsurface of the moon should not become the property of any state, organization, or individual. Instead, they were regarded as the common heritage of humankind. But what does the common heritage principle mean? There are two conflicting interpretations exemplified respectively in the initial text (1982) and subsequent revision (1994) of the Convention on the Law of the Sea. One interpretation is that the common human heritage must be used and enjoyed on terms that benefit all. The other is that the common heritage is available to be used and exploited at will on a first-come, first-served basis.

In preparatory negotiations for the CBD in the late 1980s, academics, activists, and politicians from around the world started to point out that the latter interpretation of the common heritage was predominant in cross-border research activities involving biodiversity. This was not surprising given the uneven playing field in science and innovation (see Diagram 14.1 on the technological divide and Table 14.2 mapping biodiversity against poverty).

As can be seen from Table 14.2, the burden of serious poverty and the availability of mega-biodiversity align in most cases, with only a few exceptions. Given in-country lack of resources for investment in science and technology, it is clear that most scientists who access mega-diversity are from the north. If this is

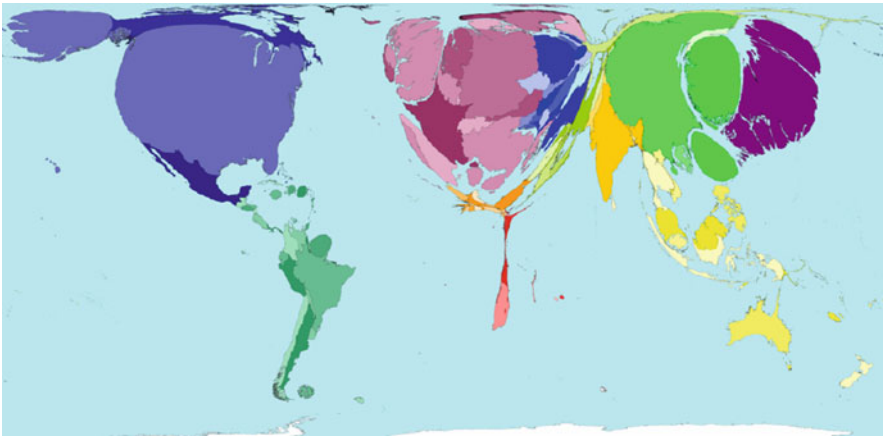

Diagram 14.1 Research and development expenditure in 2002, WorldMapper (© Copyright SASI Group (University of Sheffield) and Mark Newman (University of Michigan))

Table 14.1 Main governance instruments for benefit sharing

Benefit sharing (established sense)	Benefit sharing (aspirational sense)
Convention on Biological Diversity (1992) including national laws: e.g., Biodiversity Bill India 2002, Biodiversity Act South Africa 2004 and including Nagoya Protocol, 2010	The Universal Declaration of Human Rights, 1948, Article 27(1)
	International Covenant on Economic, Social and Cultural Rights, 1966, Article 15(b)
CIOMS International Ethical Guidelines for Biomedical Research Involving Human Subjects, 2002, Guidelines 5, 10 and 21.	Council of Europe's Convention on Human Rights and Biomedicine, 1997, Preamble
Declaration of Helsinki, 2008 including national laws: e.g. Brazilian National Health Council resolutions 1996, 1997, 1999, 2000	Human Genome Project's Ethics Committee Statement on Benefit Sharing (2000)
	UNESCO Universal Declaration on Bioethics and Human Rights (2005)

combined with a prior history of colonial exploitation and its consequences to this day, it can be argued that an unfair first-come, first-served system to resource use was being practiced rather than the more benign version of the common heritage of humankind principle (Shiva, 1991). In short, resource use was being exploitative (type 2 exploitation from Box 14.1).

Worldmapper uses a technique to resize territories with regard to some subject of interest. Diagram 14.1 is a world map resized according to research and development expenditures in 2002. Africa hardly appears on the map, while the industrialized north appears particularly bloated.

In July 2000, the World Conservation Monitoring Centre named 17 countries as mega-diverse countries: Australia, Brazil, China, Colombia, Democratic Republic

Table 14.2 Poverty and mega-diversity

Country	% <2$/day
Madagascar	89.6
Congo (DRC)	79.5
India	75.6
Papua New Guinea	57.4
Indonesia	46.0
Philippines	45.0
South Africa	42.9
China	36.3
Colombia	27.9
Peru	18.5
Ecuador	12.8
Brazil	12.7
Venezuela	10.2
Malaysia	7.8
Mexico	4.8
Australia	..
United States	..

of the Congo, Ecuador, India, Indonesia, Madagascar, Malaysia, Mexico, Papua New Guinea, Peru, the Philippines, South Africa, the United States of America, and Venezuela. Combined, these 17 countries host more than 70 % of the earth's species. The above table matches these mega-diverse countries with 2009 data of percentage of population living on or under the US$2 a day poverty line.

To address the common concern of humanity, namely, the depletion of biodiversity, developing countries demanded an end to one-sided resource use by foreign parties. Given that most repositories for biological resources were situated in the south (see Table 14.2), these were used to negotiate for concessions from developed countries. In the end, these concessions were:

- Sovereignty over genetic resources to be lodged with national governments, and no longer considered the common heritage of humankind
- A legal framework for dealing with biotechnology, in particular, those aspects that pose a threat to safety (leading to the Cartagena Protocol on Biosafety in 2000)
- Recognition of indigenous communities as the guardians of biodiversity and related traditional knowledge
- The requirement to share benefits with the providers of genetic resources, with their prior informed consent (PIC) and on mutually agreed terms (MATs)

The latter was the birth of benefit sharing as enshrined in the CBD's third principle, "the fair and equitable sharing of benefits from the use of genetic resources." To return to the question at the outset: why should a European scientist be hampered by bureaucracy when developing new products based on nonhuman

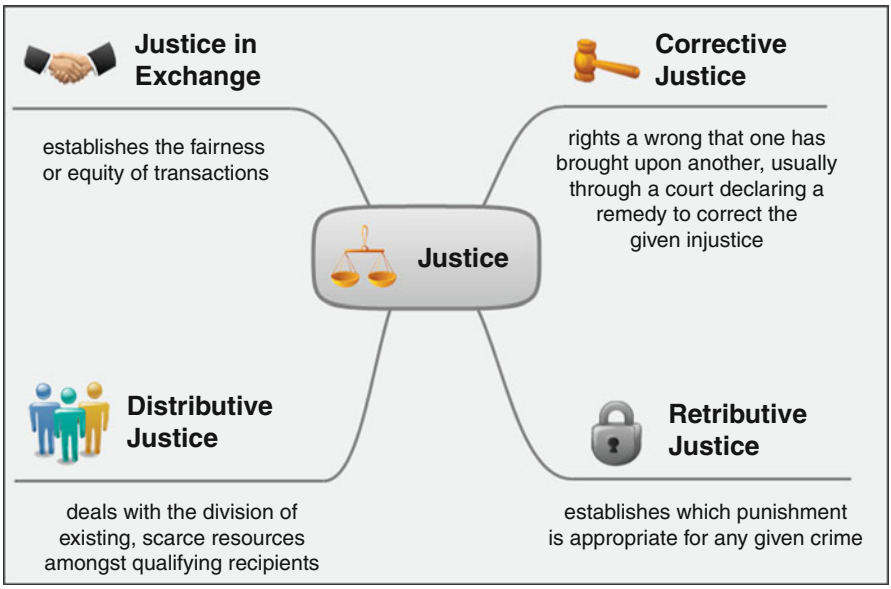

Diagram 14.2 Principles of justice

biological resources and associated traditional knowledge? Two answers are important.

The first answer is that 193 states, in other words, the world without the USA and Andorra, agreed that while the progress of science can be beneficial to humankind as a whole, it should not be based on yet another instance of wrongful expropriation of resources given the long history of colonialism.

The second answer must make reference to justice. Philosophers usually distinguish four types of justice principles, as illustrated in Diagram 14.2. The relevant principle in the context of access to resources is justice-in-exchange (Schroeder and Pogge, 2009).

Justice-in-exchange establishes the fairness or equity of transactions. It regulates the justice of giving one thing and receiving what is due in return. An interaction is considered just if all parties in the exchange receive an appropriate return for their contribution. A hidden, implicit element of justice-in-exchange is that the parties must agree voluntarily to the exchange. If something is taken from one party against their wishes, it does not make the transaction ethical simply to compensate them appropriately. Hence, what is termed prior informed consent in the context of the CBD is part of a just approach. It is an essential first step, a process requirement to achieve a just outcome.

For Aristotle, the fairness of a transaction could be judged by an outsider. The intrinsic worth of something, say a set of books, a supply of antiretrovirals, or South African microorganisms, had to be matched by a return, either in kind or in

monetary terms. Certain prices would have been deemed disproportionate by Aristotle, whether they were paid voluntarily or not. Hence, the fairness of a transaction relied on a judgment that the items exchanged were what Aristotle referred to as proportionate requitals.

Today, an understanding of justice-in-exchange based on Roman law is more common. This only requires that two competent adults (or parties) have agreed on the transaction. If somebody is willing to pay a thousand dollars for a set of books, so be it. The interaction would be considered just if the seller and the buyer had agreed on it without coercion or deceit.

What then is the second answer to the question of why a European scientist should be hampered by bureaucracy when developing new products based on nonhuman biological resources? The answer is to establish fairness in exchange. When it comes to biological resources, be they plants or microorganisms, the ideal scenario would let them be freely accessible to be used for the benefit of humankind without any inherent exploitation. In this scenario, the fair return would be access to a new product, a much needed drug for instance. Those who access resources would share the resulting benefits equitably with others. Bureaucratic barriers to the use of resources (other than for reasons of achieving sustainability) and requirements of benefit sharing would be counterproductive in a benign context where all human beings would have access to the fruits of innovation through the market. Free access to biological resources would facilitate innovation enjoyed by all, much in the spirit of the common heritage idea. But we do not live in a world thus organized. In fact, in the context of a severely unjust international economic order, which disrespects human rights (Pogge, 2008), one needs to – at the very least – avoid the most blatant exploitation, namely, that a person or a group provides access to a resource without *any* return whatsoever. Where appropriation by some (on a first-come, first-served basis) will lead to innovations unavailable to the poor, it makes sense – ethically – to fence in resources with bureaucratic procedures to aim for justice-in-exchange.

To put it simply: *those who contribute to scientific research and innovation ought to share in the resulting benefits*. If benefit sharing with the contributors of biological resources and related knowledge does not take place, scientific advancement is exploitative. For short descriptions of two cases, see Boxes 14.2 and 14.3 (for a short film on the Hoodia case, download here: http://extras.springer.com/2009/978-90-481-3122-8/).

While it is clearer now what benefit sharing according to the CBD means, it may not be clear what counts as a benefit. However, a long list of examples was given with the Nagoya Protocol. The adoption of the Nagoya Protocol on Access to Genetic Resources and the Fair and Equitable Sharing of Benefits Arising from their Utilization was a most promising development on benefit sharing. The protocol was adopted on 30 October 2010 at the tenth meeting of the Conference of the Parties to the CBD. Adoption was achieved through a consensus decision among the 193 parties, following some 6 years of intense negotiations – which frequently pitted developed countries against developing countries, and providers of genetic resources against users of those resources.

Box 14.2: Hoodia and Skeletium Cases

One of the best known benefit-sharing cases is that of the San Hoodia (Wynberg & Chennells, 2009). The San peoples, also known as Bushmen of the Kalahari, are the oldest human inhabitants of Southern Africa. For thousands of years, they lived as the sole occupants of an area stretching from the Congo-Zambezi watershed to what is now Cape Town. After centuries of genocide and marginalization imposed by colonialists, they now number approximately 100,000 people in Botswana, Namibia, South Africa, and Angola.

Their lives today are characterized by abject poverty. Yet they still possess traditional knowledge covering the biodiversity of southern Africa. This includes knowledge about the appetite-suppressant properties of the *Hoodia* succulent – a plant used in the past as a substitute for food and water when hunting.

In 1963, a South African research institute, the Council for Industrial and Scientific Research (CSIR), developed an interest in the plant. But they were unable to analyze its molecular structure until the mid-1980s when they acquired high-field nuclear magnetic resonance spectroscopy equipment. In 1995, after successfully isolating the appetite-suppressant properties, the CSIR filed for a patent. In the same year, South Africa became a party to the Convention on Biological Diversity. This meant that those using the traditional knowledge needed to obtain consent from the holders of such knowledge and negotiate a benefit-sharing agreement with them.

The CSIR never made contact with the San. Instead, the institute sublicensed its discovery to firms in Europe and the USA. A vigilant local NGO informed San leaders that their traditional knowledge had been used in a patent application and that they could either challenge the patent or demand a benefit-sharing agreement. They chose the latter.

In March 2003, the San and the CSIR signed a historic agreement which will give the San 6 % of all CSIR royalties received from license holders and 8 % of all milestone payments. Payments of around 100,000 US$ have already been received into a benefit sharing Trust. However, Pfizer and Unilever, two high-profile sublicensees, have both dropped their Hoodia product development, and in the late 2012, the future of this high-profile benefit-sharing agreement is uncertain. However, members of the San community have benefitted from capacity building, especially in matters of law and negotiation. More positively though, further benefit-sharing agreements have been negotiated.

In 2008, another agreement was concluded between the San peoples and HGH Pharmaceuticals (Pty) Ltd. The agreement covered the antidepressant properties of the *Skeletium* plant and has to date led to an income of around 80,000 US$. The company has developed the product and has completed all required efficacy and safety compliance tests required for the US market. A resulting product will be released in the second quarter of 2012.

Box 14.3: Nicosan (Formerly Niprisan) Case

Sickle cell disease is a genetic disorder which is endemic in Sub-Saharan Africa. Each year, around 300,000 babies are born with the potentially life-threatening disease or a variant. Those who survive will suffer from recurrent painful crises, which will disrupt their lives continuously. Until recently, only palliative measures were available for affected patients. However, a Nigerian traditional health practitioner (the late Rev. Ogunyale) had developed an herbal medicine recipe, which was promising.

In 1992, a memorandum of understanding (MOU) was signed between Rev. Ogunyale and the Nigerian National Institute for Pharmaceutical Research and Development (NIPRD) under the guidance of Prof. Charles Wambebe. Research commenced and led to patents granted in Nigeria, the USA, England, India, and 42 other countries in Europe, Africa, the West Indies, and the Americas between 1998 and 2000.

In 2002, a license was granted to USA company Xechem for global manufacture. A ceremony was opened by the Nigerian President to celebrate the fact that a medicine (then called Niprisan) was fully developed in Africa by African scientists to be marketed globally. The first limited production of the drug was undertaken by Xechem in 2006 while a manufacturing plant was commissioned to be built in Abuja. In 2008, the company filed for bankruptcy and the plant was closed.

The Nigerian government withdrew the license from Xechem and charged NIPRD with further production. However, in 2010, existing supplies ran out and the drug became unavailable. The research and development of Nicosan (the drug's new name) ceased at the NIPRD in the same year.

While starting out as one of the most promising cases of using traditional knowledge to develop a medicine for a hitherto neglected disease, the results were highly depressing. While the MOU signed between Rev. Ogunyale and the NIPRD was adopted as an example of best practice by the World Health Organization (WHO) and the World Intellectual Property Organization (WIPO), no benefit sharing with the reverend or his community ever took place. The clinical trial participants who were involved to bring the drug to market have no access to the drug, not only because it is no longer manufactured, but also because it was too expensive for the poor during the short duration of being available for sale. Most frustratingly, though, a drug which addresses a serious disease that poses a major public health burden in Africa exists without being manufactured. A sufferer of the disease, Tosin Ola, expresses her severe disappointment in an interview with SciDevNet:

"Before Nicosan, I was in and out of the hospital on a monthly basis, having to have regular blood transfusions, countless IV [intravenous] sticks and daily pain. But, once Nicosan started working for me, the daily pain ceased and I have not been admitted into the hospital since 2008. The sad part is that people are dying every day and suffering needlessly in pain, while the treatment . . . is nowhere to be found" (Abutu, 2010).

1. Monetary benefits may include, but not be limited to:
   (a) Access fees/fee per sample collected or otherwise acquired
   (b) Up-front payments
   (c) Milestone payments
   (d) Payment of royalties
   (e) License fees in case of commercialization
   (f) Special fees to be paid to trust funds supporting conservation and sustainable use of biodiversity
   (g) Salaries and preferential terms where mutually agreed
   (h) Research funding
   (i) Joint ventures
   (j) Joint ownership of relevant intellectual property rights
2. Nonmonetary benefits may include, but not be limited to:
   (a) Sharing of research and development results
   (b) Collaboration, cooperation, and contribution in scientific research and development programs, particularly biotechnological research activities, where possible in the party providing genetic resources
   (c) Participation in product development
   (d) Collaboration, cooperation and contribution in education and training
   (e) Admittance to ex situ facilities of genetic resources and to databases
   (f) Transfer to the provider of the genetic resources of knowledge and technology under fair and most favorable terms, including on concessional and preferential terms where agreed, in particular, knowledge and technology that make use of genetic resources, including biotechnology, or that are relevant to the conservation and sustainable utilization of biological diversity
   (g) Strengthening capacities for technology transfer
   (h) Institutional capacity-building
   (i) Human and material resources to strengthen the capacities for the administration and enforcement of access regulations
   (j) Training related to genetic resources with the full participation of countries providing genetic resources, and where possible, in such countries
   (k) Access to scientific information relevant to conservation and sustainable use of biological diversity, including biological inventories and taxonomic studies
   (l) Contributions to the local economy
   (m) Research directed toward priority needs, such as health and food security, taking into account domestic uses of genetic resources in the Party providing genetic resources
   (n) Institutional and professional relationships that can arise from an access and benefit-sharing agreement and subsequent collaborative activities
   (o) Food and livelihood security benefits
   (p) Social recognition
   (q) Joint ownership of relevant intellectual property rights

Not all of these benefits would be appropriate for benefit sharing in scientific research involving human participants, but the list gives a good idea of the diverse

Table 14.3 Main challenges for benefit sharing: Convention on Biological Diversity

Type of benefit sharing	Main challenges
Benefit sharing as justice-in-exchange 	Benefit sharing as justice-in-exchange could possibly be used by governments to neglect their duties to secure basic human welfare rights. However, benefit sharing cannot resolve distributive justice issues
	The emphasis in access and benefit sharing, as required by the CBD, must not move away from access. To obtain prior informed consent (PIC) before using nonhuman biological and associated traditional knowledge is essential
	The identification of traditional knowledge holders and their legitimate representatives remains a major challenge to achieving the goals of the CBD
	As CBD-style benefit sharing requires negotiations between users and providers of resources, unequal education, knowledge and skill levels are an impediment to just outcomes
	Managing the expectations of benefit sharing is a difficult task given that very few products ever achieve the commercial viability to lead to significant benefit flows
	Once a benefit-sharing agreement has been concluded, the expectations (as laid down in CBD-compliant national law) of Western-style governance can lead to significant tensions between users and providers of resources as well as auditors
	Resources do not respect national boundaries and benefit sharing involving several countries that can make claims to traditional knowledge, or biodiversity are difficult to handle legally
	Progressive international and national laws are not enough if poor, marginalized communities are not supported in claiming them
	The issue of benefit sharing for traditional knowledge should be promoted at the same time as the issue of land rights. However, only the UN Declaration on the Rights of Indigenous Peoples addresses both
	While the Nagoya Protocol has provided new impetus in resolving the lack of compliance with the CBD internationally, it is yet to be seen whether compliance can be achieved
	Last but not least, the fact that the USA is not a party to the CBD while being a major user of foreign biological resources poses significant ethical issues

possibilities for the sharing of benefits, far beyond profit-sharing. Before moving to benefit sharing as relevant to human resources, Table 14.3 summarizes the main challenges for realizing the spirit of the CBD.

The Declaration of Helsinki

The prevailing approach to benefit sharing for providers of human biological resources such as DNA or blood samples is the prescription of post-study obligations. Essentially, these obligations (previously known as post-trial obligations) describe a duty to provide human research participants with access to a proven beneficial health-care intervention after a study has been concluded. This means that in return for contributing to medical research, the research participants are meant to obtain access to any resulting products or interventions as a form of benefit sharing. One can see that the benefit-sharing spirit of the CBD is being maintained here too. Those who contribute to science ought to share in its benefits, to guarantee justice-in-exchange. However, it must also be noted that those who contribute to research outside the medical field, say cosmetics, are not necessarily guaranteed benefit sharing as the Declaration of Helsinki is unlikely to apply.

Post-study obligations within medical research were first introduced in the Declaration of Helsinki in 2000, when the WMA General Assembly in Edinburgh adopted paragraph 30:

> At the conclusion of the study, every patient entered into the study should be assured of access to the best proven prophylactic, diagnostic and therapeutic methods identified by the study.

This early formulation of post-study obligations was restricted to patients and, by implication, to trials involving volunteers in need of treatment. As a result, healthy volunteers enrolled in trials, as well as donors of biological materials, were excluded from benefit sharing. This focus on access to resulting products led to problems of equity. For instance, if post-study access to a drug is the only way to avoid the exploitation of research participants, those who take part in studies that do not lead to the marketing of a drug are excluded from benefits. Given that only a very small percentage of medical research eventually leads to products in pharmacies, this was a serious concern.

In 2004, the WMA's General Assembly in Tokyo added a note of clarification on paragraph 30, which opened the way for other benefits in addition to or instead of post-study access to successfully tested interventions (emphasis added):

> The WMA hereby reaffirms its position that it is necessary during the study planning process to identify post-trial access by study participants to prophylactic, diagnostic and therapeutic procedures identified as beneficial in the study or *access to other appropriate care*.

To reduce the rigidity of post-study access to successfully tested drugs, the phrase "access to other appropriate care" was added. At the same time, the term "patients" was changed to "study participants," to allow for the inclusion of healthy volunteers. However, the term "trial" was retained, thus limiting benefit sharing to those taking part in clinical trials. This changed in the 2008 declaration, adopted in Seoul. Articles 14, 17, and 33 relate to benefit sharing. Article 14 deals directly with the issue of broadening the scope of beneficiaries from clinical trial participants to study subjects. It says (emphasis added):

> The protocol should describe arrangements for post-study access by *study subject*s to interventions identified as beneficial in the study or access to other appropriate care or benefits.

It follows, then, that all medical research involving human subjects which needs approval from an ethics review body should describe, in its study protocol, post-study access to successfully tested interventions or other benefits. This implies that donors of biological samples must be included among the possible beneficiaries, as the scope is not limited to "trials."

However, such a formulation gives rise to a practical concern, namely, that compliance with it could mean that any arrangement for post-study access would suffice, as long as it was detailed in the study protocol. Even the sentence "There are no arrangements for post-study access," could arguably be regarded as compliance in that, as long as study participants and ethics review bodies know that there is no provision for post-study access, sufficient compliance with paragraph 14 would have been achieved. Hence, this obligation could be called informational rather than substantial, in which case, it does not satisfy the wider demand for benefit sharing. At first sight, this concern seems to be mitigated through paragraph 33 of the declaration, which reads:

> At the conclusion of the study, patients entered into the study are entitled to . . . share any benefits that result from it, for example, access to interventions identified as beneficial in the study or to other appropriate care or benefits.

This paragraph implies that post-study obligations are a substantial rather than an informational demand for all medical research involving existing patients. However, that still seems to leave healthy volunteers and donors of human biological samples potentially excluded from any post-study benefits, as benefit sharing is only envisaged with patients rather than all participants in medical research. This would seem contrary to the spirit of benefit sharing as understood through the CBD, which aims to reward "resource providers" in particular in order to avoid concerns about exploitation.

Here, one needs to remind oneself of the purpose of benefit sharing for human genetic resources. Formal benefit-sharing frameworks such as the CBD or the Declaration of Helsinki are only required where participants contribute to research but derive no benefits at all. In developed countries, the situation is different. Human sample donors contribute to research and in return have access to increased medical interventions, tailored to local health needs, to achieve and maintain their health. Where this is not the case as in developing countries, other solutions have to be found. In this regard, one could argue that such solutions are only required for vulnerable populations – and this is the approach taken by the Declaration of Helsinki through paragraph 17:

> Medical research involving a disadvantaged or vulnerable population or community is only justified if . . . there is a reasonable likelihood that this population or community stands to benefit from the results of the research.

This means that when ethics review bodies are presented with proposed studies on vulnerable groups which do not fall under the category of "patients," they still need to ensure that the research population or the wider community stand to benefit from the research. Hence, a study protocol which notes that there is no provision for post-study access or alternative benefits would be unethical, according to paragraph 17 (rather than paragraph 14), if it involved vulnerable populations, whether they take part in clinical trials or donate DNA. It is evident that the latest version of the declaration is therefore comprehensive in its benefit-sharing clauses, in providing somewhat intricate frameworks on which arguments in favor of benefit sharing with donors of biological samples can be based. Example cases are described in Boxes 14.4 and 14.5.

Finally, it is important to note that the 2008 Declaration of Helsinki added a benefit to the list of benefits to be shared, which was not hitherto included, namely, feedback. Article 33 requires that:

> At the conclusion of the study, patients entered into the study are entitled to be informed about the outcome of the study.

Before moving onto the next section, it is worth noting that the USA has effectively opted out of the benefit-sharing sections of the Declaration of Helsinki (Kimmelman, Weijer, & Meslin, 2009) by not recognizing the right of vulnerable populations to post-study access to successfully developed interventions or alternative benefits. Table 14.4 summarizes the main challenges in realizing benefit sharing through the Declaration of Helsinki.

The above concludes the section on the established legal sense of benefit sharing as governed through the CBD and the Declaration of Helsinki.

UNESCO Universal Declaration on Bioethics and Human Rights

The UNESCO's Universal Declaration on Bioethics and Human Rights (2005) supports a more ambitious or aspirational approach to benefit sharing, which goes beyond sharing benefits with the contributors to research. The declaration is built on earlier human rights frameworks, of which, the following two are the most important. The Universal Declaration of Human Rights (1948) Article 27(1) notes that (emphasis added)

> [e]veryone has the right freely to participate in the cultural life of the community, to enjoy the arts and *to share in scientific advancement and its benefits*.

Hence, every human being whether they contribute to science, research, and innovation, or not has the *human right* to share in the benefits of scientific advancement. While the Universal Declaration of Human Rights is a nonbinding instrument, the legally binding International Covenant on Economic, Social and Cultural Rights (1966) includes a similar human right. Article 15(b) reads:

> 1. The States Parties to the present Covenant recognize the right of everyone:
> (b) To enjoy the benefits of scientific progress and its applications.

Box 14.4: Nairobi Sex Workers

In 1982, a clinic to investigate the natural history of sexually transmitted diseases was established in Majengo, a slum in Nairobi, Kenya. In 1986, studies focusing on HIV/Aids commenced with particular emphasis on potential resistance to the virus. It appeared that about 5 % of the then 2,000 sex workers did not contract the virus, despite frequent, unprotected sex with HIV-positive men. Since 1998, the main aspiration of the clinic's studies has been the development of an HIV vaccine.

The only way to access the clinic and its health services is by enrolling in its research programs. The Majengo sex workers often have no other income or support, live in small tin shacks, work well into middle-age, and have dozens of clients every day, as payment from each is very low. They belong to an extremely socio-economically disadvantaged group, who would be unable to access health care in any other way. In return for biological samples, the clinic provides health monitoring and health education as well as treatments for all health conditions, irrespective of whether they are sex work-related or not. This includes, since 2005, access to antiretrovirals.

To date, the research has not yielded a vaccine or other treatments. However, considerable progress has been made to understand the immunological protection mechanisms at play. According to the Declaration of Helsinki, the sex workers or their community must benefit from the results of the research. Alternative benefits such as health care can be appropriate. Given that the research began in 1986, this case shows why access to developed drugs is too rigid a mechanism for benefit sharing without the proviso that other benefits might be acceptable.

As in the case of the CBD, the USA is one of the very few countries not to have ratified or acceded to the International Covenant on Economic, Social and Cultural Rights. The only other countries which are not a party to the covenant, except for tiny island states, are Cuba and South Africa. Ratification or accession requires parties to ensure that any provisions from the covenant can be enforced through the domestic legal system.

Before outlining the provisions of the UNESCO's Universal Declaration on Bioethics and Human Rights, it is important to ask the following two questions: What is the relevant justice framework for this type of benefit sharing? And why can this human rights-based approach to benefit sharing be called more ambitious or aspirational than the approach taken by the CBD or the Declaration of Helsinki?

Today, 2.7 billion people live on less than US$2/day. Of these, almost 1 billion are chronically undernourished, 1.1 billion do not have access to safe drinking water, 2.6 billion lack adequate sanitation, and nearly 2 billion have no access to life-saving drugs. People who suffer such massive deprivations are more likely to be susceptible to health risks and enter a vicious cycle of ill health, unemployment, and severe poverty. The above deprivations have little to do with science and

Box 14.5: Indonesian Virus Samples

The World Health Organization (WHO) collects virus samples for distribution to affiliated laboratories in an effort to monitor and assess the risk posed by flu and other infectious diseases, to detect mutations and develop vaccines targeted to specific strains.

In 2006, the Indonesian government decided to withhold avian flu samples from the WHO and its associated vaccine-development laboratories. The argument was that even though Indonesian samples were crucial to the development of vaccines, the results of vaccine research would be unaffordable to its citizens. Indonesia maintained that – in the spirit of the Convention on Biological Diversity – human genetic resources fall under the sovereignty of the nation state and that no global public health measures can enforce access. At this time, Indonesia was the country with the most fatal cases of avian flu.

Appealing to all members of the WHO in 2007, the WHO Director-General Margaret Chan said that cooperation is crucial to combat pandemics and that international public health security is a mutual responsibility. However, she also convened a working group to develop fairer ways for virus sharing.

After several years of negotiations, the WHO working group reached agreement on an alternative framework for virus sharing in April 2011 (WHO Pandemic Influenza Preparedness (or PIP) Framework). This framework is meant to be responsive to the concerns raised by the Indonesian government. The framework was ratified by the WHO at the May 2011 World Health Assembly (WHA) meeting and includes the requirement for two Standardized Material Transfer Agreements (SMTAs). The first SMTA contains terms and conditions which prohibit laboratories that are part of the WHO from making intellectual property claims in relation to the samples shared with them. The second SMTA, among other things, requires those outside of the WHO to commit to at least two conditions, selected from a list of options that includes giving developing countries 10 % of the resulting vaccines and/or antivirals, selling 10 % of these at an affordable price, or granting manufacturing companies within developing countries licenses to produce vaccines/antivirals at affordable royalties or royalty free.

While the PIP Framework addresses some of the concerns with regard to virus sharing, other human biological resources such as DNA and blood are not yet covered by an equivalent, legally binding framework.

innovation. While nanotechnology, for instance, might provide new techniques for water purification, all the necessary means to provide food, water, shelter, and health care to humans around the world are available today. As Amartya Sen pointed out in “Poverty and Famines” (1983), the earth’s resources are sufficient

Table 14.4 Main challenges for benefit sharing: Declaration of Helsinki

Type of benefit sharing	Main challenges
Benefit sharing as justice-in-exchange 	There are almost no examples of good practice for the compliance with post-study obligations in the medical field (except for those cases where comprehensive health care is provided, see Box 4 on Nairobi sex workers)
	Benefit sharing and avoiding undue inducement are ethical obligations that can be difficult to align. However, fear of the latter must not lead to neglecting justice-in-exchange requirements
	The pandemic influenza preparedness (or PIP) framework is to be welcomed, but only covers virus sharing. Similar frameworks need to be established to govern the exchange of other biological specimens of human origin
	Currently, no difference is made between commercial research, basic research, or publicly funded research when it comes to post-study obligations. This topic needs further attention
	The fact that the USA has opted out of the benefit-sharing requirements of the Declaration of Helsinki poses significant ethical issues given the prominence of US researchers conducting clinical trials and other medical studies in developing countries

to feed the world population (as one example of basic human need satisfaction). The main reason for famines is not a shortage of food or the lack of new scientific solutions, but rather the lack of power, sense of entitlement, and resources of the poor. It is thus a matter of distributive justice, the justice that deals with the division of scarce resources among qualifying recipients (see Diagram 14.2) that is at stake. There are enough resources to feed the world, according to Sen, including those in "famine" areas, but some are not regarded as qualifying recipients for such resources.

The main question in distributive justice, namely: *who* deserves *what* from *whom*, has been answered by the human rights framework. Those who live legitimately within a state (*who*) qualify for the receipt of income support at subsistence level plus other services to cover their basic needs (*what*) from the state (*from whom*). The International Covenant on Economic, Social and Cultural Rights from 1966 specifies individual welfare rights, and parties are committed to make these rights claimable through domestic legislation. However, not all states are in a position to respect, protect, and fulfill human rights, as this requires significant resources. It is here that cosmopolitan ethics (Pogge, 2008) as well as international legislation intervenes by adding a demand for international assistance. Hence, the justice framework for sharing the benefits of science, which the Universal Declaration of Human Rights and the International Covenant on Economic, Social and Cultural Rights requires is a distributive justice framework. Resources have to be moved from the affluent or powerful to the poor and vulnerable to secure

everybody's human rights. And it is the UNESCO's Universal Declaration on Bioethics and Human Rights which emphasizes the need for international assistance to do so.

Having clarified the justice framework involved in the more aspirational approach to benefit sharing (international distributive justice), it is also clear why it is more ambitious to demand a sharing of the benefits of science as a *universal human right* rather than a contributor right. To provide equitable access to the results of science to people who are dying because they cannot even get the most basic foods or off-patent drugs will require a mammoth effort, extraordinarily more than achieving compliance with the CBD, which in itself is a difficult task.

The advantage of the UNESCO's Universal Declaration on Bioethics and Human Rights is that it has agreed and described this mammoth commitment as detailed as is possible in a declaration. In the Preamble, it is emphasized that scientific progress can promote the welfare of human beings and that the target is *all of* humanity.

> Recognizing that, based on the freedom of science and research, scientific and technological developments have been, and can be, of great benefit to humankind in increasing, inter alia, life expectancy and improving the quality of life, and emphasizing that such developments should always seek to promote the welfare of individuals, families, groups or communities and humankind as a whole in the recognition of the dignity of the human person and universal respect for, and observance of, human rights and fundamental freedoms.

Thus, a belief in scientific progress is combined with the demand to make benefits available to all. In Article 2(f), the importance of international assistance for developing countries is emphasized. The aim is

> to promote equitable access to medical, scientific and technological developments as well as the greatest possible flow and the rapid sharing of knowledge concerning those developments and the sharing of benefits, with particular attention to the needs of developing countries

While this is more than previous instruments have included on benefit sharing, the declaration goes further by giving good practice examples through Article 15:

> 1. Benefits resulting from any scientific research and its applications should be shared with society as a whole and within the international community, in particular with developing countries. In giving effect to this principle, benefits may take any of the following forms:
> (a) special and sustainable assistance to, and acknowledgement of, the persons and groups that have taken part in the research;
> (b) access to quality health care;
> (c) provision of new diagnostic and therapeutic modalities or products stemming from research;
> (d) support for health services;
> (e) access to scientific and technological knowledge;
> (f) capacity-building facilities for research purposes;
> (g) other forms of benefit consistent with the principles set out in this Declaration.

Example 15(1)a could be aligned with benefit sharing as practiced under guidance from the CBD or the Declaration of Helsinki. To give special assistance to those who contribute to research recognizes that their efforts need to be rewarded to

Table 14.5 Main challenges for benefit sharing: UNESCO Universal Declaration on Bioethics and Human Rights

Type of benefit sharing	Main challenges
Benefit sharing as distributive justice 	While people are dying from lack of access to the most basic foods or medicines, the human right to sharing the benefits of science is unlikely to be a human right priority among policy-makers. For instance, none of the millennium development goals mentions science and innovation (except indirectly in an appeal to the pharmaceutical industry to provide affordable drugs; Goal 8E)
	While the UNESCO Declaration expands on the International Covenant on Economic, Social and Cultural Rights, it lacks the covenant's legal bite as it is a nonbinding guideline
	Other human rights, such as the right to food, are more easily specified and interpreted. What does it mean to have a human right to share in the benefits of science? The benefits of science range from interactive video war games to tuberculosis drugs
	How will the required international assistance to realize the human right to benefit sharing be mobilized, in particular in a time of financial instability?

avoid exploitation. It is therefore based on justice-in-exchange. Procedural considerations based on a contribution to science are also included in the declaration through recommendations on transnational practices. Article 21(4) requires that when "negotiating a research agreement, terms for collaboration and agreement on the benefits of research should be established with equal participation by those party to the negotiation." Hence, those who are contributing to science need not only be rewarded for their contribution but should also have a say in the direction, conduct, and dissemination of the research. One might want to term such collaboration as an equitable partnership.

The remaining benefits from Article 15 must be read as human rights, given the spirit of the declaration, and are goals of universal coverage. All human beings should be given access to the benefits as outlined from (b) to (g). Likewise, Article 24 on international cooperation covers universal human rights independent of contribution.

> Within the framework of international cooperation, States should promote cultural and scientific cooperation and enter into bilateral and multilateral agreements enabling developing countries to build up their capacity to participate in generating and sharing scientific knowledge, the related know-how and the benefits thereof.

At the time of writing, the USA has also withdrawn its financial support from the UNESCO, thereby potentially remaining outside of all leading binding and nonbinding legal instruments involving benefit sharing. The above Table 14.5 summarizes the main challenges in realizing the human right to sharing the benefits of science.

Table 14.6 Tensions between types of benefit sharing

Compensation rights	<- Tensions ->	Human rights
Benefit sharing as justice-in-exchange 	Open access and open source movements can violate compensation rights while furthering human rights	Benefit sharing as distributive justice 
	Patent applications can provide a compliance opportunity for compensation rights, but hinder the protection of human rights	
	Patents can provide financial means to comply with compensation rights, but hinder the protection of human rights	
	Significant bureaucracy necessary to facilitate benefit sharing as compensation could be used to facilitate benefit sharing as a human right	

Conclusion

Two types of benefit sharing can be distinguished. Benefit sharing as governed by the Convention on Biological Diversity and the Declaration of Helsinki aims to reward those who *contribute* to scientific progress, be it by providing resources such as plants or traditional knowledge or by taking part in medical studies. This approach avoids the most blatant exploitation, where somebody's blood sample or traditional knowledge leads to commercial products for the sole benefit of distant others. The aim of this type of benefit sharing is to achieve justice-in-exchange.

The second type of benefit sharing emphasizes that all human beings have a right to access to the benefits of science. The UNESCO's Universal Declaration on Bioethics and Human Rights is the clearest document to promote benefit sharing as a human right given that it does not shy away from the implications for affluent states. "Benefits resulting from any scientific research and its applications should be shared with society as a whole and within the international community, in particular with developing countries."

Neither type of benefit sharing is easily achieved, and to complicate matters, the two types can come into serious conflict, as outlined in conclusion in Table 14.6.

Protection of the Environment, the Biosphere and Biodiversity

15

Johan Hattingh

Introduction

For decades, scientists, educators, philosophers, ethicists, and concerned citizens have articulated strong warnings from different vantage points with a steadily growing measure of intensity that humankind is being confronted with a multilayered crisis entailing environmental degradation, biodiversity loss, climate change, and the detrimental effects this have on poor communities who depend directly on the environment and biodiversity for their livelihoods. All of these crises combine and reinforce one another through intricate internal feedback loops to form what Edgar Morin (1999) has called a polycrisis that not only places the quality of human life under threat but the very survival of life on earth.

In 1962, Rachel Carson published a book entitled *Silent Spring* (see Carson, 2002) to warn against the overuse of pesticides in agriculture, conjuring up the apocalyptic image of a world waking up one spring morning without the sounds of any bird singing. In 1968, biologist Garrett Hardin published an article on "The tragedy of the commons" pointing out that freedom in the commons, that is, open-access resources with no regulation on their use, leads to ruin for all (Hardin, 1968), while in 1972 the Club of Rome published the Meadows Report (Meadows, Meadows, Randers, & Behrens, 1972) with the self-explanatory title of *Limits to growth*. Focusing on accelerating industrialization, rapid population growth, widespread malnutrition, depletion of nonrenewable resources, and a deteriorating environment, this report warned that if present growth trends in the world continued unchanged, the world would reach physical limits to growth within 100 years. However, it also pointed out that these growth trends can be changed to establish a world that is ecologically and economically stable so that it is sustainable into the future. Similarly, *The Ecologist* also published in 1972 *A blueprint for survival* outlining "the overwhelming necessity for change towards a stable and sustainable society" (The Ecologist, 1972).

H.A.M.J. ten Have, B. Gordijn (eds.), *Handbook of Global Bioethics*,
DOI 10.1007/978-94-007-2512-6_80,

Around the same time, environmental ethics emerged as a separate academic discipline with the publication of two seminal articles. In Australia, Richard Routley (later Sylvan) (1973) published a paper with the telling title: "Is there a need for a new, an environmental ethic?" in which he called for a new, non-anthropocentric ethics based on the idea of the intrinsic value of the environment, while Arne Naess, a Norwegian philosopher, published an article in 1973 with the title "The shallow and long range, deep-ecological movement." In this article, Naess challenged the self-interested concerns of business and the middle class about pollution that may threaten a consumerist lifestyle, arguing that the solution to environmental problems should be sought on a much deeper level, that of radically questioning the identities assumed by consumers, driven as they are by a narrow egotistical and materialist notion of self. Instead, he argues for the realization of an expanded, mature self through identifying with the plight and interests of wider circles of being, based on the premise that every self is constituted by the wider circles of being in which its existence is embedded (Næss, 1973).

In parallel with this growing sense of crisis and of radical questioning, science, business, and international politics have responded with various initiatives that have recorded different measures of success over the years. The United Nations Conference on the Environment and Development (http://www.un.org/geninfo/bp/enviro.html) that was held in 1992 in Rio de Janeiro brought many of these initiatives together in a number of documents and conventions that were adopted. Among them were *Agenda 21* (http://www.un.org/esa/dsd/agenda21/) that is a comprehensive plan of action for sustainable development in the twenty-first century, the United Nations Framework Convention on Climate Change (UNFCCC) (http://unfccc.int/2860.php), and the United Nations Convention on Biological Diversity (http://www.cbd.int/). Today, however, 20 years later, serious questions are being asked about the efficacy of these initiatives in preventing or minimizing the combined crisis of unsustainable development, environmental destruction, biodiversity loss, climate change, and its disruptive impact on marginalized communities.

The urgency of responding to these crises and their primary drivers, however, has not disappeared. While population growth has become a politically loaded topic to address, and the same applies to the problem of overconsumption of about one billion of the affluent part of the world's population (Swilling & Annecke, 2012), population growth is still regarded as one of the biggest drivers behind these crises (TEEB, 2010; The Royal Society, 2012). Others (Turner, 2008) argue that the world's population still has not learned how to overcome unsustainable use of resources in industrial production and private consumption. From a biological point of view, E.O. Wilson (1992) has pointed out in 1992 already that the biodiversity crisis entails one of the biggest extinction periods that the history of life on earth has experienced in the last 65 million years, while Stephen Gardiner has argued recently (2011) that climate change confronts the world with a perfect moral storm that challenges the most basic assumptions underlying ethics and moral responsibility, paralyzing humankind into believing that nothing can or should be done about climate change.

In a strange turn of events, it seems as if these crises have been eclipsed to some extent by the financial crisis of 2008 and 2009 that has hit the world's economy and financial systems, and from which quite a number of national economies have not yet recovered from at the time of writing this chapter. Strict austerity measures, financial discipline, and smart investments will be required to overcome this financial crisis, but this has already raised the concern that little, if any, additional resources will be available to also address the challenges of environmental degradation, biodiversity loss, climate change, and the social disruption that they bring. In recent discussions of this polycrisis, it is recognized that measures to address the financial crisis will not be successful if environmental degradation, biodiversity loss, climate change, and their social impacts are not also addressed with the same measure of intensity (Stern, 2010).

With this as broader context, the focus in this chapter will fall on the challenge of protecting the environment, the biosphere, and biodiversity. In particular, an overview will be given of the conceptual, philosophical, and ethical challenges related to defining exactly what should be protected regarding the environment, the biosphere, and biodiversity and what the arguments are to justify why this should be done. The crux of this discussion will be devoted to different kinds of values that have been used to justify protection, as well as the different implications these values have for conservation management, not only in setting its goals but also in determining its tools and methods. Some of the discussion will also focus on the drivers behind biodiversity loss, destruction of the biosphere, and the environmental crisis and what if anything could be done about them. This chapter will begin with a discussion of definitions and conceptual issues and will conclude with an outlook on the future of the environment, the biosphere, and biodiversity.

Definitions

While there is substantive overlap in the meanings of *environment*, *biosphere*, and *biodiversity*, and while these concepts are sometimes used interchangeably, it is important to note that there are also subtle but important differences between them. As concepts, they do not fully coincide with one another. In its most widely accepted definition, biological diversity, or biodiversity in its abbreviated form, refers to "the variability among living organisms from all sources including, *inter alia*, terrestrial, marine and other aquatic ecosystems, and the ecological complexes of which they are part: this include diversity within species, between species and of ecosystems" (Article 2 of the United Nations Convention on Biological Diversity, 1992).

In this definition, there is reference, albeit indirectly, to both the *elements* of biodiversity such as genes, species, and ecosystems, as well as the *processes* of which they form part. The latter is captured in this definition with the reference to "ecological complexes" which entail complex and dynamic processes of interaction between "elements" over time. As such, this definition represents a movement away from a "bits-and-pieces" or "itemizing" approach to the protection of biodiversity,

to one where living and evolving wholes, and the processes making the existence of these wholes and their evolution possible are studied (O'Neill, Holland, & Light, 2008).

The biosphere is generally defined as "that part of the land, sea and atmosphere in which organisms are able to live. The biosphere is an irregularly shaped, relatively thin zone in which life is concentrated on or near the Earth's surface and throughout its waters" (*The American Heritage Science Dictionary*). According to a more general definition from the same source, the biosphere entails "all the Earth's ecosystems considered as a single self-sustaining unit." Here also the notion of life as an all-encompassing whole emerges but also the wider notion that this whole encapsulates all of the conditions that make life possible.

How incredibly fragile and also precious this biosphere is was first graphically illustrated with the photographs (http://www.nasa.gov/vision/earth/features/bm_gallery_4.html) that were taken from outer space by NASA astronauts aboard Apollo 8 on Christmas eve of 1968 of the earth rising over the moon. Statements by subsequent astronauts, for instance Loren W. Acton (http://www.solarviews.com/eng/earthsp.htm), as well as similar photographs (http://planetary.org/explore/space-topics/earth/pics-of-earth-by-planetary-spacecraft.html) from other space missions reinforced this image of the biosphere, an image of the whole earth that lies in the hands of humankind (http://farm3.staticflickr.com/2063/5769488751_83de7508b4_m.jpg) to be protected and cherished but at the same time is something that can be broken (http://www.freakingnews.com/pictures/63000/Cracked-Earth-Egg-63050.jpg) beyond repair, if not handled with care. Making the earth thus visible as a single, fragile whole inspired the notion of the biosphere as a living system *with limits* (Swilling & Annecke, 2012).

In the *Merriam-Webster Dictionary*, a distinction is made between a generalized meaning of *environment* and a more biological meaning. In a general sense, environment refers to the "circumstances, objects or conditions by which one is surrounded." In its biological sense, environment refers to "the complex of physical, chemical and biotic factors (as climate, soil and living things) that act upon an organism or an ecological community and ultimately determines its form and survival." In this comprehensive biological sense, the meaning of *environment* and *biosphere* virtually coincides, but there is also an overlap with *biodiversity*, in that the elements "making up" the environment, for example, individual living entities, species, communities of life, biomes, biological "hotspots," or ecosystems, can be emphasized, or the whole of the environment together with the natural processes of life unfolding in it. In a third meaning, environment refers in human terms to "the aggregate of social and cultural conditions that influence the life of an individual or community."

These definitions already illustrate the complex relationship between that which is taken as the environment, the biosphere, and biodiversity, and that they contain elements, entail processes, and display characteristics that are mutually dependent upon one another, and mutually influence one another in intricate feedback loops. It can thus be argued that these three terms refer to different aspects of the same unified system spanning the earth, namely, life in all of its different forms: *environment* serves as a framework concept, encapsulating the comprehensive

preconditions of life in general (e.g., the water cycle, photosynthesis, and the absorption of heat); *biodiversity* is used to refer to the many differences in and between individual living organisms, species, and ecosystems, while *biosphere* is more of a geographical term that refers to the thin "layer" of life that spans more or less the surface of the earth.

Accordingly, it is not easy to distinguish between threats to biodiversity and the biosphere that are not at the same time threats to the environment as well, and vice versa. Similarly, it is not easy to think of environmental protection that is not at the same time protecting the biosphere or biodiversity. To illustrate the point, if the protection of biodiversity is set as a goal for conservation policies, such protection will at the same time entail protection of the environment and of the biosphere. To acknowledge the overlap between these three concepts but also to prevent confusion that may emerge from using these three terms interchangeably, the term "earth system" will be used in this chapter to refer to the environment, the biosphere, and biodiversity taken together as a whole, functioning as a complex living system with its own history and evolutionary path, possibilities, and boundaries. In the discussion below, however, references to the environment, the biosphere, and biodiversity in their own right will be made when required by the context.

Before proceeding to an overview of the arguments that are used to underline the importance of protecting the earth system, it is important to first consider a few conceptual issues, as well as the drivers leading to damage of the earth system. The discussion of conceptual issues will already illustrate some of the philosophical and ethical challenges involved in efforts to identify what exactly it is that should be protected and why it is important to do so. The discussion of the drivers will facilitate an understanding of the magnitude and extent of the problem facing humankind.

Conceptual Issues

In this section, an overview will be given of philosophical and ethical issues related firstly to the *vagueness* that is often encountered around the concepts of the environment, the biosphere, and biodiversity; secondly to the impossibility of giving *scientifically objective* definitions to these three concepts; and thirdly to approaching these three concepts from an *element* or a holistic, *processes* perspective.

The first conceptual issue emerges from the vast number of definitions that exist with regards to both *biodiversity* and *environment*. Gaston (1996) and Faith (2008, p. 1, 2) discuss the different variations that exist of *biodiversity* defined as "the variety of all forms of life, from genes to species, through to the broad scale of ecosystems," while Reaka-Kudla, Wilson and Wilson (1997) give an overview of the rapid rise of the term biodiversity, and trace aspects of the term back to the ancient Greek philosopher, Aristotle. Johnson et al. (1997) in turn focus on terms and expressions related to the environment and make a very valuable contribution toward standardizing the use of the ten most commonly used environmental terms.

O'Neill et al. (2008), however, point out that there is no such thing as *the* environment. If environment refers to the "surroundings *of* some person, being or community," there is always "a variety of places, processes and objects" that make up a vast variety of environments.

This highlights the problem that *biodiversity* and *environment* are concepts that can easily be taken to mean "everything" (Faith, 2008, p. 2) so that all concerns about the environment and biodiversity are lumped together in one big whole. *Biodiversity*, for instance, has sometimes been used to mean "life" or "wilderness" or "ecosystems" or "ecosystem processes" (Faith, p. 2), while the concept of the *natural environment* is commonly used to refer to "water," "oceans," "rivers," "lakes," "the atmosphere," "climate," "the weather," "life," "ecosystems," "biomes," "biogeochemical cycles," "wilderness," "vegetation," "soil," "rocks," and "natural phenomena" (see Wikipedia entry on *Natural environment* [http://en.wikipedia.org/wiki/Natural_environment]). This vagueness should be avoided and can be avoided by not only giving more precise conceptualizations of environment and biodiversity, respectively, but also defining much more precisely what exactly should be protected with regard to the environment, the biosphere, and biodiversity and why it should be done.

In the second place, it is important to note that many scholars, including prominent philosophers and conservation biologists, have pointed out that it is impossible to formulate a definition of biodiversity that is "scientifically objective." Instead, they accept that the kind and the level of biodiversity that is set as a target to protect, to maintain, or to restore is based on certain value assumptions that characterize the identity of a certain society, and that these values should be made explicit for critical scrutiny in ongoing societal debates. The same applies to the nature and extent of environmental protection that is accepted or set as a target by a certain society. As such, this constitutes what Faith (2008, p. 2) refers to as the problem of "biodiversity plurality": the existence of a wide spectrum of biodiversity targets or models that can be pursued, bringing about the question on what grounds a decision-maker should choose between them. Similarly, there exists the problem of "environmental plurality" and the concomitant challenge for someone like an environmental manager to find appropriate and sufficient grounds to choose between different targets or models of environmental protection (see Norton, 2003; O'Neill et al., 2008).

In the next section, the discussion will focus on the typical arguments that are used to justify choosing between different environmental/biodiversity targets for protection. At this point, it is important, though, to note that the problem of environmental/biodiversity plurality and responding to it by making explicit the values on the basis of which the choice between models/targets is made constitutes a "post-positivist" approach to conservation. As Faith (2008, p. 3) has pointed out: "there is no one, correct measure of biodiversity to be discovered but many, each having different values."

In this regard, the argument goes that all facts pertaining to conservation, whether they are related to the environment in general or to biodiversity more specifically, even if they are produced by scientific studies, are value-laden. This, however, does not make conservation or conservation science a totally arbitrary and

fully subjective exercise (see Davis, 2009 for an insightful overview of this debate). On the contrary, this insight rather calls upon conservation scientists to make the values explicit that inform their work so that they can become part of the ongoing self-conscious and critical conversation taking place in societies about the sources of these values, as they are related to histories and social identities, that is, notions of who people are, how they wish to realize themselves in the present and in the future, and what role they deem conservation should play in all of this.

A third important conceptual issue to take into account is raised by biologists E.O. Wilson (1988) and David Ehrenfeld (1988). Summarized by Faith (2008, p. 3), Wilson sees the rise of the term *biodiversity* as a dramatic shift away from a "bits and pieces" to a much more holistic approach to biology. Where the protection of biodiversity was first aimed at endangered species, the emphasis shifted to the protection of ecosystems (Rolston, 2001). Wilson correctly identifies that the rapid emergence of the term *biodiversity* since the 1980s represents a growing concern about biological variety as a general phenomenon, that this variety is rapidly disappearing, and that "unlike other threatened things, is irreversible." Ehrenfeld also elaborated on this idea of a "biodiversity crisis" by emphasizing the "idea of the value of diversity in the aggregate. He argues that diversity previously was never regarded in itself to be in danger, but that biodiversity now is recognized as endangered in its own right" (Faith, 2008, p. 3).

In a slightly different formulation, Norton (2003, p. 501) also draws attention to the biodiversity as a whole when he argues that biodiversity is not merely a resource among other resources, "but a generator – a source – of biological resources." Norton argues that biodiversity is a necessary condition for the creation of biological resources. Such a holistic approach is also evident in literature about the environment and the biosphere, emphasizing that it is not only their compositional elements that are important but also the functional processes that constitute the environment and the biosphere as resilient, adaptive living wholes that should be considered as such in decision-making (Callicott, 1999).

The concepts of the environment, the biosphere, and biodiversity are brought closer to one another by placing the emphasis on the *earth system* as a functioning whole supporting all life on earth, as it was pointed out above. Accordingly, this conceptual shift from parts to the whole resonates with a significant expansion of conservation from a focus on the individual elements of the earth system, for example, species or specific species populations, even ecological "hotspots," toward a focus more on ecosystem processes, and the manner in which, for example, a population unit of a species, characterized by a certain size and geographic distribution, in interaction with other population units of other species, together contribute to the functioning, resilience, and evolution of an ecosystem or ecosystems (Luck, Daily, & Ehrlich, 2003).

Such a systems approach thus introduces *ecological effectiveness* as the primary conservation goal, in which the protection of ecologically effective population sizes and critical ecological interactions rather than maintaining minimum viable populations stands central (Soulé, Estes, Berger, & Del Rio, 2003). This is at the same time a strong argument for *ecosystem recovery* as a conservation goal for

damaged or degraded ecosystems, following explicitly formulated operational targets. The difficulty in pursuing these systemic goals, however, is uncertainty about future ecological dynamics, exacerbated by rapid environmental change: "... we cannot know exactly which interactions and which species will be most critical for the maintenance of biodiversity in the future" (Soulé et al., 2003).

In spite of such cognitive constraints, strong arguments can be formulated to explain why it is important to protect the earth system – based on the knowledge already available about its functioning and its value. Important background to these arguments is an understanding of the nature and extent of the damage that is currently done to the earth system and what the drivers behind this damage are.

Human Impact on the Earth System

According to paleontologist Niles Eldredge (http://www.actionbioscience.org/newfrontiers/eldredge2.html), Curator-in-Chief of the Hall of Biodiversity (http://www.amnh.org/exhibitions/permanent/biodiversity/) of the American Museum of Natural History in New York, human impact on the earth's ecosystems started about 100,000 years ago with the dispersion of humans around the earth and has been associated with the onset of the first phase of the Sixth Extinction period (http://extinct.petermaas.nl/). In this first phase, the biggest impact was on large game species like mammoths, mastodons, buffaloes, and big birds through overhunting. Phase 2 commenced with the onset of the Holocene epoch about 10,000 years ago when humans turned to agriculture, and the biggest impact of this phase occurred through the transformation of land to produce crops, changing on the one hand the habitats of natural species but on the other hand freeing humans from their dependence on natural ecosystems for survival, and through that, making it possible for humans to overpopulate.

Current concerns about the earth system stem from the impact of vast numbers of humans, empowered by mechanized tools, science, and technology that intensify and accelerate the impact. What makes the Sixth Extinction period different from the previous "Big Five" is that the sixth period is anthropogenic, that is, caused by humans, while all of the previous ones have been caused by natural events such as the eruption of volcanoes, the impact of a meteorite hitting the earth, or climate change. Formulated in broad terms, it is recognized that the drivers behind the current extinction period include population growth, the destruction or transformation of habitats (because of reasons that include the encroachment of agriculture), using biological resources faster than their natural rate of regeneration, clear-cutting of forests, water diversion, water extraction from rivers, pollution, alien invasive species, and climate change. The general consensus is also that these drivers are currently putting all of life on earth in the balance, unless the whole of humankind turn to and adopt a sustainable mode of living.

Factual data that are regularly updated about the current impact of human activities on the earth system, and that are based on literally thousands of scientific studies, can be found on various websites. The Convention on Biological Diversity

(http://www.cbd.int/convention/) regularly publishes a *Global Biodiversity Outlook* (http://www.cbd.int/gbo/), of which the third edition (http://www.cbd.int/doc/publications/gbo/gbo3-final-en.pdf) appeared in 2010. Other United Nations agencies also provide regularly updated data and indicators, for instance, the United Nations Environmental Programme (UNEP [http://www.unep.org/]), the United Nations Development Programme (UNDP [http://www.undp.org/content/undp/en/home.html]), and the World Bank (http://www.worldbank.org/). Private sector initiatives and nongovernmental organizations also publish regular reports on the state of the environment and biodiversity, the most important of which are the World Resources Institute (http://www.wri.org/) that published the Millennium Ecosystem Assessment (http://www.maweb.org/en/index.aspx), The Club of Rome (http://www.clubofrome.org/), the Worldwide Fund for Nature (WWF [http://wwf.panda.org/]), the International Union for Conservation of Nature (IUCN [http://www.iucn.org/]), Greenpeace (http://www.greenpeace.org/international/en/), and the Heinrich Böll Foundation (http://www.boell.org/web/137.html).

The assessment reports of the Intergovernmental Panel on Climate Change (IPCC [http://www.ipcc.ch/]) also provides very valuable information about the extent of climate change in different parts of the world and what climate change could entail under different scenarios in the future. The extent of the impacts of climate change on sustainable development and biodiversity is also discussed in these reports, as well as measures that could be taken in the area of conservation, sustainable development, and caring for biodiversity to adapt to climate change. The *Fourth Assessment Report* (AR 4 [http://www.ipcc.ch/publications_and_data/publications_ipcc_fourth_assessment_report_synthesis_report.htm]) of the IPCC appeared in 2007, and the four volumes of the *Fifth Assessment Report* are to be published during the course of 2013 and 2014.

In these reports, a bleak picture of life on earth under severe threat is sketched. In the 2010 *Global Biodiversity Outlook 3* (http://www.cbd.int/doc/publications/gbo/gbo3-final-en.pdf) of the United Nations Convention on Biological Diversity the following is stated: "The target agreed by the world's Governments in 2002, 'to achieve by 2010 a significant reduction of the current rate of biodiversity loss at the global, regional and national level as a contribution to poverty alleviation and to the benefit of all life on Earth', has not been met. There are multiple indications of continuing decline in biodiversity in all three of its main components – genes, species and ecosystems . . ."

This is confirmed by the *Millennium Ecosystem Assessment* of 2005 in which it is stated that "Over the past 50 years, humans have changed ecosystems more rapidly and extensively than in any comparable period of time in human history, largely to meet rapidly growing demands for food, fresh water, timber, fiber, and fuel. This has resulted in a substantial and largely irreversible loss in the diversity of life on Earth" (General *Synthesis* of its report on *Ecosystems and Human Well-Being*, p. 1 [http://www.maweb.org/documents/document.356.aspx.pdf]). While it is difficult to put figures on biodiversity loss, biologist E.O. Wilson has calculated in 1992 that human-induced extinctions have reached crisis proportions in that between 20,000 and 30,000 species are lost annually from a total number of

between 10 and 30 million extant species (Wilson, 1992). Using different assumptions, Pimm, Russell, Gittleman and Brooks (1995) calculated that about 140,000 species are lost per year – while the background rate of natural extinctions is calculated to be about 10 species per year (Raup, 1991). In addition, the WWF in its *Living Planet Report* of 2012 (http://wwf.panda.org/about_our_earth/all_publications/living_planet_report/) indicated a decline of almost 30 % in the Living Planet Index in the period from 1992 to 2008 (p. 18), while UNEP pointed out in 2011 (http://unep.org/geo/pdfs/Keeping_Track.pdf) that every year, 52 vertebrate species move one Red List (http://www.iucnredlist.org/) category closer to extinction.

Others have studied habitat loss and the destruction of ecosystems, and while it is equally difficult to quantify this, Primack (2006) mentions that, for instance, only 15 % of land in Europe remains unmodified by human activities, while only 9 million square kilometers of tropical rain forests remain today from an original 16 million square kilometers. Laurance (1999) estimates that the current rate of deforestation is 160,000 km^2 per year, while it is pointed out in the *Millennium Ecosystem Assessment* (2005) that 20 % of coral reefs have been destroyed and another 20 % have been severely damaged by overfishing, while 35 % of mangrove forest systems have been destroyed.

While it is important to note that this pressure on the earth system will increase in future as the demand for food rises with a growing world population, it is equally important to note the social and health impacts of environmental degradation. As it is pointed out in the *Millennium Ecosystem Assessment* (2005), habitat destruction not only impacts negatively on biodiversity but also on the livelihoods and health status of already marginalized people, that is, those most vulnerable to changes in the environment. Habitat destruction, for instance, impacts directly on water quality, and poor water quality can be a significant disease vector in poor communities.

From this, it follows that protection of the earth system is not only a "green" or conservation issue in the narrow sense of nature conservation. It also has to do with the protection of livelihoods, of human health, and the survival of people and that policies designed to address environmental degradation, threats to the biosphere, and loss of biodiversity unavoidably also have a people's agenda intertwined with them. To formulate it differently, conservation policies, measures to protect biodiversity, and strategies to safeguard the biosphere against threats such as pollution or climate change can play a significant role in the empowerment and development of marginalized communities and at the same time help to address the issue of world poverty.

Arguments for Protection of the Earth System

Why is it of the utmost importance to protect the environment, the biosphere, and biodiversity? Why are threats to the earth system such a big danger that they require urgent attention? There are typically two sets of reasons used to answer these questions: reasons based on *instrumental value* and reasons based on *intrinsic value* (Afeissa, 2009). In the first, most widely accepted set of reasons, the use value of the earth system in maintaining human well-being in the widest possible

sense of the word, is emphasized – acknowledging that there is a wide spectrum of human interests that are or can be satisfied in many different ways by the earth system. The earth system, however, is more than just a resource for human use alone. The earth system taken as a whole, as well as its component parts, have value in and of themselves, it is often claimed, regardless of any use value that humans can derive from them. In this context, the flourishing, abundance, and diversity of life in general, as well as its component parts, are seen as having intrinsic value that need to be protected for nothing but their own sake.

While both types of value provide strong arguments to protect the earth system, the ethical basis of instrumental value is often questioned for its anthropocentrism: it argues that the earth system should be protected because it is in the interest of humans to do so. Duties to the earth system are then only indirect duties; ultimately the only concern is to satisfy human interests, and this more often than not leads to exploitation or even destruction of the earth system or parts of it, including the complex processes that sustain life and its ongoing evolution. On the other hand, intrinsic value emphasizes that humans have direct duties to the earth system as a whole, its parts, and its processes, and thus claim to offer deeper or stronger reasons for their protection (Rolston, 2001). In this latter context, the challenge is to determine these duties in such a manner that they do not lead to the trap of the opposite extreme of an absolute reverence for the earth system that makes human life on earth impossible in that the earth system cannot be used to satisfy any human interests. Furthermore, critics argue that intrinsic value cannot inspire and move people to protect the earth system if the notion of intrinsic value is not combined with values that humans can strongly identify with (O'Neill et al., 2008).

Below different kinds of instrumental value will be discussed, showing how *direct use value, indirect use value, amenity value*, *option value*, and *existence value* can all be used to provide strong reasons to protect the earth system. Some discussion will also be devoted to intrinsic value and how a certain interpretation of it can provide equally strong reasons to protect the earth system.

Direct and Indirect Use Value as Basis for Protection

Resource economists, consumers, and ethicists alike emphasize that the direct use value of natural phenomena derives from transforming them into something that is useful to humans. Accordingly, a patch of land has to be cleared and plowed and watered to plant crops on it that can be harvested for the market and sold for human consumption. A river has to be dammed in places to make use of its water for agriculture and industry. Trees in a forest have to be cut to provide timber for building and furniture or pulp for paper. Animals have to be slaughtered to feed people. This transformation or primary resource extraction forms the basis of a value chain that spreads throughout society and makes a variety of other human activities possible, besides primary consumption for the sake of subsistence and survival. As such, this transformation has an economic value, and as such, it forms the material basis of human well-being.

Under the assumption that the earth is an infinite repository of raw material and energy, the direct use value of the earth system has been horribly exploited to satisfy short-term human interests, creating the problems of environmental damage, biospheric deterioration, and biodiversity loss. However, many have come to realize on rational, utilitarian grounds that this unrestrained development and expansionism (see Fox, 1995) cannot be sustained. Under the conviction that the well-being of humankind should be ensured over the long run, it was realized that the goal for resource management should be shifted from maximum benefit to maximum *sustainable* benefit, that is, benefit that can be maintained over time. This new goal was first known as *wise use*, or *conservation* of resources, and later from the 1980s as *sustainability*. As Holland (2001, p. 390) states, sustainability entails at least the hope "that we might provide for human needs with decreasing impact on the natural environment, and even reverse some of the degradation that has already occurred." Of late, sustainability has also been interpreted to include equitable sharing of the benefits and burdens of resource use (Swilling & Annecke, 2012).

One of the strong arguments often used to justify protection of the earth system is thus maintaining its direct use value over time, since it forms the material basis of all economic activity, human well-being in the present, as well as the ability of future generations to meet their needs – as the well-known definition of sustainable development of the Brundtland Report suggests: "Sustainable development is development that meets the need of present generations, without compromising the ability of future generations to meet their needs" (WCED, 1987, p. 43). There are a number of problems with this argument, though, if it is articulated purely in economic language based on the narrow assumptions of neoclassic economic theory. Economic efficiency and optimality then becomes the dominant values, leading to a weak interpretation of sustainability that has no concept of limitations and thus cannot protect the earth system from unrestrained exploitation.

In the first place, if interpreted in narrow financial terms, the espoused management goal of sustainability will not lead to the protection of the earth system as a whole. It will rather lead to a protection of only those components of the earth system that has clear economic value – reinforcing a "bits-and-pieces" approach to protection of biodiversity and the environment. If a holistic approach is followed, though, the economic argument will similarly only be able to justify protection of those processes and systems that have economic value derived from direct use. Other components of natural phenomena, or natural processes and systems that have little or no obvious economic value, will thus be left to their own devices with not special protection for them available.

In addition, those components, processes, and systems of the earth system that indeed have economic value clearly will only be protected as long as they have economic value and only up to the point where it is economically viable to do so. Bluntly formulated, this will entail the principle: *If it pays, it stays*. However, this principle cannot guarantee protection in the long run. Instead, the principle of diminishing marginal utility applies, which states that humans

will protect the earth system or its components only up to that point where they start to feel that they can spend their money better to satisfy other interests.

In the second place, a narrow financial approach to protection based on the values of efficiency and optimality entails a weak interpretation of sustainability. Formulated in economic terms, *weak sustainability* sets the management goal of maintaining the total value of capital over time (Solow, 1993). According to this view, there are different kinds of capital besides natural capital, for instance, human-made capital such as infrastructure (roads and buildings and power stations), human capital such as education, and financial capital such as funds available in a bank for utilization. Under the meaning of maintaining total capital over time, sustainability implies an infinite intersubstitutability of capital (Norton, 2003). As long as total capital is maintained, the argument goes, sustainability is achieved.

There is a problem with the notion of infinite intersubstitutability of forms of capital, however, since it implies that a natural resource, for instance a forest, can be totally "used up" over a short period of time, as long as its capital value has been transformed in other forms of capital – for instance, used for education or the building of roads, schools, and hospitals. The total and irreversible loss of a forest and all of the biodiversity and ecosystem functions it entailed, would therefore, under this interpretation of weak sustainability, still be acceptable as an instance of sustainability. Besides the problem of seeing the earth system and its functioning as merely another form of capital that can be "traded in" for another form of capital, it clearly also entertain no conception of systemic limits that should be taken into account when decisions about resource use and development paths are taken (Norton, 2003; Swilling & Annecke, 2012).

Some critics of weak sustainability therefore introduced a strong interpretation of sustainability as a corrective (Costanza, 1991). Formulated in economic terms, *strong sustainability* would entail maintaining *natural* capital over time. This introduces the notion of certain limits to the use of natural capital below which humans should not go. The notion of strong sustainability also acknowledges that "the environment provides humankind with 'benefits' which no human-made capital can replicate: both particular functions (such as climate regulation and genetic diversity) and non-eliminable inputs (such as raw materials, land, and waste assimilation capacities)" (Jacobs, 1995, p. 59).

From this point of view, there is not only recognition of the direct use value of the earth system and some of its components but also of a number of very real nondirect "services" that humans depend on for survival and well-being, for instance, the provisioning of a tolerable climate, the processing of waste, the provisioning of clean air and water, as well as the raw material required for subsistence, shelter, agriculture, etc. Strong sustainability as a management goal thus calls for much more than maintaining the commodity (direct use) value of the earth system and its components; it argues for the maintenance of the *functioning* of the earth system that provide those commodities in the first place, as well as a wide spectrum of other, indirect, and nonconsumptive use values on the basis of which protection of the earth system can also be based.

While much is already known about the functioning of the earth system, what keeps it together and going as it were, there are also many gaps in this knowledge on these topics. A certain species, for instance, or a certain process, can play a key role in the functioning of a particular ecosystem, and a fair amount of scientific or localized knowledge may be available about it, but there may be many other key components or processes of ecosystems that very little or nothing is known about. Formulated in terms of a metaphor, there may be a number of known "rivets" that keep the ecological support system intact, but there may be a number of other important "rivets" that are not known, that may be discarded or destroyed in ignorance at the peril of humankind (Rolston, 2001). Accordingly, it is often recommended that a cautious approach should be followed in human actions that may have an irreversible impact on the functioning of an ecosystem (Norton, 2003) – because humans may never know when they may destroy something that is crucial to the very functioning of the earth system they depend on for their existence and their well-being.

Amenity Value as Basis of Protection

Besides direct and indirect use value, some nonconsumptive values are also often used to justify protection of the earth system. *Amenity value*, one of these nonconsumptive values, is derived from the mere existence of natural phenomena. While the direct use value of natural phenomena is derived from transforming them, using them up as it were in consumption, amenity value is largely based on keeping the earth system relatively intact, allowing it and its components to be what they naturally are, or letting its processes and systems function and unfold as they naturally do, with the least possible human interference.

A wide range of amenity values can be distinguished that justify protection of the earth system, if not as a whole, then parts of it, in a condition as pristine, free, or wild as possible. In one of his earlier works, without actually using the term amenity value, Warwick Fox (1995) provides an insightful list of the amenity values of what he refers to as untouched nature:

- *Information value*. Scientific studies of untouched nature and the impact of human activities on it can serve as an early warning system that things are starting to go wrong with the health of ecosystems, making it possible to take early remedial measures to minimize the problem. Studying untouched nature can also yield a treasure house of information about the functioning of healthy ecosystems and what could be done to keep them functioning in a healthy state. It can also help to understand evolutionary processes and how humans are not only dependent on it, but also part of it – it helps to understand how humans have arrived at the evolutionary place they currently occupy, how the evolution of culture and nature are codependent upon one another, and how humans are currently influencing that evolutionary process. On the latter point Rolston (2001, p. 404) observes that destroying a species "is like tearing pages out of an unread book, written in a language humans hardly know how to read, about

the place where we live." It denies insight into the history of evolution in which humans are embedded, precluding "insight into the full text of natural history."

- *Recreational value*. The mere existence of natural phenomena also provides a wide range of opportunities for humans to relax from their daily activities. These opportunities can range from taking a walk in a well-preserved forest or along a pristine beach, taking a swim in a clear lake, or testing one's agility and strength by scaling a high cliff in a mountain.
- *Aesthetic value*. Fox argues that nature can also function as an "art gallery" when its components, systems, or processes are contemplated and appreciated for their beauty.
- *Religious value*. Nature, as a whole, or some natural places can also function as sources of religious experience, generating respect for creative processes and creation that surpasses that of humans.
- *Symbolic instruction value*. Fox argues that untouched nature or untouched parts of it can also serve as "monuments," reminding humans of, for instance, symbiotic relationships in nature, or hierarchical relationships in nature, or efficiency in nature in that nothing in nature is wasted.
- *Refuge value*. This is closely related to recreational value, but Fox gives it a special mention to focus on the function that untouched nature can have in the psychological rejuvenation and development of humans. With its contrast to heavily managed places, untouched nature can serve as a necessary counterpoint, helping humans to achieve a psychological balance in their lives but also prompting them to acknowledge that everything on earth need not and cannot be fully managed and that some natural things and systems and processes can just be left alone to be what they are. (As such, this interpretation of amenity value comes very close to the notion of intrinsic value that will be discussed below, but there are some important differences in the arguments for protection of the earth system that are based on amenity values and intrinsic value.)

Taken together, and in interaction with one another, the nonconsumptive amenity values listed above play a large role in the formation of *human character and identity* – of individuals as well as communities. Wild nature, for instance, extremely cold temperatures in winter, or habitats populated by large alpha-predators, can be a survival challenge to humans, but by learning to overcome these challenges with certain behavioral patterns, the character and the identities of humans and communities are formed. These challenges and responding to them become part of the "lived stories they as humans are."

While others have drawn up similar lists, giving slightly different nuances to the notion of amenity value, all of these lists emphasize the value that humans can derive from a nonconsumptive interaction with the components, systems, and processes of the earth system, keeping them as untouched and pristine as possible. Wilderness preservation and wildlife sanctuaries are clear examples of management contexts where these nonconsumptive values are foregrounded. However, these amenity values can also be enjoyed where natural phenomena are kept intact, or restored in urban or industrial spaces to enhance, for example, their

aesthetic appeal, or to break down "the hard edges" of life in manufactured environments. Parks in the centers of cities, or landscaped and beautified industrial areas, simulating natural landscapes are examples of this – serving as reminders that human well-being entails more than merely satisfying material needs.

Apart from the factual question whether the preservation of wilderness areas and wildlife sanctuaries or manufactured landscapes simulating nature are really adequate to stem the tide of biodiversity loss, habitat destruction, ecosystem damage, and destruction of the environment and the biosphere, the biggest conceptual and practical difficulty around amenity values occur when they are for all practical purposes separated from the consumptive, use value of the earth system. Such a separation occurred during the early years of industrialization in the Romantic movement, leading to an isolation of the spiritual and aesthetic dimension of human existence in the experience of nature, which represented the ideal of a rekindling of the human spirit, but also a flight to nature away from the industrialized world that is left to its own devices.

The trap of such a dichotomous world where the sphere of direct use value, dominated by efficiency and optimality, clashes with other dimensions of human existence that are equally essential for human well-being – recreation, aesthetic enjoyment, spirituality, and psychological rejuvenation – is still evident in the environmental debate today. The challenge, therefore, seems to be in finding a sufficient integration of direct use value and amenity value, and this could perhaps help to appreciate the manner in which humans are dependent for both survival and well-being on the existence of a well-functioning earth system. In the discussion below of *ecosystem services*, an effort is made visible to think direct use value and amenity value together right from the start.

Option Value as Basis of Protection

Protection of the earth system is also often justified on the basis of *option value*, an important nonconsumptive value that can be distinguished from amenity value. While direct and indirect use value as well as amenity value are derived from the known present value of components, systems, and processes of the earth system, option value is derived from the *unknown future value* that humans may derive from a well-functioning and healthy earth system. Option value entails the potential value that humans may derive from the components, systems, and processes of the earth system – whether it is direct use value or nonconsumptive amenity value. An as yet undiscovered species, for example, may in future yield the cure for AIDS; as an already discovered species that is currently regarded as of little medicinal value may prove to be highly valuable in the fight against a tropical disease that may develop in, say, 50 years' time from now. However, if these species are not in existence in the future, either to be discovered or to be used in a new application, humankind has lost its ability to exercise certain options.

But option value is not only dependent on the protection of the components of the earth system, for example, biodiversity on all of its levels (genetic, species, ecosystems). Option value is also and predominantly dependent on the systems and processes that generate, for example, ecosystems and biodiversity in the first place – and thus it is these processes that should be protected for the sake of future generations, the argument goes. In almost lyrical terms, Wilson (1988) points to *biodiversity* as a "frontier of the future" (see Faith, 2008, pp. 3–4). From an evolutionary point of view, Wilson (1988) argues that biodiversity presents "a dazzling prospect of largely unknown variety, with unanticipated uses" (Faith, p. 3). But even more importantly, from an evolutionary point of view, option value represents and recognizes the possibility of new forms of life and of forms of existence and interaction that are not existent yet but can emerge if the earth system is protected to function well and without irreversible damage.

Option value, however, is extremely difficult to translate into conservation policies and actions – mainly for two reasons. In the first place, humans are subject to cognitive constraints: they do not know exactly what the preferences of future generations will be and also do not have complete knowledge at present of all of the component parts and all of the systems and processes that maintain a healthy and robust earth system. Faith (2008, p. 3) refers to this as the problem of "unknown variety and unknown value." In the second place, humans may not be able to save all of the components of the earth system and all of its evolutionary systems and processes that will ensure its maintenance and evolution. The costs involved to do so may be prohibitive.

Norton (2003) acknowledges this uncertainty about the exact preferences of future generations, but based on general human experience, he argues that those living now may be pretty sure that future generations may not want to inherit a world that is poorer in options than the one this generation has inherited from its ancestors. Those living now may also be sure that future generations will not want to inherit a world that is full of unpleasant surprises, such as toxic waste or ecological time bombs that were passed on to them. Accordingly, Norton argues (2003, p. 301) that those living now should do their utmost best to adopt policies that ensure the healthy functioning of the creative processes of nature that will maintain complexity, biodiversity, and evolution and at the same time make it possible to learn more about the components of life, the systems, and the evolutionary processes in which they are embedded.

When it comes to the question of how much should be invested in this, Norton (2003) is hesitant to argue for protection at all costs. However, from the point of view of his environmental pragmatism in which he opts for the coexistence of a plurality of values that should inform conservation efforts, he argues that conservative safe minimum standards should be set for activities whose effects are reversible at a reasonable cost in the short or medium term. He also argues that a precautionary approach should be followed (where costs are put in the background) when human action start to have irreversible effects – for instance, pushing a species toward the brink of extinction.

Existence Value

Existence value is usually reserved for elements of the earth system, such as dramatic landscapes or magnificent animals such as lions, wolves, ice bears, whales, dolphins, elephants, and rhinoceros, but it can also be extended to the earth system as a whole, either in its component parts such as biodiversity, biomes, and ecological "hotspots" where a number of biomes intersect to bring about an unusual concentration of diversity, ecosystems, or communities of life, or conceptualized in terms of the processes at work in these systems. This value represents *the satisfaction humans experience* from the knowledge of the mere existence of phenomena such as these, over and above any of the use values mentioned above. Encountering a pride of lions in a conservation area, for instance, may be the high point of a visit to Africa, while spotting an ice bear may have the same value for those on a visit to Siberia (see Rolston, 2001): the mere existence of these animals and the species they belong to are regarded as highly valuable, and therefore, the argument goes, these animals and their species should be protected. Existence value thus move very close to the argument that the earth system, its component parts, and its processes should be protected for their own sake (see O'Neill et al., 2008), but in so far as this argument is still based on instrumental value, albeit a subtle and nonconsumptive version of it, it cannot be equated to intrinsic value, as will be shown below (see Afeissa (2009) for an insightful discussion of the difference between instrumental and intrinsic value in environmental ethics).

Ecosystem Services as Basis for Protection

While a number of different kinds of use value can serve as basis to protect the earth system, it is clear from the discussion above that these kinds of values can be separated from one another and even played off against each other if they are not put into some kind of systematic relationship right from the outset. Direct use value, for instance, always seems to be the most obvious basis for protection, but this value, if not strongly qualified by indirect use values, amenity, option, and existence values, can serve as basis to justify the complete opposite of protection, namely, the overexploitation or even destruction of the earth system.

In response to this need, the notion of *ecosystem services* has emerged in an effort to conceptualize different kinds of use values in relationship with one another, mapping how they are mutually dependent upon one another, and how they all, in combination with one another, through direct, indirect, and nonconsumptive use value, contribute not only to the physical survival of human beings but also to their identity, general well-being, and quality of life. Usually, four main categories of ecosystem services are distinguished, three of which represent direct services (namely, provisioning, regulating, and cultural services), while the fourth represents a cluster of indirect services in the sense of supporting the other direct services (Millennium Ecosystem Assessment, 2005). As such, these categories of ecosystem services cut across the distinction of the direct and indirect use values, amenity, option, and existence values that can be derived from the earth system.

Provisioning ecosystem services include things such as food, fresh water, wood, fiber, and fuel that can be directly provided by natural entities, systems, and processes. But these basic goods can also be provided by way of artificial systems such as farms, water purification plants, plantations, and refineries. The point, however, is that all of these secondary provisioning services are dependent in some way or another on direct provisioning coming from natural entities, systems, and processes.

Regulating ecosystem services include climate regulation, flood regulation, disease regulation, and purification of water. Cultural ecosystem services, in turn, include the aesthetic or spiritual experience of natural entities, systems, and processes, or using them as a source of education or a space for recreation and rejuvenation. Supporting ecosystem services form the foundation of the other services that have already been mentioned and include nutrient cycling, soil formation, and primary production of which photosynthesis is an example.

While the components of human well-being and quality of life are fields of study for the different disciplines of the social and human sciences, there is agreement among most social scientists that security, access to the basic material for a good life, health, good social relations, and freedom of choice and action form the basic components of human well-being. Security includes personal safety, secure access to resources, and protection from disasters, while the material for a good life includes adequate livelihoods, sufficient nutritious food, shelter, and access to goods. Health, in turn, requires strength, feeling well, and access to clean air and water, while freedom of choice and action entail the opportunity to be able to achieve what an individual values doing and being (Millennium Ecosystem Assessment 2005, *Synthesis*, p. vi).

What must be emphasized as the core of this approach, but is often overlooked, is that the ecosystem services that support human well-being are all based on *biodiversity*, as it is understood in the *Millennium Ecosystem Assessment* as life on earth in general. In this meaning, "biodiversity" approximates the meaning of "earth system" as it has been used in this chapter. Something of this insight is captured in the United Nations Convention on Biological Diversity (1992) where it is stated that biodiversity should be protected because it provides the foundation of the "social, economic, scientific, educational, cultural, recreational and aesthetic values" that contribute to human well-being. However, as such, biodiversity, understood as life on earth, is not only a value among other values in a human calculus of what contributes or not to human well-being. Biodiversity rather forms the basis of such a value calculus. As Norton (2003, p. 501) has argued, "biodiversity ... is not a resource among others, but a generator – a source – of biological resources." Thus, biodiversity, understood as life on earth in general (i.e., including the environment and biosphere), is a necessary condition of the use values that can be derived directly or indirectly, consumptively or nonconsumptively, from the earth system, while biodiversity as life on earth, as this necessary condition of resource values, is not a resource itself.

With this insight, a notion of value is revealed that actually falls outside the ambit of ecosystem services, or direct, indirect, and nonconsumptive use values that

can be played off against one another in a calculus of what does and what does not promote human interests. It is the notion of value that makes the ecosystem services and use values of the environment, the biosphere, and biological resources possible – and as such, this value approximates the notion of the intrinsic value of the environment, the biosphere, and biodiversity, but is perhaps not exactly coinciding with it (see Afeissa, 2009), as will be shown in the next section.

Intrinsic Value

Intrinsic value features very prominently in arguments for protection of the earth system from an ethical point of view. Since the inception of environmental ethics in the middle 1970s, different aspects of the earth system have been singled out to have intrinsic value, ranging from certain individual animals (Tom Regan), any living entity (Paul Taylor), land (Aldo Leopold), species and ecosystems (Baird Callicott and Holmes Rolston), the community of life (Aldo Leopold), the evolutionary process (Rolston), the abundance and diversity of life and its flourishing (Arne Naess), and so the list can go on. The one element common to all of these arguments is the recognition that the whole of the earth system, or its component parts and constitutive processes, have value in and of themselves, regardless of any human use that can be derived from them. On the basis of intrinsic value, it is then further argued that these elements or the whole of the earth system should be morally considered or respected in their own right and not for their instrumental value for humans. Differently formulated, intrinsic value means that humans have direct moral duties to the earth system and its component parts and processes.

While there are debates between supporters of the intrinsic value approach, with some arguing for intrinsic value as objectively located within nature (Holmes Rolston) and others maintaining that intrinsic value is subjectively attributed by humans to nature (Baird Callicott), intrinsic value in this context, in whichever way it is deemed to be constituted, can be equated to a respectful reverence for all life in its variety and abundance, for individual entities as well as for the systems and processes making this variety and abundance possible. From this perspective, any loss of abundance and variety through, for instance, human-caused extinctions, represents a loss from the rich and complex tapestry that life itself is, consisting of a continuing process of complex interaction and biological creativity that unfolds through evolution.

In the words of Holmes Rolston (2001), the loss of a species is the loss of genetic possibilities – it is the death of a type and thus the loss of a form of life itself. In so far as a species represents an adaptive fit with a particular habitat that has evolved over millennia, a human-caused extinction represents a shutdown in a very long evolutionary story, and it leaves no further possibilities of regeneration, speciation, and the creation of further biological variety. Rolston argues that artificial extinctions in distinction from natural ones impoverish the earth system and close down the spontaneous evolution that otherwise would have taken place. For Rolston, the difference between a natural extinction and an artificial extinction can in moral terms be likened to the difference between death by natural causes and murder.

Accordingly, Rolston argues (2001) that humans have no direct moral duty to preserve species from natural extinction, although they do have a direct moral duty to avoid artificial extinctions. But Rolston goes even further by claiming humans also have direct moral duties to the habitats, biomes, and evolutionary processes that generate species in their abundance and variety in the first place. It is not only important that *species* are protected but that species are protected *within the system* that they survive and evolve. In this perspective, the appropriate level of moral concern is not the individual – either persons or sentient beings – as conventional Western ethics will maintain, but rather the appropriate survival unit that leads to the existence of individuals, like species, habitats, biomes, and evolutionary processes.

The central concern of Rolston's environmental ethics is thus not so much the loss of resources that humans may experience in the destruction of the environment, the biosphere, and biodiversity but rather the killing of and insensitivity to forms of life that stands within an evolutionary history. Accordingly, Rolston argues, the core of environmental ethics should be much more than prudence; it should entail a principled responsibility with the primary duty to consider every form of life as valuable in itself and to care for and about it – except for pest and disease species. With reference to the human species as a late arrival in evolutionary history, and the tendency of this species to act in mere self-interest, Rolston states (2001, p. 414): "On the naturalistic account, the host of species has a claim to care in its own right. There is something Newtonian, not yet Einsteinian, besides something morally naïve, about living in a reference frame where one species takes itself as absolute and values everything else relative to its utility."

Like option and existence value, the intrinsic value of the earth system is extremely difficult to translate into policy terms or into action – mainly because intrinsic value is so vastly different in nature from instrumental or use value. In fact, intrinsic value is mostly evoked in arguments to oppose the overemphasis of use value that often leads to an overexploitation of the earth system and sometimes even to its destruction (see O'Neill et al., 2008). The argument then usually goes that a natural resource cannot be treated in this manner because it has intrinsic value – it is alive – and forms a part of a rich web of life that has value independent from human use value and stands to be damaged or destroyed by human activity.

Under one extreme interpretation of this approach, the appeal to intrinsic value can be seen as an argument for the total protection of nature/the earth system (see Norton, 2003, p. 125), saving all of it at all costs. However, many will reject this as a legitimate management goal because, they would claim, it cannot be implemented without severe negative impacts on human well-being. A total "hands-off" approach to the earth system, they would argue, would bring agriculture, science, and medicine to a total halt, making it impossible for humankind to survive, let alone to thrive.

There is, however, a less extreme interpretation of intrinsic value possible that still opposes the reduction of nature and life to a commodity and rather sees the intrinsic value of the earth system and of life as point of departure for a caring and careful interaction with the earth system and the life it supports, in which its

richness and diversity are embraced as valuable in itself – and is protected, cared for, nourished, and celebrated for nothing else than it being the wonder it is (Rolston, 2001). The general thrust of recognizing intrinsic value from this perspective is not in the first place to protect the earth system and life from harm but rather to enhance the earth system and the life it sustains so that it can flourish – for its own sake, in its own way (see Swilling & Annecke, 2012). The flourishing of life is thus the point of departure; it is not relegated to an afterthought after human use value has taken precedence.

From this point of view, intrinsic value does not entail a total abolishment of the human use of the earth system but rather opens up space for a modest use of it, inspired by the premise of the wonder of life as something extremely precious and fragile, something that requires respect and care – not only for the individual elements of life but also for life in general as a whole, together with all the conditions that make life possible in the first place. Under this interpretation, arguments for protecting the earth system based on the notion of intrinsic value do not stand far apart from arguments for protection based on option and existence values. The internal logic of intrinsic value, however, differs from the instrumental logic within which option and existence values are embedded. Intrinsic value arguments entail an approach of principled responsibility to be careful and take care of all life as valuable in itself, while instrumental value arguments entail a prudential approach to resource preservation in which human interests stand central.

Integrating the Value Arguments

From the discussion above, it can again be stated that protection of the earth system is more than just a green issue – in the narrow sense of focusing only on nature conservation. The different instrumental values derived from the earth system emphasize that its protection is ultimately done to ensure the well-being, and satisfy the interests of humans. In the words of Rolston (2001, p. 403), protection of the earth system justified from this perspective "is ultimately for the purpose of its enlightened exploitation." The emphasis on ecosystem services forming the foundation of the well-being of humans underscores this point. Instrumental value arguments for the protection of the earth system, however, presuppose a sort of separation between humankind on the one hand and the earth system on the other hand: The earth system is seen as something removed that stands at a distance from humans, and the mode of interaction with it is that of an object of management (often at arm's length) to make it and its component parts and processes available to "serve" humans in a variety of ways to satisfy their interests. In order for it to be available for human use, the earth system (comprising of the environment, the biosphere, and biodiversity) is simplified and reduced to become something less than what it fully is.

From an intrinsic value point of view, this separation and reductionism are challenged. Instead, the fundamental unity of humankind with the earth system is emphasized, arguing that human life, together with all other forms of life, emerged

from a long history of evolution that has value in and of itself. From this perspective, protection of the earth system, that is, ensuring that the earth system is functioning well and continuing with its process of spontaneous evolution, is done for its own sake, regardless of any use value it may have for humans. Stated in positive terms, and under a modest interpretation of intrinsic value, the earth system is protected to enhance the richness, abundance, and flourishing of life – for the sake of life itself. In practical terms, this implies that humans, while dependent for their survival and well-being on well-functioning ecosystem services, should always see the earth system, in its component parts and processes, as well as the whole that it forms, as something much more than just a commodity or an amenity or an option that are or could be of use to humans. From an intrinsic value point of view, the earth system should rather be acknowledged as the very basis of the wonder of life itself, and therefore, it should be respected, treated, cared for, and celebrated as such.

From both angles then, strong arguments can be made for protecting the earth system. From a use value point of view, it is argued that the preconditions for human well-being can be lost if the ecosystem services provided by the environment, the biosphere, and biodiversity are not protected. From an intrinsic value point of view, it is argued that life itself will be diminished if the earth system is not protected and cared for. While the internal logic of instrumental and intrinsic value approaches differ vastly from one another, a survey of the environmental attitudes of the general public in the USA (Kempton, Boster, & Hartley, 1995) has found that the earth system/the environment is appreciated both instrumentally and intrinsically.

This is an important finding, although it calls for further studies in other countries. It means that there is a lot of common ground between the espoused attitudes of environmentalists and resource users, even if the challenge clearly lies in the translation of attitudes into action in a global transition from a development path based on overexploitation and even destruction in some cases of natural resources, to one that is based on justice and respect for all of life on earth.

In rising to this challenge, it is clear that humankind will have to figure out how to combine instrumental and intrinsic value with one another in an intelligent and productive manner in the very concrete management, and life choices that will have to be made in everyday contexts. Formulated in general terms, this will require that some limits are placed on consumptive use that leads to overexploitation, damage, and destruction of the earth system, but also that realism is brought to human action in response to the runaway idealism that sometimes characterizes ideas about the nonconsumptive value of the earth system, or its intrinsic value.

Conclusion: An Outlook for the Future of the Environment, the Biosphere, and Biodiversity

At the time of writing, 40 years after the Club of Rome has published its report on the limits to growth in 1972, the outlook for the future of the earth system looks bleak. In the second finding of the *Biodiversity Synthesis* of its report on *Ecosystems*

and Human Well-Being (http://www.maweb.org/documents/document.354.aspx.pdf), the *Millennium Ecosystem Assessment* stated that "The drivers of loss of biodiversity and the drivers of changes in ecosystem services are either steady, show no evidence of declining over time, or are increasing in intensity" (p. 8). The same conclusion is reached in the *Global Biodiversity Outlook 3* that was published in 2010 by the United Nations Environmental Programme (UNEP), placing the loss of biodiversity and ecosystem services within the framework of a collective, global failure that will require extraordinary measures to turn around.

Having considered the state of biodiversity in 2010, the *Global Biodiversity Outlook 3* found that the "five principal pressures directly driving biodiversity loss (habitat change, overexploitation, pollution, invasive alien species and climate change) are either constant or increasing in intensity," and that the "ecological footprint of humanity exceeds the biological capacity of the Earth by a wider margin than at the time the 2010 target was agreed" (p. 9).

With this continuing and intensifying loss of biodiversity and ecosystem services due to human activities, the general consensus among scientists from a wide range of disciplines is that humankind is at risk to push the earth system beyond certain thresholds or tipping points "that could lead to large, rapid and potentially irreversible changes" (p. 71). As defined in the *Global Biodiversity Outlook 3*, a tipping point is a situation in which an ecosystem experiences an abrupt shift to a new state, "with significant changes to biodiversity and the services to people it underpins, at a regional or global scale," which will first and foremost affect the poor populations of the world since they are mostly directly dependent on the ecosystem services of the natural environment (p. 71, 72).

This outlook becomes bleaker if it is taken into account that the world population is expected to grow to nine billion in 2050, an increase of two billion people over the seven billion that the world population is in 2012. With higher demands placed on the agricultural sector to provide food for nine billion people, it can be expected that more and more pressure will be exerted on the earth system. At the same time, this will put more pressure on those societies that are already marginalized and are directly dependent on the maintenance of well-functioning ecosystems for their survival. For the future, this will require an intensification of an ethics of limits, justice, and sharing, in which efforts should be significantly increased to restore those ecosystems and ecosystem services that have already been damaged, to prevent further damage to those ecosystems and ecosystem services that are still intact, and to work toward a transition in which the conditions that sustain the flourishing of life on earth – all life on earth – are really cared for and enhanced.

In such an ethic of restoration, care, and transition, people and justice will have to play a central part, since life cannot be respected and celebrated without everyone enjoying their fair share of its richness and abundance (see Swilling & Annecke, 2012). While numerous examples exist of groups, organizations, and societies experimenting with the practical implementation of such an ethics in efforts to learn again how to live sustainably in a particular place, humankind is unfortunately a far way off from a position where mainstream decision-makers,

governments, and business organizations make the transition to this ethic. It is possible, though, for individuals, consumers, landowners, NGOs, and any custodian of the smallest part of the earth system to influence these mainstream role-players and to start living this ethics of becoming sustainable in a place – even if this may entail overcoming prejudice and ideological resistance.

African Perspectives

Jude M. Mathooko and Julius K. Kipkemboi

Introduction

Africa is a continent of complexities, with a wide diversity in terms of climate, topography, culture, peoples, and languages. This diversity characterizes the people's relationship with the environment and with each other. It, therefore, implies that any attempt to unify any aspect of life would be a daunting task and would require some ingenuity to do so. With pockets of diversity scattered all over the continent, a broad understanding of the African diverse landscape is of paramount importance if the African perspective in bioethics is to be fully addressed. It appears, therefore, that bioethics, which is the study of ethics in the fields of life sciences, medicine, and the related technologies, is enshrined in the lives of Africans and defines their existence and their connectivity with each other and with the environment in which they live. This environment has dictated the type of bioethics that has emerged over the years since an African draws, consciously or subconsciously, his or her bioethical practices and reflections from it. Intuitively, bioethics reflections are guided by the available resources in the familiar environment and how they are utilized while cautiously adapting to the forces of externalities.

African perspectives of bioethics revolve around harmonious coexistence with the cosmos and the promotion, defense, and protection of life, including maintaining the integrity of the human species, protecting the dignity of the person, and protecting nature and diversity. These tenets are well enshrined in the Universal Declaration on Bioethics and Human Rights (UDBHR) and it is useful to relate the African perspectives on bioethics to it. However, while most of the normative instruments for bioethics are generic and universal, they cannot be implemented

DOI 10.1007/978-94-007-2512-6_81,

in totality before being domesticated and interpreted in concurrence with the African way of thinking and acting. Further, van Bogaert (2007) stated that the diverse cultures, ethnic groups, ways of life, and world views of Africa share a common underlying concept of bioethics that is centered around the traditional ideal of kinship and personhood. This idea emphasizes the ties of kinship in which the concept of a person is tied to the community, where persons become persons only after incorporation into the community.

During the 14th Ordinary Session of the International Bioethics Committee (IBC) held in Nairobi in 2007, African perspectives were discussed and organized around the following themes: what is special about bioethics in Africa? an overview; challenges and institutional constraints on bioethics development in Africa; legislative and administrative measures for the implementation of the Universal Declaration on Bioethics and Human Rights in Africa; and moral sensibilities and emerging technologies: implications for Africa. The speakers attempted and did their best to go round these themes despite limited time. Despite their in-depth contributions, African bioethics still has glaring gaps that this chapter attempts to fill, especially the status of bioethics education in Africa. The agenda for the Nairobi IBC meeting, therefore, provides the backbone of this contribution bearing in mind the complexities attached to this issue.

Characteristics

Bioethics: New or an Old Concept in Africa?

It has been argued in several forums that bioethics is a new concept in Africa. In this chapter, a two-pronged view is given – in practice, no; as a study, yes. African communities, like other communities all over the world, have been employing bioethical approaches in tackling their life challenges since time immemorial. Bioethics is part of life and is practiced, subconsciously or unconsciously, by humans as they tackle challenges of life, transformations from one practice to the other, and during intergenerational transitions. What makes it appear as new is when it is considered as an evolving study, with its jargon and terminologies to describe it, raising the question: which comes first – the practice or the evolution of definitive terms of study? Generally, ethical activities come first and terminologies are coined to describe the actions and practices. Therefore, African bioethics, defined in terms of practices and reflections, is not new but has been in existence from antiquity to the present. It should be remembered that bioethics is not about use of terminologies and evolution of words but about actions in relation to human life *vis-à-vis* its relation with the environment.

Is There an African Bioethics?

Africa is a complex multicultural society and is believed to be the cradle of humankind, which could provide insights into medieval bioethics practices and

thinking. Lamentably, African bioethics, in its present form, has been transformed into hybrid bioethics through infusion and domination by foreign concepts developed in the Western world, some of which are not relevant to the practices in Africa. Perhaps, this could be one of the reasons why bioethics has experienced a slow development in Africa. Cultures cannot exist in isolation and are not impervious to the influence by other cultures, and the African culture is not an exception. However, it is important to realize that bioethical practices and reflections of a community or race cannot be decimated in totality by any culture without encountering some form of resistance. If bioethics is to be popularized globally, it is imperative that the best practices and reflections in each culture be harnessed and promoted without infringing on the rights of the individuals and the communities or races. This is perhaps why UNESCO member states focused on generality and universality in the UDBHR to accommodate the wishes of the different races of the world. It is time to assess how far the western bioethical ideologies have intruded into the African bioethics as a response to the scientific and technological transfer and advancement in the Western world, coupled with the rapid globalization.

In Africa, different bioethical reflections do exist, but there are also certain ethical principles that transcend both culture and geographical boundaries. Therefore, a globalized bioethics approach cannot apply to the diverse bioethical reflections in Africa and elsewhere. A truly global ethics, if there is any, should take into account bioethical pluralism, including the coexistence of alternative and competing ethical frameworks. It is therefore within this diversity of ethical reflections where the differentiation of African bioethics converges and diverges from the other ethical reflections. An effort should be made to harmonize the cultural, religious, and secular approaches to bioethics, a task that could be daunting in Africa. One wonders how many approaches and schools of thought there are on African bioethics and how much of this bioethics is migrated to the Western world. Complaints abound on the export and import of bioethical concepts into the different cultures. However, bioethics as it is today is trapped in Western categories of thought and relies heavily on Western analytical philosophy without decimating completely the African philosophical thought. Mbugua (2009) notes that the question of whether or not African bioethics exists cannot be addressed without due cognizance of the answer to the question of whether or not an African philosophy exists. He further expounds in a philosophical manner that since bioethics is one branch of ethics, to assert the existence of an African philosophy is to assert the existence of an African bioethics, which in turn, is one of the traditional branches of philosophy. However, other schools of thought postulate that to speak of African philosophy is to make a huge generalization because Africa as a continent is very heterogeneous, with numerous ethnic groups, each with a unique identity. There is a fast influence of technological transfer into the region and concomitant bioethical ideologies. While these concepts are useful as precautionary approaches, there is a need to contextualize them. Meanwhile, it could rightly be postulated that African bioethics has evolved over time and is now a hybrid between the African and Western bioethics.

Individualism Versus Communitarianism in the African Bioethical Approaches

The African cultures are tightly held by communities and each community has its own way of operation; they also think and act collectively as a community and in most cases the autonomy of an individual is eroded by decisions made by a well-structured clique of elders whose decisions are revered and final. Going against such decisions is going against the whole community and could lead to being banished from the community or a severe punishment could be meted upon you. The happiness of the community therefore supersedes that of the individual. Due to the problems of underdevelopment, poverty, preventable communicable diseases, poor healthcare infrastructure, and differences in belief systems, bioethics emerges consciously or subconsciously over time and responses to these emergencies dictate the bioethical practices and reflections. From this also emanates the African philosophy that is seen as an item of communal property rather than an activity of an individual. However, African bioethics can be approached, not only ethno-philosophically but also as professional philosophy approach. This dichotomy is extremely important if the so-called African bioethics is understood.

From the foregoing, it is clear that in reflecting on bioethics in the past traditional Africa, one has to look at the context of traditional Africa in which the social fabric was embedded in diverse cultures based on informed decision on human dignity and human rights. During this era, cultures shaped morality and consequently values that guided personal and communal life. In this regard, a person was attached to the community and this emphasizes the uniqueness of bioethics approaches in the African context (van Bogaert, 2007). The core traditional values have, however, been influenced by globalization. Individualism has taken over communitarianism and this is perhaps why Africa is grappling with the issue of informed consent in research, development, and practice of modern medicine.

Africa: ignore Bioethics at Your Own Peril: Selected Issues of Bioethical Concern

As stated earlier, African bioethics is very complex if it ever exists. To attempt to understand it requires teasing the discussion into a few aspects that could address more vividly bioethics in the African perspectives. These are not, in any way, exhaustive but will help to shed some light on the current status of the African bioethics.

Traditional Medicine

Traditional medicine in Africa is as old as human civilization. Africa has comparative advantages in indigenous medical knowledge, biodiversity, and diagnostics development. Traditional medicine is sometimes misused and is currently not regulated. Research should therefore be undertaken to identify the appropriate evidence-based tools, standards, policies, safeguards, codes of ethics, and codes

of practice for assessing and enhancing traditional medicine. Furthermore, there are several aspects of bioethics that concern and conflict with other general practices as viewed by Western bioethicists who mistakenly discern it as witchcraft or magic. This is further complicated by the fact that there is always a thin line between the spiritual aspect of healing with traditional medicine practice. This blends well with conventional medicine-religion synergy whereby the medics treat and healing is through faith.

In Africa and even beyond, traditional medicine is still respected as a cure to most diseases, with the advantage that the raw materials for such are extracted from resources available in the immediate environment, and many of the medicines are dispensed in raw form unlike the Western medicines. What the traditional medicine lacks are the bioethical guidelines and regulations. Disease ethics is treated as per traditional beliefs in some communities and some are viewed as curse and no need to seek for further medication if the traditional medication fails. Other beliefs and religions even bar a sick person to be taken to hospital, thus violating human rights pertaining to treatment. In other contexts, especially where religion has penetrated and influenced the way of thinking of the communities, both Western and traditional medicine could be used. Western medicine and traditional medicine should be viewed as two different co-existing systems that should complement each other through use of accurate knowledge acquired through dialogue.

One challenge that arises when dealing with African traditional medicine is when it is benchmarked, evaluated, and equated to that of modern medicine. Arguably, the main ethical issues in African traditional medicine are informed consent, paternalism, and lack of confidentiality. Another challenge is the fact that traditional medicine practitioners often take all the powers of decision from the patient. Van Boegart (2007), on the other hand, argues that one has to go beyond the routine conventional methods of drug development and perhaps look at the context and conditions in which the African traditional medicine is applied. Nevertheless, it is estimated that about 80 % of the population in Africa still relies on traditional medicine. The high percentage using traditional medicine is perhaps a good testimony that modern medicine has lost its efficacy against the new emerging diseases and therefore most ailing persons have lost hope in modern medicine. This is also exacerbated by the poor economies of most of the African countries, which cannot cater fully to the health of their citizens. There is still a dearth of information on how bioethical concepts can be applied to the traditional medicine. One of the missing links is research on African traditional medicine as it was largely acquired through apprenticeships in the past. There are, however, efforts being made to create synergy and complementarity of the African traditional medicine and contemporary medicine. The other challenge is dealing with quacks, whose sole interest is not the patient but money.

Legislation in Bioethics

The bioethical practices and reflections are not guided by any known legislation but by controls within the wide spectrum of communities. Communities have their own rules and regulations when dealing with bioethical practices and they slavishly

adhere to them. However, with the high diversity of communities, African bioethics lacks universality and this makes legislation on its application very complicated. Some governments have attempted to develop legislation that addresses issues related to bioethics, especially those related to life and human dignity. Issues on abortion and female genital mutilation (FGM) have recently received a lot of debate. Some communities still practice FGM even when governments have outlawed the practice. African governments should, therefore, develop controls and regulations on the application of bioethics through a universal understanding on which practices are not applicable in the modern world. Perhaps, it is the lack of legislation that has made the domestication and application of the Universal Declaration on Bioethics and Human Rights difficult.

Advancement in Medical Technologies

Issues on how emerging technologies are influencing bioethical practices in Africa are pertinent and need to be critically examined. African bioethics does not and should not dwell on Western technological advances at the expense of locally available technologies that have been used for many generations. Bioethical thinking is constructed through association with the environment in which one lives; it cannot be build on tangible instruments one has not associated with. Use of age-old technology in African health care is not new and some are as old as the early civilizations in Africa. It is proposed that they should be used alongside the modern technologies.

Embracing Bioethics in Research

The strength of bioethics lies in the regulation of research on human and animal subjects. In the past few decades, Africa has received increased funding towards international research, concentrating mainly in agricultural biotechnologies and biomedical research. There has always been debate on how this research benefits poor countries struggling with poverty and how it impacts on the existing biodiversity. On biomedical research, the main issues revolve around Article 14 (social responsibility and health) and Article 15 (sharing of benefits) of the Universal Declaration on Bioethics and Human Rights. As a response to this challenge, African countries have set up frameworks for research ethics and biosafety committees. There exist 21 national bioethics committees in various African countries (WHO, 2011) whose jurisdiction should be separate and distinct from the jurisdiction of other committees and institutional bodies (UNESCO, 2006).

The other area with challenges in research in the African context is the issue of collaborative research and sharing of benefits accruing from research. Often because of weak legal frameworks, there are cases of infringement of intellectual property rights due to an unclear research environment. Research on bioethics in Africa is in its infancy and very few universities and research institutes are engaged in such research. One of the most plausible reasons for the slow uptake is the enormous cost of undertaking research related to bioethics coupled with the high cost of equipment. With Africa being strong in biology (UNESCO, 2010), it would seem easy to embrace bioethics in research and to research on bioethics. However,

Africa needs to adopt the "fifarization concept" (*sensu* UNESCO, 2010) to ameliorate the effects of brain drain witnessed in the recent decades if it is to jumpstart this process.

Medicine has its challenges in Africa. One of the most controversial issues in medicine is clinical trials. These are usually carried out by multinational companies and often pose ethical dilemmas. Often the issues of nonmaleficence, sharing of benefits, and inadequate information and consequently informed consent emerge (Kilama, 2005; 2010). There seem to be gaps in information dissemination in clinical research trials, which has led to negative attitudes towards them. For instance, in some cases, vaccinations have been rejected because of inadequate information (Jegede, 2007). Africans, by their nature, are sensitive and skeptical of any scientific activity conducted without prior information and briefing.

African Bioethics in the Context of the UDBHR

African states have embraced the principles of the Universal Declarations on Bioethics and Human Rights and what remains for many states is the interpretation and domestication of the declaration to permit implementation. Langlois (2007) highlights the development of various instruments in the continent with specific reference to Kenya and South Africa that are in tandem with the UDBHR. She singles out particular articles of the declaration such as community consent (Article 6), vulnerability (Article 8), cultural diversity and pluralism (Article 9), social responsibility (Article 14), benefit sharing (Article 15), transnational practices (Article 21), and bioethics education, training and information (Article 23) as areas where concerted efforts in the implementation of the declaration have been realized. A number of countries in Africa have made efforts to domesticate the declaration through workshops and ethics education. In Kenya, for instance, there was a workshop on the UDBHR in 2009 organized by the UNESCO Regional Centre for Documentation and Research on Bioethics and the Kenya National Commission for UNESCO in which participants were drawn from Kenya, South Africa, and the Democratic Republic of Congo. For the UDBHR to be fully implemented in Africa, UNESCO needs to come up with facilitation strategies and a generic implementation plan that could serve as a guide for member states.

Bioethics Education in Africa

The relevance of bioethics education in Africa is not in doubt, especially with the fast advancement of science, technology, and innovations. This has encouraged the proliferation of contentious and questionable insights that could be perilous to one's own existence. For instance, a report that scientists have succeeded in creating artificial life in a test tube could be used to "play God" with life

(Saturday Nation, 2010). Furthermore, the debate on genetic engineering and genetically modified organisms (GMOs) still continues without any foreseeable conclusion. All these advances raise bioethical issues that need to be addressed before any decisions are made.

With bioethics applications becoming more apparent and its relevance transcending all spheres of life and the existence of the human race and biosphere generally, it is time that bioethics education be made a compulsory course in universities in Africa. Its inclusion in the curriculum will also enhance the understanding of bioethical dilemmas in traditional medicine, HIV/AIDS, female genital mutilation, abortion, and environmental degradation that Africa faces.

Despite the efforts by UNESCO to promote bioethics education in Africa, it is still in its infancy and its development is bedeviled by numerous challenges. Therefore, its extent and current status are unknown and also difficult to ascertain. Like in any other part of the world, bioethics is a bridge to the future. It is against this backdrop that there is need for evaluation and management of risks in health and environment domains (Dikenou, 2007). Furthermore, there is still an inadequate number of experts on bioethics and hence the need for bioethics training in the continent (Adebamowo, 2007). In pursuit of Article 23 of the Universal Declaration on Bioethics and Human Rights, UNESCO has developed a Core Curriculum on Bioethics. The curriculum, however, needs to be adopted by local institutions of higher learning and the teaching cases contextualized. The present situation in Africa is that ethics and bioethics are taught as hidden curricula in medicine and life sciences (Ogundiran, 2004). When teaching bioethics, care has to be taken not to over-emphasize Western ideologies and downplay the core values of the African traditions.

Whither and Thither Is Bioethics Education in Africa? The Case of Kenya

In Africa, transmission of bioethical information is selective and limited to those groups that are supposed to know. But because ethical issues transcend all groups, it is important that a free flow of information is ensured. Bioethical issues are relevant not only to bioethicists but also to all other spheres of life and professions. Indeed, they are relevant to individuals and societies as a whole (Cheek, 1992). Consequently, any form of information and strategy communicating bioethical issues in education must be selected and dispatched in a form that should be understandable at all levels of the society. Therefore, the goal of bioethics education should be to provide a guide that gives the correct judgment and direction for problems that people are confronted with in their daily lives (Shoji, 2004). Towards this end, it is pertinent that production of teaching materials and delivery of content for different education levels in Africa should cascade and reflect the thinking, traditions, and culture of the people. This is important, especially when tackling bioethical dilemmas, mostly in the field of medicine, both modern and traditional medicine. Most African practitioners in traditional medicine have

no background in taught medicine; they require some education on the application and use of this type of medicine. Further, textbooks and guidelines on ethical applications and approaches are needed; perhaps UNESCO could facilitate the process so that the exercise receives wider acceptability and a global view.

The extent of bioethics education in Africa is unknown and its future status is also difficult to ascertain. This could be as a result of difficulties in conceptualizing what it is and also the lack of emphasis on bioethics in the educational system. This led to the question: "*Whither and thither is bioethics education in Africa?*" In order to answer this question, Kenya will be used as a case study representing most of the African countries as far as bioethics education is concerned.

Promotion of Bioethics in Kenya by UNESCO

Over the years, UNESCO has produced several documents that are useful as reference materials for preparing curricula and teaching of bioethics. Some of these materials include, *inter alia*, the Core Curriculum on Bioethics, the 1997 Universal Declaration on the Human Genome and Human Rights: From Theory to Practice, the 2003 International Declaration on Human Genetic Data, and the 2005 Universal Declaration on Bioethics and Human Rights. Another important source of content is the UNESCO Global Ethics Observatory website. In its endeavor to advance bioethics in the universities world-wide, UNESCO also initiated the UNITWIN Programme in 1992, in which UNESCO Chairs are established within its areas of competence. The program focuses on capacity building through exchange of knowledge and sharing in the spirit of solidarity, that is, the chairs promote globally the ideals of UNESCO and complement its work (Mathooko, 2008). Through this program and with the help of UNESCO, a Chair on Bioethics was established in Kenya in 1998 and it has since been popularizing bioethics through pedagogy, workshops, and conferences. The establishment of the UNESCO Regional Centre for Documentation and Research on Bioethics in 2007 at Egerton University is a further milestone in UNESCO's efforts to promote bioethics in Kenya. The Centre is mandated to promote research and documentation; develop database and share information; collaborate and network; contribute to education and capacity building through training; and to initiate, guide and contribute to public debate on bioethical issues.

In order to support bioethics implementation in institutions, UNESCO conducts the Ethics Teacher Training Course, from which Kenya has so far benefited. This course provides training to bioethics teachers with the purpose of enhancing their skills and abilities. It further aims particularly at training a younger generation of teachers so that ethics teaching programs in the near future can expand and improve in all member states of UNESCO, Kenya being one of them. In this regard, Kenyan universities could also take the lead in bioethics education development in the region.

UNESCO has also supported meetings, conferences, and workshops in order to enhance bioethical reflections within institutions of higher learning in Kenya. Kenya has been at the forefront in the domestication of the Universal Declaration on Bioethics and Human Rights in the East African region. Already, one international conference on "*Bioethical Perspectives and Practices in Research, Medicine*,

Life Sciences and Related Technologies in sub-Saharan Africa" was organized by the UNESCO Regional Centre for Documentation and Research on Bioethics in 2008. Furthermore, a workshop on "*Sub-regional capacity building on the interpretation and domestication of the Universal Declaration on Bioethics and Human Rights*" was held in Nairobi in 2009. These efforts by UNESCO underscore and demonstrate the importance of bioethics in the modern world.

Bioethics Status in Kenyan Public Universities

Although bioethics is desperately needed in the medical fraternity, most medical training curricula are not explicit on inclusion of bioethics and very few books are available for its teaching. Kenya has in recent years played key roles in the development of bioethics instruments, but bioethics training still lags behind in the Kenyan universities despite the existence of the affirmations of the Dakar Declaration on Ethics and Bioethics in 2003 and in particular that of the necessity to put in place programs of training and teaching on bioethics. With this slow pace in the development of bioethics education, the question that remains is: *Is there a place for Bioethics teaching in universities in Kenya*? The answer is "*Yes*," although the uptake of bioethics teaching is not commensurate with the efforts by UNESCO to promote bioethics education in Kenya.

The Need for Bioethics Courses in Universities

Advances in medicine, life sciences, and their related technologies are threatening the natural being of the biosphere. These threats could come from, *inter alia*, the introduction of GMOs without adequate debate on their benefits, and the risks and impacts of the introductions of new combinations of genes that may irreversibly be part of future evolution and affect the environment and biodiversity (Kinyamario, 2009). Issues on HIV/AIDS, abortion, and others (Box 16.1) affecting the wellbeing abound in public debate and in literature. Unfortunately, universities have not confronted these societal challenges using bioethical perspectives and rarely contribute to public debate on these issues. With the rapid development of science, technology, and innovation, universities should take the lead in bioethics teaching and contribute to bioethics policy and debates.

Box 16.1
Some key bioethics topics commonly included in public universities' curricula in Kenya (Mathooko, 2007).

Abortion; euthanasia; confidentiality; death and right to die; bioengineering and experimentation; mental health; informed consent; termination of pregnancy; patient-doctor relationships; national and international codes and relevant Acts of Parliament; Clinical Officers Act; Public Health Act; Hippocratic Oath; the role of research and ethics committees; organ transplantation; in vitro fertilization; embryo transfer; science and conscience in the moral evaluation of recombinant DNA technology; policy governing use

or release of artificially-produced DNA in the ecosystem; legal and ethical issues in HIV/AIDS.

Mathooko (2008) conducted a survey on the teaching and inclusion of bioethics in the curriculum of three public universities in Kenya. The data were obtained from the universities' current catalogues, interpersonal contacts, and consultations. It was found that none of these universities had an undergraduate and/or a postgraduate degree program in bioethics. Further, no university had a department of bioethics in its structure. However, there were fragmented elements of bioethics teaching distributed within semester units or courses that were available to a very small number of students. At the end of the survey, the following observations were made about the status of bioethics courses in Kenyan universities. That:

1. There is limited inclusion and coverage of bioethics content in Kenyan public university curricula, especially in science, medicine, biotechnology, biochemistry, and biomedical science and technology where bioethics is highly needed
2. The semester distribution of the bioethics courses in the universities lacks any definite pattern. This is exemplified by the fact that the majority of the courses with ethical/bioethical dimensions were either taught in the second, third, or fourth years
3. There was limited awareness of bioethics content and aspects of focus since it does not feature prominently in the national education system and
4. Nearly all bioethics courses were theoretical with minimal reference to practical bioethical cases

Challenges Faced by Universities in Teaching Bioethics

Kenya is strategically placed as a focal point for championing efforts in networking, fostering, and integrating bioethics teaching at national and regional levels of education through capacity building, establishment of national committees, and enhancement of the implementation of the UNESCO Ethics Teacher Training Programme. This focused coordination approach could help to minimize some of the challenges faced in bioethics education. Generally, bioethics is a complex field and therefore it is pertinent that criteria for measuring the success of bioethics education should be developed before any program is implemented. Incidentally, the content surrounding bioethical issues is complex because it is made up of personal, social, and emotive aspects as well as specific biological information (Conner, 2004). Coupled with this complexity is the question of who is qualified to teach and the blurred approaches of teaching bioethics. The assessment becomes even more challenging and untenable when analyzing dilemmas and divergent views are taken into consideration. Because of the associated uncertainties, bioethical teaching requires more holistic teaching approaches that take into account feelings, aesthetics, affective dimensions, the diversity of peoples, and the environment in its totality.

Cascading bioethics content to lower levels of the education system is a daunting challenge that calls for ingenuous approaches and strategies. Involving the lower levels of the education system is appropriate because they hold a large number of students, implying that transferred content reaches a large number of students resulting to a multiplier effect for the wider community. Therefore, bioethics should be taught at all levels, but it should be imparted in a manner that a child can understand (Macer, 2004). Furthermore, bioethics education requires small groups for it to be taught effectively, but the numbers of students in all Kenyan levels of education are high. This could also create another challenge in the teaching of bioethics in Kenya. Other challenges faced by universities include the following:

1. *Human capacity to teach bioethics*: In the Kenyan universities, very few lecturers and curriculum developers have been trained in bioethics. Therefore, for bioethics education to be developed, training of lecturers in the field of bioethics is imperative.
2. *Awareness of bioethics' existence as a discipline*: Bioethics' existence as a discipline is not apparent to many lecturers since it does not feature prominently in the education system in Kenya. There is need to create awareness among the lecturers in public and private universities.
3. *Availability of teaching resources*: Since this discipline is not manifested in the education system, teaching materials have not been developed. Bioethics education teaching will require tailor-made books, e-library facilities, and even videos for it to be properly taught.
4. *Socio-cultural diversity based on many ethnic groups and languages*: This could be a major challenge, especially in the analysis of ethical dilemmas. Kenya has a diverse population with different cultural backgrounds and languages. This also reflects the manner of thinking and the way they relate with the environment. Therefore, analysis of dilemmas will require careful and skilful handling by both the teacher and the students.

Strategies for Promoting Bioethics Education in Kenya

Several appropriate strategies are proposed for promoting bioethics education in public and private universities in Kenya. These strategies either require the involvement and participation of the individual, the university and/or external entities like UNESCO for them to be implemented.

1. *Networking strategy*: Kenya is strategically placed as a focal point to boost efforts in networking, fostering and integrating the UNESCO ideals in the field of bioethics at national and regional levels through capacity building, establishment of national committees, and enhancement of the implementation of the UNESCO Ethics Teacher Training Programme. The UNESCO Chair on Bioethics at Egerton University is eager to establish networks with other Bioethics Chairs in the world. This will enhance exchange of ideas and cross-cultural understanding in the field of bioethics especially in bioethics education.
2. *Human resource capacity building strategy*: Teachers in Kenyan universities need exposure to bioethics in general and in bioethics education in particular.

They require training in bioethics teaching methods, curriculum development, and measurements and evaluation. This is extremely relevant, especially for the junior teachers. Furthermore, teachers should be trained in ethical dilemma analysis and development of teaching materials. Training on the delivery of content in a manner that makes the learners comprehend the complexities of bioethics demands that teachers should be well trained in pedagogical skills. Training approaches could be two-pronged: training on pedagogical skills and training on content.

3. *Mentoring strategy*: Cultures of mentoring are needed to bring junior and senior bioethics teachers together and to encourage intergenerational learning. Junior teachers should gain bioethics teaching experience at the early stages of their teaching careers in order to be productive in terms of not only teaching but also in research in bioethics. With this strategy, it is expected that delivery of the subject matter will be improved.
4. *Internet connectivity strategy*: Information access and flow is important in teaching and is usually a challenge in most African universities, where the Internet is lacking or, in most cases, out of order. The Internet service is unreliable and the cost of access is still a challenge to teachers. Bioethics teachers should be availed reliable Internet connectivity to facilitate the acquisition of current information for teaching.
5. *Program expansion and diversification strategy*: PhD-qualified staff are essential for bioethics teaching due to its complexity, and individuals must therefore be developed through training, study, and research involvement. Therefore, the expansion and diversification of degree programs to include bioethics education is necessary to build a critical mass for ethics teachers. UNESCO, through its institutes, should mount and sponsor a degree course in bioethics education. This would provide junior teachers with opportunities to obtain scholarships for masters, PhDs, or postdoctoral studies, or to work alongside senior teachers. This could further strengthen and sharpen their skills for teaching bioethics.
6. *Bioethics resources sharing and development strategy*: African countries appear to lag behind in their bioethical reflections and in resources development. Sharing of bioethics education materials and new pedagogical approaches should be encouraged. This way, there will be cross-fertilization of ideas in teaching of bioethics. Enjoined to this strategy is the "*Exchange visit strategy*." The UNESCO Chairs on Bioethics should initiate exchange visits to learn from each other and to exchange ideas; in addition, exchange programs should be initiated for bioethics teachers to meet and share their experiences in teaching and examining bioethics.
7. *Facilitation strategy*: There are so many activities and conferences on bioethics taking place over the world. Facilitation of teachers to attend them is vital as this will enhance the mastery of the subject matter and supplement the limited reference sources. In order to promote bioethics education and research, facilitated publication and dissemination is appropriate, especially where the teachers are facilitated to attend workshops/symposia and conferences in order

to present their bioethics research findings. UNESCO could play a leading role in supporting conference bioethics proceedings and any other materials that could enhance bioethics education.

8. *Infrastructural development strategy*: Bioethics resource centers and libraries should be established to facilitate preparation of teaching materials and research. Libraries will afford teachers and students accessibility to secondary information for teaching and research and they ought to be equipped through planned and sustained channeling of resources to the libraries.
9. *Bottom-up strategy*: In developing any curriculum and teaching materials on bioethics education, the bottom-up strategy would be appropriate where students, lecturers, and curriculum developers are all involved. This helps in deepening the understanding of the subject, creates ownership of the content and better delivery. Using a bottom-up strategy, teachers can fine-tune their teaching approaches and identify the most appropriate ways to communicate the content.
10. *Combination strategy*: This strategy takes on board all the above strategies and could be the most appropriate strategy to arrive at a workable common ground. In the event that all of them cannot be accommodated, selection of a few of the most appropriate strategies will suffice rather than choosing a single strategy.

Recommendations

It is evident that bioethics teaching in Kenya is not developed despite its societal relevance. It is required in medicine, life sciences, and in the related technologies. Its growth is hampered by several challenges that include lack of well-trained teachers to teach bioethics coupled with limited teaching materials. This chapter recommends that the relevant government ministry should declare bioethics a common core course in public universities and that universities should adopt, domesticate, and implement the UNESCO Core Course on Bioethics that has been prepared by experts from all over the world. The relevant ministry should work closely with UNESCO to oversee course implementation in the universities and, further, to cascade it to secondary and primary schools. To hasten creation of a critical mass of bioethics teachers, UNESCO should also facilitate a model International Postgraduate Bioethics (IPGB) Certificate Programme in the universities.

Conclusion

African bioethics has been hybridized through infusion and domination by foreign practices, culminating from globalization. With fast-growing developments in science and technology and emerging chronic and terminal diseases, bioethics, hybrid or otherwise, has a prominent place in Africa. The question is no longer whether Africa needs to embrace bioethics. Indeed, it can ignore it at its own peril. What needs to be put in place is education, legal framework, and contextualization

of international normative instruments such as the Universal Declaration on Bioethics and Human Rights among others. It is evident that bioethics education in Africa has not developed and requires immense resources for it to advance. Its growth is hampered by several challenges which include lack of well trained teachers to teach bioethics coupled with the absence of teaching materials. This chapter has highlighted some of the strategies that could be used to promote bioethics and some of the possible approaches of teaching bioethics education. The "*whither*" of bioethics education in Kenya and Africa can be summarized thus: *no significant progress has been made in bioethics education*" and the "*thither*" by the statement that "*the future of bioethics education is bleak unless the strategies and recommendations herein are taken into consideration by schools, universities and governments.*"

Arab Perspectives

17

Bahaa Darwish

Introduction

Bioethics in the Arab world is addressed from an Islamic perspective. The dominant institutions in the Arab world and prominent researchers writing on Arab bioethics address bioethical issues from an Islamic perspective. Though there is no old or contemporary Arab or Islamic theory of bioethics that delineates the *necessary and sufficient* principles by appeal to which bioethical issues can be justified, in addressing bioethical issues, nevertheless Arab bioethicists, most of whom are religious scholars and physicians, appeal to Qur'anic verse(s), *Hadith* (Prophet sayings and deeds), and/or jurisprudence rule(s). Therefore, in explaining the Arab perspective(s) of the global principles of bioethics, the Islamic perspective will have to be further elucidated.

The trend that gained popularity since the last decade calling for global bioethics was fostered by connecting ethics to human rights. Because ethical problems were seen to be violations of human rights, ethical principles, at least some of them, can be seen as global principles that can be acceptable across national and cultural boundaries. Though this trend has had many advocates, it does not go without challenges. Tristram Engelhardt can here be cited as one prominent challenger of the possibility of global ethics (Engelhardt, 1998). However, the overarching principles of the UNESCO Bioethics Declaration, which will be regarded in this handbook as the basis of global bioethics, are acknowledged in Islam. However, they have different weights and justifications shaped by culture and religion, and are examined by Arab bioethicists in addressing the bioethical issues. These principles can be expressed from an Islamic perspective as follows.

Humans are the vicegerent of Allah, therefore they have *dignity* that should be preserved. To preserve it, humans should avoid *harm* and seek *benefit*. To respect human dignity is to respect a human's *privacy* and *autonomy* in taking decisions limited by their *responsibility* for such decisions. People's autonomy is reflected in their right to *consent*. To preserve their dignity, *persons unable to give consent*

DOI 10.1007/978-94-007-2512-6_87,

should be given due care, and their *vulnerability* should be respected. As humans are the vicegerent of Allah, no one has superiority over the other, so the principles of *justice*, *equity and equality*, *non-discrimination* and *non-stigmatization* are invoked. This applies to current as well as *future generations*. The *environment with all its components* also has intrinsic value as Allah's creation, so it should be *protected* for the intrinsic value it has, not only for the future generations.

Therefore, the Islamic perspective of each principle needs to be understood as to how it is applied or regarded in addressing the bioethical issues from an Islamic perspective. Application of these principles will add to the explanation of the principles' connotations seen from the Islamic perspective.

Human Dignity

Human dignity is a principle that is universally acknowledged though for different reasons in different cultures. Some, especially in the West, see that humans possess dignity because they are "persons with autonomous desires, beliefs, and intentions" (Glannon, 2005, p. 92). Such qualifications are "what make a person worthy of self-respect and respect from others" (Glannon, 2005). Therefore, autonomy has a sort of priority over other principles (Aramesh, 2008).

In Islam, all sorts of life are precious and have intrinsic value because life is created by God Who creates it with His divine quality: Among God's attributes and names in the Islamic scriptures is "the Living" (*al-Hayy*) (Shomali, 2008, p. 1). However, among all forms of life in the world, human life is the most precious. In *Qur'an*, which is for Muslims the agreed-upon first source of jurisprudence, Allah says, "We have indeed honored the children of Adam, and provided for them means of transportation in land and sea, and given them wholesome food and exalted them high above the greater part of Our creation" (Qur'an17: 70). Such privileged status is conferred on humans because humans are God's vicegerents on earth (Qur'an2:30). whom Allah has endowed with reason and freewill and therefore are responsible for what they do (Shomali, 2008, p. 3; Daar & Al-Khitami, 2001, p. 60). Thus, human dignity is grounded on such sanctity of life, applied to people in life and death, and explains why humans are worthy of self-preservation, self-respect, mutual preservation, and mutual respect.

Such sense of human dignity justifies the positions of Arab ethicists towards a variety of bioethical issues. Human dignity is the concept that explains the dispute among Arab bioethicists concerning the permissibility of abortion. Most Arab ethicists see that because human life has intrinsic value, it should be respected in all stages of development beginning as an embryo, and therefore the embryo should not be attacked by aborting it or by any other way unless there is a medical necessity. The necessity about which there is nearly a consensus among most ethicists is when pregnancy threatens the mother's life. In this case, abortion is considered a necessity to save her life. Aborting a late-stage fetus (after 120 days) resulting from rape or because it is physically or mentally deformed is not considered for most ethicists as necessary.

And because human life has such privileged status and therefore should be respected, human cloning, whether reproductive or therapeutic, is considered an affront to human dignity. The first type aims at creating a full-fledged human being, while the other aims at creating embryos from which to mine embryonic stem cells to be used for therapeutic purposes. The moral objection is that the mere fact that an embryo is created violates the sanctity of human life that should be respected from the time of conception.

For the same reason, embryonic stem cell research, where embryos are created specifically for research purposes, is considered an affront to human dignity. A common theme of the Arab regional provisions is a prohibition of commercial exploitation of IVF patients and others to provide surplus embryos for research. However, on the basis of influential religious rulings, the Islamic Organization for Medical Sciences (IOMS) Seminar of November 2007 agreed that use of surplus IVF embryos within 14 days after fertilization for the purposes of treatment and scientific research, excluding introduction of human embryonic or pluripotent stem cells into non-human blastocysts, is better than wasting them (UNESCO, WHO, & ISESCO, 2008).

Donation of organs is considered an act of charity, benevolence, and altruism through which many lives can be saved. The *Qur'an* says that "whoso helps one to live, it shall be as if he had given life to all mankind" (Qur'an5:32). "Human organs are not a commodity nor a chattel, and hence should only be given for the love of fellowmen. Commercialism, entrepreneuring and organ trafficking is an affront to human dignity and hence deplored and proscribed" (AlBar, 1996). This is quite well expressed in nearly all the legal codes of the Arab countries.

Respect for human dignity is extended in Islam to the dead body, whether it is a body of a Muslim or non-Muslim. The dead body of a Muslim should be prepared after death for burial, by being washed, dressed, prayed on, then buried in a respectful place as soon as possible to avoid putrefaction, which occurs rapidly in hot climates (AlBar, 1996). It is not allowed to dig the graves or unveil the buried body. However, autopsy is allowed only if necessary, for instance, when there is the suspicion of murder (Shomali, 2008, p. 3).

As evidence for the respect of the non-Muslim human corpse, there is the story when Prophet Mohammed stood in veneration for a funeral of a Jew passing by, at the time when Jews were his bitter enemies. One of the companions exclaimed; "It is only a funeral of a Jew!" The Prophet answered "Is it not a human?" (AlBar, 1996).

Benefit and Harm

Because human life is precious and has intrinsic value, it should be protected from all kinds of harm. Therefore, avoiding, or protecting people from harm is teleological. It is to preserve the human life that has dignity.

Maximizing benefits and minimizing harm are two correlative concepts that are expressed in the following two Islamic rules: the universal rule "harm is to be

removed," and its derivative: "preventing harm has the priority over obtaining benefits." The wording of the latter rule explains why the former is universal and the latter derivative, and also explains the order of importance of "removing harm" and "obtaining benefit." Accordingly, the former rule is considered one of the universal rules of Islamic jurisprudence that Muslims are required to regard and follow in all aspects of practical life. This rule is one of the most important rules of Islamic jurisprudence because the domain of its application is wide. It can be nearly applied in all aspects of Muslim life. This rule is originated in the Prophet's *hadith*: "no harm or harming." One of the basic goals of *Shari'a* is to remove all kinds of harm of individuals and groups. IbnAtheer explained the Prophet's hadith by saying that "no harm..." means that you ought not start by harming others, and "no harming.." means do not return one's or others' harm by harming them, so there is a prohibition either to harm or to return others' harm by harm (Kassem, 1983, p. 217).

From this rule, the following rules are derived:

(a) Necessities override prohibitions: for instance, killing an attacker to defend oneself is justified: it is a necessity (self-defense) that overrides a prohibition (the act of killing); the government is justified in taking money from a person without consent if she refused to pay her debt: there is a necessity (paying her debt) that overrides a prohibition (taking one's property without her consent).
(b) Harm should not be removed by another harm: for instance, one is not allowed to save one's agricultural land by drowning another's, or to save one's money by destroying another's.
(c) In case of two harms, the lesser harm should be done: for instance, if a Muslim cannot wash before praying (which is a prerequisite for praying and a precondition for the soundness of praying), he ought to pray as he is; and a husband will be imprisoned if he refuses to pay for his wife's living costs.
(d) Preventing harm has priority over receiving benefits: for instance, the money owner is to be prevented from using his money if it is proved that he harms others by such usage (Kassem, 1983, p. 218; Khallaf, 1947, pp. 238, 239).

This universal rule and its derivatives are very well equally applied in bioethical issues. Abortion to save a mother's life is justified by the rule: "necessities override prohibitions"; aborting a deformed fetus, or a pregnancy that resulted from rape, is justified by its proponents as "harm (that) ought to be removed"; and that "the lesser harm should be selected." In the same way, those who disagree regarding aborting a deformed fetus or a pregnancy that resulted from rape appeal to the same rules in justifying their position. They see that abortion ought to be impermissible as "the lesser harm should be selected," which for them means that the future suffering of the deformed embryo or that from rape and their families is lesser than that from depriving it of the right to live. It ought also be impermissible as "harm should not be removed by another harm," which for them means that the future suffering is admittedly "harm" but should not be removed by aborting it, which is "another harm," thus using the same rules to justify their position.

Though organ donation is accepted and encouraged in Islam, donating an organ that may lead to the death of the donor is impermissible because "harm should

not be removed by another harm," and because "preventing harm has the priority over getting benefits."

Since ethics of science is the endeavor to harness scientists' non-stop curiosity and making sure that their scientific and technological products are directed towards the good of mankind, the preservation of the human values and the human rights' principles long fought for, "ethics of science and technology" can generally be justified by the Islamic rule "preventing harm has the priority over getting benefits."

Autonomy and Individual Responsibility

A form of respecting people's dignity is to respect their autonomy. As ethical principles, autonomy and individual responsibility are two correlative principles. Responsibility reveals autonomy: there is no sense in calling an agent a responsible agent if he or she is not autonomous. Autonomy without responsibility turns one into an egoist who does not take into consideration the interests of others. Such sense of the correlative principles: the autonomy of persons to make decisions, while taking responsibility for those decisions, is an important Islamic concept that is expressed in the *Qur'an* repeatedly: "No bearer of a burden can bear the burden of another" (Qur'an6:164), (Qur'an17: 15), (Qur'an35: 18), (Qur'an39: 7), (Qur'an53:38). Prophet Mohammed said, "All of you are guardians, and all of you are responsible for whom you guard." In Islam you cannot be held accountable for others' deeds and when you are praised or punished, you are praised or punished for the deed for which you are praised or punished not for another.

This responsible autonomy explains why Muslims are held responsible for their deeds in this life and why there will be "Hell & paradise" in the hereafter. If persons in Islam were not held autonomous, it would be unfair to hold them responsible for their deeds.

It is to be noted that what is confirmed here is "autonomy" not "individuality." Individuality invokes indifference and a focus on one's own interest, which is surely against the focus on cooperation and solidarity for which Islam gives much weight, as we shall see.

This concept of autonomy is reflected in the Muslim bioethicists' opinions in the domain of health and research. There is a consensus among Arab ethicists that the patients have the right to choose to be cured or not. Such right is materialized in the patients' right to give informed consent before being cured or operated on. The concept also explains their right to be told the available types of cure and to select the one they like. And it explains their right to participate as research subjects and to withdraw the consent anytime.

Autonomy has limits, however. Persons who are incurably sick do not have the right to end their lives by themselves or with the help of a physician. By so doing, they would surpass the limits of their autonomy. The act would be considered suicide, and the physician a killer. Euthanasia is prohibited based on

the rules "harm should not be removed by another harm," and "the lesser harm should be done." In Islam, killing is not only a harm, but the greatest sin a Muslim can commit.

Consent

In Islam, consent is one of the basic rights of humans as people who have dignity that ought to be respected. It is based on the jurisprudence rules: "A person's right is not to be revoked without her permission," and "Man's right is not to be used without his permission" (IOMS Islamic Organization of Medical Sciences [IOMS] (2005, p. 191). Applying such rules in the field of health care, the Islamic *Fiqh* Council ruled that "it is impermissible to recruit any person to participate in any research involving human subjects without a clear informed consent of that person. Participation in research must not involve any coercion or financial inducement or any risk other than the risks expected during the normal investigation" (rule 67/5/7) (IOMS, 2005, p. 192). Such consent ought to be provided after the agent's full knowledge of the nature of the therapy or the research and its potential consequences. This is based on the jurisprudence rule: "agreement is not achieved with ignorance." Based on the principle of justice, it is permissible to financially compensate subjects for being absent from work or/and travel cost resulting from their participation. If the intention behind money paid is to tempt the subject to give consent, then it is impermissible (IOMS, 2005, p. 211). In line with the principle of personal autonomy, no one has the right to give consent for persons who do not have the ability to consent except in exceptional cases. Such cases will be discussed later (IOMS, 2005, p. 198).

However, there is always a limit to a person's autonomy and consequently to their right to consent. It is not the subject's sole right for instance to consent to removing her uterus when she is a wife. In exercising her right, she transgresses her husband's right. Also, if a pregnant woman who has decided to participate in a clinical research knows that the research may involve certain risks to the embryo, the husband's consent becomes a condition to the research conduct because the husband also has a right to the embryo (IOMS, 2005, p. 271). Also, a person does not have the right to choose to be cured or not if his or her disease is infectious. The principle "necessities override prohibitions" is invoked here.

Persons Without the Capacity to Consent

Islam calls for giving due care to persons who are unable to give consent. These people include children, prisoners, refugees, educationally or economically disadvantaged persons, and individuals with diminished mental capacity. It is impermissible to coerce, press on, or exploit their hard financial, psychological, or mental situations to get them participate in research when they are unable to give their consent. This in Islam is considered unjust. To get persons from such

categories participate in research, three conditions must be met: the research should be intended to improve the medical interventions for such category; research subjects, as well as other people of the same category, are guaranteed access to treatments or practices developed by the research; and risks resulting from participating are not more than minimal (IOMS, 2005, p. 250).

Of these categories, children are given special care. There are few cases when it is permissible to give consent on their behalf. Such cases encompass the case when it is in the child's interest that the research be conducted. In that case, it should be left to the ethics review committees to decide whether the research be conducted or not after taking the parents' or guardians' consent. If a review committee confirms that the research is in the child's interest, then the research should be conducted even if the child objects, in order to prevent the child from missing a good chance of finding a cure or to protect the child from harming itself by such objection. The other case occurs when the research is about pediatrics and drugs used specifically for children. Here, it is permissible that the research be conducted if the risks involved are not more than minimal risk encountered during the normal investigation. This in Islam is justified by the jurisprudence rule "necessities override prohibitions" (IOMS, 2005, pp. 256, 257).

Respect for Human Vulnerability and Personal Integrity

The above paragraph explains the respect Islam gives to groups characterized as vulnerable. Respect for the body, whether dead or alive, is based on the principles of sanctity (*hurma*) and dignity (*karama*), and it serves to "acknowledge the superior status of the human being." Cremation or mutilation of the body is completely prohibited, and Prophet Mohammed is reported to have said that "breaking the bone of one who is dead is like breaking it while he is living" (Haque, 2008, p. 14).

Personal integrity is invoked also by the Arab ethicists in their objection to female genital mutilation (FGM), a tradition that is still practiced in some Arab countries, attributed wrongly to religious teachings. Ragab argues that female circumcision is unethical and that the evidence that the Prophet Mohammed recommended it is unreliable (Ragab, 2008). Elsayed et al. argue that "FGM obviously violates the fundamental ethical principles of bodily integrity, autonomy and self-determination, and is practiced without the full informed consent of the victim" (Elsayed et al. 2011, p. 67). Most religious scholars who have their saying in the bioethical discourse in the Arab world occasionally declare the disconnection between religion and FGM. To give just a few examples, a conference held in 2006 on preventing the mutilation of women's bodies was organized by *Dar al-Ifta'* in Egypt (the governmental body responsible for issuing *fatwas* (religious opinions) on Muslims' issues in life), attended by important religious experts like the former Shaykh of al-AzharTantawi, the former Minister of Awqaf, (religious endowments) Mahmud HamdiZaqzuq, the Mufti of Egypt Ali Gum'a, and the head of the World Union of Muslim Scholars, Yusifal-Qaradawi. The recommendations in the end

were: "female circumcision (FGM) is an old custom that appeared in some human societies and that some Muslims practiced in some countries without any basis in Qur'anic versus or in *hadith sahih*" (Tolino, 2011, p. 215). And then:

"The circumcision which is practiced today harms women physically and psychologically. Therefore, it should be avoided to comply with one of the highest values of Islam that is to avoid harm to the human being, as the Prophet said: '*la dararwa la darar fi- l- islam*'" (no harm or harming) (Tolino, 2011). During the session of 28 June 2007, all members of the Islamic Research Council of al-Azhar agreed that there is no basis in Shari'a for female circumcision, and that it "is a harmful custom that spread and grew steadily in a small number of Islamic communities" (Tolino, 2011, p. 215). This opinion has been shared by *Dar al-Ifta'*, which issued a *fatwa* in July 2007 where it stated that "female circumcision belongs to the category of traditions and not of religious obligations" (Tolino, 2011). Al-anba Musa, the bishop of Youth of the Coptic Church in Egypt, says, in his book *khitan al –inath : ilamata* (FGM till when), published in 2005, that "when God created man, he did it in the best form and every part of his body has a function and a role." He also declares that chastity has nothing to do with a harmful practice, because "chastity does not come from the body, but from will and spirit" and it is built "through good family, educational and religious upbringing" (Tolino, 2011, p. 217).

This does not mean that all religious scholars agree with this. Some religious scholars, such as Muhammed al-Musayyar, still think that FGM is a religious duty or at least permissible (Tolino, 2011, p. 213): a confusion that they must settle.

Privacy and Confidentiality

Privacy issues came under the spotlight as a result of the contemporary technological devices able to store and give other parties access to people's private and sensitive information, such as mining datasets (Islam and Brankovic, 2004). Confidentiality of one's information is a resultant right along with and assurance of one's right to privacy. People's privacy entails keeping all information about them confidential. People's privacy is also an entailment of their autonomy: being autonomous entails my right to the privacy of my information and my right against undue invasion of my privacy.

While privacy is a reaction to the modern technological inventions that invoked such principle, in Islam, privacy is part of a complete vision about how a human's dignity, as the vicegerent of Allah, should be protected and respected.

This principle is stressed in the Qur'an in various verses such as: "Spy not, nor backbite one another" (Qur'an49:12), "O ye who believe, enter not houses other than your own until you have obtained leave and have saluted the inmates thereof" (Qur'an24:27). However, privacy in Islam, as in every other culture, has certain boundaries.

A clear application of the principle of confidentiality in bioethics is the Islamic *Fiqh* Council decision no. 79 (10/8), which ruled in term 3 of the decision that

initially breaching confidentiality is religiously impermissible. The decision continues with terms 4, 5, and 6: Term 4 states that confidentiality is a necessity, specifically in jobs where breaching confidentiality negatively impacts the job itself, such as the medical professions, because patients depend to a large extent on professionals working in the domain of medicine for advice and consultations about issues, sometimes sensitive, related to their health. Breaching confidentiality creates distrust between the patients and medical professionals that consequently destroys the profession itself (IOMS, 2005: 277). Term 5 declares that, based on the jurisprudence rule that in case of two harms the lesser should be chosen, revealing a person's secret is not a breaching of confidentiality when the benefit of such revealing for either the person or the community outweighs the harms of its remaining confidential, or when such revealing protects the person or the community from harm (IOMS, 2005). Term 6 says that all exceptional cases in which breaching confidentiality is required or recommended must be exclusively mentioned in the medical codes with details of the methods of revealing and the parties to whom the secrets are to be revealed (IOMS, 2005, p. 278).

Equality, Justice and Equity

Justice has been a philosophical subject since Plato. However, in the twentieth century, especially in the West, the concept of distributive justice, that concerns the allocation of resources in a certain community, has moved to the core. In the West, two main theories are central to the discussion: egalitarianism and libertarianism. Most recently, an articulation of the difference between micro- and macro-level obligations of justice has gained some interest.

In Islam, justice is one of the human values that Muslims have to achieve, because it is the reason behind Allah's sending all messengers to humans throughout all ages. Allah said "we have sent Our Messengers with manifest Signs and have sent down with them the Book and the Balance, that people may act with justice" (Qur'an57:25). Justice in Islam is based on the concept of equality, and both are based on the concept of dignity of all descendants of Adam previously referred to. It should be applied to all human beings, Muslim and non-Muslim, regardless of gender, race, or social status. Allah said: "When you judge between the people, you do it with justice" (Qur'an4:58). Justice should be observed in giving witness: Allah said, "O ye who believe, be strict in observing justice and bear witness only for the sake of Allah, even if it be against your own selves, or against parents or kindred" (Qur'an4:135). He also said, "And that when you speak, hold the scales even though the person concerned be a kinsman" (Qur'an6: 152). It should also be observed in settling disputes between groups of people. Allah said, "If two parties of believers should fall out with each other and start fighting, make peace between them. If one of them should transgress against the other, fight the one that transgresses until it submits to the command of Allah. Then, if it should so submit, make peace between them with equity, and act justly. Verily, Allah loves the just" (Qur'an49: 9). Justice should also be observed in dealing with enemies:

Allah said, "let not the enmity of a people. . . incite you to transgress" (Qur'an5:2). He also said, "O ye who believe, be steadfast in the cause of Allah, bearing witness in equity. Let not a people's enmity towards you incite you to act contrary to justice; be always just" (Qur'an5:8).

Therefore, in applying the Islamic concept of justice in the healthcare domain, the egalitarian concept is the nearest concept of justice to the Islamic perspective. All healthcare professionals have the responsibility to provide all people with the highest possible attainable standard of health without any discrimination of religion, race, gender, or social status, as shall be explained later.

Non-discrimination and Non-stigmatization

If people are equal and should be treated justly, then it is easy to expect that Islam forbids non-discrimination and non-stigmatization. Allah says: "O mankind, We have created you from male and female; and We have divided you into tribes and sub-tribes for greater facility of intercourse. Verily, the most honored among you in the sight of Allah is he who is the most righteous among you" (Qur'an: 49:13).The verse clearly means that because we share one humanity, then no one is to be favored over another based on race, ethnicity, color, or gender. Allah has made us diverse as a way to help differentiate between people and come to know one another (Wafi, 1979, p. 9). In what has become known as his "farewell speech," Prophet Mohammed affirmed the same message when he said, "O people, your God is one and your father is one. All of you are the descendants of Adam and Adam is created from sand. An Arab is not to be favored over a Non-Arab except for devoutness" (Wafi, 1979, p. 10).

In the Arab states, however, at least two groups, women and the disabled, suffer from discrimination that carries a stigma, though not specifically in the domain of health care. However, the kinds of discrimination that these groups suffer from in other respects have implications for their health.

Discrimination against women still exists within some Arab families but not as a governmental attitude. This discrimination is the outcome of misconceptions among such families about the duties, rights, and relevance of certain jobs and positions in the society of each gender. It starts in these families by taking the form of favoring male over female children, and thinking that a boy's education is more important than a girl's. Evidence of such existing views is that two-thirds of those deprived of education are female. In 2005, an estimated 40% of Arab women could not read or write. The implication of illiteracy on their health is that these women will most probably be effectively blinded from the fundamental principles of health, hygiene, nutrition, and diet that can keep them and their families healthy. Illiteracy can also perpetuate customs and traditions that are harmful to women's health, such as early marriage and its ensuing early child bearing and FGM (UNDP, 2009, p. 155). Low levels of education among the females and in families in general contribute in finding compliance among the girls to such harmful habits.

In addition to the low average literacy rates among women, there is also the belief in some families of the irrelevance of the women's practicing certain jobs and/or political and economic activities, such misconceptions extend to deprive the Arab woman of practicing all her personal rights and enjoying a complete social life.

Despite the fact that we are living now the *Arab Decade on Disability* (*2004–2013*), it is estimated that about three to four million people are disabled in the Arab world (Nauk, 2011:3). Types of disability include hearing, visual, speaking, mental, learning difficulties, mobility, and lack of self-care.

During the period 2008–2009, most Arab states signed and ratified the International Convention on the Rights of Persons with Disabilities: the first legally binding instrument with full protection of the rights of persons with disabilities. Actually, they supported the importance of rehabilitating persons with disabilities and integrating them in the labor force since the League of Arab States adopted resolution 17/1993 on the Arab Agreement on the Rehabilitation and Employment of the Disabled (Nauk, 2011: 8). Nearly all Arab states now have laws that commit public and private sectors to incorporate the disabled in the labor force. However, actionable commitment to remove the obstacles that hinder the integration of persons with disabilities and to end all forms of discrimination against them remains elusive in the majority of countries. In terms of progress made in the area of rehabilitation and employment of persons with disabilities, several countries have introduced quota systems to allocate a percentage of jobs for persons with disabilities in both the public and private sectors, providing incentives and enforcement measures that range from weak to strong in different states, to private employers to hire persons with disabilities. However, in many countries, discriminatory attitudes, lack of proper rehabilitation programs, and the mismatch between vocational training and labor market demands block the prospects of those who want to improve the disabled situation (Nauk, 2011:9). Overall, "social stigma and tacit discrimination against persons with disabilities remains a significant barrier for realizing their rights and potential as catalysts of development" (Nauk, 2011:8).

In the domain of bioethics, it is argued that advances in medical technology have the potential to create disproportionate disadvantages for some social groups by encouraging the adoption of social policies that discriminate unfairly against them with significant individual and social consequences (UNESCO, 2008, p. 48). Some Arab and Muslim scholars accept sex selection by the use of pre-implantation genetic diagnosis. This may be considered a form of gender discrimination, specifically when the sex chosen is the male sex, which may imply stigmatization of the female sex (UNESCO, 2008, p. 52). However, it is important to note that Arab scholars accept sex selection only at the personal level, not at a nation level. Here, it is to be noted that in accepting sex selection, as long as it is a way of achieving a personal wish to enjoy the fruits of science to have a child with a certain sex, not to marginalize or treat the children of the other sex unjustly, by depriving them of equal chances of education or health care, selecting a certain sex is not infringement of any other fundamental principle.

As proof of the above-mentioned argument and consistent with it, the IOMS recommended, at the end of a symposium in 1998 on genetic engineering, human genome, and gene therapy from an Islamic perspective, that premarital genetic testing was highly recommendable for the couple, but that the resulting information should be kept confidential because of the sensitivity of such data and their cultural significance for some groups. Premarital genetic testing is now obligatory in some Arab countries such as in Jordan and Qatar. In an attempt to protect people against discrimination and stigmatization, the Qatari panel code 11/2004, article 331, for instance, holds legally liable anyone who discloses information pertaining to another's private life (Al-Zamman & Al-Khanji, 2008, p. 159). Accordingly, in case of divulging the genetic data resulting from the premarital genetic testing, the panel code would apply. Thus, both recommendations and the law are in harmony with the international instruments that limit cultural specificities to the protection of human rights represented in article 4, paragraph iv of the *International Declaration on Human Genetic Data* that stipulates giving due consideration to the sensitivity of human genetic data and establishing an appropriate level of protection for these data and biological samples (UNESCO, 2008, p. 52).

Respect for Cultural Diversity and Pluralism

Some writers (e.g., Engelhardt, 1998) argue that religion in general and Christianity in particular are incompatible with pluralism. Equally, there is no consensus on whether or not Islam encourages diversity and pluralism (Yitik, 2004). However, Islam supports pluralism, whether it involves the acceptance of divergences among Muslims (for example, about all aspects of Muslim life), or its tolerance of people of other religions. Therefore, upholding pluralism in Islam means respect for diversity within the Muslim community as well as between Muslims and non-Muslims.

If we start with the second meaning, we can find in *Qur'an* many verses that can be interpreted as a clear assertion of pluralism of faiths. The verse that is often cited by those who see that Islam encourages pluralism is the verse where Allah says, "there shall be no compulsion in religion" (Qur'an2: 256), a verse that clearly shows that no one is compelled to adopt Islam. Another is, "For each of you We have prepared, according to the capacity of each, a path or a highway, to enable you to approach the fountain of revealed guidance. Had Allah so willed, He would have made you all one people, but He wishes to try you by that which He has given you" (Qur'an5: 48).

From the history of Islam, the covenant of Medina (called *Mithaq-ilMedina*) is also given as evidence that Islamic tenets do not disapprove pluralism (as a way of life). When the Prophet migrated from Mecca to Medina owing to persecution in Mecca at the hands of Meccan tribal leaders, he found Medina a pluralistic society where Jews, pagans, and Muslims co-lived. Jews and pagans were divided into several tribes, each tribe having its own customs and traditions. The Prophet drew up a covenant with these tribes, guaranteeing them full freedom of their faith and also

creating a common community in the city of Medina with an obligation to defend it, if attacked from outside (Ahmad, 2009, p. 95). In this way, he gave a good example of how a Muslim pluralistic community with multiple faiths can be established.

Such example was followed throughout Islamic history. After Prophet Mohammed, the caliphs and Muslims in general followed the same way: When Jerusalem came under the rule of Islam, Omar, the second caliph, signed a pact with the inhabitants of Jerusalem, which granted security for them and their property. It recognized rights of the Jews and Christians of Jerusalem freely to practice their religion; their churches and synagogues were respected and left intact (Yitik, 2004, p. 4).

Such understanding of a pluralistic community was what allowed various Muslim rulers to encourage non-Muslims to participate in and contribute to the intellectual and political life of the community under Islamic rules. The Christians and Jews were welcomed to hold posts in public offices. Some of them became ministers, especially in the periods of the Abbasids, Mamluks, and Ottomans. Religious tolerance was well observed by the Muslim rulers of Christian Spain. At that time, in Spanish cities like Cordova, Seville, and Toledo, Christians, Jews, and Muslims lived in peaceful co-existence and many distinguished scholars and philosophers played a crucial role for exchanging cultures, the most famous of whom was Moses Maimonides (Yitik, 2004).

The Islamic civilization that flourished in the Middle Ages was based on translating the intellectual works of those who lived in the empires that existed before Islam or were contemporary with the Islamic State in the Middle Ages. Caliph Al-Mansour encouraged a large number of scientists to translate the Greek books on medicine. Caliph Al-Rasheed encouraged translating the old books of physics, astronomy, and mathematics. This translation movement culminated in the establishment of *Dar Al-Hekma* (a translation center), in the era of Al-Ma'moun, in whose time nearly all old philosophy books were translated into Arabic: a clear admittance by those caliphs of not only the possibility of living in harmony with others but also of the possibility of learning from them.

Regarding the first meaning where Islam allows divergence of opinions, much historic evidence can be found starting from the time of Prophet Mohammed. The principle of *Shura*, which Prophet Mohammed established among his followers, occasionally consulting them about various issues, is one piece of evidence that Islam is and should be based on pluralism of opinions. The different ways via which Abu Bakr, the first caliph, and Omar, the second caliph were chosen show that there is no one specific way to choose the Muslim's ruler. The story with which *fiqh* is said to have started is another piece of evidence. When the Islamic state began to expand beyond *Mecca* and *Medina*, Prophet Mohammed had to send envoys to these newly Islamic estates. He decided to send Mu'adIbnJabal to Yemen to hold the position of a judge. The Prophet asked him how he would judge the cases; IbnJabal replied that he would judge in accordance with *Qur'an*. "And what if you do not find guidance in *Qur'an*" the Prophet asked. He answered that he would seek the answer in the *Sunna*. "And if the *Sunna* does not help?" the Prophet asked. He answered that he would try to form an opinion *(ijtihad)*. The Prophet

tapped on him and thanked Allah who helped his messenger to find what pleases Allah and His messenger. Lastly, the four Islamic *fiqh* denominations, and not only one, that give different religious opinions that regulate all aspects of the Muslims' life is another clear piece of pluralism within Islam understood as a religion that regulates all Muslims' aspects of life.

In the domain of bioethics, such a principle of pluralism may raise questions about discrimination and autonomy. However, as explained above, the recommendations given by Arab bioethicists about premarital genetic testing show that cultural diversity is accepted in Islam as long as it does not infringe upon human dignity. It was also shown how their opinion and the law limit cultural specificities to the protection of human rights.

Solidarity and Cooperation

Solidarity as a moral value is not the reciprocal solidarity where individuals cooperate out of self-interest expecting mutual gain; it is the humanitarian solidarity whose motivation is the help of others – the needy – without expecting any return (UNESCO, 2008, p. 54). Such sense of solidarity is one of the life-governing principles for Muslims. Muslims should be responsive, helpful, caring, and cooperative, not indifferent or care only for their own interest. Therefore, solidarity is assured in Islam at all levels. The following Qur'anic verse is clear in expressing the concept of solidarity: "O ye who believe [. . .] assist one another in piety and rectitude, and assist not one another in sin and transgression" (Qur'an5: 2).

Prophet Mohammed confirmed this meaning by saying, "In their mutual intimacy, mercy and kindness, the believers in Allah are like one body in that if any part of the body is not well, the whole body will respond with insomnia and fever"(Hadith 6586 in Sahih Moslem: 1130). He also said, "A Muslim is a brother of another Muslim [. . .] Whoever fulfils the needs of his brother, Allah will fulfil his needs; whoever relieves his (Moslem) brother of a discomfort, Allah will relieve him of one of his discomforts in the Day of Judgment" (Hadith 6578 in Sahih Moslem: 1129).

The above-mentioned verses and Hadith show that solidarity is not restricted only to material solidarity.

In showing how to turn material solidarity into action, Islam imposes *Zakat* on all Muslims as a tool to apply such principle. Zakat is a sum of money imposed on the rich to be given to the poor. In the Qur'an, Allah addresses Prophet Mohammed telling him about the rich to "take a portion of their wealth as alms, that thou mayest purify them thereby and provide for their uplift and welfare" (Qur'an9: 103). The Qur'anic specifies that alms should be given to "the poor and the needy, [. . .] and for those burdened with debt" (Qur'an9: 60).

In this sense, it is easy to see how solidarity should be applicable in the context of the healthcare system. States and rich people have the responsibility of providing the needy with the necessary health care that can protect their human dignity, as shall be explained.

Social Responsibility and Health

Humans are defined by Spinoza as social animals, a living being who is "scarcely able to lead a solitary life" (Spinoza, 2005, p. 197). Humans in our time live in a social context ranging from the family, the national community to the global human community. The social context a human lives in and his or her status confers on him or her certain duties and responsibilities towards those he or she lives among. However, some argue that the word responsibility is rather modern in the sense of its being "a virtue that we demand of both people and organizations – speaking of socially responsible corporations, managerial responsibility, individual responsibility and so forth", and "for which we praise some people and organisations, while we criticise others for its lack" (Williams, 2008, p. 457).

However, responsibility in this sense has always been a virtue of the true Muslim. As Allah's vicegerent on earth who is endowed with reason and free will, the Muslim has responsibility towards Allah and simultaneous responsibility towards the whole creation, where creation means nature and the environment, other human beings and society as a whole (Zinken, 2007, p. 208): responsibility about which to be praised or blamed.

However, as this principle seems to be devoted to the social responsibility towards promoting health and human development, this section will be confined to such role of social responsibility showing how it has always been a part of the duties and responsibilities of the Muslim, though it is not fully achieved in the Arab world.

It has recently been recognized that the social and economic contexts people live in determine their health not less than their genetic inheritance and their personal choices and way of life. According to WHO (WHO Commission on Social Determinants of Health, 2008), income and social status; education; physical environment; employment and working conditions; social support networks; customs and traditions, and the beliefs of the family and community; genetics; health services; and gender all contribute in determining health (UNESCO, 2010:13).

In Islam, there is a much evidence to show the importance of human health grounded on the principle of sanctity of life. The responsibility for improving all determinants of health is explicitly directed towards individuals and states, and implicitly to other corporations.

In the Qur'anic injunction, "Let not your own hands push you into destruction" lies the command to save oneself from the occurrence of diseases or inflicting harm on oneself. The importance of human health is reflected in many verses and Hadiths: "Children of Adam . . . eat and drink but be not immoderate" (Qur'an7: 32). Prophet Mohammed is related to have said that, "no barrel that a human fills is more evil than a full stomach" (Hadith3349 in SonanIbnMaja: 2679). If interpreted either way, these references will show the importance of health: they will either mean that overeating and drinking may render one unhealthy, and thus being in a healthy condition is itself a duty, or that it is important to stay healthy to be able to colonize the earth, which is in modern terms to participate in the development of your community.

And because health is important, treatment, education, and sports are all religious demands.

In Islam, humans should seek remedy. "The Prophet Mohammed said, "O Servants of Allah: seek remedy. Allah who caused ailment, also brought cure and redemption." He also declared that there is a cure for every illness, though we may not know at the time. Muslims are encouraged to search for new modalities of treatment and should apply them if proved successful" (Albar, 1996). Acknowledging that treatment is basically the physician's role, in 1981, the "Islamic Code of Medical Ethics" ICME was endorsed during the First International Conference on Islamic Medicine held in Kuwait organized by IOMS, coding the physician's duties and responsibilities towards himself or herself, patients, and society. Medicine, according to the code, is a specialized knowledge, "lawful only to persons suitably educated, trained and qualified, fulfilling the criteria spelt out in the Law. A clear guidance is the Prophet's tradition: "Who-so-ever treats people without knowledge of medicine, becomes liable"" (ICME, 1981: 7). However, it is a holy mission, bringing God's mercy unto His subjects, and as mercy is as accessible to all people including good and evil, virtuous and vicious as are the rays of His sun and the coolness of His water, the medical profession should operate along that single track: God's mercy (ICME, 1981, p. 1, 2). Therefore, "It shall never yield to social pressures motivated by enmity or feud be it personal, political or military" (ICME, 1981, p. 2). In order for physicians to perform such task in the best way, they should be cheering not dispiriting, smiling and not frowning, loving and not hateful, tolerant and not edgy, tranquil as never to be rash even when he is right, neat and trim, conducive of trust and inspiring of respect, well-mannered in his dealings with the poor or rich, modest or great, in perfect control of his composure and never compromising his dignity, however modest and forbearing. They should also be truthful whenever they speak, write or give testimony, invincible to the dictates of creed, greed, friendship or authority pressurizing him to make a false statement or testimony (ICME, 1981, p. 3). They should offer good example by caring for their own health responding to the Qur'anic injunction that they ought not to make their own hands throw them into destruction," to the Prophet's advice that their bodies have rights on them, and finally to the known dictum "no harm or harming in Islam" (ICME, 1981). It is also clearly stated in the code that the physician should always be at the service of the patient, describing the patient as the physician's master for whose welfare and comfort the physician should give top priority over other considerations (ICME, 1981, p. 5). The physician should also protect the patient's secrets and keep confidential all information about him or her. The Prophet described the three signs of the hypocrite as follows: "He lies when he speaks, he breaks his promise and he betrays when confided in" (ICME, 1981, p. 6). The physician is linked to the larger moral tradition, that is: should never help one another in sin or rancor or give false legal testimony (ICME, 1981, p. 4). The physician's duties extend beyond treating patients to help in combating health-destructive habits such as smoking, uncleanliness, and so on. Physicians also have the responsibility of pressurizing the judiciary to issue the necessary legislation that can help improve health (ICME, 1981, p. 9). They should

also engage in scientific research as long as such research does "not entail the commission of sin prohibited by Islam" (ICME, 1981, p. 10).

In addition to such responsibilities of the physician to prevent and cure diseases and help in improving health, it is the responsibility of the governments to provide their people with all necessary health services responding to health needs, as well as the responsibility of the rich towards the poor at the personal as well as at the national levels to provide them with all possible means that can lead to healthy life.

Education is one important determinant of health. Knowledge in Islam is given high rank. In showing such rank, Prophet Mohammed is reputed to have said that knowledge seekers will be rewarded with paradise and that angels in the heavens bow with their wings expressing satisfaction and respect for knowledge seekers (Hadith 3641 in SonanAbiDawoud: 1493). As an indication of how important it is to educate people, there is a story that soon after *GazwatBadr* (the Battle of Badr, 624 AD), Prophet Mohammed agreed to free some of the Muslims' prisoners if every prisoner taught 10 children of Muslims reading and writing (Abu Zahra, 1986, p. 772). So, it is a heavenly duty of everyone, individuals, parents, and governments, to make knowledge accessible to all.

Sports in Islam are also acknowledged as a health determinant. Prophet Mohammed recommends Muslims to "teach (y)our children archery, swimming and horse riding" – the sports available in his time – to care for their own and their guardians' health.

Acknowledging social status' role in improving health, Caliph Omar asked rulers of other Islamic provinces to financially help youth get married from *Zakat-lmal* paid by the rich. However, the current situation in the Arab world is far from that ideal for different reasons.

At the personal and family levels, many people are neither aware of the social determinants of health, nor regard them, nor do they have the right understanding of religion regarding such issues. The result of which is the perpetuating of poor health habits and customs that negatively influence health attributing some of them wrongly to religion. Discrimination against females in the domain of education, as explained before, is one example. Traditional harmful customs adversely affecting women's health, such as early marriage and the ensuing early child bearing and FGM, is another. Lack of awareness of the importance of practicing sports for health that may cause diseases such as diabetics is a third.

At the governmental level, some states are too poor to provide all their citizens with a good standard of health and education due to the non-affordability of having strong health systems and qualitatively good education systems. In providing citizens with the necessary components of the sound physical environment that affect health, such as clean water, safe roads, health centers, hospitals, and educational institutions, some governments do not allocate to the rural areas the same care the urban areas receive, either for financial reasons or because of the absence or weakness of accountability systems or weak political will.

Sharing of Benefits

Though mostly intended at the global level, benefit-sharing from an Islamic perspective can be more considered as an application of the principles of justice and non-discrimination rather than an independent principle. Since, in Islam, justice or non-discrimination applies at the local, the regional, or the international level, the principle of sharing of benefits cannot imply something additional other than that the principles of justice and non-discrimination should be implemented. That the benefits of scientific knowledge and research should be justly distributed among countries, regions, and social groups, and between the sexes; and that research subjects should be given equitable options to benefit from their free participation in health research; and that research and ethical review capacity should be strengthened in the low-income countries in return to allow externally funded research to be conducted are all suggested models of benefit-sharing agreements (UNESCO, 2008, pp. 61–62). However, from the Islamic perspective, all these models are accepted but for different reasons: the benefits of scientific knowledge and research should be justly distributed because all humans are equal: they are the worshippers of Allah and the children of Adam. Claims of justice require that they all benefit from the results of scientific knowledge and research. Therefore, the benefit from the health research that might include access to treatments or practices developed by the research should not only be given equitably to research subjects but extended to all those who need it without compromising the right of researchers, the funding agents, or the sponsor governments. Equally, if committing organizations from high-income countries to improving research capacity in the host countries where research is conducted is meant to help international clinical research fill the inequality gaps that are left by non-existent or underperforming state actors in host countries that are unable to regulate nor can afford to fund and conduct research on local health needs (Pratt & Loff, 2011, p. 76), such entities, from an Islamic perspective, have the moral commitment to reduce health disparities between countries regardless of the benefit they will get from research conducted in such poor countries.

Protecting Future Generations

The concept of protecting future generations has emerged as a result of the booming economic growth based on the overexploitation of the natural resources and the ensuing environmental pollution and degradation. Such concept was extended to other examples of technological and scientific progress in the domain of health care that were found to have serious impact on future generations such as germ line gene therapy and xenotransplantation.

It is argued, for instance, that germ line gene therapy and xenotransplantation may have serious impact on the future generations because of the risks involved in both. The problem with germ line gene therapy lies in that the procedure is irreversible, and whether manipulations resulted from intervention adversely affect

future generations is impossible to predict in advance or to correct after being propagated to future generations (Nielsen, 1997). As for xenotransplantation, infections through viruses restricted to a nonhuman host species may be transmitted from the source animal to the human recipients to other people after being adapted to humans as a host species (Daar and Chapman, 2006, p. 107).

The Islamic opinion on gene therapy is mentioned within the broader topic of genetic engineering. Al-Qurradaghi expresses the Islamic opinion on gene therapy as follows: gene therapy is permissible if it does not lead to any harm (Al-Qurradaghi and Al-Mohammady:324). Islam encourages somatic cell gene therapy as it is like any other kind of therapy. Germ line gene therapy is prohibited for the uncertainty involved in its outcome. The extent of harm to the descendants is not clear. If it becomes certain in the future that such kind of therapy will lead to no harm, then it is permissible as long as it aims at curing diseases. Enhancement genetic engineering, through manipulating hereditary traits such as intelligence, stature or beauty, is impermissible as it may imbalance human life (Serour, 2000, p. 12).

As for the Islamic opinion of xenotransplantation, though the conclusion of the majority seems to be that using pigs for transplantation would not be a barrier to xenotransplantation, based on the Shari'a's principle that "necessities override prohibitions" – and that, in any case, the prohibition is only from eating pig tissue (Daar and Chapman, 2006, p. 115), xenotransplantation is prohibited for the risks involved.

The Islamic perspective of protecting future generations, applied in the case of germ line gene therapy, is that it is injustice to expose future generations, being equal to us, to potential harm that could have been avoided. As for xenotransplantation, it is equally unjust to expose the public to harm even if they may "benefit indirectly from successful widespread xenotransplantation due to a decrease in the societal burdens of health-care costs and years of productive lives lost due to chronic diseases" (Daar and Chapman, 2006, p. 110). The principle of "avoiding harm has the priority over getting benefits" applies to current as well as future generations.

Protection of the Environment, the Biosphere, and Biodiversity

It is widely acknowledged that Islam, like Christianity, advocates anthropomorphism: Islamic Shari'a not only places humans on top of all creation, but Allah has also "constrained the sun and the moon to serve" them (Qur'an13:2). "He has created cattle for your benefit; they are a source of warmth for you and you have other uses for them and you also eat of their flesh; and they are a credit for you when you drive them forth to pasture in the morning and when you bring them home in the evening. They carry your loads to places which you could not reach without great hardship to yourselves. Surely, your Lord is Compassionate, Ever Merciful. He has created horses, mules and donkeys that you may ride them, and also as adornment; and He will create for that purpose other means which you do not know" (Qur'an16: 5–8). "He it is Who sends down water for you from the clouds, from it you drink and with it grow trees on which you pasture your cattle.

Therewith, He grows for you corn, and the olive and the date-palm and the grape, and all kinds of fruits . . . He has constrained to your service the night and the day and the sun and the moon; and the stars too have been constrained to your service by His command . . . He it is Who has constrained the sea to your service that you may eat fresh sea-food therefrom and may take out therefrom articles that you wear as ornaments. Thou seest the vessels ploughing through it that you may voyage across the oceans seeking His bounty and that you may be grateful. He has set in the earth firm mountains lest it roll beneath you, and has made rivers and tracks that you may find your way; and He has set up other marks. By these and by stars they set their course" (Qur'an16: 10–16).

However, it does not mean that Islam gives people the right to use the environment and its components lavishly. As Allah's vicegerents, endowed with reason and provided with what have in themselves intrinsic values: the environment and the biosphere, that are also creations of Allah, humans are supposed to use them wisely. Unwise usage is a misuse of reason that Allah has endowed man and a degradation of what Allah has conferred intrinsic value on, and a violation of the responsibility given to man to protect and develop them.

Therefore, as it is clearly observed and mentioned in the economics and environment literature, protection of the environment is frequently considered in the *Qur'an* and *Sunna* to the extent that some writers see the Qur'an "greener" than the Bible which shares with the *Qur'an* common views of the natural world (Smith, 2002, p. 26).

In the early history of *Medina*, Prophet Mohammed established the first natural protectorate in Islam: a green belt of 12 miles around the city, where he prohibited people from cutting, removing trees or plants or hunting activity. He also prohibited them from polluting portable and bathing water, which by analogy Muslim jurists prohibited the throwing of garbage, harmful animals or industrial filth into waterways or under trees, in forests, or in the middle of roads that people use (Zinken, 2007, p. 216; Yousri, 2005, p. 27).

Prophet Mohammed also encouraged the practice of cultivation which he then, and still is, considered as a sort of worshipping, because according to him, any vegetation that a Muslim plants, or a crop that he sows so that human beings or animals eat, becomes an act of charity (*sadaqah*) (Yousri, 2005, p. 27). Charity should not only, then, be directed towards humans but to all creatures: "For charity shown to each creature with a wet heart, there is a reward," Prophet Mohammed declared (Smith, 2002, p. 26).

He also encouraged the revival of barren land by granting land to Muslims who are ready to reclaim it: "anyone in possession of a barren land granted to him, does not have the right to keep it after 3 years, if he does not revive it". This is due to the fear that the land will remain unutilized: a clear encouragement for not letting a beneficial natural resource remain idle (Yousri, 2005, p. 27).

Regarding the protection of living creatures, kindness to animals in Islam is an article of faith for Muslims. Prophet Mohamed ordered his followers to treat animals with gentleness and kindness (Smith, 2002, p. 26). The Prophet proscribed the killing of animals unless they prove to be dangerous for humans such as rats and poisonous snakes. "He who kills a sparrow in vain, this sparrow will cry

complaining to Allah on the day of judgment saying: O Lord, so and so killed me in vain and not for any benefit" (Yousri, 2005, p. 28). There is a tale that the Prophet related to his followers of a woman who was tortured by Allah by being put in Hell because during her life she once locked a cat up till it died of hunger Hadith 5852 in Sahih Moslem: 1076).

Though Muslims have the duty to protect the environment, the biosphere, and the biodiversity, the motivation is different from that of the conventional secular thinking. The latter's motivation to call for protection of the environment is to stop the accelerating consumption for fear of "degradation of natural resources and the increasing probability of their insufficiency to meet future material human needs" (Yousri, 2005, p. 29). The Islamic perspective is that protection, preservation, and development of the environment is a duty of the Muslim, as Allah's vicegerent who was held what is on the earth as a trust, to preserve what has been created with an intrinsic value and use it wisely, not just for any utilitarian reason whether it is the wellbeing of the current generation or the future generation. It is an understanding that the Muslim jurists arrived at in the Middle Ages before the modern understanding that stemmed out of the fear of the depletion of the natural resources (Yousri, 2005, p. 28). Muslims do not have the fear that the earth will run out of its natural resources. But on the other side as was explained, this does not mean a call for a lavish use of the natural resources. Allah expresses clearly that "He loves not the extravagant" (Qur'an6: 142).

Conclusion

In the Arab world, the concept of bioethics, understood as the discipline that encompasses the ethical issues resulting from the development of biological sciences and technology, is relatively new. Solutions given so far in the modern Arab world to such issues are mainly Islamic, reflecting the specific adoption and interpretations of the underlying principles. Bioethics is a dynamic discipline, whose issues expand as a result of the accelerating development of science and technology. It is important that the solutions given in the modern Arab world to various bioethical issues, and the interpretations given to underlying principles, continuously respond to the ethical needs of a contemporary open Arab society, that is, a society that encompasses non-Muslims and interacts with other societies. Thus, Arab bioethicists need ongoing discussions between Muslim and non-Muslim Arab bioethicists as well as between themselves and bioethicists of non-Arab cultures, specifically those from scientifically and technologically more developed countries, since it is there where most bioethical issues arise first.

Jacob Dahl Rendtorff

Introduction

The choice of "autonomy," "dignity," "integrity," and "vulnerability" as the four basic principles in European bioethics and biolaw illustrates the intention to give a solid foundation of the protection of human beings in relation to the fast developments in biomedicine and biotechnology. These principles can be said to express a European Ethical and Legal Culture (Häberle, 1997) of the recognition of the autonomy, dignity, and integrity of the human being. The principles must be seen in the framework of human rights law and the law of the human person. Persons are "liberty holders" and right-claim holders (Rendtorff & Kemp, 2000). The principles manifest the concern to protect the person and to value the development of the individual human being, which is a strong spirit of community in the European societies. The principles imply basic human rights: the right to self-determination of the individual but also legal protection of the life, privacy, and bodily integrity of the human person. Against this background, this presentation of bioethics and biolaw in Europe proposes to interpret the basic principles as being at the same time an ethical horizon of the actual bioethical and biolegal developments and as being important for the formulation of guidelines for future European politics on bioethics and biolaw.

Among the four principles autonomy is the most widely mentioned in the debate about bioethics and biolaw. It has also been widely discussed in the Anglo-American bioethical debate where the principalist philosophies of Tom Beauchamp and James Childress in their influential book *Principles of Biomedical Ethics* has become the foundation of much research in bioethics (Beauchamp & Childress, 1979). This book proposes the principle of respect for autonomy, the principle of non-malfeasance, the principle of beneficence, and the principle of justice as the foundation of biomedical ethics. This account of patient autonomy in relation to the three other principles has been widely accepted in the USA and to some extent in European countries. At the same time, it has a tendency to consider autonomy as the

only guiding principle concerning the protection of the human person and therefore forgets other dimensions of the protection of human beings that are particularly important in bioethics and biolaw.

Therefore, other supplementary principles must be taken into account when dealing with bioethical principles and the protection of human beings in bioethics and biolaw (Rendtorff & Kemp, 2000).

In particular, the principles of respect for human dignity, integrity, and vulnerability are important principles that can be proposed as principles that protect the human person, life, and bodily integrity. In this way, they are presented as more fundamental than the utilitarian account of quality of life that plays an enormous role in biomedical decision making. This approach is sometimes very instrumental and needs to be supplemented with ethical principles for protection of the human person and body. At the same time, the principles are founded as important expressions of the human culture and life world in Europe. It is presupposed that the basic principles are implicit in the public debate and the every-day understanding of the ethics of human existence. The principles must be interpreted as expression of the ethical understanding of the human person in daily ethical life.

In this way, the four principles must also be seen as an expression of the European humanistic tradition of giving a high value to individual or singular human beings and their development in society. The principles can be interpreted in the perspective of the European personalistic and existentialist philosophy from the point of view of Emmanuel Mounier's philosophy as the foundation of a European Humanistic bioethics and biolaw (Rendtorff & Kemp, 2000). As such the principles draw especially from the humanistic conception of the person and the corporeal well-being of the person that plays an extensive role in the humanism of French and Italian philosophy. But also the traditions of valuing the freedom of the individual in northern European countries are of basic importance for the understanding of the cultural foundations of the basic principles. In modern legal system, it is very important to protect the psychical and physical being of the human person as the subject of law. The basic ethical principles provide a framework for such care for body and person. The concept of a just legal order is closely linked to the protection of the life and well-being of the participants of society.

The principles can be seen as the foundation for the protection of human rights in biomedicine. The formulation of the definitions and contents of the basic principles in the different biomedical subfields contributes at the same time to formulate the protection of the human person in biomedicine. The promotion and interpretation of the autonomy, dignity, integrity, and vulnerability of the human person contributes to give stronger foundations for human rights, in particular the contribution to claim human dignity and protect the human person. In this way, the investigation of the basic principles implies their legal realization in the different legal orders in the European societies. Human rights and biorights can be seen as the concrete realization of the necessary protection of the personal sphere of human beings that is demanded by the technological development in biomedicine (Rendtorff, 2002).

There are a number of proposals for determining the metaphysical foundation of the basic principles. Without entering deeply into this discussion, the investigation

considers the principles as factually present in the debate about protection of the human person. The analysis focuses on the cultural signification of the basic principles in the public debate, the legal regulation, and the legislation processes on biomedical issues. In this context, society experiences a closer connection between ethics and law, where the basic principles are interpreted both as ethical and legal principles and they are also closely related to legal and political rights. We can say that protection of the basic ethical principles is a question of "political morality" and rights can be seen as trumps to realize the protection of the human person (Dworkin, 1977).

The relation between principles and concrete cases shall be understood as a dynamical hermeneutical relation, i.e., a case of constructive interpretations between particular cases and theoretical justifications where cases and principles mutually determine the development of bioethics and biolaw. Principles cannot only be abstractly determined but must also be seen in the light of the situation of application. At the same time interpretation of the ethical principles in these situations cannot be understood without general rules and principles. What is needed is a theory of reflective judgments to determine the relation between principles and cases. Reflective judgment according to theory of interpretation is the ability to relate principles to cases and cases to principles (Ricœur, 1995). Reflective judgment searches to find the right application of principles to new situations of decision making. In this way, there is no real contradiction between casuistry and principalism.

Also the principles should not be interpreted in a hierarchical way. They express different dimensions of the same concern for the protection of human beings. They are descriptions of different aspects of the same concern for protection of the human person. This means that the hermeneutical analysis of the signification of the principles in different ethical and legal orders and cultures leads to different interpretations and points of views about how the principles should function in the European societies and their future in the European Union. In this way, the principles can be seen as a "communitarian" expression of the ideal of a common European legal morality.

The Definitions of the Concepts of the Ethical Principles

In order to propose the basic ethical principles as essential for European bioethics, we need to say something more about their conceptual content and the foundation of their use for bioethics and biolaw in Europe. The following definitions of the concepts of the principles were based on hermeneutic analysis of the possible uses of the ethical principles combined with a critical analysis of their philosophical content. The ethical principles may be justified within a phenomenology of moral values in human intersubjective relations. The definitions were also based on empirical analysis of uses of the principles in different European countries.

Accordingly, autonomy is not only to be defined in the liberal sense as "permission" (Rendtorff & Kemp, 2000). Rather, five important meanings of autonomy can

be put forward: (1) autonomy as capacity of creation of ideas and goals for life, (2) autonomy as capacity of moral insight, "self-legislation," and privacy, (3) autonomy as capacity of decision and action with lack of outer constraint, (4) autonomy as capacity of political involvement and personal responsibility, and finally (5) autonomy as capacity of informed consent (Rendtorff & Kemp, 2000). Autonomy should be considered as a principle of the self-legislation of rational human beings taking part in the same human life world where they as human beings share as much of a form of life that they are able to understand each other. This does not exclude the recognition of pluralism as a political fact of modern society. But it is necessary to work with a more comprehensive idea of autonomy, recognizing the tensions between different conceptions of the good. The republican sense of autonomy is based on the vision of "the good life for and with the other in just institutions" (Ricœur, 1990, 202). This vision is put forward as the basis for privacy, confidentiality, and informed consent.

Autonomy is not considered as the only fundamental concept in bioethics and biolaw. Autonomy remains merely an ideal because of its structural limitations, i.e., human dependence on outer factors, lack of information, reduced capacity of reasoning, etc. This limitation of the concept of autonomy is also due to tension between the human existence as an "unencumbered self" and the embodied, embedded, character of human experience which means that the self is never really fully master over its life and situation. It must be recognized that the human person should be considered as a situated subject. In any case, autonomy is not a sufficient normative concept to ensure ethical and legal protection in relation to a number of subjects: minors, coma patients, the mentally ill, etc.

Dignity cannot be reduced to autonomy. Rather, dignity is defined both as an intrinsic value and as a matter for constructive morality in human relationships (Rendtorff & Kemp, 2000). It expresses the outstanding position of human beings in the universe. It refers to the inviolability of individual human life. It further expresses the moral responsibility of the human person. This idea of dignity must be respected in the intersubjective relations of the kingdom of ends-in-themselves. On this basis, it is possible to argue that human dignity has the following meanings as an intersubjective concept: (1) It expresses the intrinsic value of the human being in a community or society. (2) It includes respect for the moral agency of the human subject. (3) It means that every human being must be considered as being without a price and unable to be commercialized. (4) This includes that human dignity refers to the indeterminacy of the position of human beings in the universe – as they are able to create their own destiny. (5) Emotions of self-esteem, to be proud, feel shame, or having feeling of inferiority and degradation are essentially matters of human dignity that are expressed in the intersubjective relations between individuals. (6) Dignity can establish restrictions on interventions in human beings in taboo-situations, because of the necessity of human civilized behavior. (7) Finally, dignity relates to metaphysical experiences of human beings in existential limit situations where they face degrading treatment. But the relation between rights and dignity is also essential. In that context, human dignity expresses the intrinsic worth and fundamental equality of all human beings.

The principle of integrity may be said to refer to the totality of life saying that it should not be destroyed (Rendtorff & Kemp, 2000). Integrity is a coherence that in a certain sense must not be touched. This coherence, or rather "Lebenzusammenhang," is the narrative coherence of a person's life (the life story) or the narrative (historical) unity of human culture. On this basis, integrity has four meanings. (1) Integrity as a narrative totality, wholeness, completeness. (2) Integrity as a personal sphere of self-determination. (3) Integrity as a virtue of uncorrupted character, expressing uprightness, honesty, and good character. (4) Integrity as a legal notion, where it expresses the moral coherence of the legal or medical system. In bioethics and biolaw, the idea of integrity as an untouchable core, the personal sphere, which should not be subject to external intervention, is the most important. The personal body must be considered in a phenomenological perspective of the self-mastery of the body. In this perspective, the body is an expression of human subjectivity through the experience of the self in the body. Integrity expresses bodily completeness in a private sphere. In medicine, it is indispensable for trust between physician and patient. There is a close link between respect for identity and respect for integrity where a personal narrative expresses the life context of the individual. In this way, respect for integrity is recognition of the right to privacy and constitutes the virtues of the legal and medical systems.

Vulnerability of mental and corporeal life is closely linked to integrity. But it expresses more characteristics of the human condition (Rendtorff & Kemp, 2000). Protection of vulnerability is considered as the bridging factor between moral strangers in a pluralistic society, and therefore respect for vulnerability is essential to policy making in the modern welfare state. Vulnerability should be considered as a universal expression of the human condition (Lévinas, 1961). Moreover, it appeals to protection of both animals and the teleological auto-organization of the world where human beings take part of the ecosystem that also searches to preserve its integrity in evolution. However, vulnerability has been largely misunderstood in modern society, which has been guided by a so-called vulnerability reducing agenda, which aims to eliminate all vulnerability, i.e., suffering, abnormality, deafness, and disability, in order to create perfect human beings (Rendtorff & Kemp, 2000; Rendtorff, 2002). Respect for vulnerability must find the right balance between this logic of the struggle for immortality and the finitude of the earthly presence of human suffering. As an expression of the destiny of finitude, the moral receptivity of vulnerability, i.e., the respect for the vulnerability of the other, is the foundation of ethics in this time.

With these definitions of the main concepts in the principles, it is possible to describe and analyze the basic ethical principles (see below).

The Principle of Autonomy

The term "autonomy" consists of "auto" and "nomos." This means self-government in Greek language and in Ancient Greece, a city state was said to be autonomous when it was self-governing (Dworkin, 1988). In the Western tradition, autonomy

has been linked with the freedom of the individual and the possibility of the harmonious development of the human person according to personal choices, desires, and wishes for his and her future life. For Immanuel Kant, the person has moral freedom and is autonomous because it is an end in itself. Here persons are their own legislators. For John Stuart Mill, autonomy is said to be the freedom of coercion and the possibility of making one's own actions and decisions. The intimate connection between autonomy, moral independence, and personal self-development is also stressed in the European personalist and existential philosophies (Sartre, Mounier) that emphasize the personal freedom, engagement, and moral responsibility of the human individual. In the existentialist perspective, autonomy also implies a process of reflection and active presence of the individual. Existential freedom is a condition for personal identity and self-development. Autonomy is a second-order capacity of individuals to reflect on their first-order preferences and desires (Dworkin, 1988). It is important to stress that a theory of autonomy must imply positive liberty and active choices of the individual.

As the political origins of the term "auto-nomos" suggests, there is also a close connection between individual autonomy and the political organization of society. Modern political philosophies, such as those of John Rawls, Ronald Dworkin, and Jürgen Habermas, all value individual autonomy very high as the foundation of the political structure of society (Dworkin, 1977; Habermas, 1992; Rawls, 1992). In modern society, the principles of justice presuppose that human individuals are free and equal. Society is developed in a procedure of construction where autonomous agents are supposed to agree rationally on some common principles of justice (Rawls, 1992). In this context, autonomy often implies other basic characteristics, e.g., rationality, individuality, independence, and moral responsibility of the human person. It is central to the idea of liberal democracy that the individual has the possibility of self-realization and of self-development. Legitimate government has to be built on the self-determination by autonomous individuals. Therefore, protection of individual autonomy is a basic principle in all European constitutions. It is important to stress that a society built on responsible, autonomous decision making is not necessarily a society without communitarian engagements and common values. This is implicit in Habermas' notion of *Verfassungspatriotismus*, Rawls' concept of a liberal political community and Dworkin's ideas of "law as integrity" and law as an expression of "political morality." Indeed, the choice of such values should be motivated by individual decision making rather than collective coercion.

However, there is a broader and more serious communitarian critique of the concept of autonomy. It states that the concept of autonomy presupposes an institutional and cultural background. Autonomy must be recognized as a basic value if it has to have any real impact on decision making. Only a free and democratic society can make autonomy possible. At the same time, autonomy should not rule out social obligations to help others. An account of autonomy cannot be totally libertarian but must recognize the situated subject in a large number of social practices, commitments, compassions, and relations to other people (Reich, 1978). An exclusive focus on autonomy also forgets the fragile and vulnerable components of the human condition requiring care and respect for the human person.

The problem is whether autonomy implies a total substantial and procedural independency or whether it is possible to be autonomous and at the same time rely on communitarian values, the legal system, moral or religious authorities. The question is if it is possible to act autonomously in situations with little room for personal decision making because of determination of action outside the self. And in which way are autonomous decisions allowed to rely on the opinions of other persons. In this context, it should be evident that moral autonomy is related to free and autonomous choice but that this does not imply total independence from outer factors. Autonomy implies the capacity to make one's own decisions about one's own life. These decisions can, however, also be taken in collaboration with other human beings and according to other values. To be morally autonomous is related to sincere choice and personal decision making rather than to the invention of genuine personal values. Autonomy does not always have to imply one's own invention of the moral law (Sartre) but can equally imply the personal insight in moral reason and categorical imperative (Kant). Moral autonomy is a question of free moral choice according to a set of values that the individual finds right and just (Dworkin, 1988).

The central importance of autonomy for development of the human person (personal agency), political democracy, and one's conceptions of moral decision making is the background for the basic significance that is attributed to autonomy as a fundamental right that is used to justify protection of privacy, confidentiality, refusal of treatment, and informed consent. The notion of "informed consent" has been introduced after the Nuremberg Declaration and the Helsinki declarations as a basic requirement in the legislation on healthcare and biomedical practice in most of the European Countries. Every medical intervention must be legitimated by informed consent. The patient must have the right to make his own decisions about treatment and refusal of treatment. The concept of informed consent is introduced to secure a thoroughgoing self-determination of patients in medical treatment. The patient has the right to make the decisions about his own body in the context of medical treatment. We can mention some basic requirements of the doctrine of informed consent which are necessary for the functioning of the concept in practical medicine (Beauchamp & Childress, 1979). It implies that the patient has a meaningful choice and freedom in relation to the process of medical treatment. Therefore, the patient has to engage intentionally and with understanding and knowledge in the process of treatment. It has to be free and capable decisions without violence and coercion. An autonomous action implies: (1) freedom, (2) authenticity, (3) deliberation, and (4) moral reflection (Reich, 1978). The decisions made are compatible with an existing moral tradition in the hospital as long as they are made with a substantially free and independent decision with respect for the principle of autonomy. Informed consent should be considered as an event, as a process of communication and action between physician and patient that eventually leads to the decision and the undertaking of treatment. In this context, essential elements in informed consent are according to Beauchamp and Childress: (1) disclosure, (2) understanding, (3) voluntariness, (4) competence, and (5) consent (Reich, 1978; Beauchamp & Childress, 1979).

Although it has an enormous importance in biomedicine to secure the right treatment of individuals, autonomy and informed consent are concepts, which imply several problems. Thus, they cannot be the only concepts to express the humanistic concept of biomedicine and the protection of human beings in the biomedical field. It is possible briefly to mention a certain number of difficulties that necessitate complementing autonomy with other fundamental principles in bioethics and biolaw. First of all, the concept of autonomy abstracts from the vulnerable and fragile human condition and the existence of the person as a "situated subject." However, in the real world, it is not sure that the patient is able to judge the treatment process or fully understand the situation of treatment. Further, there is the problem of the correct disclosure of information and the eventual paternalist intervention of the doctor. And what about the therapeutic privilege of the doctor in a situation where the information would be of doubtful benefit for the patient? It is also possible to mention religious and moral traditions and conceptions within the hospital that are in conflict with the personal conceptions of the patients. So there may be many obstacles for respecting autonomy, and therefore, autonomy is limited as a guiding principle for biomedical treatment.

Apart from these internal difficulties in using the principle of autonomy, there are situations in bioethics and biolaw where the principle of autonomy simply does not apply (Rendtorff & Kemp, 2000). In cases concerning the unborn life, embryos, fetuses, the human body and its body parts, the body after death, organs, etc., the principle of autonomy is of little significance because one cannot say that the body before birth and after death or the different body parts have moral autonomy. This is the same for incompetent patients, e.g., minors, coma patients, or mentally diseased persons who are not able to make their own decisions. However, there is a reluctance to contribute moral value and concern to these people and living objects. Therefore, the concept of autonomy is very limited as a basic concept of bioethics and the adequate protection of the human person must take into account the other dimensions of protection: the principles of dignity, integrity, and vulnerability.

The Principle of Human Dignity

There is a close link between autonomy and dignity. Sometimes dignity is even equated with autonomy, and is seen as a part of being a human person. Human dignity has been a very influential concept in the Western tradition (Rendtorff & Kemp, 2000; Lebech, 2009). The principle of human dignity signifies that the human beings have a special position in the universe that places it over the natural and biological place of other beings in nature. As a moral being and because of its status as a human being with dignity, the human person has intrinsic value and possesses a unique place in the world. In the European cultural history, the idea of human dignity indicated the outstanding position of the human beings in the universe. The Stoics pointed to "dignitas humana" as an essential part of human existence. As moral beings with freedom, autonomy, capacity of moral reasoning

and responsibility, human beings are contributed dignity (Dignitas) that determine their value and position in the world. This idea of the intrinsic value of human life and dignity was developed in Christianity where the individual human person was regarded as intrinsically valuable. Augustine said that the human being was created in the image of God and therefore, the individual life would be inviolable. The concept of dignity as a characteristic of the human beings, who have to choose between good and evil and secure their own and the dignity of other people, was further developed in renaissance thinking, especially by Pico della Mirandola in the *Oration on Human Dignity*. Here dignity means that human beings are free to choose if they want to fall down to the lower levels that characterized animal life or ascent to the higher divine levels. In antiquity, Christianity, and the renaissance, the concept of human dignity expressed the moral superiority and responsibility of human beings in relation to themselves, animals, nature, and the whole universe (Rendtorff & Kemp, 2000).

These aspects of human dignity found a new synthesis in Immanuel Kant's philosophy about the human being as an end in itself and the idea of the categorical imperative. The Kantian idea is to treat every human being as an end in itself because of the relation between human autonomy and self-government. He states that every human being is possessing dignity and sovereignty because of its will and inner intrinsic value. In Kant's philosophy, human dignity is a basic moral principle that expresses the intrinsic dignity of Man. Although dignity is an intrinsic element of humanity that cannot be lost, human beings can be degraded and their dignity can be violated. Because of this potential degradation and violation of dignity, the protection of dignity becomes a great moral requirement that is closely linked to the concept of personal autonomy (Rendtorff & Kemp, 2000).

The close connection between dignity and autonomy is also very important in existentialist philosophy of the twentieth century. This philosophy can be seen as a contemporary way of interpreting the concept of human dignity. The underlying argument in Jean-Paul Sartre's defense of existentialism as a humanistic philosophy is the connection between human dignity, freedom, and autonomy (Rendtorff & Kemp, 2000). Because of the intrinsic capacity of choosing the meaning and significance of their own lives, human beings have intrinsic value that can be lost or destroyed. Human dignity applies to the intrinsic human capacities of engaged existence in passion and action in the world. This idea of human dignity is also present in Gabriel Marcel's catholic existentialism, in Simone de Beauvoir's argument for the equal dignity between man and woman, as well as in the antiracist argument for the extension of the concept of human dignity to the whole of mankind so that human rights are universal and inalienable (Rendtorff & Kemp, 2000). What is essential in this humanism is the protection of what is human dignity in present and future society in particular with regard to protection of human rights and dignity in sustainable development (Rendtorff, 2009).

The concept of human dignity is essential as the foundation of the development of human rights as legal instruments for the protection of the human person. This is especially present in the extension of the concept of human rights to the so-called biorights. In this context, the specifically human that is implied in the concept of

human dignity is seen as unity of body and soul. This implies that the human body and body parts as parts of the human person are expressions of human dignity and of what is specifically human (Rendtorff, 2002). Therefore, to respect the human body and body parts is a question about the respect for human dignity. The understanding of the person as bodily incarnated is the primary task in the legal regulation of the biomedical sciences. From the point of view of European bioethics, the aim of bioethics and biolaw is to protect what is specifically human, and can be understood as the human dignity in the technological development (Rendtorff & Kemp, 2000; Rendtorff, 2002). It is the task of human rights law to promote the humanistic ideals in the Western European Culture and take care of the idea of the intrinsic dignity of human beings as the foundation of autonomy and personal freedom. In this way, human dignity is more important than autonomy and self-determination, because human beings who decide for themselves can do actions that degrade and violate their dignity. Accordingly, autonomy may be limited in order to protect dignity. The respect for human dignity as an expression of what is specifically human expresses a fundamental principle of justice that goes beyond self-determination and distribution of goods in society. Accordingly, human rights express human dignity and are dependent on a view of the human person that goes beyond the sole protection of the conscious agent. The right to life, fairness, equal treatment, and other basic rights express the European constitutional culture, where the constitutional state can be seen as the "cultural gene of humanity" (Häberle, 1997).

The Principle of Integrity

Integrity is a philosophical concept that is closely connected with autonomy and dignity. It concerns the integrity of the human person and personality. The human person has a private sphere which can be described as the sphere of integrity. This sphere of integrity has at the same time a spiritual and a corporeal dimension: psychical and physical integrity. The spiritual dimension can be expressed by the concept of the zone of the "untouchable" developed by the Danish philosopher Knud Erik Løgstrup. He argues in relation to psychiatry that a permanent focus on motives for actions rather than reasons constitutes an infringement intervention in the integrity zone of the individual (Løgstrup, 1982). The infringement in this zone of the "untouchable" by the psychiatrist may imply violation of the integrity of the person and therefore psychiatry should rather be silent concerning the personal "untouchable" aspects of the human person. This concept can be generalized as a definition of integrity. Integrity in this sense concerns the untouchable core of the personality that must not be subject to unwanted external intervention. In a wider context, this implies the necessity of the protection of the personal integrity of the individual, e.g., in the access to bodily integrity or in relation to protecting individuals in relation to public storing of personal data.

But the notion of integrity also implies certain physical characteristics. The bodily incarnated human subject can be said to constitute a zone of integrity. This is the personal body which belongs to the subject as such. The personal body can in

a phenomenological perspective be said to constitute a zone of what is personal and proper to the individual. This zone of the bodily incarnated personality is proper to the individual and in existential sense singular human person and is therefore "untouchable." This means that the human body and its parts form a sphere of integrity that is supposed to be treated with special care and comprehension (Dübeck, 1997). Here integrity implies the right to life and the right to decide about one's own death.

The concept of integrity can also be seen in a legal perspective. It is an old legal principle that has become new actuality in the present legal situation. In the legal sense, the principle of integrity originates in Roman law, where it originates in the Latin "integritas" and the other notion of Latin origin "intact" as well as "noli me tangere," that signifies what is "untouchable," undisturbed, and "not be touched." In the French legal tradition, this is emphasized by the notion of "L'intangibilité de la personne" (Arnoux, 1994). In addition, the principle of integrity plays an important role in declarations of human rights and the different European constitutions and can therefore as such be said to constitute a necessary presupposition for the development of biolaw. The legal reference to the integrity of the human person sets limits to biomedical interventions in the human body. It is the realization and protection of the private sphere as a personal zone of the "untouchable" where the individual is protected by limits to the permitted intervention in the autonomy and dignity of the human person.

The protection of the physic-psychical integrity of the human person is becoming more and more central in the formulation of legal norms concerning genetic manipulation and the protection of the human genetic structure. The right to inherit a genetic substance that has not been artificially changed is an important aspect of integrity. In this way, integrity is used to protect the personal identity of the human person in connection with manipulation. This does not only concern actual people, but it also applies to what is typical for the human species. Integrity protects the genetic inheritance of future generations and opposes the manipulation of the genetic patrimony and their genetic identity. Manipulations with the human body that substantially changes personal identity can be stopped by reference to the integrity of the human person and the protection of privacy. In this context, there is an intimate connection between integrity and the private sphere of the human person as subject to individual autonomy.

Furthermore, integrity does not only apply to the human body but also concerns a wider sphere of protection of social and economic aspects of the person. Special mention merits the right to protection of information about the person, but also the right to a minimum of economic and social protection of vulnerable and weak social groups. Economical and social integrity refers to the concern for the protection of a minimum of welfare of the citizens in a welfare state.

The different perspectives on integrity manifest the close connection between integrity, personal identity, and character. As early as in Plato's ethical theory, integrity had this meaning of basic moral virtue and human character. The psychical and physical aspects of integrity confirm this comprehensive definition and relate the right to privacy that is revealed by integrity to the concepts of autonomy and dignity (Rendtorff & Kemp, 2000).

Finally, integrity can also be said to apply to the legal system as such. Ronald Dworkin uses the concept of integrity to describe the political morality of a just legal order. In this understanding of integrity, judges and agents in the legal order are said to have integrity when they build their decisions on impartiality and fairness and contribute each person "equal concern and respect." This is seen in *Law's Empire* where Dworkin talks about political morality and the integrity of the judge as well as the whole legal system as such (Dworkin, 1986). This is the objective counterpart to the subjective definition of the integrity of the human person.

The Principle of Vulnerability

The principle of vulnerability is also a very important European principle in bioethics and biolaw. Recently, it has become more and more present in the philosophical discourse. One could argue that a philosophical anthropology of the vulnerable human condition is the foundation of this concept. Vulnerability can be seen as an expression of the human condition and is therefore not only a mere descriptive concept but rather a concept with an explicit, normative content. Vulnerability is also an important notion underlying the juridical regulation of human activity. One can say that law is fundamentally institutionalized in order to protect vulnerable human beings (Rendtorff & Kemp, 2000).

The French philosopher Emmanuel Lévinas has defined the concept of vulnerability as the foundation for understanding of the human condition. He analyzes vulnerability as the foundation of morality. Morality is a compensation for man's vulnerability. The moral imperative is an imperative to take care of the other and an ethical responsibility toward the other. In this way, vulnerability can be said to imply an immanent normativity where the vulnerability is expressed in the corporeal incarnation of the other, e.g., in the face of the other. The existence of the other person expresses vulnerability and demands ethical engagement. Lévinas argues that the imperative "Thou shall not kill" is an essential expression of the need to protect vulnerable existence (Lévinas, 1961). This shows the ethical function of the corporeal finitude of human beings that becomes the foundation of Lévinas' philosophy. In this perspective, the deepest point of morality is presented in the vulnerable situation of human beings in the world. Vulnerability manifests a nonsymmetrical imbalance between the weak and the powerful; it demands the ethical engagement of the powerful to protect the weak. It is a person's vulnerability that makes one receptive for the responsibility emanating from the other as a vulnerable being. This ethical receptivity is the fundamental point of the human condition. The same concern for vulnerability as a fundamental ethical concept can also be shown in Jürgen Habermas' philosophy. His argument for communicative understanding in a domination free dialogue also situates vulnerability in the center of the ethical concern. This is openness toward the vulnerable other being taking part in a dialogue (Rendtorff & Kemp, 2000).

Vulnerability is therefore an extremely important concept as the foundation of ethical notions of care, responsibility, and empathy with the other. Vulnerability motivates ethical concern for the fragility of the human condition. The human

condition is marked by an extreme degree of fragility because of the temporal and finite character of all human life. The bodily incarnated human subject is destined for death, and it is not possible to abstract from mortality and destiny as basic to human life. Instead one has to live with mortality but also to take care of the vulnerable situated subject (Callahan, 1992).

In this context, vulnerability can also be interpreted as an important legal concept and even as the foundation of the legal system. The British philosopher of law and jurisprudence H.L.A. Hart says that the vulnerability of human beings is the background for the regulation of its activities in rules of the social institutions (Hart, 1961). Legal organization, legal principles, and concrete legal rules have the task to protect the vulnerable human being confronted with the possibility of destruction and the interventions from other people and the state. It is the task of the legal regulations of the biomedical problems to protect the weakest and the poorest in society against the discrimination and destruction from other social groups.

Within the Framework of the Welfare State

As such the basic principles constitute a sphere of protection of the human person. It is however necessary to consider the basic principles in a larger framework of the European welfare state. In this context, the concepts of state responsibility and solidarity concerning the protection of the vulnerable human beings are of essential significance.

The principles emphasize the need to protect the bodily incarnated human subject in relation to the development in modern risk society (Beck, 1986). They are also necessary tools to secure the development of the right legal rules to protect the body of the individual. The permanent pressure on the intimate human body in modern society is the background for the necessity to see the principles in the larger context of social responsibility and solidarity.

Here the concept of care is correlative to the dignity, integrity, and vulnerability of the human person. The ethics and law of the human person are closely connected to the concept of care. The humanist Erasmus already saw this concept as the basic attitude of society toward the vulnerable and weak (Rendtorff & Kemp, 2000). In modern biomedicine, the importance of care is especially present, not only between individuals but also between the state and individuals (Rendtorff, 2002). Against this background, the protection and care of vulnerable individuals becomes an integrated part of modern legal systems.

In *The Concept of Responsibility* the German-American philosopher Hans Jonas has given an argument for the thesis that the position of human beings in the modern world and the possibilities of domination and destruction of nature in industrial society have changed the ethical obligations of the human beings (Jonas, 1979). Society must be conscious about the responsibility not to destroy all life on earth. This implies state responsibility to set limits to social intervention in nature, animals, and the human body as well as a limitation of the ongoing destruction of the life-possibilities for future generations. The principle of responsibility is

founded on the intimate connection between the human body and the organic nature placing human beings as a part of the living world.

The duty to protect vulnerable and fragile life is an application of the categorical imperative in bioethics and biolaw. Jonas extends this to future generations. The imperative goes: "Act in such a way that the effects of your action are compatible with the permanence of genuine human life on earth" (Jonas, 1979 [1984], p. 11). This means that the protection of the autonomy, dignity, integrity, and vulnerability of the human person must be directed toward the protection of future generations and the variety of the species in nature to give future human beings the best possible conditions of existence. Therefore, the principle of responsibility functions as the foundation of the formulation of the basic ethical principles as legal principles. State responsibility implies conscious attitude, where decision makers respect autonomy, dignity, integrity, and vulnerability and put limits to a scientific and industrial development that manipulates the private sphere of the human person (Rendtorff & Kemp, 2000).

In a way, this concept of state responsibility is already present in the legal development in modern risk society where social intervention in the intimate sphere of the human person is more and more common. The French philosopher Paul Ricœur emphasizes the paradox that the re-moralization of the notion of responsibility means that one is approaching a society where more and more people as well as the state are responsible without being guilty. But he also shows how responsibility is responsibility toward the vulnerability of the other. He thinks that one has to find the right distance between risk, responsibility, and justice (Ricœur, 1995). While the principle of responsibility earlier indicated a well-defined juridical notion concerning attribution of responsibility for a specific action to a specific person, the intentional agent, it is the consequence of Hans Jonas definition of responsibility that human responsibility for future generations as a moral responsibility that goes beyond intentional legal agency and the following duty to take care of the week and the vulnerable must be seen as a part of responsibility. In other words, one is confronted with an extension of the content of the notion of responsibility, which means that we are also responsible for not doing anything to solve the global ecological and climate problems or the social problems of contributing with the adequate protection of the vulnerable populations. Today, it is possible to be responsible without having committed an error in a strict juridical sense. Juridical responsibility is also social responsibility. In the welfare state, this responsibility implies the duty to take care of the weak, the poor, and the sick people in society. The extension of the notion of responsibility in the modern welfare state implies that the welfare state in legislation and legal practice must continue the protection and care for the individual human body that earlier was a question of private activity or solely left to social institutions like the church and the medical profession (Rendtorff & Kemp, 2000).

The implementation of the basic ethical principles in modern legal practice does not only concern civil law and criminal law but it is also important in work, social and health law as well as in the legal system as such. The actual legal development shows an extended protection of the human person as the driving force in bioethics and biolaw. The French philosopher François Ewald shows in his famous book *L'Etat Providence* about the modern welfare state how risk society compensates for

work accidents, sickness, and social problems by developing an extended system of insurance – work and health insurance, collective systems of care that obligate firms and society to give compensation for social unhappiness even though neither the corporations nor society in a juridical perspective can be held responsible for the destiny of the individual (Ewald, 1984). In this way, many social insurances are created in opposition to the increased intervention in the intimate personality of the individual. At the same time, this means that legislation and juridical practice try to develop an extended protection of the human person by more or less implicitly applying the basic principles of autonomy, dignity, integrity, and vulnerability.

The link between responsibility and the protection of basic ethical principles constitutes the framework of social solidarity in the welfare state with regard to the formulation of norms for protection of the bodily incarnated human person in the welfare state. The project of care in the welfare state realized in social security as state responsibility protects the legal subjectivity of the vulnerable and weak. In most European constitutions, the basic principles are more or less present as indications of basic human rights of the personality. Legal subjectivity does not only imply taking part in a social contract, but is rather included as a subject for the protection of law. The legal subject has become the one who is worse respect and care (Ricœur, 1995). The subject of the law is to protect the autonomy, dignity, integrity, and vulnerability of the human personality.

The relation between basic ethical principles, rights, and protection of person and body must be seen as a consequence of the development of the welfare state and risk societies into a state of care and protection. Legal regulation is no longer built on a contractual relation between legal subjects but develops into a relation of social solidarity and collective responsibility that also concerns the basic principles related to bodily incarnated human person. In this way, law is built on social solidarity between the members of society. The law recognizes the autonomy of the individual but at same time, as the other three principles suggests, society has collective responsibility to put limits to the rights of the individual to its own body. The basic principles in relation to the human body must be considered in a broader perspective. The notions of dignity, integrity, and vulnerability are expressions of the necessary protection of the human body in the actual legal development and motivate a human rights–oriented duty to protection of the personal and corporeal sphere of the individual in the modern welfare state. In the framework of responsibility and solidarity, the basic principles confronted with the threat of powerful technological intervention in the personal sphere of the human person constitute an effort to formulate a humanistic conception of man as foundation of policy and legal regulation in the welfare state.

European Bioethics and the UNESCO's Universal Declaration on Bioethics and Human Rights

In fact, it is possible to see a strong influence of the European principles of bioethics and biolaw on the UNESCO *Universal Declaration on Bioethics and Human Rights* that implicitly can be said to be based on the basic ethical principles of European

bioethics. The concept of human dignity may be said to include the human body, because human beings are considered as a unity of body and soul, where the body has its own rights of protection of autonomy, dignity, integrity, and vulnerability. To respect the human body is therefore to recognize its dignity as manifestation of a human person. This concept of the human being does not only refer to the individual but to the common destiny of humanity as a form of life.

Already the previous UNESCO Declaration in the area of bioethics, the *Universal Declaration on the Human Genome and Human Rights* (1997), says that every human being has the right to respect for its genetic structure. Humanity ought to take care of the plurality and difference of our human genes. Society ought to have solidarity with those human beings who have weak genes and it should not systematically favor people with a specific genetic constitution and therefore, the Declaration characterizes the human genome in its diversity as the "common heritage of mankind." The human genome can be considered as an irreplaceable work of art, that we are required to protect. This concern for human dignity in genetic research is an international obligation, which goes beyond internal affairs of states and signifies that the interests of the individual always should prevail over the utilitarian use of the body in the interest of society.

When using biomedical technology, we have the obligation to respect human rights of autonomy, self-determination, and informed consent and indeed "the right not to know" if an individual does not want to know its own genetic structure. The *Universal Declaration on the Human Genome and Human Rights* connects human dignity with the legal notions of human physical and psychological integrity as an important foundation for regulation of biomedical progress. This does not mean that no intervention in the human genome should be allowed, but when gene technology is used for medical treatment, it should not be allowed to make interventions that have direct eugenic purposes of modifying specific human characteristics. The concern for the human genome as common heritage of mankind therefore includes the protection of valuable aspects of the genetic structure of future human individuals. At the same time, personal information about the genetic structure is considered as a part of the integrity and vulnerability of individuals. There is a close relation between protection of the right to privacy and this integrity that express the human body as a private sphere of self-determination.

We can deduce from the UNESCO *Universal Declaration on Bioethics and Human Rights* that the concepts of human autonomy, dignity, integrity, and vulnerability require concrete significance in bioethics and biolaw because protection of individual human beings prevails over the interests of science and society. Recognition of the significance of technological progress for collective interests, respect for the human body, extension of law to be valid for life before birth and after death and in relation to future generations are important aspects of this protection of human privacy based on protection of the inviolability of the human body. Thus, concern for human dignity precedes self-determination and society has a duty to avoid that human individuals in despair or desperation are forced to violate their own bodies in selling their organs or offering themselves for dubitable genetic experiments. The concept of humanity implied in the international conventions and

declarations can be considered as an expression of the humanism of the philosophy of the basic ethical principles that cares for humanity and wants the persistence of "real" human life on earth in the future.

Conclusion

In this chapter, the basic ethical principles of autonomy, dignity, integrity, and vulnerability in European Bioethics and Biolaw have been presented as essential to European perspectives in bioethics and biolaw. The results of the research project have been published in the BIO-MED research project report *Basic Ethical Principles in European Bioethics and Biolaw* (2000). Moreover, the research has led to the Barcelona-Declaration, proposed by partners in the project (1998), that gives a good indication of the policy implications of European bioethics (Rendtorff & Kemp, 2000; Rendtorff, 2002; Rendtorff & Kemp, 2009). Indeed, we can also see that the basic ethical principles are more or less implicitly or explicitly present in the UNESCO *Universal Declaration on Bioethics and Human Rights*. The principles are important to protect the life and dignity of bodily incarnated human person in biotechnological development, and they are historical and cultural incarnations of European morality and legal systems. They express the essence of a European human rights culture and the focus on the protection of human rights and personhood in European societies.

Indeed, the important European principles in bioethics and biolaw must be considered in the framework of responsibility, solidarity, and justice in the sense that the basic ethical principles concern the protection of human beings not only as isolated persons, but also as members of European societies and nations. In this sense, the basic ethical principles are founded in European democratic political thinking, where concern for the corporeal and psychical well-being of individuals is in the center of considerations of political philosophy in personalism, existentialism, and democratic political thinking. In this context, the basic ethical principles are not only European principles, but they also have a universalist and cosmopolitan possible application, where the concern for protection of human beings in the framework of the basic ethical principles also can be applied globally as an expression of a universal protection of the life and dignity of bodily incarnated human beings in biotechnological development.

Latin American Perspectives

19

Fernando Lolas

Introduction

The geopolitical region known as Latin America is composed of countries and territories derived mainly from the Spanish and the Portuguese empires. The designation "Latin" stresses the fact that, culturally, the countries belong to the linguistic domain of the Romance languages derived from Latin. It was coined by intellectuals during the nineteenth century in order to differentiate these nations from Europe, the Slavic and Teutonic nations, and the Anglo-Saxon ones. The term seems to have attained currency after it was employed by French politicians and writers as a way of establishing the influence of French culture in an area dominated by the Spanish and Portuguese empires. Most of the countries where Spanish or Portuguese languages are spoken share similar cultural traditions, language, and customs, and became politically independent during the nineteenth and twentieth centuries. The expression Ibero-America is also used for countries derived from Spanish and Portuguese rule. Other designations apply to countries where Spanish is spoken: Spanish America or Hispanic America (hence the term "Hispanos" in common North American parlance). In most of these countries, the official language is Spanish, although other indigenous languages are spoken and sometimes also have official status (Quechua, Guaraní, Aymara, or Mayan). In Puerto Rico, as an independent state affiliated with the US, English is also official.

In such a sensitive area as ethical regulation and research oversight, the issue of language is not a negligible one. As it has become clear throughout the years, many international and national documents regarding bioethical issues either lose their connotations in English or acquire in translation shades of meaning not intended, or absent, in the original language. This is important when considering that the linguistic space of Latin America trying to accommodate intellectual import such as bioethics may not always interpret correctly the cultural underpinnings of

concepts and uses. This applies to norms, regulations, and expressions translated and used for conditions and situations different from the original ones.

Although some degree of similarity could be expected, Latin American countries exhibit different histories and their public policies, governments, education, and insertion in the world economies make it difficult to generalize, especially in areas like health care or scientific research. The estimated Latin American population in 2010 was about 590 million and, among the countries, great differences in size and population can be observed. The majority of the population professes the Christian faith, mostly Roman Catholic, which was at some point in history the official religion of some nations. The political structure of most countries is that of a republic, although the continent has seen the emergence of dictatorships, *de facto* governments, and even attempts at establishing empires (e.g., Mexico). The poverty index ranges from 3.0 of Uruguay to more than 30 in Haiti, reflecting the disparities existent between nations. The inequities internal to each country are also important, with countries with high (e.g., Chile) and low (e.g., Haiti) human development indexes.

Intellectual Life

Indigenous cultures, prior to the arrival of European conquerors, had sophisticated systems of thought that can be reconstructed from the remnants of their empires. Their contribution to current scholarship is not evident. Academic philosophy can be dated back to the sixteenth century and was stimulated mainly by the Catholic Church, which established the first institutions of higher learning and scholarship in the Spanish colonies. At the beginning of the twentieth century, one of the dominant forms of philosophical reflection was positivism, contested by other streams of thought. Some prominent writers have expanded traditional Marxist and Christian thinking and adapted them to the particular environment of the Spanish-speaking countries. The continent is the birthplace of special forms of theological thinking, in particular the theology of liberation, and some forms of philosophical reflection inspired by European traditions.

In authoritative accounts of Ibero-American bioethics, the topic is usually dealt with on a country-by-country basis (e.g., Pessini, de Barchifontaine, & Lolas, 2010), reflecting the diversity of approaches, insights, and contributions from the nations comprising the continent. Bioethics became known to Latin American scholars during the 1980s, with precursors and pioneers in Argentina, Mexico, Colombia, and Chile (the names of José Alberto Mainetti, in Argentina, Manuel Velasco Suarez, in Mexico, and Alfonso Llano, S.J., in Colombia, are usually mentioned as pioneers in introducing bioethical thinking to the continent). The most common form adopted is the principialism emanating from the Belmont Report in the US and the seminal work of Beauchamp and Childress stating *prima facie* principles that appeared to offer a practical way of posing and solving moral dilemmas in the biological and medical sciences. Since then, the number of institutions bearing the word *bioethics* in their title, courses offered in bioethics,

and people engaged in what could be called bioethical discourse has grown steadily (Lolas, 1998). Currently, diverse forms of bioethics are present, including feminist approaches, personalist bioethics, ecological ethics, and others. In some quarters, a confusion between bioethics as an academic enterprise and bioethics as a political discourse related to human rights and protests against poverty, inequities, and political corruption determines a picture in which it is difficult to evaluate quality of the contributions.

History and Context

Most Ibero-American countries were freed from the imperial tutelage of Spain and Portugal during the first half of the nineteenth century. The period immediately following the Conquest is known as the Colony, and the dominant climate was one of paternalism in the relation between the Metropolis and the colonies. The French invasion of Spain at the beginning of the nineteenth century (1808) and the replacement of the Spanish king by Jose Bonaparte led to a nationalist movement, both in the Iberian Peninsula and in the colonies. It found expression in "*juntas*," governing bodies that produced constitutional documents and initiated a movement toward independence that consolidated after struggles against Ferdinand VII, the reinstated king, when he and his advisors did not understand that many of the juntas had been established in order to preserve, not to alter, the king's sovereignty. Inspired by the French and American Revolutions and the 1776 Constitution of the United States of America in the North, many colonies started to develop their own independentist movements inspired by free thinkers and the freemasonry. The struggle against Spanish rule was different in Brazil, which was ruled by the Royal Family of Portugal, settling there for some years, and initiated by a member of the Royal family.

The ruling classes in the remnants of the Spanish Empire were composed by "*criollos*," mostly of Peninsular and local stock, whose attitude toward the aboriginal inhabitants of the continent (known as "Indians" by the old Columbian notion that these territories were the Indies sought after by colonial powers) was no better than the one held by Spain. In point of fact, in almost all of the newly formed nations or countries, the Indians or aborigines were badly treated and left without the protection accorded them by the Spanish rule. This historical fact is a starting point for discussing part of the inequalities and the inequities that prevail in communities highly stratified by race and ethnic origin, despite declarations to the contrary in most political constitutions. The importance of multiethnicity and multiculturalism has to be considered when analyzing the application and scope of generalizations regarding human rights, ethical attitudes, and academic consolidation of bioethics.

While in some countries the Indian past and origin are greatly appreciated and vindicated, in others the traces of their influence have been diluted or lost. From an anthropological point of view, this might constitute one of the sources of the tension between different identities experienced by inhabitants and elites of the countries.

They sometimes reject completely the influence of Europe or of the new world power constituted by the United States of North America or fail to come to terms with a pervasive influence on their habits and commodities. Much of the militant voices raised against "foreign influence" will not reject enjoying the money and facilities of the imperialist countries while at the same spending time and effort in vitriolic discourses against them. The quest for identity, not always recognized as a source of tension, explains much of the superficial approaches to relevant bioethical issues in many areas of real concern.

Research ethics curricula and bioethical discourse (as an intellectual import) face the challenge of multiethnic and multicultural contexts existent in Latin America, whose indigenous population averages 11 % but varies widely, with 80 % in Bolivia, 60 % in Guatemala, and 40 % in Peru. Even language diversity is a factor hampering research, particularly in the field of social studies and public health. Stigmatization has been found to affect genomics research in populations, and the need for a "culture fair" approach to data gathering and interpretation is as an ethical an imperative as the need to respect dignity or request consent. The notion of "ethical sustainability," essential in continent-wide work, stresses what international documents identify as fundamental in the pursuit of science at the service of development. The UNESCO Universal Declaration on Bioethics and Human Rights, among other documents, underscores the vulnerability of resource-poor populations and the ethical imperative to avoid the typical "safari research": researchers from affluent societies behave as "data hunters" and disregard opportunities for real collaboration. A permanent dialogue between scientists and scholars from Latin America and those from other continents is essential if the "bi-directional" character of all ethical dialogue is to be preserved.

The history of the continent exhibits cases where human dignity was disregarded in the pursuit of scientific goals. Some vulnerable populations in the continent have fallen prey to commercial interests of pharmaceutical companies or research interests of academic institutions from industrialized countries. The ensuing mistrust in the scientific enterprise is a powerful stimulus for developing local forms of ethical oversight in consonance with community interests, cultural traditions, and scientific development. Although vulnerability is part of the human condition, and cannot be simplistically attributed to certain groups of people, it is evident that many illiterate masses in the Latin American continent, ignorant of their rights and without access to the benefits of civilization, are vulnerable to exploitation and discrimination. This may partly explain the curious phenomenon of inferiority complexes that result in aggressive stances against dominant world cultures.

The very notion of bioethics and its attendant methodology as an intellectual enterprise is an import introducing the tenets and fundaments of the culture in which it was born and its standards of scholarship and argument. The idea of a dialogical transdisciplinary discipline and other features are caricaturized in attempts at "re-discovering" the same under new terms or gestures.

The search for new fields of inquiry and problems is a recent feature of Latin American bioethics. Roughly *three periods or stages* can be discerned in the development of bioethics in the continent. A first one is characterized by contact

with publications from the US and reproduction of ideas and topics. A second period marks the sometimes critical reaction to bioethics methods and problems. Finally, a third stage of creative appropriation and original developments is visible only in selected groups or centers. The influence of European thinking has begun to be felt in more recent decades.

As a social *process*, bioethics has arisen out of emotional reaction towards undesirable effects of science and technology, which in the continent has been associated with the effects of imperialism and dominance from the North. As *procedure* for arriving at decisions, the social institution of the committee or the national commission has been adopted as the standard of practice. Finally, as an academic *product*, the Latin American scenario is rich in initiatives, although not all of them of equal merit or value.

In all three forms of conceptualization of bioethics, peculiarities can be worked out. For instance, a national commission for analyzing and deliberating on bioethical issues, modeled after the European model, presupposes a democratic frame of mind and clear organization of the state in order not to produce conflicts with the legal system. Academically, the relation of students to teachers and opinion leaders is influenced by the cultural traditions. In general, it may be stated that the period of assimilation of bioethics, still unfinished, will certainly lead to institutions adequate to the idiosyncrasy and uses of the populations.

Norms, Laws and Regulations

The version of bioethics that achieved early and widespread currency in Latin American countries is the one which places great emphasis on the medical and biological importance of the bioethical tradition and discourse. Of the two original strands discernible by the second half of the twentieth century, one emphasizing ecological concerns and the other insisting upon rehumanizing medicine, the latter is most commonly associated with the word. This is certainly changing as time goes by, but it is evident when considering the impact of bioethical thinking upon norms and regulations. Bioethical principles are frequently invoked in the fields of hospital care and the relation between healthcare professionals and the population. They also find expression in norms, regulations, and laws related to scientific research. In all the countries of the continent, consideration to ethical standards is given to hospital and ambulatory care, with legislations passed on such diverse subjects as patients' rights, access to treatment, and duties of medical professionals toward users of healthcare systems. In the majority of the countries, biomedical research is regulated by technical norms complementing and expanding the ethical principles held by transnational drug companies or scientifically advanced countries (in the continent, the presence of US research is widespread). A useful compilation can be found at the website of the Office of Human Research Protection, updated every year (www.hhs.gov/ohrp/international/index.html).

A National Commission of Bioethics (or a commission at the national level with a similar designation and comparable tasks) is not present in every country as an

active body recognized as essential for democratic dialogue. In some cases, the political orientation of those who proposed it or the compromises of some of their members made consensus difficult. In others, difficulties concerning the scope and character of the national body were voiced. Viewed in perspective, most of these national bodies are related to the health sector and serve as advisors to governments in the areas of scientific research, health policies, and general orientation of the legal system as it relates to health care and research. In only a few cases do these bodies enjoy sufficient financial and administrative autonomy to serve as a critical forum for discussion on policymaking or legislation. One notable example is Mexico, with a funded national commission operating throughout the entire country. The first countries to establish such national commissions were Argentina and Mexico in 1992, followed by Cuba (1996), Dominican Republic (1997), Ecuador (1998), Venezuela (1998), Colombia (2001), Uruguay (2001), Bolivia (2003), Costa Rica (2003), Panama (2003), and El Salvador (2009), among other countries. In some countries, the bioethics body is part of a preexisting institution, like Peru, incorporated into Consejo Nacional de Salud. In Brazil, a national commission devoted to research has operated since 1996. These bodies have different origins, forms of operation, scope of influence, and activities. In Chile, for instance, a law from 2006 rules that the members of the national commission will be appointed by the Senate upon proposal from the president of the republic.

The existence of hospital ethics committees, research ethics committees, and ethics committees of professional associations is already common in all the countries of the Latin American continent. Overall, the quality of their work and performance are difficult to ascertain. Many of them are composed by members not duly qualified to the tasks, and accreditation by international agencies is not a common practice. Perhaps the main weakness is the lack of appropriate legislations and regulations. In addition, the general culture does not consider work in these bodies as equivalent to administrative, clinical, or research activities, and time and effort of members are not compensated financially or in terms of professional promotion.

Teaching and Training

Advanced programs and training opportunities exist in almost every country in the Latin American region, some at the level of doctorate. The progressive inclusion of bioethical topics in undergraduate training has resulted in a wide array of opportunities for professionals in the biological and health sciences. However, many teaching programs replicate what used to be taught as professional deontology, legal aspects of the professions, or miscellaneous topics not included in other areas. A unified set of concepts, methods, and aims of these teaching activities would greatly facilitate the constitution of a disciplinary discourse and would improve accreditation practices. Several initiatives in this direction have come from the work of a group of practitioners under the aegis of UNESCO (RedBioética), or from

institutions offering virtual courses in several languages (e.g., the CITI program promoted by a consortium of institutions, mostly in the US, with a Spanish language version widely used in Latin America).

In the training sphere, the imprint of the ideological orientation of the institutions is evident, with manifestations of doctrinarian character in the position towards issues like abortion, euthanasia, assisted reproduction, and research. The aim of regulatory bodies to have professionals conversant with responsible conduct of research, appropriate policymaking, and respect for human dignity and rights is not always evident in advanced curricula. Despite the interest and enthusiasm on the part of institutions for advanced training, a general picture of confusion emerges. It is a common experience that persons with advanced degrees in bioethics do not find appropriate working opportunities in the field and continue performing duties at institutions that either do not value appropriately this expertise or do not have enough funds to profit from bioethical training (i.e., improving the work of clinical, professional or research ethics committees, accrediting oversight bodies, etc.). This signalizes a potentially limiting factor in the effort to increase the "bioethical alphabetization" of scientific and practice communities and hampers the development of a truly representative form of bioethics in Latin American countries.

During the 1990s, several master's programs were established in leading institutions of the region with the aid of the Complutense University of Madrid. The Bioethics Program of the Pan American Health Organization (PAHO), which existed until 2010, was a joint venture with the University of Chile and the Chilean government. In addition to encouraging training, it helped publish the journal *Acta Bioethica* (ISSN 0717–5906), a trilingual publication (English, Spanish, Portuguese) of the Centro Interdisciplinario de Estudios en Bioética (CIEB) of the University of Chile, indexed in most relevant databases of scientific and medical literature. The CIEB also edits series of books and monographs freely available at the websites www.bioetica.uchile.cl and www.actabioethica.cl. The trend toward establishing advanced degrees in bioethics has accelerated and institutions strive to have masters or doctorate programs as a matter of prestige and influence. The question about the employability and real working opportunities for these graduates is seldom posed. Master's-level programs in accredited institutions are on the rise, with varying degrees of involvement. Useful information can be obtained at the universities involved, and also at the UNESCO website (www.unesco.org).

Not many continent-wide initiatives exist and the ones that do, for instance the work of the Fogarty International Center of the National Institutes of Health, meet with resistance in some quarters for the prejudice indicated before that it might represent a pervasive form of ideological penetration. There are other initiatives stemming from cultural and international foundations and institutions, but efforts to constitute a unified group of practitioners and a set of standards of practice are in the process of consolidation. Mutual recognition of credits and activities between universities and other higher learning institutions presents some difficulties, which can be solved by conjoint efforts.

Institutionalization of Bioethics. Organizations and Societies

The UNESCO GEOBS database lists 68 institutions bearing the name bioethics in the region of Latin America. Some of them are programs or institutes, others are teaching facilities.

There are active users of the bioethical discourse in all countries of the region, with the establishment of hospital, research, and professional ethics committees and a reasonable knowledge of international regulations and practices. The actual situation, as it appears in field studies and through anecdotal evidence, is different from what is claimed by some authors, with inappropriate or inexistent policies for obtaining informed consent, scarce attention to research integrity issues, no specific training on responsible conduct of research, and a discussion climate dominated by political/ideological slogans when not by religious biases. The impact of bioethics on policymaking is more a rhetorical device than an actual practice. In the continent, with its gross inequities in access to health care, it could be said that a large *know-do gap* exists. Much of the knowledge accumulated and of the technologies developed does not reach large segments of the population. This is probably one of the greatest bioethical challenges as it affects public health and well being of populations.

In the course of its development, bioethical discourse has also found expression in the constitution of associations and groupings. FELAIBE (Latin American Federation of Institutions in Bioethics) was initiated by the pioneers Alfonso Llano, Colombia, José Alberto Mainetti, Argentina, and Manuel Velasco-Suárez, México, and has survived a series of avatars. It organizes meetings, identifies prospective contributors to the bioethical movement, and brings together professionals from different backgrounds. FLACEIS, expressly devoted to research ethics committees, has more or less the same aims concentrating on research ethics and its practice in different countries. In many countries, local bioethics societies exist, with membership from active professionals in the fields of medicine, the sciences, and the law. Groupings such as the so-called RedBioética with relation to UNESCO, transient societies organizing meetings, and NGOs also work in the broad area of bioethics. During the existence of the Pan American Health Organization (PAHO) Program on Bioethics, this group also served a continental purpose of bringing together practitioners and scholars from different countries. Other professional societies have either direct connections with the bioethical discourse (like Sociedad Iberoamericana de Derecho Médico, SIDEME) or have constituted "bioethical chapters" within their respective organizations. Many professional associations have also incorporated the term *bioethics* for some of their activities.

Belonging to a national society or academy does not always constitute proof of competence or scholarly background. Membership is subject to waxing and waning, depending on the need to establish good professional contacts or acquire influence. Although the same happens in other parts of the world, the climate in many Latin American countries is signaled by a context in which political and administrative corruption, both actual and perceived, demands an analysis of the level at which certain customs or activities may affect scientific integrity, good

clinical practices, and professional conduct. It is expected that the work of societies devoted to bioethics may have an impact on societal regulation of moral behavior.

Bioethics societies exist currently in all countries of the Latin American region, and their structure, membership, and contributions can be consulted in the chapters devoted to each country.

At universities and other teaching institutions, bioethics (or some of its derivatives) occupy a place in curricula and are represented as institutes, centers, or study groups, with or without third-party support.

A Typology of Perspectives

In many respects, Latin America is a continent in transition. For instance, it finds itself in an epidemiological transition. Old diseases of poverty and underdevelopment, such as infectious diseases, coexist with diseases of civilization, such as chronic ailments. In the bioethical sphere, there is also a transition. The problems inherent in the state of undeveloped independent thinking coexist with sophisticated analyses of individual rights and access to the benefits of civilization. Political thinking influences the uses of bioethical discourse at the macro level in the countries of the Latin American region, as evinced by the conformation of national commissions and advisory bodies. The term *bioethics* has become current in common parlance, at least in professional circles. Everywhere groups are established, courses offered, and journals published with the word *bioethics* in their designation.

Several streams can be discerned in the continent. On the one hand, there is the influence of the Catholic Church and other Christian religions, which try to impose their agenda on the bioethical discourse. On the other hand, a strong secular movement, mostly imposed by the economic and social realities, is evident in policymaking and the establishment of guidelines and regulations for research and clinical practice. The university work is reflected in training programs at the master's level, in the teaching of undergraduates in the sciences, and in the publication of a growing body of literature, not always original but indicative of an interest in the furtherance of bioethical knowledge.

In the overall picture, there are countries with low development of bioethics, countries in the process of acquiring the bioethical discourse, and countries with developments at the institutional and conceptual levels. Among the latter, the examples of Mexico, Brazil, Argentina, Colombia, and Chile can be mentioned. In these countries, several groups have been formed, sometimes in contradiction to each other, but reflecting an enduring interest in bioethics institutions, discourse, and applications. The existence of discrepant views about different topics of social interest is a sign of maturity, provided the canons of tolerant discussion and the acceptance of differences are respected. This is not always the case, with militant groups claiming to have a monopoly on human rights and institutional organization.

The existence of national bodies for bioethics counseling of governments, ministries of health, and society in general is widespread. However, the existence

of these bodies does not always mean that they are consulted or that they make a contribution to the discussion of issues. In many cases, they are nominated on the basis of political proximity to the leading parties, and, in others, they are not provided with sufficient funds for a proper functioning. The case of Mexico can be singled out as a commission endowed with adequate means for serving the needs of a federal country, a reasonable budget, and enough personnel to fulfill its mission.

Publications and Scholarship

There are several periodic publications in different countries. With few exceptions they are not included in international index services. Books bearing the word *bioethics* in the title have been produced in almost all countries in the continent. Originality of contributions, as estimated by current standards of scholarship, is not a strong characteristic. The road to a mature scholarship is hampered in the institutions due to a lack of opportunities for working in the area at academic and learning institutions.

The existence of publications in each country depends on adequate funding and, more critically, on the continuous production of intellectual deliverables. The overall quality of the publications in the periodicals surveyed is acceptable. However, there is a great need for achieving a more original contribution to world bioethics and more rigorous standards for publication. When analyzing medical and scientific publications, the results regarding ethical considerations are mixed.

As an academic community develops, students should be aware of the developments that take place. Like other communities of this type, objectionable practices arise, with plagiarism, fabrication and falsification of data, biased accounts, and ideological orientations of arguments. In many respects, an "ethics of bioethics" is needed in Latin America.

When viewed globally, the contribution of Latin American scholars is still in need of a more critical analysis and deeper compromise with standards of scholarship. The production of written materials and websites has increased ostensibly in the last decades. The listing of periodic publications, their publication policies, and the impact of their contributions is considered in the chapters devoted to each country. The following list, compiled by Dr. E Rodriguez, Santiago, gives an idea of those titles in Spanish or Portuguese that have been present in most libraries (for supplemental information, the reader is referred to the Scielo, Latindex, or Scopus databases).

Future Prospects. Toward a Biocentric Ethics for Latin America

In a continent characterized by inequities and social disparities, undoubtedly the most pressing need is sound reflection on social issues from a bioethical point of

view and with the capacity to influence political and technical decision-making. To this end, current state of development seems a good starting point but one that does not ensure realization of the expectations of large segments of the population. A resolution of the know-do gap will certainly need to improve education, communication, and professional training. A resolution of the gap between what is available and what problems should be solved needs political elites well aware of their responsibility towards the public and academic elites really believing in dialogue and tolerance for contributing to the developmental effort.

The main decision to be taken is whether to professionalize the work in bioethics or make it an ancillary discipline to the training of health and other professionals. This should be responded to by stating that, aside from alphabetizing the communities, making them aware of their rights and duties, professionals that are capable of original thinking should be trained, who can liberate themselves from self-imposed constraints, such as the rejection of outer influences or the ignorance about the true position of their contributions in a globalized world of knowledge.

As a continent in transition, with disparities and differences, there is the expectation that collaboration between the countries could be achieved. To this end, all forms of expected or alleged supremacy of one over the others should be avoided and a climate of dialogue and collaboration should ensue. Tolerance is a much-needed attribute of the societies, all the more so in places where funding is scarce and opportunities for development rare.

The political and socioeconomic climate greatly influences academic endeavors, and bioethics is no exception. The countries of the Latin American continent rank high in perceived and actual corruption in government and administration. Issues discussed in academic circles, or considerations related to health research and health care should be considered against the background of this societal characteristic. As a continent with great inequities in access to health care, the benefits of scientific progress or the welfare of civilization, the influence of bioethical thinking is undoubtedly more than a luxury and should be considered a necessity of the times.

Fundamental Issues

There are fundamental issues related to psychosocial and biomedical research in Latin America. One is the very notion of research. Standards of scholarship and university training are not uniform throughout the continent. This affects the way in which ethics is considered. Sometimes it is possible to argue that to insist on the ethical oversight of scientific practices is misguided, considering that the idea of what research really is is fuzzy or nonexistent in some contexts. In point of fact, research is frequently confused with other activities, such as surveillance or industry-guided clinical trials, or areas such as social science where the need for ethical evaluation is not considered due to a presumed low risk. These misunderstandings may need some time to disappear and may require an in depth-analysis of cultural practices. An exploration of what research really is in different cultural

settings constitutes an interesting field of inquiry. Some aspects of this cultural difference in conceptualization and of the difficulties in devising appropriate methods to tackle with ethical issues were addressed by the Program on Bioethics of the Pan American Health Organization (PAHO), a collaborative effort of the Chilean Government, the University of Chile through CIEB, and PAHO, which was operative from 1994 through 2010. The history and development of science funding in Latin America is a much-needed enterprise and should be pursued alongside training in ethics and integrity (Lolas, 2006).

The experience gathered throughout the years has demonstrated that an ethical approach to science and technology, in the current state of development of disciplines, by necessity must incorporate specialized knowledge, be based on deliberation and dialogue, and depends on an organic and cohesive community. This community includes researchers, policymakers, politicians, administrators, students, and laypeople. Because research is a cultural process shaped by expectations, hopes, and practices, it cannot be examined isolated from other aspects of social life. In point of fact, ethical oversight of research cannot be treated independently from the general "ethical level" of the community at large. Political and administrative corruption, if present in a country and accepted as normal, cannot be irrelevant for the establishment of sound scientific practices. The notion of *ethical sustainability* suggests that any change in attitudes, goals, and practices must be based on sound argument and endure over time. A sustainable effort depends critically on the establishment and maintenance of communities: epistemic communities (or cultures), practice communities, and moral communities. These communities rarely overlap, although it might be expected that the moral one embraces the others and its foundations include knowledge and its applications. A biocentric ethics is not simply another form of applied ethics. It represents a change in the paradigmatic construction of the moral universe. It goes beyond the classical anthropocentrism in the formulation of moral imperatives. It is knowledge on how to produce, expand, and apply knowledge. It is also an indication that the very foundation of welfare and progress includes a joint consideration of goals and means; goals formulated as culture and civilization, and means legitimated by discursive practices permitting respect of persons, living beings, and environment, tolerance of diversity, and agreement on basic principles of communality. To achieve this long-term goal, adapted to the historical peculiarities of a world region and started from the analysis of biomedical and psychosocial research, one's contribution depends on dialogue and common discourse. The establishment of a network of users of the bioethical discourse has been an important mission of several institutions and will continue to be in the future.

Common Features of Latin American Bioethics

Among the features that seem to be characteristic of Latin American bioethics, one that is frequently mentioned is the communitarian orientation, as opposed to a more individualistic approach (Bulcock, 2010). This assertion is in need of empirical

demonstration, for the fact that extended families participate in decision-making processes in health care or care for their elders is probably valid in some rural areas but it does not seem a universal characteristic of urban populations, particularly in the great megacities of Brazil or Mexico. While it is true that some ethnic groups do in fact show a predominant orientation towards group decisions (relevant in obtaining informed consent and necessarily of importance for conducting medical research), the characterization of bioethical thinking as communitarian, which stresses a potentially important difference with the bioethical discourse from the North, it is not an exclusive character of Latin American bioethics (Lolas, 2009).

Perhaps more interesting to note is the fact that bioethical discourse – or something akin to it – is manifested and applied in the context of sociopolitical interests. While these sometimes overlap or are confused with academic pursuits, the impact it has on the institutionalization is not negligible. Under the name of bioethics, political agendas seeking social justice or opposition to conservative movements are promoted. At the same time, religious orientations manifest other forms of utilization of the bioethical discourse for the benefit of other groups. In no way do these utilitarian uses of the bioethical enterprise serve the cause of developing an academic discipline, as it seems to be the case in other traditions. It is not the content but the manner of implementing the discursive practices that separates Latin American contributions from other traditions and contributes to its identity. As indicated above, the formative stages of Latin American bioethics can be characterized by replication, critical appropriation, and creative contribution. The latter is still a development to come in the form of critical decisions regarding institutionalization. For instance, despite manifest efforts to establish graduate programs and generate specialists in bioethics, it is by no means clear whether the social demand allows for the existence of professional bioethicists, whose role in the scientific or the professional spheres is far from clear, or whether the contribution of academics to pressing needs of the communities will have the effect expected from political and social reform. That bioethics may constitute a weapon for social struggle against imperialism or against political orientations is not a proof that its fate as an academic discipline is obscure or nonexistent. Remembering the admonition of one of the world pioneers of bioethics, the German theologian Fritz Jahr (1895–1953), one of the first and foremost duties of a community of ideas is to use properly the language it employs. The fuzzy boundaries of topics surrounding human rights, social justice, the search for truth, and others make it imperative that the bioethics community in Latin America devotes its best efforts to carefully demarcate fields of interest and inquiry and to not abuse a term that has become polysemic and partly useless because of abuse. The construction of an academic discipline depends on the existence of a critical group of persons respectful of the rights of others to dissent, tolerant of the differences, and devoted to academic pursuits in the first place.

The great inequities observable in access to the benefits of science and civilization are a good stimulus for the development of a local Latin American bioethics. Social injustice and exclusion, discrimination against minorities and disadvantaged populations, and great deficiencies in the provision of social services are among the

challenges faced by Latin American bioethicists in the near future. Some of these challenges are not much different from the ones observable in other regions of the world. The creative solutions and the importance of ethical discourse in posing the right questions and searching for the appropriate answers will depend to a great extent on the work of dedicated practitioners and academics, on intellectual solvency, and on the recognition by society at large of the importance of bioethics for posing dilemmas and choosing adequate responses (Lolas, 2010a, b).

The continent is a natural reservoir of biological diversity, thus bringing the ecological aspect of macrobioethics to the forefront of preoccupation and interest. Ecological ethics, the somewhat forgotten strand of thought at the very beginning of the origin of European bioethics, with Fritz Jahr, and American neo-bioethics, with Aldo Leopold and Van Rensselaer Potter, has an important role to play in developments that should take place in Latin America. Biological diversity is of interest not only from a theoretical point of view. It has a darker side when the exploitation of it by imperialistic powers is considered. The search for gold and riches was one of the great forces behind conquest and colonization. The exploitation of the natural resources without benefiting the populations of the continent is a serious bioethical concern that should have a place in the development of the discipline with a distinct Latin American emphasis (Brena, & Teboul, 2009).

Lucie Kalousova and Raymond De Vries

Introduction

Scholars disagree on exactly when bioethics was "born." Was it in the years immediately after Nuremberg? Was it in the 1950s with the move of "pastoral medicine" into the realm of ethical confrontation? Was it in the late 1960s and early 1970s with the founding of the Hastings Center and the Kennedy Institute? While the exact date of the birth of bioethics as a distinct area of inquiry and practice is debatable, it is clear that bioethics is now part of the landscape of the life sciences in the United States and Canada. In both countries, accrediting agencies have declared that hospitals must have a mechanism for considering ethical issues that arise in patient care, all federally funded research that involves human beings or animals must be reviewed by a board constituted to protect the subjects of research, biotechnology corporations regularly appoint "ethics advisory boards," a plethora of seminars offer training in bioethics for those who need – or wish to offer – ethical advice, and bioethics courses have become a regular part of the curriculum at universities, colleges, and medical schools. It would be even fair to say that the bioethics discipline crystallized and emerged from North America (Fox, Swazey, & Watkins, 2008; Roy, Dickens, & Williams, 1993). Given that bioethics is well established in these North American countries, the *Universal Declaration on Bioethics and Human Rights* has the difficult task of finding its way into preexisting frameworks for thinking about matters bioethical. Furthermore, the *Declaration*, with its emphasis on communal good and responsibility for future generations, must contend with an approach to bioethics that has, until recently, given little attention to justice, focusing instead on autonomy and individual benefit.

This collision between the history of bioethics in North America and the *Declaration* has kept the impact of the UNESCO document on the practice of, and debates within, bioethics in this region to the minimum. Indeed, the arrival of the *Declaration* was barely noticed in North America. Six years after its enactment, there is little evidence that it has played the role the drafting committee had intended – as a guideline for policy makers and practitioners (Solbakk, 2011). Aside from its mismatch with bioethical ways of seeing in North America, some commentators believe the Declaration has been ineffectual because of its use of vague language and its lack of direct recommendations (Macpherson, 2007; Schuklenk, 2010).

In order to situate the Declaration in the North American context, the chapter begins by recounting the foundational moments and historical trajectory of bioethics in the region and then moves on to examine the meaning of the individual articles in this social and cultural setting. An evaluation of the impact of the Declaration on the bioethics conversation in North America concludes the chapter.

Historical Development of Bioethics in North America

The United States and Canada have well-developed institutional bodies for deliberating on bioethical questions and for developing regulations pertaining to research and clinical ethics. Federal organizations and ad hoc committees offer guidance on ethical issues in the life sciences and medicine; federal research funds are available for exploring the ethical, legal, and social implications of new medical technologies; and several universities have "centers for bioethics" that do research, offer advice to clinicians and researchers, and contribute to the education of health professionals and research scientists. This network of bioethical bodies emerged from the community of North American scholars who began exploring ethical questions in medicine and the life sciences in the 1960s. Their work was a turn from the traditional practitioner-dominated approach to medical ethics to a more inclusive discussion. As Keirns, Fetters, and De Vries (2009) note:

> In the 1960s and 1970s a series of scandals, together with unprecedented technological challenges in medicine, transformed the insider's game of medical ethics to an interdisciplinary project that came to be called 'bioethics'. The ethics of medicine became a topic, not just for medical practitioners, but for scholars from the humanities and social sciences; these 'strangers' to the clinic and the research laboratory began to make judgments about the moral problems of medicine.

Because North American bioethics is informed by a strong awareness of its founding moments and because, as Fox puts it, "[North] American bioethics is an expression and a part of the society and culture from which it has emanated" (1996, pp. 5–7), it is necessary to offer a bit of detail about how bioethics came into being in the United States and Canada in order to understand the reception of the *Declaration* in North America. There exist several accounts of the beginnings of bioethics, a reflection of the fact that the recounting of the genesis of a discipline is inevitably an exercise in aligning one's historical and political imaginations.

While some North American bioethicists prefer a historical narrative that favors strong political leadership of a few outspoken individuals, others place more emphasis on gradual change. Fox et al. (2008) identify several major competing stories of the emergence of bioethics in North America. These stories can be divided into two main accounts. The first contains event-centered "big bang" perspectives that see the emergence of bioethics as a response to new technological developments or hotly debated issues. The second account includes narratives that attribute the rise of bioethics to "a number of converging social, cultural, and political phenomena and events, and medical and scientific developments" (Fox et al., p. 32). It takes into account both the generative power of events and the wider societal influences that helped push bioethics to the forefront of public debates. This accounting places less emphasis on turning points and personas, and more on the timing of the intellectual gestational period.

In both the United States and Canada, bioethics began to germinate in the 1950s, in a decade when medicine made "miraculous" advances. In 1952, the first open-heart surgery was performed and by the mid-1950s, polio vaccines became routinely available. It seemed that the possibilities of modern medicine were boundless, but the medical professionals who were involved in testing and early adoption of new therapies were aware that these advances did not come without human experimentation and disproportionately large risks to the first patients undergoing these procedures (Jonsen, 1998). This discomfort from within medicine was coupled with challenges to medicine from without. Along with other institutions, medicine was increasingly seen as racist, sexist, and oppressive, leading to a call for oversight by nonphysicians. This external oversight began as early as 1958 when the Law-Medicine Research Institute at Boston University began to investigate the "actual" practices of medical professionals within the United States (Fox et al., 2008). Keirns et al. (2009) explain:

> In this cultural climate, old-style medical ethics – granting unilateral authority to physicians to make decisions about certain aspects of life, death and medical care – was deemed insufficient. New technologies such as the ventilator, incubator and artificial feeding tube brought the promise of success in medicine's long struggle with disease and death, but they also increased the risk of prolonged suffering and technological dependence. Doctors were not trusted to respond to the pressing questions created by the new machines of medicine. From the 'God Committees' of 1960s' Seattle... to debates about genetic enhancement, physicians were (and are) no longer trusted to be the sole decision-makers on matters medical.

The social turmoil of the 1960s underlined the need for clearer definitions of patient rights in experimentation. Scientists and medical professionals began to raise their voices above their typical professional boundaries, and reached out to the general public. Notably, Henry K. Beecher, a physician, published an article titled "Ethics and Clinical Research" where he discussed several examples of unethical research on the part of medical researchers. He made a strong argument for the practice of truly informed consent: "The statement that consent has been obtained has little meaning unless the subject or his guardian is capable of understanding what is to be undertaken and unless all hazards are made clear. If these are not

known, this, too, should be stated. In these situations the subject at least knows that he is to be a participant in an experiment" (Beecher, 1966, p. 372). Jonsen terms this period "The Decade of Conferences" (1998), but one might also call this period "The Decade of Patient Rights" or "The Decade of Hesitation." The debates that were emerging regarded issues as diverse as eugenics, food safety, and human experimentation.

The sense of movement during this period is perhaps best characterized by a term used by a German theologian Thielicke in a keynote speech to a panel of scholars and theologians brought together by the Institute for Religion at the Texas Medical Center. The group was assembled in 1967 to deliberate on the first human heart transplant. In his address, Thielicke spoke of the "ambiguity of progress" . . . "the half-light between creation and fall" (Guinn, 2006, p. 32). The uncertain and charged atmosphere, with its call for the empowerment of patients in the medical system, gave rise to a core group of scholars, including medical professionals, who placed increased emphasis on individual patient rights. This focus coincided with the consumer rights movement in the United States, and the bioethics community in North America has retained that individualized focus since then (George J. Annas, 2005, p. 30).

By the end of the 1960s, bioethics centers began appearing in the United States, among them the Hastings Center (1969) and the Kennedy Institute (1971). Canada established their first Center for Bioethics in 1976, affiliated with the Clinical Research Institute in Montreal (Roy et al., 1993). The growth of these centers contributed to wider dissemination of knowledge about bioethical issues. Popular media that were previously captivated by stories of miraculous medical progress began to take interest in the human costs and controversies behind medical discoveries. Gradually, bioethical questions came to the attention of the public and eventually these questions arrived before the US Congress (Fox et al., 2008; Hoffmaster, 2001).

Under the influence of the outrage that followed revelations about the Tuskegee Experiment (Reverby, 2009), the US Congress established a body for addressing the ethics of medical research: the National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research (Jonsen, 1998). From 1974 to 1978, this body considered the ethical principles that should guide medical research in the United States and ultimately issued the well-known Belmont Report (http://ohsr.od.nih.gov/guidelines/belmont.html). The Belmont Report established a principle-based approach to ethical decisions in research involving human subjects, setting out three essential principles: (1) respect for persons, (2) beneficence, and (3) justice.

Notably the commission did not ground these principles in the idea of "human rights." Instead they found their justification in "our cultural tradition":

> The expression "basic ethical principles" refers to those general judgments that serve as a basic justification for the many particular ethical prescriptions and evaluations of human actions. Three basic principles, "*among those generally accepted in our cultural tradition*," are particularly relevant to the ethics of research involving human subjects: the principles of respect of persons, beneficence and justice. (United States & National Commission for the Protection of Human Subjects of Biomedical & Behavioral Research, 1978)

After the limited term of this first commission expired, it was replaced by The President's Commission for the Study of Ethical Problems in Medicine and Biomedical and Behavioral Research and stayed functional from 1980 to 1983 (Jecker, Jonsen, & Pearlman, 2007).

During this decade, bioethics became a part of the official discourse in regulating research and medical practices in North America. The prominent debates no longer focused on *who* has the right and authority to regulate experimentation, but *how* and *how much* it should be regulated. As Jonsen points out, the conversation over the issues at stake assumed a new tone, "the discourse over research could be directed toward resolutions that would be widely accepted in American society" (Jonsen, 1998, p. 158). The strong connection between bioethicists and the political establishment has remained a stable part of the landscape of North American bioethics. Of the past five American presidents, four established a committee or a commission dedicated to providing guidance on matters pertaining to science, medicine, and technology to the President and the Congress (Jecker et al., 2007).

It is worth noting that the bioethics commissions reflected the political orientation of Presidents they served (see: bioethics.gov/cms/history). The National Bioethics Advisory Commission (NBAC) was created by President Clinton to explore the ethical issues associated with cloning and with the use of human subjects. The NBAC had a largely technocratic approach to its work – "thin bioethics" in the words of John Evans (2002) – focusing its energies on developing guidelines to aid researchers in doing their work (http://bioethics.georgetown.edu/nbac/). The President's Council on Bioethics (PCBE), appointed by President G.W. Bush in order to provide advice on stem cell research, took a much broader approach to bioethics. Rather than efforts to create guidelines for the ethical practice of medical research, the PCB spent more time exploring how new medical technologies altered what it means to be a human (http://bioethics.georgetown.edu/pcbe/). President Obama's Presidential Commission for the Study of Bioethical Issues has steered a middle course, reviewing the ethical challenges of new developments in medicine, including synthetic biology and neuroscience (http://bioethics.gov/).

This brief historical account demonstrated that bioethics has a well-established tradition in North America. The *Declaration* is poised to make a difference in countries with no established bioethical infrastructure and in countries that have begun to develop conversations about ethical decision making and guidelines (Have & Jean, 2009). The *Declaration* can certainly help with these tasks, but it should come as no surprise that the *Declaration* may pass unnoticed in North America.

UNESCO Principles in North American Context

The articles of the *Declaration* are fundamentally split between those that secure individual rights and those that promote justice and the welfare of the collectivity. Culturally and historically, the North American bioethical tradition has relied heavily on traditions that focus on individual decision making: Bioethical issues in this region are rarely framed as questions of justice or even human rights. Rather, they have been

understood in the context of individual autonomy, and thus give little attention to collective justice. In the sections below we discuss how the articles of the Declaration fit, or do not fit, within the existing incarnation of bioethics in North America. The articles that have no relevance to this region are not explicitly discussed.

Informed Consent

North American bioethics has focused on respect for individuals, their rights, freedoms, and liberties, as evidenced by the widespread adoption of the informed consent procedures that stand at the heart of articles 5, 6, 7, and 9. The research community in the United States remains conscious of its painful history with medical experiments that were performed without consent or regard for human rights (Katz et al., 2008; King, 1992). Most notorious is the Tuskegee Syphilis experiment that left hundreds of poor African-Americans untreated for the sake of observing the natural progression of the disease even after penicillin became widely available in 1947.

Today, oversight of the ethical integrity of research in North America falls on the shoulders of appointed Institutional Review Boards (IRBs) in the United States and Research Ethics Boards (REBs) in Canada. REBs and IRBs serve largely the same functions. In Canada, their decision making is guided by the Tri-Council Policy Statement: Ethical Conduct for Research Involving Humans published by the Canadian Panel on Research Ethics (Canadian Institutes of Health Research, 1998). In the United States, these institutionally affiliated regulatory bodies are approved by the Office for Human Research Protection and are charged with reviewing and monitoring all research that involves human subjects. Institutional Review Boards serve as the guardians of human rights in biomedical research (http://www.hhs.gov/ohrp/). One of their major responsibilities is making sure that every research project has a well-planned informed consent procedure. Those who are unable to give an informed consent, such as minors, are typically given the opportunity to provide an assent.

Informed consent as practiced in the United States has not been unchallenged. Canadian scholar Charles Taylor critiqued informed consent as built on an "atomistic" view of the human actor. He wrote: "The social nature of man is not just that men cannot physically survive alone, but much more that they can only develop their characteristically human capacities in society. The claim is that living in society is a necessary condition of the development of rationality, in some sense of this property, or of becoming a moral agent in the full sense of the term, or of becoming a fully responsible, autonomous being … [O]utside society … our distinctively human capacities could not develop" (Taylor, 1985, pp. 190–191). His understanding of consent stems from his work on relational autonomy, and is closer to the understanding of consent depicted in the *Declaration*.

Although informed consent permeates all domains of academic research in the United States and Canada with human subjects, academics debate the effectiveness of this practice in actually informing patients and research subjects. In her fieldwork in ICU nurseries, for example, Anspach (1993) found that the "assent-model" was frequently used instead of informed consent, especially when the parents were

expected to have a difficult time making a decision. Similarly, in his study of the work of nurses in hospitals, Chambliss (1996) found that the informed consent process was at best a "polite fiction" engaged in by patients and staff. It seems that although the United States and Canada already have codified respect for individuals into their research standards, clinical practices occasionally do not live up to their spirit. Corrigan argued that some of the shortcomings of the current informed consent practices can be accounted for by recognizing that some have treated informed consent as "an ethical panacea" and allowed its existence in an ethical void where it is simply executed without attention to the relevant social and cultural environment (Corrigan, 2003). The study of the informed consent procedures by these and other researchers needs to be taken very seriously because it points to the gap between policy intentions and practice. Unfortunately, the *Declaration* offers no guidance on the best approach in translating policy prescriptions and institutional rituals to effective practice and misses a key opportunity to contribute to the current conversation on the topic.

Justice as a Bioethical Issue

A key point of difference between the North American tradition of bioethics and the framework put forth in the *Declaration* is found in the distinct emphasis on whose benefit comes first. While the *Declaration* champions equity and communality, the committees that typically serve as bodies of bioethical oversight in the United States focus on individual patient empowerment. There is a fundamental distinction between justice for individuals and justice based on the notion of equity. Drawing on the *Nicomachean Ethics* by Aristotle (1962), Gabriel d'Empaire points out – in his chapter on the genesis of Article 10 published in Ten Have and Jean (2009) – there are at least two basic definitions of justice – commutative justice and distributive justice. While commutative justice is concerned with overseeing interpersonal transactions and ensuring that all parties exercise their rights equally, distributive justice focuses on the equal distribution of wealth in society (Aristotle, 1962; d'Empaire, 2009).

The conflict here – a conflict that remains unresolved in the *Declaration* – is between "equal rules" and "equal shares" orientations to justice. Individualistic societies, like the United States, emphasize "equal rules" – fairness is achieved when everyone is constrained by the same rules, and those who succeed (in terms of health and wealth) have properly earned their position in society. In less individualistic societies, the emphasis is on "equal shares" – a notion of fairness that recognizes equal rules affect the wealthy and the poor differently, and thus, there must be an effort to insure equality of result.

Nondiscrimination and Pluralism

Articles 11 and 12 underscore the value of inclusiveness, nondiscrimination, and pluralism. Both cultural and religious pluralism are embedded in the founding

documents of the United States and Canada and have been a central component of national identities in both the countries, in spite of the fact that these ideals have not always been realized. These are values that have a special place in North America's past, present, and future because it has been a place populated by a diverse group of immigrants. Pluralism and diversity are not interchangeable, although it may appear so at times. Plurality implies a more active engagement with each other's values and may not be fully achieved, even when the population is diverse.

Pluralism, when nations take it seriously as a form of governance, implies conflict. It forces interest groups into disagreements about the ethical underpinnings of their values. Societies, whether they are diverse or homogeneous, need to work toward establishing a common ground to find answers to bioethical questions that respect all. Full pluralism requires a person to take into account and fully respect minority ethical views even if they stand in opposition to accepted bioethical standards and "may appear to endanger the universally accepted norms" (Revel, 2009, p. 208). Setting international standards for bioethics and human rights, even standards that call for pluralism, is not an act of pluralism. From that perspective, Articles 11 and 12 force one to consider a question: Is global bioethics possible? Can culturally specific and contextually dependent standards of bioethics be expressed in a pluralistic manner? The *Declaration* tries to remedy the implied conflict by asserting that pluralism must exist within limits and is "not to be invoked to infringe upon human dignity, human rights, and fundamental freedoms, nor upon the principles set out in this Declaration, nor to limit their scope." There is an internal tension here: Is "dignity" realized the same way in all cultures? And if not, how can it be realized across different cultures without imposing the values of one culture upon another?

In the United States, matters pertaining to bioethics are most often administered on the level of local committees. This became the standard practice as a result of the 1983 report of the President's Commission for the Study of Ethical Problems in Medicine and Biomedical and Behavioral Research that recommended that every health care facility create a multidisciplinary body to deal with bioethical questions (see: http://bioethics.gov/cms/history). The role of each committee would be to "(a) confirm the patient's diagnosis and prognosis; (b) provide a forum for discussing the social and ethical issues that a particular case might raise; (c) educate staff on the identification and resolution of ethical problems; (d) formulate institutional policy and procedural guidelines on decision making; (e) review treatment decisions made for specific patients by doctors and surrogates; and (f) mediate conflict over patient care between health care professionals, patients, family members, and the institution" (Bulger, Bobby, & Fineberg, 1995, p. 541). This local approach allows community standards to inform bioethical decisions, although we do not know the extent to which decisions made in these committees are representative of the community, or if the voices of ordinary community members are heard by committees where health care professionals are in the majority.

The operation of hospital ethics committees (HECs) has not been extensively investigated in the United States or Canada, although the day-to-day work of these committees is a major determinant of their effectiveness in regulating medical

practice and channeling communication between medical professionals and patients. The few studies that have been done have found inequality of access among different types of health care providers and patients (Griener & Storch, 1992; McBurney, 2001). While researching HECs, Canadian scholars Griener and Storch (1992) found that the committees reinforced the existing professional power structures, rather than providing effective mediation. Doctors held a majority of the power within the committees, and the evidence presented by nurses was discarded as less valuable. Their findings are well aligned with the power structure in medical decision making as described by Anspach (1993). Similar conclusions were reached by a more recent research project executed by McBurney (2001). While McBurney recognized the systematic effort for more balanced ethical decision making, she suggests that the obvious imbalance might simply be replaced by more "subtle, cautious paternalism" (McBurney, 2001, p. 196).

Although not always advocated for with great success, Articles 11 and 12 of the *Declaration* are among priorities of the North American bioethical community. Here again there is a need for more guidance on how the articles can be put into practice in an effective manner.

Solidarity and Social Responsibility and Sharing of Benefits

Taken together, these articles are intended to promote distributive justice, encouraging policy makers to promote solidarity and cooperation in access to food, clean water, health care, a healthy environment, and the benefits of medical research. As noted above (see the section on Article 10), these goals, while recognized as noble in North America, often take second place to the culturally more important goals of individual freedom and responsibility. While North American bioethicists argue that health research done by western governments and corporations in low resource countries should be guided by an interest in human development (London, 2005), in practice, these countries are seen as a resource for developing new therapies and medications for western populations. Discussions of the ethical problems of international research center on improving efficiency, streamlining procedures, and on things like "transparency," "quality," and "independent oversight" (Glickman et al., 2009) – all worthy ideas, but none of which require attention to concerns articulated in these articles.

Appropriate Level of Ethical Review of Research in Other Countries

The United States, Canada, and indeed other western countries continue to struggle with the appropriate level of ethical review in other countries. In 2010, the American public learned about the unethical testing of sexually transmitted diseases on Guatemalan mental patients between 1946 and 1948. Disguised as inoculations, patients were injected with disease agents by the US Public Health Service. The administrators of these trials took advantage of less established guidelines for protecting human rights in the community where they were experimenting, and carried out trials that

would have not been approved in the United States at the time (Reverby, 2009). There are also ethical concerns with US government-supported international trials of HIV transmission rates between mothers and infants in African and Asian countries (G. J. Annas & Grodin, 1998). In this trial, some mothers were administered a treatment that was known to prevent transmission, while others were given a placebo. While these trials were ongoing and exploiting ill mothers and children in the developing world, the international community debated their appropriateness (Ballantyne, 2010; Lurie & Wolfe, 1997). This runs sharply against Article 21.

The United States has been working toward establishing (and maintaining) clearer guidelines for medical trials outside of the country, although they often are difficult to enforce. When the US government officially admitted to having supported the unethical medical research in Guatemala, the US president, Barack Obama, ordered the Presidential Commission for the Study of Bioethical Issues (PCSBI) to begin an investigation of whether the "Federal regulations and international standards adequately guard the health and well-being of participants in scientific studies supported by the Federal Government (Presidential Commission for the Study of Bioethical Issues, 2011, p. 1)." The PCSBI did not use the *Declaration* in its deliberations. After a series of meetings, the panel issued a document assessing the current state of bioethics in international research. Their final report underlines lack of unity in rules of ethical research internationally and takes no notice of the UNESCO *Declaration* (Presidential Commission for the Study of Bioethical Issues, 2011).

Their final report highlights that the United States is in a very unique position with respect to taking responsibility for enforcing transparent and just bioethical standards, especially with respect to their involvement in the developing world. Their federal resources fund more clinical trials than any other country can afford. Further, it is arguable that US-based pharmaceutical companies are among the most powerful on the world, and they are able to administer trials on their own (Law, 2006).

Conclusion

The Declaration has had little visible impact on the field of bioethics in North America. This lack of attention is likely the result of the development of a bioethics framework in Canada and the United States that predates the Declaration by more than three decades. Rather than setting the agenda for bioethics, the Declaration must find its way into the existing agendas of clinical and research ethics in North America. This task has not been easy, as it requires both structural and cultural accommodation. The existing *organization* of bioethics, including the centers that proffer bioethical advice, the regulations that govern the monitoring of human research, and the agencies that fund bioethics research, has developed in a *cultural* climate that is focused on individualism, autonomy, and the belief that societal good is best served by individuals seeking their own best interests. The justice-oriented approach of the Declaration is thus at odds with the present structure and culture of North American bioethics.

This is not to say that the Declaration is of no use in North America. Bioethics in this part of the world is beginning to recognize the need to consider justice and solidarity alongside autonomy, making the Declaration more relevant to the ethical questions that emerge here. Recent research (Wilkinson & Pickett, 2010) has shown that the high levels of inequality found in North America and other highly individualistic societies harms the wealthy as well as the poor: High inequality is associated with higher levels of crime, a less-educated work force, shorter life expectancies, and higher infant mortality for the rich as well as the poor. If citizens of North America can be convinced that their individual interests, including their health, are best served by solidarity and sharing, a concern with justice may replace the existing preoccupation with autonomy.

Section IV

Religious Perspectives

Buddhism

21

Soraj Hongladarom

Introduction

Siddhartha Gautama, a prince from what is now southern Nepal, gave rise to Buddhism some two thousand and five hundred years ago. He attained Enlightenment, the state of total liberation from all causes of suffering, at the age of 29 thus became the Buddha, literally one who has already awoken. The Buddha spend 45 years in north India teaching to his disciples, planting the root of the religion which then spread out across its land of origin to become a world religion. Now, Buddhism has adherents living in areas ranging from Mongolia and some parts of Russia and Sri Lanka and many countries in Southeast Asia, such as Thailand, Myanmar, Laos, Cambodia, and Vietnam. Buddhism is now the world's fourth largest religion, after Christianity, Islam, and Hinduism.

A special characteristic of Buddhism is that it is a nontheistic religion; that is, it does not recognize a God or a Supreme Being who created the world and who is the ultimate source of ethical judgment. On the contrary, the religion recognizes the dharma, or the way things are naturally, as the source of how things come to be as well as how action should be judged ethically. Another Indian religion, Jainism, also shares this characteristic of being nontheistic. The term "nontheistic" is used in this context to contrast with "atheistic," which means no recognition of any ultimate source of meaning or value judgment whatsoever. Instead, Buddhism and Jainism are nontheistic in the sense that they do recognize an ultimate source of meaning and ethical judgment. Such a source, however, is not based on a personal conception of a supreme deity.

The goal of being a Buddhist is to perfect oneself so that eventually one achieves total liberation of oneself from the cycle of births, deaths, and rebirths known as *samsara*. This is a belief shared by Buddhism, Jainism, and also Hinduism. When one does not realize the total liberation, one wanders around from one life to another, depending on what one has done in the previous life. If one does something "unwholesome" (akusala), or negative, one is reborn in a lower realm such as that of

animals, hungry ghosts (*preta*), or hell beings. On the contrary, positive or "wholesome" (*kusala*) action results in a rebirth in one of the heavens. However, the time a being spends in any of these realms, higher or lower, is limited. That is, no matter how bad one's action in one life has been, one has to spend only a limited amount of time in hell. After the time is up, one is propelled again to take another birth in one of the realms in samsara, and if the causes and conditions that propel one to wander in samsara are still there, one will wander around this cycle indefinitely. All the major three Indian religions, Buddhism, Jainism, and Hinduism, concur that such wanderings around in samsara are totally unsatisfactory, and the goal of a serious practitioner is to find a way toward releasing oneself from it. Each of the three major religions here offers slightly different ways toward this release. When one reaches the state of total liberation from samsara, so that one will not be reborn there again, it is said that one has achieved the status of the *arahat*, or one who has defeated all defilements which are causes of taking a life in samsara. This is an ultimate goal of being a Buddhist.

In a nutshell, Buddhism offers three stages of practice to achieve the state of total liberation, namely, disciplined conduct (*sila*), meditation (*samadhi*), and wisdom (*prajna*). Disciplined conduct means that one always observes what one is doing both through the physical, verbal, and mental aspects so that one does not commit any action which will result in taking a birth in the lower realms. Disciplined conduct will be very relevant in the discussion of Buddhist ethics and bioethics as we will see later. It is the foundation of the further practices which involve purifying the mind through meditation and achieving total understanding of the way things really are. When one has mastered disciplining one's own physical, verbal, and mental conduct, one goes on to practice meditation to stabilize and purify one's mind. Through this effort in meditation, one gains an insight into the real nature of all things, and it is this wisdom that destroys *avidya*, or fundamental ignorance, that is the direct cause of attaining total liberation, which is known as Nirvana.

These are the basics of the Buddha's teaching. Later, Buddhism branched out into two main groups, namely, the Theravada (or Hinayana) and Mahayana. The differences between the two are more on what is emphasized rather than any differences in the doctrine. Theravada Buddhism is practiced mostly in Sri Lanka, Myanmar, Thailand, Laos, and Cambodia, while Mahayana is practiced in China, Japan, Korea, and Vietnam. In the Tibetan speaking area of China and Bhutan, moreover, a special branch of Mahayana is practiced known as the Vajrayana. Basically speaking, the Theravada emphasizes realizing the eventual release of oneself from samsara, which was the Buddha's apparent goal in his teaching during his lifetime. However, a few centuries after the Buddha's death, a group of monks started to reconfigure the goal of practice. Instead of trying to achieve total liberation from samsara in this lifetime, this group of monks emphasized instead the goal of themselves becoming a Buddha in the future. This is the key aspect of Mahayana Buddhism. According to the Mahayanists, one should instead become a bodhisattva, or one who vow to practice and perfect oneself, not only in order to release oneself from samsar, but also to become a Buddha in the

future so that one has the capacity needed to free all sentient beings from samsara. Thus, in a nutshell the main difference between these two branches of Buddhism is on different emphasis on the goal of practice rather than any doctrinal difference. The main content of the teaching remains the same in both traditions. Furthermore, within Mahayana itself, another branch emerged, that of Vajrayana, which retained the core objective of the Mahayana while introducing their own special kinds of practices. While both Mahayana and Vajrayana subscribe to the bodhisattva ideal where the aim of practice is eventually to become a Buddha, Vajrayana introduces special techniques not found in the other tradition which it claims help the practitioner realize the final aim much faster. It is possible, according to Vajrayana, for the practitioner to realize Buddhahood within this very lifetime, whereas it would take many lifetimes to do so according to purely Mahayana practice.

In this article, the main teaching of the Buddha will be referred to which is shared by both the major traditions of Buddhism. Among the key concepts directly relevant to bioethics are compassion and interdependence. In the next section, these two key Buddhist concepts will be explained in detail. Then, in the section that follows, it will be shown that Buddhist teachings are not in conflict with the global ethical principles stated in the Universal Declaration on Bioethics and Human Rights. Furthermore, Buddhist perspectives on a variety of bioethical issues will be discussed based on these two key concepts. The bioethical issues that will be discussed are those involving beginning of life, end of life, and human vulnerability.

Compassion and Interdependence

The key concepts which are directly relevant to judgment of action are compassion (*karuna*) and interdependence (*pratityasamutpada*). Compassion is the wish to relieve all beings of their suffering. It arises when one feels the sufferings that others are feeling and wish to share in those suffering and to eliminate those sufferings. Compassion is one of the four immeasurables, which are the qualities that one needs to cultivate as an essential part of one's practice to attain Enlightenment and Buddhahood. The four immeasurables (also known as the four brahmaviharas) are so called because one practices these four qualities that emphasize complete lack of boundaries between oneself and others, as well as lack of boundaries between any being whatsoever. The love and joy that are parts of the immeasurables cannot be measured because they are boundless, extending toward all beings in the universe. They consist of loving-kindness, compassion, sympathetic joy, and equanimity. Loving-kindness consists in the wish to impart happiness to all beings without any kind of discrimination. One wishes all beings to be happy and always to meet with causes and conditions of happiness. It does not matter where those beings reside; they could be gods in heaven, or hungry ghosts, animals, or hell beings. In practicing loving-kindness, as well as the other three immeasurables, one does not make any distinction between beings. Instead, one radiates love and the wish of happiness to every being without exception.

The second immeasurable, compassion, is the wish that all beings are relieved from suffering. Again, there is no discrimination. The practitioner shares in the sufferings and pain of all sentient beings and there is a genuine wish to eliminate those sufferings from them. One sees oneself in all beings; as no being wants to experience and endure sufferings, one wishes that no being at all suffers or is in pain. This, together with the other immeasurables, is the basis for concrete action of Buddhas and bodhisattvas to help the beings in samsara. The third immeasurable, sympathetic joy, is the feeling of happiness and joy that spontaneously arises when one realizes that other beings are happy. The joy that arises is as spontaneous as a bell which spontaneously rings itself when another bell nearby is ringing. Sympathetic joy is an antidote of envy and jealousy and is a very important quality for those who wish to practice to become a bodhisattva. The fourth and last immeasurable, equanimity, is the feeling of sameness, equality, and undifferentiatedness toward all beings. In fact, it is a basis of immeasurability because it underlies the feeling that all beings need to be considered equally without any discrimination. In practicing equanimity, one does not distinguish one group of beings from others. Naturally, people would normally differentiate between those which are closer to them, such as the members of their family, members of their villages and community, and those who are strangers and have nothing to do with them. This differentiation gives rise to the separation, for example, of "us" and "them," which leads to competition and conflict. In practicing equanimity, one tries to do away with this feeling of separation. One tries to regard a stranger and a close member of one's own family as deserving the same treatment and the same love and compassion. Buddhist teachers usually say that the practice of equanimity can be said to be accomplished when one does not see and feel any kind of distinction at all between oneself and another; it is the realization that any sentient being deserves the same love and compassion as does one's own self.

It is quite clear how compassion and the other three immeasurables are important in ethical decision-making and judgment. If one can see that there is no distinction between a sentient being and oneself, then anything that one would not do to oneself will not be done toward the other being either. For example, one naturally would not act to harm oneself; thus, the practice of loving-kindness and equanimity would imply that one would not do the same harm to any other being either. This is a basis for not harming other beings. Compassion and the other immeasurables also underscore the realization that every sentient being wants happiness and seeks to avoid suffering and pain. Since we know from our own first-hand experience that we ourselves want happiness and do not want pain, all other beings share the same feeling. Hence, it is thoroughly unwholesome to cause pain and suffering in others.

The other key Buddhist teaching is about interdependence (*pratityasamutpada*) and emptiness (*sunyata*). In fact, the two concepts here always imply each other. Interdependence is the characterization of things when the being of each depends on their relation and dependence on others. A table, for example, is what it is only because it rests on a floor, consists of four legs (in most cases), has a flat top, made of some kind of material (such as wood or plastic), and is used so that things can be

put on its top. All these characteristics of the table depend on other things, and without those things, the table cannot be what it is. Another way of putting it is that a table always has a boundary, a line where the table ceases to be a table and whatever lies outside it begins. This line demarcates the table from its environment. If this line is nonexistent, then the table cannot be a table at all, so its very being depends on its relation to the other, in this case whatever lies outside the table itself. Since all objective entities whatsoever must have this line that demarcates them from their environment, all things are thus interdependent on others.

This way things depend on other things also implies that they are "empty of their inherent character." This typical Buddhist way of describing the way things are means that things are empty of whatever that forever makes them what they are. This idea is closely related to the idea, also central to Buddhism, that things are always changing and in flux. Here, Buddhist philosophy resembles Heraclitus' thought in ancient Greek philosophy who says that things are always changing and one cannot enter the same river twice. As things are always changing, they change from being one thing to another. A table, for example, has not always been a table from a very ancient time. Instead it used to be a tree, and before that, the tree used to be something else, such as carbon molecules in the air. Things change and our designation of what they are changes accordingly. In Buddhist terms, if the table had its own "inherent character," it would mean that the table would remain a table in eternity, for anything that possesses an inherent character would be able to remain what it is without depending on others in any way. Since that is not possible, all things then do not possess inherent character. This is just another way of saying that all things are "empty of their inherent character." Since all things are interdependent, they are empty of their character because the characteristic of being interdependent means that any essential feature that would enable the things always to remain what they are is not there. Furthermore, all things being empty of their inherent character also means that they are interdependent because when they lack their inherent character, any feature that would tell us what they are is ultimately dependent on other things. This is why Nagarjuna, a Buddhist saint in the second century A.D., emphasized that emptiness is just interdependence and the other way round (Nagarjuna, 1995).

What is distinctive about Buddhist thought is that interdependence and emptiness not only apply to material things but also to the self or the ego too. This is perhaps the most important part of Buddhist philosophy and what makes it unique among philosophies and religions in the world. A startling conclusion offered by Buddhism here is that even our own selves, whatever we refer to when we use the first person pronoun " I," is not exempt from being interdependence and empty too. In fact, the self is composed of various mental and physical elements which are exhaustive, and when these elements are analyzed, it is found that no self is there; thus, what is understood to be the self is nothing but a conglomeration of various elements and episodes. It is always changing and interdependent. What one understands to be the subject of one's own thoughts, feelings, and action is ultimately an illusion. Whatever is commonly understood to be the subject behind the changing mental and bodily episodes is analyzed to be nothing over and above those episodes themselves; hence,

what is taken to remain behind as the subject is just another such episode. This doctrine is known as the doctrine of non-self (*anatman*). It is not a doctrine that says that there is absolutely speaking no self, but it says that what we take to be the self behind our own thoughts and action is not exempt from the rule of interdependence and emptiness of all things. Contemplation of this truth, as well as the truth of all things as interdependent and empty, is a key ingredient in one's practice toward attaining total liberation from samsara and attaining Nirvana.

Compassion and interdependence are always linked to each other closely. In fact, Buddhist teachers usually say that compassion and interdependence are like the two wings that a bird needs in order to fly. Just as a bird needs two wings to fly, so too does a practitioner need both compassion and the realization of the wisdom of interdependence in order to attain Nirvana and Buddhahood. In compassion, one sees the ultimate interlinking of all beings with one another; in the same vein, in emptiness and interdependence, one realizes the same interlinking of all beings, which leads to compassion toward all beings as there is absolutely nothing that separates oneself and all other beings.

Foundation of Buddhist Ethics

As a nontheistic religion, the foundation of ethics in Buddhism is not based on the command of God. Instead, it is based on *dharma*, or the nature of things. Another key doctrine in Buddhism and other Indian religions which is relevant here is the *law of karma*, which says roughly that any action will have consequences into the future and an explanation of why things are the way they are at present is because of prior causes and conditions. In this way, action in the present comprises a cause and condition for the way things will be in the future; hence, the law of karma is an expression of the main characteristic of dharma, namely, that things are always determined by causes and conditions. (There are a number of excellent introductions to Buddhism, such as Gethin (1998) and Siderits (2007). An introductory text in Buddhist bioethics is Keown (2001)).

Nevertheless, the law of karma should not be confused with fatalism or complete determinism. That the way things are depends on their causes and conditions does not imply that things must always be the way they are, or that the future will always be predetermined. The future can be fully open depending what kind of action is taken at present. Man is free in taking his own course of action because that is a prerequisite for them to realize the highest goal, which is only achievable through one's own effort. Moreover, this freedom must also be presupposed as a basis for moral responsibility. Within samsara itself, there has to be someone who gets to heaven as a result of someone's doing some kind of deed in the previous life. Without being free to taking one's own course of action, reward and punishment as a kind of encouragement and deterrent of action would not be possible. An action that is ethically valuable must be done out of intention. This is why something done by a zombie or an unconscious robot would never be ethically valuable (neither good nor bad). Since freedom

is already implied in the concepts of intention, then one has to have freedom in order to perform deeds that would result in a change in the course of one's path in samsara and also ultimately a path leading beyond it.

This compatibility between the law of karma and freedom to act points to the important role that motivation or intention (*cetana*) plays in Buddhist ethics. According to Buddhism, the nature of an act itself is not as important as the motivation behind performing the act as the arbiter of the result that will ensue as a consequence of performing the act. For example, there are three types of defilements, namely, greed (*lobha*), anger (*dosa*), and delusion (*moha*). These are "defilements" because they defile the mind, obscuring it and obstructing it toward the real path and the real goal. Action done out of defiled motivation, such as action done by greed or anger, always takes one out of the real path, which is the realization of Nirvana. As such it is an "unwholesome" action (*akusalakarma*), as it leads one outside of the real path and hence is negative. On the contrary, action that is "wholesome" (*kusalakarma*) leads one on the right path and eventually contributes to one realizing the ultimate goal.

In a nutshell, then, Buddhist ethics consists in whether an action is performed under the right intention or motivation or not. An intention is "right" just in case it is free from the three defilements, when it is done out of purely altruistic and compassionate motif under the correct understanding that things are empty and interdependent, and is "wrong" otherwise.

Specific Issues

The teaching of Buddhism is in accord with the general ethical principles outlined in the UNESCO Declaration on Bioethics and Human Rights, a document which is accepted by all member states. For example, Buddhism fully endorses the concept of human dignity and rights, which is stated in Article 3 of the Universal Declaration and is perhaps the most fundamental concept in the general bioethical principles endorsed by the member states. The first clause of Article 3 says "Human dignity, human rights and fundamental freedoms are to be fully respected." The teachings on compassion and interdependence fit with the conception of human dignity in that they promote human welfare and respect. Since all beings, humans included, deserve to be happy and to be relieved of sufferings and since it is not enough for the Buddhist merely to wish these beings to be happy and not to suffer (otherwise they would be contradicting their own wishes), there needs to be concrete mechanisms by which all beings, especially humans, are actively relieved of sufferings. The text of Article 3 is one such mechanism. The concepts of rights and fundamental freedom also follow logically from that of dignity.

Moreover, Clause 2 of Article 3 is very interesting. It says: "The interests and welfare of the individual should have priority over the sole interest of science or society." It is discussed elsewhere in this chapter that Buddhism pays special attention to the concept of solidarity among individuals, which is seen to function as an antidote to the overly individualistic tone of much current ethical thinking that

is focused on the role of the autonomous individual. However, the Buddhist emphasis on solidarity (discussed in the section on Vulnerability below) does not conflict with the language of Clause 2 here, for both are applied in different contexts. Promoting solidarity among individuals is not the same thing as subjugating the interests of the latter to those of the society or community. Individuals can enjoy solidarity among other fellow individuals without having their interests subjugated in this way. In fact, solidarity can even promote the interests of individuals and can well act as a foil by which individuals join forces to resist against the state or society. As for the interest of science, it is clear that the interest of the individuals need to take priority, for the benefits of science will eventually accrue to none other than the individual human beings themselves; hence, it would be self-contradictory to put up the interest of science above that of the individuals.

As for the more specific issues, literature on Buddhist perspectives on these issues in bioethics is voluminous and is growing rapidly. Unlike the monotheistic religions such as Christianity and Islam, which seem to have rather clear-cut views on a number of bioethical issues, Buddhism does not have a united front, so to speak, on these issues. There is no central authority in Buddhism who can issue statements on behalf of the whole religion in the way that the pope can for Roman Catholics. Many Buddhist monks and scholars disagree among themselves as to what the proper Buddhist attitude should be on these issues. This is not surprising given the fact that the Buddha himself specifically did not appoint any one of his disciples to be the leader after his death. Instead, he encouraged each of his students to follow the teaching, taking the teaching itself as their leader when the Buddha himself is no longer in this world. Thus, for Buddhists the most important authority is their own understanding of the teaching, which is recorded in the Scriptures. However, different Buddhist groups such as the Theravadins and Mahayanists do not recognize exactly the same set of Scriptures as authoritative. While the Mahayanists accept the Theravada *Tripitaka*, or the Three Baskets of the Buddha's teachings, as authoritative, they added many more texts which are not accepted by the Theravadins.

All this leads to a basic principle in Buddhist ethics. In deciding what the Buddhist perspective should be on an issue in bioethics, the texts or the Scriptures alone are not enough. One has to add to the content or the meaning of the texts with one's own interpretation. Since bioethical issues are new and obviously did not take place in the Buddha's time, one can certainly not find any direct reference to them in the Scriptures. Thus, one has to interpret, and the lack of central interpretive authority and the emphasis on one's own internal understanding mean that judgments on the Buddhist perspective on any specific bioethical issue can diverge widely.

Nonetheless, this does not mean that anything goes. Even if the emphasis is ultimately one's own internal understanding of the texts and the teaching, there is enough centrality in the teaching itself, such as those on compassion, interdependence, and emptiness discussed above, to enable one to judge whether an interpretation is correctly Buddhist or not. These teachings are central to Buddhism in that all the schools, Theravada, Mahayana, and Vajrayana, accept

them as comprising the core of the teaching self. Hence, in this section, the interpretation offered will follow these key Buddhist concepts and will be divided into the following sections, namely, Beginning of Life, End of Life, distribution of scarce resources, and human vulnerability.

Beginning of Life

Perhaps the most widely discussed issue regarding a Buddhist perspective on the beginning of life centers around human reproductive cloning. The theistic religions tend to regard reproductive cloning in a negative light, as they look at the practice as imitating God's work. What seems to be objectionable according to the perspective of the theistic religions is that human reproductive cloning subverts the natural course of things designed by God where humans reproduce themselves asexually. Furthermore, since a human being is created in God's image, cloning a human being, producing somebody who is just like his or her original in every detail, would be tantamount to challenging God's role in this respect.

On the contrary, Buddhism, being a nontheistic religion, does not have anything particularly negative to say about human or animal reproductive cloning. If the cloning is performed with altruistic intention, such as when an owner suffers from a psychological trauma as a result of a loss of her pet and can only get over it when the pet is cloned and brought back, then the action can be viewed positively. Buddhism does not regard the action in itself as wrong, and in this case, nobody is harmed. That a nonunique creature is now created as a result of the cloning hardly counts as a reason for the action being wrong in Buddhism because Buddhism does not see anything wrong in nonuniqueness. What is wrong is how one performs action that leads to negative karmas.

However, in the case of therapeutic cloning, where stem cells are cultured which are taken from cloned embryos, Buddhism is more ambivalent. Since the embryos would have to be destroyed, Buddhism views it as a destruction of living organisms and thus regards it to be wrong. One of the most important aspects of the *sila*, or disciplined conduct, is that the practitioner should not harm or kill any sentient beings. Doing so will create a chain of negative karmas such as being reborn in the lower realms and so on, which is a great obstacle toward realizing Enlightenment in the future. However, if therapeutic cloning is performed out of altruistic motives, such as when the action is needed to provide tissues for treatment of life-threatening diseases (and where this is the only possible option), then the ambivalence is much more visible. According to Somparn Promta (2004), one has to distinguish between "personal" and "social" morality. Therapeutic cloning involving destruction of cloned embryos may be wrong according to personal morality, as the embryos have to be destroyed, but according to social morality, this action may be right to a certain extent because it creates something good or useful for society. Suppose the only way to treat a life-threatening disease is to culture tissues out of cloned embryos which will have to be destroyed, then Promta (2004) would view this as something positive according to social morality because in this imperfect world,

one has to make a choice, and since therapeutic cloning here would result in many people being cured of this disease, then the choice weighs toward adopting the therapy as a necessary course for society to take, even though it involves destruction of life which clearly is a wrong action. Simply put, then, personal morality is the kind of morality that is centered only within an individual or a person; the question is whether such and such action is right or wrong from the perspective of the person alone. Social morality, on the other hand, takes a wider view toward the society or community as a whole and regards the value of action as whether it contributes to the welfare of the society as a whole or not.

The distinction between personal and social morality can also be found in Promta's discussion of abortion (Promta, 1998). Clearly, abortion is wrong in Buddhism because it directly involves destruction of life. But according to the perspective of social morality, Promta sees abortion as something necessary even if ultimately wrong for the society because there can be cases where abortion needs to be performed for the good of society as a whole, such as when legalization of abortion leads to reduction or elimination of underground, very unsafe abortion clinics (Promta, 1998).

End of Life

End-of-life issues tend to be more controversial than beginning-of-life issues (except for abortion, which obviously straddles the two). There are already a lot of literature on euthanasia, definition of death, organ transplantation (which is closely related to end-of-life issue), and a growing number on palliative care (See, for example, Keown, 2005). According to Damien and John Keown, Buddhism is opposed to both active and passive euthanasia because it believes in the sanctity of life, and here the Keowns believe that Buddhism is not different from Christianity in this respect (Keown and Keown, 1995). They cite a text from the *Vinaya*, which is one Basket in the *Tripitaka*, the main canon of Buddhism, where a monk is expelled from the order because he advocates death to a terminal patient. By "making death an aim," which means praising death and persuading another to prefer it rather than life, the monk violates the basic monastic rule against killing a human life, and the Keowns take this text as supporting the conclusion that in Buddhism sanctity of life is maintained and euthanasia is forbidden. However, the Keowns also argue that in the case where all hopes of medical help are lost, one should not fight against death to the last minut, but should resign to the inevitable, and it is here that the Keowns say that Buddhism would approve of palliative care in general.

Keown's argument here is disputed by Roy Perrett (1996), who argues that since motive is of crucial importance in deciding the value of an action, one should look closely at the motive behind a particular act of euthanasia to see whether it is pure or not. Motive is pure when it is free from the defilements of greed, anger, or delusion and when it is performed with the intention of benefitting the whole rather than just oneself. Hence, if there was an altruistic motive behind an act of euthanasia, such as to end a patient's life that is clearly terminal and full of intense pain, then such an

act would not be objectionable. However, the dispute between Perrett and the Keowns is couched in term of the debate between the Theravada and Mahayana, with Perrett taking the Mahayana position and the Keowns the Theravada. This is unfortunate because both traditions do share the same core doctrines together. It seems that Buddhist scholars tend to emphasize the differences between these two main branches of Buddhism rather than the similarities. However, key Buddhist doctrines, such as compassion, interdependence, and emptiness of the self and of phenomena, can be found both in Theravada and Mahayana. Thus, instead of scholars adhering themselves to one tradition and debating among themselves, they should focus more on the core teachings that are already shared by all the Buddhist traditions and base their own interpretations of contemporary bioethical issues from there.

Viewed in this light, it can be said that even within the Theravada tradition adhered to by Keown, a support can be found for euthanasia as an act of love and compassion. The whole idea of sanctity of life makes full sense in the context of a theistic religion like Christianity, where life is created by the creator and human life especially is created in the image of the creator himself. While the Buddhist's injunction against killing can certainly be used as a support for the view that Buddhists view life as sanctified, the very concept of sanctity or sanctification is a theistic concept and as such finds no place in Buddhist thought. Thus, one can only talk about life being "sanctified" in Buddhism in a roundabout way where the root meaning of "sanctity" is somehow left behind. This in any case would imply that Buddhist thought somehow follows that of the theistic religions. On the contrary, a nontheistic religion such as Buddhism, in strict literal sense, would forego all talks about "sanctity" or "dignity" all together and instead talk about the value of each form of life in samsara and its capacity for realizing the ultimate goal, which in this case a human being is in a more advantageous position than, say, a hungry ghost or even a deity in heaven, because only a human being not distracted as much by the intense pains or pleasures that beings in the lower and higher realms suffer, respectively. Thus a human being is more valuable in Buddhism than a heavenly deity. This is different from the position of theistic religions, where the heavenly beings are more valuable because they are closer to God.

Furthermore, even in the case of explicitly "making death one's aim," it can be argued that if the purpose of making death an aim is to benefit beings, then the act can become a great self-sacrifice and thus is ethically commendable. A well-known story is that of a bodhisattva, who came across a sick and very hungry mother lion who had to take care of her cubs. Being sick and weak, the lioness was in no position to hunt for herself and for her cubs. Seeing the lioness and her cubs, the bodhisattva felt great compassion and offered his own body to the lioness so that it could gain strength and was thus able to feed her cubs. Viewed from one perspective, this is clearly an act of suicide, but in fact the bodhisattva was praised for his self-sacrifice, in fact the highest form of altruism. It is clear, however, that scarcely anyone alive today would be as self-sacrificing as the bodhisattva in the story, but the story points to the ideal of total self-sacrifice, of who does not have any regard at all for the interest of his own being. In the case of euthanasia, the story seems to

show that making death one's aim does not have to be wrong in all circumstances. There can be some circumstances where doing so can be a form of altruism and highly compassionate act too.

Another important issue in end of life concerns how the concept "death" should be defined. In the past, such as during the Buddha's time, this was not a problem because it was easy to find out who is actually dead. However, with the advent of modern technologies that can keep someone breathing for a very long period who would have been dead otherwise, there has arisen a controversy as to how death should be exactly defined and what the Buddhist perspective should be on this. The issue surrounding definition of death is also connected closely with organ transplantation. Carl Becker (1990) argues that the Buddhist perspective on death is that as long as the body is still warm, the person should not be declared dead. He cites a passage from the *Visuddhimagga*, an early Theravadin commentary, to support this point. Since warmth is necessary for life, it is conceptually impossible for there to be a body which is dead and warm at the same time. This precludes any possibility of declaring someone dead (because he is brain-dead), while his body is still warm because of the respirator.

How death is defined is clearly associated with the issue of organ transplantation. However, even if there were no controversy in defining death, there are much more ethical conundrums regarding organ transplantation itself. The problem centers on how the organs should be distributed. Since there are much more patients who are in need to organs to be transplanted than the number of organs available, how are the organs to be distributed? How should the patients be selected, according to their worth or on a first-come-first-serve basis? On the supply side, should there be the principle of "presumed consent" or "opt-out" system?

The Buddhist principle of compassion can play a clear role here. Potential donors who are also Buddhists need to be reminded that stating their intention as organ donors is a very generous and compassionate act to do and is actually in accordance with the rightful path which will lead eventually toward the ultimate goal of achieving Nirvana. Thus if they make their intention clear as an organ donor, it would be ethically permissible for the doctors to take the organs from them even though they are only brain-dead because through this act they have made a very generous act of compassion. Since the deceased obviously cannot take away their organs to their next lives, they should make the organs available to those who still need them in this life. As for the "opt-out" or presumed consent system, the compassion principle would say that it is rather difficult to presume that everybody is as compassionate as another. Thus, presuming that everybody would agree to be a donor unless they explicitly indicate otherwise might not be tenable because many might not want to become a donor but do not take the trouble of registering their intention. As for the problem of how patients should be selected to receive the donated organs, the principle of equanimity (*upekkha*), which as we have seen is one of the four immeasurables, would mean that distribution out of compassion should be blind. That is, it should not take into account any specific properties that separate one being from others at all. There should not be any kind of discrimination either in form of excluding certain individuals or groups or favoring some

groups or some individuals over others. As a result, the only viable form of distribution here would be something like drawing a lottery or using the first-come-first-serve basis. However, since time spent in waiting is of crucial importance for the patients, the first-come-first-serve basis is fairer than the lottery one. This first-come-first-serve basis, nonetheless, cannot be used at all times without any exception because there can be cases where a patient needs an organ much more than another because the former is in a more serious stage of her disease but may have registered herself on the waiting list later than the other whose disease is not as serious. In this case, it seems that the principles of compassion and equanimity would say that the patient whose disease is more serious should get the organ first even if she comes later on the waiting list.

Another end-of-life issue that has become talked about more in recent years is palliative care. Here, Buddhism can make positive impacts by caring for patients in palliative care centers (Garces-Foley, 2003). Spirituality naturally plays a large role in these centers, as the patients there are moving closer toward death. Being closer to death, they should be reminded that death is inevitable not only for them but also for everybody, who in fact never knows when they will die. Buddhist monks, nuns, and practitioners can help palliative care patients prepare for their end in this lifetime without struggling against it at all costs. Buddhism teaches that death is not the final end where everything will be extinguished forever. On the contrary, death is only a transformation. It is a transition from one lifetime to another, if one still wanders in samsara, which is the case for most people. In such a case, then, another lifetime can be expected. According to the law of karma as stated in the *Abhidhammattha Sangaha*, the quality of the next lifetime very much depends on the quality of life spent in this lifetime, and more importantly, it is the quality of the state of mind at the very moment of death that actually determines what kind of life the person will have to face after he or she is dead (Bodhi, 2007, p. 201). For example, if the person is relaxed and is in a meditative state when she dies, then it can be expected that she will enjoy a rebirth in one of the higher realms. On the contrary, if the person is angry or depressed at the moment when she dies, then it is very likely that she will be reborn in a lower realm. Consequently, it is of utmost importance that the person is in a state of wholesome mind (*kusalacitta*) when she dies, and the palliative care center can arrange for an atmosphere that is most conducive to this.

Vulnerability

The concept of vulnerability has become prominent in recent years as a counterweight to the concept of autonomy. A standard view in mainstream bioethics has been that a person is autonomous and is only vulnerable when conditions befall her in such a way that she cannot function as she normally could. Thus, a disabled person is vulnerable because she cannot function as well as an able bodied person. An elderly is also vulnerable in this sense because she is more susceptible to illnesses and injuries than a youth in the prime of her life.

Viewing a person only as an autonomous agent seems to miss this important aspect of being a human, where vulnerability can be also seen as pervading an entire aspect of being a human. Being a human in this sense is in itself vulnerable, as a human is susceptible to disease, is in a frail condition relative to the environment, and so on. As a vulnerable person deserves and needs active protection, categorizing every human being as vulnerable then can function as a guiding principle in bioethics where each human being is accorded with a special status that emphasizes the need for protection and special care. This dimension, however, appears to be lacking in the normal characterization of humans only as autonomous agents. Jan Solbakk (2011) writes that the concept of vulnerability can be seen from two different angles. One is that every human being is vulnerable. This conception leads to a realization of the concept of human rights where every human being regardless of their ethnicities, nationalities, gender, age, physical condition, etc. deserves and is entitled to special care and protection because of his or her status, qua a human being, as being vulnerable. Another angle of how vulnerability is viewed is that one is vulnerable in this sense only when one happens to be in a certain condition that prevents one from being able to function or perform as well as a "normal" person. In this sense, being vulnerable is not a universal condition; a "normal" human being is not vulnerable in this sense, and only someone who has lost some kinds of abilities or lacks certain features of a normal person can be vulnerable. This second sense sounds rather strange, however, when the concept is applied to women for it implies that being a woman is a "normal" condition for a human being. These two angles of the meaning of "vulnerability," taken together, can provide a foundation for a whole set of bioethical guidelines, one that emphasize not the isolatedness of individuals or their individual capacities to perform as presupposed by autonomy but human solidarity and capacities that each human has in relating to one another, helping, and caring one another.

The text of Article Eight of the UNESCO Declaration on Bioethics and Human Rights states: "In applying and advancing scientific knowledge, medical practice and associated technologies, human vulnerability should be taken into account. Individuals and groups of special vulnerability should be protected and the personal integrity of such individuals respected" (Universal Declaration, 2005). According to Solbakk (2011), the text of the article appears as a result of a compromise. The first sentence of the article, which refers to "human vulnerability" as a whole, points to the first angle of the meaning of vulnerability where vulnerability is a characteristic of humanity as such. In this case, research and development in medical technologies should pay special attention to the fact that every human being is vulnerable. Knowledge and technologies should be developed with the understanding that humans are frail and need special protection. Thus any kind of development that would result in any threat to the survival or flourishing of humanity needs to be stopped. In the second sentence, the emphasis is more toward vulnerability in the sense of loss of normal capabilities, and clearly, these are the groups that need special protection relative to those who are stronger because they have not lost these capabilities. Women, children, the elderly, and the disabled

people are especially vulnerable in this sense, and hence, they need special protection and care.

Buddhism would agree strongly with the principle of vulnerability presented here. The emphasis that the concept of vulnerability has on human solidarity and on their need for special care and protection accords well with the Buddhist precept on compassion and interdependence. Since all human beings are interrelated, no human being can stand alone apart from every other. In this sense, the fact that all humans are interrelated means that everyone is vulnerable, and this fits well with the Buddhist teaching on interdependence, which says that all things, not only humans, are what they are because of their interrelatedness with their total surroundings. When the concept of vulnerability is viewed according to the second sense, the Buddhist concept of compassion can play a key role in emphasizing the fact that these vulnerable groups need special protection and care. They need to be protected and helped simply because their conditions are such that they arouse spontaneous acts of compassion from everyone and actual, concrete help from those who are able to help. Just as a child arouses the feeling of compassion from an adult, the vulnerable group arouses compassion from all humans. It is important to note, however, that compassion here is not to be confused with pity. Pity has a sense that one who feels pity may also feel that he or she is somehow superior than the one to whom the pity is directed. But that is an unwholesome attitude according to Buddhism. When one feels that one is superior to others, a vicious separation between self and others arises, and it is this separation, this bolstering of the ego, that is directly inimical to the realization of the ultimate goal. Hence, the compassion needs to be purely altruistic and universal. It is a feeling that is based ultimately on total loss of any sense of the ego that only serves to separate oneself from the world.

Conclusion

One of the more controversial points within Buddhist bioethics is the question whether there can be any act which is right or wrong in and of itself, and the position taken in this article is that any act is right just in case it is done with compassion and the other immeasurables, and wrong otherwise. Compassionate act arises out of the realization that one's own sense of ego always stands in a way of pure and universal compassion and that any act that arises with this egoistic tendency cannot be fully compassionate, hence should be judged as ethically wrong. Even an act aiming toward death can be a prime example of a pure and universal compassionate act, such as the bodhisattva's dedication of his own body for the hungry lioness alluded to earlier. In this sense, then, it could be seen that there is a sense in which an act cannot be right and wrong in and of itself. Telling a lie, viewed in this light, can be a good act if by so doing the words uttered can create harmony and can lay a path toward eventual realization of the goal in the minds of the listeners and when the one who utters the words fully intend these results without any egoistic motive at all. However, these are viable only in very

exceptional circumstances, and in normal situation, those who have just started their journey toward the realization should instead focus on following the precepts which are aimed at disciplining their own body, speech, and mind, which means that in almost all cases one should not tell a lie. Buddhist ethics, then, cannot be fully separated from other aspects of Buddhist teachings, all of which are concentrated upon demonstrating that samsara, or this experienced world, is unsatisfactory and full of sufferings, that there is a cause of these sufferings in samsara, that the ultimate goal of total liberation from samsara does exist, and that there is a way leading toward final realization of the ultimate goal. These are the four noble truths, which comprise the most fundamental and important part of the Buddha's teaching to his students.

Catholicism

22

Gerard Magill

Introduction

Roman Catholicism has developed a sophisticated system of morality, both theoretical and practical, that involves multiple tiers of interaction, including official church teaching with specific directives about what is permissible or prohibited, academic discourse by scholars, outreach by professionals in health care, and the daily practice of the moral life by the faithful. To understand varying Catholic teachings on morality in general and bioethics in particular, it can be helpful to begin by discussing different levels of authority in the Catholic church.

Teaching Authority of the Catholic Church

The Catholic Church teaches that God's covenant of salvation is revealed in Holy Scripture with a living transmission of biblical revelation through the Holy Spirit across history, creating a divinely inspired tradition in the church. The authentic interpretation of God's revelation in scripture and tradition is the responsibility of the church's magisterium of bishops in communion with the pope. However, the faithful guided by the church magisterium, shares this responsibility for the living tradition of revelation that undergirds the continuing mission of the church through salvation history. The church magisterium of the pope and bishops teaches on matters of faith and morals, including bioethics, with a range of authority from official Vatican doctrine to its implementation in practical directives for bioethics by national conferences of Catholic bishops.

Because of the extraordinarily large size of Catholic health care in the United States, the teaching from the *United States Conference of Catholic Bishops* (USCCB) is adopted here as an example of how Vatican teaching on morality is implemented at a national level to guide bioethics. Catholic health care in the United States provides approximately one-sixth of the nation's health care, serving

approximately 600 hospitals and 1,400 care facilities (long-term care). Because of the size of Catholic health care in the United States, it has a professional organization called the *Catholic Health Association* (founded in 1915) with its own journal (six issues annually), *Health Progress*, that has regular contributions to bioethics discourse. Moreover, in the United States, there is a National Catholic Bioethics Center that publishes a quarterly journal, *The National Catholic Bioethics Quarterly*, as well as an extensively adopted newsletter, *Ethics and Medics*. Also, the USCCB has developed a set of directives to implement Vatican teaching on bioethics, the *Ethical and Religious Directives for Catholic Health Care Services*, now in its fifth edition (USCCB, 2009). Although these *Directives* are designed for and only have jurisdiction over health care in the United States, they implement Vatican teaching in a manner that can have relevance for Catholic bioethics universally.

This discussion of the teaching authority of the Catholic church moves from a broad to a narrow explanation with three distinct components. The first component discusses the comprehensive and systematic teaching of Catholic morality found in the *Catechism of the Catholic Church* (Catechism, 1994) and the church's *canon law* (Canon Law, 1983). The second component examines the foundations of Catholic morality that are explained in the only Papal Encyclical dedicated exclusively to morality so far, *Veritatis Splendor, The Splendor of Truth*, issued by Pope John Paul II in 1993. The third component bridges church teaching on Catholic morality with Catholic bioethics by discussing the *Ethical and Religious Directives for Catholic Health Care Services* from the United States Bishops (USCCB, 2009).

The first component of this discussion of the teaching authority of the Catholic church discusses the *Catechism of the Catholic Church*, authorized by Cardinal Joseph Ratzinger and approved by Pope John Paul II (Catechism, 1994). The *catechism* presents official Catholic teaching on all matters of faith and morality, providing a comprehensive and systematic reference for understanding Catholic morality in general and bioethics in particular. Church doctrine in the *catechism* is consistent with the church's *canon law* (Canon Law, 1983) that also was approved by Pope John Paul II. These documents provide the authoritative foundation for official Catholic teaching on matters of faith and morality.

The highest level authority of church teaching pertains to Papal Infallibility and the magisterium of bishops. In July 1870, the doctrine of Papal Infallibility *ex cathedra* was defined at the First Vatican Council (1869–1870) in Rome in a doctrinal constitution titled, *Pastor Aeternus*, number 3074. Nearly a hundred years later, the Second Vatican Council (1962–1965) in Rome promulgated many doctrinal constitutions. In particular, the *Dogmatic Constitution on the Church*, number 25, clarified the role of the magisterium of bishops over the centuries. This constitution explained that beyond the *ex cathedra* infallibility of the pope in matters of faith and morality, the ordinary magisterium of bishops has authentic teaching authority (Sullivan, 1983).

This understanding was reiterated in teaching from the *Congregation for the Doctrine of the Faith* in 1990 titled, *Donum Veritatis, Instruction on the Ecclesial*

Vocation of the Theologian. The document explained that teachings presented by the bishops in a definitive way must be firmly accepted. These levels of authority in Catholic church teaching reflect a hierarchy of truths, as discussed in Vatican II's *Decree on Ecumenism*, number 11. Also, Catholic church teaching includes the contribution of Catholic theologians. The Papal Encyclical, *Veritatis Splendor*, number 110, explained that the role of theologians includes this responsibility regarding church teaching: "to develop a deeper understanding of the reasons underlying its teachings to expound the validity and obligatory nature of the precepts it proposes." In other words, given the relation between the Catholic magisterium of bishops and the hierarchy of truths taught by them, theologians have a legitimate role as collaborative partners in full communion with the church (Happel & Walter, 1986; O'Donovan, 1982).

The second component of this discussion of the teaching authority of the Catholic church examines the Papal Encyclical, *Veritatis Splendor*. On specific issues of morality, there has been no *ex cathedra* infallible teaching bearing the full and explicit weight of Papal Infallibility as was taught in Vatican I. However, there has been one Papal Encyclical dedicated exclusively to Catholic moral theology, *Veritatis Splendor*. Many Papal and Vatican documents mention particular issues related to moral theology and bioethics, and they will be discussed later. The approach to Catholic moral theology that is explained in this encyclical is consistent with and calls upon the teaching of the *catechism* and *canon law* mentioned above. The following summary of *Veritatis Splendor* presents the foundations for morality in Catholic teaching.

The purpose of the encyclical *Veritatis Splendor* was to address fundamental questions regarding Catholic moral teaching, based upon the traditional doctrine of natural law with its universally and permanently valid precepts, while recognizing that the church's *catechism* provides a complete and systematic exposition of church moral teaching (number 4–5). After a reflection upon the teachings on morality in the bible (Chap. 1), the encyclical addressed four foundational issues in morality to highlight the principles underlying church teaching (Chap. 2).

The first foundational issue in *Veritatis Splendor* is the understanding of human freedom and rightful autonomy in morality in a manner that integrates the ethical realm with the realm of salvation. Here, the encyclical alludes to the traditional teaching of natural law that recognizes the role of human reason in discovering and applying the moral law. The encyclical explains that human reason draws its truth and authority from the eternal law, reflecting divine wisdom itself (numbers, 35–53). As explained by St. Thomas Aquinas, the natural law is the participation of the eternal law in the rational creature (Rhonheimer, 2011).

The second foundational issue in *Veritatis Splendor* deals with conscience whose imperative character formulates moral obligation in light of the natural law and constitutes the proximate norm of personal morality (numbers 54–64). The third foundational issue explains that in the relationship between the person and specific actions, an individual's fundamental option in life cannot be disconnected or separated from concrete behavior. Here, the church explains that there is a substantive integrity or personal unity of moral agents in their body and soul (65–70).

The fourth foundational issue in *Veritatis Splendor* deals with the meaning of moral action that entails the rational ordering of the human act to the good and the voluntary pursuit of that good. Here, the encyclical explains that moral life is inherently teleological in the sense that it consists in the deliberate ordering of human acts to God as the supreme good and ultimate end (*telos*) of humanity. Again, the encyclical turns to Aquinas to explain that the morality of the human act depends on the object being rationally chosen by the deliberate will (the moral object). The object is to be understood as the proximate end to a deliberate decision which determines an individual's act of willing. Hence, there are moral actions that can be described as intrinsically evil (*intrinsice malum*) insofar as the object of the human act involved is incapable of being ordered to God, independently of ulterior intentions or circumstances of the individual. This reflects the Catholic tradition's understanding of three sources of morality: the chosen object, the intention, and the circumstances. Examples of intrinsically evil acts include abortion, euthanasia, torture, slavery, prostitution, and human trafficking (numbers, 65–81). The final section of *Veritatis Splendor*, Chap. III, discusses how the moral good integrates faith and morality, presenting universal and unchanging moral norms as being in service to true freedom.

To bridge Catholic teaching on morality in general with bioethics in particular, the third component of this discussion of the teaching authority of the Catholic church considers the *Ethical and Religious Directives* from the United States Conference of Catholic Bishops (USCCB, 2009), which for brevity is referred to as *Directives*. The *Directives* are now in the fifth edition published in 2009. The preamble and introduction explain that the purpose of the *Directives* is to reaffirm ethical standards of behavior in health care based on church teaching and to present authoritative guidance about specific moral issues. There are six main parts, each with two sections: there is an expository introduction that provides the context for each of the main categories and there is a series of prescriptive directives about the truths of Catholic faith and their significance for the categories discussed. The six parts discuss a different category. Part one discusses social responsibility of Catholic health care services. Part two examines the pastoral responsibility and spiritual responsibility of Catholic health care. Part three considers the professional-patient relationship. Part four analyzes the beginning of life. Part five analyzes the seriously ill and dying. Part six deliberates on forming new partnerships with other than Catholic organizations and providers.

The above points about the teaching authority of the Catholic church present several components: a component that deals with the comprehensive and systematic approach to morality, a component that addresses the foundations of morality, and a component that bridges Catholic teaching on morality with the specific arena of bioethics. From these components, a general framework for Catholic bioethics can be suggested that relates the sanctity and conscience of the human person with moral actions understood in light of the natural law, as discussed in the next section.

Framework for Catholic Bioethics

The sanctity and conscience of the individual person reflects the integration of the ethical realm and the realm of salvation, with moral actions that shape the person's fundamental option to the good, being enlightened by the natural law. This succinct statement presents a framework for Catholic bioethics by considering two related aspects, discussed below. Of course, there are many excellent studies on Catholic bioethics that explore theoretical and practical issues in depth, (Kelly, Magill and ten Have, 2012; Kelly, 2007; Shannon & Kockler, 2009; Walter & Shannon, 2005). This analysis seeks to present a simple framework to address principles and problems in Catholic bioethics.

The first aspect of the framework for Catholic bioethics relates the dignity of the individual with the sanctity of the person in the context of the common good. The Catholic tradition holds that religious and moral truths in faith are not beyond the grasp of reason. The dignity of the human person is grounded in being created in the image of God. The sanctity of the human person deepens this concept in relation to the redemption of humanity after the fall. The integrative nature of the dignity and sanctity of the human person must be understood within a communal context of social responsibility or the common good that shapes the ecclesial mission of the church. Catholic teaching affirms this reciprocity in its health care ministry especially in terms of respect for life (sanctity) and the right to health care (common good).

On the one hand, the sanctity of human life means that it must be respected and protected from the moment of conception. This teaching is the basis for the church prohibition against direct abortion and euthanasia. However, the sanctity of human life is also the basis for church teaching permitting the withdrawal of futile care at the end of life. Also, respecting the sanctity of human life undergirds the church's teaching about the dignity of marriage and the need to maintain the unitive and procreative meaning of marital intimacy – this is the church's rationale for its teaching against contraception as well as in vitro fertilization procedures, as discussed in the *Instruction on Respect for Human Life in Its Origin and on The Dignity of Procreation* from the Congregation for the Doctrine of the Faith in 1987 (Rhonheimer, 2010). On the other hand, because of the church's commitment to human dignity and the common good, the US Bishops in part one of the *Directives* assert there is a human right to adequate health care, especially for the poor and vulnerable.

The second aspect of the framework for Catholic bioethics relates the meaning of moral truth, moral norms, and moral action with the natural law. Catholic teaching explains that moral truth is gleaned from the natural law, adopting the explanation of Aquinas mentioned above. However, there is considerable debate about what this means precisely with varying emphasis upon physical/biological reality versus personal reasoning as properly reflective of the meaning of natural. The camps in this disagreement over the meaning of natural law are often referred to in terms of physicalism versus personalism. The ethical debate typically divides into a conservative camp, being aligned with a physicalist approach, and a progressive camp, being aligned with a personalist approach, to explain the meaning of moral norms and actions (Kelly, Magill and ten Have, 2013).

Views of moral norms can reflect either a universally determined outlook adopting a physicalist, conservative approach or an outlook that is attentive to historical consciousness adopting a personalist, progressive approach. While there is general agreement between conservatives and progressives that a physical act cannot itself determine morality, insofar as intention and circumstances are necessary components for ascertaining morality that are distinct from the physical action, there is considerable disagreement about the moral meaning of particular actions. The progressive, personalist camp generated a theory called proportionalism that justifies moral action after weighing nonmoral goods in light of the intention and circumstances involved. This theory remains influential in Catholic bioethics, even though proportionalist theories in general were rejected as a legitimate normative method in Catholic morality in the encyclical *Splendor of Truth*, no. 75 and 79. The Catholic debate over artificial contraception amply illustrates this divided understanding of the meaning of natural law and its role in determining moral norms: the physicalist, conservative perspective (as occurs in official Catholic teaching) prohibits artificial contraception, and the personalist, progressive perspective justifies artificial contraception in particular circumstances.

This framework for Catholic bioethics, with the aspect that relates the dignity and the sanctity of the individual in the context of the common good and the aspect that relates the meaning of moral truth with the natural law, enlightens multiple practical issues. The history of Catholic moral theology and of Catholic bioethics is extensive, and it is important to be mindful of the development over two millennia of this robust tradition of church teaching and scholarly discourse (Kelly, 1979; Mahoney, 1987), though the focus of this analysis is upon the principles and issues in Catholic bioethics today.

The sections below address the practical issues in Catholic bioethics that typically elicit most controversy and discussion within the United States but also globally. These practical issues are presented in two clusters: clinical ethics both at the start and at the end of life and professional and organizational ethics in health care. Within each cluster, a specific principle in Catholic bioethics is discussed that helps to resolve the dilemmas that can occur when both good and bad effects accompany moral action. Under the discussion of clinical ethics the principle of double effect, which is developed from the teaching of St. Thomas Aquinas, is discussed to address situations in which an individual action involves good and bad effects. In contrast, under the section "Professional and Organizational Ethics," the principle of cooperation, which is developed from the teaching of St. Alphonsus Liguori, is discussed to address situations in which good and bad actions of two different agents coalesce.

Clinical Ethics at the Start of Life

The teaching of the Catholic church against all forms of direct abortion is well known, protecting human life from the time of conception. Catholic teaching on human life has significant implications for both ethics and politics in the public

square (Lee & George, 2008). To explain official Catholic teaching on abortion, in 1995 Pope John Paul II issued a Papal Encyclical, *Evangelium Vitae, The Gospel of Life*. This encyclical further developed the previous teaching in 1987 from the Congregation for the Doctrine of the Faith, *Donum Vitae. Instruction on Respect for Human Life in its Origins and on the Dignity of Procreation*. It is important to note that although Catholic teaching protects human life from conception, this teaching is an assumptive stance given the high stakes involved. The Encyclical *Evangelium Vitae* acknowledges that while "the Magisterium has not expressly committed itself" to what are described as "philosophical affirmations" about the start of life, life is protected from conception, as explained in number 60: "What is at stake is so important that, from the standpoint of moral obligation, the mere probability that a human person is involved would suffice to justify an absolutely clear prohibition of any intervention aimed at killing a human embryo. . .. *The human person is to be respected and treated as a person from the moment of conception*" (number 60). The core teaching on abortion is that "the direct and voluntary killing of an innocent human being is always gravely immoral . . . and can never be licit either as an end in itself or as a means to a good end" (number 57); "direct abortion, that is, abortion willed as an end or as a means, always constitutes a grave moral disorder" (number 62).

Related to this teaching on protecting human life from conception is the prohibition of creating embryos in the petri dish via in vitro fertilization (IVF) outside of the natural environment of the uterus. This prohibition occurs because the IVF process disrupts the integration of the unitive and procreative aspects of marital intimacy that was at the core of Pope Paul VI's 1968 Papal Encyclical against artificial contraception, *Humanae Vitae* (number 12). The IVF process can be used to create embryos not only for treatment of infertility but for other purposes, such as for embryo testing and selection based upon genetic conditions in the process of preimplantation genetic diagnosis (PGD), or for planning so-called designer babies based on genetic profiling, or for research related to human cloning (Guenin, 2008). Catholic teaching in bioethics forbids all of these.

There is another problem that is raised by this strict prohibition of abortion. Catholic teaching against abortion includes contraceptive devices or pharmaceuticals that prevent a fertilized egg from nidating in the uterus. Insofar as human life is protected from the moment of conception, the fertilized egg is included under this protection, and hence, these contraceptive measures are tantamount to abortion. Given the large numbers of Catholic women using these contraceptive measures, with the concomitant number of contraceptive abortions that can occur in daily Catholic life, the teaching against abortion encounters significant issues of effectiveness or credibility – not least because many Catholic women who identify themselves as being firmly opposed to abortion may find themselves participating in these abortive contraceptive measures, perhaps with surprising frequency.

Catholic teaching against abortion specifically prohibits direct abortion. However, some types of termination called indirect abortions are permitted. Two types of cases elicit continuing controversy in Catholic bioethics that can be construed as

legitimate, indirect abortions. The cases deal with the imminent threat of a woman's death in pregnancy requiring the termination of embryonic or fetal life: ectopic pregnancy and pulmonary hypertension.

Principle of Double Effect: Ectopic Pregnancy and Pulmonary Hypertension

Although the Catholic tradition refers to double effect reasoning in dilemma circumstances as applying the "principle" of double effect, what occurs is an interpretation of permissible or proscribed effects, distinguishing between morally intended acts and their unintended side effects within a particular framework of moral reasoning. This section discusses four issues: first, the principle of double effect with its traditional conditions; second, the application of the principle to the settled case of a pregnant woman with a cancerous uterus; third, the use of the principle to clarify the controversial case of ectopic pregnancy; and fourth, the use of the principle to clarify the controversial case of pulmonary hypertension.

First, the principle of double effect is attributed to St. Thomas Aquinas, and over subsequent centuries its four conditions were developed, formulated specifically by Jean Pierre Gury (1801–1866). The four conditions can be explained in this manner. Condition one: the morally intended action as the object of the act must be either good or morally indifferent. Condition two: the bad effect must not cause the good effect but the bad effect and good effect may occur simultaneously. Condition three: the agent must directly intend the good effect, with the bad effect being unintended albeit foreseen. Condition four: there must be a proportion between the intended good effect and the unintended, though permissible, bad effect.

Second, the application of the principle of double effect to the settled case of a pregnant woman with a cancerous uterus can be described in this manner. Condition one: the morally intended action is to remove the cancerous organ, the mother's uterus, to save her life. Condition two: the harm to the fetus occurs at the most simultaneously with the removal of the uterus: the fetus is not killed as a means to achieve the end of saving the mother. Condition three: the bad effect of the death of the fetus is merely foreseen but not intended. Condition four: the proportion between the good and bad effect is that no other intervention would be possible to save the one life that can be rescued (the mother's) rather than lose both lives (the mother and the fetus).

Catholic teaching, from a generic standpoint, accepts that the principle of double effect can be implemented when the death of an embryo or fetus is foreseen but not intended. The *Directives* of the US Bishops states the following in number 47: "Operations, treatments, and medications that have as their direct purpose the cure of a proportionately serious pathological condition of a pregnant woman are permitted when they cannot be safely postponed until the unborn child is viable, even if they will result in the death of the unborn child" (USCCB, 2009).

Applying the principle of double effect to a pregnant woman with a cancerous uterus is now a settled case in Catholic teaching on bioethics. Pope Pius XII

explained in his "Address to the Associations of the Large Families" on November 26, 1951: "The reason is that, if, for example, the safety of the future mother, independently of her state of pregnancy, might call for an urgent surgical operation, or any other therapeutic application, which would have as an accessory consequence, in no way desired or intended, but *inevitable*, the death of the foetus, such an act could not be called a *direct* attempt on the innocent life. In these conditions the operation can be lawful, . . . provided that it is not possible to postpone it till the birth of the child, or to have recourse to any other efficacious remedy" (Odile & Liebard, 1978).

Further ratification of this settled case of legitimately removing a cancerous uterus from a pregnant woman was documented by the U.S. Bishops' Committee on Doctrine in a statement published on June 23, 2010: "The . . . scenario describes a situation in which an urgently needed medical procedure *indirectly* and unintentionally (although foreseeably) results in the death of an unborn child. In this case the surgery *directly* addresses the health problem of the woman, i.e., the organ that is malfunctioning (the cancerous uterus). The woman's health benefits directly *from the surgery*, because of the removal of the cancerous organ. The surgery does not directly target the life of the unborn child. The child will not be able to live long after the uterus is removed from the woman's body, but the death of the child is an unintended and unavoidable side effect and not the aim of the surgery" (USCCB, 2010).

In this case, conservative and progressive interpretations of natural law reasoning, as well as the official teaching of the magisterium of the church, agree that a cancerous uterus can be legitimately removed from a pregnant woman despite foreseeing the death, unintended but unavoidable, of the fetus. Conservative and progressive views argue their support for the case in different ways. For example, proportionalist reasoning would consider the first and second conditions of the principle of double effect to be dependent on the third and fourth conditions that focus upon proportionality and intentionality. Nonetheless, consensus has been reached on the case. That consensus has yet to be developed in the next two cases.

Third, the principle of double effect in the settled case of the cancerous uterus can be used to clarify cases of ectopic pregnancy. When a fertilized egg nidates in a fallopian tube, it creates a life-threatening circumstance for the mother. At times, the situation resolves itself naturally, but typically medical intervention is required. There are two main options. Salpingectomy involves the surgical removal of part of the fallopian tube with the fertilized egg within. This can be justified in a similar manner to the removal of a cancerous uterus from a pregnant woman, insofar as the conditions of the principle of double effect would be exactly similar, most especially that the death of the embryo is merely foreseen but unintended. The more controversial intervention is a salpingotomy involving the removal of the embryo and its surrounding trophoblast but leaving the fallopian tube intact. The advantage here is to preserve the fertility of the fallopian tube while resolving the underlying pathology. The dilemma, however, is that the moral action appears to target the embryo directly, either by use of the drug methotrexate or by surgical intervention.

There are three contrasting ways of justifying this more controversial approach of salpingotomy. The first argument involves a progressive perspective reflecting a proportionalist approach that would weigh the relevant goods, recognizing that the embryo is destined to die whatever transpires. The argument would be that salpingotomy, saving the mother's life and preserving the fertility of the fallopian tube in question, is a more proportionate intervention (causing the most good and least harm) than salpingectomy that involves removal of the fallopian tube with concomitant compromise of the woman's fertility in that fallopian tube (Kelly, 2004). Of course, if the embryo could be removed and otherwise saved, a proportionalist analysis would support doing so, but that is not yet medically feasible. However, as mentioned previously, Catholic teaching does not accept proportionalist approaches.

The second argument involves a conservative perspective arguing that salpingotomy could be permitted, physically removing the embryo while adhering to the Catholic prohibition of direct abortion. The argument is that the meaning of the moral action is to save the mother, albeit foreseeing but unintentionally causing the death of the embryo by physically removing it – the emphasis here is upon physically removing the embryo, recognizing that it will inevitably die rather than directly killing it. The conservative moral philosopher Martin Rhonheimer, among others, makes this nuanced argument by presenting a moral action theory based on Thomistic virtue ethics (Rhonheimer, 2011). He recognizes that the intervention involves killing the embryo insofar as the intervention is aimed at the embryo in a physical manner, but this is not tantamount to a morally direct action. The physical action is not morally decisive. For example, if the embryo could be removed physically and transferred to life support, then that should be done (just as the proportionalist approach would argue), but it is not yet medically feasible. Because saving the embryo is not possible does not mean that the intervention to save the mother entails morally direct killing of the embryo. He makes a similar argument to justify the historical intervention of craniotomy as the necessary physical action to save the life of the mother when otherwise both mother and fetus will die (Rhonheimer, 2009).

It is interesting that both the conservative moral action theory and the proportionalist analysis agree that the physical removal of the embryo cannot determine the moral meaning of the intervention. However, the conservative moral action theory refuses to justify the intervention based on a weighing of goods, such as is argued in a proportionalist analysis. However, distinguishing between these theories with regard to the practical analysis involved can appear like making a technical distinction without a substantive difference. The weighing of goods that characterizes proportionalist analysis involves the identical points upon which conservative moral action theory justifies the removal of the embryo: the embryo cannot survive whatever occurs (of course, the embryo would be saved in both approaches if it was medically feasible), the life of the mother can be rescued, and the physical removal of the embryo is not sufficient to determine the moral meaning of the action. In other words, it appears that complex cases of moral analysis like ectopic pregnancy can bring conservative and progressive approaches

together both with regard to the conclusion of directly removing the embryo and also with regard to the points made to justify the conclusion.

The third argument on ectopic pregnancy involves the use of the principle of double effect, such as argued by the Catholic moral theologian John Touhey. He justifies salpingotomy as the removal of the embryo in an indirect manner. He explains that an intervention may be justified, such as by the drug methotrexate, insofar as the physical intervention deals with the trophoblast that develops into the placenta, thereby not directly or physically removing the cytoblast (within the trophoblast) that develops into the embryo and fetus. He explains that removing the trophoblast with the cytoblast inside is akin to removing the cancerous uterus with the fetus inside using the traditional principle of double effect (Touhey, 1995). This argument differs from the proportionalist analysis and the conservative moral action theory insofar as those approaches justify the direct physical removal of the embryo. In contrast, the purpose of applying the principle of double effect is to avoid the direct, physical removal of the embryo itself. The double effect reasoning is that the removal of the embryo is an indirect and unintended, albeit unavoidable and foreseen, side effect of legitimately removing the trophoblast, within which the cytoblast that becomes the embryo is contained.

Each of these three arguments draws the same conclusion in Catholic bioethics: that salpingotomy can be justified even though it entails killing the embryo (either directly or indirectly). Of course, a conservative argument can be made against salpingotomy as constituting a direct abortion insofar as the embryo is removed from the fallopian tube. However, official Catholic teaching has not yet taken a definitive stance on this case. The above analysis has been presented in detail to illustrate how the normative approaches in Catholic morality and Catholic bioethics function, especially with regard to the foundational teaching on protecting life from conception.

Fourth and finally, the use the principle of double effect can clarify controversial cases dealing with pulmonary hypertension caused or exacerbated by pregnancy. The clinical situation can arise when there is an imminent threat of death to a woman, often around the 11th week of pregnancy, due to pulmonary arterial hypertension that can cause cardiogenic shock resulting in cardiac arrest. The cause of the pathology is the placenta (as a shared organ between mother and fetus) that becomes hypoxic. In such cases, akin to ectopic pregnancy, the fetus is destined to die whatever transpires, and the only life that can be saved is the mother's life.

The same analysis that pertains to ectopic pregnancy can be applied to this case. First, using proportionalist analysis, removing the fetus can be justified by weighing of goods (causing the most good and least harm) – but this theoretical approach has been rejected by Catholic teaching. Second, adopting conservative moral action theory, removing the fetus can be justified by distinguishing between its physical removal and the moral meaning of the action. In this case, as in ectopic pregnancy, a progressive approach involving a proportionalist analysis and a conservative approach involving moral action theory make the same points to justify removing the fetus: the fetus cannot survive whatever occurs, the life of the mother can be

rescued, and the physical action of removing the fetus is not sufficient to determine the moral meaning of the action.

In contrast to these two approaches, a third argument involves the use of the principle of double effect to justify the death of the fetus as an indirect side effect, as follows. The underlying pathology causing or exacerbating the pulmonary hypertension of the mother is the placenta that has become hypoxic. The placenta, as a shared organ between mother and fetus, must be removed. However, the removal of the placenta can only occur by evacuating the uterus with the amniotic membranes containing the fetus, such as by dilation and curettage (D and C). The direct, physical action of removing the amniotic membranes containing the fetus is akin to the removal of the cancerous uterus with the fetus contained within. In the case of pulmonary hypertension, the death of the fetus is unintended, though foreseen and unavoidable. An additional point should be noted in this case. Even if the fetus was already dead in the uterus, the placenta can continue as a functional organ for some time, even weeks. Hypothetically, action in this case to resolve the underling pathology by removing the fetus alone would not be sufficient – only the removal of the placenta can achieve that purpose. In sum, the principle of double effect in Catholic bioethics can be applied to this case (Magill, 2011).

Clinical Ethics at the End of Life

The principle of double effect also can be used to resolve dilemmas in end-of-life care in which withholding or withdrawing treatment (between which there is no morally significant difference), including medically assisted feeding, is deemed to be futile. Because Catholic teaching recognizes that the life of the body is not an absolute good, there is no moral obligation to keep a patient alive whatever the circumstances or cost. The Catholic tradition has developed a working principle that permits allowing patients to die when futile measures are legitimately withdrawn. That is, withdrawing futile measures lets patients die of their underlying pathology and does not constitute killing them: the intent to withdraw futile treatment is distinct from intending the inevitable and foreseen death of the patient. However, any form of direct euthanasia or assisted suicide is prohibited in Catholic teaching, as explained in the 1980 *Declaration on Euthanasia* from the Congregation for the Doctrine of the Faith.

There has been considerable debate over the treatment of patients in a persistent vegetative state (PVS), and the US Bishops updated their teaching on this matter in the 2009 fifth edition of their *Directives* in number 58, where they made these points. There is an obligation, but only in general principles, to provide medically assisted feeding (nutrition and hydration) to patients in chronic and irreversible conditions, such as PVS patients. However, in specific cases medically assisted feeding is morally optional, not morally obligatory, if it cannot reasonably be expected to prolong life or it is excessively burdensome or it causes significant physical discomfort to the patient, such as when a patient draws close to death.

This teaching reflects a more basic distinction, discussed in *Directives* number 56–57, that guides decision-making in health care by differentiating between proportionate and disproportionate means, reflecting the longstanding distinction in the Catholic tradition between ordinary and extraordinary means (Hamel & Walter, 2007). The distinction revolves around the crucial conjunctives *and*/*or*, as follows: "A person has a moral obligation to use ordinary or proportionate means of preserving his or her life. Proportionate means are those that in the judgment of the patient offer a reasonable hope of benefit *and* do not entail an excessive burden or impose excessive expense on the family or the community" (*Directive*, 56, emphasis added); "A person may forgo extraordinary or disproportionate means of preserving life. Disproportionate means are those that in the patient's judgment do not offer a reasonable hope of benefit *or* entail an excessive burden, or impose excessive expense on the family or community" (Directive, 57, emphasis added). That is, ordinary or proportionate means have a much higher bar to meet (benefit *and* burden analysis) than extraordinary or disproportionate means (benefit *or* burden analysis).

Moreover, the Catholic tradition is supportive of organ and tissue procurement after a patient has died. Catholic teaching retains an open stance on donation after cardiac death (DCD). This practice raises a controversial issue. DCD occurs with nonheart beating cadavers (NHBCs) using cardiopulmonary criteria for death rather than brain death. Technically, for a small period of time after using cardiopulmonary criteria for death before brain death occurs, patients could be artificially resuscitated. In theory, such patients are beyond the point of self-resuscitation but technically could be artificially resuscitated, though there would be immense brain damage. In other words, the patient is not completely dead but will never be resuscitated – that is a condition of initiating the process of DCD.

Professional and Organizational Ethics

In addition to issues in clinical ethics at the start and end of life in which the traditional principle of double effect can be so helpful to resolve dilemmas about patient care, the Catholic tradition also engages issues related to professional and organizational ethics for which another ethical principle, the principle of cooperation, can be helpful to resolve dilemmas. The relation between patients and clinicians is foundational in Catholic bioethics, such as explained in part three of the *Directives* of the US Bishops. In addition to respecting patient rights, autonomy, and consent, this relationship provides the context for fostering professional virtue (Pellegrino & Thomasma, 1993). In health care today, there are increasing conflicts of interest that compromise both the health care professional and health care organizations. From the perspective of individual professionals, ethical dilemmas arise, for example, from financial incentives or partnership with device manufacturers. From the perspective of organizations, ethical dilemmas arise, for example, when mergers occur between Catholic and other than Catholic organizations that

provide services prohibited by the Catholic tradition, such as elective sterilizations that contravene Catholic teaching on contraception.

The Catholic tradition has developed a sophisticated principle of cooperation to guide professionals and organizations through these moral dilemmas. The principle functions in situations where an individual or organization as a moral agent is connected with the wrongdoing of another agent. For example, in a merger between a Catholic hospital and a community hospital that performs sterilizations, the principle is applied to make arrangements that keep the Catholic facility at a sufficient distance from the sterilization procedures and profits of the community hospital while having closer affiliation on other morally legitimate aspects of the merger. This type of arrangement using the principle of cooperation was explained by the United States National Conference of Catholic Bishops in a *Statement on Tubal Ligation* (USCCB, 1983) as well as in an appendix to the earlier third edition of the *Ethical and Religious Directives for Catholic Health Care Services* (USCCB, 1995). Subsequent editions of the Directives have removed this appendix on "The Principles Governing Cooperation."

There are two basic distinctions that need to be made. First, formal cooperation is never permitted whereby an individual or organization is morally complicit by directly participating in or intending the wrongdoing of another individual or organization. For example, if a Catholic hospital partnered with a community hospital in order to provide sterilizations and share the resulting profits that arrangement would intend the wrongdoing as formal and illicit cooperation.

Second, material cooperation is permitted in situations of duress that permit material connection between two moral agents: the wrongdoing of one is not intended by the other, and there is sufficient distance between the two moral agents to avoid one being perceived as morally complicit in the wrongdoing of the other. For example, if a politician is proabortion, Catholic citizens may vote for that candidate provided they do not support the candidate's proabortion stance. Furthermore, Catholic politicians may vote for proabortion legislation in government provided they indicate they are opposed to abortion and that the law being passed further limits the harm of previous abortion legislation.

Pope John Paul II, in his 1995 Encyclical *Evangelium Vitae*, wrote the following (number 73): "when it is not possible to overturn or completely abrogate a pro-abortion law, an elected official, whose absolute personal opposition to procured abortion was well known, could licitly support proposals aimed at *limiting the harm* done by such a law and at lessening its negative consequences at the level of general opinion and public morality." In the subsequent paragraph (number 74), the pope summarized the principle of cooperation in this manner, using action against innocent human life as an example: "it is never licit to cooperate formally in evil. Such cooperation occurs when an action, can be defined as a direct participation in an act against innocent human life or a sharing in the immoral intention of the person committing it." Many organizational arrangements in health care employ this principle of cooperation to resolve ethical dilemmas that involve conflict of interest or organizational complicity in wrongdoing (Watt, 2005).

Emerging Issues in Catholic Bioethics

The framework for Catholic bioethics that enlightens clinical, professional, and organizational issues in health care also is helpful for considering emerging issues in bioethics. These three substantive issues illustrate the moral landscape that Catholic bioethics will have to traverse for many years ahead.

Since the sequencing of the human genome, the accomplishments of cloning, and the creation of human embryonic stem cells, science and biotechnology present enormous challenges to Catholic bioethics (Shannon & Walter, 2003). At a foundational level, technological enhancement may change the meaning of human identity, the species, and the ecological environment. Hence, religious bioethics must keep apace to scrutinize and guide foundational changes to the human condition and global environment (Cole-Turner, 2011).

More particularly, the manipulating of pluripotent stem cells raises profound ethical and ontological questions about when human life actually begins and what type of research may be morally permissible at the earliest stages of embryogenesis. For example, insofar as adult stem cells can be turned into pluripotent stem cells that can then be used for procreation (as has occurred in mice experiments), the moral status of human pluripotent stems cells needs to be clarified for research purposes, even though it would be immoral to use these cloned cells for human procreation (Magill & Neaves, 2009).

Furthermore, because embryonic stem cell research is inherently controversial due to the unavoidable destruction of the human blastocyst when procuring these cells, there will be increasing pressure to use excess blastocysts that remain in cryopreservation in IVF clinics. There are approximately 400,000 excess IVF embryos in the United States. Perhaps the Catholic tradition can shed light on the possibility of using these embryos by deploying its principle governing letting patients die and its principle governing organ procurement from dead patients, as follows.

The standard of care in IVF clinics now is to freeze 5-day embryos after they have developed into blastocysts because they subsequently implant more effectively to the uterus. At the blastocyst stage, the embryonic stem cells have already developed. Frozen blastocysts cannot live forever in a state of cryopreservation. Catholic teaching permits them being withdrawn to thaw and die – akin to withdrawing life support from an adult patient (cryopreservation being the embryo's life support). Moreover, just as organs can be procured after a patient dies while the organs are still viable, a similar process is feasible for blastocysts. There is a molecular marker that identifies the point at which the blastocyst cannot recover, yet the embryonic stem cells remain viable. That molecular marker for the blastocyst is akin to the criteria of death used for organ procurement. In other words, the Catholic tradition could deploy its principles governing letting patients die and organ procurement to obtain embryonic stem cells in a morally legitimate manner from unwanted, excess frozen embryos (Magill, 2009). This remains an open question.

Finally, excess embryos in cryopreservation present another opportunity for an imaginative approach in the Catholic tradition. Official Catholic teaching,

for example, in the *Instruction on Respect for Human Life in Its Origin*, forbids surrogacy, understood as a woman carrying a pregnancy for an infertile couple. Perhaps Catholic teaching can be developed to permit a specific type of surrogacy. The condemnation of surrogacy was in the context of assisting infertility. But a different context may elicit a more acceptable meaning for surrogacy. Given the pro-life teaching in Catholicism, there are families in which the mother would be willing to accept a frozen embryo, have it implanted in her womb, and gestate it to birth – as a form of early adoption. If official Catholic teaching makes such a change, it would constitute another example of the capacity for doctrinal development in the Catholic tradition, in this case making a significant contribution to Catholic bioethics.

Conclusion

Catholic bioethics has developed a remarkably nuanced and comprehensive approach to health care, especially to resolve complex moral dilemmas. The teaching authority of the church and a general framework for Catholic bioethics guides discussions at the practical level. The principle of double effect helps to resolve dilemmas in clinical ethics, such as at the start and at the end of life. And the principle of cooperation helps to resolve professional and organizational dilemmas, such as regarding conflicts of interest or mergers between organizations. These practical topics will continue to elicit much discussion, as will emerging issues in biotechnology that will dominate the landscape of Catholic bioethics for years ahead.

Introduction

As one comes to the era of globalization, it appears that the need to search for and promotion of universal ethical principles are never more pressing and justified. The Universal Declaration on Bioethics and Human Rights is a notable initiative of such endeavor in the field of bioethics. Adopted by the Member States in the General Conference of the United Nations Educational, Scientific, and Cultural Organization (UNESCO) in 2005, the Declaration addresses States with a universal framework of bioethical principles for their legislation and policies formulation. It avows that a universal bioethical consensus has been reached despite cultural and moral diversities. Moreover, pluralistic dialogue, while it should be promoted, is justified only insofar as it is not in conflict with the most fundamental moral commitments that the global community shares (Article 12).

Yet, as globalization opens up the possibility of pluralistic dialogue among different moralities, it brings one no less opportunity to recognize irresolvable disagreements among contending moral communities upholding diverse perspectives. In the field of bioethics, examples of prominent issues include the moral controversies of abortion, embryonic stem cell research, euthanasia, and just allocation of healthcare resources. Appeal to the moral commitments that the Declaration avows to be fundamental to all – human dignity and human rights, or maximization of benefit and avoidance of harm, or individual autonomy – could hardly yield much conclusion in these bioethics issues.

Rather, what is commonly found are different levels of deadlock. On one level, moral debates persist because competing moral communities understand those values differently (Engelhardt, 1996). For instance, respect for human dignity is often the central value that both advocates and opponents of euthanasia defend in their debates, yet they disagree profoundly with each other on whether euthanasia should be morally justified (Somerville, 2009). On another level, moral

DOI 10.1007/978-94-007-2512-6_90,

communities also differ in their views on how various values should be prioritized. For example, should individuals have equal rights to healthcare or should those who could benefit the most be given priority (see e.g., Daniels, 1981 & Brock, 2001)? Should individuals be free to sell their organs or should organ selling be banned since commoditization of body parts violates human dignity (see, e.g., Taylor, 2009 & Kerstein, 2009)?

The Declaration, nonetheless, may be read as advocating a "thin" liberal view that aims just to break the deadlock. Instead of supporting a particular moral account of human dignity, human rights, or fundamental freedoms that is central to a certain approach to bioethical issues, a thin liberal view may propose that respect of individual dignity, rights, and freedom necessitates individuals to respect each other's moral choices equally. Fundamental to this proposal is that individuals, as moral agents, are characterized primarily by their capacity to make independent and autonomous choices, including which morality they want to commit. The Declaration is a framework that serves to protect individuals from political authority to restrict their choices of moral life that they want to pursue. Thus read, however, one wonders if the Declaration is a consensus arrived by diverse moral communities on any substantial ethical commitments that they share or on an acknowledgement that there is a lack of it. After all, while the Declaration recognizes and gives regards to cultural diversity or pluralism, the respect is only secondary (Article 12).

Indeed, the Declaration holds a clear and strong stance on the practice of informed consent to medical intervention and scientific research. For persons with the capacity to consent, sufficient information must be given for them to make independent decision on whether to undertake any medical intervention or research (Articles 5 and 6). However, as the Declaration celebrates the value of self-determination and leaves considerable room for independent moral agents to decide on what should be central to their decisions, it falls short to offer specific guidance on various contentious bioethical issues that involve entities without the capacity to consent, such as abortion and embryonic stem cells research. Such issues are often narrowed down to disputes over the moral status of the entities involved as this affects if the key principle of respecting human rights and human dignity should concern them. Yet, this may result in overlooking other ethical concerns that should also be taken into consideration.

To what extent the Declaration can be fruitfully and universally practiced should thus call for further exploration. For one thing, if the Declaration is to be practiced, it does not take place in a vacuum. It must be applied within a specific sociocultural context that inherits a certain established orthodoxy, which presupposes a particular moral vision of good life and human flourishing. Such specific morality offers rich though often taken-for-granted resources that are not only central in fostering solidarity among members of a social community, but are also fundamental to the ethical reasoning behind one's specific understandings and prioritization of values. Much as procedural justice characterizes the formulation of legislation and public policy in modern societies, moral vision is crucial in justifying the substance of legislation and public policy and hence must be given serious consideration.

Insofar as the practice of the Declaration is concerned, due recognition of a moral vision shared by a social community is important to understand what specifically do the values of human dignity, human rights, and fundamental freedoms account for in their bioethical decision making. Besides, it also reveals that for members of moral communities that do not uphold individual rights and self-determination as the most fundamental values, the Declaration may even appear to them as begging the question of why they should compromise their moral commitments to that of the global community should they be in conflict. Instead of being a neutral moral authority, the Declaration may well be deemed as yet another moral community that defends a particular moral perspective in the pluralistic world, albeit a perspective that offers limited moral guidance.

The aim of this chapter is to question the universality of the Declaration from a Confucian perspective. Specifically, it exemplifies its contention by highlighting a different medical decision-making approach that is widely practiced in societies which are under the influence of Confucian culture. In contrast with physician paternalism that was common in the past or patient self-determination that is widely practiced in modern liberal societies, distinctive in this approach is the prominent role played by the family in medical decision making in addition to the patient and the physician. It entails a dynamic interplay among the patient, the family, and the physician that aims at reaching a harmonious decision. This chapter points out that although this Confucian shared decision-making approach might be rationalized by the values of individual rights and autonomy, it is justified by Confucians based on rather different ethical reasoning. Moreover, it further contends that the attempt to justify the Confucian shared decision-making approach with the values of individual right and autonomy is at odds with the Confucian morality.

While this chapter does aim to validate the Confucian practice of medical decision making, it does not assert that it ought to be a universal practice. Besides, nor does it advocate moral relativism. Rather, this chapter intends to reveal the challenge to universalize bioethics in moral pluralism and the concern of moral disorientation and impoverishment resulting from the pursuit of universal bioethics. It hopes to show that ongoing moral dialogue should be given precedence over the mere pursuit of a universal morality if one is to truly appreciate and respect the diversity and richness of human values and civilizations in the age of globalization.

To this end, the next section of this chapter will first outline some salient moral elements of Confucian ethics. It aims to highlight a conception of personhood and moral agency that is significantly different from the one presupposed by the mainstream bioethics. The rest of the chapter will exemplify the contention by focusing on the practice of informed consent. It will first bring into light a medical decision-making approach that is commonly practiced in Chinese societies rooted in Confucian tradition. It points out the typical roles that are played by the physician, the patient, and the family in the medical decision-making process. It will then discuss from the Confucian perspective the ethical justification of this common practice and its moral significance for pursuing a Confucian vision of flourishing life. In the subsequent section, the common challenges to the Confucianism approach are examined. It shows that even though it may appear

that the Declaration could also accommodate the Confucian practice of informed consent, the moral assumptions and justification that it argues for are in fact different and in potential conflict with the Confucian morality. It reveals that while the Declaration promotes individual independence and self-determination, Confucians value shared life experience and harmonious interdependence as they hold that this is crucial for human flourishing. This chapter concludes with a reminder of the importance of open intercultural dialogue.

Confucianism and Bioethics

It is well known that Chinese societies have strong family culture. This is supported by a conception of personhood and moral agency that is deeply rooted in Confucian tradition that is quite different from the one advanced by the Enlightenment movement in the West. While a comprehensive understanding of Confucian teaching would require an explanation of its metaphysical belief in the order of things in nature, this chapter will confine its discussion on the earthy aspect of Confucian teachings and its key implications to bioethics. It aims to explain the ethical significance of Confucianism in contemporary society and why its Western counterpart, even without committing to the metaphysical belief held by Confucianism, may appreciate the insights offered by this long-standing tradition, just as Confucians may learn from them based on the moral experience that is common to humanity.

Central to Confucian ethics is how to pursue human flourishing by living a way of life that would enable virtues cultivation according to the human nature. In the Confucian view, human beings are by nature social, interdependent, and related to each other (Tao, 2004; Hu, 2002 and Yu & Fan, 2007). A flourishing human life, consequently, is not primarily characterized by individual freedom and independence, but by perfection of personal character that allows one to form proper human relationships with others in a harmonious (*he*) manner. This entails personal effort and commitment to pursue a life-long process of virtues cultivation by developing the capacity that is naturally endowed within every human. Mencius, an eminent early Confucian master, holds that anyone is capable to become an exemplary person with perfect character (*junzi*) if one makes the effort (see *Mencius* 6B:2). Yet, he also warns that "slight is the difference between man and the brutes. The common man loses this distinguishing feature, while the *junzi* retains it." (*Mencius* 4B:19) And such distinguishing feature is "understood the way of things and had a keen insight into human relationships. (Shun) (a well-acknowledged ancient sage) followed the path of morality. He did not just put morality into practice" (*Mencius* 4B:19). Key to Confucian ethical teachings is thus the path of morality, i.e., the way of life that human beings should pursue in order to cultivate and practice their virtues, and the social structures that society should sustain to promote human flourishing.

Family is valued by Confucians as the most fundamental social structure where self-cultivation begins and is thus of crucial importance to human flourishing. Among the five basic types of human relationships identified in Confucianism (i.e., parent–child relationship, sibling relationship, husband–wife relationship,

superior–subordinate relationship, and friendship), three of them are familial relationships. Moreover, the familial relations are also the prototypes of the nonfamilial ones. Hence, in the Confucian classic *The Great Learning*, it teaches that "the ancients who wished to illustrate illustrious virtue throughout the kingdom, first ordered well their own states. Wishing to order well their states, they first regulated their families. Wishing to regulate their families, they first cultivated their persons." (Legge, 1975, pp. 4–5) For Confucians, family is the basic building block of society and family order is the foundation of social order. Through properly serving one's roles in the family, one not only cultivates oneself with the virtues that are prerequisites for undertaking other social roles, one also contributes to social stability from the bottom-up by building a harmonious family. Hence, when being asked why he does not take part in government, Confucius replied that "simply by being a good son and friendly to his brothers a man can exert an influence upon government … How can there be any question of his having actively to 'take part in government'?" (*Analects* 2:21, see also *Analects* 1:2).

Family is thus central to a Confucian way of life because it is the locus of virtues cultivation throughout a human life. Specifically, for family to be regulated, one first needs to learn and practice within the family how to properly relate to one's fellow members in accordance with rites. And as one grows up, one reciprocates the family and carries on the good of family by cultivating the young and serving the old. Instead of individual autonomy and independence, in Confucian societies, adulthood is characterized by competence in taking good care of one's family. Moreover, whereas adult children may get married and thereby starting up a new family life, yet this is considered as a continuity and growth of the families of the married instead of departure from them. Their participation in family affairs, especially the important ones, would always remain.

In particular, Confucianism holds that the parent–child relationship which every human is born with and the natural affection (*qin*) embedded in it are the root of morality. The strong affection that parents have toward their child drives them to be highly attentive to the well-being of their dependent child. Among other things, they show their child the significant human good of love and interpersonal bond. For Confucians, it follows that as one grows up, one ought to reciprocate the good by being a filial child. Filial piety (*xiao*) thus entails not only provision of material goods, but also serving one's parents with a caring and reverent attitude (See *Analects* 3:26, 4:18 and 2:8). Yet, it is also important to be aware of the rather common mistake to construe filial piety as requiring absolute obedience and children should always be submissive to their parents. Instead, one should follow what is morally right. If parents require children to do wrong, a filial child not only should not follow, but even has an obligation to correct the parent though one should do so in a tactful way (Nuyen, 2004). It is with this understanding that filial piety is regarded as the root of the cardinal and all-encompassing Confucian virtue *ren* (See *Analects* 1:2, *Mencius* 4A:19 & 4A:27), which in one simple but important sense means "love your fellow men" (*Analects* 7:22, see also *Mencius* 4B:28). And it is also often referred as a moral force that comes with one's ability to show benevolence and kindness toward others (see, e.g., Chan, 1963).

In the Confucian view, cultivation of virtues starts with the family because it recognizes the anthropological fact that one naturally feels more deeply and emphasize for those who are intimately related to us. It follows that it is by developing and extending one's familial affections to distant others that one cultivates the virtue of *ren* (see *Mencius* 1A:7). Hence, when his student Tsai Wo commented that the ancient Chinese rites that requires children a three-year morning period for their late parents as their filial duty was too long, Confucius questioned if Tsai Wo had not been given 3 years of love by his parents and denounced him as "unfeeling" (*bu ren*) (*Analects* 17:21). This is because Confucius acknowledges that "the different rules for the mourning rites were established in harmony with (men's) feelings . . .The more pain it gives, the more slowly is it healed. The mourning of 3 years, being appointed with its various forms in harmony with the feelings was intended to mark the greatest degree of grief." In contrast, the mourning period for those who are less related should be shorter (Legge, 1976, pp. 391–394).

Besides, it is important to note that Confucians recognize the family as an organic social reality that has its own intrinsic moral value and autonomy. It has interests that are common to its members and deeply intricate with their personal ones, yet its interest is not just a sum of its individual members' interests (See Brennan & Fan, 2007). Much as family plays a significant role to its members' personal welfare, the value of family is not merely instrumental. Family is not a joint venture set up by voluntary individuals but a social reality that everyone is born into for better or worse. While some are fortunate to be with a well-functioning family, some have to make more effort to foster and maintain one. The ancient sage Shun, for example, is well known to have a rather difficult family life to begin with. Yet, in either case, Confucian morality holds that given the human nature, assuming the familial roles and responsibilities properly is central to cultivation and practice of virtues. This entails not weighting the interests of each member equally, but accommodating with other members in an appropriate way that will serve the best interest of the family and the members. Hence, it is important to note that while Confucianism appreciates the ethical value of family, it is not ignorant of challenges that individuals may face in fulfilling their family obligations. Quite the contrary, it acknowledges them but contends that both individuals and society have their roles to play in pursuing human flourishing. For individuals, this is how they become autonomous moral agents. Insofar as public policy is concerned, this implies that its formulation should take into account the value of family in human flourishing and sustain this moral good accordingly (Fan, 2002).

In Confucian societies, the primacy of familial relationships, virtue of *ren* and interdependence, are thus presumed in the discussion of bioethical issues as moral agency is characterized by these moral goods. Instead of emphasizing individual's right to one's own body and the liberty of independent decision making, healthcare decisions and policies are oriented toward fostering meaningful human relationships that are marked by virtues and interdependence to meet the human social needs. In this alternative ethical framework, the family is assumed to be the primary caretaker of its members and is naturally involved in their healthcare decision

makings by taking into account the interest of the family as a whole. Bioethical issues such as end-of-life decision making, surrogate reproduction, abortion are seldom discussed as a matter that concerns only the dying patient, the gametes donor and recipient, or the pregnant woman and fetus. For Confucians, these issues entail significant familial obligations and implications on the family's existing and future life that ought to be given due regard. Moreover, the Confucian approach to bioethics is often context specific and it calls for dynamic interactions between family members to arrive at ethically appropriate decisions. It is a lively process in which individuals cultivate and practice virtues by assuming their proper roles in light of the context.

To more fully explain the implications of Confucian teachings to bioethics, the next section will focus on discussing the usual practice of medical decision making and informed consent in Confucian societies that is rather different from the one commonly advocated by the mainstream bioethics. It aims to show that participations of the family and the physician in the patient's medical decision making are justly presumed in Confucian societies just like the right of the patient to make autonomous and independent medical decision is often assumed in the Western liberal societies. This is because they are founded on their respective prominent conception of moral agency that is quite different from the other. The subsequent section will then evaluate common challenges to the Confucian practice of medical decision making. It acknowledges the ethical significance of individual right to autonomous medical decision making as a remedy for the Confucian practice in some contexts though by no means it should be a substitute for it.

Medical Decision Making in Confucian Societies

In societies where Confucianism is at home, most notably in China, Taiwan, and Hong Kong, the practice of informed consent is marked by shared decision making among the patient, the patient's family, and the physician. While their degree of participation in the process may vary in different specific contexts, the typical roles played by the physician, the family, and the patient are as follows:

The physician is not only a source of information but sometimes also a facilitator to consensus building in the medical decision-making process. He/she is responsible for providing and explaining the diagnosis, prognosis, and potential benefits and risks of each available treatment option to the patient and his/her family members. While the physician is still a highly regarded professional in Confucian societies, physician paternalism is no longer a common practice. Informed and written consent is legally required for the physician to undertake any major medical intervention on the patient. In mainland China and Taiwan, consent can be given by competent adult patients and/or their families (Cong, 2004 and Tai & Tsai, 2003). Although informed consent by competent adult individual patients was formally introduced in mainland China in recent years, family participation in important medical decision remains the widely accepted norm (See Chen & Fan, 2010 and Cong, 2004). In Hong Kong, though the competent adult patient should be

the legal authority to consent, it is customary for the physician to disclose critical information to the family (especially the adult children of the elderly) before the physician and the family share the information with the patient (see Chan, 2004). Involving the family in medical decisions and consensus building is recommended by the Hong Kong Hospital Authority, a statutory body that takes care of over 90 % of inpatient services of the Hong Kong population (Hospital Authority, 2010), as a "good practice" unless the patient objects the practice (Hospital Authority, 2002).

Nonetheless, the physician is still entrusted with safeguarding the best interests of the patient based on professional judgment, particularly in cases involving medical emergency or patients without capacity to consent. For instance, in the guidelines issued by the Hong Kong Hospital Authority on withholding or withdrawing life-sustaining treatment for incompetent and terminally ill patient, it advises that much as healthcare professionals should arrive at a consensus with the patient's family, they should also consider if the family's decision is in apparent conflict with the best interests of the patient. Moreover, the physician is legally empowered to provide life-sustaining treatments to the patient in emergency even without the family's consent (Hospital Authority, 2002).

The substantial role of the family in medical decision making is distinctive in Confucian societies. As explained in the last section, for Confucians, the family is considered as an autonomous moral agent that has the responsibility to take care of the well-being of its members. Hence, if serious illness is diagnosed, the family is often informed and consulted even before the patient. The family can then evaluate the extent of psychological burden the medical information may place on the patient, and the best way to break the bad news to the patient. In addition, the family may even request the physician to cooperate with their decision on how to convey the information to the patient (Fan, 2000). In mainland China and Taiwan, this is reflected by the family's authority and responsibility to decide what medical information the patient is psychologically and intellectually capable to receive and the physician's cooperation with the family. While the preferences and wishes of the patient should be taken into account, likewise the patient should be aware that the medical decision is not only about his/her individual well-being but also those that are dear to him/her. Confucian societies acknowledge that the interests of a family and its individual members are deeply intricate. Thus, even though in Hong Kong, respecting the patient's autonomy is one of the guiding ethical principles in making decision on forgoing life-sustaining treatment, no less emphasized is that the decision should also be a "consensus-building process between the care team and the patient and the family" and this entails "*involvement of the patient when he/she is mentally competent, and his/her family regardless of the mental capacity of the patient*, *unless a mentally competent patient refuses to have the family involved*" (Hospital Authority, 2002, pp. 7–8, emphasis original).

Hence, in contrast to the requirement of informed consent advanced by the Declaration, a prominent feature of the shared medical decision-making approach in Confucian societies is that it is far less individualistic. In the Confucian view, the family has the major responsibility to take good care of its ill member, and healthcare policy in Confucian societies should facilitate the family to

fulfill this role. This entails that the family not only should be able to participate in making the patient's medical decisions, but also to learn about the diagnosis and prognosis even prior to the patient. Being the most closely related, there is a prima facie case that the family is in the position to know not only what would be the patient's wishes, what would serve the patient's best interest, and what would be the possible impacts on the family, but also how to strike a balance among them should they are in conflict. Besides, more importantly, the shared decision-making process is also a good opportunity for the family members, including the patient, to understand each other's concerns from different perspectives and discuss what would be the best for all involved. For Confucians, illness is not only suffered by the patient, it is a misfortune of the whole family. The Confucian approach to shared decision making is a consensus-building process that not only serves to arrive at a unified and harmonious decision, but also to maintain family integrity (Fan, 2011).

In contrast with the mainstream bioethical principle of informed consent as advanced by the Declaration, individual autonomy is not presupposed to be of primary importance for Confucians. The patient is not primarily characterized by independence or self-sufficiency. Quite the contrary, the patient would be excused from his/her usual responsibilities regardless if he/she has the capability to discharge them. It is widely accepted that the vulnerable patient should be taken care of by the family and physician (Cong, 2004). In particular, it is an important filial obligation of adult children to look after their elderly parents in the Confucian tradition, and the elderly is naturally most commonly found to be critically ill or needing long-term healthcare. Instead of the fear of losing individual autonomy and independence as health declines, quite the contrary, the Confucian elderly deem that it is a blessing to be taken care of by their adult children (See Tao, 2007 and Chan, 2007). In fact, this is an achievement for the elderly to be pound of as it implies that they have duly fulfilled their parental obligation in cultivating their children. Of primary importance for Confucians is thus the cultivation and practice of virtues that allow individuals to live well interdependently. Such interdependence would not result in the fear of losing the self for Confucians because human relations constitute an important part of the self for them (see Hu, 2002).

Virtue is also central to the practice of medicine. Medicine is an esteemed profession in Confucian tradition not only because it requires a high level of knowledge and skill, but also kindheartedness. The practice of medicine is well known as an "art of *ren*" (*yi nai ren shu*) in Confucian societies and a Confucian physician should aspire to be a "*ren* practitioner of the art of *ren*" (*ren sin ren shu*) in addition to be knowledgeable and skillful in medicine. The virtue of *ren* is of crucial importance to the practice of medicine as it informs the physicians that their primary subjects are not diseases or disorders, but their patients and their primary concern should be the welfare of their patients.

The Confucian teaching thus reminds that the physician is also in a significant interpersonal relationship with the patient. A Confucian physician is expected to have the heart of benevolence like a parent (*yi zhe fu mu xin*) when treating one's patient as the physician–patient relationship is modeled on that between

parent and child. The physician thus has the duty to look after the welfare of the patient that often goes beyond simply observing the patient's right to self-determination. Apart from offering advice to the patient, as mentioned, a Confucian physician is also entrusted with the duty to protect the medical interests of the patient in the practice of shared medical decision making. Moreover, the virtue is also essential for physicians to be compassionate toward their patients' sufferings, which is particularly important when the physician and patient are confronted by the limitation of medicine. In contrast, although such understanding of medical professionalism is also advocated in the Hippocratic tradition, the value of benevolence is construed in a markedly different manner in modern bioethics. For example, the influential work of Beauchamp & Childress defines benevolence in two principles. One is the "principle of positive benevolence," which "requires agents to provide benefits." And the other is the "principle of utility," which "requires that agent balance benefits and drawbacks to produce the best overall results." Both principles, it is important to note, are to be distinguished from "the virtue of benevolence, various forms of care, and nonobligatory ideals of benevolence" (Beauchamp & Childress, 2009, p.197).

As pointed out by Chan (2004), Tse and Tao (2004), Fan and Tao (2004), and Chen and Fan (2010), the participations of the patient, the family, and the physician may result in a lack of definite locus of decision making in the Confucian approach. Depending on the context, the input from the patient, the family, and the physician may carry different weights in the decisional outcome. The multilateral decision-making process requires the physician, the family, and the patient to exchange their perspectives on what would be the optimal choice. Undoubtedly, this may result in indeterminacy characterized by unclear locus of decision making (Chan, 2004 and Tse & Tao, 2004) that could be avoided by unilateral decision making, where individual autonomy of the patient and thereby his/her choice is pivotal. Yet, Confucian recognizes that there is no fast and hard rule to follow because sensible medical decision making must take into account various specifics such as the urgency, the nature of the medical information, the respective psychological and intellectual capacities of the patient and the family members, the character of familial bonds, etc. Spared by the indeterminacy is the necessary room and flexibility for apt and harmonious decisions to be possible. It entails a reciprocal process of exchanges between the patient, the family, and the physicians, during which the virtues of them are practiced and cultivated.

Challenges of the Confucian Practice of Shared Medical Decision Making

While shared medical decision making is widely practiced in Confucian societies, it is certainly not without objections. This section outlines the common challenges against the Confucian approach and evaluates the extent to which the principle of informed consent that is advocated by the Declaration may be useful to address the concern.

The fact that unfortunate and tragic cases happen under the current practice of shared medical decision making in Confucian societies prompts question about the ethical legitimacy of the approach. For example, the family may choose not to disclose to the patient that he/she is seriously ill but consent to a surgery of limited chance of success for the patient, and the patient eventually dies on the surgery table. Or the family may refuse aggressive treatment even if it might be the only possible remedy. There are two major objections which hold that shared medical decision making is the cause of such cases. First, some may attribute such medical tragedies to unintelligible or even harmful decisions made by the family for the patient. Second, some may argue that it is dubious what the family regards as the best decision would indeed be the same as that of the patient since they may uphold different values (see, e.g., Wear, 2003). It is possible that the patient would have made a different decision, had there been an opportunity for him/her to decide independently. In either objection, it is contended that the mainstream practice of informed consent should replace the shared decision-making approach.

It is important, however, to distinguish between the above two objections as the primary concern of them is different. In the first objection, the fundamental ethical concern is whether a decision is indeed in the best interest of the patient. It does not criticize a particular medical decision-making approach per se but the decisional outcome. It hence does not in essence challenge the Confucian practice of shared decision making or support the requirement of informed consent, for even under the practice of informed consent, the patient is free to consent or refuse to a treatment regardless if this would be in his/her best interest. The formality of informed consent hence does not necessarily address the first objection, though there is a widespread presumption in the mainstream bioethics that individual is the best defender of his/her interest.

Yet, some may contend that the fundamental value of informed consent, in fact, is such self-determination. This is also the primary ethical concern of the second objection to the practice of shared decision making. It argues that the patient's decision should be absolute even if others disagree the decision would be in the best interest of the patients, let alone if it is of the family. The involvement of the family, however, may deprive the patient of sufficient medical information to choose for oneself without the interference of others. Besides, it may further suggest that if the patient does value contribution from the family or the physician in his/her decision, he/she may invite their participation in the process. Yet, even so, informed consent must be given by the patient when major medical intervention is to be performed on him/her. Likewise, for refusal of intervention, the patient should have the right to decline medical intervention even against medical advice, provided that he/she is well informed of the possible consequence.

There is certain an appeal of the second objection that justifies the requirement of informed consent. For one thing, it may protect the patient from being deceived or harmed by others. Although there is a prima facie case that the family would look after the welfare of the patient, conflicts between family members do exist and some may be intense and difficult to resolve. The fact that the interests of family members are deeply intricate in some cases may unduly undermine the individual

wishes and interests of the patient. Moreover, even though the family may intend to lessen the patient's psychological burden, the deceived patient may question the need for undergoing aggressive treatments, hold false hope or fear, or miss the opportunities to carry out his/her last wishes (Wear, 2003).

Yet, the fact that the shared decision-making approach may not apply well in some cases does not mean that it should be replaced entirely. The problems may not be caused by the decision-making approach as such, but by improper application of the same. (See Li and Wen (2010) for a case study that serves to illustrate the distinction.) Although the Confucian approach does not support that only the patient's individual interests and wishes should matter, neither does it hold that they can be overlooked. Instead, the approach respects the family, which includes the patient, to have the room and authority to decide what would be the best all things considered, subject also to the professional judgment of the physician that the decision is not in apparent conflict with the patient's medical interests. This entails effort from both the family and the physician to look into the contextual details and the dynamics at different stages of decision making, such as the diagnosis and prognosis, the psychological reaction of the patient, and the resources available. It is an interactive process among the family, the patient, and the physician. In the Confucian view, being fully informed and self-determined would not alleviate the anxiety over undergoing aggressive treatment, ease concern about treatment outcome, or ensure one could carry out one's last wishes, if what in fact needed are care and assurance from those whom one has a close and trusting relationship with.

Hence, even though the option of informed consent as advanced by the Declaration should be available to safeguard the individual interests of the patient, it should not be adopted as the default practice in Confucian societies. Rather, what Confucians may learn from its western counterpart is that such a principle of informed consent can be introduced as a corrective available for the patient to initiate should he/she find that the shared decision-making approach fails in his/her circumstances. This means that unless the patient requests otherwise, the physician may presume that he/she could inform and consult the family about the patient's healthcare. Given the cultural background, this is a respect for both the patient and the family because it acknowledges the value of the family and being a family member is an important identity to the patient. This is comparable to the respect of individual right of self-determination in societies where individual autonomy and independence are upheld as fundamental values.

It is thus also of crucial importance not to rationalize the Confucian approach of shared decision making by the values of individual right and autonomy, for this would undercut the values and way of life that are truly fundamental to Confucian ethics (Fan, 1997). In fact, as informed and written consent becomes more formally required in China in recent years, its ethical implication also surfaces. As the physician becomes more watchful of his/her legal liability that is founded on the rights of the patient or the family, the relationship between the physician and the patient or the family turns more contractual in nature. For the physician, cultivating and practicing the virtue of benevolence becomes secondary to honoring the right of

self-determination of the patient, and safeguarding the medical interests of the patient becomes less pressing than protecting oneself from being sued (see Cong, 2004 and Hui, 2005). The significant role of the physician in the shared decision-making process may as a result be threatened since virtue is no longer recognized as central to the practice of medicine. Moreover, although informed consent is founded on the value of individual autonomy in the West, Cong (2004) noted in his study that in China, physicians barely considered the requirement for them to seek formal informed consent from the patient is due to the value of autonomy. What the physicians were rather conscious of, instead, were the legal implications of the formality of informed consent.

The value of the family in Confucian way of life may likewise be disoriented by the liberal rationalization. Confucianism appreciates family as a given social reality that every human being inherits. It provides both moral contexts and resources that cultivate individuals to be moral agents based on a vision of human flourishing that is characterized by interpersonal care, connectedness, and dependency. Correspondingly, for Confucians, the participation of the family in the patient's healthcare is the default. While it does presume that the participation is valued by the patient, this should not be reduced as conditional upon invitation from the patient as the mainstream principle of informed consent suggests. Instead, in Confucian societies, the principle is more aptly to be regarded as a measure available to protect the patient should the family become dysfunctional. On the one hand, this would ensure that individual interests and preferences would not be sacrificed against the patient's wishes. Yet, on the other hand, this also recognizes that in Confucianism, moral priority is given to a way of life where interdependence, familial life, and harmonious human relationship are valued over one that advances independence, individual choices, and rights. This is analogous to the ethical orientation implied by the Declaration toward a way of life where individual autonomy is given precedence over other ethical values. While individuals may place family as central in their lives, this is justified insofar as this is their free choice.

Concluding Remarks

Whereas this chapter confines its discussion on informed consent from a Confucian perspective, what it aims to show is the challenge posed by moral pluralism to the endeavor to identify a set of practical bioethical principles that are universally binding. While human dignity, human rights, and fundamental freedoms may well be widely shared values, the Universal Declaration on Bioethics and Human Rights should also note that diverse moral communities have different prioritizations and specific understandings of those values. It is of crucial importance to recognize that this entails more than what the Article 12 maintains where cultural diversity and pluralism are "acknowledged" to be secondary to the rest of the Declaration. When faced with complex bioethical issues, societies must develop their policies not only by taking into account the values that are advanced by the Declaration, but also

those that are central to their ethical traditions and deeply embedded in their people's daily lives. This is not to argue for moral relativism or to invoke cultural exceptionalism, but to remind the importance of open cross-cultural pluralistic dialogue in attaining better understanding of the richness of human ethical commitments and to call for room for such exchanges.

Aaron L. Mackler

Introduction

This chapter begins by introducing key terms that are important to understanding the Jewish ethical tradition, then surveys authoritative documents of the tradition, and briefly sketches varied approaches or "streams" in contemporary Judaism. It then examines central Jewish values in comparison with those found in the UNESCO Universal Declaration on Bioethics and Human Rights. Major issues near the end of life, and at the beginning of life, are considered.

Ethical concerns have always been central to Judaism and have been understood within the broad context of Jewish life (this chapter draws extensively on Mackler, 2003). Basic concepts in Judaism include God; Torah or "Teaching"; and the community of Israel, the Jewish people. For Jews and Jewish thinkers across a wide spectrum of beliefs, both individuals and the Jewish community as a whole participate in a covenantal relationship with God. Torah is central to this relationship and basic to Jewish life. God in love gave the Torah to the Jewish people, and through them to the world. In its narrowest sense, Torah refers to the first five books of the Bible, Genesis through Deuteronomy, traditionally termed the "Written Torah." More broadly, Torah includes the extensive "Oral Torah" and refers to all Jewish traditional teaching – in fact, all authentic Jewish thought and practice.

Jewish ethics has been understood within this context, not sharply distinguished from other spheres of life. One example of this holistic approach may be found in the Holiness Code of the Book of Leviticus (Ch. 19). This passage includes numerous ethical responsibilities, including the mandate to "love your neighbor as yourself," (Lev. 19:18) intermixed with ritual commandments. All represent aspects of the general injunction of this section: "You shall be holy, for I, the Lord your God am holy." (Lev. 19:2) Both ethical and ritual perspectives are important in answering the question, "What ought I to do?" For this code, as for the Jewish tradition in general, all aspects of human activity meld together holistically in a life of service to God and one's fellow.

Two additional features of the Holiness Code represent views that have continued in Judaism's development. First, the passage is introduced by God instructing Moses, "Speak to the whole Israelite community, and say to them..." (Lev. 19:2). The call to holiness and all that follows are not understood exclusively or even primarily as pertaining to individuals, but to an entire community. Second, the commitment to holiness entails particular behavioral norms that are expected of individuals and the community. Such norms are traditionally termed *mitzvot* (singular, *mitzvah*, "commandment"). A *mitzvah* is a shared normative practice, expressing what members of the Jewish community may expect from one another, as well as an action significant in covenantal relationship to God.

Each *mitzvah* contributes to a system of *halakhah*, a word literally meaning "path" or "way" and signifying Jewish normative practice, often translated as "Jewish law." Supporters argue that *halakhah*'s role as a legal system provides for cohesion and a sense of community among Jews worldwide, as well as within local communities. It offers continuity with the past, maintaining continuity of the covenantal community over time and affording contemporary individuals the benefit of accumulated wisdom of the past. *Halakhah* traditionally has been understood to express both God's will and God's wise and beneficent counsel. It thus provides a means for the expression of God's love and of the Jew's love for God. Finally, the very fact of the centrality of *halakhah* to Jewish ethics over the millennia might be seen as itself carrying normative weight. A *halakhah*-centered approach simply is the Jewish way to do ethics; to use Wittgenstein's image, such are the rules of the language game of Jewish ethics.

While *halakhah* has been central to Jewish life and thought, it has not been the only ethical guide. Accompanying *halakhah* has been *aggadah*, or narrative. This term broadly refers to Jewish theological reflection, lore, articulation of values, expressions of meaning, and cultivation of virtues. Returning to the Holiness Code of Leviticus 19:2, Moses Nahmanides (1194–1270) writes that the opening call to holiness is not merely an introductory phrase but an injunction in its own right. Without this, a person might observe all rules and yet be a "scoundrel with Torah license" (commentary to Lev. 19:2). The call to holiness includes, but also goes beyond, the specific norms of *halakhah*. Classically, the relationship between *halakhah* and *aggadah*, between the letter and the spirit of the law, is essentially symbiotic. In the image of Abraham Heschel, *halakhah* is like a body, while *aggadah* is spirit. *Halakhah* without *aggadah*, its animating spirit, is like a corpse. *Aggadah* without *halakhah*, its worldly concretization, is like a ghost, too ethereal to be realized (Heschel, 1955, 341).

Judaism

Foundational Sources: Scripture and Tradition

Judaism values both Scripture and tradition. For Jews, the Bible is the Hebrew Bible, also referred to as *Tanakh* or "Old Testament." A special status is recognized

for the Torah, Genesis through Deuteronomy. Some believe that this was presented by God to Moses, word by word and letter by letter, in a form identical to contemporary printed texts. Others see the Torah as largely written by humans, perhaps with Divine inspiration. A range of thinkers understand the Torah to be divine in its origin but shaped significantly by human reception, transmission, and interpretation.

For traditional Judaism, Scripture and tradition represent distinct but complementary aspects of God's revelation. Central to tradition is the Oral Torah, which is classically understood both as the interpretation and development of the written Scripture and as a parallel oral communication from God that was faithfully transmitted in oral form through many generations.

Since late antiquity, numerous works of "Oral Torah" have been given written form. Together, these constitute central resources for deliberation in bioethics and other areas (see Feldman, 1998, pp. 3–18). The *Mishnah* (meaning "study") was compiled in the early third century by Rabbi Judah Hanasi, presenting material that developed and was transmitted orally over the preceding centuries. The *Talmud* (like Mishnah, a term meaning "study") is in many ways the central work of the tradition. It records commentary on and discussion stemming from the Mishnah, developing over succeeding centuries. The Babylonian Talmud, compiled in Babylonia (currently Iraq) in the sixth and seventh centuries, is often referred to simply as "the Talmud".[1] Three types of post-Talmudic literature offer the most significant contributions to the fabric of *halakhah*. One genre represents commentaries on the Talmud. A second major genre is that of responsa, in Hebrew *teshuvot* (singular, *teshuvah*, "responsum" or "response"). These are the *halakhic* decisions of rabbinic authorities, addressing specific issues or cases, and collectively constitute the case law of Judaism. A third genre is represented by legal codes. Codes are not formally enacted, but come to be recognized as authoritative, similar to the way in which the *Oxford English Dictionary* or *Encyclopaedia Britannica* have come to be recognized as authoritative. The first major systematic codification was produced by Moses Maimonides (Rambam, Rabbi Moshe ben Maimon) in the twelfth century and is known as the *Mishneh Torah* ("repetition of the teaching"). The most authoritative code of law is the *Shulhan Arukh* ("set table"), written by Rabbi Joseph Karo in the sixteenth century, published with interspersed glosses of Rabbi Moses Isserles, termed the *Mappah* ("tablecloth" for the set table).[2]

Classically, individuals seeking to follow Jewish ethics would be guided by a variety of influences, including narratives, rituals, exhortations to virtue, maxims, and communal customs, and significantly by *halakhah*. Traditional *halakhah*, like secular case law, utilizes analogies with precedent cases to decide new cases.

[1]Passages from the Mishnah traditionally are identified by the name of the tractate, followed by the number of the chapter and paragraph within the chapter; e.g., *Sanhedrin* 4:5. References to the Talmud are given by the name of the tractate and the page on which the reference may be found (e.g., *Sanhedrin* 37a).

[2]References to the Shulhan Arukh are given by the name of the section (or its abbreviation), followed by chapter number and paragraph within the chapter (e.g., *Yoreh Deah* [*Y.D.*] 339:1).

Compared to other legal systems, *halakhah* is markedly open ended, decentralized, and religiously sensitive, but it is a legal system nonetheless. The paramount authority in discerning *halakhic* guidance in a given case is the rabbi, and religious authority for the community as a whole is provided by rabbinic leadership. For most of the past two millennia, leadership has been decentralized, resting with various rabbis in local communities. Classically, positions are articulated by individual rabbis whose authority comes to be recognized by their colleagues and by communities. Leaders of various academies and rabbis of cities and communities all enjoyed significant authority, most generally deferred to tradition and current consensus.

The balance of subjective and objective authority is a point of contention among Jewish writers. Almost all would agree on the importance of the individual taking account of objective norms in formulating his or her own judgment. At the same time, tradition acknowledges significant authority of each individual in exercising his or her stewardship of health and well-being.

Streams Within Judaism

Judaism does not recognize a central human authority, and different Jews differ on numerous issues. One may speak of different "movements" (or "streams") in Judaism. These are not tightly defined denominations, but help in describing the range of views. The three largest movements are generally termed Orthodox, Conservative (or Masorti, "traditional"), and Reform (or Progressive). All three have their roots in responses to modernity in nineteenth-century Germany. Representatives of each movement tend to see their movement as in many ways the most authentic Jewish approach, as well as the path offering the best prospects for the future. Each movement is complex and includes a broad range of stances, although some generalizations can give a sense of tendencies common within each.

Reform Judaism as it emerged in the nineteenth century understood the essential truths of Judaism to be unchanging: monotheism and a universalist ethic of love of neighbor. Ethical truth was largely defined by liberal thought and progressive Western culture, in particular the ethics of reason of Kant. Other aspects of Judaism, including *halakhah* and traditional expressions of the Oral Torah, were at best secondary and readily changeable. Throughout the history of Reform Judaism, autonomy has been central to the articulation of Jewish ethics. Autonomy has taken various forms: a Kantian sense of the individual following dictates of universal reason; an individual liberty right of choice; a complex Jewish self, authentically making choices that reflect an identity that is significantly shaped by community and covenant with God. In recent decades, some Reform thinkers have accepted an increased role for *halakhah* in offering guidance to individuals, but individual autonomy remains predominant.

Orthodox Judaism developed as a movement in response to Reform. While modernity may bring benefits, the Enlightenment and modern thought pose threats to the integrity of Judaism. Orthodox Judaism tends to present itself as continuing the unchanged Judaism of the past. Torah in general and *halakhah* in particular are

essentially unchanging. As noted above, the text of the Written Torah is seen as identical to that presented by God to Moses. Oral Torah is understood primarily in terms of its articulation in the Talmud (based on material communicated by God to Moses) and received now as tradition from the past. While new situations may call for thoughtful application of past precedents, Orthodox leaders tend to stress the need for caution and a desire to minimize change. Tendencies to emphasize the role of received tradition over reason, *halakhah* over *aggadah*, and stringency over flexibility are common in Orthodoxy. The rabbi, articulating traditional consensus, is the primary authority.

The Conservative movement also developed as a traditionalist response to Reform, but of a more centrist sort. Conservative thinkers agree with their Orthodox colleagues that *halakhah* plays a definitive role in Jewish life and Jewish ethics. At the same time, *halakhah* has historically developed over time, through gradual evolution and by means of textual and judicial interpretation. Such development, by such means, should continue; the model is one of "tradition and change." The determination of which developments are appropriate is primarily made by rabbinic leadership, but there is also an appeal to broader communal insight. Conservative writers characteristically attend to the historical development of *halakhah*. While Torah is in some sense eternal, it develops in a way that manifests its strength and vitality as a living tradition. Past sources are read diachronically, tracing streams within the tradition and often finding divergent tendencies as well as ongoing development. Development has been, and should continue to be, organic, gradual, and evolutionary. Conservative writers generally seek a balance between the authority of the individual and that of his or her rabbi.

A smaller Reconstructionist movement developed originally as a tendency within Conservative Judaism but shares much with Reform/Progressive approaches. Reconstructionism tends not to think of a theistic or personal God, but to emphasize the culture and practices of the Jewish people.

Jewish Values and the UNESCO Universal Declaration on Bioethics and Human Rights

Traditional Jewish values and principles accord powerfully with those expressed in the UNESCO Universal Declaration on Bioethics and Human Rights (UNESCO 2005). The Mishnah (*Sanhedrin* 4:5) interprets the first chapter of Genesis:

> Therefore was a single man [Adam] created, to teach you that anyone who destroys a single person from the children of man is considered by Scripture as if he destroyed an entire world, and that whoever sustains a single person from the children of man is considered by Scripture as if he sustained an entire world; and for the sake of peace among people, that no one could say to his fellow, my ancestor was greater than your ancestor; . . . and to proclaim the greatness of the Holy One, blessed be He, for man stamps many coins with the same die and they are all the same as one other, but the King of the kings of kings, the Holy One, blessed be He, stamps every man with the die of the first man and not one of them is the same as his fellow.

Like the UNESCO document (Arts. 2–3), this foundational text of Judaism affirms the intrinsic dignity and value of each individual. For Jewish tradition, respect for people (*kevod habriyot*) represents a powerful obligation. Saving and preserving life (*pikuah nefesh*) justifies virtually any action that would otherwise be prohibited and is commanded as a positive obligation by Leviticus 19:16, "do not stand idly by the blood of your neighbor."

Judaism sees healing as an important way to help others and save life, as the UNESCO statement values health throughout, explicitly in articles 14–15. Historically, some Jewish thinkers have raised a theoretical question regarding the compatibility of human attempts to heal with respect for divine sovereignty. The Bible, indeed, depicts God as purposefully causing illness (as well as famine and other forms of human suffering) and providing healing. It is clear for the tradition, though, that God expects humans to assume the responsibility of active stewardship and to help others. Healing is grounded in biblical mandates to heal the injured (Exodus 21:19), to restore that which has been lost (including lost health) (Deuteronomy 22:2), and to love one's neighbor as oneself (Leviticus 19:18). As expressed in the *Shulhan Arukh* (*Y.D*. 336:1), "The Torah gave permission for the physician to heal. That is a *mitzvah*, and is in the category of saving life [*pikuah nefesh*]." As an expression of this mandate to heal, Jewish writers strongly support medical and scientific research – as with UNESCO – provided that it is directed toward human benefit and in accord with ethical commitments and prudent judgment (Articles 2, 15).

All Jewish thinkers acknowledge a role for reason and experience in shaping ethics. The understanding of this role and its relation to tradition vary widely. In classical Judaism, appeals to universal reason and human experience are less central than are appeals to sacred texts and tradition. At the same time, Judaism has viewed all of humanity as participating in a covenantal relation with God, understood as the covenant of God with the "children of Noah." This covenant entails basic moral responsibilities that are incumbent on all human persons, such as prohibitions against murder and robbery. The extent to which these norms should be viewed as natural law, and in what sense of the term, has been vigorously debated (see Novak, 1998).

The Mishnah proclaims the fundamental equality of all people, as none can boast of superior ancestry. Jewish ethics historically focused on the responsibilities of Jews to fellow Jews. This focus reflected not only a theoretical valuing of the community but also the practical social conditions under which Jews lived. For most of Judaism's history, Jews lived in independent Jewish communities or semi-autonomous communities within a broader corporate state. For most of the past two thousand years, Jews were discriminated against to one extent or another, oppressed, or at best tolerated by what was experienced as an external non-Jewish world. The tradition includes some discussions of the ethical responsibilities of all persons. Most theologians have endorsed the Talmud's statement that not only Jews but righteous individuals of all nations will enjoy the salvation of a portion in the world to come (*Sanhedrin* 105a). Historically, ethical responsibilities of Jews toward non-Jews were recognized; these tended to fit a model of a responsible but distant ethics of strangers, reflecting the real-life context of the time. Traditional

sources instructed that non-Jews together with Jews should receive financial support for the poor, visiting of the ill, and other works of philanthropy. The extent to which these mandates were carried out, and relations between Jews and non-Jews generally, varied greatly.

Since about 1800, large and growing numbers of Jews came to have the status of individual citizens within secular states. The advent of modernity entailed both radically new ideas and a radically new life situation. Modern thinkers increasingly came to see in the Bible's account of "having God begin humankind with but one pair of people an early intuition of the truth that all ethics is necessarily universal. Put symbolically, one Divine Parent meant that all human beings have familial obligations to one another" (Borowitz, 1990, p. 99). Most contemporary thinkers recognize important responsibilities for all of humanity, in addition to special responsibilities for members of one's community – the Jewish community, as well as local and national communities. Judaism strongly supports UNESCO's valuing of equality and solidarity (Articles 10, 13).

Jewish tradition teaches that all belongs ultimately to God. God has granted humans authority over the use of resources with the expectation that we will use these resources responsibly and to help those in need. The Bible proclaims: "God favors no person, and takes no bribe; He executes judgment for the fatherless and the widow, and loves the stranger, giving him food and clothing" (Deut. 10:17–18). Over the centuries, Judaism developed the Hebrew Bible's value of justice and institutions for support of the poor into a system of *tzedakah*, literally meaning justice and signifying support for the poor and needy. Justice is also affirmed in the UNESCO declaration (Article 10).

The Mishnah provides a strong foundation for pluralism and respect for differences among people. For many Jews, most powerfully in Reform Judaism, this supports the importance of individual autonomy and the requirement for informed consent (Articles 5–6). Orthodox rabbi Irving Greenberg likewise declares that "the patient himself must have a role in therapy. The patient is in the image of God; thus the greater the role in the patient's own therapy, the greater the patient's own dignity" (Greenberg, 1986, p. 142). Most Orthodox authorities, however, emphasize the requirements of objective norms. Providing benefit and avoiding harm significantly constrain individual choice. Differing Jewish writers articulate differing specifications and balancing among these values.

End of Life

Judaism's commitment to life and healing tends to support the provision of treatment to sustain life. For some Orthodox authorities, the obligation to maintain life-sustaining treatment is virtually absolute. Humans are mandated to sustain life, and any continuation of life, even when marked by suffering, is esteemed as a benefit for the patient, as well as a requirement of God's sovereignty. Most Orthodox authorities are even more reluctant to withdraw treatment than to withhold it because they construe "withdrawing" as an action. Even these thinkers acknowledge that

treatments often entail risk, or may be only questionably effective, allowing some room for decisions about providing treatment. Still, in virtually all circumstances, all treatment that is effective in prolonging life must be provided.

Many Jews agree that life is intrinsically good but allow a greater scope for treatment decisions. Ethicist Benjamin Freedman argues that, even assuming the obligation to pursue healing, a patient retains significant authority and responsibility for medical decisions. The norm of clinical practice is that choices must be made between different treatments with different side effects, different risks, and different possible benefits. Real choices must be made about which treatments to pursue. In such cases, traditional Judaism should agree that the patient should listen to guidance from health care professionals, and then the patient should make the choice as steward of his health (Freedman, 1999).

A central text regarding decisions to forgo life-sustaining treatment is found in the commentary of Moses Isserles in the *Shulhan Arukh* (Y.D. 339:1):

> It is forbidden to cause the dying person to die more quickly. For example, if one is a *goseis* (dying person) for a long time and is unable to expire, it is forbidden to remove the pillow or mattress from underneath him,...and one does not move him from his place. However, if there is something causing a hindrance to the soul's departure, such as if there is a noise near the house such as a woodchopper, or if there is salt on his tongue, and these are delaying the departure of the soul, it is permitted to remove them–this is not a [significant] action, but is *only removing an impediment*.

While physiological details are unclear, many have seen in this passage a recognition that it is not always possible or appropriate to artificially postpone death. Conservative rabbi Avram Reisner argues that mechanical respirators and transfusions may represent impediments. A dying patient could refuse these, so long as the intention is not to achieve death, but to avoid burdens and to allow death to occur naturally (Reisner, 2000, pp. 265–69). Conservative rabbi David Feldman offers a more general interpretation: "A clear distinction is thus implied between the deliberate termination of life and the removal of means that artificially prolong the process of death....While physicians, then, may not disconnect life-support systems where they shorten life thereby, they may do so to shorten the dying process." (Feldman acknowledges that since "it is difficult to tell the difference between shortening life and death, the principle is a moral one more than a practical one." Feldman also differs from the Orthodox claim that withdrawing treatment is far more problematic than withholding. "At the outset, the physician should connect the support systems of respiration or circulation; he should not decline to do so on the grounds that this may be prolonging death. He must give the patient every chance for life. Having connected the systems conditionally, however, he may remove them if he then determines that their function was not prolongation of life but of death" (Feldman, 1986, p. 95)).

Conservative rabbi Elliot Dorff advocates an approach of evaluating benefits and burdens for treatment decisions regarding terminally ill and permanently unconscious patients. Appealing to texts as well as experience, Dorff argues "that we should use the benefit to the patient as the primary criterion in determining a course of action rather than our ability to accomplish a limited medical goal (such as

keeping one or more organs functioning)." (Dorff 2000a, p. 312) A variety of medical treatments may be forgone based on "our compassionate attention to the best interests of the patient" (as defined primarily by the patient, to the extent possible). A presumption supports the provision of artificial nutrition and hydration, but this presumption is rebuttable: these measures may be forgone for a terminally ill patient (at the request of the patient or surrogate) if they are seen not to serve the patient's best interests (Dorff, 2000b, pp. 344, 348–54).

A statement from the Reform movement develops a different rationale to support views similar to those of Dorff. "Once a medical treatment ceases to be effective and beneficial it ceases to be 'medicine' as that practice is conceived by Jewish tradition. . . .Treatments which do not effect 'healing' are not *medicine* and thus are not required" (Plaut & Washofsky, 1997, p. 348).

Some Reform authorities would accept any refusal of treatment articulated by an individual on grounds of patient autonomy. A minority are even willing to accept active killing when autonomously chosen by a suffering patient. Generally, however, Reform and other Jews reject suicide, assisted suicide, and euthanasia. Most judge that such acts exceed the scope of legitimate stewardship. As well, acceptance of euthanasia and assisted suicide is likely to threaten and harm vulnerable patients. In appropriate cases it may be legitimate to decide to forgo treatment. When medical treatment offers hope to cure and save life, it should be pursued. However, many Jews argue that life-sustaining treatment may be forgone if it merely prolongs the dying process, if it offers no hope for cure, or if it imposes burdens or fails to benefit the patient.

Beginning of Life

There is wide agreement among Jewish writers that a fetus has value and that elective abortion generally is wrong. However, if there is a conflict between the life of the fetus and the life of the woman, the imperative to protect the woman's life takes precedence. Writers express diverse views about whether and to what extent the woman's health and well-being also could justify abortion. A precedent from the Book of Exodus (21:22–23) has been influential in the Jewish tradition. "When men fight, and one of them pushes a pregnant woman and a miscarriage results, but no other damage ensues, the one responsible shall be fined. But if other damage ensues, the penalty shall be life for life...." The Hebrew Bible also contains passages that reflect the value of the unborn child and God's relationship with individuals before birth. In ascertaining concrete responsibilities, however, the clear distinction between the status of woman and fetus in Exodus 21 has exerted greater influence and provides a touchstone for the later development of Jewish law and ethics.

A central text in rabbinic deliberations about abortion is found in the Mishnah (*Oholot* 7:6): "If a woman is having [life-threatening] difficulty giving birth, one dismembers the fetus within her and brings it forth limb by limb, because her life comes before its life. Once the greater part has emerged, one may not touch it, for one may not set aside one life (*nefesh*) to save another." All Jewish authorities agree

that the fetus has a lesser status than that of the woman, though there is debate as to whether this status is virtually equivalent to hers or significantly lower, according greater scope for permissible abortions. All Jewish authorities agree that abortion is permitted to save the woman's life, though the permissibility of abortion for other reasons is contested.

Most authorities agree that abortion is mandated to save the pregnant woman from significant threats to her health. Many accept abortion in some circumstances to avoid the woman's suffering, even when her health is not directly threatened. The abortion of a fetus with a serious genetic disease, such as Tay-Sachs disease, is often approached in these terms. Jewish writers typically do not claim that the future suffering of the child after birth would make his or her life not worth living, but rather justify such abortion when it would save the woman from anguish that she would find unbearable.

Some further stretch the rubric of therapeutic abortion. Precedents allowing abortion to guard the woman's psychological health may be expanded to include such variables as physical strength, stress, and personals needs. Some, especially among Reform Jews, emphasize that the tradition does not consider the fetus a person, and so the value of the woman's autonomy is decisive, not only legally but morally as well. Even these writers acknowledge a need for thoughtfulness in making moral decisions about abortion.

A perspective on abortion may be provided by framing the issue in terms of the intrinsic dignity and value of human life, sometimes expressed as the sanctity of life. All Jewish authorities are committed to this principle but specify and balance this principle and others differently. For Jewish thinkers, the life of the fetus or unborn child has value and deserves respect, but somewhat less so than the woman. According to some authorities, the status of the fetus is virtually equal to that of the mother; commitment to the sanctity of life demands abortion to save the woman's life but condemns abortion in any other circumstance. For other Jewish thinkers, the imperative to preserve the life of the woman is more broadly construed, entailing a commitment to preserve health. This approach reflects leniency with regard to fetal life but also stringency to preserve the woman's life and health. Yet other Jewish writers emphasize that the sanctity of life and respect for human dignity involve more than safeguarding biological existence. There are limits to the sacrifice and suffering a pregnant woman is obligated to undergo, even to preserve the life of the fetus.

For Judaism, the fetus must be respected as potential personal life, but does not have the full status of a person at any stage of gestation. All Jewish writers would permit abortion when necessary to save the mother's life. Most Jewish authorities would permit abortion to avoid a serious threat to the mother's health. Many Jewish thinkers would accept abortion in some other circumstances to avoid significant personal suffering for the mother.

Jewish writers tend to accept the use of reproductive technologies when desired by an infertile couple. Concern must be paid to the physical and personal well-being of all involved, especially children. Many express great caution regarding the use of donor gametes, though some accept this in appropriate cases.

Conclusion and General Values

Judaism attempts not only to address particular medical issues but to help shape a way of life that reflects core values such as respect for persons, life, healing, and justice. Jewish tradition affirms the intrinsic value and dignity of each human person. Each individual and the community as a whole are responsible to support others and to provide for basic needs, including health care. The *Shulhan Arukh* (Y.D. 335), following earlier sources, describes visiting the sick (*bikkur holim*) as not only an act of loving-kindness but a personal obligation incumbent on all. Visitors are expected to care for the tangible needs of the patient as well as engage in conversation and prayer. The community is responsible to provide for health care as a matter of justice, *tzedakah*. This responsibility is not unlimited, for individuals and communities legitimately pursue other concerns. While Jewish norms are not incumbent on modern nations, justice is required; Jewish understandings of justice may contribute to broader national and international dialogue.

Diverse Jewish writers would agree on the important value of reverence for human life. One clear implication of this value is that, as a moral matter, abortion is at least prima facie wrong, that is, the moral prohibition against abortion is binding unless outweighed by competing ethical considerations. As well, reverence for human life supports attention to problems of poverty and attitudes of selfishness, which contribute to the prevalence of abortion and harm human well-being in many other ways.

Introduction

Bioethics finds a new type of anthropological approach. In nuce, this means, from a Christian perspective, a circumstantial, profound approach, in all the cases that concern the defense, the protection, or the development of life as a special and inestimable gift of the Creator. In this sense, it is better understood why the Church considers itself a defender ex officio of life, as it is the servant of life, the servant of the Living God. Having appeared during the last decennia of the twentieth century, bioethics has triggered an increased interest for the study of moral rules of life not just in the medical or juridical world, but also in the Christian ecclesiastical area. The Church Fathers have condemned from the very beginning abortion and suicide, as bioethical approaches avant la lettre. At the same time, they have encouraged scientific knowledge and research, medicine, and everything that is useful for man, starting from the premise that man was created by God with the purpose of contributing, in the Holy Spirit, to the perfection of His creation, of being a collaborator of the Creator, who is supporting and developing the human creativity, ingenuity, and creative fantasy. Actually, the healing of any suffering, the curing of any human incapacity, according to the saving and regenerating example of the Redeemer, is part of what is called the apostolic mandate, the sacramental priesthood. While in the Catholic and Protestant area there have been concerns for the domain of bioethics since the first scientific debates appeared in this regard, at the middle of the last century, in the Orthodox area, despite a sporadic interest and openness to this issue, it was only at the beginning of the 1990s that the Orthodox theologians, especially those belonging to the Churches from behind the Iron Curtain, were able to come into contact with the preoccupations of bioethics and began to research such topics. The explanation of this gap is obvious, as the great Orthodox Churches (the Russian and the Romanian ones) were not in the position to have much information on this new domain and their main concern was to support ecclesial perspective that has in its center the respect and life protection as much as

possible. It was only during the age of freedom that these Churches were able to penetrate into the area of bioethics in all the due depth (Astărastoae & Trif, 1998, 17). The concerns of the Orthodox Churches that had not been within the sphere of influence of any communist state had been rather directed toward dogmatic, pastoral, missionary, or doctrinal issues and only sporadically and occasionally to bioethical issues. This domain was a new one and, prudently, the newcomers first studied the how Catholic and Protestant Christians – with a profound modern and especially postmodern experience – had extended their pastoral and missionary experience and the traditional rules of respecting and promoting life on this new scientific field. For the Orthodox theology, it is an obvious thing that man has been created in the image of God and with the destiny of an unlimited resemblance to Him; that is why man is a completely special being, with a particular cosmological dignity and position (Engelhardt, 2003, 65). Sure, along with the theological, Christian, and theistic vision, today, there is also a humanist, secular, or atheist bioethical vision. Approaching the specifics of bioethics in the Orthodox area, it will be referred to the Christian Orthodox bioethics, to its fundamental principles, to the way in which it approaches life and the contemporary challenges in relation to life. Being really a science with a subtle definition, bioethics is permanently exposed to the risk of losing its meanings and values or of having them distorted by a secular, utilitarian approach although other approaches exist such as virtue ethics.

The Specifics of the Orthodox Bioethical Perspective

Christian bioethics aims to provide a reliable light on the way of life, so that man, using the divine gift of his mind, creativity, may act in good faith from the perspective of the evangelical prescriptions and in relation to His Creator, as it is stated by its classical definition, which affirms that it is a "new discipline, combining biological knowledge to the knowledge of the system of human values" (Potter, 1971, 1; Macer, 1995, 29). The solutions proposed by the Christian bioethics are fully true to human life, to the Creator, and to the entire creation, highlighting the limits of human science, courage, and reason. Christian bioethics puts the respect and protection of life in relation with the search for salvation, from an eschatological perspective, and to the protection, respect, and promotion of human dignity, being inspired by care for man, by love and respect for the human being (Vicol, 2006, 16). The specifics of the Orthodox bioethics consist in a deep respect for human life, for the manifestation of the living and of man in all his fullness. That is why any bioethical approach, from an Orthodox perspective, has in view to support and to protect life, to consolidate the principle of love and respect toward the great gift of life made to us by God, and the lens through which an Orthodox bioethicist looks at everything is not usefulness, but serving God by serving man, promoting good, solidarity, and philanthropy. In the official documents of the Orthodox Church, in relation to bioethics, a few aspects have received particular attention: promoting life and human dignity in any situation; avoiding any personal profit following therapeutic interventions; discerning mind and lucidity in any medical

decision, which has to rely on a deep respect for the patient, as a perfect image of God; a deeper understanding on the medical responsibility toward supporting and defending life, catechizing the clergy and the believers concerning the medical interventions of any kind, etc. The suffering person, who is in need and hurting, is seen as Christ the pilgrim or as a concealed Christ (who is to be recognized in the image of the brother who is in pain). Any man, especially a man who is in difficulty, is considered and evaluated as an expression of the Redeemer's kindness, and basis of the final and eschatological judgment, according to which what is done to the sick person is appreciated in the terms: "You have done it to Me" (Mathew 25, 40). The Christian doctor is a doctor who serves his suffering fellow, being always a merciful Samaritan. The Orthodox bioethics speaks about Jesus Christ, "the Doctor of our souls and of our bodies, the One Who can heal any disease and infirmity, Who can turn suffering into a hymn of praise and can transfigure joy in the light of His resurrection. This beautiful expression does nothing else except to put the incarnated Son of God – as He really is – in the centre of the medical world, of hope and of healing" (Astărastoae, Scripcaru, & Scripcaru, 1994, 12). Christian bioethics helps not to destroy the human civilization, not to mock the divine creation, but to provide the society we live in with an authentic axiological system.

The Principles of the Romanian Orthodox Bioethics

Not everything that is possible is also allowed. Even though, due to the present amazing technical progress, man has numerous possibilities of scientific quest, not everything his powers can accomplish also has a moral end. Man is not the creator of life; he is just one of its beneficiaries and has the divine duty to administrate the creation in agreement with the divine moral laws. The reason is simple: life must be protected under any circumstances and everything that is contrary to it or endangers or deforms it is forbidden. What does not preclude is not opposed to the human right to freedom, because, as it is well known, not everything that is possible is also good, and one's freedom ends where the other's freedom begins. From an Orthodox perspective (B.O.R. Documente. 2004. Pozitia Bisericii Ortodoxe Române faţă de transplantul de organe), bioethics is grounded in the divine Revelation. That is why respect for life, as a precious divine gift, as it was stated before, lies at the heart of any debate and at the basis of any approach. The premise from which the Orthodox bioethical approach starts is that God – the Creator – is the absolute master of life and death. That is why sovereignty over life belongs exclusively to him, man having only the obligation to contribute to defending and supporting it (according to Gen. 1:21,27; 9:6; Deut. 32:39; Ex. 20:13; Job 1:21; Acts 17:28;). Naturally, this is the basis of the idea that man is not allowed to act on private foundations of life by means of medical techniques so as to radically transform it or even to initiate a new human type (Geisler, 1989, 45). Bioethics has for its main source the revealed will of God, because it is only in this way that it can promote life in the best and most correct way, maintaining its relation to the Creator of life. When Christian bioethical

discourse would be outside the revealed doctrine, it would grow speculative and would turn to ideology, i.e., to artificial and false ideas. Another point refers to the fact that at the heart of the human research should be the respect for man's life and dignity, as man is a being with a special role in creation, being created in the image of God. The dignity of life comes from the fact that its source is God Himself, that man has been created by means of a special act by the Creator, being in the image of God and having the perspective of a permanent similarity to Him, so that any act that degrades life is an act of disrespect toward God Himself. God has created nothing for destruction and He supports life providentially, which encourages us to be promoters of life, for by defending life we honor our Creator and respect the great and beautiful gift of life and dignity (Breck, 2003, 15–16). Another principle has in view the fact that human life has a sacred character, because it has been created by God and God Himself is sacred and a source of sacredness (cf. Lev. 20, 26). Human life is sacred through its origin and destiny, that is why it is inviolable and lies at the heart of man's interests. The sacredness of life relies on the fact that man was created by the All-holy God in His image, and God is a model, promoter, and supporter of holiness. At the same time, the holiness of life involves values such as image of God, human person, dignity, respect, and perfection (Lossky, 1993, 144). Human life is a gift; humans have done nothing to come into existence and whatever they do they cannot make it perfect or make it longer beyond God's will. Coming from God and having for one's destination the relation with God, through one's return to the Father, man acquires value by reflecting the divine value; his entire life acquires light and value through its very connection to the Creator; that is why it can be said that human life has an inner value, given by its eternal origin and destiny. God, Who is love, has given men the existence as a gift of His endlessly overflowing love; He has given it to them so that they may live in an eternal loving communion with Him (Col. 1, 12, Ephes. 1, 18). The sacred gift of life is the most important component of human life, the only really precious gift that man has ever received. That is why a human person can by no means be the instrument of purposes that are foreign to his development, as man finds his total and definitive fulfillment only in God and in His redeeming plan. One can state that the sacredness and inviolability of human life is the only universal principle that has no restriction and no exception (Maximilian, Milcu, & Poenaru, 1994, 69). The principle of naturalness rejects everything that goes against the natural development of life or stops the natural development of man in harmony to the laws God has engraved in the creation. This is also one of the reasons why euthanasia, for instance, is fought against and refused, not just because life is the gift of God and what you cannot give you also cannot take, but also because the earthly human life must end naturally, according to the Creator's decision and according to one's biological infirmities, and not according to one's arbitrary will. Natural is everything that comes from God, and forgery and artificiality is everything opposed to the divine will or to the laws of nature, which are also of divine origin. Artificiality is opposed to life through its alterity in relation to life and to life's purpose; that is why Christian bioethics rejects any artificial thing that is directly or indirectly opposed to life. The eschatological

principle holds that everything human persons do in support of life has to take into account the fact that this earthly, biological life does not represent everything, is not a purpose in itself but is just a preparation for the eternal life, an exercise preparing men for the eternity, a time of trial and edification of one's perfection. That is why the human life and man's deeds have to be directed to eternity, to immortality, which saves from idolatrise the culture of life itself, which otherwise – in theory – would draw near the vitalism of the ancient, pagan religions, or to the contemporary consumerism and materialism. "Live fully, here and now"– this would be man's best slogan, the most correct one, were he not meant for deification, spiritualization, and transfiguration (Yannaras, 1996, 55). The eschatological principle gives force to faith, gives wings to hope, and chases away the temptation to divert the actions in favor of promoting life from their true meaning and purpose. The dominant principle that should characterize all the human actions is that of solidarity and love, the biggest Christian commandment, the very essence of the Creator and of man's perfection (according to Mt. 22:37–39). Man was not created alone; in order to be able to become perfect, he was given the opportunity to live in community and in communion; that is why, the manifestation of human solidarity is natural as equal beings in front the Creator, but as persons who love one another and manifest their mercy to each other, according to God's model. Solidarity supposes not just supporting the universal human effort, but also sacrificing human persons for their fellows, every moment of their life, up to the sacrifice of their own life. It is out of love for their fellow men that all the social work and mutual assistance among people have come. It is also out of love for people that there are innumerable persons serving their fellows' needs, even to the point of sacrificing their lives for their fellows' sake. The incarnated Son of God gives humans the supreme example of love and solidarity, receiving a human body for their sake, suffering, dying, and being resurrected, for their salvation, for their good, out of His great love and in order to show his solidarity with them. God's arrival into the heart of the human history is the active principle animating all humans, too, to serve their fellow men in need through their friendship. According to this logic, any medical intervention should be carried out with the fully informed consent of the respective person, who should be aware of all the moral, spiritual, or medical implications of the respective act. When this consent cannot be expressed, the only actions allowed should be those that maintain life. It is a human duty to prevent somebody's death, by any legal and moral means, but also to contribute to treating, curing, or correcting the imperfections of man's biological life (Atkinson, 1985, 205). A being of joy and of hope, the Christian celebrates life, serving the God of life, appreciates biological life, along with the eternal one, as a marvelous gift of God, promoting the idea that man should rise above different ideologies and doctrines, and man's life is truly a good thing, a value in itself and a sacred gift (Breck, 2003, 19). Life is a *talent* that was entrusted to men so that they may transform it and increase it, turning it into a gift for the others. No person is an iceberg floating uselessly on the oceans of history. Any human person is part of a large family in which each one has his own place and role. Science can change life, but it cannot transform it. What men need is

a change of Life and Death. This is the calling of the Church. Beside all the things above, one should take into account as well the fact that the Church values the concept of person, namely, of living entity created for communion, creative, open for dialogue, who finds one's purpose only in communion, is indivisible, capable of relations and self-reflection, free, unique, with the vocation of a distinct contribution to the world's soteriological progress, but especially with a great moral responsibility (Stăniloae, 1997, 359). Christian personalism has in view the fact that between part (man) and whole (mankind) there are fine, multiple, and complex intrinsic connections, so that a man cannot express entirely the whole of humanity, and that can be assumed and saved only with each and every man. In this sense, one should understand that what is good for just one man should be good for the entire mankind and the other way round. Namely, all that can support life in a particular case becomes norm for the whole. It is not just the soul that has value, in the case of man, but man as a whole, because man, body and soul, material and spiritual, is a being with a subtle definition, a mediator between the two worlds and having value as a whole. It can be said that man is a special being, and the body is his interface for space and time or the way of manifestation of his spirit under these conditions of existence. The extremely special value of man is also given by the fact that for him, God Himself arrived in the human history, received a human body, and became a Man. And to save a man is to save his divine dignity, to fully honor God the Creator. God is the One who saves man; that is why man should also be someone through whom God acts, an *alter Christus*. The morality of the medical act can only be appreciated by relating it to a transcendent principle; otherwise, it is changeable in a permanently fluctuating environment, depending on the will, knowledge, and ideology that mark – at a certain moment – man's life. Man's intrinsic, absolute value in front of any ideology, turns any medical intervention – from a Christian perspective – into an intervention that concerns the human body, not like a piece of meat, like something ordinary that can be found in large quantities on Earth, but as a special material individualization, as a personal way of relating with one's fellows, and especially as a special environment for the manifestation of God's presence. That is why saving the integrity of a man's body is an instance of praising God, and a way of contributing to the accomplishment of His Creation.

Bioethical Structures Within the Orthodox Church

From an inter-Orthodox viewpoint, on the level of the world Orthodoxy, on the occasion of the Meeting of the First Hierarchs of the Orthodox Churches from Constantinople (Istanbul) in 2008, it was decided to create an Inter-Orthodox Bioethical Commission, so that it may express a common Orthodox viewpoint in matters of bioethics. This agreement has been substantiated through the meeting organized by the Ecumenical Patriarchy, between May 23 and 26, 2011, at the Orthodox Academy of Crete in Kolimbario. The event was presided by the Eastern

Orthodox Metropolitan Ioannis (John) of Pergamon (Zizioulas) and debated the main contemporary issues related to bioethics.

In the Romanian Orthodox Church, the most open out of the churches from former communist space, the interest for bioethical topics became obvious after the 1989 events, when the communist regime in Romania was stripped of power and a democratic journey of the country began, more precisely, even since 1992, when the Holy Synod of the Romanian Orthodox Church approved the creation of a Consultative Commission of Bioethics, meant to provide specialized expertise on current matters in the domain. Important is also the decision of the same forum, which in the year 2001 decided that bioethical topics should be a priority on the agenda of the high forum. At the same time, a proposal of the Committee for the elaboration of the principles and methodologies for the approach, study, and evaluation of this topic was approved, namely, that the four large university centers of the country (Bucharest, Iaşi, Cluj, and Timişoara) would function a local bioethics commission, made up of five theologians, five scientists, and a lawyer, dealing with bioethical topics, and the results of the research may be handed over to the National Consultative Commission of the Romanian Orthodox Church on Bioethical Issues, which was created on the same date, with members from within the four subcommissions. This commission elaborates conclusion and hands them over for approval to the Holy Synod. The Commissions functioned since 2001 until 2003, they handed over their proposals to the Consultative Commission and then to the Chancery of the Holy Synod, their expertise being felt in the decisions of the high Romanian Orthodox forum on organ transplant (2004), abortion (2004), and euthanasia (2005) (Iloaie, 2009).

Within the Orthodoxy, a notable preoccupation is also the concern for bioethics of the Russian Orthodox Church, which has expressed its position concerning different topics in the domain on the occasion of the well-known document entitled *Fundaments of the Social Concept of the Russian Orthodox Church*, expression of the Jubilee Episcopal Synod of the Russian Orthodox Church, Moscow, August 13–16, 2000.

The American Orthodoxy, closer to the top scientific research has, through its different jurisdictions, very clear positions on a set of bioethical matters covering a large array of problems. Locally, each autonomous Orthodox Church has its own consultative bioethical structures and expresses knowledgeable viewpoints, on different occasions, concerning bioethical issues under debate.

Along with the Romanian and the Russian Orthodoxy, the Greek one is very active in supporting – from a social viewpoint and in the media – the perspective of the Orthodox Church on the main bioethical issues. From this viewpoint, it can be said that the Greek Orthodoxy highlights the need of an ethics concerning procreation and the need to eliminate abortion from the preoccupations of its own believers, but also the need for a major ecotheological vision, while the Russian Orthodoxy is concerned by matters related to the ethics of the work and of the techniques of genetic manipulation, while the Romanian Orthodoxy is preoccupied by the interdisciplinary, technological-scientific approach and the substantiation of the bioethical issues.

The Position of the Orthodox Church on the Main Bioethical Themes

Abortion

The ecclesial writings from the beginning of the second century, the Holy Fathers' and church writers' works of the third century, as well as the ecclesiastical rules and canons state the concomitance of the body and soul even since the moment of fertilization, as they are formed both at once, which shows that even since the conception stage, it can be talked about the existence of a concrete and true human person.

The entire Orthodox Christianity considers abortion as deliberate murder, as it starts from the belief that human life begins with procreation, namely, at the moment of the fertilization that gives birth to the unique zygote, the unique cell made up of two gamete cells. This conviction relies on scriptural texts (Ps. 138, 13–16; Is 49, and so on; Luke 1, 41, 44) as well as on the scientifically established fact that even since the moment of conception, there is genetic uniqueness and probably cellular differentiation that, if the embryo is allowed to develop normally, will produce a living human being. Man's life is considered sacred even since the beginning, since it is clear that it is dealing with the existence of a soul even since the moment of conception. The fetus has always and constantly been considered a complete human being. The artificial interruption of a pregnancy has always been considered a crime, a homicide, in the orthodox tradition. By abortion, one ends a human life, a human existence, even though it may have been in the beginning stages. The fetus, in his personal life, is an autonomous human being and a complete human person, living and developing independently from his maternal environment. So, ending a pregnancy is not the right of the person bearing him. The fact that the pregnancy does not yet concern the fully developed person does not mean that it can be reduced to a thing, becoming an object – good for property, for sale, or for storage. At the same time, it does not mean that the pregnant person may freely take any action concerning the fetus, as she can do concerning any other part of her body. The fetus is not a thing or an object or a simple part of the woman's body, but gene with life in evolution, united to the life of the pregnant person. This special particularity of the fetus as person in evolution cannot be contested. Consequently, the fetus is and has to be protected by the civil law as something special. From this results the intransigence of Orthodox bioethics concerning abortion: man exists as man since the moment of his conception until the moment of his biological death. So, during any moment of man's life, if there is an intervention against man's survival, it is considered homicide. Extrapolating, children are not therefore their mother's property, their parents' property, or even the society's property for any of them to take any action concerning the children even since their mother's womb. The orthodox Church has always been – in all the times and places – against abortion, which it considered a crime against human life, and which it situated among the outrageous sins, which diminish and annihilate the communion of its perpetrators with God. It is true that there are some nuances,

like when a woman is raped, however, the child has no fault and mother should keep him; also when the mother's life is threatened, the choice is hers. It is about saving a life and losing the other without being able to keep them both. Being an act directed against human life, the abortion is comprised and forbidden by the sixth commandment of the Decalogue: *Thou shalt not kill* (Deut. 5, 17). The principle against abortion (and not only) could be best synthesized in the following words: all that is committed against the human being is committed to a certain extent against God's will.

Organ and Tissue Transplant

By tissue and/or organ transplant is understood the complex medical activity that, for therapeutic purposes, replaces tissues and/or organs no longer working from a morphological and functional viewpoint, from the body of a human subject, with other similar ones, proved as being healthy. The organ transplant represents a really laudable techno-medical performance of today's science. It is a performance of the medical science and practice that the Church blesses as long as through the transplant, one solves the crisis determined by the lack of other healing solutions and the normal life of one person is restored without taking the life of any other person: no one should be killed for someone else to live. To carry out a transplant is to implant in a certain part of the body a tissue or an organ taken from another part of one's own body or from someone else. From a living donor can be drawn one of his double organs (e.g., kidneys) or tissues (skin, bone marrow, blood). When living tissue is transferred from one part to another of the same organism, it is called an onto-plastic (autograft) transplant. When dealing with the transplant of a tissue or an organ from one individual to another belonging to the same species, it is called a homoplastic transplant. A heterologous transplant, finally, is a transplantation of tissue from an animal to a human being. The drawing and the transplant of human tissues and organs are carried out for therapeutic reasons. The Orthodox Church agrees to organ transplant as long as it is carried out not for a material interest, but out of love, if the donor consents and the respective transplant does not endanger either his life or that of the receiver. A problem is raised by organ and/or tissue drawing and transplant from persons experiencing cerebral death. The Orthodox Church has established a few criteria concerning the carrying out of this practice: one should respect the dignity of the person (donor, receiver, doctor); the operation should have a therapeutic purpose; it should be for the benefit of one's fellows; it should respect the life and even the death of the human person; it should respect human rights and the spiritual dimension of the human existence, from the very moment of its conception; it should not be determined by political or economic opportunism, by medical curiosities, which are in fashion in the present secularized world. At the same time, the donation should rely on the spirit of sacrifice, should not be the object of a financial deal, should be carried out in order to cure or treat a disease, should be the only solution at that moment, should benefit of the agreement of both parties, and should not be part of a human embryo, who is

a being with rights and cannot express his consent, and a drawing would mean his destruction. The receiver of the gift has the chance of continuing his life, while the giver no longer has that chance in the terrestrial area. There are critical situations in which the organ transplant comes as a saving solution, and here one can refer to the people born with malformations or other congenital diseases and who otherwise would not have any solution for survival. Organ donation can be considered as well as a gift out of human solidarity, the individual's moral obligation concerning the respect for life and saving human life being superior to keeping one's physical integrity. So, tissue and organ transplant, on the one hand, helps save the life of those who otherwise would not have had any chance of survival, and, on the other hand, offers to the one who gives the joy of prolonging a life, following in this way the example of one's Redeemer Jesus Christ. The Orthodoxy is flexible concerning this aspect, criticizing and being opposed to the situations of organ traffic, of high-quality medical assistance refusal in order to get a person into the situation of becoming a donor, even unintentionally, or to the situations in which this solution does not have a minimum theoretical success. As sacrifice and as a way of diminishing human suffering, the organ transplant benefits of the approval of the Orthodoxy, being seen as a form of love for human fellow.

Cloning

There is no synodal document with a determined position concerning cloning. However, the opinions expressed by the Orthodox theologians help to support a unitary viewpoint. The Church does not agree with the idea of cloning because this technique of genetic manipulation supposes the creation of copies of DNA fragments (molecular cloning), of cells (cellular cloning), or of organisms. Cloning is a piece of evidence of human power going over its limits, substituting itself to the divine power, because the cloned organism is identical from a genetic perspective with the ancestral cell or organism he came from. So, between the original and the cloned person there is genotype identity, as they share the same genetic patrimony, yet there is no phenotype identity. Between the two organisms there is no bigger identity than between two twins, who also share the same genetic patrimony, yet each one has his identity, his personality, his destiny, which differ depending on their environment, on their education, on their culture, on their own free choices and decisions, each one being endowed with will. So, cloning is not a process of procreation, but is reproduction on an animal breeding level, being, namely, an offense against the dignity of the person obtained through cloning. A clone has no father and mother; it is not the fruit of an act of love between parents, but a laboratory product, obtained using a serial man-making-machine, an object produced on order. The moral issue that arises is that this procedure can create errors, is highly susceptible to failure, produces many abnormalities, can create significant misbalances in the ecosystem, nullifies the individuality and uniqueness of the human being, and can create significant juridical and identity-related complications. At the same time, it violates man's fundamental rights, hurting the

dignity of man and of the divine creation, creates the suspicion of the immediate possibility of racial selection, puts man in God's place, introduces stereotype and repetition in the uniqueness of life, undervalues the body, which is a temple of the Holy Spirit (I Cor. 3, 16), and may even create true biological bombs or may be used as racial weapon. That is why the Orthodox theologians do not accept this procedure and do not find any moral justification for it. The attempts made to obtain human beings without any connection to love and to family should be considered contrary to ethics, as they go against the dignity of both human procreation and of the conjugal union. In 1998, the Romanian Parliament voted in favor of a law that forbids cloning. However, the debate continues, especially as the atheistic moralists or those belonging to different secular groups, relying on a so-called right to progress and research (a Marxist-Darwinist projection, an ideological distortion), support the view that no legislative restriction should exist concerning cloning. Orthodoxy, through its theologians, considers this technique unnatural and not useful for the common love and good, but rather a technique supporting petty economic or racial interests. Thus, it rejects cloning with determination. Only organisms created naturally, respecting the laws of creation, can be viable and sustainable. And then, can someone guarantee that no genetic errors are introduced in the creation, without having the possibility of eliminating them? So, it would be better to stop playing God. The issue of cloning is an actual piece of evidence that science without solid spiritual and moral principles is positioned against man.

Euthanasia: Assisted Suicide

By euthanasia, which in Greek means "beautiful death" or "easy death," one understands the medical help meant to put an end to the life of someone suffering from an incurable disease. The practice of euthanasia supposes the ceasing of the medical treatment, which subsequently leads to death, or even the ingestion of deadly substances or the use of lethal techniques. It is used especially in the case of those who say that they have incurable diseases or an age they consider sufficient for life and so they wish to put an end to their earthly existence. Those who support euthanasia start from the following premises: the ill person's right to a decent death, the presumption that the diagnosis is always a correct one and cannot be changed, the idea that there is no other alternative for helping the incurably ill person. What is neglected, however, is the fact that death should intervene naturally and not artificially, that no one cannot establish the certitude of the diagnosis, but can only approximate it. At the same time, there are enough cases in which, despite an extremely unfavorable diagnosis, the patient either completely recovered, or his health condition considerably improved. One cannot forget that the Nazi practice of programmed euthanasia, meaning by it a means to ensure the supremacy of the white and "strong" race, constituted the first applied political program concerning euthanasia. Death for the believer indicates his relationship and his primary dependence on God; he puts his life into God's hands in an act of total submission. The euthanasia and the suicide constitute the sign of the vindication by man of the right

to dispose of himself, of his own life and death. Any legislation should recognize and consecrate and defend the fundamental right to life, but not to death. Because, granting the right to life and death, the legislation turns to absurd and annuls itself. Life is sacred and inviolable. There is no life devoid of meaning, of value, of dignity, just as there is no death devoid of dignity except for that caused by suicide or euthanasia. The Orthodox Church clearly and firmly states its position against euthanasia – under any form – considering it deliberate murder and asking for the punishment of those who make themselves guilty of it. A doctor must save lives, not end them, and in any situation human life has an indestructible and indelible dignity. Euthanasia is not a natural process, as it involves a choice. The life that a man cannot give should not be ended by man, even if it is his own life. Only God is the master, the source and the author of life, and only He has the right to take it. What is not yours cannot constitute a subject of choice or transaction. Orthodoxy rejects any action or accident by which one could try to end someone's life and any way by which someone could try to end his own life, recommending the administration of all the natural treatments meant to ease the patient's pain. Suffering has, for an Orthodox Christian, a soteriological sense; it has a sense, and death is the most important moment of this life, as it is the passage gate to the world of eternity; that is why illness and death have something mysterious in them, as they do not lack the presence of God in them. When man artificially intervenes to hurry death, he goes against the Creator's will and becomes an opponent even of his own humanity. At the same time, no medical or economic reason can justify euthanasia, this being a barbarian act and a sign of behavioral and civilizational estrangement.

Contraception

In the Orthodox perspective, the family governed by authentic love cannot be infertile; of course this is not an infallible rule, for love and marriage can occur where, for various reasons, the family cannot have children. But its fruits can be either material or spiritual. The purpose of a marriage is the accomplishment of the two married people through a complete love, which can lead them to get closer to God and to salvation. When among the family fruits there are children as well, they are a great gift and blessing from God. Orthodoxy does not want to intervene in the intimate life of its believers, considering the marriage holy under all its aspects, including its bodily aspect. At the same time, man's purpose is to grow in his likeness with God, in perfection, but also to perpetuate the human species. It is true that, in principle, man has reason and can decide if and how many descendents he shall have, although, in the end, the One who decides is the Creator. However, the Church accentuates the priorities – perfection, salvation, and the perpetuation of the species – thereby it recommends abstinence for the natural regulation of different situations. Some theologians associate abstaining from procreation by different means to the sin of Onan. Others, in exchange, without any approval of some ecclesiastical decisional forum, accept any non-abortive contraceptive means. Normative remains, however, Saint Paul's recommendation: commonly

agreed-upon-abstinence for a while (I Cor. 7, 5). Even though Orthodoxy has not clearly stated its position by means of a synod so far, the tendency goes, however, toward the promotion only of the teaching preached by the Holy Apostle Paul – temporary commonly agreed-upon-abstinence.

Artificial Insemination

Here as well Orthodoxy also does not have any normative document, yet the bio-moralists and Orthodox moralists consider that if the insemination occurs with biological material from the two spouses, who are totally, partially, or temporarily infertile, or have any other medical problem and the birth can occur only through artificial insemination, then, because it serves love and the family, this thing is blessed. The condition is that both of the spouses should agree to it, and the biological material should belong and should be used only within the same couple. The import from somebody else is seen as a form of technicized adultery and is not accepted.

Experiments with Human Beings and Consent

The Orthodox Church does not have any synodal document concerning this issue. The historical experience shows that through medical experiments was discovered the antidote for many human diseases and sufferings, but, at the same time, some of them only served some people's pride, folly, or stupidity, being true experiments of torture (Clement, 1996, 23). Theologians, philosophers, people in the service of culture, or politicians have gradually pronounced themselves in time on the need, the use, or the rules that should accompany the medical research, many of them being opposed to the medical experiments on man, these means being considered as violating man's dignity and serving rather human vanity than mankind's welfare. At the same time, it is considered that medical experiments on man create suffering and humiliate the human being, taking away some of its physical or psychological integrity, terrorizing the future of the respective persons. It is a noble and moral thing to wish the welfare of mankind and to do everything to cure the different ailments affecting man's physical or spiritual life, but, in this approach, one must take into account a few rules. Any medical experiment needs to be carried out with the consent of the subjects after having previously informed them correctly on the respective scientific research, on the risks that they run and on the consequences of these experiments. At the same time, any experiment on man should not mutilate or create damages hindering the adequate functioning of the human body, and so the total or partial destruction of some healthy organs for the sake of research would be even more unacceptable. The latter should have a unique purpose – namely, to serve man, not someone or the other's ambitions, pride, or will for power (Fiori, 1996, 1123). Informing the subjects undergoing the tests is obligatory, in any situation, always before the beginning of any form of medical treatment, the only ethical exception being that of a major emergency that does not allow for such procedures.

Increasingly stronger voices ask for the forbidding of the experiments on animals, as part of God's creation, with its own dignity and meaning, the animals being unable to express their agreement. Numerous theologians see in these experiments a diabolical form of humiliation for the creation and a source of useless suffering, stating that good scientific medical results can be obtained using other means as well.

Conclusion

Bioethics is a big challenge for our contemporary society that implies promotion of human dignity and ecclesiastical community responsibility with liability and caution.

It is truly a science of life, of the rules of human life lived according to the natural divine principles, according to the providential and redeeming plan of the Creator. Ethical clarifications have no other purpose but to impose respect for life, for human dignity, for man's inalienable and divine rights. The dialogue between science and faith can be realized by means of reason, which is common for both of them. From here comes the need for a philosophical-moral reflection in the medical and biological domain as well. So, bioethics is understood as a discipline with a rational epistemological status, opened toward theology seen as a suprarational science, final instance, and "horizon of meaning." Bioethics is situated in the vanguard of science and of the means for promoting the transformation of one's world; it is the very guard of one's mentalities' purification and the keeper of life's treasure, protecting human beings from violating the sacredness and holiness of life. The Orthodoxy, through its different local Churches, by means of the agreement of some pan-Orthodox meetings, has formulated certain positions concerning the main bioethical issues, which it sees as norms meant to guide the believers on their way to salvation. By respecting them, the Orthodox believer enters the communion of love of the ecclesiastical community. By not respecting them, however, he creates not only suffering and disorientation, but also estrangement from the ecclesiastical body. An important role in this guidance goes to each priest in his own parish, in his spiritual relation with his parishioners. Personalist Christian bioethics is engaged in the defense and in the promotion of man's life, from birth to man's natural end, and invites all the Christians and all the good-willed people to participate to the realization of the great project of a new culture of life. Christian bioethics, in the light of the Orthodoxy, is truly a science of life, of the rules of the human life lived according to the natural divine principles, according to the providential and redeeming plan of the Creator.

Protestantism

26

Evert van Leeuwen

Introduction

Protestantism is the collective name of the religious groupings in Christianity which arose from the sixteenth century on. It is the third flow of religious thought and belief in Christianity, besides (Roman) Catholicism and (Eastern) Orthodoxy. The scope of this article makes it impossible to deal with all the varieties of Protestantism which developed during the last 500 years. The main characteristics can however be given by five Latin phrases starting with an S: *Solus Christus* (i.e., only in Jesus Christ can salvation be founded; He is the Redeemer of mankind), *Sola fide* (i.e., only by faith mankind can be saved from sin), *Sola scriptura* (i.e., only the Bible can be regarded as the Word of God; nature or tradition cannot be regarded as such), *Sola gratia* (i.e., only Divine Grace can yield salvation), and *Soli Deo Gloria* (i.e., only God receives honor and glory). These characteristics have been interpreted in many ways with respect to moral actions and their evaluation in terms of good and bad or with regard to the question of human responsibility. It is hard to cover all of them, but a systematic historical overview can give some insight into the main religious, political, and economical key points that need to be understood when dealing with specific moral views of a stream of Protestant moral thinking.

Systematic Historical Overview

The name Protestantism was coined at the Reichstag (Diet) of Speyer in 1529 in Germany, when a part of the German princes protested against and rejected the withdrawal of an earlier agreement (1525) on the freedom of religion. The Emperor of the Holy Roman Empire, Charles V, tried to bring back order in the German parts of his empire after the war with Frans I of France. He therefore reconfirmed the

Edict of Worms of 1521 in which the reformer Martin Luther was condemned, outlawed, and the combustion of his writings ordered. Protestantism therefore arose not so much out of a religious dispute as well as through a political act with a considerable moral weight. Later, in 1555 a settlement was reached through application of the slogan "Cuius regio, eius religio" (Whose realm, his religion). Understanding the roots of Protestantism requires understanding of this intertwinement of religious thought and moral and political action. Max Weber has given a clear explanation of the intertwinement in his famous essay "The Protestant Ethic and the Spirit of Capitalism" (1905). Still, the intertwinement is more complicated than one between economical strategies and virtues based on religion. It also entails the rise of citizenship and individual freedom as moral and political factors. The rise of commerce in Medieval and Renaissance Italy and France, and the ways in which the Catholic Church had indulged itself in politics and trade, already initiated in the twelfth-century heretic lay movements like the Albigensians (or Catharism) and the Waldenses. In both cases material wealth and prosperity were denied in favor of spiritual and personal salvation or purity. The movements reflect the need of spiritual and personal development of faith as can also be seen in the works of, for instance, the Cistercian Bernard of Clairvaux and the Dominican Meister Eckhart. In the United Kingdom (Ockham, Wycliffe) and in Bohemia (Jan Hus), similar movements arose a century later with the aim of reforming the Catholic Church. In their development these reformers, like the later Protestant leaders, the Augustinian monk Martin Luther, the lawyer John Calvin, and the pastor Huldrych Zwingli, stressed the difference between faith as the source of moral behavior and morality as a system of rules of conduct. They also preached soberness and poverty as a Christian lifestyle and were in conflict with the practice of indulgences as the partial or full remission of penance of sinful behavior. In this way the reformers reflect partly St. Augustine and his De Civitate Dei or City of God, stating that the Earthly City should be subordinated to it. For another part they rely on the rise of individual conscience and the strengthening of personal faith in moral matters. In this the reformers did not try to support or stimulate economical prosperity but instead denounced the striving for wealth. Sola fide, together with Sola Scriptura as the only source of the Word of God, can be considered as their offspring.

The work of St. Augustine has been influential on the rise of Protestantism in another sense as well. St. Augustine fiercely combated Pelagius who preached that human beings could perfectly perform good works on their own, without Divine Grace or intervention. In this Pelagius denied the doctrine of the original sin in which mankind is condemned by the sin of Adam. Pelagius proclaimed that free will is sufficient to fulfill the Divine Law and that man is capable to avoid sinning. St. Augustine defended according to Pelagius Manichaeism in his doctrine of the original sin and the Fall of Adam. St. Augustine, however, though a follower of Mani in his youth, had also denounced the fatalistic ways of belief of Manichaeism, in which the struggle between the spiritual world of Light and the material world of Darkness, Evil, has a main place. St. Augustine therefore defended both predestination as the belief that God is omniscient and eternal and the free will of human beings, who are created after the image of God and therefore can make decisions

without any cause forcing them. According to a strict interpretation of the doctrine of predestination, nothing happens, has happened, or will happen that is not willed by God at the moment of creation. This interpretation seems to leave no room for the personal free will. St. Augustine did however uphold the notion of free will but under the condition of the original sin. Therefore, mankind is able to strive for the good, but is dependent on Divine Grace in order to succeed. Moreover, predestination implies that God has elected already before the beginning of time those who will be saved by God's Grace. The tension between the doctrines of free will and predestination is therefore not altogether solved. Within Catholic theology the debate on free will returned especially between 1200 and 1400, in the works of St. Thomas, St. Bonaventura, and Duns Scotus. Gradually it was acknowledged that the good works of humans could be preparatory to salvation. Scotus argued against St. Augustine that humans are basically good and not sinful and that goodness can facilitate reconciliation with God. The Catholic Church developed more and more to recognition of free will as a ground for moral action and moral responsibility. The Protestant theologians of the sixteenth century radically broke with that development. Luther and even more Calvin claimed that only faith could be a starting point for salvation and not free will. Luther even denied free will in his early works. Above faith, Calvin also believed in the double doctrine of predestination, meaning that God in His omniscience did not only ordain the course of happenings in this world but in His Wisdom has also decided beforehand who will be saved and who will be eternally condemned. The room of personal free action is therefore very limited, and reconciliation of man with God is only dependent on Divine Grace (Sola Gratia). Opponents of the strict view on predestination and the limitation of free will were severely attacked by Calvin. Michael Servetus, for instance, a Spanish physician, inventor of the pulmonary circulation and pharmacologist, was first betrayed by Calvin to the Inquisition and then, when Servetus fled to Geneva, trialed and burned alive by orders of Calvin. Servetus was an outspoken opponent of the doctrine of predestination as well as the role of Divine Grace in Calvin's work. Another opponent, the Savoyard Sebastian Castellio, was banned from Geneva and considered as an instrument of the Devil. Castellio defended free will as the ground for moral respect and as a force to perform good works. In his acknowledgment of free will and the possibility to be good, he became a forerunner of the later Armenians and the Rotterdam philosopher Pierre Bayle.

The common restriction to three main reformers of Protestantism, Luther, Calvin, and Zwingli, has not only to do with their theological work, preaching, and writing. It has also to do with their ambitions as makers and managers of new religious entities and political strategies. Luther supported the German princes in their struggle with King Ferdinand and the Emperor Charles V, Calvin had his strong ambition to be the ruler of Geneva, and Zwingli supported the Swiss farmers in their struggle. On a bigger scale, Protestantism mainly broke through in countries which wanted to liberate themselves from the Habsburg dynasty and the authority of the Catholic Church. In the United Kingdom, the Anglican Church or Church of England was founded to enable Henry VIII to divorce and remarry. The King became the head of the Church of England. In the Netherlands, Protestantism played a major role in the

revolt against Spain, a revolt which started over a dispute about taxation. In France things turned out otherwise. Henry IV, leader of the French Huguenots, could only become king of France when he would return to the Catholic religion. France had already seen bitter and bloody fights between Catholics and Huguenots, and when he accepted his conversion to Catholicism, he allegedly spoke the famous words "Paris vaut bien une messe" (Paris is worth a mass).

The wars, fights, and political ambitions concomitant with the establishment of a recognized religion easily do forget that many forms of Protestantism are based on communality. Instead of the authority of the Pope and the Catholic Church as the organizing institution, Protestant Churches act as local communities with a council as its main authority. The strength of the communal organization has been especially clear in the movement of the Anabaptists and Baptists. The Anabaptist movement originated in Switzerland during the days of Zwingli. Zwingli, like Calvin and Luther, defended the baptism of infants, but one of his main followers became convinced that conversion and confession should give reason to rebaptize (Anabaptism). The movement associated itself partly with the Peasants' War (1523–1526) in Germany, led by the spiritual Thomas Müntzer. Müntzer, like Zwingli, stated that each human being could find his own way to heaven, without or within the church. He actively supported the farmers in their financial demands and their request of human rights. Luther however distanced himself from this worldly business and stated that he strived for a reformation of the church. Only later he notched with the demands of the princes. The belief of the Anabaptists that the human free will is sufficient to establish heaven on earth rapidly gained influence, and some of the Anabaptist leaders did not eschew violence to transform their beliefs into reality. Jan van Leiden started in this line of thinking a New Jerusalem in the German city Münster. The community lasted 1 year after which the radical Anabaptists were killed. Most of the Anabaptists however are known for their peacefulness, their willingness to share goods in the community, and their avoidance of governmental authority. After the expulsion from Zürich, they fled over Europe and tried to live a pure life and avoid earthly power in organized society. In this way they broke with the Catholic tradition which considered society as an organized Christian body. The Hutterites, the American Amish, and the Mennonites are examples of this communal way of life. In England the Puritan movement gave later birth to Baptist Churches. Baptists stand for the belief that the profession of faith should be prior to being baptized. It then signifies the purification of sin by God's Will. Like in case of the Anabaptists, the statement of personal faith is elementary for baptism as well as belonging to the community of believers. Because of their rejection of the sacrament of infant baptism, both Anabaptist and Baptist believers were prosecuted in Europe for many years. Many of the communities decided to emigrate from Europe to America. Both North and South America have active religious communities that sometimes go back for more than 400 years.

Within the further development of Protestantism, the communal life and the five S's hold their leading position. When Lutheranism led into dogmatic ruling within the German Churches, a new flow came up in the seventeenth century, called Pietism. Soon the movement was followed in the United Kingdom by the Methodist

movement, which was also inspired by the Dutch theologian Arminius who rejected the strong form of the double predestination. In the Netherlands the Calvinistic reform had chosen to follow another theologian, Gomarus, at the synod meeting of 1619. But soon after the meeting, a movement for further reformation started, mainly under the influence of the theologian Gisbertus Voetius. All these movements have in common the claim that the dogmatic rulings of the Protestant Churches and their political influence are considered imperfect and should be complemented by a morality and lifestyle in which the Bible, especially the New Testament, is followed as close as possible. Emphasis was thus given to the individual ethics of behavior and personal, methodological study of the Scripture. More radicalized movements took the communal life very seriously, and they started communities both in Europe, like Jean de Labadie, and in the Americas. German Mennonites (Anabaptists), for instance, established a village in Brazil's province Santa Catarina, called after the birthplace of Menno Simonsz, Witmarsum. Besides emphasis on a communal life (for instance, by calling themselves "Brethren"), on personal faith, and on the study of the Bible, many of the pious movements shared a sense of living in the End Time in which disasters occur and during which man should be prepared for the return of Christ. The Holy Spirit is also active in this period of time which led in the nineteenth century to Pentecostal Churches following Methodist and Baptist beliefs in the purification of all sin, through the gift of the Holy Spirit. Individual belief is brought in these churches to its maximum, together with the belief in Divine Presence and the restoration of Christianity in its pure way. Jehovah's Witnesses came, for instance, out of the nineteenth-century pious thinking, stating that the End Time has come and rejecting many aspects of Catholic and Protestant belief, because of their willingness to adjust to former gentile concepts such as the immortality of the soul. The communal tradition again is very strong in their organization. As such the developments in the seventeenth towards the twenty-first century can be seen as stressing the faith of the individual together with a strong commitment to the life in the community.

Protestant Ethic and Morality

From the need, already felt in the early seventeenth century, to restore the original intentions of the Reformation and to develop a pious lifestyle and strict morality, it may be concluded that the mainstream of the Protestant Churches adopted general rules in accordance with the politics of the region, state, or country. Economical factors, like the freedom to trade in the Netherlands and in the German harbors like Bremen, or the ownership of land in North America; political ideas like those of Benjamin Franklin; and social demographic factors and differences, like those between the Latin and francophone languages and the Saxon and Celtic languages, helped to shape Protestant ethic and morality. Differences in perspective with respect to the original sin, predestination, the freedom of the will, and the possibility to reconcile or even reunite oneself with the Divine Presence furthermore differentiated the moral perspectives in personal behavior. Nowadays a large

variety of moral views coexist in Protestantism and it is hard to summon some common key views. The belief in the Divine Trinity, for instance, has been rejected, not only by Servetus or the Cathars but also by churches ranging from the Unitarian Churches to streams of Pentecostal religion and Jehovah's Witnesses. Servetus was executed by Calvin, Isaac Newton had to keep his Unitarian beliefs for himself, Charles Darwin was raised as a nonconformist Unitarian, and Swedenborg influenced both Charles Sanders Peirce and William James with his views. The dispute on the theory of evolution and Divine creation has roots in a long tradition of divergent Protestant views on man and nature in relation with Divine Governance. Some issues seem however to give a common ground to the diversity and they will be discussed here.

Individuality. Protestantism arose together with the growing conscience of citizens and farmers that they could act morally based on their freedom. Personal responsibility cannot be evaded nor traded against indulgences or payments to the church. Although the freedom of the will is counteracted by the doctrine of predestination, Protestantism as such recognizes the freedom of the will in matters of ethics and morality. Mankind has the choice to decide between good and evil. Differences have to do with the question whether or not mankind is able to overcome the original sin with or without Divine Grace or by accepting Christ's sacrifice.

The brokenness of nature. In contrast to the Catholic Church, nature is considered to be broken since the Fall of Adam. Even when the doctrine of original sin is rejected, one has to see that nature is not good in itself. Differences have to do with the possibility to overcome the brokenness. Mankind has the task to preserve the partial goodness of nature and to repair it when possible. Within disputes about genetic modification or the use of stem cells, the issue of how far mankind has the task of being a cocreator plays an important role.

Communalities. Protestants belong to churches which form the core of their communities. These communities can be highly organized, like in Calvinism, but can also take looser forms like in brotherhoods. Participation in the community is more important than citizenship or belonging to a state. The separation between the church and state is prepared and stimulated by many forms of Protestantism, but not by all. Especially in pious and Calvinistic circles, a theocratic conception of the state, implying that the rules of Christianity should be the starting point of legal thinking, still survives. One should not forget that both Calvin and Luther studied law before becoming reformers.

Salvation. In moral matters mankind should strive to do what is considered good and to avoid evil. This does however not imply that good works will be sufficient to be saved. In ethics there is no final reward given in the afterlife. Only Divine Grace can save man, and differences continue to exist on the question whether reconciliation with God can be reached in earthly life.

Health, disease, and death. It is man's task to preserve health as much as possible. Disease and death signify the brokenness of nature after Adam's Fall. Within Protestantism it is a matter of dispute how far preventive measures based on medicine can go. Some Calvinistic Churches hold, for instance, that mankind has to

accept what has been ordained by God's Will. Vaccination is therefore rejected as an inacceptable means to avoid predestined fate. Others stimulate medicine as a means to restore the original goodness of nature and as a task given to mankind. Healing is however not always considered as a result of medicine and scientific human thinking. In many churches miracles are still accepted as well as the powers of prayer and devotion. Healing then means a form of reconciliation with God's Will. If one believes that the brokenness of nature cannot be overcome by human deeds, then it follows that every healing in the end is the effect of Divine Grace.

Abortion. Whether or abortion can be allowed at all, or in some circumstances, has been a recent dispute in Protestantism. Especially the more pious types of Calvinism, Lutheranism, and the churches that arose from the Methodist and Baptist movements reject abortion in any case. The churches that adjusted themselves to the changing political and social environment tend to accept abortion in some circumstances, making the pregnant woman responsible for her own life and body. In general Protestant morality has mostly considered birth as the moment in which a new fellow human being comes into existence, instead of the moment of fertilization.

Suicide, euthanasia, and physician-assisted suicide. Suicide has always been condemned by Protestants, but opposite to the Catholic views, the act of suicide does not imply eternal condemnation. After all, Divine Grace will decide who will be accepted or rejected after death. Martyrs in ancient times as well as those who fell in the hands of the Inquisition in later times are revered, even when they consciously risked their lives for the sake of their religious views. Physician-assisted suicide and euthanasia are accepted by some churches but rejected by many others. The dispute has to do with the freedom of the will to end one's life, when one sees no future left than unbearable suffering while human means are exhausted and also with the belief that God may have reasons to let someone suffer which man cannot understand but should accept.

Health insurance. Insurances as such have always been a matter of dispute within Protestantism. Because of predestination and the reliance on the community, sailors and fishermen did not insure themselves. They relied on their community to take care of their relatives in case of accidents. Some churches still reject the idea of health insurance as a violation of their beliefs and the morality that follows from it. They consider charity as sufficient within the community to take care of every kind of disaster.

Protestantism and the UNESCO *Universal Declaration on Bioethics and Human Rights*

From the small overview of Protestantism above, it is possible to deduce the main points of concordance with the UNESCO Universal Declaration on Bioethics and Human Rights. The first ten articles of the declaration are in accordance with the recognition of personal, individual conscience and responsibility and with the communal aspects of Protestant religion and its emphasis on justice and being

equal in the eye of God. Several points of discussion are still there and need to be discussed in the Protestant communities. First, health and disease are not simply the result of human and scientific endeavor. They can also be considered by communities as being given by God's command and therefore need to be accepted by the individual. That requires a balance to be settled between what is considered God's command on the one hand and human rights and freedom of research on the other. The declaration takes the latter as fundamental, while in many branches of Protestantism, human rights and the freedom of research are not taken to be fundamental but subjected to the Divine Law. Limits that follow from the Divine Law have to be respected, and although human beings are created in the image of God, their capacity to repair and cocreate will always be subjected to the brokenness of nature that follows from the original sin. Prudence in the progress of science and moral consideration of the goals of scientific endeavor are therefore constantly needed to avoid human hubris or recklessness. Death and disease are considered to be unavoidable and need to be accepted as part of the imperfectness of this world. Discussion of these matters in the international community could very well take place with other Christian Churches, like the Catholic and the Orthodox Church, but also in dialogue with Judaism and Islam. Within those religions the discussion on how the Divine Law limits human rights and the freedom of research also has been a fundamental debate over the centuries with similar but also dissimilar outcomes.

Second, respect for autonomy as the expression of the responsibility of the individual before God is mostly related to the demands of the community. "Love thy neighbor" is considered to be a rule that trumps autonomy in many ways. The declaration asks for human solidarity in this regard, but the communal dimension of Protestantism on the one hand does not simply endorse a system of healthcare insurance, while it on the other hand commands that one should help those who are in need without any restraint. The diakonia, or diaconate, has always had an important place in Christian Religion and has been regarded in Protestantism in some of its branches as a more prominent religious way of dealing with the sick and the poor than a system of healthcare insurance which is based on reciprocity. Ultimately the perspective of how the religious community should relate itself to the secular authorities in nations and states is at stake when it comes to justice in healthcare.

Third, transnational practices are within Protestant communities not without dispute. Besides support given on the ground of charity, the conviction that everyone's destiny and salvation is either determined by God's Will or by the morality of the individual person has traditionally implied that missionary works should be supported, while on the other hand, a certain kind of indifference towards the fate of people with other religious beliefs has been expressed. A dialogue in which all religions can take part as the starting point of a global community in which people take care of the sick and the poor has been started in many places of the world after the Second World War, but as yet has not resulted in a commitment in which all different Protestant Churches are united.

Conclusion

Protestantism in its earliest forms has paved the way in many respects of the secular perspective of human rights and respect for personal autonomy. On the other hand it stresses the lack of human capacity to overcome the brokenness of nature and consequently warns for the hubris in scientific endeavor. The intertwinement of religion and secular authority or politics is expressed in the dominant place of the concept of the Divine Law that needs to be obeyed. Discussion on that concept and the perspective of human rights and freedom of research needs to be started with many of the Protestant Churches.

Taoism

27

Hong-wen Li

Introduction

Taoism (also Daoism) is a somewhat hybrid religion that is developed in close relationship with other spheres of Chinese culture. Its unique characteristics include the creative force of Tao, multiple heavens, and the potential of human transformation toward immortality. This makes it difficult to classify Taoism under a single framework. Taoism has never been a unified religion and has constantly consisted of a combination of teachings based on a variety of original revelations (Kohn, 1991).

From Shang dynasty (c. 1600–1028 B.C.E) documents and artifacts, Taoists have inherited its belief of ancestor worship and divination, its emphasis on the written language in ritual, and its hierarchical organization system into their religious beliefs and practices. The *Yijing* or *Book of Changes* is another important source of Taoism. As a divination manual, it plays a key role for the guidance and support in Taoist cosmological speculation and alchemy. In cosmology and alchemy, the eight trigrams show the directions and dimensions of the universe while the hexagrams signify subtle stages and times of cultivation (Kohn, 2009, p. 1–8).

Although Taoists do not share the doctrine of lifelong learning emphasized by Confucians – they are likely in favor of unlearning with the goal of a more natural state of mind *wu-wei* – they do agree with Confucians concerning the importance of cosmic harmony and social virtues. Confucianism focuses on ritual formality (*li*), sees society as hierarchically structured, and proposes a set of virtues that have imposed a great impact on Taoist communities and practice (Kohn, 2009, p. 14).

What Is Tao?

The basic principle of Taoism is, of course, Tao, which is normally regarded as beyond description and human perception and understanding – "the Tao that can be told is not the constant Tao" (Laozi, 2008, p. 1). But the manifestation of the Tao can be perceived.

The word "tao" is usually translated as "path," "way," "road," "method," or "principle." Basically, the nature of Tao has a twofold structure: the "eternal Tao," which is the mysterious and inaccessible Tao at the center of the cosmos, and "the Tao that can be told," which is at the periphery, visible and tangible in the natural and known world. As a philosophical concept, Tao is the most important idea in the philosophical Taoism (tao-chia) and religious Taoism (tao-jiao).

Tao as the Origin of Universe

In the cosmological sense, Tao is the origin of the universe, the basis of all existing things, the law governing their development and change, and the ultimate god of Taoism. Tao is fundamentally the void or nothingness yet encompassing everything. Right at the beginning of *Tao Te Ching*, Tao is defined as "the origin of Heaven and Earth" and "the mother of myriad of things." "Heaven and Earth" in Chinese means nature or the universe; "the myriad things" means all the beings in the world (Wang, 2010, p. 7). Tao is the creator and sustainer of everything in the Universe. It is described as follows: "There was something undefined and complete, coming into existence before Heaven and Earth. . ." (Laozi, 2008, p. 62). Hence, Tao is the origin of universe and the root of all things, which precedes God in time.

Tao as the Reality

Tao as ultimate reality is at times characterized as the origin and source of all things (Lai, 2008, p. 76). *Dao Te Ching* Chap. 1 suggests that *chang tao*, conceived of as the entirety of reality, is greater than the sum of its individual parts. This is a metaphysical understanding of the concept Tao. *Tao Te Ching* tells:

> The Tao gives birth to One. One gives birth to Two. Two gives birth to Three. Three gives birth to all things. (Laozi, 2008, p. 117)

The Tao has two essential aspects discriminated as *Wu* (Being-without form) and *You* (Being-within-form). The former is the state before Tao comes down to its actuality, which is invisible and abstract, while the latter is the state of Tao manifested in the things, which is visible and concrete. Wu and You are thus regarded as the two sides of one coin. They are dialectical and interdependent opposites, perhaps best understood as aspects of Tao. Wu and You are interdependent in the same way that reality and its manifestation are interdependent (Lai, 2008, p. 77).

Tao and De

The concept of Virtue (De) is closely related to Tao, both of which are served as the basis of Taoist doctrines. *Dao De Jing* relates, "All respect Tao yet value Virtue" (Laozi, 2008, p. 137). One common explanation of Virtue is that it is the specific manifestation of Tao in specific things. Taoists think Tao and Virtue as the general principles and guidelines for their beliefs and behavior. In practice, they both cultivate Tao but also cultivate Virtue. A set of principles for Taoist everyday action and behavior are derived from the Tao and Virtue. These principles include nonaction, nonpassion, nondesire, nonstruggle, and the pursuit of simplicity and truth.

Tao and Wu-wei

The Tao follows the way of naturalness, which means *wu-wei* in Taoist philosophy. Particularly, Tao is the model of conduct to be followed by the Taoist disciples, and it is linked with *wu-wei* (nonaction) and *wu* (empty, noting) in this respect. Taoists believe that without nonaction, nothing can be achieved. Nonaction is not a refusal to go against nature but rather an acceptance of nature's laws, which is to reasonably and effectively use the laws of nature. It is in line with nature rather than in contradiction with it (Zhao, 2010, p. 64–65).

Many people may misunderstand nonaction as a passive philosophy. The simplest interpretation of *wu-wei* is that it means doing nothing or as little as possible. This can be understood politically or metaphysically. However, *wu-wei* does not mean doing nothing but rather doing significant things, that is, *wei-wu-wei*. As Laozi says: "Do nothing and do everything" (Laozi, 2008, p. 90). In this sense, nonaction is the precondition of action. It demands the abandonment of the inferior but gaining the key. Leaving alone one thing, one can do other things. Doing nothing, one can be free from worry. Thus, nonaction is the secret to preserve one's health and keep inner happiness. If one is ignorant of nonaction, and works feverishly and blindly, one is like *Kuafu* chasing the sun, who died on the road because of exhaustion and thirst according to an ancient Chinese fable (Zhao, 2010, p. 66).

Philosophical Taoism and Religious Taoism

Taoism is deeply embedded in Chinese culture and has incorporated several important elements that are present in Chinese history even before the beginnings of Taoism. It forms an integral part of Chinese culture and contributed greatly to the cultural development. Basically, various cultural perceptions and religious practices were established and had an everlasting impact on Taoist philosophy, cosmology, ritual, and religious practices.

Philosophical Taoism

Philosophical Taoism is tao-chia (Daojia), which was a school of philosophy dated back to Laozi and Zhuangzi. Religious Taoism is tao-jiao (Daojiao), which is the traditional religion in China. The distinction between "philosophical Taoism" and "religious Taoism" is much like the distinction between contemplative Taoism and the kind of Taoism seen as "purposeful" and "practical" Taoism (Robinet, 1997, p. 3). In Western languages, "Taoism" encompasses the meanings of both tao-chia and tao-jiao. Even Chinese are confused about their differences. They often use the two terms interchangeably, which have different dimensions of meanings besides similarities and close relations to each other in the long history of Taoism.

Li Yangzheng discriminates Daojia and Daojiao clearly in the following aspects: (1) they differ in ultimate goals: the former aims to realize a spiritual transcendence for its followers, while the latter aims to immortalize by means of arts; (2) differ in the principle to follow: the former advocates nonaction, while the latter appeals to the divine agents; and (3) differ in the ways of demonstrating forms of existence: the former states felt the presence only in the intellectual world, while the latter through its clergy and popular arts (Li, 2009, p. 12).

Tao Te Ching (*Daode jing*) is the earliest and best-known text of philosophical Taoism, which is associated with the philosopher Laozi, who was a contemporary of Confucius and later divinized and grew into the Highest Lord Lao, a major deity of the Taoist religion still worshiped widely today. The book *Tao Te Ching*, a short text in about 5,000 Chinese characters, 81 chapters, has been translated almost into all the languages in the world. People found that it not only serves as a philosophy of life but also as a guidance in areas like economy, military affairs, science, politics, and even the stock market. *Tao Te Ching* is written in verse, a stylized prose that has strong parallels and regular patterns. It is a complicated and confusing riddle of philosophy.

The second major text of philosophical Taoism is the *Zhuangzi*, named after the philosopher Zhuangzi (c. 370–290 B.C.E.). The text *Zhuangzi* consists of 33 prose chapters that also contain materials from other early Taoist strands. The philosophy of Zhuangzi focuses on perfect happiness or free and easy wandering, the state of utmost spontaneity that is reached when one fully realizes one's inner nature and destiny as given by Tao and stops trying to evaluate and judge things or strive for unsuitable situations beyond one's reach. To achieve this mental state, one should detach from society and practice making all things equal, fasting the mind, and sitting in oblivion. The result will be a life that is perfected, unhindered by concepts, and completely at ease in the world, plus exceedingly skillful at all tasks (Kohn, 2009, p. 50).

Religious Taoism

Taoism is normally regarded as an indigenous traditional religion in China. It is generally accepted that Taoism organizations were established by Celestial Master

Zhang Daoling during the Eastern Han Dynasty 1,900 years ago. However, there is common reference to the Three Ancestors: the Yellow Emperor, Laozi, and Celestial Master Zhang. And the original Taoist doctrines can be dated back to Laozi in the Spring and Autumn Period (TAC, 2002, p. 7).

Ancient Taoists were enthusiastic alchemists, who attempted to produce immortality pills by smelting minerals such as aluminum and mercury. Early Taoists attached great importance to minerals, mainly lead, mercury, sulfur, gold, and silver, from which they believed elixirs could be made. They had hoped that these elixirs could free them from the terrors of death. Of course, no immortality pills were ever made. The experiments in alchemy, though irrational from a modern science perspective, greatly promoted advances in science and technology in ancient China, including the development of ancient chemistry and production of gunpowder. Their records of experiments became valuable documents in ancient Chinese chemistry.

Moreover, Taoism has made great a contribution to traditional Chinese medicine. A folk saying says, "Nine out of ten Taoists are doctors." Taoists' pursuit of longevity and health leads to many Taoists practicing in medicine. Some renowned senior Taoists, like *Ge Hong* in Jin Dynasty, *Tao Hongjing* in Southern and Northern Dynasty, and *Sun Simiao* in Tang Dynasty, were all well-known doctors and pharmacists.

Modern Taoism begins with the Song dynasty in the tenth century. Its main representatives are the ritual masters, unorganized by lay practitioners who perform various rituals and service for the people. As Chinese society is dominated more by the merchant and the educated elite, religious concerns shift toward exorcism, fortune-telling, and healing. One school is notably different in this period: Complete Perfection, founded by Wang Chongyang in 1170, is monastic, ascetic, and focused on personal self-cultivation. With the support by the government rulers and emperors, it becomes the second leading school of modern Taoism. In this sense, the fate and shape of Taoism is closely connected with the imperial court.

The fate of Taoism today is closely linked with politics. It was suppressed from the founding of the People's Republic of China, in 1949, until 1978. Since then it has made a major comeback but remains under tight control and administered through various government agencies. As Lai Chi-Tim has pointed out, modernization, antireligious policies, and government officials' misunderstanding of Daoism still present a great challenge to the survival of this indigenous religious tradition in China (Chi-Tim, 2003). People choose the Taoist life for different reasons: to take refuge from civilian life, do community service, rise in the official hierarchy, become a hermit, or establish a Taoist-based business (Kohn, 2009, p. 188).

In the course of long history, Taoism has been transmitted and adapted beyond China. Especially Taoist thought and long life practices have spread in several East Asian countries, notably Korea, Japan, and Vietnam. In the West, the *Tao Te Ching* is widely known, and people gain benefits from its concepts of nonaction, softness, and naturalness. Taoist health practices, typically taiji quan and qigong, are becoming popular in the West.

Basic Beliefs of Taoism

The ideological system of Taoism is said to be complicated to cover a wide range of contents. Generally speaking, it evolved into a religious culture based on three main original resources: the worship of heaven and ancestors, Taoist theories and beliefs regarding immortality, and ethical Confucianism and folk religious customs. So Taoism as a religion is strictly different from Taoism as philosophy. The latter is only beheld as a resource of the Taoist doctrine.

Deities and immortals, as models of achieving Tao, are worshiped by followers of Taoism. Tao gathers to form the Three Purities, that is, the Celestial Worthy of Primordial Beginning or Jade Purity, the Celestial Worthy of Numinous Treasure or Highest Purity, and the Celestial Worthy of the Way and its Virtue or Supreme Purity. Below the Three Purities, the emanations of Tao are a mass of deities such as the Jade Emperor, the Four Heavenly Emperors and the Five Emperors of the Five Directions, and immortals who humans can become through self-cultivation (TAC, 2002, p. 12).

Taoists believe deities and immortals dwell in the sacred mountains, which provide tranquil environment for their self-cultivation. Early Taoist priests mostly lived on sacred mountains. Later, some Taoist priests accepted appointments at the imperial court at the orders of the emperors and lived in temples built for them in cities. With the development and flourishing of Taoism, many large sites of Taoist activity were built in sacred mountains and cities, some of which are called "palaces" because of their palatial dimensions (TAC, 2002, p. 78).

Taoist priests gather together for morning and evening prayers each day. They hold prayer rituals to give blessings on the birthdays of deities and conduct rituals to expiate the sins of the dead. Such rituals can also be held at the request of followers. They also hold large-scale rituals, such as Grand Universe Ceremony, to pray for prosperity and peace in the nation, good weather for crops, and world peace. Besides these, Taoist priests are mainly engaged in self-cultivation (TAC, 2002, p. 30).

The Taoist Body

Basically, Taoism does not share the idea of the Western philosophical dualism of body and mind. Rather, it is a theory that takes life to be the unity of body and spirit. J.W. Freiberg's in-depth analysis provides a reconstruction of Taoist notions of spirit, ontology and consciousness by the archaeological method (Freiberg, 1975).

Physical Immortality of Body

The highest ideal of Taoism is to acquire immortality. To achieve this goal, one must practice Taoism both inside and outside one's physical existence. Inner practice involves physical and breathing exercise, concentrated contemplation,

and the taking of elixirs. Later, this type of practice gradually came down to refining the interior elixirs (*neidan*). The basic principle of this practice is to cultivate the self both spiritually and physically. External practice involves doing good deeds and helping others so as to acquire more merit and virtue. If one succeeds in both aspects, one could enter into the world of immortals (TAC, 2002, p. 9). Immortals are similar to magical practitioners, but the latter use their skills in service for society and may or may not eventually ascend to the paradises. Many immortals' tales recount stories of their wondrous feats.

It is commonly believed that extrication from the predicament of the worldly worries is the fundamental concern of every religion, and there is no exception for Taoism. As Qiang Yu pointed out, what makes the difference is that, while other religions appeal to afterlife for the realization of the ideal life, Taoism cares about how human beings can live forever and never die and how freedom and extrication can be achieved in one's life time (Yu, 2006, p. 134).

The Taoist belief of immortality of human beings reflects an ontological existence paradox: pursuing infiniteness in a finite life. The eternal life was attained in one of two modes: as an ecstatic going-along with the transformations of the universe or as an ecstatic union with the Tao. The belief of physical immortality of body demonstrates that the meaning and value of human beings lie in the release of potentiality of individual life and the accumulation of energy equaling that of the Heaven and Earth. Only in this way can the timely finiteness of an individual be surpassed and freedom be achieved.

Body and Qi

Taoists believe that the body is Dao in its concrete, manifest, and individual form, made up of *qi*, the cosmic vital energy that pervades all (Kohn, 2009, p. 52). Qi is the material force of universe and the basic stuff of nature. In ancient sources, it is associated with mist, fog, and moving clouds. It is contained in the food one eats and the air one breathes.

But basically, *qi* is the life force in the human body and as such forms the basis of physical vitality. Without *qi*, one cannot survive. As Zhuangzi said: "Human life is the accumulation of *qi*; death is its dispersal" (Chen, 2007, p. 524). Qi animates life and furnishes the functional power of events; its quality and movement determine human health. Everyone receives a certain amount of *qi* from the nature. If he uses out all of it, then he will die.

It is natural that everyone needs to survive and keep healthy through *qi* cultivation. In order to do so, one needs to draw *qi* into his body from air and food, as well as from other people through sexual, emotional, and social interaction. One can get ill if he breathes bad air, overburden his body with food and drink, get involved in negative emotions, or engage in excessive sexual or social interactions.

The basic ideal of *qi* cultivation is to create harmony in the body and keep a balanced state of being in the person. If one achieves this proper state in the body and person, then he keeps the upright *qi* (*zhengqi*), which without moral sense is

quite different from the basic idea of *zhengzi* conceived by Confucians. This harmonious state is matched by health in body, defined as no illness; health in nature, defined as regular weather patterns; and health in society in the peaceful coexistence among families, clans, villages, and states. In the same token, perfection of *qi* means its optimal functioning in the body.

The opposite of this balanced state is wayward *qi* (*xieqi*), also called deviant, pathogenic, or even evil *qi*. Whereas upright *qi* moves in a regular, steady, and harmonious rhythm, benefiting health and long life, wayward *qi* is disorderly and dysfunctional, violating the normal order of the nature and human body existence and creating harm to human body and person. In this sense, wayward *qi* loses the balanced pattern of flow and cannot keep the normal dynamic forces of change. Wayward *qi* appears when *qi* moves either too fast or too slow or becomes excessive or depleted. This can happen either out of outside influences such as too hot or too cold or internal irregularities such as strong emotions or anxiety (Kohn, 2009, p. 53–54).

The Honor of Death

Taoism believes that the Heaven and the Earth are everlasting, but life is accidental and death is certain. Life is transitory, but the universe is endless. In this sense, Laozi said that Heaven and Earth are ruthless. Life floats briefly in the limitlessness of space and time, just as Zhuangzi said: "if you use what is limit to pursue what has no limit, you will find yourself in danger" (Chen, 2007, p. 113). So, life is temporary and accidental, and death is eternal and certain. It is a natural transformation from life to death. Death means a return to the eternal world. It seems that death does not amount to much, so the Taoist attitude to death is to be indifferent to it.

Zhuangzi showed a deep contempt for death. There was an interesting story about Zhuangzi's philosophy of death. When his wife died, he sang songs and played drums on a basin. He celebrated her return to nature, while most people think death as the end of individual existence seems tragic. His reason was that human body as the form of *qi* is the demonstration of Tao, and the death of body is the constantly changing of forms of Tao. Indeed, one does not necessarily mourn on the death but should willingly, actively, and joyfully participate in this change.

It is not right to make a conclusion that this reflects a negative attitude to life by Zhuangzi, who is neither an optimist nor a pessimist and thinks of joy and sorrows as alternating and inseparable like day and night or birth and death (Zhuangzi, 2001, p. 23). According to Zhuangzi, the liberation from selfhood is seen above all as a triumph over death, grasping the Way/Tao through accepting one's dissolution as part of the universal process of transformation without horror of physical decomposition and mortality.

Death cannot be avoided. Then it is better to regard death as normal and matter of necessity. Only in this way, one can keep a peaceful mind and not worry about death too much. If death comes, it is no use mourning, and it is better to follow the nature and keep calm. Laozi knew that misfortune and happiness as a unity of two

opposites: "Happiness is where misfortune lies lurking; misfortune is what happiness depends on" (Laozi, 2008, p. 151).

In Taoism, death is but one stage in the transformation of life. While the Indians abhor such endless transformations and invented ways of release from the cycle of rebirth, Zhuangzi says: "What incalculable joy this is!" (Chen, 2007, p. 519). The Taoist so identifies himself with the transformative aspect of Nature that, notwithstanding the pains and sufferings, he regards life as joy, freedom, and spontaneity. In the celebration of the transformative life of the Mother, death exists no more, and it is swallowed up by life (Chen, 1974).

Self-cultivation and Religious Practices

Taoism believes that one can achieve immortality through self-cultivation. It is easy to get confused that there is seemly a tension between religious Taoist attitude to death, enthusiastically pursing immortality and longevity, and that of philosophers as Zhuangzi, seeing death as a natural process neither optimistically nor pessimistically. The tension makes it right to distinguish philosophical Taoism and religious Taoism.

The Taoists created many methods of self-cultivation, such as sitting motionless, concentrating the mind, promoting the flow of *qi*, breathing, combining of controlled breathing and physical exercises, and practicing martial arts (*gongfu*). Most traditional Chinese methods of health preservation and promotion, including *qigong*, martial arts, and traditional Chinese medicine, have close links with Taoism. It is said that *taijiquan* (Chinese shadow boxing) was invented by Zhang Sanfeng, a Taoist priest of Mount Wudang.

Nourishing *qi*, or *qi* cultivation, refers to a kind of state of self-preservation and relaxation, using the *qi* to achieve a harmonious communication between spirit and body. The control of *qi* means the power to guide the energetic process to one or the other part. Laozi said: "Can you control your mind so that it never strays from the way of Tao? Can you control your breathing so that it is soft and gentle like a newborn babe? Can you cleanse your inner vision until you see noting but the light?" (Laozi, 2008, p. 22–23). Some scholars interpret these quotations as "three steps of nourishing *qi*" (Zhao, 2010, p. 103).

The earliest documented form of *qi* cultivation is guiding it through the body in a combination of deep breathing and visualization. Described also in inward training, it allows people to come closer to Tao and create harmony in and around themselves. Healing exercises are the physical component of Taoist body cultivation, which serve to heal diseases, enhance vitality, and create a sense of connection to Tao. All these practices can lead to a state of ultimate transcendence, called immorality. Immortals overcome natural patterns, live forever, move freely through Heaven and Earth, and execute various magical feats (Kohn, 2009, p. 64).

Taoist religious practice includes meditation and ritual. They both require a period of purification, a strong self-control, a healthy body, good mental focus, and visualization practice. Meditation involves various methods of concentration, such as quietist simplicity and inward training; certain types of observation or

insight, such as sitting in oblivion and inner observation; and some forms of visualization, such as nourishing the inner organs, actualizing the gods and engaging in relations with divine beings. Taoist rituals may be sponsored by the state, a temple, a community, or a family, in each case serving a specific purpose. In the ritual, the Master, assisted by other helpers, invites the gods to participate with petitions for good fortune, and creates a level of harmony.

Taoists believe that, through the adjustment of an individual's inner energy or the complement of the outer material elements, one can restore damage to the initial inherent harmony caused in the course of perception and practice and can regain a rebirth and become "the absolute" that never fades (Yu, 2006, p. 136).

Taoist Bioethics

A New Perspective for Bioethics

It is declared that one lives in the face of robust moral pluralism with profound and at times angry disagreements in the form of conflicting metaphysical accounts. Many once coherent traditional accounts have fragmented, if not fallen into incoherence. One confronts the postmodernity of numerous competing accounts, with a loss of focus within once-dominating accounts. It appears that controversies among irresolvable moral and metaphysical views define the human condition. Different traditional and competing accounts are different genres of perspectives, with incommensurable paradigms, life worlds, and thought styles. The deep disputes and disagreements among moral and metaphysical strangers are said to be the stuff of the culture wars (Engelhardt, 2007).

With a strong sense of a need to respond to the moral pluralism, many people, who regard traditional accounts as intact and coherent, attempt to extend or recover the vigor of traditional accounts often rooted in religious commitments with deep metaphysical explanations. The traditionalist way of response to moral pluralism and cultural diversity is a disposition to a cultural counterrevolution. Traditionalists attempt to criticize and even reform the modern liberal lifestyle and values – free choice and autonomy – which are deemed as the core ideas of bioethics discourse.

Taoist bioethics, thus coined, is a new perspective beyond Confucian bioethics, Christian bioethics, Islamic bioethics, and any other competing theory of bioethics. Taoism, as a philosophical school and a religious belief system, has its cultural identity and position in the long history of Chinese philosophy and religion. Actually, this traditional way of thought has many implications for bioethical issues, for example, a naturalistic way of life and harmony of body and mind.

Criticism of the Principle of Autonomy

The dominant modern North American and Western European models of bioethics are radically criticized by Confucian bioethicists who claim that these models

regard individuals as ideally atomic persons to make decisions themselves autonomously, ignoring the deeply family-centered character of social reality that is appreciated by Confucianism (Fan, 2007). While it is right to claim that Confucianism as a Chinese philosophical school is at odds with the take-for-granted principle of autonomy, it is short-sighted to take Confucianism as the only cultural pattern in China to resist the Western bioethical values. Needless to say, Taoism with Confucianism and Buddhism stands at the center of Chinese culture, always shaping the Chinese lifestyle and thought style. Thus, it is necessary to identify the Taoist bioethical thought concerning the principle of autonomy, confirming its cultural identity in this period of moral pluralism.

Specifically, Zhuangzi's intrinsic idea of freedom is comparatively different from the principle of respect for autonomy. This difference demonstrates that the principle of respect for autonomy is based on individual subjectivity and consciousness, while Zhuangzi's idea of freedom aims to dissolve them by the way of losing self (Li, 2008). Zhuangzi demands human beings go back to the inner mind and heart, where the true freedom lies in. As one knows, the principle of autonomy basically derives from the Kantian deontology theory that defends freedom, reason and dignity of human being. According to Kant, moral responsibility originates from practical reason rather than from God or authority. The autonomy of free will is self-legislation of reason.

Unlike Immanuel Kant, Zhuangzi does not pursue subjectivity based on pure reason and practical reason. He claims freedom of human life, which means freedom of physical body and mind, through dissolution of individual subjectivity rather than the Kantian way of pursing freedom, which means practical reason of free will. In a word, Zhuangzi insists on the unity of body and mind through the practice of Tao: losing self. This is totally different from the Western way of dualism: the separation of body and mind. Therefore, Taoism, Zhuangzi as its representative, objects to the principle of autonomy that is popular among academics (Beauchamp & Childress, 2001).

Core Values and Basic Ideas

Taoism as a traditional Chinese philosophy and religion does not have any close relationship with global bioethics principles which is made in the context of modern ideology. However, Taoism as a cultural background does have effects on Chinese practice and application of global bioethics principles. In the UNESCO Universal Declaration on Bioethics and Human Rights, a set of global bioethics principles are declared to be respected: human dignity and human rights, autonomy and individual responsibility, respect for human vulnerability and personal integrity, privacy and confidentiality, equality, justice and equity, respect for cultural diversity and pluralism, solidarity and cooperation, etc. These principles are what modern people think about human life and human health practice. Although Taoism has a different model with these ideas, it is quite reasonable to think that Taoism has a basic philosophy of respect for human life from the perspective of naturalism.

Taoist ethics focus on the creation of harmony within the community and the larger universe. All Taoist activities are closely connected to Heaven and Earth, who signal their disapproval through disasters, personal misfortunes, sickness, and harm. Thus, Taoism advocates the Tao's way in accordance with the law of Nature, with the core value of harmonious coexistence between human and nature.

In order to live properly in the Tao, Taoists have to realize that all beings are an integral part of the whole nature and universe, which functions in accordance with Tao and thus is fundamentally good. The universe, with the force of Tao, manifests a perfect goodness of cosmos – goodness can be learned by human beings as a guideline to reach well-being and inner harmony in moral and social rules. The goodness, once realized, is the ultimate goal for Taoists to purse Tao.

Thus, Taoist rules and community structures as social life are basically set to serve the individuals to realize the perfect goodness – universal connectedness with Tao. Taoists get to know that while the universe is essentially perfect, single beings can be involved in this process to a certain degree. Ideal Taoists have realized their inner nature to the peaceful and harmonious state, with the body and mind spread by the purity of Tao. On the contrary, people living in conflict and trouble cannot realize their true potential and inherent harmony, resulting in disharmony and immoral and harmful actions which are at odds with Tao and the nature of Heaven and Earth.

Take Taoists' food as an example. The monastic food is usually vegetarian. The food should neither be too hot nor too cold, too spicy or too bland, nor should it contain any harmful stuff. It aims to harmonize the body, supporting health and long life. Besides, every taking of food is conducted with a special ritual of sharing it with all beings, from the gods above to the demons below, from the emperor to all people on earth.

Another good example concerns alcohol and sex in daily life. In order to become immortals, Taoist monastics had rules against intoxication and sexual behavior. Both could impede the flow of energy in the person and harm Heaven and Earth. Alcohol is blamed for offensive behavior, rule violations, causing accidents, and getting lost on the road. It is best to stay away from wine completely and create one's own inner liquor from *qi*. Sexual activity is forbidden for Taoist monastics because it will cause harm to human body and reduction of *qi*.

In a word, Taoists are required to keep in mind the harmony and benefit of the cosmos, avoiding all activities that could cause disturbance among personal life, families, villages, country, and state. The goal of Taoist religious life is the universal vision of harmony in the world.

The Value of Life and Universal Love

Taoism has been emphasizing the value of life since it was founded. For Taoists, true and full love means the acceptance and rejoicing in whatever life brings. This philosophy is held by Zhuangzi who celebrates life in all its transformations – every

form of life, long lived or short lived, ugly or beautiful, all receive affirmation. A true Taoist willingly submits himself to the process of change, letting Mother Earth take him back to Her womb.

Being a true Taoist, one should integrate and sublimate his personal love for wife, mother, and friend in the transpersonal love for life, Nature, and all transformations (Chen, 1974). If death is merely one stage of life's endless transformations, the loved ones have not been lost to a person. In this sense, the love of Tao – the unchanging way of life – is universal love, which transcends selfish love for the average person in everyday life.

Ziran and Naturalist Life

The Taoist ethical system derived from the conception of ziran, which is often translated "nature" to designate entities in the natural world and the relations between them. The natural way of ethical response corresponding to a world of ziran is wuwei: noninterference, or letting things be. Noninterference has many significant ethical implications, including an avoidance of inflexible, absolutist ideals and unilateral and dictatorial methodologies. Ziran-wuwei describes an ethical framework that is grounded in respect for individual spontaneity, regarding the practice of ziran-wuwei as natural to humanity and therefore comes as the natural essence of human being (Lai, 2008, p. 107). In this sense, ziran is identified by some scholars as the core value of Taoist ethics, in which interpersonal relationships are characterized by naturalness and peace (Liu, 1999).

With regard to the relationship between human beings and nature, Taoism advocates respect for nature and follow nature to lead a naturalist life. "People conform to the earth. The earth conforms to heaven. Heaven conforms to the Tao. The Tao conforms to its own nature" (Laozi, 2008, p. 64). Taoists pursue a natural life, a calm psychology, a pure style, and a simple life. A calm mood can promote health, longevity, and prosperity. The naturalistic Taoist attitude toward life includes the following aspects.

First, imitate nature. Life lies in movement. But the movement is at best exercised at a uniform speed as stillness and nonaction. Taiji shadow boxing (tai ji quan) is a good example. Second, eat and drink naturally. Light food, such as beans, vegetables, and fruits, is marvelous for one's health. Third, merge into nature. "People conform to earth." This requires that one returns to a state of being a son of the Earth, breathing fresh air, swimming in the sea, visiting a forest, and living on a high mountain. Fourth, think naturally. A healthy body is dependent on a healthy mind. Open-minded people are healthy. Thinking naturally can lead to a peaceful and happy life. Fifth, understand nature. "Empty your mind of all thoughts. Let your heart be at peace. Watch the turmoil of beings, but contemplate their return. . . Immersed in the wonder of the Tao, you can deal with whatever life brings you, and when death comes, you are ready" (Laozi, 2008, p. 35–36). In a word, the best way of life is follow nature (Zhao, 2010, pp. 119–122).

Taoist Attitude to Technology

One lives in a time when technology has profoundly influenced every sphere of one's life and fundamentally changed the quality of one's body, existence, and modes of behavior. It is widely recognized that bioethics is such a research discipline that aims to make an ethical response to the issues arising in the application of modern biotechnology to medicine. Thus, the attitude to technology, broadly speaking, shapes bioethicists' answers to the ethical problems concerning with biotechnology use. And it was claimed that Asian countries and regions have shown a somewhat different pattern of response to such biomedical innovations (Lee & Ho, 2007). Though Taoism is almost overlooked by bioethicists to discuss the related bioethical issue, it is one of cultural pattern behind the dynamics of such responses.

Zhuangzi, as a Taoist philosopher, has come up with a very enlightening philosophical idea about technology: Technology is the demonstration of Tao. His concept of technology demands that the development of technology conform to the essence of Tao. Undoubtedly, the technological activities should aim for truth, but what is more important is the seeking for Tao. The fact that Zhuangzi examined technology within the framework of Tao is actually a representation of an outlook on value and ethics, which has a deep influence over the development of technology in ancient China (Zhang & Wang, 2004).

It is claimed that the major danger issuing from a rapidly globalizing biotechnology lies in the relation of medicine to human nature. Stephen Erickson worries that human beings are very much *in*, but they are not altogether *of* the world. The biotechnology model of medicine colonizes all aspects of human nature, reaching the capacity to manufacture specifically designed individual human nature. Moreover, biogenetic engineering will further encourage tendencies toward depersonalization with the high values of productivity and efficiency. The economic lenses of biotechnology industry rationalistically drive the world and reinforce the domination of technology, while human beings are marginalized in this process. It is likely that the metaphysical dimension human nature will be erased and replaced (Erickson, 2007).

Taoist philosophy criticizes the alienation of human nature, which is caused by overuse of technology including biotechnology in medicine. From Zhuangzi's philosophy of technology, it is natural to indicate that the strong intervention to human body and life by modern biomedicine violates the basic principle of Tao: *ziran-wuwei*. At the same time, the overuse of biotechnology in medicine has gone against the basic bioethical principle of nonmaleficence, which is said to be one of four basic principles of bioethics.

Conclusion

The construction of Taoist bioethics is an academic endeavor to respond to the cultural diversity that shapes bioethical thoughts and clinical practitioners and an

attempt to define a Chinese cultural identity in the process of globalization of global bioethics. Bioethics has been developed in a cultural diversity background since it was introduced to China in the 1980s. Any efforts aiming to construct and reconstruct a model of global bioethics should not overlook the great impact of Taoism on Chinese lifestyle and thought style that shapes the basic ideology shared by Chinese on bioethical issues.

Section V

Specific Issues from a Global Perspective

Bioethics Education

28

Henk A. M. J. ten Have

Introduction

Bioethics is the discipline that is focusing on ethical issues in medicine, health care, and associated technologies (see ▶ Chap. 1 on "Global Bioethics" in this handbook). Today, it is taught in many countries around the world. Everyone is nowadays confronted with moral questions concerning disease, disability, dying, and suffering. Doctors and nurses need to know about these ethical issues and how to respond sensibly and with compassion to questions and worries patients might have. Ethics teaching is, therefore, required by every medical school in countries such as the United States, the United Kingdom, and Bulgaria. This is not the case in many other countries where ethics teaching is either nonexistent or grossly deficient. Also, the quality of the teaching can be very different.

Several years ago, the author visited a medical school in Côte d'Ivoire. An enthusiastic colleague was teaching medical students a course on patient's rights. The general rationale for the course was that people need to be informed about their health condition, they need to give permission if they are treated, and they can refuse to be included in a research project. This is true for developed countries and equally true in developing countries. The circumstances for the course were awful. Students were cramped into a small room without furniture and glass in the windows; educational equipment was lacking as well as electricity, let alone internet connection. The teacher was standing in front of an antiquated whiteboard that had lost its utility long ago. While the temperature was tropical and humid, students recognized the importance of the subject: these are basic democratic rights of citizens and they seemed eager to learn about it. Somewhat later and in similar circumstances, the author observed a course in Senegal. A medical doctor in a white uniform was reading a text about medical secrecy. The students had no possibility to make notes (no space, no chairs), books were too expensive, and computers unavailable. The reading was dull and did not seem to inspire many students. In Togo, another colleague tried – unsuccessfully – to convince the dean of the

science department that bioethics nowadays is an important discipline and that it should be taught in the university. Similar experiences can be obtained in many other countries. Bioethics education is extremely diverse; its significance is often, but not always, acknowledged but its implementation varies enormously.

In this chapter, the focus will be first on how and why bioethics education has developed rapidly in the last five decades. Nowadays, bioethics teaching is practiced in many settings and there is a plethora of publications on this subject. The second section will discuss the ongoing issues and controversies in bioethics education. Due to its relatively recent history, bioethics education is still lacking a solid body of experience and is facing many challenges. These challenges become particularly evident when the focus is on the global perspective, which is the purpose of the third section of this chapter. International organizations such as UNESCO are increasingly interested in promoting bioethics education at an international level. International cooperation and exchange of experiences can contribute to solving some of the quandaries of bioethics education, as will be argued in the fourth section, focusing on the problems of implementing and improving education in bioethics as well as the various modalities to address and ameliorate these problems. The final section of this chapter will conclude with reflections on education in general. Education has always been a major concern of philosophers, and present-day bioethics education should take these philosophical concerns into account.

The Development of Bioethics Education

The emergence of bioethics in the 1970s was immediately associated with growing interest in ethics education. The medical curriculum in many countries was the first to introduce professional ethics teaching. This was unavoidable since the revolutionary changes in medical science and technology after World War II as well as the innovations in diagnosis and treatment significantly impacted medical education; the new moral quandaries of these changes could not be ignored in professional education. In the early 1970s, there was a rapid growth of ethics teaching programs in the United States. In 1972, ethics teaching programs could be identified in 12 medical schools, growing to 95 in 1976 and 114 in 1980 (out of 125 existing schools) (Pellegrino & McElhinney, 1982). In these efforts, more than 1,000 faculty members have been involved. This situation has been stabilized since 30 years (Eckles, Meslin, Gaffney, & Helft, 2005; Goldie, 2000). In order to be certified, all medical schools are now required to include bioethics in their curricula (Persad, Elder, Sedig, Flores, & Emanuel, 2008). It is clear that in other countries, developments followed later but with a similar pattern of dissemination and institutionalization. In the 1980s, bioethics education expanded in Western Europe. Before that time, there was no formal medical ethics teaching, although in some (particularly Mediterranean) European countries, medical ethics was already taught in incidental courses in "medical deontology" (emphasizing the duties of medical doctors), often in connection to law, forensic medicine, or history of medicine.

In the United Kingdom, recommendations to develop medical ethics teaching were only launched by professional bodies (General Medical Council, British Medical Association, and Institute of Medicine) in the mid-1980s. In 1993, the General Medical Council made bioethics a core subject in the UK medical curriculum, and ethics teaching has now an accepted place in the medical curriculum (Mattick & Bligh, 2006a). In the Netherlands, although the first chair of medical ethics had been established in 1974, it took almost two decades before all medical schools had introduced ethics courses in their curriculum (Ten Have, 1995). In the Nordic countries, formal courses in ethics were introduced in medical curricula in the 1980s (Nordic Committee on Bioethics, 2002). Bioethics teaching now has an established place in the medical curriculum within the European Union (Claudot, Alla, Ducrocq, & Coudane, 2007). Countries in Central and Eastern Europe followed in the 1990s. Before the collapse of the communist system, ethics has been taught as part of mandatory ideological training for health professionals. This context made it difficult later to introduce bioethics education, particularly since in a number of university courses in Marxism have been transformed into courses in bioethics. With substantial international support, many countries, however, were able to achieve significant improvement and expansion in bioethics education (Borovecki, ten Have, & Oreskovic, 2006).

The gradual expansion and dissemination of bioethics education in medical schools was associated with an ever-widening scope. First, ethics teaching was initially introduced in undergraduate medical education but later it is expanded into the graduate curricula as well as specialization programs, emphasizing clinical ethics but also continuing education (Pegoraro & Putoto, 2007). In 2004, the number of medical schools in North America with ethics education in the clinical years had doubled compared to 1985 (Lehmann, Kasoff, Koch, & Federman, 2004). Bioethics education had also rapidly expanded in residency programs in several specialties (e.g., internal medicine, pediatrics, family medicine, psychiatry). Current US data show that 99 % of surgery residencies now include some mode of explicit ethics education while it was nonexistent in 1997 (Grossman, Posner, & Angelos, 2010). Second, bioethics education was no longer confined to future medical practitioners but also included in the professional training of other health professionals. There was a specifically rapid development of ethics education in nursing (Fry, 1989). Third, bioethics education was advocated for other scientific disciplines, for example, biology, biochemistry, genetics, and the life sciences (Dawson, 2009). This was in line with the wider notion of bioethics coined by Van Rensselaer Potter, combining scientific knowledge with philosophy and ethics in order to better understand the contemporary problems of applying new knowledge and emerging biotechnologies. Fourth, bioethics education was regarded as essential for young scientists and professionals studying in university but increasingly also for graduate and more experienced colleagues in health-care practice, research facilities, and laboratories. The increasing number of hospital ethics committees, for example, created a need for specific postgraduate courses and programs to better equip its membership. Quandaries and controversies in research often resulted in encouragement of specific ethics programs for researchers.

Fifth, bioethics education has become relevant for the general public and policy-makers, demonstrating that bioethics is no longer regarded as a merely academic discipline but as a major driving force for public debate and policy-making in present-day societies. Sixth, the number of online ethics courses and programs for various health professions is rapidly growing (Stoddard & Schonfeld, 2011).

Global Outreach and Cooperation

Most recently, bioethics education has become the focus of international activity and cooperation. In 1993, the World Summit on Medical Education recommended that ethics should always receive full attention in medical school (World Summit, 1994). The World Medical Association is since long involved in promoting medical ethics. In 1999, it passed a resolution recommending that all medical schools should make teaching of medical ethics obligatory in the curriculum (Claudot et al., 2007). In 2005, it has launched a medical ethics manual as a guiding teaching aid in medical schools around the world (WMA, 2005). Since 2002, the World Health Organization is focusing on ethical issues related to global health and health care, particularly in research ethics. Although it has published many relevant documents, it has not specifically addressed bioethics education. In 2000, the Fogarty International Center, part of the National Institutes of Health in the U.S., launched the new International Bioethics Education and Career Development Award Program. It is funding bioethics training initiatives in developing countries but specifically focused on research ethics. The most extensive and broad effort has been undertaken by UNESCO (the United Nations Educational, Scientific and Cultural Organization) that has launched its ethics education program in 2004. This program aims at the integration of ethics into scientific education in all member states. It has been built up in several steps (Ten Have, 2008). The first step is focused on providing information. Policy-makers at governmental level but also in universities and academies of science do not often have adequate information about what exist and what is lacking in the field of bioethics education. It is, therefore, necessary to identify existing ethics programs as well as expertise and to exchange experiences. In order to establish a database of ethics teaching programs, standardized forms have been developed to describe teaching programs, so that the substance of each program can be examined and various programs analyzed and compared. Within a group of countries, experts are identified who actually are teaching within a university setting. The experts are invited to take part in a regional meeting; in advance, they are invited to provide data on their programs and to return the descriptive forms so that existing programs can be discussed during the meeting. Often, it is the first time that experts have insight in the programs taught by their colleagues in the same and neighboring countries. In the meeting, information can be clarified, difficulties identified, and problems discussed with colleagues. With the empirical data obtained and clarified, it is easier to subsequently explore what will be necessary for the future and how international collaboration can help to promote ethics teaching. Regional expert meetings have been organized in

Budapest (October 2004), Moscow (January 2005), Split (November 2005), Muscat (November 2006), Istanbul (March 2007), Marrakesh (June 2008), Abidjan (December 2008), Dakar (March 2009), and Kinshasa (July 2009). Currently, 235 teaching programs have been validated and entered into the UNESCO Global Ethics Observatory database, covering 43 countries, mainly from Central and Eastern Europe, the Arab region, and Africa. The advantage of this database is that detailed information concerning each teaching program is available in comparative format (www.unesco.org/shs/ethics/geobs).

One common finding so far is the vulnerability of ethics teaching programs. Often, the programs are taught by enthusiastic teachers, but there is no firm institutional basis, nor any systematic effort to create a future generation of ethics teachers.

As a second step, an ethics teacher training course has been set up to remedy these problems and to make sure that a new generation of professionals and scientists will be encouraged to teach ethics in a professional manner. This ethics teacher training has taken place in Romania (2006), Kenya (2007), Slovak Republic (2007), Saudi Arabia (2007), Belarus (2008), Croatia (2010 and 2011), and Serbia (2011). The focus of the courses is on didactic skills required for ethics teaching rather than on content issues of bioethics.

The third step in the ethics education program has been the development of a proposal for a core curriculum in bioethics, on the basis of the *Universal Declaration on Bioethics and Human Rights*, adopted by all member states of UNESCO in 2005. Because there is consensus on the fundamental principles of bioethics in the declaration, this can be considered as a basis for what should be minimally included in a bioethics course. An Advisory Expert Committee on the Teaching of Ethics, composed of members of the International Bioethics Committee and the World Commission on the Ethics of Scientific Knowledge as well as representatives of the UNESCO Chairs in Bioethics, the Academy of Sciences for the Developing World (TWAS), and the World Medical Association (WMA), has developed the proposal with teaching units related to the principles of the declaration. For each unit, the possible objectives and contents are described and proposals for teaching materials, resources, and assessment methods are provided. The proposal has taken into account the recommendations of a consultation meeting with 30 experts, mainly from developing countries. The proposal has also been tested in a number of universities all over the world (Argentina, Armenia, Belarus, Israel, Japan, Moldova, and the Russian Federation). Based on these experiences, the proposal has recently been revised. It is currently in translation into Arabic, French, Russian, and Spanish. The core bioethics course can assist scholars who want to establish teaching programs in bioethics in various cultures and regions. Also, books with cases from various countries are available to be used in the units of the course.

Finally, UNESCO is the only UN organization with the possibility to establish university chairs that can help to implement its program in a specific country or region. UNESCO chairs in bioethics are currently located in Argentina, Brazil, Israel, Kenya, Mexico, Portugal, Spain, and USA. Regional documentation centers

are also an important resource for future activities since they will make information and documentation from the region itself available and distribute information materials from other regions and UNESCO. Centers have been established in Vilnius University (Lithuania), Egerton University (Kenya), and the Academy of Sciences in Cairo (Egypt).

Controversies

The impressive proliferation of bioethics education in many countries and for multiple audiences is reflected in the vast body of literature on the subject that can be consulted nowadays. However, the most striking characteristic of this literature is its enormous heterogeneity (Claudot et al., 2007; Eckles et al., 2005; Goldie, 2000). Even within the same country, there is ample variety, not only in the type of programs offered and didactic approaches used, but also in quantitative terms. The reported number of teaching hours can vary from 5 to 200 (Silverberg, 2000). A recent survey in the USA showed that in medical schools, the required hours of instruction in bioethics averaged 35.6 but ranging from 9.0 to 125 h (Persad et al., 2008). In the Netherlands, all eight medical schools have ethics courses but the number of teaching hours is varying substantially. The same is true for the degree of integration in the core curriculum (Ten Have, 1994). In a study carried out in 18 European countries, the number of teaching hours was ranging from 0 to 107 h (Claudot et al., 2007).

Reading the scholarly literature, one gets a bewildering impression of variability. Methods of bioethics teaching are wide ranging. Some programs are primarily based on plenary lectures while others use a variety of methods, from patient consultations, case discussions, simulations, role-playing, and games. Many teaching programs consist of specific courses while others are fully integrated in other components of the curriculum. Though most programs are assessed, evaluation methods and instruments vary considerably. This variability creates a perplexing situation. Almost anyone and every significant organization seem to agree that bioethics teaching is necessary and should be mandatory for contemporary and future health practitioners and scientists. At the same time, there is no consensus on the relevant core ethical contents, processes, and skills necessary for medical practice. Controversies seem to exist in major dimensions of teaching programs.

Objectives

Why is there bioethics teaching? What does one hope to achieve with education in bioethics? In most of the scholarly literature, distinctions are made between three types of objectives: knowledge, skills, and attitudes. For example, if the focus is on informed consent, students should know what it is; they should have information

and facts about this concept, but they should also learn how to apply it in practice and why it is important to establish relations with patients and research subjects. The skills objective is most often mentioned but in different formulations. An essential skills component related to the first objective is that of learning to recognize ethical issues. Since medicine itself is a moral profession, value judgments are pervasive in clinical decisions (Pellegrino & McElhinney, 1982). Because moral concerns are inseparable from technical concerns, it is not always easy to identify the normative dimension of clinical decisions. Students should, therefore, learn how to identify which aspects of decisions are technical in nature and which are ethical, and they should be able to assess how technical and ethical aspects are related to each other (Ten Have, 1995). Other skills often mentioned are formal and analytical. Skills should be developed in identifying relevant moral principles, analyzing the normative dimension of clinical decisions, critically analyzing moral arguments, or justifying personal decisions regarding ethical issues. Skills can also focus on critical reflection and self-criticism. A different approach was taken by a consensus meeting in the USA in 1983 identifying more substantial skills such as the ability to obtain a valid consent or knowing how to proceed if a patient refuses treatment (Culver et al., 1985). The third objective claims that the attitudes of students should be influenced. Bioethics education should make them more sensitive to ethical questions and, especially the values of patients, to elicit a sense of moral obligation and personal responsibility, to tolerate ambiguity, and to respect different moral views (Callahan & Bok, 1980).

The UNESCO database shows that the overwhelming majority of programs are focusing on the first type of objective: providing knowledge and information as well as identification of moral issues. Skills objectives are also important, ranging in frequency from (1) analysis and reasoning to (2) understanding and explaining to (3) justification and argumentation. Influencing attitudes is less common but still half of the programs aim at producing good conduct. The basic controversy in fact is whether bioethics education should aim at improving medical decision-making (and, therefore, emphasize the skills of ethical analysis) or at producing better physicians (and thus aim at attitude formation and good conduct). The underlying assumption of both aims is that better decisions as well as better physicians both will lead to enhanced quality of patient care.

Methods

How should bioethics be taught? A variety of didactic approaches are presented in the literature ranging from plenary lectures, small-group discussions, movie-triggered debates, and role-playing. The majority of medical schools in the USA are using four teaching methods: discussion/debates, readings, writing exercises, and lectures (DuBois & Burkemper, 2002). Most medical schools in the United Kingdom use a combination of large and small-group teaching

(Mattick & Bligh, 2006a). The UNESCO database shows that in non-Western countries, lectures are the most commonly used method while case discussions are used in 50 % of the programs. Lectures are commonly used to transmit knowledge and key concepts and to introduce topics. Small groups are focused on interactive debate and discussion. Many teachers emphasize the need for case-based learning (Fox, Arnold, & Brody, 1995; Ten Have & Essed, 1989). Cases relate the teaching to real-life situations. Cases also are best discussed in group sessions and practical exercises. This makes the teaching more relevant for the students; it is also closer to what is going on in medical practice in distinction to the classroom. Barnard (1988) has criticized the trend to use cases. The focus on cases suggests that ethics is a tool for problem-solving rather than an approach to cultivate professionalism and humane approaches that could prevent similar cases in the future. In general, too much emphasis on pragmatism and relevancy can undermine the perception of ethics as a broader perspective of values and virtues that invites to recognize ethical problems in the first place.

There is also discussion about whether it is more desirable to have specific courses on ethics or ethics education integrated in other courses (Fox et al., 1995). Since separate courses are often isolated and marginalized, it is better to showcase that ethics is an everyday component of good medical practice (Goldie, 2000). What is often recommended is team teaching, combining expertise in ethics, medicine, and humanities. This reflects the interdisciplinary nature of bioethics. It furthermore shows that professional competence includes moral qualities.

It is obvious that the discussions on teaching methods reflect the evolution of bioethics education. In the early stage, ethics educators came from other disciplines such as theology and philosophy. They continued to use the methods of plenary classroom teaching with cognitive aims and formal lectures that were common in their own disciplines (Goldie, 2000). In this stage, ethics was taught as a separate course in the preclinical years. The traditional model of bioethics education, therefore, emphasized particular teaching methods: lectures, small-group discussions, and reading. Nowadays, more alternative models are flourishing, using a broader range of methods such as student presentations, movies, patient interviews, panel discussions, mock trials, and emphasizing more active learning through games, role-playing, and interviews with simulated patients (Fox et al., 1995). Widening the range of teaching methods is also dependent on the goals of teaching. If a broader range of aims is introduced, there is a concomitant need for a variety of teaching methods throughout the curriculum (Goldie, 2000). Shaping attitudes and virtues as well as enhancing moral development will require different methods than promoting knowledge and cognitive skills. This will also stimulate the initiating of more teaching activities in the clinical phase of the curriculum, with grand rounds, ward rounds, case conferences, and simulated patients. A similar change in teaching methods over time was noted in the United Kingdom: programs have become more oriented toward student experiences, clinical problems, and integrated teaching, with less emphasis on ethical theory (Mattick & Bligh, 2006a).

Content

What should bioethics educators be teaching? The subject matter of teaching programs depends on how narrow or broad the notion of "bioethics" is interpreted. It also depends on the setting in which the teaching takes place. The topics will vary whether the teaching is focused on medical students, residents, nurses, or science students. But the topics will also vary according to the cultural and social context in which bioethics education is developing. In the first stage of its development, the main setting was the undergraduate medical curriculum. This is reflected in several surveys showing that the content areas for bioethics teaching, at least in medical schools in the USA, are rather limited. The majority of teaching programs is focused on six areas: informed consent, health-care delivery, confidentiality and privacy, quality of life/futility/provision of treatment, death and dying, and euthanasia and assisted suicide (DuBois & Burkemper, 2002). For preclinical courses in North American medical schools, the focus is even more restricted: all programs cover consent, end-of-life issues, confidentiality, and truth-telling (Lehmann et al., 2004). But again, there is wide variety. Both Silverberg (2000) and Goldie (2000) present in their surveys a long list of topics addressed in bioethics teaching programs. What is not mentioned are issues of social justice, access of health care, and equitable distribution of health-care resources – issues that are important in a European perspective (Gillon, 1996). Teachers of medical ethics and law in the United Kingdom issued a consensus statement in 1998 outlining the core content of a minimum basic curriculum. They mention 12 topics: informed consent and refusal of treatment, the clinical relationship (truthfulness, trust, and good communication), confidentiality, medical research, human reproduction, the new genetics, children, mental disorders and disabilities, life/ death/ dying and killing, vulnerability, resource allocation, and rights (Consensus Statement, 1998).

The focus on identifying more or less exhaustive lists of topics that need to be covered in bioethics education is one approach to substantiate bioethics programs. Another approach is to structure the teaching program around different ethical perspectives such as deontological theories, utilitarianism, care ethics, and virtue ethics (Ruyter, 2004). The advantage is that this will provide the students with a framework to understand and interpret specific ethical problems arising in practice. When ethical theories rather than concrete experiences or cases are the basic structure of the program, it is also less relevant to cover all possible topics in contemporary bioethics. The topics will function as examples for the application of the theories so that students will learn how to approach new and emerging topics later. In comparing case-oriented and method-oriented programs, it was found that case conferences, although positively received by the students, lack a general theoretical framework for case analysis and interpretation (Ten Have, 1995). At the same time, a focus on methods (or theories) does not sufficiently engage the practical experiences of students. Combining the advantages of both approaches will result in a two-tiered approach of interconnecting the theoretical and practical perspective: clarifying important normative positions and methods of case analysis in the preclinical program followed by a regular sequence of ethical case conferences in the major clerkships.

Evaluation

What are the best ways to assess bioethics teaching programs? Here again, there is almost universal agreement that teaching programs need to be assessed. Otherwise, the effect of the programs remains unclear and there is no indication how they can be improved. There is also widespread agreement that the outcomes of the programs need to be assessed in the students. Otherwise, it is not clear what the students have learned. Programs that are not evaluating students are not taken seriously and have a marginal status in the curriculum as a whole. Nonetheless, in educational practice, students are not always evaluated. A survey among North American medical schools found that only half of the schools formally evaluate students. If there is evaluation, it is focused on moral reasoning abilities. Only a third of the schools assess students' behavior in ethically difficult situations (Lehmann et al., 2004).

This discrepancy between ideal and practice is related to controversies about what evaluation should take into account and how it should be performed. If there is no consensus on the goals and methods of bioethics education, it is difficult to determine what exactly should be assessed: knowledge, skills, attitudes, or behavior? Of course, each individual program can be assessed depending on its goals, but this does not allow comparison between programs so that finally it remains unclear what are more and less effective approaches in education.

There is not a lack of assessment methods as such. The literature provides examples of written assessments (multiple-choice questions, essays, case vignettes, short-answer questions), oral assessments (presentations, simulations, standardized patients, clinical observation exercises, direct observation of patient interactions), self-assessment reports, and portfolios (Campbell et al., 2007; Eckles et al., 2005; Wong & Cheung, 2003).

In assessment studies, two basic questions can be asked. One is what is the effect of bioethics education; the other is what teaching method is preferable. The first question is often addressed in technical terms: how can we measure the effects of teaching? The selection of an appropriate assessment method depends on the goals of the teaching programs (Goldie, 2000). For evaluating cognitive aspects, one can test dimensions such as ethical problem-solving, constructing rational arguments, recognizing moral problems, and understanding concepts (Wong & Cheung, 2003).

The problem is that knowing does not imply doing. Various assessment strategies are, therefore, performance-based. Quite a few studies are focused on the development of moral reasoning skills. Some studies indicate that bioethics education contributes to an increase in moral reasoning (Self, Wolinsky, & Baldwin, 1989; Smith, Balint, Krause, Moore-West, & Viles, 1994). Another focus is on ethical sensitivity, using case vignettes to measure the ability to recognize moral issues. Studies show a decline in ethical sensitivity after the first year of undergraduate medical training (Hébert, Meslin, & Dunn, 1992) but it is unclear whether and how bioethics education can remediate this trend.

Certain skills are difficult to measure, for example, interactional competence. Ethics teaching apparently improves confidence of residents in dealing with ethical

issues, but the conclusions are based on questionnaires and not on observed actual behavior (Sulmasy, Geller, Levine, & Faden, 1993). Studies also show that small-group ethics teaching is more effective than lectures and large-group seminars in promoting "students' potential ethical behavior" (Goldie, Schwartz, McConnachie, & Morrison, 2001), but this conclusion is based on whether or not their written replies to case vignettes came close to the professional consensus judgment regarding the cases. Even more difficult to measure is the goal of moral development and producing virtuous professionals. Although different methods are available (observation, videotaping, structured clinical examinations, simulated patients) (Wong & Cheung, 2003), it is questionable whether qualities and virtues such as compassion and integrity will be quantifiable and measurable at all. The focus of assessment efforts apparently is on evaluating process issues, procedures for decision-making, skills, rather than on understanding the problems and their context or on good professional conduct. Empirical outcomes research, although fashionable, has serious shortcomings, not only because the current instruments are inadequate, but also because it presupposes that only those goals that are practical and measurable need to be taken into account. The fact that most assessment studies are focused on moral reasoning and ethical sensitivity suggests that ethics is only a "competency" that is necessary to facilitate medical decision-making.

The second basic question in assessment studies is which teaching methods are preferable. The simplest way to answer this question is to ask students and to measure satisfaction or preferences about usefulness or relevance of the teaching. Recently, more comparative studies of teaching methods have been done. But there are only few studies that show that any teaching method is superior to others. Most studies compare a lecture-based curriculum (more passive learning) with a case-based curriculum (active learning). The traditional seminar proved superior to case-based teaching using standardized patients in terms of knowledge and performance (Robb et al., 2005). Group discussions added to case-based teaching will enhance students' abilities to recognize and analyze ethical issues (Smith, Fryer-Edwards, Diekema, & Braddock, 2004). In nursing education, traditional classroom teaching was less effective than small-group problem-based learning in ethical discrimination ability (Lin, Lu, Chung, & Yang, 2010). Similar conclusions were reached for first year medical students (Goldie et al., 2001). Case-based education improved the overall awareness of ethical issues, but remarkably also led to a 50 % reduction in duration of stay for patients in the surgical intensive care unit (Holloran, Starkey, Burke, Steel, & Forse, 1995). Comparing online delivery of bioethics education to traditional classroom delivery, Stoddard and Schonfeld (2011) found no difference except for scoring multiple-choice questions that was higher in the traditional approach.

Two Different Philosophies of Bioethics Education

The different views on objectives, methods, content, and evaluation reflect essentially two diverging views of bioethics education.

Modest View

In most of the literature, the view of bioethics education is modest. Ethics is introduced in the medical curriculum in order to better assist health professionals. The focus is on facilitating the practice of clinical medicine or research. Ethics teaching is a way of learning skills for analyzing and resolving the ethical dilemmas that will confront health professionals in their future practices. Ethics teaching can help them to be better prepared for dealing with problematic patient cases and make them more confident in decision-making and more effective in communicating with patients, families, and colleagues.

This view of bioethics education is also pragmatic. One should focus on what is practical and measurable. It is assumed that it is not realistic to expect that ethics education can create moral physicians or make ethical scientists. How can a limited number of courses bring about a change in behavior or character of health professionals? Moral character is already there when students enter the university. The best purpose of bioethics education, therefore, is teaching skills (Eckles et al., 2005). Gillon (1996) is very explicit: medical ethics teaching was not intended to improve the moral character of future doctors. It is not the role of bioethics instructors to inculcate virtues such as empathy, honesty, and integrity.

It seems, however, that the philosophy of bioethics education is moving towards a broader conception. The focus on identifying and analyzing ethical issues is characteristic for the early stages of bioethics education but now there is movement beyond the traditional model with many alternative models aiming to influence students' attitudes, behaviors, and characters (Fox et al., 1995). Apparently, there is growing consensus that the ultimate goal of bioethics education is to produce good health professionals and scientists (Goldie, 2000).

Broad View

In this view, bioethics education is basically a long-term effort to create virtuous health professionals and scientists. It is moral education aimed at character formation, integrity, and professional virtues. The assumption is that only in this way bioethics teaching can contribute to enhancing the quality of patient care. Bioethics education was introduced and promoted to counteract dehumanizing and objectifying tendencies in contemporary medicine and health care. It is not just there to facilitate medical decision-making but it should contribute to making medicine more humane. For this reason, bioethics education has a broader focus on the humanities, liberal arts, social sciences. and philosophy, so that medical activity is located in a wider human context. This broad perspective on bioethics education is endorsed in several ways. For example, the accreditation standards of the American Association of Medical Colleges require that undergraduate students demonstrate scrupulous ethical principles in caring for patients, for example, honesty, integrity, and respect (LCME, 2004). This implies that these ethical principles must be taught and evaluated but also that future physicians must show

these principles in their professional behavior. The same approach is taken in the United Kingdom. The majority of British medical schools now state that the aim of ethics teaching is "instilling ethical behavior in medical students" (Mattick & Bligh, 2006a, p. 182). More so, they claim that they are successfully accomplishing this goal. Also the UK consensus statement of bioethics educators underlines that ethics teaching should reinforce the aim of medical education: the creation of good doctors. The current emphasis on professionalism reinforces this point of view. Rather than transmission of information and knowledge, the learning of values and attitudes is important, since they constitute an identity which is an intrinsic component of professionalism.

It is remarkable that the need for teaching ethics is reemphasized every time when professional behavior turns out to be problematic. An example is the case of Harold Shipman, an English doctor who most probably murdered about 250 patients. One of the recommendations of the government investigation report in 2004 was to improve the teaching of ethics (Mattick & Bligh, 2006b). Ethics teaching is regarded as a remedy against lack of virtuous behavior. A similar approach was taken in scientific research. The last two decades have witnessed a cascade of cases of scientific misconduct, plagiarism and falsification scandals, and many ethical problems due to financial conflicts of interests. In the USA, the National Institutes of Health and the National Science Foundation have required as of January 2010 that graduate and postdoctoral researchers funded by grants must receive education in responsible conduct of research. Ethics education should promote research integrity and research ethics. Apparently, one course of ethics is considered as an effective antidote to social and cultural tendencies that allow and even encourage scientific misconduct. Although it is assumed that the aim of ethics teaching is to produce better physicians or researchers, such view of ethics as instantaneous prescription is obviously misguided. Public trust in science cannot be restored with a single bioethics course (Salerno, 2008). Bioethics education is not a medication that can be provided or a remedy that can be injected when the whole body is affected. Bioethics is not like other disciplines contributing to medical education: it is an intrinsic part of medicine itself as a moral enterprise. It is focused on understanding and transmitting the basic values of the profession. This transmission is continuous and not the result of an incidental or supplementary educational intervention. Medical education is a process of socialization and of "moral enculturation," transmitting a distinctive medical morality (Haffert & Franks, 1994). This is not a process visible in formal ethics teaching, but a substantial part of the "hidden curriculum." Studies of the hidden curriculum show that it has substantial ethical impact, for example, loss of idealism, emotional neutralization, acceptance of hierarchy, and competition rather than cooperation (Lempp & Seale, 2004).

Such a view of medical education implies that there is a continuous transmission of values and virtues framing and shaping professional identity. Ethics is not a tool that can be added from the outside but it is already there, intrinsic in the culture in which medical training operates. Formal and explicit bioethics education runs the risk of not only being extraneous to the internal morality of medical education

(as a peripheral course) but it can even be antithetical to the values emphasized in the hidden curriculum. These values may make health professionals more cynical. But articulating ethical skills will not be a remedy. Haffert and Franks (1994) recommend acknowledging that ethics is permeating medical education, though in an implicit and not articulated way. There is a difference between what is taught and what is learned. Three practical steps will follow. First, bioethics education needs to establish an overall value climate, recognizing that ethics teaching is a responsibility at organizational level. Second, all faculty is involved in ethics education, not merely in the classroom but rather at the bedside and in the laboratory; it is, therefore, important to teach the teachers. Third, bioethics education is already based on virtues before it even starts to be explicit and formal and before it addresses facts and skills. This answers the often raised question: can virtues be taught? They are continuously taught in the process of professional formation. But one course alone will not do the job. Teaching virtues is an institutional mission (Branch, 2000; Shelton, 1999).

The two philosophies of bioethics education formulate different perspectives, a broad one aiming at virtuous professionals and a narrow one aiming at ethically skilled practitioners. Both perspectives cannot be isolated from the fundamental question why there is bioethics education in the first place. If bioethics education was primarily introduced to counter the "dehumanizing" effects of modern science and technology in the context of health care and science, reiterating a reduced image of patients as subjects of technical-ethical skills, and a focus on the human body and biology, teaching has to move beyond a purely analytic and cognitive model of education. Otherwise, it would merely reinforce the myopic views and problems that necessitated the introduction and expansion of bioethics education in the first place. But at the same time, the impact of bioethics education should not be overestimated. Most ethics formation is taking place throughout the hidden curriculum. The best bioethics education can do is to make this informal education explicit so that the harmful effects of the hidden curriculum can be counteracted. This requires a sustained and long-term effort, creating "an educational climate that positively influences medical students' moral development" (Branch, 2000, p. 505).

Problems and Challenges

The growth of the scholarly literature on bioethics education is fueled by the persistence of problems and challenges.

- The overwhelming number of publications, statements of interest, and declarations of importance notwithstanding, there is not an impressive lot of bioethics teaching in practice in most countries. Persad et al. (2008) point out that in the US bioethics education, although required, comprises only 1 % of the medical school curriculum. Many educational activities are sporadic and occasional. In Europe, most hospitals have only short-term initiatives, not longer courses or programs, while nobody seems to take responsibility for the activities (Pegoraro & Putoto, 2007).

- There is a serious lack of qualified teachers. Not even half of the bioethics instructors in the USA have published a single article in bioethics (Persad et al., 2008). For many teachers of bioethics, this is not their primary academic focus. A survey in 2004 showed that 20 % of medical schools in the US and Canada did not even fund teaching in ethics (Lehmann et al., 2004). In general, there is almost no faculty development in bioethics education. There are only a few efforts to teach the teachers and to create the next generation of bioethics instructors.
- Resources for bioethics education (teaching materials, funding for library resources, program examples) are generally insufficient for teaching. More than 50 % of medical schools in the United Kingdom are inadequately resourced for teaching medical ethics (Fulford, Yates, & Hope, 1997).
- There is not a lot of international exchange of information. It will be helpful if detailed information about syllabi and teaching experiences would be available. The UNESCO database is currently the only comparative database but it provides information for a limited number of countries. This lack of cooperation is resulting in absence of coordination or strategic planning.
- It is difficult to know the quality of teaching programs. Since detailed information is generally not available and assessment studies scarce, there are no criteria to compare and evaluate the quality of education.
- The expansion of bioethics education has reintroduced the issue of interdisciplinarity although bioethics itself was conceived as an interdisciplinary effort. In bioethics teaching, medical ethics is usually taken as a paradigm since it has the longest history. The presupposition of educational interventions often is that students involved in bioethics teaching are medical students. Nowadays, more and more students from other disciplines, for example, the natural sciences or social sciences, are involved in bioethics education. The question arises how to teach for heterogeneous groups of students coming from different disciplines and with heterogeneous backgrounds and interests.

Growing Consensus

Controversies and challenges have not prevented that over the last few decades, areas of consensus seem to have emerged. Many scholars now agree that certain approaches of teaching are preferable, that there is a need of comparative studies, and that a common core of programs can be defined.

Preferable Teaching Approaches

The most successful teaching program is vertically and horizontally integrated in the curriculum (Stirrat, Johnston, Gillon, & Boyd, 2010). Pellegrino and McElhinney (1982) already advocated early on that an educational program should start with an introductory course in the first year, followed by integrated teaching in

the clinical years. This will have the advantage that in the preclinical years, the fundamentals of bioethics and the moral point of view can be explained but that the teaching will be integrated in courses in subsequent years and applied during the specific rotations later on (Ten Have, 1994). This approach demonstrates that ethics is a continuous activity during medical education. Bioethics education is not isolated but part of the daily routine. Integration usually requires team teaching, cooperation between clinicians and ethicists. This mode of teaching has been regarded since a long time as the optimal way of ethics instruction (Pellegrino & McElhinney, 1982). However, most medical schools in the US do not provide an integrated bioethics curriculum (Silverberg, 2000). Another point of agreement is that active learning is better than passive learning. A student-centered approach is preferable, especially in bioethics education since it will encourage reflection and critical thinking. This also explains the popularity of the case method. When students can select cases and examples for ethics instruction, the learning process can focus on real-life experiences.

Comparative Studies

The majority of publications on bioethics education are from North American authors. Relatively little is known, therefore, of the experiences in other countries and cultures. Comparative studies of programs can help to identify what is effective and what is not and to identify what would be an ideal program. Most studies compare teaching programs in the same country, for example, case-oriented and method-oriented programs (Ten Have, 1995). A precondition for such a comparison is that extensive descriptive studies are published of specific programs. Here also, there is a lack of information. A review of mainly US literature found only five descriptive studies of ethics curricula (Eckles et al., 2005). Much more comparative information is currently available in the UNESCO database but this is not used so far in the scholarly literature. Ethics teachers usually have little idea about what is going on in other countries. Their programs are focused on the ethics debates in their own states. Nonetheless, it might be useful to take note of ethics teaching elsewhere. Educators will be surprised how much there will be in common in teaching worldwide. It illustrates how much bioethics has become a global endeavor. People far away are in fact very close to us in aspirations, values, and rights.

Defining a Common Core

An interesting recent development is the determination of a common core for bioethics teaching programs. American authors are usually skeptical. They argue that there is no ideal bioethics curriculum: “there is nothing like a common core curriculum in medical ethics at present” (DuBois & Burkemper, 2002, p. 437). Lehmann et al. (2004) are more optimistic. Although they conclude that there currently is no common standard for ethics education, they stress that there is

a need for a model curriculum. The same need for a consensus statement on specific topics to include in a core ethics curriculum is recently expressed by Lakhan, Hamlet, McNamee, and Laird (2009). In Europe, several efforts have been undertaken to define a core curriculum. In the Netherlands, at the instigation of the medical association, all teachers of bioethics agreed on the structure of a core program in medical schools, identifying the contents, the goals, and the evaluation methods (Ten Have, van Wijmen, & van der Ploeg, 1994). However, this proposal was a voluntary commitment without any measures to implement or enforce it. It is unclear today whether there is any common core in the programs actually taught. In the United Kingdom, all teachers of bioethics and law made a consensus statement in 1998 on a model core curriculum. The statement mentioned specific topics that should be included in bioethics curricula. Studies later showed that only 4 of the 12 topics recommended were covered in the teaching programs of most medical schools (Mattick & Bligh, 2006a). Thereupon, a revised version of the core proposal was published in 2010 (Stirrat et al., 2010). Comparison of UK and US curricula makes clear that all medical schools in the UK cover at least a number of similar topics (e.g., informed consent, clinical relationships, confidentiality, the new genetics) (Mattick & Bligh, 2006b) while American programs can differ widely. Two European projects were focused on formulating a common core curriculum. Dickenson and Parker (1999) report on agreement on a core curriculum with common workbooks for several European countries. Pegoraro and Putoto (2007) stress the need to formulate a common base for the provision of bioethics education; there are too many gaps, too many varieties, and too haphazard activities in a survey on bioethics education in hospitals in ten European countries.

A different approach is taken by Thornton and colleagues. Rather than identifying specific topics that should be included in a common core, they refer to areas, for example, history of medical ethics and bioethics, theoretical foundations and methods of analysis, and the cultural context of bioethics (Thornton, Callahan, & Nelson, 1993). At an international level, the recent proposal for a core curriculum in bioethics launched by UNESCO demonstrates that agreement is possible regarding specific topics, modules, and objectives.

Efforts to define a core curriculum are not uncontested. It is argued that the need for standardized curricula will result in a quest for uniformity in order to reduce variance in health-care practices and in order to guarantee that students can be objectively assessed. This tendency is favoring numbers over values, transforming bioethics education in a quantifiable enterprise (Fins, 2010).

Conclusion

In the year 405, St. Augustine was consulted by a young colleague about the best approach to teach an introductory course in Christianity. In his treatise on catechetical instruction, Augustine addressed the issues of subject matter, objectives, and methods of instruction. The crucial question is: what is good education? In Augustine's view, education is not successful if it is not passionate and inspired.

All starts with the spirit, that is, the enthusiasm, devotion, and concentration of the teachers. Their tongue should be guided by their heart. Education is not merely focused on knowledge or skills but it should motivate and inspire. Teachers and learners are united in the same endeavor; they all want to be better persons (Christopher, 1946).

These ideas are reiterated in a recent reflection on education (Jackson, 2012). The ultimate aim of education is transformative. Its goal is "to effect beneficial changes in humans, not just in what they know and can do but, more important, in their character and personality, in the kind of persons they become" (O.c., p. 94). Education is fundamentally a moral enterprise. It is, what John Dewey has called, the manifestation of humankind's responsibility to conserve, transmit, rectify, and expand "the heritage of values we have received" (Dewey, 1934, p.87).

Bioethics education has a similar though more restricted mission. It invites students to participate in a specific professional community, grasping and shaping what is valuable in being a professional. Ethics teaching is not a remedy or antidote that can be injected into the medical curriculum to compensate, complement, or supplement lack of virtues and values or to provide a dimension of "humanitarianism" or "professionalism" to unidimensional persons focused on science, rationality, and objectivity. On the contrary, it is focused on constructing professional identities and shaping character. In building and reinforcing professional identity, knowledge and practice are linked.

Bioethics and Human Rights

29

Thomas Faunce

Introduction

The corpus of international human rights (as textually established by instruments such as the *Universal Declaration of Human Rights* (UDHR), the *International Covenant on Civil and Political Rights* (ICCPR), and the *International Covenant on Economic, Social and Cultural Rights* (ICESCR)) developed after the Second World War as an expression of the commitment of governments and the peoples they represented to principles sustaining three great social virtues: justice, equity, and respect for human dignity. It was also, though this was less well recognized or acknowledged, a profound reaffirmation of an idealist view of reality and the norms humans create to function within it. Nations incorporated judicially enforceable social and economic human rights in their constitutions that provided, for example, guarantees about access to health services and medicines as well as civil and political freedoms of speech, association, and prohibitions on torture or arbitrary and unlawful detention or death. Hope grew that such commitments would mark the start of a process whereby governments would not only provide physical security but maintain social structures that allowed their citizens to flourish in good health. Expectations were that states would prioritize programs (such as those implementing the United Nations *Millennium Development Goals*) that aimed to gradually reduce warfare, poverty, corruption, childhood and maternal mortality, and lack of equitable access to health services and essential medicines. UN human rights institutions and non-governmental organizations began to play crucial roles in this process. So, too, did the expanding capacity for individual citizens to petition human rights committees and courts concerning violations of human rights.

Bioethics arose as an academic discipline in roughly the same period. Bioethics may usefully be described as the application of moral philosophy to ethical problems in the life sciences (Harris, 2001). Prominent manifestations of bioethics included guidelines produced by groups of eminent persons in controversial areas

such as reproductive and end of life issues, as well as genetic testing, manipulation, and data storage (Faunce, 2005; Jonsen, 2000; Pellegrino, 1995). Norms of bioethics have also been devised to regulate the conduct of scientific research, access to, and quality and safety of technology, medical services, essential medicines, and other preconditions for health (Harris, 2001).

This chapter discusses the normative origins of bioethics and human rights. The view presented here is that the normative systems of bioethics and human rights are idealist in that they attempt to shape human conduct according to principles derived (like our understandings of time and space) a priori so that true statements are capable of being made about them that do not necessarily correlate with common experience. This chapter then analyzes the intersections of bioethics and human rights in the context of their responding to two great contemporary challenges: the policy influence of supranational corporations and their capacity to relate to the emerging preeminent social virtue of environmental sustainability.

Normative Origins of Bioethics and Human Rights

Many scholars of bioethics and human rights endorse the view that the principles underpinning those normative areas (as well as legislative and judge-made law) arrived in liberal democracies by a process (chiefly among policy and lawmakers) of what is termed "reflective equilibrium" or "coherence reasoning" from the hypothesis that societies, like individuals, when properly oriented strive to maintain foundational virtues, such as justice and fairness (Dworkin, 1977; Nussbaum, 1999; Rawls, 1976). Respect for human dignity is another such a virtue particularly associated with international human rights law (Faunce, 2005). According to this model, consistent application of foundational principles sustained those virtues, and the normative systems could in turn be reinvigorated by seeking to make new principles and laws coherent with that base, or by calibration between the normative systems (Faunce, 2005). Others distrust such ideas as having uncertain and quasi-mystical natural law elements that can be exploited by messianic totalitarian leaders (Hart, 1979; Kelsen, 1948).

Closely allied with the idea of foundational social virtues as a normative foundation for bioethics, laws, and human rights was the well-established intellectual notion of a hypothetical social contract. This concept seemed less mystical in part because it seemed to link to national legal texts such as the *Virginia Declaration of Rights 1776*, the *American Declaration of Independence 1776*, the French *Déclaration des Droits de l'Homme et du Citoyen 1789*, and other constitutional arrangements derived from them. Many see the global culmination of such ideals and world conscience in the United Nations' *Universal Declaration on Human Rights* of 1948. This is particularly true of Article 1:

> All beings are born free and equal in dignity and rights. They are endowed with reason and conscience and should act towards one another in a spirit of brotherhood.

International human rights itself undoubtedly remain highly suspect, particularly in Islamic societies, for its lack of connection with religious law as expressed in the

Quran or *Sunnah*. In such societies, norms of international human rights are consistently qualified by *shari'a*-based Islamic criteria and by suspicions that the primary norm-creating bodies in international human rights are dominated by the representatives of developed, northern countries or large corporations with alien social values (Abdullahi Ahmed, 2005).

What appears to have been less thoroughly considered, however, is whether what is manifesting in the development of governance systems like bioethics, law, and human rights is an emergent pattern of ordering from low-level rules toward greater complexity characteristic of all life (as revealed by a considerable volume of good research into the organization, for example, of simple organisms such as slime mold or ants to brains, cities, and computer programs) (Johnson, 2001). This leads to the hypothesis, explored here, that it is an illusion to regard normative systems like bioethics and human rights as entirely arising from core documents driven by influential groups or personalities, or being denigrated. Rather, bioethics and human rights may be emergent expressions of a unique human contribution to the perception and heightening of order in the universe – conscience. Let us trace some philosophic origins of this idea.

The philosopher Benedict de Spinoza in his seventeenth century *Ethics* (Bk II, Prop. XLIV) wrote that it is the nature of reason properly applied to perceive things truly, that is, as they are in themselves not as contingently existing in past, present, or future circumstances revealed to us by sensory experience. This pronouncement and its implications have often been ignored or dismissed as a peculiar type of idealist rhetoric. How, for example, could it make us view things any closer to reality or more ethically to regard them as not bound by forward-flowing time? Such a position was contradicted by our sensory experience. Yet Spinoza's profound realization (and others following on from it) paved the way for major scientific as well as ethical breakthroughs in thinking – the realization that there could be true statements about reality that did not appear to correlate with common sense.

Immanuel Kant took Spinoza's insight a few steps further in his eighteenth century *Groundwork of the Metaphysics of Morals* and his *Critique of Pure Reason*. Kant influentially contended that the capacity to form ethical concepts in the form of goals or end points for future actions based on principles applicable to all rational beings is a core distinguishing characteristic of the well-developed human mind. It arises, he maintained, proportionally with our capacity to view our place in the world more objectively, including viewing ultimately our understanding of time and space as arising a priori as necessary preconditions for sensory experience (rather than being determined by it). The freedom of individuals to set conceptual goals presupposes a capacity to reject them, and Kant reasoned that laws (backed up by official enforcement) provide an external constraint upon persons whose selected end points would otherwise unduly interfere with the capacity of other rational beings to choose their own goals.

Kant's was an optimistic moral philosophy about human nature, and it set the tone for what became known as the Enlightenment Tradition with its implicit understanding that humanity's increasing use of rationality would shape more

peaceful and harmonious social structures. Ethics, Kant saw as permitting rationalization of voluntary self-constraint by minds seeking to consistently apply principles capable of general application and becoming virtuous. The more people acted from a concept of duty (often against the opposition of their own sensual inclinations) to consistently apply such principles, the more humanity was morally developing toward a type of collective enlightenment. Those principles also rose in ethical value the more they facilitated the capacity to flourish equally in all other rational beings. Kant summarized this by stating (in his *Introduction to the Doctrine of Virtue*) that virtue arises from consistent voluntary decisions to act (despite internal or external obstacles) upon principles capable and worthy of application by all rational humans. Martha Nussbaum has convincingly demonstrated how it is an error to claim that the works of the central "enlightenment" theorist, Immanuel Kant, reveal an obsession with idealized duty and principle to the exclusion of character-formation and the training of the passions (or to make the same claim against seminal utilitarians such as Henry Sidgwick, Jeremy Bentham, and JS Mill) (Nussbaum, 1999).

Yet thinking like that of Spinoza and Kant, discussed here, had implications not only for ethics but for the emerging science of physics. In his *Critique of Pure Reason*, Kant wrote that "we can never represent to ourselves the absence of space, though we can quite well think it as empty of objects." (Kant, 68) Likewise, he stated that "appearances may one and all, vanish; but time (as the universal condition of their possibility) cannot itself be removed." (Kant, 75) The twentieth century physicist Albert Einstein, who studied Kant's ideas in his youth, probably drew upon this insight (that space and time might exist in ways that seem at odds with everyday sensory experience) to ponder what physical laws (such as the general and special theories of relativity) might answer physical anomalies such as why the speed of light is constant regardless of the speed of its source (Faunce, 2011a).

A corollary of such "pure" reasoning, as Kant perceived, was that knowledge (including moral truths about the role of principles and virtues in constraining free will) could also arise from a suprasensible part of nature that has the potential to be true, despite not necessarily correlating with common experience. Such realization may have been a critical factor in development (particularly by other enlightenment philosophers such as John Locke, physician, philosopher, and founding father of human rights jurisprudence) of the concept of inalienable human rights (granted by nature to all people) even though such a position had no foundation in sociological facts about governance of the time. John Locke was a physician pupil of Sydenham, a great clinical empiricist inheritor of the Hippocratic tradition. It is interesting to speculate that a major factor promoting both the corpus of human rights norms, as well as the norms of bioethics deriving from the *Hippocratic Oath*, was loyalty to the professional virtue of relief of individual human suffering (Faunce, 2007).

In any event, though the constitutions of nation states increasingly incorporated (particularly as a result of Locke's philosophic influence) the claim that the basis of human rights obligation could reside in an ideal applicable to all people as part of

the "nature of things" rather than be entirely constrained by the interests of a King or religion, the origins of that principle were never fully explored or appreciated.

Overlap Between Bioethics and International Human Rights

Historically, the systems of bioethics and international human rights have many intriguing historical parallels. Medical ethics, for instance, provided the original core of bioethics, and its basic principles may be viewed as derived from the tradition represented by the Hippocratic Oath (Davey, 2001).

Proving a breach of the *Hippocratic Oath's* ethical obligation to "do no harm" was central to the conviction of the Nazi doctors at the Nuremberg Trials after the Second World War for nonconsensual, brutal experimentation; sterilization; and active nonvoluntary euthanasia. Those proceedings spurred creation of a tripartite collection of documents that remain central to medical ethics: the *Declaration of Geneva* (or the modernized *Hippocratic Oath*), the *Nuremberg Declaration on Human Experimentation*, and the *International Code of Medical Ethics*. These international medical ethics documents can be viewed as synergistic with the tripartite international Bill of Human Rights: the *UDHR*, as well as the latter *ICCPR* and the *ICESCR*. A major distinction, however, was that the former bioethics instruments were unambiguously directed at relationships between individuals, the latter human rights documents chiefly with relations between individuals and states.

Particularly overlapping with norms of bioethics in the *UDHR* were provisions requiring respect for human dignity and equality (articles 1 and 2), as well as the human right to life (article 3). Others resembled components of medical ethics in prohibiting torture or cruel, inhuman, or degrading treatment or punishment (article 5), requiring nondiscrimination (article 7), freedom from arbitrary interference with privacy (article 12), and progressive realization of the human right to a standard of living adequate for health and medical care (article 25). In the same category was the human right to share in scientific advancement and its benefits (article 27) (Claude & Issel, 1998).

Consent to medical treatment and experimentation is one area of explicit overlap between bioethics and international human rights. Article 7 of the *ICCPR* provides that "no one shall be subjected without his free consent to medical or scientific experimentation." Under general comment 20, the United Nations Human Rights Committee has interpreted this to require "special protections" – for example, no institutionally nominated surrogate decision-making – for persons "under any form of detention or imprisonment," or those hospitalized on grounds of necessity or involuntarily due to mental illness. It could extend also to protect patients from doctors who were institutionally prevented from providing such "free consent," even where such physicians were not considered state agents (Faunce, 2007).

Contemporary international human rights and bioethics clearly overlap in the regional *European Convention on Human Rights and Biomedicine*. In force since 1997, the regulatory impact of this convention has been more significant than its

limited ratification might at first indicate; the European Court of Human Rights having referred to and taking into it in dealing with the cases where the countries were involved that did not ratify or even sign it. This convention covers matters such as equitable access to health care (article 3), consent (Chap. II), private life and right to information (Chap. III), the human genome (Chap. IV), scientific research (Chap. V), and organ and tissue removal from living donors for transplantation (Chap. VI) (Council of Europe, 1997).

In considering the intersections between bioethics and human rights, it is important to take into account article 38 of the *Statute of the International Court of Justice*. This provision identifies international conventions and customary international law, among others, as the sources of international law. Thus, as a Declaration, rather than an international convention, the *UDHR* did not directly create binding human rights norms under international law upon signatory states.

International humanitarian law, as an aggregation of customary and treaty-based norms concerned with the treatment of the wounded, civilians, and prisoners of war, has many areas of overlap between bioethics and human rights law. The *Geneva Conventions* in 1949, the *Hague Convention* of 1907, and the *Genocide Convention* (what year?) and *Nuremberg Charter* (what year?) all impose upon states positive duties to permit and negative duties to hinder the exercise of medical professionalism amid armed conflict. These have now achieved status as customary international law. Medically related NGOs, such as the International Red Cross, Physicians for Human Rights, and Médècins Sans Frontières, though staffed by professionals required by bioethics to owe distinct obligations to their patients are increasingly involved in monitoring, preventing, alleviating, and even defining state violations of international humanitarian law. Along with nonphysician groups such as Amnesty International and Human Rights Watch, many of their members view themselves as at the vanguard of a cosmopolitan world order normatively governed more by human rights than by bioethics (Faunce, 2005).

The UNESCO *Universal Declaration on the Human Genome and Human Rights* (1998) and UNESCO *Universal Declaration on Bioethics and Human Rights* (2003) are other instances of texts with clear overlap between bioethics and human rights (Nys, 2005). The former pronounces that the human genome symbolically represents part of the common heritage of humanity, while forbidding practices contrary to human dignity, such as human reproductive cloning. The latter instrument, though also nonbinding under international law, arguably provides, if not a codification, then a promotion of bioethical norms onto the global normative stage. Particularly important are norms of technology transfer and social responsibility in relation to essential medicines that specifically apply to corporations (Faunce, 2007). Article 14(2) of the *Universal Declaration on Bioethics and Human Rights* provides:

> Taking into account that the enjoyment of the highest attainable standard of health is one of the fundamental rights of every human being without distinction of race, religion, political belief, and economic, or social condition, progress in science and technology should advance:

(a) Access to quality health care and essential medicines, especially for the health of women and children, because health is essential to life itself and must be considered to be a social and human good
(b) Access to adequate nutrition and water;
(c) Improvement of living conditions and the environment;
(d) Elimination of the marginalization and the exclusion of persons on the basis of any grounds
(e) Reduction of poverty and illiteracy

Article 15 – sharing of benefits provides:

1. Benefits resulting from any scientific research and its applications should be shared with society as a whole and within the international community, in particular with developing countries. In giving effect to this principle, benefits may take any of the following forms:
   (a) Special and sustainable assistance to, and acknowledgement of, the persons and groups that have taken part in the research
   (b) Access to quality health care
   (c) Provision of new diagnostic and therapeutic modalities or products stemming from research
   (d) Support for health services
   (e) Access to scientific and technological knowledge
   (f) Capacity-building facilities for research purposes
   (g) Other forms of benefit consistent with the principles set out in this Declaration
2. Benefits should not constitute improper inducements to participate in research.

There are now many tribunals both at national and regional levels, authoritatively interpreting norms of bioethics at least partially in terms of international human rights. These include the English Court of Appeal and House of Lords, as well as the European Court of Human Rights. In *Case of D v United Kingdom*, for example, the European Court of Human Rights held that deportation of an HIV/AIDS-infected patient to his developing country of origin was state conduct which violated his human right to be protected from inhuman or degrading treatment or punishment. The judges reasoned that such deportation would result in his being denied adequate medical treatment and exposed to poor public health conditions (*D v. UK*, 1997). In many other jurisdictions around the world, judicial cases concerning new reproductive technologies, end of life decisions, privacy, and informed consent are now heavily influenced by international human rights norms, either because of parliamentary or judicial incorporation of human rights into domestic law, or to remedy a common law lacuna, or legislative ambiguity or obscurity.

The international right to health (as specified in article 12 of the *ICESCR* and in over a hundred national constitutions) also provides an important area of overlap between bioethics and human rights. The international right to health, for example, has core obligations to provide the basic preconditions for existence (food, water, sanitation, housing, nontoxic environment) including reasonable access to essential health services and products (Toebes, 1999). Approaches to the implementation of the international human right to health have involved defining universal outcome measures that measure compliance with the core state obligations of the human right to health, establishing systematic reporting to responsible international bodies to monitor progress on implementation and compliance with international

human rights obligations, and highlighting civil rights violations, such as discrimination against protected groups, that inhibit access to healthcare services (Kinney, 2001). A UN special rapporteur has been appointed to work on these issues, but has been largely symbolic in function owing to an understandable reluctance to confront some of the main corporate and sovereign obstacles to implementing the right.

The human right to health, particularly in domestic constitutions, indeed has often been interpreted as a largely symbolic, non-individually enforceable, progressively realizable concession to normative decency or attempt to claim political legitimacy. Technical and financial, as well as conceptual limitations, currently prevent it involving a justiciable guarantee for each person of a minimum level of actual health. Progressive realization of such a right requires effective use of available resources. The minimum content of this core, which cannot be set aside on grounds of progressive realization, may be conceptualized as a responsibility to reduce serious threats to the health of individuals, or the state's population, according to international standards (Ngwena, 2003).

Effective state infectious disease control and equitable provision of essential medicines as well as taxpayer-funded health services in medical emergencies comprise a compelling and justiciable minimum core public health component of the right to health. Courts have enforced the right to health in domestic constitutions to make states, for example, provide basic treatment to HIV/AIDS patients. In 2002, the South African Constitutional Court unanimously found the government in breach of s 27(1) ("right of access to healthcare services") and 27(2) ("progressive realization" of the right to health) in that Constitution. It held that the government's policy of restricting the anti-HIV drug "nevirapine" to 18 sites was unreasonably rigid and inflexible, denying babies of HIV-infected mothers outside those sites a potentially life-saving therapy. The Court took note of the fact that the drug was apparently affordable, easy to administer, and recommended by the WHO (*Minister of Health v. Treatment Action Campaign*, 2002).

The Challenge of Supranational Corporations

So, after the Second World War, the peoples of the world through their governments seemed set on a course of prioritizing ideals such as those expressed in the normative systems of bioethics and human rights – ideals that seemed strongly to emerge from a commitment to conscience as well as foundational social virtues such as justice, equity, and respect for human dignity. Yet something went badly wrong.

The governments of the world started to prioritize a different set of international legal commitments to people lacking in any fundamental or necessary commitment to conscience or foundational social virtues. These were increasingly politically and normatively powerful artificial persons in the form of transnational corporations. What commenced to cut across the ideal of bioethics and human rights was a process of private sector lobbying of state officials and indoctrination of

politicians into the so-called neoliberal free market ideology. This manifested in World Trade Organization (WTO) agreements that created huge financial penalties for nations seeking to reestablish taxpayer control over areas such as water, food, power, telecommunications, or health services and investor-state dispute mechanisms that allowed supranational corporations to sue governments when legislation or policies (though otherwise coherent with bioethics or human rights) impeded their investments.

Pertinent examples included the WTO agreements such as that on *Trade-Related Aspects of Intellectual Property Rights* (TRIPS) and the *General Agreement on Trade in Services* (GATS). These did have provisions that allowed exemption for government policies necessary to protect public order and morality (articles 27(2) and XIV (a), respectively). Public order or morals, however, were not defined in such agreements, and trade dispute panels had to rely on dictionary definitions such as that which defined public morals as "standards of right and wrong conduct maintained by or on behalf of a community or nation." Naturally, such a definition implied varying cultural, religious, and other national contexts, rather than the notion that there was or could be consensual and clearly defined systems of global bioethics or human rights. Indeed, since the 1990s in particular, the WTO has been able to create a politically influential, profit-driven global corporate agenda for global governance in healthcare policy with no explicit requirement to consider norms of bioethics or human rights (Abbott, 2005).

A state can now elect, for example, as have many OECD countries, to place "hospital services" on its "schedule of commitments" to be covered by the "liberalizing" rules of the WTO GATS agreement. This executive action (mostly no specific parliamentary scrutiny or democratic mandate is constitutionally necessary) facilitated a reorganization of ownership and management of public hospitals towards a "for fee" private insurance-oriented model. Under this patients with insurance were increasingly exposed to the moral hazard (contrary to basic bioethics and human rights norms) that an assessor at their insurance company (specifically tasked to do this) would find it more lucrative to find a reason to deny their claim than honor their premium. Likewise, under the GATS "market access" requirement, subsequent (more bioethics and human rights-minded) governments were hindered from legislating to regulate the total number or market share of foreign private healthcare services or suppliers.

The GATS rule of "national treatment" additionally required that a "liberalizing" government could not provide, even unintentionally, more favorable conditions to domestic healthcare companies than to foreign corporations. The most favored nation (MFN) rule obligated such administrations to also ensure that most favorable treatment, in terms of trade, granted to any foreign company was extended to all foreign companies wishing to enter this "liberalized" sector. The "domestic regulation" rule likewise made domestic laws and regulations, including those which protected the public's health and safety, subject to challenge and possible elimination if they were determined to be "unnecessary barriers" to trade, or more "burdensome than necessary" to assure the quality of a service. These changes often facilitated a brief influx of foreign venture capital, but created

a one-way policy agenda toward global privatization of healthcare services regardless of adverse population health impacts and infringements of basic bioethics and human rights norms.

The WTO TRIPS agreement created a process of influencing the way states used bioethics and human rights norms to balance intellectual monopoly privileges (IMPs). This can be seen, for example, in its express exceptions to IMP protections over pharmaceuticals such as compulsory licensing by governments to allow generic manufacture of medicines (after payment of reasonable compensation to any patent holder) if such medicines were required to be cheaper and more readily available for public health reasons. Yet, a so-called "data exclusivity" requirement (allowing prolonged withholding from generic competitors of data revealed by pharmaceutical patent holders to drug regulators for safety, quality, and efficacy assessment prior to marketing approval) seemed designed to undermine compulsory licensing. Indeed, any nation (such as Brazil or Thailand) that has attempted to invoke WTO TRIPS compulsory licensing to provide essential medicines (particularly to treat HIV/AIDS) in fulfillment of its bioethics and human rights obligations has been threatened with trade sanctions by nations such as the USA at the behest of their patented pharmaceutical corporations.

The WTO TRIPS agreement has actually inhibited the capacity of governments to deal rationally with the global burden of disease in accord with core components of bioethics and the international human right to health. This interpretation is supported by the 2001 TRIPS clarification known as the *Doha Declaration on TRIPS and Public Health*. This Declaration symbolically affirmed the capacity of WTO members to use the full exceptions in the TRIPS agreement to promote public health by facilitating access to affordable medicines while implicitly acknowledging their lack of capacity or will to do so (Abbott, 2005; Correa, 2002).

Bilateral and regional preferential trade agreements have additionally facilitated the plans of multinational pharmaceutical and managed care corporations to exploit "liberalized" markets and challenge universalist (taxpayer-funded and egalitarian) domestic health and medicines policies, often on the grounds that they created nontariff trade barriers, or insufficiently rewarded "innovation" or "research and development" (Faunce, 2007).

Supranational corporations continued to lobby governments under the thrall of the neoliberal ideology that market forces (though often monopolistic or collusive in operation) would provide a viable alternative to normative systems like bioethics and human rights in providing for the essential needs and flourishing of citizens. When international civil society defeated the Multilateral Investment Agreement (MIA) these corporations turned to regional deals (Chap. 11 of the North American Free Trade Agreement between the USA, Canada, and Mexico) and bilateral investment treaties (BITs). These allowed those corporations to sue for damages (before a panel of trade arbitrators with a vested financial interest in perpetuating such a system) governments that impeded investments by legislation otherwise coherent with bioethics or human rights. Governments were sued, for example, by corporations in Canada (when they legislated to prohibit toxic lawn chemicals or gasoline) and in Uruguay and Australia (when they tried to reduce

smoking in young people by introducing plain packaging of tobacco products) (Faunce, 2011b).

Thus health policy debates began to rationalize widespread deaths among increasing numbers of poor, uninsured patients and those who could get access to essential medicines (because of fiercely protected patents or lack of corporate R&D interest in that area) as temporary market failures or "adjustments" (Holmer et al., 2000). The corporate sector ascribed the causes of this lack of consumer capacity, for example, to government policies fostering unemployment or restricting business innovation, as well as to high costs of rent, food, and education (Kinley & Chambers, 2006).

Particular challenges created for bioethics and human rights by global governance via supranational corporations include protecting in priority to shareholder profits the interests and welfare of the million or so women and girls under 18 trafficked yearly for prostitution, 10 million refugees, or 5 million internally displaced persons; the victims of any one of the 35 or so wars currently raging across the earth, of state-promoted torture, or rape in the guise of "ethnic cleansing"; or any of the 250 million children exploited for labor, sexual gratification, or as soldiers, as well as the 1.2 billion people living in severe poverty, without adequate obstetric care, food, safe water, or sanitation. Gender discrimination, poverty, famine, and displacement by warfare are significant factors in large numbers of children in African countries still failing to receive basic information from health professionals about how to avoid infection with HIV/AIDS, despite often over 20 % of the population being seropositive (Fidler, 1998).

The Challenge of Environmental Sustainability

The virtue of environmental sustainability has been linked to the idea that this planet should be treated as a distinct living entity (James Lovelock's Gaia Hypothesis) (Lovelock, 1991). It has become a symbolic rubric focusing public and governmental attention on the interaction between human health, technological development, and sustainability of the biosphere (McMichael, 2002). In this emerging discipline, anthropogenic climate change and environmental degradation as well as poverty and lack of necessary fuel and food are targeted as intrinsically global environmental pathologies the resolution of which requires concerted efforts to implement a wide range of not just renewable energy technologies (such as those using nanotechnology) but bioethical principles including those related to protecting the interests of future generations and preservation of biodiversity. By logical extension the application of renewable energy technologies, for example, utilizing nanotechnology to improve solar energy conversion to electricity, or to purify soil or water, can be regarded as forms of planetary nanotherapeutics.

Salutary facts driving academic and policy interest in planetary medicine are not only the greenhouse-gas-driven increase in severe weather events, but the projected increase of global human population to 10 billion by 2050 with associated energy consumption rising from ≈400 EJ/year to over 500 EJ/year beyond the capacity of

existing fossil-fuel-based power generation. The research underpinning planetary medicine also emerges strongly from influential commentaries such as the Intergovernmental Panel on Climate Change (IPCC, 2007) and the Stern report (Stern, 2007) as well as the United Nations *Millennium Development Goals*.

Environmental sustainability as a primary social virtue can be linked with so-called "ecocentric" or "biocentric" bioethics. This is also known by terms such as *Deep Ecology* and expressed in documents like the *Earth Charter* or *Earth Manifesto*. It involves two key ethical principles. The first is that the flourishing and diversity of nonhuman life forms has intrinsic value requiring protection by policies and technologies that reduce the number of humans along with their demands on those other species. The second holds that human flourishing itself requires a deepening respect for right relations with ecosystems which should be reflected in the choices our species make about the use of new technologies.

It is difficult to discern environmental sustainability as a clearly defined ethical virtue or principle in contemporary media and policy debates between those with Christian, Islamic, or secular perspectives; those enmeshed in securing the embellishments of institutional or corporate financial power; and those (such as the "Occupy Wall St." protestors) critiquing the desuetude of that power in the face of moral crises. One finds, for example, little if any reference to environmental sustainability in ethical works derived from religious traditions, or from academic schools such as utilitarianism ("act on principles maximizing the greatest good for the greatest number") or deontologic idealism ("act on principles capable of universal application"). It could, of course, be argued that the concept of environmental sustainability is present implicitly in such doctrines or in core religious concepts like Buddhist compassion, Christian conscience, or Islamic *taqwa*.

Those supporting environmental sustainability as an emerging foundational social virtue alongside the human-focused justice, equity, and respect for human dignity could argue that the "virtue ethics" position supports the social virtue of environmental sustainability because its achievement is one of the central altruistic goals of good people in our age. Such goal-oriented virtue-based approaches to ethics have been criticized as too readily subjugating individual liberties and flourishing to the attainment of ostensibly wider social aims (Crisp & Slote, 1997). On the other hand, non-goal-oriented virtue ethics theories are commonly subjected to objections emphasizing their circularity and failure to provide determinate guides to action particularly in pluralist societies.

The less human-centered social virtue of environmental sustainability (as a normative basis for bioethics and human rights) can also be viewed as an extension from moral concerns in related areas such as protection of animals, based on their common capacity to suffer and the primacy of norms preventing suffering as far as practicable for the majority of our interactions. This focus on the normative primacy of "suffering" creates conceptual difficulties for those who rely upon it to argue that ecosystems (such as wild rivers or rainforests) deserve ethical status or legal rights. Why should expanding the circle of empathy require proof that an entity can suffer because it possesses a nervous system that we can readily discern as comparable to our own?

Attempts have been made by some economists to frame the bioethics of sustainability chiefly in terms of the fictional notion of perpetual growth in gross domestic product (GDP). Such formulations often pay obeisance to the fictional power of deregulated markets and the "invisible hand" of entrepreneurial self-interest to ethically regulate demand upon earth's resources. Other economists, however, have striven to factor our moral responsibilities concerning the finite and fragile resources of the biosphere much more centrally into their economic calculations. The virtues of ecological sustainability and environmental integrity, for instance, were influentially propounded by eco-economists such as the EF Schumacher (with his concept of "small (and local) is beautiful") and Kenneth Boulding (with his idea of "Spaceship Earth" as a closed economy requiring recycling of resources). In doing this, the former drew upon Buddhist ethical principles and virtues, while the latter relied upon those resonating with the Quaker tradition.

The economist Herman Daly similarly drew on the laws of thermodynamics and the tendency of the universe to greater entropy (dispersal of energy) to champion the idea of "steady-state" economics that financially values maintenance of ecosystems equally with production and profits. Such an approach could be extended to suggest that bioethics, human rights, and economic principles be coherent not just with thermodynamics, but with physical laws and patterns of symmetry such as those underpinning electromagnetism, gravity, general relativity, and quantum physics, as well as other principles that are nonfalsifiable, without necessarily correlating with our sensory-oriented experience of the world.

Many economists interested in developing greater moral and scientific credibility for their discipline are investigating the bioethics of sustainability through the lens of human population and ecosystem science. One such approach, for example, defines sustainability as involving the persistence of diversity and ethical ideas of human flourishing among human communities, as well as the preservation and regeneration of ecological systems.

Case Study: Global Artificial Photosynthesis

In its present technologically unenhanced form, photosynthesis globally already traps around 4,000 EJ/year solar energy in the form of biomass. Nanotechnology researchers now are actively redesigning photosynthesis to achieve, for example, low-cost, local-domestic conversion of sunlight, water, and carbon dioxide into fuel for heating and cooking (Hurst, 2010). Nanotechnology is not only facilitating the capture of electromagnetic radiation from the sun but helping its transfer to improvements of the reaction center where it splits water to produce hydrogen (for fuel) and oxygen and then to reduce atmospheric carbon dioxide via the enzyme RubisCO to make carbohydrate food. Those methods seek to replicate how plants perform a single quantum computation, sensing many states simultaneously and so enhancing the efficiency of the energy capture and transfer at physiological temperatures (Gray, 2009).

Numerous competitively funded research teams have dedicated artificial photosynthesis-related projects already underway in many developed nations (Sanderson, 2008). Enhanced artificial photosynthesis, if applied consistently with bioethics and human rights, could assist crop production on marginal lands; reduce atmospheric CO2 levels; lower geopolitical and military tensions over fossil fuel, food, and water scarcity; and create carbon-neutral hydrogen fuel for domestic, community, and industrial storage. Practical "artificial leaf" systems have been developed and are on the threshold of commercial rollout (Reece et al., 2011).

Establishing how bioethics and human rights meet the twin challenges of corporate globalization and environmental sustainability will be equally important with facilitating the scientific collaborations that will allow global artificial photosynthesis to take place in time to address the major societal and environmental challenges that the expanding human population and its dependence on fossil fuels are currently creating (Faunce, 2012).

The essence of a bioethical or human rights principle conceived in an ideal sense (and thus not merely derived mechanistically from a written religious or legal code, guideline, or declaration) as meeting these challenges is that it should be widely or even universally applicable (for example, depending on context, extend to protecting, respecting, or fulfilling the interests of all human beings, or animals, lifeforms, or ecosystems). The traditions of bioethics and human rights derive from profound consideration of the relations of humans with each other and nature. They should provide a calibration system against which can be critiqued for example the behavior of those artificial corporate persons currently self-interestedly dominating domestic and international trade law and policy in ways likely to be inimical to global artificial photosynthesis.

At present, the foundational social virtues and ethical principles likely to underpin any rollout of a new source of renewable energy and basic food will be perceived by many policy makers as likely to derive from corporate-driven free market ideology, religious authority, or indirectly through confronting the necessities of survival – an understanding that without such norms or rules of behavior the majority of humans could not live well with each other, or for very long.

A macroscience project to promote equitable global use of artificial photosynthesis represents an excellent opportunity to create a high profile awareness of nanotechnology, bioethics, and human rights as positive joint-contributors to overcoming major contemporary public health and environmental problems (Faunce, 2011a). One particular area of looming conflict will be between such a vision will be IMPs such as patents. Many of the nanotechnological techniques and structures, as well as the artificial proteins involved in artificial photosynthesis will be the subject of patents. The process of photosynthesis is as central to life on earth as DNA; thus, there are likely to be major debates over whether patents should be allowed over any part of the photosynthetic process. Such debates will be unlikely to inhibit patents being taken out over all aspects of artificial photosynthesis, but if excessive patents cause artificial photosynthesis ownership to become fragmented, "follow-on" research may be hampered by the high cost and difficulty in negotiating contracts with large numbers of patent owners (Faunce, 2011b).

Creating governance principles consistent with bioethics and human rights to deal with such issues will be an arduous and complex process. A good point of departure for such a governance journey might be a UNESCO *Declaration on the Bioethics and Human Rights of Global Artificial Photosynthesis*. Such a document would not have the force of law (under article 38 of the Statute of the International Court of Justice). However, it might become important as a symbolic utterance that guides ethical debate and law reform at international and domestic levels.

The UDBHR has many features that would be relevant to shaping the bioethical and human rights principles governing global artificial photosynthesis. These include, first, application to individuals, communities, and private corporations as well as states (article 1) and, second, a focus on "access to adequate nutrition and water," "improvement in living conditions and the environment," and "reduction in poverty and illiteracy" (article 14). The UDBHR also emphasizes the need to recognize the importance of freedom of scientific research and equitable access to medical, scientific, and technological developments (article 2); sharing its benefits with particular attention to the needs of developing countries (article 15); and safeguarding and promoting the interests of the present and future generations (article 2). UDBHR article 21.3 likewise relevantly requires that states and public and private corporate actors should recognize the "importance of research contributing to the alleviation of urgent global health problems" (Faunce, 2011b).

There are however bioethical issues much more specific to global artificial photosynthesis that could be raised by means of a specific UNESCO Declaration. These include whether photosynthesis in its natural form should be considered a subject to common heritage of humanity principles (as under specific United Nations Declarations and Conventions are the human genome, the moon, the outer space, the deep sea bed, our natural or cultural world heritage) or indeed a part of a new category of ethical and international law principles in the category of planetary common heritage. A statement in such a UNESCO Declaration that photosynthesis (in either its natural or artificial forms) was the common heritage of humanity could be important in wider governance moves to restrict corporate ownership through intellectual property rights or misuse by nation states for strategic or military purposes. Other questions may involve developing specific principles by which artificial photosynthesis technology can best address within defined time pressures critical problems of global poverty and environmental degradation (Faunce, 2011a, 2012).

One specific outcome of such normative intersections could be provisions supporting science-based assessment of the cost-effectiveness of such new technologies before government subsidy. Another might involve a commitment to withdraw investor-state dispute settlement rights once a nation has achieved a specific score on a rule of law index. Yet another might be a provision that supranational corporations, as a legal requirement of their registration, be ineffect 'married' through a requirement to undertake obligations to global public goods (annually selected by a regulatory authority) and restrain salaries for chief executives within a set proportion of those of political leaders. Sustainable government support for new renewable energy options like solar fuels could derive from a tax on global financial transactions

(Faunce, 2007). The treaty creating such a Tobin tax could include provisions preventing fraud through financial incentives to informants and their lawyers on the model of act us False Claims Act (Faunce, 2011b).

It is an act profoundly coherent with bioethics and human rights to imagine a world where every road, building and vehicle is "doing" photosynthesis more efficiently than plants and where each household could generate its own basic carbohydrate food and ethanol fuel for cooking, heat, and light simply and cheaply from a roof unit that required as inputs only photons, water, and carbon dioxide. It is also ethical to consider the pressure that thereby would be taken off the natural environment to provide land for crops or sources of fuel.

Conclusion

We have seen that there are now two powerful normative systems intersecting (and not necessarily in the public or environmental interest) with bioethics and human rights – domestic law (constitutional, judge made, as well as legislative) and international trade and investment law. The idea has been advanced that bioethics could be evolving toward justiciable and enforceable international human rights as part of a functional global social contract and this implies a combination of both self-assurance about the latters regulatory and symbolic importance, as well as mistrust of governments to otherwise uphold the principles and virtues that sustain them.

The conceptual heart of any global social contract can no longer be considered to involve contractual-type guarantees involving rules about when any one person's freedom can be interfered with by another's, when the aims of the state should not unduly infringe those of its citizens and guarantees of basic social, cultural, and economic support. The obligations of supranational corporations and the capacity of citizens and the environment to be protected from them must also be part of a hypothetical global social contract and the national constitutional norms derived from it.

Both bioethics and human rights carry the promise of enlarging the objects of human sympathy and so the applicable range of principles and rules available to decision-makers. One such emerging social virtue is "environmental sustainability" and it is critical for the survival of our civilization and our planet that it takes its place alongside justice, equity, and respect for human dignity in the normative foundations of bioethics and human rights. Global artificial photosynthesis may emerge as the technology best able to shape the moral revolution that places environmental sustainability at the heart of the world's governance arrangements.

Biobanking

30

Darren Shickle

Introduction: What Is a Biobank?

The Organisation for Economic Co-operation and Development (2009: 1) defined human biobanks and genetic research databases as "structured resources that can be used for the purpose of genetic research, which include: (a) human biological materials and/or information generated from the analysis of the same; and (b) extensive associated information."

However, there is no consensus on a definition for biobanks. Some, for example, the Council of Europe (2006), only use the term biobank population collections and have a separate definition for other collections of biological materials biobanks. Thus, the former would be applied to large cohorts (some such as UK Biobank are as big as 500,000 people) recruited from the general public, while the latter tend to be smaller collections of samples and associated data obtained from patients with a specific disease cohort of patients.

Population cohorts are prospective, collecting detailed information on lifestyle, exposures, and demographic risk factors and then following up the cohort over time to observe what diseases they subsequently develop. They allow researchers to examine the associations between genetic and environmental risk factors for a range of diseases. They tend to be expensive because of the number of subjects to be recruited but also because of follow-up over many years. Even with their large size, there may only be sufficient disease outcomes to study the more common diseases.

For rarer diseases, disease-specific collections are more appropriate. These are retrospective and seek out individual who already have the disease and then look for markers associated with particular genes and other risk factors by comparing with a control group who do not have the disease.

H.A.M.J. ten Have, B. Gordijn (eds.), *Handbook of Global Bioethics*,
DOI 10.1007/978-94-007-2512-6_100,

There are various funding models for biobanks:

- Piggybacked onto hospital clinical services, usually pathology departments
- Funded by grants from research funding bodies as part of their open calls for applications, rather than specific advertisements for biobank proposals
- Funded via specific calls for proposals to support biobanking initiatives to enable or accelerate biobanking research
- Initiatives by governments or large funding bodies, to set up a resource for their research community
- Private sector funding

The term biobank also need not be restricted to human biological material, so, for example, there are biobanks containing samples from other animal species, plants, microbes, etc. However, for the purpose of this chapter, the main focus will be on human biobanks.

Shickle, Griffin, and El-Arifi (2010) proposed a classification for different sorts of biobanks to facilitate a more focused consideration of the ethics and governance issues with each. However, for the purpose of this chapter, the principles of the United Nations Educational, Scientific and Cultural organization (UNESCO) Universal Declaration on Bioethics and Human Rights will be discussed in the context of all the categories of biobank.

It should be noted that that are two other relevant UNESCO documents:

- International Declaration on Human Genetics Data (2003)
- Universal Declaration on the Human Genome and Human Rights (1997)

However, it is outside the scope of this chapter to describe the similarities and differences between these various documents, and the issues relevant to biobank are adequately highlighted by considering the generic Universal Declaration on Bioethics and Human Rights.

Universal Declaration on Bioethics and Human Rights

Articles 1 and 2 are general provisions relating to the scope and aim of the Declarations. The principles themselves are specified within Articles 3–17. Articles 18–21 describe application of the principles. Promotion of the declaration is described in Articles 22–25. Final provisions are laid out in Articles 26–28.

Human Dignity, Equity, and Respect for Cultural Diversity

This section relates the principles as stated within the Universal Declaration on Bioethics and Human Rights (UDBHR) to biobanks. Some of the principles contain broad statements of values which while uncontroversial, without in-depth exploration of their meaning, have limited utility when applied to policy or legislation. Thus, for example, human dignity and human rights (Article 3) and respect for human vulnerability and personal integrity (Article 8), while important concepts to underpin a review of the ethical issues relating to biobanks, will not be discussed in

detail in this chapter, as they have been addressed elsewhere within this Compendium and Atlas of Global Bioethics.

Article 10 (equality, justice, and equity) states that "[. . .] the fundamental equality of all human beings in dignity and rights is to be respected so that they are treated justly and equitably." This is expanded upon in Article 11 (nondiscrimination and nonstigmatization) which requires that "[. . .] no individual or group should be discriminated against or stigmatized on any grounds, in violation of human dignity, human rights and fundamental freedoms." Article 12 emphasizes respect for cultural diversity and pluralism although "[. . .] such considerations are not to be invoked to infringe upon human dignity, human rights and fundamental freedoms, nor upon the principles set out in this Declaration, nor to limit their scope."

Article 17 deals with protection of the environment, biosphere, and biodiversity. While there are biobanks involving other animals and plants, the focus of this chapter has been on human biobanks. The Secretariat of the Convention on Biological Diversity (2002) has also produced guidelines on access to genetic resources and fair and equitable sharing of benefits although the scope explicitly excludes human genetic resources.

The Human Genome Organisation (1996) (HUGO) has recognized that the Human Genome Project, the Human Genome Diversity Project, and other genetic research have given rise to a number of concerns:

- Fear genome research could lead to discrimination against and stigmatization of individuals and groups and be misused to promote racism
- Loss of access to discoveries for research purposes, especially through patenting and commercialization
- Reduction of human beings to their DNA sequences and attribution of social and other human problems to genetic causes
- Lack of respect for the values, traditions, and integrity of populations, families, and individuals
- Inadequate engagement of the scientific community with the public in the planning and conduct of genetic research

The Human Genome Diversity Project (HGDP) (Cavalli-Sforza, 2005) is a resource that is aimed at promoting worldwide research on human genetic diversity, with the ultimate goal of understanding how and when patterns of diversity were formed. In the collection of the lymphoblastoid cell lines from worldwide populations, the HGDP was acutely concerned with ethical, legal, and social issues. At its founding meeting, HGDP adopted ethical guidelines (Greely, 2001), the key points of which were as follows:

- The HGDP and its participating researchers must always respect the humanity of the sampled individual and the cultural integrity of the sampled population.
- Informed consent is both an ethical imperative and a legal requirement.
- Researchers should actively seek ways in which participation in the HGDP can bring benefits to the sampled individual and their communities.
- One way to avoid bringing harm to the sampled individuals or their communities is by protecting the confidentiality of those sampled and, in some cases, of their entire community.

- Although very unlikely, it is nevertheless possible that the results of the HGDP might lead to the production of commercially beneficial pharmaceuticals. Should a patent be granted on any specific product, the project must work to ensure that the sampled population benefits from the financial return from sales.
- Human history – and the human present – is full of racism, xenophobia, hypernationalism, and other tragedies, stemming from beliefs about human populations. In the past, some of those tragedies have been perpetrated by, or aided by, the misuse of scientific information. All those involved in the HGDP must strive, in every way possible, to avoid misuse of the project data.
- Many people in the world have, at best, a limited understanding of human genetics. Some fear the consequences of human genetic research, in part because of the limits of their understanding. It is essential that a worldwide "public awareness" program is included within the project to educate people about its aims, methods, and results.
- The ethical issues faced by the project will evolve over time and must therefore be kept under continual review.
- The transfer of technology to developing regions of the world, which is an integral part of the proposed project, should contribute positively to the development of self-sufficiency in these regions. The help given should not be superficial and of only short-term usefulness.
- There should be a feedback of information to populations that participate in the HGDP.

Cell lines were only included within the resources if donors have provided informed consent to permit use of sample in studies of human history or evolution. A protocol for confidentiality protection for donors of samples was also established. Other information may have been collected by the various researchers who contributed to the collection, but the only information about ethnic and geographical origin (in degrees of latitude and longitude) and sex was stored within the HGDP biobank.

Autonomy and Consent

Autonomy and individual responsibility (Article 5), in the context of biobanks, have received considerable attention in ethics literature in particular in relation to consent (Articles 6 and 7) and, to a lesser extent, privacy (Article 9).

The first paragraph of Article 6 (consent) applies to preventive, diagnostic, and therapeutic medical interventions and hence is not relevant to biobanks as there are no interventions directly associated with the biobanks, although data and samples stored within the biobanks may have been generated as a biproduct of such interventions. However, paragraph two requires that:

> Scientific research should only be carried out with the prior, free, express and informed consent of the person concerned. The information should be adequate, provided in a comprehensible form and should include modalities for withdrawal of consent. Consent may be withdrawn by the person concerned at any time and for any reason without any disadvantage or prejudice.

Beauchamp and Childress (2001) identified the following elements of the process leading to informed consent:

1. Threshold elements (preconditions)
   (a) Competence (to understand and decide)
   (b) Voluntariness (in deciding)
2. Information elements
   (c) Disclosure (of material information)
   (d) Recommendation (of a plan)
   (e) Understanding (of 3 and 4)
3. Consent elements
   (f) Decision (in favor of a plan)
   (g) Authorization (of the chosen plan)

Usually, potential biobank participants will have the mental capacity to give consent. As with other forms of research, there is the potential for concern when research subjects are in a dependent relationship with the research, for example, when a patient is asked to provide consent by a health profession responsible for their clinical care. Thus, the request for consent should usually be made by someone independent of this dependent relationship or at least who has a more junior role.

Article 7 lays out special protections to be given to persons without the capacity to consent. In particular, there are requirements to act in the best interests of the person lacking mental capacity and to involve the person concerned to the greatest extent possible in the decision-making process of consent, as well as that of withdrawing consent. It is difficult to demonstrate that participating in most research (unless when there is therapeutic benefit from an intervention that is only available within a clinical trial) is in the best interest of the participant, even if they have full mental capacity. The key is recognized in paragraph (b) when the caveat is introduced of only exposing the person to minimal risk and minimal burden AND if the research is expected to benefit the health of other persons in the same category. These requirements are consistent with many examples of national legislation, for example, the Mental Capacity Act 2005 in the United Kingdom (Shickle, 2006a). Thus, a person lacking mental capacity should not be recruited into a population biobank or for a biobank for a disease where there would be other patients who have mental capacity to give consent. But in principle, there would be no impediment for establishing a biobank to collect samples for conducting research on conditions that cause mental incapacity.

As Hoeyer (2008) has pointed out, human tissue has been stored and used for research on a regular basis for more than 80 years, and then suddenly during the 1990s, collection of human tissue, under the label of biobanks, started to attract considerable debate in the ethics literature.

There are three categories of consent that could be required within a biobank (Shickle, 2006b):

- Consent to collect data/samples directly from the data subject
- Consent to use data/samples collected for other purposes
- Consent for research to be performed on the data/DNA

Consent to collect data/samples from the data subject within a biobank should not, a priori, be ethically problematic as long as Beauchamp and Childress' elements are addressed. Explaining to potential biobank participants the aim of the biobank, what they are being asked to do, what sorts of questions they will be asked, and what samples will be collected is not dissimilar to the information that should be disclosed for any other research study (Shickle, 2006b). For most biobanks, in particular the retrospective case-control biological sample collection, it should also be relatively easy to explain what analysis will be performed on the data/samples and by whom, for example, in order to look for linking between sequences of DNA and particular risk factors among people with or without the disease. There are also no a priori ethical problems with prospective studies and longitudinal collection of data: many nonbiobank research studies do this. The consent problem with DNA biobanks arises when the information that ought to be disclosed during the consent process becomes increasingly uncertain. For example, unlike most research studies, where the research is performed by those who collect the data/samples, within biobanks this is not usually the case. At best, it is only possible to say that researchers will be vetted for legitimacy, but that they could be from not-for-profit or commercial sectors, may be from the country where the data/samples are collected, or could be international. Similarly, there could be reassurances that (other than exceptional circumstances, such as under a court order) the biobank will only be used for research approved by an independent research ethics committee. Given that most biobank participants are relatively healthy at the time of recruitment, it is also not possible to specify which diseases will be explored. It is this uncertainty that has caused particular debate.

Various solutions have been proposed, which have moved away from an absolute requirement to obtain informed consent (Shickle, 2006b). For example:

- Blanket consent, in which biobank participants assent to their data/samples being used for all forms of future medical research
- Preauthorization models in which participants are able to specify particular sorts of research that may or may not be performed using their data/samples
- Waived consent, in which an independent third party decides whether future uses of data/samples are appropriate

Johnsson, Hansson, Eriksson, and Helgesson (2008) conducted a survey of biobanks in Sweden to find out the incidence of cases of patients withholding their consent for samples to be stored within a biobank. Patients refused consent to either storage or use of their samples in 1 in 693 cases, and 1 in 1,580 confirmed this decision by completing a dissent form. One in 19,059 withdrew their consent. They therefore thought the consent process represented a minimal threat to the quality of research. However, they concluded that:

> A complex and costly administration has been set up to protect the small minority of patients who do not want their samples to be stored in biobanks or used in research. (Johnsson et al., 2008: 3)

They recognized that the findings might not be generalizable to other contexts or cultures and that the right to say "no" might be justified, no matter how small the

minority utilizing it. However, they thought the means to protect this right seemed flawed and that the lack of dissent in an explicit opt-in consent system justified a move to presumed consent as part of an "opt-out" system. In response to this paper, Laurie (2008) thought that Johnsson et al. had overlooked:

> [. . .] the costs of establishing a defensible opt-out system that gives patients adequate information about who might have access to their samples or information, and for what purposes. (Laurie, 2008: a337)

Laurie argued that a stronger evidence base is required in order to better understand:

> [. . .] what patients and public understand about samples, records and research; how well informed they are; and whether low opt-out rates truly reflect well placed trust or simply poorly informed apathy. (Laurie, 2008: a337)

Ludman et al. (2010) contacted 1,340 people for reconsent for transfer of previously collected data to the US federal database of Genotypes and Phenotypes (dbGaP). Interviews were conducted with 365 of the 86 % of the sample who reconsented. Respondents said that it was very (69 %) or somewhat (21 %) important that they were asked for permission. Many thought that alternatives to consent, such as notification-only or opt-out to be unacceptable (67 % and 40 %, respectively).

Article 9 requires that "[. . .] the privacy of the persons concerned and the confidentiality of their personal information should be respected. To the greatest extent possible, such information should not be used or disclosed for purposes other than those for which it was collected or consented to, consistent with international law, in particular international human rights law."

Many studies exploring public attitudes to participating in biobanks have highlighted that potential biobank participants have concerns about privacy and confidentiality (Shickle et al., 2003). For example, in a representative survey of 4,659 US adults conducted by Kaufman, Murphy-Bollinger, Scott, and Hudson (2009), 91 % would be concerned about protecting their privacy if they were part of a biobank, although this should be set against a high concern (79 %) about privacy of their medical information more generally. Respondents were more content to allow academic/medical researchers access to their data than government-funded researchers. They were most concerned about pharmaceutical companies accessing their data, although the study authors were unclear whether this was due to privacy concerns or disapproval of the industry's profit motive. Thirty-seven percent would worry that the study data could be used against them and most wanted guarantees that their data could not be accessed by insurers, employers, or law enforcement officials. However, despite these concerns, 60 % would participate in a biobank.

The question therefore arises whether there is a particular problem relating to biobanks and an Article 9 right to privacy? Are people more concerned about the data and samples that they may donate to a biobank compared with the data or samples that they may be asked for as part of a standard research project? While it has been suggested that there are features of genetic/genomic test information that mean that it should have additional protections (McGuire et al., 2008), most of the

data contained in biobank is information that could be collected within other forms of medical research and indeed research in other academic specialties. Similarly, blood, urine, etc., could also be collected in nonbiobank research. The public do seem to perceive genetic information as being more sensitive because genetic information is perceived as being an integral part of who they are (Melas et al., 2010). Do they perceive data controllers and data protection procedures to be intrinsically more untrustworthy than within other studies? There is no reason to suspect this, but it is a consistent research finding that the public consider certain data users to be more untrustworthy or are concerned that their DNA could be used to identify them (Shickle et al., 2003; Melas et al., 2010). This is despite the fact that most genetic data generated from a biobank has limited or no clinical or predictive value and most biobank participants are law abiding. Of course the privacy concerns about biobanks may just be an artifact of academics going out and asking people whether they are concerned about privacy and biobanks. Given that people do agree to participate in biobanks, it may be that the concern about breach of privacy is outweighed by their perception of the worth of the research and hence the importance of them participating.

As Hoeyer noted from his review of the literature on the ethics of research biobanking, there is a:

> [...] clear discrepancy between the concerns of donors, legislators and ethicists. The academic debate and legislatory action tend to focus on informed consent, and most of the concerns that donors have remain unattended to. (Hoeyer, 2008: 429)

While there were no clear trends, Hoyer made the following tentative observations:

- The type of tissue asked for and the position of the donors in relation to the research project seem to be important: the more people feel they need medical research results, the more likely they seem to donate.
- Only a minority would never participate in biobank research, but the social groups most likely to abstain differ between national contexts.
- A majority, or at least a substantial minority, think the donor should have a say concerning retention of tissue. This is generally interpreted as support of a consent requirement, but whether people prefer broad or specific consent and when and under which conditions differs remarkably between the surveys.
- Commercial access to public biobanks is accepted by a majority, although it is viewed more as a necessary evil than as the preferred research infrastructure.
- Mostly, donors are interested in getting access to research results, particularly of relevance to their own health, but the conditions differ widely.

Solidarity and Cooperation

The HGDP ethics guidelines recognized that it was unlikely that the HGDP would lead to commercially valuable products. Article 4 (benefit and harm) required that "[...] in applying and advancing scientific knowledge, medical practice and associated technologies, direct and indirect benefits to patients, research

participants and other affected individuals should be maximised and any possible harm to such individuals should be minimised." Direct benefits for an individual from participating in a biobank are negligible, and harms are more likely to arise in relation to dignity, integrity autonomy, etc., rather than harm to physical or mental well-being. Indeed, population benefits may be unclear when a biobank is first established, but rather they are created as a resource for researchers to use in order to conduct research that may generate benefits downstream. Individual patients and members of the public are asked to join this enterprise and make altruistic donations of their personal data and tissue.

Article 13 (solidarity and cooperation) suggests that "[. . .] solidarity among human beings and international cooperation toward that end are to be encouraged." "Solidarity" and "altruism" are concepts that underpin much of the publicity materials for biobanks. For example, the strap line for UK Biobank is "Improving the health of future generations."

Notes of the UK Biobank consultation meeting with industry described UK Biobank as:

> [. . .] a long term endeavour and the altruistic contribution of participants will benefit future generations . . . The contribution of participants to the project should be seen as a gift to biomedical science in the public interest. (UK Biobank, 2003: 5)

The language within the UK Biobank Ethics and Governance Framework went further:

> Participation will be presented as an opportunity to contribute to a resource that may, in the long term, help enhance other people's health. (UK Biobank, 2007: 5)

The use of the word "opportunity" suggests that participation is something that a citizen would want to do, if not ought to do, as part of an obligation to improve the health of future generations.

The UK Human Genetics Commission (2002) went further and used the language of "duty":

> Genetic knowledge may bring people into a special relationship with one another. We lead our lives as members of large and small communities and we have certain duties to other members of these communities. Such duties can include not causing harm to others and doing things to help them. Sharing our genetic information can give rise to opportunities to help other people and for other people to help us and we have a common interest in the benefits that medically-based genetic research may bring. We have, therefore, set out a concept of *genetic solidarity and altruism*. This supports the idea that, for example, although nobody should feel pushed into taking part in genetic research, when they make this decision people should be aware that by taking part they might help those suffering from disease. (Emphasis in original) (Human Genetics Commission, 2002: 6–7)

Petersen (2005) explored use of the language of citizenship within published documents pertaining directly or indirectly to UK Biobank. Petersen felt that words and phrases such as "altruistic," "gift," "sharing," "opportunities to help others," "common interest," etc., have a strong resonance in liberal democracies, especially with a widening of the concept of social citizenship and an emphasis on the duties of citizenship. However, he felt that the term "genetic solidarity" represented

a significant modification of the concept of social solidarity, which in its conventional usage implies cohesion, shared aims, and interested and single-minded unity of purpose. He saw the conjunction of "genetic" and "solidarity" as being consistent with:

> [. . .] the increasingly prominent worldview of 'genetic welfare', whereby genetic considerations tend to prevail over social ones and there is a change in our perceptions of rights, responsibilities and duties. It is the language of an emergent biological citizenship, involving the linking of biology and identify. (Petersen, 2005: 284)

Obligations for protecting future generations are specifically addressed with Article 16 which requires that the impact of life sciences on future generations, including on their genetic constitution, should be given due regard.

The main genetic issue in relation to protection of future generations would be impact on the gene pool. The gene pool can be affected in various ways:

- Prolonging the life of individuals with genetic conditions who would otherwise not reach reproductive maturity or who would be unable to reproduce
- Manipulation of the genome within inheritable material, for example, via gene therapy
- Selective termination of pregnancy for particular genetic disorders or traits
- Introducing evolutionary pressure on partnership and reproductive choices of individuals

Biobanks may lead to downstream interventions that could theoretically lead to the first of these. While any genetic research can add further to the pressures driving the latter three, the association between biobanks with these is likely to be tenuous.

Article 14 (social responsibility and health) suggests that "[. . .] the promotion of health and social development for their people is a central purpose of governments that all sectors of society share." This is unlikely to be contested. However, Article 14 goes on to suggest that "[. . .] the enjoyment of the highest attainable standard of health is one of the fundamental rights of every human being without distinction of race, religion, political belief, economic or social condition" and that progress in science and technology should be directed to advance this aim. Including "highest attainable standard of health" as a fundamental human right is however likely to be contested and indeed unattainable. A critique of this is outside the remit of this chapter on biobanks, but suffice to say that all healthcare systems involve some degree of rationing and hence suboptimal health for its service users. However, while the general direction of this article is important, it is not relevant to most biobanks. The aim of biobanks is to facilitate research that would lead to the highest attainable standard of health, but there are lots of intermediate steps between biobanks and final product and benefits and probability of success are often exaggerated.

Sharing of Benefits

Article 15 (sharing of benefits) proposes that "[. . .] benefits resulting from any scientific research and its applications should be shared with society as a whole and within the international community, in particular with developing countries."

The Human Genome Organisation Statement on the Principled Conduct of Genetic Research (1996) was based on the following principles:

- Recognition that the human genome is part of the common heritage of humanity
- Adherence to international norms of human rights
- Respect for the values, traditions, culture, and integrity of participants
- Acceptance and upholding of human dignity and freedom

It went on to recommend that:

> Undue inducement through compensation for individual participants, families and populations should be prohibited. This prohibition, however, does not include agreements with individuals, families, groups, communities or populations that foresee technology transfer, local training, joint ventures, provision of health care or on information infrastructures, reimbursement of costs, or the possible use of a percentage of any royalties for humanitarian purposes. (Human Genetic Organisation, 1996: 3)

A subsequent statement by the Human Genome Organisation Ethics Committee (2000) dealt specifically with this issue of benefit sharing and how to distribute profits that may accrue to commercial enterprises, governments, or academic institutions on the basis of the participation of particular communities. The Committee recognized that there are different definitions of community and that communities may have different beliefs about what constitutes a benefit. However, prior discussion was needed with groups or communities on the issue of benefit sharing. They also recognized that as a species, we all share in essence the same genome and at this collective level, the genome is the common heritage of humanity. However, at specific places within the genome, individuals (with the exception of identical twins) exhibit significant variation. At a minimum, all research participants should receive information about general research outcomes and an indication of appreciation. The Committee recommended that all humanity share in, and have access to, the benefits of genetic research and that benefits should not be limited to those individuals who participated in the research. Even in the absence of profits, the Committee recommended that immediate benefits as determined by community needs could be provided. But profit-making entities should dedicate a percentage of their annual net profit (1–3 % was suggested) to healthcare infrastructure and/or to humanitarian efforts.

Many of the smaller biobanks do not have the resources to consider issues relating to intellectual property rights (IPR), but even within the larger population biobanks, IPR issues are often poorly addressed, or the policy is deferred until after the collection phase is complete. For example, UK Biobank is probably the largest biobank with the highest international profile and most often used as a gold standard for other biobanks to follow (it has recruited 500,000 people aged between 40 and 69 years from across the United Kingdom). UK Biobank completed sample collection in 2010 but did not finalize its access procedures until the end of 2011 (UK Biobank, 2011).

Pathmasiri, Deschênes, Joly, Hemmings, and Knoppers (2011) identified three phases within the life cycle of a biobank in which IPR may be relevant: creation, collection, and access phases. They proposed that scope for IPR within the first two of these phases is limited. Within the creation phase, the biobank may wish to

copyright logos, software for interviews, or new health questionnaires. Patents may be sought for innovative equipment developed for storage of samples. However, only in exceptional cases would these intellectual property (IP) protections be financially lucrative. Within the collection phase, the main focus is privacy and protection of access to data and samples. The emphasis is on contractual and procedural mechanisms rather than IPR. The main scope for IPR is in relation to research that accesses the data and samples contained within a biobank, leading to patents for new diagnostic tests, new applications of existing medications, new medications, or copyrights in publications.

Pathmasiri et al. (2011) raised the question as to whether publically funded biobanks should claim any ownership of IPRs that are developed as a result of access to biobank data and samples. They did recommend that biobanks acknowledge the possibility of "downstream IPRs" and that these ought to be clearly and preemptively specified within IP policies and access agreements before granting access to the biobank to mitigate future misunderstandings and litigation. Pathmasiri et al. conceded that a biobank, and of course the public that paid for it, might wish to benefit from downstream IPR as there was considerable time, energy, and money involved in collecting, processing, and storing of samples. However, they pointed out that biobanks only provide the raw material for the research and do not take part in the inventive steps to develop patents, and hence, they argued that biobanks should not have rights in patents, etc. The main argument of their paper was that publically funded biobanks should be satisfied with benefits "in kind" rather than financial. Underpinning this argument is the recognition that aim of the majority of publicly funded biobanks is to promote the development of new knowledge by giving the research community access to data samples. It is further argued that the most efficient way to acquire these benefits is to, firstly, maximize the use of the biobank in research and, secondly, maximize the dissemination of knowledge developed by the research projects that used the biobank. Pathmasiri et al. claimed that the need to negotiate additional potential IPRs before obtaining access to the biobank resource translates into added access procedures, approvals, and delays and hence additional hurdles that put of use of the biobank and be counterproductive to the aims of the biobank owners.

In addition, Pathmasiri et al. (2011) suggested that the financial return from downstream IPRs for the biobank may be an unpredictable source of income, and biobanks would be better advised to ensure that the funding needed for maintaining the biobank is secured from access fees. They also pointed out that the additional administrative burden of negotiating and monitoring IPR would need to be offset against any income. While it is true that for smaller biobanks the likelihood of generating significant and reliable IPR income would be low, larger population biobanks are likely to attract significant interest from international research groups, and hence, the extra work in setting up robust access and IP arrangements would be warranted.

Most of the costs associated with a biobank are upfront, relating to the collection phase and to a lesser extent the creation phase. The case is usually made to funders on the basis for the need for establishing the biobank as an infrastructure for

research. The funding is made on this basis without an expectation that that the funding will be returned, although the initial grant often does not give sufficient attention as to how the resource will be funded on a long-term basis during the access phase. For most biobanks, there is an expectation that access fees would cover at least the cost of retrieving and processing the data and samples for each request and that this income would also offset the cost of maintaining the biobank itself. The main IPR concern for most biobanks is to set up a mechanism to prevent exclusive licensing practices which lead to higher prices for diagnostic tests and pharmaceuticals developed from utilizing the biobank and hence adversely affect the public who freely donated the samples that facilitated the patent-creating research in the first place. The most infamous example of this (although not directly related to a biobank) was when Myriad Genetics marketed predictive genetic tests for breast cancer, as prices that were considered by some to be excessive, on the back of patents it held for sequences within the BRCA 1 and 2 genes (Marsh, 2010; Park, 2010).

The patent system and other intellectual property rights were enacted in recognition of the need to reward the investment of individuals leading to innovation, and that innovation, generally, is in the public interest. Thus, researchers, especially within the for-profit sector, will need to be afforded some IPR protection as incentive for doing the research, but at the same time, providing some guarantees for society that the patented innovations are not priced out of the reach of parts of society who have capacity to benefit. The US National Institutes of Health [NIH] (2005) and the Organisation for Economic Co-Operation and Development (2006) have both produced guidelines for best practice for the licensing of genetic inventions. The NIH guidelines discouraged exclusive licensing:

> Whenever possible, non-exclusive licensing should be pursued as a best practice. A non-exclusive licensing approach favors and facilitates making broad enabling technologies and research uses of inventions widely available and accessible to the scientific community. When a genomic invention represents a component part or background to a commercial development, non-exclusive freedom-to operate licensing may provide an appropriate and sufficient complement to existing exclusive intellectual property rights. (NIH, 2005: 18415)

The NIH guidelines go on to state that:

> PHS [Public Health Service] encourages licensing policies and strategies that maximize access, as well as commercial and research utilization of the technology to benefit the public health. For this reason, PHS believes that it is important for funding recipients and the intramural technology transfer community to reserve in their license agreements the right to use the licensed technologies for their own research and educational uses, and to allow other institutions to do the same, consistent with the Research Tools Guidelines. (NIH, 2005: 18415)

In addition to more specific principles and examples of best practice, the OECD guidelines contained four general principles and recommended that licensing practices should:

- Foster innovation in the development of new genetic inventions related to human healthcare and should ensure that therapeutics, diagnostics, and other products and services employing genetic inventions are made readily available on a reasonable basis

- Encourage the rapid dissemination of information concerning genetic inventions
- Provide an opportunity for licensors and licensees to obtain returns from their investment with respect to genetic inventions
- Have reasonable certainty over their rights and the limitations to those rights in relation to genetic inventions

Given its size, both in terms of size of cohort and budget, UK Biobank is proposing to take a more robust approach to IPR compared with other publicly funded biobanks, and intends to explicitly retain ownership of the resource:

> UK Biobank's approach to Intellectual Property Rights (IPR) is structured on the basis that it seeks to encourage use of the UK Biobank Resource for health-related purposes by bona fide researchers. To this end, UK Biobank will retain ownership of its rights in the Resource (so that it is available to all other approved researchers), while at the same time facilitating the availability of clinical advances (e.g. diagnostics and treatments) arising from its use. UK Biobank is the owner of the property in the samples and the database (which will be added to, and updated, throughout the life of the Resource) and retains all the intrinsic IPRs in the data in the Resource (notably database rights and copyright). (UK Biobank, 2011: 10)

Pathmasiri et al. (2011) also proposed that one way that biobanks could achieve a goal for wide diffusion of knowledge and applications is to request that biobank users return research findings to the biobank within a designated time frame. These results can then be made available to the wider research community, who could make use of them within other research.

UK Biobank has also given a clear indication that it:

> [. . .] would not expect naturally-occurring genetic sequences, biomarkers, proteins or biochemical processes to be made the exclusive preserve of one party. (UK Biobank, 2011: 10)

UK Biobank proposes to have no claim over inventions and associated IPRs that are developed by researchers as a result of using the resource. However, it is intended to have a "reach-through" provision to restrict the exercise of these rights if IPR is used to restrict health-related research and/or access to healthcare unreasonably. In the event that conduct is considered "unreasonably restrictive," UK Biobank:

> [. . .] reserves the right to require that a licence of such rights is granted back to UK Biobank on an irrevocable, perpetual, global, royalty-free, fully sub-licensable basis so that other researchers who are granted access to use the Resource can exercise such rights to the extent necessary to conduct their research project. (UK Biobank, 2011: 10)

It remains to be seen how UK Biobank operates this proposed approach to IPR once access to the resource has begun. It also remains to be seen whether smaller biobanks would be able to institute similar restrictions. Given the pressure to demonstrate that the resource is being used and hence show to funders that the money spent on establishing the biobank is worthwhile, it would be courageous for a biobank administrator to place barriers to exploitation of the resource, when, for the more common conditions at least, there is a global oversupply of samples.

The Icelandic Health Sector Database was operated under a license by deCODE genetics. In turn, deCODE genetics entered into an exclusive sublicense agreement with Hoffman-La Roche that will give the latter exclusive access to the database to

explore the genetic origins of 12 diseases. This sublicense agreement promises that Iceland will be provided, free of charge for the patent term, any products that are developed using data from the Icelandic database. While the decode model received considerable criticism (Greely, 2000) and the company eventually went bankrupt in 2009, the model of subsidized healthcare costs might be attractive to a country with a cash-limited health economy. Other countries that have established national biobanks have also hoped that it would attract pharmaceutical and biotechnology companies to set up facilities within their country, so earning additional tax and economic activity.

Paragraph 2 of Article 15 states that "[. . .] benefits should not constitute improper inducements to participate in research." While there are rarely any direct financial inducements for donating tissue, within publicly funded biobanks at least, there may be some degree of coercion for patients to participate in disease-specific biobanks, if they believe that this is the best hope of finding a cure.

Support groups for patients with genetic disorders are generally keen supporters of the research community and oppose measures that they perceive might hinder the research process. For example, commenting on the Myriad Genetics case, Sharon Terry, the cofounder of PXE International, wrote:

> A sweeping, broad-brush approach would cause wide-ranging disruption to research and development for innovative diagnostics and treatments to the detriment of individuals and families in need of medical breakthroughs. (Terry, 2010: 24)

PXE International is a support group established by families with *pseudoxanthoma elasticum* (PXE). When Sharon Terry's children were first diagnosed with PXE, Sharon and her husband started exploring research options and in addition to establishing the support group developed their own biobank and retained IPR. When they were approached by two separate research groups for blood samples, they were:

> [. . .] shocked to find out that they wouldn't share [samples] and expected us to allow blood to be drawn from small children twice in 1 week. There was no central repository for the precious blood of people with this rare condition . . . We began to scheme about what we would do if we were managing research on this disease. It seemed to us that not only did PXE need a central repository for blood and tissue, it also needed a large cohort of affected people to give researchers a comprehensive understanding of the condition's manifestations and progression . . . Soon after we started the PXR International Blood and Tissue Bank, the researcher in whose lab we banked our samples actively tried to thwart access to the bank by other researchers. We were appalled, maybe naïvely, that researchers would put their needs for publication, funding, promotions, and tenure ahead of the needs of people living with disease . . . Fortunately, this problem was counterbalanced by interactions with other researchers here and abroad, with whom real collaboration occurred. One of these relationships led to a joint application for the patent on the gene associated with PXE – the first time lay people in an advocacy group have applied for the patent. We consider ourselves stewards of the gene and know that the real issues will be played out in its licensing. (Terry, 2003: 168–170)

Article 15, specifically notes the importance of benefit sharing with developing countries. Sheremeta and Knoppers (2007) recognized that in view of the trend toward population genetic research and the widening gap between the developed

and the developing world, mechanisms are required to ensure that the benefits of this research can be shared equitably. They suggested that if the biotechnological advances derived from genomics are applied correctly, then there is potential to affect a revolutionary transformation in medicine and healthcare over the next few decades. But they also warned that if used "inappropriately and unwisely" the power of genome-related biotechnologies would inevitably exacerbate existing inequities.

Emerson, Singer, and Upshur (2011) noted examples of "scientific-imperialism" and "biocolonialism" in which vulnerable populations had been exploited in research. They believed that this has led to many communities and governments in low-to-middle income countries being understandably reluctant to trust foreign researchers and permit access to human tissues. As a way of rebuilding this relationship, Emerson et al. (2011) proposed a "tissue trust" as a way of promoting host capacity by either requiring that research is conducted within country or charges an export fee that could be used to develop this capacity. The model also includes requirements in terms of governance structures and community engagement.

Moral standards for sharing of research benefits with the developing world have been proposed (El Setouhy et al., 2004). However, the main focus of these frameworks is in terms of fairer benefits to participants and the community in which they live, during the research. As has been mentioned previously, the benefits from participating in a biobank are negligible. Thus, it is the wider global healthcare agenda that is relevant here and not one specific to biobanks, with downstream diagnostic tests or therapies being equitably shared and accessible to deprived populations. That said, the initiatives such as the Human Genome Diversity Project will be important to ensure that the outputs of genomic research take into account different polymorphisms around the world. After all, no developing country would be able to afford the £60 million spent on establishing UK Biobank.

Conclusion: "Biobank Exceptionalism"?

The main focus of the discussion within this chapter has been on Articles 6 (consent) and 15 (sharing of benefits), reflecting the main foci of debate about biobanks within the academic literature. It should be noted that while the scientific (and indeed the ethics) community has paid particular attention to producing solutions to the consent problem within biobanks and the public are presented with arguments why participating in a biobank participant is a way of solidarity, scientists have been less forthcoming with solutions to address the sharing of benefits.

It is true that biobanks provide an infrastructure and a resource for research, rather than being a research enterprise in their own right. It is also true that seeking informed consent for data/sample donation is more complicated because of the uncertainty about how the resource will be used and by whom.

However, this should not mean that biobanks should be automatically exempt from the usual a priori moral obligation to seek informed consent. Of course, there are examples of research where consent is not sought because it is not practicable or appropriate to do so, and if necessary, biobanks should use similar justifications.

It is true that intellectual property rights are more difficult when there are many organizations involved. It is also true, that the funders of biobanks want to encourage research that will benefit the public. However, these difficulties should not mean only the researchers (whether in for-profit or not-for-profit organizations) should only be the ones to benefit from the investment made by those who fund the biobank and those who donate their data/DNA.

Genetic exceptionalism is the claim that genetic information is special and hence should be treated differently from other forms of personal or medical information, based on its ability to predict the future, identify individuals, implications for other family members, and/or scope to discriminate/stigmatize. However, to various degrees, these characteristics are also true of nongenetic information. In any case, the information generated from research on biobank samples could rarely, if ever, be used in these ways. While the particular issues relating to biobanks require specific attention, this should not mean that the principles within the Universal Declaration on Bioethics and Human Rights do not apply.

Biometrics

31

Emilio Mordini

Introduction

Biometrics has passed through its pioneering period and is now increasingly used for people identification and/or authentication online, in border controls, in health systems, e-commerce, e-government, and so on. Rapid decreases in price, better performance, and dramatic improvements in sensor technology and data storage capacity have made biometrics practical both for consumer applications and for governmental purposes.

Any innovative technology program needs a continuous investigation of its possible ethical implications. Biometrics could play a pivotal role in ensuring more reliable identification schemes both at local and global levels. Yet one should carefully balance the benefits with ethical and social risks. The relevance of ethical implications of biometrics is self-evident: it is not only a consequence of the scale of the phenomenon and of the current historical period. Its relevance is mainly a consequence of the deeply rooted ethical significance of some issues raised by biometrics. Many of the problems are related to individual identity such as protection of personal data, confidentiality, individual liberty, and the relationship between individual rights and common good.

This chapter will first provide an overview of the development and the state of art of biometric technology in the wider context of the history of personal recognition. The main ethical implications of biometrics will be then discussed under two main headings, fundamental and specific ethical issues. Fundamental issues concern the central question whether biometrics are per se demeaning and abusive of human dignity. Among specific issues, the focus will be on questions related to privacy and data protection, questions related to surveillance, and questions related to large-scale applications. After confronting ethical issues raised by biometrics with the Universal Declaration on Bioethics and Human Rights, the conclusion will indicate the potential contribution of biometric technology to the development of human rights in low-income countries.

Biometrics

The Origins

The word "biometrics" comes from the ancient Greek and literally means measure (metrics) of life (bio). It was coined in the late nineteenth century by Francis Galton (1822–1911), an English geographer, anthropologist, naturalist, and pioneer in eugenics. Galton modified a previous Greek neologism invented by Anglican priest and polymath William Whewell (1794–1866) who first used the term "biometry" to mean "calculation of life expectancy" (Whewell, 1831, p. 375). Galton slightly modified the term from biometry to biometrics and changed its meaning by using it with the sense of "application of mathematics to biology" (Galton, 1901, p. 7). According to Galton's original definition, "the primary object of Biometry is to afford material that shall be exact enough for the discovery of incipient changes in evolution which are too small to be otherwise apparent" (Galton, 1901, p. 9). Galton put strong emphasis on quantitative aspects of biological research (Bulmer, 2003). He took inspiration from "The Origin of Species" to focus on the measurement of individual differences among living organisms, but differently from Darwin, he was convinced that evolutionary chance is not gradual but progresses through major breaks in continuity. In particular, Galton focused on mental and physical characters in human beings and to what extent they depend on biological heritage and environmental and developmental conditions.

Further to Galton, the word biometrics was used to mean various methods of measurement of physical and behavioral features of an individual in order to:

1. Study hereditary and environmental factors which concur to determine these features
2. Study variability over time of these features
3. Investigate their possible association with pathological conditions
4. Assess to what extent they are unique for each individual and can be used as identifiers

Biometric applications have included the following applications:

1. Medical applications: medical parameters (e.g., weight, height, body diameters, blood pressure, measurement of biochemical components in the blood). These biometric features are normally used for clinical purposes. By comparing measurements collected from an individual with previous measurements from the same individual, and with average values obtained from healthy individuals, medical doctors may infer information about the state of health of the subject. These measurements could also be aggregated in order to deduce meaningful medical data about physiological and pathological conditions of human communities.
2. Natural science applications: the statistic study of quantitative variance of anatomical and physiological features, in humans, animals, and plants, is a powerful instrument to study the inheritance and evolution of characters and the transformation of species.

3. Social science applications: biometrics were used to provide scientific foundation to the so-called anthropology of human races and to racist theories.
4. Forensic applications: biometric forensic applications have been twofold. On the one hand, in the past biometrics provided foundation to prejudicial scientific discourses such as physiognomy and phrenology; on the other hand, they have been used for criminal identification by exploiting the uniqueness of some biometric features, notably the disposition of epidermal ridges of human fingers which leave an impression called "fingerprint." Galton first noticed that fingerprints have the characteristic of being different in each human being, even in identical twins. From this observation, he proposed the use of fingerprints for the identification of criminals and victims in the course of the police investigation (Bulmer, 2003). Impressions of fingers, invisible to the naked eye (latent fingerprints), may be left behind on a surface at a crime scene and further retrieved, which explains the great relevance of this biometric application in forensic practice.
5. Applications for personal recognition: there is some evidence that in ancient times, biometric features were used for individual recognition purposes: a number of archeological artifacts show that fingerprint impressions have been used as a signature since the Neolithic era. European explorer Joao de Barros recorded the first known example of fingerprinting in China during the fourteenth century. The Spanish explorer wrote that early Chinese merchants used fingerprints to settle business transactions, and those Chinese parents used footprints and fingerprints to differentiate children from one another. In order to be a good identifier, a biometric feature should satisfy four basic requirements: (1) collectability, which means that the feature should be easily measurable; (2) universality, which means that the feature exists in all individuals of a given species; (3) uniqueness, which means that the feature should be present in a distinctive way in each individual; and (4) permanence, which means that the feature should remain stable over time. Many body features have been investigated, yet – till to the introduction on digital biometrics – only fingerprints satisfied all these conditions.

Personal Recognition

Today biometrics are largely thought of as providing ways of managing and authenticating the identities of individuals, and only few scholars remember different biometric applications. How did biometrics come to this point? One needs to refer briefly to the history of methods for personal recognition and their significance in human civilization.

The need for specific methods for identification is presumably connected with the birth of the first urban societies during the so-called Neolithic Revolution. From at least three million years ago, humans have lived by hunting (or fishing) and gathering edible items (such as fruit and insects). Only a few thousand years ago,

the mankind developed a new economic model based on farming (cultivated crops and domesticated animals). The transition from an economy based on hunting and gathering to an economy based on farming implied many epochal consequences, among which the emergence of sedentary dwelling. Human groups gave birth to sedentary communities organized in small villages and towns. Farming economy also meant the creation of food surpluses, which promoted trade of food and food-related products (e.g., salt, which was probably one of the first commodities because of its ability to preserve food). Growing societal complexity, alongside developments in intra – and intersocietal trade, made the identification of foreigners increasingly vital to the normal functioning of these early societies. One has indirect evidence of this, in the Odyssey, whose plot is based on a series of recognitions of a hero who is travelling abroad, far from his own homeland, striving for going back home. Indeed, the reading of the Odyssey allows listing the main identifiers used by early human communities. They include a description of physical appearance (e.g., body size and shape, skin and hair color, face shape, physical deformities and particularities, wrinkles and scars) and artificial and more permanent body modifications (e.g., branding, tattooing, scarification). Finally they include physical (e.g., passes, seals, rings) and mental tokens (e.g., memories, poems, music, recollection of family and tribal links).

As population densities increased, also social hierarchies developed. The birth of the great empires (Egyptian, Chinese, and Assyrian) introduced new important drivers for personal identification, taxation, conscription, and the administration law. The Roman Empire was the first cosmopolitan society in the West providing for a universal identification system through a tripartite codified name scheme, which was related to the birth of the first comprehensive legal system on property and political citizenship. The Roman name scheme remained partly operational in Europe during the Middle Ages, yet most mediaeval "nomadic" individuals – e.g., beggars, pilgrims, merchants, and professional soldiers – were identified only through community membership, certified by passes and safe-conducts issued by religious and civil authorities.

The modern era saw increased mobility associated with new geographic discoveries, urbanization, and, later on, industrialization. The need for more effective recognition schemes emerged in parallel with the development of post-Westphalia polities. The first passports were issued in France by Louis XIV, and the first legislation in the West linking personal identities to birth registration was enacted during the French Revolution. The passage from the mediaeval identification scheme based on community membership (e.g., family, guild, village, manor, parish) to an identification scheme based on a document issued by the state central authority is full of meaning. The new citizen who emerged from this process was an unmarked individual who was distinguishable only through her name, nationality, and place and date of birth. Religion, ethnicity, race, cast, and social conditions became irrelevant in order to identify individuals, at least in theory. Actually the history of how nation states kept on using identification schemes largely based on racial, religious, and ethnic categories is sadly infamous. The most horrible event of the twentieth century,

the Shoah, was made possible chiefly by the existence of an effective, automated, bureaucratic apparatus for certifying racial identities (Black, 2001).

After World War II, a new powerful driver for personal identification emerged: the welfare state. The welfare state, which first appeared in north Europe, was based on the provision of services via redistributionist taxation. In order to be properly enforced, both redistributionist taxation and welfare provision need robust and reliable systems for personal identification, which is witnessed inter alia by the increasing numbers of identity and entitlement documents (e.g., social cards, social insurance number) that are generated by each state which provides social benefits and services.

Finally after the agricultural, the industrial, and the welfare state revolutions, we are now on the verge of a new, epochal transition. The world has reached a degree of interconnectedness never experienced before. Today, about two billion persons are moving each year across large geographic distances (International Air Transportation Association, 2010), about two billion and a half people are connected to the Internet (Internet World Stats, 2013), and the number of active cell phones in the world is exceeding the world population (SI team, 2013). This situation dramatically transcends national control and state regulations and has momentous consequences for traditional identification schemes, which cannot rely any longer only on identification documents issued by nation states. The tourist hoping to use her credit card in any part of the globe, the asylum seeker hoping to access social benefits in her host country, and the banker hoping to move money from one stock market to another in real time – all have the same need. They must prove their identities and be certain of others' on a global level. In such a context biometrics are emerging as the possible answer.

The Birth of Automated Biometrics

Till the 1970s fingerprints were the sole, relevant example of biometrics used for identification purposes. Conventional fingerprinting was based on the comparison between two sets of analog representation, one set obtained in the past from a known individual and one set collected in the present, either on the crime scene or from unknown individuals that should be identified or whose identity should be verified. Until the advent of digital technologies, fingerprints were collected by using ink and a card or by using dark powder and tape (latent fingerprints). Fingerprints were then compared with the fingerprints on recorded files (comparative dactyloscopy). The whole process was time demanding, rather cumbersome, and its accuracy critically depended on expert's competence and experience.

As all repetitive and boring activities, also fingerprinting was waiting for automation, and this became possible in the 1970s, when first the Japanese National Police Agency and then the FBI automated the process of classifying, searching for and matching fingerprints.

The birth of Automated Fingerprint Identification Systems (AFIS) was not a trivial event because it was the starting point of contemporary, digital biometrics.

The discovery that fingerprints could be turned into numbers (i.e., digitalized) and processed as numeric strings opened the way for finding a number of new biometric identifiers, which could not be appreciated by naked eyes, but that could be captured and processed by specific sensors. Beyond fingerprints, other unique and stable biometric features were soon discovered, e.g., iris structure, retina texture, face and hand geometry, body and ear shape, voice, signature dynamics, and gait.

Simplifying greatly, one may think of automated biometric systems as identifying or authenticating individuals on the basis of three steps. (1) Biometric samples are captured by way of sensors which record physical inputs from the biometric traits presented by the subject (e.g., fingers, face, iris). Sensors are mechanical devices which are modified by the input signal, in a way which is proportional to the magnitude of the signal. This generates an electric output. Through the repetitive measurement of the electric output at certain interval of time, the magnitude of the voltage is turned into a proportional number, which is encoded as a binary number, or a gray code, or still in other ways. The overall process is called "analog-to-digital conversion." The analog-to-digital conversion is the occurrence which makes automatic biometrics radically different from any traditional, human performed biometrics. From the moment in which the representation of the relevant properties of an item is turned into digits, one can operate through numbers. This has dramatic consequences. First, the digit format allows collecting, processing, storing, and retrieving a huge amount of data in a short period of time, which was definitely impossible with analog representations. Second, digital representations have different qualities from analog representations; the most important is that digital representations display information in terms of discrete values and consequently can be compared by using quantitative and probabilistic criteria. Data handling and probabilistic comparison are the two events which allow the full automation of the whole recognition process. (2) The next step is the creation of templates, which are normalized representations of the biometric sample. In real life there is a continuous variability, and in order to get a model reliable enough, one needs to merge and normalize signals captured in different moments and under different conditions. Templates can be generated mainly in two ways, either a series of analog signals are combined, creating a compound signal which is then digitalized, or each of the series of analog signals is digitalized individually, and then the results combined. Whichever method is employed, the aim is the same: to overcome variations between individual signals due to contextual factors such as lighting conditions or background noise. Templates are then stored as digital representations (e.g., in a central database or on a card – though central databases are increasingly unpopular and unnecessary). When, on a subsequent occasion, (3) the subject presents their biometrics to the system, it will produce a new template which can be matched with the existing template created on enrolment (i.e., at steps (1) and (2)). This matching of earlier and later templates is not expected to be exact, but will make reference to a given confidence interval, a margin of error deemed appropriate to the particular context in which the biometric system is deployed. When a template is compared with a database (one-to-many comparison),

the process is known as "identification"; when it is compared to a specific existing template (one-to-one comparison) – say, the template stored in a passport – the process is known as "verification." It is important to draw reader's attention on the fact that the database used for identification should not be necessarily centralized. Actually today, there is the tendency – both for privacy and security reasons – to use dispersed, networked databases. A special case is then when one is interested in checking whether an individual is not in a given database (i.e., screening). In such a case one compares the biometric sample against a database with the aim not to match it. In other words, one is not interested in ascertaining the identity of an individual, but in knowing who the subject is not (negative identification).

Engineers usually distinguish between strong, weak, and soft biometric features (Jain, Patrick, & Ross, 2008).

"Strong biometrics" are features that can be considered unique (at least extremely unlikely to be found equal in two individuals) and permanent (at least enduring for very long periods of time). Although no physical property can ever be truly unique or permanent, some properties can be treated as though they were. For instance, in human beings, fingerprints, hand skin patterns, iris structure, hand veins, and the retina texture can be practically considered unique and stable. The same would hold true for DNA, which is however rarely considered a biometric trait, chiefly because of historical reasons and because its usage is often subjected to specific legislations. The early development of biometric technologies has been chiefly based on strong biometrics. Logically speaking, identification based on strong biometrics is hardly different from identification based on artificial tokens. What changes with biometrics is that the token is no longer an external object associated to the person, but it is a bodily feature. This explains the popular aphorism, according to which biometrics are turning the human body into a password, which would be true in any case only for strong biometrics.

"Weak biometrics" are features that are "less unique" or "less stable" than those used as strong biometrics. In humans, weak biometrics include features like body shape, odors, behavior (e.g., gestures, gait, face dynamic), voice, body sounds, and electrophysiological phenomena (e.g., hearth and muscular electrical activity, brain waves). Weak biometrics can be used for identification purposes provided that they are not used in isolation. Given that one can only in part establish a be-univocal correspondence among them and a given individual, they should be used only in context (by considering also space and time coordinates) or in association. This implies that in order to use them efficaciously, one should collect also other details such as geo-spatial localization and the time in which the feature has been collected. One could also fruitfully merge two or more weak biometrics, or different biometric modalities targeting the same biometric feature, or associate weak biometrics with soft biometrics.

With the expression "soft biometrics," engineers refer to features which are too generic to be an identifier. They include categories such as gender; age; race and ethnicity; weight; height; and eye, skin, and hair color. Soft biometrics can be fruitfully used to reinforce strong and weak biometrics. Basically they allow to reduce the number of odds and consequently to refine the identification process.

Next Generation Biometrics

Advances in sensor technologies, which enable different bodily and behavioral characteristics to be captured, have been the main technological driver of next generation biometrics, which is largely based on weak and soft biometrics. Emerging biometrics include technologies which measure "motor skills" (i.e., the ability of a human being to utilize muscles), technologies which measure electromagnetic body signals, and finally technologies which measure human-computer interaction patterns (Mordini & Tzovaras, 2012). Examples of emerging biometrics include gait recognition (analysis of walking patterns); dynamic facial features, eye blinking, lip movements, and smile recognition; voice recognition (analysis of vocal behavior); signature/handwriting or other authorship-based biometrics; electrocardiogram (ECG, records the electromagnetic signals produced by the heart as measured on the skin); electroencephalogram (EEG, records the electromagnetic signals generated by the brain as measured on the scalp); electrooculogram (EOG, records eye movements); electromyogram (EMG, records muscle activity); body odor recognition; keystroke or mouse dynamics; and online behavior recognition. According to Yampolskiy (2011) next generation biometrics could be classified under the common heading of behavior-based authentication mechanisms. Yampolskiy suggests that these authentication mechanisms are characterized by "the incorporation of time dimension as a part of the behavioral signature" (p. 378).

Most new biometrics require less user cooperation and can be run almost unobtrusively and in a way transparent to the subject; they can also capture signals from a distance, or on-the-move. They are consequently the ideal candidate for being integrated in ambient intelligence environments and in any other ambient destined to be constantly automatically supervised. Finally, given their lower discriminatory capacity and lower degree of stability, new biometrics are often integrated in multibiometric systems, targeting a sole biometric feature but using different kind of sensors (multimodality) or several biometric features in parallel or sequentially (multibiometrics).

Ethical Implications of Biometrics for Personal Recognition

Since the 2001 terrorist attacks on the American mainland, many governments have seen in biometrics an opportunity for significant advances and breakthroughs in securing people and their assets. In the United States "Every major piece of post-9/11 federal security legislation included biometrics provisions" (Gates, 2006, p. 417). Despite this, there has been little evidence to suggest that security measures based on biometrics prevented any major act of terrorism, while on the other hand, biometric devices have begun to become commonplace in domains outside the security sphere. Border control, electronic identification and authentication, e-commerce, e-banking, and e-health have all seen significant take-up of biometric technologies.

While biometrics offer certain advantages in many of their applications (e.g., a greater convenience-to-security ratio than traditional authenticators and identifiers such as complex passwords), civil liberties and privacy advocates have argued that these advantages should be carefully weighed against the potential down and dark sides of biometrics. Biometrics, some would argue, are a key component of a pervasive surveillance apparatus, employed by governments, whose primary aim is not specifically the prevention of terrorism, but more generally to monitor and control their citizens. A sharp debate is emerging about whether biometric technology offers society any significant advantages over other forms of personal identification and whether it constitutes a threat to privacy and a potential weapon in the hands of authoritarian governments (Mordini & Green, 2008).

There are two main categories of ethical concerns surrounding biometric technologies: one is related to more fundamental issues while the other is directly related to specific biometric applications.

Fundamental Ethical Issues Raised by Biometrics

What turns bodily properties and behavioral traits into biometric features is their measurability. Only measurable anatomical and physiological features can be considered biometric features. If a human property can be measured, this means that it can be treated as a physical, quantifiable phenomenon. In other words, biometric features are human attributes described in terms of physical quantities, such as length, mass, time, electric current, temperature, amount of substance, and luminous intensity. Per se this is not outrageous, biomedical science has always quantified human bodily features for clinical purposes, but is it ethically legitimate to use this technique for identifying persons? If identity and identification concern the essence of an individual, would biometric identification run the risk to reduce the richness of human identity to a sum of mere physical quantities? Do biometric identification technologies threaten human dignity by denying humanity itself? Would biometrics be inherently demeaning? If this is the case, biometrics should be just banned, no matter what application one is considering.

This fundamental question was clearly expressed by the French National Consultative Ethics Committee for Health and Life Sciences, in the Opinion on "Biometrics, identifying data and human rights," whose importance deserves a full quotation: "Do the various biometric data that we have just considered constitute authentic human identification? Or do they contribute on the contrary to instrumentalizing the body and in a way dehumanising it by reducing a person to an assortment of biometric measurements? Is there not a possibility that this attempt to arrive at a biometric simplification, which cannot ever capture an individual's essence, could in fact lead to misrepresentation, to seeing nothing but the biometric persona, however scientifically determined? They may reduce human beings to an accumulation of data and cartographic criteria" (French National Consultative Ethics Committee on Health and Life Sciences, 2007, p. 3).

Italian philosopher Giorgio Agamben first formulated the argument that is, still today, the reference for all those who contend the ethical legitimacy of biometric technologies themselves. Agamben (2008) argues that the gathering of biometric data is a form of biopolitical tattooing, akin to the tattooing of Jews in Auschwitz extermination camp. "The problem – Agamben states - concerns the juridical-political status (it would be simpler, perhaps, to say bio-political) of citizens of the so-called democratic states where we live. [. . .] There has been an attempt the last few years to convince us to accept as the humane and normal dimensions of our existence, practices of control that had always been properly considered inhumane and exceptional" (p. 201). The arguments runs at it follows, the body features that human beings use in everyday life to identify their fellows are biographical signs, embodied languages, which tell the biography of the subject. This is the case with human faces, body gestures, voices, odors, and even wrinkles and scars, which tell the story of the subject and are inscribed into her biography. Human bodies are truly words made flesh. This is the dimension which would be nullified by biometric identification. Biometrics are pure bodily signatures mechanically extracted from our bodies by impersonal devices. They speak of our biology rather than our biography. In this sense biometrics would not only depersonalize the subject, but they would definitely dehumanize her. Biometrics – concludes Agamben's argument – turn the human persona into bare life, which can be scorned, humiliated, and finally exterminated. Ancient Greeks had two words for life, *zoe* and *bios*. *Zoe* is the life common to animals, humans, and gods, just life. *Bios* is life that is particular to humans, particular because it is life in the human context, with meanings and purposes. Agamben argues that there are times when rulers create indistinct zones between human life (bios) and bare life (zoe). Following Carl Schmitt and Walter Benjamin, Agamben calls these times "states of exception." In states of exception, humans are stripped of all meanings except the fact they have life and that life, like the life of an animal, can be taken at any point without it being considered murder, as happened in the concentration camps.

Specific Ethical Issues Raised by Biometrics

Beyond the fundamental question whether biometric identification is itself demeaning, there are a number of ethical issues that have been raised in the last decade about particular technologies and some specific biometric applications. They can be categorized under three main issues: (1) questions which are related to privacy and data protection, (2) questions which are related to the so-called surveillance society, and (3) questions which concern large-scale applications.

Biometrics and Respect for Privacy and Data Protection. Biometrics have generated several privacy and data protection concerns, most of them are related to the degree of protection to be accorded to biometric data and to the legitimacy of biometric database. Finally, some questions have been also raised in relation with biometric data sharing, notably for security and law enforcement purposes.

Is Biometric Data Personal Data? By definition personal data is any data which is related to an identified or identifiable person. It is important to note that it is still personal data, any data which – complemented by further information – could drive to identify an individual. This specification, which could not pose particular problems in the past, is today quite problematic because of the increasing capacity for data mining processes. As a matter of fact, today almost any detail concerning an individual could be used, at least in principle, to identify her. Personal data is thus destined to become an ever-expanding area. This is quite relevant because most legislations deserve a special protection to personal data, in particular when data is sensitive, say, when it concerns (a) the racial or ethnic origin of the data subject, (b) her political and philosophical opinions, (c) her religious beliefs or other beliefs of a similar nature, (d) her physical or mental health condition, (e) her sexual life or orientation, and (f) her criminal record. In all these cases, personal data can be collected only for one or more specified and lawful purposes and only provided that they are adequate, relevant, and not excessive in relation to the purpose or purposes for which they are processed. Moreover, data should not be kept for longer than is necessary, the data subject should be notified, and she should provide her informed consent to data collection and have the right to rectify and erase data in any moment. It is out of discussion that biometric row data (the analog representation of biometric features as they are captured by sensors) is personal data; what is instead controversial is to what extent they are sensitive data and whether biometric templates should be considered personal data as well. In principle biometric data, although personal, should not be considered sensitive because it does not concern any category of sensitive data. Moreover, most biometric features are public, and it would be bizarre to consider, e.g., face aspect, voice intonation, and body shape as human attributes which deserve special protection. Yet it has been argued – not without reason – that what turns bodily attributes into biometric features is the specific process through which sensors capture the signal and translate it into digital representations. Algorithms generate a new item which is no longer a pure bodily attribute, but it is a new digital entity; what is the ethical and legal status of the digital body? Who owns digital representations of the body? Do they deserve the same protection that the law reserve to flesh body parts? Some have argued that digital body representations should be considered as an extension of the physical body (Rodotà, 2011). Such an extreme position was espoused by the European Group of Ethics (EGE), the ethical advisory body of the president of the European Commission. The EGE Opinion n.20 on Ethical Aspects of ICT Implants in the Human Body reads, "We shall not lay hand upon thee". This was the promise made in the Magna Carta – to respect the body in its entirety: *Habeas Corpus*. This promise has survived technological developments. Each intervention on the body, each processing operation concerning individual data is to be regarded as related to the body as a whole, to an individual that has to be respected in its physical and mental integrity. This is a new all-round concept of individual, and its translation into the real world entails the right to full respect for a body that is nowadays both physical and electronic. In this new world, data protection fulfills the task of

ensuring the "habeas data" required by the changed circumstances – and thereby becomes an inalienable component of civilization, as has been the history for *habeas corpus*" (European Group on Ethics in Science and New Technologies, 2005, p. 29). According to this perspective personal data protection would be the most relevant legal instrument safeguarding individual freedom against any arbitrary state action, notably when data concerns the human body as it is the case with biometrics. Actually in the proposed reform of the European Data Protection Directive, the European Commission has proposed to the European Parliament to consider biometric data sensitive by default, as the same level of data concerning religion, ethnicity, sexual life, etc. (European Data Protection Supervisor, 2013).

A further data protection issue raised by biometrics concerns the ethical and legal status of biometric templates. Templates are not directly and easily linked to any bodily feature. Actually they are normalized digital representations obtained by processing through proprietary algorithms the outputs of biometric sensors. Would it be possible to reverse the algorithm and reproduce the original biometric sample? This is one of the main current controversies surrounding the status of biometric data. The issue is much more nuanced than it could appear (Yanushkevich, Stoica, Shmerko, & Popel, 2005). First of all, there is not only one biometric and one modality, and it makes little sense to tackle this issue in general terms. As a matter of fact, there is evidence that some biometric templates can be partly reversed but it is limited to a few biometric modalities (fingerprints, face, and more recently iris). Moreover, one should understand well what "reversing" means. Many people fear that it is possible to reconstruct the original biological and behavioral characteristic of an individual from a template. This is an urban myth. In some cases templates could be used to re-create artifacts that might be exploited for spoofing the system (e.g., fake fingerprints or a facial mask), which is admittedly a serious security breach. Yet till today, it has never been possible to duplicate faithfully the original body feature as it exists in real life. In addition the current trend is to encrypt templates so making almost impossible to reverse them. Decisions about the ethical and legal status of biometric templates may have important practical consequences because – if template were judged less privacy threatening than row data – legislations could mandate to store only them in biometric systems, so preventing some data protection objections to biometrics.

Biometric Databases. Biometric databases are one of the most controversial areas of biometrics. The main aim of these databases is to prevent citizens from establishing more than one identity by obtaining several identity documents (e.g., passports, ID cards, social security card) with different names. Such a risk is particularly serious in those states which do not possess a general register of residents or are introducing it at the same time as the new identity documents. However, the creation of centralized biometric databases accessible over networks in real time presents significant operational, security, and privacy concerns. Operational and security concerns include:

1. Risk of collapse of the system: if networks fail or become unavailable, the entire identification system collapses.

2. Security risks: in order to prevent system collapse, designers often build in high redundancy in parallel systems and mirrors; this increases security risks and vulnerabilities.
3. Large centralized biometric databases represent significant targets for hackers and other malicious entities to exploit. There are significant risks associated with transmitting biometric data over networks where they may be intercepted, copied, and tampered with, often without any detection. Privacy concerns include:
    1. Function creep: large centralized databases are alleged to be more prone to function creep (secondary uses) and insider abuse.
    2. Proportionality: considering operational and security risks, some argue that there is no proportionality between risks and potential benefits; yet this critically depends on the goal that the users are trying to achieve with the system.
    3. Sensitive data: when large-scale biometric databases store the full and complete images of the biometrics involved in addition to the templates, all privacy risks are exacerbated.

The current situation is mixed and together with countries which have adopted centralized biometric databases (e.g., Finland, Sweden, Norway) or are about to (e.g., France, UK), others did not. In particular, it is worth mentioning Germany, where the Parliament had ruled out the possibility of a biometric nationwide database. According to the German Parliament, a central biometric database would be incompatible with the *Recht auf informationelle Selbstbestimmung* (right to informational self-determination) which forms part of the fundamental rights of the German *Grundgesetz*. In the USA, the main limitation to biometric data collection is provided by the Fourth Amendment which protects against unreasonable searches and seizures.

A further issue raised by biometric databases concerns the creation of multimodal and multibiometric databases, which may embrace several biometrics including DNA, often linked with other databases, such as credit card databases, costumer databases, social insurance databases, and electronic health record databases. Although data linkage is often justified by reasons of efficacy and effectiveness, it is apparent that the capacity for eliciting sensitive personal information of these large data networks is huge. Although some legislations (e.g., in the EU) formally prevent data linkage and fusion, other legislations do not address this issue, and several data fusion centers have been created in the last decade by the US Department of Homeland Security and the US Department of Justice. Actually the only way to prevent data linkage would be to create non-interoperable databases, because if databases are technically linkable, it will be always possible to public authorities to overcome legal barriers by using an executive order (e.g., public health emergency, threat to national security, or any other "exceptional situation").

Biometric databases also increase the risk of function creep. "Function creep" is the term used to describe the expansion of a process or system, where data collected for one specific purpose is subsequently used for another unintended or

unauthorized purpose. Although some examples of function creep are fairly innocuous, function creep has always the potential to erode public trust and destroy confidence in a given system. When function creep results from a deliberate intention, it represents a serious ethical breach. In the context of biometric applications, one should distinguish between two different situations: when biometrics are used beyond the limits for which the system was officially adopted and when biometrics are misused to generate extra, unauthorized information. As regards the former, it is evident that any identification scheme can be carried out with a hidden agenda (e.g., sorting out some social groups, eliciting the feeling of being under observation in the subject) and biometrics are no exception. According to the ISO SC37 Harmonized Biometric, in these cases one should refer to a "subversive use" of biometrics – i.e., an attempt to subvert the correct and intended system policy – rather than to function creep. Biometric systems might also be misused to generate details that are not relevant to personal recognition and which could be exploited for unintended or unauthorized purposes. This holds particularly true when row biometric data (analog representations, such as photographs, tapes, images) is stored in the system. Misuse also entails risks of stigmatization and discrimination against ethnical and religious minorities, persons with disabilities or suffering from any medical disease, and older people. Sensitive information could be elicited from raw biometric data; for instance, faces could be suggestive of ethnicity, religious beliefs, sexual orientation, as well as political/philosophical opinions; most biometrics could also unravel medical sensitive information (e.g., metabolic diseases which alter face or body shape, vessel diseases which make impossible to collect hand vein images); also physical and mental disabilities could be revealed by some biometrics (e.g., demented persons could be unable to follow operator's instructions, people suffering from certain neurological disabilities could be unable to keep their fingers still for the time necessary to keep their fingerprints, blind persons may have difficulty in getting themselves aligned with the iris scanner).

Biometric Data Sharing. There are many reasons for sharing biometric data between different actors and agencies; however, when speaking of "biometric data sharing," one usually refers to sharing biometric data between nations for security and law enforcement purposes. The better known international agreements about biometric data sharing are the "Prüm Treaty" and the "Five Country Conference Protocol." The Prüm Treaty is an agreement about 13 EU member states (Austria, Belgium, Estonia, Finland, France, Germany, Hungary, Italy, Luxembourg, Netherlands, Romania, Slovenia, Spain) for mutual online access to national fingerprint and DNA databases. The Five Country Conference Protocol is an agreement to share biometric data in the form of fingerprints for security and law enforcement purposes. The Protocol includes the UK, Australia, Canada, United States of America, and New Zealand. A similar multilateral initiative is in progress also within the countries of the Association of Southeast Asian Nations (ASEAN). Moreover, there are various bilateral agreements for biometric data sharing between single countries.

Data sharing poses a number of technical problems – which chiefly concern standards and technical interoperability – as well as momentous political and

ethical issues. The main issue is likely to be reciprocity. Provided that all actors in principle agree with the need to ensure a basic level of data protection and respect for informational privacy to these databases, the international community has widely divergent views about acceptable levels of data protection, and to date there is not agreement on common international privacy principles which could provide a framework for the use of biometric data. The EU, for instance, prohibits transferring personal data of EU citizens to a country or territory outside the EU unless that country or territory ensures the same level of data protection of the EU. Official stances of this kind are unavoidably destined to create dead-end situations, as it has happened, for instance, with an endless discussion between the EU and the USA about data sharing of air passengers. On the one hand, in today's globalized and interconnected world, it is simply unthinkable the idea to limit data flow only to a group of country; on the other hand, it is hard to imagine that all countries would share the EU vision on privacy and data protection. The level of privacy protection of biometric data shared also includes the issue whether it is proper – and if so, under what circumstances – for Armed Forces to share biometric data gathered in a combat or peacekeeping mission with law enforcement and immigration authorities of their own country or of other countries. This leads to the main – and probably more worrisome – ethical issue in international biometric data sharing. Basically shared biometric databases consist of a mixed population of data, which includes sentenced criminals, persons only suspected of illegal activities, comprising alleged terrorists and drug traffickers, immigrants, etc. Data collected for noncriminal purposes, such as immigration-related records, is combined with and being used for criminal or national security purposes with little to no standards, oversight, or transparency. The ethical legitimacy to put all these categories of persons together, to share their biometrics, and eventually to treat them as they were all (potentially) dangerous criminals is highly questionable.

Biometrics and Surveillance. The word "surveillance" is a French word which literally means oversight, supervision (*surveiller*). The first attested usage of this word dates back to 1768 (Centre National de Ressources Textuelles et Lexicales, 2013) in the *Éphémérides du Citoyen*, which was the first, and most influential, economics periodical to be published in France. During the French Revolution, a network of Surveillance Committees was set up by the National Convention by a law of 21 March 1793 with the task of monitoring all foreigners, listing and arresting suspects. Interestingly enough they were also in charge of delivering citizenship certificates (Lapied, 2002).

Michel Foucault has been the main contemporary scholar who focused on the relationship between power and surveillance. He was intrigued by the role of surveillance in inducing social conformity and self-discipline. The point of departure for the French philosopher was that power tends to be exerted by controlling bodies, through a widespread surveillance apparatus, rather similar to the network of revolutionary Surveillance Committees (Foucault, 1980). Foucault defines the "disciplinary society" a society in which all bodily aspects of life are carefully monitored by different agencies including law enforcement authorities, the school system, the judicial system, and the public health system.

Later scholars have pointed out that Foucault's disciplinary model has been today replaced by a "society of control" where the political problem is no longer monitoring citizens, but rather managing the endless flow of persons, goods, and personal information. In the society of control, "what is important is no longer either a signature or a number, but a code: the code is a password (. . .) The numerical language of control is made of codes that mark access to information, or reject it" (Deleuze, 1992, p. 6).

Biometric identification technologies not only open the door to an enormous potential for surveillance in more traditional terms, but they seem to be integral to the ideal of the new "society of control." Through biometrics one can identify, trace, and monitor the continuous flow of people which constitutes one of the main elements of globalization. By allowing identification processes on global scale, biometric technologies could in principle even provide a unique and unambiguous identifier to each world inhabitant. "If the international system did embrace extensive use of biometrics or another globally unique identifier, the move could signal the effective end of anonymity. It would become feasible to compile a complete profile of a person's activities – including where the person has gone, what he has spent money on, with whom he has been in contact, what he has read, etc. This death to anonymity would meanwhile be coupled with asymmetry in information: the individual's every move could be monitored, yet he may not have any knowledge of this surveillance. Beyond privacy, such a state of affairs does not bode well for the exercise of other fundamental freedoms such as the right to associate or to seek, receive, and impart information – especially as the intimidation of surveillance can serve as a very restrictive force" (UNESCO. Information for All Programme, 2007, p. 40).

Reliability of Biometric Technologies. A further issue related to biometric surveillance as well as biometric databases and large-scale applications concerns the robustness and reliability of biometric systems. As mentioned earlier, biometric recognition is probabilistic in its nature; it means that there is always a percentage of false positive (people erroneously recognized) and false negative (people erroneously *not* recognized). This could be acceptable provided that the margin of error of each specific application is carefully calibrated according to the particular context in which the biometric system is deployed. This is not a purely technical question; on the contrary, it implies nuanced ethical, legal, and political decisions. Think, for instance, of biometric systems used for surveillance and biometric systems used for forensic purposes. The principle of presumption of innocence is a main tenet of western juridical civilization. This principle dictates that a court should always choose the interpretation that favors the defendant. It implies that in order to be accepted as an evidence, biometric systems should be calibrated in a way to minimize false positive even if this implies a higher rate of false negative (this would not be the case with old, analog fingerprint recognition based on experts' eyes, which were not probabilistic in essence). But if the same system is used, say, for screening air passengers, it should be calibrated in a way to minimize false negative, say, the odds that a terrorist escapes security checks, even if this implies a higher rate of false positive, say, innocent passengers unjustly stopped at

the biometric checkpoint. Moreover, it is almost impossible an (ethically) proper calibration in the case of large-scale applications, where a false (negative or positive) rate of, say, 0.1 % may correspond to many thousands of recognition errors. In any case the number of people affected by biometric errors would be disproportionately high.

Beyond issues raised by biometric errors, there are other aspects related to system reliability that should be considered. The first one is vulnerability to attacks. Generally speaking, there are two types of attacks, direct and indirect. Direct attacks are performed at the sensor level outside the digital limits of the system, and therefore no digital protection mechanisms can be used. In a direct attack, also called spoofing, a person tries to masquerade as another one by falsifying data and thereby gaining an illegitimate advantage. Indirect attacks are performed inside the system and are due to intruders, such as cyber-criminal hackers, by bypassing the template generator or the matcher, by manipulating the templates in the database, or by exploiting the possible weak points in the communication channels. While countermeasures against indirect attacks pose the same ethical and legal problems posed by any measure of cybersecurity, countermeasures to spoofing attacks are more problematic. The typical countermeasures to spoofing attack are aliveness detection that aims at detecting physiological signs of life and consequently prevents identification with dead body parts or artificial copies and multimodal biometrics. The main problem with both these countermeasures is that they increase disproportionately the amount of personal information gathered by, and stored in, the system, which is extremely questionable in terms of respect for privacy and data protection principles. In other words, in order to make the system less vulnerable to attack, one is often obliged to increase its informational intrusiveness to a degree which would be hardly acceptable. This problem is going to become more and more complex. For instance, current research to prevent possible attacks based on unconscious or enforced identification and volition control is investigating the possibility of using biometrics (e.g., electrophysiological biometrics) for intention and emotion detection.

Finally there is a third aspect of reliability of biometric systems, which concerns their security, notably the risk of identity theft. Identity theft occurs when someone uses a person's name and sometimes other parts of their identity – such as their biometrics – without the person's knowledge or consent to obtain services or goods or uses the person's identity information to make false claims for services or goods. In principle biometrics could make identity theft harder. On the other hand, any biometric system can be attacked by stealing the identity of security-cleared users, and only the user himself can know of an identity theft attack is ongoing. The problem with biometric identity theft is that a biometric identifier cannot be easily changed as a PIN or a password. In particular, when a strong biometric feature has been stolen and duplicated, its usability is lost forever. In other words, a stolen biometric feature is a sort of "digital amputation," which makes that biometric feature definitely useless for identification purposes. A possible strategy to circumvent the risk of biometric identity theft is to avoid using strong biometrics and to adopt systems based on weak biometrics and multibiometrics. It is also important to

avoid large databases, which can be easily attacked, and prefer systems based on authentication (one-to-one) rather than on identification (one-to-many). However, the risk that a biometric system – created with the aim to increase personal security – could generate more vulnerabilities both to people and to their assets poses serious ethical and political questions.

Large-Scale Applications. The advent of large-scale applications has been one of the most important events in biometrics. Many countries, including the USA and the EU, incorporate biometric data into passports, ID cards, visas, and other documents for use in large national-scale automatic biometric identification systems. In the USA, for instance, there are two largest biometric databases in the world, each one of them holding more than 100 million records, the FBI's Integrated Automated Fingerprint Identification System (IAFIS) and DHS's Automated Biometric Identification System (IDENT), which is part of US-VISIT program.

Technically speaking, large-scale systems have several requirements, which include high-level scalability, considerable computational power, and support for large databases (tens or hundreds of millions of records). From an ethical point of view, they should respect all privacy and data protection requirements that have been previously discussed. Their potential for surveillance has been also debated and should not be overlooked.

More recently, however, a new category of large-scale applications has emerged, applications for economic, political, and social purposes in low-income countries. The most impressive example is the India's Universal ID program, which aims to provide a unique identity to 1.2 billion residents.

Most low-income people in countries in Africa and South Asia have weak and unreliable documents, and the poorer people in these countries do not have even those unreliable documents. In 2000, UNICEF calculated that 50 million babies (41 % of births worldwide) were not registered at birth and thus destined to lack any reliable identity document in the future. In a world system where nearly all states in low-income countries are not able to provide their citizens with reliable identity documents, biometrics is likely to be the sole hope for most of these people to have trustworthy identity documents. This is critical for many reasons, not the least because identity documents are essential to ensure respect for fundamental rights. "For many—refugees, potential voters or pensioners—some form of official documentation can be an essential step towards security, freedom, entitlement and inclusion (. . .) The utility and morality of identity systems and technologies depend largely on context, perspective and need. The identity gap between rich and poor countries also shapes the debate on identification and the specific role of biometric technology. In rich countries, biometric identification is mainly used in areas relating to security and policing (. . .) In poor countries, biometrics is more commonly employed in developmental applications. This is not always a clear distinction. Some "developmental" identification programs in poorer countries have been influenced or driven by security concerns. Conversely, some rich countries have used biometric identification for broader purposes (. . .) However, the overall picture is an emphasis on surveillance in richer countries and an emphasis on authentication or verification in poorer ones" (Gelb & Clark, 2013, p. 12).

It is important to emphasize that biometrics are the only large-scale identification systems that could also be run by small private actors and independent agencies instead of heavy governmental structures. This would make possible to imagine a global system for personal recognition starting from low-income countries, which would be closer to the Internet than to the Leviathan. The fear that biometrics might lead to a unique, global identifier – a digital cage from which one could never escape – is probably misplaced. On the contrary, biometrics could permit to create separate digital IDs for particular purposes by applying different algorithms to the same biometric characteristic or by selecting different biometric features of the same individual and using weak and multiple biometrics. As well as providing the appropriate level of security for each application, this would make it much easier to revoke biometric templates if they become corrupted or are stolen. Still more important, these processes do not need cumbersome, centralized structures but can be easily implemented by a web of local authorities, as it has been demonstrated by the penetration of biometric technology and applications in Asian and African markets.

Biometrics vis-à-vis the Universal Declaration on Bioethics and Human Rights

As previously mentioned, automated biometrics are "borderland" technologies, in the sense that they are at the intersection between medicine, life sciences, information, and security technologies. While discussing ethical issues raised by biometrics, it is then particularly relevant to consider the Universal Declaration on Bioethics and Human Rights, which specifically addresses "ethical issues related to medicine, life sciences and associated technologies as applied to human beings" (UNESCO, 2005, p. 76).

The main principles of the Declaration that are relevant to biometrics are likely to be Article 3 (Human dignity and human rights), Article 6 (Consent), Article 8 (Respect for human vulnerability and personal integrity), Article 9 (Privacy and confidentiality), Article 10 (Equality, justice and equity), Article 11 (Non-discrimination and non-stigmatization), and Article 12 (Respect for cultural diversity and pluralism).

Article 3 reads that "1. Human dignity, human rights and fundamental freedoms are to be fully respected; 2. The interests and welfare of the individual should have priority over the sole interest of science or society." One should emphasize the central role played by respect for human dignity, which requests a serious ethical scrutiny of dignity issues raised by biometrics, and the priority accorded to interests and welfare of the individual over societal interest. The former point is essential to understand the current debate about security and surveillance technologies. In case of conflict between the interest of the individual and the interest of society, the individual must prevail. To be sure, it is often possible to frame security problems in win-win terms, and many alleged conflicts between individual rights and security needs could be solved by increasing both individual rights and societal security,

yet when a real conflict exists, the Declaration points out that the sole, tenable, ethical solution consists in giving priority to individual rights.

Article 2 (Consent) requires that "scientific research should only be carried out with the prior, free, express and informed consent of the person concerned." This article does not limit the need for informed consent to biomedical research, but extends this principle to "scientific research" in general. This unavoidably implies that research on biometrics, when it involves human beings, should undergo to the same strict regulations which rules the discipline of informed consent in medicine. Of course this should not entail the simple transposition of bioethical rules to biometric research, but it demands that informed consent is carefully considered and tailored on the specific situation of biometric research.

Article 8 deals with respect for human vulnerability and personal integrity and requires that "individuals and groups of special vulnerability should be protected and the personal integrity of such individuals respected." The relevance of this article to biometrics dwells on the actual risk that biometric applications are not properly designed in order to ensure full accessibility to disable and disadvantaged individuals and groups. In particular, in case of large-scale applications, it is paramount that engineers apply principles, methods, and tools to promote universal design of biometric devices and disabilities should not prevent the usage of biometric recognition systems.

Article 9, which focuses on privacy and confidentiality, has an obvious relevance to biometrics. In particular, this article requires that collection of personal information is consistent with "international human rights law." It implies that in the deployment of biometric application, it should be mandatory to carry out a wider human right impact assessment, which includes, but it should not be limited to, a privacy impact assessment.

Article 10 (Equality, justice and equity), Article 11 (Non-discrimination and non-stigmatization), and Article 12 (Respect for cultural diversity and pluralism) collectively draw the attention on the risk that biometric identification could favor discrimination, stigmatization, and racial and ethnic harassment. This is a real risk, notably in large-scale applications and if biometric databases are used for people profiling. This is not, however, the unavoidable destiny of biometrics. On the contrary, as previously mentioned, biometrics could become an important component of developmental policies in low-income countries by facilitating civil identification and, indirectly, promoting equality, justice, and equity.

Conclusion

The need for recognition schemes is inherent to human civilization itself. With biometrics, for the first time in the history of human species, human beings have really enhanced their capacity for personal recognition by amplifying their natural, physiological, recognition scheme, based on the appreciation of physical and behavioral appearances. Complex personal recognition schemes, tattoos, seals, passports, badges, safe-conducts, passes, passwords, PINs: biometrics would

make obsolete all these traditional identification paraphernalia and – at least in the long run – promise to replace all of them. This is not, however, without ethical risks, and a cautious and mindful approach is required.

Real-life applications of biometric technologies – being fundamentally embedded in societal structures, historical narratives, the development of state authority, and so on – are concerned with more than pure biology or pure physicality. As such, the process of abstraction and reification from which the biometric body would emerge according to Agamben and other radical critics is itself a philosophical abstraction. In other words, although rhetorically suggestive, philosophical arguments against biometrics are hardly tenable. Biometrics themselves are not likely to threaten human dignity more than any other modern technology.

People – and sometimes scholars – are victims of the illusory belief that personal identification per se threatens basic liberties and infringes the private sphere. To be sure, any process of personal identification implies that individuals are recognized subjects of rights and obligations, and this could be seen as a limitation of individual liberty. Yet there would be no rights, no liberty, without personal identities. No political, civil, and social right can be enforced on anonymous people. One can claim her rights, including the right to refuse to be identified, only if she is an identifiable subject and if she has a public identity.

In ancient Greece, slaves were called "faceless," *aprosopon*. The word that in Greek designates the face, *prosopon*, is also at the origin of the Latin word *persona*, person. The person is thus an individual with a face; this is to say, out of metaphor, one becomes a person when she is identifiable. Biometrics could contribute to give a face to such a multitude of faceless people who live in low-income countries, contributing to turn these anonymous, dispersed, powerless crowds into the new global citizens.

Certainly, then, there are reasons for the ethical and political concerns surrounding biometrics, and a careful democratic scrutiny of biometric applications is needed; but these reasons are fortunately balanced by some reasons for hope.

This chapter was partly supported by European Commission Grant No. 261698 awarded to the project SAPIENT "Supporting Fundamental Rights, Privacy and Ethics in Surveillance Technologies."

Clinical Research in Resource-poor Settings

32

Jan Helge Solbakk and Susana María Vidal

Introduction

This chapter addresses the ethical challenges pertaining to clinical research in resource-poor settings. First, a brief account of the history of biomedical research ethics in four different stages is provided, emphasizing elements of particular relevance in the present context. Second, the impact of the global spread of the neoliberal market model on the conception and organization of biomedical research is analyzed, including key drivers and factors behind the so-called globalization of biomedical research, the dramatic outsourcing of clinical research during the last 15 years to poor and low-income countries, and the implicated deregulation of international ethical guidelines and declarations pertaining to clinical research in resource-poor settings. Third, some key concepts and measures about human development, poverty, and resource-poor settings are introduced, emphasizing the need for implementing comparative measures able to reflect the level of human development in a more fine-tuned way than which is possible by applying the gross national product (GNP) per capita criterion. For these reasons, it is proposed to view the concept of "resource-poor settings" and the characteristics of health systems in such settings in light of the Human Development Index, as well as through other metrics suggested by the United Nations Development Program, UNDP, such as the Human Poverty Index, HPI. Fourth, the conception of social vulnerability is introduced, so as to be able to differentiate between different situations of special

vulnerability necessary to observe when conducting clinical research in resource-poor settings. In connection with this, it is also suggested to make use of the capabilities approach to human development and human poverty developed by Martha Nussbaum. Capabilities are here understood as the foundation of basic political principles, which are to be constitutional guarantees, and become the basis of human rights and an essential contribution to an all-out notion of justice. Consequently, capabilities are viewed as a universal pattern which applies to all individuals alike, and finding out about capabilities thus implies inquiring about what an individual or group of individuals is able *to be and to do* with their lives, and what resources are available for them to fully develop as human beings. Fifth, from this vantage point, the debate about exploitation in international clinical research is critically scrutinized, and it is claimed that those who reduce exploitation to unfair *distribution* of benefits fail at a crucial point because the analysis of the fairness of an interaction cannot be done on the basis that the reality of the community or of individuals is a fact of the world that falls outside the scope of consideration. An alternative analytical approach is suggested, that is, that in order to analyze fairness in an ethically sustainable way, one should take into account the conditions of vulnerability, including the trigger factors, the human needs of the individuals and communities implicated, the opportunities that they have had and they currently have to make decisions, and the scope of real options available to them; and finally, the opportunities that the individuals have had to develop their capabilities. Sixth, the concepts of risk, benefits, needs, and compensation in biomedical research are made the subject of a similar analysis, and the introduction of a human-rights-based and capabilities-oriented approach to biomedical research is suggested, something that would assert that some goods are nonnegotiable values and that the baseline is determined by the previous human rights prevailing condition of the individuals taking part in the research. Therefore, any intervention intended to satisfy an unsatisfied basic human need (human right) should not be referred to as benefit in research. It is a right, and fulfilling it is a legal and ethical obligation; consequently, any interaction that would take advantage of this situation should be deemed as a potential exploitation of vulnerable subjects. Finally, referring to Article 15 of the Universal Declaration on Bioethics and Human Rights on benefit sharing, the global responsibilities pertaining to multinational research in communities with low human development are briefly addressed.

The Four Stages of Biomedical Research Ethics

Even though the history of research ethics can be traced back to the onset of medicine (and there are several narratives about this; see Annas & Grodin, 1992; Gracia, 1998; Jonsen, 1998; Rothman, 1995), it is in the twentieth century that this history takes a decisive turn, in particular with regard to two aspects: first, the expression of international norms pertaining to biomedical research ethics in public policies and state regulations, and second, the emphasis on a clear link between human rights and the rights of subjects of research. Three stages have been

identified in this history, the last one dating back to 1947 and named by its author "the regulated clinical research and the new ethics of responsibility of experimenting with human beings" (Gracia, 1998). The main characteristic of this stage is precisely the establishment of a normative framework that regulates medical practices linked with research, that is, a model of responsibility that governs medicine so as to strike a balance between the intentions to obtain new knowledge and the practices carried out to achieve it by involving human beings. Consequently, research should be carried out without any kind of discrimination, with informed consent and with a rigorous benefit-risk evaluation. Three fundamental normative documents witness this history, two of which represent an accurate and clear reflection of the reaction that the Western World had against the horrors of war, and a much later third one reflecting the consensus of the World Medical Association with regard to the ethical standards that should govern the practice of physician investigators. These three documents are the Nuremberg Code (1947), the Universal Declaration on Human Rights (1948), and thirdly the Declaration of Helsinki (1964). The normative orientation characteristic of these documents is their rootedness in human rights, something which has been followed up in the Convention on Human Rights and Biomedicine of the Council of Europe (1997) and in the declarations adopted by UNESCO, in particular the most recent one, that is, the Universal Declaration on Bioethics and Human Rights (2005), UDBHR. The core assumption and commitment that links these normative documents and gives rise to what has been called a *universal ethical standard* is that all human beings are entitled to egalitarian treatment based on the respect of their dignity and personal integrity. The notion of human dignity is already present in the Preamble of the Declaration of Human Rights and in its Article 1 it is stated: "All human beings are born free and equal in dignity and rights. They are endowed with reason and conscience and should act towards one another in a spirit of brotherhood." Also, the Nuremberg Code is inspired by this notion, and the World Medical Association subsequently took respect of dignity and integrity to be the basis on which the whole normative structure of the Declaration of Helsinki was to rest: "In medical research in human beings, the concern about the well being of human beings must always be given primacy over the interests of science and society " (Article 5), thus placing respect for human beings above any other interest, even that of science and society as a whole, and leaning away from the paradigm that had marked science until then. In the late 1970s, a new normative model emerged, based on the so-called Belmont Report (The National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research, 1979). The report was a reaction to one of the most infamous forms of biomedical research carried out in the United States, that is, the Tuskegee Study, an observational study conducted between 1932 and 1972 in the state of Alabama, and involving black people suffering from syphilis who were deprived of treatment even though efficient treatment to stop the disease was available (Brandt, 1978). In terms of normative orientation, the Belmont Report took distance from the human-rights-based frameworks mentioned above and proposed instead a framework inspired by the Anglo-American liberal tradition. Three basic ethical principles were suggested to deal with ethically

conflictive situations involving research with human beings: the principles of respect for persons, beneficence, and justice. In addition, the report suggested using these principles as a method to assess research, and it even moved a step further by proclaiming existing ethical codes and declarations as inefficient. Thus, a new pathway toward normative development was opened – *principlism* – deviating from the human-rights-based approach rooted in human dignity (Beauchamp & Childress, 1979). The recommendations of the Belmont Report were promptly adopted and backed by the American Medical Association and other medical organizations in the United States, and in practice, it became a much more influential normative document than the previously suggested codes and declarations. As will be shown later, the principlist framework proposed in the Belmont Report differed from the human-rights-based approach not only in terms of orientation but also with regard to margins of protection of individual research subjects.

As already mentioned, most ethical frameworks pertaining to biomedical research developed in the period of 1947–1979, including the Belmont Report, were the reactive result of unethical studies performed on citizens, especially individuals belonging to particularly vulnerable groups, such as racial minorities, prisoners, mentally ill or incapable people, and children or elderly people with serious diseases. From the 1980s, the history of biomedical research marks a difference through the implementation of a new research model named "multinational." Before this period, such studies were rare. From the 1980s onward, studies funded by high-income countries and carried out in low-income countries with participation of their populations started to flourish. In turn, this new model brought about not only different forms of research but also new and more complex ethical challenges. For this reason, it seems appropriate to add a fourth stage to the history of biomedical research, that is, the stage of "post-Helsinki and deregulation of multinational research." At least two research events have been paradigmatic with regard to the ethical challenges generated in the wake of the implementation of the multinational research model. The first event pertains to 15 clinical trials conducted in 1997, using placebo as a comparative alternative to 'standard of care' for the purpose of reducing perinatal HIV transmission, in spite of the fact that effective treatment had been available since 1994. The trials involved 17000 pregnant women and were carried out in Uganda, Haiti, the Dominican Republic, Thailand and in Sub-Saharan Africa. Three other trials conducted at the same time, two in the USA and one in Thailand, differed from the other 15 studies in two important respects: the absence of placebo-controls and the access of all patients enrolled in the studies to antiretroviral drugs. The second event was the Surfaxin Study, proposed by the Pennsylvania-based Discovery Laboratories in 2001, that is, a comparative study against placebo of a new surfactant in critically premature neonates in Latin American Neonatal ICUs. The study was suggested to be carried out in public hospitals in Peru. These trials were allegedly performed or meant to be performed with the participants' informed consent (IC), and they had a negative benefit-risk ratio for the control groups receiving placebo. Independent assessments of these studies were carried out, but the sample selection was not equitable since different ethical standards were used for the treatment of participants in the country

of origin of the protocols compared to participants from low-income countries. With the emergence of the multinational research model generated in affluent countries and used to conduct trials on groups and populations in poor and low-income countries, new forms of regulations also arose. Such is, for example, the case of the CIOMS' *International Ethical Guidelines for Biomedical Research Involving Human Subjects* (CIOMS 1993). Its guideline number 8 pays particular attention to research involving subjects in underdeveloped communities and states:

> Before undertaking research involving subjects in underdeveloped communities, whether in developed or developing countries, the investigator must ensure that:
>
> - persons in underdeveloped communities will not ordinarily be involved in research that could be carried out reasonably well in developed communities;
> - the research is responsive to the health needs and the priorities of the community in which it is to be carried out:
> - every effort will be made to secure the ethical imperative that the consent of individual subjects be informed; and
> - the proposals for the research have been reviewed and approved by an ethical review committed that has among its members or consultants persons who are thoroughly familiar with the customs and traditions of the community.

The CIOMS guidelines from 1993 were followed by other recommendations suggested by different international governmental and nongovernmental organizations and interest groups. At the same time, existing declarations and guidelines pertaining to biomedical research, such as the Declaration of Helsinki and the CIOMS guidelines, underwent revisions so as to make it easier for researchers and companies involved in multinational research to carry out trials in resource-poor settings (for this, see below).

New Times, New Models, New Standards

The 1990s were marked by a global dissemination of a neoliberal market model following the fall of the Berlin Wall and notably as the sole model option for both high and low human development countries. This was accompanied by a new world strategy for the markets following the economic policy prescriptions established by the Washington Consensus, on basis of which Washington-based international financial institutions such as the World Bank and the International Monetary Fund instituted a new economic policy for developing countries, starting with Latin America (Washington Consensus, 2003). Alongside this, health-related companies, especially the pharmaceutical industry, developed their global market strategy in accordance with these recommendations. This new international economic order had a profound impact on clinical practice as well as on biomedical and health-related research. Three characteristics mark the new scenario of international biomedical research:

1. *A new model of biomedical research* where the financial support previously offered by international companies to the most prestigious universities and expressed in incentives for physician investigators was transformed into direct contracts with the principal researchers, notably outside academia, thus creating

a long list of conflicts of interest (Elliott, 2004; Vidal, 2006). In 1991, 80 % of the investment of the pharmaceutical industry aimed at clinical research went to researchers working in academic medical centers (under the incentive model), whereas in 1998, just 40 % of these funds went to academic institutions (Klein & Fleischman, 2002); the rest was allotted to researchers hired directly or through intermediary companies, such as Contract Research Organizations (CROs). Since 1996, it is known that most of the financial investment in biomedical research is not targeting the most demanding health needs in the world, in particular not the most prevalent diseases in poor countries impacting the global burden of disease and responsible for the major part of world mortality. It is this enormous discrepancy between prevalent health needs and research priorities that has been coined *the 10/90 gap* (World Health Organisation, WHO, 1996). This metaphor was introduced to depict the major inequity in the world with respect to whose diseases are favored in ongoing or planned research programs. In concrete terms, this means that at least 90 % of the economic resources spent annually on medical research are targeting the health needs of the richest 10 % of the world's population, which implies that the needs of 90 % of the world's population have to be met from the remaining 10 % of research funding (Solbakk & Vidal, 2012). Unfortunately, studies on the so-called globalization of clinical research indicate that this gap has not diminished, although during the past 15 years, the number of people from poor and low-income countries enrolled in clinical trials has substantially increased (Glickman et al., 2009; Matsoso et al., 2005; Petryna, 2007; Thiers, Sinskey & Berndt, 2008). On the contrary, evidence from these studies suggests that during this trial period, the relative availability of new drugs to populations in poor and low-income countries has not increased, whereas the gap between wealthy nations and poor and low-income countries with regard to who benefits from the advances of clinical research and development has continued to widen.

2. Globalization of biomedical research
   Since the 1990s, there has been an increase in research carried out by international pharmaceutical companies and research groups from affluent countries in poor and low-income countries. To illustrate this, of the 5,000 ongoing clinical trials in the world in 2007, more than 40 % were conducted in "nontraditional" research zones (Petryna, 2007). At the same time, an increasing number of phase II and III trials have been outsourced to India and countries in Latin America and sub-Saharan Africa. There are different explanations behind the steady increase of biomedical research in poor and low-income countries. First, a growing development of restrictive regulations in affluent countries, to protect the subjects of research (Moreno, 2001) combined with a highly bureaucratic regulatory system, makes the process of ethics approval more complex and slow in these countries (Glickman et al., 2009). Second, the normative standards and regulations in poor and low-income countries tend to be more flexible (or simply nonexisting), allowing researchers to use different ethical and scientific standards from those required in the countries of origin (for instance, the use of different versions of the same protocol for different countries, one including

placebo in the control group and the other, the best proven treatment). Third, the ethical assessment of research ethics committees in poor and low-income countries is less rigid, in part due to insufficient training of committee members, as well as to the pressure the committees are exposed to when they do not enjoy proper independence. A fourth explanation relates to the ease of recruiting subjects in these countries, due to the fact that big layers of the population are considered functional illiterates, and therefore sign (sometimes incomprehensible) IC forms (Lorenzo, Garrafa, Solbakk & Vidal, 2010). Fifth, no doubt, in poor and low-income countries, carrying out research is less costly and a physician and a nurse charge many times less than in a high-income country when involved in research (Glickman et al., 2009). Sixth, legal issues are less risky and insurance costs are much lower in poor and low-income countries than is the case in high-income countries. Finally, the search for new markets by pharmaceutical companies is also a factor that might help to explain the outsourcing of research to poor and low-income countries. In addition, some "noncommercial," scientific reasons for conducting research in poor and low-income countries should be kept in mind as well:

- Research into prevention and treatment of prevalent diseases in the population participating in the research
- Provision of less costly alternative treatments for the populations that have no access to existing drugs in the market
- Identification of virgin populations of treatment making evidence easier to document

3. *Normative deregulation*. The third characteristic that marks the new scenario of international biomedical research relates to the systematic attempt at relaxing the requirements embedded in international ethical declarations and guidelines pertaining to biomedical research, especially those frameworks which have enjoyed high normative credibility, such as the Declaration of Helsinki and the UNESCO Universal Declaration on Bioethics and Human Rights (UDBHR). Attempts to dilute the requirements of the Declaration of Helsinki have been oriented toward easing the ban on the use of placebo in the control group (this started with an explanatory note included in 2002 to Article 29 and became a separate article (Article 32) during the revision in Seoul in 2008); giving less importance to post-trial research obligations of researchers and sponsors to participants and communities implicated in the research; invalidating the notion of a unique standard of treatment in the case of adverse events or post-research damage; and, finally, giving less relevance to the idea that the population participating in a trial will be able to obtain benefits from the results (so clearly expressed in the former Article 19 of the Declaration (Solbakk & Vidal, 2012)). The modifications of this influential normative document have been perceived so severe by some Latin American bodies that they have declared themselves against keeping the Declaration of Helsinki as a normative frame of reference for biomedical research and have instead suggested the use of the Universal Declaration on Bioethics and Human Rights (Declaración de Córdoba, 2008). Likewise, after the UDBHR

was approved, it became the subject of harsh criticisms (ten Have, 2006), including questioning the quality of the experts involved in the process of drafting the document and the legitimacy of the UN body behind it (Landman & Schuklenk, 2005). In addition, the human-rights-based approach of the UDBHR was discredited as a kind of "ideology" (Williams, 2005), and its reference to respect for human dignity as its foundation was seriously criticized due to the alleged unusefulness of the concept of dignity for medical ethics (Macklin, 2003). In fact, the rejection has been so strong that in some papers and books on biomedical research ethics published during the last years (Emanuel et al., 2008), the UDBHR is not even mentioned, neglecting the fact that it was approved by acclamation by all Member States of the United Nations. In the same period, different "recommendations" pertaining to ethical aspects of research in developing countries have also been suggested (National Bioethics Advisory Commission, 2001; Nuffield Council on Bioethics, 2002) as well as "consensus" documents of dubious legitimacy due to the lack of representativity of its participants (Schuklenk, 2004). Characteristic of these documents is that they go even further than the revised versions of the Declaration of Helsinki and of the CIOMS guidelines in diluting post-trial obligations and the requirements pertaining to protecting the rights of research subjects. This situation has evidently led to a weakening of international norms and frameworks as protective safeguards, especially in relation to biomedical research carried out in poor and low-income countries and on vulnerable groups and populations in these countries. At the same time, it has helped to promote the principlist model of the Belmont Report, since it appears to be more flexible and adaptable to the interests and needs of researchers and their sponsors.

Some Concepts About Development, Poverty, and Resource-Poor Settings

The term "resource-poor settings" is at least ambiguous. During the last years, there have been different ways of classifying countries and regions, some of which can be traced back to the times of the Cold War naming most of the poor countries as the Third World (Sauvy, 1952). During the last years, the World Bank has suggested an economic classification for operational and analytical purposes, where the main criterion applied is the gross national product (GNP) per capita. Based on this indicator, every economy is classified as low income, middle income (subdivided into lower middle and upper middle), or high income, even though some other analytical measures based on geographic regions are also used (The World Bank http://data.worldbank.org/about/country-classifications). Finally, in recent years, new comparative measures reflecting the level of *human development* in social groups and countries have started to be used, such as the *Human Development Index* (HDI). The *Human Development Report* has defined human development as the

process of enlarging people's choices (UNDP, 2007). According to this view, human development has three components (UNDP, 2010):

- Well-being: expanding people's real freedoms so that people can flourish
- Empowerment and agency: enabling people and groups to act – to drive valuable outcomes
- Justice: expanding equity, sustaining outcomes over time, and respecting human rights and other goals of society

The measure takes into account three aspects of human development of which income level is just one:

- Life expectancy at birth, as an index of population health and longevity
- Knowledge and education, as measured by the adult literacy rate
- The combined primary, secondary, and tertiary gross enrollment ratio, and standard of living, as indicated by the natural logarithm of gross domestic product per capita at purchasing power parity

On the other hand, poverty is conceived of as both the lack of ability to produce or develop the productive potential and the impossibility to reach a minimal acceptable vital realization because of being deprived of the capabilities, the opportunities, and the basic rights to do it. Consequently, poverty is not just a financial state, since being poor affects life in many ways. For these reasons, it is here proposed to view the concept of "resource-poor settings" in light of the Human Development Index, as well as through other metrics suggested by the United Nations Development Program, UNDP, such as the Human Poverty Index, HPI. These measures provide accurate and clear reflections of the condition of human beings and of communities, while at the same time, they also permit to include in this analysis extremely poor groups living in high-income countries, that is, groups which cannot be visualized by means of employing average standards such as the GNP measure. The Human Poverty Index uses indicators that capture nonfinancial elements of poverty, such as life expectancy, adult literacy, water quality, and children suffering from underweight. Here, the term "resource-poor settings" will refer to those that can be considered of having low human development and high human poverty.

Characteristics of Health Systems in Resource-Poor Settings

The Report of the International Bioethics Committee of UNESCO on Article 14 of the UDBHR, *Social Responsibility and Health* (IBC, 2010), states what is already well known, that is, that the greatest share of health problems is attributable to the *social* conditions in which people are born, live, and work. This fact was already established several years ago by the World Health Organization (Wilkinson & Marmot, 2003), through the introduction of the notion of *social determinants of health*, SDH. Among such determinants count poverty, overpopulation, malnutrition, lack of access to health services, lifestyles, the physical environment, genetic inheritance, migration, lack of access to drinking water, and the environmental consequences of progress. From this vantage point, the main health problems in the world

are extreme poverty and hunger, high mortality rate in children under 5, lack of maternal health improvement, inadequate prevention and control of HIV/AIDS, tuberculosis and malaria, limited access to essential medicines, and restricted access to water supply and sanitation. These are all barriers seriously impeding health improvement, and they refer to neglected diseases in neglected populations. In more concrete terms, the following data indicate the main health problems situation:

- Maternal mortality: Data from 2005 show that the maternal mortality ratio was 9/100,000 per live births in developed countries, 450 in developing countries, and 900 in sub-Saharan Africa. In the year 2008, the bulk of maternal deaths occurred in developing countries, corresponding to 99 % of women who died during pregnancy or in childbirth (WHO, 2011).
- Infant mortality: Even though this indicator has notably improved during the second half of the twentieth century in some poor countries, this situation has come to a standstill over the last years. The majority of children under 5 years die from avoidable diseases, which means that an adequate sanitary intervention might improve their condition.
- Meanwhile, infant malnutrition is still frequent. 115 million children under the age of 5 suffer from ponderal stagnation with uneven progress. In Africa, for instance, this number increased from 24 million in 1990 to 30 million in 2010. In Asia, this number is estimated to be even higher, around 71 million for the same year (WHO, 2011). About 178 million children in the world have extremely low height for age, a common used measure to indicate chronic malnutrition. These children are more likely to have learning difficulties.
- Similar realities are depicted with respect to both infectious diseases, such as pneumonia and diarrheal diseases, and to neglected tropical diseases, which affect more than 100 million people primarily belonging to poor populations living in tropical and subtropical climates. In the case of HIV, there has been progress in the prevention and treatment of the disease; however, the antiretroviral rates are still low in poor and low-income and in middle-income countries (36 % overall), with significant variations at regional level (WHO, 2011).
- Essential medicines continue being scarce and costly for poor and low-income countries. As stated by WHO: "Surveys in more than 40 mainly low-income and middle-income countries indicate that the selected generic medicines were available in only 42 % of health facilities in the public sector and 64 % of such facilities in the private sector. Lack of medicines in the public sector forces patients to purchase medicines privately. In the private sector, generic medicines cost on average 630 % more than their international reference price, while originator brands are generally even more expensive" (WHO, 2011, p. 18). These figures are of great importance when discussing multinational research, because it raises a fundamental question, whether poorly developed countries and communities should be considered vulnerable and why. Thus, this situation does not only represent a description of the state of affairs, as has frequently been the case; it also suggests a *prescriptive* orientation and draws a line under which individuals and groups should be entitled to special protection.

Social Vulnerability and Social Determinants of Health

It is a fact of the world that socially disadvantaged populations have less access to health resources, get sicker, and die earlier than those in more privileged social positions. Hence, it could without doubt be said that they are highly vulnerable populations, mainly due to social, economic, and sometimes political conditions. For this reason, they could also rightly be viewed as victims of forms of vulnerability that require special protection in a given situation as is the case with biomedical research. Article 8 of the Universal Declaration on Bioethics and Human Rights states:

> In applying and advancing scientific knowledge, medical practice and associated technologies, human vulnerability should be taken into account. Individuals and groups of special vulnerability should be protected and the personal integrity of such individuals respected.

In the Report of the International Bioethics Committee on the *Principle of Respect for Human Vulnerability and Personal Integrity* (IBC, 2011), the conditions taken into account are those that more or less directly impinge upon the capacity to live as a free, autonomous individual and the right to live in a world where significant inequalities in the capacity to meet everyone's basic needs are adequately addressed. The report distinguishes between different situations of *special* vulnerability:

- Situations that are determined by personal (permanent or temporary) disability or disease
- Situations that are related to social, political, and environmental determinants, for example, culture, economy, relations of power, and natural disasters
- Situations of vulnerability in the health-care setting, in research, and in the development and application of emerging technologies in the biomedical sciences

In the report, it is clearly shown how social, economic, and political conditions can put individuals in vulnerable situations, prior to a research-oriented intervention is conducted. In such situations, the research can contribute to an improvement of the situation or, conversely, to a worsening of existing conditions. The report goes further in the definition of the field of vulnerability when it states:

> That is also why human vulnerability and personal integrity, the other essential concept evoked in Article 8, relate to each other. When a part of our body is inappropriately 'touched' (this is the meaning of the ancient Latin verb from which the noun 'integrity' stems), our life itself, or at least our health, may be threatened. When our freedom is hampered, either by adverse circumstances or by the actions of others, we experience a "wound" to our identity, to its value and dignity. Preservation of integrity implies protection against these kinds of intrusions, the capacity to "say no" to any sort of impingement upon our freedom or to any sort of exploitation of our body and our environment. We are nonetheless committed at least to seek to ameliorate the effects of harms and disadvantages imposed by circumstances. This is a prerequisite of human flourishing and self-fulfillment. (IBC, 2011, para 8, p. 3)

The different groups of vulnerable people here envisaged are people whose human development is seriously impaired and who have a high human poverty rate as well, affecting their decision-making capability that allows them to

decide what they want for themselves and the way they want and can plan their own project of happiness. It is when basic human needs are satisfied that the flourishing of those capabilities and a truly human development are enabled (UNDP, 1999).

Martha Nussbaum contends that human capabilities refer to a definition of dignity: an idea of human dignity with broad cross-cultural resonance and great intuitive power that turn it into a universal value. Capabilities are here understood as the foundation of basic political principles, which are to be constitutional guarantees, and become the basis of human rights and an essential contribution to an all-out notion of justice (Nussbaum, 2002, pp. 4–15, 70–101; Nussbaum, 2011). Capabilities constitute, then, a universal pattern which applies to all individuals alike. Finding out about capabilities thus implies inquiring about what an individual or group of individuals is able *to be and to do* with their lives, and what resources are available for them to fully develop as human beings. So far, the epistemological and normative potentials of the capability approach have not been systematically explored in relation to ethical problems surrounding human disease and health, let alone the issue of biomedical research. However, since the approach establishes a link between human development and human rights, it provides a framework making it possible to identify ethical problems in such a way that they reflect the reality in which they are created (Vidal, 2010). This refers both to the trigger factors that determine them and the way to solve them, and it draws as well attention to certain responsibilities regarding who is to take part in the resolution process. In addition, it refers to what ought to or ought not to be done in certain circumstances, and under what conditions biomedical research would be ethically appropriate. From the consideration that human development is linked to human dignity, which is the milestone of human rights, follows the conclusion that those individuals whose human development is seriously impaired (and are thus vulnerable) do not exercise their human rights in a proper manner, to the detriment of their personal dignity and integrity (Solbakk, 2011). Consequently, satisfying basic human needs essential for developing capabilities entails moral obligations not only for states but also for other public and private actors of the society who interact in a cooperative way with vulnerable people and populations. Furthermore, if one conceives of these types of vulnerability as affecting human dignity and integrity, then it will be easier to see why there exists no "possible transaction," no negotiation around them; rather fulfilling them is mandatory. Needles to say, states are responsible for satisfying people's needs and for promoting, protecting, and respecting human rights. Important in this context is, however, also to address the question to what extent and in what ways individuals, social groups, and – above all – powerful stakeholders, with a capacity to intervene, bear such obligations. Considerable progress has been made regarding the responsibility of states to cooperate with other states. In this respect, Article 24 on *International Cooperation* of the Universal Declaration on Bioethics and Human Rights provides invaluable guidance. Furthermore, even if the question about the obligation of other stakeholders than states with regard to satisfying people's needs and for promoting, protecting, and respecting human rights has not been finally settled, there is definitely no doubt

as to the justifiability of imposing a prohibition on actions seeking to obtain some benefits based, precisely, on such situations of vulnerability and their determining factors. This issue will be the subject of further exploration in the paragraph below when addressing the nature of benefit and the phenomenon of exploitation in biomedical research.

Exploitation in Biomedical Research

During the last few years, a fierce debate has emerged with regard to the phenomenon of *exploitation* in biomedical research. Two different approaches have gained a lot of attention in the international literature. One is related to a justice perspective where exploitation is considered as a form of injustice, in particular regarding distribution of goods involved in a certain interaction between two parts. The second approach takes as its frame of reference the Kantian and neo-Kantian concept of human dignity as the base from which each individual should be respected by him or herself, independent of the particular situation or the consequences of that situation.

Regarding the first perspective advocates of this approach usually prefer the term "transaction" among individuals who act out of their own free will, thus giving rise to forms of distribution of goods deemed as "fair." Most of the contributions pursuing this perspective have dismissed the Marxist theory of exploitation, even though it has been one of the most widely developed theories in political and moral philosophical literature, because it has been considered to be more closely related to the relative profit (value) in human labor (theory of the labor value), especially in connection with surplus value. Marxist or neo-Marxist currents are more closely linked to the distributions of profits in relation to the labor or resources provided by each party in the processes and their results (Carse & Little, 2008, pp. 206–245). Even though its application in biomedical research looks complex, the theory of value and surplus value should be reconsidered in this field. On the other hand, a group of libertarian bioethicists and philosophers in the USA also advocating a justice approach have suggested to focus the attention on and advocate the division of "social surplus" created in a given transaction. The theoretical underpinnings of this stance have been developed by Alan Wertheimer (Wertheimer, 2008, pp. 63–104). This author asserts that any research involves a *transaction* in which two aspects should be taken into account:

- The participants' voluntary nature, especially of the most vulnerable part of the transaction
- The way in which the "benefits" are distributed between the two parties interacting

This assertion, on which the so-called fair benefit approach is based, makes a distinction between "harmful exploitation" and "mutually advantageous exploitation":

> By mutually advantageous exploitation, I refer to those cases in which both parties (the alleged exploiter and the alleged exploited) reasonably expect to gain from the transaction

> as contrasted with the pretransaction status quo.... I shall generally presume that mutually advantageous transactions are also consensual. (Wertheimer, 2008, pp. 67–68)

Supporters of this stance have assigned strong importance not to "what" is at stake but "how much." They state that oppression, attack, deception, betrayal, coercion, or discrimination may be harmful to people, but it is not exploitation. From this vantage point, A exploits B when B receives an *unfair* level of benefits as a consequence of the interaction between A and B (Participants in the, 2001 Conference on Ethical Aspects of Research, 2004). Fairness is related to the burden to be borne by B and the amount of benefits to be received by A, something which applies to biomedical research. Some authors close to this perspective include further elements in their definition: "Exploitation occurs when wealthy or powerful individuals or agencies take advantage of the poverty, powerlessness or dependency of others by using the latter to serve their own ends without adequate compensating benefits for the less powerful or disadvantaged individuals or groups" (Macklin, 2004, 101–102).

The second approach to the question of exploitation draws on the tradition from Immanuel Kant and considers exploitation no longer as the unfair distribution of benefits, but rather as disrespect for human dignity. Exploitation then occurs when one of the parties "utilizes" the other one as a "mere means" or as an instrument to serve their own purpose (Carse & Little, 2008, pp. 206–245). For evident reasons, this approach does not consider the option of compensation, since *utilizing* the individual is the problem itself and such action cannot be compensated with goods. Within this position, there are also various perspectives. Some equate the respect for dignity with satisfying the criteria of informed consent ("consent-based criterion"); others consider that exploitation affects the subjective sense of dignity held by each individual, while a third group of authors hold that some actions inherently violate human dignity, as, for example, sexual exploitation and slavery (Carse & Little, 2008, pp. 206–245).

In addition to these two perspectives, there are other views which have been given very little attention in the literature, and which highlight the importance not of *what* or *how much* is part of the transaction but *why* (Carse & Little). In this respect, the whys and wherefores may refer to a number of aspects: Why does the transaction take place? Why do vulnerability situations exist? Why is an individual or population chosen to take part? Why do they voluntarily accept the terms and conditions? (Carse & Little). And what is more: why is that individual or community in a situation of vulnerability? Exploitation then occurs every time somebody obtains a benefit through another (by utilizing someone else) who is in a state of a special vulnerability (Carse & Little). As already alluded to in the paragraph on the concept of vulnerability, situations of special vulnerability define part of the discussion. Consequently, those who reduce exploitation to unfair *distribution* of benefits fail at a crucial point since analysis of the fairness of an interaction cannot be done on the basis that the reality of the community or of individuals is something given "per se" (status quo) that falls outside the scope of consideration. When it comes to analyzing fairness, one should take into account the conditions of

vulnerability, including the trigger factors, the human needs of the individuals and communities implicated, the opportunities that they have had and they currently have to make decisions, and the scope of real options available to them; and finally, the opportunities that the individuals have had to develop their capabilities. In Alex London's wording, to avoid falling into *moral minimalism*, it is necessary to take into account the economic, social, and political reality of the individuals and take it as the starting point to devise the conditions and requirements of any model deemed as "fair" (London, 2005). This does not only relate to local conditions of fairness but also to global conditions that may put (or have put) such individuals and communities at a disadvantage and lead (or have led) them into their current situation of vulnerability. The implications of the so-called TRIPS regime (Trade-Related Aspects of Intellectual Property Rights) pertaining to essential medicines illustrate this point in a dramatic way. Although this regime has been presented as the most efficient and cost-effective way of promoting medical innovations, it is a fact of the world that it represents a substantial infringement on the possibilities of producing cheaper versions of patented drugs, something which, in turn, reduces the access possibility of cost-saving-oriented patients in the affluent part of the world as well as of patients in poor and low-income countries to cheaper and/or affordable medicines. Finally, as observed by Thomas Pogge, for the group of stakeholders most in need, the TRIPS regime is undoubtedly "socially harmful" in a dramatic way: "Millions of deaths from AIDS and other treatable or curable diseases are due to the suppression of manufacture and trading of generic drugs" (Pogge, 2008, p. 5). Any conception of exploitation that fails to consider these aspects will be – to say the least of it – reductionist in scope and hardly without any credibility with regard to providing the ethical prescriptions pertaining to multinational research. Furthermore, such conceptions will prove insufficient with regard to installing the responsibilities necessary to modify a situation that prior to the research was undertaken had been unfair. Finally, it seems rather irrelevant to devote so much energy and time to the discussion on defining exploitation, if it is instead possible to define the basic necessary conditions that may enable individuals and communities to take part in decision-making processes and in the development of their own capabilities, and to decide what they want to be and what they wish to do with their lives. Such a baseline seems to be the one that ought to determine the feasibility of research studies in these social groups.

Benefits in Biomedical Research

For many years, medicine has held a very clear stance on how to benefit patients; in fact, well-doing or *beneficence* has been part and parcel of a physician's moral obligation for centuries. This was mainly related to the paternalistic idea of well-doing, the content of which was defined by medicine itself. In the second half of the twentieth century, informed consent suddenly became part of medical practice and the concept of benefit dramatically changed by introducing what the patients themselves understand as such. Therefore, benefit does not only mean what

medicine may understand as such; it also includes other values that form part of people's life projects and happiness.

In biomedical research, the concept of benefit is more complex because every research is conducted under uncertain conditions and the goal is, precisely, to prove the efficiency or efficacy of a new intervention. The technical notion for this kind of uncertainty is *clinical equipoise*, which coins a situation where there is "...no consensus within the expert clinical community about the comparative merits of the alternatives to be tested" (Freedman, 1987, p. 144), that is, "...whether being in the treatment arm or the placebo arm of a placebo-controlled trial is preferable" (Brody, 1997, p. 607). As observed by Weijer, the acknowledgement of such a kind of uncertainty is of crucial importance in the ethical assessment of a trial, because it "...frames the ethical preconditions of clinical research as an issue in medical epistemology" (Weijer, 2000, p. 71). Even when confronted with the uncertainty required in clinical trials, the ethical assumptions of medicine have been:

- *That the expected benefit was a kind of knowledge that could be generalized*. For this reason, benefit has never been a problem for the scientific community, because the intention is to find a new kind of knowledge that is to benefit mankind as a whole.
- *That in order to achieve this benefit, the following principles should be taken into account* (Pellegrino, 2009):
  - The researcher's prudent judgment
  - Technical competence
  - Benevolence (virtues of researchers)

Article 6 of the Nuremberg Code states that the degree of risk to be taken should never exceed the one determined by the humanitarian importance of the problem to be solved by the experiment. The Declaration of Helsinki (1964) establishes the priority of individuals to seek knowledge, thus marking a significant change of paradigms in research patterns, which had been overtly utilitarian until then. The pre-Seoul version of Article 5 of the Declaration of Helsinki states: "In medical research in human beings, the concern about the well being of human beings must always be given primacy over the interests of science and society." Also, Article 16 states that any medical research with human beings should be preceded by a careful comparison of the expected risks against the foreseeable benefits for the individual or others. This does not prevent healthy volunteers from taking part in medical research. Consequently, there is a new idea of benefit within the context of the R/B ratio, thus giving the term "benefit" a relative connotation. Benefit is what one can obtain when taking part in research studies with regard to the intervention being assessed. Risks are evaluated in terms of the likely harm that may be inflicted in the intervention. This means that the risks and benefits being assessed should be of an equal nature and, notably, *related to each other*. At the start of the twenty-first century, this concept changed radically, which became apparent in the discussions over the definition of exploitation. According to this attempt at introducing a radically new conception of benefit with no interconnection with the conception of risk, there is no exploitation if there is adequate compensation (*fair benefit*). So, what is then, according to this view, the nature or the content of benefit? Says Emanuel (2004):

"It is important to state how much each party receives in the interaction; this will determine whether there is exploitation or not" (Participants in the, 2001 Conference on Ethical Aspects of Research, 2004). This view proposes that the risk-benefit relation can be changed to represent a relation including the community at large as well. Consequently, the subjects may be exposed to high (physical) risks, and they or the community may receive some material benefit to compensate them in a "fair" manner, because under this new concept, the interaction (biomedical research) is a contractual relationship. But this allegedly new turn raises the question: who determines the benefit/compensation? Four answers seem to be possible:

- The scientific community, researchers, and sponsors. They establish the benefits that may satisfy the needs of the individuals or the community in terms of what they consider proper and which are accepted by the community.
- The individuals themselves. That is, the individual is the one who can and must determine the scope of the benefits and the risks they are ready to face.
- The Ethic Research Committee. Most of the documents establish that the ERCs should assess risks in an independent way, but they do not always refer to the benefits, at least when their nature is different from that of the risks (or maybe it is expected that they evaluate risk and benefit of different nature).
- The society and the state. That is, they set the general rules so that the research can be carried out.

Amid this confusion between benefits and compensations in a transaction, the following listed interventions are included under the title of benefits for the individuals or the communities:

- Medical assistance to be received by participants in a research study. Health care during the research development (to treat the pathological process and other pathologies occurring at the same time). This has been considered as a benefit especially where poor communities have no access to treatments or health services, or the existing ones are of low quality.
- Assistance provided to treat the harm that was inflicted as a result of the research (harm compensation). This view considers as a benefit the treatment of foreseeable harm which has been reported to the patient in the IC and which is deemed to have been accepted by them. The same goes for some reported risks which treatment is not an obligation, and it rather becomes part of the list of benefits. Some protocols consider the treatment of unforeseeable harm (unexpected adverse events), as well as the treatment of adverse events, as a "benefit" of the research.
- Post-research benefits. The availability of interventions when their results have proved to be effective has been a topic of lengthy discussions, and in many cases, this has been considered as a benefit that may "reasonably" be offered to participants in the research.

The debate has been broadened as to who should receive this "benefit": the participants (with or without the control group), all of those affected by the pathology, or the community. In many cases, this has been offered as part of the so-called compensations under the name of post-research benefit. The question that remains to be answered is whether the satisfaction of basic human needs

(not covered in the community where the research is being done because of the socioeconomic conditions and a low human development, with specific vulnerabilities) may be considered as a benefit in comparison with the physical risks to be run by the individuals taking part in the research. This question comes before the question about the obligations for necessary compensation, since it is an exchange that utilizes such vulnerability to create the necessary conditions for a *transaction* that is essentially asymmetric.

Needs, Benefits, and Compensations in Medical Research

Here, it is proposed to define as benefits such actions or interventions that may do "good." This conception excludes the compensation for harm or risk the individuals may be exposed to. The idea of *good* should be defined by those who are to receive a benefit that they need and not by those who are to provide it. The first basic idea is that the rate should be established among two situations of similar nature (e.g., physical damage, physical benefit). A good may be oriented toward satisfying a basic human need as long as it is not part of a transaction. No negotiation is possible when dignity and human integrity are involved; they cannot be negotiated, because they have a value that cannot be expressed in terms of price. Thus, people suffering from hunger are not eligible for research studies where the indirect benefit is receiving food, even though the individual may accept the risk resulting from the administration of a drug and may consider it as a reasonable option for his/her family. This example, extreme as it may seem, is not very different from those situations where research subjects are provided basic health-care services as a compensation for taking part in research or treatments that they would otherwise not be given to treat their condition. Unsatisfied human needs, the degree of vulnerability, and the deprivation of the individual and the community play a key role in this issue. From this view follows that a benefit should be defined as an intervention bearing the same nature as the risk. It should include the effective results of the drug being tested, the treatment with the best proven standard for the control group, and the post-research treatment in the case it has proved to be successful. Where it is not possible to provide a benefit of the same nature or the direct obligations have already been fulfilled, some considerations should be made about the indirect benefits:

- They should not satisfy a basic human need which is a reflection of a violation of a human right.
- They should be defined by the individuals, the communities, or the host states (prior to the IC).
- They should be approved by an independent local REC duly experienced to assess the research, where the participants directly involved are represented.
- They should have the participants' IC (competent and voluntary) given under no coercion.
- They should aim at increasing human capabilities so that the communities can satisfy their own needs regarding that problem in particular.

A human-rights-based approach in biomedical research would assert that some goods are nonnegotiable values and that the baseline is determined by the previous human rights prevailing condition of the individuals taking part in the research. Therefore, any intervention intended to satisfy an unsatisfied basic human need (human right) should not be referred to as benefit. It is a right, and fulfilling it is a legal and ethical obligation; consequently, any interaction that would take advantage of this situation should be deemed as a potential exploitation of vulnerable subjects. The assumption, then, is that the communities under extreme necessities should not take part in biomedical research, except when:

- The country offers appropriate protective measures to the individuals (REC, IC, and independent supervisions)
- The research is to be done with that specific group because their characteristics are typical of the pathology (and cannot be carried out in the same way in an invulnerable community)
- The goal is to benefit the direct research participants instead of a health priority that had been previously detected
- The individuals will be treated in the same way as in similar research in a developed country (universal standard)
- The individuals and the community will have access to the results of the research

For this to become true, the 1993 CIOMS standards should then be resumed exactly as it was originally conceived, giving place to a new step in the history of research ethics.

Global Responsibilities Pertaining to Multinational Research in Communities with Low Human Development

Article 15 of the Universal Declaration on Bioethics and Human Rights states: "Benefits resulting from any scientific research and its applications should be shared with society as a whole and within the international community, in particular with developing countries." This is a commitment all Member States of the UN family have adopted. However, very little research has been undertaken to explore how a normative framework for benefit sharing of this kind should look like. To indicate a way of turning such a commitment vis-à-vis impoverished countries and communities into something more than fine words the dominance of the market-driven language of the TRIPS regime should be critically scrutinized. This regime not only reduces the access possibility of existing drugs for millions of people in great need, it also hampers dramatically development of new, essential medicines targeting ailing people in the poorest parts of the world. For this reason, it has been suggested to introduce an additional patent language for drug innovation – a patent 2 regime besides the existing TRIPS regime – covering the field of new essential drugs (Pogge, 2008). Pogge discusses two possible models, the push model and the pull model. Here, the focus will be on the second model, because it resonates better with a human-rights-based approach to multinational research. The first element, which is common to both

models, is that essential medicines should no longer be considered private goods protected by the TRIPS regime but as public goods freely accessible to any drug manufacturer in the world to make use of them in terms of generic drug production. This open – and costless – access element must, however, be supplemented with an alternative incentive for research; if not, the original drug producer would lose most of its income from its innovation. For this reason, the introduction of a global burden of disease (GBD)-oriented research incentive is suggested, that is, an incentive that is directly tied to the effect a new essential drug has on the reduction of the global burden of disease. In Pogge's own words, the idea goes as follows:

> The basic idea is to institute – complementary to existing monopoly patents – a new kind of patent for essential medicines that entitles the patent holder, during the life of the patent, to be rewarded out of public funds in proportion to the impact of the invention on the GBD. (Pogge, 2008, p. 244)

From the perspective of the principle of benefit sharing of the Universal Declaration on Bioethics and Human Rights, this supplementary patent regime has several attractive assets. First, it would stimulate close collaboration between the patent holder and generic producers to mass produce the drug so as to "enhance affordability and availability of its medicines to poor patients and hence their favorable impact on the GBD" (Pogge, 2008, p. 245). Second, with such a model in place, there would be an incentive for the patent holders to ensure that all patients for whom the drugs would have an essential health impact "have real access to them" (Pogge, 2008, p. 245). Third, it would represent a powerful incentive toward developing not only new treatments for chronic patients (the most lucrative target group under the present TRIPS regime) but treatments, including vaccines, that will "reduce the GBD in the most cost-effective way" (Pogge, 2008, p. 246), something that would imply a much more intensive research focus on the ailments of the poorest of the poor in the world. Consequently, this would also provide genuine research benefits for people living in resource-poor settings. Finally, with the implementation of a patent 2 language to stimulate the development of essential medicines, the drug innovators would in addition have a powerful incentive to help poor and low-income countries to improve their health-care systems so as "to enhance the impact of their inventions there" (Pogge, 2008, p. 246). With such a supplementary patent language in place, large numbers of the poorest communities and peoples in the world would no longer be left out when strategies for medical research are made and the benefits of medical innovations are distributed. In addition, it would help to bring together stakeholders that under the present regime live apart from each other and often in sharp opposition to each other, that is, drug developers and the generic drug producers. These considerations lead finally to a point with regard to the power struggle taking place on the level of language in international research ethics necessary to tackle, that is, the lack of concerted actions and strategies among the critics of the double moral standard of international research in terms of joint publications and joint policymaking activities to counterbalance the Anglo-American dominance in international research ethics. As observed by Pogge in relation to the implementation of the TRIPS regime:

> The unjust rules we are seeking to reform exist because others have managed to coordinate in their support. The agribusiness, software, entertainment, and pharmaceutical industries have overcome their differences to throw their political clout behind a joint (TRIPS/TRIPSplus) strategy that—together—they got their governments to impose on the world. Those seeking to protect the poor have undeniably made great and often successful efforts of many kinds. But we have not managed to coordinate on a joint political strategy, and our dispersed efforts are therefore greatly hampered by the powerful and continuous impoverishing impact of unjust institutional arrangements. (Pogge, 2008, p. 257)

It is in the power of democratic states in the most affluent parts of the world to take the lead to change this horrible and undignified situation seriously impairing the lives and capabilities of millions of people living in resource-poor settings. In this way, they would also fulfill part of their commitment in relation to Article 15 of the Universal Declaration on Bioethics and Human Rights, by making multinational medical research a fair enterprise aimed at enhancing human capabilities.

Conclusion

All Member States of the UNESCO have adopted the Universal Declaration on Bioethics and Human Rights: a tremendous achievement in the normative history of mankind. It is, however, also a fact that the health and lives of millions of people in this world are at risk due to the grossly unjust way resources for health and for health research are distributed. In this chapter, the focus of attention is clinical research in resource-poor settings. The analyses here provided and the message conveyed is that it is in the power of democratic states in the most affluent parts of the world to take the necessary steps to change this situation so as to enable millions of people suffering from treatable diseases due to dire economical, environmental, social, and political conditions to freely choose their way of fulfilling their human capabilities, in accordance with the powerful vision expressed in the Universal Declaration on Bioethics and Human Rights to respect human dignity, human rights, and fundamental freedoms.

Codes of Conduct

33

Robert Baker

Introduction

In the aftermath of the Second World War, a system of global institutions arose to facilitate international collaboration in rebuilding a war-devastated world and to construct new and better institutions of international understanding and collaboration. The United Nations (UN) and associated ancillary international organizations were created as a replacement for the failed League of Nations (LN). Among the UN's ancillary organizations dealing with biomedicine are the Council for International Organizations of Medical Sciences (CIOMS, founded 1949), which is a subcouncil of the World Health Organization (WHO, founded 1948), and the United Nations Educational, Scientific and Cultural Organization (UNESCO, founded 1946). The World Medical Association (WMA), a professional society, was founded independently of the UN in1947. All of these organizations are *international* in the sense defined by the English philosopher Jeremy Bentham (1748–1832), the term's originator: that is, they designate declarations or treaties involving two or more nations. Over the ensuing decades, these international organizations issued a series of documents asserting bioethical duties, principles, rights, and responsibilities that are *global* in the sense that they apply worldwide, without reference to nations or national boundaries. These documents are foundational for global bioethics, and this chapter examines some of the major global codes of conduct, declarations, and rights documents, focusing on the most influential. Among those analyzed are the WMA's Declarations of Geneva and Helsinki and its International Code of Medical Ethics, the CIOMS International Ethical Guidelines for Biomedical Research Involving Human Subjects, and UNESCO's

Universal Declaration on Bioethics and Human Rights. Most of these texts are regularly revised and updated. The most recent versions are readily available on the Internet; however, earlier versions documenting pivotal changes are not readily accessible, and full texts of these versions have been provided as part of this chapter.

The Declaration of Geneva and the Hippocratic Oath: A Prototype for Global Bioethics

The biblical notion that old things that have passed away can become new again is exemplified in the foundational documents of global bioethics. The Hippocratic Oath, the earliest recorded statement of professional medical self-regulation (*circa* fifth–fourth century BCE), was the basis of the first document of global bioethics, the WMA's Declaration of Geneva (1948). For those unfamiliar with the text, in the Hippocratic Oath a physician's apprentice swears to abide by an apprenticeship contract and a code of ethical conduct. These apprentices pledge not to act unjustly toward or to harm the sick, and not to have sexual relations with them, but always to use their *techne* – the term from which "technique" and "technology" derived – in ways that make the sick better rather than worse. Apprentices, moreover, were not to use health-endangering medicines, like drug-soaked vaginal tampons, because they endangered *women's* lives and were not to attempt surgical procedures beyond their expertise, like cutting out bladder stones.

According to a literal translation by classicist Heinrich Von Staden (1996), the code states the following:

> (3. i) And I will use regimens for the benefit of the ill in accordance with my ability and my judgment, but from [what is] to their harm or injustice I will keep [them].
> (4. i) And I will not give a drug that is deadly to anyone if asked [for it],
> (4. ii) nor will I suggest the way to such a counsel. And likewise I will not give a woman a destructive pessary [i.e., a destructive vaginal suppository].
> (5. i) And in a pure and holy way(ii) I will guard my life and my *techne*.
> (6. i) I will not cut, and certainly not those suffering from stone, but I will cede [this] to men [who are] practitioners of this activity.
> (7. i) Into as many houses as I may enter, I will go for the benefit of the ill,ii.) while being far from all voluntary and destructive injustice, especially from sexual acts both upon women's bodies and upon men's, both of the free and of the slaves.
> (8. i) And about whatever I may see or hear in treatment, or even without treatment, in the life of human beings – things that should not ever be blurted out outside – I will remain silent, holding such things to be unutterable [sacred, not to be divulged].

What allowed this code to endure has less to do with these practical precepts, which do not address the issues of abortion or euthanasia, and has everything to do with later interpretations by readers and translators imbued with Stoic, Judeo-Christian, and/or Islamic morality who read into the Hippocratic text stirring affirmations of the sanctity of life and prohibitions against euthanasia and abortion. Thus, although line 4.ii reads literally as "I will not give a woman a destructive pessary," a popular translation by Victorian physician-classicist Francis Adams (1849) renders 4.ii as "I will not give to a woman a pessary to produce abortion." Historically, Adams' Victorian reading and dozens of similar translations are inconsistent with ancient Greek practices, since infanticide was commonplace, and Hippocratic texts describe techniques for performing abortions. Nonetheless, interpretations like these transformed the oath into a life-affirming ethics that became a talisman for Western medical ethics that could and did serve as a rallying point for physicians in Germany and in Nazi-occupied Europe who resisted the Nazi eugenic sterilization and infanticide initiatives.

This anti-Nazi reaffirmation of life would make the oath an ideal basis for publicly reasserting traditional medical values after the Second World War ended. As it happened, throughout the war, the basement pub of the London home of the BMA had become a gathering place for physicians attached to the allied armies of America, Australia, Canada, Latin America, New Zealand, the United Kingdom, as well as those serving with the Czech, Dutch, Free French, Norwegian, and Polish resistance movements. Striving to preserve this camaraderie in the postwar period, representatives of 27 national medical societies from Africa, Asia, Australia, Europe, the Middle East, and North American founded the WMA in 1947 to address the medical needs of a war-ravaged world by sending medical instruments, pharmaceutical supplies, and textbooks to areas in need of assistance – and to restore "the honor of medicine (Pridham, 1951)."

Medicine's honor was in disrepair because during the war, German physicians had committed "crimes against humanity. . .which shocked the whole profession. The fact that such horrors could be perpetrated by doctors underlined the need for. . .a modern version of the Hippocratic oath named. . .the Declaration of Geneva" (WMA, 1949a, p. 12). The Declaration was approved at the WMA's first annual conference in 1948 as a means of teaching medical students "to honor the traditions of Medicine and to absorb its humanitarian purposes—the succor of the bodily and mental needs of the individual irrespective of class, race or creed; the cure of disease; the relief of suffering; the prolongation of human life; and the prevention of disease" (WMA, 1949a, p. 12). As the authors of the Declaration noted, the tradition of oath swearing had been abandoned in many countries, including all of Nazi- and Fascist-occupied Europe. This new form of the Hippocratic Oath was designed "to impress on newly-qualified doctors the fundamental ethics of medicine and to raise the general standard of medical conduct" for "every age and every country" (WMA, 1949a, p. 12).

The new oath was drafted in English and translated into French and Spanish for approval by the WMA's 27 member organizations. The original text reads as follows.

Declaration of Geneva
Serment de Geneve
Declaracion en Genebra

At the moment of being admitted as a Member of the Medical Profession

Au moment d'être admis au nombre des membres de la Profession Médicale,

EN EL MOMENTO de ser admitido como Miembro de la Profesión Médica

I solemnly pledge myself to consecrate my life to the service of humanity.

Je prends l'engagement solennel de consacrer ma vie au service de l'humanitié.

Promento solèmnemente consagrar mi vida al sevicio de la humanidad.

I will give my teachers the respect and gratitude which is their due.

Je garderai à mes maîtres le respect et la reconnaissance qui leur son dûs.

Otorgar a mis maestros los respectos, gratitud y consideraciones que mercen.

I will practice my profession with conscience and dignity.

J'exercerai mon art avec conscience et dignité.

Ejercer mi profesion dignamente y a conciencia.

The health of my patient will be my first consideration.

Je considèrerai la santé de mon patient comme mon premier souci.

Velar solicitamente, y ante todo, por la salud de mi paciente.

I will respect the secrets that are confided in me.

Je respecterai le secret de celui que se sera confié à moi.

Guardar y respetar los secretos a mi confiados.

I will maintain by all means in my power, the honor and the noble traditions of the medical profession.

Je maintiendrai, dans toute la mesure de mes moyens, l'honneur et les nobles traditions de la profession médicale.

Mantendré en todo la medida de mis medios el honor y las nobles tradiciones de la profesión médica.

My colleagues will be my brothers.

Mes collègues seront mes frères.

Considerar como hermanos a mis colegas.

I will not permit considerations of religion, nationality, race, party politics or social standing to intervene between my duty and my patient.

Je ne permettrai pas que des considérations de religion, de nation, de race, de parti, ou de classe sociale, viennent s'interposer entre mon devoir et mon patient.

Hacer caso omiso de credos politicos y religiosos, nacionalidades, razazas, rangos sociales, evitando que éstos se interpongan entre mis servicios profesionales y mi paciente.

> I will maintain the utmost respect for human life, from the time of conception; even under threat, I will not use my medical knowledge contrary to the laws of humanity.
>
> Je garderai le respect absolu de la vie humaine dès la conception. Même sous la menace, je n'admettrai pas de faire usage de mes connaissances médicales contre les lois de l'humanité.
>
> Velar con sumo interés y respeto por la vida humana, desde el momento de la concepcion, y aun bajo amenaza, no emplear mis conocimientos médicos para contravenir las leyes humanas.
>
> I make these promises solemnly, freely, and upon my honor.
>
> Jes fais ces promesses solennellement, librement, sur l'honneur.
>
> Solemne y espontáneamente, bajo mi palabra de honor, prometo cumplir con lo antedicho. (World Medical Association, 1949b)

The parallels between the Declaration and the Hippocratic Oath original speak for themselves. The oath's code of conduct has been reformulated as a pledge of service to humanity, and the traditional pledge to benefit the patient was supplemented by a commitment not to "permit considerations of religion, nationality, race, party politics or social standing to intervene between my duty and my patient" and by a vow that "even under threat, I will not use my medical knowledge contrary to the laws of humanity." These refer directly to the Nuremberg War Crime Trials of Nazi doctors invoking the then new concept of "laws of humanity" – a precursor of the concept of "human rights" – that had no precedent in earlier codes, oaths, principles, or rules of national medical societies.

It is noteworthy that the powerful prohibitions against abortion read into the Hippocratic Oath and reflected in many national medical society codes, oaths, and precepts were muted in the Declaration. Thus, the English version of the Declaration only requires physicians to "maintain utmost respect for human life, from the time of conception," without specifying what is meant by "respect for human life." The French and the second Spanish versions of the oath, in contrast, tighten this provision by requiring "absolute respect for human life," that is, respect without exception for human life in any form or stage – including humans in their embryonic form. These linguistic nuances respond to a pragmatic need for compromise in fashioning documents for acceptance in many medical and national cultures. In 1948, however, the animating spirit of the Declaration was the world medical profession's shared horror and condemnation of physician participation in the Holocaust and the profession's resolve that never again would students graduate from medical school unaware of medicine's fundamental commitment to serve the patient and the health of humanity above all else.

Since it was first adopted, the Declaration has been modified five times, in 1968, 1984, 1994, 2005, and 2006. To indicate the nature of these changes, below find the most recent version of the Declaration with deletions to the original English

indicated by cross through lines, for example, ~~deletion~~, and additions by italics, for example, *addition*. These changes reflect a half century of moral reform: the words "my sisters" reflect advances toward gender equality, just as the words "age," "disease," "disability," "gender," and "sexual orientation" reflect the struggle to banish discrimination on the basis of age (ageism), disease (especially discrimination against people stricken with HIV and AIDS), disability (the biases of the able against those with disability), and a rejection of sexist and homophobic biases. Similarly, the change from "laws of humanity" to "human rights" reflects and documents the worldwide recognition of human rights as the moral basis of global bioethics. Fulfilling the ambitions of its authors, this first formulation of a global medical ethics is now the basis of the most commonly sworn medical student initiation and/or graduation oaths worldwide.

Declaration of Geneva —2006

At the time of being admitted as a member of the medical profession:

I solemnly pledge to consecrate my life to the service of humanity;

I will give to my teachers the respect and gratitude that is their due;

I will practice my profession with conscience and dignity;

The health of my patient will be my first consideration;

I will respect the secrets that are confided in me, *even after the patient has died*;

I will maintain by all the means in my power, the honor and the noble traditions of the medical profession;

My colleagues will be *my sisters and* brothers;

I will not permit considerations of *age*, *disease or disability, creed, ethnic origin, gender*, nationality, political affiliation, race, *sexual orientation*, social standing or *any other factor* to intervene between my duty and my patient;

I will maintain the utmost respect for human life ~~from the time of conception~~;

I will not use my medical knowledge ~~contrary to the laws of humanity~~ *to violate human rights and civil liberties*, even under threat;

I make these promises solemnly, freely and upon my honor.

(WMA, 2006a)

In the half century since its founding, virtually every medical society in the world has joined the WMA, from Order of Physicians of Albania and the AMA to its founding chapter, the BMA, and the Medical Association of the Bahamas, down the alphabet to the Chinese Medical Association, the Russian Medical Society, and the Vatican, Venezuelan, and Vietnamese medical associations – ending with the Zimbabwe Medical Association. A pillar of global bioethics, the WMA has become the conscience of medicine, issuing the *Declaration of Tokyo* (2006c) condemning physician participation in torture. In the same year, the WMA also issued *The Declaration of Lisbon on the Rights of the Patient* and *the Malta Declaration on Hunger Strikers* (WMA, 2006d). It later issued *The Declaration of Ottawa on Child*

Health (WMA, 2009). The WMA works closely with the UN and the World Health Organization to provide disaster aid where needed and to protect the integrity of medicine and its practitioners and the rights of sick people, patients, and research subjects. The WMA's most influential declarations, however, deal with human subjects research, and much of this brief introduction to the documentary basis of global bioethics focuses on these declarations.

The Nuremberg Code

It is an ironic twist of history that although one of the WMA's major objectives was the rehabilitation of medical ethics after the discovery of German physicians' inhumane medical experiments on unconsenting involuntary human subjects, the WMA did not issue a code of research ethics until a decade and one half after its founding. This might, at first, appear puzzling since 1947, the very year in which the WMA was founded, a US war crimes tribunal had formulated the following code of research ethics in passing judgment on the 23 German physicians accused of crimes against humanity.

Nuremberg Code – 1947

The great weight of the evidence before us is to the effect that certain types of medical experiments on human beings, when kept within reasonably well-defined bounds, conform to the ethics of the medical profession generally. The protagonists of the practice of human experimentation justify their views on the basis that such experiments yield results for the good of society that are unprocurable by other methods or means of study. All agree, however, that certain basic principles must be observed in order to satisfy moral, ethical and legal concepts.

1. The voluntary consent of the human subject is absolutely essential.
   This means that the person involved should have legal capacity to give consent; should be so situated as to be able to exercise free power of choice, without the intervention of any element of force, fraud, deceit, duress, overreaching, or other ulterior form of constraint or coercion; and should have sufficient knowledge and comprehension of the elements of the subject matter involved as to enable him to make an understanding and enlightened decision. This latter element requires that before the acceptance of an affirmative decision by the experimental subject there should be made known to him the nature, duration, and purpose of the experiment; the method and means by which it is to be conducted; all inconveniences and hazards reasonably to be expected; and the effects upon his health or person which may possibly come from his participation in the experiment.

   The duty and responsibility for ascertaining the quality of the consent rests upon each individual who initiates, directs or engages in the

experiment. It is a personal duty and responsibility which may not be delegated to another with impunity.
2. The experiment should be such as to yield fruitful results for the good of society, unprocurable by other methods or means of study, and not random and unnecessary in nature.
3. The experiment should be so designed and based on the results of animal experimentation, and a knowledge of the natural history of the disease or other problems under study that the anticipated results will justify the performance of the experiment.
4. The experiment should be so conducted as to avoid all unnecessary physical and mental suffering and injury.
5. No experiment should be conducted where there is an a priori reason to believe that death or disabling injury will occur; except perhaps, in those experiments where the experimental physicians also serve as subjects.
6. The degree of risk to be taken should never exceed that determined by the humanitarian importance of the problem to be solved by the experiment.
7. Proper preparations should be made and adequate facilities provided to protect the experimental subject against even remote possibilities of injury, disability, or death.
8. The experiment should be conducted only by scientifically qualified persons. The highest degree of skill and care should be required through all stages of the experiment of those who conduct or engage in the experiment.
9. During the course of the experiment the human subject should be at liberty to bring the experiment to an end if he has reached the physical or mental state where continuation of the experiment seems to him to be impossible.
10. During the course of the experiment the scientist in charge must be prepared to terminate the experiment at any stage, if he has probable cause to believe in the exercise of the good faith, superior skill and careful judgment required of him that a continuation of the experiment is likely to result in injury, disability, or death to the experimental subject. (United States of America v. Karl Brandt et al., 1949).

Despite the Nuremberg judges' claim that "all agree" that experiments on human subjects are justifiable only if "certain basic principles [are] be observed," in point of historical fact, before 1947, no national medical society and, more specifically, none of the societies that founded the WMA had a code of research ethics – except for the American Medical Association (AMA), which had hurriedly adopted some principles of research ethics immediately *after* the commencement of the Nuremberg Trials. Thus, the Nuremberg judges' prefatory statement that "all agree" upon "certain basic principles" of research ethics was profoundly mistaken: no principles

of research ethics had been formulated by any medical society or research organization prior to 1946. The judges had been mislead by "the evidence before [them]," specifically that offered by the AMA's representative at the trial Andrew Ivy (1893–1978) who had testified, quite plausibly, that the Hippocratic Oath was a universal medical ethics that prohibited killing humans in scientific experiments and who then suggested, quite misleadingly, that all medical researchers implicitly accepted common principles of research ethics.

The Nuremberg Code, however, was not without precedent. Its ten principles of research ethics had been suggested to them by Ivy and by his colleague, the Austrian-American psychiatrist Leo Alexander (1905–1985). Ironically, Alexander modeled his suggestions on the 1931 Germany Ministry of Health (*Reichgesundheitsrat*) guidelines on human experimentation with which he was familiar because he had studied medicine in Berlin (Annas & Grodin, 1992; Schmidt, 2004; Weindling, 2005). Nonetheless, except for the AMA and the Germany Ministry of Health, no medical society or governmental institution had issued formal rules for the regulation of research on human subjects before the tribunal issued the Nuremberg Code in 1947.

The International Code of Medical Ethics

The Declaration of Geneva did not directly address the primary focus of the Nuremberg Doctors' Trials, research on human subjects, and so, Jules Voncken (1887–1975), a Belgian physician familiar with continental traditions of *déontologie médicale* (i.e., medical ethics), argued the case for an international code of medical ethics to address human subjects research. Voncken was inspired by Ivy's speeches and articles (Ivy, 1946b, 1947, 1949) which summarized a report he wrote for the AMA (Ivy, 1946a) that described Nazi experiments on human subjects as a "tragedy, which surpasses all of the inhumanities of man to man record [ed] in human history" Ivy (1946a, p. 8). Ivy observed that "the experiments performed on human subjects without their consent, or by coercion, are contrary to the laws of humanity and ethical principles of the medical profession which have been in practice for 22 centuries" (Ivy, 1946a, p. 9). "By common agreement," Ivy claimed(1946a, p. 10), three basic principles should be adopted by all medical societies to protect the human rights of experimental subjects. First among these is the "consent of the subject" who has "been informed of the hazards if any"; the second principle requires that prior animal experimentation justify the likelihood that "the experiment [will] yield results for the good of society unprocurable by other means of study and must not be random and unnecessary in nature" (Ivy, 1946a, p. 10). Finally, the third principle requires that experimenters be scientifically qualified, that they "avoid all unnecessary suffering and injury," and that there be "no *a priori* reason to believe that death or disabling injury will occur, except in such experiments, as [in the Cuban-US] Yellow Fever [of 1900], where the experimenters serve as subjects along with non-scientific personnel" (Ivy, 1946a. p. 10). "The indicted Nazi physicians and scientists" on trial at Nuremberg, Ivy declared,

"ignored these ethical principles and rules, which have been well established by custom, social usage and the ethics of medical conduct, and which are necessary to insure the human rights of the individual." (Ivy, 1946a, pp. 8–11) It was time, Ivy argued, for medical societies to expressly state these time-honored principles that they implicitly accepted. Voncken followed through, proposing that the newly formed WMA develop an international code of ethics that would serve this purpose, among others.

Yet although the WMA did promulgate an international code of medical ethics in 1949, that code did not respond to the Ivy-Voncken call for fundamental statement of the human rights of people serving as research subjects. The experiments condemned at the Nuremberg Trials were so horrible that they were ascribed to the inhumane nature of the Nazism, and so, a code condemning these experiments was deemed irrelevant to normally humane researchers. Consequently, when the WMA convened its third General Assembly in 1949, it adopted a more general statement of medical ethics that contained none of the provisions recommended by Ivy, Voncken, or the Nuremberg Tribunal as essential to preventing the abuse of the human subjects of medical research. Instead, they issued a code based on provisions common to the various official oaths and/or guild-like regulations accepted by the WMA's member medical societies. These set standards of competent medical practice and rules for resolving intrapractitioner disputes. Few of these codes had anything to say about the rights of patients. Not surprisingly, therefore, the first international code of ethics states that doctors' only duties toward the sick are to provide emergency care, to maintain confidentiality, to refer patients to specialists, and to preserve human life from conception – except for the lives of pregnant women since therapeutic abortions, that is, abortions to save a pregnant woman's life or to preserve her health, are deemed permissible only if national laws allow them.

International Code of Medical Ethics
World Medical Association – 1949
Duties of Doctors in General

A doctor must always maintain the highest standards of professional conduct.

A doctor must practice his profession uninfluenced by motives of profit.

The following practices are deemed unethical:

a. Any self-advertisement except such as is expressly authorized by the national code of medical ethics;

b. Collaborate in any form of medical service in which the doctor does not have professional independence;

c. Receiving any money in connection with services rendered to a patient other than a proper professional fee, even with the knowledge of the patient.

Any act, or advice which could weaken physical or mental resistance of a human being may be used only in his interest.

A doctor is advised to use great caution in divulging discoveries or new techniques of treatment.

A doctor should certify or testify only to that which he has personally verified.

Duties of Doctors to the Sick

A doctor must always bear in mind the obligation of preserving human life from conception. Therapeutic abortion may only be performed if the conscience of the doctors and the national laws permit.

A doctor owes to his patient complete loyalty and all the resources of his science. Whenever an examination or treatment is beyond his capacity he should summon another doctor who has the necessary ability.

A doctor shall preserve absolute secrecy on all he knows about his patient because of the confidence entrusted in him.

A doctor must give emergency care as a humanitarian duty unless he is assured that others are willing and able to give such care.

Duties of Doctors to Each Other

A doctor ought to behave to his colleagues as he would have them behave to him.

A doctor must not entice patients from his colleagues.

A doctor must observe the principles of *The Declaration of Geneva* approved by The World Medical Association.

(WMA, 1949c)

The1949 International Code of Medical Ethics was a first step forward, but, as is typical of baby steps, it was hesitant and faltering: a minimalist code that was the best that could be agreed by the WMA's founding medical societies at the time. It has been revised three times since 1949 and has been supplemented by specific declarations on such complex and controversial issues as the role of physicians in treating hunger strikers. On more mundane matters, the revised code no longer contains the word "abortion," and the procedure is not singled out as morally suspect. Moreover, reflecting the influence of the worldwide bioethics movement – the current code asserts the physician's duty to "respect a competent patient's right to refuse treatment." Patients' rights were delineated further in the WMA's 2005 *Declaration of Lisbon on the Rights of the Patient* (WMA 2005). The WMA's 2006 International Code of Medical Ethics is below.

International Code of Medical Ethics
World Medical Association - 2006
Duties of physicians in general

A physician shall always exercise his/her independent professional judgment and maintain the highest standards of professional conduct.

A physician shall respect a competent patient's right to accept or refuse treatment.

A physician shall not allow his/her judgment to be influenced by personal profit or unfair discrimination.

A physician shall be dedicated to providing competent medical service in full professional and moral independence, with compassion and respect for human dignity.

A physician shall deal honestly with patients and colleagues, and report to the appropriate authorities those physicians who practice unethically or incompetently or who engage in fraud or deception.

A physician shall not receive any financial benefits or other incentives solely for referring patients or prescribing specific products.

A physician shall respect the rights and preferences of patients, colleagues, and other health professionals.

A physician shall recognize his/her important role in educating the public but should use due caution in divulging discoveries or new techniques or treatment through non-professional channels.

A physician shall certify only that which he/she has personally verified.

A physician shall strive to use health care resources in the best way to benefit patients and their community.

A physician shall seek appropriate care and attention if he/she suffers from mental or physical illness.

A physician shall respect the local and national codes of ethics.

Duties Of Physicians To Patients

A physician shall always bear in mind the obligation to respect human life.

A physician shall act in the patient's best interest when providing medical care.

A physician shall owe his/her patients complete loyalty and all the scientific resources available to him/her. Whenever an examination or treatment is beyond the physician's capacity, he/she should consult with or refer to another physician who has the necessary ability.

A physician shall respect a patient's right to confidentiality. It is ethical to disclose confidential information when the patient consents to it or when there is a real and imminent threat of harm to the patient or to others and this threat can be only removed by a breach of confidentiality.

A physician shall give emergency care as a humanitarian duty unless he/she is assured that others are willing and able to give such care.

A physician shall in situations when he/she is acting for a third party, ensure that the patient has full knowledge of that situation.

A physician shall not enter into a sexual relationship with his/her current patient or into any other abusive or exploitative relationship.

Duties Of Physicians To Colleagues

A physician shall behave towards colleagues as he/she would have them behave towards him/her.

A physician shall not undermine the patient-physician relationship of colleagues in order to attract patients.

A physician shall when medically necessary, communicate with colleagues who are involved in the care of the same patient. This communication should respect patient confidentiality and be confined to necessary information.

(WMA, 2006c)

The Declaration of Helsinki

Although the Nuremberg Code on human subjects experimentation was issued as international humanitarian law, it was indelibly tarred with the stigma of Nazism, and so, it seemed irrelevant as a precedent for regulations governing the conduct of sane and honorable researchers. The Nuremberg Code also seemed unsuitable for regulating normal medical research. For example, Article 1 required research subjects to be legally capable of consent. Since incapacitated adults, children, and patients with some psychiatric illnesses were not legally capable of consent, Article I inadvertently prohibited experiments to develop new drugs for treating conditions affecting them. The requirement of prior animal experimentation (Article 3) was also problematic since many diseases were unique to humans and could not be studied in animals. Complicating matters further, standards of competent medical research were in flux in the 1950s after British epidemiologist Sir Austin Bradford Hill (1897–1991) had established randomized controlled trials as the standard for unbiased medical experimentation (Yoshioka, 1998).

So the development of global research ethics had to start afresh. Yet since the WMA's member societies lacked any shared tradition or overlapping consensus on research ethics, it took a full decade for them to agree on common standards. By the 1960s, many member societies had developed their own research ethics policies, so some measure of overlapping consensus on ethical principles for research ethics could be agreed. In 1961–1962, the WMA issued a draft declaration on research ethics, and in 1964, a revised version was adopted as *the Declaration of Helsinki*.

DECLARATION OF HELSINKI—1964

INTRODUCTION

It is the mission of the doctor to safeguard the health of the people. His knowledge and conscience are dedicated to the fulfillment of this mission.

The Declaration of Geneva of the World Medical Association (1964) binds the doctor with the words "The health of my patient will be my first consideration"; and the International Code of Medical Ethics declares that, "Any act

or advice which could weaken physical or mental resistance of a human being may be used only in his interest."

Because it is essential that the results of laboratory experiments be applied to human beings to further scientific knowledge and to help suffering humanity, the World Medical Association has prepared the following recommendations as guide to each doctor in clinical research. It must be stressed that the standards as drafted are only a guide to physicians all over the world. Doctors are not relieved from criminal, civil and ethical responsibilities under the laws of their own countries.

In the field of clinical research a fundamental distinction must be recognized between clinical research in which the aim is essentially therapeutic for a patient, and the clinical research, the essential object of which is purely scientific and without therapeutic value to the person subjected to the research.

I. Basic principles

1. Clinical research must conform to the moral and scientific principles that justify medical research and should be based on laboratory and animal experiments or other scientifically established facts.

2. Clinical research should be conducted only by scientifically qualified persons and under the supervision of a qualified medical person.

3. Clinical research cannot legitimately be carried out unless the importance of the objective is in proportion to the inherent risk to the subject.

4. Every clinical research project should be preceded by careful assessment of inherent risks in comparison to foreseeable benefits to the subject or to others.

5. Special caution should be exercised by the doctor in performing clinical research in which the personality of the subject is liable to be altered by drugs or experimental procedure.

II. Clinical Research combined with professional care

1. In the treatment of the sick persons, the doctor must be free to use a new therapeutic measure, if in the doctor's judgment it offers hope of saving life, reestablishing health, or alleviating suffering.

If at all possible, consistent with patient psychology, the doctor should obtain the patient's freely given consent after the patient has been given a full explanation. In case of legal incapacity, consent should also be procured from the legal guardian; in case of physical incapacity the permission of the legal guardian replaces that of the patient.

2. The doctor can combine clinical research with professional care, the objective being the acquisition of new medical knowledge, only to the extent that clinical research is justified by its therapeutic value for the patient.

III. Nontherapeutic clinical research

1. In the purely scientific application of clinical research carried out on a human being, it is the duty of the doctor to remain the protector of the life and health of that person on whom clinical research is being carried out.

2. The nature, the purpose and the risk of clinical research must be explained to the subject by the doctor.

3a. Clinical research on a human being can not be undertaken without that person's consent after being informed; if the person is legally incompetent the consent of the legal guardian should be procured.

3b. The object of clinical research should be in such a mental, physical and legal state as to be able to exercise fully the power of choice.

3c. Consent should, as a rule, be obtained in writing. However, the responsibility for clinical research always remains with the research worker; it never falls on the subject even after consent is obtained.

4a. The investigator must respect the right of each individual to safeguard his/her personal integrity, especially if the subject is in a dependent relationship to the investigator.

4b. At any time during the course of clinical research the subject or the subject's guardian should be free to withdraw permission for research to be continued.

The investigator or the investigation team should discontinue the research if in their judgment, it may, if continued be harmful to the individual.

(WMA, 1964)

Drawing authority from the Declaration of Geneva and the International Code of Medical Ethics, the Declaration of Helsinki formulates what many consider the first global code of research ethics. Yet, although the Nuremberg Code is never referenced in the Declaration, as historian Susan Lederer has observed, its influence is evident throughout – even if, as Lederer also notes, the Declaration waters down many Nuremberg precepts to the point of fecklessness (Lederer, 2004). The reduction in authoritativeness is striking. Whereas the Nuremberg Code states "basic principles [that] must be observed in order to satisfy moral, ethical and legal" conduct of experiments on humans, the Declaration merely makes "recommendations as guide[s]." More substantively, whereas the Nuremberg Code unequivocally declares the "voluntary consent of the human subject" as "absolutely essential" to ethical experiments on human subjects, the Declaration of Helsinki considers informed voluntary consent necessary only for nontherapeutic experiments. In therapeutic contexts, "the doctor must be free to use a new therapeutic measure" irrespective of whether the subject is informed or consents (Sec. II.1) – although, "if at all possible, consistent with patient psychology, the doctor should obtain the patient's freely given consent." For the most prevalent form of clinical experimentation – experiments to discover new drugs that might prove therapeutic for patients – the first formulation of the Declaration of Helsinki had declared that the informed voluntary consent of legally competent research subjects was optional.

About a decade later, in a second Declaration of Helsinki (WMA, 1975), the WMA fashioned a radically different document which, unlike its predecessor, required signed informed consent statements from research subjects or their legal

guardians in all types of research – including experiments that benefit patients therapeutically. Moreover, prior to the commencement of research, the wording of these consent forms and of the protocols describing the research project had to be approved by independent research ethics committees (called "institutional review boards," or IRBs, in the US and research ethics committees or boards, RECs or REBs, elsewhere). Written statements of informed subject consent were no longer optional; they were a presumptive requirement of all research on human subjects – except in cases in which a physician "considers it essential not to obtain informed consent" and has received an exemption from a research ethics committee.

Strengthening the role of the research ethics committee further, Sec. I.8 stipulates that research "not in accordance with. . .this Declaration should not be accepted for publication." Thus, any research conducted without a subject's or surrogate's signed consent or without the approval of a research ethics committee was unpublishable. The International Committee of Medical Journal Editors (2011), an organization that represents every major medical journal in the world, enforces this provision. The 1975 revision of the Declaration of Helsinki II thus requires that all human subjects research be reviewed by a research ethics committee, that this committee insure that informed consent be part of the research protocol, and that subjects or their guardians sign written consent forms. Furthermore, it made formal review and approval by such research ethics committees a prerequisite of publication in a medical journal. By dint of these provisions, the second version of the Declaration of Helsinki became the first enforceable code of global research ethics – and of global bioethics.

Declaration of Helsinki II—1975

Recommendations guiding medical doctors in biomedical research involving human subjects.

Introduction

It is the mission of the medical doctor to safeguard the health of the people. His or her knowledge and conscience are dedicated to the fulfilment of this mission.

The Declaration of Geneva of the World Medical Association binds the doctor with the words: "The health of my patient will be my first consideration," and the International Code of Medical Ethics declares that "Any act or advice which could weaken physical or mental resistance of a human being may be used only in his interest."

The purpose of biomedical research involving human subjects must be to improve diagnostic, therapeutic and prophylactic procedures and the understanding of the aetiology and pathogenesis of disease.

In current medical practice most diagnostic, therapeutic or prophylactic procedures involve hazards. This applies *a fortiori* to biomedical research.

Medical progress is based on research, which ultimately must rest in part on experimentation involving human subjects. In the field of biomedical

research a fundamental distinction must be recognized between medical research in which the aim is essentially diagnostic or therapeutic for a patient, and medical research the essential object of which is purely scientific and without direct diagnostic or therapeutic value to the person subjected to the research.

Special caution must be exercised in the conduct of research which may affect the environment, and the welfare of animals used for research purposes must be respected.

Because it is essential that the results of laboratory experiments be applied to human beings to further scientific knowledge and to help suffering humanity, the World Medical Association has prepared the following recommendations as a guide to every doctor in biomedical research involving human subjects. They should be kept under review in the future. It must be stressed that the standards as drafted are only a guide to physicians all over the world. Doctors are not relieved from criminal, civil and ethical responsibilities under the laws of their own countries.

I Basic principles

1. Biomedical research involving human subjects must conform to generally accepted scientific principles and should be based on adequately performed laboratory and animal experimentation and on a thorough knowledge of the scientific tradition.
2. The design and performance of each experimental procedure involving human subjects should be clearly formulated in an experimental protocol which should be transmitted to a specially appointed independent committee for consideration, comment and guidance.
3. Biomedical research involving human subjects should be conducted only by scientifically qualified persons and under the supervision of a clinically competent medical person. The responsibility for the human subject must always rest with a medically qualified person and never rest on the subject of the research, even though the subject has given her consent.
4. Biomedical research involving human subjects cannot legitimately be carried out unless the importance of the objective is in proportion to the inherent risk to the subject.
5. Every biomedical research project involving human subjects should be preceded by careful assessment of predictable risks in comparison with foreseeable benefits to the subject or to others. Concern for the interests of the subject must always prevail over the interest of science and society.
6. The right of the research subject to safeguard his or her integrity must always be respected. Every precaution should be taken to respect the privacy of the subject and to minimize the impact of the study on the subject's physical and mental integrity and on the personality of the subject.

7. Doctors should abstain from engaging in research projects involving human subjects unless they are satisfied that the hazards involved are believed to be predictable. Doctors should cease any investigation if the hazards are found to outweigh the potential benefits.
8. In publication of the results of his or her research, the doctor is obliged to preserve the accuracy of the results. Reports of experimentation not in accordance with the principles laid down in this Declaration should not be accepted for publication.
9. In any research on human beings, each potential subject must be adequately informed of the aims, methods, anticipated benefits and potential hazards of the study and the discomfort it may entail. He or she should be informed that he or she is at liberty to abstain from participation in the study and that he or she is free to withdraw his or her consent to participation at any time. The doctor should then obtain the subject's freely given informed consent, preferably in writing.
10. When obtaining informed consent for the research project the doctor should be particularly cautious if the subject is in a dependent relationship to him or her or may consent under duress. In that case informed consent should be obtained by a doctor who is not engaged in the investigation and who is completely independent of this official relationship.
11. In cases of legal incompetence, informed consent should be obtained from the legal guardian in accordance with national legislation. Where physical or mental incapacity makes it impossible to obtain informed consent, or when the subject is a minor, permission from the responsible relative replaces that of the subject in accordance with the national legislation.
12. The research protocol should always contain a statement of ethical consideration involved and should indicate that the principles enunciated in the present Declaration are complied with.

II Medical research combined with professional care (clinical research)

1. In the treatment of the sick person, the doctor must be free to use a new diagnostic and therapeutic measure, if in his or her judgement it offers the hope of saving life, re-establishing health or alleviating suffering.
2. The potential benefits, hazards and discomfort of a new method should be weighed against the advantages of the best current diagnostic and therapeutic methods.
3. In any medical study, every patient – including those of a control group, if any – should be assured of the best proven diagnostic and therapeutic method.
4. The refusal of the patient to participate in a study must never interfere with the doctor–patient relationship.

5. If the doctor considers it essential not to obtain informed consent, the specific reasons for this proposal should be stated in the experimental protocol for transmission to the independent committee.
6. The doctor can combine medical research with professional care, the objective being the acquisition of new medical knowledge, only to the extent that medical research is justified by its potential diagnostic or therapeutic value for the patient.

III Non-therapeutic biomedical research involving human subjects (non-clinical biomedical research)

1. In the purely scientific application of medical research carried out on a human being, it is the duty of the doctor to remain the protector of the life and health of that person on whom biomedical research is carried out.
2. The subjects should be volunteers – either healthy persons or patients for whom the experimental design is not related to the patient's illness.
3. The investigator or the investigating team should discontinue the research if in his/her or their judgement it may, if continued, be harmful to the individual.

In research on man, the interest of science and society should never take precedence over considerations related to the well-being of the subject. (World Medical Association, 1975)

From this point forward, the Declaration of Helsinki underwent recurrent study, debate, and revision. These revisions often responded to controversies in the research community about such issues as the level of care appropriate for patients in a control group, especially in developing world. Some studies had used placebo controls in developing world studies, even though known effective treatments were available. In its fourth revision, the Declaration of Helsinki (WMA, 1996) prohibited this practice on the grounds that there should be no double standards in human subjects research: all research subjects should be treated alike, irrespective of whether they happened to live in the developed or the developing world. In the sedately bureaucratic prose of the Declaration, this statement on global justice reads as follows: "II.3 In any medical study, every patient – including those of a control group, if any – should be assured of the best proven diagnostic and therapeutic method. This does not exclude the use of inert placebo in studies where no proven diagnostic or therapeutic method exists." Researchers from the developed countries would later challenge this provision on the grounds that it limits the use of placebos in experiments designed to develop inexpensive alternatives to proven vaccines and therapies, of the sort that would fit the limited health-care budgets of developing world countries and nongovernmental organizations (NGOs).

Later versions of the Declaration of Helsinki shed the earlier rhetoric of recommendation, declaring the Declaration (Sec. A.1) "a statement of ethical principles to provide guidance to physicians and other participants in medical research involving

human subjects" (WMA, 2000). More substantively, Sec. II.3 (WMA, 2000) reiterates that "in any medical study, every patient – including those of a control group, if any – should be assured of the best proven diagnostic and therapeutic method." Since this provision seems to rule out experiments to establish less expensive means of addressing the HIV/AIDS epidemic, it became a subject of considerable debate. In response, the WMA reluctantly amended its position with the following addendum in 2001 that some researchers have interpreted as permitting such experiments:

> . . .a placebo-controlled trial may be ethically acceptable, even if proven therapy is available, under the following circumstances:
> 13 Where for compelling and scientifically sound methodological reasons it is necessary to determine the efficacy or safety of a prophylactic, diagnostic or therapeutic method
> . . .. All other provisions of the Declaration of Helsinki must be adhered to, especially the need for appropriate ethical and scientific review.
> (WMA, 2001)

The most recent reversion of the Declaration of Helsinki (WMA, 2008) expands the scope of the Declaration by welcoming researchers other than physicians to abide by its provisions. It also expands protections for disadvantaged or vulnerable communities stating that such research is justified in such communities only if "there is a reasonable likelihood that this community or population stands to benefit from the results of the research" (WMA, 2008, Sec. 17). Finally, it requires clinical trials to be registered in a publicly accessible database before recruitment of their first subject, and it further stipulates that research protocols address the issue of post-study benefits to participants and state provisions for participants' access to information about the results of a study.

CIOMS Guidelines

In a curious way, the second international organization issuing a global bioethical declaration about research ethics owes its origins to attempts to standardize death certificates. Jacques Bertillon (1851–1922), chief of Statistical Services of the City of Paris, convened the first International Classification of Causes of Death in 1893. A series of international conferences on standardizing international diagnostic standards followed, and in the 1920s, the League of Nations became the official convener of such conferences. In 1948, in the aftermath of World War II, the United Nations accepted this responsibility assigning this task to the newly founded WHO. The WHO, in turn, collaborated with UNESCO to established CIOMS in 1949, charging the new council with the responsibility of updating, revising, and publishing the International Classification of Diseases (ICD). It has done this on a regular basis ever since; the latest version is ICD-10.

In the 1970s, as newly independent nations in the developing world began to cope with issuing standards for ethically permissible research on their citizens, WHO tasked CIOMS with preparing guidelines that would interpret the

1975 version of the Declaration of Helsinki for special circumstances in the developing world. CIOMS' *Proposed International Ethical Guidelines for Biomedical Research Involving Human Subjects* was published in 1982. As it turned out, CIOMS not only had a mandate to view research ethics from a developing world perspective, but since it had always been an organization of public health officials, scientists, and statisticians, as well physicians, it brought a new perspective to issues in research ethics. Its membership included scientists specializing in public health and infectious disease (microbiologists, virologists) who belonged to societies whose moral traditions differed from those of physicians and who respected the moral authority of the UN and the WHO even though they were indifferent to the physician-oriented ethics of the Declaration of Geneva. CIOMS ethical guidelines are thus distinctive not only because of their mandated focus on the developing world but because they emanate from the perspective of biomedical and public health researchers who address ethical issues in epidemiological and genetic research beyond the scope of research normally conducted by physicians. Thus, in addition to its guidelines on human subjects research, CIOMS has also issued *International Guidelines for Biomedical Research Involving Animals* (CIOMS, 1985); *The Declaration of Inuyama: Human Genome Mapping, Genetic Screening and Gene Therapy* (CIOMS, 1990); and *International Guidelines for the Ethical Review of Epidemiological Studies* (CIOMS, 1991).

CIOMS first guidelines on human subjects research (CIOMS, 1982) were almost immediately obsolesced by the challenges of the worldwide HIV/AIDS epidemic (recognized in the same year, although it probably originated decades earlier). CIOMS (1993) published new guidelines focused on the developing world and the challenge of discovering new inexpensive ways of preventing and treating HIV/AIDS (CIOMS, 1993). These have since been superseded by guidelines issued in 2002 and 2009 (CIOMS, 2002, 2009). Because CIOMS research ethics guidelines originated as a commentary on the Declaration of Helsinki, over time, the commentaries evolved into a separate and in many ways distinctive document. Below is a summary of the topics dealt with in the CIOMS 2002 and 2009 guidelines and a sample of CIOMS commentary illustrating the application of abstract philosophical reflections on social justice to practical contexts in a way distinctively characteristic of the research ethics guidance offered by CIOMS.

SUMMARY OF TOPICS: CIOMS 2002, 2009: INTERNATIONAL ETHICAL GUIDELINES FOR BIOMEDICAL RESEARCH INVOLVING HUMAN SUBJECTS (Adopted from CIOMS 2009 and Macrae 2007)

THE GUIDELINES

1. Ethical justification and scientific validity of biomedical research involvinghuman subjects

Ethical Review

2. Research ethics review committees (IRBs, REBs, RECs)
3. Ethical review of externally sponsored research

Informed Consent

4. Individual informed consent

5. Obtaining informed consent: essential information for prospective research subjects

6. Obtaining informed consent: obligations of sponsors and investigators

7. Inducement to participate

8. Benefits and risks of study participation

9. Special limitations on risk when research involves individuals who are not capable of giving informed consent.

Developing World Research and Choice of Controls

10. Research in populations and communities with limited resources

11. Choice of controls in clinical trials

Vulnerable Persons and Groups

12. Equitable distribution of burdens and benefits in the selection of groups of research subjects

13. Research involving vulnerable persons

14. Research involving children

15. Research involving individuals who by reason of mental or behavioral disordersare not capable of giving adequately informed consent

Women and Pregnant Women as Research Subjects

16. Women as research subjects

17. Pregnant women as research participants

Systemic Issues

18. Safeguarding confidentiality

19. Right of injured subjects to treatment and compensation

20. Strengthening capacity for ethical and scientific review and biomedical research

21. Ethical obligation of external sponsors to provide health care services

APPENDICES

Appendix 1. Items to be included in a protocol for biomedical research on human subjects

Appendix 2. The Declaration of Helsinki

Appendix 3. The phases of clinical trials of vaccines and drugs

The point to appreciate in reviewing the following sample commentary is that in striking contrast to the oaths and codes reproduced earlier, this commentary has the character of a philosophical treatise. Its style and construction, while not unprecedented, are nonetheless unusual in the arena of human subjects research regulation. This sample is offered to illustrate, for those unacquainted with CIOMS' statements on research ethics, how the organization develops its guidelines. The first paragraph opens with a characterization of "justice," a subject that has preoccupied philosophers at least since the publication of Plato's *Republic*. This characterization is then used to justify a series of principles of research ethics as they apply to the

developing world: such as the principle that a research project should leave a low-resource country "better off or. . .no worse off" than it was previously." In the next paragraph, this precept is invoked to justify the principle of "least vulnerability" of subjects chosen. In a later section, "Application," principles are specified in ways that single out some forms of research conducted in the developing world as "exploitive." A careful reader of CIOMS commentaries can thus follow the development of a guideline from an abstract moral concept, to a general principle, to a specific guideline, to the specification of which sorts of research conducted in the developing world are condemnable as "unethical."

Sample Commentary

(Preface CIOMS 2009, 17, 18)

Justice refers to the ethical obligation to treat each person in accordance with what is morally right and proper, to give each person what is due to him or her. In the ethics of research involving human subjects the principle refers primarily to distributive justice, which requires the equitable distribution of both the burdens and the benefits of participation in research. . ..

In general, the research project should leave low-resource countries or communities better off than previously or, at least, no worse off. It should be responsive to their health needs and priorities in that any product developed is made reasonably available to them, and as far as possible leave the population in a better position to obtain effective health care and protect its own health.

Justice requires also that the research be responsive to the health conditions or needs of vulnerable subjects. The subjects selected should be the least vulnerable necessary to accomplish the purposes of the research. Risk to vulnerable subjects is most easily justified when it arises from interventions or procedures that hold out for them the prospect of direct health-related benefit. Risk that does not hold out such prospect must be justified by the anticipated benefit to the population of which the individual research subject is representative.

APPLICATION OF REFLECTIONS ON SOCIAL JUSTICE GUIDELINE 10

(CIOMS 2009, 51–52)

This guideline is concerned with countries or communities in which resources are limited to the extent that they are, or may be, vulnerable to exploitation by sponsors and investigators from the relatively wealthy countries and communities.

Responsiveness of research to health needs and priorities. The ethical requirement that research be responsive to the health needs of the population or community in which it is carried out calls for decisions on what is needed to fulfill the requirement. It is not sufficient simply to determine that a disease

is prevalent in the population and that new or further research is needed: the ethical requirement of "responsiveness" can be fulfilled only if successful interventions or other kinds of health benefit are made available to the population. This is applicable especially to research conducted in countries where governments lack the resources to make such products or benefits widely available. Even when a product to be tested in a particular country is much cheaper than the standard treatment in some other countries, the government or individuals in that country may still be unable to afford it. If the knowledge gained from the research in such a country is used primarily for the benefit of populations that can afford the tested product, the research may rightly be characterized as exploitative and, therefore, unethical.

UNESCO's Universal Declaration on Bioethics and Human Rights (UDBHR)

In 2005 UNESCO issued an eight-page document, the *Universal Declaration on Bioethics and Human Rights*, consisting of a preamble—asserting its provenance and heritage—followed by 28 articles, divided into five sections. The section entitled Principles lays out the core of the document: 15 articles (Articles 3–17, which are reproduced below) designed to guide member nation states of the UN, international organizations, corporations, non-governmental organizations and UNESCO itself with respect to bioethical issues. The first of these principles, Human Dignity and Human Rights, states a fundamental premise of human rights theory: "(a) Human dignity, human rights and fundamental freedoms are to be fully respected. (b) The interests and welfare of the individual should have priority over the sole interest of science or society" (UNESCO, 2005, Article 3). The Declaration closes in the same vein, reasserting the preeminence of human rights, fundamental freedoms and human dignity over all other principles (UNESCO, 2005, Article 28).

The UDBHR, the most recent addition to global bioethics, consolidates six decades of progress into a single, all encompassing statement of global bioethics, grounding them in a fundamental moral concept: human rights. Thus unlike earlier statements of global bioethics that addressed only physicians, or healthcare researchers, and which confined themselves to narrow topics (research on humans, research on animals, research on the human genome, physicians treatment of hunger strikers, the rights of patients etc.) this is a broad foundational statement of bioethics generally, that lays the foundation for addressing these issues as well as the conduct of nation states and the nature of transnational agreements, emphasizing the importance of transparency and open discussion and respect for cultural diversity and human rights.

UNESCO – Universal Declaration on Bioethics and Human Rights—2005

Article 3 – Human dignity and human rights

1. Human dignity, human rights and fundamental freedoms are to be fully respected.
2. The interests and welfare of the individual should have priority over the sole interest of science or society.

Article 4 – Benefit and harm

In applying and advancing scientific knowledge, medical practice and associated technologies, direct and indirect benefits to patients, research participants and other affected individuals should be maximized and any possible harm to such individuals should be minimized.

Article 5 – Autonomy and individual responsibility

The autonomy of persons to make decisions, while taking responsibility for those decisions and respecting the autonomy of others, is to be respected. For persons who are not capable of exercising autonomy, special measures are to be taken to protect their rights and interests.

Article 6 – Consent

1. Any preventive, diagnostic and therapeutic medical intervention is only to be carried out with the prior, free and informed consent of the person concerned, based on adequate information. The consent should, where appropriate, be express and may be withdrawn by the person concerned at any time and for any reason without disadvantage or prejudice.
2. Scientific research should only be carried out with the prior, free, express and informed consent of the person concerned. The information should be adequate, provided in a comprehensible form and should include modalities for withdrawal of consent. Consent may be withdrawn by the person concerned at any time and for any reason without any disadvantage or prejudice. Exceptions to this principle should be made only in accordance with ethical and legal standards adopted by States, consistent with the principles and provisions set out in this Declaration, in particular in Article 27, and international human rights law.
3. In appropriate cases of research carried out on a group of persons or a community, additional agreement of the legal representatives of the group or community concerned may be sought. In no case should a collective community agreement or the consent of a community leader or other authority substitute for an individual's informed consent.

Article 7 – Persons without the capacity to consent

In accordance with domestic law, special protection is to be given to persons who do not have the capacity to consent:

(a) Authorization for research and medical practice should be obtained in accordance with the best interest of the person concerned and in accordance with domestic law. However, the person concerned should be

involved to the greatest extent possible in the decision-making process of consent, as well as that of withdrawing consent;

(b) Research should only be carried out for his or her direct health benefit, subject to the authorization and the protective conditions prescribed by law, and if there is no research alternative of comparable effectiveness with research participants able to consent. Research which does not have potential direct health benefit should only be undertaken by way of exception, with the utmost restraint, exposing the person only to a minimal risk and minimal burden and, if the research is expected to contribute to the health benefit of other persons in the same category, subject to the conditions prescribed by law and compatible with the protection of the individual's human rights. Refusal of such persons to take part in research should be respected.

Article 8 – Respect for human vulnerability and personal integrity

In applying and advancing scientific knowledge, medical practice and associated technologies, human vulnerability should be taken into account. Individuals and groups of special vulnerability should be protected and the personal integrity of such individuals respected.

Article 9 – Privacy and confidentiality

The privacy of the persons concerned and the confidentiality of their personal information should be respected. To the greatest extent possible, such information should not be used or disclosed for purposes other than those for which it was collected or consented to, consistent with international law, in particular international human rights law.

Article 10 – Equality, justice and equity

The fundamental equality of all human beings in dignity and rights is to be respected so that they are treated justly and equitably.

Article 11 – Non-discrimination and non-stigmatization

No individual or group should be discriminated against or stigmatized on any grounds, in violation of human dignity, human rights and fundamental freedoms.

Article 12 – Respect for cultural diversity and pluralism

The importance of cultural diversity and pluralism should be given due regard. However, such considerations are not to be invoked to infringe upon human dignity, human rights and fundamental freedoms, nor upon the principles set out in this Declaration, nor to limit their scope.

Article 13 – Solidarity and cooperation

Solidarity among human beings and international cooperation towards that end are to be encouraged.

Article 14 – Social responsibility and health

1. The promotion of health and social development for their people is a central purpose of governments that all sectors of society share.
2. Taking into account that the enjoyment of the highest attainable standard of health is one of the fundamental rights of every human being without

distinction of race, religion, political belief, economic or social condition, progress in science and technology should advance:

(a) Access to quality health care and essential medicines, especially for the health of women and children, because health is essential to life itself and must be considered to be a social and human good;
(b) Access to adequate nutrition and water;
(c) Improvement of living conditions and the environment;
(d) Elimination of the marginalization and the exclusion of persons on the basis of any grounds;
(e) Reduction of poverty and illiteracy.

Article 15 – Sharing of benefits

1. Benefits resulting from any scientific research and its applications should be shared with society as a whole and within the international community, in particular with developing countries. In giving effect to this principle, benefits may take any of the following forms:
   (a) Special and sustainable assistance to, and acknowledgement of, the persons and groups that have taken part in the research;
   (b) Access to quality health care;
   (c) Provision of new diagnostic and therapeutic modalities or products stemming from research;
   (d) Support for health services;
   (e) Access to scientific and technological knowledge;
   (f) Capacity-building facilities for research purposes;
   (g) Other forms of benefit consistent with the principles set out in this Declaration.
2. Benefits should not constitute improper inducements to participate in research.

Article 16 – Protecting future generations

The impact of life sciences on future generations, including on their genetic constitution, should be given due regard.

Article 17 – Protection of the environment, the biosphere and biodiversity

Due regard is to be given to the interconnection between human beings and other forms of life, to the importance of appropriate access and utilization of biological and genetic resources, to respect for traditional knowledge and to the role of human beings in the protection of the environment, the biosphere and biodiversity.

(UNESCO 2005).

Conclusion

The global bioethics codes, declarations, and oaths discussed in this chapter were issued by a new order of international organizations dedicated to facilitating

interstate collaboration in the aftermath of the Second World War. They have not been rigid statements carved in stone. They have been open to revision in response to changing ethical conceptions or changing circumstances. They all strive to facilitate the development of the biomedical and health-care science and medical practices for the benefit of humanity – without ever forgetting the ways in which biomedicine was at one time horribly abused.

Commodification of Human Tissue

34

Herjeet Marway, Sarah-Louise Johnson, and Heather Widdows

Introduction

Commodification is an important topic in ethics generally and in bioethics in particular. In ethics, it is prominent in debates about the self, prostitution, slavery, and labor conditions and practices in the global market (such as child labor and sweatshops). In bioethics, it is salient in the discourse on the sale of body parts, surrogacy, and genetic therapy and enhancement. In short, since commodification deals with the possible (it need not be actual, as will be discussed below) transformation of "people" into "commodities," it is relevant to all issues that threaten to encroach upon the boundaries of personhood, and in particular to those where there is a risk that the body or relationships will fall prey to such treatment. The concerns of commodification also relate to several of the provisions in the Universal Declaration on Bioethics and Human Rights, most notably on equality (Art. 10), human vulnerability (Art. 8), autonomy (Art. 5), and consent (Art. 6). The debate, for instance, is firmly rooted in the need to safeguard the bodily dignity and integrity of persons – particularly of the most vulnerable – by treating them justly and equitably. In addition, it highlights how, though autonomy and informed consent are central in bioethics, some conceptions fail to provide adequate protections for individuals, and justice requires extra precautions be put in place. Thus, commodification is a far-reaching and pressing issue in global ethics and bioethics.

These discussions, however, have been fraught with disagreement with regard to what constitutes commodification, whether commodification occurs, and (if it does) whether it is ethically significant. In order to clarify these questions, this chapter will focus exclusively on commodification in bioethics, and in particular in the sale of body parts, though the discussion parallels the contours of the wider commodification debate.

To do this, the chapter will first explore what constitutes commodification; second show, using examples of kidney, reproductive tissue, and reproductive organ sale or "rental," that there is evidence of commodification in bioethics; and third argue that a market in these areas is ethically impermissible, because it leads to exploitation, because some things should not be for sale, and because commodification is destructive of social goods. Thus, this chapter defines commodification, highlights instances of commodification that are symptomatic of a wider trend, and concludes that commodificatory practices should be resisted.

What is Commodification?

The first section will provide a working definition of commodification. Although there are slight differences in the way the term is used in bioethical debates, this chapter regards two interconnected elements as central to any concept of "commodification": First that it transforms "persons" into "things"; and second that it changes "relationships" into "contracts." These will be considered in turn.

The first aspect of commodification is that it turns "persons" into "things." Instead of taking human beings to be ends in themselves that ought to be respected as such (a broadly Kantian position), it takes persons and their parts to be objects and commercializes them – or, as Marx puts it, it attributes a "use" and "exchange" value to them. To elaborate, a "use value" typically relates to the physical properties of an external object, whereas an "exchange value" is an expression of the worth of that object if it were traded (Marx, 1875). A commodity (or to commoditize) requires both use and exchange value, whereas an object (or to objectify) only needs use value. However, the Marxist categories do not map directly to how the term is employed in bioethics, where a commodity need not always pertain to a fully tradable *product* (such as diamonds or wheat), but rather can refer to objectifying and commercializing *processes* (as discussions on commodifying children using sex-selective technology have shown – Widdows, 2009). Thus, in this discipline, use and exchange value (separately and/or together) are regarded as indicative of moves toward commodification in some form. Drawing this all together, to commodify is to take something of intrinsic worth (such as "persons") and to objectify it by giving it a use value (so it has – or is subjected to processes that liken it to – the status of "things") and to commercialize it by giving it an exchange value, or by implying that it *could* be sold, (further degrading it to the level of tradable "things"). Thus, individuals and their parts become thought of not as "persons" but as "things."

The second feature of commodification is that it reduces bonds with other human beings to formal covenants; it moves "relationships" into the territory of "contracts," in a parallel way to which "persons" become "things" and are for sale relationships between people enter the market place. A view in which relationships are for sale runs counter to most philosophical accounts of persons, and most especially to those where individuals are intrinsically social beings, embedded in complex relations with others, as philosophers such as Aristotle (2004), Taylor (1992), and Sandel (1998) have argued. In the market, however, according to Marx (1844), workers are alienated (to maximize profits), not just from their labor, and its products, but from others, such that the market converts relationships between men to relationships between property owners. Taking this as a whole, to commodify, is to de-emphasize that individuals are, constitutively, relational beings and have interdependent ties to others and particular needs and wants, and instead is to shift toward seeing the connections between individuals as interchangeable, established and disestablished as the market requires, and valued only in extrinsic monetary terms. That is "relationships" between individuals become mere services for "contracts."

Importantly, for both elements of commodification, it need not be the case that these kinds of trades are *in fact* happening to qualify as commodificatory. What matters is *how* persons and relationships are regarded; if they are treated (through language or conception, for instance) as being objects where trade could legitimately occur, then commodification has occurred. That is, moving from "persons" to "things" and "relationships" to "contracts," "includes *not only actual buying and selling, but also market rhetoric, the practice of thinking about interactions as if they were sale transactions*" (Radin, 1987, 1859, original emphasis). Though one may not partake in buying and selling of body parts or services, for instance, engaging in the view that they could be bought and sold is itself to endorse a commodificatory shift; it is to treat something which is not a "thing" or subjectable to "contract" *as if* it were. Thus, it is not only the act but the "social practice for treating things as commodities, i.e. as properties that can be bought, sold, or rented" (Resnik, 1998, p. 388) which amounts to commodification.

This section sought to provide a working definition of commodification. It has stated that commodification is the (actual or implied) transformation of: first "persons" into "things," and second "relationships" into "contracts."

Is Commodification Evident in Bioethics?

The second section of the chapter uses this definition to explore the extent to which commodificatory practice is apparent in bioethics, paying particular attention to kidney and reproductive tissue and organ sale or rental as indicative of a general trend in this field. It does this in two subsections: First it sets out key developments in organ and reproductive technologies, and second it considers whether or not commodification is occurring in these areas by examining whether "people" are

becoming "things" and whether "relationships" are becoming "contracts." It argues that commodification is occurring in these instances, and by extension in bioethics, since new technologies encourage parts of human beings to be seen as objects, which are – or are spoken of *as if* they are – "for sale," and thus that this makes it more likely that relationships are regarded as similar to commercial transactions rather than complex human connections between people.

Advances in Kidney and Reproductive Technologies

First, this subsection briefly describes the technological and medical developments relating first to kidneys and then to reproduction. Starting with kidneys, successes in transplant technology and anti-rejection drugs have, most obviously, led to the possibility of kidney transplants and a prolonged and better quality of life, free from cumbersome dialysis. Many individuals with end-stage renal disease have benefitted from these advances. In 2010, for instance, at least 73,180 kidney transplants were performed in 95 countries across the world, with the USA, Norway, and France among those carrying out the most transplants per million of the population (Global Observatory on Donation and Transplantation [GODT], 2010a), and the USA, China, and India the top three in absolute terms (16,898; 5,540; 5,000 transplants, respectively) (GODT, 2010b). These developments have, therefore, helped numerous people. However, currently, demand for kidneys still outstrips supply in almost every country of the world; in the UK, in 2010, 6,871 (UK Transplant Support Service Authority, 2011), in the USA, in 2012, 92,749 (Organ Procurement and Transplant Network, 2012), and "globally, at least 200,000 people are on waiting lists for kidneys and many more have no access to transplantation or dialysis services" (Garwood, 2007). Undoubtedly then, there is an unmet desire for kidneys worldwide. Nonetheless, the breakthroughs in this area have led to the chance for successful transplants, with many lives extended and improved.

There has been similarly marked progress in reproductive technologies and the potentials they offer. Advances in in vitro fertilization (IVF) in particular have meant that eggs can now be fertilized externally and then implanted in a uterus for gestation. Individuals have taken advantage of these procedures. By 2009, for instance, 170,000 babies were born using IVF treatment, which accounted for around 2 % of all babies in the UK (HFEA, 2010), and between 1978 and 2010, approximately 3.75 million babies had been born through assisted reproduction methods worldwide (European Society of Human Reproduction and Embryology, 2010). Such technologies have enabled additional possibilities; for instance, while during pre-IVF, only traditional surrogacy (using the surrogate's egg) was achievable, post-IVF, gestational surrogacy (categorically not using the surrogate's egg) became realizable. Again, this has led to an uptake in gestational surrogacy globally; the Permanent Bureau of the Hague Conference on Private International Law's (PBHCPIL) *Preliminary Report* (2012), for instance, states that international arrangements are growing at a "rapid pace" (PBHCPIL, 2012, p. 5) and that across a sample of five agencies between 2006 and 2010, there was an "increase of nearly

1,000 %" (PBHCPIL, 2012, 8, original emphasis) in such agreements. Such technologies have made new procedures in reproduction viable and they are increasingly being used.

Along with these new technologies and procedures have come ever more sophisticated notions of what is possible and desirable, as well as greater expectations of entitlement: for instance, there are now assumptions with regard to both having children when infertile and with regard to the type of children one might have (Widdows, 2009); and, similarly, the fact that kidneys can be transplanted leads to the belief that individuals are entitled to these organs. Such expectations are understandable from the individual's perspective; a kidney transplant is life altering – it can provide some 50 % of the function of two healthy kidneys, compared with just 5 % by dialysis (UK National Kidney Federation, 2011) – and having a child is an urge felt by many. However, meeting the expectations of individuals is not the only factor to bear in mind; other pressing ethical issues, such as commodification, must also be considered.

Commodification Relating to Kidneys and Reproduction

This subsection will explore the claims of commodification, paying attention to examples of kidney and reproductive tissue and organ sale and rental (and it is trading in, rather than donating, body parts that commodification arguments typically object to – see Dickenson, 2007). It discusses both elements of the working definition above – first whether "persons" are made into "things," and second whether there is a move from "relationships" to "contracts" – and argues that there is indeed a commodifying trend in both these areas, and by extension in bioethics.

"Persons" to "Things"

First, then, the transition from "persons" to "things" will be explored. As discussed, two elements are identified in the commodification process – how far persons are becoming: first objects (objectified); and second for sale (commercialized). It is important to remember, as noted above, that these are connected and bioethicists are often concerned not with whether sale *actually* occurs or (to use Marxist language) with whether there is an exchange value (though often it does and there is – as will be discussed), but with when the language of the market enters the debate and persons (and their parts) come to be regarded *as if* they could be sold. With this in mind, this section will consider the extent to which "persons" are assuming the form of "things."

New technologies have permitted parts of the body to become thought of as distinct from the person from whom they come in a way that was not feasible before. Kidneys, for instance, can be removed from one body and reissued to another, and likewise, gametes can be extracted from one person, manipulated using artificial fertilization methods, and implanted in the womb of a third party in order to create a child. Only because it is possible to separate these parts from

people is it possible to consider them as "objects" and "objects of potential trade" at all. Objectification is beginning to occur then with this ability to "detach" parts and see them as disembodied.

On this characterization, objectification happens – or arguably happens – in donation as well as sale. However, in donation, even though "parts" are removed from persons, commodification does not occur because such parts are not thought of as being saleable. Moreover, because of the nature of donation, donating contradicts the assumptions of the market model and may, in fact, be something that reduces commodification (a point to which this chapter will return in the discussion on social goods). By contrast, in sale, commodification is evident in the practices of trade and in the market rhetoric that surrounds it. The discussion on body parts, for instance, is suffused with the language of the market: It *assumes* that one's (or another's) body and its parts are saleable. An Indian woman, for example, reported that she wished she had, "a third kidney, [so she had] *two* to sell" (Scheper-Hughes, 2002, p. 3), and surrogates are described as having a "womb for rent" (Armour, 2012, p. 231) with one seeing herself as ". . .strictly the hotel" (Ragone's study in Van Zyl & Van Nierkerk, 2000, p. 405) in the arrangement. These examples show both objectification and commercialization (together clearly commodification) happening, as terms such as "hotel" and the wish of having more to sell are undoubtedly market rhetoric. Thus, transplant and reproductive technology have enabled new procedures and also made it much easier for parts – kidneys and wombs (which of course cannot be "detached" from the person) – of "persons" to be conceptualized as tradable objects, as "things."

Commodification is even more conspicuous in instances where markets – which trade "things" – have been formalized or are practiced, since kidneys and the reproductive parts or services that are exchanged become, by definition, commodities with a price. For instance, in Iran, kidney sale is legal with "compensation" fixed at 10 million Rials (USD $1,090) (Bagheri, 2006), and in other jurisdictions, including some US states, the Ukraine, and India, there are open markets in reproductive parts – in the USA, for example, some agencies buy eggs for $7,000, with this fee increasing by $500 for each sale (up to six times) (Family Creations, 2008) and others literally offer male college students an on-campus mobile vehicle in which to ejaculate and sell their sperm (Sperm Mobile, 2007). In addition to such obvious markets, there are many unofficial "black" and flouting "gray" markets. For instance, despite exact figures being difficult to come by and varying, reports suggest that, on average, kidneys can fetch up to $5,000 on the "black" market, though this stoops to as low as $650 in some countries, like Kenya (Havoscope, 2012); and, to bypass laws, some infertility clinics in the Mediterranean offer "all expenses paid holidays" that also provide opportunities for egg-selling under the guise of "donation" (Cyprus IVF, 2007) on the "gray" market. Here, as in all markets and practices of sale, body parts are commodities, "things" sold at a "price." Where there are markets then, there is overt evidence of the objectification and commodification of human tissue and organs.

Thus, commodification occurs to some degree both when body parts are treated *as if* they could be traded and by *literally* trading them on a legal or illegal market.

Where body parts and the use of bodies are objectified and commercialized, "persons" are moving toward being "things"; they are deemed commodities – as simply objects to buy and sell.

"Relationships" to "Contracts"

The second element of the definition of commodification to apply to the sale of body parts is whether "relationships" are being transformed into services for "contracts." There are two aspects to consider – the extent to which relationships are becoming: first artificially fragmented, and second saleable. As with "persons" to "things" above, evidence of commodification in relationships is not limited to the existence of actual markets but extends to regarding them as though they were tradable. The possible shift from "relationships" toward "contracts" will be discussed in this light.

Developments in technology and seeing "persons" as "things" have begun to alter the form and structure of relationships. For instance, reproductive technologies and various types of surrogacy make it possible to create numerous parenting relationships (genetic, gestational, or social), but these are often crudely determined and demarcated through contracts, with the gestational relationship in particular relegated to a specific functional role with a start and finish. One surrogate, for example, reports, "it's like a contract and it severs it completely at the end because it's a job done and you're paid for it and that's the end of it" (Baslington, 2002, p. 64). The language of the market enables gestation to be considered a discrete task. Yet, it is unclear that such intimate relationships – even without a biological tie – could be so easily compartmentalized. Indian surrogate, Sonal, for instance, reports about her first child as a gestational mother, "When they took her away I cried for 3 days. I missed her so much" and of her second pregnancy, "I will feel like I am giving my child to someone else" (BBC News, 2011). Despite such feelings, and her pleas to help look after the child, the nature of the contract meant that she was expected to relinquish all bonds, and, Carolina, the Irish intended "mother," was adamant that a relationship between Sonal and her child should not be maintained: "I will always be eternally grateful to Sonal for what she has done, but I felt there has to be a cut off point" (Baslington, 2002, p. 64). The connections between the surrogate and child, which would normally continue, are artificially severed in surrogacy contracts of this kind, and it is treated as a finite nine-month "job," rather than an interaction of a different order, one which involves human relationships and feelings. Some surrogates may be different to Sonal and express a preference not to maintain ties with the child, though this in itself is not an argument for labeling surrogacy as mere paid work (and, if fact, studies indicate that mechanisms, such as "support" strategies and payment, are important in discouraging an attachment to the child – Baslington, 2002; Ragoné, 1994). Either way, the "boxing-up" of "relationships" in this manner is to start thinking of individuals as resources and as providers of "contractual" pregnancy services rather than bearers of "relationships." It is to treat parenting and the ties with the children involved as if they were not "relational," but "fixed term contracts," equivalent to other work.

In a different, but somewhat parallel, way, current "relationships" of kidney donor and recipient are being transformed too. The combination of medical advances, desires for prolonged lives, and the "person" to "thing" shift generates a want for kidneys which, when compounded by market rhetoric, makes it possible to regard acquiring a kidney as a service. For example, one Israeli man preferred to pay for a live kidney from a peasant in Georgia rather than wait for one, claiming, "I chose a better way. I was able to see my donor. . .He was young, strong, healthy. Just what I was hoping for" (Scheper-Hughes, 2002, p. 52). Having the option to buy is reflected in the language here, which is like that of a purchaser inspecting a prospective kidney provider rather than that of a receiver of a gift from another human being. At the same time, potential vendors are encouraged to sell, but left to face the consequences once the onerous operation is over (Aman, 2009; Zheng, 2011). In sale rhetoric, once the service is fulfilled and payment made, all relations are terminated, but this disregards the particular human responses that envelop this arduous procedure and treat it like any other "service." In these examples, whether a buyer or seller, the physically and psychologically demanding process of getting a kidney is reduced to an isolated act in the framework of sale, and the language of the market facilitates this by making the complex relationship of gift a delimited transactional affair. Thus, through the language of the market, the act of selling a kidney is artificially enclosed, separated from the person, and thought of as being sellable as a service in that distinct form to another. This makes it easier to begin to think of persons not as relational beings but as kidney sources, and with it comes a shift from "relationship" to a model that implies services for "contract."

This move is more apparent in practices of sale where "services" are formally priced, as they are for both commercial surrogacy and kidney sale. Where gestational surrogacy is legal, for example, costs to the intended parents to cover the entire arrangement (including fertilization, surrogate's fees and costs, legal and agency fees) can range from $70,000–150,000 in the USA (Ellis, 2012; Campbell, 2010) to $12,000–35,000 in India (Delhi IVF, 2012; Medical Tourism Corporation, 2012). That these elements, and in particular the surrogate's "job," have a formal cost associated (usually a fraction of the overall amount) is unambiguous evidence of seeing her as providing a service. Similarly, since kidneys on "black" and "gray" markets have a price attached – buyers can pay, on average, $150,000 and up to $250,000 (Havoscope, 2012), though again brokers, middlemen, gangs, and doctors receive the lion's share of the fee (Smith et al., 2011) – this indicates the exchange is a formal "contractual" service. Financial compensation at these rates moves away from thinking of the seller as giving an invaluable gift (of life) to providing a purchasable (kidney or child creation) service. Thus, the relationship of donor/recipient is changing into that of buyer/service provider by being allocated a formal monetary value and by being brought into the contractual model. "Relationships" are becoming "contracts."

This section has considered whether, and the extent to which, commodification is occurring in bioethics using the examples of kidney and reproductive tissue and organ sale or rental. There are indeed grounds for claiming that "persons" are being turned to "things" when body parts are being objectified and then turned into

objects for sale, either by being bought and sold in the market or by being treated *as if* these body parts and services become commodities. Likewise "relationships" become "contracts" in similar conditions; kidney sale and gestational surrogacy contracts diminish the relationship of "givers" of "gifts of life" to those of "sellers" of a "product" or "providers" of a "service." In presenting such interactions as transactions in the market, the complexity inherent in these human relationships is reduced. These products and services are presented as *mere* commodities – exchangeable with other products and services or with money – and assumed to be equivalent in nature. Thus, rather than seeing persons fundamentally as human beings with whom others have relationships, including ties of gift-giving, friendship, and love, with *an intrinsic value*, in the extremes of the market model "bodies of persons are regarded as resources" (Chadwick, 1989, p. 137) and nothing more (instrumental value). Therefore, there is evidence of commodification in the two senses defined earlier – turning "people" into "things" and "relationships" into "contracts" – in the sale or rental of human tissue and organs, so claims that there are commodifying practices present in bioethics seem to be well founded.

What Is Wrong with Commodification?

The previous section explored how commodification is a common phenomenon in bioethics. Implicit in this discussion was the assumption that commodification is ethically problematic – that people should not be things and that human relationships suffer if they come to resemble the exchanges of the market. However, these claims merit justification, as they are often contested. This section will, therefore, explore and respond to arguments from those who dismiss commodification as an ethical concern and instead advocate a market model. Two grounds for a pro-market approach – first valid consent, and second fair price – will be briefly outlined before the insufficiencies of such views, and the persisting ethical problems of commodification, are exposed.

First then the market model rejects misgivings about commodification in one of two ways. In one set of rebuttals, some contend that sale is unproblematic as long as people have the right to consent. If there is demand and supply, then individuals ought to be able to trade whatever they wish, including body parts and services, since this respects their autonomy. Julian Savulescu, for example, argues, "...to ban a market in organs, paradoxically, is to constrain what people can do with their own lives" (2003, pp. 138–139), and Carmel Shalev takes a similar line for paid surrogacy adding, to disallow enforceable contracts, "implies that women are not competent, by virtue of their biological sex, to act as rational, moral agents." (1989, p. 11) This view asserts that a "market approach plus consent" allows maximal respect for individual choices, and that allowing such choices is ethically important, and certainly more urgent than paternalistic worries that restrict what individuals can and cannot do with their own bodies.

Others also deny that commodification, or the sale of body parts per se, is particularly problematic. They argue that a market is permissible in principle, but

that safeguards must be in place to ensure that such a market is ethical. For instance, Erin and Harris propose that the market be a confined geopolitical area (perhaps, the European Union) in order to alleviate the worst forms of exploitation that comes from inequality. Likewise they suggest single fair price could be ensured by having a single purchaser (like the National Health Service) who would also be responsible for testing organs for disease and verifying their origins before distributing them according to medical need (Erin & Harris, 2003, p. 137). Others argue that ethics requires improvement of the current market conditions. Accordingly, they argue that rather than criminalize transactions in human tissue and organs – a practice already ongoing – it would be much better to properly regulate and to create "fair-trade" (Humbyrd, 2009, p. 116): sale which is safer and more equitable (a familiar argument in ethics, whether for drugs, prostitution, or any illegal practice). The claim is that non-sale models are patently less fair than sale as everyone but the donor benefits in donation, whereas the donor – who takes the biggest risks – is only rightly financially rewarded in the sale (Matas, 2004). On this account, regulation of the present system would be better than disallowing sale altogether and a "market plus fair price" model is one that could be ethical.

However, these pro-market arguments fail to address broader ethical concerns which arise from commodification and which cannot be tackled simply by insisting on consent, by setting a fair price or by seeking a fair-trade: First that of exploitation; second that some things should not be for sale; and third that contractual relationships destroy other social goods. The rest of the chapter will focus on bringing out these key commodificatory harms.

Exploitation

The first commodificatory concern which is not addressed by consent or fair price is that once persons can be considered resources (things or providers of services) – rather than persons deserving of respect in themselves – they are far more open to exploitation. While market proponents might claim that the risk of exploitation can be mitigated and absorbed by competent adults (the consent view) or the possibility reduced by the introduction of an equitable fee (fair price), this underestimates: first the vast global inequalities within and between countries that distort notions of consent and fair price, and second the way market rhetoric and market models make exploitation more likely precisely because they encourage the conception of persons as things and relationships as contracts.

First, exploitation is made likely simply by the fact of inequality, both globally and within societies. Such inequality is feature of the market. The market is not a "neutral" system of exchanging goods or services between free and equal agents, but inherently skewed to favor some more than others. This is so for any market but, as Anne Phillips argues, "more so, and more intrinsically than other markets, markets in bodies rely on inequality" (Phillips, 2011, p. 14). It is more likely, for instance, that those who sell kidneys or rent wombs are poor and buyers affluent, and in a global market, the gap is even greater. As Nancy Scheper-Hughes argues,

"In general, the flow of organs follows the modern routes of capital: from South to North, from Third to First World, from poor to rich, from black to white, from female to male" (Scheper-Hughes, 2000, p. 193). This is a pattern of market biases toward the global rich at the expense of the global poor, and the market in body parts and services is sustained by these disparities (for its supply of buyers and sellers), and the market model ignores this partiality (asserting that trades happen between supposedly free and equal parties).

Within this context, both the fair price and consent arguments begin to look ineffectual. For those who believe consent alone is enough, the fact that the seller has consented, and is not physically shackled or compelled, to engage in the transaction, does not equate to making a "free autonomous choice" in the usual meaning of this term. For someone who is poor, for example, the "choice" often can be "desperate" and so "inherently undesirable, chosen only when the range of possible choices is extremely limited" (Widdows, 2011, p. 89). Agreeing to a desperate choice then does not seem as if it provides the ethical protection that the doctrine of consent is intended to provide. For instance, Fatolaa F, an Iranian kidney-seller, opted to sell, but post-sale states, "like a cigarette end we have been thrown out. We are crushed by poverty and exploited by parasitic mercantile capitalism that press us to sell our only remaining belongings – our kidneys" (Zargooshi, 2001, p. 1791). In this example, the sale was agreed to but only reluctantly because of the dire economic circumstances, and thus is hard to regard as full "consent." To pin an argument for the sale of body parts and services exclusively on the agent's consent disregards factors that led to that consent (such as poverty) and exposes individuals to exploitation.

Likewise, for those who think a fair price is the way forward, just because there is a "reasonable fee," it does not mean that the arrangement is equitable or that the seller has a "good deal." Rather, once the economic disparities are taken into account, offering money at all can smack of a coercive force – an "offer that is too good to be true" – and this is especially the case for those in extreme poverty. That is, even if a "fair price" could be established, the inequalities serve to exacerbate the vulnerability of the sellers to this kind of contract in particular because, in contexts where buying basic amenities is the primary (if not sole) financial struggle, money in exchange for anything – including human tissue, organs, and services – can begin to look appealing. In this vein, the World Health Organisation (2004) acknowledged the risk of exploitation, given global inequalities, and urged Member States to "protect the poorest and vulnerable groups from transplant tourism and the sale of tissue and organs." Allowing the sale – "fairly priced" or otherwise – of body parts at all, therefore, will lead to exploitation.

To claim that a market model is unproblematic and commodificatory concerns unfounded so long as there is a sufficiently "fair price" paid to a seller or insofar as the seller "freely chooses" to do so then seems disingenuous in the context of vast global inequalities. Neither the "market plus" consent nor fair price approach will counteract the exploitation of impoverished sellers (a key commodificatory issue) under such conditions.

The second reason why the market model is inappropriate is because it encourages commodification, which in turn enables exploitation. Permitting the sale or rental of body parts facilitates a view of them as tradable "things" and as services for "contract." The inherent value of persons and relationships are degraded and, exploitation becomes easier and impoverished views of persons, including the self, are encouraged. For instance, if market rhetoric is entrenched, then it is likely that individuals might think it plausible that they can legitimately use their bodies and sell an organ or sign a paid surrogacy agreement and without this harming their personhood more broadly. Yet, by thinking of organs as "not really me" but a discrete and sellable part of oneself, it is easier to fall into subordination for that "part" without recognizing it as a domination of the whole person (Phillips, 2011, p. 8). A single kidney might be sold in a transaction, but the advantage is over the entire individual since "persons" cannot ethically be thought of as "things" with component parts to trade. Similarly, by assuming that relations with a child can be neatly "carved-up" into a separate gestational service when a "smoothly completed surrogacy contract and an unconcerned 'surrogate' mother" (Pateman, 1988, p. 215) is a fiction, make it more likely that such an arrangement falls short of adequate protections for the surrogate. It is not just services that are being bought, but relationships between people that are unethically subjected to the market and misused. Thus, it is false to adopt the view that one can consensually exploit particular parts or services, such as kidneys and wombs, and equally mistaken to think such exploitation excludes damage to the self.

The market model, therefore, is inappropriate since it cannot properly deal with ethical concerns relating to exploitation in two ways. First, it is unable to diminish a context of global inequalities that make it highly probable that persons in desperate circumstances might "consent" to do anything – including sell body parts – for money – even if set at a "fair price." Such individuals are often the most vulnerable, yet it is precisely these individuals that tend to become sellers in the market. To present the sale of body parts as a genuine and neutral economic option given this, is simply exploitative. Second, the market approach perpetuates the myth that parts of the self can be sold without this impacting the self in general. This is false picture because, in the process of commodifying discrete parts, the whole self suffers exploitation too. Thus, the market model does not overcome the problem of exploitation while arguments against commodification – with their worries about turning "persons" into "things" and "relationships" into "contracts" – are underpinned by concerns about degrading selves and taking unfair advantage of the most vulnerable, and so are better able to preempt this ethical problem.

Some Things Should Not Be for Sale

A second issue commodification raises that the pro-market approach cannot account for is that some things should not be for sale at all (Marx, 1844; Sandel, 1998; Walzer, 1983). Sometimes referred to as the "theory of 'blocked exchanges'"

(Wolff, 2011, p. 176), this view suggests that the nature of a particular good determines whether it should be put on, or kept off, the market; if selling would destroy the essential character of the good, then it ought not be for sale (Wolff, 2011, p. 176). A case in point is love or friendship; these are inherently valuable goods because of the deep bonds (of trust, affection, generosity, shared histories, and more) between individuals that they intrinsically involve, and selling love or friendship would eliminate these features (Sandel, 2012). Returning to "relationships" becoming "contracts," this can be explored by considering the expectations and entitlements of the parties in either case (Widdows, 2009). By way of example, if "friendship services" were purchasable, all the ties and connections that exist in relationship mutate into the enforceable, but relationally detached, set of expectations and entitlements of contract; checking up on a "friend's" welfare stems not from a loving bond but from what is expected by her in the arrangement, and likewise cooking a meal for a "friend" who has recently received some bad news is based not on sympathy with her plight but on what she feels entitled to by paying for this service. Thus, the very nature of "relationships" as deep bonds with others disappears in "contracts," so friendship *cannot* be put on the market.

Similarly, it seems like the market is not an appropriate way in which to govern human tissue and organs, since this is qualitatively different from objects like cars, and it does not work well with relationships, since these are different to being parties to contracts. That is, sale is an improper structure for bioethical matters because it ignores that the substance of the agreement is the body itself (Dickenson, 2007) – physically extracting organs and gametes, or implanting embryos for gestation, or carrying a child. Further the market is not the best approach for bioethics because it ignores that there are different "spheres of justice," each regulated by distinct principles (Walzer, 1983) – so organs and reproductive parts might be better dealt with by relationships of gift-giving than sale. For instance, receiving a kidney or a child after gestation is not a transactional matter that other individuals *should* expect or feel entitled to; rather, it is more appropriate to think of them as gifts they are lucky to receive and which the donators or volunteers might change their minds about giving. Thus, managing body parts and services by using the language of sale, with its concomitant expectations and entitlements, instead of (say) gift, with its relational roots, appears to be the wrong sphere for the substance of the good.

To illustrate, if the kidney one "orders" or the child one "commissions" through IVF sex-selection and gestational surrogacy turns out to be less than what was expected (say by being incompatible with the body in the case of the kidney, or a girl instead of a boy with the child) and one cannot return the "item," does one feel disappointed with the organ or child and entitled to compensation for not getting what was paid for? And, in the case of the child in particular, does it fundamentally alter how one views her as somehow less than ideal (Widdows, 2009)? Thinking about the language of "contract" rather than "relationships" in these examples highlights how expectations of fulfillment and assumptions of entitlement that are the norm for buying cars or painting houses seem inappropriate when applied to

relationships or bodies. This suggests that inanimate objects on the one hand and human tissue or relationships on the other are not comparable, and though sale might be permissible in the former, it is not the correct sphere for the latter, because market rhetoric destroys the nature of the donating and parenting relationship. Thus, such goods should not be for sale, and this is a further concern that a commodification analysis exposes but which is invisible on the market model.

Therefore, while the market fails to acknowledge that sale alters the essential makeup of a good, commodification arguments recognize how the fundamental constitution and purpose of inherently valuable human goods (like "persons" and "relationships") become distorted when sold, and it is this that commodification debate seeks to avoid.

Social Goods

The final reason why commodification is ethically problematic but which the market approach misses is that it has a detrimental effect on social goods and communal relationships (Titmuss, 1970). The position is that valuable societal attitudes which are encouraged by practices of "gift" and "donation" are eroded by sale; essentially that "financial incentives and other market mechanisms can backfire by crowding out nonmarket norms" (Sandel, 2012, pp. 113–114). Sale should, therefore, be rejected in order to preserve these broader goods.

To elaborate, the market, "creates relationships of trade, exchange and contract rather than relationships of gift, participation and shared endeavour" (Widdows, forthcoming), and this is so not only at an individual level but a communal one too. These differing approaches – contract and gift – carry with them sets of values that can lead to two distinct pictures of society, and in particular of social capital. For example, Richard Titmuss, in his research on blood sale and blood donation (1970), argued that blood that was donated led to attitudes of sharing and solidarity in contrast to blood that was sold which invoked a sense of individualism and a prevalence for the rights of ownership. Further, he contended that the blood donor's belief (that a system of collective goods would be beneficial) and the wider healthcare context (the UK's nonmarket model) were mutually reinforcing:

> The ways in which society organises and structures its social institutions – and particularly its health and welfare systems – can encourage or discourage the altruistic in man; such systems can foster integration or alienation; they can allow the "theme of gift" – of generosity towards strangers – to spread among and between social groups and generations. (Titmuss, 1970, p. 255)

In a self-fulfilling cycle, a context of gift and participation leads to equivalent attitudes in individuals, from which they are more likely to contribute to and support social goods; by contrast, a background of sale leads to feelings of social disengagement in persons, which reduces the opportunities for developing the kind of virtues that could bolster common goods. Thus, the social costs – alienation and selfishness, for instance – of a market model are too great.

Such arguments have been drawn on widely. Similar claims, for instance, have been advocated for state funding of particular goods; allowing nonmarket provision in many areas of citizen's lives (including free concerts and universal health care) can be socially beneficial by opening up the possibility of social cohesion, solidarity, and trust (Wolff, 2011). Again, the communal benefits are vastly more important than allowing a free market in these areas. Most recently, this approach was reiterated by the Nuffield Council on Bioethics in their report *Human Bodies: Donation for Medicine and Research*, where they noted, "departure from the altruistic model. . .could run the risk of irreversible damage to important communal virtues" (Nuffield Council on Bioethics, 2011, p. 147), and so payment for organs, such as kidneys, (although not gametes), should continue to be prohibited. Thus, while market rhetoric erodes social capital, the language of gift enhances it. Sharing, solidarity, and common goods, therefore, are part of a gift model whereas they are not at the forefront or even existent in contract, and donation is more likely to generate attitudes of altruism and trust than sale. These are significant social goods that ought to be protected and cultivated.

A market model then does not give weight to social goods but concerns about commodification in bioethics – how individual "contracts" for service undermine "relationships" of gift-giving in society – highlight, from the outset, how shared goods and virtues are important for persons and communities alike. It is not just the effect on individual cases of selling or renting human tissue and organs but – and importantly – to society as a whole that matters. That is, "[i]t is likely that a decline in the spirit of altruism is one sphere of human activities will be accompanied by similar changes in attitudes, motives and relationships in other spheres" (Titmuss, 1970, p. 224). It is these kinds of shifts that society should resist. These harms, which commodification arguments illuminate, are again obscured in the market model.

This section has discussed how pro-sale arguments are unable to deal with concerns about inequality and exploitation, or the intuition that some things should not be for sale, or the importance of fostering social goods. By contrast, an approach which focuses on commodification can recognize and critique the inequality of the market and the impossibility of a fair price and the pretensions of "free choice" in a context of global disparities; it can account why some things, including body parts and types of relationships, should not be for sale; and show that allowing sale is detrimental to common goods and destructive of social capital. Thus, commodification in bioethics remains a problem that needs to be combated by circumventing sale: because the market is unjust and, even if it was not; because "persons" and their parts and "relationships" should not be sold; and because common goods, if tradable, would have devastating effects on social cohesion and solidarity.

Conclusion

This chapter sought to explore the nature of commodification, to map its occurrence in bioethics and to consider its ethical significance. Commodification was defined as having two key features: first that of turning "people" to "things"; and second of

transforming "relationships" into "contracts." Using this framework, commodification in two areas of bioethics – that of kidney sale and reproductive tissue and organ sale and rental – was investigated. In both cases, "persons" were regarded as if "things" with kidneys, reproductive tissue, and wombs to rent all available as purchasable "products" on the market, and "relationships" considered "contracts" with donating and parenting relationships "carved-up" and sold as discrete services with an artificial start and end point. From here, it was argued that pro-market counterarguments about "free choices" to sell or rent or allowing a "fair-trade" in human tissue and organs were ethically unsustainable: There is, given vast global inequalities, a high risk of the most vulnerable being exploited by a market scheme; some goods, like bodies and relationships, should not be on the market at all as this destroys their intrinsically valuable nature, and the detrimental effect of sale over gift on social goods, such as solidarity and trust, is neglected in market rhetoric. Since commodification is a trend in bioethics, and since having a fair market will neither stop the worries relating to commodification itself nor its consequences, this chapter concludes that a trade in human tissue and organs is not ethically permissible, because to allow a market commodify "persons" and "relationships" is exploitative, damages their nature, and erodes common goods. Commodification and commodificatory practices should, therefore, be resisted.

Corruption

35

Jennifer E. Miller and William English

Introduction

Problems of "corruption" pose unique challenges in many areas of concern to bioethics, including the research, development, and marketing of drugs, the delivery of foreign and disaster aid, and the allocation and quality of medical care. However, although it is tempting to think one knows corruption when one sees it, defining corruption and diagnosing its influence are easier said than done. Corruption can take many forms, and evaluating them requires understanding both their underlying logic and the prospects for change.

The purpose of this chapter is to identify and to catalog forms of corruption that pose serious challenges relevant to bioethics and to suggest avenues of reform, but a number of claims and concepts need to be clarified at the outset. This chapter begins by providing a broad outline of the reasons that biomedical fields are vulnerable to corrupting influences, before turning to a more detailed examination of different types and examples of corruption. This chapter focuses, in particular, on issues related to the pharmaceutical industry and does so for three reasons: It is useful for illustrating the intersection of different sorts of concerns, it is an area increasingly scrutinized by the bioethics literature, and it reflects the scholarly expertise of the authors. This chapter concludes with a discussion of the costs of corruption and strategies for reducing it, while emphasizing the need for continued vigilance and study.

Are Biomedical Fields Particularly Vulnerable to Corruption?

At the outset, it is important to note that corruption is a particular concern and vulnerability in biomedical fields for at least six reasons.

First, biomedical decisions often rely on expert judgment, making those without expertise dependent on the good faith of specialists. This asymmetry in knowledge

creates vulnerabilities that present opportunities for corruption. Lay people must trust doctors to give their honest opinion and recommend diagnostic testing or therapies based on medical evidence, trust researchers to disclose study risks, trust pharmaceutical manufacturers to produce safe and effective drugs, and so on. Likewise, doctors must trust the veracity and completeness of journal articles and the medical education they receive pertaining to the products they prescribe. Outsiders simply do not have the expertise to make these determinations on their own on a case by case basis. Thus, they must rely on the judgment of others, and the corruption of expert judgment will be a recurrent concern.

Second, even for experts, biomedical issues often involve complexities and uncertainties that present serious epistemological challenges. Getting to the truth of a matter may take years of data collection and careful analysis. Even then, experts may disagree about, say, the relative effectiveness of a treatment or the public health risks of a chemical. The complexity of such issues, multiple parties involved, and the extensive research that must inform their resolution increases the possible opportunities for corruption. For example, those concerned with the accessibility and affordability of life-saving medicines will need to become familiar with intellectual property and patent law, the TRIPS agreement, international tiered pricing systems, concerns over reimportation, drug diversion, and drug counterfeiting, nonexclusive licensing agreements, patent pools, and more philosophical questions regarding what can be reasonably expected from a for-profit company in terms of its philanthropy and charitable giving. Moreover, when there are disagreements regarding scientific questions, those interested in a particular outcome, regardless of its truth, might try to influence the funding of studies, the collection of data, the analysis, interpretation, and dissemination of results, etc. Ultimately, complexity increases opportunities for corruption, and biomedical research is full of complex issues.

Third, many commercial enterprises related to biomedical fields depend heavily on decisions made by regulatory bodies and thus have an extraordinary interest in influencing the regulatory process. For example, the business model that makes originator pharmaceutical companies viable rests on drug approvals and patent protections. Pharmaceutical companies have an extraordinary stake in decisions made by the Food and Drug Administration regarding patent life, clinical trial standards, ongoing evaluation requirements, and so on. The situation is similar for the medical device industry and hospital systems. Moreover, the dynamism of biomedical fields means that regulatory and legal regimes will often be playing "catch-up" in trying to adequately respond to new developments. Because of the disproportionate influence of regulatory decisions (compared to most industries) and the complexity of issues involved, biomedical enterprises must remain closely engaged with the regulatory environment. Although appropriate, this creates extra incentives for "gaming" and "regulatory capture" (to be explained shortly).

Fourth, the large amounts of money involved make healthcare, and the pharmaceutical sector in particular, vulnerable to corruption and unethical practices.

The global expenditures for general health services total more than $3 trillion USD annually (Poullier, Hernandez, Kawabata, & Savedoff, 2002). In some countries, medicines account for up to 65 % of total health expenditures, and, in the least developed countries, medicines are the second largest household expenditure, after food (World Health Organization [WHO], 2011). Although financial interests are not the only kinds of interest that can corrupt, the extraordinary amounts of money at stake in biomedical fields make them ripe for abuse. Self-serving interests are likely to target biomedical fields for the same reason that the outlaw Willie Sutton robbed banks: because that is where the money is.

Fifth, it is important to note that biomedicine can involve uneven distributions, not only of wealth and expertise, but also of power. Individual and smaller interests, even when they represent valid ethical claims, may have little recourse in dealing with the larger political, economic, and social forces that are operative in biomedical fields. Disparities in legal resources, human and financial capital, political clout, and media representation can exacerbate whatever forms of corruption exist and stifle reform efforts.

Finally, the challenges involved in diagnosing and dealing with corruption in biomedical fields are only compounded by the field's increasing globalization. Different countries have different regulatory regimes, political institutions, and social expectations. The standards by which one judges corruption in one country may be different than the standards appropriate for another country. For example, in the United States, pharmaceutical companies are largely prohibited or capped in their gift-giving practices to doctors and hospitals; however, in developing countries, companies are often encouraged to support local hospitals and physician practices through "capacity building" partnerships. One of the central questions when analyzing corruption from an international perspective is determining which standards have universal validity and which must be calibrated to the unique situation of a particular society.

What Is Corruption?

It is important, in the first instance, to distinguish corruption from a wider range of undesirable outcomes. If a surgeon's hand slips on the operating table, this may considerably harm a patient, but one would not call the surgeon corrupt. Likewise, the necessity of triage in emergency medical situations, although unfortunate, is not in itself an instance of corruption – although the process by which priority is assigned may become corrupt if driven by considerations one believes are illegitimate. What, then, is the basis for identifying an act or practice as corrupt?

The term "corruption" is itself rooted in a biological metaphor: the physical corruption of organisms. When normal capacities decline, organs begin to fail, decay sets in, and so on, a body becomes corrupt. Indeed, disease is a paradigmatic example of corruption, understood in contrast to a "healthy" body. Things are corrupt when they no longer work as they should. Inherent, then, in the very idea

of corruption is a notion of how things should work – a standard or ideal by which to judge deviations as genuine failings.

Such ideals must be "realistic" for the accusation of corruption to be meaningful. A world in which hands never slip or unanticipated disasters never strike would be desirable, but more than one can reasonably expect. By contrast, one can reasonably insist that scarce medical resources be rationed on the basis of need, that new drugs undergo objective trials to establish their safety, that research subjects be informed of known risks and provide their consent, and so on. When such practices (and the ends they serve) are compromised, one can say they have been corrupted. Generally, corruption involves catering to interests that are at odds with the ultimate ideals or goals believed to be legitimate.

Any discussion of corruption thus requires identifying how things ought to (and indeed can) work, and this, in turn, involves identifying the goods or outcomes that ought to be achieved or the legitimate procedures that ought to be followed. In many areas of bioethics, these standards are clear. There is broad agreement that a society should seek to achieve a patient's well-being, public health, scientific understanding, personal autonomy, human dignity, and so on. Indeed, these widespread convictions have been codified in important international frameworks, such as UNESCO's Universal Declaration on Bioethics and Human Rights. The declaration recognizes 15 ethical principles which should inform any approach to bioethical issues, including broad respect for "human dignity, human rights and fundamental freedoms" (UNESCO, 2005, Article 3). However, there are of course situations in which such principles can come into conflict. Public health may require placing an individual with a dangerous infectious disease in quarantine against their wishes. Drug trials in developing countries may benefit recipients of a drug, but involve leaving a control group without effective care. Or, as often happens, biomedical advances may present new quandaries regarding the proper tradeoffs between (and interpretations of) apparent goods: For example, is the destruction of embryos for stem cell research permissible if it promises to advance medical science?

Much of what people usually indicate when they talk about "bioethics" involves wrestling with these difficult questions about the appropriate tradeoffs between such goods. For the purpose of this chapter, however, these larger debates will be placed to the side. Rather, the focus is on elucidating types of corruption that arise most clearly once ultimate goals/procedures/standards are in place.

Given its scope, The Universal Declaration on Bioethics and Human Rights provides a particularly useful expression of such standards, and many problems of corruption can be understood as deviations from core ethical principles articulated in the document. In particular, corrupt practices often create disproportionate harms compared to benefits (Article 4), violate standards of consent (Article 6), and skew the legitimate sharing of benefits (Article 15). Frameworks such as the declaration perform a valuable service in articulating common standards that can act as criteria for diagnosing corruption. However, it is also important to note that differences found across international contexts may provide reasons to recalibrate the standards by which one assesses corruption. Ultimately, addressing corruption involves

indentifying and neutralizing influences judged to be illegitimate, and this means that questions about the appropriate ideals by which to judge corruption will always be relevant to the analysis of any particular case.

Types of Corruption

Distinguishing Formal and Substantial

The classic exemplar of corruption is bribery, which occurs when an individual entrusted with an official duty betrays that duty in exchange for a private side payment. The reason for condemning bribery is presumed in the definition itself. One should not violate one's official duty. However, this description of bribery masks an important background assumption, namely, that the duty in question is a good one. When institutions are in good order, this will indeed be the case. However, if an institution is itself dysfunctional, bribery could conceivably help achieve a better outcome overall. For example, a Nazi doctor may have violated the institutional agenda of the Nazi regime by choosing not to run dangerous experiments on prisoners if their relatives paid a bribe. Such bribes could be said to corrupt Nazi medical research. However, since such research was itself corrupt, a bribe of this sort might actually promote a (marginally) better outcome. It is for this reason that one needs to distinguish between *formal corruption* and *substantial corruption*.

Formal corruption is defined in reference to the explicit rules of a particular institution or practice. Violating "the rules" is what is considered corrupt, and as long as one follows the rules, the charge of formal corruption cannot be raised. This is how most legal perspectives treat corruption. *Substantial corruption* goes deeper and is defined in reference to the ultimate purposes that an institution or practice is supposed to serve. If those purposes are subverted by illegitimate influences, this is the basis for identifying an arrangement as substantially corrupt.

This distinction is important because, as the Nazi medical case suggests, instances of formal corruption need not be substantially corrupt. Indeed, if an institution is itself substantially corrupt, formal corruption may be the only way to improve it in the short run. A large body of literature in economics and political science is premised upon this basic observation and seeks to show how certain types of formal corruption may make poorly designed institutions function better (for example, under certain conditions, bribes paid to public officials in dysfunctional regimes may increase their responsiveness to citizens' needs). Much work in public policy is aimed at trying to address this disconnect by more closely aligning formal corruption with substantial corruption, crafting laws and putting into place procedures that guard against an institution's substantial corruption.

The flip side of this distinction is equally important: Substantial corruption need not involve formal corruption. That is to say, the simple fact that existing laws are not broken does not guarantee that an influence is not substantially corrupting. Rather, one must judge substantial corruption from the perspective of the larger

purposes that institutions and laws are meant to serve. As hinted at above, this may appear hopeless if there is widespread disagreement about what those larger purposes are. However, even when such purposes are agreed upon, diagnosing substantial corruption can be difficult – particularly because there are so many kinds of potentially subversive influences. Moreover, it is generally infeasible to develop and enforce rules that proscribe all forms of substantial corruption, and thus many kinds of corruption may fly below the radar screen of the standards that define formal corruption. Because problems involving formal corruption (bribery, etc.) are relatively straight forward, this chapter focuses on examining forms of substantial corruption that often do not map on to formal corruption, particularly "conflicts of interest," "gaming the system," and "regulatory and institutional capture."

Conflicts of Interest

Conflicts of interest are perhaps the most studied form of corruption in bioethics, and there is an expansive literature considering their nature, effects, and possible remedies. The UNESCO Universal Declaration on Bioethics and Human Rights, for example, obliges parties to declare all conflicts of interest as a means for promoting "professionalism, honesty, integrity and transparency in decision-making" (UNESCO, 2005, Article 18). Defined as "a set of circumstances or conditions in which professional judgment of a primary interest, such as the integrity and quality of research, tends to be unduly influenced by a secondary interest, such as personal financial gain," conflicts of interest are ubiquitous across the terrain of contemporary medical practice and biomedical research (Emanuel & Thompson, 2008, p. 760). However, it is important to note that not all conflicts of interest are necessarily driven by financial considerations. Prestige, publications, time constraints, etc., can provide competing secondary interests as well. To get a better sense of what conflicts of interest (COIs) look like in practice, consider two well-known cases. The first involves a financial COI, possibly rising to the level of a bribe, in which a drug maker's sponsorship practices had the potential to bias the judgment of healthcare providers. The second case involves nonfinancial competing interests common in academia.

Cases of companies attempting to influence the prescribing practices of doctors or formulary decision makers through financial benefits have been frequently documented in health policy literature. One of the more egregious of these cases involved TAP Pharmaceuticals, which offered a $20,000 "educational grant," later increased to $500,000, to a specific HMO to persuade its medical director to reverse his earlier finding that TAP's product Lupron, a hormonal drug for prostate cancer, was bioequivalent to a competitor's drug, Soladex (Brody, 2007). Since Lupron was more expensive, this finding of bioequivalence would ensure that the cheaper rival drug would be added to the Massachusetts managed care organization's formulary instead of Lupron, thereby reducing TAP's market share and profits. Having been accused of inappropriately using "educational grants" and other types of inducements such as Aspen ski trips, golf outings, and paying for doctors' bar tabs (also disguised as "educational grants") as part of their strategy of influence, TAP ultimately settled a legal case brought against it for $875 million (Angell, 2004).

It is important to note, however, that conflicts of interest need not be financial or orchestrated by business interests. The "Slutsky case," which involved a nonfinancial competing interest common in academia, illustrates this well. Driven by the professional prestige and advancement attached to publishing, Robert Slutsky, a junior research cardiologist at the University of California-San Diego (USDC), falsified data to improve the statistical significance of a number of studies, lied about performing others, and listed multiple coauthors for articles without permission. An investigating committee reviewed 137 articles published by Slutsky in a 7-year period, an atypically productive publication rate. They found 48 of the articles to be "questionable" and an additional 10–12 to be fraudulent (Jones & McLellan, 2000).

Unfortunately, cases of scientific fraud by top researchers appear more common than one would hope. Not long before the Slutsky incidence, John Darsee, a top young cardiovascular researcher and fellow at Harvard, was found to have fabricated data for an NIH-funded study (Culliton, 1983; Kochan & Budd, 1992). More recently, Marc Hauser, a professor of Psychology at Harvard, resigned after being found responsible for multiple counts of scientific misconduct, and South Korean researcher Hwang Woo-Suk, once a national champion, was found to have fabricated data on somatic-cell nuclear transfer published in the journal *Science*.

Both financial and nonfinancial conflicts of interests can be found in many forms in biomedical fields, but at what point do they become a threat to the integrity of a practice and require intervention? Consider, briefly, the range of other conflicts that can arise and the kinds of questions they provoke: Can a doctor who has a financial stake in a particular treatment center be trusted to refer only patients who really need the treatment to that center? Can a primary care physician in a developing country be trusted to act in the best interest of the patient when a clinical trial is offering thousands of dollars to enroll a patient? Can an overworked nurse eager to leave her shift on time be trusted not to overmedicate (within the allowable range) a difficult patient who keeps ringing the call bell?

Some of these conflicts might be adequately managed by self awareness and conscientious behavior. Others might call for more formal strategies of vigilance such as transparency and disclosure requirements. Or one might think it necessary to eliminate the conflicts outright by asking professionals to excuse themselves from certain engagements when the magnitude of their competing interest is large enough (in effect, leaving judgment to parties with no secondary interests at stake). Of all the COIs that recurrently surface, perhaps the most complex are those that involve relationships between medical professionals and the pharmaceutical industry.

Whether the actions of TAP Pharmaceuticals discussed above rose to the level of *quid pro quo* bribery is debatable, but there is little doubt they created a serious conflict of interest. A long history of similar strategies of influence within the pharmaceutical industry has led to increased oversight of the benefits conferred to healthcare professionals in an attempt to ensure that conflicts of interest are minimal and do not rise to the level of bribery, whether explicit or implicit. However, although the *quid pro quo* exchange of money or gifts for prescriptions may appear easy to recognize and condemn as illegitimate, the propriety of speaking and consulting fees paid to doctors raises a much more complex set of issues.

Pharmaceutical companies and patients have a compelling interest in information about new and useful drugs being disseminated to the medical community. Moreover, doctors and other medical researchers are the ones who have the medical expertise necessary for understanding and communicating the benefits of drugs. Paying them for their expert services to act as educators and advocates on behalf of a drug's benefits may, in itself, be entirely reasonable. But at what point does remuneration for such services begin to bias their expert judgment and corrupt their own and other's prescribing practices?

Many physicians perceive themselves, but not necessarily their colleagues, as above such corrupting influences (Kassirer, 2005). However, critics complain that companies would not pay consulting and speaking fees if they were not effective at influencing doctors. This begs the larger question of whether such influence is educational and based "on the merits," or whether expert judgment can be biased or bought outright. Medical associations often defend the relationships between doctors and industry as essential to advancing the development of new drugs, vaccines, and medical devices. Moreover, it is hard to find a medical authority who has not received industry funding: "Virtually all of the top speakers on medical topics are employed in some capacity by one or more of the country's pharmaceutical companies" (Kassirer, 2005, p. 19). Aristotle's concern that corruption of the best becomes the worst is perhaps worth considering on this point.

Drawing a line between fair and reasonable compensation for the educational services of experts on the one hand and payments that turn experts into shills for an inferior or more costly product is not easy to do at the level of theory or practice. There have been increasing calls by industry codes of conducts to standardize compensation of experts, in the hopes this will make it harder to buy off strategic targets and disguise the payments as consulting or speaking fees. Another remedy, enacted by a handful of states in the USA, and soon to become US federal law as part of the Sunshine Act, requires drug companies to publicly disclose all payments and other benefits given to physicians. Reformers hope that such transparency will dissuade companies and doctors from arrangements whose details are so incongruous as to raise obvious concerns of corruption or bias. Only time will tell if this strategy accomplishes the intended effects and whether it extracts a cost in terms of the quality of medical education.

In considering the larger landscape of COIs in biomedical fields, one final point of clarification is in order: One must be careful to distinguish *conflicts of interest* from *conflicts between interests*. The former presumes that the "primary interest" at stake takes clear precedence over whatever "secondary interests" there may be. For example, a doctor's primary interest clearly ought to be the promotion of her patient's health. If a doctor prescribed a drug *contrary to medical consensus* because it secured her a kickback payment from a pharmaceutical company, this would be reason to judge that this conflict of interest had corrupted her medical judgment and her patient's care.

In contrast, *conflicts between interests* describe those cases in which the appropriate primary interests are themselves contested or incommensurable. If a vaccine promised to save a large number of lives were it administered to a population but

would also produce severe disabilities in small fraction of recipients, public health officials would arguably be confronted with two primary interests – the interests of those who would perish without the vaccination and the interests of those who would be disabled by it. Such conflicts between interests raise larger questions about the proper ethical frameworks by which to adjudicate claims, which, although profoundly important, are beyond the scope of this chapter.

Gaming the System: Adhering to the Letter of the Law but Not the Spirit

"Gaming the system" is a type of substantial corruption that specifically does not entail formal corruption. Rather, gaming involves adhering to the letter of the law while acting contrary to its spirit (Salter, 2010). Laws/rules are generally underspecified and thus leave room for creative ways to evade their intended purposes. However, if these purposes are good ones, then acting contrary to them is a form of corruption. Keep in mind, however, that one might strategically respond to laws or rules in ways that do not subvert their intended purposes. Drawing the line between gaming and legitimate strategic responses can be difficult and often demands nuanced judgment.

Consider the following scenario. Suppose an international regulation requires that a certain drug not be tested on those below the age of consent because the drug is believed to cause developmental problems in young children. Countries of course differ in how they define the age of consent. In most Western countries, it is 18 years of age, while in many developing countries, it is a few years younger. A researcher who has a substantial interest in studying the efficacy of the drug in young adult populations might strategically choose to field the trial in those developing countries that place the age of consent at 14 rather than 18. The researcher would thus gain access to a younger population in a way that promises to substantially enhance the conclusions of the study. Moreover, the researcher would have accomplished this while staying within the technical bounds of the regulation. Whether this is an instance of gaming the system is up to debate, although there are reasons to believe this strategy is not only appropriate but beneficial.

If the real purpose of the regulation was to keep the drug from being administered to very young children still in early stages of development (say, under 6 years old), then, in fact, this would not be an instance of gaming. The age of consent rule was functioning as a convenient benchmark that would exclude experimentation on the very young, and the researcher's selective targeting of younger adolescents did not violate this ultimate, underlying standard. At the same time, this targeting may have enhanced the quality of medical knowledge in ways that would not have been possible if the Western criterion of 18 had been strictly enforced.

However, suppose another researcher wanted to study the drug's effect on infants and decided to field the study in Cambodia, an impoverished country that has no legally defined age of consent. Technically, this study might not violate the letter of the law which only prohibits testing on populations defined as under the age of consent within a legal regime. However, by exploiting this unanticipated loophole that is an artifact of Cambodia's underdeveloped legal code, the researcher

would clearly be violating the legitimate intent of the international regulation. This would rise to the level of substantial corruption and be a clear instance of gaming the system.

Gaming can take place on a number of levels, and researchers or corporations need not be the culprits. The problem of drug diversion is one instance of gaming that can take place at the "grassroots" level. Pharmaceutical companies have increasingly set up tiered pricing systems to maximize access to their products, paying special attention to lower income developing countries. These tiered pricing arrangements generally involve providing drugs to poorer populations for little or no cost. However, the good intentions of these programs can be twisted if the donated or significantly discounted drugs are diverted and resold at higher prices. When this happens, not only do drugs not reach poor patients in need but legitimate sales in developed markets are also crowded out. It is generally difficult to make every manifestation of this sort of arbitrage illegal, but if the practice becomes widespread, it limits access to drugs for traditionally vulnerable populations.

Practices of "gaming" the law impose two sorts of costs on society. First, there are the immediate, negative consequences of an instance of gaming itself. In the hypothetical Cambodia study, this would include the risk and harm of developmental problems to which infant research subjects are exposed, and in the tiered pricing example, decreased medical access for the poor.

The second cost imposed by gaming accrues to the system at large. If there are intensive efforts directed toward gaming the system, then those in charge of developing laws and regulations must be much more detailed and narrow in their approach. They must exhaustively specify every aspect of a law in an attempt to head off illegitimate strategic responses. However, there is a real worry that in doing so they will overreach and rule out benign or useful innovations as well. Also, extensive and detailed regulations can often be more costly and difficult to monitor and enforce. In the cost-benefit calculations that underlie any regulatory enterprise, expectations of gaming will tend to increase the costs of regulations and decrease their benefits. Additionally, belief that gaming is widespread can lead the public to lose trust in an institution or system at large, thereby decreasing its effectiveness (a concern that will be examined in greater detail below).

Gaming the System: Betraying the Integrity of Institutions

Taking a broader perspective, gaming can include not only attempts to circumvent legal rules but also strategies that betray the integrity of institutions, twisting them for illegitimate purposes. For example, suppose a scientist conducted quality research which raised questions about the safety or comparative economic value of a company's product. If that company hired a public relations firm to write and place articles attacking the character of the scientist, this could be described as gaming the institution of journalism. Even if the articles did not rise to the legal definition of defamation or libel, they would have corrupted the standards of journalistic integrity. Such gaming of the *modus operandi* of legitimate institutions is but a larger analog of the problem of legal gaming. This sort of gaming at large can be exacerbated by disparities in power and knowledge. Moreover, strategic

considerations embedded in the way that biomedical research is conducted make it particularly vulnerable to gaming. Consider the following, prominent example.

In 1987, Dr. Betty J. Dong signed a contract with Boots Pharmaceuticals, known at the time as Flint Laboratories, to conduct a comparative effectiveness study of their drug Synthroid. The study concluded in late 1990 with the surprising results that Synthroid was not superior; all four compared drugs were bioequivalent. Dong's concluding paper was accepted by the *Journal of the American Medical Association* (JAMA) and scheduled for publication on January 25, 1995. Days prior to its scheduled publication, Dong withdrew the paper because of a threatened legal action stemming from a confidentiality clause in the original research contract signed in 1987. The contract read: "... Data obtained by the investigator while carrying out this study is also considered confidential and is not to be published or otherwise released without written consent from Flint Laboratories, Inc" (Rennie, 1997, p. 1239). Dong reports that she signed the contract after being reassured by a UCSF patent officer that "no pharmaceutical company would have the gall to violate so flagrantly the norms of academic research" (Brody, 2007). However, Boots threatened to sue Dong for damage if sales of Synthroid suffered in any way as a result of the article.

According to *JAMA* deputy editor Drummond Rennie, "Boots waged an energetic campaign to discredit Dong's study and prevent publication," despite having conducted around three site visits per year of the study and Flint having approved the "detailed experimental design and analysis of the data" in its contract with Dr. Dong (Rennie, 1997, p. 1238). At one point, Boots suggested Dong had been bought off by rival drug maker Daniels Pharmaceuticals to produce the unfavorable results. When UCSF, Dong's academic home, investigated Boots' allegations, they found no major errors with the study, but that the company was indeed aiming to suppress unfavorable findings (Brody, 2007; Rennie, 1997).

Many observers suggested that Boots' aggressive data suppression efforts were driven in part by the company's pending merger with BASF AG' subsidiary Knoll Pharmaceutical. Synthroid's market power was an important factor influencing the company's purchase price, valued at $1.4 billion in March of 1995 (Brody, 2007; Rennie, 1997). However, the merged Boots/Knoll advised JAMA that they also intended to prevent publication of Dong's study. In fact, they published their own article in the *American Journal of Therapeutics* using Dong's data without consent or attribution and reaching opposite conclusions. Critics considered this an attempt to prevent other journals from publishing Dong's study because of journals' rules against duplicate publications.

Thanks to a *Wall Street Journal* expose on April 15, 1996, the FDA learned of the company's failure to submit Dong's data and the publication of a misleading article in 1992 (Berg & Mayor, 1992). Boots/Knoll eventually negotiated and allowed UCSF to publish the manuscript in *JAMA*, due in part to FDA pressure and poor public perception, according to the *JAMA* expose. Boots/Knoll was later the subject of a class action lawsuit by thyroid patients who claimed harm from the delayed publication. The company settled the suit for over a hundred million dollars.

Companies have a legitimate interest in questioning the rigor of studies that affect their bottom line. They reasonably want to ensure they are not the victims of shoddy research. However, they also have a financial interest in seeing negative studies discredited regardless of their quality. Moreover, there are many ways in which a company may legally try to influence researchers in ways that compromise the integrity of science – in particular, through the threat of expensive lawsuits and bad publicity.

Indeed, the fear of impoverishment from expensive legal fees, character defamation, or loss of sponsorship is not unfounded. Consider a case in which legal defense fees for a small organization totaled a significant amount of their annual operating budget. In the late 1990s, Bristol-Myers Squibb, maker of the statin drug Pravachol, took the Canadian Coordinating Office for Health Technology Assessment (CCOHTA) to court to reportedly delay them from publishing a report declaring that all available statin drugs were approximately bioequivalent. CCOHTA ultimately won the case, but only after spending 13 % of its annual budget, which was roughly equivalent to a single day of sales revenues for Pravachol in Canada (Brody, 2007). It is easy to understand why the threat of a lawsuit or character assignation may be sufficient to deter individuals and smaller researcher centers from acting against the interests of a large company, and this represents a prominent class of temptations for companies to game the systems of legal activism, publicity, and grant making (Brody, 2007).

Institutional Capture: Corrupting Dependencies

Along with character assignations and expensive lawsuits, the threat of withdrawing sponsorships, or the promise of funding for only certain types of projects, can corrupt the conduct of research or the integrity of advocacy groups. These are but pieces of a larger concern that well-established economies of influence operate in biomedical fields in ways that create dependences that compromise the independence and objective judgment of third parties.

On the one hand, industry donations and grants to nonprofits are highly commendable for their generosity. However, if donations are accompanied by tacit strings, they can easily rise to the level of a corrupting influence. This is of particular concern for smaller organizations for which grants can command a significant share of their annual operating budget.

Indeed, cases in which pharmaceutical sponsorships dominate medical societies' operating budgets are not uncommon. On the one hand, the financing is helpful and possibly laudable; however, it is also easy to imagine ways in which this could corrupt the integrity of such organizations. For example, in 2009, Daiichi Sankyo funded 70 % of the American Society of Hypertension's (ASH) annual budget ($3.3 million) and asked the society to create a training and accreditation program for its salesmen (Ornstein & Weber, 2011). However, critics questioned whether ASH could actually demand any reforms of the company's practices, as this could jeopardize 70 % of the society's budget. More generally, can medical societies be expected to render objective judgments and medical education regarding their major industry sponsors?

It is important to emphasize that these concerns about corrupting dependencies are not hypothetical. There are many documented cases in which companies withdrew research funding because of practices or outcomes they deemed unfavorable. For example, Apotex pharmaceutical company was reported to have abruptly canceled its contracts with Dr. Nancy Olivieri in the late 1990s after she insisted on disclosing her concerns about the safety and efficacy of Apotex's drug deferiprone to patients in her study (Healy, 2004). The merits of Olivieri's concerns continue to be debated, but the determination with which Apotex sought to defund and discredit her is not. Similar strategies have been deployed to marginalize other sorts of research as well. For example, some allege that Eli Lilly, the largest individual sponsor of the Hastings Center in 2000, discontinued supporting the center after it published a series of papers on antidepressants that collectively failed to promote Eli Lilly's blockbuster drug Prozac (Healy, 2004).

Again, there is nothing clearly illegal or perhaps even unreasonable about companies making donations with strings attached or not offering to perpetually fund projects. However, in such situations, the independence of recipient organizations cannot be taken for granted, and there are good reasons to expect that targeted donations can have a corrupting influence on the objectivity of beneficiaries.

As suggested by concerns regarding regulatory capture (to be examined shortly), economies of influence in biomedical fields interact with political institutions as well. These interactions can raise particularly difficult issues across international contexts. For example, many have questioned how effective independent ethics committees (IECs) in developing countries can be if they are underfunded, understaffed, or politically undercut by clauses that require their decisions to be approved by state officials. It is thought that clinical trial companies can command enough political power to ensure that state officials provide a sympathetic hearing. Moreover, there appears to be a tacit understanding among some IECs in developing countries that if they disapprove of too many studies submitted to them, research sponsors can and will seek out other IECs (Lemmens & Freedman, 2000). This leaves IECs on a rather short leash with regard to their real ability to stop trials that raise ethics- and safety-related red flags.

Finally, no discussion of corrupting dependencies would be complete without mentioning the fact that political influences can raise the stakes of corruption. The political process can, of course, be useful for negotiating outcomes that benefit the common good. However, it can also be a site where deals are struck that have enormous costs or implications that are difficult to defend from the standpoint of a compelling public interest. A recent byline in the *Los Angeles Times* – "A company controlled by a longtime political donor gets a no-bid contract to supply an experimental remedy for a threat that may not exist" – could perhaps be recycled to describe deals made in many countries, year in and year out, administration after administration (Willman, 2011, November 13). In this case, it was for a $433 million plan for the US government to buy a smallpox vaccine of unknown effectiveness for a disease that has been considered eradicated worldwide since 1979. Some may wish to debate whether this was a prudent public health

decision, but the larger lesson proposed here is simply that when the financial stakes are high, as they often are in biomedical fields, stakeholders have reason to seek powerful political interventions – which may prove an additional avenue for corruption.

Regulatory Capture

"Regulatory capture" refers to the phenomenon of regulators being influenced by those whom they are supposed to regulate in ways that shape regulations to the detriment of the common good. In an ideal regulatory environment, one might hope that: (1) those tasked with regulatory oversight would have a clear understanding of the industry under their purview, (2) the need for welfare-enhancing regulations and the details of how they should work would be apparent, and (3) regulators would be primarily driven by considerations of the common good rather than the private interests of industry or special interest groups. Unfortunately, the knowledge needed for (1) and (2) is very difficult to obtain and political forces make (3) difficult to achieve as well. That is to say, regulators are often highly dependent upon those they regulate for both epistemological and political reasons.

Epistemologically, regulators of complex industries generally must rely on industry insiders in order to obtain an accurate understanding of how things work, as well as an appreciation of the complexities that any proposed changes involve. Consultation processes during the development of regulations and "notice and comment" periods for proposed changes aim to facilitate this exchange of important information. However, there is an underlying asymmetry of information, and regulators face a difficult task in assembling and filtering industry feedback. Some of this feedback will be vitally important for crafting sensible rules; other feedback may aim to influence regulations in ways that benefit an industry or a group to the detriment of public welfare – granting special exemptions, lowering liability, erecting barriers to competition, and so on.

Politically, the regulatory enterprise is subject to a general problem that plagues democratic institutions when they deal with decisions that have concentrated benefits and diffused costs. In short, if regulations will impose significant costs or benefits on a small number of agents, those agents are likely to be much more motivated and successful in their lobbying efforts than a large number of people who all have a small amount to gain or lose.

For example, suppose that extending patent protection by 1 year for a commonly prescribed drug will keep its price $100 higher than it would otherwise be (with competition from generics). If a million people take the drug each year, then the total cost of the patent extension to consumers will be $100 million – not a small amount! However, any single consumer only stands to lose $100 due to the patent extension. For most consumers, it will not be worth investing considerable time calling congressional representatives, organizing publicity campaigns, drafting and submitting review comments, etc., to fight the extension. Conversely, the drug company stands to gain $100 million, and it would thus be worthwhile for them to invest a large amount of resources on lobbying efforts to preserve the patent. Ultimately, the drug company with many millions of dollars on the line is likely to

be more motivated and effective in exercising regulatory influence than dispersed, individual consumers who only stand to lose $100 each.

The phenomenon of regulatory capture means that in judging the wisdom of regulatory oversight, one must take into account not only the hypothetical benefits of optimal regulations but also ask whether regulators can garner the expertise and political support needed to implement them. However, recognizing the problems posed by regulatory capture can also enhance the practice of regulation by reminding both regulators and those with diffuse interests to remain vigilant with respect to the influences of special interests.

Finally, it is important to note that, as in the case of gaming, diagnosing regulatory capture depends on nuanced judgments, and, as in the case of conflicts of interest, it is important to distinguish between the kinds of disagreements that may arise. On some issues, the need for regulations, and the details of such regulations, may be unambiguous and the regulatory task thus straightforward. On other issues, the questions of whether and how things should be regulated will be far from certain and require thoughtful research, reflection, and debate. It is entirely appropriate for the interests and expertise of the regulated to be represented in these discussions. Ultimately, however, regulators need to adjudicate between narrow, self-serving interests and the larger public interest in order to avoid corruption of the regulatory enterprise. Often, there will be legitimate concerns on both sides of an issue, and the task is to judge whether one side is ultimately more compelling. Moreover, in cases where neither side is more compelling, it is often preferable for regulators reach a principled compromise, rather than let the regulatory process become a political battleground for incommensurable interests.

The case of drug patents illustrates the complexity of these issues. Drug patents are widely recognized to provide property rights that are essential for a sustainable and innovative pharmaceutical industry. Patents enable companies to profit from the considerable investments they make in drug research and development, and those investments in turn benefit public health. Thus, it is in the public's interest to grant and protect patents. But, how long should patent protection last? The answer admits of less precision than one might hope, and, at the margins, drug companies and consumers have conflicting short-run interests.

Extending patents will benefit drug companies at the expense of consumers in the short run. However, consumers ultimately benefit in the long run from the existence of some patent regime. If *either* consumers or drugmakers completely captured the regulatory process, the outcome would likely be detrimental to long-term pharmaceutical innovation. The details of a compromise between no patents and permanent patents may be arbitrary in some respects, but still superior to endless back and forth renegotiations in the short run. Furthermore, once a framework is firmly in place, interest groups have fewer reasons to expend resources on political influence, which may benefit both their bottom line and the health of the regulatory enterprise in the long run. Thus, one part of the challenge of preventing regulatory capture is figuring out what should be on the regulatory bargaining table in the first place. The greater challenge, however, lies in judging the quality of information and arguments that bear on the details of any regulatory proposal.

The Costs of Corruption in Healthcare and Biomedicine

The types of corruption outlined above can be found across a wide range of industries, practices, and political systems. They are meant to highlight the kinds of influence and conflicts that can generate substantial corruption at large. However, as noted at the outset, there are reasons to believe that corruption is a particular concern for the field of biomedicine. The role played by expert judgment, the complex and uncertain nature of many issues, the dependence on regulatory bodies, the large amounts of money involved, the globalization of biomedicine across different international contexts, and disparities in wealth and power in biomedical fields all combine to create heightened opportunities for corruption.

While there is some debate and ambiguity about just how costly and harmful current practices of corruption are, there is no doubt that their existence, coupled with their perceived existence, generates short-term and long-term costs. In the short term, corruption involves not living up to a realistic and legitimate standard. In this sense, substantial corruption does an immediate injury to those whose interests are aligned with the legitimate standard, although this may not be visible. However, in the long term, corruption also imposes costs that accrue to society at large. In biomedical fields, these costs can include (1) substandard medical care and research and decreased medical access and affordability and human research subject protections, (2) weakened stakeholder trust that undermines the long-term sustainability of institutions and industries, (3) overregulation, and (4) malaise about the possibility of reform and the acceptance of a culture of corruption as the way things are done.

First, corruption can decrease the affordability and accessibility of healthcare and lead to substandard medical care and inferior research. For example, if research results showing that older cheaper drugs are bioequivalent to newer more expensive drugs are suppressed, then doctors may unknowingly prescribe more expensive treatments. Or, doctors may be tempted to recommend newer, costlier, or even inferior products if the speaking or consulting fees are overly enticing. Moreover, lawsuits, over perceived or actual corrupt practices, further drive up costs and lessen the affordability of healthcare. Although each instance of corruption may have its specific winners and losers, over time corrupt practices are likely to raise medical costs for everyone.

Second, corruption is costly for institutions and industries because it weakens stakeholder trust. If people perceive an institution to be corrupt, they may restrict their engagement with it, which can undermine the effectiveness of the institution at large. For example, if someone is convinced that medical professionals or drug manufacturers are corrupt, he or she might decline helpful medical treatment. If the corruption of medicine runs deep, this could perhaps be a reasonable response. However, it would be tragic if individuals ceased to avail themselves of beneficial medical resources because the corrupt practices of a conspicuous few lead to systematic distrust in the larger institution. Similarly, perceptions of corruption in the way that foreign disaster and medical aid are handled can cause a loss of confidence that cripples goodwill donations, investments, and further aid.

The third cost imposed by corruption accrues to the system at large in the form of overregulation. Unduly burdensome regulation can impede critical collaborations, reduce innovation, and incur expenses that exceed their benefits. Calls for regulation are an understandable response to scandals involving corruption, but the costs of regulation may undermine the ultimate goals they are supposed to serve.

Finally, cynicism can result from an abundance of corruption leading to general malaise about attempting reform efforts. Likewise, individuals who would not normally engage in corruption may decide that it is the only way to get things done. If the culture or leadership of a society or institution is sufficiently warped, corrupt practices may in fact appear ok to individuals because that is "the way things are done."

Ultimately, the stakes of addressing the challenges of corruption in biomedicine could not be higher. At some level, they involve matters of life and death, as well as other important concerns about the responsible use of resources, the safety of products, and the quality of patient care and human research subject protections.

Conclusion: Prospects for Reform?

In reviewing different types of corruption, this chapter has already touched on a number of implicit strategies for reform, including transparency, independent monitoring, and incentive design. In conclusion, it is worth briefly considering the strength and weaknesses of these strategies, as well as the additional role that might be played by ethical persuasion.

The promise of transparency is straightforward and succinctly captured by Justice Louis Brandeis's famous quip that "sunlight is the best disinfectant." If a relationship or conflicting interest cannot hope to bear the scrutiny of public attention, this is a good indication that it is problematic. Moreover, if relevant parties are aware that payments, gifts, and other forms of influence and dependence will be public knowledge, this provides a powerful motive for self-restraint.

There are, however, at least two limitations of transparency requirements. First, they may be hard to enforce if there are ways to hide or to simply not report information. Second, even if the relevant information is disclosed, it may have no behavioral effects if the dependencies in question are commonly accepted as the status quo. Indeed, critics of the Sunshine Act in the United States, which requires pharmaceutical companies to disclose all payments to physicians, point out that many physicians and patients consider such payments to be a sign of a doctor's eminence and expertise. Thus, it is not clear that there is a public mandate for doctors and companies to change their current behavior.

The concept of independent monitoring builds upon the basic promise of transparency but deepens it by assigning the power of oversight to a third party and by specifying more detailed standards for compliance. Independent monitoring can, in theory, be carried out by government regulators, private organizations such as accrediting agencies, or even by sufficiently independent compliance departments within firms. Independent monitoring takes for granted certain standards, which

need not rely on the whims of public opinion, and seeks to verify compliance with them. Although there are many instances of successful monitoring efforts, it can still be a challenge for third parties to gain the knowledge needed to verify compliance. Moreover, as suggested by the examination of corrupting dependencies and regulatory capture, the independence of monitors can be undermined by the lobbying efforts of those who are monitored or subverted by a powerful industry unwilling to be subject to the risks of scrutiny. Incentive design tries to address these sorts of larger, underlying strategic problems.

The hope animating incentive design is that, by understanding the nature of the strategic interests involved, regulators can change the rules of a game so that self-interested players act in ways that promote a better outcome. Put simply, incentive design attempts to make it in people's interest to be good, and this is typically accomplished by developing rules that put those with conflicting interests in a position to monitor and challenge each other within some framework that is considered to be fair. In the political realm, this takes the form of the division of power between branches, which allows "ambition to check ambition." In biomedical fields, it can entail arrangements as diverse as whistleblower laws that reward insiders who expose illegal behavior while providing sufficient protections, tort laws that assign liability for products or actions that hurt others, or public "notice and comment" procedures that allow everyone interested in a regulatory decision to have their say. Accreditation programs that contain strong public relations components, communicating to stakeholders an institution's verified commitment to excellence in ethics, can also realign incentives in meaningful ways.

Designing good incentives is a worthwhile enterprise and is what much of the legal and regulatory process aims, in theory, to accomplish. It will continue to describe many successful approaches to reforming corruption. However, there are inherent limits to the project of incentive design that one should not lose sight of. The incentives for those in power to design better incentives are often lacking, and at a theoretical level, one can always ask who will incentivize the incentivizers. Put another way, at some level, one must hope that individuals can be motivated by more than just the immediate material incentives they face. Furthermore, there will always be limits to the scope and inclusiveness of any reform, and institutions will never be designed so well that it *always* pays to do the right thing.

Ultimately, ethical persuasion is likely to be an important component of any successful reform. At the level of motivation, if those involved in some practice can be persuaded that it is in fact corrupt, this conviction can play a role in changing behavior (which is not to suggest material incentives will not exercise influence as well). Also, ethical persuasion plays a role in diagnosing and analyzing the problems with corrupt practices in the first place. To return to a point made at the outset of this chapter, the charge of corruption always implicitly involves some judgment about why the status quo is bad and how things could be better. Attempting to persuade those involved in a corrupt practice of its vices is an important enterprise, as is trying to dialogue with and persuade the larger public (UNESCO, 2005, Article 18). This is why documents such as UNESCO's Universal Declaration on Bioethics and Human Rights are so useful. Such efforts to

dialogue, clarify, educate, and persuade help establish the standards of evaluation that enable us to judge a state of affairs as corrupt. In so doing, they also illustrate the importance of reform.

Because of the limits inherent in all strategies of reform and the ever-changing landscape of biomedical fields, there is not likely to be any permanent solution to the general problem of corruption. Moreover, meaningful reform efforts can be difficult to organize because of economic challenges and collective action problems. However, there are reasons to believe that specific problems of corruption do admit of improvement through a mixture of the strategies explored above. Indeed, the very diagnosis of corruption suggests that things could realistically be better. Developing an understanding of the nature of corruption is one important step in the process of reform and the central purpose of this chapter. Although this analysis hopes to advance the search for enduring improvements, the complexities of corruption documented here likewise demonstrate the need for continued study and vigilance.

Disasters

36

Dónal P. O'Mathúna

Introduction

Disaster bioethics is a relatively new topic. At every stage in preparing for disasters, developing risk reduction strategies, and responding to disasters, ethical and value-based decisions are made. These have seldom been made explicit. This is beginning to change as organizations recognize the importance of ethics in disasters and put structures in place to address ethics explicitly.

The need for greater attention to disaster ethics is coming from those in the field. Research reveals that those receiving assistance identify unethical practices by well-meaning responders (O'Mathúna, 2010; Pittaway, Bartolomeim, & Hugman, 2010) and responders themselves struggle with ethical dilemmas which can haunt them when they return home (Schwartz et al., 2010). An early publication for the UN's Disaster Management Training Programme identified ethical dilemmas that permeate every aspect of disaster relief (Jensen, 1997). These range from "small" individual decisions, like a truck driver allowing looters to take some of his aid to ensure he gets the rest to survivors, to the field manager considering breaking head-office policy because his own moral compass suggests another approach is better, to government officials deciding whether to permit outside military forces to assist humanitarian aid provision. The scale of impact differs, but the ethical quandaries persist. This chapter will examine some of the more frequent ethical issues, focusing on three areas: disaster responses, disaster research, and healthcare during disasters.

The underlying premise of this chapter is that ethics is concerned both with fundamental values, rights, and dignity and with pragmatic dimensions. Trust can be built as sound ethical decisions are made and good practices flourish; trust can be destroyed by unethical behavior. Promoting a culture of ethics can increase cooperation and collaboration, while unethical practices lead to conflict and

disunity. Ethical practice contributes to an atmosphere of mutual respect, where responders benefit from the satisfaction of knowing they are promoting goods that go beyond the physical to enhancing survivors' dignity.

Disasters Defined

Disasters have been defined in various ways, but they are characterized by extensive damage and human suffering. They lead to what have been called the 6Ds: destruction, death, disease/disorders, displacement, disappearance, and disarray (Sumathipala et al., 2010). According to the Centre for Research on the Epidemiology of Disasters (CRED), a World Health Organization (WHO) collaborating center, a disaster is "an unforeseen and often sudden event that causes great damage, destruction and human suffering" and "which overwhelms local capacity, necessitating a request to national or international level for external assistance" (www.emdat.be). CRED tracks disasters globally, with an event classified as a disaster if 10 or more people are killed, 100 or more people are affected, authorities declare a state of emergency, or an appeal is issued for international assistance.

The World Medical Association (WMA) defines a disaster as "the sudden occurrence of a calamitous, usually violent, event resulting in substantial material damage, considerable displacement of people, a large number of victims and/or significant social disruption" (WMA, 2006). While disasters vary in nature, they share several common features:

- Sudden, unexpected onset requiring prompt response
- Massive damage to materials, infrastructure, and the environment
- Large numbers of human casualties, with difficulties accessing survivors
- Complications to relief efforts from weather, pollution, infection, and psychological factors
- Insecurity due to physical dangers, conflict, or violence
- Broad media attention (WMA, 2006)

Disasters are usually categorized into one of three groups: natural disasters (such as floods, earthquakes, or mudslides), technological disasters (such as industrial accidents, transport accidents), or complex emergencies, which involve natural and human causes. Disasters can also be conflict related (due to war or terrorism), which raise additional factors and complications which will not be addressed here. These classifications help to identify some of the major causes of the disasters but can be very arbitrary. However disasters are grouped, it is clear that their frequency is on the increase (see Figs. 36.1 and 36.2).

The devastating effects of disasters are well known from recent examples. These include the ongoing drought in the Horn of Africa, the 2011 great East Japan earthquake, the 2011 flooding in Australia, the 2010 earthquake in Haiti, hurricane Katrina in the USA in 2005, and the 2004 Indian Ocean tsunami. While large-scale disasters receive widespread attention, smaller disasters occur regularly, averaging one per day. For example, in 2010 winter storm Xynthia killed 65 people across

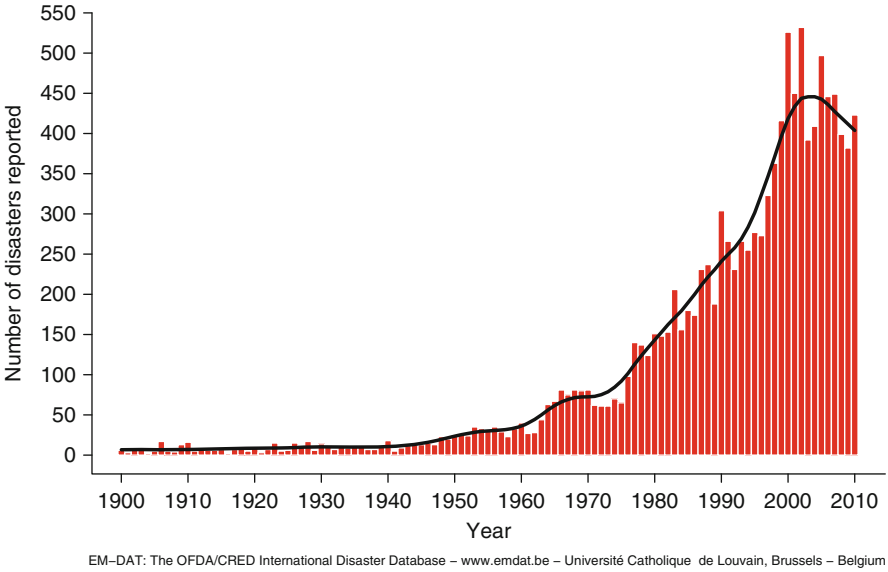

Fig. 36.1 Natural disasters reported 1900–2010

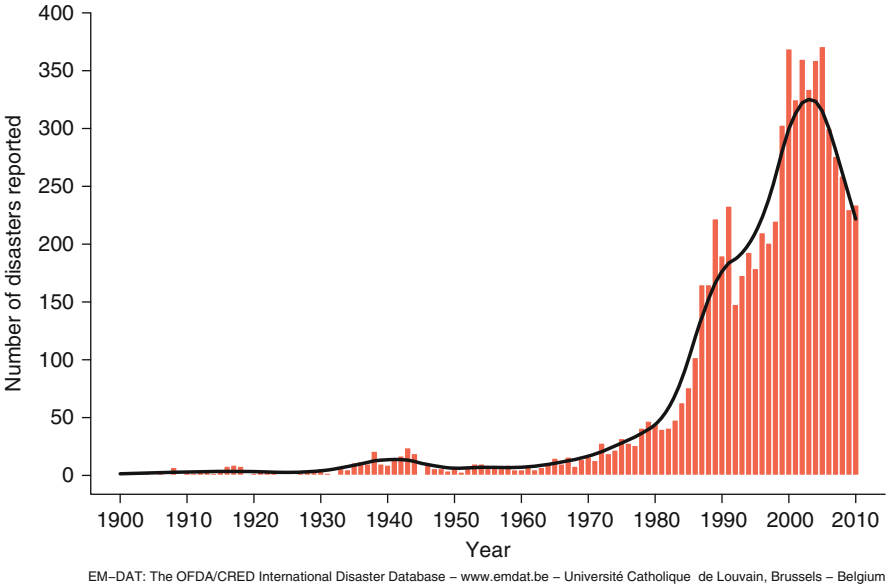

Fig. 36.2 Technological disasters reported 1900–2010

Europe, while flooding later that year killed 43 people in Portugal (www.emdat.be). According to the United Nations International Strategy for Disaster Reduction (UNISDR), the number of natural disasters is increasing steadily, with 2010 being the deadliest year in decades: 373 natural disasters killed 300,000 people, impacted 200 million more, and cost over US$100 billion (www.unisdr.org/archive/17613). Foremost among these were the Haitian earthquake that killed over 222,000 people and a heat wave in Russia that killed 56,000 people.

The frequency of disasters is projected to continue to increase. One assessment found that climate-related disasters (which make up 98 % of all disasters) will impact 375 million people annually by 2015, a 50 % increase on recent averages (Ganeshan & Diamond, 2009). Financial costs are also increasing, especially in more urbanized regions. The year 2011 was the costliest year ever for damages from disasters, estimated at between US$350 and $380 billion, largely due to the Japanese earthquake (www.unisdr.org/archive/24588). Disaster preparedness and risk reduction are top priorities for the United Nations (UN) and many other organizations.

Disaster Response Ethics

Disasters are commonly categorized as natural, technological, or complex emergencies. Such categories might help with donations, as people help more when disasters are natural. However, even these classifications have ethical dimensions. Such distinctions are based on an assumption that humans have little to do with causing natural disasters. People appear to have greater sympathy for those impacted by earthquakes or volcanic eruptions than when the disaster is caused by human error or deliberate sabotage. A natural disaster is seen as uncontrollable, while technological disasters could have been avoided. The damage and suffering caused by natural events are seen as random, while a sense of injustice or victimization exists with technological disasters. Why was the nuclear reactor built near us and not them? Why was the building code not enforced more strictly?

Such distinctions are convenient and commonplace, yet not easily sustainable under careful analysis. For example, the 2010 earthquake in Haiti was smaller in magnitude than one that occurred soon afterward off the coast of Chile. However, the number of people killed, injured, and made homeless was many times greater in Haiti than in Chile. The scale of aid needed in Haiti, and continuing to be needed, was vastly greater also. Although each disaster could be classified as natural, human factors played a large role in the scale of the disaster. Those need to be considered if lessons are to be learned so that other potential disaster victims can benefit. The destructiveness of Haiti's earthquake was influenced by the country's history and economics, where the vast majority live under the poverty line. This impacted the quality of housing and the resources available on the ground to respond to the disaster. While some of this can be traced to corruption in recent Haitian leadership, part of the problem stems from colonial days and indemnities required by France after Haiti became independent.

Understanding these factors is important for ethics because it impacts how disaster response is perceived. If some disasters are seen as completely unpredictable natural events, the response may be restricted to helping people in the immediate aftermath. Disaster preparedness may be limited to developing better defenses or early warning systems. But if the human contribution to disasters is identified, an ethical responsibility exists to make changes in those factors. This may motivate those involved to enact the necessary changes to reduce future pain and suffering.

A practical example of this is the observation that disasters increasingly impact urban settings. This is partly due to expanding urbanization of the world. When disasters hit more urbanized regions, the death toll tends to be lower, but the economic cost greater. Exceptions occur to this, such as the earthquakes in Haiti and one in Sichuan, China, in 2008. At the same time, more people are living in urban regions and individual cities are growing to unprecedented sizes. For example, in 1950 there were 75 cities in the world with a population over one million; in 2008, there were 431 such cities (IFRC, 2010).

Urbanization itself is not a bad thing. But the way urbanization is occurring is putting in place conditions for future disasters. For example, the probability of earthquakes is not increasing, but their devastation is – because of where and how building is occurring (IFRC, 2010). Currently, almost all the growth in urbanization is taking place in low- and middle-income countries, particularly in Asia. Much of this occurs as informal or illegal settlements, inadequately constructed houses, and building on sites at high risk for floods, landslides, earthquakes, or industrial accidents. These practices are allowed because of either a lack of knowledge of good planning principles, an unwillingness to act on those principles, or an inability to afford good housing. Such urbanization creates a "vulnerability gap" where those with lower incomes are being placed at higher risk of disaster (IFRC, 2010). Addressing such inequalities in disaster risk reduction is an ethical issue.

Disaster preparedness must therefore go deeper than preparing to rescue people after the disaster strikes. It must go to the core of why such social inequalities exist and are permitted to continue. Adam Smith (1790), after the Lisbon earthquake of 1755, wondered how "a man of humanity in Europe" would respond to news of a disaster in China. He speculated that he would express sorrow for the victims, reflect on the precariousness of human life, and then go back to his business or pleasure as if nothing had happened. He would be deeply disturbed at the loss of his own little finger but would sleep soundly while a hundred million people perished in some faraway land.

"Human nature startles with horror at the thought, and the world, in its greatest depravity and corruption, never produced such a villain as could be capable of entertaining it" (Smith, 1790, III.3.4). Nevertheless, today news of disasters travels the world, yet many go to bed worried about their own concerns. The human conscience, what Smith called "this judge within," should signal when people value themselves too much and others too little. It shows "the propriety of generosity and the deformity of injustice" (Smith, III.3.4). Ethics must address issues of conscience and character if it is to impact disasters. The dignity of those who look on is at stake, just as is the dignity of those directly impacted by disasters.

Encouraging others to respond generously after disasters raises other ethical issues. For years, "the starving child image" was used to raise funds for humanitarian aid (Jensen, 1997, p. 49). The ethical appropriateness of such images is now questioned because of how they impact people's perceptions of those in need. The problem is not that suffering is revealed, but that an image is conveyed of helpless victims who cannot help themselves. Even when consent was given during the disaster, people have been shocked to see themselves on public display when they later saw their photographs used to raise relief funds (Pittaway, Bartolomei, & Hugman, 2010). Such images of helplessness do not contribute to an atmosphere of mutual respect and dignity. The potential ethical implications of all fund-raising activities should be explored. "Do they convey respect for the dignity of the survivors? Have we carefully considered the effect of the images of reality we project on the psyche and inter-cultural attitudes in the constituencies from which we hope to raise funds?" (Jensen, 1997, p. 51). Other images can be dignifying, such as those showing donated animals that empower people to provide for their families and communities. The choice of image reflects concern for the ethical values projected directly or indirectly, intended or unintended.

Disaster responses must prioritize the immediate needs of disaster survivors but should also consider the long-term implications. Emergency aid should be tied into longer-term sustainable development. If not, tragic situations can arise where those seeking to do good end up causing harm in the long run. For example, after an earthquake in Guatemala, so much food was donated that the price for local crops was depressed (Jensen, 1997). As a result, crops unaffected by the earthquake were never harvested. Unless carefully monitored, disaster relief can end up promoting dependency. On the other hand, relief can lead to unsustainable economies. When relief workers purchased goods and services within the disaster region, prices can increase dramatically. While some survivors benefit greatly from this, the higher prices can leave basic necessities unaffordable for other survivors. Local organizations and businesses also lost many of their staff to international organizations who paid higher salaries.

None of these issues have simple solutions, but they are not just financial or strategic problems. Ethical values influence all the choices made. Recognition of these values is crucial to avoiding long-term negative consequences. For this reason, the International Federation of Red Cross and Red Crescent Societies (IFRC) has developed a code of conduct for those responding to disasters to which 492 humanitarian organizations have become signatories (IFRC, 1994). The voluntary code commits organizations to making decisions during disaster relief based on ten ethical principles:

1. The humanitarian imperative comes first.
2. Aid is given regardless of the race, creed or nationality of the recipients and without adverse distinction of any kind. Aid priorities are calculated on the basis of need alone.
3. Aid will not be used to further a particular political or religious standpoint.
4. We shall endeavour not to act as instruments of government foreign policy.
5. We shall respect culture and custom.

6. We shall attempt to build disaster response on local capacities.
7. Ways shall be found to involve programme beneficiaries in the management of relief aid.
8. Relief aid must strive to reduce future vulnerabilities to disaster as well as meeting basic needs.
9. We hold ourselves accountable to both those we seek to assist and those from whom we accept resources.
10. In our information, publicity and advertizing activities, we shall recognize disaster victims as dignified human beings, not hopeless objects (IFRC, 1994).

These principles provide an important starting place for organizations and individuals as they consider the ethical implications of the many decisions they make regarding disaster response and planning.

Evidence and Disasters

A compassionate response to the suffering caused by disasters is important. Those responses are always limited by availability, and aid must then be allocated on the basis of need alone (IFRC, 1994). This fundamental principle is often taken for granted, but important reasons underlie it (Milletts-King, 2006). A needs-based approach satisfies the notion that all people have the right to such items as life, safety, or food. Such rights are inherent to all individuals. A needs-based approach helps reduce discrimination and prejudice, where resources might be distributed based on race, religion, class, or gender. Being impartial can help foster trust and cooperation, facilitating the provision of need to more people. A needs-based approach also helps ensure that limited resources are used as effectively as possible for those who need them the most.

A needs-based approach to relief requires accurate knowledge of those needs. Unfortunately, precise data on needs are often limited, especially immediately after a disaster strikes (Bradt, 2009). Conducting needs assessments in disaster settings is challenging and points to the importance of identifying predisaster resources and infrastructure. For example, Sri Lanka was hit by the 2004 Indian Ocean tsunami with over 30,000 deaths and about half a million people displaced (Yamada et al., 2006). Sri Lanka received much international assistance, but inattention to needs assessments meant that some resources sent were not what were needed. Unlike other countries, Sri Lanka had a strong public health system which mobilized quickly to prevent an infectious disease epidemic. Lack of awareness of these local resources led to duplication of services by foreign nongovernmental organizations (NGOs). Some people received unnecessary cholera vaccination or malaria prophylaxis because NGOs incorrectly assumed these diseases were endemic (Yamada et al.). At the same time, needs assessments revealed that, contrary to expectations, few people were critically injured in Sri Lanka. A characteristic of this tsunami was that people either drowned or escaped with few physical injuries.

Local and international coordination is needed to identify needs accurately and ensure those needs are met with appropriate resources. This was lacking

in Sri Lanka, resulting in some camps for displaced persons receiving excess food and inappropriate clothing, while other camps were short of supplies. Sleeping mats and hygiene kits were always needed, but news reporters found that international crates arrived with "winter jackets, expired cans of salmon, stiletto shoes, winter tents, thong panties, and even Viagra" (http://msnbc.msn.com/id/6954302). Presumably sent with the best of intentions, shipping unneeded items uses resources that could have been spent more wisely. Such mistakes can hurt on a deeper level. The same news report quoted a woman displaced by the tsunami reacting to another box of unneeded clothing saying, "We're not beggars. We don't need these hand-me-downs."

Needs must be accurately assessed to avoid such situations and develop effective responses. Such an evidence-based approach has been slow to gain acceptance among humanitarian aid providers. "Without appropriate evidence, allocation is based on estimates and professional judgement, and needs assessments in practice play a minor part in determining allocations" (Milletts-King, 2006, p. 26). Currently most disaster relief operations make decisions based largely on expert opinion, authority, or nonrigorous studies (Bradt, 2009). Such approaches are problematic as this type of evidence can be of low quality. However, "the limited corpus of rigorous studies is notable" (Bradt p. 488). Rigorous studies include randomized controlled studies (RCTs) of interventions, quasi-experimental studies using matched control groups, and systematic reviews of such studies.

Overall, "much of the existing operational research related to emergencies and disasters lacks consistency, is of poor reliability and validity and is of limited use for establishing baselines, defining standards, making comparisons or tracking trends" (UNISDR, 2011, p. 46). As a result, globally accepted standards for performance and accountability during disaster relief operations do not exist. All of this points to the importance of generating evidence to guide disaster responders and policy makers. As with any research involving human subjects, conducting such research raises ethical issues.

Disaster Research Ethics

Research provides answers to various types of questions. Disasters can raise many different questions, some of which are listed in Table 36.1.

Each type of question is best addressed by a particular research method. Some research evaluates interventions, seeking to understand, for example, whether certain medications are effective and safe or which policies are most effective. Intervention studies randomize individuals or groups to receive one intervention or another, striving to be as objective as possible. Other research methods, common in the social sciences, address different research questions with interviews or focus groups. These studies raise different ethical issues, although some overlap exists. All research should respect subjects, minimize risks, and respect confidentiality. However, different types of research will raise distinctive ethical issues.

For example, "reciprocal research" seeks to transform "people from subjects of research to participants in research" and "has the potential for bringing about

Table 36.1 Possible disaster research questions (Adapted from Jesus & Michael, 2009)

General topic	Potential research questions
Mass casualty management	Which approaches to triage work best in particular types of disasters?
	Do people displaced after disasters fare better in camps or dispersed among the general population?
New technology	Are point-of-care diagnostic devices effective guides in disaster settings?
	What methods of detecting chemical, biological, or radiological exposures work best in disaster settings?
Infectious diseases	Which vaccines for specific diseases work best in disaster settings?
	What public policy strategies work best to prevent the outbreak of epidemics after disasters?
Mental health	How do disaster survivors cope with their experience of the disaster?
	What training and support best prevent burnout among disaster responders?
Resource management	What are the most urgent/prevalent health needs among disaster survivors?
	Are the needs of women, children, or other special populations addressed differently from those of men?
Education and assessment	What types of training best prepare individuals as disaster responders?
	What outcome data can be collected during disasters to improve future disaster responses?

social change" (Pittaway, Bartolomei, & Hugman, 2010, p. 247). The objectivity of intervention research, where confounding factors are controlled as much as possible, is not a factor here. For the social scientist, research in humanitarian settings seeks both to contribute knowledge to a better understanding of the world and to change policies or attitudes so that the lives of those studied are improved. Many within this research tradition hold that research into people's suffering is only justified if relieving that suffering is an explicit objective.

Intervention research is well established within medicine. The ethics of such research has been explicitly addressed in guidelines like those of the WMA Declaration of Helsinki and the Council for International Organizations of Medical Sciences (O'Mathúna, 2010). While a specific set of guidelines addressing disaster research has not been adopted internationally, the core ethical principles of these other guidelines are directly applicable (Jesus & Michael, 2009).

However, concerns have been expressed that research ethics in general has become too cumbersome and overly bureaucratic (O'Mathúna, 2011). Such critiques are generally raised concerning the research ethics review process and regulatory frameworks, which can always be improved. The underlying reason for research ethics should be the focus: to promote respect for research subjects and ensure risks of harm are minimized. Henry Beecher's highly influential 1966 article on medical research ethics began by listing numerous ways in which published research projects had violated ethical principles. Stimulated by such publications and revelations about unethical research, research ethics procedures have become well established for intervention research. Beecher saw value in research ethics review and informed consent, but he also held that the most reliable safeguard to ethical research involving humans was "the presence of an intelligent, informed,

conscientious, compassionate, responsible investigator" (Beecher, 1966, p. 1360). Developing character traits and virtues such as these in researchers remains challenging, yet is central to what research ethics should be about.

Past ethical problems and failures can stimulate interest in promoting ethical practice. Recalling and discussing such blemishes can both help to prevent similar problems in the future and instill humility in current decision-making. Intervention research has many such examples, from the Tuskegee syphilis experiments to more recent HIV drug trials in low- and middle-income countries. More recent studies are revealing ethical concerns in social science research in disaster settings. Although the research involved interviews, not experimental drugs, harm has resulted, leading to calls for closer attention to disaster research ethics. For example, a sociologist with a strong working relationship with women in refugee camps found that things changed when she proposed conducting research with the same women. The women became wary of her motives because of a "deep fear of exploitation by researchers" (Pittaway, Bartolomei, & Hugman, 2010, p. 236). When this was explored further, some of the concerns about research came from beliefs held by the women themselves, including:

- Overly high expectations of receiving humanitarian aid
- Fears of backlash from community leaders and authorities
- Mistrust of foreign, Western researchers or local researchers from a different class or ethnic group

Other concerns could be traced to ethically questionable practices in previous research:

- Names and photographs of research subjects were released without authorization, at times putting them in danger.
- Promised feedback from researchers never arrived.
- Researchers "flew in" and "flew out" causing inconvenience and more problems than benefits.
- Consultation about recommendations and proposed strategies never occurred.
- Researchers were unable to cope with the stories they were told by the women interviewed.
- Interviewees were retraumatized without being provided support.

One research subject noted that after putting previous researchers in contact with women who had been raped and were willing to have their stories recorded: "We never heard from them again – we decided then that we would never work with researchers again. They stole our stories" (as cited in Pittaway, Bartolomei, & Hugman, 2010, p. 236). A men's group in a refugee camp reported:

> You know many of the organizations came to the refugee camp and they see the refugees in many ways as the monkeys... like a monkey in a cage... and then they thought that if we show this monkey to... the big countries of power like the EU [European Union], they will have a lot of money and it will benefit us [the non government organizations]... They documented things [stories] of the women that is oppressed, then when they get money they use some for the refugees but mostly they use for themselves. (Pittaway, Bartolomei, & Hugman, 2010, p. 230)

Such researchers likely did not intend to cause harm, but in research, good intentions are not good enough. Research in disaster settings engages people in vulnerable situations and has the potential to cause good or harm. In other disaster research, people have been pressured into participating, biological samples have been smuggled out of disaster settings, and informed consent has been ignored (O'Mathúna, 2010). Researchers often get caught up in the goals of their projects and may not see other aspects or potential conflicts of interest, some of which may violate ethical principles.

Disaster research covers a wide range of practices and raises many different ethical issues. The following sections will examine some ethical principles that are particularly relevant to disaster research. Some examples will be given to illustrate how the principles apply in disaster settings. However, this section will not address all the ethical issues in disaster research and will not provide an exhaustive discussion of each topic. Some of these topics are examined in more depth elsewhere (O'Mathúna, Gordijn, & Clarke, 2012). However, much further work is needed on disaster research ethics.

Beneficence

The underlying motivation for disaster research is generally the ethical principle of beneficence: to do good for disaster survivors, both current and future. This is accomplished by generating high-quality evidence that can be used to give strong recommendations in disaster planning, prevention, or responses. In responding to disasters, the primary motivation is to do the most good for as many people as possible (Bradt, 2009). However, in many areas of disaster response, what will bring about the most good is not clearly understood. Many myths and fallacies about health risks and health needs during disasters exist in both public perceptions and views of some responders (Magone, Neuman, & Weissman, 2011). Good-quality evidence is needed to identify the best ways to help people after disasters.

For example, panic is believed to be widespread after a disaster, yet evidence shows that most survivors do not panic. Empirical research has shown that survivors remain calm and play crucial roles in helping to rescue people and treat their injuries (Magone, Neuman, & Weissman, 2011). In the immediate aftermath of the 2004 tsunami in Sri Lanka, thousands of people came from the affected regions and nearby to search for survivors, care for the injured, and provide basic needs (Yamada et al., 2006). These informal networks were mobilized before government agencies responded or international teams arrived. Empirical research in other countries has found that the vast majority of disaster survivors are rescued by other survivors (Magone, Neuman, & Weissman, 2011). These research findings have important implications for disaster preparedness training and planning, highlighting the importance of conducting research immediately after disasters.

Research can also provide evidence to prevent the provision of ineffective or harmful interventions. Because of the trauma of disasters, psychological care of different types has been offered to survivors. Thousands of well-meaning

counselors arrive in disaster settings to help survivors. However, a systematic review of research on psychological debriefing to prevent posttraumatic stress disorder (PTSD) showed that it is not generally effective (Rose, Bisson, Churchill, & Wessely, 2002). Similarly, critical incident stress debriefing (CISD) was initially used to help disaster responders process their experiences and avoid subsequent negative effects (Alexander & Klein, 2009). When empirical data became available, CISD was shown to either be ineffective or to worsen the situation. On the other hand, for those exhibiting PTSD symptoms, cognitive behavioral therapy (CBT) can be safe and effective, although many people do not respond to CBT for various reasons. The WHO and other organizations recommend against using debriefing sessions that push people to share their experiences beyond what they would naturally disclose (WHO, 2003). Other research shows that most (but not all) disaster survivors benefit more from practical help and general conversations with family and friends rather than professional counseling (O'Mathúna, 2010).

While conducting research in disaster settings is challenging practically and ethically, the results are needed to provide evidence to guide responders. Otherwise, well-meaning responders will continue to send inappropriate aid with unintended consequences. Some international disaster responses have been found to undermine local disaster relief efforts and, in places, set back local organizational infrastructural. Such outcomes were surely unintended, but "good intentions do not excuse bad outcomes" (Bradt, 2009, p. 483). High-quality research can help identify why problems resulted and how they can be avoided in the future.

Vulnerability

Disaster research should recognize the inherent vulnerability of people in disaster settings. The devastation that disaster survivors endure means that rescue and relief should take precedence over research. Vulnerability is usually raised in research as a concern either that subjects may not be able to give informed consent because of outside influences or that participating in the research may cause additional harms (O'Mathúna, 2010). On the other hand, labeling people as vulnerable and thus unable to give truly informed consent could be "inaccurate and potentially stigmatizing" (Collogan, Tuma, Dolan-Sewell, Borja, & Fleischman, 2004, p. 365). Little research has been conducted on the decision-making capacity of those affected by disasters, but the available evidence suggests that most people are able to make informed decisions, even when extremely upset by disasters. At the same time, some people are more deeply impacted by the disaster to where their decision-making capacity is impaired. The potential vulnerability of disaster survivors imposes additional duties on disaster researchers to ensure that subjects are adequately informed.

Labeling people as vulnerable can be problematic if it leads to a paternalistic attitude or to the exclusion of certain groups from research important for them (Levine, 2004). Giving people the opportunity to participate in research could be beneficial and dignifying for them. For example, a research project assessed the

hurricane-related stressors among adult patients at an outpatient psychiatric clinic 1 week after hurricane Katrina (O'Mathúna, 2010). Some staff members at the clinic were concerned that patients might feel pressured into completing the surveys. Patients were told they could refuse to be involved and could talk to the clinic staff about any concerns they had with the research. Approximately 1 % of the patients refused to participate, while those who participated reported that they appreciated that the researchers were trying to understand how the hurricane had affected them personally.

Vulnerability must be taken into account in disaster research but provides little specific guidance for research ethics. Disaster survivors should be viewed as capable of consenting or refusing to participate in research, although appropriate steps should be taken to evaluate whether individuals may have impaired decision-making capacity. As with any group of research subjects, disaster survivors will show a range of capacities that should be assessed during the informed consent process. At the same time, "the concept of vulnerability should remind us of the fragility of human life and the importance of protecting people from unnecessary harm. As such, it points to other important ethical principles that need to be taken seriously with all participants" (O'Mathúna, 2010, p. 69). How these are addressed depends on the details of each study, such as whether it is observational or interventional, its risks and benefits, how soon after the disaster it is conducted, what conflicts of interest are involved, and other factors.

Informed Consent

Informed consent is a bed-rock ethical principle in research. The most heinous ethical violations in research have occurred when informed consent has been ignored. The unethical medical research conducted in Guatemala in the 1940s by US researchers is abhorrent partly because the subjects were not given the opportunity to consent to their involvement. Research is regarded as a voluntary activity, and therefore, not seeking informed consent is disrespectful and a violation of the individual's rights. Informed consent for research is regarded by the UN a "nonderogable right" and therefore cannot be exempted if individuals have the capacity to give it.

Informed consent in disaster research raises many challenges, especially if the situation is chaotic, fraught with danger or stress, and involves translation of technical information and if research is an alien concept for participants. The urgency involved with disasters and other emergencies has raised the possibility that some research should be permitted without informed consent. Researchers in the USA can obtain a waiver for written informed consent in emergency situations if the patient is unconscious and no relative is available. When such waivers have been used in multicenter emergency medicine trials, recruitment has been faster and higher than when informed consent is required. Some claim such consent waivers will lower ethical standards in research; others reject these concerns and claim informed consent is a legalistic ritual in medical research which does not actually respect patients' autonomy (O'Mathúna, 2011).

Waiving informed consent in any research can have far-reaching consequences. Research on an experimental blood substitute was conducted on trauma patients on their way to hospitals. As the patients were unconscious, an approval to waive informed consent was obtained. However, the study was harshly criticized for this in academic and media sources. "Severe public resistance to research conducted without informed consent, even when consent is impossible to obtain due to an emergent condition, suggests that extending a waiver of informed consent to include disaster research would face similar opposition" (Jesus & Michael, 2009, p. 113).

As a way of respecting people's dignity, especially in disaster settings when they may have lost everything else, informed consent provides people some control over themselves and what happens to them. The Working Group on Disaster Research and Ethics (WGDRE) was constituted after the Indian Ocean tsunami and has been developing draft guidelines for disaster research (Sumathipala et al., 2010). These guidelines insist that informed consent always be obtained for disaster research, even with the challenges this entails. The consequences of using people as research subjects without their consent could far outweigh any potential evidence gained. When such practices would be revealed, the potential for erosion of public trust in research and public health systems could have long-term consequences and undermine future research efforts (Pittaway, Bartolomei, & Hugman, 2010).

Humanitarian Misconception

One challenge with informed consent is to ensure that people understand the risks and benefits of research. In medical research, the risks include unknown adverse effects, while the benefits might include receiving an intervention that is more effective than current standard care. However, the clearest beneficiaries are future patients who will be treated with the benefit of whatever knowledge is gained from the project. In the research, to justify randomly assigning people to one intervention or another, "clinical equipoise" should exist. This means that the researchers do not know which intervention is most effective or safest. If they did know which was best, that should be provided to the patients.

However, subjects in medical research frequently do not understand this distinction between research and therapy. Studies have found that patients often think that being a research subject ensures they get the newest and best treatments (Ahmad & Mahmud, 2010). Subjects often believe that researchers decide between interventions based on their individual needs – not the toss of a coin in random allocation. This can make it difficult to accurately weigh up the risks and benefits and has become known as the "therapeutic misconception" – the mistaken belief that being a research subject is a way to obtain the best therapy.

Something similar has been identified in humanitarian research and called the "humanitarian misconception" (Ahmad & Mahmud, 2010). Here, people may believe they are more likely to receive humanitarian aid if they agree to participate in research. In some cases, they may be correct if the only effective medical care

available is from the research team. In that case, however, they may unwittingly expose themselves to risks from experimental interventions, as has been alleged in the Trovan case during a 1996 meningitis outbreak in Nigeria (O'Mathúna, 2010).

Such concerns can be addressed in intervention studies through a detailed informed consent process. However, other types of research do not begin from a situation of clinical equipoise and do not seek to objectively assess the effectiveness of interventions. The reciprocal research method mentioned above seeks both to generate new knowledge and to help participants. People agree to be interviewed assuming this will provide benefits for them or their community, or lead to improved policies or practices. Such projects have both research and humanitarian goals and must make this clear to participants. One way this can be done is by promoting the "principle of reciprocity," whereby tangible benefits for participants are identified ahead of time through discussions with potential participants (Pittaway, Bartolomei, & Hugman, 2010). The benefits can be in the area of training or providing participants opportunities to present their concerns to others. Even in medical research, the principle of reciprocity is increasingly accepted, where patients are entitled to be informed of the outcome of the research and to share in any resulting benefits. As with overcoming any misconception, clear communication and active dialogue clarify expectations and promote respect on all sides.

Cultural Issues

Another factor complicating disaster research (and humanitarian aid in general) is the cultural difference that can exist between researchers and participants. Disasters strike all over the world, but disaster researchers frequently come from one culture to conduct projects in another. One principle in the IFRC code of conduct for disasters is that cultures and customs should be respected (IFRC, 1994). Cultural sensitivity is not the same as ethical relativism, where any practice is accepted on the basis of cultural values (Pittaway, Bartolomei, & Hugman, 2010). Hence, if a local authority insists on making all research decisions for those in his jurisdiction, a process of dialogue and negotiation should be initiated where fundamental human values and rights are promoted and protected.

Ethical Review and Oversight

Given the general chaos and infrastructural breakdown following disasters, research ethics approval and oversight may be low on survivors' priority list. Nonetheless, researchers should ensure that their studies are both ethically sound and methodologically rigorous. Research ethics committees have emerged as a way to facilitate this through peer review. Disaster research projects will usually be reviewed by researchers' home institutions, but a role for dedicated research ethics committees is increasingly being suggested. For example, Médecins Sans Frontières (MSF) is an international medical humanitarian aid organization which

developed an independent research ethics review board to approve research projects conducted by MSF researchers (Schopper et al., 2009). The board is composed of people familiar with humanitarian organizations and representative of different professions and geographical regions. Their work is carried out electronically, with face-to-face meetings every 18 months.

Many of the board's functions are similar to those of other ethics review committees. However, a distinctive feature of disaster research is the need to get projects started unexpectedly and quickly. All disaster research does not need this, but for projects investigating the earliest stages of the disaster aftermath, speed is of the essence. For this reason, the MSF board will review a "generic" research protocol and grant approval without knowing the specific location or nature of a disaster (Schopper et al., 2009). When the disaster occurs, the research team submits a finalized protocol for expedited review and can quickly deploy to the field. However, the MSF board also requires that such projects gain approval from national authorities at the disaster site.

Such a model allows for careful planning, reflection, and review away from the time pressures of the disaster, with final adjustments made once the disaster occurs. Other governmental or international relief agencies could provide such preapproval as part of disaster readiness planning and as a way to encourage research into needed topics. Preapproval would also facilitate oversight and coordination of research once a disaster strikes. Such a model was developed after the 1995 Oklahoma City bombings in the USA (Collogan, Tuma, Dolan-Sewell, Borja, & Fleischman, 2004). All bombing-related research projects had to obtain ethics approval from the University of Oklahoma Institutional Review Board. This helped both to coordinate the research enterprise and to project survivors from being burdened by numerous requests to participate in different research projects. In this way, research ethics review can both facilitate ethically sound research and fulfill its requirement to protect research participants.

Disaster Healthcare Ethics

Responders to disasters include people from a wide variety of backgrounds. Among these are many healthcare professionals who volunteer to help injured and traumatized survivors. The outpouring of well-intentioned help is often tainted by criticisms about lack of preparedness, coordination, and appropriate skills (Krin et al., 2010). Many responders return from disasters experiencing what have been called "vicarious traumatization," "compassion fatigue," and "burnout," although these terms have not been clearly delineated (Alexander & Klein, 2009, p. 88). While this section will focus on healthcare professionals, many similar issues are faced by researchers and other aid workers whose well-being also needs to be taken into account (O'Mathúna, 2010).

The negative experiences of disaster responders relate to the devastation they have seen, the human pain and suffering they have witnessed, physical fatigue, and frustration with difficult working conditions. At the same time, many responders

report positive results from their involvement in disasters, especially the development of resilience. After the 2003 outbreak of SARS (severe acute respiratory syndrome) in Hong Kong, frontline healthcare workers reported that along with some "survivor guilt," their work in the disaster had positive effects by affording them the opportunity to reassess their life values and priorities and deepen their relationships (Alexander & Klein, 2009).

Responders often have to make ethical decisions that they struggle with in the field and afterward. These ethical dilemmas are faced daily but have received relatively little attention (Sheather & Shah, 2011). Triage decisions are the most obvious: choices must be made to treat some people or not treat others. These decisions should be based on objective, medical criteria (Merin, Ash, Levy, Schwaber, & Kreiss, 2010; WMA, 2006). Rationally, it makes sense to triage people in disaster settings to expectant management (i.e., not to treat them) when they have burns covering more than half their body. However, in the field, such guidelines can be much less clear-cut, leading to ethical conflict over whether or how to follow them. Military medical units often treat civilian casualties and transfer them to local hospitals when severely injured soldiers arrive. Sometimes they know the local facilities do not have the resources to keep these patients alive. They know they will soon die but are told there is no alternative.

Such ethical dilemmas deeply impact healthcare professionals. Cases have been reported of healthcare professionals being overwhelmed with guilt over not being able to do enough to help people. A qualitative study of 20 Canadian-trained healthcare professionals who had volunteered in disaster settings identified four general types of ethical challenges experienced (Schwartz et al., 2010):

- Resource scarcity and decisions over allocating those resources
- Social injustice, arising from inequalities, exploitive industries, or violence
- Frustration with aid agency policies or agendas
- Healthcare professionals' roles and interactions

While some of these ethical challenges arise in high-income settings, they are intensified by the degree of scarcity; the extent of need; lack of familiarity with cultural, social, and professional norms; and poorly defined roles. The researchers contacted three medical organizations that send healthcare professionals to disasters (Schwartz et al., 2010). None of them had specialized ethics training for field workers but relied on them using their professionalism and standard codes of ethics.

Such professional ethics training is of value, but these researchers found that it sometimes contributed to the ethical challenges in the field. The ethical dilemmas are similar enough to lead professionals to look to their professional codes, yet in disaster settings, some ethical principles become impossible to uphold completely. One such area is where public health interests come into direct conflict with the needs of individual patients. Healthcare professionals trained in Western ethics strongly favor individual needs and patient autonomy, yet in disaster settings, public interests often take priority. This can produce feelings of isolation and distress over triage decisions (Schwartz et al., 2010).

Western ethics training usually focuses on resolving ethical dilemmas in rational ways by identifying ethically sound options. In analyzing cases and dilemmas,

ethical principles are identified and prioritized according to professional values or individual preferences. Such "ideal morality" assumes that moral goodness is always possible. Ethics is seen as a way to help people act ethically, leaving them confident that they have done the right thing. Moral dilemmas, in this approach, either do not really exist or show that further analysis is needed to identify ideal ethical solutions.

When such an approach is brought into disaster settings, its inadequacy becomes apparent quickly. Humanitarian ethical dilemmas "often entail choosing between undesirable alternatives" (Jensen, 1997, p. 7). Using a Western approach to ethics can result in frustration and guilt, as Schwartz et al. (2010) found. This leads some to question whether ethics can provide any concrete guidance in disasters. Claims have been made that "the world today is simply too complex and too diverse for prescriptive ethics" (Jensen, 1997, p. 50). Yet the outcry over certain decisions, such as questions about whether some patients were euthanized without their knowledge during hurricane Katrina, shows that the solution does not lie in ethical relativism.

Recent work on "nonidealized morality" provides a useful model for disaster ethics. In this approach, "moral dilemmas should be understood as situations of unavoidable moral wrongdoing or failure" (Tessman, 2010, p. 798). Ideal morality focuses on ideal situations and abstract principles, but these can be divorced from the realities of actual situations. Nonideal morality starts by describing the real world, including its wrongs and injustices. It acknowledges that, "Not all wrongs can be rectified, not all losses can be compensated, not everything can be repaired or replaced, and – especially given the limits of psychological resilience – not everyone can recover" (Tessman, p. 801). The failure and guilt are real, because sometimes no choice is ideal. True dilemmas exist where all options carry a bad side. When a doctor chooses to operate on one patient and leave another to die, guilt is normal. The challenge then is to develop ways to better prepare people to address such nonideal moral dilemmas, to assist them in the field as they wrestle with such decisions and their consequences, and to support them when they return home and have to process their experiences. This requires examination of the emotional dimensions of ethics, including guilt, forgiveness, grief, and anger, even though these typically are not addressed in ethics training.

Conclusion

Disasters are increasingly prevalent. In addition to complex issues of global inequalities and responsibilities to help one's fellow humans, disasters raise many challenging ethical issues. Our understanding of disasters needs to be furthered so that the multiple contributions to their causes – human and natural – can be addressed. Foremost among the ethical issues is identifying reliable strategies to prepare for future events and minimize the risk of harm. While saving lives and healing wounds are the immediate priorities, longer-term development strategies must be considered at all stages of relief. From the beginning, ethical considerations are involved and should be explicitly addressed.

In developing effective preparation and response strategies, the highest quality evidence available should be used. For many decisions, this is lacking, pointing to the need for disaster research. Many different research questions need to be addressed, each with their distinctive ethical issues. International guidelines should be developed and adopted to ensure that all disaster research, especially that carried out in low- and middle-income countries, is conducted to the highest ethical standards. International ethics review committees, like that of MSF, need to be set up to approve and monitor research occurring in regional disasters. As a way to respect the contributions made by research subjects in these projects, research findings should be incorporated into policies and practices so that disaster planning and prevention becomes increasingly evidence based and beneficial to those living in disaster-prone regions.

The ethical challenges facing disaster responders are only beginning to be addressed in detail. Few investigations have been conducted into the factors that help responders cope in the field. One factor is selection of responders to identify those most resilient, and the other is training (Alexander & Klein, 2009). Much work is needed to develop tools and training programs that will help prepare healthcare professionals (and researchers) for the ethical challenges and decisions they will face in the field. Support mechanisms are needed to help responders address the ethical challenges as they arise in the field. For example, one field hospital in Haiti developed a system of ad hoc ethics committees to deliberate on the ethical decisions being made and share their burden (Merin, Ash, Levy, Schwaber, & Kreiss, 2010). Without such supports, some survivors will not be helped effectively and may even be harmed, while some responders will return with debilitating moral distress. "If we fail to give this set of issues careful and considered attention, the consequences range from burnout and reduced ability of aid organizations to attract and retain [healthcare professionals] to do fieldwork, to avoidable suffering of all involved" (Schwartz et al., 2010, p. 53). Much further work remains to be done on this significant topic.

Dual Use

37

Michael J. Selgelid

Introduction

While recent developments in genetics and biotechnology may have tremendous benefits regarding the advancement of medicine and improvement of human health and well-being, they could also enable causation of harm. Of particular concern is the "dual use" phenomenon, whereby the very same scientific knowledge and/or technology that can be used for good purposes can also be used for bad purposes. Discoveries that may facilitate scientific progress and/or prevention or treatment of disease, for example, may (sometimes) also facilitate production of biological weapons of mass destruction.

The dangers of dual-use life science research are illustrated by a series of controversial experiments that have been published during the twenty-first century. Australian researchers, for example, accidentally created a superstrain of mousepox. They used genetic engineering techniques to insert an interleukin gene into the mousepox virus genome. While their hope was that the altered virus would induce infertility in mice and thus provide a powerful new means of pest control, the virus they produced unexpectedly killed both mice that were naturally resistant to and mice that had been vaccinated against ordinary mousepox. They published their findings, along with description of materials and methods, in the *Journal of Virology* in 2001 (Jackson, Christensen, Beaton, Hall, & Ramshaw, 2001).

In a second study, American researchers artificially synthesized poliovirus "from scratch." Following the map of the polio (RNA) genome, which is published on the Internet, they bought and strung together corresponding strands of DNA. Addition of the synthesized genome to a solution containing cellular ingredients (but no live cells) led to the creation of a "live" virus that paralyzed and killed mice. They published their findings, along with description of materials and methods, in *Science* in 2002 (Cello, Paul, & Wimmer, 2002).

While both of these studies revealed information that may be important to the advancement of science and/or medicine, they both have implications for biological weapons making. The technique that led to creation of vaccine resistant mousepox, for example, might also enable creation of vaccine resistant smallpox. The technique used to synthesize polio might enable artificial synthesis of smallpox (or other biological weapons agents).

Smallpox is one of the most feared biological weapons agents. Historically, smallpox has been one of humankind's worst enemies. It killed 300–500 million people during the twentieth century alone (Oldstone, 1998). The mousepox experiment is significant because there is no curative treatment for smallpox. Vaccine is our only defense against it. The polio experiment is significant because aspiring bioterrorists would not usually have easy access to smallpox – because all remaining samples of the virus are, officially anyway, supposed to be held in secure facilities (in the US and Russia). The potential ability to synthesize smallpox, therefore, might provide bioterrorists with access to an especially dangerous biological weapon agent that would otherwise have been unavailable to them.

In public controversy surrounding these two studies, critics complained that the research in question should not have been conducted and/or published (Selgelid, 2007). At the very least, according to many, the materials and methods sections of the published articles should have been omitted or altered. Publishing such studies in such detail, they claimed, provides aspiring bioterrorists with detailed "road maps," "blueprints," or "recipes" for the making of dangerous biological weapons.

Similar controversy has surrounded more recent research on influenza. In 2005, for example, American scientists synthesized the 1918 Spanish flu virus using techniques similar to those used in the polio study – and they likewise published their findings along with description of materials and methods (Tumpey et al., 2005). This study is significant because the virus in question was responsible for one of the worst epidemics in human history. The 1918 flu killed between 20 and 100 million people over the course of just a year or two (Crosby, 1989).

The most recent and, to date, most controversial dual-use experiments have involved research with the H5N1 avian influenza virus. In this case, researchers in the Netherlands and USA succeeded in creating strains of H5N1 that are "airborne transmissible" between ferrets, which provide the best model for influenza in humans. This is important because public health experts have long wondered whether H5N1 could possibly become transmissible between humans and thus potentially lead to a severe pandemic. The ferret research apparently yields an affirmative answer to this question.

Much debate has surrounded the question of whether or not detailed description of the materials and methods of this ferret flu research should be published. The researchers involved, and many others in the scientific community, have argued in favor of publication on the grounds that this may facilitate (1) development of vaccines against dangerous strains of H5N1 that may eventuate in the future and (2) surveillance and thus recognition of relevant changes occurring in H5N1 in nature (Enserink, 2011). The hope with regard to (2) is that this would provide

advanced warning if a pandemic strain is about to emerge and thus enable early implementation of preparatory public health measures.

On the other hand, these potential benefits of publication (of research details) might actually be quite limited. The idea that details regarding these particular studies need to be published in order to enable production of vaccines against naturally occurring transmissible H5N1 and/or to provide advanced warning that transmissible H5N1 is about to occur in nature seems to presuppose that when (and if) transmissible H5N1 evolves in nature, this will occur via the same genetic changes generated in the laboratory. But there are presumably any number of different ways via which transmissible H5N1 might evolve in nature (Selgelid, 2011). If this is correct, then developing vaccines against specific strains produced in the lab, or keeping an eye out for the natural emergence of strains similar to those produced in the lab, might not do much good.

With regard to the benefits of surveillance, meanwhile, an important lesson learnt from pandemic H1N1 (swine flu) is that there is not much that can be done to contain outbreaks of pandemic strains of influenza once they emerge. The point here is that even if publication of details of these studies allows somewhat earlier detection that a transmissible strain of H5N1 is emerging in nature, there might not be much that can (effectively) be done with this information to forestall or contain the epidemic/pandemic foreseen.

Appropriate vaccine production, of course, could be useful – but large-scale vaccine production takes months, while influenza spreads rapidly. The influenza virus is prone to a great deal of genetic mutation, and specific vaccines are needed to protect against specific strains of influenza. This is why different vaccines for seasonal influenza are offered each year and why it would be difficult to prepare vaccines against naturally occurring transmissible strains of influenza before such strains actually arise.

Even if benefits regarding vaccine development and/or surveillance are real, furthermore, they might be achieved without making details of these studies available to the general public. Those specifically involved in vaccine production and/or relevant surveillance, that is, could be informed about details of the ferret flu research on a need-to-know basis.

While the benefits of publishing full details about this research are thus arguably limited, the potential harms might be enormous. Though it is not transmissible between humans, ordinary H5N1 kills approximately 60 % of humans infected. While the airborne transmissible strains of H5N1 produced in the above-mentioned research were not deadly to ferrets, the ultimate worry is that the research in question could (eventually) lead to production of a strain of H5N1 that is transmissible among humans and as deadly as ordinary H5N1. Such a strain could cause enormous harm if intentionally released by bioterrorists or others bent on wreaking havoc. If such a virus were intentionally (or accidentally, for that matter) created and released, perhaps one-half of the world's population would become infected, and 60 % of those infected would die. Given the current world population of 6,800,000,000 people, roughly two billion human lives could be lost.

In December 2011, the US National Science Advisory Board for Biosecurity (NSABB) recommended that *the results* of the research in question be published, but that *detailed description of materials and methods* be omitted from the published articles. After a WHO meeting in February 2012 reached the opposite conclusion – recommending publication of the ferret flu research in full detail – the NSABB reversed its initial recommendation in March 2012. The articles in question were finally published, in full, in June 2012 (Herfst et al., 2012; Imai et al., 2012).

UNESCO Guidance?

Dual-use life science research poses ethical questions about what kinds of research should be conducted and/or published, and ethical questions about how the scientific enterprise should be governed. The following analysis considers the extent to which UNESCO's *Universal Declaration on Bioethics and Human Rights* (UDBHR) (2005) provides guidance regarding dilemmas posed by dual-use life science research.

UDBHR "Article 4 – Benefit and Harm" states that "In applying and advancing scientific knowledge, medical practice and associated technologies, direct and indirect benefits to patients, research participants and other affected individuals should be maximized and any possible harm to such individuals should be minimized." While this sounds like a sensible principle, it unfortunately provides little clear guidance about what should be done in cases where the very same research that might benefit society might also be used to cause harm. Consider the ferret flu research, for example. On the one hand, according to Article 4, it should have been conducted and published because this may be necessary to realize the potential (and arguably significant) benefits described above. On the other hand, according to Article 4, the requirement to minimize possible harms perhaps entails that it should not have been conducted and/or published. Rather than clarifying what should be done in the case of dual-use research, Article 4 highlights why it is commonly thought that dual-use research poses a dilemma in the first place. In the case of dual-use research, benefits come with risks, and so it is impossible to maximize the former and minimize the latter at the very same time.

Perhaps the point of Article 4 is that the overall benefits and risks of any given research project and/or publication should be evaluated, and that the project and/or publication should go forward if the benefits are likely to outweigh the risks, and that the project and/or publication should not go forward if the risks are likely to outweigh the benefits, all things considered. Again this sounds quite plausible. The problem, however, is that in the case of dual-use research it will often be difficult to predict what the ultimate long-term consequences of a research project and/or publication will turn out to be. The potential harms associated with dual-use research, for example, partly depend on the future actions of malevolent actors – but it will often not be easy and/or even possible to predict whether or not such

actors will actually misuse the research in question and/or what the ultimate consequences will be in the event that they do.

Application of Article 4 thus presumably requires appeal to other UDBHR principles. "Article 20 – Risk Assessment and Management" holds that "Appropriate assessment and adequate management of risk related to medicine, life sciences and associated technologies should be promoted." Determining whether or not the benefits of any given research project or publication (likely) outweigh the risks, or vice versa, thus requires good risk assessment. While this sounds correct, again, it might not get us very far. Among other things, risk assessment in the case of the ferret flu research, for example, would involve estimations of the likely motivations, abilities, intentions, and actions of potential malevolent actors (i.e., aspiring bioterrorists) and the consequences thereof. It would also involve estimations of the likelihood of naturally occurring H5N1 mutating into a pandemic strain that could be better controlled if the research in question is conducted and published and estimation of the benefits that would thereby be realized. Risk assessment, that is, should include assessment of the risks of not conducting and/or publishing the research in question as well as the risks of conducting and publishing such research. Even with the best risk assessment, however, all of these things are radically uncertain.

Even if it were possible to make good estimations of potential and/or likely risks and benefits of dual-use research and/or publication thereof, furthermore, deciding what should be done would require appeal to appropriate risk-taking strategies – but there is no general agreement about what these would/should be. UDBHR offers no guidance about this. Suppose that, on the best estimates from rigorous and well-informed risk assessment, it is determined that (1) there is a relatively good, say 10 % chance, that publication of ferret research details would end up saving 5,000,000 lives, but (2) there is a small, say 1 %, chance that publication would lead to bioterrorism that causes 500,000,000 deaths. Would Article 4 and Article 20 (together) then imply that publication should or should not occur?

While questions about the ethical acceptability of restricting or censoring especially dangerous research are paramount in debates about dual use, meanwhile, there are numerous statements in UDBHR that appear to favor scientific freedom and openness in the dissemination of scientific information. Its preamble states that "based on freedom of science and research, scientific and technological developments have been, and can be, of great benefit." Article 2 refers to "the importance of freedom of scientific research and the benefits derived from scientific and technological developments" and the aim "to promote … the greatest possible flow and the rapid sharing of knowledge concerning those developments and the sharing of benefits." Article 15 states that "Benefits resulting from any scientific research and its applications should be shared with society as a whole and within the international community … In giving effect to this principle, benefits may [include] … access to scientific and technical knowledge." Article 24 states that "States should foster international dissemination of scientific information and encourage the free flow and sharing of scientific and technical knowledge."

While these statements appear to be at odds with the idea of censoring dual-use research, it is unclear if they are meant to favor complete scientific freedom and openness in the sharing of scientific information without exception. It is likewise unclear how these statements can or should be squared with Article 4 (in cases where free sharing of scientific information might, or is likely to, pose serious risks and/or do more harm than good). Reason for doubting that absolute value should be placed on the free sharing of information is, in any case, provided by "Article 27 – Limitations of the Application of the Principles" which implies that "application of the principles of this Declaration" may be limited "by law, including laws in the interest of public safety … for the protection of public health or for the protection of the rights and freedoms of others." That it may be appropriate for governments to take (e.g., legislative) actions necessary to protect against dual use dangers, furthermore, is suggested by Article 21, which holds that "States should take appropriate measures, both at the national and international levels, to combat bioterrorism."

While much debate about dual use has questioned whether there should be top-down as opposed to – and/or in addition to – bottom-up governance of dual-use research (Miller & Selgelid, 2008), therefore, UDBHR is not clearly opposed to the former. In the case of bottom-up governance measures, "Article 23 – Bioethics Education, Training and Information" states that "In order to promote the principles set out in this Declaration and to achieve a better understanding of the ethical implications of scientific and technological developments … States should endeavour to foster bioethics education and training at all levels as well as to encourage information and knowledge dissemination programmes about bioethics." This call for increased bioethics education is well aligned with at least one area where consensus has emerged in debates about dual-use life science research. Most would agree that one thing needed to address the dangers of dual-use research is increased education of scientists about (bio)ethics in general, the dual-use phenomenon, ways in which their own research might be misused by malevolent actors, and requirements of the Biological and Toxins Weapons Convention (BTWC) (Rappert, 2010). Empirical research has shown that scientists often lack awareness of the dual use problem and the BTWC in particular (Dando & Rappert, 2005).

"Article 19 – Ethics Committees" is also highly relevant to dual use. It states that "Independent, multidisciplinary and pluralistic ethics committees should be established, promoted and supported at the appropriate level in order to … assess scientific and technological developments, formulate recommendations and contribute to the preparation of guidelines on issues within the scope of this Declaration." A popular idea in debates about dual use is that the role(s) of existing (ethics) committees should be expanded – and/or that new committees should be established – to scrutinize dual-use research (Miller & Selgelid, 2008). While it is common for existing committees to review research proposals regarding (laboratory or environmental) biosafety and human (and animal) subject protection, that is, an additional role for existing – or new – committees should arguably involve evaluation of dangers associated with potential malevolent use of the research (or publication) under consideration and evaluation of whether or not potential benefits

outweigh such dangers (National Research Council, 2004; WHO, 2010). While Article 19 is not explicit about this role in particular, committee fulfillment of such a role is in line with its spirit and that of UDBHR in general.

Conclusion

This chapter has illustrated dilemmas posed by dual-use research, focusing on recent studies regarding H5N1 transmission in particular. In this and other cases of dual-use research, controversy has surrounded questions about whether or not potentially dangerous scientific information should be published. These questions are not easy to answer because achievement of the benefits that might result from publication involves significant risks of harm – i.e., because malevolent actors might use the published information for nefarious purposes, bioterrorism being of particular concern. While UDBHR "Article 4 – Harms and Benefits" is especially relevant to dual-use research, it fails to provide clear guidance about how dual-use research should be governed. Though UDBHR emphasizes the importance of the free sharing of scientific information, some statements of UDBHR (at least implicitly) suggest that censorship might be called for in exceptional circumstances to prevent harms associated with bioterrorism. "Article 23 – Bioethics Education, Training and Information" and "Article 19 – Ethics Committees" are consistent with popular ideas that have emerged from debates about dual-use research – i.e., that, among other things, increased ethics education of scientists is needed, and there is a crucial role to be played by (ethics) committees in the review of research posing dual use dangers.

Given the ethical importance of dual use life science research, more explicit international policy and/or guidelines explicitly addressing dual-use research are wanted. Because both the potential benefits and potential risks of dual-use research affect global public health, a governance framework specific to dual-use research should ideally be developed by an international body – such as WHO or UNESCO. Because UDBHR was not specifically developed to address dual-use research in particular, its failure to provide clearer guidance about the dual-use problem is perhaps forgivable. (And though UDBHR provides unclear guidance about crucial matters – such as censorship – it does not clearly provide wrong guidance). In light of the potentially catastrophic consequences of dual-use research, on the other hand, the failure of WHO, UNESCO, or some other relevant international (e.g., UN) body to develop and implement an international policy framework specific to dual-use research would be unfortunate . . . and (depending upon what unfolds in the future) possibly tragic.

Fiachra O'Brolcháin and Bert Gordijn

Introduction

Although we now face issues that are global in scale, much of our moral thinking (as well as political action) is concerned with local issues, both temporally and geographically. This can be most clearly observed in the response to the environmental problems we face. The effects of environmental degradation and global warming are becoming apparent (United Nations Environment Programme, 2011), and will affect future generations, particularly in terms of interests such as subsistence. The effects are currently most keenly felt in the "developing world," where many struggle to gain access to sufficient food and to clean water (United Nations Development Programme, 2011). Future generations will have to cope with greater degrees of global warming, further environmental degradation, and presumably fewer resources than we now have (in order to cater for a larger population). These harms are caused by the actions of current generations, but will be felt by future generations through no fault of their own. Despite widespread awareness of these harms, it has been difficult to make the changes necessary to mitigate or prevent them. Expanding the moral circle to take into account all the people of the globe as well as future generations is proving to be a difficult task. The response to the environmental crisis illustrates current problems in addressing new dilemmas that are global in scope and that will affect the lives of future generations.

Against this background of emerging problems concerning global inequality and harms and costs for future generations, this chapter addresses the question of the ethical desirability of the further development of human enhancement technologies (HETs). HETs hold out the promise of improving the lives of those who can access them. However, their widespread adoption might have major implications beyond individual quality of life, affecting the social, economic, and demographic structure of society. They might increase existing inequalities, thus exacerbating harms associated with inequalities (such as crime and social unrest) and potentially undermining people's right to a life of dignity. Thus, the decisions we make now

regarding HET might affect future generations considerably. We first discuss the concepts of HET, equality of dignity, and rights and protection of future generations. Next, we briefly address the relevance of UNESCO's Universal Declaration on Bioethics and Human Rights, which we use as a normative instrument for our analysis. Then we present the cases against and in favor of HET. Finally, we will discuss both positions and explore whether there is a middle-way to be found between them.

HET, Equality of Dignity, and Rights and Protection of Future Generations

The term "HET" covers a wide variety of technologies, many of which are already in existence, ranging from brain-computer interfaces, genetic interventions,[1] cosmetic surgery to neuropharmaceuticals.[2] Many of these are medical in origin, but may have applications attractive to those with no therapeutic needs, as is the case with much cosmetic surgery. We define enhancement as "the directed use of biotechnical power to alter, by direct intervention, not disease processes but the 'normal' workings of the human body and psyche, to augment and improve their native capacities and performances" (The President's Council on Bioethics, 2003: 16). In the future, HET might perhaps prolong people's maximum life span; make them fitter, stronger, and more resistant to diseases; allow them to determine their own moods; and improve their cognitive abilities.

HETs have the potential to have an effect on inequality, although whether they are likely to increase or decrease inequality is the subject of much debate. Inequalities in health, in the global disease burden, and in the distribution of wealth are major global issues. The continuing existence of severe global poverty is one instance of inequality that is of immense moral concern. The extent of global inequality is noteworthy: according to Thomas Pogge (2008: 104–5), "high income countries" with 15.7 % of the global population possess 79 % of aggregate global income, while the bottom 15 % survives on 0.2 % of the global product. The lives of many of those living in severe poverty may, in many cases, result in a breach of the fundamental equality of all human beings in dignity, if not in rights (UNESCO, Article, 10). A person may formally have the rights to life and to work, but circumstances (such as famine or severe poverty) may result in them being unable to live a life of dignity, particularly if human dignity is considered as intertwined with a life of human flourishing as Martha Nussbaum (2006) suggests. Thus, while someone may have the right to many things, circumstances, such as severe poverty,

[1]Somatic genetic interventions have been performed on human beings in clinical trials since 1989. They only affect the individual. In contrast germ-line genetic interventions have not been performed on human beings yet. They would result in alterations that could enter the gene-pool by being passed on from one generation to the next.

[2]Neuropharmaceuticals are drugs that affect neurological functioning. As such, they might enhance mood as well as cognition.

may render this right hollow and have a negative impact on their dignity. The UNESCO declaration (adopted by 193 nations) commits nations to at least addressing issues of equality of dignity and rights.

Much philosophical interest has recently focused on future generations. Many of these questions concern the obligations current generations have towards future generations and the implications that these obligations have in terms of distributive justice. Areas of concern surround the pursuit of policies that accrue benefits for current generations but impose costs for future generations. Our current actions can result in harms for future generations through the creation of conditions that will make their lives more difficult. For instance, our ineffective efforts to cut emissions of global greenhouse gases mean that future generations will have to bear the brunt of climate change, triggering intricate questions of intergenerational justice (Gordijn and Ten Have, 2012). More generally, our use of natural resources will affect what resources will be available to future generations, and our response to poverty will affect the societies into which future generations will be born. In the case of HET specifically, certain types of HET have the capacity to radically alter the genome of future generations; thus, we might affect what sort of future generations exist along with impacting on the conditions in which they exist. Although there is an academic debate regarding whether or not we can have any obligations towards future generations, by adopting the UNESCO declaration, nations have committed themselves to protecting them.[3]

UNESCO Universal Declaration on Bioethics and Human Rights

In 2005, UNESCO adopted by general acclamation the *Universal Declaration on Bioethics and Human Rights*. Its aim is to provide a universal framework of principles and procedures to guide states in formulating their legislation and policies in the field of bioethics. This Declaration is an important global regulatory framework that commits UNESCO members to upholding its principles in relation to bioethical issues. As such, it provides a touchstone for ethical debates on HET, an agreed-upon basis, and starting point for thinking about the topics.

The UNESCO Universal Declaration on Bioethics and Human Rights aims (amongst other things) "to promote equitable access to medical, scientific and technological developments, as well as the greatest possible flow and the rapid sharing of knowledge concerning those developments and the sharing of benefits, with particular attention to the needs of developing countries" Article 2 (f); emphasizes the "fundamental equality of all human beings in dignity and rights" so that "they are treated justly and equitably" (Article 10), and stresses the importance of human dignity and human rights (Article 3). Moreover, it also

[3]There is debate regarding whether future generations can, given that they do exist yet, be the bearers of rights. Given that the UNESCO Declaration is being used a normative guide in the chapter, we accept the view that obligations to future generations exist.

acknowledges that due regard must be given both to protecting future generations (Article 16) and to protecting the environment, the biosphere, and biodiversity (Article 17). However, the commitment to respecting human dignity and rights is of central importance to the Declaration. The list of principles is bookended by statements stressing the centrality of protecting human rights, basic freedoms, and human dignity. As such, it is reasonable to interpret the Declaration as viewing the latter as preeminent.

The Case Against Enhancement

While HET seem to have many attractions, their development poses significant threats as well. We will outline three reasons for objecting to the development of HET. The first worry regarding HET is that they could be mainly available to only a small and affluent percentage of the global population. Thus, those who already control the majority of the world's wealth might gain further advantages (i.e., increased intelligence, looks, lifespan, disease-resistance) as a result of HET. Secondly, some authors advance the concern that HET might harm future generations both indirectly and directly. Thirdly, there is the argument that the project of pursuing enhancement represents a type of Promethean hyperagency, that the development of enhancement technologies is an example of a hubristic desire for mastery over nature that leads to the loss of openness to the unbidden.

Increasing Inequity and Injustice

One of the most common objections to the use of HET is that they might aggravate existing inequalities. Enhancements might confer relative advantages on the enhanced in relation to the unenhanced. HET might provide the rich with the opportunity to ensure that their children, as well as having educational and health-care advantages, will also be better looking, less prone to disease, and more intelligent. Enhancements such as neuropharmaceuticals, smart-clothes, and brain-implants might in the long term be available to everyone, but initially the cost would most likely be prohibitive. In this scenario then, people who could afford, and were willing, to use these enhancements would gain a significant advantage over those who are unable to afford the same. Certainly, someone who has constant and instant access to the online world, an enhanced memory, or a greater capacity for concentration and information-processing will have many advantages over those without. If these enhancements are expensive, the advantages offered by them will fall to the wealthy. In such societies, upward social mobility would be far more difficult as people's positions would be fixed by their access to enhancements, thus creating a greater impediment to social mobility than currently exists. When the best-paid and/or most satisfying jobs require people to be above a specific cognitive threshold or to possess certain physical and/or mental abilities and skills, those with enhancements would have the advantage. Furthermore,

the development of these technologies is likely to require great technical, scientific, and medical expertise, most likely to stem from companies operating in wealthy markets or from wealthy government-funded research and health-care systems. As such, these technologies and enhancements are unlikely to be readily available for the majority of people who live in the developing world.

When successfully using germ-line genetic interventions for enhancement purposes, it will in principle even be possible that new "posthuman" species will emerge, raising fears that an unbridgeable inequality might arise. In such a scenario, people might still have moral equality and formal equality of opportunity but enhancement inequalities would mean that these rights are hollow. The poor will, as Peter Singer (2009) notes, be stuck with the genetic lottery and will fall further and further behind. Being without enhancements, they would have little chance to gain important positions and thus little chance to escape from relative poverty. A vicious circle of poverty would then be created.

Globally, an enhancement divide would become apparent between nations. Affluent nations will have far greater access to HET than all but a very small minority in the developing world. The consequence is that the existing medical divide will become even more pronounced. Currently, the global health divide is already striking – with many affluent countries having a life-expectancy in the seventies, compared to under-forties for some countries in sub-Saharan Africa (Marmot, Friel, Bell, Houweling, and Taylor, 2008; Pogge, 2008). The development of HET has the potential to further increase divides in living standards, life-expectancy, and wealth. With enhancements, the populations of the affluent parts of the world will be better able to protect their positions should they want to. They will be better able to set the terms of trade and the distribution of resources in their favor.

Harms to Future Generations

Indirect harm: The inequalities discussed above can be considered indirect harms for future generations. Less equal societies have a greater overall burden of health and social problems. For instance, income inequality has negative societal effects: health and social problems such as violence, mental illness, and educational failure are more common amongst the poor in any given society than they are amongst the rich. Although there is a debate over whether future people can be harmed (given that their existence is dependent on us and the policies we choose), we can say that they are wronged if we choose a policy that will harm them. If we accept that inequalities cause harms, choosing policies that will exacerbate inequalities is causing harm or at least failing to prevent harm. Future people will be born into inequitable conditions not of their choosing and will suffer the harms arising from inequalities. Insofar as HET increase societal inequalities, they will be a source of indirect harm for future generations. If HETs make inequalities more difficult to overcome, they will increase societal ills. If access to newer HET is mainly the preserve of the wealthy, their use of HET such as smart-drugs, brain-computer interfaces, and mood enhancers is likely to ensure their continued dominance. In the

most extreme scenario, raised by Peter Singer (2009), germ-line engineering might see social and economic privileges become biologically embedded, as the rich genetically alter their children to ensure their benefits. Such inequalities would be even more difficult to overcome than inequalities arising from lack of education, poverty, or lack of access to technology. If HET makes future societies more unequal, future generations can be said to be harmed by our choice to adopt HET. We are either (1) causing indirect harm to future generations by using HET in the knowledge that they will increase inequalities and thus negatively affect the lives of future generations; (2) failing to prevent indirect harms to future generations by allowing the use of HET to increase inequality; or (3) failing to benefit future generations by allowing the use of HET to increase inequality.

Direct harm: There are some fears regarding direct harms to future generations arising as a result of enhancements. For instance, germ-line genetic "enhancements," like any technological development, have the potential to create unforeseen problems for future generations. Alterations to the germ-lines of future generations could, given that the human genome is a complex product of evolution, backfire in numerous ways. For instance, an enhancement that increases memory-capacity may, due to the complexity of the neuropsychological processes at work, have a negative impact on mood, or an enhancement that reduces racism by reducing the biologically encoded aversions to other races risks reducing positive moral emotions (such as aversions to morally repugnant things) on the same continuum. Moreover, genetic interventions that are currently perceived as advantages might prove disadvantageous in future contexts vastly different from contemporary ones. Similarly removing perceived genetic disadvantages might leave us (as a species) vulnerable in unanticipated ways. For instance, the removal of a trait perceived as "undesirable" might for generations appear innocuous, but may leave future people vulnerable to the emergence of new pathogens.

Loss of Openness to the Unbidden

The quest to develop HET is characterized by Michael Sandel (2007) as being a Promethean project. Not only does Sandel highlight the problems that HET will pose to individual autonomy and equality, but he also asks questions from a perspective outside the usual liberal framework, referring to the moral status of nature and the proper stance of humanity towards the given world. He argues that pursuing enhancement represents a type of hyperagency, an example of our impulse to master nature, including human nature, so that it will serve our purposes and satisfy our desires. Sandel argues that increasing our mastery over nature, including our own natures, will transform three features of the moral landscape – humility, responsibility, and solidarity (2007, 86). He contends that in a world which prizes mastery, for example, the ability to specify the sex and genetic traits of children, people's openness to the unbidden (particularly in the case of parenting), a key source of humility, would diminish. He continues that the social basis of humility would also be diminished, as people would no longer have the restraining knowledge that their talents and abilities are due in part to luck. This in turn would lead to an explosion of responsibility, as now parents would be responsible

for more choices regarding the lives of their children – they would be responsible for choosing traits and for failing to choose traits. Domains once governed by "fate" or luck would now be arenas of choice and therefore responsibility. Sandel suggests that this would reduce social solidarity, as people would be less alive to the fortuitous nature of their lot, and thus have less reason to share their fate with those less fortunate. Ultimately, he implies that the project of mastery epitomized by HET will distract humanity from reflecting critically on the world and deaden the impulse to social and political improvement (Sandel, 2007).

The Case for Enhancement

We will outline three reasons in favor of the further development of HET. The first states that individuals should have the right to use new scientific technologies to improve their lives. A second argument advanced by proponents is that HET can make people healthier, happier, longer-lived, more intelligent, and physically stronger. In addition, it is argued that moral enhancement might play a significant role in motivating societies to reduce inequality and environmental degradation.

Rights

There exists a presumptive case stating that people have a right to use enhancements to improve their own lives so long as their use of enhancements causes no harms to other people. The assumption is that people should be allowed to make certain choices (regarding reproduction or their own bodies) according to their own values irrespective of the values of society, so long as they harm no others. Emphasizing negative rights (entitlements to non-interference), proponents of HET often appeal to rights in arguing that HET should be developed. Advocates such as Nick Bostrom (2003) (Bostrom and Roache, 2007, 2009) and Julian Savulescu (2007, 2009) contend that enhancement technologies should be made widely available and that individuals should have the choice over whether and which enhancements to apply to themselves and furthermore that parents should have the right to select enhancements for their children. They argue that enhancements offer great potential for valuable and beneficial human uses, such as increased longevity, healthier lives, greater cognitive capacities, and the opportunities to control emotions. So long as there is adequate information available, public debate, and education, there is no reason to forbid people from using enhancements. Furthermore, it is held that the right to use enhancement technologies is connected with rights to bodily autonomy, reproductive freedom, and free expression. The concept of autonomy suggests that so long as a person is not harming others, they are within their rights to alter their body as they see fit, for example, to implant a brain-computer interface or to take mood enhancers. From this perspective, to ban people from using enhancements would be a violation of their autonomy, liberty, or reproductive freedom.

Improvement and Beneficence

In addition, a consequentialist reason is advanced in favor of use of HET. Proponents claim that there are many ways in which enhancements can improve people's lives. After all, it would be better if people were healthier, happier, longer-lived, more intelligent, and physically stronger. Therefore, if biomedical enhancements can achieve this, there exists a powerful incentive to develop these interventions. The widespread use of cognitive enhancements may also enable greater scientific breakthroughs, or enhance people's abilities to work and to appreciate their lives. Mood enhancements could be used to ensure that people are, invariably, happy or content. Utilitarians aim to maximally promote well-being. From this perspective, therefore, insofar as enhancements can contribute to an overall increase in well-being, they should be pursued.

This consequentialist line of reasoning has been taken further so that some proponents of HET contend that there is in fact an obligation to enhance future generations. The obligation to enhance is based on two underlying obligations: the obligation to do good (beneficence) and the obligation not to do harm (non-malfeasance). The obligation not to cause harm can be characterized in both a positive and a negative fashion. The positive obligation not to cause harm means that we must not deliberately act in a manner that will produce harms; the negative argument states that we must not stand by or fail to act if doing so will result in avoidable harms. Thus, if enhancements are available and provide the opportunity to prevent avoidable harms or to do good, there is an obligation to use them. For example, Savulescu and Kahane (2009) argue in favor of the "principle of procreative beneficence," which suggests that couples who decide to have a child have an obligation to select the child who, given her genetic endowment, can be expected to have the most well-being. Similarly, Harris (2007) argues that there is a moral obligation to use enhancements if we are concerned with human welfare.

Moral Enhancement

Despite huge technological progress, our moral progress does not seem to have kept pace. We are willing to live in a world rife with the most horrendous inequalities. Even in the face of climate changes that will affect everyone, including the wealthy, we appear unwilling to accept decreases in our standard of living for the sake of future generations. However, some advocates of HET suggest a new technology-based solution. In recent discussions of HET, the issue of moral enhancement has become prominent. The idea of "moral enhancement" connects ethics with HET by aiming to improve our moral capacities via biological alterations. The assumption is that there is a biological basis for our moral inclinations. Moral enhancements do not yet exist but, in theory, they might be possible. Tom Douglas (2008) argues that due to our increased understanding of the biological and neurological underpinnings of emotions, enhancements could be used to attenuate "counter-moral" emotions, such as aggression and racism. Douglas (2011) expresses the hope that

morally enhanced individuals would be less prejudiced, pollute less, and care more about the environment and global poverty. Moral enhancements are also said to promise to increase our motivations to act morally. For instance, Persson and Savulescu (2008) contend that our moral dispositions are biological and that their core consists of altruism and of dispositions stemming from the "tit-for-tat" patterns of reciprocal behavior. These patterns give rise to our sense of justice and fairness, to gratitude, anger, remorse, and forgiveness. They argue that moral enhancement would consist in the strengthening of our altruism and in making us more just and fair. Furthermore, Savulescu and Persson argue that in order to eliminate the risks of cognitive enhancements being used for ultimately malevolent ends, it is imperative that moral enhancements are developed.

Therefore, assuming that what is rightly and rationally desired is a just and sustainable world, which is currently some distance away, then moral enhancements might be a way to achieve these goals, if they could indeed be used to make people less greedy, less aggressive, and less competitive. Enhancements could then arguably also be developed to ensure that we have more concern for future generations. Moral enhancements might make people more concerned with the plight of the impoverished and more concerned with environmental degradation. The UNESCO Declaration emphasizes (Article 15) that solidarity amongst human beings is to be encouraged. Article 17 stresses the protection of the environment, the biosphere, and biodiversity. Much of the damage being done to the biosphere and the environment is due to the appetites of those in affluent nations, who crave entertainments, cheap travel, and cheap food. The prospect of people who cared more about global poverty and the environment and who were less prone to violence, prejudice, and racism is certainly an intriguing one.

Discussion

Review of the Case against Enhancement

Increasing Inequity and Injustice

As discussed above, HETs have the potential to increase inequalities. The advantages conferred by HET imply relative disadvantages for those who lack access. These disadvantages might be seen in employment opportunities, in education, in sport, in economic opportunities, and in general social life. If the use of HET becomes widespread, those without will be relatively impoverished. This is likely to reduce their ability to participate in their societies, and may impinge on their access to healthcare, education, and political life. Let us call this the *exclusion argument*. Such exclusion risks creating social unrest and discontent.

The necessity of competing for jobs and societal positions may result in people finding themselves forced into enhancement arms-races in order to compete. People may find themselves willing to sacrifice significant goods in order to pursue HET. Let us call this the *arms-race argument*. The existence of enhancements will increase the pressure on those at the bottom of society, who are often struggling

with bills (in the developed world) or with hunger (in many parts of the rest of the world). In many places, education and healthcare are unavailable. People make enormous sacrifices in order to feed their families or children. The widespread adoption of HET would result in yet another rung on the ladder to achieving a life of human dignity. Thus, people may feel pressurized into working longer hours in worse conditions or into taking great risks in order to gain parity.

However, those with enhancements might also come to resent the existence of these inequalities. Let us call this the *resentment argument*. From the perspective of people with enhancements, those without enhancements could be seen as imposing unfair costs the society. A refusal to select the best possible embryo, or to otherwise enhance children, or to use enhancements to improve one's performance in sports, exams, or socializing might become socially unacceptable. The claims of the unenhanced on the resources of any society might come to be resented by those with enhancements as the choice to remain unenhanced will impose costs that must be borne by the rest of the society. Questions will arise as to whether those who have chosen not to obtain enhancements are entitled to extra resources to compensate them for certain losses (i.e., loss of earnings). Those without enhancements might require more healthcare, or extra-tuition. In such a scenario, it is plausible that the enhanced might begin to question the rights of the unenhanced to remain unenhanced or to have unenhanced children. Thus, it is possible that future debate will not concern the right to use enhancements, but the right not to use them.

One might respond that enhancements will trickle down and eventually be available to everyone, as Harris (2007) has asserted. While this argument appears plausible, it does not counter fears of inequality, as those at the top would continue to have access to newer and better HET. If HET continues to develop at a great pace, and the newest developments continue to provide great benefits, inequalities will continue to exist. The trickle-down argument makes a good case against any sort of moratorium on the development of HET due to inequalities, but does not address the fundamental problem of inequalities arising from HET.

The issues of inequality arising from HET will most likely be addressed by individual states according to the principles of distribution that they consider fair and just. This still leaves the issue of inequality between states to be confronted. The UNESCO Declaration on Bioethics and Human Rights is addressed to States (Universal Declaration, Article 1.2) and so does not explicitly address the issue of inequalities between states. However, the preamble to the declaration explicitly recognizes that decisions regarding ethical issues in medicine, the life sciences, and associated technologies may have an impact on individuals and humankind as a whole and also that new approaches to social responsibility should ensure that progress in science and technology contributes to justice, equity, and the interest of humanity. As such, the potential for harmful inequalities arising from HET to exist between states and peoples ought to be an area of concern.

The threats posed by HET of exacerbating inequalities are compelling and must be addressed. Current inequalities resulting from HET are trivial in comparison with inequalities in the global disease burden, for example, but the strange and (at times) troubling futures suggested by HET force us to look afresh at the

problems of inequality. The potential of HET to exacerbate existing inequalities suggests not that we abandon the development of HET (as they are only one form of inequality) but that we have an urgent need to address both national and international inequalities.

Harms to Future Generations

Indirect harm: Future societies will face significant ethical and political debates regarding the maintenance of equality in such societies. The enhanced might resent paying taxes for health and educational goals that, due to enhancements, they and their children no longer require, while the unenhanced will most likely resent their inability to compete with the enhanced. It is even conceivable that the right to remain unenhanced will be attacked, as to remain unenhanced may be viewed as socially irresponsible. Moreover, when it comes to things such as genetic enhancements, the unenhanced cannot be held responsible for the decisions of their forebears. Widespread use of enhancements risks entrenching extant inequalities if their adoption benefits the wealthy disproportionately.

As such, we have an obligation to be extremely careful with the development and distribution of HET. Our actions will affect levels of inequality that future generations, through no fault of their own, must confront. Given that inequalities cause indirect harms, it is incumbent on current generations to ensure that new technological developments do not contribute to these indirect harms. Stringent rules and regulations will be required to safeguard people's rights and to ensure that harmony exists between the enhanced and the unenhanced. Consequently, a laissez-faire approach to the development and distribution of HET appears problematic.

Direct harm: As discussed above, one of the main objections to the use of HET is that they will result in direct harms to those who use them as well as to future generations. It could be said that, by definition, something that causes harms could not be an enhancement, but this is not the approach we will take. Firstly, some technologies may be enhancements in certain contexts and harmful in others. Secondly, some technologies might enhance mood, cognition, or physical strength (for example) but have harmful side effects or long-term effects.
