Metallocene polymers, ranging from crystalline to elastomeric, have been commercialized since the early 1990s. They show increased impact strength and toughness, better melt characteristics because of the control over molecular structure, and improved film clarity. Most early applications have been in specialty markets where value-added and higher-priced polymers may compete.

In the USA Exxon Chemical and Dow Plastics were the leaders in the metallocene technology. While Exxon explored both mono- and bis-cyclopentadienyl metallocenes, Dow focused on "constrained geometry catalysts" based on Ti-monocyclopentadienyl metallocenes. Exxon first produced metallocene-based polymers with its *Exxpol* catalysts in 1991. Dow uses its *INSITE* technology to make ethylene–octene copolymers, introduced in 1993. Copolymers with up to 20 wt% octene are sold as *AFFINITY* "plastomers," competing with specialty polymers in packaging, medical devices, and other applications. Dow, producing its own catalyst, considers that it leads to the uniform introduction of comonomers and long-chain branches that improve processability of otherwise linear polymers.

In 1995, Exxon received a patent and conducted successful test runs of a new m-LLDPE technology using the super-condensed mode (SCM) process, which allows for the operation of gas-phase reactors with higher levels of liquids, increasing plant productivity by 60–200 % at half of the plant cost (Univation Technologies 2008; Sirohi and Ramanathan 1998). There have been other engineering developments where loop reactors or multi-reactors have been used in sequence for the production of copolymers with desired composition and performance. These technologies eventually resulted in the production of multilayered PE particles, which resemble the earlier acrylic resins produced in emulsion or suspension processes and broadly used as compatibilizers in a variety of polymer blends (Utracki 1997a, b). Thus, it is of no surprise that the number of patents in PE technology is large (Dow has been issued over 100 US patents related to *INSITE* technology, NOVA Chem. 120 CA patents, etc.) and litigations provide a rich feeding ground.

18.3.4 Post-metallocene Catalysis

The beginning of the post-metallocene catalysis dates back to 1997; the new catalysts most often have imine instead of Cp ligand. They are characterized by high activity, possibility of adjusting polymer MW and MWD, as well as copolymerization of olefins with polar monomeric and macromeric species. A wide spectrum of catalysts based on light and heavy transition metals were patented and published in open literature. There are also several types of catalysts with intermediate structure – pseudo metallocene with a post-metallocene imine ligand. More recent post-metallocene catalysts use M-complexes (Sc, La) and ligands containing O, N, P, and S activated by MAO. Pd(II) and Ni(II) R-diimine catalysts (DuPont's Versipol™) are also used for copolymerization of C_2 with a variety of

functionalized olefins. Notably, they do not need a co-catalyst/activator (Brookhart et al. 1983, 2007).

During the last 10 years, Mitsui Chem. has been developing new, single-site, post-metallocene catalysts capable of modifying polymer molecular structure. Large enhancement of catalyst activity was found for Zr salts complexed with two phenoxyimine ligands (Mitsui and Fujita 2001). The authors showed that under mild polymerization conditions, certain salicylaldimine complexes of M Group IV lead to higher activity than that of metallocenes (Makio et al. 2002, 2011). The highest activity exhibited by a Zr-FI catalyst reached a catalyst turnover frequency (TOF) of 64,900 s^{-1} atm^{-1}, thus two orders of magnitude greater than that seen with Cp_2ZrCl_2 under the same conditions. At 50 °C, the Ti-based FI catalysts with fluorinated ligands produce, at high-rate, living, monodispersed, high MWPEs ($M_w/M_n < 1.2$, $M_n > 400$ kg mol^{-1}). The maximum TOF, 24,500 min^{-1} atm^{-1}, is three orders of magnitude greater than those for known living ethylene polymerization catalysts. The versatility of the FI catalysts leads to new polymers which are difficult or impossible to prepare using the metallocene technology. For example, it is possible to prepare low-molecular-weight ($M_v \sim 1$ kg mol^{-1}) PE or EPR with olefinic end groups, UHMWPE or EPR, high-molecular-weight poly(1-hexene) with atactic structures including frequent regions of monodispersed poly(ethylene-*co*-propylene) with various propylene contents, and a number of polyolefin block copolymers [e.g., polyethylene-*b*-poly(ethylene-*co*-propylene), syndio-polypropylene-*b*-poly(ethylene-*co*-propylene), polyethylene-*b*-poly(ethylene-*co*-propylene)-*b*-syndio-polypropylene].

One of the numerous advantages of the FI catalysis is its capability for producing nearly monodispersed, low-MWPE with a variety of functional end groups (Sainath et al. 2009), which may be converted into a salt and oxidized into an epoxy or an amino-terminated group (Matoishi et al. 2011). However, so far there is little commercial interest for these new materials. On the one hand, this may originate in the continuously growing number of new catalysts that have higher productivity and versatility but on another caused by inadequate thermal stability of the system and the current global economic problems (Ittel et al. 2000).

18.4 Characterization of Polyethylenes (PEs)

18.4.1 Standard Test Methods

As with any other polymer, PE needs to be tested using standard methods, tailored to the needs, viz., determination of MW, chemical structure; morphology; and thermal, mechanical, and dielectric properties. During a century of testing, the methods and equipment have been developed, which although expensive make the task relatively simple. For example, MW is determined using the size exclusion chromatography (SEC, previously known as gel permeation chromatography, GPC; Striegel 2004), the chemical analysis is performed using a Fourier transform infrared spectroscopy (FT-IR), and stereospecificity of macromolecule by the

nuclear magnetic resonance (NMR) in a number of its versions, e.g., using ^{1}H or ^{13}C NMR, determining dyads (r, m), triads (mm, rm + mr, rr), and/or higher order n-ads. The other methods include X-ray powder diffraction (XRD) and secondary ion mass spectrometry (SIMS).

These standard tests are used for PE, but mostly these are part of special procedures capable of distinguishing a wide variety of polymer and copolymer structures unknown in other polymers.

18.4.2 Specific Methods of PE Characterization

There are several levels of macromolecular structures belonging to:
- Configuration, the intrinsic structure that cannot be changed without breaking a bond
- Conformation, imposed by stress, σ; strain, γ; pressure, P; or temperature, T
- Micromorphology discussed in terms of submicron-sized crystalline unit cells
    Thus, macromolecular **Configuration** belongs to the sub-nanometer structures such as:
- Chain tacticity of tertiary carbon macromolecules
- Head-to-head, head-to-tail, and tail-to-tail configuration in polyvinyls
- *Trans* (the planar zigzag) versus *gauche* ($\alpha = 120°$) configuration
- *Cis* and *trans* isomerism and 1,2- versus 1,4-addition of dienes
- Branching (short and long)
- Copolymerization (short sequence: *co*, *stat*, *ran*, *alt*; long sequence: block, graft, star, star-block; networks: *cross*, *inter*, etc.)
- Ladder, planar, dendromeric, and other macromolecular structures
- Isomerism that can be changed only by bond breakage
    Conformation (*scale* 1–30 nm) – kinetic arrangements of chain elements in space, engendered by rotation about bonds, e.g., from *trans* to *gauche* position or vice versa, e.g., random coils, helices, and folded chains. Conformation depends on internal and external forces, e.g., interactions, σ, γ, P, and T, as well as on the route used for its creation (thermodynamically nonequilibrium structures).

Micromorphology (*submicron* scale) is related to vitrification and crystallinity, viz., crystalline unit cell shape and size; lamellae type, shape, and size; and stress-induced shish-kebab crystals. Dramatic changes of micromorphology may be introduced by gel spinning of UHMWPE [*Dyneema*® (DSM); *Spectra*® (Honeywell)] or UHMWPP [Innegra®, Innegra Technologies] high-performance fabrics used in ballistic composite applications.

As discussed above, the diverse polymerization methods primarily affect **configuration**. One needs to know how changes in catalyst, monomer composition, or reaction variables affect the intrinsic nature of the macromolecules, thus the final performance of the resin.

18.4.2.1 Temperature Rising Elution Fractionation, TREF
Invented in the late 1970s the TREF is a method for fractionating semicrystalline polymers from solution according to composition and microstructure. In TREF the

polymer is dissolved at elevated temperature and then slowly cooled to crystallize on regular-shaped column support. In the following step, the sample is eluted by fresh solvent at successively rising temperature intervals, collecting and analyzing the fractions, which then are injected into a SEC determining MW and MWD of each slice of the PE melting point. Initially, the homebuilt instruments and experimental procedures varied from one laboratory to the next, but since the late 1990s the commercial systems are available (Wild 1990). TREF is usually classified as preparative and analytical (respectively, p-TREF and a-TREF) (Wijga et al. 1960).

Preparative Temperature Rising Elution Fractionation, p-TREF

In the **p-TREF** mode, ca. 1–5 g of polymer is dissolved and loaded onto column packing (e.g., 1.4 kg of sea sand), then cooled to room temperature (RT). Next, the crystallized polymer is eluted at successively higher T. For example, extraction over $T = 30\text{--}150\,^\circ\text{C}$ divided into 10–15 T-steps (Shirayama et al. 1965). After these preliminary tests a large-scale, robust, and continuous system was developed for unsupervised operation (Wild et al. 1971, 1982). The instrument consisted of a stainless steel column L/D = 0.60/0.12 m packed with Chromosorb-P support onto which 4 g of polymer was crystallized by slow cooling (2 K h^{-1}) from a hot xylene solution in a T-programmed oil bath. A variety of PEs followed a linear dependence between the elution T and the degree of SCB (Usami et al. 1986; Kelusky et al. 1987). Hazlitt and Moldovan (1989) described an automated TREF system capable of a semi-preparative fractionation of 0.5 g of LLDPE. The cooling rate of 2.5 K h^{-1} was used and the column was packed with steel shot (0.57 × 0.57 mm) for improved heat transfer.

Ramachandran et al. (2011) measured the structure and branch content of LLDPE using a small-angle neutron scattering (SANS). The scaling approach quantified SCB and LCB content in polymers concurrently, thereby illustrating the distribution of these branches within the fractions. Additionally, new quantities such as the average LCB length and hyperbranch content were measured providing further insight into the structure. LLDPE used in this study was fractionated using p-TREF. For commercial LLDPE these results evidenced LCB, which could be attributed to post-reaction processes. TREF has been particularly useful in analyzing Z-N–LLDPE, recovering 98 % of the eluted polymer. The main advantage of p-TREF is that it provides also samples for external analysis, by DSC, IR, SEC, ^{13}C NMR, SANS, etc.

Analytical Temperature Rising Elution Fractionation, a-TREF

The **a-TREF** was developed later than p-TREF with instrumentation "borrowed" from SEC. However, because of the nature of fractionation in TREF, the sample preparation is different and some device is needed for controlling the cooling and heating cycles. Furthermore, a calibration is needed for the plot of the elution T versus SCB, which requires different standards than those used for SEC calibration.

Wild and Ryle (1977) described a-TREF that used solvent reservoir, degasser, pump, and detectors (e.g., refractive index, RI). PE was crystallized by slow cooling a solution of 0.2 g in 5 mL TCB on Chromosorb-P packing. TREF was performed at

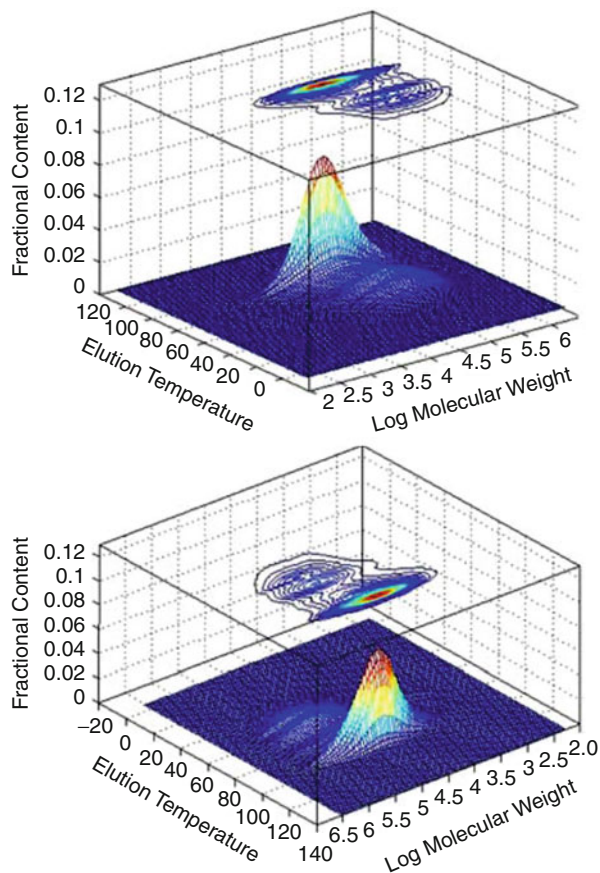
a flow rate of 6 mL min^{-1} and a rate of *T*-rise of 8 K h^{-1}. The RI response and the separation *T* were recorded continuously. A calibration curve of methyl content versus elution *T* was obtained using p-TREF fractions of LDPE and LLDPE. This information was transformed into comonomer content (e.g., mol% of C$_8$) versus elution time; as shown in Fig. 18.4, the semilogarithmic plot is linear. Over the years TREF system was refined by reducing the column and sample size, the *T*-programmed gas chromatography oven was replaced with an oil bath, and the detector was also replaced by multiple ones (e.g., FTIR and ^{13}C NMR, while polymer concentration was measured by IR) with better sensitivity and baseline stability (Knobeloch and Wild 1984).

Not only PEs but also their blends have been successfully analyzed (e.g., LDPE with LLDPE dissolved in α-chloronaphthalene) (Kelusky et al. 1987).

TREF/SEC (GPC)

During the 1980s a-TREF/SEC evolved into an integrated system, where p-TREF provided fractions for a wide range of subsequent testing, e.g., SEC, ^{13}C-NMR, XRD, DSC, solution viscosity, and FT-IR (Nakano and Goto 1981; Hazlitt and Moldovan 1989). For example, Usami et al. (1986) studied the mechanism of SCB distribution (SCBD) in LLDPEs, using TREF, SEC, ^{13}C-NMR, DSC, and FTIR measurements. They examined six LLDPEs (polymerized using Z-N-type catalyst in gas, slurry, bulk, and solution) and one LDPE. They concluded that Z-N-type polymers had a bimodal SCBD from two types of active sites in Ti-based heterogeneous Z-N catalysts; one produced an alternating copolymer, while the other a random one. The former sites lead to higher SCB concentration peak of the bimodal SCBD and lower MW, while the latter an opposite: lower SCB concentration peak and higher MW. An example of TREF/SEC results is displayed in Fig. 18.5 (Vadlamudi et al. 2009).

Mirabella and Ford (1987) studied the molecular structure of a series of commercial C$_{2+4}$ Z-N–LLDPE copolymers (with ca. 7 wt% of *n*-butene) and compared it to that of LDPE and HDPE. The tests determined SCB, LCB, MW, MWD, and the melting behavior of LLDPE – the latter strikingly different from that of LDPE and HDPE. In commercial LLDPE, the SCB content decreased with increasing MW. The LLDPEs had relatively narrow MWD ($M_w/M_n = 4.0 \pm 0.5$) and no LCB.

Fig. 18.5 Inter- and intramolecular branching distribution of tailored LLDPEs; two side views and surface contours of the averaged 3D bivariate (MW-1-hexene content) distribution from SEC and TREF corresponding to M and T effects. The profile on the *right* corresponds to 180° rotation over the *vertical axis* of the *left*-hand-side profile (Vadlamudi et al. 2009)


The broad and multimodal SCBD was responsible for the unique melting and crystallization behavior, in commercial LLDPEs decreasing with increasing MW.

Hosoda (1988) also studied Z-N–LLDPE. The MW and MWD were determined using SEC with a refractometer and LALLS. The SCB was calculated from FT-IR spectra, while SAXS provided information on the crystalline lamellar thickness. ^{13}C NMR spectra of LLDPE solutions in *o*-dichlorobenzene (ODCB)/perdeuteriobenzene provided the triad sequence distribution, average sequence length, and run number in ethylene/*n*-butene copolymer. There are many ways to display the plethora of results, but the most interesting is the global cross-plot of MWD and composition; the authors called this "the bird's-eye view" presented in Fig. 18.6.

The first fully automatic 3D-SEC/TREF system was described by Yau and Gillespie (2001). The instrument was based on the Waters 150C SEC, and in addition to RI detector, it had IR, viscometer, and dual-angle light scattering (LSc). With the autosampling facility, it run 16 samples with 4 h/sample test time. During the following years, the instrument underwent modifications (Yau 2007)

Fig. 18.6 "Bird's-eye view" of LLDPE;^{13}C NMR signal intensity versus SCB and MW for commercial Z-N–LLDPE (Hosoda 1988)
that widened the applicability of the 3D-SEC/TREF, providing MW, MWD, SCB, LCB, and LCB distribution.

The company Polymer Char (Valencia, Spain) was created for developing fully automated PO characterization instruments. The first device, commercialized and patented in 1994, was the ***CRYSTAF***, crystallization analysis fractionation, for the fast measurement of the chemical composition distribution (CCD) in PE, PP, copolymers, and blends. Next came the SEC (with a quadruple detector system) and then SEC/a-TREF and p-TREF instruments. The first commercial, fully automated cross-fractionating SEC/TREF apparatus for microstructure characterization of POs was described by Ortin et al. (2007). The instrument yields a bivariate distribution CCD by TREF fractionation and then SEC fraction analysis in a single run. A schematic diagram of this new cross-fractionation instrument is shown in Fig. 18.7.

TREF/FT-IR Method

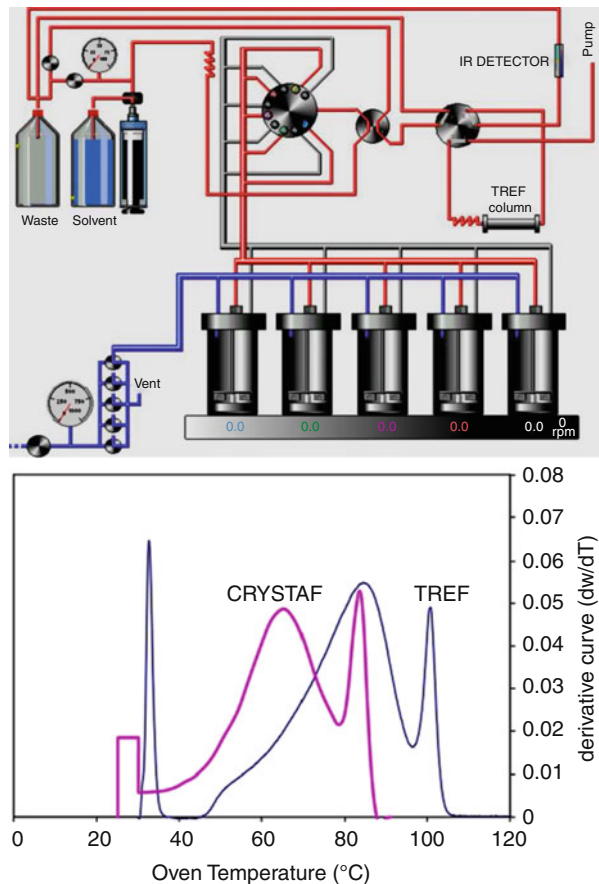
Another approach to characterization of PO was explored by Mahdavi and Nook (2008) and by Zhang (2009). In both cases, TREF and FT-IR were used for analyzing a series of different polymers or copolymers, e.g., LDPE, HDPE, LLDPE and C_{2+8} copolymers, PE, eicosane (C_{20}), ethylene–vinyl acetate copolymer (EVAc), PS, PS-*g*-EVAc, ethylene–methyl acrylate (EMA), respectively. In both articles a p-TREF was used, FT-IR furnishing the information on polymer concentration and composition. However, while Mahdavi and Nook carried out extensive, external testing, Zhang used the CRYSTAF–TREF 200+ connecting the FT-IR spectrometer to MW detectors. Both teams stressed the benefits of the FT-IR detectors.

LDPE, HDPE, and LLDPE films have similar structures, differing primarily by SCB. In consequence, it is possible to distinguish between LDPE, HDPE, and LLDPE from their FTIR spectra. Butyl branches were determined using the –CH_3 rocking band at 894.5 cm^{-1}. The amount of unsaturation was measured after bromination. The branch distribution and melting endotherm of each fraction were analyzed with ATR FT-IR and DSC. The results indicated that the SCB frequency decreased and the crystallinity increased as a function of an increasing
Fig. 18.7 Cross-fractionation SEC/TREF; injection valve shown in "load" position A; "inject" position marked as B (Ortin et al. 2007)

TREF elution T. Low-T fractions had tails related to waxy moieties in LDPE. The melting point of the fractions increased with increasing elution T, and the endotherms were sharper for high-*T* fractions indicating thicker lamellae and/or more perfect crystals.

18.4.2.2 Crystallization Analysis Fractionation, CRYSTAF

CRYSTAF is a process for the analysis of composition distribution in semicrystalline polymers, determination of the branching distribution in PE, or tacticity in PP. Similarly like **TREF**, CRYSTAF is a separation method that fractionates species of differing crystallizability by slow cooling of a polymer solution (Monrabal 1993, 1994; Monrabal et al. 2007; Monrabal and del Hierro 2011). The method was developed as a process that speeds analysis of CCD in POs (Ortín et al. 2010). It shares with TREF the same fundamentals on separation according to crystallizability, but fractionation takes place during crystallization instead of dissolution. The analysis is carried out in stirred crystallization vessels without support, by monitoring the polymer solution concentration while decreasing *T*. Aliquots of the solution are filtered (through an internal filter inside the vessel) and the supernatant liquid analyzed by a concentration detector. The process resembles a stepwise fractionation by precipitation, except that here attention is paid to the polymer that remains in solution instead to the precipitate. The automated instrument (shown in Fig. 18.8) has been available since 1994.

Fig. 18.8 (*left*) Schematic diagram of an automated TREF–CRYSTAF apparatus and (*right*) chromatographs of a bimodal LLDPE resin as detected by TREF and CRYSTAF


Dry samples are placed in the crystallization vessels, dissolved, crystallized, and sampled. The polymer concentration is measured by an FT-IR at increasing T. The instrument may be converted into a CRYSTAF–TREF system capable of running both types of measurements in the same hardware. Each method provides complementary information on the CCD in some complex resins.

As shown by a red curve in Fig. 18.8 (right), the CRYSTAF chromatograph starts at T just below T_m, and upon cooling first, the most crystalline fraction precipitates. The fractionation continues as T decreases crystallizing the macromolecules with increasing branch content. The last data point, at the lowest T, represents highly branched or amorphous polymer, i.e., the fraction which would not crystallize. The first derivative of this curve corresponds to the CCD and is similar in shape to the one obtained in TREF with a T shifted by about 16 °C; the shift originates in the difference between the crystallization and dissolution T. The CRYSTAF method has been often reviewed (Hamielec and Soares 1996; Soares et al. 1998; Soares and Hamielec 1999; Pasch et al. 2000; Monrabal 2000, 2011;

Gownder 2001; Anantawaraskul et al. 2005; Monrabal et al. 2007; Suriya et al. 2011; Monrabal and del Hierro 2011).

The latter reviews also provide information on the next-generation method, the crystallization elution fractionation, CEF. The experiments are performed in a modified Polymer Char TREF instrument. The instrument incorporates an autosampler for 70 vials of 10 mL. The dissolved samples are injected with the pump flow into the column head, and the dynamic crystallization process begins at a set cooling rate and crystallization flow. As the crystallization ends, the oven starts the heating program and flow is adapted to the elution flow passing through the column to a dual wavelength IR detector, so concentration and composition may be measured. A dual capillary viscometer was added for measuring the composition – MW dependence. Thus, the same instrument may be programmed to run TREF, dynamic crystallization, or CEF. Analysis of complex PO takes about half an hour.

However, in the normal growth pattern, the technology becomes progressively more complex. New catalysts, new multi-catalyst/multi-reactor processes, blending of various PO and additives result in complex structures, especially in terms of CCD, severely complicating their characterization. Certain combinations of POs may result in ambivalent results if only TREF or CRYSTAF is used. To obtain unequivocal results for complex PP or PE copolymer or blend, both TREF and CRYSTAF should be conducted.

18.4.2.3 Recent Alternatives: HTLC, CFC

During the last few years, other methods for PO microstructure analysis have been proposed. Of these, the high-temperature liquid chromatography (HTLC) is the most promising. Using two sets of columns, one may fractionate the polymer according to composition (TREF part) and then MW (SEC part) or vice versa.

Petro et al. (2005) were one of the pioneers of the multidimensional liquid chromatography (LC) for characterization of polymers. The multidimensional LC comprises several HPLC subsystem separated into subcomponents. For characterization of a single polymer, the sample is injected into a first dimension HPLC, separating the polymer into fractions, optionally using flow-through detectors (e.g., mass, universal concentration, light-scattering detector), and then injecting the sampled portions into a second dimension HPLC unit. The role of these subcomponents is detection during a flow through. Generally, the first dimension HPLC subsystem can be adapted for distinguishing between chemical composition and/or structural variations of polymer sample components (e.g., reverse-phase chromatography, mobile-phase compositional gradient elution chromatography, or mobile-phase T-gradient elution chromatography), while the second HPLC subsystem is preferably for MWD with a universal concentration or mass detector, such as an evaporative light-scattering detector (ELSD). Furthermore, a third, fourth, or higher dimension HPLC subsystem may be added, such as liquid chromatography, gas

chromatography, electrophoretic chromatography, flow-field fractionation, flow injection analysis, or mass spectrometry. The methods and instruments described in the invention are useful for:

- Characterizing individual polymer samples or their libraries
- Polymer fingerprinting – determining both compositional/structural characteristics and molecular size/molecular weight characteristics
- An effective scale-up of a polymerization process, in a microscale or nanoscale format

HPLC more rapidly separates PO copolymers or blends than conventional TREF or CRYSTAF. The new PL XT-220 rapid screening HPLC system enables one to perform isocratic and gradient separations at $T = 30$–$220\ ^{\circ}C$ with rapid switching between up to six different columns, each with different solvents (Pasch et al. 2009).

One of the advantages of the HPLC is its ability for analyzing crystalline and amorphous POs (Van Damme et al. 2011). The recent patent describes a method and apparatus for chromatography of a PO using a flowing solution through an LC with graphitic carbon stationary phase for determining the monomer-to-comonomer ratio of a PO copolymer. The strategy is to use SEC for determining MW and MWD and HPLC for assessing the chemical composition. Thus, the HPLC determines composition of a C_{2+3} copolymer in steps: (a) flowing a solution into contact with an LC comprising graphitic carbon and (b) introducing a solution of the copolymer into the liquid mobile phase so that the copolymer emerges in the effluent stream with a retention factor that varies as a function of the monomer-to-comonomer ratio in copolymer. Brief reviews of new methods for PO analysis that include SEC, HPLC with evaporative light-scattering detector, FTIR, and ^{1}H-NMR spectroscopy are available (Heinz and Pasch 2005; Macko and Pasch 2009; Roy et al. 2010; Dolle et al. 2011).

Another recent alternative to TREF/SEC is the cross-fractionation chromatography (CFC), described by Ortín et al. (2010). The instrument is based on a high-resolution a-TREF combined with a dedicated SEC column oven and equipped with five vessels for sample preparation. Polymer detection is made through an IR4 detector for maximum sensitivity and long-term baseline stability. A sample placed in a stainless steel vessel is dissolved at $T = 140$–$160\ ^{\circ}C$ with stirring. The instrument loads the polymer solution into the TREF column where it crystallizes and then as T increases elutes in fractions (or "slices"). Next, the solution is transmitted to the SEC columns, which provide the MWD of each fraction. The relative area of the individual chromatograms reflects the compositional heterogeneity, while their retention time and shape relate to MW. However, the procedure must be optimized for the sample size. CFC was found desirable for analyzing blends of m- LLDPE having different densities and MW. The full CCD $\times$ MWD was determined in 12 h by elution 24 TREF fractions into the SEC columns. The bivariate distribution (intensity vs. MW and T) may be displayed in a 3D plot.

18.4.2.4 LCB Index (LCBI) and Slice LCB Index (SLCBI)

The LCB indices provide a measure of LCB as a function of a fraction (slice) of the MWD. Two indices are involved, an average LCB index (LCBI = $\langle g ' \rangle_{avg}$) of the entire sample and the slice LCB index (SLCBI = g'_i); these are defined in Eq. 18.1:

$$\frac{\langle g' \rangle_{\mathrm{avg}} = \sum_{i=1}^{n} C_i [\eta_i]}{\sum_{i=1}^{n} C_i [kM_i^a]} = \frac{\sum_{i=1}^{n} C_i [\eta_i]}{kM_v^a \sum_{i=1}^{n} C_i}$$

$$g'_i = \frac{[\eta]_i}{kM_v^a}$$

$$(21.1)$$

Here the index "i" refers to a retention volume slice, C_i is the polymer concentration measured by SEC for the slice i, M_i is MW determined by light-scattering analysis at retention volume slice i, and $[\eta_i]$ is the intrinsic viscosity determined by viscometry of slice i. The constants k and a are the Mark–Houwink coefficients for a linear polymer of the same chemical composition; M_v is the viscosity-average MW (Lue and Kwalk 2005).

The portion of a composition having a particular MW range and a particular SLCBI may be expressed in terms of wt% calculated from the SEC measurements. Its value should be 100 wt% at zero retention volume and zero after the polymer composition has fully eluted. For various applications, the SLCBI should be determined for a specific MW, e.g., $M_w = 100$ or 300 kg mol^{-1}. An example of the SLCBI plot is presented in Fig. 18.9. Here PE-1 represents the most common behavior. Its blends with PE-2 are expected to be advantageous with good transparency and mechanical performance resulting from strong interactions between phases.

18.4.2.5 Summary and Conclusions for POs

From the chemical point of view, POs are simple materials composed of C and H. However, the configuration diversity of even the simplest polymethylene results in a spectrum of properties. The situation becomes more complex for polymers of the general formula $(C_nH_{2n})_{DP}$ where $n \geq 3$ and the degree of polymerization, DP, is large. The next level of complexity is encountered with blends and copolymers, e.g., poly(ethylene-*co-n*-olefin) or poly(propylene-*co-n*-olefin). However, today the ultimate challenge for characterization is found in POs obtained during multi-catalyst/multi-reactor/multi-monomer polymerization processes.

Fortunately, as the complexity of macromolecules increases, the precision and sophistication of instruments designed for their characterization improve. The analytical and preparative fractionating columns of GPC used in the 1950s are transformed into automatic multicolumn, multi-detector, high-temperature SEC. Similar advance is observed for TREF and CRYSTAF, now fused into CFC. At the same time, new methods are being developed for faster and more precise characterization by means of the multi-detector liquid chromatography, HTLC or HPLC.

Fig. 18.9 Slice long-chain branching index (SLCBI) as a function of a slice MW determined by SEC for two polymers in a favorable blend (Lue and Kwalk 2005)
Various mathematical models have been proposed for TREF and CRYSTAF, but none predicts crystallization and co-crystallization effects during the fractionation with sufficient precision. Thus, for the accurate determination of semicrystalline copolymer microstructure, one should use the two optimized complementary methods: TREF and CRYSTAF.

18.5 Polyethylene Blends

PE mixtures constitute an important part of commercial blends. The information in Appendix, Table 18.12, suggests five major steps in the production of commercial PE, which result in different types of PE, commercially available at present, viz., **1935** – LDPE with LCB; **1950** – LLDPE or HDPE catalyzed by, e.g., Cr_2O_3, NiO, Mo_2O_3, or CoO; **1953** – the Ziegler–Natta (Z-N) catalysis for HDPE, UHMWPE, and LLDPE with a broad MWD and heterogeneous comonomer placement; **1975** – the metallocene catalysis producing narrow MWD and homogeneously distributed SCB; and **1997** – post-metallocene catalysis that leads to PE copolymers with adjustable MW and MWD as well as copolymerization of olefins with polar monomers and macromers.

As a consequence, before 1953, the only possible blends were those of LDPE with other polymers than PO or with elastomers (e.g., chlorosulfonated polyethylene rubber, CSR; chlorinated butyl rubber, CBR; ethylene/propylene/diene copolymers, EPR, EPDM; thermoplastic olefinic elastomer TPE, TPO). However, in addition to the original autoclave polymerization, already in 1938, a tubular reactor was introduced and its product had different properties than that from the autoclave. Also varying the reaction condition affected the degree of short- and long-chain branching in LDPE; thus, blending different LDPEs offered a way for optimizing the resin to specific applications.

The first LDPE/HDPE blends were patented by du Pont de Nemours before Z-N polymers became available (Roedel 1961). The blend comprised an experimental HDPE ($\rho = 0.939$–1.096 g mL^{-1}; $T_m \approx 120$ °C) obtained by polymerizing C_2 in its own medium at $T \approx 0$ °C and $P \approx 31$ MPa, using, e.g., a hydroxy-cyclohexyl-L-hydroperoxide catalyzed by ferrous chloride tetrahydrate. The blend showed 50 % moisture permeability of that by LDPE. In 1958 Phillips Petroleum patented PE/PE blends, either cross-linked in electron accelerator or not (Canterino and Martinovich 1963; Nelson 1964). Mitsubishi disclosed PO blends comprising vinyl–trimethoxysilane-grafted polyolefin (PP, LDPE, EPR, or EVAc) and ethylene–acryloyloxy tetramethylpiperidine copolymer. These water-cross-linkable resins were used for the manufacture of weather-resistant cross-linked PO pipes in outdoor applications (Ohnishi and Fukuda 1993). Thermally reversible cross-links (based on ionic interaction between maleated- and glycidyl methacrylate-grafted polyolefins) were also proposed (Okada 1994; Okada and Masuyama 1994).

Starting in the early 1950s, development of LDPE with LLDPE was the principal aim of the Z-N period for the film-blowing applications. It was patented by all major PE manufacturers, viz., du Pont de Nemours and DuPont of Canada Ltd., Phillips Petroleum, Celanese, and Esso. Some blends were cross-linked chemically or in electron beam. Incorporation of as little as 5 wt% of LDPE significantly improved the strain-hardening behavior of LLDPE, thus greatly improving process ability and performance (e.g., the heat sealability, puncture resistance, tensile and optical properties). However, in some cases for >35 % LLDPE in LDPE modification of film-blowing line was needed. Blends of broad MWD LLDPE/LLDPE also were advantageous (Utracki 1998).

During this initial period, blending was dominated by mechanical compounding involving:

- Preparation of ingredients (drying, sizing, heating, etc.)
- Premixing (dry blending, homogenization, breakage of agglomerates, fluxing, etc.)
- Melt mixing (usually with degassing)
- Forming, e.g., granulation, pelletization, or dicing

Mixing is the oldest process developed for rubbers by Hancock in 1820. The development of several types of mixers (including sigma blade internal mixers and twin-screw extruders, TSEs) may be traced to it. The single-screw extruder (SSE), inherited by the plastics industry from macaroni manufacturers in 1892, is good for continuous squeezing out a material, but not for mixing it. In 1939 Leistritz built an electrically heated, air-cooled SSE, having L/D = 10, automatic temperature control, variable screw speed, and nitride barrel, which underwent a rapid growth in L/D as well as modifications to improve its homogenization capability. Several types of mixing screws, mixing elements, and "add-ons" have been developed. The complex nature of the process was slowly unraveled, leading to educated attempts in maximalization of the elongational flow, as well as balancing the dispersive and distributive mixing in linear or chaotic flows. Many of these devices were developed in parallel with the evolution of TSE that ended by the late 1950s (Utracki and Shi Gerard 2002).

However, already by mid-1950s advantages of reactor mixing started to be explored. Hoechst patented a slurry cascade process for the polymerization of HDPE in a CSTR, capable of using different reaction conditions and/or monomer composition. The tubular, loop, or FBR also offered such possibilities – these became fashionable before the 1960s. An advantage of reactor blending was the countless possibilities of compatibilization and adjustment of the blend performance characteristics for large-scale applications. On the negative side was the loss of opportunities for smaller compounders and manufacturers for fine tuning the blend performance for specific applications.

The compounding technology of PE blends has been expanded by the need for the addition of fillers, reinforcements, and nanoparticles, the latter treated as inorganic macromolecules that require compatibilization and dispersion. The reactive compatibilization in a TSE developed by the end of the 1980s revitalizing the academic and industrial interest in the mechanical compounding of blends.

18.6   Essentials of Polymer Blending

The essentials or the fundamental knowledge that offers understanding why the blends behave as they do is being discussed in several chapters of this book, namely, ▶ Chap. 2, "Thermodynamics of Polymer Blends"; ▶ Chaps. 3, "Crystallization, Micro- and Nano-structure, and Melting Behavior of Polymer Blends" and ▶ 8, "Morphology of Polymer Blends"; ▶ Chap. 4, "Interphase and Compatibilization by Addition of a Compatibilizer"; ▶ Chap. 5, "Reactive Compatibilization"; ▶ Chap. 7, "Rheology of Polymer Alloys and Blends"; ▶ Chap. 9, "Compounding Polymer Blends"; ▶ Chaps. 13, "Physical Aging of Polymer Blends" and ▶ 14, "Degradation, Stabilization, and Flammability of Polymer Blends"; and ▶ Chap. 21, "Recycling Polymer Blends". The aim of writing the following pages is to focus on what is unique and essential for the PE/PE blends, referring to the broader perspectives presented in these chapters. The unique aspects of the PO blends are the great range of molecular configurations combined with small entropy and enthalpy of mixing, which taken together made prediction of blend performance particularly difficult.

18.6.1 Miscibility of Polyethylene Blends

18.6.1.1 Introductory Notes
Several methods have been used for detecting PE_1/PE_2 phase behaviors, i.e.:
- *Nondirect*, e.g., DSC, XRD, light scattering (LS), atomic force microscopy (AFM), electron and optical microscopy, and rheology
- *Direct*, for example, SANS, small-angle light scattering (SALS), or nuclear reaction analysis such as direct excitation exchange NMR (Akpalu and Peng 2008; Wachowicz et al. 2009)

As discussed in ► Chap. 2, "Thermodynamics of Polymer Blends" of this handbook, miscibility of polymer blends is usually presented as an isobaric phase diagram with the lower or upper critical solution temperature, T_c = LCST or UCST (see Fig. 2.15). Most PE/PE blends show UCST, while LCST occurs more frequently in other blends. There is a significant difference in the rate of phase separation and the generated morphology when a single-phase blend is "quenched" into either the metastable or spinodal regions. The phase separation within the metastable region occurs via nucleation and growth (NG) resembling crystallization – NG leads to polydispersed drop sizes. Since phase separation within the spinodal region follows the spinodal decomposition mechanism (SD), these blends may not need compatibilization. Furthermore, the SD blends most efficiently combine the advantageous properties of both polymers, for example, high modulus of one component with high elongation at break of another.

For proper understanding of the immiscible blends, it is important to take into account the interphase. In binary blends, the interphase thickness is inversely proportional to the interfacial tension coefficient, v_{12}; thus, the poorer the miscibility, the larger the interfacial tension coefficient and the smaller the interphase thickness, Δl. The latter variable ranges from $\Delta l \approx$ 2–65 nm, the former for uncompatibilized, highly immiscible systems, and the latter for reactively compatibilized polymer alloys. Owing to the thermodynamic forces, the polymeric chain ends and the low-molecular-weight components concentrate within the interphase. Thus, in binary blends this third region is characterized by low entanglement density, low viscosity, and poor interphasial adhesion. These drawbacks must be alleviated by compatibilization.

Miscible polymer blend is defined as a polymer mixture homogeneous down to the molecular level, in which the domain size is comparable to macromolecular dimension, associated with the negative value of the Gibbs free energy and heat of mixing, $\Delta G_m \approx \Delta H_m \leq 0$, and positive second derivative: $\partial^2 \Delta G_m / \partial \phi^2 > 0$. One may also ask at what dispersed drop size, d_d, the blend may be declared thermodynamically miscible; the answer based on NMR seems to be $d_d \leq 2$ nm (Utracki 2002). Often a small configurational difference leads to immiscibility, e.g., LLDPE prepared with Ti-based catalyst is immiscible with another one based on V catalyst. Even more strangely, a single LLDPE produced with multisided Z-N catalyst may show phase separation of fractions produced at different catalytic sites.

While miscibility of the low-MW substances is driven by entropy, in polymer blends it is the enthalpy that dominates the phase behavior. In PE/PE blends the absence of the specific interactions and small entropic effects lead to precarious miscibility. In any PO blend including PE_1 and PE_2, a mixture is composed mostly of –CH_2– groups with few –CH_3 end groups. Evidently, the intermolecular interactions between them are weak and immiscibility dominates the behavior. The PE_1/PE_2 blends with different type chain structure are usually immiscible. The immiscibility is not limited to the resins with different comonomers. For example, two LLDPEs, both being C_{2+6} copolymers polymerized using Z-N-type catalyst, but one

based on Ti, the other on V, are immiscible (Utracki and Schlund 1987b, d; Schlund and Utracki 1987c, e). By contrast, some LLDPEs, especially those containing a small amount of C_4 comonomer, show limited miscibility with the linear HDPE.

The PE immiscibility refers to the molten as well as to the solid state. Note that the small changes in molecular structure lead to difference in T_m, what affects a sequence of crystallizations of different blend components. Thus, in most cases the spherulites of one PE (having higher T_m) are encapsulated by those of the other PE. Co-crystallization of two PEs into single-type isomorphic cells rarely has been observed (Utracki 1989a, 1991).

18.6.1.2 Mean-Field Approach

During the years 1992–1998, numerous publications emerged from Prof. Graessley's laboratory. The model PEs with different structures (see Fig. 18.10) were commercial (e.g., HDPE or PP) or from laboratory (e.g., hydrogenation/deuteration of diolefins, anionic reaction for PIB, Z-N catalysis using a V-based catalyst in C_6 for poly (ethylene-*co*-α-olefin) or later a metallocene catalyst. The thermodynamic properties of numerous PO blends were extracted from the pressure–volume–temperature (PVT) data (Walsh et al. 1992; Krishnamoorti et al. 1996) or from SANS results (Krishnamoorti et al. 1994, 1995; Graessley et al. 1994, 1995; Reichart et al. 1997; Alamo et al. 1997).

Several mean-field theories have been developed for predicting liquid/liquid thermodynamic behavior (Huggins 1941; Flory 1941; Simha and Somcynsky (S-S) 1969; Koningsveld 1985; Koningsveld and Kleintjens 1985; Koningsveld et al. 1987; Dee and Walsh (D-W) 1988). These theories were found useful in explaining some basic behavior of solutions and blends, e.g., decreasing miscibility with increasing MW, as well as they identified the driving force for miscibility in a given system For example, S-S and D-W equations of state (eos) were fitted to the *PVT* data of blends (Walsh et al. 1992; Park et al. 1999; Utracki and Simha 2001; Moulinié and Utracki 2010).

Assuming the validity of the corresponding states principle, the eos is expressed in reduced variable form, where the reducing parameters, $P*$, $T*$, and $V*$, depend on the two Lennard–Jones potential parameters: $\varepsilon*$ and $v*$:

$$\left. \begin{array}{l} \widetilde{P} = P/P* \rightarrow \quad P* = zq\varepsilon*/(sv*) \\ \widetilde{T} = T/T* \rightarrow \quad T* = zq\varepsilon*/(Rc) \\ \widetilde{V} = V/V* \rightarrow \quad V* = v*/M_s \end{array} \right\} \quad (P*V*/T*)M_s = Rc/s \qquad (18.2)$$

Here $\varepsilon*$ and $v*$ are measures of the maximum attraction energy and the segmental repulsion volume, respectively, $qz = s(z - 2) + 2$, $v*$ a specific volume for a molar segmental mass M_s, $R = 8.314462$ [JK^{-1} mol^{-1}] is the universal gas constant, and $z = 12$ is the lattice coordination number. The data analyzed by Walsh et al. (1992) were based on the mixtures of commercial HDPE, PP, and EPR copolymers containing
Fig. 18.10 (**a**) United atom group models for monomers of PE, PP, poly(ethyl ethylene) (PEE), poly(hexene-1) (PH1), poly(ethylene propylene) (PEP), PIB, and head-to-head PP (hhPP). *Circles* designate CH_n groups, *solid lines* represent C–C bonds inside the monomer, and *dotted lines* indicate the C–C bonds linking the monomer to its neighbors along the chain. (**b**) United atom models of iPP, hhPP, and PEP homopolymer chains constructed by linking monomers of (**a**) (Freed and Dudowicz 2005)

16, 24, 43, and 77 wt% C_2, etc. Miscibility and shape of the phase separation curves, i.e., LCST or UCST, were estimated from the magnitude of P^* and T^*.

Besides eos, the statistical thermodynamic theories also predict variations of the reduced cohesive energy density, $\widetilde{CED}$; solubility parameter, δ; and the internal pressure, $\widetilde{p}_i$:

$$\widetilde{CED} = \widetilde{U}/\widetilde{V} = \left(y/2\widetilde{V}\right)\left[AQ^4 - 2BQ^2\right] \Rightarrow \delta = \sqrt{CED}$$

$$= \sqrt{\widetilde{CED}} \times P^* \left(\partial \widetilde{U}/\partial \widetilde{V}\right)_{\widetilde{T}} = \widetilde{p}_i$$

$$= -\frac{1}{2}\left[3AQ^4 - 2BQ^2\right]\left(\partial y/\partial \widetilde{V}\right) + \left(2y/\widetilde{T}\right)\left[AQ^4 - BQ^2\right] \qquad (18.3)$$

Here, U is the internal energy of the system, y is the occupied volume fraction, and $A = 1.011$ and $B = 1.2045$ are the cell constants. The dependencies originally written for a single-component liquid are readily extended to binary systems (Moulinié and Utracki 2010):

$$\langle P^* \rangle = qz\langle \varepsilon^* \rangle/(\langle s \rangle \langle v^* \rangle); \quad \langle T^* \rangle = qz\langle \varepsilon^* \rangle/R\langle c \rangle; \quad \langle V^* \rangle = \langle v^* \rangle/\langle M_o \rangle$$

$$\langle P^* \rangle \langle V^* \rangle/R\langle T^* \rangle = (\langle c \rangle/\langle s \rangle)(1/\langle M_o \rangle)$$

$$\langle c \rangle = \sum_i c_i x_i; \quad \langle s \rangle = \sum_i s_i x_i; \quad \langle M_o \rangle = \sum_i M_{si} s_i x_i / \sum_i s_i x_i \qquad (18.4)$$

$$\langle \varepsilon^* \rangle \langle v^* \rangle^m = \sum_{i,k} X_i X_k \varepsilon_{i,k}^* \left(v_{i,k}^*\right)^m; \quad m = 2,4$$

where the two values of m reflect the volumetric Lennard–Jones (L-J) 6–12 potential. From Eqs. 18.1 and 18.3 the pairs of L-J parameters were computed for HDPE, PP, and EPR with variable C_2 content (data Walsh et al. 1992). Simplified molecular configuration of these macromolecules is presented in Fig. 18.11.

Fig. 18.11 The L-J potential parameters, ε^* and v^*, versus ethylene content (Data Walsh et al. 1992). Since in miscible systems they are proportional to each other, the lack of proportionality at high C_2 content may indicate phase separation
Fig. 18.12 The H-F binary interaction parameter, χ, for head-to-head blend with PIB as functions of temperatures (*solid circles* are for 1/T(K), open for T °C) (Data Krishnamoorti et al. 1996). The parameters calculated from SANS results
The calculation results are presented as ε^* and v^* versus ethylene content, C_2 in Fig. 18.12. It has been observed that for single-phase liquids, single component, solution, or miscible blend, the L-J potential parameters are linearly related, e.g., for molten polystyrenes (PS) the following dependence was found (Utracki 2005):

$$\varepsilon* = a_0 + a_1 v*; \quad a_0 = 13.44; \quad a_1 = 0.455; \quad r = 0.952 \qquad (18.5)$$

The data in Fig. 18.11 show an anomaly – there is a common trend for neat polymers and blends containing up to about 25 wt% of C_2, but due to phase separation, at higher C_2 content, the trend is not followed.

For SANS measurements of thermodynamic interactions in binary PO blends, one component should be deuterated. This was done starting with partially unsaturated samples and catalytically hydrogenating or deuterating them in solution. The specimens were prepared by solution blending of one hydrogenated and one deuterated polymer such as polybutylene (PB), thus HPB and DPB, respectively. The measurements were performed at $T = 27$–$167\ ^{\circ}C$ (one-phase region) (Balsara et al. 1992). In these experiments not only molecular configuration, but also non-negligible isotope effect had to be taken into effect. The data were interpreted using the Huggins–Flory (H-F) incompressible random phase approximation into ΔG_m for binary liquids (Krishnamoorti et al. 1994a, b, 1995; Graessley et al. 1994, 1995; Alamo et al. 1997):

$$\Delta G_m/RT = \phi_i \ln \phi_i/V_i + \phi_j \ln \phi_j/V_j + X_{ij}(T)\phi_i\phi_j$$
$$\chi_{ij}(T) = v_o X_{ij}(T)/RT \cong v_o(\delta_1 - \delta_2)^2/RT \tag{18.6}$$

where δ_i and δ_j are volume fractions and V_i and V_j are the volumes per monomeric unit. The interaction energy density X_{ij} is proportional to the H-F binary interaction parameter, χ_{ij}, and an arbitrary reference volume, v_o, which for blends was calculated following the square-average Berthelot rule:

$$v_o = \left(v_{oi}v_{oj}\right)^{1/2}$$

An example of calculations is shown in Fig. 18.12 as the Huggins–Flory binary interaction parameter, χ versus temperature (SANS data from Krishnamoorti et al. 1996). The extrapolated Arrhenius dependence suggests that the system is miscible up to about $118\ ^{\circ}C$.

The H-F Eq. 18.6 has two parts: the ϕ-dependent configurational entropy derived from the lattice model without free volume and the enthalpic part taken from the Hildebrand's theory of regular solutions (Shinoda 1978; Reichart et al. 1997; Maranas et al. 1998). More recent version of Eq. 18.6 was used for the interpretation of SANS data, and it will be discussed in reference to the lattice cluster theory (LCT) (Freed and Dudowicz 2005).

For a series of polyethylene–hexene (PEH $= C_{2+6}$) and polyethylene–butene (PEB $= C_{2+4}$) blends, Krishnamoorti et al. (1994b) proposed a four-parameter empirical expression:

$$\chi_{12}(\phi,T) = \beta_{12}(T) + \gamma_{12}(T)/\phi_1\phi_2$$
$$\beta_{12}(T) = A_\beta/T + B_\beta; \quad \gamma_{12}(T) = A_\gamma/T + B_\gamma \tag{18.7}$$

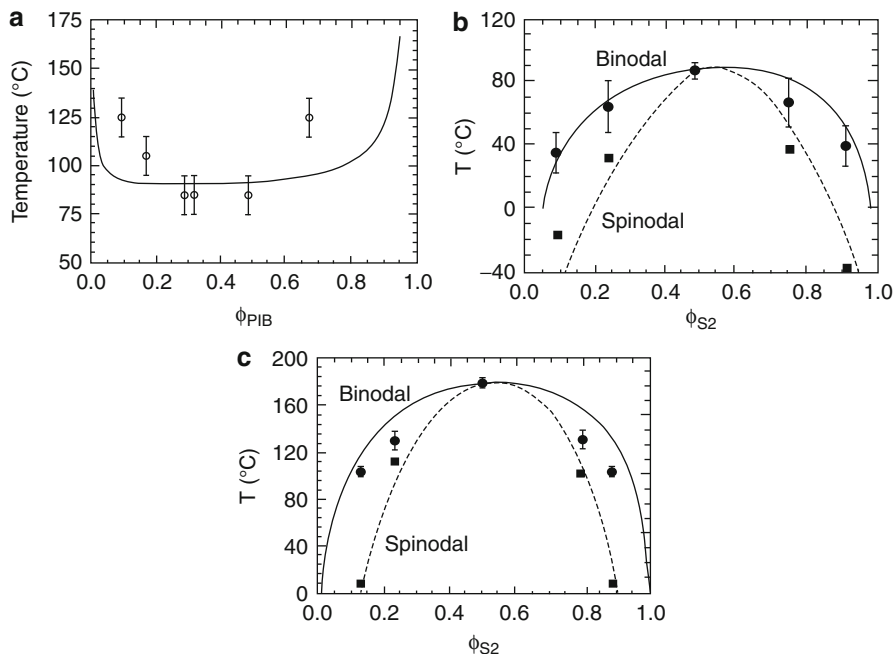
Accordingly, plotting $\chi_{12}(\phi, T)\phi_1\phi_2$ versus $\phi_1\phi_2$ should linearize the dependence. Plot of β_{12} and γ_{12} parameters versus $1/T$ should also be linear; the parameters are positive, indicating UCST-type phase separation. Having the numerical values of d_i for individual PO structure elements, in principle, the miscibility of two polymers could be predicted from their difference: $(\delta - \delta)^2$. A similar linear increase of $\chi_{12}(\phi, T)$ with decrease of T was reported for most PO blends, although


Fig. 18.13 (**a**) Phase diagram for PIB/H66B blends based on a quenching-calorimetry procedure. The LCST spinodal curve was calculated using X(T) for PIB/D66A blends (Krishnamoorti et al. 1995). (**b**) Calculated and experimental UCST binodal and spinodal for *H66/D52*. The calculations were based on SANS data in the single-phase region (Krishnamoorti et al. 1994). (**c**) Calculated and experimental UCST binodal and spinodal for *H52/D*66. The calculated and experiment results were obtained as in Fig. 18.11b (Krishnamoorti et al. 1994)

in some cases LCST type or only a part of phase separation curve was observed (Krishnamoorti et al. 1994b, 1995; Graessley et al. 1994, 1995; Alamo et al. 1997). Examples are displayed in Fig. 21.13.

The PE–PE interactions originate in induced dipole moment, which makes them highly sensitive to configurational changes. For example, they show strong deviation from the behavior predicted by the copolymer theory. Empirically the immiscibility was found related to the comonomer content and the difference in the branch length, the latter well correlating with δ. PE blends are homogeneous when the branch content is low, but they phase separate when there are ≥ 8 branches/100 backbone carbons. For sufficiently high MW, phase segregation may also be caused by the H^1/D^2 isotope effects. However, several blend types showed behavior inconsistent with this explanation (Graessley et al. 1995).

Reichart et al. (1998) studied blends of metallocene statistical copolymers of C_2 with a range of propylene, 1-butene, 1-hexene, or 1-octene content, i.e., C_{2+3}, C_{2+4}, C_{2+6}, and C_{2+8} ($M_w/M_n \approx 2$). As expected, the new data scattered less than those for the Z-N copolymers, confirming the validity of the earlier observations. Thus, the interaction parameters obeyed Hildebrand's assumption as being controlled by

Fig. 18.14 Isothermal, relative solubility parameters of C_{2+3}, C_{2+4}, C_{2+6}, and C_{2+8} versus comonomer content at $T = 118\ °C$, $142\ °C$, $167\ °C$, and $196\ °C$. The effect of deuteration was removed. The data are displaced vertically from those at $118\ °C$ by 0.3, 0.6, and 0.9 (Data: Reichart et al. 1998)
Table 18.4 Solubility parameter $(\delta - \delta_{ref})^{1/2} = A–B\ x$ (Reichart et al. 1998)

T (°C)	A	B	r_2
118	1.634	0.0134	0.948
142	1.553	0.0117	0.949
167	1.485	0.0108	0.952
196	1.409	0.0097	0.945

the enthalpy, viz., the solubility formalism. As shown in Fig. 18.14, the isothermal values of $(\delta - \delta_{ref})^{1/2}$ linearly depend on x, the α-olefin comonomer content and T, thus are independent of SCB. The parameter δ_{ref} takes into account the two reference states for the hydrogenated and deuterated polymers (Table 18.4).

Furthermore, the illustrated dependence is the same as found earlier for model copolymers with different SCBD, indicating that variations in comonomer distribution have little effect on solubility.

The data displayed in Fig. 18.14 indicate that the interaction strength parameter, X, decreases as T increases. Rabeony et al. (1998) observed that the intermolecular interactions are only a function of density for UCST blends far from a critical point, i.e., the free volume: $X(P, T) = X(\rho)$. Within the range $T = 60–200\ °C$ and $P \leq 200\ MPa$, a good superposition of data on a single curve was obtained for the UCST blends and poorer ones for LCST. Increasing density increased X in UCST and decreased it in LCST, thus making the blend less miscible in the first and more soluble in the second case. The effects of T and P on miscibility may be predicted from the free volume changes. For LCST blends, the density-predicted trends are correct, but here the interactions depend on T and P in a more complex way.

The older mean-field theories are often based on the lattice model of ill-defined a priori size and shape, neglecting variability of monomer structures in PO copolymers and blends. Several newer approaches have been proposed, viz., the polymer reference interaction site model (PRISM) (Schweizer and Curro 1989, 1997), the Monte Carlo (MC) simulations (Sariban and Binder 1987; Müller and Binder 1995; Weinhold et al. 1995; Escobedo and de Pablo 1999), the continuum field theory (CFT) (Fredrickson et al. 1994), or an analytical lattice models (Dudowicz and Freed 1991). The latter model leads to relatively simple mathematical expressions, which offer an insight into basic thermodynamics, but again do not predict how monomer structure affects blend miscibility.

Chen et al. (2000, 2002) studied phase behavior of binary blends of linear and branched poly(ethyl-ethylene), PEE. The branched PEE_{br} had 54 arms ($M_A = 13.7$ kg mol^{-1}) attached randomly to a saturated hydrocarbon backbone ($M_B = 10$ kg mol^{-1}). Blends of this compound with two linear PEE_{lin} ($M_L = 60$ and 220 kg mol^{-1}) were investigated by SANS. Blends containing high-MW linear polymer phase separated, whereas the ones with lower MW were miscible at all concentrations. The first publication provided experimental details and compared the LCST phase diagram with theory (Fredrickson et al. 1994; Fredrickson and Liu 1995). The theory assumed Gaussian statistics and did not account for a disparity between the statistical segment lengths of linear and branched polymers. Thus, for correct prediction of the phase diagram, two average statistical segment lengths had to be assumed: 0.57 and 0.76 nm for the linear and branched polymer, respectively.

The second publication examined miscibility of two series of poly(ethylene-*r*-ethyl-ethylene), PEE *xx* polymers with different percentages (*xx*) of ethyl–ethylene (EE) repeat units.

- *The first series* consisted of comb/linear blends in which the first component was a heavily branched comb polymer (B90) containing 90 % EE and an average of 62 long branches with $M_w = 5.5$ kg mol^{-1} attached to a backbone with $M_w = 10.0$ kg mol^{-1}. The comb polymer was blended with six linear PEExx copolymers, all of which had $M_w = 60$ kg mol^{-1} and EE content ranging from 55 % to 90 % (coded L55–L90).
- The second series consisted of linear/linear blends; the first component, with $M_w = 220$ kg mol^{-1} and 90 % EE, coded L90A, and the second components were the same as in the first series of linear polymers ($M_w = 60$ kg mol^{-1} and L55–L90). The investigated concentration was 50 wt%, except for the blend of branched B90 and linear L90 (both components had 90 % EE), for which 25/75 and 75/25 concentrations were also examined.

The blends of linear PEE90 ($M_w = 220$ kg mol^{-1}, 50 wt%) formed single phase with linear $M_w = 60$ kg mol^{-1} PEE83 and PEE78 but phase separated from PEE73, PEE68, and PEE55. However, a PEE90 comb polymer ($M_w = 350$ kg mol^{-1}) was miscible with linear PEE90 but phase separated in all blends with linear PEE_{xx} random copolymers. The results showed that phase behavior in PO blends depends on (1) differences in SCB, which produce enthalpic contributions, and (2) LCB contributing

excess entropy of mixing. Both effects increase the interaction parameter; thus, each one may induce phase separation between linear and branched PO. Furthermore, the LCB significantly narrows the miscibility window of the studied blends. The results were interpreted using CFT (Fredrickson et al. 1994; Fredrickson and Liu 1995) as the only theory directly predicting the LCB effects on PO blend miscibility. The field theory was developed from the random phase approximation (RPA) and H-F theories that focus on the importance of the excess entropy arising from long-range effects.

18.6.1.3 Effects of Molecular Structures

Freed et al. developed the lattice cluster theory (LCT) specifically to account for diversity of segmental structures, affecting blend miscibility, viz., the critical point $[T_c, \phi_c]$, chain swelling $[T_\Theta]$, as well as the scale and intensity of composition fluctuations (Freed and Bawendi 1989; Foreman and Freed 1997; Freed and Dudowicz 1998, 2005; Dudowicz et al. 2002). As an example, several monomeric and polymeric structures are shown in Fig. 18.15, and LCT predictions of the phase behavior the authors are discussed in details.

The simplified LCT (SLCT) expresses the free energy of mixing, ΔF^{mix}, of a high-MW binary homopolymer blend at incompressible limit, as (Freed and Dudowicz 1998)

$$\frac{\Delta F^{\text{mix}}}{N_1 kT} = \frac{\phi}{M_1}\ln\phi + \frac{1-\phi}{M_2}\ln(1-\phi) + \phi(1-\phi)\{\Delta\}$$

$$\{\Delta\} \equiv \frac{(r_1 - r_2)^2}{z_2} + \frac{\varepsilon}{kT}\left\{\frac{z-2}{4} - [p_1(1-\phi) + p_2\phi]\right\}$$

$$-\phi(1-\phi)\left(\frac{\varepsilon}{kT}\right)^2\left[\frac{z+2}{4} + r_1(1-\phi) + r_2\phi\right] \quad r_\alpha = \frac{N_\alpha^{(2)}}{M_\alpha} = 1 + \frac{s_\alpha^{(tri)}}{s_\alpha} + 3\frac{s_\alpha^{(tetra)}}{s_\alpha}$$

$$\tag{18.8}$$

Here ϕ and N_1 are the volume fraction and number of united atom groups, z is the lattice coordination number, and $\varepsilon = \varepsilon_{11} + \varepsilon_{22} - 2\varepsilon_{12}$ is the blend exchange energy. The parameter N_α^i expresses the number of dissimilar sets of i sequential bonds in α-chain. The only coefficients in Eq. 18.8 (see Table 18.5) are the ratios of $r_\alpha = N_\alpha^{(2)}/M_\alpha$ and $p_\alpha = N_\alpha^{(3)}/M_\alpha$ where M_α is the number of united atom groups in polymer α, which may be represented in terms of the respective numbers $s_\alpha^{(tri)}$ and $s_\alpha^{(tetra)}$ of tri- and tetrafunctional united atom groups, a monomer of species α.

The first two terms on the right-hand side of Eq. 18.8 represent the H-F configurational entropy, while the noncombinatorial entropy contribution is given by $\phi(1-\phi)[(r_1 - r_2)/z]^2$; the latter originates from the local correlations associated with the packing of monomers with different sizes and shapes.

The theory is based on an extended lattice model where monomers have molecular structures illustrated in Fig. 18.15. Individual groups [CH_n; $n = 0$–3] occupy single lattice sites, and the bonds between united atom groups correspond to the
Fig. 18.15 Structural models of united atom monomers whose structural parameters r_α and p_α are listed in Table 21.5. *Filled circles* denote monomer portions lying on the chain backbone, while *open circles* represent those belonging to the side groups. *Dashed horizontal lines* designate the bonds to neighboring monomers, and vertical lines with *arrows* and *symbols k* (or *m*) indicate that a given monomer has *k* (or *m*) united atom side group connected units (Freed and Dudowicz 1998, 2005)

C–C bonds in the actual molecules. The LCT is an analytical molecular-based theory for the statistical thermodynamics of molten polymers, associated with recognizing the degree to which the distinct chemical structures of the individual monomers are relevant. LCT also incorporates free volume and uses the nonrandom

mixing principle. The theory went through several modification and simplifications, making it easy to use in comparison to MC or PRISM (Freed and Dudowicz 1996).

LCT has been applied to binary blends with variable SCB (Freed and Dudowicz 1996), predicting miscibility and interfacial properties of PO blends (Dudowicz and Freed 1996), to copolymers (Dudowicz and Freed 1997, 1998) and other systems. However, the most important is the discovery of four classes of critical behavior (Freed and Dudowicz 2005). The classification comes from data recalculated via SLCT binary interaction parameter, χ_{SANS}, calculated from the SANS data:

$$\chi_{SANS}/C = a + (b + c\phi)/T;$$
where
$$a = [(r_1 - r_2)/z]^2;$$
$$b = (\varepsilon/k)[(z - 2)/2 - (2p_1 - p_2)/z]; \qquad (18.9)$$
$$c = 3\varepsilon(p_1 - p_2)/kz$$

The classification is based on Eq. 18.9 parameters (a, b, c) presented in Table 18.6.

Table 18.6 Four classes of PO blends (After Dudowicz et al. 2002; Freed and Dudowicz 2005)

Parameters	Class I $a=0,$ $b>0$	Class II $a\neq 0,$ $b>0$	Class III $a\neq 0,$ $b<0, c=0$	Class IV $a\neq 0,$ $b<0, c\neq 0$

L or U CT	UCST	UCST	LCST	LCST
Examples	PPE/PEE; PP/PE; PE/PIB; PE/P2B; PE/PEP	PH1/PEP	PPE/PEP; PE/PEP	PIB/PEP

The critical point coordinates for LCST or UCST are (ϕ_c, T_c); ξ_o is the correlation length amplitude at ϕ_c; Gi is the Ginsburg number, which estimates the crossover from mean-field- to Ising-type behavior; $\delta T_\theta^{(i)} \equiv (T_\theta^{(i)} - T_c)/T_c$.

The phase diagrams of PO-type random copolymers may be more complex than those for homopolymers with different, but uniform, molecular structure. Thus, similar to SLCT, but simplified further, is the basic lattice cluster theory (BLCT). The version was developed for the random copolymers or random and block copolymer systems.

The preliminary work involved binary blends of ethylene/norbornene random copolymers studied by ^{13}C NMR spectroscopy. The miscibility was observed for norbornene content >50 % where the microstructure changes due to side group crowding. The SLCT computations indicate that the chain stiffness significantly affects miscibility – the entropic contribution to χ seems to be the controlling factor. Experimental miscibility diagrams agreed reasonably well with LCT predictions (Delfolie et al. 1999).

The BLCT is based on Flory–Huggins random copolymer theory with two significant improvements: (I) description of the polymer–polymer interactions in terms of the united atom groups and (II) addition of entropic contributions to the interaction parameter χ_{ij} (Dudowicz and Freed 1997, 2000b). The Helmholtz free energy of mixing in BLCT formalism is given by:

$$\frac{\Delta F^{\text{mix}}}{kT} = \frac{\phi}{M_1}\ln\phi + \frac{1-\phi}{M_2}\ln(1-\phi) + \phi^2\chi_{11} + (1-\phi)^2\,\chi_{22} + \phi(1-\phi)\chi_{12}$$
$$M_1 = n_A s_A + n_B s_B; \quad M_2 = n_C s_C + n_D s_D$$

$$(18.10)$$

With the interaction parameters

Fig. 18.16 Computed LCT phase boundaries for PPxPEE1-*x*/PEE blends (at $P = 0.1$ MPa) with the same polymerization indices $N_1 = N_2 = 320$ but different compositions x of the random copolymer. The *solid lines* indicate the spinodal for the PP/PEE system (Dudowicz and Freed 1997, 2000b)
$$\chi_{11} = -\frac{z}{2}\left[\frac{\varepsilon_{AA}}{kT}m_A^2 + \frac{\varepsilon_{BB}}{kT}m_B^2 + 2\frac{\varepsilon_{AB}}{kT}m_A m_B\right] - \frac{r_1^2}{z^2}$$

$$\chi_{22} = -\frac{z}{2}\left[\frac{\varepsilon_{CC}}{kT}m_C^2 + \frac{\varepsilon_{DD}}{kT}m_D^2 + 2\frac{\varepsilon_{CD}}{kT}m_C m_D\right] - \frac{r_2^2}{z^2} \qquad (18.11)$$

$$\chi_{12} = -\frac{z}{2}\left[\frac{\varepsilon_{AC}}{kT}m_A m_C + \frac{\varepsilon_{AD}}{kT}m_A m_D + \frac{\varepsilon_{BC}}{kT}m_B m_C + \frac{\varepsilon_{BD}}{kT}m_B m_D\right] - \frac{2r_1 r_2}{z^2}$$

where ε_{ij}(i, j = A, B, C, D) are nearest-neighbor van der Waals attractive energies between groups of atoms. The effects of chain stiffness and side groups and steric interaction have been incorporated into the basic lattice cluster theory, BLCT. Defining s_i as the occupancy number, the compositional fractions may be expressed as

$$\frac{n_A s_A}{M_1} = m_A = 1 - m_B = \frac{x s_A}{x s_A + (1 - x)s_B}$$

$$\frac{n_C s_C}{M_2} = m_C = 1 - m_D = \frac{x s_C}{x s_C + (1 - x)s_D} \qquad (18.12)$$

An example of computed phase boundaries for homopolymer/copolymers is presented in Fig. 18.16.

18.6.1.4 Assessing Miscibility from the Flow Behavior

The PO_1/PO_2 blend miscibility depends on the degree of difference of their chain structures and concentration. As a rule, different PE types are immiscible with each other. However, since for controlling PO properties a small amount of

comonomer may be incorporated, without detailed information, it is impossible to predict if a given resin grade will be miscible with another PO or not. For example, for controlling crystallinity of HDPE, it usually contains a small amount of C_3 or C_4 comonomer. It was reported that some LLDPEs (containing a small amount of C_4) have limited miscibility with HDPE (Kotani et al. 1990; Taka et al. 1990).

Generally, it is difficult to judge if a PO blend is miscible or not. Because of small difference between the refractive indices (RI), the melt turbidity is often absent during or after the phase separation. When crystallized, co-crystals may form under specific set of the thermodynamic and kinetic conditions, e.g., co-crystallization is possible when the components are isomorphic or miscible in the amorphous and crystalline phase (Olabisi et al. 1979).

Two principles have been used for detecting miscibility by rheological means:
- Molecular polydispersity effect on a rheological function – assuming miscibility one may compute what effect incorporation of another polymer should have, compare with the experimental data, and draw conclusion. The following functions have been examined:
- Coordinates of the Gross frequency relaxation spectrum maximum (see below).
- Deviation from the log-additivity, $\log \eta_{blend} = \sum w_i \log \eta_i$, etc.
- Cross-point coordinates (G_x, w_x), where $G_x \equiv G' = G''$
- Free volume gradient of viscosity: $a_1 \equiv d \ln h/d(1/h)$
- Initial slope of the stress growth function: $m = 1/n$
- The power-law exponent, n, etc.
- Effect of the inherent nature of the two-phase flow
- Deformability of the dispersed phase leads to behavior not observed for single phase
- Extrudate swell parameter, $B = D/D_o$
- Strain (form) recovery, γ_r
- Yield stress, σ_y

Gross frequency relaxation spectrum, $H_G(\tau)$, leads to (Utracki and Schlund 1987)

$$\widetilde{H}_G \equiv H_G/\eta_o = (2/\pi)r^{-m_2} \sin(m_2\theta); \quad \text{but}: \int_{-\infty}^{\infty} \widetilde{H}_G d\ln\omega = 1 \qquad (18.13)$$

Here the two equation parameters, r and θ, are defined in terms of the Carreau–Yasuda equation (Carreau 1968, 1972; Yasuda 1979, 1981):

$$(\eta - \eta_\infty)/(\eta_o - \eta_\infty) = [1 + (\tau\dot{\gamma})^{m_1}]^{-m_2} \qquad (18.14)$$

Since the integral over the reduced Gross frequency spectrum equals zero-shear viscosity, η_o, the coordinates of the maximum, ω_{max}; $\widetilde{H}_{G,max}$, are related to MW

Fig. 18.17 The five types of
the viscosity/concentration
dependence in polymer blend
(Utracki 1991)
and MWD, respectively. In miscible blends, the general relation between the relaxation spectrum of a mixture and its composition follows the third order blending rule:

$$H_G(\tau) = \sum w_{ijk} H_{Gijk}(t/\tau_{ijk}) \quad \Rightarrow \quad H_G(\omega) = \sum w_i H_{Gi}(\omega) \qquad (18.15)$$

The second dependence is valid when all fractions are either entangled or not. Thus, $H_G(\tau)$ of a miscible blend is a linear combination of the component relaxation spectra and their weight fractions, w_i; *ergo* deviation from linearity in plots of log H_G versus M_w/M_n and log w_{max} versus log η_o indicates immiscibility.

Another approach to miscibility effect on flow is through analysis of the constant stress viscosity–concentration dependence. For solutions of small molecules, the log-additivity rule is most often found:

$$\log\eta_{blend} = \sum_i w_i \log\eta_i \qquad (18.16)$$

However, for polymer blends the situation is more complex as four additional forms of this dependence have been identified, namely, negatively deviating blends (NDB), positively deviating blends (PDB), and combination of these two, i.e., PNDB and NPDB (see Fig. 18.17).

It is interesting that for perfectly miscible low-MW paraffins (Utracki 1983) as well as for HDPE (Bai et al. 2010) blends, a PDB was observed. The effect originates in a more efficient packing of different size statistical segments, which leads to a reduction of free volume and increase of viscosity.

In the case of noncompatibilized blends, the chain ends and low-molecular-weight additives migrate to the interphase, providing a low-viscosity lubricating

layer in shear flow, which results in the NDB behavior (Utracki 1989a). It has been shown that steady-state flow of immiscible polymer blends is governed by (Utracki 1991; Bousmina et al. 1999)

$$
\begin{aligned}
&\ln\eta_{\text{blend}} = \ln\eta_{\text{layers}} + \Delta\ln\eta_{\text{emulsion}} \\
&1/\eta_{\text{layers}} = (\phi_A/\eta_A) + (\phi_B/\eta_B) + k\sqrt{\phi_A\phi_B}; \quad k \propto (\eta_i\Delta l)^{-1} \\
&\Delta\ln\eta_{\text{emulsion}} = \eta_{\max}\left\{1 - \left[(\phi_1 - \phi_{1I})^2/(\phi_1\phi_{2I}^2 + \phi_2\phi_{1I}^2)\right]\right\}
\end{aligned}
\tag{18.17}
$$

In the second relation in Eq. 18.17, the k-parameter is inversely proportional to the thickness of the interphase, Δl, and the interphase viscosity, η_i. Thus, a large negative deviation from the additivity is a sign for the interlayer slip, hence immiscibility. However, the slip may be eliminated by compatibilization, which results in the yield stress at low stress level and PDB. In such a case, tests at higher stresses may show a progressive change of the viscosity–concentration curve from PDB to deepening NDB. Equation 18.17 (in its initial form) was found to follow well the η_o versus ϕ dependence for immiscible m- LLDPE/LDPE blends (Liu et al. 2002). Blends with the viscosity ratio $\lambda \equiv (\eta_1/\eta_2)_{\sigma = \text{cont}} > 3.8$ behave like suspensions – the viscous drops are nondeformable and these emulsions are expected to follow a PDB behavior, at least up to the phase inversion volume fraction, ϕ_I.

Hussein and his colleagues studied miscibility of various types of the PE_1/PE_2 blends following their melt rheology and crystallization. The authors assumed that for miscible blends the rheological behavior linearly changes with composition, while the PDB or NDB is an evidence of immiscibility by the emulsion or interlayer slip mechanism, respectively. However, the rheological response also is related to the system free volume content (v), and addition of branched polymer with lower v increases the rheological signal, even if the system is miscible. However, phase separation that leads to emulsion-like system, indeed, increases the departure from linearity (additivity). Table 21.7 summarizes results of these publications. The data suggest that (1) the PE/PE miscibility depends on MW; (2) blends with m-LLDPE are more miscible than those with Z-N–LLDPE, i.e., the regularity of branch placement along the main chain is more important than branch content; (3) increasing the branch length from C_4 to C_8 increases miscibility of LLDPE with LDPE; and (4) decreasing SCB enhances miscibility with HDPE.

In 1987 Utracki and Schlund characterized a series of ten Z-N–LLDPEs, LDPE, and their LLDPE/LDPE blends (Utracki and Schlund 1987; Schlund and Utracki 1987a, b). Properties of the ten experimental resins are listed in Table 18.8. Since for full evaluation of performance a large quantity of material was needed, the blends were compounded in a corotating twin-screw extruder (TSE), using commercial LPX-30, LLDPE-10 (both Z-N–LLDPE), and LDPE-102. Two series of blends were prepared: Series I of LPX-30 with LLDPE-10 and Series II of LPX-30 with LDPE-102. The miscibility was judged from the location of the Gross relaxation spectra maximum (Eqs. 18.12, 18.13, and 18.14). Two dependencies for the

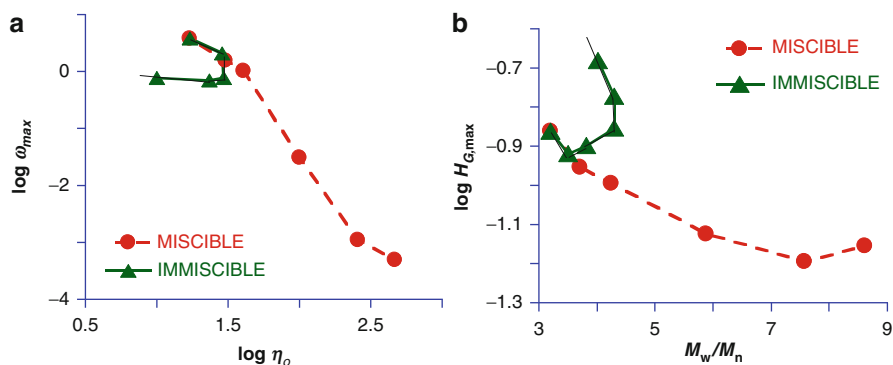
M_n and M_w are in kg mol^{-1}; LLDPE-8, LLDPE-9, and LLDPE-10 have bimodal MW distribution


Fig. 18.18 (**a**) Correlation between the abscissas of relaxation spectrum maximum and the zero-shear viscosity for PE/PE Series-I (miscible LPX-30/LLDPE-10) and Series-II (immiscible LPX-30/LDPE). (**b**) Correlation between the ordinate of relaxation spectrum maximum and the polydispersity factor M_w/M_n for PE/PE Series-I (miscible LPX-30/LLDPE-10) and Series-II (immiscible LPX-30/LDPE)

two series of PE blends are shown in Fig. 18.18a, b. Evidently, Series I is miscible, while Series II is not. The conclusions were confirmed by measuring the extrudate swell. In immiscible LPX-30/LDPE blends, the strain recovery of elongated droplets created disproportionately large extrudate swell, $B = d/d_o$ (Utracki and Schlund 1987; Schlund and Utracki 1987).

Good historical review on the *Characterization and Optimization of Polyethylene Blends* is a part of the PhD thesis (Cran 2004). Zhao and Choi (2006) reviewed miscibility of PE blends in three parts: (1) miscibility inferred from indirect methods, (2) interaction parameters, and (3) molecular simulation. Unfortunately, only selected binary blends of HDPE, LDPE, Z-N–LLDPE, and m-LLDPE, from ca. 1990 to 2000, are discussed. The authors postulate that the branch content, BC, of the two components determines miscibility, while MW, MWD, and branch length are secondary. However, the presence of a few long-chain branches could induce immiscibility in the blends.

18.6.2 Rheology

Rheology may be used for detecting miscibility or for changing it – there is a reciprocal interaction between the flow and equilibrium thermodynamics. The simple and elegant way for expressing it is by using the Gibbs energy of mixing of a flowing system and then computing the binodal and spinodal curves:

$$\Delta G_{\dot{\gamma}} = \Delta G_{\mathrm{m}} + \Delta E_{\dot{\gamma}} = \Delta G_{\mathrm{m}} + E_{\dot{\gamma}} - \sum_i \phi_i E_i$$

$$\text{binodal:} \quad \left(\partial \Delta G_{\dot{\gamma}} / \partial \phi_i\right)_{P,T,n_j}^{\text{phase}-1} = \left(\partial \Delta G_{\dot{\gamma}} / \partial \phi_i\right)_{P,T,n_j}^{\text{phase}-2} \qquad (18.17)$$

$$\text{spinodal:} \quad \left(\partial^2 \Delta G_{\dot{\gamma}} / \partial \phi_1^2\right)_{P,T} = 0$$

Thus, the problem is reduced to selection of expressions for ΔG_{m} and $E_{\dot{\gamma}}$ followed by an appropriate algebra. An example of results is displayed in Fig. 18.19 for a blend that is being shear homogenized (Soontaranun et al. 1996). However, this behavior is not universal as the different topographies of PE result in either thermorheological simplicity (linear- and short-chain-branched PE) or two different types of thermorheological complexity, i.e., LCB-mPE has a temperature-dependent spectrum, whereas LDPE complexity requires a modulus shift (Resch et al. 2011). Equation 18.17 suggests that homogenization and demixing depend on the sign of the derivative: $(\partial^2 E_s / \partial \phi^2)$. If its value is negative, the homogenization is to be expected; if it is positive, shear demixing is to be expected.

At low concentration of a second polymer, blends have dispersed-phase morphology of a matrix and discrete second phase. As the concentration increases, at the percolation threshold volume fraction of the dispersed phase, $\phi_{\mathrm{c}} \cong 0.16$, the blends' structure changes into co-continuous. Maximum co-continuity is achieved at the phase inversion concentration, ϕ_{I}. The morphology as well as the level of stress leads to different viscosity–composition dependencies. The deformation and dispersion processes are best described by microrheology, using the three dimensionless parameters: the viscosity ratio (λ), the capillarity number (κ), and the reduced time (t^*), respectively (Taylor 1932):

Fig. 18.19 Computed spinodals at constant shear rates, $\dot{\gamma} = 0.01 - 1.0$ s^{-1}, for a shear homogenizing blend (Soontaranun et al. 1996)
$$\lambda \equiv \eta_{\text{dispersed}}/\eta_{\text{matrix}}; \quad \kappa \equiv \sigma_{ij}d/v_{12}; \quad t^* \equiv t\dot{\gamma}/\kappa \qquad (18.18)$$

where $\eta_{\text{dispersed}}$ and η_{matrix} are the dispersed phase and matrix viscosity, respectively, σ_{ij} is the local stress, $\dot{\gamma}$ is the deformation rate, d is the droplet diameter, and v_{12} is the interfacial tension coefficient. The equilibrium deformation is reached at the reduced time, $t_d^* \simeq 25$, whereas the break at $t_b^* \simeq 160$. Thus, the dispersion process is controlled by the type of flow field, the viscosity ratio (at a given stress), the interfacial tension coefficient, as well as the duration of deformation.

At concentration, $\phi_2 \geq 0.005$, the dynamic process of dispersion is paralleled by coalescence. The dynamic equilibrium morphology is a net result of the dispersive and coalescing processes. The dynamic coagulation rate is related to the projected area of the drop, $d* \propto \phi_2^{2/3}$. Thus, during the shear flow, the rates of the diameter change may be expressed as

$$\left.\begin{array}{l} (dd/dt)_{\text{coalescence}} \propto \dot{\gamma}\phi^{8/3}/d \\ (dd/dt)_{\text{break}} \propto -\dot{\gamma}d/\kappa_{cr}t_b^* \end{array}\right\} \qquad (18.19)$$

According to these equations, the shear rate is expected to affect similarly coalescence and breakup; thus, increasing or decreasing $\dot{\gamma}$ should only slightly affect the degree of dispersion. However, the flow-induced coalescence depends on concentration, whereas the break is independent of ϕ. Thus, concentration discriminates these two processes. Also, the rate of break is proportional to d, whereas the coalescence is proportional to $1/d$. Thus, coalescence is not expected to play a major role at the beginning of the dispersion process when the drops are large – importance of this process increases with the progress of dispersion.

Droplet growth dynamics have been studied, experimentally and theoretically, by Vinckier et al. (1998). The diluted blends had $\lambda \approx 1$. The experiment started by

pre-shearing the material at a high rate to create small droplets. Then, the shear rate was reduced, and droplet coalescence was followed as a function of time under shear (Vinckier et al. 1998). Thus, by selecting appropriate test conditions, one may study dynamics of coalescence and the breakup processes (Vinckier et al. 1998; Tucker and Moldenaers 2002).

Results of recent experimental and theoretical studies of PP blends with a series of C_{2+8} m-LLDPE η_o (200 °C) = 0.7, 1.4, and 7.3 kPa s followed a modified Lee and Park equation. Good fit to the stress growth viscosity was obtained and indicated that shearing at low rate of $\dot{\gamma} = 0.1$ s^{-1} for about 30 min reduced the interfacial area by 88 %, 48 %, and 42 %, respectively; hence, the most viscous blend coalesces the easiest.

Increasing concentration of the minor phase changes the blends' morphology from drop dispersion to increasingly interconnected structures. At the phase inversion volume fraction, ϕ_I, the distinction between the dispersed and matrix phases vanishes – the morphology becomes co-continuous. It has been observed that the onset of continuity in polymer blends occurs at the volume fraction of the dispersed phase: $\phi_{onset} = 0.19 \pm 0.09$, i.e., near the percolation threshold concentration, $\phi_{perc} = 0.156$ (Lyngaae-Jørgensen and Utracki 1991). The co-continuity may result in several desirable properties, for example, synergism between rigid and ductile blend components that leads to materials with advantageous combination of high modulus and high impact strength.

The predictive relation for the volume fraction at phase inversion, $\phi_{1I} = 1 - \phi_{2I}$, is given by the following dependence:

$$\lambda = [(\phi_m - \phi_{2I})/(\phi_m - \phi_{1I})]^{[\eta]\phi_m} \tag{18.20}$$

where ϕ_m is the maximum packing volume fraction: $\phi_m = 1 - \phi_{perc}$. Equation 18.20 postulates that at the phase inversion, the two nominal blends, polymer-1 in polymer-2 and polymer-2 in polymer-1, have the same *relative* viscosity. For immiscible polymer blends the two equation constants, $[\eta] = 1.9$; $\phi_m = 0.84$, provided good description of data (Utracki 1991).

The percolation threshold near $\phi_p \approx 0.2$ is evident in several plots of η_o versus ϕ, of LDPE/branched PE (Peón et al. 2003), LDPE/HDPE (Sarkhel et al. 2006), or melt strength of LDPE/LLDPE (Field et al. 1999; Ho et al. 2002). The latter authors noted that for film-blowing bubble stability, miscibility and melt strength in elongation are important. For good process ability of LLDPE, ≥20 wt% of LDPE was required.

The miscible blends of LDPE/m-LLDPE often follow the Friedman and Porter (1975) equation:

$$\eta_{o,\,blend} = \left[\sum w_i(\eta_{oi})^{1/3.4}\right]^{3.4} \tag{18.21}$$

Schlund and Utracki (1987) carried out extensive rheological studies on two series of PE blends both containing LLDPE (C_{2+4} with $M_w/M_n = 3.22$) polymerized with Cr catalyst. Series I was its blend with LLDPE (C_{2+6} with $M_w/M_n = 8.94$) polymerized with Ti catalyst, while Series II contained LDPE ($M_w/M_n = 4.00$);

Series I was found miscible, Series II immiscible. In the second series the percolation concentration in plots of η_o or extrudate swell versus ϕ was hardly detectable but dramatically evident in the plot of the T and P coefficient, a. The latter was determined by plotting η_o as a function of the free volume fraction, f (Utracki 2011):

$$\log\eta_{\sigma=const} = a_o + a_1/[f + a] \tag{18.22}$$

The effect may be related to variation of the interphasial area and the excess free volume.

18.6.3 Compatibilization of Polyolefins

Only in rare cases (mixtures with $\phi_2 < 0.1$ or compositions near the phase inversion) the compatibilization may not be necessary. However, even in these cases it has beneficial effects on the performance. The compatibilization must (1) reduce the interfacial tension and facilitate dispersion, (2) stabilize the generated morphology against modification during the subsequent processing steps, and (3) enhance adhesion between the polymers' domains, facilitating the stress transfer, hence improving the mechanical properties of the product. Details of compatibilization are provided in ▶ Chaps. 4, "Interphase and Compatibilization by Addition of a Compatibilizer" and ▶ 5, "Reactive Compatibilization" of this handbook.

In essence, the compatibilization is a control of the interface of two immiscible PO phases, i.e., the interphase. In the simplest case, this is accompanied by partial dissolution of parts of the compatibilizer in the two phases. However, too much compatibilizer or using too high MW may form micelles then mesophases that reduce the blend performance. A compatibilizer must be designed by taking the thermodynamic and kinetic parameters into account.

In the case of PO blends, compatibilization most frequently aims for improved ductility and/or transparency. The Z-N–LLDPE obtained using multi-sited catalyst constitutes a specific case – the homopolymer may have phase-separated morphology that requires compatibilization. It has been known that addition of 5–20 wt% LDPE needs to be used for improved performance. However, explanation for this is rather recent (Robledo et al. 2009). The relaxation spectrum of the blend may be decomposed into three components: (1) Z-N–LLDPE matrix, (2) LDPE dispersed drops, and (3) a thick interphase with its own viscoelastic properties, obtained by interaction between the high-MW linear fraction of the LLDPE and the low-MW linear LDPE macromolecules.

Four methods of compatibilization have been used with PO blends:
- Addition of a compatibilizer: either a small amount (0.5–4 wt%) of tailored copolymer, a multipurpose compatibilizer-*cum*-impact modifier, or a cosolvent. Here, the elastomeric polymers or copolymers are primarily used (see Appendix, Table 18.11).
- Reactor compatibilization, wherein sequential steps PO-1, compatibilizer, and PO-2 are polymerized with the same or different catalyst (see Appendix, Table 18.11).

- Reactive compatibilization in a compounder that generates the desired quantity of either block or graft copolymers, which form chemical bonds across the interphase.
- Physical compatibilization that generates fine, nonequilibrium morphology and locks it by nucleated crystallization. The process may be carried out in the molten or solid state.
  Several types of reactive compatibilization have been used:
- Chain cleavage and recombination that lead to formation of random copolymers
- Reactions involving chain end groups of both polymers, forming of block copolymers
- Reactions between chain end of one polymer and side group forming graft copolymers
- Covalent grafting and cross-linking that result in high-MW copolymers
- Ionic bonding

During these reactions, the copolymers are produced at the interface. The method is superior to that of compatibilizer addition. Since TSEs are operated with short residence time, to complete the reactive compatibilization, one must use either high concentration of reactive groups, highly reactive functional groups, or efficient catalyst; hence, it is required that:

- There is sufficient mixing to achieve the desired dispersion.
- Reactive functionalities will form covalent or ionic bonds.
- The reactants are capable reacting across the interphase.
- The reaction rate is high.
- The formed bonds are stable.

18.6.4 Compounding Polymer Blends

The shear flow is inefficient for dispersing one polymer in another if they significantly differ in viscosity, especially for $\lambda \geq 3.8$. The elongational field is more proficient and rapid. It exists anywhere where the streamlines are not parallel. In elongational flow:

- The magnitude of interfacial area increases more rapidly than in shear.
- The rate of spatial separation between drops is higher.
- The energy consumption is reduced.
- The temperature is more stable (no shear heating).

Mighri and Huneault (2001, 2002) reported interesting differences in drop deformation and breakup during the Couette flow at increasing stress, between Newtonian and viscoelastic drops (see Fig. 18.20). While Newtonian drops elongated as κ (see Eq. 18.18) increased, the viscoelastic ones elongated only up to a critical value, characteristic of the system. Next, as the stress increased further, the deformed drops began to contract in the flow direction, thus elongating in perpendicular to the flow direction. This deformation increased with shear stress until breakup. Such a behavior is related to the normal forces present at high deformation rates in viscoelastic systems such as the investigated EPR/PP one. In Couette flow,
Fig. 18.20 Contrasted deformability of Newtonian and viscoelastic drops – 2D drop length-to-width versus the capillarity number (Mighri and Huneault 2001)

the breakup of these viscoelastic drops was initiated by a flow disturbance, caused by a stress gradient across the flow gap, when drop ends are in different planes, experiencing different shear stress. Other dispersion mechanisms, e.g., erosion, have also been observed for the viscoelastic, but not for Newtonian systems. Comparing the stress tensors of shear with elongational flows, it is evident that the reported problems associated with the deformation-opposing normal forces in shear are absent in elongation.

A single-screw extruder (SSE) operates on the principle of laminar shear flow. The lamellas of each polymer are thinned down along the screw length without folding. If the screw is long enough (for a given system), eventually the lamellas may break into fibers and these disintegrate into drops (Lindt and Ghosh 1992). To improve the mixing capabilities of SSEs, diverse mixing screws and add-on devices have been developed. The motionless mixers (MM) operate on the principle of splitting the flow stream into channels, reorienting and dividing them. The devices are quite efficient as distributive mixers, but they do not provide the dispersive function. The extensional flow mixer (EFM) has strong, controllable dispersive capabilities (Nguyen and Utracki 1995; Bourry et al. 1995; Luciani and Utracki 1996, 1997). The results demonstrated better blending performance of the SSE + EFM system than that of a twin-screw extruder, TSE.

In order of importance the polymer blending aims at producing materials with improved toughness, strength, rigidity, process ability, and heat deflection temperature (HDT) and with reduced permeability. Designing a blend for specific performance means that its morphology must be optimized. Furthermore, different properties require different morphologies, viz., for toughness, the elastomeric component should be dispersed as spherical drops with micron or submicron diameter, while for the reduction of permeability, the minor phase should be in form of relatively large drops, $d \cong 50 \ \mu m$, that during the biaxial stretching (e.g., while blow molding of containers) could be deformed into thin lamellas,

etc. Thus, selecting suitable compounding method is important. For example, under comparable conditions, uncompatibilized PE/PS blends emerging from SSE, TSE, and SSE + EFM showed the number average diameter, $d_n \cong 650$, 1.6, and 1.2 μm, respectively.

There are several mathematical models that attempt describing the variations of blend morphology during compounding in a TSE (Utracki and Shi 1992; Shi and Utracki 1992; Bordereau et al. 1992; Huneault et al. 1995; Delamare and Vergnes 1996). They require the following inputs: screw configuration, extrusion conditions, and polymer properties. Usually, the pressure profile and local strains in the extruder are first computed, and then, using this information, the average drop size along the screw is calculated from the microrheological rules supplemented by the coalescence kinetics. Due to the very rapid change of blends' morphology during the first instant after the mixing is stopped, there are some doubts regarding the accuracy of the models. Certainly, they may describe well the morphological changes, but even quenching the specimens within a second does not guarantee that the observation represents the true state present during mixing.

18.6.5 Polyolefin Degradation and Stabilization

Polyolefins are susceptible to several degradative mechanisms, out of which thermo-oxidative and thermomechanical are dominant. The PO stability depends on macromolecular configuration and it follows the order: HDPE > LLDPE > LDPE > i-PP. Chemiluminescence, FT-IR, mechanical properties, and thermogravimetry have been used for detecting and quantifying degradations (Cran 2004).

Degradation occurs during compounding, forming, and lifetime of an article; thus, stabilizers are needed. However, since these substances are expensive, they are added in a quantity just sufficient to protect the polymer during the first compounding, forming, and serving cycle – to be recycled, the polymer must be restabilized as:

- Degradative processes may have changed macromolecular structure.
- Different residual stabilizers may be present. It was observed that when recycling resins from different sources, these stabilizers may co-react, into inert compounds.
- The new additives should not react antagonistically with old ones,

In the following text, the principles of degradation and methods of stabilization will be discussed, first in the context of melt compounding and forming, then concerning the postforming processes (Herbs et al. 1997; Zweifel 1998). An excellent review of degradation of polymer blends was published by La Mantia (1992).

18.6.5.1 Degradation and Stabilization During Processing

Compounding and forming are carried out in the melt, at higher T and P and in intensive shear field. Owing to the enhanced chain mobility in the molten phase, the degradation processes are rapid. The compounding and/or melt forming of commodity plastics requires heating them to the processing temperature, $T_{process} = 175-300\,°C$,

for several minutes at a time. In the absence of stabilizers, this may lead to severe reduction of MW, thus performance. Depending on the type of polymer and processing conditions, one or several degradation mechanisms may take place (Klemchuk 1997; Zweifel 1998):

- Thermo-oxidative degradation of macromolecules in the presence of oxygen (O_2). The process is catalyzed by metals and metal ions, accelerated by heat and shear.
- Auto-oxidation – an autocatalytic free radical degradation in the presence of O_2. It affects polymers during aging; thus, it is controlled by diffusion of O_2 in solid state.
- Mechanochemical degradation caused by high stresses during mixing, blending, compounding, or processing. It results in chain scission and generation of free macroradicals. The process leads to the thermo-oxidative degradation as described above. Depending on the relative concentration of the tertiary carbons, the macroradicals terminated by different mechanism reduces or increases MW.

In principle, since compounding and forming are carried out in an enclosed heated space, e.g., in an extruder, they are conducted in the absence of oxygen and destructive radiation, which dominate the postforming degradation. For addition polymers, the thermo-oxidative and mechanochemical degradations are most important. These processes are mostly radical, but in the presence of specific catalysts, they may ionically decompose. During storage, PO chains slowly react with ambient oxygen forming peroxy, hydroperoxy, or peroxy-acid groups (the auto-oxidation). When heated, these decompose into free radicals that start the degradative chain reactions (Bateman 1954). Their rate is related to unsaturation, viz., the time to failure at 100 °C was 10,000, 500, 69, and 15 h, respectively, for PP, HIPS, SBR, and BR.

In a stress field, macromolecules are susceptible to bond breakage. This process also generates free radicals that lead to the degradative chain reactions. In POs, the free radical chain reactions lead to chain scission, grafting, or double-bond formation. Proportions of these structures depend on the concentration of tertiary carbon atoms. Thus, chain scission dominates degradation of PP, whereas grafting and cross-linking occur in HDPE. The LLDPEs, with copolymeric structures, show more complex behavior caused by the presence of all three reactions. Since chain scission statistically affects the longest chains, it reduces MW and narrows MWD. The opposite is true for the chain branching. The easiest method of identification of the prevailing mechanism is to use the dynamic mechanical test at low frequency. The time-dependent variation of the storage and loss moduli gives independent information about, respectively, grafting and chain scission (Schlund and Utracki 1987a).

As shown in Table 18.9, to be effective, stabilization should involve addition of several agents active within a specific stage of the degradation process, viz., initiation, propagation, or termination. Thus, it is important to use a cocktail of properly formulated stabilizers that is optimized to inhibit degradation of a specific polymer type.

Table 18.9 Stabilization strategies (Gätcher and Müller 1989; Zweifel 1998)

| Examples of stabilizers | Degradation | |
	Thermo- and auto-oxidative	Photooxidative
Complexing agent: N,N'-bis(o-hydroxybenzyl) oxalyl dihydrazide	Metal deactivation	(Not applicable)
UV absorbers: hydroxybenzophenones, triazoles, triazines, oxanilides, etc.	(Not applicable)	Absorb UV portion of sunlight
Quencher: Ni chelates	(Not applicable)	Deactivate excited chromophores
Hydroperoxide decomposers: phosphites and phosphonites, organosulfur compounds	Reacts with peroxides	Reacts with peroxides
Radical scavengers hydroxylamines, benzofuranone derivatives, etc.	Reacts with free radicals	Reacts with free radicals
H-donors: hindered phenols, secondary and sterically hindered aromatic amines, etc.	Reacts with macroradicals	Reacts with macroradicals

To stabilize POs against degradation during the melt processing, antioxidants (e.g., hindered phenols, sulfide esters, organic phosphites, secondary aromatic amines, and hindered amines), peroxide decomposers (usually a phosphite), and frequently acid acceptors (e.g., calcium stearate) are used. For special applications, metal deactivators may be needed.

The following rules were formulated regarding stabilization of recyclates:

- Antioxidants, hydroperoxide decomposers, and processing stabilizers should be added in quantity required by the process and service time under given exposure.
- Light stabilizers should be added depending on the foreseen storage conditions, applications, and service lifetime.

It is important to recognize that additives suitable for one type of resin may have detrimental effects on another and/or on their additives. Furthermore, the stabilizing systems of one polymer type may neutralize the system of another polymer. For example, to stabilize postconsumer waste (PCW), 55–75 wt% PO, 5–25 wt% PS, 5–15 wt% PVC, and 0–10 wt% other thermoplastics, 0.1–0.5 wt% of a stabilizer mixture was added. The mixture comprised a sterically hindered phenol [pentaerythritol ester] and tris(2,4-di-tert-butylphenyl) phosphite at a ratio of 5:1–1:5. For other compositions of PCW, different stabilizers, viz., thiopropionic acid, benzophenones, oxalides, benzotriazoles, HALS, and/or CaO, may have to be used (Pauquet et al. 1994).

18.6.5.2 Post-processing Degradation and Stabilization

During the life-span of the polymeric products, they are exposed to a wide range of degradative influences. Besides the previously mentioned oxidative and hydrolytic processes, the photodegradation, thermal aging, physical aging, as well as biodegradation may be present.

The photooxidation takes place when UV irradiation causes formation of free radicals that in turn absorb oxygen molecules. Most double-bond structures in

rubbers and aromatics readily absorb photo energy at 200–360 nm. Hydroperoxides are powerful chromophores for PO with tertiary carbon.

As shown in Table 18.9, stabilization against photooxidative degradation is accomplished by adding similar mixture of additives as that used for the thermo-oxidative degradation. The main difference is replacement of a metal deactivator by UV absorbers with high extinction coefficient in the range of 300–400 nm (e.g., hydroxy benzophenones, triazoles, triazines, oxanilides) and quenchers (e.g., Ni chelates). In principle, UV absorbers act as transformers, converting the high photo energy into heat. However, they are also being consumed in reactions with perox-ides; hence, they must be protected against oxidation, e.g., by phenolic antioxi-dants. Similarly, quenchers deactivate the excited chromophores by energy transfer, but they also enter into other stabilizing reactions, e.g., decomposing hydroxy peroxides, thus slowly are consumed during the service time.

18.6.5.3 Effect of Reprocessing on Performance

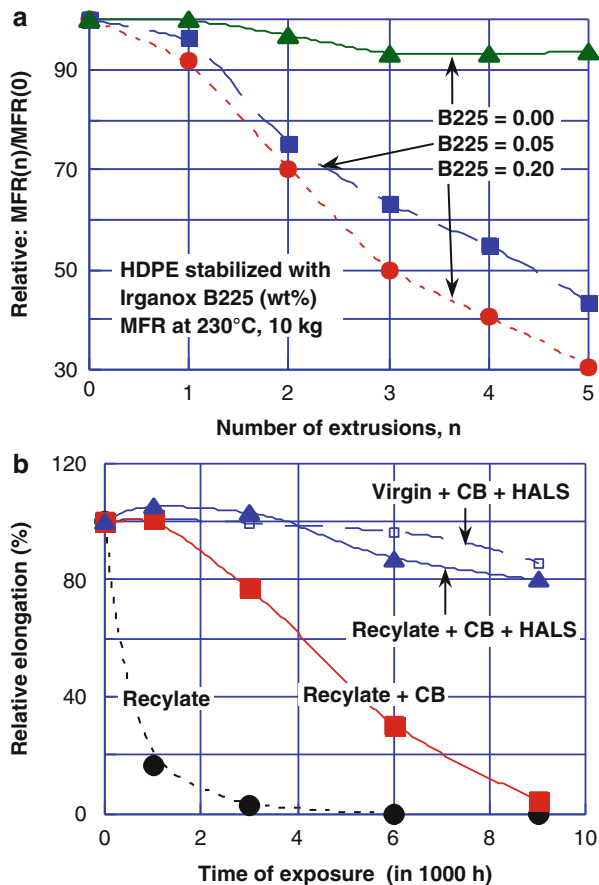
Figure 18.21a, b illustrates the extent to which the judicious stabilization is able to protect PO resins and their blends from the thermo- or photodegradation. As they indicate, the recyclates even after five extrusions show performance within 10 % approximating that of a virgin material. Similar behavior is expected for strongly immiscible polymer blends, under the condition that the recyclates will be re-compatibilized to recover the original morphology.

It is noteworthy that additives used for one type of resin may have detrimental effects on another resin and/or on its additives. This was dramatically shown by blending several grades of PA-6 with POs produced by different manufacturers – the aim was to determine the interfacial properties of PA/PO blends (Luciani et al. 1997). Mixing a PA with a PO containing phosphite stabilizer resulted in a rigid membrane formed at the interface through reaction between $-NH_2$ end groups of PA and phosphite acidic functionality. The membrane increased melt viscosity and decreased the degree of dispersion. The detrimental effects are most likely in the presence of heat and light stabilizers.

To recycle polymer blends it is important to regenerate the morphology and to restabilize the ingredients. Thus, it is necessary to provide adequate mixing, re-compatibilize and restabilize the blend. Frequently, the recycled blends should be impact modified. There are two reasons for this: (i) contamination of the composition by other polymers and (ii) degradation of the usually less stable compatibilizers and impact modifiers.

Useful properties of mixed resins can be obtained without compatibilization when:

- Recycling commingled resins of the same chemical species, e.g., recycled resin with virgin resin, LLDPE with LDPE, and m-PO with ZN-PO.
- Components are nearly miscible with each other, e.g., Z-N–LLDPE with some PP or *m*-LLDPE, and HDPE with some LLDPE.
- Content of the dispersed phase does not exceed 5–15 vol%.
- Blends have co-continuous morphology.
- Materials developed for aesthetic, not structural reasons, viz., compositions showing nacreous or wood-grain effect.

Fig. 18.21 (**a**) Effects of addition of Irganox B225 (1:1 blend of Irganox 101 and Irgafos 168) on repetitively extruded (up to five times) HDPE. The stabilizer was added in the amount of 0, 0.05, and 0.20 wt% (After Herbst et al. 1997). (**b**) Stabilization effects of HALS on a virgin and recycled LLDPE/LDPE blends with and without carbon black (CB) (After Herbst et al. 1997)


It is seldom recognized that mixing two PE resins from different sources constitutes blending with all what this term implies. Polyethylenes prepared using different catalysts or containing different comonomers are mostly immiscible. Furthermore, miscible blends that have widely different molecular weights are difficult to homogenize – frequently surface of the manufactured article is coarse due to "fish eyes" or gel particles being left behind after inadequate compounding. Incorporation of virgin PE to recycled one is frequently done to improve performance (La Mantia 1997; Zahavich and Vlachopoulos 1997). The incorporation must be done according to the standard rules of blending: adequate blending, compatibilizing, and stabilizing. For the miscible or well-compatibilized blends, the modulus (E) and yield stress (σ_y) are additive, whereas the maximum strain at break (ε_b) follows the inverse additivity rule:
$$Y = \sum_i \phi_i Y_i \bigg|_{Y=E,\,\sigma_y} \quad ; \quad \frac{1}{\varepsilon_b} = \sum_i \frac{\phi_i}{\varepsilon_{bi}} \qquad (18.23)$$

where ϕ_i is the volume fraction of polymer i. The dependencies are illustrated in Fig. 18.20.

There are diverse factors that make blends to disobey these rules. It has been frequently observed that blending two semicrystalline resins (e.g., HDPE/PP) enhances the heterogeneous nucleation which leads to higher crystallinity and finer crystals. As a result, blends' stress and modulus show a positive deviation from additivity – considered synergism. For example, for augmenting heterogeneous nucleation of LDPE and/or LLDPE with 2–60 wt% recycled HDPE, the mixture was compounded with 0.1–1.5 wt% ZnO and 0.1–2 wt% glycerol monostearate. The resulting blends could be foamed, extruded, molded, or cast to form films having up to 100 % higher elongation and 50–90 % increase in transverse film strength over LDPE alone. The products were used for packaging (Lee 1995) (Fig. 18.22).

On the opposite side is the antagonism observed in the elongation at break. This dependence originates in reduced adhesion between phases. Numerous mechanisms are responsible for it. For example, in the PE/PP blends, there is a phase separation – any low-molecular-weight impurity migrates to the interphase lowering its viscosity and reducing the strength. This may be seen using an acoustic microscope – coarse PP crystals in PE/PP blends are virtually rattling inside the matrix – there is a physical void around them. The void is created by the change of

density on crystallization. Materials having such micromorphology will have reduced maximum elongation, below the level predicted by Eq. 18.23.

Blends of two or more POs were recycled in the solid state at the processing temperature, T_p, such that $T_{m1} < T_p < T_{m2}$ (T_{m1}s are the softening points of the blends' components, provided that $T_{m1}–T_{m2} > 20$ °C). The components were PE, PP, PS, and polydienes – virgin, recycled, or mixed. The preferred POs were PE and PP, and preferred blends were those containing at least one PE, particularly a substantially linear ethylene polymer (Lai and Edmondson 1995). Reground PP from automotive interior parts was contaminated with up to 15 wt% of POM. At present, there is about 16 kg of PP per 1 kg of POM, the latter used for clips, fasteners, door-lock buttons, pivots, grilles, seat-belt buckles, etc. Presence of POM facilitated processability, and it had little effect on the tensile strength of recycled PP, and it improved modulus by ca. 12 % (Naitove 1996).

18.7   PE/PE Blends by Type

Historically, there were four major inventions in PE manufacture, i.e., LDPE, HDPE, Z–N–LLDPE (and Cr–LLDPE), and *m*-LLDPE. Blending them resulted in six categories: (1) LDPE/HDPE, (2) LDPE/Z–N–LLDPE, (3) LDPE/*m*-LLDPE, (4) HDPE/Z–N–LLDPE, (5) HDPE/*m*-LLDPE, and (6) Z–N–LLDPE/*m*-LLDPE. However, in reality, many modern blends are multicomponent as the "homopolymers" are frequently modified by small amount of comonomer. Numerous resin grades for specific application may be blends, e.g., Z–N–LLDPE with a small amount of LDPE that promotes strain hardening in elongational flow, essential for the film formation and wire coating or foaming. Thus, saying that there are six categories of binary blends is a simplification.

The following text will present these categories of PO blends and then it will attempt identifying characteristic properties and applicability of each. Avoiding duplication, the patent information to these blends will remain in Appendix, Table 18.11. The PE/PE blends have been reviewed (Utracki 1989a, b; Hamid and Atiqullah 1995; Utracki 1997; Cran 2004; Zhao and Choi 2006; Isayev 2011).

18.7.1 LDPE/HDPE Blends

Because miscibility of two PE resins depends on the degree of difference of their chain structures, HDPE blends with LLDPE are not expected to form single-phase melt or co-crystallize. However, since for controlling density HDPE may contain C_3 or C_4 comonomer, some HDPE blends with LDPE showed limited miscibility.

Depending on MW, molten LDPE/HDPE blends phase separate, but on rapid cooling, they may crystallize into single-type crystals with single T_m. The structure is not at the thermodynamic equilibrium since slow cooling leads to separated peaks for LDPE and HDPE (sometimes with an intermediate residual peak). The phase separation in LDPE/HDPE blends mainly depends on the MW of the HDPE

component. The immiscibility of LDPE/HDPE blends is often reflected in poor mechanical properties. Here, compatibilization and processing are the keys to success.

In 1977 Idemitsu Petrochemicals announced that immiscible blends of LDPE with HDPE, with EPDM, or with an atactic polypropylene, aPP, are suitable for the production of soft, thin films, with improved properties for packaging (Sakane et al. 1979). Similar blends, LDPE with HDPE, PP, and EP block copolymer, were proposed by Shin-Kobe Electric Machinery (1984) for films with good modulus, tear strength, and no sagging behavior. Also, Showa Denko (1983) found that immiscible, but lightly compatibilized, blends of LDPE with either HDPE or MDPE are suitable for films with uniform thickness and anisotropic tensile strength.

Hoechst disclosed blends having a bimodal MWD, comprising 50–80 wt% HDPE blended with either LLDPE or LDPE. The alloys were found suitable for molding or extrusion of tubes, pipes, and other articles requiring high stress crack resistance (Boehm et al. 1992). While most LDPE/HDPE blends were found immiscible, some reports stress that they formed homogeneous melt and could be quenched into co-crystals with a single T_m. There are two other variables that need a thought – the degree of LCB in LDPE and MW of both polymers (Zhao and Choi 2006).

18.7.2 LDPE/Z-N–LLDPE Blends

Miscibility is identified as an existence of a single phase; thus, the term refers to liquid systems: solutions and melts (some authors treat co-crystallization as a solid-state miscibility). Most polymer blends available on the market are immiscible, but with adequate interactions across the interphase. For example, by 1980 ca. 42 % film producers used immiscible LLDPE/LDPE blends, where LLDPE improved modulus and strength and LDPE enhanced processability and ductility. Properties of LLDPE/LDPE blends have been described in several publications (Utracki and Schlund 1986, 1987; Schlund and Utracki 1987; Zahavich and Vlachopoulos 1997). Blends of LLDPE with PP were also studied (Dumoulin et al. 1987, 1988, 1991; Dumoulin and Utracki 1990). Similarly, blends of PE with PC were described (Utracki and Sammut 1989, 1990b).

Blending Z-N–LLDPE with LDPE is widely established as a means for improving various properties of LDPE, and the commercial importance, melt behavior, and performance of LDPE/LLDPE film blends are well documented. While most blends of this type are reported miscible, the phase separation has been reported for some blends in the molten and semicrystalline state; in the latter case, two crystal populations were observed by DSC and TEM. Increasing the SCB from C_4 to C_8 promoted miscibility (Hussein et al. 2003; Hussein and Williams 2004b). However, the last statement contradicts the observation of LDPE/m-LLDPE (Fang et al. 2005). Furthermore, reduction of LLDPE MW improves miscibility (Hussein and Williams 2004a. Zhao and Choi (2006) concluded that miscibility of LDPE blended with Z-N–LLDPE or m-LLDPE is determined by LCB. The difference in branch content is the major factor, while those in MW, MWD, and SCB are secondary.

Shear and elongational data of LDPE/LLDPE blends have been reported, indicating thermorheological complex behavior. In unidirectional shear or elongational flow, the linear range of viscoelastic deformation is reduced and the terminal relaxation times are shifted toward that of LDPE (Wagner et al. 2004). Significantly, the strain-hardening (SH) behavior of LLDPE/LDPE blends entirely originates in LDPE. The nonlinear strain does not depend on the composition for blends with LDPE but rather on the SH of LDPE. Such a behavior may be understood by assuming the existence of two phases in the blends: the first containing highly branched low-MW chains from both polymers and the second composed of the high MW of both polyethylenes.

Several LDPE/Z-N–LLDPE blends have been found to be miscible in the melt and when cooled quickly do not segregate into separate crystalline phases, while slow cooling results in the formation of independent crystalline phases. It was suggested that the addition of HDPE to immiscible LDPE/LLDPE blends may induce full miscibility of the resulting ternary blend (Lee and Denn 2000). Blending Z-N–LLDPE with LDPE may improve processability, toughness, impact strength, optical clarity, environmental stress cracking resistance, as well as resistance to thermal embrittlement and increased tear resistance.

The blends comprising LDPE with Z-N–LLDPE have improved stiffness and abrasion resistance and reduced water vapor permeability. Celanese patent application from 1961 stressed the improvement of LLDPE processability (Wissbrun et al. 1962, 1965). In a contemporary DuPont application, 10–50 wt% LLDPE was blended with LDPE to obtain materials suitable for the use as heat-shrinkable films (Golike 1962). Since LLDPE differs from LDPE by the presence of short side groups introduced as a part of the comonomer unit and by the absence of long-chain branching, there have been several attempts to create the latter chain structure by addition of radicals to molten LLDPE, expecting that these will graft on some LLDPE macromolecules converting part of the resin into LDPE-like polymer. These long-branched molecules would be simultaneously blended with unmodified LLDPE macromolecules creating an intimate PE/PE blend possessing all the superior characteristics of the LLDPE/LDPE blend. The main problem associated with this technology was the difficulty in controlling uniformity of product. The small quantity of peroxides tended to form pockets of degraded resins that contaminated the product. In 1971, Exxon Research and Engineering disclosed reactive grafting of PE or PP. The extruder was modified for separately feeding the polymer and grafting the monomer and peroxide (Steinkamp and Grail 1976).

In 1979, the *UNIPOL*™ process for gas-phase production of LLDPE was introduced by the Union Carbide Corp. Since the new resins were difficult to process on the lines designed for LDPE, by 1982 several patents were issued for improvement of LLDPE processability by blending it with other polyolefins, viz., LDPE, PP, and olefinic rubbers. Ethylene copolymers, rubbers, EPDM, EVAc, maleated polypropylene, EPR, etc., have also been used (Cowan 1983; Turtle 1983; Fukui et al. 1983; Haas 1983; Hert 1983). Thus, blends LLDPE/LDPE were found miscible at low LDPE contents, then immiscible at high LDPE. Addition of HDPE as cosolvent resulted in miscible tertiary blends (Lee and Denn 2000).

In Societé Chimique des Charbonnages patent application of 1982, Z-N–LLDPE was blended with 2–25 wt% LDPE for the manufacture of films with large difference of tensile strength in the machine and transverse direction (Hert 1983). The reversed compositions were disclosed in Japan the following year. Thus, LDPE was blended with LLDPE at ratios varying from 100:20 to 100:90. The alloys were reported useful for the production of packaging films (Asahi Chem. Ind. 1985). A 1984 patent from Mobil Oil described LLDPE blends with 10–45 wt% LDPE, PP, or EPR copolymer with a high propylene content, 2–15 wt% EPR. The blends had high modulus and excellent clarity (Bahl et al. 1985). LLDPE was grafted with dimethylamino ethyl methacrylate, t-butyl amino ethyl methacrylate, vinyl pyridine, or allyl urea. The copolymers were used as reactive components for PO alloys with acidified polymers, viz., maleated LLDPE or PP (Baker and Simmons 1991). In 1992, Euro-Matic developed blends comprising Z-N–LLDPE with LDPE at a ratio of about 3:10. These resins were used for blow molding hollow balls containing pressurized air and consisting of two hemispheres welded to form a ball with a wall thickness of 0.5–1.8 mm (Moss and Modigh 1994).

Delgadillo-Velázquez et al. (2008a) studied the thermorheological effect of LCB for a number of LLDPE/LDPE. A C_{2+6} Z-N–LLDPE was blended with four LDPEs having the zero-shear viscosity at 150 °C, $\eta_o = 8, 44, 73$, and 132 kPa s. The LDPE content in blends was 1, 5, 10, 20, 50, and 75 wt%. The elongational behavior of the blends was studied using a Sentmanat extensional rheometer (SER). The blends showed strain hardening at all LDPE concentrations including 1 wt%. It is noteworthy that at LDPE < 20 wt% the effects of its addition were non-detectable in the shear field. Above that concentration, a positive deviation behavior (PDB) from log-additivity rule was observed, in the whole range of temperatures. The DSC showed three peaks at high LDPE contents that may be taken as an evidence of some co-crystallization.

In the recent patent application (Mavridis 2011), blends of Z-N–LLDPE with 0.3–0.8 wt% of high-MW LDPE (MW ≥ 100 kg mol^{-1}; MI = 0.1–0.6 dg min^{-1}; $\rho = 0.91$–0.94 g mL^{-1}) were described. The LLDPE ($\rho = 0.915$–0.940 g mL^{-1}; MI = 0.2–10 dg min^{-1}) must have the slice LCB index, $LCBI \geq 0.96$, in any portion of the composition: C_{2+n}, where $n = 2$–12, preferably 4 or 6. Blown films of these LLDPE/LDPE blends exhibited an enhanced balance of properties and high transparency (haze of a 2.5 μm film was <15 %).

Blends of 95–15 wt% Z-N–LLDPE (or preferably m-LLDPE) with m-VLDPE were patented by Univation Technology (German et al. 2006). The linear and without long-chain branching m-VLDPE had $\rho < 916$ kg m^{-3} and MI = 5 dg min^{-1}, while LLDPE had $\rho = 916$–940 kg m^{-3} and MI = 0.5–20 dg min^{-1}. The blends were formed into blown and cast film for packaging and liquid containers and for surface protection during manufacturing or transportation.

In a Phillips application, two Z-N type polymers were blended; 10–80 wt% of low-MW LLDPE [$\rho \geq 940$ kg m^{-3}, MI > 25 dg min^{-1}, and $M_w/M_n = 2$–12] with 20–90 wt% of a high-MW LLDPE [$\rho \leq 955$ kg m^{-3}, MI = 2–10 dg min^{-1}, and $M_w/M_n = 2$–10]. The blends with MI > 0.05 dg min^{-1} showed excellent film processability and improved transparency (Coutant and Martin 1995). The best performing blends with high transparency were probably miscible.

18.7.3 LDPE/m-LLDPE Blends

In 1977 Phillips Petroleum Co. developed blends of Z-N–LLDPE using C_{2+4} and C_{2+6} copolymers which were disclosed as suitable for pipe extrusion (Larsen 1982). The same year, Mobil Oil announced reactor blends of PE (copolymer of C_{2+4} and/or C_{2+6}) for production of blown films that exhibited improved MD/TD tear balance. The latter materials were produced in a multistage, gas-phase, fluidized bed polymerization process with in situ blending. The resulted bimodal MWD resins had 0.35 to about 0.75 wt% of a higher-MW component (Ali et al. 1994).

In 1992 the 3 M disclosed blends that comprised 100 parts VLDPE [*Flexomer* or *Attane* 80–95 mol% ethylene and 5 mol% C_{4-8} comonomer(s)] and 15–600 parts m-LLDPE [*DOWLEX* ethylene copolymer with 2–8 mol% C_8]. The blends showed excellent processability. Formed into 10–300 μm thick films, they were used for transdermal drug delivery devices as single-layer backings. The films were clear, colorless, transparent to visible light, and sealable at relatively low temperature. They were permeable to O_2, stable to various common components of transdermal delivery devices, strong, and comfortable and did not absorb significant amounts of common elements of transdermal carriers (Godbey and Martin 1993, 1994).

An early study of LDPE/m-LLDPE indicated immiscibility accompanied by good interactions that at constant loading of ≤ 25 wt% LLDPE resulted in additivity of the mechanical properties. The latter resin was DOWLEX 2045, a C_{2+8} m-LLDPE copolymer. Rapid quenching resulted in formation of two phases and slow cooling produced an additional third peak (Müller et al. 1992). In a contemporary patent application from W. R. Grace, improved heat-shrinkable PE films were described. These comprised single-site catalyzed copolymer of C_2 with C_{3-8} alpha-olefin and m-LLDPE with $\rho \geq 900 \, kg \, m^{-3}$ and blended with another polymer of C_2 and a C_{3-8} alpha-olefin and a second comonomer (e.g., vinyl acetate, alkyl acrylate, CO, butadiene, styrene, acrylic acid, and a metal salt of an acrylic acid) or an α-olefin homopolymer. These films had improved shrinkability, impact resistance, and optical properties as compared to homogeneous copolymers. The blends were found useful for manufacturing packaging films (Babrowicz et al. 1994).

Blends of PE with PP are immiscible; thus, for enhancement of the interphasial interaction, copolymerization has been used (Da Silva et al 2000, 2001). For example, m-LLDPE was blended with ethylene–propylene–butene-1 terpolymer (*ter*-PP: 2.9/92.4/4.7 wt%). Even in the presence of immiscibility, the enhancement of interactions at 20 wt% of *ter*-PP sufficiently improved processability and performance to warrant commercial interest (Cho et al. 1997).

Replacing Z-N–LLDPE by m-LLDPE in blends with LDPE resulted in an improvement of film properties. This may originate from improved miscibility, which in turn depends on the MW of m-LLDPE, branch content (BC), and composition distribution (CD) (Hussein et al. 2003; Hussein and Williams 2004). In addition to the improved physicomechanical properties, the processability of m-LLDPE blends with LDPE is better than that of Z-N–LLDPE. LDPE/ m-LLDPE blends with the same MI as those with Z-N–LLDPE are inherently tougher; thus, they may be thinner for the equivalent mechanical properties in

plastic bags. However, the miscibility difference depends on branch content (BC). Thus, at the same MW and MWD but low-BC (14.4 CH_3/1,000 C), Z-N–LLDPE/ LDPE blends are more miscible than m-LLDPE/LDPE, whereas at a *high-BC* = 32.2 CH_3/1,000 C the situation was reversed. The high-BC m-LLDPE blends with LDPE were partially miscible with phase separation for LDPE-rich blends.

Exxon Chem. (Stehling et al. 1995) disclosed blends of linear ethylene interpolymer that comprised m-LLDPE and VLDPE (Appendix, Table 18.12). The polymers prepared using metallocene catalyst had narrow MWD, M_w/M_n = 1–3, and a narrow chemical composition distribution (CCD), expressed by its index, CDBI > 50 %, and measured by TREF. The components could have the same MW but different BC, the same BC but different MW, or BC that increase with MW. The blends had either M_w/M_n > 3 or CDBI < 50 % or both these inequalities. They could be multimodal in respect to MW and/or BC. They were generally free of components having both a higher average MW and a lower average BC than other blend components and have a density of ρ = 910–940 kg m^{-3}. The blends could be coextruded or compounded with other polymers for additional improvement of processability and of performance (Stehling et al. 1995). Similar blends of either Z-N type or metallocene VLDPE with SCB were blended with LDPE (Chen et al. 2001). The blends of C_{2+4} m-VLDPE1 with LDPEs showed co-crystallization, thus at least a partial melt miscibility at all compositions. However, blends of VLDPE1 with C_{2+8} m-VLDPE2 co-crystallized at ≤50 % VLDPE2 content, whereas blends of VLDPE2 with C_{2+8} Z-N–VLDPE3 co-crystallized at ≥50 % of VLDPE2. Notably, miscibility and morphology of these blends showed little MW dependence; only the distribution of branches along the chains was important.

In 1994 Exxon Chemical deposited EP application for blends that included (a) the base polymer derived from C_2 and optionally an α-olefin having MI = 1–5; (b) from 1 to 45 % by weight of (a) + (b) of a second polymer co-crystallizable with (a) and derived from C_2 and at least one olefinically unsaturated comonomer having MI = 0.5–4.5 units below that of (a) and which responds rapidly to cross-linking. The materials were developed for use as shaped coatings or wire and cable insulation (Wong and Varrall 1994). Many other patents followed from Exxon for blends, e.g., m-LLDPE, VLDPE, or LDPE, having melt index, MI = 0.1–10, 10–30 wt% of a secondary co-crystallizable C_{2+n} copolymer, e.g., LLDPE, VLDPE, or LDPE, having MI ≥ 80 % lower than that of the first polymer, and moisture cross-linking additives (e.g., a silane, a silanol condensation catalyst, and a free radical initiator) were disclosed (Wong and Varrall 1994; Datta et al. 2006).

Hameed and Hussein (2002) blended m-LLDPE (C_{2+4} and C_{2+6}; low and high MW) with LDPE. The miscibility was investigated by indirect rheological methods. Assuming that for miscible blends the rheological behavior should be additive, the authors noted that MW has a strong effect on miscibility, but not on the concentration behavior, i.e., initial addition of m-LLDPE to LDPE formed immiscible system, while in reversed situation single phase remained. The immiscibility was observed for blends comprising >20 wt% m-LLDPE. Pérez et al. (2005) observed that immiscibility of m-LLDPE (SCB = 10.5/1,000 C) with LDPE takes place only

for 52.5 wt% of the latter component. Curiously, m-LLDPE copolymerized with C_4 and C_6 comonomers showed similar immiscibility with LDPE.

The next publication in this series focused on the immiscibility of C_{2+6} LLDPE prepared either with Z-N or metallocene catalyst, having variable BC and CD with LDPE or HDPE (Hussein 2003; Hussein et al. 2003). The effect of CD on miscibility was judged by comparing blend of Z-N–LLDPE with m-LLDPE – for the same MW and similar BC, better miscibility was observed for the former than for the latter system. Similarly, a high-BC m-LLDPE (32.2 CH_3/1,000 C) was more miscible with LDPE than a low-BC m-LLDPE (14.4 CH_3/1,000 C) of similar MW and MWD. In blends with HDPE, the composition distribution (CD) had no effect on miscibility, but increase of SCB resulted in a phase separation. These conclusions were confirmed in a later publication on C_{2+4} Z-N–LLDPE blends with LDPE (Hussein and Williams 2004a, b). In particular, while low-MW C_{2+8} Z-N–LLDPE was miscible with LDPE, the miscibility of high-M_w Z-N–LLDPE with LDPE was limited to blends with >50 wt% Z-N–LLDPE. However, increasing the branch length in Z-N–LLDPE from C_4 to C_8 increased miscibility with LDPE.

Fang et al. (2005) studied the thermal and rheological properties of two types of m-LLDPEs, two LDPEs, and their blends. The C_{2+6} m-LLDPE-1 was immiscible, whereas the C_{2+8} m-LLDPE-2 was miscible with the LDPEs, indicating that increasing the length of SCB in m-LLDPEs promoted miscibility with LDPE. The Palierne (1990, 1991) emulsion model provided good predictions of the linear viscoelastic behavior for both miscible and immiscible blends. The low-frequency data showed an influence of the interfacial tension on the elastic modulus of the blends for the immiscible blends.

18.7.4 HDPE/Z-N–LLDPE or Cr–LLDPE Blends

In 1981, Showa Denko announced that blown films from HDPE blends with 50–55 wt% Z-N–LLDPE have improved strength and transparency over those of neat HDPE (Showa Denko 1983). The industrial interests in these systems grew over the years. For example, while blends of LDPE and HDPE slowly cooled from the melt formed separate crystalline phases, those of HDPE with LLDPE may co-crystallize – the presence of these single crystals may indicate miscibility. The phase separation in HDPE/Z-N–LLDPE or HDPE/m-LLDPE blends has been frequently reported, but some blends of this type are miscible in the melt and solid states. MD simulation by Choi (2000) suggests that miscibility of HDPE with C_{2+4}–LLDPE depends on BC – the computed critical level for phase separation was 4 SCB/100 C. This finding is consistent with the SANS data on model polymers (Alamo et al. 1997). The latter authors reported that HDPE blends with hydrogenated/deuterated polybutadiene are miscible at all concentrations when the branch content is low, SCB <4 for $M_w = 100$ kg mol^{-1}, but immiscible for SCB $\geq$ 8 branches/100 C. However, in blends of HDPE with ULDPE, miscibility (or partial miscibility) was observed only at low ULDPE content, when blends of m-LLDPE with m-HDPE are fully miscible in the molten and crystalline state (Guimares et al. 2003).

The tensile, flexural, and impact properties of HDPE/LLDPE blends significantly deviate from the rule of mixtures, especially at HDPE/LLDPE $\approx$ 1; this effect has been attributed to the blend amorphous phase. Thus, the resistance to slow crack growth (SCG) of LLDPE blended with HDPE may be higher by 30–50 % than that of neat LLDPE. On the opposite concentration range, addition of 10 wt% LLDPE to HDPE yields tough blend without unduly affecting other tensile properties. In blends of film-grade m-LLDPE/HDPE, addition of ca. 25 % m-LLDPE improves the tear resistance and film stiffness compared with films made entirely from HDPE. The use of m-LLDPE in blends with flame-retarded HDPE improves processability and impact resistance compared to blends using conventional Z-N–LLDPE. Films blown from binary blends of HDPE with 50–55 wt% LLDPE showed improved strength and transparency over that of neat HDPE. In the following patents, the company disclosed immiscible blends of LDPE with either HDPE or MDPE. These were well suited for films with uniform thickness and anisotropic tensile strength (Showa Denko 1981, 1983).

Phillips Petroleum patented PE blends prepared by dry powder blending followed by compounding in an internal mixer or an extruder. The two PEs were 30–70 wt HDPE, narrow MWD LLDPE, and 30–70 wt% HDPE, having significantly different MW (Bailey and Whitte 1984). The former was Z-N–LLDPE [Ti catalyst; $\rho \leq 955$ kg m^{-3}, MI = 0.1–50 g/10 min, and M_w/M_n = 2–10], while the second comprised low-MW HDPE [Cr catalyst; $\rho \geq 955$ kg m^{-3}, MI = 25–400 g/10 min, and M_w/M_n = 2–35]. The blends were used for the produced pipes, films, and bottles with good mechanical properties and environmental stress crack resistance, ESCR.

Phillips disclosed blends comprising 1–30 wt% LDPE [ρ = 910–930 kg m^{-3}, MI = 6 dg min^{-1}] blended with 99–70 wt% Cr-catalyzed LLDPE [ρ = 910–940 kg m^{-3}, MI < 1 dg min^{-1}, M_w/M_n > 6]. The blends had synergistic increase of tear strength and reduction of haze (Benham et al. 1995). Similar effects were also reported for LLDPE blends with 10–40 wt% of an ethylene–vinyl acetate copolymer, EVAc [ρ = 920–945 kg m^{-3}, MI = 6–10 dg min^{-1}, and 10–20 wt% VAc]. The materials had good processability and high tear strength and transparency (Benham and McDaniel 1994). In 1991, Hoechst disclosed blends having a bimodal MWD. The materials comprised 50–80 wt% HDPE blended with either Z-N–LLDPE or LDPE. The alloys were found suitable for molding or extrusion of tubes, pipes, and other articles requiring high ESCR (Böhm et al. 1994).

Blends of HDPE with an elastomeric C_{2+8} Z-N–LLDPE (SCB = 25 mol% of C_8 and LCB) are partially miscible under quiescent conditions, but under sheared conditions, they develop complex morphologies composed of fine globular interconnected domains, probably originating from coarsening after SD (Tabtiang et al. 2001). Thus, miscibility of these blends is enhanced by flow, and after its cessation parallel liquid–liquid and solid–liquid phases separate. The process leads to the formation of an interpenetrating morphology comprising amorphous PE and copolymer and crystalline PE.

Solvay patented blends comprising (A) high-density copolymer, C_{2+n}, where n = 4–10 ($\rho \geq 950$ kg m^{-3}, MI$_5$ = 0.05–2 dg min^{-1}; α-olefin content 0.15–1 mol%),

with (B) 42 wt% of another copolymer, C_{2+m}, where $m = 4$ or 6 ($\rho \geq 969$ kg m^{-3}, MI$_2 \geq 100$ dg min^{-1}, and $M_w/M_n > 4$ copolymerized with 0.8 mol % of C_4 or C_6 alpha-olefin) (Mattioli et al. 2002). The copolymers were synthesized using two "in-series" suspension polymerization reactors: (I) in a first reactor, at 40 °C, the C_2 was polymerized in a medium comprising a diluent, H_2, a catalyst based on Ti or Zr and a co-catalyst (MAO), to form 53–63 wt% of the component (A); (II) the product from the first reactor was introduced into the second reactor and C_{2+n}, $n = 4$–10, α-olefin was added, and the remaining part of the patented system [37–47 wt% copolymer (B)] was formed. The blends were used for the production of pipes with improved creep resistance while maintaining other mechanical properties (e.g., resistance to crack growth). This is one of many patents for the production of partially miscible blends, where polymerization controls composition and configuration of macromolecules producing optimized resin grades.

Exxon patented blends of high-MW HDPE with 20–50 wt% of Z-N–LLDPE or m-LLDPE (Mehta et al. 1994). The HDPE had $\rho > 0.94$ g mL^{-1} and MI$_2 < 0.1$ dg min^{-1} and LLDPE $\rho = 0.90$–0.93 g mL^{-1} and MI$_2 = 0.5$–5 dg min^{-1}. The LLDPEs were C_{2+6} copolymers for films with dart drop impact strength >500 g. The blends with improved resistance to environmental stress cracking (ESC) were used for the production of medium-density pipes or geomembranes [U.S. Patent 6,649,698 to Equistar Chem.]. Simulating blends of HDPE with LLDPE having three LCBs and up to 40, C_4 SCB suggested that about 3/100 C is needed for phase separation (Fan et al. 2002).

18.7.5 HDPE/m-LLDPE Blends

Phillips Petroleum applied for patents for HDPE/m-LLDPE blends with improved processability. These comprised 30–70 wt% low-MW HDPE [Cr catalyst, $\rho \geq 955$ kg m^{-3}, MI $= 25$–400 g/10 min, and $M_w/M_n = 2$–35], and 30–70 wt% high-MW LLDPE [Ti catalyst, $\rho \leq 955$ kg m^{-3}, MI $= 0.1$–50 g/10 min, and $M_w/M_n = 2$–10]. The blends were used for pipes, films, and bottles with enhanced mechanical properties and ESCR. In another patent 5–40 wt% low-MW HDPE [Ti catalyst, $\rho \geq 955$ kg m^{-3}, MI ≥ 25 dg min^{-1}, and $M_w/M_n = 2$–8], blended with 60–95 wt% high-MW HDPE [Cr catalyst, $\rho \geq 93$ kg m^{-3}, MI $= 1.5$–15 dg min^{-1}, and $M_w/M_n = 6$–100], yielded blends with MI $= 0.05$ dg min^{-1} and excellent ESCR (Martin et al. 1994). In another document, 10–80 wt% low-MW LLDPE [$\rho \geq 940$ kg m^{-3}, MI > 25 dg min^{-1}, and $M_w/M_n = 2$–12] was blended with 20–90 wt% of a high-MW LLDPE [$\rho \leq 955$ kg m^{-3}, MI $= 2$–10 dg min^{-1}, and $M_w/M_n = 2$–10]. The blends were reported to have MI > 0.05 dg min^{-1} and improved optical properties (Coutant and Martin 1995).

ExxonMobil patented blends of 60–95 wt% linear m-VLDPE ($\rho = 0.916$ g mL^{-1}; 5–15 wt% comonomer C_3–C_{12}; $M_w/M_n = 2$–3, bimodal, produced in the gas phase using di-Cp metallocene catalyst) with HDPE ($\rho \geq 0.940$ g mL^{-1}) have shown that blown and cast films may be downgauged by up to 30 % for similar performance to those of conventional films (Halle 1999; German et al. 2004).

Three Z-N-type HDPEs from BP (M_w = 62, 137 and 292 kg mol^{-1}) were blended with C_{2+8} m-LLDPE from Dow (narrow MWD, different MW and C_8 content) (Stephens et al. 2003). Miscibility very much depended on the C_8 comonomer content, for 5.3 mol% of C_8 being miscible, but immiscible (with UCST) for 8.5 and 12.3 mol% C_8. After extracting the solubility parameters, the authors concluded that miscibility of low-MW fraction of HDPE with broad MWD is significantly higher than that of the high ones.

Hameed and Hussein (2007) studied blends of m-LLDPE with HDPE varying the MW and branch content (BC) in m-LLDPE. No influence of MW on miscibility was observed for polymers with low BC ($\approx$2/100 C). However, at high-BC levels (ca. 4/100 C) MW did affect miscibility of m-LLDPE/HDPE blends. Low-MW m-LLDPE/HDPE blends were miscible at all compositions, while high-MW phase segregated into layered morphology. The HDPE-rich blends co-crystallized, whereas m-LLDPE-rich phase showed separate crystallization. Mechanical properties of these blends strongly depended on blend miscibility and properties of components. It is noteworthy that the high-BC pairs had poor mechanical properties, caused by weak interphase.

The effect of MW on phase separation was discussed for one branched LLDPE blended with linear PE of different MW (Hill 1994). While at high MW there was a region of phase-separated blends, at low MW the system was fully miscible. The effect of branch length on the miscibility of HDPE blended with C_{2+8} m-LLDPE was studied by Shin et al. (2008). The m-LLDPE had variable C_8 content (21–45 wt%) which apparently did not affect miscibility. At the same composition and MW, the miscibility of HDPE with C_{2+8} m-LLDPE was slightly better than that with C_{2+4} m-LLDPE. The results suggested phase separation leading to UCST.

In 2009, Equistar Chemicals obtained patent protection for thick blend films manufactured from HDPE (ρ > 0.955 g mL^{-1}, MI$_2$ < 1.0 dg min^{-1}) blended with m-LLDPE (ρ = 0.900–925 g mL^{-1}, MI$_2$ < 5.0 dg min^{-1}). The films 50–200 μm thick had the tear strength in the machine direction (MD) >20 % than that of a film with the same modulus prepared from a neat HDPE (Mavridis 2009).

Blends of ZN-HDPE with metallocene or single-site catalyzed hyperbranched LLDPEs (m-LLDPE branching content 7.2 wt% and HbPE with comonomer content 17.8 wt%, respectively) were prepared by dissolving the ingredients in xylene at 130 °C (Poltimäe et al. 2011). Next, the mixtures were cooled in liquid N_2 and freeze-dried under vacuum. The double melting peaks in DSC endotherms were observed in all blends, indicating separate crystallization of the two polymers. However, limited degree of co-crystallization was detected in the LLDPE/HbPE blends and HDPE/HbPE blend rich in HbPE component.

18.7.6 Z-N–LLDPE/m-LLDPE Blends

For facilitating film blowing of Z-N–LLDPE, the polymer may be blended with LDPE, known for its strong SH behavior. However, on conventional process lines, films from neat LLDPE are also being produced, but with considerable difficulties. Generally,

film-grade m-LLDPE is easier to process than Z-N–LLDPEs with the added benefit of better physicomechanical and optical properties. Blending Z-N–LLDPE with m-LLDPE having different comonomer may result in phase separation (controlled by branch content and branch type) and a reduction of the mechanical properties.

Intuitively, the two LLDPE types are structurally sufficiently different that immiscibility might be expected. The experimental data published by Rana et al. (2000) for blends of C_{2+8} Z-N- and metallocene-type LLDPE seem to confirm the expectation. The authors studied rheological and morphological behaviors of three binary blends of C_{2+8} with different melt index (MI), density, and comonomer contents (SCB) of the kind used for film blowing. In these blends, one component was made using a Z-N and the other a metallocene catalyst. The miscibility depended on the value of the MI, density, and SCB. When the latter was similar, then the melt viscosity was a weight average, expected for a miscible blend. The microtomed surface prepared during fast or slow cooling indicated separate crystallization of the two components, regardless of the density, MI, and SEC. The Z-N–LLDPEs had larger spherulites and ring space than those of the m-LLDPEs, independently of the cooling rate. The melt rheology was reflected in the mechanical and film properties. The blend miscible in the molten state showed linearity in the mechanical properties, whereas the immiscible blends showed positive or negative deviation from linearity, usually associated with the type of morphology and the interphasial interactions.

In 1992, Phillips Petroleum applied for patent protection of blends comprising melt-blended high- and low-MW LLDPE, having the melt viscosity (at 100 s^{-1}) of, respectively, $\eta > 5$ and $\eta < 0.3$ kPa s. The polymers were blended in two stages: first the high-MW polymer was blended with a small amount of the low-MW one, and then an additional low-MW polymer was incorporated in a second stage to form the final blend. The materials had good processability and excellent physical properties. The process provided improved resins for the production of films with low fish-eye content, for blow molding, extrusion of pipes, wire coating, and injection or rotational molding (Coutant 1994).

Two (C_{2+6} and C_{2+8}) Z-N–LLDPEs and two m-LLDPEs (C_{2+4} and C_{2+8}), η_o ranging from 11 to 34 kPas, were blended with a single LDPE (Delgadillo-Velázquez et al. 2008b). The focus was on the effects of the LLDPE manufacture and the effects of LCB. It was found that m-LLDPE is more compatible with LDPE at all concentrations as compared to blends with Z-N polymer. The elongational flow was a sensitive tool capable for detecting subtle changes in PE macrostructure, e.g., low levels of LCB. DSC indicated that in solid state m-LLDPEs are miscible with an LDPE. These results have not been confirmed by Robledo et al. (2009), who also compared Z-N type (C_{2+8}) and m-LLDPE (C_{2+6}) in blends with 5 and 15 wt% LDPE. Blends with m-LLDPE were thermorheologically complex showing immiscibility, while those with Z-N–LLDPE obeyed the time–temperature superposition principles (t-TSP), but exhibiting a linear viscoelastic response, characteristic for immiscible systems with a sharp interface. The broad linear response in the Z-N-type

blends may be related to strong interactions between the high-MW fraction of the LLDPE and the low-MW chains of the LDPE phase, forming a thick interface with its own viscoelastic properties. The interphase may play a key role in extensional properties, orientation phenomena, the final microstructure, and system performance.

Frederix et al. 2010 studied the properties of three series of polymers: high-density ethylene/hexene Z-N–LLDPE (HD), C_{2+8} m-LLDPE (LL), and C_{2+8} m-ULDPE (UL). The blends LL/HD, UL/HD, and UL/LL comprised about 0, 25, 50, 75, and 100 wt% of each polymer. The crystallinity of melt-compounded blends was 77 %, 46 %, and 16 %, for the HD, LL, and UL, respectively. The zero-shear viscosity (η_o) indicated immiscibility of the three binary series over the whole composition range. For most blends, the temperature shift of the crystallization (T_c) and melting (T_m) peaks from those of neat copolymers indicated partial miscibility in the crystalline or the amorphous region. In some cases, the presence of intermediate endotherm and exotherm between the two main peaks of the melting and crystallization traces, respectively, indicated hybrid crystals. A marked positive deviation of the upper T_c from the linear mixing rule was observed for the three systems. A nucleating effect from the interface of the phase-separated domains promoted early crystallization in the upper T_c phase. The SAXS data reveal electron density fluctuations at a much larger scale than that of the semicrystalline structure, demonstrating the occurrence of micro-phase separation in the melt prior to crystallization. Solubility of low-T_m chain species in the amorphous layers of the high-T_m phase was also evident. AFM and DMTA support micro-phase separation in the three systems.

Cycloolefin copolymer (COC) is an amorphous, clear metallocene product of norbornene and ethylene with a spectrum of attractive performance characteristics. Thus, COC (MFI at 190 °C and 2.16 kg = 1.7 dg min^{-1}, $\rho = 1{,}020$ kg m^{-3}) was blended with C_{2+6} LLDPE (MFI at 190 °C and 2.16 kg = 3.2 dg min^{-1}, $\rho = 920$ kg m^{-3}). The mechanical properties of the blends indicate immiscibility, despite the increased LLDPE crystallinity. The presence of COC improved the thermo-oxidative stability. Quasi-static tensile tests showed that increasing fraction of COC in the blends accounts for an enhancement of the elastic modulus and a decrease in the strain at break, while tensile strength passes through a minimum. A significant reduction of the creep compliance of LLDPE could be achieved only for the COC fractions exceeding 20 wt% (Dorigato et al. 2010).

18.8   Conclusions and Outlook

18.8.1 Future Trends in PE Synthesis

The future activities in PE synthesis are expected to have three aspects:
1. Improve activities of the metallocene catalytic systems, e.g., by developing (1) bulky, weakly coordinating co-catalysts (perfluorophenylborate, boranes)

and (2) more efficient MAO-activated catalyst and (3) by reducing the amount of MAO required for the activation (Kaminsky 2012).

2. Continue the development toward commercialization of the new class of post-metallocene catalysts based on transition metal (Ti, Zr, Hf, V, ...) complexes without Cp, but with imino-carboxylate and imino-amido ligands and sometimes with a neutral Lewis acid acting as a co-catalyst (Makio and Fujita 2009; Makio et al. 2011; Ivanchev et al. 2012). These systems are capable efficiently polymerized monomers containing polar group. Furthermore, different reactions are possible, e.g., anionic polymerization, ring-opening polymerization, or polycondensation.

3. Polymeric nanocomposites (PNC) are relatively new materials on the market with an array of interesting properties and applications (Utracki 2004; Kaminsky et al. 2006; Compton and Nguyen 2010). There are many types of nanoparticles (historically starting with layered clay), but the common problem originating from the nature of nano-size is the dispersibility – on the nanoscale the Lennard–Jones forces form aggregates, which are difficult to break. One method that has been used for dispersing clay in polyamide matrix was the addition of clay to monomer and polymerization of the suspension (Okada et al. 1988). Evolution of PE synthesis, especially the metallocene and post-metallocene catalysts, offers a new and potentially highly efficient route to new materials with a wide range of properties generated not only by the nanoparticles but also the PE structures that dispersed and coated those (Kaminsky et al. 2006).

18.8.2 Future of Commercial PE Blends

- The key to the equilibrium phase behavior of the PE/PE blends is that in the molten state – upon solidification the polymers crystallize or vitrify. Both of these states are affected by kinetics and aging. Molten blends are either miscible or immiscible with UCST or LCST after the phase separation via SD or NG mechanism. Extensive experimental studies of blended model polymers have been published.

- The early theories of phase separation are of the mean-field, cell, or cell-hole lattice (statistical thermodynamics) type. The theory takes into account the configurational entropic and enthalpic contributions, but since these are weak, the effects on miscibility are not as predictable as that for other PO blends. Nevertheless, the enthalpy as a difference of the solubility parameters well correlate with the experimental data being independent on SCBD and SCB if SCB $<$ 5/100 C. This observation is unexpected, since the miscibility was reportedly controlled by entropy, e.g., chain stiffening led to phase separation.

- The newer theoretical models attempt incorporating the model macromolecular chain structures using either mathematical modeling via MC, molecular

dynamics (MD), PRISM, CFT, etc. Evidently, another possibility is an analytical approach where the configurational elements are identified taking into account MW, SCB, and LCB and their concentration and distribution. This has been done by Freed and Dudowicz, who formulated the lattice cluster theory (LCT) in its full, basic (BLCT), and simplified (SLCT) versions. The latter approach identified four classes of PE blends, defined by structure and led to two UCST and two LCST classes.

Nomenclature

^{13}CNMR   Carbon-13 nuclear magnetic resonance
^{1}HNMR   Hydrogen nuclear magnetic resonance
ABC   Alloying–blending–compounding
ABS   Acrylonitrile butadiene styrene
AE   Aminoethyl
AGR   Annual growth rate
An   9-Anthryl
APME   Association of Plastics Manufacturers in Europe
AR   Autoclave reactor
ATBN   Amine-terminated butadiene nitrile liquid rubber
ATR   Attenuated total reflection (in FT-IR)
a-TREF   Analytical temperature rising elution fractionation
BAF   Tetrakis[3,5-bis(trifluoromethyl)phenyl]borate
BC   Branch content
BLCT   Basic lattice cluster theory (LCT)
bPET   Branched polyethylene terephthalate
BR   Polybutadiene, butadiene rubber

Bu   Butyl

Bz   Benzyl

C_{2+i}   Abbreviated notation for poly(ethylene-*co*- *i*-olefin); $i = 3, 4, 6, 8, \ldots$.

CA   Cellulose acetate

CBR   Chlorinated butyl rubber

CCD   Chemical composition distribution (or charge-coupled detector)

CED   Cohesive energy density

CEF   Crystallization elution fractionation

CFC   Cross-fractionation chromatography

CFT   Continuum field theory

CGC   Constrained geometry catalyst

CHX   Cyclohexyl

CMC   Critical micelles concentration

CO   Carbon monoxide

COD   1,5-Cyclooctadiene

COPO   Poly(carbon monoxide-co-polyolefin), a linear, alternating terpolymer

CORI   Corotating, fully intermeshing TSE

Cp   Cyclopentadienyl

$Cp = C_5H_5{}^-$ Cyclopentadienyl anion$^-$

CPE   Chlorinated polyethylene

CR   Chloroprene, or neoprene, rubber

CRNI   Counterrotating, non-intermeshing TSE

CSR   Chlorosulfonated polyethylene rubber

CSTR   Continuously stirred tank reactor

CTM   Cavity transfer mixer

CUT   Continuous use temperature

DAB   1,4-Diazabutadiene

DIPP   2,6-Diisopropylphenyl

DR   Drawdown ratio

DSC   Differential scanning calorimetry

D-W   Dee and Walsh theory

EAA   Ethylene acrylic acid copolymer or "carboxylated PE"

EBA   Ethylene butyl acrylate copolymer

EEA   Elastomeric copolymer from ethylene and ethyl acrylate

EFM   Extensional flow mixer

EGMA   Ethylene-glycidyl methacrylate copolymer

ELSD   Evaporative light-scattering detector

EMA   Ethylene-maleic anhydride copolymer

EMAc   Copolymer from ethylene and methacrylic acid

EPDM   Ethylene-propylene-diene terpolymer

EPR   Ethylene-propylene rubber

EPR-MA   Maleated ethylene-propylene rubber (EPR)

EPS   Polystyrene foam; expanded PS

Et   Ethyl ($C_2H_5{}^-$)

EVAc   Copolymer from ethylene and vinyl acetate
EVAc-MA   Copolymer from ethylene, vinyl acetate, and methacrylic acid
EVAL   Copolymer of ethylene and vinyl alcohol
FBR   Fluidized bed reactor
FOA   Fluorinated octyl acrylate
FT-IR   Fourier transform infrared (spectroscopy)
GF   Glass fiber or glass fiber-reinforced plastic
Gi   The Ginsburg number
GMA   Glycidyl methacrylate
GPC   Gel [permeation chromatography (see SEC)
HALS   Hindered amine light stabilizer
HAS   Hindered amine stabilizer
HBA   Hydroxybenzoic acid
HDPE   High-density polyethylene
HDPE-MA   Maleated high-density polyethylene
HDXLPE   High-density cross-linked polyethylene
hhPP   Head-to-head polypropylene
HIPS   High impact polystyrene
HMWPE   High-molecular-weight polyethylene
HNA   Hydroxy naphthoic acid
HTLC   High-temperature liquid chromatography
Hx   Hexyl
ICRR   Intermeshing, counterrotating TSE
ID and OD   Inner and outer pipe diameters
Ind   Indentyl
i-**PB**   Isotactic polybutylene
i- **PP**   Isotactic polypropylene
LA   Lactic acid
LC   Liquid chromatography
LCB   Long-chain branching
LCBPE   Long-chain branched PE
LCP   Liquid crystalline polymer
LCST   Lower critical solution temperature
LCT   Lattice cluster theory
LDPE   Low-density polyethylene
L-J   Lennard–Jones (theory, potential, parameters)
LLDPE   Linear low-density polyethylene
M   Transition metal in a catalyst
MA   Methyl acrylate
MAH   Maleic anhydride
MAO   Methylaluminoxane
MBS   Copolymer from methyl-methacrylate-*co*-butadiene-*co*-styrene
MC   Monte Carlo simulation
MD   Machine direction

MDPE   Medium-density polyethylene

Me   Methyl (CH_3-)

Mes   Mesityl

MFR   Melt flow rate

m-**LLDPE**   Metallocene LLDPE

m-LLDPO   Metallocene PO

MM   Motionless mixer

M_n, M_w Number, weight average molecular weight

MW   Molecular weight

M_w/M_n Molecular polydispersity index, MWD

MWD   Molecular weight distribution usually expressed as M_w/M_n

Nb   Norbornyl

NDB   Negatively deviating blends

NG   Nucleation and growth mechanism

NIR   Near-infrared (spectroscopy)

NMR   Nuclear magnetic resonance

Np   Naphthyl

NPDB   Negatively–positively deviating blends

NR   Natural rubber

ODCB   *o*-Dichlorobenzene

OM   Optical microscopy

P(HB-b-I-S)   Block copolymer of hydrogenated butadiene, isoprene, and styrene

P(S-b-MMA)   Block copolymer of styrene and methyl methacrylate

PA   Polyamide

PA-46   Poly(tetramethylene adipamide)

PA-6   Poly-ε-caprolactam

PA-66   Poly(hexamethylene diamine-adipic acid), polyhexamethylene-adipamide

PA-6IT6   Poly(caprolactam-*co*-hexamethylene diamine-isophthalic/terephthalic acids)

PA-mXD6   Poly(*m*-xylylenediamine -adipic acid-*co*-caprolactam)

PAr   Polyarylate

PARA   Aromatic (mainly amorphous) polyamide

PB1   Poly(butene-1)

PB2   Poly(butene-2)

PBD   Polybutadiene

PBMA   *Polybutyl* methacrylate

PBSA   Poly(polybutylene succinate-*co*-adipate)

PBT   Polybutylene terephthalate

PC   Polycarbonate of bisphenol-A

PCL   Poly-ε-caprolactone

PCW   Postconsumer waste

PD   Polydispersity, M_w/M_n

PDB   Positively deviating blends

PE Polyethylene
PEA Polyetheramide
PEB = C$_{2+4}$ Poly(ethylene butylene)
PEE Poly(ethylene propylene)
PEEI Polyesteretherimide
PEEK Polyetheretherketone
PEE *xx* Poly(ethylene-*r*-ethyl-ethylene); random copolymer with *xx*% of ethyl–ethylene (EE) units
PEG Polyethylene glycol
PEH=C$_{2+6}$ Polyethylene–hexene
PEI Polyetherimide
PEi≡C$_{2+I}$ Poly(ethylene-*co*-α-olefin), PEi≡C$_{2+I}$; *i* = 3–8
PEN Poly(ethylene 2,6-naphthalene dicarboxylate), or polyethylene naphthalate
PEP=C$_{2+3}$ Poly(ethylene butylene)
PEP Poly(ethylene propylene)
PEST Thermoplastic polyesters such as PET, PBT, and PEN
PET Polyethylene terephthalate
PETG Polyethylene terephthalate glycol; copolymer
PEtI Polyethyleneimine
PEX Cross-linked polyethylene
PGI Polyglutarimide
Ph Phenyl
PH1 Poly(hexene-1)

PHBA Poly(β-hydroxybutyric acid)
PHBV Poly(hydroxybutyrate-*co*-valerate)
Phenoxy Polyhydroxyether of bisphenol-A
PHV Poly(hydroxy valerate)
***p*$_i$** Internal pressure
PI Polyimide
PIB Polyisobutylene
PIB Polyisobutylene
PLA Polylactic acid
PMA Polymethylacrylate
PMMA Polymethylmethacrylate
PMP Poly-4-methyl-1-pentene, also TPX
PNDB Positively–negatively deviating blends
PO Polyolefin
POM Polyoxymethylene
PP, *i*-PP Isotactic polypropylene (*a*- PP – atactic; *s*-PP – syndiotactic)
PPA Polyphthalamide (also polypropyleneadipate)
PPE Poly(propylene ethylene)
PPE Polyphenylene ether

PPG   Polypropylene glycol
PP-MA   Maleated polypropylene
PPS   Polyphenylene sulfide
Pr   Propyl
PRISM   Polymer reference interaction site model
PS   Polystyrene
PSF   Polysulfone
PS-g-EPR   Styrene-grafted EPR
PS-g-EVAc   Styrene-grafted EVAc
PS-g-PP   Styrene-grafted PP
p-TREF   Preparative temperature rising elution fractionation
PVAc   Polyvinyl acetate
PVAl   Polyvinyl alcohol
PVC   Polyvinyl chloride
PVDC   Polyvinylidene chloride
PVDF   Polyvinylidene fluoride
PVF   Polyvinyl fluoride
PVME   Polyvinylmethylether
PVP   Polyvinyl pyridine
PVT   Pressure-volume-temperature
py   Pyridyl
QC   Quality control
RI   Refractive index
RPA   Random phase approximation
R-TPO   Reactor-blended thermoplastic olefinic elastomer
SAN   Styrene acrylonitrile
SANS   Small-angle neutron scattering
SAXS   Small-angle X-ray scattering
SB   Styrene–butadiene copolymer
SBR   Styrene–butadiene elastomer
SBS   Styrene–butadiene–styrene three-block copolymer
SCB   Short-chain branching
SCBD   Distribution of SCB
SCM   Super-condensed mode of *m*-LLDPE production
SD   Spinodal decomposition mechanism
SEBS   Styrene–ethylene/butene–styrene three-block copolymer
SEBS-MA   Maleated SEBS
SEC   Size exclusion chromatography
SEM   Scanning electron microscopy
SH   Strain hardening
SIMS   Secondary ion mass spectrometry
SIS   Styrene–isoprene–styrene three-block copolymer
SLTC   Simplified lattice cluster theory (LCT)
SMA   Styrene–maleic anhydride

SMMA   Styrene–methyl methacrylate block copolymer
sPS   Syndiotactic polystyrene
S-S   Simha and Somcynsky cell-hole theory
SSE   Single-screw extruder
SSSE   Solid-state shear extrusion
TD   Transverse direction
TEM   Transmission electron microscopy
T_{g} Glass transition temperature
THF   Tetrahydrofuran
TIBA   *tri*-Isobutyl aluminum
T_{m} (°C)   Melting temperature
TMA   *tri*-Methyl aluminum
TMS   Trimethylsilyl
TO   Turnovers, number of moles of monomer polymerized per mole of metal in the catalyst
TOF   Catalyst turnover frequency
TPE   Thermoplastic elastomer
TPO   Thermoplastic olefinic elastomer
TPU   Thermoplastic urethanes
TPV   Thermoplastic vulcanizate
TR   Tubular reactor
TREF   Temperature rising elution fractionation
TSE   Twin-screw extruder
t-TSP   Time–temperature superposition (also: t-T)
UCST   Upper critical solution temperature
UHMWPE   Ultrahigh-molecular-weight polyethylene (over 3 Mg mol^{-1})
ULDPE   Ultralow-density polyethylene
UV   Ultraviolet light spectroscopy (irradiation)
UV-Vis   Ultraviolet–visible light spectroscopy
VCH   Vinyl cyclohexane
VLDPE   Very low density PE
XLPE   Cross-linked polyethylene
XRD   X-ray powder diffraction
Z-N   Ziegler–Natta catalyst
Z-N–LLDPE   Ziegler–Natta-catalyzed LLDPE
ZN-LLDPO   Ziegler–Natta-catalyzed PO
ΔG_{m} Gibbs free energy and heat of mixing
δ Solubility parameter
ρ Polymer density

Table 18.10 Chronology of polyolefin technology

Date	Event	Inventor/company	Comment	Reference
1898	Polymethylene obtained by thermal decomposition of diazomethane with $T_m = 128\ ^\circ C$	Hans von Pechmann. In 1953, Kantor and Osthoff produced UHMWPE from diazomethane + BF_3	White, waxy powder in 1898, while UHMWPE (MW = 3,000 kg mol^{-1}) in 1953 had $T_m = 132\ ^\circ C$	R.A.V. Raff, J.B. Allison, *Polyethylene* (Interscience Publication, New York, 1956); Germ. Pat. Appl., B25064 (1955). http://en.wikipedia.org/wiki/Polyethylene#History
1933	PE obtained at $P = 120$–300 MPa and $T = 140$–180 °C from a mixture of ethylene (C_2), benzaldehyde, and oxygen. The early ICI design utilized stirred autoclave reactors	Eric W. Fawcett and Reginald O. Gibson at the ICI Works in Northwich, England	White, waxy powder, due to contamination by O_2; the reaction was irreproducible. The first PE patents were registered by ICI in 1936	http://archive.thisischeshire.co.uk/2006/8/23/275808.html; E.W. Fawcett, R.O. Gibson, M.H. Perrin, J.G. Patton, E.G. Williams, British Patent 471,590 (1937)
1935	ALKATHENE, the high-pressure polyethylene (HPPE) or low-density PE (LDPE: $\rho = 915$–940 kg m^{-3}); polymerization in an autoclave with benzoyl peroxide and hydroxyperoxide Three years later IG Farben (BASF), introduced a tubular reactor technology	M. Perrin and W. R. D Manning at ICI. In 1933 invented the autoclave polymerization of LDPE, commercialized by ICI in 1938	Commercial production of ALKATHENE beginning in 1938 for submarine telegraph and then later the radar cables. The technology transferred to the USA delegation in 1941	Poly – The All Star Plastic, Popular Mechanics, pg 126, July 1949; S.W. Bigger, P.J. Watkins, M.A. Raymond, S.S. Verenich, J. Schei, Characterization of oligomeric by-products produced during the high-pressure polymerization of ethylene, Eur. Polym. J. **32**(4), 487–492 (1996); http://www.chemsystems.com/about/cs/news/items/PERP%200809_1_LDPE.cfm
1938	High-pressure tubular reactor for the continuous production of LDPE (Lupolen). Tubes 0.5–1.6 km long, with ID = 70 mm, and OD/ID ≈ 2.6 were made of high-strength steel	IG Farbenindustrie, now BASF – Ludwigshafen engineers developed a new high-pressure reactor	The first tubular reactor was invented by IG Farbenindustrie in 1938, but commercial production started after the WWII in 1953	http://www.basf.com/group/corporate/en/about-basf/history/1925–1944/index; High pressure equipment for LDPE plants, http://www.uhde-hpt.com/index

Year				References
1943	Union Carbide Corp. (UCC) commercialized in 1943 a LDPE process in a tubular reactor. Sumitomo also patented (U.S. Patent 4168355) ethylene copolymerization in reactor with ID = 19 mm and L = 190 m at P > 100 MPa. At present (2012) tubular reactors dominate the LDPE production. Length-to-diameter of tubular reactors = 250/1.0–12,000/1.0	LLDPEs from tubular or cascade loop reactor have fewer LCB and broader MWD than autoclave products. Modeling of an industrial slurry-phase olefin catalytic polymerization of two loop reactors in series was carried out by U. Thessaloniki and Total Petrochemicals	The slurry copolymerization of ethylene with other olefins uses a Z-N catalyst, an organometallic, and H_2 as MW regulator in two or more reaction zones producing PE with broad MWD and $\rho < 0.945$ g mL^{-1}. A mathematical model accounts for the effects of T and P, rates of catalyst addition, monomers and diluent, on MW, MWD, and viscosity	J.C. Swallow, in *Polythene*, ed. by A. Renfrew and P. Morgan, 2nd ed. (Interscience, New York, 1960), pp. 1–10; T.Y. Xie, K.B. McAuley, J.C.C. Hsu, D.W. Bacon, Gas-phase ethylene polymerization, Ind. Eng. Chem. Res. **33**, 449–479 (1994). CA Patent 1162700A of 21 Feb 1984 to Sumitomo Chem.; V. Touloupides et al., Modeling and simulation of an industrial slurry-phase catalytic olefin polymerization reactor series, Chem. Eng. Sci., **65**, 3208–3222 (2010)
1944	Further research on LDPE and large-scale commercial production licensed by ICI	Bakelite Corporation at Sabine, TX and Du Pont at Charleston, WV	Insulation for ultra- and superhigh (UHF and SHF, respectively)coaxial cables of radar sets	Poly – The All Star Plastic Popular Mechanics, pg 126, July 1949
1948	Radiative cross-linking LDPE produced dimensionally and thermally stable material different from the original LDPE	M. Dole, Argonne Natl. Lab. (ANL)	The radiative cross-linking was followed by UV (G. Oster et al.) and then by chemical with peroxides (Scott)	M. Dole, J. Macromol. Sci., Chem. **A15**, 1403 (1981); G. Oster et al. J. Polym. Sci. **34**, 671 (1959); H.G. Scott, U.S. Patent 3,646,155, 1972
1949	Oligomerization of ethylene by LiAlH4 (the Aufbau or buildup reaction). The work was followed by oligomerization of ethylene by catalytic activity of AlEt3	At ambient P and $T \approx 170$ °C, K. Ziegler (Kaiser Wilhelm Institute) dimerized ethylene to butene-1, propylene to 2-methyl-1-pentene, and butene-1 to 2-ethyl-1-hexene	Ziegler presentation in 1952 on the Aufbau reaction started collaboration with Natta. The 2-methyl-1-pentene was the starting material for industrial synthesis of isoprene, while the 2-ethyl-1-hexene opened up the way to terephthalic acid	K. Ziegler, A forty years' stroll through the realms of organometallic chemistry, Adv. Organometal. Chem. **6**, 1–17 (1968); L. Cerruiti, Hyle, Intl. J. Philos. Chem. **5**, 3–41 (1999); G. Wilke, Angew. Chem. Int. Ed. **42**, 5000–5008 (2003)

Table 18.10 (continued)

Date	Event	Inventor/company	Comment	Reference
1951	HDPE $\rho = 0.96$ polymerized at $T = 230–270\ °C$, $P = 4 – 8$ MPa, with NiO on activated carbon, Mo_2O_3 or $CoMoO_4$ on alumina, activated by electropositive metals, e.g., Na or Li. Producing HDPE with $\rho = 0.96\ g\ mL^{-1}$	Standard Oil Co., E. Field, M. Feller, U.S. Patent 2,691,647, 12 Oct 1954, filed 06 Dec 1952; A. Zletz, U.S. Patent 2,692,257; 2,780,617, priority 1951	Zletz recorded the polymerization to PO on 21 July 1950; the reaction was conducted in benzene solution initially with H_2 as an activator	Edmund Field, Morris Feller, Promoted Molybdenum-Alumina Catalysts in Ethylene Polymerization, Ind. Eng. Chem., 49, 1883–1884 (1957); A. Zletz, Ethylene polymerization with conditioned alumina-molybdenum catalysts, U.S. Patent 2,692,257, 19 Oct 1954
1951	Catalytic polymerization in gas phase or in a slurry at mild $T = 70–100\ °C$, $P = 3–4$ MPa (later $T = 40–260\ °C$, $P = 0.7–4.8$ MPa) into LLDPE (with hexene): $\rho = 0.93–0.97\ g\ mL^{-1}$. By the late 1956, the system also produced HDPE in the Phillips double-loop reactor	Marlex, disclosed by J. P. Hogan and R. Banks, Phillips Petroleum Co. slurry process. The PE was recovered from slurry by flashing off the diluent. Phillips catalyst is less expensive and easier to work with than Z-N	The first catalyst: Cr_2O_3 on amorphous SiO_2 or Al_2O_3 (at $T = 230–800\ °C$, with H_2) was discovered when dimerizing C_2. Second was a Cr compound with Ti, Ga, and/or Sn oxide. A 1998 patent significantly enhanced Phillips catalyst with $AlEt_3$ on SiO_2 as a base for partially reduced bis-triphenyl silyl-Cr	J.P. Hogan, R.L. Banks, U.S. Patents 2,825,721 of 04 Mar 1958, by others: 2927915; 2,939,892; 3,087,917; 3,351,623; 3,622,521; 3,635,840; 3,676,417; 4,376,851; 4,342,854 and British Patent 853,414 to Phillips Petroleum Co.; H.L. Hsieh, Catal. Rev.: Sci. Eng. **26**, 631–651 (1984); Arduini et al., CA Patent 2,192,722 of 06 Dec 1998, to NOVA Chem
1952	The authors correlated properties of LDPE with molecular structure, characterized by long- and short- chain branching (LCB and SCB, respectively) and the molecular weight (MW)	In 1944, Roedel from DuPont postulated formation of SCB via intramolecular chain transfer, which reduced crystallinity, density, modulus, and solubility	The elongation at break, Vicat temperature, and hardness are controlled by both density and MW, while melt viscoelasticity by LCB and MW	See a series of five articles on: The Molecular Structure of Polyethylene from DuPont (by Roedel, Bryant and Voter, Billmeyer, Beasley, and by Sperati et al.) in, J. Am Chem Soc. **75**, 6110–6133 (1953)

Year				References
1953	Popular catalyst for HDPE, LLDPE, and i-PP. Polymerization at $P \leq 5$ MPa, $T \leq 90$ °C, $M_w = 1–10$ kg mol^{-1}., then to UHMWPE with $M_w \geq 1{,}000$ kg mol^{-1}. Development of Ziegler catalyst was precipitated by observed catalytic reaction caused by Ni, followed by systematic examination of other metal for their effects on reaction. These identified Ti, Zr, Hf, etc., are good candidates for the polymerization catalysts	Karl Ziegler and Erhard Holzkamp from Kaiser Wilhelm Institute. Starting in the mid-1960s a series of patents was issued for the second generation of Z-N catalyst. It was later found that addition of Mg compound tenfold increased the catalyst activity	Ziegler–Natta (Z-N) catalyst with oxides or hydroxides of a metal from groups IVB, VB, and VIB with AlEt$_3$. For example, TiCl$_4$ activated by Al(C$_2$H$_5$)$_3$ or Al (C$_2$H$_5$)$_2$Cl in a hydrocarbon medium. PE density: $\rho = 0.88–0.96$ g mL^{-1}. By 1984, at least 32 companies applied for patents on Z-N catalyst	K. Ziegler, H. Breil, E. Holzkamp, H. Martin, DE 973,626, 1953; U.S. 3,257,332 of 21 June 1966; K. Ziegler, Angew. Chem. **67**, 541–547 (1955); L. Cerruti, Hyle, Intl J. Philos. Chem. **5**, 3–41(1999); H.L. Hsieh, Catal. Rev. Sci. Eng. **26**(3–4), 631–651 (1984); S. Sivaram, Ind. Eng. Chem., Prod. Res. Dev. **16**, 121 (1977); Catalyst composition for polymerization of olefins, U.S. Patent 4292200 of 29 Sept 1981 to Solvay and Cie; T.E. Nowlin, Prog. Polym. Sci. **11**, 29–55 (1985)
1954	New catalyst for polymerization of ethylene, which contains Ti + 2 and complexing and reducing agents for controlling MW	A W Anderson from DuPont suggested a coordination catalyst: TiCl$_4$ with phenyl–Mg–Br in, e.g., cyclohexane (CHX)	The new catalyst polymerized C$_2$ at ambient T and P to polymers with density ranging from about $\rho = 0.92$ to 0.98 g mL^{-1}	A.W. Anderson, U.S. Patent 2,905,645 of 22 Sept 1959 (filed 16 Aug 1954) to E. I. du Pont de Nemours & Co., Wilmington, Del
1954/ 1955	Hoechst (reincorporated in 1952 from IG Farben after WWII) started production of HDPE in a slurry cascade process involving two CSTRs, capable of forming either low- or high-MWD HDPE	Farbwerke Hoechst AG produced Hostalen at low pressure using Ziegler catalyst. The HDPE had high crystallinity, $X = 65–85$ %, and $T_m = 130$ °C	Since 1960, GUR® ultrahigh-molecular-weight polyethylene (UHMWPE) has been manufactured by Ruhrchemie. In 1988, the company merged with Hoechst AG and in 1999 with Celanese AG, forming Ticona	A.G. Hoechst. http://www.referenceforbusiness.com/history2/22/Hoechst-A-G; R.A.V. Raff, J.B. Allison, *Polyethylene* (Interscience Publication, New York, 1956)

1955	The use of H_2 for controlling MW during polymerization of C_2 improved the Ziegler process and PE performance	E. J. Vandenberg of Hercules Powder	The method was claimed applicable to any $CH_2=C(RR_1)$ monomer or comonomer, especially C_2 or C_3	E.J. Vandenberg, U.S. Patent 3,051,690 of 28 Aug 1962 to Hercules Powder; Chem. Eng. News, **40**(36a), 25–26 (1962)
1955	The catalyst polymerizing mono-α-olefinic monomers (e.g., propylene). The catalyst [$TiCl_4$ + $AlEt_3$] was deposited on neutral support such as TiO_2	Guyer from Esso. The patent describes composition developed by Ziegler, but his name is not mentioned	The catalyst on solid support was dispersed in n-heptane then propylene added. The reaction was carried out at ambient P and $T = 20$–$150\,°C$	Walter R.F. Guyer, Polymerization catalyst, U.S. Patent 3,008,943 of 14 Nov 1961 (filed 01 Dec 1955) to Esso Res. & Eng. Co.
1955	Natta et al. used Ziegler catalyst for polymerization of propylene to i-PP. U.S. Patent of 1973 describes i-PP consisting of head-to-tail connected propylene units, having $M_v \geq 20\ kg\ mol^{-1}$, and being crystalline due to steric arrangement along the main macromolecular chain. The authors discovered the principles of the regio- and stereospecific polymerization of 1-alkenes, e.g., propylene into i-PP, s-PP, or a-PP	Giulio Natta et al.; Politecnico – Milano, patents assigned to Montecatini Edison SpA. The Z-N catalysts are based on Natta et al. U.S. Patent 3,715,344 and Kaminsky et al. DE Patent 3,240,382 of 1984	Z-N catalyst is based on transition M (Groups 3–8) and organometallic (Groups 1, 2, and 13), for example, Cp_2ZrCl_2 + MAO. The modern Z-N catalysts are either (1) $MgCl_2$ supporting $TiCl_3$ complex or (2) bridged complex of Ti, Zr, or Hf. More recent post-metallocene catalysts use an M-complex (Sc, La) and ligands containing O, N, P, and S activated by MAO	G. Natta, Angew. Chem. **68**, 869–887 (1956); G. Natta, Angew. Chem. **76**, 553–566 (1964); G. Natta, G. Mazzanti, P. Longi, F. Bernardini, Chim. Ind. **41**, 519–526 (1959); G. Natta, P. Pino, G. Mazzanti, U.S. Patent 3,715,344 of 06 Feb 1973, to Montecatini Edison SpA.; http://en.wikipedia.org/wiki/Ziegler%E2%80%93Natta_catalyst; J. Schmidt, T. Risse, H. Hamann, H.-J. Freund, J. Chem. Phys. **116**, 10861 (2002)

Year				
1955	Homogeneous catalysis using Z-N catalyst in a hydrocarbon (toluene), Cp_2TiCl_2 with an Al-alkyl compound, $Al(C_2H_5)_3$ – i Cli: $(C_5H_5)_2Ti(C_2H_5)Cl/Al(C_2H_5)Cl_2$	Breslow for Hercules Powder Co. Owing to low activity the system was not used	Polymerization of C_2 at $-10 < T\,°C < 100$, at nearly ambient P in the presence of 0.01–0.5 mol% of oxygen. Kinetics was described 15 years later	S. Breslow David, Polymerization of ethylene, U.S. Patent 2,827,446, of 18 Mar 1958 (filed 27 Sept 1955), to Hercules Powder Co.; Breslow and Newburg, J. Am. Chem. Soc. **79**, 5072 (1957); 81 (1959) 81; K.R. Meyer, Dissertation, TH München, 1969
1955	Commercialization of UHMWPE, $M_w = 0.2$–4 Mg mol^{-1}, $\rho = 0.925$ g mL^{-1}, produced using Ziegler catalyst, later metallocene	Ruhrchemie AG (now Ticona), also Mitsui, Braskem	Gel spun into high-performance ballistic fibers such as Dynema (1970) by DSM	S.M. Kurtz, *The UHMWPE Handbook: Ultra-high Molecular Weight Polyethylene in Total Joint Replacement* (Academic, 2004)
1956	Another disclosure based on modified Ziegler catalyst for either isomerization of hydrocarbons or olefin polymerization in the presence of subhalide of Ti or Zr	Thomas from Sun Oil Co. Polymerization was carried out at $T = 60$–80 °C and $P = 517$ kPa	A 2 wt% of $TiCl_4$ was deposited on γ-alumina. Reaction with H_2 at 300 °C reduces Ti + 4 to Ti + 2 or Ti + 3, which catalyzed polymerization in the presence of $Al(alkyl)_3$	C.L. Thomas, Gamma alumina supported titanium and zirconium subhalides polymerization catalysts and preparation thereof, U.S. Patent 3153634 of 20 Oct 1964 to Sun Oil Co.
1956	New polymerization catalyst for ethylene was prepared by slurring ethylaluminum sesquibromide, $Al_2Br_3Et_3$, with ethylhexyl titanate in *n*-heptane	Hagenieyer and Edwards to Eastman Kodak Co. The catalyst, activated by C_2, was used for polymerizing or copolymerizing olefins	The polymerization took place in a slurry reactor using hydrocarbon as the suspending medium at near ambient T and P	H.J. Hagenieyer Jr., B. Edwards Marvin, U.S. Patent 3067183 of 04 Dec 1962 (filed 15 Oct 1956), to Eastman Kodak Co.
1957	Fluidized bed reactor for polymerization of ethylene with Phillips Cr[VI] catalyst on SiO_2/	Dye from Phillips Petroleum Co. disclosed a gas-phase polymerization of HDPE. The	Ethylene + catalyst are fed to the lower part of the 3-segmented vertical reactor, passing through a reaction zone to cyclone	R.F. Dye, U.S. Patent 3023203 of 27 Feb 1962 (filed 16 Aug 1957), to Phillips Petroleum Co.;

Table 18.10 (continued)

Date	Event	Inventor/company	Comment	Reference
	Al_2O_3 supports at $T = 75$–100 °C and $P = 2$–3 MPa. HDPE from the Phillips catalyst had the highest crystallinity ($X = 90$–95 %) and density $\rho = 0.92$–0.96 g mL^{-1}	UNIPOL patent was originally deposited 14 Mar 1975 by UCC. The PE powder was removed from the fluidized bed reactor (FBR) and gas returned back to it	separating solids from remaining gases. The residence time in FBR was 3–5 h and conversion 97–99 % at 75 % lower energy cost than that in CSTR	A.R. Miller, U.S. Patent 4003712, 18 Jan 1977, to Phillips Petroleum Co; F.J. Karol, G.L. Goeke, B.E. Wagner, W.A. Fraser, R.J. Jorgensen, N. Friis, U.S. Patent 4302566 of 24 Nov 1981 & 4,621,952 of Nov 11 Nov 1986 to Union Carbide Corporation (UCC)
1957	Hercules Powder started production of HDPE (HITAX) in Parlin, NJ, in the presence of Karl Ziegler, whose catalyst the company has licensed	The first plant for the production of HDPE in the USA	Ziegler was the Institute Director and Manager of the organization for the patents defense; in 1956–1999, 149 infringements and objections had to be warded off	"Karl Ziegler," by GDCh &Max-Planck-Institut of 08 May 2008 honours his achievements in the field of organometallic catalysis and chemistry; http://www.kofo.mpg.de/media/2/D1105213/0478051227/Festschrift_e.pdf
1959	The first LLDPE (Sclaire resins) was produced by DuPont Canada Ltd. in a solution process using Z-N vanadium (V) catalyst: $VO(O\text{-}n\,\text{butyl})_2$ Cl, and Al $(Et)_{1.5}Cl_{1.5}$. The comonomer was $C_{4\text{–}20}$, with the Al/V ratio increasing with comonomer MW from 5:1 to 12:1	Elston from DuPont Canada Ltd. patented Advanced SCLAIRTECH technology with a single-site catalyst, which produced a bimodal ethylene–hexene copolymer for films or injection moldings	The Advanced SCLAIRTECH process uses two CSTR with CHX as a solvent and metallocene catalyst at $T = 160$–220 °C and $P = 3$–34 MPa. Process advantage is the heat recovery. The patent for the first time uses the homogeneity index, HI calculated from T_m	Clayton Trevor Elston. Process for preparation of homogenous random partly crystalline copolymers of ethylene with other $\tilde{\alpha}$ olefins, U.S. Patent 3645992 of 29 Feb 1972; CA Patent 703704 of 09 Feb 1965 to Du Pont of Canada Ltd.); D. Malpass, *Introduction to Industrial Polyethylene* (Wiley, 2010); J. Gray, Prog. Rubber Plast. Technol. 1(1), 1–12 (1985)

1960	The patent describes catalyst for polymerization of unsaturated monomers, such as C_2 or C_3. Conversion $\geq 99.5\%$ was achieved with 0.0005 g Ti per 1 g of $CoBr_2$	W. A. Hewett for Shell Oil Co.	The catalyst has small crystals of metal salts. The metals with atomic weight 24–209 are claimed, e.g., Co or Mg dihalide, deposited on $TiCl_4$ with $AlEt_3$ or $AlClEt_2$ as activator	W.A. Hewett, Catalysts and their preparation, U.S. Patent 3,238,146 of 01 Mar 1966 (filed 21 Mar 1960) to Shell Oil Co.
1963	Solution polymerization of ethylene was described in the CA patent of 1963. The reaction uses a Z-N-type catalyst, viz., $CpMLX_n$ [$M = Ti$, Hf, or Zr; $L =$ heteroligand; $X =$ activable ligand; $n = 2$ for Ti] with an ionic activator [$Ph_3CB(C_6F_6)_4$]. Gillis, Zboril, and Hughson developed a heat-treated (at 180–250 °C) catalyst for solution copolymerization of C_2 with C_{3-12} at 105–320 °C. The catalyst was TiX_4 VOX_3 ($X =$ Cl or Br) and AlR_nX_{3-n} ($R =$ phenyl or alkyl; $n = 2$ or 3). The catalyst mixture was heated to 180–250 °C and then cooled to $T < 150$ °C. Next, the extra VOX_3 (not heat treated) was added	A. W. Anderson, E. L. Fallwell, and J. M. Bruce to du Pont de Nemours; Vaclav G. Zboril to DuPont Canada and Gillis, Zboril, and Hughson; Zboril and Brown to Novacor Chem. (International)	The catalyst comprises a Group IVB–VIB transition metal and an organometallic compound of a metal belonging to Groups I–IIIA. A preferred polymerization copolymerization method of C_2 with C_{3-20} is the high-T "solution" process, where the monomer and polymer are soluble in the reaction medium. The Gillis et al. catalyst showed superior activity to catalysts in which additional VOX_3 was not added or added at temperatures above 150 °C. The catalyst was activated with $AlEt_2Cl$ or Al-siloxane compound at the atomic ratio: $Al/(Ti + V) = 0.8–7.0/1$ and $V/Ti = 0.15–4.0/1$	Arthur W. Anderson, Ernest L. Fallwell, John M. Bruce, Jr., CA Patent 660869 of 09 Apr 1963 to E.I. du Pont De Nemours and Co.; V.G. Zboril, U.S. Patent 4,430,488, of 1984, priority 1980 to Du Pont Canada Inc.; D.J. Gillis, V.G. Zboril, M.C. Hughson, U.S. Patent 5,492,876, of 20 Feb 1996 to Novacor Chem. (International); V.G. Zboril, S.J. Brown, U.S. Patent 5,589,555, of 31 Dec 1996 to Novacor Chem.; S. Brown, X. Gao, R. Spence, E. Von Haken, Q. Wang, P. Zoricak, CA Patent 2228802 of 25 Apr 2006 (Filed 19980) to Novacor Chem

Date	Event	Inventor/company	Comment	Reference
1967	Catalyst [based on cyclopentadienyl-Cr + 2 and adsorbed on dehydroxylated SiO_2] was granted in 1973. Owing to catalyst heterogeneity, polydispersity of HDPE resulted in improved processability	Karapinka et al. to UCC. The chromocene catalyst on aluminum phosphate support was similar to that of Phillips Petroleum Co., invented by Hogan and Banks	The system shows high activity, but differs from Ti- and V-based catalysts as they produce HDPE with broad MWD. The catalyst contains active sites with different geometries and activities	G.L. Karapinka, U.S. Patent 3709853 of 09 Jan 1973, to UCC; F.J. Karol, G.L. Karapinka, C. Wu, A.W. Dow, R.N. Johnson, W.L.J. Carrick, Polym. Sci. Part A-1 **10**, 2621–2637 (1972); F.J. Karol, C. Wu, W.T. Reichle, N.J. Maraschin, J. Catal. **60**, 68–76 (1979)
1968	Catalysts for polymerizing ethylene and its mixtures with α-olefins are obtained by mixing a hydride or an organometallic compound of a metal belonging to Groups I–III with $TiCl_4$ with an anhydrous $MgCl_2$ or $ZnVCl_2$. Other catalyst is (1) a compound of Ti, V, or Zr and (2) a complex, e.g., $MCl_{2p}AlRCl_{2p}AlCl_3$ [M = Ba, Ca, Mg or M_n; $R = C_1–C_{20}$; $n = 1–4$; $p \leq 1$; M/transition metal atomic ratio = 0.1–50]	A. Mayr, P. Galli, E. Susa, G. DiDrusco, E. Giachetti, from Montecatini Edison SpA	Catalyst was prepared by ball milling $MgCl_2$ with $TiCl_4$, dispersed in n-heptane with $Al(C_4H_9)_3$ at $T = 75$ °C. C_2 and H_2 were introduced and for 2 h the polymerization was carried out at 1 MPa; PE yield ranged from 50 to 590 kg/1 g of Ti	Adolfo Mayr, Paolo Galli, Ermanno Susa, Giovanni Di Drusco, Ettore Giachetti,CA 906981 of 08 Aug 1972; CA 910891 of 26 Sept 1972; CA 923483 of 27 Apr 1973; CA 949542 18 June 1974; CA 991620, CA 991621 & CA 991628 of 22 June 1976; CA 1076544 29 Apr 1980; U.S. Patent 4298718 of 03 Nov 1981 (priority 25 Nov 1968) to Montecatini Edison/Montedison SpA. (Italy)
1971	Dow deposited a patent on the use of two reactors, primary and auxiliary, for the solution polymerization of C_2 with C_3 into impact-modified HDPE + EPR	John H. Mitchell from Dow Chem. Co.	Ziegler catalyst was a mixture of $TiCl_4$ + $AlEt_3$ (see U.S. Patent 3,051,690 to Hercules or U.S. Patent 3,257,332 to K. Ziegler)	J.H. Mitchell, U.S. Patent 3,914,342 of 21 Oct 1975 (priority 13 July 1971) to Dow Chem. Co.

Year				References
1971	Henrici-Olive and Olive from Monsanto Research S. A. postulated that ligands in Z-N catalysts may lead to specific structures of macromolecules. The possible reasons:	(1) Due to steric factors the stability of olefin-to-M complex decreases with olefin size; (2) the bond between ligand and M is unstable	(3) The ligand influence takes place through σ- and π-electrons, i.e., more electronegative ligand, weaker M–R bond and more reactive; (4) bulky ligands enhance stereospecific polymerization	G. Henrici-Olive, S. Olive, Angew. Chem., Int. Ed. Engl. **10**, 105 (1971)
1972	Gas-phase polymerization of ethylene and α-olefins using a dual-reactor process: the CSTR for the preparation of pre-polymer and FBR for the polymerization step	The Naphtachimie continuous two-stage process uses in series a stirred tank and fluidized bed reactors (FBR)	The process after amalgamation was adopted by BP Chemicals for the production of HDPE and LLDPE	R. Dormenval, L. Havaa, P. Mangin, Process for dry polymerization of olefins, U.S. Patent 3922322, 25 Nov 1975, priority 17 Nov 1972, to Naphtachimie France
1973	Addition of a small amount of water to the Z-N soluble catalyst: (Cp_2TiCl_2) with $AlEt_3$–iCli greatly increased the catalyst activity	Reichert and Meyer, TU Munich, studied kinetics of polymerization as function of the Al/Ti ratio	At Al/Ti > 1 excess of Al acts as a deactivator, while for Al/Ti < 1 the polymerization has the "living" character	K.H. Reichert, K.R. Meyer, Makromol. Chem. **169**, 163 (1973); K. Meyer, K.H. Reichert, Angew. Makromol. Chem. **12**, 175 (1970); K.H. Reichert, Angew. Makromol. Chem. **13**, 177 (1970)
1973	Multiple reactors for controlling MWD of HDPE (in parallel or in cascade with different feeds) have been known in the plastics industry as described in a patent DE 656,469 (1938) or U.S. Patent 2363951 (priority 1937) for PS or PVC production. The "Advanced Cascade Process (ACP)" with three reactors in cascade is an	Hoechst's slurry Hostalenis produced via advanced cascade process (ACP), which uses three CSTR in a cascade, enabling the production of multimodal HDPE and/or LLDPE (with butene) resins in butane. For example, the first CSTR is alimented with C_2, the second with C_2 and C_4, and	ICI patented polymerization or copolymerization of ethylene using transition metal complex (preferably Z-N catalyst on support) at $P = 30$–100 MPa and $T = 100$ °C in pentane. Multi-reactor with different feeds and/or conditions or a tubular reactor with different reaction zones may be used. Several other LDPE manufacturers (e.g., DuPont, Mitsui)	L.L Bohm, in *Progress and Development of Catalytic Olefin Polymerization*, ed. by T. Sano, T. Uozumi, H. Nakatani, M. Terano (Technol. Edu. Pub., Tokyo, 2000); R.R. Cooper, K.S. Whiteley, U.S. Patent 4,133,944 of 09 Jan 1979 to ICI; K. Kawai, K. Mashita, K. Hanji, H. Takao, CA 1162700 A, 21 Feb

	extension of the 1954 Hostalen bimodal process technology for the production of multimodal HDPE	the third with C_2 and a small amount of C_4	modified the ICI HP process by introducing non-peroxide catalysts	1984 to Sumitomo Chem.; N. Platzer, Ind. Eng. Chem. **62**, 6–20 (1970); A.W. Anderson, G.S. Stamatoff, U.S. Patent 4,076,698, 28 Feb 1978 to du Pont; T. Shiomura, Y. Kinoshita, Y. Kokue, U.S. Patent 4,128,607, 05 Dec 1978 to Mitsui
1975	Discovery that addition of H_2O into metallocene homogeneous catalyst, Cp_2MCl_2 (M = Zr, Ti, Hf) + AlR_3 at a molar ratio of H_2O to $Al(CH_3)_3 \approx 1:1$, results in formation of the methylaluminoxane (MAO) soluble in organics: R_2AlO $[RAlO]_nAlR_2$. In comparison to Z-N the m-type catalyst activity is higher by a factor of 10–100. The linear or branched oligomeric MAO is particularly an efficient co-catalyst for Cp_2ZrCl_2. Diverse metallocenes have been described, e.g., in U.S. Patents 4752597, 5017714, Europe Patents A320762, A416815, A537686, A669340, 0485823, 0549900, 0576970. Furthermore, in U.S. Patent 5403942, R.-J. Becker,	Walter Kaminsky and Hansjörg Sinn (Univ. Hamburg) discovered the key beneficial role of moist MAO for a metallocene-catalyzed polymerization of olefins, cycloolefins, dienes, styrenes, etc. The discovery was followed by numerous patents on the modification/improvements, e.g., L. H. Slaugh and G. W. Schoenthal, U.S. Patent 4665047 of 12 May 1987 to Shell; H. W. Turner, U.S. Patent 4752597 of 21 June 1988, to Exxon; F.R.W.P. Wild, L. Zsolnai, G. Huttner, H. H. Brintzinger, ansa-Metallocene Derivatives: IV, J. Organometal. Chem., 232, 233–247 (1982); Angew. Chem., 107, 1255 (1995); etc.	Accidental contamination of $AlEt_3$ by water greatly increased Z-N catalytic activity and led to the development of diverse metallocene catalysts. By contrast, with earlier catalysts, the metallocene copolymers have well-defined structure, a single active polymerization center leading to high polymerization efficiency (1 kg polymer per 1 g catalyst), narrow MWD, and uniform properties. Metallocenes show better thermal stability, facile incorporation, high α-olefins even at high concentration (plastomers), and control of stereostructure. Most frequently, the active part of Z-N catalyst is a zirconocene cation	W. Kaminsky, in *History of Polyolefins*, ed. by R.B. Seymour, T. Cheng (1986), pp. 257–270; J. Polym. Sci. Part A: Polym. Chem., **42**, 3911–3921 (2004); Metallocene catalyzed polymerization, RAPRA Rev. Rep. **10**(7) (1999). The initial patent [DE 3007725 of 29 Feb 1980] was abandoned once learned about earlier work by Reichert and Meyer (1973); H.W. Sinn, W.O. Kaminsky, H.-J.C. Vollmer, R.O.H.H. Woldt, U.S. Patent 4404344 of 1983 to BASF; W. Kaminsky, H. Hahnsen, K. Kulper, R. Woldt, U.S. Patent 4542199 of 17 Sept 1985, to Hoechst; B.A. Harrington, M.G. Williams, Rubber World **230**, 20–26 (2004); P.C. Möhring,

	S. Gurtzgen, and R. Schrader detail preparation of MAO by addition of H_2O to a solution of AlR_3 in an inert solvent, using a mixing nozzle and a static mixer		N.J. Coville, J. Organometal. Chem. **479**, 1–29 (1994); R.-J. Becker, S. Gurtzgen, R. Schrader, U.S. Patent 5403942 of 04 Apr 1995 (filed 16 Mar 1994), toWitco GmbH
1977	Discovery of MAO by W. Kaminsky group and identification of its structure as linear or cyclic, [-Al(Me)-O-]$_{10-15}$, were crucial for the increase of catalyst activity, by a factor of 10,000 or more. Thus, the expensive MAO plays a key role in metallocene catalysis	Metallocenes (esp. zirconocenes) treated with MAO polymerize up to 21 kg PE/(mmol Zr h). The C_2H_4 mer insertion time into a growing chain is about 10 μs. Two types of MAO have been used as co-catalysts: MAO (1) and MAO (2) prepared in the ratio $Al/H_2O = 2$ and 3. The complexes, zirconocene/MAO, belong to the most active catalysts. The active site consists of Zr and 6–20 Al atoms	H. Sinn, W. Kaminsky, Adv. Organomet. Chem. **18**, 99 (1980); W. Kaminsky, RAPRA Rev. Rep. **10**(7) (1999); J. Justino, Polym. Intl. **44**, 407–412 (1997); W Kaminsky, Metallocenes, in *Ullmann's Encyclopedia*, Ind. Chem. **22**, 685–601 (2006)
1977	CdF Chimie modified the standard high-P radical polymerization for LDPE by using N_2 and H_2O [N_2 caused phase separation; water improved dissipating reaction heat]. These modifications reduced the reaction conditions to $P = 30–80$ MPa and $T = 150–300$ °C. Z-N catalyst at high T caused an ionic radical	The reaction took place in a multi-zone CSTR, in the presence of up to 28 wt% N_2 and some H_2O. Demixing caused by N_2 reduced LCB and increased unsaturation. H_2O increases MW and LCB and reduces unsaturation. The presence of comonomers (e.g., C_4, C_6, or C_8) improved the reaction stability. LDPE density was controlled by comonomer content, while MWD by H_2 concentration. H_2O improved conversion up to the saturation concentration. Retrofitting the ICI system reduced the LDPE production cost by 15–20 %	D. Constantin, J.P. Machon, Eur. Polym. J. **14**, 703–708 (1978); D. Constantin, M. Hert, J.P. Machon, Europ. Polym. J. **17**, 115–120, (1981); D. Constantin, M. Hert, J.-P. Machon, Structure of polyethylene produced at high pressure by simultaneous ionic and radical mechanisms, Makromol. Chem. **179**, 1581–1591 (1978)

1978	UNIPOL gas-phase polymerization in a fluidized bed reactor was introduced by Union Carbide Corp. (UCC). Expected capacity 450 kt year^{-1} for copolymerization of C_2 with C_{3-8} comonomers	The novel technology is a combination of gas- and slurry-phase reactions at $P = 0.7-2.1$ MPa and $T = 100$ °C	Cascaded processes are suitable for bimodal Spherilene PE from LyondellBasell (Covezzi 1995; Galli 1995) and Borstar PE from Borealis and Borouge (Avela et al. 1998)	Anon., Low pressure LDPE, Mod. Plast. **56**, 42–43 (1979); Anon., New route to low density polyethylene, Chem. Eng., 80–85 (1979); U.S. Patent 4,363,904 of 14 Dec 1982 to UCC
1981	A solution copolymerization of C_2 with C_{3-12} at $T = 105-320$ °C for the preparation of high-MW LLDPE. The catalyst was obtained by solution mixing $TiCl_4$ or $VOCl_3$ and $AlEt_3$ at $T < 30$ °C, heating to $T = 150-300$ °C for 10–600 s, then injecting to a solution of AlR_nX_{3-n}, [R = alkyl, cycloalkyl, or aryl having 1–20 carbons, $n = 1, 1.5, 2,$ or 3 and X is Cl or Br	Hamilton and Zboril from DuPont Canada Inc. The solvent (hexane, heptane, octane, methylcyclohexane, hydrogenated naphtha, but preferably CHX), used in the preparation of the catalyst was the same as that used in the polymerization process	The coordination catalyst was fed to the reactor containing hydrocarbon solvent and appropriate monomers. Polymerization was carried out at $T = 105-310$ °C. The catalyst was deactivated and either left in the obtained LLDPE ($\rho = 0.915-0.965$ g mL^{-1}) or the solution was passed through a bed of activated alumina or bauxite to remove at least a part of the deactivated catalyst residues	M.A. Hamilton, V.G. Zboril, Process for the preparation of polymers of α-olefins at high temperatures, CA 1171065 of 17 July 1984 (filed 06 Jan 1981, expired 17 July 2001); M.A. Hamilton, V.G. Zboril, U.S. Patent 4431784 of 14 Feb 1984 (filed in 1981) to Du Pont Canada Inc.
1982	$C_2 + C_8$ type LLDPE with density of $\rho = 0.927$ g mL^{-1}	DuPont Canada	Replacing $C_2 + C_4$ type films with the $C_2 + C_8$ type permitted rotomolding downgauging by 30 %	R. Martino, Mod. Plast. 126–128 (1984)
1984	Ansa-metallocene complexes have been studied for olefin polymerization, e.g., polymerizing i-PP with an ansa-titanocene. The bridged ligands change the catalysts and the polymer structures, also affecting MW and MWD	Kaminsky et al.; see also reviews by Möhring and Coville (1994) and by Wang (2006)	Catalysts with metal from Group 3 [Coord. Chem. Rev. **248**, 397–410 (2004)] or 4 [J. Organomet. Chem. **542**, 191–204 (1997)] have been studied. (N.b., ansa = a bridge between two functional ligands)	W. Kaminsky, J. Polym. Sci. Part A: Polym. Chem. **42**, 3911–3921 (2004); P.C. Möhring, N.J. Coville, J. Organometal. Chem. **479**, 1–29 (1994); B. Wang, Coord. Chem. Rev. **250**, 242–258 (2006)

1985	Deposition of Dow modification of Z-N catalyst incorporating $MgCl_2$. Numerous versions of the new catalyst are listed	William M. Coleman from Dow Chem Co.	Improved Ziegler–Natta catalysts with $MgCl_2$, Ti, and V compounds producing narrow MWD PE copolymers	W.M. Coleman III, U.S. Patent 4,612,300 of 16 Sept 1986 (deposited 06 June 1985) to The Dow Chemical Company
1985	A solution copolymerization of C_2 with C_{3-12} at $T = 105$–$320\ ^\circ C$ into high-MW LLDPE comprised feeding monomers, a catalyst, and a hydrocarbon solvent to a reactor, polymerizing the monomers, recovering the polymer, and deactivating the catalyst by injecting H_2O followed by desalination. The coordination catalyst was obtained combining (i) a solution of AlR_nX_{3-n} (R = alkyl C_{1-20}; $n = 1, 1.5, 2$, or 3, and X = halogen) with a solution of $TiCl_4$ and $VOCl_3$ at $T < 30\ ^\circ C$, heating to $T = 150$–$300\ ^\circ C$ for $t = 5$ s to 60 min, and adding $VOCl_3$	Zboril and Müllhaupt from DuPont Canada Inc. modified the Hamilton and Zboril polymerization process [U.S. Patent 4431784 of 14 Feb 1984]. Polymerization was carried out in CHX at $T = 105$–$320\ ^\circ C$ and $P = 0.1$ MPa. The improvement comes from the second component of the catalyst, primarily from aluminoxanes. High catalyst activity and acceptable polymer color were reported	The second catalyst component was a solution of an aluminoxane in a hydrocarbon solvent, selected from between aluminoxanes: (i) linear, $R'AlO$ $(R'AlO)_m$–AlR'_2 [where R' is C_{1-20} alkyl and cycloalkyl and $m = 0$ or an integer], and (ii) cyclic, $$\left[(R2''AL\!-\!O) \right]$$ $R'' = C_{1-20}$ (alkyl or cycloalkyl), the atomic ratio of $Al/(Ti + V)$ in the second component $= 0.9$–10. The organoaluminum was mixed with the Ti and V at a ratio of $Al/(Ti + V) = 0.2$–2.0	V.G. Zboril, R. Müllhaupt, Solution process for the preparation of polymers of alpha-olefins, U.S. Patent 4769428 of 06 Sept 1988, (filed in 16 Oct 1986, priority 1985) to Du Pont Canada Inc.
1986	The transition metal in a Z-N-type catalyst was prepared by reacting Mg(alkoxide)$_2$ with $TiCl_4$ and an organoaluminum compound: $AlR_{3-n}X_n$ (R = organo group, $n = 0$–2)	E. I. Band and W. E. Summers, III for Stauffer Chem. Co. Isotacticity of the PP obtained using the new catalyst was 95 % pure	Mg(2-butoxyethoxy)$_2$ $(Z\!-\!(CH_2)_n\!-\!O)\!-\!Mg\!-\!(O(CH_2)_m\!-\!OR_2)$ (where $m, n = 1$–12) is soluble in hydrocarbons, such as heptane or toluene for the synthesis of i-PP at 70 °C and $P = 0.7$ MPa	E.I. Band, W.E. Summers III, Transition metal catalyst component containing magnesium alkoxy alkoxides, U.S. Patent 4698323 of 06 Oct 1987 (filed 29 Sept 1986), to Stauffer Chem. Co.
1986	Metallocene/MAO catalysts (e.g., Z-N type) are soluble, thus unsuitable for the gas- or slurry-	In the 1980s a series of patents (e.g., from Exxon Chem) disclosed methods of supporting	The U.S. Patent 6720396 lists >50 patents on the catalyst supporting methods and offers detailed discussion on their	H.C. Welborn Jr., U.S. Patent 4701432 of 20 Oct 1987 (filed 1986); J.A.M. Canich,

	phase processes. Adsorption on a solid support (silica, alumina, MAO, etc.) with or without organosilicon spacers transforms these systems into heterogeneous catalysts for the solvent-less polymerization	catalyst of Groups IV and III, aiming at increased activity, reduction of the amount of co-catalyst, and increasing MW of the resulting polymer	properties. The main application for the new catalytic systems has been for the gas-phase or slurry copolymerization of C_2 with higher α-olefins. High catalyst activity ($\leq$36 kg PE/mmol Zr h) has been noted	G.F. Licciardi, U.S. Patent 5057475 of 13 Sept 1990, both to Exxon Chemical; Kao et al., U.S. Patent 6136747 of 24 Oct 2000, to UCC; S.L. Bell, A.G. Vadagama, U.S. Patent 6720396 of 13 Apr 2004, to Univation Technol.; G.G. Hacky, Chem. Rev. **100**, 1347–1376 (2000); M.C. Haag et al., J. Mol. Catal. A: Chem. **197**, 223–232 (2003)
1989	Soluble in hydrocarbons chiral catalyst Et(bisindenyl)ZrCl$_2$/ MOA copolymerized cyclopentene with ethylene at $T = -10$–20 °C	Kaminsky and Spiehl incorporated up to 10 mol% of cyclopentene monomeric units into cycloolefin copolymers (COC)	The technology was transferred to Ticona (now TOPAS Advanced Polymers), which in 2000 started production of C_2 with norbornene as TOPAS COC	W. Kaminsky, R. Spiehl, Copolymerization of cycloalkenes with ethylene in presence of chiral zirconocene catalysts, Makromol. Chem., **190**, 515–526 (1989)
1990	Catalysts with a cyclopentadienyl group based on transition metals of group IVB (Zr, Hf, Ti) with a co-catalyst, e.g., alumoxane	J. A. M. Canich from Exxon Chem.	Polymerization of C_{3-20} (esp. propylene) into crystalline poly(α-olefins) in solution, slurry, gas, or bulk phase	Jo Ann M. Canich, U.S. Patent 5,026,798 of 25 June 1991 (deposited 13 Sept 1990) to Exxon Chemical Patents Inc.
1990	A monocyclopentadienyl metal complex, CpMX$_n^+$ A$^-$ (M is metal of Groups 3–10), is a Z-N-type catalyst for olefin polymerization	Stevens and Neithamer from Dow Chem. Co. $\mathrm{Cp^*{-}M^{+}}$ with $Z{-}Y$, $(X)_n$, A^-	In the preferred compounds M = Zr or Ti, while Z = SiR$_2$N(R*); n = 1 or 2; X = alkyl or aryl; Y = N- or P-containing group; A = non-coordinating Bronsted anion	J.C. Stevens, D.R. Neithamer, Metal complex compounds, U.S. Patent 5064802 of 12 Nov 1991 (deposited 03 July 1990) to The Dow Chemical Co.

1991	First commercialization of metallocene PE based on Kaminski (1976) $ZrCl_2Cp_2$ catalyst	Exxpol® technology by ExxonMobil to produce Exact® PE via gas phase	Metallocene: mPE (Enable™) and mPP (Exceed™, Vistamaxx™) propylene-based elastomers	http://www.exxonmobilchemical.com/Chem-English/about/news-releases.aspx
1991	A coordination catalyst was prepared by (i) mixing a solution of AlR_nX_{3-n} [R = phenyl or C_{1-4} radical, X = Cl, or Br and n = 2 or 3; e.g., $AlEt_2Cl$] in a solvent, with a solution of TiX_4 and VOX_3 at $T < 30$ °C and heating the mixture to T = 180–250 °C for t = 15–300 s [the atomic ratio of $Al/(Ti + V)$ = 0.2–3.0:1 and V/Ti = 0.05:1–1.5:1]; (ii) cooling the solution to $T < 150$ °C; and (iii) adding a solution of VOX_3 thus increasing the V-content to $\geq$10 at.%. Combine the cold solution with that of (a) AlR_nX_{3-n} and (b) $R''_3SiO(R''_2SiO)_mAlR''_2$ [where R'' is a C_{1-6} alkyl radical and m = 0–4, e.g., $EtMe_2SiOMe_2SiOAlEt_2$]. In the coordination catalyst $Al/(Ti +$ V) = 0.8–7.0:1; and V/Ti = 0.15–4.0:1	Gillis, Zboril, Hughson, Hamilton, Russell, Harbourne, Müllhaupt, Hughson from DuPont Canada Inc. and/or Novacor Chem. (International) This is the next level of Z-N catalyst modification for solution copolymerization of C_2 with C_{3-12}: See U.S. Patents 4431784, 4769428	A solution polymerization for high-MW LLDPE uses a coordination catalyst at T = 105–320 °C. The catalyst was heat treated at 180–250 °C, then cooled to a $T < 150$ °C. Additional VOX_3 was added and catalyst activated with an Al compound. The catalyst had greater activity than the one without additional VOX_3 or with that added at $T >$ 150 °C. After reaction, the catalyst was deactivated using, e.g., tri-i-propanol amine, acids, salts, or alcohols. After deactivation, the polymer solution might be passed through a bed of activated alumina or bauxite to remove part or the catalyst residues. LLDPE was pelletized with an antioxidant	D.J. Gillis, V.G. Zboril, M.C. Hughson, Solution process for the preparation of polymers of a-olefins, CA 2081887 of 07 Aug 2001, filed 05 Apr 1991; A. Hamilton Michael, G. Russell Charles, A. Harbourne David, M. Rolf, G. Zboril Vaclav, CA 1220189 of 07 Apr 1987 (filed 03 July 1983); Zboril Vaclav G. and Müllhaupt Rolf.,CA 1257863 of 25 July 1989 (filed 17 Oct 1985); Gillis Daniel John, Zboril Vaclav George.Hughson Millard Clifford, CA 2081887 of 07 Aug 2001 (filed 05 Apr 1991); U.S. Patent 5492876 of 20 Feb 1996 (filed 01 Feb 1994, priority 1991) to Du Pont Canada Inc. or to Novacor Chemicals (International) S.A.

Table 18.10 (continued)

Date	Event	Inventor/company	Comment	Reference
1991	New coordination catalyst is (i) a mixture of MgR^1_2 and AlR^2_3 [R^1 and $R^2 = C_{1-10}$ alkyls]; (ii) TiX_4 at the molar ratio Mg: Ti $= 4$:1–8:1, that of halide: Mg $= 1.9$:1–2.6:1; and Mg: Al $= 1.0$:0.1–1.0:0.4. The CHX solutions were mixed for 5 s at $T = 30\,°C$ and heated to $T < 300\,°C$ for 5–60 s and then to $T = 170$ to $220\,°C$ for 10–120 s. The catalyst activator was $AlEt_3$ mixed with an $R''OH$, $R'' = C_{2-8}$ alkyl radical, e.g., t-butyl alcohol (molar ratio of 0.05:1–1: 1). The precursor comprised a VOX_3 at a ratio V: Ti $= 1$:6–4: 1	Brown, Ungar, and Zboril, from Novacor Chem. (International) This is the next modification of Z-N catalyst for solution copolymerization of C_2 with C_{3-12}. See U.S. Patents 4431784, 4769428, 5492876	LLDPE was polymerized in solution with a coordination catalyst at $T = 180$–$320\,°C$ and $P = 4$–20 MPa. The new modification relates to a method for activating Z-N coordination catalysts using an alkoxy aluminum alkyl compound prepared by mixing an alcohol and alkyl aluminum. The activator retains its activity and is easy to prepare simplifying the polymerization process. Small amount of H_2 may be used for MW control (see Elston CA Patent 703704 of 1965 to DuPont of Canada Ltd.)	S.J. Brown, R.K. Ungar, V.G. Zboril, Activation of catalyst in ethylene polymerization at high temperatures, CA 2119737 of 03 June 2003 (filed 25 July 1992), to Du Pont Canada Inc. (Canada); U.S. Patent 5519098 of 21 May 1996 (filed 12 Oct 1994, priority 1991) to Novacor Chemicals (International)
1991	A coordination catalyst was prepared at $T < 30\,°C$: (i) a mixture of MgR^1_2 and AlR^2_3 [R^1 and $R^2 = C_1$–C_{10} alkyl radicals], (ii) a reactive halide, and (iii) $TiCl_4$; molar ratios: halide, Mg $= 2.2$–10 2.4; Mg:Ti $= 5$; and Al:Ti $= 0.9$. The catalyst activator was prepared by mixing	Zboril and Brown, from Novacor Chemicals (International) S.A. This is the next level modification of Z-N catalyst for solution copolymerization of C_2 with C_{3-12}. See U.S. Patents 4431784, 4769428, 5492876, and 5519098. The technology described in these patents was	A solution copolymerization of C_2 with C_{3-12} into high-MW LLDPE was carried out using a coordination catalyst at $T = 105$–$320\,°C$ and $P = 4$–20 MPa in a tubular reactor or in a system of reactors each operating under different conditions, in an inert solvent at $T > 105\,°C$. The catalyst was activated with a solution of aluminum alkyl and alkoxy aluminum	V.G. Zboril, S.J. Brown, Control of a solution process for polymerization of ethylene, U.S. Patent 5589555 of 31 Dec 1996 (priority 1991) to Novacor Chemicals (International); CA 2119738 of 18 July 206 (PCT filed 25 Sept 1992) to Du Pont Canada Inc.;J.C.-K. Huang,

	a δ-TiCl$_3$ supported on activated MgCl$_2$ in the presence of AlEt$_3$. The new catalyst showed 50-fold higher catalytic activity		surface $\rightarrow$ TiCl$_3$/surface + Me; Me + Me$_3$Al $\rightarrow$ C$_2$H$_5$ + AlH(Me)$_2$	G.A. Somor, Catal. Lett. **35**, 205–214 (1995)
1995	Multizone circulating reactor (MZCR) disclosed by Montel Technology is a modified FBR polymerizing olefins in 2-tubular polymerization zones, to which one or more α-olefins are fed in the presence of catalyst, e.g., TiCl$_4$+ MgCl$_2$ 3EtOH, described in U.S. Patent 4399054 of 1983 to Montedison SpA	Govoni, Rinaldi, Covezzi, and Galli, modified the UNIPOL FBR forming a vertical closed-loop reactor. The PE particles circulated through a fast fluidization riser then densified, under gravity flowing through a downer again to enter the raiser, etc.	The catalyst was the reaction product of a Ti compound and MgCl$_2$ in the form of spherical particles with a diameter of 1–100 μm. The high-productivity gas-phase polymerization in MZCR gave multilayered particles with designed chemical composition and MWD	G. Govoni, R. Rinaldi, M. Covezzi, P. Galli, U.S. Patent 5698642 of 16 Dec 1997 (filed 19 July 1996), to Montel Technology Co. ; M. Covezzi, G. Mei, Chem. Eng. Sci. **56**, 4059–4067 (2001); F. Lona, J App. Polym. Sci. **93**, 1053–1059 (2004). M. Ferraris, F. Rosati, S. Parodi, E. Giannetti, G. Motroni, E. Albizzati, U.S. Patent 4399054 of 16 Aug 1983 to Montedison SpA
1995	The polymerization catalysts were Ni and Pd diimines. Variations of P, T, and ligands changed the PE structure from branched and amorphous to a linear and semicrystalline, HDPE. Copolymerization of ethylene with functionalized comonomers was found feasible	Brookhart from UNC and his colleagues from DuPont. The catalyst has (1) highly electrophilic, cationic Pd and Ni metal centers; (2) sterically bulky R-diimine ligands; and (3) non-coordinating counterions	Brookhart et al. reported on Pd(II) and Ni (II) R-diimine catalysts (DuPont's Versipol™ catalyst) for copolymerization of C$_2$, R-olefins, cycloolefin, and functionalized olefins. This post-metallocene catalyst does not need co-catalyst/activator, such as MAO	L.K. Johnson, C.K. Kilian, M. Brookhart, J. Am. Chem. Soc. **117**, 6414 (1995); S.D. Ittel, L.K. Johnson, M. Brookhart, Chem. Rev. **100**, 1169–1203 (2000); WO Pat. Appl. 9623010, 03 Apr 1995; U.S. Pats. 5866663, 02 Feb 1999; 5880241, 03 May 1999; 5880323, 09 Mar 1999; 5886224, 23 Mar 1999; 5891963, 06 Apr 1999 all to DuPont
1995	The dithiophosphinate catalyst precursor capable of complexing with M = Cr, Ti, Ni, Zr, Hf, V, W, and Mo was initially used for oligomerization of α-olefins	Somogyvari, Creed, Nicola, Sanger, Law, Cavell, from the University of Alberta. The invention started a long-term search for a proprietary catalyst (based on phosphinimine), capable of olefin polymerization	The invention relates to oligomerization of α-olefins in the presence of a catalyst precursor having a dithiophosphinate and heterobifunctional ligands with a phosphine and imine or a similar center, in the presence of an $AlR_{3-n}X_n$ activator	F. Somogyvari Arpad, C.B. Lorraine, N.A. Pietro, S.A. Rodney, L.D. John, C.R. George, CA 2357805 of 04 Feb 2003 (filed 21 May 1996, priority 1995); U.S. Patent 5,557,023 of 17 Sept 1996 (filed 1995) to University of Alberta
1996	In 1959 Elston patented solution polymerization of LLDPE at $T = 160-220\,°C$ and $P = 3-34$ MPa. At lower T polymer could precipitate, thus changing into a suspension polymerization	Zboril, Kiel, Karnik, Burke, Foy, Iatrou, (Nova Chem.) patented a method of premixing cold reactants with a portion of hot reacting solution before injecting it to the main reactor without causing undue precipitation of the warmer reactor contents and changing the reaction mechanism	The chemical reactor has an intensive micro-mixing zone and a less intensively mixed principal reactor, with a re-circulation loop to exchange reactants between the two. The reactor is suitable for bulk, mass, and solution reactions with a cold feed stream, i.e., mixing a liquid at $T = 20-200\,°C$ with viscous solution at $110-300\,°C$	Z.V. George, K.D. Edward, K. Umesh, CA 2193431 of 19 June 1998 (filed 1996), to Nova Chem. Ltd. (Canada); A.L. Burke, E.C. Foy, J. Iatrou, U. Karnik, D. Edward Kiel, V. George Zboril, U.S. Patent 6024483 of 15 Feb 2000 (priority 27 Mar 1997); U.S. Patent 6319996 of 20 Nov 2001 (filed 12 Nov 1999) to Nova Chemical (International) S.A.
1996	Post-metallocene FI catalyst for PE copolymerization: (1) it may produce functionalized olefinic copolymers; (2) it is	Kawai, Kitahara, Fujita, Japanese Patent 1996, 325283, and Japanese Patent 1996, 325315;	Salicylaldimine complexes (phenoxyimine) of Group 4 metals show substantially higher activity than the metallocenes	M. Mitani, J. Saito, S. Ishii, Y. Nakayama, H. Makio, N. Matsukawa, S. Matsui, J. Mohri, R. Furuyama, H. Terao,

	characterized by high catalyst activity; and (3) It is capable of controlling polymer microstructure (tacticity)	U.S. Patent 7,053,159; 7,393,907, of 2006 (priority 2000), to Mitsui		H. Bando, H. Tanaka, T. Fujita, Chem. Rec. **4**, 137 (2004); Makio et al. (2011)
1997	The single-site post-metallocene catalyst for solution polymerization (e.g., in toluene) of olefins or conjugated dienes is based on bis-phenoxyimine ligand of a transition metal from Groups 3–11, e.g., Ti, Zr, Hf, V, Nb, and Ta. The co-catalyst is an organometallic compound, e.g., a methylaluminoxane (MAO), added to initiate polymerization. The reaction was conducted at 25 °C, for 30 min in an ethylene gas atmosphere at normal pressure, and then terminated with a small amount of butanol; polymer was precipitated with MeOH, acidified with HCl, filtered, and dried at 80 °C. In the FI catalyst with MAO and a variety of R-groups, the activity ranged from 0.4 to 6,552 kg-PE/(mmol Zr h)	Fujita, Tohi, Mitani, Matsui, Saito, Nitabaru, Sugi, Makio, and Tsutsui, from Mitsui Chemicals, Inc. Post-metallocene catalysts are more varied than metallocene. These are using a wide variety of M from Ti to Cu. Also ligands have diverse structures. Thus, close to M radicals R^1 and R^2 control the reaction. They are structurally and electronically flexible showing dependent on M electron-receptive or electron-donating properties. Ivanchev et al. discussed another group of binuclear phenoxyimine Ti catalysts	The invention describes new type of catalyst with excellent polymerization activities (PAC). Depending on M, ligand, co-catalyst, and polymerization conditions, the PAC ranges from 0.003 to 7,200 kg polymer/(mmol M h), thus within 7 orders of magnitude. The new catalyst has a formula: $M = Zr$; $m = 1–3$; R^1 to R^5 = hydrocarbon; R^6 and X = halogen	T. Fujita, Y. Tohi, M. Mitani, S. Matsui, J. Saito, M. Nitabaru, K. Sugi, H. Makio, T. Tsutsui, Olefin polymerization catalysts, transition metal compounds, processes for olefin polymerization, and α-olefin/conjugated diene copolymers, U.S. Patent 6,309,997 B1, 30 Oct 2001, to Mitsui Chem.; Makio et al. (2011); S.S. Ivanchev, A.V. Yakimansky, N.I. Ivancheva, I.I. Oleinik, G.A. Tolstikov, Ethylene polymerization using catalysts based on binuclear phenoxyimine titanium halide complexes, Europ. Polym. J. **48**,191–199 (2012)

1997	D. W. Stephan, J. C. Stewart, D. G. Harrison, S. J. Brown, J. W. Swabey, Q. Wang, from Nova Chem. (International)	Catalyst useful in slurry- or gas-phase olefin polymerizations comprises an organometallic complex (a Group 4 metal with a cyclopentadienyl and phosphinimine ligands) on a solid particulate support. The complex + an activator (e.g., aluminoxane) create excellent catalyst. One hr polymerization at $T = 90\,°C$ and $P = 1.38$ MPa gave PAC = 57 kg/(mmol Ti h)	By contrast, with the Fujita et al. patent, this one is for a solution polymerization of C_2 copolymers at $T > 80\,°C$, with the catalyst system comprising unbridged Group 4 metals with 3 ligands: a monocyclopentadienyl, a phosphinimine ≥ 1 uni-negative, activation reactive ligand. Polymerization at $T = 160\,°C$ gave PAC = 1 kg/(mmol Ti h)	D.W. Stephan, J. C. Stewart, D. G. Harrison, U.S. Patent 5965677 of 12 Oct 1999 (filed 29 Oct 1997); CA Patent 2210131 of 02 Aug 2005; D. W. Stephan, J. C. Stewart, S. J. Brown, J. W. Swabey, Q. Wang, U.S. Patent 6063879 of 16 May 2000 (priority 1997); CA Patent 2206944 of 29 Aug 2006 (filed 30 May 1997), to Nova Chem
1998	Brown, Gao, Jeremic, Koch, McKay, von Haken Spence, Wang, Zoricak, Xu, to Nova Chemicals, Ltd.	The new catalyst comprises (A) an organometallic complex and (B) an activator. The complex $A = M(PI, H, L_n)$, where $M = Ti, Zr, Hf$; $PI =$ phosphinimine; $H =$ hetero-; $L =$ activable ligands, with (depending on the valency) $n = 1$–3. The activator is methylaluminoxane, MAO. In patent (1) none of the three ligands are Cp. In patent (2) two valencies of P are hetero-substituted and Cp replaces hetero-ligand H	In patent (1) solution polymerization was conducted in CHX at $T = 160\,°C$ and $P = 1$ MPa, either in a solution batch reactor (SBR) or in a continuous reactor. Concentration of catalyst and activator was 200 and 210 μmol L^{-1}, respectively. The activity was ≤ 12 kg PE per 1 g of M. According to patent (2) the reaction was conducted at $T = 160\,°C$ and $P = 10$ MPa. The activity was ≤ 303 kg PE per 1 g of M	(1) St.J. Brown, Xiaoliang Gao, Q. Wang, P. Zoricak, R.E. von Haken Spence, Wei Xu CA 2243775 of 12 June 2007 (filed 21 July 1998); U.S. Patent 6147172 of 14 Nov 2000, priority 21 July 1998; (2) R.E. von Haken Spence, L. Koch, D. Jeremic, S.J. Brown, CA 2254841 of 06 Feb 2007 (filed 26 Nov 1998); U.S. Patent 6234950 of 22 May 2001, priority 15 Nov 1998, all to Nova Chemicals, Ltd., or Nova Chemicals (Intl.) S.A.

Table 18.10 (continued)

Date	Event	Inventor/company	Comment	Reference
1998	PE having $M_w/M_n > 8$ was obtained in a multistage copolymerization of C_2, with C_{3-10} α-olefins, catalytically in one or more reactors. The catalyst comprises (a) solid product of $MgCl_2 + ZrCl_4$, (b) $AlMe_2Cl$, and (c) $AlEt_3$, molar ratio $(b)/(c) < 10$. Then, optionally, activating the pre-catalyst and polymerizing the monomer(s)	T. Dall'Occo, G. Baruzzi, C. J. Schaverien from Basell Technology Co. The catalyst comprises Ti, Zr, or V; $MgCl_2$; an alkyl Al compound; and optionally an electron donor compound, e.g., alkyl, cycloalkyl, or aryl esters of polycarboxylic acids (phthalic or succinic)	Multistage polymerization for the preparation of broad MWD PE uses the same catalyst, but in several reactors with different concentration of H_2. Such a procedure leads to a large amount of "bad" oligomers. Basell's new Zr catalysts, without H_2, produce low-MWPE of narrow MWD, without these undesirable oligomers	T. Dall'Occo, G. Baruzzi, C.J. Schaverien, U.S. Patent 6,479,609 of 12 Nov 2002 (priority 09 Mar 1998); T. Dall'occo, G. Baruzzi, D. Brita, M. Sacchetti, Catalyst for the polymerization of olefins, CA 2382009 of 22 Mar 2001 (filed 29 Aug 2000; priority 1999) to Basell Technology Company BV
1998	A catalyst for slurry- or gas-phase olefin polymerizations comprises an organometallic complex of a Group 4 metal (unbridged and having a Cp, a phosphinimine, and an activable ligands) and co-deposited ionic activator [e.g., triphenylcarbenium tetrakis (pentafluorophenyl) boron] on a metal oxide support pretreated	Brown, Ciupa, Chisholm, Ciupa, Jeremic, McKay, to Nova Chemicals (International) S.A. The productivity of the new catalyst was about 6 kg PE/(1 g catalyst h), leaving <1 ppm of Ti in PE, thus PAC > 48 kg PE/(mmol Ti hr)	In these patents the catalyst support was SiO_2 and hydrotalcite: $(Mg_{1-x} Al_x(OH)_2)_n + An\text{-}x/n\ m\ H_2O$ [$x = 0\text{--}0.5$; $m > 0$, A = anion with $n = 2$ or 3]. For eliminating the surface –OH, the particles (size <5 μm) were treated with alumoxanes and trialkyl aluminum [Al $(C_{2, 4, 6})_3$]. The activator was MAO. The product had $\rho = 0.910\text{--}0.935$ g mL^{-1} and ≥30 wt% C_{4-8} comonomer. Polymerization in a stirred, gas-phase	(1) M. Ian, J. Dusan, B.S. John, Process for preparing supported olefin polymerization catalyst, CA 2228923 of 06 Aug 1999 (filed 06 Feb 1998), to NOVA Chem. Ltd.; U.S. Patent Appl. 2002/0010078 A1, (filed: 04 Apr 2001, priority 06 Feb 1998); (2) M. Ian, C. Alison, C.P. Scott, Heterogeneous metallocene catalyst, CA
				References
	with, e.g., an aluminum alkyl. The catalyst, R_3-P = N-M(Cp)-L_2, had M = Ti, Zr, or Hf and fivefold substituted Cp, phosphinimine, and two univalent ligands, e.g., Cl. The phosphinimine ligand was tri-(tertiary butyl) phosphine-imine	reactor used a NaCl seedbed, at $T = 100\ °C$ and $P = 1.4$ MPa, and showed the catalyst activity PAC $\leq$ 220 to 360 kg PE/(mmol Ti h)		2237231 of 08 Aug 2006 (filed 08 Aug 1998); U.S. Patent 6235671 of 22 May 2001 (filed 14 Apr 1999, priority 08 May 1998), all to Nova Chemicals, Ltd., or Nova Chemicals (International) S.A.
1998	The disclosures in U.S. Patents 5519098 and 5589555 describe modification of the Novacor Z-N catalysts. Patent (1) describes new, based on Ti, V and a low amount of Al and Mg catalyst used for copolymerization of olefins. The molar ratio Mg/Al = 4.0:1–8.0:1 and Mg/(Ti + V) = 4.0:1–8.0:1. Its novel preparation method increased the polymer MW at high-T polymerization. Patent (2) provides Z-N catalyst having molar ratios Mg/Al = 4.0:1–5.5:1 and Mg/Ti = 4.0:1–5.5:1	Jaber and Brown, from Nova Chemicals (International) S.A. A solution copolymerization of $C_2 \geq 40$ wt% with C_{3-12} into high-MW LLDPE was described. Using the new coordination catalyst, the reaction was carried out at $T = 105$–$320\ °C$ and $P = 4$–20 MPa	The new catalyst comprises (i) a mixture of an alkyl aluminum $Al^1(R^1)_3$, and Mg $(R^2)_2$, where $R^1 = C_{1-4}$ and $R^2 = C_{1-4}$ alkyl radicals in a molar ratio Mg/Al^1 = 6:1–8:1; (ii) a halide R^3Cl where $R^3 = C_{1-4}$ alkyl radicals; (iii) $TiCl_4$; (iv) $VOCl_3$ (Ti/V = 90:10–75:25; and (v) $(R^4)_2Al^2OR_5$ where R^4 and $R^5 = C_{1-4}$ with molar ratios Mg/(Ti + V) = 6.0:1–8.0:1; Al^1/(Ti + V) = 1:1–1.5:1; halide/Mg = 1.9:1–2.3:1; and Al^2/(Ti + V) = 3.0:1–4:1	(1) I. Jaber, S.J. Brown, Mixed titanium–vanadium catalysts for solution ethylene polymerization, U.S. Patent 6084042 of 04 July 2000 (filed 29 June 1998); CA 2271680 of 24 Nov 2009; (2) I. Jaber, Low aluminum and magnesium Z-N solution catalysts, U.S. Patent 6130300 of 10 Oct 2000 (filed 27 Jan 1999, priority 12 Mar 1998); CA 2232099, of 08 Aug 2006, to Nova Chemicals (International) S.A.

Table 18.10 (continued)

Date	Event	Inventor/company	Comment	Reference
1998	A dual-reactor process for a solution copolymerization of C_2 uses two different catalysts in the two reactors: (A) catalyst with a phosphinimine ligand in the first and (B) Z-N catalyst in the second. Alternatively, in the two reactors the polymerization may be carried out at different T and P. The reaction is relatively easy to control, producing LLDPE with desired MWD for the molded goods or films. Resulting LLDPE has excellent processability, balance of dart impact and tear strength, and excellent optical properties	Brown, Chisholm, JaberJeremic, McKay, Wang, to Nova Chemical (International) S.A. or NOVA Chem. LTD. (Canada) The produced LLDPE had M_w = 66–234 kg mol^{-1} and MWD = 2–21. As disclosed in patent (3) the polymerization in a dual reactor may also be carried out in a slurry process, when the polymer is no longer soluble in the solvent	Copolymerization of C_2 with C_{3-12} α-olefins, in cyclohexane, starts in a reactor (A) at T = 80–200 °C and P = 3.4–55.2 MPa with a catalyst (M = Ti, having a phosphinimine ligand) and its co-catalyst. The copolymerization continues in a second stirred reactor (B) at a higher T in the presence of a Z-N catalyst comprising a transition metal (e.g., Ti + V) and a co-catalyst: Al $(X')_a(OR)_b(R)_c$ where X' = halide; OR = alkoxy or aryloxy group; R is a hydrocarbyl; and a, b, and c are each 0, 1, 2, and 3 with the proviso that $a + b + c$ = 3 and $b + c \geq 1$	(1) I. Jaber, S.J. Brown, CA 2247703 of 17 Apr 2007 (filed 22 Sept 1998), U.S. Patent 6277931 of 2001 Aug 21 (filed 1999 Aug 30); (2) S.J. Brown, CA 2245375 of 15 Aug 2006 (filed 19 Aug 1998); U.S. Patent 6372864 of 16 Apr 2002 (filed 2000 Oct 31); (3) M. Ian, J. Dusan, W. Qinyan, P. Scott Chisholm, CA 2254512 of 12 Jan 2008 (filed 25 Nov 1998); U.S. Patent 6235853 B1 of 22 May 2001 (filed 15 Nov 1999), all to Nova Chemical (International) S.A. or Nova Chemicals Ltd. (Canada)
1999	MAO such as RAl-O (R-AlO)$_m$AlR$_2$ [R = C$_{1-20}$ hydrocarbyl] may contain residual Al(alkyl)$_3$ poisoning the catalysts. Its treatment with carbohydrates such as monosaccharides or polysaccharides (e.g., cellulose, starch, or sugar) significantly improves the catalyst activity	Hoang, Jeremic, Kearns, McLaren Coulter, Donaldson, to NOVA Chemicals (International) S.A. (CH)	In the U.S. Patent 4431788 of 14 Feb 1984, Kaminsky mentioned olefin polymerization with a transition metal catalyst and starch + Al(alkyl)3. The NOVA patents report that addition of cellulose enhanced productivity by 20 % increasing to 32 % if the cellulose + Al (alkyl)3 was filtered out	P.P. Minh Hoang, D. Jeremic, J.R. Kearns, I.M. Coulter, R.D. Donaldson, "Sweet" MAO, U.S. Patent 6750170 B2 of 15 June 2004 (filed 04 Dec 2001); U.S. Patent 6340771 B1 of 22 Jan 2002 (filed 22 Dec 1999), to NOVA Chemicals (International) S.A. (CH)

| 1999 | A supported catalyst for the polymerization of olefins has ≥ 2 catalysts with different propagation and/or termination constants. Each has ≥ 1 phosphinimine ligand described by Stephan et al. in 1997 [CA Patents 2210131 and 2206944; U.S. Patents 5965677 and 6063879]. The polymer shows a broad MWD. Catalysts according to this invention have a surprising, desirable H_2 response | McKay Ian; Ciupa Alison; Hall Barbara Christine, to NOVA Chemicals Solution polymerization in pentane (C_5) or hexane (C_6). The mixed catalyst had high activity. The mixed catalysts, phosphinimine + Z-N, provided LLDPE with a broad MWD | At RT SiO_2 and $Al(Et)_3$ were introduced to reactor filled with solvent (C_5), C_5 was removed at 70 °C, and a suspension of Bu_2Mg and $Al(Et)3$ in hexane was injected. After stirring for 2 h the solvent was flushed off, t-BuCl + $TiCl_4$ in C_5 added. Reaction at $T = 90$ °C and $P = 1.4$ MPa gave LLDPE with MWD ≈ 2.5, nearly unaffected by H_2. PAC ≤ 342 kg PE/(mmol Ti h) | M. Ian; C. Alison; H.B. Christine, Mixed Phosphinimine Catalyst, CA 2278042 of 16 Dec 2008 (filed 19 July 1999); U.S. Patent 6235672 B1 of 22 May 2001 (filed 14 July 2000, priority 19 July 1999) to NOVA Chemicals Corp. (Canada) or Nova Chemical (International) S.A. |
| 1999 | The C_{2-12} α-olefins might be copolymerized into LLDPE having suitable MW and SCB in the presence of a tridentate complex of a Groups 8–10 "late" metal. The new catalyst evolved from the cited above U.S. Patents 5557023 and 5589555. Its formula is shown in the right column | Xu, Wang, Wurz, to NOVA Chemicals here M = Fe Co, Ni or, Pd; R = H or hydrocarbyl; W = O, N, S, or B; Y and Z = P; L = Cl, alkyl, or alkoxy | Slurry or solution polymerization was carried out in toluene in the presence of MAO at $P = 2$ MPa for $t = 10$–30 min and $T = 50$ and 140–160 ° C. Polymerization was terminated by adding MeOH. Polymer properties from the slurry and solution processes were comparable (excerpting the rate). The average values were $M_w = 470$–976 kg mol^{-1}, $T_m = 134 \pm 1$ °C, MWD = 1.7–2.6, PAC = 0.3–0.9 kg PE/(mmol cat*h). The results were affected by the catalyst, comonomer type, and content (s) | Wei Xu, Qinyan Wang, Ryan Paul Wurz, Group 8, 9 or 10 transition metal catalyst for olefin polymerization, U.S. Patent 6239237 B1 of 29 May 2001 (filed 22 Apr 1999); CA 2303767 of 02 Mar 2010 (filed 06 Apr 2000, to Nova Chemicals (International) S.A. or Nova Chemicals Corp. (Canada) |

1999	New organometallic complexes with Group 4 transition metals (Ti, Zr, Hf) have a phosphinimine and two or more cyclopentadienyl ligands. Some of these exhibit unusual NMR behavior. Well-defined crystals of the inventive complexes have been isolated and analyzed by X-ray crystallography. They behave as active polymerization catalysts, producing 62 kg of polymer per 1 mmol of Ti, which is more than obtained with their metallocene analogs	Spence, Brown, Wurz, Jeremic, Stephan, to NOVA Chemicals Cp_n / $M-N=P$ with R_1, R_2, R_3 / Lp	The organometallic complex of interest is shown left with $M = Ti$; each Cp is an indenyl; each of R_1, R_2, and R_3 is an alkyl (e.g., $t\text{-}C_4$) bonded to P; $n = 2$ or 3; $n + p = 3$; and when $p = 1$, L is monoanionic ligand. The gas-phase copolymerization of C_{2-10} in the presence of the catalyst with a supported activator at $P = 0.1\text{–}2.0$ MPa and $T = 60\text{–}130\,^{\circ}\text{C}$. The process may be conducted in the presence of a hydrocarbon diluent or solvent	R.E. von Haken Spence, S.J. Brown, R.P. Wurz, D. Jeremic, D.W. Stephan, Hydrocarbyl phosphinimine/cyclopentadienyl complexes of group IV metals and preparation thereof, CA 2282070 of 09 Dec 2008 (filed 10 Sept 1999); U.S. Patent 6440890 of 27 Aug 2002 (filed 06 Sept 2000, priority 10 Sept 1999) to NOVA Chemicals Corporation (Canada) or NOVA Chemicals (International) S.A.
2001	A catalyst system for olefin polymerization comprises SiO_2 treated with H_2SO_4 Deposited on sulfated SiO_2 aluminoxane (MAO) and Deposited an organometallic complex. The latter has the structure shown right. Ligands	Gao, Chisholm, Kowalchuk, Donaldson (Nova Chemicals Corp.) L_1 / M — $(L_3)_n$ / L_2 $M = Ti$, Zr, or Hf	Gas-phase polymerization was conducted at $T = 80\text{–}90\,^{\circ}\text{C}$ and $P = 1.4$ MPa. A seedbed of dry NaCl was used. A tri-isobutyl aluminum (TIBAL) was used as a poison scavenger. Some copolymerizations were studied by injecting hexene into the reactor. After addition of the scavenger, C_2 was used to push the catalyst system into the reactor. The supported catalyst activity was PAC ≤ 276 kg PE/(mmol Ti h)	Xiaoliang Gao, P.S. Chisholm, M.G. Kowalchuk, R.D. Donaldson, Catalyst for olefin polymerization, U.S. Patent 6734266 of 11 May 2004 (filed 13 Feb 2002, 23 Feb 2001); CA 2338094 of 15 Sept 2009 (filed 23 Feb 2001), to NOVA Chemicals (International) S.A. or NOVA Chemicals Corporation (Canada)

Year				
	L_{1-3} are, respectively cyclopentadienyl, heteroatom (e.g., phosphinimine) and activable (e.g., halide or methyl). The catalyst is used in slurry or a gas-phase process			
2001	The phosphinimine catalyst comprises (1) $(Cp)_a M(PI)_b (L)_c$ [PI = phosphinimine; Cp = indenyl, cyclopentadienyl, fluorenyl (substituted or not); L = H or halogen, a C_{1-10} hydrocarbyl, alkoxy, or aryl oxide; M = Ti, Zr, or Hf; and $a = b = 1$; $c = 1$ or 2 and $a + b + c =$ the valence of M]; (2) an activator, e.g., a salt of tetrakis (pentafluorophenyl) borate; and (3) at least one $Al(Me)_3$ with a methylaluminoxane, MAO	Brown, Swabey, Dobbin, (NOVA Chemicals Corp.)	Continuous solution polymerization of C_{2-20} with a phosphinimine catalyst and a boron activator [at $T = 170{-}250$ °C, $P = 10{-}40$ MPa in the presence of $Al(C_{1, 2, or 4})_3$] leads to PE having a relatively broad MWD, $\rho = 0.910{-}0.935$ g mL^{-1} and good processability. The PE is suitable for the preparation of blown or cast films, blow-molded parts, extruded goods, and injection-molded products	S.J. Brown, J.W. Swabey, C.J.B. Dobbin, Solution polymerization process catalyzed by a phosphinimine catalyst, CA 2347410 of 08 Sept 2009 (filed 11 May 2001); U.S. Patent 6,777,509 B2 of 17 Aug 2004 (filed 17 Apr 2002, priority 11 May 2001), to NOVA Chemicals Corporation (Canada) or Nova Chemicals (International) S.A (CH)
2001	The invention provides a Z-N catalyst for solution polymerization of olefins in the presence of low Al and Mg content	Jaber I. (Nova Chemicals Corp.) used Ph_3SiOH, $Al(Et)3$ or $Al (O-Et)3$, at a molar ratios: Si: Ti = 0.25:1–4:1; Al:Ti = 1	The catalysts are effective for the solution polymerization of olefins at $T = 180{-}250$ °C. $TiCl_4$ and $Mg(Et, But)$ at a ratio Mg:Ti = 5	J. Isam, CA 2365718 abandoned 18 Dec 2009 (filed 18 Dec 2001; U.S. Patent 6878658 of 12 Apr 2005 (filed 09 Dec 2002, Nova Chemicals Corporation (Canada)
2004	Multizone tubular reactor for C_2 polymerization at $P = 12{-}20$ MPa. The reactor length was $L = 1.87$ km and inner	The LDPE reactor had three zones: preheating, primary and secondary reactions, and injection ports: 2 or 3 for C_2 and 3 or 4 for	The low- (140–160), mid- (160–190), and high-$T = 190{-}250$ °C initiators were, respectively, t-butyl peroxy pivalate	Jin-Suk Lee, Byoung-Yong Chung, Myung-Jae Lee, Kun Lo: Method of ethylene polymerization, U.S. Patent Appl.

	diameter ID = 40–60 mm. The resulting LDPE had $\rho \approx 0.925$ g mL^{-1}, MI = 1–2 g/10 min, and polydispersity index 10–17	catalyst. As T increased different peroxides were injected	(TBPV), TBP-octanoate (TBPO), and di-TBP (DTBP)	20060149004, Publ. 2006-07-06, Priority 19 Nov 2004, to Samsung Total Petrochem
2004	Priority date of Borealis patent for the Advanced Cascade Process (Hostalen ACP) using the Z-N Avant Z-501 or Avant Z-509 catalysts	M. Baeckman, W. Gustafsson, E. Van Praet, R. Van Marion, U.S. Patent Appl. 2009/0252910 to Borealis	Three reactors in series with Z-N catalyst on MgCl$_2$ support #1 a polymerizing low-MW HDPE, #2 a midrange C$_2$ + C$_4$ copolymer, and #3 the high-MW copolymer	J. Schut, Plastics Eng. Blog, posted 30 June 2010; Baeckman et al., Multimodal PE composition, U.S. Patent Appl. 2009/0252910 of 08 Oct 2009, to Borealis Technology Oy
2005	The new co-catalyst comprises (A1) MAO; (A2) an Al-alkyl, Al (R)$_a$(OR$_1$)$_b$X$_c$ [R and R$_1$ = C$_{1-10}$ hydrocarbyl; X is a halide; and $a + b + c = 3$ and A2 < AlJ; and (A3) a halogenated phenol (hPl). The alkyl in A2 is C$_{1, 2 \text{ or } 4}$. The ratio of A2/Al = 0.1/1–0.5/1. 6. The catalyst system, (A) a CpTi [NP(t-Bu)$_3$]Cl$_2$ and (B) the co-catalyst, is suitable for olefin polymerization	Jaber, Swabey, Gao, Carter, Baar, to NOVA Chem. The modified MAO where R = Me ≡ C$_1$ and R$_1$ is C$_{2-8}$: $$\left[\underset{\mid}{\overset{R}{}} -(Al-O)- \right]_x \left[\underset{\mid}{\overset{R^1}{}} -(Al-O)- \right]_Y$$	The halogenated phenol, e.g., pentafluorophenol, C$_6$F$_5$OH, permits the substitution of a portion of the expensive MAO with inexpensive Al(alkyl)$_3$. This co-catalyst is most frequently used with an organometallics having ≥1 PI ligand. The copolymerization of C$_2$ with C$_{3-10}$ may be carried out at $T = 30$–$280\,^\circ$C and $P = 14$–22 MPa in a dual-reactor system	I. Jaber, J.W. Swabey, X. Gao, C.A. Garret Carter, C.R. Baar, Modified (MAO + aluminum alkyl), CA 2503461, filed 01 Apr 2005; U.S. Patent Appl. 2006/0223960 A1, Published 05 Oct 2006 (filed 28 Feb 2006 (priority 01 Apr 2005), to NOVA Chemicals Corporation(Canada) or NOVA Chemicals (International) S.A.
2006	For a gas- or slurry-phase reaction, the catalyst should be adsorbed on porous particles	McKay, Jeremic, Jacobsen, Mastroianni to NOVA Chemicals	A supported catalyst for olefin polymerization comprises an ionic activator, an organometallic catalyst, and	I. McKay, D. Jeremic, G.B. Jacobsen, S. Mastroianni, Supported polymerization

(e.g., SiO$_2$) then added an activator system: (1) a cation capable of reacting with a metallocene and forming a transition metal complex active for the polymerization of α-olefins; (2) a compatible anion having up to 100 non-hydrogen atoms and containing at least one substituent comprising a moiety having an active hydrogen; and a CpM(PI)L$_n$ complex where M = Ti, Zr, or Hf; three ligands: Cp = substituted η-5; PI = phosphinimine; L = activable; n = 1 or 2	(International) S.A; Ineos Europe Ltd. MAO such as RAlO (R-AlO)$_m$AlR$_2$ [where R = C$_{1-20}$ hydrocarbyl] may contain residual Al(alkyl)3 poisoning the catalysts. Its treatment with carbohydrates such as monosaccharides or polysaccharides (e.g., cellulose, starch, or sugar) significantly improves the activity	a support material. The selected activator must contain an active hydrogen moiety. The organometallic catalyst is characterized by having a phosphinimine ligand and a substituted cyclopentadienyl ligand having 7–30 carbon atoms. The supported catalyst exhibits excellent activity in gas-phase olefin polymerizations and may be used under substantially "non-fouling" polymerization	catalysts, CA 2587230, filed 02 May 2007 (priority 30 May 2006), to NOVA ChemicalsCorp. (Canada); INEOS Europe Ltd.; U.S. Patent Appl. 2008/0045406 A1 of 21 Feb 2008; now U.S. Patent 7863213 of 04 Jan 2011 (filed 07 May 2007), to NOVA Chemicals (International) S.A; INEOS Europe Ltd
2008 Pro-catalyst for olefin polymerization was prepared: (a) reacting MgRaRb (Ra and Rb = C$_{1-8}$ hydrocarbyl) with a source of active chlorine (HCl, isopropyl chloride, and tertiary butyl chloride) at T = 30–80 °C; (b) adding a soluble Hf$_4$ compound (e.g., tri-benzyl-HfCl) for the molar ratio Hf/Mg = 1/10–1/100; (c) adding a TiCl$_n$(OR)$_m$ (n = 2–4 and n + m = 4, preferably TiCl$_4$); Mg/Ti = 5/1–10/1; (d) adding an electron donor and then a second increment of TiCl$_4$	Wang, Zoricak, and Ronne-Newman, from NOVA Chem. Corp In olefin polymerization the pro-catalyst must be combined with an organoaluminum co-catalyst, such as a methylaluminoxane (MAO). The polymerization takes place at T = 160–250 °C and P = 14–22 MPa	An Mg–Ti olefin polymerization pro-catalyst was prepared by reacting a di-organo-magnesium (DOM) with a source of active chlorine in the amount insufficient to completely convert the DOM to MgCl$_2$, removing unreacted DOM, adding Hf + 4 species to the washed MgCl$_2$ support, then depositing Ti$_4$ species on the supported Hf. The new pro-catalyst is highly active in the solution polymerization of olefins when combined with a co-catalyst	Q. Wang, P. Zoricak, J.R. Newman, Magnesium-Titanium-Hafnium for high temperature polymerization, CA 2629550; U.S. Patent Appl. 2009/0264282 A1 of 08 Aug 2009, priority 21 Apr 2008, to NOVA Chem. Corp

Table 18.10 (continued)

Date	Event	Inventor/company	Comment	Reference
2009	Two catalysts, based on Cr and Fe on $MgCl_2/AlEt_n(OEt)_{3-n}$, were used for C_2 polymerization	(DSM) Fe catalyst had $3\times$ lower activity than that based on Cr, but it produced $15\times$ higher MW	Mixtures of the two catalysts resulted in bimodal distribution of PE MW and good processability and performance	N. Kukalyekar, L. Balzano, G.W.M. Peters, S. Rastogi, J.C. Chadwick, Macromol. React. Eng., **3**, 448–454 (2009)
2009	Chevron Phillips developed a single-reactor bimodal HDPE technology using a dual metallocene catalyst with Elf Atochem solid super acid (SSA), which consists of a support for a solid catalyst component, formed from a porous mineral oxide, modified to carry on the surface, Al and/or Mg Lewis acid sites	The modified metallocene catalyst can also create broad MWD bimodal or multimodal HDPE in a single Phillips loop reactor. Catalyst activity ≤ 11.7 kg PE/mmol Zr	Patents on SSA activator/co-catalyst are Thierry Saudemont, Roger Spitz, Jean-Pierre Broyer, Jean Malinge, Nathalie Verdel, activator solid support for metallocene catalysts, U.S. Patent 6239059 of 29 Mar 2001 (filed 02 Oct 1998, priority 02 Oct 1997) to Elf Atochem, S.A.	Qing Yang, K.C. Jayaratne, M.D. Jensen, M.P. McDaniel, J.L. Martin, M.G. Thorn, J.T. Lanier, T.R. Crain, U.S. Patent 7619047 of 17 Nov 2009 (filed 22 Feb 2006); U.S. Pat. Appl. 20110201770 of 18 Aug 2011 to Chevron Phillips Chemical Company, LP
2012	Control of long-chain branching (LCB) of HDPE was obtained by using a modified Phillips chromium on silica catalyst. The analysis by SEC-MALS (SEC coupled to multiangle light scattering) shows that LCBs are concentrated in the molecular weight peaks	Schwerdtfeger, Ding, Masino, Martin, Yu, from Chevron Phillips	The modified catalyst can control production of LCB increasing its frequency to >40/106 C atoms. This improves processability and melt strength, reduces sag, prevents pipe ovality, improves shear thinning, and reduces extrudate swelling	Eric Schwerdtfeger, Plastics Engineering Blog, Posted on 07 Feb 2012; E. Ding, A.P. Masino, J.L. Martin, Y. Yu, U.S. Patent Appl. 20120077665 of 29 Mar 2012, to Chevron Phillips Chemical Company LP

Table 18.11 Evolution of polyolefin blends

Year	Development	References
1937	This first patent on the use of rubber for toughening polyolefins disclosed an addition of rubber "as a softening agent" to "saturated, linear hydrocarbons of the linear type." The MW of rubber was greater than that of paraffin, e. g., MW = 0.8–500 kg mol^{-1}	P.J. Gaylor, Standard Oil Development Co., French Patent 812,490, 11 May 1937
1942	High-pressure LDPE was blended with cyclorubber, to give compounds useful for bonding PE to metal	C.L. Child, R.B.F.F. Clarke, B.J. Habgood, British Patent 544,359, 09 Apr 1942
1951	Discovery of isotactic PP was immediately followed by search for low-T impact improvement, initially by blending with either LDPE or elastomers, later by copolymerizing with ethylene and dienes into EPR and EPDM	J.P. Hogan, R.L. Banks, U.S. Pat. Appl., 333,576, filed 27 Jan 1953, to Phillips Petroleum Co.
1955	The first LDPE/HDPE blends were patented by du Pont de Nemours. Incorporation of 20 wt% HDPE (ρ = 0.939–1.096 g mL^{-1}; $T_m \approx 120\,^{\circ}$C) into LDPE reduced its moisture permeability by 50 %	M.J. Roedel, U.S. Patent 2983704 of 09 May 1961, filed 13 Oct 1959, to du Pont de Nemours (priority 1955)
1958	5–120 parts of LDPE were blended with chlorosulfonated polyethylene, CSR, cured or not (with tribasic lead maleate). The blends found were used as smooth, non-tacky, tough films or coatings for natural or synthetic rubbers	V.C. Boger, A.G. Thomas, U.S. Patent 2854425, filed 30 Sept 1958, to B. F. Goodrich Co.
1958	PP was blended with 5–50 parts of chlorinated butyl rubber, CBR, in the presence of a non-peroxide curative (e.g., oxides or sulfides of Zn, Cd, Mn, Fe, or Pb) on a roll mill at 138–157 °C. The dynamic vulcanization resulted in materials useful for high tensile strength applications	A.M. Gessler, W.H. Haslett Jr., U.S. Patent 3037954, 05 June 1962, Appl. 15 Dec 1958, to Esso Research & Engineering Co.
1958	To improve the low-temperature flexibility of PP, it was blended with 5–20 wt% polyisobutylene (PIB). The Montecatini patent was the first one on the low-temperature modification of PP. The Esso patent used butyl rubber, BR, the Sun Oil document, 5–50 wt% PE (MW = 1.6 Mg mol^{-1} for high impact strength and low brittleness temperature). BASF patent described the use of narrow MWD PIB (0.5–40 wt%)	F. Ranalli, Italian Patent 583501, 14 Oct 1958, to Montecatini; Schramm, K., U.S. Patent 2939860, 07 June 1960; Esso Res. and Eng.; British Patent 893540, 11 Apr 1962; Sun Oil, British Patent 952089, 11 Mar 1964; H. Merkel, G. Cramer, German Patent 1145791, 21 Mar 1963, to BASF
1958	Phillips Petroleum blended LDPE with LLDPE for improved stiffness, abrasion resistance, and reduced H$_2$O vapor permeability. The most important was the gage reduction by 15–30 % for the plastic bags, sacks, and stretch films	P.J. Canterino, R.J. Martinovich, U.S. Patent 3086958, 23 Apr 1963, Appl. 1958; W.M. Nelson, Belgiam Patent 647,311, 29 Oct 1964, Appl. 1963, to Phillips Petrol.; W. R. Grace and Co., British Patent 904,985, 05 Sept 1962; Wissbrun et al. (1962, 1965); Golike (1962); R.M. Lillis, C. van Thomas,
	In the DuPont Canada patent deposited in 1961, 10–50 wt% HDPE (a copolymer of C$_2$ and C$_4$) was blended with LDPE or its copolymers for generating films of high clarity and stiffness were heat shrinkable. The improved film may be manufactured by blending of	

Table 18.11 (continued)

Year	Development	References
	polymers of density $\rho = 0.950$–0.965 and MI < 10, with ≤ 30 % of LDPE (MI $= 0.1$–10, $\rho = 0.910$–0.945 g mL^{-1}). Wissburn et al. in the 1965 Celanese patent particularly stressed improved processability	U.S. Patent 3998914 of 21 Dec 1976, to du Pont of Canada; J. Nancekivell, Canad. Plast. 27–30 (1982); 18–20 (1984); 27–32 (1985)
	In 1983 Union Carbide Corporation, UCC, started selling LLDPE/LDPE blends for check-stand sacks	
1958	Low-density polyethylene (LDPE) was blended with polyisobutylene, 25–40 wt% (PIB), and a copolymer of styrene and isobutylene, 0–10 wt% (PSIB), for the use as transparent, impermeable, shrink-wrap packaging films. In the Phillips patent, LLDPE was blended with PIB to manufacture grocery bags. In the BASF patent, a pre-blend comprising 60 wt% PIB and LDPE was granulated and subsequently compounded with LDPE	J.R. Briggs, R.G. Newburg, R.E. Clayton, U.S. Patent 2,854,435, 30 Sep 1958, to Esso Res. and Eng.; R.J. Martinovitch, R.P. March, U.S. Patent 3,074,616, 22 Jan 1963, Appl. 1959, to Phillips Petroleum; H. Dietrich, German Patent 1,288,293, 30 Jan 1969, Appl. 1961, to BASF A.-G.
1958	The first patent on polyamide/polyolefin, PA/PO, blends comprised 10–80 wt% of either PA-6 or PA-66 with either LDPE or PP. The resins, used to produce sheets, films, fibers, or bottles, reported showing excellent processability, good printability, and low permeability	R.B. Mesrobian, C.J. Ammondson, British Patent 889,354, 14 Feb 1962, Appl. 1958, to Continental Can Co., Inc.
1959	Partially cross-linked polyethylene (by either peroxides or irradiation), XLPE, was blended with polybutadiene, 5–40 wt% BR, to improve resistance to cut at elevated temperatures and elongation. The blends were found suitable for wire coating	Q.P. Cole, U.S. Patent 2,912,410, 10 Nov 1959, to General Electric Co.
1959	Polyethylene, PE, blended with immiscible polymers (e.g., PVC, PIB, PS) was compatibilized by addition of graft copolymer (e.g., styrene or vinyl acetate grafted on PE)	Houillières du Bassin-du-Nord et du Pas-de-Calais and Ethylene-Plastique, French Patent 1,193,104, 30 Oct 1959
1959	Polypropylene, PP, was blended with 5–20 wt% elastomers [styrene–butadiene, SBR, or butadiene–acrylonitrile, NBR] to produce materials useful for blow molding of bottles, free from brittleness and stress cracking. In a later patent, EPR, BP, and PIB, with a dicarboxylic acid anhydride, were used	Shell International Research Maatschappij N. V., British Patent 873,227; 933,727, 14 Aug 1963, Appl. 27 Aug 1959; Belgian Patent 611,727, 19 June 1962, Appl. 21 Dec 1960
1959	For improved processability and mechanical properties of polyethylene, HDPE or LLDPE, it was blended with elastomeric polyethylene–polypropylene copolymer, EPR. For further enhancement of properties, either polypropylene, PP, or polybutene, PB, could also be added. In ICI patent, HDPE was blended with 30–60 wt% EPR for improved processability and impact strength	L. Corbellini, German Patent 1,137,859, 11 Oct 1962, Appl. 1959, to Montecatini; J.W. Crawford, W.G. Oakes, British Patent 941,083, 06 Nov 1963; German Patent 1,217,608, 16 May 1966, to Imperial Chemical Industries Ltd.
1960	These are the first patents on polypropylene, PP, blended with ethylene–propylene rubbers, 10–60 wt% EPR, for improved low-temperature impact strength.	W.M. Schilling, U.S. Patent 3200173, 10 Aug 1966, Appl. 1960; British Patent 975,877,

(*continued*)

Table 18.11 (continued)

Year	Development	References
	In Esso patent, PP was blended with varying amount of polyisobutylene, PIB, and polyethylene, LDPE, to give marked improvement in tear strength and impact. In the Shell patent, reactor powder blending of PP with 0.1–10 wt% EPR (2–25 wt% ethylene) was disclosed. In Farbwerke Hoechst patent, PP was blended with 5–70 wt% LLDPE, for good mechanical properties at low temperature	18 Nov 1964, to Hercules Powder; British Patent 950,551, 26 Feb 1964; G.A. Short, U.S. Patent 3,354,239, 21 Nov 1967, to Shell Oil Co.; R. Holzer, K. Mehnert, German Patent 1,145,792, 21 Mar 1963, Appl. 23 Jan 1960, to Hoechst A.-G.
1960	PE, PP, and their homologues were blended with ethylene–vinyl acetate, EVAc, and cured with free radicals into products showing desired impact strength and modulus. The blends were used for manufacturing of fibers, films, or moldings	Monsanto Co., British Patent 967,334, 19 Aug 1964, Appl. 27 Apr 1960
1960	Blends of PE with 0.1–50 wt% of copolyamides (e.g., LDPE with 5 wt% PE–PA-6 copolymer) showed higher gloss, transparency, and elasticity; lower stress corrosion; and reduced permeability	H. Craubner, G. Illing, A. Hrugesch, German Patent 1,138,922, 31 Oct 1962, Appl. 1960, to Badische Anilin und Soda-Fabrik A.-G.
1960	Mechanical properties of polyolefins, PO, were improved by blending them with 0.5–50 wt% polycarbonate, PC. For example, LLDPE + 5 wt% PC showed improved impact strength, modulus, hardness, and HDT	H. Peters, F. Schuelde, German Patent 1,146,251, 28 Mar 1963, Appl. 22 Jan 1960, to Farbwerke Hoechst A.-G.
1960	To improve dyeability, flexibility, and toughness of isotactic polypropylene, PP, it was compounded in a Banbury-type mixer with ethylene–vinyl acetate, 7 wt% EVAc. Several other ethylene copolymers were also used. In Miliprint patent, EVAc or ethylene–ethyl acrylate copolymer, 18–32 wt% EVAc or EEA, was found to improve impact strength, elongation, and low brittleness temperature of PP. In Firestone patent, linear polybutadiene, BR, was used. The Mitsubishi patent disclosed improvements of PP impact strength properties by blending it with 0.5–25 wt% ethylene–aliphatic esters, e.g., EVAc	Holladay, H. P., Salyer, I. O., U.S. Patent 3433573, 18 Mar 1969, Appl. 1960, to Monsanto; Miller, A., Reddeman, N. G., Belgian Patent 620,703, 14 Nov 1962, to Miliprint; Reid, R. J., Conard, W. R., Belgian Patent 617,870, 21 Nov 1962, to Firestone; Sakata, R., Kuroda, T., Masuda, K., Nakayama, Y., Tanaka, M., Japanese Patent 003,964, 13 Feb 1968, to Mitsubishi Petrochem
1961	High-density polyethylene, HDPE, was blended with 15 wt% EPR. The blend had good impact resistance	A.-G. Farbwerke Hoechst, Belgian Patent 589,358; 612,855, 19 July 1962, Appl. 19 Jan 1961
1961	HDPE, LDPE, or LLDPE, blended with styrene–acrylonitrile copolymer, 2–6 wt% SAN, showed improved crack resistance. Furthermore, a synergistic behavior was observed when 0.1–1 wt% 2,4,6-tri-alkyl phenol was also added. In Esso patent, the mechanical properties of PE were improved by blending it with 5–25 wt% copolymers of mono- and diolefins, EPDM	A.L. Jankens, Belgian Patent 625,004, 20 May 1963, Appl. 24 Nov 1961, to Dow Chemical Co.; Prillieux, M., Delbende, P., Moulin, M., French Patent 1,289,580, 06 Apr 1962, Appl. 1961, to Esso Standard S. A.

<div align="right">(continued)</div>

Year	Development	References
1961	Blending two chlorinated LLDPEs, CPEs containing 40 or 70 wt% Cl, yielded materials with good moldability, impact resistance, and thermal stability	A.-G. Farbwerke Hoechst, Belgian Patent 621,775, 27 Feb 1963, Appl. 1961
1961	Polypropylene, PP, was blended (without compatibilizer) with 20–40 wt% LLDPE, for improved impact resistance and low brittleness temperature	Esso Research & Engineering Co., British Patent 934,640, 21 Aug 1963, Appl. 13 Feb 1961
1961	These are the first patents on PP/PE/EPR blends. Polypropylene/polyethylene, PP/PE, blends were compatibilized by addition of EPR. The resulting blends showed improved low-temperature brittle point and Izod impact strength. In UCC patent, 50–96 wt% was blended with 2–25 wt% PE and 2–25 EPR and/or PIB	L.S. Rayner, J.A. Bond, M. Clark, R.E. Nott, British Patent 958,079, 13 May 1964 Appl. 1961; British Patent 1,026,254, 1966, to ICI; J.P. Lehane Jr., U.S. Patent 3137672, 16 Jan 1964, to Hercules Powder; W.M. Jayne Jr., U.S. Patent 3256367, 14 June 1966to UCC.
1962	LDPE, or its copolymers blended with poly-1-butene, PB, showed improved processability and resistance to environmental stress cracking	A. Rudin, H.P. Schreiber, French Patent 1,349,823, 17 Jan 1964, Appl. 23 Mar 1962, to Canadian Industries Ltd.
1963	Isotactic PP was blended with 3–50 wt% syndiotactic PP, sPP. The blends had excellent impact strength at low T and freedom from surface crazing upon repeated flexing	D.D. Emrick, U.S. Patent 3268627, 23 Aug 1966, Appl. 16 May 1963, to Standard Oil Co.
1963	Polypropylene, PP, was compatibilized with polyethylene, PE, by grafting PP with a basic monomer and PE with an acidic monomer, then blending the modified polymers. Thus, PP was modified with dimethylamino ethyl methacrylate while PE with methacrylic acid. These were blended in 1:1 ratio to result in high-performing alloys	R. Langworth, U.S. Patent 3299176, 17 Jan 1967, Appl. 24 June 1963, to E. I. du Pont de Nemours & Co.
1963	Impact properties of HDPE, LDPE, or LLDPE were improved by blending them with EPDM and PP or polybutene, PB	H.P. Schreiber, British Patent 1,037,819; 1,037,820, 03 Aug 1966, Appl. 1963, to Canadian Industries Ltd.
1963	LDPE and PP were blended with 1–10 wt% polyoxymethylene, POM, for improved melt flow, processability, and extrudate appearance	A. Rudin, H.P. Schreiber, Canadian Patent 688,416; 688,578, 09 June 1964, Appl. 18 May 1963, to Canadian Industries Ltd.
1964	Polyethylene, 10–81 wt% LDPE, was blended with butyl rubber, 15–50 wt% BR, and ethylene–vinyl acetate copolymer, 4–40 wt% EVAc, for cold molding of sealing gaskets	R.J. Ceresa, N.E. Davenport, T.L. Trudgian, British Patent 1,112,024, 01 May 1968, Appl. 1964, to W. R. Grace and Co.
1965	PP was blended with polybutadiene, 5–15 wt% PB, and linear PE, 2–15 wt% LLDPE or HDPE. Good balance of properties was reported	I. Aijima, H. Sakurai, T. Koseki, Japanese Patent 011,539, 27 May 1969, Appl. 09 July 1965, to Asahi Chemical Industry Co., Ltd.

(continued)

Table 18.11 (continued)

Year	Development	References
1966	PE was blended with ethylene–methacrylic acid copolymer, 80 wt% ionomer, and ethylene–vinyl acetate, 10 wt% EVAc, for films with high toughness, stiffness, and impact resistance	M.C.K. Willott, British Patent 1,118,545, 03 July 1968, Appl. 1966, to Imperial Chemical Industries, Ltd.
1966	To improve the low-temperature impact strength of PP, it was blended with a small amount of HDPE and ethylene–propylene block copolymer, EP	Asahi Chemical Industry Co., Ltd., British Patent 1,154,447, 11 June 1969, Appl. 02 Feb 1966
1967	For improved stress crack resistance, PE was blended with 1–95 wt% styrene–butadiene, SBR, or p-methylstyrene–isoprene block copolymer	S. Minekawa, K. Yamaguchi, K. Toyomoto, E. Fujimoto, Y. Takeuchi, Japanese Patent 016,429, 06 May 1971, to Asahi Chem. Ind. Co., Ltd.
1968	Polyolefin, PP or PE, blended with polyvinyl alcohol, 2 wt% PVAl, showed good mechanical, hygroscopic, and antistatic properties. The blends were formed into films, fibers, and tubes or used for coatings	S. Minekawa, K. Yamaguchi, K. Toyomoto, E. Fujimoto, Y. Takeuchi, Japanese Patent 008,585, 12 Sept 1969, to Asahi Chem. Ind. Co., Ltd.
1968	Polymer alloys were prepared by blending PE or its copolymer with lactams, then polymerizing the latter. For example, ethylene–vinyl pyrrolidinone copolymer, EVP, was blended with ε-caprolactam for molding application	R.W. Hill, R.P. Anderson, S.V. Scroggins, U.S. Patent 3,539,662, 10 Nov 1970, Appl. 12 July 1968, to Gulf Research and Development Co.
1968	Polyolefins, PP or HDPE, were blended with amorphous ethylene copolymer, 5–100 EVAc, and 1–80 parts of either polyoxymethylene, POM; polymethylmethacrylate, PMMA; polystyrene, PS; or styrene–methyl methacrylate copolymer, SMM, (as well as inorganic fillers) to extrude into paperlike films	S. Yamamoto, S. Honda, H. Shimizu, Japanese Patent 043,468; 043,469; 043,470, 23 Dec 1971, Appl. 26 Jan 1968, to Sekisui Chemical Co., Ltd.
1968	PP/PE blends were compatibilized by addition of EPR. The resulting materials showed improved low-temperature impact strength	H.J. Leugering, H. Schaum, South African Patent 004,328, 08 Jan 1970, to Farbwerke Hoechst A.-G.
1968	PP or PE was blended with EPR and ethylene–acetoxybicycloheptene copolymer, to increase impact and tensile strength, as well as brittle resistance. In the later patent, PP and EPR were separately dissolved then blended, precipitated, and processed. The blends showed fine, uniform dispersion of the rubber phase, resulting in superior mechanical properties	K. Shirayama, K. Iketa, Japanese Patent 021,303; 021,305, 16 June 1971, Appl. 23 Feb 1968; M. Asada, T. Tokumaru, S. Saito, M. Saeki, H. Ueda, Japanese Patent 008,145, 08 Mar 1972, to Sumitomo Chem. Co.
1969	PE was blended with <15 wt% EPDM, to give resistance to corona discharge. The blends were used as insulating materials for high-voltage cables	H. Matsubara, Japanese Patent 030,095, 05 Aug 1972, Appl. 29 May 1969, to Sumitomo Electric Ind., Ltd.
1969	PP or poly(pentene-co-propylene) was reactor blended with ethylene–butene, or ethylene–pentene, copolymer. The product was melt blended with PP for improved	I. Yamazaki, T. Fujimaki, Japanese Patent 007,627, 03 Mar 1970, Appl. 24 Dec 1969;

(*continued*)

Table 18.11 (continued)

Year	Development	References
	performance. In the second patent, EPR was blended with PP. The alloys showed good mechanical properties. In the Sumitomo patent, for improved impact strength, PP was blended with 5–30 wt% of either polyhexene or polyoctene	007,141, 29 Feb 1972, Appl. 26 Nov 1969, to Showa Denko; K. Shirayama, S. Shiga, H. Watanabe, Japanese Patent 008,370, 10 Mar 1972, Appl. 25 Feb 1969, to Sumitomo Chem
1969	Polypropylene, >70 wt% PP, was blended with ≥5 wt% ethylene–vinyl acetate–vinyl chloride copolymer, EVAc and HDPE, to give materials with low-temperature impact resistance	M. Kojima, M. Tanahashi, Japanese Patent 014,710, 02 May 1972, Appl. 05 Nov 1969, to Chisso Co., Ltd.
1970	LDPE was blended with PIB in an SSE at the shear rates 600,000 s^{-1}, for 34 μs. No thermal degradation was observed. The PIB drop size was 2–5 μm	F. Urban, O. Buchner, K. Steigerwald, K.H. Fauth, H. Gehrig, German Patent 2,028,751, 16 Dec 1971, Appl. 11 June 1970, to BASF A.-G.
1970	PP was blended with hydrogenated styrene–butadiene or styrene–isoprene block copolymer, 6–8 wt%. The alloys were used for the manufacturing of materials with good transparency and impact strength	L.M. Porter, German Patent 2,156,681, 18 May 1972, Appl. 16 Nov 1970, to Shell International Research Maatschappij N. V.
1971	Blends comprising 40–20 wt% polyolefin, PE or PP, with 60–80 wt% of ethylene–propylene–dicyclopentadiene = 47.5:47.5:5 or ethylene–propylene–ethylidene–norbornene = 61:35:4 were disclosed. The blends were masticated and partially cross-linked with peroxides or sulfur, keeping the gel content at 45–96 %. The product could be shaped into articles with good properties without vulcanization. The material may be reprocessed	W.K. Fischer, South African Patent 72 00,388, 23 Aug 1972, U.S. Ref., RE 32,028; W.K. Fischer, U.S. Patent 3806558, 23 Mar 1974, Appl. 12 Aug 1971, to Uniroyal Inc.
1971	Reactive grafting of polyolefins, PE or PP, was disclosed. The extruder was modified for feeding the polymer, the monomer to be grafted and a peroxide. As an example, PP was grafted with acrylic acid	Steinkamp and Grail (1976)
1972	Good mechanical properties were reported for PP or PE blends with chlorosulfonated polyethylene, 4.5 wt% CSR, and filled with a large amount of CaSO$_4$	K. Shikata, K. Okamura, S. Nakamura, Japanese Patent 097,946, 13 Dec 1973, to Tokuyama Soda Co.
1972	LLDPE was blended with atactic polypropylene, 0.1–5 wt% aPP. Blown and stretched films showed large anisotropy in tensile strength and elongation, making them useful for packaging	K. Nakamura, T. Kimura, H. Tsunoda, Japanese Patent 083,174, 06 Nov 1973, Appl. 10 Feb 1972, to Sanyo Pulp Co., Ltd.
1972	UCC discovered the very low density polyethylene, VLDPE, and ultralow-density polyethylene, ULDPE, as copolymers of C$_2$ with α-olefin (C$_{4-8}$) having high SCBD, ρ = 0.860–0.915 g mL^{-1} and T_m = 60–90 °C. UCC used the 2nd-generation Z-N	Levine and F.J. Karol, U.S. Patent 4011382 of 08 Mar 1977 priority 1975, to UCC; E. Berger et al., U.S. Patent 4292200 of 29 Sept 1981, priority

Table 18.11 (continued)

Year	Development	References
	catalyst with MgO. The VLDPE (comonomer C_{3-8} = 6 wt%) with $\rho < 0.91$ g mL^{-1} and modulus $E <$ 140 MPa was produced in a fluidized bed at $T =$ 10–80 °C and $P < 7$ MPa, in a mixture of gases (C_2, C_{3-8}, molar ratio = 1: 0.35–1:8 and 3–5 mol% H$_2$), with a catalyst system comprising a precursor. For PE with $\rho < 0.86$–0.9 g mL^{-1} reaction $T < 60$ °C and $P < 2.5$ MPa are needed. VLDPE has higher α-olefin content than LLDPE	1972, to Solvay and Co.; A. Delbouille et al., U.S. Patent 4250284 of 10 Feb 1981 priority 1969, to Solvay; E.R. Smith, U.S. Patent 5032463 of 16 July 1991, priority 1988, to Viskase; Fujii et al., U.S. Patent 5110870, of 05 May 1992, priority 1989, to Mitsubishi Kasei; Farley et al., U.S. Patent 6,932,592, 23 Aug 2005, to ExxonMobil; Lustig et al., U.S. Patents 5439717, 08 Aug 1995, 5256351 of 1993-10-26, priority 1985, to Viskase; Karol et al., EP 0120,503, of 11 Oct 1984 priority 1983, to UCC; L.M.J. van Assldonk, S.J. Brown, U.S. Patent Appl., 2011/0144289 of 16 June 2011, to Nova Chemhttp://www.novachem.com/researchtech/docs/2010-19.pdf; S. Sivaram, Second Generation Ziegler Polyolefin processes, Ind. Eng. Chem. Prod. Res. Dev. **16**(2), 121–127 (1977); Anonym. VLDPE – a new class of polyethylene, Plast. Rubber **11**(2), 34–36 (1986)
	These linear elastomers are produced by coordination polymerization using a Phillips or Z-N catalyst at low P and T. Here belongs Mxsten XLDPE from Eastman Chem. and Attane ULDPE from Dow. The first metallocene-catalyzed VLDPE was a hexene copolymer with $\rho = 0.912$ g mL^{-1}, made in the UNIPOL gas-phase process with Z-N catalyst and introduced by ExxonMobil as Exceed metallocene VLDPE. The resin has outstanding sealing properties (hot tack and seal strength) compared with ZN-VLDPE. The solution polymerization in a hydrocarbon usually is carried out in a continuously stirred tank reactor (CSTR), at $T = 160$–300 °C and $P = 2.5$–10 MPa with the residence time of 1–5 min [Dow in 1992 and UCC in 1984]	
	The resins are used for geotextile, hose and tubing, ice and frozen food bags, food packaging and stretch wrap, as well as impact modifiers for blending with other polymers. VLDPE has high flexibility, toughness, sealing, and softness	
1973	PE was blended with ≤35 wt% PP; ≤15 wt% polydimethylsiloxane, PDMS; and 5–35 wt% PPE, PA-6, PC, PET, or Phenoxy. The blends were used for injection molding of products with good processability, high rigidity and impact strength, and long life under sterilization in boiling water or irradiation	A. Plochocki, T. Bek, J. Bojarski, L. Czarnecki, L. Grabiec, J. Kepka, P. Machowski, Polish Patents 097,228, 30 Dec 1978; 100,160, 17 Apr 1979; 100,669, 15 May 1979, Appl. 21 Dec 1973, to Institut Chem. Ind.
1973	HDPE was blended with 50 wt% PP, having matched melt flow index, to give good flowability, weld-line strength, surface quality, and low-temperature impact strength	D. Moorwessel, R. Glasser, G. Pfirrmann, German Patents 2,306,892; 2,306,893, 22 Aug 1974, Appl. 13 Feb 1973, to BASF A.-G.
1974	PP (70–90 wt%) was reactor blended with 8–25 wt% PE and 2–10 wt% EPR for high impact strength down to −60 °C. R-TPO had good hardness and is distinguished by a melt index, MFI 230/5, lower than that of the PP contained therein but higher by the coefficient 1.3–7.0 than that of a PP prepared in the presence of the same catalyst as the molding composition having the same RS	H. Strametz, H.J. Leuering, K. Rust, M. Engelmann, Ger. Offen, 2,417,093, 06 Nov 1975; U.S. Patent 3998911, of 21 Dec 1976, Appl. 07 Apr 1975, Priority 08 Aug 1974, to Hoechst A.-G.

(*continued*)

Table 18.11 (continued)

Year	Development	References
1975	PP was blended with ethylene-5-ethylidene-2-norbornene-propylene copolymer, EPDM, having a high ethylene length index (ELI), to give moldings with good tensile strength. In the following patent, EPDM was blended with LDPE. The blends exhibited superior tensile strength, significantly better than that predicted from additivity. The polymers were blended on a two-roll mill. The thermoplastic polymer blends are useful to prepare molded products, tubing, liners, and like products	P.T. Stricharczuk, German Patent 2,644,644, 07 Apr 1977, Appl. 06 Oct 1975; C.J. Carman, M. Batiuk, R.M. Herman, U.S. Patent 4046840, 06 Sept 1977, Appl. 23 Feb 1976, to B. F. Goodrich Co.
1975	Homogeneous blends of immiscible polymers can be prepared in a high-stress, low residence time extruder (e.g., Patfoort extruder sold by FN). Thus, LLDPE was blended with PS to give blends with good mechanical properties	G.A.R. Patfoort, Belgian Patent 833,543, 18 Mar 1976,; Fabrique Nationale Herstal, Neth. Pat. Appl. 007,963, 18 Sept 1977, Appl. 18 Sept 1975
1976	In a series of patents, the dynamic vulcanization of PP was disclosed. Thus, 60 wt% PP was blended with butyl rubber, BR; elastomeric ethylene–vinyl acetate, 35–85 wt% EVAc, with polyolefins, PE or PP; chlorosulfonated polyethylene rubber, $\geq$50 wt% CSM, with polyolefins, PE or PP; or EPDM, with PP. The blends showed excellent toughness, elongation, and impact strength and a wide range of Shore hardness and dimensional stability. In the latter patent, a PO was compatibilized with an elastomeric block copolymer, NBR. The compatibilization nearly doubled the blend tensile strength and increased its elongation at break by a factor of 4	A.Y. Coran, R. Patel, German Patent 2,757,430, 06 July 1978; U.S. Patent 4130534; A.Y. Coran, B. Das, R. Patel, U.S. Patent 4130535, 19 Dec 1978, Appl. 27 Dec 1976; A.Y. Coran, R. Patel, U.S. Patent 4141878, 27 Feb 1979, Appl. 14 Apr 1977; German Patent 2,805,930, 17 Aug 1978, Appl. 14 Aug 1977; Europ. Pat. Appl., 036,279, 23 Sept 1981; U.S. Patent 4355139, 1982, Appl. 10 Mar 1980, to Monsanto Co.
1976	PP/LDPE blends were compatibilized by addition of 2–22 wt% EPR. Blending was done in two stages, curing EPR before the second portion of PP was added. The resulting materials had good mechanical, low-temperature impact and optical properties	T. Huff, U.S. Patent 4087485, 02 May 1978, Appl. 1976, to Exxon Research & Engineering Co.
1976	To improve modulus of HDPE, it was blended with a graft copolymer of HDPE with vinyl or vinylidene monomer (e.g., styrene)	H. Yui, T. Kakizaki, H. Sano, Japanese Patent 014,752, 09 Feb 1978, Appl. 27 July 1976, to Mitsubishi Petrochem. Co., Ltd.
1977	Soft, thin films, with improved cuttability, suitable for packaging materials, were prepared by blending a mixture of LDPE and HDPE, with EPDM or atactic polypropylene, aPP	S. Sakane, K. Minato, M. Takashige, Japanese Patent 000,052, 5 Jan 1979, Appl. 03 June 1977, to Idemitsu Petrochem. Co., Ltd.
1977	PE blends, suitable for extrusion of pipes, were obtained by blending two types of LLDPE, one with C_4 and the other with C_6 comonomer. The blend also contained carbon black, CB	O.E. Larsen, Canadean Patent 1,120,630, 23 Mar 1982, Appl. 12 Oct 1977, to Phillips Petroleum Co.

(*continued*)

Table 18.11 (continued)

Year	Development	References
1977	PP blends with 5–20 wt% LDPE and 1–15 wt% EPR showed excellent transparency and mechanical properties. Similarly, in Daicel patent PP was blended with 15–85 wt% ABS and 0.5 wt% CPE (or low-molecular-weight PS) as a compatibilizer (?). EPR patented blends of 10–60 wt% PP with EPR block copolymer and a peroxide-containing polyolefin copolymer to give a masterbatch that subsequently was blended with 60 wt% EPDM and to give elastomeric alloy with excellent mechanical properties	T. Oita, T. Hara, R. Samejima, K. Tanabe, Japanese Patent 108,146, 20 Sept 1978, Appl. 03 Mar 1977, to Sumitomo Chem.; M. Kamosaki, S. Tokuhara, M. Kita, N. Nakashima, Japanese Patents 146,748; 146,753, 20 Dec 1978, Appl. 27 May 1977, to Daicel Ltd.; A. Yamamoto, M. Shiraishi, S. Nakayama, Y. Tsurugi, H. Nakanishi, Japanese Patent 001,386, 08 Jan 1979, Appl. 07 June 1977, to EP Rubber Co., Ltd.
1979	PP was sequentially blended with EPR, then with PE. The blend showed co-continuous morphology resulting in excellent impact and mechanical properties, superior to those observed for blends with a particulate dispersion	T. Huff, Europ. Pat. Appl., 015,066, 03 Sept 1980, Appl. 31 Jan 1979, to Exxon Res. Eng. Co.
1979	A 60 wt% PP was blended with polyamide, 20 wt% PA-6 or PA-66, and glass fibers, 20 wt% GF, for superior tensile and impact strength	Asahi Fiber Glass Co., Ltd., Japanese Patent 030,451, 27 Mar 1981, Appl. 23 Aug 1979
1979	Polyethylene, 70 wt% PE; polyamide, 20 wt% PA-66; and 3 wt% of ethylene–fumaric acid graft copolymer were mixed to reduce moisture permeation and to improve impact strength. In 1982 DuPont introduced PA/PO blends, Selar™, to be used as additive to polyolefin to reduce permeability	P.M. Subramanian, Europ. Pat. Appl., 015,556, 17 Sept 1980, Appl. 06 Mar 1979, to E. I. du Pont de Nemours; "Selar™ Barrier Resins," Bulletins E73971, E73973, E73974 by du Pont
1979	PE was grafted with 0.1–5 wt% maleic anhydride and blended with 1–50 wt% EPDM. The blend showed excellent adhesion to polar materials	A. Honkanen, M. Arina, R. Holstii, Finnish Patent 064,805, 30 Sept 1983, Appl. 10 Dec 1979, to Neste Oy
1979	PP was blended with 5 wt% PDMS for improved processability, impact strength, and elasticity	U. Grigo, L. Morbitzer, K. Arlt, R. Binsack, J. Marten, German Patent 2,905,357, 21 Aug 1980, Appl. 13 Feb 1979, to Bayer A.-G.
1979	A patent on reactor-blended thermoplastic olefinic elastomer, R-TPO, was disclosed. Thus, PE was polymerized in the presence of an active catalyst and an already polymerized olefinic copolymer (e.g., ethylene-co-1-butene) or the sequence was reversed. The blend had superior resistance to environment stress cracking, and the blown film showed few fish eyes	Y. Morita, N. Kashiwa, Europ. Pat. Appl., 022,376, 14 Jan 1981, Appl. 09 July 1979, to Mitsui Petrochemical Industries, Ltd.

Table 18.11 (continued)

Year	Development	References
1980	In 1979 UNIPOL™ process for gas-phase production of LLDPE was introduced by the UCC. Since the new resins were difficult to process on the LDPE processing lines, several patents were issued for LLDPE blends with, e.g., LDPE or PP, which had better processability In 1982 a number of patent applications for blends of LLDPE, with other polyolefins, co-polyolefins, and olefinic elastomers, for example, ethylene copolymers and thermoplastic elastomers (e.g., TPO, EPDM, EPR, EVAc, PP-MA,), have been filed	A. Haas, F. Raviola, EP Appl. 042,743, 13 Jan 1982; A. Haas, French Patent 2,526,803, 18 Nov 1983; M. Hert, French Patent 2,528,055, 09.121983, to Soc. Chim. Charbon., SA; P.M. Hughes, EP Appl. 045,455, 10 Feb 1982, Appl. 1980, to Shell Oil; M.A. Cowan, EP Appl. 095,299, 30 Nov 1983, to Intercont. Plast.; K.C. Janac, R.C. Puydak, D.R. Hazelton, EP., Appl., 092,318, 26 Oct 1983, Appl. 26 Mar 1982, to Exxon Res. & Eng. Co.; B.L. Turtle, EP Appl. 095,253, 30 Nov 1983, to BP; O. Fukui, Y. Inuizawa, S. Hinenoya, Y. Takasaki, French Patent 2,522,331, 02 Sept 1983, to Ube
1980	To improve its low-temperature impact strength, polyethylene, PE, was blended on a roll mill with polybutadiene rubber, 10 wt% PB	E.G. Kent, U.S. Patent 4,423,181, 27 Dec 1983, Appl. 10 Mar 1980, to Polysar Ltd.
1981	Polyethylene, 50–95 wt% HDPE, was blended with LLDPE for improvement of film strength and transparency	Showa Denko (1983)
1981	Polyethylene, PE, was blended with neoprene rubber at a ratio 1:1. The blends were irradiated by electron beam for improved tensile strength and other mechanical properties	A.Y. Coran, R. Patel, U.S. Patent 4,348,266, 07 Sep 1982, Appl. 02 Apr 1981, to Monsanto
1981	Polypropylene, 100 parts PP, blended with 8–25 parts of amorphous ethylene–propylene copolymer, EPR, and 2–10 parts crystalline EPR showed improved impact strength. In the Idemitsu patent, PP was blended with maleated LDPE, EVAc, and inorganic filler, to give blends with good melt strength and rigidity	P. Galli, M. Spataro, Europ. Pat. Appl., 077,532, 27 Apr 1983, Appl. 14 Oct 1981, to Montedison; Idemitsu Petrochemical Co., Japanese Patent 096,640, 08 June 1983, Appl. 04 Dec 1981
1982	Semicrystalline ethylene–propylene copolymer, EP, was blended with amorphous EP and inorganic filler. The blends had good processability, mechanical properties, and impact strength. In the Mitsubishi patent, crystalline EP was blended with styrene–isoprene block copolymer, 5–30 wt% SIS, and polystyrene, 3–5 wt% PS, to give good paintability	Ube Industries, Japanese Patent 162,652, 27 Sep 1983, Appl. 23 Mar 1982; Japanese Patent 168,648; 168,649, 05 Oct 1983, Appl. 30 Mar 1982; Mitsubishi Petrochem. Co., Ltd., Japanese Patent 213,039, 10 Dec 1983, Appl. 04 June 1982
1982	Polypropylene, 94 wt% PP, was blended with chlorinated polyethylene, 6 wt% CPE. The blends had good processability and gave moldings with good mechanical properties	R. Newe, E. Lange, H. Hoffmann, K. Wetzel, East German Patent 207,381, 29 Feb 1984, Appl. 05 Apr 1982, to VEB Chemiekombinat Bitterfeld

(continued)

Table 18.11 (continued)

Year	Development	References
1982	Polypropylene, 50–90 wt% PP, and/or ethylene–propylene block copolymer, EP, was blended with talc having particle size $d = 5$–20 μm. The materials had high impact strength. In the following patent, PP was blended with 5–40 wt% styrene-grafted chlorinated polyethylene, CPE, to give high modulus and impact resistance	Chisso Corp., Japanese Patent 036,149, 28 Feb 1984, Appl. 24 Aug 1982; Japanese Patent 213,038, 10 Dec 1983, Appl. 03 June 1982
1982	Polypropylene, 35 wt% PP, was blended with polyisobutylene, 50 wt% PIB, and ethylene–vinyl acetate copolymer, 15 wt% EVAc, to give alloys useful for films, moldings, and extrusions	C.B. Shulman, Europ. Pat. Appl., 116,783, 29 Aug 1984, Appl. 27 Dec 1982, to Exxon Research and Eng. Co.
1982	Polyethylene, PE, blends from LDPE, HDPE, and MDPE were found suitable for manufacturing films with uniform thickness and anisotropic tensile strength	K.K. Showa Denko, Japanese Patent 157,837, 20 Sep 1983, Appl. 15 Mar 1982; Japanese Patent 176,234, 15 Oct 1983, Appl. 09 Apr 1982
1982	Linear low-density polyethylene, LLDPE, was blended with 2–25 wt% LDPE to give films with large difference of the tensile strength in the machine and transverse direction	M. Hert, French Patent 2,528,054, 09 Dec 1983, Appl. 03 June 1982, to Societé Chim. des Charbonnages S. A.
1982	Low-density polyethylene, LDPE, was blended with 1–40 wt% poly(2-ethyl-2-oxazoline), PEOX. The blends had excellent adhesion to substrates, e.g., thermoplastic polyesters, viz., PET	S.M. Hoenig, D.P. Flores, S.P. Ginter, U.S. Patent 4,474,928, 02 Oct 1984, Appl. 28 June 1982, to Dow Chemical Co.
1982	Ethylene polymer blends are prepared by mechanical blending of dry powders or compounding in an internal mixer, a compounder or (preferably) combining the two methods. The two polymers are high-density, narrow MWD LLDPE and HDPE, significantly differing in MW. PE films with superior tear strength with <30 wt% LDPE and >70 wt% Cr-type LLDPE with $M_w/M_n > 6$. Bailey, Whitte, Coutant Martin, and Benham et al. to Phillips Petroleum Co; Cobler et al. to Dow Chem. Co. (mixing on the blow line); Harris to Media Plus. Blends of a high-MW ethylene–α-olefin copolymer, a low-MW PE with narrow MWD, and low levels of LCB for films with good ESCAR are useful for the manufacture of films, pipes and wire coating	Bailey and Whitte (1984), Coutant and Martin (1995), Benham and McDaniel (1994), Benham et al. (1995); U.S. Patent 5,681,523, 28 Oct 1997, to Dow Chem. Co.; U.S. Patent 6822051, 23 Nov 2004, to Media Plus, Inc.
1982	Low-density polyethylene, LDPE, was blended with HDPE, PP, and EP block copolymer, to give films with good modulus, tear strength, and sagging	Shin-Kobe Electric Machinery Co., Ltd. (1984)
1983	Low-density polyethylene, LDPE, blended with linear low-density polyethylene in a ratio 100:20–90 gave alloys useful for production packaging films	Asahi Chemical industry Co., Ltd. (1985)
1984	Linear low-density polyethylene, LLDPE, was blended with low-density polyethylene, 10–45 wt% LDPE; polypropylene, PP; and/or ethylene–propylene copolymer [with a high propylene content], 2–15 wt% EPR. The blends had high modulus and clarity	Bahl et al. (1985)

(*continued*)

Table 18.11 (continued)

Year	Development	References
1985	Polyethylene, PE, blended with 10–40 wt% ethylene–vinyl carboxylate or an acrylate copolymer exhibited notched Izod impact strength more than three times larger than that of functional group-free PE	T.O. Broadhed, Europ. Pat. Appl., 209,294, 21 Jan 1987, Appl. 15 July 1985; to Du Pont Canada, Inc.
1985	Polyolefin blends with good compatibility comprised 100 parts PO and 0.1–100 parts polytransoctanamer, PTO. For example, PP with 9 wt% PTO showed about 5x higher impact strength at $T = -40$–23 °C than PP alone	M. Kita, K. Hashimoto, Japanese Patent 131,043, 13 June 1987, Appl. 04 Dec 1985, to Daicel Huels Ltd.
1987	Transparent-, impact-, and "blush"-resistant blends were obtained by compounding linear low-density polyethylene, LLDPE, with hydrogenated styrene–butadiene block copolymer, SEBS	G. Holden, D.R. Hansen, Europ. Pat. Appl., 308,001, 22 Mar 1989, Appl. 1987, to Shell Int. Res. Maatschappij BV.
1987	Polypropylene, PP, blended with polyoctadecene, POD, was found to show temperature-sensitive transparency (thermochromic blends)	S. Tanaka, J. Sakai, T. Fukao, K. Wakatsuki, K. Wakamatsu, Europ. Pat. Appl., 285,414, 05 Oct 1988, Appl. 1987, to Sumitomo Chemical Co., Ltd.
1989	Polypropylene, PP, reactor blends were obtained with high yield using a chiral metallocene catalyst and an aluminoxane. The preferred blends comprised 60–95 wt% of a crystalline isotactic PP homo- or copolymer produced in the first stage and (the second stage) random copolymer ethylene–propylene (and another 1-olefin), as well as a partly crystalline polymer of the second 1-olefin. The moldable blends showed good flow properties and a very good low-temperature impact strength	M. Schreck, A. Winter, V. Dolle, H. Kondoch, M. Antberg, J. Rohrmann, U.S. Patent 5,322,902, 21 June 1994, Appl. 21 Dec 1989, U.S. Appl. 19 Dec 1990, to Hoechst Aktiengesellschaft
1990	Three-component polypropylene, 1–99 wt% PP, blends comprised 1. either acidified PP, its mixture with PP, or a mixture of PP with carboxylic acid-modified EPR; 2. 99–1 wt% of maleated polymer [e.g., poly(methyl methacrylate-co-styrene-co-MA]; and 3. epoxy group-containing copolymer [e.g., 0.1–300 phr of ethylene–methyl methacrylate–glycidyl methacrylate = 65-15-20 or ethylene–vinyl acetate–glycidyl methacrylate = 85-5-10]. The blends were used to mold car bumpers and fenders, with good stiffness and low-temperature impact resistance	H. Abe, T. Fujii, M. Yamamoto, S. Date, U.S. Patent 5,278,233, 11 Jan 1994, Appl. 14 June 1990, U.S. Appl. 12 June 1991, to Sumitomo Chemical Co., Ltd.
1990	Polypropylene (PP) was blended with ethylene-co-vinyl alcohol (EVAL) and maleated polypropylene (PP-MA). The blends were extruded through a sheeting die that engendered overlapping layers of EVAL. Their presence reduced permeability by gases or liquids through the PP wall	M.R. Kamal, G. Lohfink, L. Arghyris, S. Hozhabr-Ghelichi, PCT Int. Appl., 006,837, 30 Apr 1992, Appl. 16 Oct 1990, to McGill University

(continued)

Table 18.11 (continued)

Year	Development	References
1990	Linear low-density polyethylene, LLDPE, was blended with very low density polyethylene, VLDPE. The polymers prepared using metallocene catalyst had narrow molecular weight distribution, $M_w/M_n = 1–3$. Blending resulted in resins having the density $\rho = 910–940$ kg m^{-3}	Stehling et al. (1995)
1991	Polyolefin blends with density of $\rho = 930–940$ kg m^{-3} at 23 °C and MFI(90/2.16) = 0.05–1.0 dg min^{-1} comprised high-density polyethylene, 50–80 wt% HDPE [polymerized in two stages, with a broad bimodal molecular mass distribution, $\rho = 940–960$ kg m^{-3} and MFI(90/2.16) = 0.01–0.5 dg min^{-1}], and linear low-density polyethylene, 20–50 wt% LLDPE [$\rho = 910–925$ kg m^{-3} and MFI (90/2.16) = 0.5–2.0 dg min^{-1}]. The blends were used for forming tubes and pipes with high stress crack resistance	Boehm et al. (1992); U.S. Patent 5,338,589, 16 Aug 1994, U.S. Appl. 03 June 1992, German Appl. 05 June 1991, to Hoechst Aktiengesellschaft
1991	Linear low-density polyethylene, LLDPE, was graft modified by incorporation of basic groups from, e.g., dimethylamino ethyl methacrylate, t-butylamino ethyl methacrylate, vinyl pyridine, or allyl urea. These copolymers were then used as reactive components for alloys with acidified polymers, viz., maleated polyolefins	Baker and Simmons (1991)
1991	Linear low-density polyethylene, LLDPE, was blended with low-density polyethylene, LDPE, at a ratio of about 0.3. The blends were used for blow molding hollow balls containing pressurized air and consisting of two hemispheres welded to form a ball with a wall thickness $t = 0.5–1.8$ mm	Moss and Modigh (1994)
1991	Blends comprising 30–70 wt% low-molecular-weight (MW) polyethylene, DPE [made using a chromium catalyst, having density $\rho \geq 955$ kg m^{-3}, MI = 25–400 g/10 min, and $M_w/M_n = 2–35$], and 30–70 wt% high-MW ethylene copolymer, LLDPE [made using a titanium catalyst, having $\rho \leq 955$ kg m^{-3}, MI = 0.1–50 g/10 min, and $M_w/M_n = 2–10$], showed improved processability. The blends were used to produce pipes, films, and bottles with enhanced mechanical properties as well as the environmental stress crack resistance, ESCR. In the following patent 5–40 wt% low-MW HDPE [made using a titanium catalyst, with density $\rho \geq 955$ kg m^{-3}, MI ≥ 25 dg min^{-1}, and $M_w/M_n = 2–8$] blended with 60–95 wt% high-MW HDPE [from chromium catalyst, with density $\rho \geq 930$ kg m^{-3}, MI = 1.5–15 dg min^{-1}, and $M_w/M_n = 6–100$] yielded blends with MI = 0.05 dg min^{-1} and ESCR. In the last patent	Martin et al. (1994), Coutant and Martin (1995), Appl. 16 Apr 1993, Appl. 18 Sep 1991, to Phillips Petroleum Company

Table 18.11 (continued)

Year	Development	References
	10–80 wt% low-MW LLDPE [$\rho \geq 940$ kg m^{-3}, MI > 25 dg min^{-1}, and $M_w/M_n = 2$–12] was blended with 20–90 wt% of a high-MW LLDPE [$\rho \leq 955$ kg m^{-3}, MI = 2–10 dg min^{-1}, and $M_w/M_n = 2$–10]. The blends had MI > 0.05 dg min^{-1} and had improved optical properties	
1991	Polyethylene, PE Rigidex™ or Innovex™, was blended with liquid crystal polyester, 0.01–5 wt% LCP, to give materials with good melt processability, low viscosity, and reduction of the specific energy during compounding	P.T. Alder, J.G. Dolden, D.G. Othen, PCT Int. Appl., 008,231, 29 Apr 1993, Appl. 22 Oct 1991, to British Petroleum Co.
1991	Compositions comprised 10–80 wt% low-MW polyethylene, HDPE [$\rho \geq 940$ kg m^{-3}], and 20–90 wt% high-MW ethylene–hexene copolymer, LLDPE [$\rho \leq 955$ kg m^{-3}]. The blends had a MFI > 0.05 g/10 min. The blend showed improved optical and physical properties, resulting in better blow-molded products	W.R. Coutant, J.L. Martin, Eur. Pat. Appl., 533,160, 24 Mar 1993; Norwegian Patent 9203,598, 19 Mar 1993; Hungarian Patent T62,631, 28 May 1993; Japanese Patent 5,194,796, 03 Aug 1993, Appl. 18 Sep 1991, to Phillips Petroleum Co.
1991	Ethylene–propylene copolymer (EPR, EPDM, or their mixture with $T_m = 35$–55 °C) was blended with ethylene copolymer (very low density polyethylene VLDPE with density 885 kg m^{-3} and $T_m = 65$–90 °C), PP or PP block copolymers, and 0–7 phr talc. The blend showed excellent moldability, surface appearance, and hardness, as well as good impact resistance	T. Nishio, T. Nomura, N. Kawamura, H. Sato, A. Uchikawa, I. Tsutsumi, Y. Goto, Europ. Pat. Appl., 519,725, 23 Dec 1992, Appl. 21 June 1991, to Mitsubishi Petrochemical Co.
1991	N,N-diethylaminoethyl-, lycidyl methacrylate, or acrylic acid chloride was used	N. Koyama, M. Usui, H. Furuhashi, S. Ueki, U.S. Patent 5,382,634, 17 Jan 1995, Appl. 25 Apr 1994, Jap. Appl. 15 Mar 1991, to Tonen Corporation
1991	Polymer alloys comprised 20–30 wt% PP, 25–35 wt% uncross-linked elastomeric ethylene-propylene-1,4-hexadiene, EPDM (60–80 wt% ethylene), 30–50 wt% ionomer, and 2–3 wt% ethylene/n-butyl acrylate/glycidyl methacrylate, EBA-GMA. The blends were used in applications where a wide temperature range and abrasive conditions were encountered	R.L. Dawson, U.S. Patent 5,206,294, 27 Apr 1993, Appl. 6 Nov 1991, to E. I. du Pont de Nemours & Co.
1991	Deposition of patent on the constrained geometry catalyst technology (CGCT) based on the transition metals, M = Ti, Zr, Hf. The resulting PO is substantially linear. The preferred composition comprises 10–95 wt% of homogeneously branched linear α-olefin copolymer ($\rho = 0.930$–0.965 g mL^{-1}, MWD = 1.8–2.8, single T_m)	S.-Y. Lai, J.R. Wilson, G.W. Knight, J.C. Stevens, P.-W. S. Chum, Elastic substantially linear olefin polymers, CA 2120766 of 08 July 2008 (filed 15 Oct 1993; priority 15 Oct 1991); U.S. Patent 5,272,236 of

Table 18.11 (continued)

Year	Development	References
	and 5–90 wt% of heterogeneously branched C_2C_8 copolymer ($\rho = 0.935$ g mL^{-1})	21 Dec 1993 (deposited 15 Oct 1991); P.-W.S. Chum, R.P. Markovich, G.W. Knight, Shih-Yaw Lai, Fabricated articles made from ethylene polymer blends, CA 2160705 of 22 Aug 2006 (filed 190 Apr 1994; priority 28 Apr 1993); Ethylene polymer film made from ethylene polymer blends, U.S. Patent 5847053 of 08 Dec 1998 (filed 11 Apr 1997; priority 15 Oct 1991), to The Dow Chemical Company
	Lai, Wilson, Knight, Stevens, Chum, Markovich, to the Dow Chemical Company	
	The SCBDI = wt% of macromolecules having a comonomer content within 50 % of the median total molar comonomer content, calculated from TREF (temperature rising elution fractionation) data. The elastic, substantially linear C_2–C_8 copolymer has $0.01 \leq$ LCB/1000C ≤ 3, $M_w/M_n = 1.5$–2.5, $2 \leq$ SCB (CH$_3$/1000C) ≤ 30), and short-chain branch distribution index: SCBDI > 50 %. The homogeneously branched copolymer may be produced as described in C. T. Elston (DuPont Canada Ltd.) patent. Films produced from the bimodal MWD new copolymers show good impact and tensile properties	
1991	Polypropylene, 50 wt% PP, was blended with a linear low-density polyethylene, 10–50 wt% LLDPE, and a low-molecular-weight ethylene–butene plastomer (a compatibilizer). The blends were useful for melt-spun or melt-blown fibers or fabrics. In the following patent heat sealable at 100 °C, blends were disclosed. They comprised 30–70 wt% ethylene–alpha-olefin copolymer prepared using a metallocene catalyst, VLDPE or plastomer [with density $\rho = 880$–915 kg m^{-3}, MI = 1.5–7.5 dg min^{-1}, $M_w/M_n \leq 3.0$, $T_m = 60$–100 °C], and 70–30 wt% propylene–alpha-olefin random copolymer [with 88–100 mol% propylene]. The blends showed good processability, resistance to tearing, and tensile strength. They were useful for manufacturing packaging films, tubes, trays, etc.	K.W. Bartz, L.P. Land, A.K. Mehta, A.A. Montagna, PCT Int. Appl., WO 06,169 A1, 01 Apr 1993, Appl. 16 Sep 1991; A.K. Mehta, M.C. Chen, U.S. Patent 5,358,792, 25 Oct 1994, Appl. 22 Feb 1991, 23 Apr 1993, to Exxon Chem. Co.
1991	Polypropylene, 55–90 wt% PP, was blended with poly (1-butene), PB, as a dispersed phase and optionally with up to 10 wt% of low-MW poly(α-olefin-co-ethylene) plastomer compatibilizer. The blends were useful for manufacturing fibers and nonwovens, with good "hand" and tensile strength	K.W. Bartz, J.C. Floyd, P. Meka, F.C. Stehling, PCT Int. Appl., WO 006,168, 01 Apr 1993, Appl. 16 Sep 1991, to Exxon Chemical Patents, Inc.
1991	Semicrystalline polyolefin blends and method of their preparation were described. The blends were reported to show enhanced inter-spherulitic and interlamellar strength. The first polymer should have higher crystallinity and crystallization temperature than the second. Thus, 50–99.9 wt% PP was blended with ethylene–α-olefin copolymers, either a stereo block polypropylene or an ethylene–propylene copolymer, EPR	A. Lustiger, Can. Pat. Appl., 2,083,664, 21 June 1993, Appl. 20 Dec 1991, to Exxon Research and Engineering Co.

<div align="right">(continued)</div>

Table 18.11 (continued)

Year	Development	References
1991	Vinyl-trimethoxysilane-grafted polyolefin, PO (e.g., PP, LDPE, EPR, or EVAc), was blended with and ethylene–acryloyloxytetramethylpiperidine. The water-cross-linkable blends were found useful for manufacturing weather-resistant cross-linked polyolefin pipes for outdoor applications	S. Ohnishi, T. Fukuda, Eur. Pat. Appl., 548,565, 30 June 1993, Appl. 12 Dec 1991, to Mitsubishi Yuka Industrial Products Corp.
1991	Blends comprised 1–70 wt% of either metallocene polypropylene, PP, or a copolymer of propylene with ≤10 mol% ethylene or C_2–C_{20} α-olefin that has $M_w/M_n \leq 3$ and 30–99 wt% of a similar copolymer but with $M_w/M_n = 3.5$–10. The blends were used for films having excellent low-temperature heat sealability and blocking resistance	T. Fujita, T. Sugano, H. Mizuno, H. Uchino, U.S. Patent 5,331,054, 19 July 1994, Appl. 19 Oct 1992, Jap. Appl. 21 Oct 1991, to Mitsubishi Petrochemical Co., Ltd.
1991	Radiation-resistant, heat-sealable polypropylene, PP, blends (softer and tougher than similar ones) comprised 1–99 wt% mesomorphous PP or its copolymer, ethylene–vinyl acetate (EVAc) and/or ethylene–acrylic acid copolymer (EAA) and polybutene (PB). For example, films were prepared by blending, extruding, and then quenching. The resins were useful for manufacturing medical goods, tapes, ostomy bags, packaging materials, drug delivery patch, medical type, etc.	D.L. Wilfong, R.J. Rolando, Eur. Pat. Appl., 547,834, 23 June 1993, Appl. 18 Dec 1991, to Minnesota Mining and Mfg. Co.
1992	Polyolefin, 100 parts PO [PE, PP, or EPR], was grafted with 0.01–20 parts of the monomers' mixture [consisting of 5–50 mol% of glycidyl (meth)acrylate and 95–50 mol% of acrylamide, vinylpyrrolidone, acrylic acid esters, and/or methacrylic acid esters]. Grafted PO was used as modifier for engineering plastics or as adhesion improver for filled plastics	T. Teraya, S. Kikuchi, K. Yokoyama, Y. Fujita, Japanese Patents 61 45,260, 61 45,261, 24 May 1994; Eur. Pat. Appl., 596,654, 11 May 1994, Appl. 28 Oct 1993, JP Appl. 30 Oct 1992, to Tonen Corp.
1992	Heterogeneous ion exchange materials contained 44–55 wt% of an ion exchange resin dispersed within a blend of LLDPE and HDPE (having $MW > 200$ kg mol^{-1}.) The maximum density of LLDPE, and minimum density of HDPE, was approximately 940 kg m^{-3}. The ion exchange material was selected from between anionic, cationic, and amphoteric ion exchange resins and their mixtures	A. Giuffrida, U.S. Patent 5,346,924, 13 Sep 1994, Appl. 23 Sep 1992, to IP Holding Company
1992	Linear low-density polyethylene, LLDPE, was blended with starch and at least one ionic compound (in such amount that the concentration of anions and cations was between 0.002 and 5 mol kg^{-1}) to produce high-frequency sealable articles. The starch could also contain ≤50 wt% of a plasticizer. The alloys could be processed by calendering, extrusion, etc., to produce multilayer films or sheets weldable or sealable by induction heating at high frequency, useful in packaging, paper making, etc. The presence of the starch improved the long-term biodeterioration of the materials	C. Dehennau, T. Depireux, I. Claeys, Eur. Pat. Appl., 587,216, 16 Mar 1994; Japanese Patent 62 07,046, 26 July 1994, Appl. 01 Sep 1992, to Solvay et Cie.

Table 18.11 (continued)

Year	Development	References
1992	Polymer blends comprised melt-blended high- and low-molecular-weight polyethylenes, PE, having the viscosity (at $100\,\mathrm{s}^{-1}$) of, respectively, $\eta > 5$ and $\eta < 0.3$ kPas. The two polymers were blended at two stages: first the high-molecular-weight polymer was blended with a small amount of the other polymer, and then an additional low-molecular-weight resin was incorporated. The blends showed good processability and excellent properties. They were used for production of films with low fish-eye content, blow molding, pipes, wire coating, and injection or rotational molding	Coutant (1994)
1992	Reactor blends of high-density polyethylene, HDPE with butene and/or hexene, were produced in a multistage, gas-phase, fluidized bed polymerization, where blending occurred in situ. The resulted bimodal molecular weight distribution resin had 35–75 wt% of the higher-molecular-weight component. The blown films had improved MD/TD tear balance	Ali et al. (1994); Dammert et al., U.S. Patent 6,185,349 of 06 Feb 2001 (filed 1999) to Borealis Polymer Oy
	PE blends were prepared during polymerization. This strategy has been widely implemented in syntheses of multimodal PE compositions. The blown film showed MD/TD tear balance. The bimodal blend contained 0.35–0.75 weight fraction of a higher-MW component. Ali A.H. et al. to Mobil Oil Co.; Dammert et al. to Borealis. Catalyst: $TiCl_4$/pentanol deposited on MgO/acetic acid and then treated with tri-n-hexyl-aluminum solution. Reactor blending during the slurry polymerization gave two PE fractions with different MW. Borealis generated multimodal resins for optical cables using slurry-/gas-phase reaction with Z-N catalyst with $MgCl_2$	
1992	Polyolefin blends with improved barrier properties comprised 85–99.5 wt% of a polyolefin (e.g., high-density polyethylene, HDPE) with 0.5–15 wt% of high-nitrile polymer (e.g., an acrylonitrile–butadiene copolymer). The alloys were found useful for molding plastic bottles, automobile gasoline tanks, and other containers having limited or restricted permeability to gases, vapors, or organic liquids. These materials also showed good chemical resistance, strength, and processability	G.P. Coffey, E.S. Perec, N.W. Standish, L. Melamud, J. Smola, Eur. Pat. Appl., 586,066, 09 Mar 1994; Japanese Patent 61 57,837, 07 June 1994, Appl. 23 July 1992, to Standard Oil Co.
1992	Blends comprising very low density polyethylene, 100 parts VLDPE [80–95 mol wt% ethylene and C_4–C_8 comonomer(s)], and linear low density polyethylene, 15–600 parts LLDPE (ethylene copolymer with 2–8 mol% octene), showed excellent processability. They were formed into 10–300 μm thick sheets, useful for transdermal drug delivery devices as single-layer backings. They were clear, colorless, transparent,	Godbey and Martin (1993, 1994)

<div align="right">(continued)</div>

Table 18.11 (continued)

Year	Development	References
	permeable to oxygen, stable to various common components of transdermal delivery devices, strong, comfortable, and not absorbing significant amounts of elements of transdermal carriers. Sheets made from the blends could be heat sealed at a low temperature	
1992	Heat-shrinkable film comprised single-site catalyzed copolymer of ethylene and a 3–8C alpha-olefin, LLDPE with $\rho \geq 900$ kg m^{-3} blended with another polymer of ethylene and a 3–8C alpha-olefin and a second comonomer [e.g., vinyl acetate, alkyl acrylate, CO, butadiene, styrene, acrylic acid, and a metal salt of an acrylic acid], or an alpha-olefin homopolymer. The films had improved shrinkability, impact resistance, and optical properties as compared to prior art and were used in packaging	Babrowicz et al. (1994)
1992	Polyolefin blends formulated for heat seamable roof sheeting comprised 25–95 wt% of amorphous PO having <1 wt% crystallinity (<60–61 wt% ethylene, dicyclopentadiene, and/or ethylidene norbornene); 5–75 wt% of a crystalline polymer, i.e., PE, PP, poly(ethylene-co-propylene), poly(ethylene-b-octene), or poly(ethylene-b-butene), having 2–65 wt% crystallinity; 20–300 phr of a (non) reinforcing filler; and 20–150 phr of either paraffinic oil, naphthenic oil, and/or wax. The materials exhibited good adhesion. Neither an adhesive nor curing was necessary	J.A. Davis, J.K. Valaitis, Eur. Pat. Appl., 564,961, 13 Oct 1993; Canadian Patent 2,093,397, 07 Oct 1993; U.S. Patent 5,286,798, 15 Feb 1994; Japanese Patent 60 65,434, 08 Mar 1994, Appl. 06 Apr 1992, to Bridgestone/Firestone, Inc.
1992	Blends comprising cycloolefin polymer, 0–95 wt% PCO; polyethylene, 0–95 wt% PE; and 0.1–99 wt% block copolymer(s) were prepared for moldings with outstanding properties, viz., improved melt viscosity, elongation at break, impact strength, toughness, hardness, and modulus. The block copolymers of ethylene (or propylene) and norbornene blocks were obtained in the presence of aluminoxane and a metallocene catalyst, resulting in $M_w/M_n \leq 2$	U. Epple, M.-J. Brekner, U.S. Patent 5,359,001, 25 Oct 1994, Appl. 20 Apr 1993, Ger. Appl. 22 Apr 1992, to Hoechst A.-G.
1992	Blends included 70–90 wt% of a polymer derived from ethylene and at least one higher alpha-olefin (e.g., LLDPE, VLDPE, or LDPE having MI = 0.1–10), 10–30 wt% of an auxiliary co-crystallizable polymer derived from ethylene and at least one olefinic comonomer (e.g., LLDPE, VLDPE, or LDPE having MI $\geq$ 80 %, below that of the first polymer), and moisture cross-linking additives including a silane, a silanol condensation catalyst, and a free radical initiator. Cross-linking was rapid; thus, the moisture-curing step subsequent to extrusion of an electrical cable	Wong and Varrall (1994)

Table 18.11 (continued)

Year	Development	References
	was short. The blends could contain processing aid (fluorinated polymer and/or polyethylene with high MI) and 5–70 wt% filler. They were used for shaped coatings and cable coating	
1992	Polyethylene blends having toughness and elastic recovery comparable to those of plasticized PVC comprised $\geq$50 wt% of a copolymer of ethylene and either butene or hexene [LLDPE, $\rho = 880$–915 kg m^{-3}, MI $\leq$ 1 dg min^{-1}, long-chain branching =0.5–1.5 long chains/1,000C, $M_{\mathrm{w}} \geq 200$ kg mol^{-1}]; $\geq$5 wt% of a copolymer of ethylene and either vinyl acetate or ethyl acrylate, EVAc or EEA; and 5–30 wt% liquid hydrocarbon oil. The blends showed essentially no yield point and behavior similar to that of cross-linked materials, although they were not cross-linked (strain recovery). They were found competitive with plasticized PVC in terms of both physical properties and economics	M.R. Rifi, U.S. Patent 5,326,602, 05 July 1994, Appl. 01 Dec 1992, to Union Carbide Chemicals & Plastics Technology Corporation
1992	Linear low-density polyethylene, 90–99 wt% LLDPE, was blended with polymethylmethacrylate, 10–11 wt% PMMA, and optionally a compatibilizing copolymer, viz., SEBS, EPR, ethylene–styrene block copolymer, ES. The blends were found to produce blown films with improved tear in the machine direction, modulus, and impact strength	D.V. Dobreski, J.J. Donaldson, U.S. Patent 5,290,866, 01 Mar 1994, Appl. 16 Apr 1992, to Mobil Oil Corp.
1992	Continuous process for the preparation of polyisobutylene, PIB, blends with at least one other polymer, e.g., polyolefin, PO, was described. PIB was continuously polymerized in ethylene. The resin was fed to a degassing extruder where it was mixed with PO, fillers, and/or additives. The process was used for the preparation of blends in a simpler and more cost-effective manner than that of prior art	H. Gropper, E. Kolk, K.H. Fauth, G. Isbarn, G. Scherer, German Patent 4,319,181, 27 Jan 1994; French Patent 2,694,010, 28 Jan 1994, Appl. 22 July 1992, to BASF A.-G.
1992	Thermoplastic rubber blends with good adhesion to reinforcing agents comprised 10–100 wt% polyolefin grafted with polar monomers (e.g., 27–75 wt% PP grafted with vinyl acetate, acrylic acid, methacrylic and itaconic acid, or maleic acid anhydride) and elastomer(s) (EPDM, NBR, or BR) that could be dynamically cross-linked by peroxide, silane, or sulfur. The blends may also contain 0.3–2.5 wt% plasticizer, fillers, pigments, processing aids, and flame retardants. They showed bondability to solids, especially after application of high temperature and pressure, thus were used for the production of conveyor belts, hoses and V-belts	S. Luepfert, F. Roethemeyer, E. Maeder, Eur. Pat. Appl., 580076, 26 Jan 1994; German Patent 4,223,984, 27 Jan 1994, Appl. 21 July 1992, to Continental A.-G.

Table 18.11 (continued)

Year	Development	References
1992	Polyolefin compositions with improved toughness, flexibility, and high clarity were prepared by blending 90–95 wt% setereoregular polymer or copolymer of 4-methyl-1-pentene, PMP, with polybutene, PB, having $M_n < 500$	M.J. Hagenson, H.F. Efner, L.C. Hasselbring, W.H. Beever, Eur. Pat. Appl., 556,843, 25 Aug 1993, Appl. 20 Feb 1992, to Phillips Petroleum Co.
1992	Polyolefin (PO = PP, HDPE, EPR, or PMP) was blended with an impact modifier, 0.1–5 wt% colorant and/or 5–50 wt% of opacifiers, and a styrene–diolefin block copolymer, grafted with 1–6 mol% of acrylic acid, maleic anhydride, or sulfonate functionality (SEBS, SEPS, radial SEB, or SEP). To improve scratch resistance the blend contained 100–3,000 ppm Zn stearate and 16–22C fatty acid amide. The alloys were injection molded into parts showing impact, scratch, and abrasion resistance. They were used to manufacture interior trim for vehicles and in other applications where a scratch- and scuff-resistant plastic material is required	J. O'Leary, S. Musgrave, PCT Int. Appl., WO 93 21,269, 28 Oct 1993; Australian Patent 93 36,840, 10 Oct 1993; Australian Patent 93 40,363, 18 Nov 1993, Appl. 09 Apr 1992, to ICI Australia Operations Proprietary Ltd.
1992	To prepare polyolefin blends, PO (e.g., EVAc, PE, PP, EPR), with vinyl polymers, 10–200 parts of vinyl monomer [e.g., (meth)acrylates, styrenics, vinyl chloride, glycidyl methacrylate, maleic anhydride, acrylonitrile, divinylbenzene] and 0.01–4.0 parts of a free radical initiator were used to impregnate 100 parts of PO particles at $T = 20$–130 °C. After 50–99 wt% of the monomer was absorbed, the particles were dispersed in water and the free radical polymerization initiated. Good adhesion between the components in the extruded or molded articles was achieved	T. Vestberg, I. Lehtiniemi, U.S. Patent 5,300,578, 05 Apr 1994, U.S. Appl. 27 Jan 1993, Fin. Appl. 27 Jan 1992, to Neste Oy
1992	Polyolefin, PO, blends with copolymers of vinyl acetate and acrylate esters, EVAc (20–40 wt% VAc), were extruded into films, weldable by high-frequency currents. It replaced PVC flexible films, e.g., in inflatable goods. For example, 400 μm PVC film, inflated to 100 m bars, after 13 days, had lost 72 wt% of the pressure, while the new blends (15 wt% VAc in the blend) of 200 μm film lost 50 wt% in 19 days	G. Benatre, French Patent 2,688,511, 17 Sep 1993, Appl. 13 Mar 1992
1992	Polyolefin, PO, molding compositions, suitable for the use in automotive application, comprised polyolefin wax [$M_w = 1$–50 kg mol^{-1}, $M_w/M_n = 1.8$–4.0, and $T_m = 120$–160 °C] and 1–80 wt% of either a PO [$M_w \geq 100$, $M_w/M_n = 1.8$–4.0, and $T_m = 120$–160 °C], an olefinic copolymer derived from at least two different olefins [$M_w \geq 100$, $M_w/M_n = 1.98$–4.0, and $T_m = 90$–160 °C], or an elastomer with $T_g < -20$ °C. The blends could be impact modified by incorporation of a copolymer. They were molded, extruded, or blow molded into articles showing high modulus, hardness, scratch resistance, and low shrinkage	B. Bachmann, A. Winter, European Patent 563,818, 6 Oct 1993, Appl. 31 Mar 1992, to Hoechst A.-G.

<div align="right">(continued)</div>

Table 18.11 (continued)

Year	Development	References
1992	Blends of PE (selected from VLDPE and/or LLDPE), with 13–17 wt% ethylene–butene plastomer copolymer [Mitsui's TAFMER™, $\rho < 900\,\mathrm{kg\,m^{-3}}$, $T_\mathrm{m} = 55$–$85\,^{\circ}\mathrm{C}$], and 35–50 wt% ethylene–vinyl acetate copolymer, EVAc, were used for film blowing, useful as packaging materials for foods. The film had shrink properties in MD and TD similar to those of EVAc film and plastic orientation properties similar to those of VLDPE films. In the U.S. Patent the biaxially oriented heat-shrinkable multilayer stretch film comprising 65–80 wt% VLDPE and a plastomer was reported useful as poultry wrap	B.L. Wilhoit, European Patent 562,493, 29 Sep 1993; Ralph, D. J., U.S. Patent 5,279,872, 18 Jan 1994, Appl. 17 Feb 1993, Appl. 23 Mar 1992, to Viskase Corp.
1992	Polyolefin, PO [of ethylene, propylene, butylene, 4-methylpentene, and their copolymers with 1-alkenes, vinyls, (meth)acrylates – preferably PP], was grafted at a ratio 1:9–4:1 with 1–20 wt% of (meth)acrylic acid and ≥ 30 wt% of styrene and/or alkyl- and/or halo-substituted styrene, methacrylic ester, and 0–60 % of other comonomers [e.g., vinyl aromatic, ester], at least some of the acid units of methacrylic acid and/or acrylic acid bearing a charge and being associated with non-polymeric counterions [e.g., 90 % methyl methacrylate, 5 % butyl acrylate, and 5 % methacrylic acid with either Ca^{2+} or Mg^{2+}. The ionomer could be blended with PO either during or after manufacturing. The blends were extruded either directly or after pelletization. They exhibited high sag resistance without increased viscosity. PP fibers could be used for strapping, netting, slit tape, rope, twine, bags, carpet backing, foamed ribbons, upholstery, rugs, pond liners, awnings, swimming pool covers, tarpaulins, bristles, sutures, nonwoven fabrics, bedsheets, bandages, diaper liners, etc.	R.G. Hamilton, M.T. McCarty, Eur. Pat. Appl., 589,659, 30 Mar 1994; U.S. Patent 5,319,031, 07 June 1994; Candian Patent 2,106,344, 25 Mar 1994; British Patent 93 03,861, 31 May 1994; Japanese Patent 62 012,048, 02 Aug 1994, Appl. 24 Sep 1992, to Rohm and Haas Co.
1992	Polyolefin blends comprised 25–95 wt% of a crystalline random copolymer, EPR1 (of propylene with ethylene and/or an alpha-olefin), and 5–75 wt% of a mixture consisting of PE and EPR2. The density of EPR1 was about equal that of the mixture. The blends had good transparency and impact resistance even at low temperatures and were used to manufacture food containers, medical, packaging films, etc.	G. Cecchin, R. Ghisellini, D. Malucelli, European Patent 557,953, 01 Sep 1993, Appl. 24 Feb 1992, to Himont, Inc.
1992	Nonwoven textile materials comprised fibers obtained from a blend of 5–95 wt% propylene, PP (or propylene/ ethylene copolymer with ≤ 10 wt% ethylene, EPR), and 95–5 % polyolefin, PO, selected from EPDM, EPR, LLDPE, etc. The materials have been used in disposable personal hygiene products or protective clothing. The products showed improved strength, drapability, softness, and bonding performance	K. Ogale, M.E. Strasinic, Eur. Pat. Appl., 598,224, 25 May 1994, Appl. 15 Oct 1993; Canadian Patent 2,108,819, 01 May 1994; Japanese Patent 62 00,093, 19 July 1994; U.S. Patent 5,346,756, 13 Sep 1994, Appl. 30 Oct 1992, to Himont Inc.
1992	Polypropylene, PP, was blended with a random crystalline terpolymer of 96–85 wt% propylene, 1.5–5.0 wt% ethylene, and 2.5–10 wt% 4–8C alpha-	L. Clementini, A.F. Galambos, G. Lesca, K. Ogale, L. Spagnoli, M.E. Starsinic, L. Giuseppe,

<div align="right">(continued)</div>

Table 18.11 (continued)

Year	Development	References
	olefin. The blends were used to manufacture strands of multiple monofilaments or staple fibers with high resiliency and shrinkage, for pile fabric, textiles, geotextiles, or carpets. The carpet yarn had a twist retention of over 30 %, shrinkage on heat setting at 143 °C of at least 15 %, and uniform shrinkage	European Patent 552,810, 28 July 1993, Appl. 29 May 1992, to Himont Inc.
1992	Blends comprising polypropylene, 50–97 wt% PP [or a PP block copolymer with ethylene block], and 50–53 wt % of an ethylene/4–18C alpha-olefin copolymer [α-olefin content = 10–60 wt%, $\rho \leq 913$ kg m^{-3} obtained by using a metallocene catalyst and aluminoxane] were found useful as automobile trims and trims of electrical instruments. They showed high moldability, improved impact resistance at room and low temperature, and balance of rigidity and impact resistance	K. Shichijo, Eur. Pat. Appl., 593,221, 20 Apr 1994; Japanese Patent 61 92,500, 12 July 1994, Appl. 15 Oct 1992, to Mitsubishi Petrochemical Co., Ltd.
1992	A multilayer film comprised polypropylene, PP [or PP copolymer with 20–40 wt% hydrocarbon resin], in the core; outer layers from PP, LLDPE, PB, or their blends with 4–15 wt% PP; and the intermediate layers from polyolefin-based carboxylic acid or maleic anhydride. An oxygen barrier layer from EVAL, PVDC, PEST, or PA could also be used. The films were biaxially oriented at ratios of 3:1–8:1. They had low moisture transmission rate, toughness, abrasion resistance, good clarity and gloss, suitable as moisture barrier packaging for food, pharmaceuticals, and electronics	P.S. Gautam, Eur. Pat. Appl., 588,667, 23 Mar 1994, Appl. 20 Sep 1993; Br. Pat. Appl., 93 03,823, 22 Mar 1994; Australian Patent 93 47,378, 24 Mar 1994; Canadian Patent 2,106,258, 19 Mar 1994; Japanese Patent 61 98,826, 19 July 1994, U.S. Appl. 18 Sep 1992, to W. R. Grace & Co.
1992	Ternary blends contained 87–96 wt% LLDPE (with either butene-1, hexene-1, or octene-1), 1–10 wt% isotactic polybutene, 1–10 wt% PS, and 0.01–10 wt% color and anti-blocking agents. The blends exhibited improved process efficiency in terms of extruder amps/ rpm ratio, while the terpolymer substantially retained the inherent strength of the LLDPE. The compositions were used for blown films and for the manufacture of waste bags	S.P. Evans, P.P. Shirodkar, US 5,258,463, 02 Nov 1993, Appl., 24 Aug 1992, to Mobil Oil Corporation
1992	Semicrystalline polyolefin blends were prepared by mixing two different random copolymers of propene with 4–10C alpha-olefin at a ratio from 1:3–1:1. The first copolymer contained 1–10 wt% of C$_{4–10}$ alpha-olefin (1-butene, 1-pentene, 1-hexene, 1-octene, and 4-methyl-1-pentene), whereas the second 15–40 wt% of the same comonomer. The mixing was carried out in reactors, polymerizing the monomers in the presence of stereospecific catalysts supports on active magnesium dihalides, in at least two sequential stages. The resulting R-TPOs showed limited	G. Cecchin, F. Guglielmi, European Patent 560,326, 15 Sep 1993, Appl. 10 Mar 1992, to Himont Inc.

(*continued*)

Table 18.11 (continued)

Year	Development	References
	solubility in xylene, low heat-sealing temperature, and high melting point and were used for the production of heat-sealable laminated mono- or bi-oriented films suitable for the food industry	
1992	PE blends were prepared during polymerization. This strategy has been widely implemented in syntheses of multimodal PE compositions. The blown film showed MD/TD tear balance. The bimodal blend contained 0.35–0.75 weight fraction of a higher-MW component	Ali et al. (1994); Dammert et al., U.S. Patent 6,185,349 of 06 Feb 2001 (filed 1999) to Borealis Polymer Oy
	Ali A.H. et al. to Mobil Oil Co.; Dammert et al. to Borealis. Catalyst: $TiCl_4$/pentanol deposited on MgO/acetic acid and then treated with tri-n-hexyl-aluminum solution	
	Reactor blending during the slurry polymerization gave two PE fractions with different MW. Borealis generated multimodal resins for optical cables using slurry-/gas-phase reaction with Z-N catalyst with $MgCl_2$	
1993	Polyethylene blends comprised a low-density polyethylene, ≤60 wt% either LDPE or LLDPE; postconsumer recycled high-density polyethylene, 4–30 wt% HDPE; and an effective amount of a compatibilizer comprising 0.1–1.5 wt% ZnO and 0.1–2 wt% of glycerol monostearate. The blends could also contain 5–30 pph of a blowing agent. The blends were used to make aesthetically appealing foamed products for use as cushioning materials or as packaging films	S.-T. Lee, U.S. Patent 5,428,093, 27 June 1995, Appl. 05 Nov 1993, to Sealed Air Corporation
2003	Polymer blends (mechanical) comprised (A) 35–85 wt% Z-N i-PP ($T_m > 130\,°C$) and (B) 30–70 wt% metallocene α-olefin-co-PP with crystallizable α-olefin sequences [narrow MWD, composition distribution single T_m]. The blends showed improved processing, unexpected compatibility, single T_m, and increased tensile strength	S. Datta, C. Cozewith, P. Ravishankar, E.J. Stachowski, Elastic blends comprising crystalline polymer and crystallizable polymers of propylene, U.S. Patent 6867260 of 15 Mar 2005 (filed 22 Apr 2004; priority 29 June 1999, U.S. Patent 6642316); Datta et al. (2006)
	Datta, Cozewith, Ravishankar, Stachowski, Gadkari to ExxonMobil Chemical Patents, Inc.	
	The (A) component is either i-PP with <10 wt% comonomer, while (B) is preferably crystallizable C_2–C_3 copolymer. Blends were mechanically mixed	
	ExxonMobil developed poly(propylene-co-ethylene) Vistamaxx™ post-metallocene resin. The polymerization procedure for the blend component is described in U.S. Patents 5198401 of 30 Mar 1993 and 5057475 of 15 Oct 1991; catalyst system of enhanced productivity, 5153157 of 06 Oct 1992, to Exxon Chem	
2004	The copolymers of the blend were prepared using (a) a silyl chromate catalyst, $(R_{10})3Si-O-CrO_2-O-Si(R_{10})_3$ wherein $R_{10} = C_{1-10}$ alkyl, and (b) a phosphinimine catalyst, $(L)_n$-M-$(PI)_m(X)_p$ where M = Ti, Hf, or Zr;	Kazakov Alexei, Yim Gary, Polyolefin blends and pipe, CA 2508436, filed 26 May 2005; U.S. Patent 7,309,741 of (filed

(*continued*)

Table 18.11 (continued)

Year	Development	References
	PI = phosphinimine ligand; ligand L = Cp, indenyl, or fluorenyl; X = Cl or C_{1-4} alkyls; $m = n = 1$; and $p = 2$. A catalyst activator includes alumoxanes (e.g., MAO) with a molar ratio of Al:M = 50:1–250:1 and ionic boron-containing activators. Kazakov and Yim, to NOVA Chemicals	01 June 2004); U.S. Patent Appl. 2008/0090040A1 (filed 14 Nov 2007, priority 01 June 2004) now U.S. Patent 7696281 of 13 Apr 2010 to NOVA CHEMICALS CORPORATION (Canada) or NOVA Chemicals (International) S.A.
	The invention describes PE blends of a low-MW HDPE made using a Z-N-type or Cr-based catalyst and a high-MW m-LLDPE made using a Group 4 single-site-type catalyst. The blends are suitable for the manufacture of pipes, tested according to ASTM D 2837 or ISO 9080	
	A polyolefin blend comprises (a) 30–80 wt% of a low-MW copolymer [85–99.5 wt% of C_2 and 0.05–15 wt% of C_{4-8} α-olefin, $\rho = 0.953$–0.965 g mL^{-1}, and MFR (2.16 kg 190 °C) = 0.1–20.0 g/10 min] and (b) 70–20 wt% of a high-MW copolymer [85–99.9 wt% of C_2 and from 15 to 0.1 wt% of C_{4-8} α-olefin, $\rho = 0.915$–0.940 g mL^{-1}, and an MFR (21.6 kg 190 °C) = 0.05–5.0 g/10 min]. The selected resins were blended in a compounder and then extruded as pipes	The ionic activators are disclosed in, e.g., U.S. Patents: by James C. Stevens, David R. Neithamer, 5132380 of 21 July 1992 (filed 12 Sept 1991), to Dow Chem. Co.; and by Howard W. Turner, Gregory G. Hlatky, Richard R. Eckman, 5198401 of 30 Mar 1993 (filed 30.07 1991) to Exxon Chemical Patents Inc.
2009	Solution polymerization of HDPE ($\rho = 0.890$–0.970 g mL^{-1}) takes place in ≥2 reactors. The process (a) provides a first C_2 and C_{4-10} feed to ≥1 continuously stirred tank reactor (CSTR) in the presence of a catalyst, producing a first PE component; (b) the second (tubular) reactor (TR) is fed with the first PE solution, enriched by preheated $T \geq 100$ °C monomer(s) and solvent. The weight ratio of the additional solvent to C_2 = 20/1–0.1/1, and the additional C_2 = 1–50 wt% of the C_2 added to CSTR	L.M.J. Van Asseldonk, S.J. Brown, Multi reactor process, CA 2,688,217 of 11 June 2011 (filed 11 Dec 2009); US 8,101,693 B2 of 24 Jan 2012 (filed 06 Dec 2010; priority 2009) to NOVA Chemicals (International) S.A.
	Asseldonk and Brown, from NOVA Chemicals (International) S.A.	
	This document describes a process with one CSTR and one TR, but a single STR may also be used – in the former case a catalyst should be injected to each reactor. While the main catalyst is Z-N type, use of a single-site one may offer additional advantages blending homogeneously and heterogeneously branched chains	
	This multi-reactor system used for copolymerization of C_2 with higher α-olefins comprises a CSTR connected in series to a tubular reactor (TR). The latter receives a polymer solution from the CSTR. Polymerization in TR improves efficiency, by reducing the amount of energy required to recover the polymer and residual comonomer from the solution. The use of preheated C_2 in TR mitigates the contaminating gel problems (fouling TR and creating "fish eyes" on film) and reduces hexane extractables	

Table 18.12 Patented polyolefin blends

Year	Development	References
1937	This first patent on the use of rubber for toughening polyolefins disclosed addition of rubber "as a softening agent" to "saturated, linear hydrocarbons of the linear type, the mean molecular weight of which is greater than that of paraffin, e.g., between 800 and 500,000"	P.J. Gaylor, Standard Oil Development Co., French Patent 812,490, 11 May 1937
1942	High-pressure, low-density polyethylene, LDPE, was blended with cyclorubber, to give compounds useful for bonding polyethylene to metal	C.L. Child, R.B.F.F. Clarke, B.J. Habgood, British Patent 544,359, 09 Apr 1942
1951	Discovery of isotactic polypropylene, PP, was immediately followed by search for low-temperature impact improvement, initially by blending with either polyethylenes or elastomers, later by copolymerizing with ethylene and dienes into EPR and EPDM	J.P. Hogan, R.L. Banks, U.S. Pat. Appl., 333,576, filed 27 Jan 1953, to Phillips Petroleum Co.
1958	Low-density polyethylene, 5–120 parts LDPE, was blended with chlorosulfonated polyethylene, 100 parts CSR, with or without curing agent (tribasic lead maleate). The blends found were used as smooth, non-tacky, tough films or coatings for natural or synthetic rubbers	V.C. Boger, A.G. Thomas, U.S. Patent 2854425, filed 30 Sept 1958, to B. F. Goodrich Co.
1958	Polypropylene, PP, was blended with 5–50 parts of chlorinated butyl rubber, CBR, in the presence of a non-peroxide curative (e.g., oxides or sulfides of Zn, Cd, Mn, Fe, or Pb) on a roll mill at 138–157 °C. The dynamic vulcanization resulted in materials useful for high tensile strength applications	A.M. Gessler, W.H. Haslett Jr., U.S. Patent 3037954, 05 June 1962, Appl. 15 Dec 1958, to Esso Research & Engineering Co.
1958	To improve the low-temperature flexibility of polypropylene, PP, it was blended with polyisobutylene, 5–20 wt% PIB. The Montecatini patent was the first one on the low-temperature modification of PP. In the Esso patent, butyl rubber, BR, was incorporated. In the Sun Oil patent, 50–95 wt% PP (MW = 4 Mg mol^{-1}) was blended with PE (MW = 1.6 Mg mol^{-1}) for high impact strength and low brittleness temperature. In BASF patent 0.5–40 wt% PIB (with narrow molecular weight distribution) was used	F. Ranalli, Italian Patent 583,501, 14 Oct 1958, to Montecatini S. G.; K. Schramm, U.S. Patent 2,939,860, 07 June 1960; Esso Res. & Eng. Co., British Patent 893,540, 11 Apr 1962, Appl. 1960; Sun Oil Co., British Patent 952,089, 11 Mar 1964, Appl. 9 Aug 1960; H. Merkel, G. Cramer, German Patent 1,145,791, 21 Mar 1963, Appl. 1961, to BASF A.-G.
1958	First polyethylene–polyethylene, PE/PE, blends were patented; both cross-linked (using electron accelerators) and uncross-linked components were disclosed. In Phillips patent, low-density polyethylene, LDPE, was blended with linear low-density polyethylene, LLDPE, for improved stiffness and abrasion resistance and reduced water vapor permeability. In the Celanese patent, improvement of processability was particularly stressed. In the DuPont patent, 10–50 wt% LLDPE was used with LDPE or its copolymers for generating heat-shrinkable films	P.J. Canterino, R. J. Martinovich, U.S. Patent 3,086,958, 23 Apr 1963, Appl. 1958; W.M. Nelson, Belgian Patent 647,311, 29 Oct 1964, Appl. 1963, to Phillips Petroleum; W. R. Grace & Co., British Patent 904,985, 05 Sep 1962, Appl. 1960; Wissbrun et al. (1962, 1965), Appl. 1961, to Celanese; Golike, R. C., Belgian Patent 619,351, 27 Dec 1962, Appl. 1961, to du Pont de Nemours

Table 18.12 (continued)

Year	Development	References
1958	The first PE/PE blends were patented by du Pont de Nemours, Phillips, Celanese, and DuPont of Canada Ltd. The first were LDPE/HDPE blends, but later LLDPE/LDPE blending dominated the film-blowing application. Even a small amount of LDPE significantly improved LLDPE processability as well as the heat sealing, puncture resistance, tensile, and optical properties. However, for >35 % LLDPE in LDPE modification of film-blowing line was needed. Also LLDPE/LLDPE blends with broad MWD showed improved processability and performance	M. J. Roedel, U.S. Patent 2983704 of 09 May 1961 to du Pont de Nemours (priority 1955); P. J. Canterino, R. J. Martinovich, U.S. Patent 3,086,958, 23 Apr 1963, Appl. 1958; Nelson. W. M., Belgian Patent 647,311, 29 Oct 1964, Appl. 1963, to Phillips Petrol.; W. R. Grace and Co., British Patent 904,985, 05 Sept 1962, Appl. 1960; K. F. Wissbrun, R. H. Ball, P. J. Rossello, Belgian Patent 614,282, 22 Aug 1962; British Patent 994,376, 10 June 1965, Appl. 1961, to Celanese; R. C. Golike, Belgian Patent 619,351, 27 Dec 1962 (filed 1961); R. M. Lillis, C. van Thomas, U.S. Patent 3998914 of 21 Dec 1976 (filed in 1974), to du Pont of Canada Ltd; J. Nancekivell, Canad. Plast., May 1982, 27–30, ibid., Sept 1985, 27–32; L. A. Utracki, Commercial Polymer Blends, 658 pg., Chapman and Hall, London (1998); Anon., Canad. Plast., March 1984, 18–20
	The first PE/PE blends were disclosed by Phillips Petroleum in 1958. In the patent, LDPE was blended with LLDPE for improved stiffness and abrasion resistance and reduced H2O vapor permeability. The most important was the gage reduction by 15–30 % for plastic bags, sacks, and stretch films. By 1980 ca. 42 % of film producers used immiscible LLDPE/LDPE blends. The PE miscibility refers to the molten and solid states	
	In the DuPont patent of 1961, 10–50 wt% LLDPE was used with LDPE or its copolymers for generating heat-shrinkable films. In the 1965 Celanese patent, improvement of processability was particularly stressed. The 1976 DuPont Canada patent specified density of the two components as ρ = 0.950–0.965 and 0.910–0.945 g ml^{-1}, the MI = 0.1–10 with less than 30 wt% of LDPE. In 1983 UCC started selling LLDPE/LDPE blends for check-stand sacks	
	Most PE blends are immiscible, e.g., LLDPEs C$_{2+6}$ prepared with Ti-based catalyst are immiscible with one based on V catalyst	
1958	Low-density polyethylene, LDPE, was blended with polyisobutylene, 25–40 wt% PIB, and a copolymer of styrene and isobutylene, 0–10 wt% PSIB, for the use as transparent, impermeable, shrink-wrap packaging films. In the Phillips patent, LLDPE was blended with PIB to manufacture grocery bags. In the BASF patent, a pre-blend comprising 60 wt% PIB and LDPE was granulated and subsequently compounded with LDPE	J. R. Briggs, R. G. Newburg, R. E. Clayton, U.S. Patent 2,854,435, 30 Sep 1958, to Esso Res. and Eng.; R. J. Martinovitch, R. P. March, U.S. Patent 3,074,616, 22 Jan 1963, Appl. 1959, to Phillips Petroleum; H. Dietrich, German Patent 1,288,293, 30 Jan 1969, Appl. 1961, to BASF A.-G.
1958	The first patent on polyamide/polyolefin, PA/PO, blends comprised 10–80 wt% of either PA-6 or PA-66 with either LDPE or PP. The resins, used to produce sheets, films, fibers, or bottles, were claimed to show excellent processability, good printability, and low permeability	R. B. Mesrobian, C. J. Ammondson, British Patent 889,354, 14 Feb 1962, Appl. 1958, to Continental Can Co., Inc.

Table 18.12 (continued)

Year	Development	References
1959	Partially cross-linked polyethylene (by either peroxides or irradiation), XLPE, was blended with polybutadiene, 5–40 wt% BR, to improve resistance to cut at elevated temperatures and elongation. The blends were found suitable for wire coating	Q. P. Cole, U.S. Patent 2,912,410, 10 Nov 1959, to General Electric Co.
1959	Polyethylene, PE, blended with immiscible polymers (e.g., PVC, PIB, PS) was compatibilized by addition of graft copolymer (e.g., styrene or vinyl acetate grafted on PE)	Houillières du Bassin-du-Nord et du Pas-de-Calais and Ethylene-Plastique, French Patent 1,193,104, 30 Oct 1959
1959	Polypropylene, PP, was blended with 5–20 wt% elastomer [styrene–butadiene, SBR, or butadiene–acrylonitrile, NBR] to produce materials useful for blow molding of bottles, free from brittleness and stress cracking. In the later patent, EPR, BP, and PIB, with a dicarboxylic acid anhydride, were used	Shell International Research Maatschappij N. V., British Patent 873,227; 933,727, 14 Aug 1963, Appl. 27 Aug 1959; Belgian Patent 611,727, 19 June, 1962, Appl. 21 Dec 1960
1959	For improved processability and mechanical properties of polyethylene, HDPE or LLDPE, it was blended with elastomeric polyethylene–polypropylene copolymer, EPR. For further enhancement of properties, either polypropylene, PP, or polybutene, PB, could also be added. In ICI patent, HDPE was blended with 30–60 wt% EPR for improved processability and impact strength	L. Corbellini, German Patent 1,137,859, 11 Oct 1962, Appl. 1959, to Montecatini SG.; J. W. Crawford, W. G. Oakes, British Patent 941,083, 06 Nov 1963; German Patent 1,217,608, 16 May 1966, Appl. 1961, to Imperial Chemical Industries Ltd.
1960	These are the first patents on polypropylene, PP, blended with ethylene–propylene rubbers, 10–60 wt % EPR, for improvement of the low-temperature impact strength. In Esso patent, PP was blended with varying amount of polyisobutylene, PIB, and polyethylene, LDPE, to give marked improvement in tear strength and impact. In Shell patent, reactor powder blending of PP with 0.1–10 wt% EPR (2–25 wt% ethylene) was disclosed. In Farbwerke Hoechst patent, PP was blended with 5–70 wt% LLDPE, for good mechanical properties at low temperature	W. M. Schilling, U.S. Patent 3,200,173, 10 Aug 1966, Appl. 1960; British Patent 975,877, 18 Nov 1964, Appl. 1962, to Hercules Powder; Esso Res. and Eng., British Patent 950,551, 26 Feb 1964, Appl. 21 Aug 1961; G. A. Short, U.S. Patent 3,354,239, 21 Nov 1967, Appl. 1962, to Shell Oil Co.; R. Holzer, K. Mehnert, German Patent 1,145,792, 21 Mar 1963, Appl. 23 Jan 1960, to Hoechst A.-G.
1960	Polyethylene, PE; polypropylene, PP; and their homologues were blended with ethylene–vinyl acetate, EVAc, copolymer and cured with free radicals into products showing desired impact strength and modulus. The blends were used for manufacturing of fibers, films, or moldings	Monsanto Co., British Patent 967,334, 19 Aug 1964, Appl. 27 Apr 1960
1960	Blends of polyethylene, PE, with 0.1–50 wt% of copolyamides (e.g., LDPE with 5 wt% PE–PA-6 copolymer) showed higher gloss, transparency, and elasticity; lower stress corrosion; and reduced permeability	H. Craubner, G. Illing, A. Hrugesch, German Patent 1,138,922, 31 Oct 1962, Appl. 1960, to Badische Anilin und Soda-Fabrik A.-G.

(*continued*)

Table 18.12 (continued)

Year	Development	References
1960	Mechanical properties of polyolefins were improved by blending them with 0.5–50 wt% polycarbonate, PC. For example, LLDPE + 5 wt% PC showed improved impact strength, modulus, hardness, and HDT	H. Peters, F. Schuelde, German Patent 1,146,251, 28 Mar 1963, Appl. 22 Jan 1960, to Farbwerke Hoechst A.-G.
1960	To improve dyeability, flexibility, and toughness of isotactic polypropylene, PP, it was compounded in a Banbury-type mixer with ethylene–vinyl acetate, 7 wt% EVAc. Several other ethylene copolymers were also used. In Miliprint patent, EVAc or ethylene–ethyl acrylate copolymer, 18–32 wt% EVAc or EEA, was found to improved impact strength, elongation, and low brittleness temperature of PP. In Firestone patent, linear polybutadiene, BR, was used. The Mitsubishi patent disclosed improvements of PP impact strength properties by blending it with 0.5–25 wt% ethylene–aliphatic esters, e.g., EVAc	H. P. Holladay, I. O. Salyer, U.S. Patent 3,433,573, 18 Mar 1969, Appl. 1960, to Monsanto; A. Miller, N. G. Reddeman, Belgian Patent 620,703, 14 Nov 1962, Appl. 27 July 1961, to Miliprint; R. J. Reid, W. R. Conard, Belgian Patent 617,870, 21 Nov 1962, Appl. 19 May 1961, to Firestone; R. Sakata, T. Kuroda, K. Masuda, Y. Nakayama, M. Tanaka, Japanese Patent 003,964, 13 Feb 1968, Appl. 1964, to Mitsubishi Petrochem
1961	High-density polyethylene, HDPE, was blended with 15 wt% ethylene–propylene copolymer, EPR. The blend had good impact resistance	Farbwerke Hoechst A.-G., Belgian Patent 589,358; 612,855, 19 Jul. 1962, Appl. 19 Jan 1961
1961	Polyethylenes, HDPE, LDPE, or LLDPE, blended with styrene–acrylonitrile copolymer, 2–6 wt% SAN, showed improved crack resistance. Furthermore, a synergistic behavior was observed when 0.1–1 wt% 2,4,6-tri-alkyl phenol was also added. In Esso patent, the mechanical properties of PE were improved by blending it with 5–25 wt% copolymers of mono- and diolefins, EPDM	A., L. Jankens, Belgian Patent 625,004, 20 May 1963, Appl. 24 Nov 1961, to Dow Chemical Co.; M. Prillieux, P. Delbende, M. Moulin, French Patent 1,289,580, 06 Apr 1962, Appl. 1961, to Esso Standard S. A.
1961	Blending two chlorinated LLDPEs, CPEs with 40 and 70 wt% Cl, resulted in materials with good moldability, impact resistance, and thermal stability	A.-G. Farbwerke Hoechst, Belgian Patent 621,775, 27 Feb 1963, Appl. 1961
1961	Polypropylene, PP, was blended (without compatibilizer) with a linear low-density polyethylene, 20–40 wt% LLDPE, for improved impact resistance and low brittleness temperature	Esso Research & Engineering Co., British Patent 934,640, 21 Aug 1963, Appl. 13 Feb 1961
1961	These are the first patents on PP/PE/EPR blends. Polypropylene/polyethylene, PP/PE, blends were compatibilized by addition of ethylene–propylene copolymer, EPR. The resulting blends showed improved low-temperature brittle point and Izod impact strength. In UCC patent, 50–96 wt% was blended with 2–25 wt% PE and 2–25 EPR and/or PIB	L. S. Rayner, J. A. Bond, M. Clark, R. E. Nott, British Patent 958,079, 13 May 1964 Appl. 1961; British Patent 1,026,254, 1966, to ICI; J. P. Lehane, Jr., U.S. Patent 3,137,672, 16 Jun. 1964, Appl. 1962, to Hercules Powder; W. M. Jayne, Jr., U.S. Patent 3,256,367, 14 June 1966, Appl. 1962, to Union Carbide Corp.

(continued)

Table 18.12 (continued)

Year	Development	References
1962	Polyethylene, LDPE, or its copolymers when blended with poly-1-butene, PB, showed improved processability and resistance to environmental stress cracking	A. Rudin, H. P. Schreiber, French Patent 1,349,823, 17 Jan 1964, Appl. 23 Mar 1962, to Canadian Industries Ltd.
1963	Isotactic polypropylene, PP, was blended with syndiotactic polypropylene, 3–50 wt% sPP. The blends showed excellent impact strength at low temperature and freedom from surface crazing upon repeated flexing	D. D. Emrick, U.S. Patent 3,268,627, 23 Aug 1966, Appl. 16 May 1963, to Standard Oil Co.
1963	Polypropylene, PP, was compatibilized with polyethylene, PE, by grafting PP with a basic monomer and PE with an acidic monomer, then blending the modified polymers. Thus, PP was modified with dimethylamino ethyl methacrylate while PE with methacrylic acid. These were blended in 1:1 ratio to result in high-performing alloys	R. Langworth, U.S. Patent 3,299,176, 17 Jan 1967, Appl. 24 June 1963, to E. I. du Pont de Nemours & Co.
1963	Impact properties of polyethylenes, HDPE, LDPE, or LLDPE, were improved by blending them with ethylene–propylene–diene terpolymer, EPDM, and with polypropylene PP, or polybutene, PB	H. P. Schreiber, British Patent 1,037,819; 1,037,820, 03 Aug 1966, Appl. 1963, to Canadian Industries Ltd.
1963	Polyethylene, LDPE, or polypropylene, PP, were blended with 1–10 wt% polyoxymethylene, POM, for improved melt flow properties, processability, and extrudate appearance	A. Rudin, H. P. Schreiber, Canadean Patent 688,416; 688,578, 09 June 1964, Appl. 18 May 1963, to Canadian Industries Ltd.
1964	Polyethylene, 10–81 wt% LDPE, was blended with butyl rubber, 15–50 wt% BR, and ethylene–vinyl acetate copolymer, 4–40 wt% EVAc, for cold molding of sealing gaskets	R. J. Ceresa, N. E. Davenport, T. L. Trudgian, British Patent 1,112,024, 01 May 1968, Appl. 1964, to W. R. Grace and Co.
1965	Polypropylene, PP, was blended with polybutadiene, 5–15 wt% PB, and linear polyethylene, 2–15 wt% LLDPE or HDPE. Good balance of properties was claimed	I. Aijima, H. Sakurai, T. Koseki, Japanese Patent 011,539, 27 May 1969, Appl. 09 July 1965, to Asahi Chemical Industry Co., Ltd.
1966	Polyethylene, PE, was blended with ethylene–methacrylic acid copolymer, 80 wt% ionomer, and ethylene–vinyl acetate, 10 wt% EVAc, to give films with high toughness, stiffness, and impact resistance	M. C. K. Willott, British Patent 1,118,545, 03 July 1968, Appl. 1966, to Imperial Chemical Industries, Ltd.
1966	To improve the low-temperature impact strength of polypropylene, PP, it was blended with a small amount of polyethylene, HDPE, and ethylene–propylene block copolymer, EP	Asahi Chemical Industry Co., Ltd., British Patent 1,154,447, 11 June 1969, Appl. 02 Feb 1966
1967	Polyethylene, PE, was blended with 1–95 wt% styrene–butadiene or p-methylstyrene–isoprene block copolymer, to improve stress crack resistance	S. Minekawa, K. Yamaguchi, K. Toyomoto, E. Fujimoto, Y. Takeuchi, Japanese Patent 016,429, 06 May 1971, Appl. 15 Mar 1967, to Asahi Chemical Ind. Co., Ltd.

(*continued*)

Table 18.12 (continued)

Year	Development	References
1968	Polyolefin, PP or PE, blended with polyvinyl alcohol, 2 wt% PVAl, showed good mechanical, hygroscopic, and antistatic properties, for the manufacturing of films, fibers, tubes, and coatings	S. Minekawa, K. Yamaguchi, K. Toyomoto, E. Fujimoto, Y. Takeuchi, Japanese Patent 008,585, 12 Sep 1969, Appl. 25 Jan 1968, to Asahi Chemical Ind. Co., Ltd.
1968	Polymer alloys were prepared by blending polyethylene, PE, or its copolymers with lactams, then polymerizing these. For example, ethylene–vinyl pyrrolidinone copolymer, EVP, was blended with ε-caprolactam for molding application	R. W. Hill, R. P. Anderson, S. V. Scroggins, U.S. Patent 3,539,662, 10 Nov 1970, Appl. 12 July 1968, to Gulf Research and Development Co.
1968	Polyolefins, PP or HDPE, were blended with amorphous ethylene copolymer, 5–100 EVAc, and 1–80 parts of either polyoxymethylene, POM; polymethylmethacrylate, PMMA; polystyrene, PS; or styrene–methyl methacrylate copolymer, SMM (as well as inorganic fillers) to extrude into paperlike films	S. Yamamoto, S. Honda, H. Shimizu, Japanese Patent 043,468; 043,469; 043,470, 23 Dec 1971, Appl. 26 Jan 1968, to Sekisui Chemical Co., Ltd.
1968	Polypropylene/polyethylene, PP/PE, blends were compatibilized by addition of ethylene–propylene block copolymer, EPR. The resulting blends showed improved low-temperature impact strength	H. J. Leugering, H. Schaum, South African Patent 004,328, 08 Jan 1970, Appl. 1968, to Farbwerke Hoechst A.-G.
1968	Polypropylene, PP, or polyethylene, PE, was blended with ethylene–propylene copolymer, EPR, and ethylene–acetoxybicycloheptene copolymer, to increase impact and tensile strength, as well as brittle resistance. In the later patent, PP and EPR were separately dissolved then blended, precipitated, and processed. The blends showed fine, uniform dispersion of the rubber phase, resulting in superior mechanical properties	K. Shirayama, K. Iketa, Japanese Patent 021,303; 021,305, 16 June 1971, Appl. 23 Feb 1968; M. Asada, T. Tokumaru, S. Saito, M. Saeki, H. Ueda, Japanese Patent 008,145, 08 Mar 1972, Appl. 1 Nov 1968, to Sumitomo Chemical Co., Ltd.
1969	Polyethylene, PE, was blended with <15 wt% EPDM, to give resistance to corona discharge. The blends were used as insulating materials for high-voltage cables	H. Matsubara, Japanese Patent 030,095, 05 Aug 1972, Appl. 29 May 1969, to Sumitomo Electric Ind., Ltd.
1969	Polypropylene, PP, or poly (pentene-co-propylene) was reactor blended with ethylene–butene or ethylene–pentene copolymer. The product was melt blended with PP to give material with improved performance. In the second patent, ethylene–propylene copolymer, EPR, was blended with PP. The alloys showed good mechanical properties. In the Sumitomo patent, to improve impact strength, PP was blended with 5–30 wt% of either polyhexene or polyoctene	I. Yamazaki, T. Fujimaki, Japanese Patent 007,627, 03 Mar 1970, Appl. 24 Dec 1969; 007,141, 29 Feb 1972, Appl. 26 Nov 1969, to Showa Denko; K. Shirayama, S. Shiga, H. Watanabe, Japanese Patent 008,370, 10 Mar 1972, Appl. 25 Feb 1969, to Sumitomo Chem
1969	Polypropylene, >70 wt% PP, was blended with ≥5 wt% ethylene–vinyl acetate–vinyl chloride copolymer, ethylene–vinyl acetate copolymer, and HDPE, to give materials with low-temperature impact resistance	M. Kojima, M. Tanahashi, Japanese Patent 014,710, 02 May 1972, Appl. 05 Nov 1969, to Chisso Co., Ltd.

<div align="right">(continued)</div>

Table 18.12 (continued)

Year	Development	References
1970	Polyethylene, LDPE, was blended with polyisobutylene, PIB, in a single-screw extruder at the shear rates 600,000 s^{-1}, for 34 μs. No thermal degradation was observed. The PIB drop size was 2–5 μm	F. Urban, O. Buchner, K. Steigerwald, K. H. Fauth, H. Gehrig, German Patent 2,028,751, 16 Dec 1971, Appl. 11 June 1970, to BASF A.-G.
1970	Polypropylene, PP, was blended with hydrogenated styrene–butadiene or styrene–isoprene block copolymer, 6–8 wt%. The alloys were used for manufacturing of materials with good transparency and impact strength	L. M. Porter, German Patent 2,156,681, 18 May 1972, Appl. 16 Nov 1970, to Shell International Research Maatschappij N. V.
1971	Blends comprising 40–20 wt% polyolefin, PE or PP, with 60–80 wt% of ethylene–propylene–dicyclopentadiene = 47.5:47.5:5 or ethylene–propylene–ethylidene–norbornene = 61:35:4 were disclosed. The blends were masticated and partially cross-linked with peroxides or sulfur, keeping the gel content at 45–96 %. They could be shaped into articles with good properties without vulcanization	W. K. Fischer, South African Patent 72 00,388, 23 Aug 1972, U.S. Ref., RE 32,028, U.S. Patent 3,806,558, Appl. 12 Aug 1971, to Uniroyal Inc.
1971	Reactive grafting of polyolefins, polyethylenes (PE), or polypropylenes (PP) was disclosed. The extruder was modified, allowing to feed polymer, grafting monomer and peroxide. As an example, PP was grafted with acrylic acid	R. A. Steinkamp, T. J. Grail, U.S. Patent 3,953,655, 27 Apr 1976, Appl. 09 Apr 1971, to Exxon Research and Engineering Co.
1972	Polyolefins, PP or PE, blended with chlorosulfonated polyethylene, 4.5 wt% CSR, and filled with large amount of CaSO4 showed good mechanical properties	K. Shikata, K. Okamura, S. Nakamura, Japanese Patent 097,946, 13 Dec 1973, Appl. 28 Mar 1972, to Tokuyama Soda Co., Ltd.
1972	Polyethylene, LLDPE, was blended with atactic polypropylene, 0.1–5 wt% aPP. Blown and stretched films showed large anisotropy in tensile strength and elongation, making them useful for packaging	K. Nakamura, T. Kimura, H. Tsunoda, Japanese Patent 083,174, 06 Nov 1973, Appl. 10 Feb 1972, to Sanyo Pulp Co., Ltd.
1972	In 1975 Union Carbide Corp. (UCC) discovered the very low density polyethylene (VLDPE) or "ultralow-density polyethylene" (ULDPE), i.e., copolymers of C$_2$ with α-olefin (C$_{4-8}$) having ρ = 0.860–0.915 g ml^{-1}. VLDPE has higher α-olefin content than that in LLDPEs. These linear elastomers are produced by coordination polymerization using a Phillips or Z-N catalyst at low P and T. Here belong Mxsten XLDPE from Eastman Chem. and Attane ULDPE from Dow. The first metallocene-catalyzed VLDPE was a hexene copolymer ρ = 0.912 g ml^{-1} introduced by ExxonMobil as Exceed 1012CA, made in the UNIPOL gas-phase process. Exceed (m-VLDPE) has outstanding sealing properties (hot tack and seal strength) compared with Z-N VLDPEs VLDPE has low crystallinity (X = 7–30 %) densities ρ = 0.875–0.915 g ml^{-1} and melting point,	I. J. Levine, F. J. Karol, U.S. Patent 4,011,382 of 08 Mar 1977 priority 1975, to UCC; E. Berger et al., U.S. Patent 4,292,200 of 29 Sept 1981, priority 1972, to Solvay & Co.; A. Delbouille et al., U.S. Patent 4,250,284 of 10 Feb 1981 priority 1969, to Solvay & co.; E. R. Smith, U.S. Patent 5,032,463 of 16 July 1991, priority 1988, to Viskase Corp.; T. Fujii et al., U.S. Patent 5,110.870, of 05 May 1992, priority 1989, to Mitsubishi Kasei; Farley et al., U.S. Patent 6,932,592, 23 Aug 2005, priority 2001, to ExxonMobil; S. Lustig et al., U.S. Patent 5439717, 08 Aug 1995,

Table 18.12 (continued)

Year	Development	References
	T_m = 60–90 °C. It is a linear copolymer, with high SCB, made by copolymerization of C_2 with alpha-olefins (e.g. C_8), initially using a Phillips or Z-N-type catalyst and then metallocene one. VLDPEs are used for geotextile, hose and tubing, ice and frozen food bags, food packaging and stretch wrap, as well as impact modifiers for blending with other polymers. VLDPE shows the physical properties of LLDPE, high flexibility, toughness, sealing, and softness	priority i985, and U.S. Patent 5256351 of 1993-10-26, priority 1985, to Viskase Corp.; Karol et al., EP 0120,503 (WO 84/03888), of 11 Oct 1984 priority 1983, to UCC; L. M. J. van Assldonk, S. J. Brown, U.S. Patent Appl., 2011/ 0144289 0f 16 June 2011, filed 2010, to Nova Chem. http://www. novachem.com/researchtech/docs/ 2010-19.pdf; S. Sivaram, Second generation ziegler polyolefin processes, Ind. Eng. Chem.. Prod. Res. Dev., **16**(2):121–127 (1977); Anonym. VLDPE – a new class of polyethylene, Plast. Rubber **11**(2):34–36 (1986)
	The solution polymerization in a hydrocarbon usually is carried out in a continuously stirred tank reactor (CSTR), at T = 160–300 °C and P = 2.5–10 MPa with residence time of 1–5 min. In 1991 Exxon introduced the first metallocene VLDPE (Exceed 1012CA, ρ = 0.912 g ml^{-1} based on Z-N catalyst), followed by Dow in 1992 and UCC in 1984. UCC used the 2nd-generation Z-N catalyst with MgO. The VLDPE (comonomer C_{3-8} = 6 wt%) with ρ < 0.91 g ml^{-1} and modulus E < 140 MPa was produced in a fluidized bed at T = 10–80 °C and P < 7 MPa, in a mixture of gases (C_2, C_{3-8}, molar ratio = 1:0.35–1:8 and 3–5 mol % H2), with a catalyst system comprising a precursor. For PE with ρ < 0.86–0.9 g ml^{-1} reaction T < 60 °C and P < 2.5 MPa are needed	
1973	Polyethylene, PE, was blended with ≤35 wt% polypropylene, PP; ≤15 wt% polydimethylsiloxane, PDMS; and 5–35 wt% PPE, PA-6, PC, PET, or Phenoxy. The blends were used for injection molding of products with good processability, rigidity, impact strength, and long life under sterilization in boiling water or by irradiation	A. Plochocki, T. Bek, J. Bojarski, L. Czarnecki, L. Grabiec, J. Kepka, P. Machowski, Polish Patent 097,228, 30 Dec 1978; Polish Patent 100,160, 17 Apr 1979, Appl. 21 Dec 1973; Polish Patent 100,669, 15 May 1979, Appl. 21 Dec 1973, to Inst. Chem. Ind.
1973	High-density polyethylene, HDPE, was blended with 50 wt% polypropylene, PP, having matched melt flow index, to give good flowability, weld-line strength, surface quality, and low-temperature impact strength	D. Moorwessel, R. Glasser, G. Pfirrmann, German Patent 2,306,892; 2,306,893, 22 Aug 1974, Appl. 13 Feb 1973, to BASF A.-G.
1974	Polypropylene, PP, was reactor blended with polyethylene, PE, and ethylene–propylene copolymer, EPR, to give high impact strength R-TPO, especially at low temperature	H. Strametz, H. J. Leuering, K. Rust, M. Engelmann, German Offence 2,417,093, 06 Nov 1975, Appl. 1974, to Hoechst A.-G.
1975	Polypropylene, PP, was blended with ethylene-5-ethylidene-2-norbornene-propylene copolymer, EPDM, to give moldings with good tensile strength. In the following patent, EPDM was blended with LDPE to give unexpectedly high tensile strength	P. T. Stricharczuk, German Patent 2,644,644, 07 Apr 1977, Appl. 06 Oct 1975; C. J. Carman, M. Batiuk, R. M. Herman, U.S. Patent 4,046,840, 06 Sep 1977, Appl. 23 Feb 1976, to B. F. Goodrich Co.

<div align="right">(continued)</div>

Table 18.12 (continued)

Year	Development	References
1975	Homogeneous blends of immiscible polymers can be prepared in a high-stress, low residence time extruder (later labeled Patfoort extruder and sold by FN). Thus, LLDPE was blended with PS to give blends with good mechanical properties	G. A. R. Patfoort, Belgian Patent 833,543, 18 Mar 1976, Appl. 18 Sep 1975; Fabrique Nationale Herstal, Netherland Patent Appl. 007,963, 18 Sep 1977, Appl. 18 Sep 1975
1976	In a series of patents, dynamic vulcanization of polypropylene, PP, was disclosed. Thus, 60 wt% PP was blended with butyl rubber, BR; elastomeric ethylene–vinyl acetate, 35–85 wt% EVAc, with polyolefins, PE or PP; chlorosulfonated polyethylene rubber, ≥50 wt% CSM, with polyolefins, PE or PP; or ethylene–propylene–diene, EPDM, with PP. The blends showed excellent toughness, elongation, impact strength, a wide range of Shore hardness, and dimensional stability. In the latter patent, a compatibilizing block copolymer was disclosed of NBR with polyolefins, e.g., PP. Compatibilization nearly doubled the blend tensile strength and increased its elongation at break by a factor of 4	A. Y. Coran, R. Patel, German Patent 2,757,430, 06 July 1978; U.S. Patent 4,130,534; A. Y. Coran, B. Das, R. Patel, U.S. Patent 4,130,535, 19 Dec 1978, Appl. 27 Dec 1976; A. Y. Coran, R. Patel, U.S. Patent 4,141,878, 27 Feb 1979, Appl. 14 Apr 1977; German Patent 2,805,930, 17 Aug 1978, Appl. 14 Feb 1977; European Patent Appl., 036,279, 23 Sep 1981; U.S. Patent 4,355,139, 1982, Appl. 10 Mar 1980, to Monsanto Co.
1976	Polypropylene/polyethylene, PP/LDPE, blends were compatibilized by addition of 2–22 wt% EPR. Blending was done in two stages, curing EPR before the second part of PP was added. The resulting materials had good mechanical, low-temperature impact, and optical properties	T. Huff, U.S. Patent 4,087,485, 02 May 1978, Appl. 1976, to Exxon Research & Engineering Co.
1976	To improve modulus of high-density polyethylene, HDPE, it was blended with a graft copolymer of HDPE with vinyl or vinylidene monomer (e.g., styrene)	H. Yui, T. Kakizaki, H. Sano, Japanese Patent 014,752, 09 Feb 1978, Appl. 27 July 1976, to Mitsubishi Petrochemical Co., Ltd.
1977	Soft, thin films, with improved cuttability, suitable for packaging materials, were prepared by blending polyethylene, a mixture of LDPE and HDPE, with EPDM or atactic polypropylene, aPP	S. Sakane, K. Minato, M. Takashige, Japanese Patent 000,052, 5 Jan 1979, Appl. 03 June 1977, to Idemitsu Petrochemical Co., Ltd.
1977	Polyethylene blends, suitable for extrusion of pipes, were obtained by blending two different types of linear low-density polyethylenes, LLDPE, one with butene and the other hexene comonomer. The blend also contained carbon black, CB	O. E. Larsen, Canadian Patent 1,120,630, 23 Mar 1982, Appl. 12 Oct 1977, to Phillips Petroleum Co.
1977	Polypropylene, PP, blends with low-density polyethylene, 5–20 wt% LDPE, and ethylene–propylene copolymer, 1–15 wt% EPR showed excellent transparency and mechanical properties	T. Oita, T. Hara, R. Samejima, K. Tanabe, Japanese Patent 108,146, 20 Sep 1978, Appl. 03 Mar 1977, to Sumitomo Chemical Co., Ltd.
1977	Polypropylene, PP, was blended with 15–85 wt% ABS and 0.5 wt% CPE (or low-molecular-weight PS) as a compatibilizer	M. Kamosaki, S. Tokuhara, M. Kita, N. Nakashima, Japanese Patent 146,748; 146,753, 20 Dec 1978, Appl. 27 May 1977, to Daicel Ltd.

(*continued*)

Table 18.12 (continued)

Year	Development	References
1977	Polypropylene, 10–60 wt% PP, was blended with ethylene–propylene block copolymer, EPR, and a peroxide-containing polyolefin copolymer to give a masterbatch that subsequently was blended with 60 wt% EPDM, to give elastomeric alloy with excellent mechanical properties	A. Yamamoto, M. Shiraishi, S. Nakayama, Y. Tsurugi, H. Nakanishi, Japanese Patent 001,386, 08 Jan 1979, Appl. 07 June 1977, to Japan, EP Rubber Co., Ltd.
1979	Polypropylene, PP, was sequentially blended with EPR, then with PE. The blend showed co-continuous morphology resulting in excellent impact and mechanical properties, superior to those observed for blends with a particulate dispersion	T. Huff, European Patent Appl., 015,066, 03 Sep 1980, Appl. 31 Jan 1979, to Exxon Research and Engineering Co.
1979	Polypropylene, 60 wt% PP, was blended with polyamide, 20 wt% PA-6 or PA-66, and glass fibers, 20 wt% GF, for superior tensile and impact strength	Asahi Fiber Glass Co., Ltd., Japanese Patent 030,451, 27 Mar 1981, Appl. 23 Aug 1979
1979	Polyethylene, 70 wt% PE; polyamide, 20 wt% PA-66; and 3 wt% of ethylene–fumaric acid graft copolymer were mixed to reduce moisture permeation and to improve impact strength. In 1982 DuPont introduced PA/PO blends, Selar™, to be used as additive to polyolefin to reduce permeability	P. M. Subramanian, European Patent Appl., 015,556, 17 Sep 1980, Appl. 06 Mar 1979, to E. I. du Pont de Nemours & Co.; "Selar™ Barrier Resins," Bulletins E73971, E73973, E73974 by du Pont
1979	Polyethylene, PE, was grafted with 0.1–5 wt% maleic anhydride and blended with 1–50 wt% EPDM. The blend showed excellent adhesion to polar materials	A. Honkanen, M. Arina, R. Holstii, Finnish Patent 064,805, 30 Sep 1983, Appl. 10 Dec 1979, to Neste Oy
1979	Polypropylene, PP, was blended with 5 wt% PDMS for improvement of processability, impact strength, and elasticity	U. Grigo, L. Morbitzer, K. Arlt, R. Binsack, J. Marten, German Patent 2,905,357, 21 Aug 1980, Appl. 13 Feb 1979, to Bayer A.-G.
1979	The first patent on reactor-blended thermoplastic olefinic elastomer, R-TPO, was disclosed. Thus, polyethylene, PE, was polymerized in the presence of an active catalyst and an already polymerized olefinic copolymer (e.g., ethylene-1-butene copolymer) or the sequence was reversed. The blend had superior resistance to environment stress cracking, and the blown film showed fewer fish eyes	Y. Morita, N. Kashiwa, European Patent Appl., 022,376, 14 Jan 1981, Appl. 09 July 1979, to Mitsui Petrochemical Industries, Ltd.
1980	In 1979 UNIPOL™ process for gas-phase production of the "linear low-density polyethylene," LLDPE, was introduced by the Union Carbide Corp. Since the new resins were difficult to process on the processing lines designed for the low-density (high pressure) polyethylenes, LDPE, soon several patents were	A. Haas, F. Raviola, European Patent Appl. 042,743, 13 Jan 1982, to Soc. Chim. Charbon.; P. M. Hughes, European Patent Appl., 045,455, 10 Feb 1982, Appl. 1980, to Shell Oil Co.; Cowan, M. A,

<div align="right">(continued)</div>

Table 18.12 (continued)

Year	Development	References
	issued for LLDPE blends with other polyolefins, e.g., LDPE or PP	European Patent Appl. 095,299, 30 Nov 1983, to Intercont. Plast., Inc.; K. C. Janac, R. C. Puydak, D. R. Hazelton, European Patent Appl., 092,318, 26 Oct 1983, Appl. 26 Mar 1982, to Exxon Res. & Eng. Company; B. L. Turtle, European Patent Appl. 095,253, 30 Nov 1983, to British Petroleum Co.; O. Fukui, Y. Inuizawa, S. Hinenoya, Y. Takasaki, French Patent 2,522,331, 02 Sep 1983, to Ube Industries, Ltd.; A. Haas, French Patent 2,526,803, 18 Nov 1983; M. Hert, French Patent 2,528,055, 09 Dec 1983, to Soc. Chim. Charbon., SA
	In 1982 numeroU.S. Patentent applications for blends of linear low-density polyethylenes, LLDPE, with other polyolefins, co-polyolefins, and olefinic elastomers have been filed. For example, ethylene copolymers, thermoplastic elastomers (TPO), EPDM, EPR, EVAc, maleated polypropylene, and PP-MA have been used	
1980	To improve its low-temperature impact strength, polyethylene, PE, was blended on a roll mill with polybutadiene rubber, 10 wt% PB	E. G. Kent, U.S. Patent 4,423,181, 27 Dec 1983, Appl. 10 Mar 1980, to Polysar Ltd.
1981	Polyethylene, 50–95 wt% HDPE, was blended with LLDPE for improvement of film strength and transparency	K. K. Showa Denko, Japanese Patent 059,242, 08 Apr 1983, Appl. 05 Oct 1981
1981	Polyethylene, PE, was blended with neoprene rubber at a ratio 1:1. The blends were irradiated by electron beam for improved tensile strength and other mechanical properties	A. Y. Coran, R. Patel, U.S. Patent 4,348,266, 07 Sep 1982, Appl. 02 Apr 1981, to Monsanto
1981	Polypropylene, 100 parts PP, blended with 8–25 parts of amorphous ethylene–propylene copolymer, EPR, and 2–10 parts crystalline EPR showed improved impact strength. In the Idemitsu patent, PP was blended with maleated LDPE, EVAc, and inorganic filler, to give blends with good melt strength and rigidity	P. Galli, M. Spataro, European Patent Appl., 077,532, 27 Apr 1983, Appl. 14 Oct 1981, to Montedison S.p.A.; Idemitsu Petrochemical Co., Ltd., Japanese Patent 096,640, 08 June 1983, Appl. 04 Dec 1981
1982	Semicrystalline ethylene–propylene copolymer, EP, was blended with amorphous EP and inorganic filler. The blends had good processability, mechanical properties, and impact strength. In the Mitsubishi patent, crystalline EP was blended with styrene–isoprene block copolymer, 5–30 wt% SIS, and polystyrene, 3–5 wt% PS, to give good paintability	Ube Industries, Ltd., Japanese Patent 162,652, 27 Sep 1983, Appl. 23 Mar 1982; Japanese Patent 168,648; 168,649, 05 Oct 1983, Appl. 30 Mar 1982; Mitsubishi Petrochem. Co., Ltd., Japanese Patent 213,039, 10 Dec 1983, Appl. 04 June 1982
1982	Polypropylene, 94 wt% PP, was blended with chlorinated polyethylene, 6 wt% CPE. The blends had good processability and gave moldings with good mechanical properties	R. Newe, E. Lange, H. Hoffmann, K. Wetzel, East German Patent 207,381, 29 Feb 1984, Appl. 05 Apr 1982, to VEB Chemiekombinat Bitterfeld

(continued)

Table 18.12 (continued)

Year	Development	References
1982	Polypropylene, 50–90 wt% PP, and/or ethylene–propylene block copolymer, EP, was blended with talc having particle size $d = 5$–20 μm. The materials had high impact strength. In the following patent, PP was blended with 5–40 wt% styrene-grafted chlorinated polyethylene, CPE, to give high modulus and impact resistance	Chisso Corp., Japanese Patent 036,149, 28 Feb 1984, Appl. 24 Aug 1982; Japanese Patent 213,038, 10 Dec 1983, Appl. 03 June 1982
1982	Polypropylene, 35 wt% PP, was blended with polyisobutylene, 50 wt% PIB, and ethylene–vinyl acetate copolymer, 15 wt% EVAc, to give alloys useful for films, moldings, and extrusions	C. B. Shulman, European Patent Appl., 116,783, 29 Aug 1984, Appl. 27 Dec 1982, to Exxon Research and Eng. Co.
1982	Polyethylene, PE, blends from LDPE, HDPE, and MDPE were found suitable for manufacturing films with uniform thickness and anisotropic tensile strength	K. K. Showa Denko, Japanese Patent 157,837, 20 Sep 1983, Appl. 15 Mar 1982; Japanese Patent 176,234, 15 Oct 1983, Appl. 09 Apr 1982
1982	Linear low-density polyethylene, LLDPE, was blended with 2–25 wt% LDPE to give films with large difference of the tensile strength in the machine and transverse direction	M. Hert, French Patent 2,528,054, 09 Dec 1983, Appl. 03 June 1982, to Societé Chim. des Charbonnages S. A.
1982	Low-density polyethylene, LDPE, was blended with 1–40 wt% poly(2-ethyl-2-oxazoline), PEOX. The blends had excellent adhesion to substrates, e.g., thermoplastic polyesters, viz., PET	S. M. Hoenig, D. P. Flores, S. P. Ginter, U.S. Patent 4,474,928, 02 Oct 1984, Appl. 28 June 1982, to Dow Chemical Co.
1982	Ethylene polymer blends are prepared by mechanical blending of dry powders or compounding in an internal mixer or a compounding extruder or (preferably) combining the two methods. Bailey, Whitte, Coutant, and Martin, to Phillips Petroleum Co; Cobler et al. to Dow Chem. Co. (mixing on the blow line); Harris to Media Plus, Inc. Blends of a high-MW ethylene–α-olefin copolymer and a low-MWPE with narrow MWD and low levels of LCB for films with good ESCAR are useful for the manufacture of films, pipes, and wire coating	F. W. Bailey, W. M. Whitte, Ethylene polymer blends, U.S. Patents. 4,461,873 (24 July 1984, filed 22 June 1982); 4,547,551 (15 Oct 1985); 5,380,803 (10 Jan 1995), all to Phillips Petroleum Co.; U.S. Patent 5,681,523 (28 Oct 1997), to Dow Chem. Co.;U.S. Patent 6822051 (23 Nov 2004), to Media Plus, Inc.
1982	Low-density polyethylene, LDPE, was blended with HDPE, PP, and EP block copolymer, to give films with good modulus, tear strength, and sagging	Shin-Kobe Electric Machinery Co., Ltd., Japanese Patent 096,156, 02 June 1984, Appl. 24 Nov 1982
1983	Low-density polyethylene, LDPE, blended with linear low-density polyethylene in a ratio 100:20–90 gave alloys useful for production packaging films	Asahi Chemical industry Co., Ltd., Japanese Patent 044,540, 09 Mar 1985, Appl. 19 Aug 1983
1984	Linear low-density polyethylene, LLDPE, was blended with low-density polyethylene, 10–45 wt% LDPE; polypropylene, PP; and/or ethylene–propylene copolymer [with a high propylene content], 2–15 wt% EPR. The blends had high modulus and clarity	S. K. Bahl, P. J. Canterino, R. Shaw, British Patent 2,152,515, 07 Aug 1985, Appl. 04 Jan 1984, to Mobil Oil Corp.
1985	Polyethylene, PE, blended with 10–40 wt% ethylene–vinyl carboxylate or an acrylate copolymer exhibited notched Izod impact strength more than three times larger than that of functional group-free PE	T. O. Broadhed, European Patent Appl., 209,294, 21 Jan 1987, Appl. 15 July 1985; to Du Pont Canada, Inc.

(*continued*)

Table 18.12 (continued)

Year	Development	References
1985	Polyolefin blends with good compatibility comprised 100 parts PO and 0.1–100 parts polytransoctanamer, PTO. For example, PP with 9 wt% PTO showed about 5× higher impact strength at $T = -40$–23 °C than PP alone	M. Kita, K. Hashimoto, Japanese Patent 131,043, 13 June 1987, Appl. 04 Dec 1985, to Daicel Huels Ltd.
1987	Transparent-, impact-, and "blush"-resistant blends were obtained by compounding linear low-density polyethylene, LLDPE, with hydrogenated styrene–butadiene block copolymer, SEBS	G. Holden, D. R. Hansen, European Patent Appl., 308,001, 22 Mar 1989, Appl. 1987, to Shell Int. Res. Maatschappij BV
1987	Polypropylene, PP, blended with polyoctadecene, POD, was found to show temperature-sensitive transparency (thermochromic blends)	S. Tanaka, J. Sakai, T. Fukao, K. Wakatsuki, K. Wakamatsu, European Patent Appl., 285,414, 05 Oct 1988, Appl. 1987, to Sumitomo Chemical Co., Ltd.
1989	Polypropylene, PP, reactor blends were obtained with high yield using a chiral metallocene catalyst and an aluminoxane. The preferred blends comprised 60–95 wt% of a crystalline isotactic PP homo- or copolymer produced in the first stage and (the second stage) random copolymer ethylene–propylene (and another 1-olefin), as well as a partly crystalline polymer of the second 1-olefin. The moldable blends showed good flow properties and a very good low-temperature impact strength	M. Schreck, A. Winter, V. Dolle, H. Kondoch, M. Antberg, J. Rohrmann, U.S. Patent 5,322,902, 21 June 1994, Appl. 21 Dec 1989, US Appl. 19 Dec 1990, to Hoechst Aktiengesellschaft
1990	Three-component polypropylene, 1–99 wt% PP, blends comprised 1. either acidified PP, its mixture with PP, or a mixture of PP with carboxylic acid-modified EPR; 2. 99–1 wt% of maleated polymer [e.g., poly(methyl methacrylate-*co*-styrene-*co*-MA]; and 3. epoxy group-containing copolymer [e.g., 0.1–300 phr of ethylene–methyl methacrylate–glycidyl methacrylate = 65-15-20 or ethylene–vinyl acetate–glycidyl methacrylate = 85-5-10]. The blends were used to mold car bumpers and fenders, with good stiffness and low-temperature impact resistance	H. Abe, T. Fujii, M. Yamamoto, S. Date, U.S. Patent 5,278,233, 11 Jan 1994, Appl. 14 June 1990, US Appl. 12 June 1991, to Sumitomo Chemical Co., Ltd.
1990	Polypropylene, PP, was blended with ethylene-*co*-vinyl alcohol, EVAL, and maleated polypropylene, PP-MA. The blends were extruded through a sheeting die that engendered overlapping layers of EVAL. Their presence reduced permeability by gases or liquids through the PP wall	M. R. Kamal, G. Lohfink, L. Arghyris, S. Hozhabr-Ghelichi, PCT Int. Appl., 006,837, 30 Apr 1992, Appl. 16 Oct 1990, to McGill University
1990	Linear low-density polyethylene, LLDPE, was blended with very low density polyethylene, VLDPE. The polymers prepared using metallocene catalyst had narrow molecular weight distribution, $M_w/M_n = 1$–3. Blending resulted in resins having the density $\rho = 910$–940 kg m^{-3}	F. C. Stehling, C. S. Speed, C. H. Welborn, Jr., U.S. Patent 5,382,630; 5,382,631, 17 Jan 1995, Appl. 04 Feb 1993, 25 May 1990, to Exxon Chemical Patents, Inc.

(*continued*)

Table 18.12 (continued)

Year	Development	References
1991	Polyolefin blends with density of ρ = 930–940 kg m^{-3} at 23 °C and MFI(90/2.16) = 0.05–1.0 dg min^{-1} comprised high-density polyethylene, 50–80 wt% HDPE [polymerized in two stages, with a broad bimodal molecular mass distribution, ρ = 940–960 kg m^{-3}, and MFI(90/2.16) = 0.01–0.5 dg min^{-1}], and linear low-density polyethylene, 20–50 wt% LLDPE [ρ = 910–925 kg m^{-3} and MFI(90/2.16) = 0.5–2.0 dg min^{-1}]. The blends were used for forming tubes and pipes with high stress crack resistance	L. Boehm, H. F. Enderle, H. Jastrow, European Patent Appl., 517,222, 09 Dec 1992; U.S. Patent 5,338,589, 16 Aug 1994, US Appl. 03 June 1992, German Appl. 05 June 1991, to Hoechst Aktiengesellschaft
1991	Linear low-density polyethylene, LLDPE, was graft modified by incorporation of basic groups from, e.g., dimethylamino ethyl methacrylate, t-butylamino ethyl methacrylate, vinyl pyridine, or allyl urea. These copolymers were then used as reactive components for alloys with acidified polymers, viz., maleated polyolefins	W. E. Baker, A. H. Simmons, Canadian Patent Appl., 2,028,784, 16 May 1991, Appl. 29 Oct 1990, to Queen's University at Kingston
1991	Linear low-density polyethylene, LLDPE, was blended with low-density polyethylene, LDPE, at a ratio of about 0.3. The blends were used for blow molding hollow balls containing pressurized air and consisting of two hemispheres welded to form a ball with a wall thickness t = 0.5–1.8 mm	H. Moss, J. G. Modigh, U.S. Patent 5,320,887, 14 June 1994, Appl. 04 Mar 1993, GB Appl. 27 Feb 1992, to Euro-matic Ltd.
1991	Blends comprising 30–70 wt% low-molecular-weight (MW) polyethylene, HDPE [made using a chromium catalyst, having density $\rho \geq$ 955 kg m^{-3}, MI = 25–400 g/10 min, and M$_w$/M$_n$ = 2–35], and 30–70 wt% high-MW ethylene copolymer, LLDPE [made using a titanium catalyst, having $\rho \leq$ 955 kg m^{-3}, MI = 0.1–50 g/10 min, and M$_w$/M$_n$ = 2–10], showed improved processability. The blends were used to produce pipes, films, and bottles with enhanced mechanical properties as well as the environmental stress crack resistance, ESCR. In the following patent 5–40 wt% low-MW HDPE [made using a titanium catalyst, with density $\rho \geq$ 955 kg m^{-3}, $MI \geq$ 25 dg min^{-1}, and M$_w$/M$_n$ = 2–8] blended with 60–95 wt% high-MW HDPE [from chromium catalyst, with density $\rho \geq$ 930 kg m^{-3}, MI = 1.5–15 dg min^{-1}, and M$_w$/M$_n$ = 6–100] yielded blends with MI = 0.05 dg min^{-1} and ESCR. In the last patent 10–80 wt% low-MW LLDPE [$\rho \geq$ 940 kg m^{-3}, $MI >$ 25 dg min^{-1}, and M$_w$/M$_n$ = 2–12] was blended with	J. L. Martin, M. B. Welch, W. R. Coutant, M. P. McDaniel, U.S. Patent 5,306,775, 26 Apr 1994, Appl. 16 Apr 1993; U.S. Patent 5,319,029, 07 June 1994, Appl. 16 Apr 1993; W. R. Coutant, J. L. Martin, U.S. Patent 5,380,803, 10 Jan 1995, Appl. 16 Apr 1993, Appl. 18 Sep 1991, to Phillips Petroleum Company

(*continued*)

Table 18.12 (continued)

Year	Development	References
	20–90 wt% of a high-MW LLDPE [$\rho \leq 955$ kg m^{-3}, $MI = 2$–10 dg min^{-1}, and M$_w$/M$_n = 2$–10]. The blends had $MI > 0.05$ dg min^{-1} and had improved optical properties	
1991	Polyethylene, PE Rigidex™ or Innovex™, was blended with liquid crystal polyester, 0.01–5 wt% LCP, to give materials with good melt processability, low viscosity, and reduction of the specific energy during compounding	P. T. Alder, J. G. Dolden, D. G. Othen, PCT Int. Appl., 008,231, 29 Apr 1993, Appl. 22 Oct 1991, to British Petroleum Co.
1991	Compositions comprised 10–80 wt% low-MW polyethylene, HDPE [$\rho \geq 940$ kg m^{-3}], and 20–90 wt% high-MW ethylene–hexene copolymer, LLDPE [$\rho \leq 955$ kg m^{-3}]. The blends had a MFI $>$ 0.05 g/10 min. The blend showed improved optical and physical properties, resulting in better blow-molded products	W. R. Coutant, J. L. Martin, European Patent Appl., 533,160, 24 Mar 1993; Norwegian Patent 9203,598, 19 Mar 1993; Hungarian Patent T62,631, 28 May 1993; Japanese Patent 5,194,796, 03 Aug 1993, Appl. 18 Sep 1991, to Phillips Petroleum Co.
1991	Ethylene–propylene copolymer (EPR, EPDM, or their mixture with $T_m = 35$–$55\ ^\circ$C) was blended with ethylene copolymer (very low density polyethylene VLDPE with density 885 kg m^{-3} and $T_m = 65$–$90\ ^\circ$C), PP or PP block copolymers, and 0–7 phr talc. The blend showed excellent moldability, surface appearance, and hardness, as well as good impact resistance	T. Nishio, T. Nomura, N. Kawamura, H. Sato, A. Uchikawa, I. Tsutsumi, Y. Goto, European Patent Appl., 519,725, 23 Dec 1992, Appl. 21 June 1991, to Mitsubishi Petrochemical Co.
1991	"Living" polypropylene, PP, or ethylene–propylene random copolymer, EPR [prepared in the presence of a catalyst consisting of an organic aluminum and a vanadium compound], was modified by reacting the terminal groups with a (meth)acrylic derivative to give a substantially monodispersed copolymer, suitable for further compounding and blending. Vinyl-, allyl-, trimethylsiloxyethyl-, 2-trimethylsiloxypropyl-, N, N-dimethylaminoethyl-, N, N-diethylaminoethyl-, glycidyl methacrylate, or acrylic acid chloride were used	N. Koyama, M. Usui, H. Furuhashi S. Ueki, U.S. Patent 5,382,634, 17 Jan 1995, Appl. 25 Apr 1994, Japanese Appl. 15 Mar 1991, to Tonen Corporation
1991	Polymer alloys comprised 20–30 wt% PP; 25–35 wt% uncross-linked elastomeric ethylene-propylene-1,4-hexadiene, EPDM (60–80 wt% ethylene); 30–50 wt% ionomer; and 2–3 wt% ethylene/n-butyl acrylate/glycidyl methacrylate, EBA-GMA. The blends were used in applications where a wide temperature range and abrasive conditions were encountered	R. L. Dawson, U.S. Patent 5,206,294, 27 Apr 1993, Appl. 6 Nov 1991, to E. I. du Pont de Nemours & Co.
1991	Deposition of patent on the constrained geometry catalyst technology (CGCT) based on the transition metals, M = Ti, Zr, Hf. The resulting PO is substantially linear. The preferred composition comprises 10–95 wt	S.-Y. Lai, J. R. Wilson, G. W. Knight, J. C. Stevens, P.-W. S. Chum, Elastic substantially linear olefin polymers, CA 2120766 of

(*continued*)

Table 18.12 (continued)

Year	Development	References
	% of homogeneously branched linear α-olefin copolymer (ρ = 0.930–0.965 g ml^{-1}, MWD = 1.8–2.8, single T_m) and 5–90 wt% of heterogeneously branched C_2C_8 copolymer (ρ = 0.935 g ml^{-1})	08 July 2008 (filed 15 Oct 1993; priority 15 Oct 1991); U.S. Patent, 5,272,236 of 21 Dec 1993 (deposited 15 Oct 1991); P.-W. Steve Chum, R. P. Markovich, G. W. Knight, S.-Y. Lai, Fabricated articles made from ethylene polymer blends, CA 2160705 of 22 Aug 2006 (filed 190 Apr 1994; priority 28 Apr 1993); Ethylene polymer film made from ethylene polymer blends, U.S. Patent 5847053 of 08 Dec 1998 (filed 11 Apr 1997; priority 15 Oct 1991), to The Dow Chemical Company
	Lai, Wilson, Knight, Stevens, Chum, Markovich, to the Dow Chemical Company	
	The SCBDI = wt% of macromolecules having a comonomer content within 50 % of the median total molar comonomer content, calculated from TREF (temperature rising elution fractionation) data. The elastic, substantially linear C_2–C_8 copolymer has 0.01 ≤ LCB/1000C ≤ 3, M_w/M_n = 1.5–2.5, 2 ≤ SCB (CH3/1000C) ≤ 30), and short-chain branch distribution index: SCBDI > 50 %. The homogeneously branched copolymer may be produced as described in C. T. Elston (DuPont Canada Ltd.) patent. Films produced from the bimodal MWD new copolymers show good impact and tensile properties	
1991	Polypropylene, 50 wt% PP, was blended with a linear low-density polyethylene, 10–50 wt% LLDPE, and a low-molecular-weight ethylene–butene plastomer (a compatibilizer). The blends were useful for melt-spun or melt-blown fibers or fabrics. In the following patent heat sealable at 100 °C blends were disclosed. They comprised 30–70 wt% ethylene–alpha-olefin copolymer prepared using a metallocene catalyst, VLDPE or plastomer [with density ρ = 880–915 kg m^{-3}, MI = 1.5–7.5 dg min^{-1}, M_w/M_n ≤ 3.0, T_m = 60–100 °C], and 70–30 wt% propylene–alpha-olefin random copolymer [with 88–100 mol% propylene]. The blends showed good processability, resistance to tearing, and tensile strength. They were useful for manufacturing packaging films, tubes, trays, etc.	K. W. Bartz, L. P. Land, A. K. Mehta, A. A. Montagna, PCT Int. Appl., WO 06,169 A1, 01 Apr 1993, Appl. 16 Sep 1991; A. K. Mehta, M. C. Chen, U.S. Patent 5,358,792, 25 Oct 1994, Appl. 22 Feb 1991, 23 Apr 1993, to Exxon Chem. Co.
1991	Polypropylene, 55–90 wt% PP, was blended with poly (1-butene), PB, as a dispersed phase and optionally with up to 10 wt% of low-MW poly(α-olefin-co-ethylene) plastomer compatibilizer. The blends were useful for manufacturing fibers and nonwovens, with good "hand" and tensile strength	K. W. Bartz, J. C. Floyd, P. Meka, and F. C. Stehling, PCT Int. Appl., WO 006,168, 01 Apr 1993, Appl. 16 Sep 1991, to Exxon Chemical Patents, Inc.
1991	Semicrystalline polyolefin blends and method of their preparation were described. The blends were reported to show enhanced inter-spherulitic and interlamellar strength. The first polymer should have higher crystallinity and crystallization temperature than the second. Thus, 50–99.9 wt% PP was blended with ethylene–α-olefin copolymers, either a stereo block polypropylene or an ethylene–propylene copolymer, EPR	A. Lustiger, Canadian Patent Appl., 2,083,664, 21 June 1993, Appl. 20 Dec 1991, to Exxon Research and Engineering Co.

<div align="right">(continued)</div>

Table 18.12 (continued)

Year	Development	References
1991	Vinyl-trimethoxysilane-grafted polyolefin, PO (e.g., PP, LDPE, EPR, or EVAc), was blended with and ethylene–acryloyloxytetramethylpiperidine. The water-cross-linkable blends were found useful for manufacturing weather-resistant cross-linked polyolefin pipes for outdoor applications	S. Ohnishi, T. Fukuda, European Patent Appl., 548,565, 30 June 1993, Appl. 12 Dec 1991, to Mitsubishi Yuka Industrial Products Corp.
1991	Blends comprised 1–70 wt% of either metallocene polypropylene, PP, or a copolymer of propylene with ≤ 10 mol% ethylene or C_2–C_{20} α-olefin that has $M_w/M_n \leq 3$ and 30–99 wt% of a similar copolymer but with $M_w/M_n = 3.5$–10. The blends were used for films having excellent low-temperature heat sealability and blocking resistance	T. Fujita, T. Sugano, H. Mizuno, H. Uchino, U.S. Patent 5,331,054, 19 July 1994, Appl. 19 Oct 1992, Jap. Appl. 21 Oct 1991, to Mitsubishi Petrochemical Co., Ltd.
1991	Radiation-resistant, heat-sealable, polypropylene, PP, blends (softer and tougher than similar ones) comprised 1–99 wt% mesomorphous PP or its copolymer, ethylene–vinyl acetate, EVAc, and/or ethylene–acrylic acid copolymer, EAA, and polybutene, PB. For example, films were prepared by blending, extruding, and then quenching. The resins were useful for manufacturing medical goods, tapes, ostomy bags, packaging materials, drug delivery patch, medical type, etc.	D. L. Wilfong, R. J. Rolando, European Patent Appl., 547,834, 23 June 1993, Appl. 18 Dec 1991, to Minnesota Mining and Mfg. Co.
1992	Polyolefin, 100 parts PO [PE, PP, or EPR], was grafted with 0.01–20 parts of the monomers' mixture [consisting of 5–50 mol% of glycidyl (meth) acrylate and 95–50 mol% of acrylamide, vinylpyrrolidone, acrylic acid esters, and/or methacrylic acid esters]. Grafted PO was used as modifier for engineering plastics or as adhesion improver for filled plastics	T. Teraya, S. Kikuchi, K. Yokoyama, Y. Fujita, Japanese Patents 61 45,260, 61 45,261, 24 May 1994; European Patent Appl., 596,654, 11 May 1994, Appl. 28 Oct 1993, JP Appl. 30 Oct 1992, to Tonen Corp.
1992	Heterogeneous ion exchange materials contained 44–55 wt% of an ion exchange resin dispersed within a blend of LLDPE and HDPE (having $MW > 200$ kg mol^{-1}.) The maximum density of LLDPE, and minimum density of HDPE, was approximately 940 kg m^{-3}. The ion exchange material was selected from between anionic, cationic, and amphoteric ion exchange resins and their mixtures	A. Giuffrida, U.S. Patent 5,346,924, 13 Sep 1994, Appl. 23 Sep 1992, to IP Holding Company
1992	Linear low-density polyethylene, LLDPE, was blended with starch and at least one ionic compound (in such amount that the concentration of anions and cations was between 0.002 and 5 mol kg^{-1}) to produce high-frequency sealable articles. The starch could also contain ≤ 50 wt% of a plasticizer. The alloys could be processed by calendering,	C. Dehennau, T. Depireux, I. Claeys, European Patent Appl., 587,216, 16 Mar 1994; Japanese Patent 62 07,046, 26 July 1994, Appl. 01 Sep 1992, to Solvay et Cie.

(*continued*)

Table 18.12 (continued)

Year	Development	References
	extrusion, etc., to produce multilayer films or sheets weldable or sealable by induction heating at high frequency, useful in packaging, paper making, etc. The presence of the starch improved the long-term biodeterioration of the materials	
1992	Polymer blends comprised melt-blended high- and low-molecular-weight polyethylenes, PE, having the viscosity (at $100\ s^{-1}$) of, respectively, $\eta > 5$ and $\eta < 0.3\ k\ Pa\ s$. The two polymers were blended at two stages, first the high-molecular-weight polymer was blended with a small amount of the other polymer, and then an additional low-molecular-weight resin was incorporated. The blends showed good processability and excellent properties. They were used for production of films with low fish-eye content, blow molding, pipes, wire coating, as well as for injection or rotational molding	W. R. Coutant, European Patent Appl., 588,147, 23 Mar 1994; Can. Pat., 2,099,750, 02 Mar 1994; Japanese Patent 61 82,756, 05 July 1994, Appl. 01 Sep 1992, to Phillips Petroleum Co.
1992	Reactor blends of high-density polyethylene, HDPE with butene and/or hexene, were produced in a multistage, gas-phase, fluidized bed polymerization, where blending occurred in situ. The resulted bimodal molecular weight distribution resin had 35–75 wt% of the higher-molecular-weight component. The blown films had improved MD/TD tear balance	A. H. Ali, J. T. T. Hsieh, K. J. Kauffman, Y. V. Kissin, S. C. Ong, G. N. Prasad, A. L. Pruden, S. D. Schregenberger, U.S. Patent 5,284,613, 08 Feb 1994, Appl. 04 Sep 1992, to Mobil Oil Corporation
1992	Polyolefin blends with improved barrier properties comprised 85–99.5 wt% of a polyolefin (e.g., high-density polyethylene, HDPE) with 0.5–15 wt% of high-nitrile polymer (e.g., an acrylonitrile butadiene copolymer). The alloys were found useful for molding plastic bottles, automobile gasoline tanks, and other containers having limited or restricted permeability to gases, vapors, or organic liquids. These materials also showed good chemical resistance, strength, and processability	G. P. Coffey, E. S. Perec, N. W. Standish, L. Melamud, J. Smola, European Patent Appl., 586,066, 09 Mar 1994; Japanese Patent 61 57,837, 07 June 1994, Appl. 23 July 1992, to Standard Oil Co.
1992	Blends comprising very low density polyethylene, 100 parts VLDPE [80–95 mol wt% ethylene and C_4–C_8 comonomer(s)], and linear low-density polyethylene, 15–600 parts LLDPE (ethylene copolymer with 2–8 mol% octene), showed excellent processability. They were formed into 10–300 μm thick sheets, useful for transdermal drug delivery devices as single-layer backings. They were clear, colorless, transparent, permeable to oxygen, stable to various common components of transdermal delivery devices, strong, comfortable, and not absorbing significant amounts of elements of transdermal carriers. Sheets made from the blends could be heat sealed at a low temperature	K. J. Godbey, P. G. Martin, PCT Int. Appl., WO 94 03,539, 17 Feb 1994; U.S. Patent 5,264,219, 23 Nov 1993, Appl. 07 Aug 1992, to Minnesota Mining and Mfg. Co.

<div align="right">(continued)</div>

Table 18.12 (continued)

Year	Development	References
1992	Heat-shrinkable film comprised single-site catalyzed copolymer of ethylene and a C_{3-8} alpha-olefin, LLDPE with $\rho \geq 900$ kg m^{-3} blended with another polymer of ethylene and a C_{3-8} alpha-olefin and a second comonomer [e.g., vinyl acetate, alkyl acrylate, CO, butadiene, styrene, acrylic acid, and a metal salt of an acrylic acid], or an alpha-olefin homopolymer. The heat-shrinkable films had improved shrinkability, impact resistance, and optical properties compared to prior art and were used in packaging	R. Babrowicz, B. C. Childress, K. R. Ahlgren, G. P. Shah, European Patent Appl., 597,502, 18 May 1994, Appl. 13 Nov 1992, to W. R. Grace and Co.
1992	Polyolefin blends formulated for heat seamable roof sheeting comprised 25–95 wt% of amorphous PO having <1 wt% crystallinity (<60–61 wt% ethylene, dicyclopentadiene, and/or ethylidene norbornene); 5–75 wt% of a crystalline polymer, i.e., PE, PP, poly (ethylene-*co*-propylene), poly(ethylene-b-octene), or poly(ethylene-b-butene), having 2–65 wt% crystallinity; 20–300 phr of a (non)reinforcing filler; and 20–150 phr of either paraffinic oil, naphthenic oil, and/or wax. The materials exhibited good adhesion. Neither an adhesive nor curing was necessary	J. A. Davis, J. K. Valaitis, European Patent Appl., 564,961, 13 Oct 1993; Can Pat., 2,093,397, 07 Oct 1993; U.S. Patent 5,286,798, 15 Feb 1994; Japanese Patent 60 65,434, 08 Mar 1994, Appl. 06 Apr 1992, to Bridgestone/ Firestone, Inc.
1992	Blends comprising cycloolefin polymer, 0–95 wt% PCO; polyethylene, 0–95 wt% PE; and 0.1–99 wt% block copolymer(s) were prepared for moldings with outstanding properties, viz., improved melt viscosity, elongation at break, impact strength, toughness, hardness, and modulus. The block copolymers of ethylene (or propylene) and norbornene blocks were obtained in the presence of aluminoxane and a metallocene catalyst, resulting in $M_w/M_n \leq 2$	U. Epple, M. -J. Brekner, U.S. Patent 5,359,001, 25 Oct 1994, Appl. 20 Apr 1993, Ger. Appl. 22 Apr 1992, to Hoechst A.-G.
1992	Blends included 70–90 wt% of a polymer derived from ethylene and at least one higher alpha-olefin (e.g., LLDPE, VLDPE, or LDPE having MI = 0.1–10), 10–30 wt% of an auxiliary co-crystallizable polymer, derived from ethylene and at least one olefinic comonomer (e.g., LLDPE, VLDPE, or LDPE having MI $\geq$ 80 %, below that of the first polymer), and moisture cross-linking additives including a silane, a silanol condensation catalyst, and a free radical initiator. Cross-linking was rapid; thus, the moisture-curing step subsequent to extrusion of an electrical cable was short. The blends could contain processing aid (fluorinated polymer and/or a polyethylene with high MI) and 5–70 wt% filler. They were used for shaped coatings and cable coating	W. K. Wong, D. C. Varrall, European Patent Appl., 584,927, 02 Mar 1994, Appl. 24 July 1992, to Exxon Chemical Patents Inc.
1992	Polyethylene blends having toughness and elastic recovery comparable to those of plasticized PVC comprised $\geq$50 wt% of a copolymer of ethylene and either butene or hexene [LLDPE,	M. R. Rifi, U.S. Patent 5,326,602, 05 July 1994, Appl. 01 Dec 1992, to Union Carbide Chemicals & Plastics Technology Corporation

(*continued*)

Table 18.12 (continued)

Year	Development	References
	ρ = 880–915 kg m^{-3}, MI $\leq$ 1 dg min^{-1}, long-chain branching = 0.5–1.5 long chains/1,000C, M$_w \geq$ 200 kg mol^{-1}]; $\geq$5 wt% of a copolymer of ethylene and either vinyl acetate or ethyl acrylate, EVAc or EEA; and 5–30 wt% liquid hydrocarbon oil. The blends showed essentially no yield point and behavior similar to that of cross-linked materials, although they were not cross-linked (strain recovery). They were found competitive with plasticized PVC in terms of both physical properties and economics	
1992	Linear low-density polyethylene, 90–99 wt% LLDPE, was blended with polymethylmethacrylate, 10–11 wt% PMMA, and optionally a compatibilizing copolymer, viz., SEBS, EPR, ethylene–styrene block copolymer, ES. The blends were found to produce blown films with improved tear in the machine direction, modulus, and impact strength	D. V. Dobreski, J. J. Donaldson, U.S. Patent 5,290,866, 01 Mar 1994, Appl. 16 Apr 1992, to Mobil Oil Corp.
1992	Continuous process for the preparation of polyisobutylene, PIB, blends with at least one other polymer, e.g., polyolefin, PO, was described. PIB was continuously polymerized in ethylene. The resin was fed to a degassing extruder where it was mixed with PO, fillers, and/or additives. The process was used for the preparation of blends in a simpler and more cost-effective manner than that of prior art	H. Gropper, E. Kolk, K. H. Fauth, G. Isbarn, G. Scherer, German Patent 4,319,181, 27 Jan 1994; French Patent 2,694,010, 28 Jan 1994, Appl. 22 July 1992, to BASF A.-G.
1992	Thermoplastic rubber blends with good adhesion to reinforcing agents comprised 10–100 wt% polyolefin grafted with polar monomers (e.g., 27–75 wt% PP grafted with vinyl acetate, acrylic acid, methacrylic and itaconic acid, or maleic acid anhydride) and elastomer(s) (EPDM, NBR, or BR) that could be dynamically cross-linked by peroxide, silane, or sulfur. The blends may also contain 0.3–2.5 wt% plasticizer, fillers, pigments, processing aids, and flame retardants. They showed bondability to solids, especially after application of high temperature and pressure, thus were used for the production of conveyor belts, hoses and V-belts	S. Luepfert, F. Roethemeyer, E. Maeder, European Patent Appl., 580076, 26 Jan 1994; German Patent 4,223,984, 27 Jan 1994, Appl. 21 July 1992, to Continental A.-G.
1992	Polyolefin compositions with improved toughness, flexibility, and high clarity were prepared by blending 90–95 wt% setereoregular polymer or copolymer of 4-methyl-1-pentene, PMP, with polybutene, PB, having M$_n$ < 500	M. J. Hagenson, H. F. Efner, L. C. Hasselbring, W. H. Beever, European Patent Appl., 556,843, 25 Aug 1993, Appl. 20 Feb 1992, to Phillips Petroleum Co.
1992	Polyolefin (PO = PP, HDPE, EPR, or PMP) was blended with an impact modifier, 0.1–5 wt% colorant and/or 5–50 wt% of opacifiers, and a styrene–diolefin block copolymer, grafted with 1–6 mol% of acrylic	J. O'Leary, S. Musgrave, PCT Int. Appl., WO 93 21,269, 28 Oct 1993; Australian Patent 93 36,840, 10 Oct 1993; Australian Patent 93

(*continued*)

Table 18.12 (continued)

Year	Development	References
	acid, maleic anhydride, or sulfonate functionality (SEBS, SEPS, radial SEB, or SEP). To improve scratch resistance the blend contained 100–3,000 ppm Zn–stearate and C_{16-22} fatty acid amide. The alloys were injection molded into parts showing impact, scratch, and abrasion resistance. They were used to manufacture interior trim for vehicles and in other applications where a scratch- and scuff-resistant plastic material is required	40,363, 18 Nov 1993, Appl. 09 Apr 1992, to ICI Australia Operations Proprietary Ltd.
1992	To prepare polyolefin blends, PO (e.g., EVAc, PE, PP, EPR), with vinyl polymers, 10–200 parts of vinyl monomer [e.g., (meth)acrylates, styrenics, vinyl chloride, glycidyl methacrylate, maleic anhydride, acrylonitrile, divinylbenzene] and 0.01–4.0 parts of a free radical initiator were used to impregnate 100 parts of PO particles at $T = 20–130\,°C$. After 50–99 wt% of the monomer was absorbed, the particles were dispersed in water and the free radical polymerization initiated. Good adhesion between the components in the extruded or molded articles was achieved	T. Vestberg, I. Lehtiniemi, U.S. Patent 5,300,578, 05 Apr 1994, U.S. Appl. 27 Jan 1993, Finnish Appl. 27 Jan 1992, to Neste Oy
1992	Polyolefins, PO, blends with copolymers of vinyl acetate and acrylate esters, EVAc (20–40 wt% VAc), were extruded into films, weldable by high-frequency currents. It replaced PVC flexible films, e.g., in inflatable goods. For example, 400 µm PVC film, inflated to 100 mbars, after 13 days, had lost 72 wt% of the pressure, while the new blends (15 wt% VAc in the blend) of 200 µm film lost 50 wt% in 19 days	G. Benatre, French Patent 2,688,511, 17 Sep 1993, Appl. 13 Mar 1992
1992	Polyolefin, PO, molding compositions, suitable for the use in automotive application, comprised polyolefin wax [$M_w = 1–50\ kg\ mol^{-1}$, $M_w/M_n = 1.8–4.0$, and $T_m = 120–160\,°C$] and 1–80 wt% of either a PO [$M_w \geq 100$, $M_w/M_n = 1.8–4.0$, and $T_m = 120–160\,°C$], an olefinic copolymer derived from at least two different olefins [$M_w \geq 100$, $M_w/M_n = 1.98–4.0$, and $T_m = 90–160\,°C$], or an elastomer with $T_g < -20\,°C$. The blends could be impact modified by incorporation of a copolymer. They were molded, extruded, or blow molded into articles showing high modulus, hardness, scratch resistance, and low shrinkage	B. Bachmann, A. Winter, European Patent 563,818, 6 Oct 1993, Appl. 31 Mar 1992, to Hoechst A.-G.
1992	Blends of PE (selected from VLDPE and/or LLDPE), with 13–17 wt% ethylene–butene plastomer copolymer [Mitsui's TAFMER™, $\rho < 900\ kg\ m^{-3}$, $T_m = 55–85\,°C$], and 35–50 wt% ethylene–vinyl acetate copolymer, EVAc, were used for film blowing, useful as packaging materials for foods. The film had shrink properties in MD and TD similar to those of EVAc film and plastic orientation properties similar to	B. L. Wilhoit, European Patent 562,493, 29 Sep 1993; D. J. Ralph, U.S. Patent 5,279,872, 18 Jan 1994, Appl. 17 Feb 1993, Appl. 23 Mar 1992, to Viskase Corp.

<div align="right">(continued)</div>

Table 18.12 (continued)

Year	Development	References
	those of VLDPE films. In the U.S. Patent the biaxially oriented heat-shrinkable multilayer stretch film comprising 65–80 wt% VLDPE and a plastomer was reported useful as poultry wrap	
1992	Polyolefin, PO [of ethylene, propylene, butylene, 4-methylpentene, and their copolymers with 1-alkenes, vinyls, (meth)acrylates – preferably PP], was grafted at a ratio 1:9–4:1 with 1–20 wt% of (meth)acrylic acid and $\geq$30 wt% of styrene and/or alkyl- and/or halo-substituted styrene, methacrylic ester, and 0–60 % of other comonomers [e.g., vinyl aromatic, ester], at least some of the acid units of methacrylic acid and/or acrylic acid bearing a charge and being associated with non-polymeric counterions [e.g., 90 % methyl methacrylate, 5 % butyl acrylate, and 5 % methacrylic acid with either Ca^{2+} or Mg^{2+}. The ionomer could be blended with PO either during or after manufacturing. The blends were extruded either directly or after pelletization. They exhibited high sag resistance without increased viscosity. PP fibers could be used for strapping, netting, slit tape, rope, twine, bags, carpet backing, foamed ribbons, upholstery, rugs, pond liners, awnings, swimming pool covers, tarpaulins, bristles, sutures, nonwoven fabrics, bedsheets, bandages, diaper liners, etc.	R. G. Hamilton, M. T. McCarty, European Patent Appl., 589,659, 30 Mar 1994; U.S. Patent 5,319,031, 07 June 1994; Canadian Patent 2,106,344, 25 Mar 1994; British Patent 93 03,861, 31 May 1994; Japanese Patent 62 012,048, 02 Aug 1994, Appl. 24 Sep 1992, to Rohm and Haas Co.
1992	Polyolefin blends comprised 25–95 wt% of a crystalline random copolymer, EPR1 (of propylene with ethylene and/or an alpha-olefin), and 5–75 wt% of a mixture consisting of PE and EPR2. The density of EPR1 was about equal that of the mixture. The blends had good transparency and impact resistance even at low temperatures and were used to manufacture food containers, medical, packaging films, etc.	G. Cecchin, R. Ghisellini, D. Malucelli, European Patent 557,953, 01 Sep 1993, Appl. 24 Feb 1992, to Himont, Inc.
1992	Nonwoven textile materials comprised fibers obtained from a blend of 5–95 wt% propylene, PP (or propylene/ethylene copolymer with $\leq$10 wt% ethylene, EPR), and 95–95 % polyolefin, PO, selected from EPDM, EPR, LLDPE, etc. The materials have been used in disposable personal hygiene products or protective clothing. The products showed improved strength, drapability, softness, and bonding performance	K. Ogale, M. E. Strasinic, European Patent Appl., 598,224, 25 May 1994, Appl. 15 Oct 1993; Canadian Patent 2,108,819, 01 May 1994; Japanese Patent 62 00,093, 19 July 1994; U.S. Patent 5,346,756, 13 Sep 1994, Appl. 30 Oct 1992, to Himont Inc.
1992	Polypropylene, PP, was blended with a random crystalline terpolymer of 96–85 wt% propylene, 1.5–5.0 wt% ethylene, and 2.5–10 wt% $C_{4–8}$ alpha-olefin. The blends were used to manufacture strands of multiple monofilaments or staple fibers with high resiliency and shrinkage, for pile fabric,	L. Clementini, A. F. Galambos, G. Lesca, K. Ogale, L. Spagnoli, M. E. Starsinic, L. Giuseppe, European Patent 552,810, 28 July 1993, Appl. 29 May 1992, to Himont Inc.

(*continued*)

Table 18.12 (continued)

Year	Development	References
	textiles, geotextiles, or carpets. The carpet yarn had a twist retention of over 30 %, shrinkage on heat setting at 143 °C of at least 15 %, and uniform shrinkage	
1992	Blends comprising polypropylene, 50–97 wt% PP [or a PP block copolymer with ethylene block], and 50–53 wt% of an ethylene/C_{4-18} alpha-olefin copolymer [α-olefin content t = 10–60 wt%, $\rho \leq$ 913 kg m^{-3} obtained by using a metallocene catalyst and aluminoxane] were found useful as automobile trims and trims of electrical instruments. They showed high moldability, improved impact resistance at room and low temperature, and balance of rigidity and impact resistance	K. Shichijo, European Patent Appl., 593,221, 20 Apr 1994; Japanese Patent 61 92,500, 12 July 1994, Appl. 15 Oct 1992, to Mitsubishi Petrochemical Co., Ltd.
1992	A multilayer film comprised polypropylene, PP [or PP copolymer with 20–40 wt% hydrocarbon resin], in the core; outer layers from PP, LLDPE, PB, or their blends with 4–15 wt% PP; and the intermediate layers from polyolefin-based carboxylic acid or maleic anhydride. An oxygen barrier layer from EVOH, PVDC, PEST, or PA could also be used. The films were biaxially oriented at ratios of 3:1–8:1. They had low moisture transmission rate, toughness, abrasion resistance, good clarity, and gloss, suitable as moisture barrier packagings for food, pharmaceuticals, and electronics	P. S. Gautam, European Patent Appl., 588,667, 23 Mar 1994, Appl. 20 Sep 1993; British Patent Appl., 93 03,823, 22 Mar 1994; Australian Patent 93 47,378, 24 Mar 1994; Ca. Pat., 2,106,258, 19 Mar 1994; Japanese Patent 61 98,826, 19 July 1994, US Appl. 18 Sep 1992, to W. R. Grace & Co.
1992	Ternary blends contained 87–96 wt% LLDPE (with either butene-1, hexene-1, or octene-1), 1–10 wt% isotactic polybutene, 1–10 wt% PS, and 0.01–10 wt% color and anti-blocking agents. The blends exhibited improved process efficiency in terms of extruder amps/rpm ratio, while the terpolymer substantially retained the inherent strength of the LLDPE. The compositions were used for blown films and for the manufacture of waste bags	S. P. Evans, P. P. Shirodkar, US 5,258,463, 02 Nov 1993, Appl., 24 Aug 1992, to Mobil Oil Corporation
1992	Semicrystalline polyolefin blends were prepared by mixing two different random copolymers of propene with C_{4-10} alpha-olefin at a ratio from 1:3 to 1:1. The first copolymer contained 1–10 wt% of C_{4-10} alpha-olefin (1-butene, 1-pentene, 1-hexene, 1-octene, and 4-methyl-1-pentene), whereas the second 15–40 wt% of the same comonomer. The mixing was carried out in reactors, polymerizing the monomers in the presence of stereospecific catalysts supports on active magnesium dihalides, in at least two sequential stages. The resulting R-TPOs	G. Cecchin, F. Guglielmi, European Patent 560,326, 15 Sep 1993, Appl. 10 Mar 1992, to Himont Inc.

(continued)

Table 18.12 (continued)

Year	Development	References
	showed limited solubility in xylene, low heat-sealing temperature, and high melting point and were used for the production of heat-sealable laminated mono- or bi-oriented films suitable for the food industry	
1992	PE blends were prepared during polymerization. This strategy has been widely implemented in syntheses of multimodal PE compositions. The blown film showed MD/TD tear balance. The bimodal blend contained 0.35–0.75 weight fraction of a higher-MW component.	A. H. Ali, J. T. T. Hsieh, K. J. Kauffman, Y. V. Kissin, S. Christine Ong, G. N. Prasad, A. L. Pruden, S. D. Schregenberger, Producing blown film and blends from bimodal high density high molecular weight film resin using magnesium oxide supported Ziegler catalyst, U.S. Patent 5,284,613 of 08 Feb 1994 (filed 1992) to Mobil Oil Co.; Dammert et al., U.S. Patent 6,185,349 of 06 Feb 2001 (filed 1999) to Borealis Polymer Oy
	Ali A.H. et al. to Mobil Oil Co.; Dammert et al. to Borealis. Catalyst: $TiCl_4$/pentanol deposited on MgO/acetic acid and then treated with tri-n-hexyl-aluminum solution	
	Reactor blending during the slurry polymerization gave two PE fractions with different MW. Borealis generated multimodal resins for optical cables using slurry-/gas-phase reaction with Z-N catalyst with $MgCl_2$	
1993	Polyethylene blends comprised a low-density polyethylene, ≤60 wt% either LDPE or LLDPE; postconsumer recycled high-density polyethylene, 4–30 wt% HDPE; and an effective amount of a compatibilizer comprising 0.1–1.5 wt% ZnO and 0.1–2 wt% of glycerol monostearate. The blends could also contain 5–30 pph of a blowing agent. The blends were used to make aesthetically appealing foamed products for use as cushioning materials or as packaging films	S.-T. Lee, U.S. Patent 5,428,093, 27 June 1995, Appl. 05 Nov 1993, to Sealed Air Corporation
2003	Polymer blends (mechanical) comprised (A) 35–85 wt% Z-N i-PP ($T_m > 130$ °C) and (B) 30–70 wt% metallocene α-olefin-*co*-PP with crystallizable α-olefin sequences [narrow MWD, composition distribution single T_m]. The blends showed improved processing, unexpected compatibility, single T_m, and increased tensile strength	S. Datta, C. Cozewith, P. Ravishankar, E. J. Stachowski, Elastic blends comprising crystalline polymer and crystallizable polymers of propylene, U.S. Patent 6867260 of 15 Mar 2005 (filed 22 Apr 2004; priority 29 June 1999, U.S. Patent 6642316); Sudhin Datta, Avinash C. Gadkari, Charles Cozewith, Alpha-olefin/propylene copolymers and their use, U.S. Patent 6982310 of 03 Jan 2006 (filed 06 May 2005; priority 03 July 2003, USPat. 6635715) to ExxonMobil Chemical Patents, Inc.
	Datta, Cozewith, Ravishankar, Stachowski, Gadkari to ExxonMobil Chemical Patents, Inc.	
	The (A) component is either i-PP with <10 wt% comonomer, while (B) is preferably crystallizable C_2–C_3 copolymer. Blends were mechanically mixed	
	ExxonMobil developed poly(propylene-*co*-ethylene) Vistamaxx™ post-metallocene resin. The polymerization procedure for the blend component is described in U.S. Patents. 5198401 of 30 Mar 1993 and 5057475 of 15 Oct 1991; catalyst system of enhanced productivity, 5153157 of 06 Oct 1992, to Exxon Chem	

Table 18.12 (continued)

Year	Development	References
2004	The copolymers of the blend were prepared using (a) a silyl chromate catalyst, $(R10)_3$Si-O-CrO$_2$-O-Si$(R10)_3$ wherein R10 = C_{1-10} alkyl, and (b) a phosphinimine catalyst, $(L)_n$-M-$(PI)_m(X)_p$ where M = Ti, Hf, or Zr; PI = phosphinimine ligand; ligand L = Cp, indenyl, or fluorenyl; X = Cl or C_{1-4} alkyls; $m = n = 1$; and $p = 2$. A catalyst activator includes alumoxanes (e.g., MAO) with a molar ratio of Al:M = 50:1–250:1 and ionic boron-containing activators. Kazakov and Yim, to NOVA Chemicals	K. Alexei, Y. Gary, Polyolefin blends and pipe, CA 2508436, filed 26 May 2005; U.S. Patent 7,309,741 of (filed 01 June 2004); U.S. Patent Appl. 2008/0090040A1 (filed 14 Nov 2007, priority 01 June 2004) now, U.S. Patent 7696281of 13 Apr 2010 to NOVA CHEMICALS CORPORATION (Canada) or NOVA Chemicals (International) S.A.
	The invention describes PE blends of a low-MW HDPE made using a Z-N type or Cr-based catalyst and a high-MW m-LLDPE made using a Group 4 single-site-type catalyst. The blends are suitable for the manufacture of pipes, tested according to ASTM D 2837 or ISO 9080	The ionic activators are disclosed in, e.g., J. C. Stevens, D. R. Neithamer, U.S. Patents 5132380 of 21 July 1992 (filed 12 Sept 1991); to Dow Chem. Co.; H. W. Turner, G. G. Hlatky, R. R. Eckman, 5198401 of 30 Mar 1993 (filed 30.07 1991) to Exxon Chemical Patents Inc.
	A polyolefin blend comprises (a) 30–80 wt% of a low-MW copolymer [85–99.5 wt% of C_2 and 0.05–15 wt% of C_{4-8} α-olefin, $\rho = 0.953$–0.965 g mL^{-1}, and MFR (2.16 kg 190 °C) = 0.1–20.0 g/10 min] and (b) 70–20 wt% of a high-MW copolymer [85–99.9 wt% of C_2 and from 15 to 0.1 wt% of C_{4-8} α-olefin, $\rho = 0.915$–0.940 g mL^{-1}, and an MFR (21.6 kg 190 °C) = 0.05–5.0 g/10 min]. The selected resins were blended in a compounder and then extruded as pipes	
2009	Solution polymerization of HDPE ($\rho = 0.890$–0.970 g mL^{-1}) takes place in ≥ 2 reactors. The process (a) provides a first C_2 and C_{4-10} feed to ≥ 1 continuously stirred tank reactor (CSTR) in the presence of a catalyst, producing a first PE component; (b) the second (tubular) reactor (TR) is fed with the first PE solution, enriched by preheated $T \geq 100$ °C monomer(s) and solvent. The weight ratio of the additional solvent to C_2 = 20/1–0.1/1 and the additional C_2 = 1–50 wt% of the C_2 added to CSTR	Lauwrence Martin Jozef Van Asseldonk, Stephen John Brown, Multi reactor process, CA 2,688,217 of 11 June 2011 (filed 11 Dec 2009); US 8,101,693 B2 of 24 Jan 2012 (filed 06 Dec 2010; priority 2009) to NOVA Chemicals (International) S.A.
	Asseldonk and Brown, from NOVA Chemicals (International) S.A.	
	This document describes a process with one CSTR and one TR, but a single STR may also be used – in the former case a catalyst should be injected to each reactor. While the main catalyst is Z-N type, use of a single-site one may offer additional advantages blending homogeneously and heterogeneously branched chains	

<div align="right">(continued)</div>

Table 18.12 (continued)

Year	Development	References
	This multi-reactor system used for copolymerization of C_2 with higher α-olefins comprises a CSTR connected in series to a tubular reactor (TR). The latter receives a polymer solution from the CSTR. Polymerization in TR improves efficiency, by reducing the amount of energy required to recover the polymer and residual comonomer from the solution. The use of preheated C_2 in TR mitigates the contaminating gel problems (fouling TR and creating "fish eyes" on film) and reduces hexane extractables

Abstract

In this chapter, an overview of the commercially important polymer blends is presented with a particular emphasis on the rationale for their commercial development, the compatibilization principles, their key mechanical properties, and their current applications and markets. To facilitate the discussion, the commercial polymer blends have been classified as follows into 13 major groups depending on the type of the resin family they are based on.

  (i) Polyolefin blends
 (ii) Styrenic blends
(iii) Vinyl resin blends
 (iv) Acrylic blends
 (v) Elastomeric blends
 (vi) Polyamide blends
(vii) Polycarbonate blends
(viii) Poly(oxymethylene) blends
 (ix) Polyphenyleneether blends
 (x) Thermoplastic polyester blends
 (xi) Specialty polymer blends
(xii) Thermoset blend systems
(xiii) Biodegradable polymer blends

Within each major category, the individual polymer blends of industrial significance have been described with relevant data. Since the discussion is limited only to those blends that are actually produced and used on a commercial scale, the relevant cost and performance factors that contribute to the commercial viability and success of various types of blends have been outlined.

In comparing the different blends, the specific advantages of each type, as well as any potential overlap in performance with other types of blends have also been discussed. The fundamental advantage of polymer blends, viz., their ability to combine cost-effectively the unique features individual resins, is particularly illustrated in the discussion of crystalline/amorphous polymer blends such as the polyamide and the polyester blends. Key to the success of many commercial blends, however, is the selection of intrinsically complementing systems or the development of effective compatibilization methods. The use of reactive compatibilization techniques in commercial polymer blends has also been illustrated under the appropriate sections such as the polyamide blends.

In many commercial blends, rubber toughening plays an important and integral part of the blend design. Combining high impact strength with other useful properties such as heat and solvent resistance can significantly enhance the commercial value of a blend. Hence, the nature of the impact modifiers used and the role of morphology on properties have been discussed under the appropriate cases of commercial blends. The chapter concludes with an outline of the potential trends in the commercial polymer development.

19.1 Introduction

Synthetic polymers represent an ubiquitous class of raw materials that are used in a wide spectrum of applications ranging from textiles, packaging, construction, automotive, industrial, electrical, and electronic equipments to appliances, toys, and various other consumer goods affecting our everyday life. Thus, polymers play an important major role in the global economy. The current global overall consumption of polymers used as plastics (i.e., excluding the textile fibers) is about 280 million metric tons/year (280 Mt/year) with a growth rate of 4–5 % (Reseau-plasturgie 2012). Among these, the commodity thermoplastics consisting of polyolefins (PE and PP), PVC, styrenics, PET bottle resins together represent ≥85 % of the total volume (Figs. 19.1 and 19.2). The higher-performance, value-added engineering thermoplastic resins such as ABS, PC, PMMA, POM, polyamides, PBT, and others represent about 10 % of the total market volume of thermoplastics with an annual global consumption of >20 million tons (Fig. 19.3). Polymer blends are a subgroup of such engineering plastics, with an estimated global consumption of over 2 Mt/year. The historical origin and development of polymer blends technology has been reviewed in another chapter of this handbook, viz., ▶ Chap. 1, "Polymer Blends: Introduction." In this chapter, only the various types of commercially significant polymer blend families will be discussed in detail.

The primary motivation for the commercial development of polymer blends has been to adjust the cost-performance balance and tailor-make products for specific end-use applications. Thus the commercial growth of polymer blends in the last several decades outpaced the growth rate of existing polymers by at least 2 %. The demand for polymers and the polymer blends will continue to increase as the global economy continues to grow. Several key factors contribute to the commercial success and continued interest in the polymer blends, such as those listed below:

1. The blending of commercially available polymers is a more cost-effective method of developing a new product that meets the specific customer or market requirements, as opposed to developing a totally new polymer which generally involves higher research and development costs and more importantly, prohibitively higher capital costs for the plant.
2. Polymer blends can fill the cost-performance gaps in the existing commercial polymers. Several properties can be uniquely combined in a blend that a single resin often cannot provide. In some cases, synergistic improvements in properties such as toughness and heat resistance are achievable.
3. Polymer blending can be done at a relatively low cost using an extruder. Production of new polymers, on the other hand, requires capital-intensive plants and reactors that must operate on a reasonably large scale for reasons of economics.
4. The flexibility of extruder blending enables custom production of different blends in a wide range of production volumes. Polymerization plants are generally not as flexible and not economical for small-volume production.
5. Polymer blends provide an avenue for diversifying and expanding the product line for resin producers and suppliers, without significant investment risks.

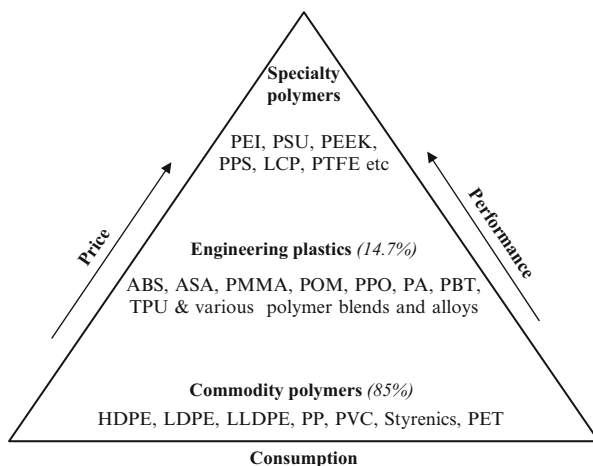
Fig. 19.1 Global consumption of thermoplastics (ca. 230 Mt/year) (Reseau-plasturgie 2012)


Fig. 19.2 Price/Performance profile of commercial thermoplastic polymers

6. Blends can be formulated, optimized, and commercialized generally at a much faster rate (from concept to commercialization) than new polymers, provided there are no major technical hurdles for the compatibility development between the components.

7. The development of an effective compatibilization technology, whenever it is needed, allows the resin supplier to establish a proprietary and competitively advantageous position. Effective compatibilization is also essential for polymer blend fabricated product's mechanical strength, toughness, and long- term durability during its intended service life.

8. Blends offer a useful, economic means of upgrading recycled or off-specification polymers.

Fig. 19.3 Global
consumption of engineering
thermoplastics (>20 Mt/year,
in 2012)
The terms "polymer blends" and "polymer alloys" have already been defined in the other chapters of this handbook, viz., ▶ Chap. 1, "Polymer Blends: Introduction" and ▶ Chap. 2, "Thermodynamics of Polymer Blends." In the trade literature, these terms have often been used interchangeably. In the context of current discussion, only the term "polymer blends" will be employed most of the time, except specifying, where possible, the origin of the technological compatibility between the components in each type of blend. Table 19.1 lists the commercially available polymer blends according to their primary structural categories indicated in Fig. 19.1.

19.1.1 Compatibilization Mechanisms in Commercial Polymer Blends

To be useful, most commercial polymer blends are either designed or selected to have some degree of the technological compatibility between the components to resist delamination and loss in ductility. Compatibility is defined here as the ability for the polymer components to coexist either as molecularly miscible or as morphologically distinct phases, but interfacially stabilized, without a tendency for delamination.

The compatibility in polymer blends can result from any of the following mechanisms:

1. Thermodynamic miscibility between the components such as in the case of polystyrene (PS) and poly(2,6-dimethyl 1,4-phenylene ether) (PPE) blends.
2. Partial miscibility at segmental level between the blend components, even when they are phase separated, imparting a low interfacial tension and an adequate

[a]Compatibilization mechanisms are defined here as the underlying principles responsible for the blend's desirable properties, delamination resistance and morphology stability. Compatibility may originate from inherent miscibility, partial miscibility or low interfacial tension between the components or through a chemical means, such as reactive graft-coupling or addition of interfacial agent
[b]No compatibilizer is used. Low interfacial tension between the components is responsible for the inherent compatibility in these systems
[c]The dispersed phase is selectively cross-linked via dynamic vulcanization to stabilize the blend morphology
[d]Partial miscibility between the components leads to self-compatibilization even though these systems are phase separated. Experimentally, these blends exhibit two T_g's, but different from each of the pure components due to a small amount of mutual miscibility
[e]Grafting involves direct chemical reaction between the components during melt mixing, generating a graft copolymer as the compatibilizer
[f]Ionic or chelate complex interactions between the components at the interface, may lead to compatibilization

    level of interfacial adhesion, e.g., in ABS/polycarbonate, PBT/polycarbonate, PVC/nitrile rubber blends.
3. Compatibilizing effects of interfacial agents such as block or graft copolymers that reduce the interfacial tension, stabilize the morphology, and strengthen adhesion at the interface.

    Although complete miscibility between polymers is generally rare, when this does happen, it provides a unique opportunity to custom tailor the blend properties by simply adjusting the blend ratio. The immense commercial success of PPE blends with high-impact polystyrene (HIPS) is primarily attributed to the miscibility between PPE and PS, that enabled one to combine the low cost and easy processability features of HIPS with the high-performance (high heat resistance and strength) features of PPE. There was also some synergistic improvement of the toughness due to the improved ductility of the blend matrix resulting in improved rubber toughening efficiency. Simple melt mixing in extruder-type compounding equipment is adequate to make an alloy from such miscible polymers.

    Even in the phase-separated blends, where some degree of partial miscibility or compatibility exists between the components, simple melt blending in an intensive

shear mixer is adequate for making well-dispersed, reasonably stable blend products with useful combination of properties, e.g., in polypropylene/ethylene-propylene rubber blends or ABS/polycarbonate blends. The self-compatibilizing nature of these blends stems from the partial miscibility and the mutual interpenetration of the individual component's polymer chains at the interface. Slight modifications of the polymer backbone are often employed, particularly in the case of styrenic and ABS resins to induce partial miscibility with other resins.

Compatibilization of the highly immiscible commercial polymer pairs has thus far been a technically more challenging task for the polymer technologists in the industry to make cost-effective, high-performance polymer blend products. Significant progress has, however, been made in recent years in utilizing compatibilizers based on graft or block copolymer or other interfacial agents that effectively reduce the interfacial tension between the components to achieve useful levels of ductility and delamination resistance, while at the same time stabilizing the morphology against processing effects. Interfacial compatibilization in commercial polymer blends is generally achieved through reactive extrusion in which the block or graft copolymer compatibilizer is generated in situ at the interface. The end groups or pendant groups in some commercial polymers such as polyamides (amine or carboxyl), polyesters (carboxyl or hydroxyl), and styrene-maleic anhydride copolymers (anhydride group) are useful for this purpose. In most other cases, the polymer backbones must appropriately be modified to include reactive functionalities by graft reactions with small molecules (e.g., maleation of polyolefins with maleic anhydride) or through copolymerization techniques.

The recent advances in reactive extrusion technology, involving reactive modification of polymers and/or reactive blending to form graft or block copolymer compatibilized blends in an extruder, have resulted in several successful commercial blends of otherwise highly immiscible polymer pairs, such as polyamide/olefinic elastomer, polyamide/polyolefin, and polyamide/PPE blends. In many cases, the reactive modification of the base polymers and the subsequent reactive blending can be combined into a one-step, sequential operation in a twin-screw extruder, making this an economically attractive process. Reactive compatibilization is still a growing technology aimed at the development of useful blends from otherwise highly immiscible polymers, and particularly those from crystalline polymers. Specific examples of reactive modification and reactive blending will be discussed later, in individual cases. Further details on compatibilization can be found in the other chapters of this book, viz., ▶ Chap. 4, "Interphase and Compatibilization by Addition of a Compatibilizer" and ▶ Chap. 5, "Reactive Compatibilization."

19.1.2 Rationale for Polymer Blends

Commercial polymer blends belong to one of the following three categories:
1. Blends of amorphous/amorphous polymers
2. Blends of crystalline/amorphous polymers
3. Blends of crystalline/crystalline polymers

While the specific advantages of each type of the blends will be discussed later in detail for the individual cases, the general motivations for making commercial polymer blends may be any of the following factors:

- Lower cost
- Improved dimensional stability
- Improved heat resistance
- Improved processability
- Improved toughness
- Improved weatherability
- Improved solvent resistance
- Improved flame resistance
- Improved moisture resistance
- Improved esthetics and appearance, etc.

Many commercial polymer blends often include an elastomer, to improve the impact strength of the blend under conditions of stress concentration (notched Izod impact strength) and to lower the ductile-brittle transition temperature of the blend. The elastomeric dispersions are judiciously employed either in the matrix phase, in the dispersed polymer phase, or in both phases, depending upon the requirement and the fracture behavior of the blend. As a general rule, the more brittle component in a given polymer blend has a greater need for rubber toughening.

However, an overwhelming factor in determining the impact strength of an immiscible or partially miscible blend is the degree and efficiency of interfacial compatibilization that either is inherent in or has been designed into the blend system. If the interfacial adhesion or compatibilization is poor, the elastomer dispersion alone will not improve the toughness. Further details on the role of compatibilization and rubber toughening effects in polymer blends will be discussed later with specific commercial examples. Combining a high level of impact strength with a high level of heat resistance and/or chemical resistance has been the primary thrust of most commercial polymer blends (Figs. 19.4 and 19.5).

19.1.3 Polymer Blend Processing

Most commercial polymer blends are produced by melt-mixing in continuous compounding equipment such as single-screw or twin-screw extruders and kneader-extruders. Twin-screw extruders are now well established and widely used for polymer blends manufacturing because of their great versatility and production efficiency. Owing to their segmented barrel and screw designs, twin-screw extruders offer the advantage of multiple processing zones. The degree of shear mixing, residence time, and the temperature in each of these zones can be varied at will by simply changing the order and/or the type of the screw elements and kneading blocks, and using separately controlled heaters.

Currently, there are three common types of twin-screw extruders (TSE) available for thermoplastic polymer compounding, viz.,
Fig. 19.4 Notched Izod vs. DTUL (°C at 1.8 MPa) of some commercial polymer blends

(1) Intermeshing corotating TSE
(2) Intermeshing counterrotating TSE
(3) Nonintermeshing counterrotating TSE

Among these, the intermeshing corotating twin-screw extruder is the most common type of equipment used by the polymer blends manufacturers. The barrels and screws of all commercial intermeshing corotating TSEs have modular designs allowing the processor to rearrange the barrel and screw components in different configurations to suit the processing needs of different polymer blends. In these modular designs, the desired screw configuration for a given polymer blend processing is obtained by assembling the various screw elements, viz., the conveying, kneading, and mixing elements in a desired manner to achieve consistent blend products.

The corotating twin-screw extruders also offer the choice of multiple ports for liquid injection, venting, and downstream feeding purposes. For example, the twin-screw extruder can be readily adapted to combine both the polymer modification and polymer-polymer grafting steps of a reactive blending process into a single-pass, multistage reactive extrusion process.
Fig. 19.5 Notched Izod vs. DTUL (°C at 0.45 MPa) of some commercial polymer blends

The polymer that needs to be functionalized is fed at the throat of a corotating twin-screw extruder and melt-mixed with a suitable grafting agent and catalyst in the initial zones. After vacuum venting to remove the unreacted and volatile materials, the "functionalized polymer" melt is then mixed with the second polymer and other components (impact modifier, fillers, additives, etc.) added through the downstream feed ports. The temperature and the shearing conditions in these latter zones of the extruder are controlled to promote intimate mixings. Polymer-polymer grafting, compatibilization, and the morphology development in the blend occur at this stage of extrusion. Thus all the sequences of the complex blending process can be accomplished in an economically viable one-step, extruder process.

Many commercial blends are often not as complex as above and can be made by simple melt-blending without a compatibilizer because of partial miscibility between the components. However, even in these cases, good intimate mixing (dispersive and distributive) between the components is necessary to ascertain a morphologically stable, good-quality product. Although twin-screw extruders are now invariably

preferred for polymer blending, many of the older plants also use the single-screw extruders, with mixing devices, for the reason of their low capital costs. There are many detailed reviews available regarding the theory and practice of twin-screw extruders and their mixing mechanisms in polymer processing (Chung 2000; Manas-Zloczower 2009; Hyun et al. 2011). Further discussion on the extruder compounding processes relevant to polymer blend manufacturing can also be found in another chapter of this handbook, viz., ▶ Chap. 9, "Compounding Polymer Blends."

Although commercial twin-screw extruders can be as large as 300 mm in size, capable of compounding up to 40 t/h, the actual type and size of the equipment used depend on the type of the polymer blend and the production volume. Normally, for engineering polymer blends, twin-screw extruders of about D = 90 mm size (L/D ≅ 30–40) and capable of compounding at 700–1,000 kg/h, are used. For blending PVC or elastomer blends, other types of compounding equipment are used; e.g., Farrell continuous mixer (FCM), Buss cokneader, or a batch mixer, such as Banbury, have also been used.

The technological details on commercial polymer blends are kept proprietary by the manufacturers, particularly with respect to the exact compositions of the commercial grades and the processes used to make them. Even when the patent literature is available for a given type of polymer blend, often one cannot infer the actual compositions and processes used for the commercial blends. Hence, in reviewing the technology of commercial polymer blends, certain assumptions and generalizations have to be made regarding the compositional effects on the properties of some commercial blends, where the literature information is lacking. However, in the following sections, all relevant technological principles behind the various commercial blends have been outlined along with a discussion of their key properties, differentiating values and applications based on a reasonable evaluation of the literature available to date.

19.2 Polyolefin Blends

Polyolefins (PO) constitute the largest single group among all the commercial thermoplastics, amounting to >50 % of the global volume of all commercial polymers. The polyolefin family comprises of (a) polyethylenes of various types, viz., high-density polyethylene (HDPE), low-density polyethylene (LDPE), linear low-density polyethylene (LLDPE); (b) polypropylene (PP) homopolymer and PP-b-E/P block copolymers; (c) ethylene-propylene rubbers (d) ethylene-octene copolymer and other polyolefin elastomers (POEs) (e) ethylene copolymers with other comonomers such as ethyl acrylate, acrylic/methacrylic acid, and the ionomers; (f) specialty polyolefins such as poly(4-methyl,1-pentene), poly(1-butene), etc. Among these, HDPE, LDPE, and LLDPE and polypropylene (PP) are the four most widely used polyolefins amounting to a current global consumption of >125 million metric tons (Nexant 2012). Polyethylenes together represent about 60 % and polypropylenes about 40 % of the global market share for polyolefins.

Because of the wide range of properties available within POs, generally there has not been any major need to blend polyolefins with other types of polymers.

Furthermore, the immiscibility of the commodity polyolefins with other types of polymers has also been a major reason for the lack of commercial interest in such blends, although with the advent of reactive modification and grafting chemistry, significant progress has been made in compatibilizing such dissimilar polymer systems as PA/PO blends (Ide and Hasegawa 1974; Epstein 1979; Hobbs et al. 1983).

Blending within the family of polyolefins has, however, been more common (Plochocki 1978). Although they are usually immiscible with each other, there exists some degree of mutual compatibility between them. The similarity of their hydrocarbon backbones and the closeness of their solubility parameters, although not adequate for miscibility, account for a relatively low degree of interfacial tension. For example, the solubility parameters of polyethylene, polyisobutylene, ethylene-propylene rubber, and polypropylene are estimated to be 16.0, 16.4, 16.5, and 17.0 $J^{1/2}$ $cm^{3/2}$ respectively, all very close to each other (VanKrevelen 1990). Similarly, the interfacial tension coefficients between PE or PP and EP-elastomers are quite small (typically ca. 0.1 MN/m) (Shih 1990; Wu 1989). Hence, polyolefin blends have been made since the early days of polyolefin commercialization via a simple melt mixing, without a compatibilizer.

The crystalline polyolefin homopolymers (HDPE and PP) have often been blended with low-modulus/elastomeric polyolefins such as LDPE, EP-rubber, in order to improve the toughness. Hence, toughened POs have been known for a long time commercially. Most of the toughened PO blends are simple mixtures of POs and olefinic elastomers melt blended in an extruder without a compatibilizer. However, recent advances in polymerization technology have allowed the production of toughened polypropylenes ("Impact PP"), through a sequential polymerization of ethylene-propylene copolymer in the PP matrix leading to blends with some block or graft copolymer exhibiting improved modulus/toughness balance (Galli and Haylock 1991).

19.2.1 Blends Based on Polyethylenes (HDPE, LDPE, LLDPE Based Blends)

HDPE, LDPE, and LLDPE are the three main types of commercial polyethylenes with a combined global consumption of >80 Mt/year. HDPE is a strictly linear homopolymer while LDPE is a long-branched homopolymer because of the different methods of polymerization. LLDPE, on the other hand, is a linear ethylene copolymer with small amounts of α-olefin comonomers such as butene, hexene, or octene. Traditionally, polyethylenes are classified according to the densities. The density of polyethylene decreases as the branching and/or comonomer content increases. The crystallinity and the properties associated with crystallinity, such as stiffness, strength, and chemical resistance, progressively decrease from HDPE to LDPE/LLDPE to POE grades.

Among the different types of polyethylene listed in Table 19.2, the HDPE is the most crystalline form with a reasonably high stiffness and strength. Hence, it is widely used in the injection molding, blow-molding, extrusion, and film applications. LDPE and LLDPE polymers, on the other hand, are the softer and tougher grades of

Table 19.2 The key features of commercial polyethylene homopolymers and copolymers

	HDPE	LDPE	LLDPE	Plastomer	PE elastomers (POE)
Comonomer (wt%)	None	None (branched)	2–5	10–25	>25
Density	0.94–0.97	0.91–0.92	0.91–0.92	0.87–0.91	0.85–0.87
Crystallinity	High	; Decreasing ⟶			
Modulus	High	; Decreasing ⟶			
Toughness at low temp.	Moderate	; Increasing ⟶			

polyethylene and hence are used primarily ($\geq$80 %) in the film applications. Because of the continuous nature of the film extrusion process, it is more amenable for blending different types of polyolefins to achieve specific improvements in the processability and properties of the desired film products. Some examples of commercial polyethylene blends will be discussed in the following section. A more detailed discussion on the polyethylene blends may also be found in another chapter of this handbook, viz., ▶ Chap. 18, "Polyethylenes and Their Blends."

19.2.1.1 Toughened HDPE (HDPE/LLDPE and HDPE/Olefinic Elastomer Blends)

HDPE is a highly crystalline polymer with a good combination of stiffness, strength, toughness, and chemical resistance. Hence, it is widely used in a variety of blow-molded rigid containers, pipe and profile applications, as well as film applications. However, for the automotive and miscellaneous outdoor and environmental applications, the low-temperature impact toughness and notch-sensitivity of HDPE often needed some improvement. Similarly, for the heavy-duty film applications such as in industrial bagging, agricultural, and geomembrane applications, improvement in toughness, puncture resistance, and environmental stress crack resistance was also needed. Hence, blending of low-modulus/rubbery modifiers has been used for a long time to achieve the above-described toughness in HDPE.

Blending of an elastomeric polyolefin such as polyisobutylene was used early on, to improve the dart impact and tear strength of the HDPE films (Anonymous 1974). Some commercial grades of HDPE utilized this rubber toughening technology (Haartman et al. 1970). With the advent of high melt-flow LLDPE resins and the lower-modulus/rubbery ethylene-α-olefin copolymers (plastomers and polyolefin elastomers-POEs), it is now more common to use these for toughening of HDPE, instead of the traditional rubbers, due to their improved processability and cost.

Thus, blends of HDPE with up to 30 % LLDPE have been considered for producing thinner-gauge films with improved tear strengths and toughness (Forger 1982; Kosoff 1987; Ogah and Afikuwa 2012). Blending LLDPE lowers the modulus and improves the tear strength of HDPE films (Fig. 19.6). In addition, the melt-processability and heat-sealability properties are also improved. Likewise, blending of LLDPE in LDPE is also used to improve the film processability and properties. More recently, polyolefin elastomers (POE) have been used in HDPE blends to significantly improve the low-temperature toughness of HDPE
Fig. 19.6 Effect of LLDPE on the modulus and tear strength of HDPE blend films
Fig. 19.7 Effect of POE content on the impact strength of HDPE-POE blends

(Anonymous 2006a). Typically, 5–20 wt% POE is blended in HDPE to achieve the desired low-temperature toughness (Fig. 19.7).

Commercially, the melt blending of an impact modifier in HDPE can be done simply during the extrusion process used for making the blown film or blow-molded rigid containers or in the extrusion of pipes and ducts. Ideally, such low-temperature

impact-resistant HDPE blends are particularly useful in many commercial applications such as in automotive underhood, industrial liquid/gas pipes, pipe fittings, and pipes for water transportation, geomembranes for environmental and waste-water management, agricultural and industrial packaging films, etc.

19.2.1.2 HDPE/Ionomer Blends

Commercial ionomers are ethylene-methacrylic acid copolymers and terpolymers in which the carboxylic acid moiety is partially neutralized with sodium or zinc, to promote interchain ionic bonding. Ionomers exhibit excellent low-temperature toughness, chemical resistance, and adhesion. However, they lack in stiffness and heat resistance. Hence, ionomer blends with polyolefins such as polyethylene have been developed which, upon reinforcing with suitable fillers, seem to give a unique combination of high strength, excellent low-temperature toughness, and moderate stiffness and heat resistance (Surlyn® HP, DuPont). Key to this technology appears to be the selection of a suitable surfactant that must be added in small amounts (0.3 %) to aid the dispersibility of glass fibers, yet retain high toughness (Murphy 1986).

The blend is reported to have an interpenetrating network (IPN)-type morphology, with the ionomer as the continuous phase. An unusual feature of this blend is the high notched Izod impact strength of >1,000 J/m at 23 °C and >760 J/m at −29 °C, even in the presence of 15 % of chopped glass fiber. In the absence of the surfactant additive, the blend with the same level of glass fiber showed somewhat poorer impact properties, e.g., notched Izod of <500 J/m at −29 °C and elongation at break of <3 %. In the presence of the surfactant additive, an ionomer/polyolefin blend reinforced with 15 % glass (Surlyn® HP) exhibits a flexural modulus of 1,600 MPa, a high notched Izod of >1,000 J/m and a moderate DTUL of 82 °C (at 0.45 MPa). These properties were claimed to be good enough to enable this blend to compete with the impact-modified polyamides in some applications.

19.2.1.3 HDPE/Polystyrene Blends

A blend of PS in HDPE (interpenetrating network) was commercially sold for some time, as expandable beads (Arcel®, ARCO; Neopolen® S, BASF) for making cellular foams (Kossoff 1987). Although PS and polyethylene are immiscible, closed-cell foams made from this immiscible pair appear to combine the rigidity of PS with the solvent resistance and abrasion resistance of HDPE. Hydrogenated styrene-butadiene-styrene block copolymers are known to compatibilize the PE/PS blends. However, these no longer seem to be commercially used.

19.2.1.4 Polyethylene/Polyamide Blends

A graft copolymer-compatibilized blend of PA-66-PA-6 (75/25) copolymer with HDPE was commercially offered as a barrier resin for making permeation-resistant solvent containers (Selar® RB, DuPont) (Subramanian 1984). Before melt blending with the PA, the PE backbone was modified by grafting with such reagents as maleic anhydride (Steinkamp 1976). A graft-coupling reaction between the PA and the maleated polyethylene, involving an amine/anhydride addition reaction, leads

to the graft copolymer formation at the interface, which reduces the interfacial tension and stabilizes the PA dispersion in the HDPE matrix.

By proper choice of the molecular weight, melt rheology of the PA, and processing conditions, a platelet-like dispersion of the PA in HDPE matrix could be achieved (Subramanian 1985). Since PA is a good barrier to hydrocarbons and many organic solvents, the platelets in HDPE provide the desired permeation resistance to solvents that HDPE lacks. On the other hand, polyethylene matrix provides the toughness, moisture resistance, and low cost advantages compared to PA. The blend was designated as a "laminar barrier" blend.

The PA/PE "grafted blend" was offered commercially as a concentrate (Selar$^{®}$ RB) to be melt blended with HDPE to a final PA/HDPE ratio of ca. 15/85 for subsequent blow molding into containers such as gasoline tanks, solvent containers, etc. This laminar barrier blend of HDPE and PA was reported to provide up to 100-fold improvement in the barrier to permeation of such organic solvents as toluene, relative to pure HDPE, or a similar blend composition containing PA as a uniform spherical dispersion.

The HDPE/PA laminar barrier blend technology has not been commercially utilized. A potential problem could be the high sensitivity of the morphology to the process conditions, which could lead to a lack of reproducibility in achieving the desired platelet morphology. The advent of coextrusion blow molding thwarted the blend's market penetration. Coextrusion assures a more uniform barrier layer of PA that can be relied upon for permeation resistance. Other techniques such as surface fluorination of polyethylene and SiOx coating, to improve the resistance to permeation of oxygen and solvents, are also commercially competing technologies.

19.2.1.5 HDPE/PET Blends

Blends of post-consumer recycled HDPE (from milk bottles) and post-consumer recycled PET (from soda bottles) were investigated for their potential utility (Akkapeddi 1992; Dagli and Kamdar 1994). The blend is highly immiscible and some level of compatibilization could be achieved by the use of functionalized polyethylenes such as ethylene-glycidyl methacrylate (E-GMA copolymer) or maleic anhydride-grafted polyethylene (MAnh.-g-HDPE) as reactive comptatibilizers. However, the blends lacked enough performance benefits to be commercially useful.

19.2.2 Polyolefin Blends Based on Polypropylene

19.2.2.1 Impact-Modified Polypropylene (PP/EPR Blends)

Polypropylene is a very large-volume thermoplastic with a current annual global consumption of over 62 Mt (Ceresana 2012). It is used in a variety of applications such as fibers, films, and molded parts. Commercial polypropylene homopolymer is produced by the stereospecific polymerization of propylene in the presence of Ziegler-Natta-type catalysts, which gives an isotactic polymer of high crystallinity. Due to this crystallinity and a reasonably high melting point (165 °C), isotactic polypropylene exhibits a useful combination of properties such as good stiffness,

strength, heat, and solvent resistance. The hydrocarbon nature of the backbone imparts it excellent hydrolytic and dimensional stability. In addition to these properties, polypropylene's low density, 900 kg/m^3, and relatively low cost makes it an attractive candidate for many applications and often competing with even the higher-priced engineering thermoplastics.

The crystallinity of isotactic polypropylene homopolymer, PP, however, leads to its well-known brittle behavior at low temperatures or when impacted under conditions of stress concentration, i.e., in the presence of sharp notches. For example, the low-temperature drop weight (Gardner) impact strength of unmodified PP is typically <2 J (at −30 °C) and its notched Izod impact strength is <40 J/m at room temperature, both significantly lower than that of polyethylene. This brittleness of polypropylene is related to the spherulitic morphology and the intrinsic tendency of PP for crazing followed by unstable craze growth and crack propagation under conditions of stress concentration and/or low temperatures (Kinloch and Young 1983; Friedrich 1983).

Commercial impact-modified PPs were developed during the early 1970s by melt blending about 5–25 wt% ethylene-propylene rubbers (EP or EPDM) with the polypropylene homopolymer via extruder compounding (Holzar 1966). Some LDPE or HDPE is often used to assist the dispensability of the EP rubber and enhance the impact/modulus balance of the product (D'Orazio et al. 1982). For the toughening of PP, EP rubbers meet the normal criteria for impact modifiers. Toughening of rigid polymers generally requires the formation of fine rubber dispersions with good adhesion to the matrix and thus providing multiple sites for crazing and localized shear yielding as mechanisms for the impact energy dissipation. Although not miscible, there exists a reasonable level of compatibility between EP rubbers and the polypropylene matrix due to their similarity in the hydrocarbon-type structures and the closeness of solubility parameters which leads to low interfacial tension and an adequate level of interfacial adhesion (Krause 1972). Hence, a small particle size dispersion of EP rubber is readily achievable by adjusting the molecular weights and melt viscosity ratio of EPR to PP and through the proper choice of mixing conditions (Yeh and Bisley 1985; Rifi et al. 1987). The control of the rubber-phase morphology in polypropylene is also dependent on the rubber composition (ethylene/propylene ratio), crystallinity, compounding and processing methods, as well as rheological properties. A slight cross-linking of EPDM rubber leads to better morphology stability during high-shear flow conditions such as injection molding (Dao 1982, 1984).

Commercial impact-modified PPs based on such blends exhibit excellent notched Izod impact strengths ranging from 80 to 800 J/m and moduli ranging from 1,000 to 1,700 MPa. Because of the large number of commercial suppliers and grades, no attempt will be made to describe the properties of any specific types of commercial impact-modified PP blends, except to generalize the trends in the impact/modulus behavior with respect to the content and the nature of the EPR.

In general, for best impact modification, the ethylene-propylene copolymer must have >30 % propylene and show essentially no crystallinity (Rifi et al. 1987). The size and distribution of the EP rubber particles in the polypropylene matrix depend on the molecular weights and the melt viscosity ratio between the two polymers, as

Fig. 19.8 Typical behavior of the effect of EPR content on the modulus and the low temperature impact strengths of PP/EPR blends (adapted from Rifi et.al. 1987)
well as the mixing conditions (Speri and Patrick 1975; Jang et al. 1985). Particle size must be <3 μm and preferably be <1 μm for optimum impact strengths. Melt index ratio of PP/EPR, MI ≅ 10–60, was found to give acceptable dispersion size. The volume fraction and the particle size distribution of the rubber dispersion affect the modulus, impact strength, and melt flow of the blend significantly.

Although historically, commercial impact modified PP has been produced by extruder compounding, more recent advances made in the catalyst and polymerization technology allowed the production of these blends via an "in situ" process in the reactors (Rifi et al. 1987; Galli and Haylock 1991). By using a "super-active" catalyst and a gas phase, fluidized-bed reactor technology, the ethylene/propylene copolymer is allowed to polymerize and grow within the polypropylene homopolymer particle, polymerized earlier in the same reactor without isolation. The reactor technology could be tailored to produce a wide choice of products ranging from impact-modified polypropylene to thermoplastic elastomer-type PP/EPR blends (TPOs) by a judicious choice of the reaction conditions and the component feed ratios. The particle size of EPR in reactor TPOs is reported to be much smaller and hence more efficient in impact modification.

Impact vs. modulus balance of the extruder-compounded blends of PP/EPR is illustrated in Fig. 19.8. While the flexural modulus values are comparable, the low-temperature impact strength of the reactor-made PP/EPR blend products is usually better than that of extruder-made blends.

Conventional extruder compounding process for making impact-modified PP and thermoplastic polyolefin blends (TPOs) is still widely used to date, particularly by the independent compounders because of the versatility of this process for making a variety of specialized products having a wide range of performance characteristics. Compounding additive packages for improved heat stability, weatherability, and paintability is readily feasible in the extruder blending process. Colors, pigments, and fillers can also be blended in during the compounding of the PP/EPR blends.

Impact-modified polypropylene is used for injection molding automotive, consumer, and appliance parts. For example, the medium-impact PP is widely used for automotive interior trim. High-impact PP is used for battery cases, fenders, and truck liners. Impact PP is also used extensively in the houseware and appliance markets.

19.2.2.2 Thermoplastic Polyolefin Blends (TPOs)

Thermoplastic polyolefin (TPO) is a generic name that refers to polyolefin blends usually consisting of some fraction of polypropylene (PP), polyethylene (PE) or polypropylene block copolymer (PP-b-EP or "BCPP"), and a thermoplastic olefinic rubber, with or without a mineral reinforcing filler such as talc or wollastonite. Common rubbers include ethylene propylene rubber (EPR), EPDM rubber, ethylene-octene (EO) copolymer rubber, ethylene-butadiene (EB), and styrene-ethylene-butadiene-styrene (SEBS) block copolymer rubbers. Currently, there are a great variety of commercial polypropylene homopolymers, PP block copolymers, and olefinic rubbers available to make a wide range of TPO blends with densities ranging from 0.92 to 1.1.

Thermoplastic polyolefin blends (TPOs) can have properties ranging from flexible elastomers to tough rigid materials, each specifically formulated in a melt compounding process, to meet the needs of a particular application (Srinivasan 1991; Spencer 1990). The rigid or semirigid TPOs are essentially not much different from the impact-modified polypropylenes, except that higher levels of EP rubber are used during compounding of TPO to achieve additional low-temperature impact strength and minor levels of reinforcing fillers are added for additional stiffness. Such compounded TPOs generally contain 20–40 % elastomer, such as EPDM or POE (typical is 35 % EPDM or POE) in a conventional or impact polypropylene.

Generally, the TPOs are produced by extruder compounding processes in which the polypropylene resin is blended with an ethylene copolymer rubber (EPR or other polyolefin elastomers or POEs), along with a desired level of reinforcing fillers. The components are blended together at 210–270 °C under high shear using a twin-screw extruder or a continuous mixer.

The specific composition of the TPO blend produced depends on the balance of flexural modulus (stiffness) and impact toughness (drop impact and notched Izod) properties needed to meet the target performance specifications. In the formulation of TPO blends, the polypropylene is used normally as the major component, i.e., as the matrix phase, to provide the needed rigidity and thermal stability, while the elastomer dispersion provides the low-temperature impact toughness. A minor amount of a mineral filler such as talc provides additional stiffness and dimensional stability to the TPO. Hence, the levels of elastomer and mineral filler modifiers are carefully adjusted to achieve the desired balance of properties in the TPO.

The following is typical rigid TPO blend composition (Hemphill et al. 2005):

- 60–65 % Polypropylene – generally an impact copolymer or homopolymer
- 25–30 % Elastomer (EPR, EPDM or POE)
- 10 % Talc + small amounts of other additives

The small amount of other additives include heat stabilizers, UV stabilizers, mold-release agents/lubricants, paint-adhesion promoters, mar and scratch-resistance improving additive, etc.

In contrast to the rigid TPOs described above, low-modulus/flexible grades of TPO blends are also produced commercially. In flexible TPOs, the rubber content can be as high as 60 %, and in some cases, the dispersed rubber may also be partially cross-linked during the mixing without losing the thermoplastic character of the matrix. However, the latter type of "dynamically vulcanized" elastomeric alloys or thermoplastic vulcanizate rubbers (TPVs) are considered as a separate class of elastomeric materials and hence will be discussed under elastomer blends. On the other hand, the "soft" TPO blends discussed here contain a low-modulus olefin copolymer elastomer as the major component with some polypropylene added to impart melt processability.

Typically, a soft TPO would be composed of (a) 60 wt% of an olefinic elastomer of high melt strength, (b) 30 wt% PP homopolymer or impact PP copolymer and (c) 10 wt% of mineral filler.

The commercially important rigid and semirigid TPOs may have flexural moduli upto 2,000 MPa and service temperatures ranging from -40 °C to 130 °C. These TPOs are noted for their excellent toughness, high notched Izod impact strengths, and reasonable level of chemical resistance. The largest market for TPO is in the automotive area because of the material's low cost, low specific gravity, low temperature toughness, and weatherability. The rigid type of TPOs are extensively used for injection-molded automotive interior or exterior fascia which target high ductility at -30 °C and high part rigidity. Such paintable TPOs or those with molded-in colors are used for bumper fascias, grilles, air dams, side moldings, etc. Typical properties of TPO grades used in automotive applications are illustrated in Table 19.3. As may be noted, in these TPOs, the balance between the stiffness and toughness depends on the type and level of rubber and the level of mineral filler (usually the talc) used in the blend. The current annual consumption of TPO blends in the transportation market segment alone is >1.5 million metric tons. Lower cost and recyclability are the primary reasons for the rapid growth of TPOs in the automotive bumper applications, relative to SMC, PURIM, and steel.

TPO blends with added UV stabilizers are used in outdoor applications such as in roofing. Such TPOs are also used in a wide variety of exterior and interior structural parts such as in tractor, truck, and recreational vehicles, lawn and garden equipment, snowmobile body panels, industrial equipment and fan shrouds, etc. The low-modulus, soft TPO blends can be extruded into sheets and thermoformed for use in automotive interior skins that are competitive with products like vinyl, leather, and thermoplastic urethanes (TPUs). Advances in the development of specialty high melt strength elastomers that complement the rheology-modified polypropylenes are now enabling the formulation of high melt strength TPOs, extending their use in new thermoforming, profile extrusion, and blow molding applications (Weaver et al. 2006).

Table 19.3 Typical properties of some commercial TPOs used in automotive applications

Property	ASTM	Units	Compounded TPO		Reactor TPO
					Adflex®
			Daplen® EE015U	Daplen® EE109AE	KE051P
			Borealis	Borealis	LyondellBasell
	Filler level (%) →		10	20	None
Specific gravity	D792		0.94	1.04	0.89
Flexural modulus	D790	MPa (kpsi)	1,150 (167)	1,500 (218)	820 (119)
Tensile strength at yield	D638	MPa (kpsi)	16.5 (2.4)	17 (2.5)	17 (2.5)
Elongation at break	D638	%	100	70	500
Charpy impact, notched, at 23 °C	ISO179	kJ/m² (ft-lb/in.)	50 (24)	40 (19)	NB
Charpy impact, notched, at −20 °C			7 (3.3)	6 (2.9)	–
HDT at 0.45 MPa	D648	C	89	92	80
Key applications			Automotive exterior, bumper fascias, trim	Automotive exterior bumper fascias, trim	Automotive interior panels

Until recently, all compounded TPOs were based on PP/EP rubber blends. However, the new metallocene catalyst-based polyolefin elastomers (POEs) are now steadily displacing the EPR and EPDM rubber modifiers in the TPO blends due to the ease of handling and the overall lower cost of POEs. The evolution of the use of POEs in TPO blends will be discussed in the next section.

19.2.2.3 Polyolefin Elastomer (POE)-Based TPO Blends

The development of novel metallocene catalyst systems for polyolefin polymerizations represents a true technological breakthrough with very wide ramifications in the plastics industry (Wigotsky 1995; Schut 1996; Zamora and Miller 1997). As the latest-generation catalysts, the metallocenes differ from the traditional Ziegler-Natta catalysts in that they have well-defined single catalytic sites and well-understood molecular structures. Typically, they consist of a transition metal such as zirconium sandwiched between suitably substituted cyclopentadienyl ring structures to form a sterically hindered or "constrained geometry" metal catalyst site. With these new generations of catalysts, a wide variety of monomers can be polymerized or copolymerized in high efficiency but more importantly, various parameters such as comonomer distribution, polymer molecular weight, molecular weight distribution, molecular architecture, stereospecificity, degree of linearity, or branching can be independently and precisely controlled.

While the range of the new metallocene-based polymers includes such specialty polymers as cyclo-olefin copolymers (COC), syndiotactic polystyrene, ethylene/styrene copolymers, which are still in the developmental stage, commercially, the most prominent candidates are the ethylene/α-olefin copolymers such as ethylene/butylene or hexene copolymers (Exxon's Exact®) or ethylene/1-octene copolymers (Dow's Engage® and Affinity®). Depending on the comonomer content, these copolymers have been classified as plastomers or elastomers. At comonomer levels of >25 %, the copolymers exhibit the characteristics of thermoplastic elastomers such as high softness, toughness, flexibility, and resilience and hence been referred to as polyolefin elastomers (POE). Compositionally, these POEs usually contain 65 % ethylene and 35 % octene-1, hexene-1, or butene-1 as comonomers.

As a result of the controlled long-chain branching in otherwise linear polymers, the processability of these resins is claimed to be significantly enhanced compared to the standard LLDPE and EP rubber materials. Environmental stress crack resistance of metallocene polyolefin is also claimed to be significantly better. A wide range of densities (0.86–0.93), flexural modulus (10–100 MPa), melting points (60–120 °C), and melt flow index (0.5–125) is available in the commercial metallocene-based ethylene copolymers.

Thermoplastic polyolefin (TPO) blends of metallocene-based polyolefin elastomers (POE) with polypropylenes have gained commercial significance because of the improved melt flow and toughness compared to the conventional TPOs based on EPR or EPDM blends made with high melt-flow PP (Toensmeier 1994). In comparative tests with 70/30 PP/elastomer blends, the blends with POE maintained ductile behavior at −29 °C even with high melt flow index PP (MFI = 35), while the corresponding EPR-based blends were brittle with PP of MFI = 20. In addition, they showed improved knit-line strengths.

Because of their high shear-thinning and melt elasticity, plastomers and POEs disperse well in the PP matrix yielding fine elastomer domain dispersions leading to the better properties. POEs are easier to handle as they are available in pellet form, whereas EPDM is typically baled and needs additional equipment for feeding into the extruder compounding process. POEs also offer improved melt flow in TPO blends compared to EP copolymer-type elastomers. Currently, POEs account for about a third of the elastomer volume used in the compounded TPOs.

19.2.2.4 In-reactor TPO Blends Based on Polypropylenes

An in-reactor TPO may be defined as a reactor-produced polypropylene copolymer (PP-b-E/P), containing between 22 % and 55 % ethylene-propylene copolymer blocks. Small amounts of other comonomers, such as octene-1 or butene-1, may also be present so as to provide unique functionality. In-reactor propylene block copolymers containing less than 20 % ethylene are fairly hard and are usually classified as impact polypropylenes. Reactor-made polymers containing >50 % ethylene are soft and also have relatively poor elastomeric properties – these are classified as plastomers.

In-reactor TPOs are made in special polypropylene reactors, and they are designed to be cost- competitive to some extent against the compounded TPOs.

Table 19.4 Comparison of key features of reactor vs. compounded TPOs

TPO	Method	Advantages	Disadvantages
Compounded TPO	Extruder compounding of PP, elastomer, filler and additives	Flexible sourcing to optimize for lower cost and wider range of products	Compounding capital
Reactor TPO	• Reactor TPOs made by sequential copolymerization of PP and EP copolymer • Compounding with fillers and additives needed	• Excellent dispersion • Lower need for rubber than compounded TPO • Improved melt-flow	• Need special catalyst and reactor technologies • Somewhat higher cost • Reactor elastomer may not be quite as efficient as compounded TPO for low temperature toughness

However, in situ TPOs with high elastomer content are difficult to produce, and high levels of other additives, such as fillers and especially colorants such as carbon black, must still be done by compounding. In-reactor TPOs are used to reduce cost and increase the end-use value in those cases where the TPO does not need to be compounded prior to fabrication. In-reactor TPOs are mostly used in the automotive applications such as bumpers, interior impact trim, under-the-hood cladding, wire harness, weather strip, etc.

Some flexible grades of in-reactor TPOs ("r-TPO"), trademarked as Hifax®, are commercially produced by Lyondell-Basell using their Catalloy® process technology. Due to the higher levels of rubber dispersion in PP, these soft r-TPOs exhibit high toughness, flexibility, moisture barrier properties, and environmental stress-crack resistance and hence used in roofing and geomembrane applications. Typically, these flexible reactor TPOs exhibit a low modulus of ≤ 80 MPa, Shore A hardness of <90, a tensile elongation at break of >800 %, and a brittleness temperature of < -70 °C. They are widely used in geomembrane applications for (i) waste management- municipal solid waste landfill caps, wastewater treatment reservoirs; (ii) water containment in aquaculture ponds, decorative and golf course pond liners, and in (iii) water conveyance for canal liners, storage reservoirs, storm water ponds, tunnel liners, etc. The relative advantages and disadvantages of reactor vs. compounded TPOs are shown in Table 19.4.

19.2.2.5 Thermoplastic- Elastomeric Blends(TPEs) Based on Polypropylene

Thermoplastic elastomer blends comprising fully cured elastomer dispersions in a matrix of thermoplastic polyolefin such as PP have been commercial for some time. These blends have been made by the technology of dynamic vulcanization (Speri and Patrick 1975). The process consists of melt mixing and dispersing a high volume fraction of an elastomer such as EPDM rubber or nitrile rubber (NBR) into a thermoplastic matrix such as PP, using a compatibilizer if necessary, and then selectively cross-linking the dispersed elastomer during the extrusion, with specific curing agents. The resulting elastomeric blends display the typical properties of

cured rubbers such as high elastic recovery, low compression or tension set, yet process like thermoplastics, due to the presence of PP thermoplastic matrix. Commercial, elastomeric polyolefin blends produced by the dynamic vulcanization include EPDM/polypropylene blend (Santoprene®); Nitrile/polypropylene blend (Geolast®); Butyl rubber/polypropylene (Trefsin®). The technology of these blends will be discussed under the "Elastomeric Blends" heading.

Thermoplastic vulcanizates (TPVs) typically contain 60–70 % EPDM and 30–40 % impact polypropylene. These products contain a low level of cross-links, but they are true thermoplastic materials. TPVs have superior strength, high-temperature mechanical properties, hot oil and solvent resistance, and better compression set than partially cured material. These materials are almost always "dynamically cured," which refers to the process whereby the rubber phase is vulcanized during melt mixing with the molten non-cross-linked plastic.

TPVs have many of the elastomeric properties of vulcanized rubbers and yet can be molded or extruded using conventional thermoplastic fabrication equipment. They derive their properties from a unique physical network of seemingly incompatible structures, which coexist through chemical bonding. These structures can generically be referred to as soft-block and hard-block components. The soft blocks are amorphous, rubber-like elastomer components. The hard blocks, which are crystalline with their melting point above room temperature, form domains that prevent plastic deformation and provide tensile strength at normal-use temperature. TPVs can exhibit a range of properties because of the different types of hard and soft blocks, ratio of blocks, degree of polymer linearity, crystallinity, and cross-linking. Properties can be further changed by coblending and compounding with other vulcanized rubber components.

TPV market is primarily in automotive sealing where TPVs are displacing EPDM in less demanding (e.g., static) molded window seals. However, compression set remains an issue in more demanding (e.g., dynamic) applications such as door seals. TPVs are also increasingly used in overmolding on engineering plastics to achieve soft-touch tactile feel to the molded parts.

19.2.2.6 Reactor-Made Polypropylene/Nonolefinic Polymer Alloys

A new class of "reactor-made" alloys or "in situ" graft copolymer compatibilized blends of polypropylene with other amorphous, nonolefinic polymers have been commercially introduced by Montell recently under the trade name of Hivalloy® (DiNicola 1994). The commercial Hivalloy G series consisting of polypropylene/polystyrene alloys were first launched on a pilot scale in mid-1994 and later fully commercialized in 1996. Their Hivalloy W series are developmental grades of polypropylene/acrylic alloys, while the Hivalloy T series are experimental grades of polypropylene/styrene-maleic anhydride (SMA) copolymer alloys. All these reactor-made PP alloys are produced by Montell's proprietary "Catalloy" or "reactor granule" technology (Galli and Haylock 1991; Galli et al. 1994), which is a multistage, multimonomer polymerization process.

The fundamental basis for the reactor granule technology starts with the formation of a highly porous polypropylene particle first by the polymerization of propylene

monomer using a "super-active," third-generation, Ziegler-Natta initiator system which consists of a $MgCl_2$-supported, electron donor-modified $TiCl_4/AlR_3$ catalyst in a very high surface area, spherical particle shape ("Spheripol" process). A unique feature of this catalyst system is the high uniform porosity that is maintained during the polymerization in the growing PP particles. As the polymerization takes place, a growing skin of PP polymer is formed from the active sites on the surface of the expanding initiator particle. Proper control of the morphological structure of the initiator particles and the polymerization process results in the formation of highly porous PP granules.

These highly porous PP granules or beads are then used as the "reactor bed" for subsequent polymerization of one or more nonolefinic monomers such as styrene and methyl methacrylate. Since the latter polymerization is generally free radical, it results in the simultaneous formation of the nonolefinic polymer as well as its graft copolymer with PP uniformly distributed in micron-scale domains within the individual PP granules. This "in situ" generated graft copolymer then effectively compatibilizes and stabilizes the PP blend morphology during subsequent melt processing such as injection molding. The blends exhibit typical multiphase morphology behavior with the nonolefinic polymer generally forming the fine dispersed phase in the continuous PP matrix phase (DeNicola 1992). The PP matrix may contain additional rubber particle (EPR-type) dispersions for impact toughening of the blend.

The mechanical properties of these reactor-made alloys offer a balance of stiffness and toughness not generally attainable through the simple melt blending of the same polymer systems, primarily due to the effective graft copolymer compatibilization and good interfacial adhesion between the component phases. The Hivalloy reactor blends have been positioned by Montell to compete against ABS alloys and other low-end engineering resins based on at least some of the comparable properties, better chemical resistance, and a lower specific gravity. The higher T_g of the amorphous, nonolefinic polymer dispersion (PS, Acrylic, SMA) is expected to reinforce the PP matrix yielding a somewhat higher stiffness, strength, and heat distortion temperature, while the high crystalline melting point, ductility, chemical resistance, and high melt flow characteristics of PP are maintained. The following is a summary of the properties and applications of the two reactor-made alloys, viz., PP/PS and PP/acrylic polymer alloys.

Reactor-Made, Polypropylene/Polystyrene (PP/PS) Alloys

A series of reactor alloys of PP and PS were developed in the mid-1990s by former Montell (now part of LyondelBasell) under the Hivalloy G trade name, in the unreinforced, rubber–toughened, and glass-reinforced forms. These reactor-made Hivalloy-grade PP/PS and PP/PMMA alloys are no longer available. The lack of a cost-performance balance was the probable business reason for their discontinuance. Nevertheless, for the purpose of comparison with other PP blends such as TPOs, the typical properties of PP/PS and PP/PMMA are illustrated in Table 19.5. A key feature of these PP/PS alloys was claimed to be the impact strength/stiffness envelope that reportedly exceeded the performance of conventional PP and approached in some aspects with those of other engineering resins such as acetals,

Table 19.5 Properties of some "reactor-made" PP/PS and PP/PMMA alloys

Property	ASTM	Units	PP/PS	PP/PS/EP	PP/PMMA
Density	D792	kg/m³	0.94	0.92	0.95
Mold shrinkage	D955	%	1.3	1.2	1.4
Water absorption, 24 h	D570	%	<0.2	<0.2	<0.05
Flexural modulus	D790A	MPa (kpsi)	1,520 (220)	1,200 (170)	1,380 (200)
Flexural strength	D790A	MPa (kpsi)	43 (6.2)	33 (4.8)	39 (5.7)
Tensile strength at yield	D638	MPa (kpsi)	33 (4.8)	27 (3.9)	30 (4.3)
Elongation at break	D638	%	45	200	180
Notched Izod, at 23 °C	D256	J/m (ft-lb/in.)	135 (2.5)	No break	160 (3.0)
Instrumented impact	D3763	J (ft-lb)			
Total energy, at 23 °C			36 (27)	40	44 (32)
Total energy, at −20 °C				47	
Heat deflection temp.	D648	°C			
at 0.45 MPa			93	88	90
at 1.82 MPa			60	55	57

PC/ABS, PC/PBT. Depending on the PS content in the blend, the flexural modulus and DTUL increased predictably above that of PP while maintaining a high level of ductility and ultimate elongation. The notched Izod impact toughness could be raised to a "no-break" level particularly with the incorporation of some ethylene-propylene (EP) or styrene-ethylene/butylene-styrene block copolymer (SEBS) rubber modifiers. Compounding varying levels of glass fibers and reinforcing mineral fillers provided the desired balance of stiffness and toughness in these PP/PS alloys. The reinforced grades showed improved stiffness and creep resistance compared to PP alone to be able compete against reinforced polyamides and polyesters, particularly in applications that do not require high-temperature performance. Typical applications explored with these PP/PS alloys included automotive bumper beams, pillars, sporting and recreational equipment, sledge hammer handles, and other consumer tools and appliance components. The lighter weight to stiffness and toughness balance of these alloys was claimed to be a key advantage compared to the PC alloys.

Reactor-Made, Polypropylene/Acrylic Polymer (PP/PMMA) Alloys
A series of reactor alloys based on polypropylene and methyl methacrylate copolymer were briefly commercialized in the mid-1990s by Montell (now LyondelBasell), under the Hivalloy brand, but later discontinued. Nevertheless, the typical properties of such an alloy are shown in Table 19.5. These alloys were claimed to exhibit excellent weatherability, surface appearance, and colorability in addition to a good stiffness/toughness combination. In comparative SAE J1960 exterior weathering tests, PP/acrylic alloy showed superior color and gloss retention compared to ASA and PC/PBT (Sherman 1997; Hivalloy Data sheets 1997). The UV resistance of the blend must originate from the acrylic polymer, which may be enriched on the surface of the part. The attractive refractive index of the blend also makes it easy to color with molded-in colors.

Typical applications explored with the PP/acrylic polymer reactor alloys included automotive exterior mirror housings, interior trim and handles, truck wheel fenders, marine/outdoor recreational equipment, building and construction applications such as the outer layer for siding, etc. The apparent good weatherability, colorability, and mechanical properties of these alloys were believed to be good enough to compete against the well-established engineering resins such as ABS, ASA, PC/ABS, and PC/PBT. However, the lack of a cost-performance balance caused the commercial discontinuation of these PP/acrylic alloys.

19.3   Styrenic Blends

Styrenic resins, a family of commercially significant polymers and copolymers derived from styrene, rank among the major volume polymeric materials used, with an annual global consumption of nearly 26 Mt (Nexant 2012). Their low cost, ease of processability, and good balance of properties account for widespread use. Commercial styrenic thermoplastic resins may be classified into the following types:

1. Polystyrene (PS) and high-impact polystyrene (HIPS)
2. Styrene-acrylonitrile copolymer (SAN) and its impact-modified versions, viz., ABS (polybutadiene rubber grafted SAN), ASA (acrylate rubber grafted SAN), AES (EPDM rubber grafted SAN)
3. Styrene-maleic anhydride copolymer (SMA) and terpolymers with methyl methacrylate (SMA-MMA) and acrylonitrile (SMA-AN)
4. Styrene-methyl methacrylate copolymer (S-MMA)
5. Styrene-butadiene block copolymers [di, tri, and radial block $(S-B)_n$]

Among these, polystyrene is the lowest cost, most widely used commodity-type resin with an annualized global consumption of nearly 11 Mt in 2011 (Orhon 2012). This is followed by SAN, SMA, S-MMA, and the other specialty styrenic copolymers. All the styrenic resins are basically amorphous polymers with reasonably high glass transition temperatures ranging from about 100 °C to 130 °C, and heat distortion temperatures ranging from about 80 °C to 120 °C, depending upon the comonomer and impact modifier content. Because of the commodity nature of styrenic resin business, generally, there is less motivation to make blends via a compounding route which adds cost and sacrifices clarity. Improvements in styrenic resin properties such as strength, toughness, heat, and chemical resistance are generally made through copolymerizations (with acrylonitrile or methylmethacrylate) and in situ rubber-grafting techniques directly in the reactors.

Although the unmodified styrenics, viz., polystyrene, SAN, SMA, SMMA copolymers, exhibit good clarity, strength, and rigidity, they are invariably brittle for many applications. Hence, the rubber-modified styrenics such as HIPS and ABS, which combine a good level of impact strength with moderate heat resistance, have become more widely accepted in many molding and extrusion applications. Structurally, HIPS and ABS may themselves be considered as blends, since they contain ≥5 % polybutadiene rubber as a discrete phase, dispersed as 0.1–5 μm-size

particles in the matrix of polystyrene or SAN copolymer (Echte 1989). However, the rubber phase in these resins is incorporated during the free radical polymerization of styrene or S-AN monomer mixture via a mass, suspension, or emulsion polymerization process that results in the graft-coupling of the rubber phase to the matrix phase. In the context of the current discussion on blends, HIPS and ABS are not considered as blends, but more as impact-modified resin systems made in a reactor, although several grades of ABS are produced routinely by captively melt blending with SAN to adjust the rubber levels to the desired property specifications. However, HIPS and ABS are themselves used as base resins for blending with other thermoplastic resins to make new blends with desired combinations of properties.

The general motivation for blending styrenic resins with other polymers, particularly with the higher-priced, high-T_g, amorphous engineering resins such as polycarbonate, or polyphenylene ether, is primarily to lower the cost and improve the processability of the latter resins. The main reason for blending styrenic resins with crystalline polymers such as PA6 and PBT is to improve the solvent and chemical resistance which the styrenics lack.

19.3.1 Polystyrene and High-Impact Polystyrene (HIPS)-Based Blends

Because of its inherent brittleness, polystyrene homopolymer itself has limited application in blends. However, its impact-modified version, viz., HIPS, is more widely used. HIPS itself is a reactor-made multiphase system with 5–13 % polybutadiene ("cis"-rich) dispersed as discrete particles in the polystyrene phase, with an optimum particle size of mean diameter of 2.5 μm. The rubber in HIPS is chemically grafted to some extent to the polystyrene. The effective volume of the rubber dispersion is actually increased through the occlusion of some polystyrene. To optimize the impact strength, the rubber particle size ($\geq$2.5 μm) and the distribution is normally controlled by the agitation and the proper choice of other process conditions during the polymerization. The property improvements in HIPS, viz., increased impact strength and ductility, are accompanied by the loss in clarity and a decrease in the tensile strength and modulus compared to the unmodified polystyrene.

19.3.1.1 Blends of Polystyrene with S-B Block Copolymers (PS/SBC Blends)

Styrene-butadiene block copolymers (SBC) with a high (70–85 %) styrene content are commercially produced and marketed as transparent, stiff, and tough thermoplastic resins under the trade names of Styrolux® (Styrolution), K-Resin® (Chevron-Phillips), Finaclear® (Total petrochemical), and Clearene® (Denka-Kaguku). Unlike other more elastomeric types of styrene-butadiene block copolymers, the rigid SBC resins contain only $\leq$25 % polybutadiene rubber content. Structurally, these SBC polymers are composed of polystyrene (S) and polybutadiene (B) blocks, linked together in an unsymmetrical star-block [(S-B)$_x$] structure.

This star-block architecture results from the unique, sequential anionic polymerization and coupling process used. Due to the high styrene content of these resins, the polystyrene blocks form the major matrix phase, thus retaining high rigidity and DTUL while the PBD blocks form the minor dispersed phase leading to a high level of ductility and toughness, e.g., high tensile elongation to break of up to 300 %. Because of the extremely fine lamellar morphology of PBD dispersions ($<0.1\ \mu m$), the SBC resins retain a high level of clarity (Koller 1998). Due to their ease of processing and low density (1.01 g/cc), ca. 20–30 % lower than competing high clarity resins like polycarbonate, the SBC resins are cost-competitive in many clear thermoforming applications.

Since the SBC resins cost about twice as much as general-purpose polystyrene, there has been a significant motivation for blending SBC and polystyrene to lower the cost of the final SBC product without sacrificing the clarity, ductility, and impact toughness. Currently, 80 % of SBC resin used is in the form of blends with polystyrene. In most of the thermoforming clear packaging applications of SBC, the cost of the product is lowered by blending about 30–40 wt% of the lower-cost polystyrene, without sacrificing the clarity and toughness. The best blend ratio for an application is primarily determined by part design. Since biaxial orientation during the forming process increases part toughness, shallow draw parts like lids require higher SBC content than do deep-draw parts such as disposable cups. In practice, in most of the SBC/PS blended parts, the SBC content is usually in the 40–80 % range. The effect of PS/SBC blend ratio on two key properties, viz., the tensile elongation at break (a measure of ductility) and % transmission (a measure of transparency) is illustrated in Fig. 19.9.

Commercially, the SBC and PS melt blending is done directly by the fabricators during the sheet extrusion thermoforming or extrusion blow molding processes (Traugott 1985; Salay 1991). Such SBC/PS blends are widely used in various thermoforming (60 %), injection molding (20 %), films (8 %), and blow molding (7 %) applications. SBC/PS blends are very commonly used in the thermoforming clear packaging for food-service, medical packaging markets such as in the thermoformed clear yogurt containers, drinking cups, plates, tubs, trays, pharmaceutical bottles, shrink labels and blister packaging, etc. Injection molding applications include toys, hinged boxes, cases for electronic equipments, appliance parts, medical devices, etc.

Another promising area of growth is for SBC blends with higher-performing styrenics such as styrene-methyl methacrylate (SMMA) and SAN, in order to "down-engineer" applications currently in higher-cost PC, acrylic, or clear ABS. Potential uses include molded appliance parts and medical devices and extruded graphic display profiles.

19.3.1.2 Polystyrene or HIPS Blends with Poly(phenylene ether) (PPE/HIPS Blends)

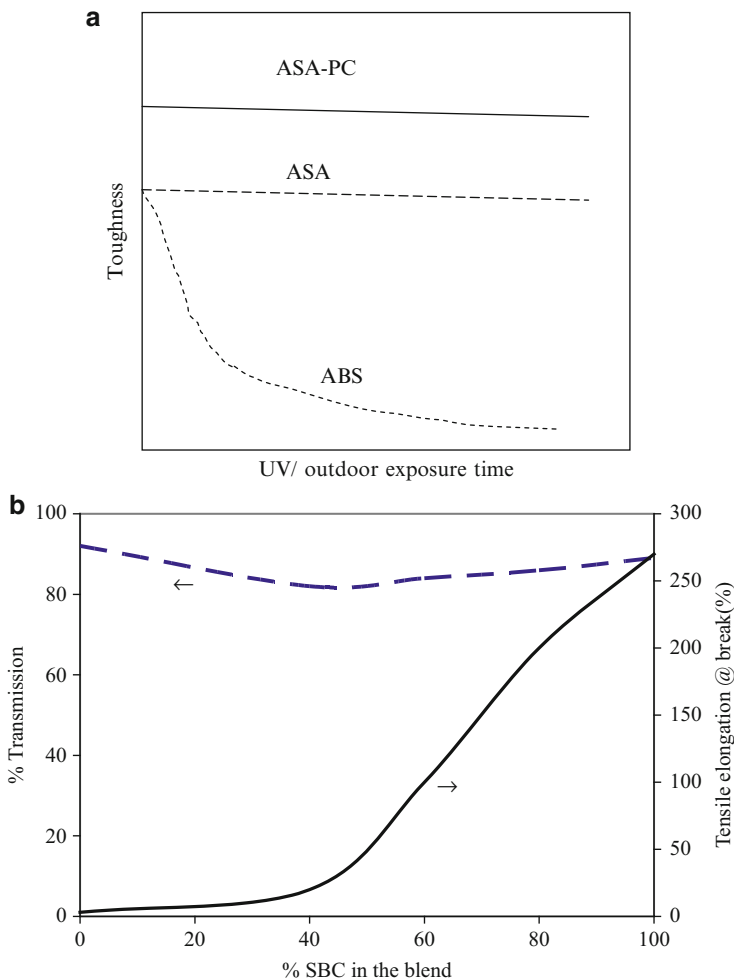
Blends of polyphenylene ether (PPE, also known as PPO[®]) with HIPS are, by far, the most successful of all the commercial blends. General Electric company, which originally introduced this blend commercially in 1964 under the trade name Noryl[®], has since sold all their Plastics business to Sabic. Noryl[®] resins are now


Fig. 19.9 (**a**) Schematic representation of the weatherability of ASA & ASA-PC vs ABS (**b**) Effect styrene-butadiene copolymer (*SBC*) in polystyrene/SBC blends on the transparency and tensile elongation at break (Anonymous 2006)

commercially produced and marketed by Sabic, although there are also other producers of such blends in Europe and Asia.

PPE is the acronym used for poly (2,6-dimethyl 1,4-phenylene ether), a high-T_g (205–210 °C) polymer produced by the oxidative coupling polymerization of 2,6-dimethyl phenol (Hay 1959, 1976). Sometimes, a minor amount of 2,3,6 trimethyl phenol is used as comonomer. Although PPE exhibits a good level of ductility and toughness along with a high heat distortion temperature, its high softening temperature and high melt viscosity precluded it from being used as a commercial molding resin, by itself. However, the discovery that blending PPE

with high-impact styrene could lead to improved processability and impact properties resulted in the successful commercialization of these blends (Cizek 1968). By simply adjusting the blend ratio, a wide spectrum of blend products with the desired combinations of DTUL, impact strength, processability, and cost balance could be produced. This versatility of tailor-making the blends for various levels of performance led to their rapid commercial success.

Key to this success, however, was the observed miscibility between the PPE and the PS phases resulting in a single-phase matrix with a single glass transition temperature that can be varied at will with the blend ratio. This thermodynamic miscibility between PPE and PS was established by various characterization techniques, viz., glass transition temperature (Schulz and Gendron 1972; Fried et al. 1978), electron microscopy (Kambour et al. 1980), small-angle X-ray scattering and calorimetric methods (Weeks et al. 1977), the latter showing a negative heat of mixing over the entire composition range. The presence of polybutadiene rubber particle dispersions in such a homogeneous matrix was found to lead to significant synergistic enhancement of the toughness of the blend, due to both the crazing and shear yield mechanisms of toughening (Bucknall 1977; Yee 1977). The particle size and the amount of rubber, however, affect the impact, modulus, and tensile properties of the blend.

Commercial PPE/HIPS blends may span a wide range of blend ratios, i.e., a PPE/HIPS blend ratio of about 25/75 to 60/40. Typical properties of commercial PPE/HIPS blends with varying PPE content are shown in Table 19.6. As expected, with increasing PPE content, the heat distortion temperature can vary from 90 °C to about 150 °C, because of the increasing T_g in these miscible blends. The melt rheology and flow characteristics again depend predominantly on the ratio of PPE to HIPS, with the molecular weights of PPE and HIPS also playing an important role (Schmidt 1979; Priest and Porter 1972). All the blends exhibit good ductility and impact strength. The notched Izod values range from 250 to 500 J/m. The rubber particles in HIPS contribute to the enhanced toughness of the blend. Since PPE is inherently more ductile than polystyrene, the efficiency of rubber toughening increases as the PPE content in the blend increases. Shear yielding process also contributes to the overall toughening effect, in addition to the usual craze-toughening mechanism. In blends containing ≥50 % PPE, shear yielding is the dominant mode of energy dissipation (Yee 1977). Unlike the case of polystyrene, the blend needs smaller-size (≤2 μm) rubber particles for optimum impact strength properties (Bucknall 1972). For higher impact strength, additional blending of styrene-butadiene-styrene (S-B-S) block copolymer-type elastomers and their hydrogenated derivatives, S-EB-S, are often employed. The ratio of PPE to PS in the blends can be determined from the ratio of the IR peaks at 854 and 700 cm^{-1}, respectively (White and Hallgreen 1983). The rubber particle size is determined by transmission electron microscopy using osmium tetroxide staining (Bucknall 1977).

Most of the PPE/HIPS blends are utilized by the injection molding process, although blow molding and extrusion/thermoforming applications are also increasingly practiced. Low moisture absorption and the good melt stability of PPE/HIPS blends along with their broad range of melt viscosities enable the fabricators a wide

choice of processing conditions. PPE/HIPS blends are used in a wide range of applications in the automotive, business equipment, appliance, electrical/electronic, and industrial markets. The automotive applications include instrument panel frames, interior trim, glove boxes, fuse boxes, connectors, wheel covers, mirror housings, etc. Flame-retarded grades are used for business machine housings, which are also often foamed to reduce the specific gravity and blow molded to reduce processing costs. Appliance parts and housings include those for refrigerators, washers, dryers, dishwashers, power tools, etc. The blends exhibit extremely low moisture absorption and good electrical properties suitable for electrical and electronic applications such as TV cabinets, connectors, electrical junction boxes, housings, relays, and bobbins.

The low moisture absorption and excellent hydrolysis resistance of PPE/HIPS blends coupled with their high dimensional stability makes them suitable for water meters and pump housings, plumbing parts, and a variety of fluid handling equipment parts. Some perceived building and construction applications include roofing panels, insulation, flooring substrates, etc. The high heat distortion temperature of PPE/HIPS led to its evaluation in microwave packaging. In applications requiring clarity, a blend of PPE and crystal PS containing no polybutadiene (Noryl® TN300, Sabic) is also offered commercially. Trays and packages that can be safely heated in microwave ovens have been made from such blends.

19.3.2 ABS Blends

Among the styrenic resins, acrylonitrile-butadiene-styrene (ABS) resins enjoy a unique position of being considered as engineering thermoplastics due to their outstanding high-impact strength performance over a wide temperature range coupled with good stiffness, and moderate heat and chemical resistance. ABS resins have now established globally to be the largest-volume (36 %) among all engineering thermoplastic resins used today. The current global production capacity of ABS resin is estimated to be nearly 10 Mt/year (NCPS 2011).

ABS resins are composed mainly of styrene (over 50 %) and varying amounts of acrylonitrile comonomer in the SAN polymer backbone and polybutadiene as a chemically grafted rubber dispersion. While the styrene units provide the rigidity and ease of processability, the acrylonitrile units contribute to the chemical resistance and heat stability. The polybutadiene rubber particles in ABS provide the toughness and impact strength. Structurally, ABS itself is a two-phase polymer blend system with the dispersed polybutadiene rubber phase (0.1–1 μm) embedded in a continuous matrix of SAN copolymer. Thus, the composition of ABS resins can vary widely, allowing the production of several grades tailored for different end-use applications.

ABS is commercially produced by the free radical polymerization of styrene/ acrylonitrile monomer mixture (usually 3:1 wt. ratio) in the presence of polybutadiene (of high "cis" content), which is added as a solution (ca. 10 %) in the mass polymerization process or as a latex seed during the emulsion polymerization

(30–60 % rubber) (Ku 1985). The emulsion-grade ABS is usually blended with virgin SAN copolymer to produce an ABS with a desired level of rubber (10–25 %). The impact strength, modulus, tensile strength, processability, and surface gloss of ABS depend on the rubber content and its particle size and distribution that is determined by the polymerization process and its conditions. The high-rubber ABS (25–50 % rubber) grades can be made only by emulsion process, and such resins (e.g., "Blendex" grades from Sabic) are often used for compounding with other thermoplastic resins such as polyvinylchloride (PVC) for impact modification (Dotson and Niznik 1991). The bulk polymerization process (continuous or suspension) produces low-gloss, medium-impact grades of ABS.

Due to its large scale of production and relatively low cost, ABS bridges the gap between the commodity plastics and the higher-priced engineering thermoplastics such as polycarbonate. Large-volume applications for ABS include appliance parts (including electrical/electronic) and automotive/transportation uses. A growing portion of ABS resins is now used in polymer blends. While the standard ABS resins inherently have a wide range of useful engineering properties, it is possible to extend and improve these properties further for certain niche applications via blending with other polymers. For example, blending with PVC can improve the flame retardancy of ABS at a low cost. Blending with higher-T_g, engineering resins such as polycarbonate and polysulfone can improve the heat distortion temperatures. On the other hand, use of ABS in blends with other resins can bring the advantages of low cost, improved impact strength, and processability. These will be discussed with the following examples of blends.

19.3.2.1 ABS/PVC Blends

Incorporation of 10–40 wt% ABS into PVC improves its impact strength, processability, and hot tear strength. Commercially, ABS/PVC blends are available from several sources, but more often, these blends are made in situ by the fabricators of sheet or profile extrusions. High-rubber, low-modulus grades of ABS made by emulsion polymerization are often used for the impact modification of PVC. Because of the thermal degradation problem of PVC, blending is done typically in Banbury-type mixers. The blend exhibits significantly improved notched Izod impact strength ($\geq 1,000$ J/m) over PVC. Although PVC is immiscible with ABS, the interfacial tension between the SAN phase and PVC is low enough to allow enough compatibility. The rubber particles, of course, are responsible for the enhancement of toughness. The primary application of this type of ABS/PVC blend, particularly in Western Europe, is in the manufacture of foil for vacuum thermoforming automotive and mass-transit interiors. The fabricators blend the powders of PVC and ABS and use the blend captively for the foil manufacture. Similar blends of PVC with MBS and ASA as impact modifiers are also used. These will be discussed in another section of this chapter entitled "PVC/Impact Modifier Blends" (Sect. 19.4.1).

Precompounded blends of ABS and PVC have also been commercially available for molding and extrusion applications as low-cost alternatives to flame-retarded grades of ABS and PPE/HIPS blends. Commercial ABS/PVC blends offer

Table 19.7 Properties of some commercial, styrenic resin/PVC blends

high-impact strength coupled with flame-retardant characteristics (self-extinguishing, V-O ratings of UL-94) at a reasonable cost (Table 19.7). Such ABS/PVC blends have been used in appliance and business machine housings, TV cabinets, electrical and electronic component manufacture. Although the low cost, flame retardancy advantages of ABS/PVC blend are attractive, the thermal instability of PVC poses processing problems requiring careful control of processing conditions and temperature. In the injection molding markets, the processing disadvantages of ABS/PVC blend are limiting its growth, while improved versions of flame-retardant grades of ABS, ABS/PC, and PPE/HIPS blends are steadily gaining competitive advantage due to their superior processability.

19.3.2.2 ABS-Polycarbonate Blends

Blends of ABS and polycarbonate (PC) were first commercially introduced in the 1960s (McDougle 1967; Grabowski 1964). After an initial sluggish growth, these blends have now gained increased acceptance by resin fabricators and end users. Currently, ca. 1 Mt/year of ABS/PC blends are produced globally (Reseauplasturgie 2012). There are many suppliers of ABS/PC blends, primarily by those who produce the polycarbonate and/or ABS.

ABS/PC blend is an essentially immiscible blend (Echte 1989; Suarez and Barlow 1984; Kim and Burns 1988) with three distinct phases, viz., the PC phase, the SAN copolymer phase, and the grafted polybutadiene rubber phase dispersed within the SAN phase (as in the ABS to begin with). Depending upon the blend ratio, the continuous phase can either be the ABS (or more correctly, the SAN phase) or the PC phase. In spite of the immiscible nature, the blends exhibit good toughness, particularly in the region of 30–65 vol% PC (Weber and Page 1986). A primary reason for the good properties and delamination resistance in ABS/PC blends is partial miscibility between the PC and SAN phases, which leads to low interfacial tension and high interfacial adhesion, particularly when the SAN contains ≥25 % acrylonitrile (Keitz et al. 1984). The partial miscibility between PC and SAN has been demonstrated by the small yet finite increases in

the T_g of SAN phase and similar decreases in the T_g of PC phase (Kim and Burns 1988; Morbitzer et al. 1985). The polymer-polymer interaction parameter for this blend was calculated to be slightly positive ($\chi_{12} = 0.03$). Some interpenetration of the chains at the phase boundary is responsible for the increase in the interfacial strength.

Properties of ABS/PC blend depend on the blend ratio. Blends containing major amounts of ABS (e.g., Cycoloy EHA) show improvements in DTUL and tensile properties relative to ABS but not in the notched Izod impact strength (Table 19.8). But as the polycarbonate level in the blend increases (particularly at PC ≥ 50 %), the notched Izod impact strength improves significantly, even at low temperatures. The ductile-brittle transition temperature in the latter blends is shifted to significantly lower temperature (Weber and Paige 1985), even compared to polycarbonate alone. The high dimensional stability, the excellent impact toughness at low temperatures, low gloss, and easy processability features of ABS/PC blends have led to their application in automotive interior instrument panels and, more recently, in exterior body panels, wheel covers, etc. ABS/PC is also used in business machine housings, snow throwers, snowmobiles, and other such equipment housings. A continued high growth rate (ca. 10 %) is expected for the ABS/PC blends because of their balance of high impact and heat resistance properties and moderate cost.

19.3.2.3 ABS/Polyamide Blends

Blends of ABS with commercial polyamides such as PA6 and PA66 are highly incompatible due to their dissimilar polarity, and accordingly, simple blends of ABS and PA exhibit poor delamination resistance with no practical value. Hence, several different approaches for compatibilization of the ABS-PA blends were investigated in the literature. In one approach, ABS was modified by copolymerization with acrylamide to improve the compatibility between ABS and PA-6, presumably through hydrogen bonding interaction (Grant et al. 1988).

In another approach, the SAN backbone of ABS was modified through copolymerization with maleic anhydride. This modification introduced controlled amounts of an anhydride functionality on ABS, which upon subsequent melt blending with a PA reacts to form a graft copolymer of SAN and PA at the interface (Eq. 19.1).

wwwwww NH₂   +   Maleic anhydride-SAN copolymer   →   PA-SAN graft copolymer
Polyamide

Equation 19.1 Polyamide graft coupling reaction with maleic anhydride modified SAN or ABS

The above graft-coupling reaction effectively compatibilizes the blend by reducing the interfacial tension and improving the interfacial adhesion leading to high impact strength. Such ABS-PA blends were initially commercialized in the 1990s by Monsanto under the trade name of Triax® 1000, utilizing the reactive compatibilizers (Lavengood 1987). Currently, these ABS/PA blends are commercially offered by Ineos ABS under the trade name of Triax® and by Styrolution under the trade name Terblend® N.

In another compatibilization technique, commercial ABS was directly modified by reactive extrusion with fumaric acid, without the need for copolymerization in a reactor, and the resulting "maleated ABS" was blended with a small amount of maleated EP rubbers followed by final PA6 blending, to make very high-impact ABS/PA6 blends (Akkapeddi et al. 1990). It was found that for maximizing the impact strength in the 50/50 ABS/PA6 blends, the ABS optimally had to contain about 25 % PBD rubber and about 5 % maleated EP rubber additionally preblended. Since polyamides are crystalline with high melting points and solvent resistance, it is desirable to keep the PA as the continuous phase and ABS as the dispersed phase in the blends. However, the ABS/PA blends tend to form cocontinuous morphology, which becomes somewhat finer and more stabilized with the compatibilization (Jafaria et al. 2002). Typically, such compatibilized, commercial ABS/PA blends (Terblend N, Styrolution) exhibit good solvent resistance coupled with high impact strengths and heat resistance (Table 19.9).

Some applications pursued for the ABS/Polyamide blends are: unpainted automotive interior parts, center consoles, steering wheel covers, air inlet systems,

helmets, equipment housings, etc. ABS/PA blends have not developed a significant market growth presumably because they are unable to compete with the more widely established PPE/PA blends or ABS/PC blends to offer any tangible cost-performance benefits.

19.3.2.4 ABS/PBT Blends

The primary motivation to blend ABS with PBT was to combine the property advantages of crystalline PBT such as its high solvent and chemical resistance, high melting point, and ease of thin-wall injection moldabilty with the excellent impact toughness, stiffness balance of ABS. However, the high incompatibility of PBT and ABS required a suitable means of compatibilization. Various reactive compatibilization methods were investigated such as by using a maleic anhydride-grafted ABS or an epoxide-functionalized polymer such as a glycidyl methacrylate copolymer or epoxidized styrene-butadiene copolymer as reactive compatibilizers (Akkapeddi 1992; Ohtsuka 1995). Commercial ABS/PBT blends were developed (Novalloy®, Daicel; Verolloy®, Plastxworld) using such reactive compatibilization,

compounding techniques. Thin-wall moldability, high surface gloss, and chemical resistance are the key attributes of ABS-PBT blends useful in appliance parts and equipment housings. ABS/PBT blends have still not established any commercial significance.

19.3.2.5 ABS/Thermoplastic Polyurethane Blends (ABS/TPU)

Commercial ABS/TPU blends contain thermoplastic polyurethane elastomer (TPU) as the main blend component. The blends were first introduced in 1990 by Dow Chemical Co., under the trade name Prevail®. These blends characteristically exhibited low modulus (340–1,000 MPa) and high impact strength at low temperatures, e.g., notched Izod values of 370–1,500 J/m at $-29\ ^\circ C$. The TPU component of the blend imparts high toughness and also allows paintability without a primer. ABS component imparts heat resistance (for paint ovens) and good tensile strength in the blend. The blend was projected to be useful for automotive soft bumper fascias, but faced stiff competition from TPOs. Typical properties of ABS/TPU blends are shown in Table 19.9.

19.3.3 Acrylic-Styrene-Acrylonitrile (ASA) Terpolymer-Based Blends

Acrylic-Styrene-Acrylonitrile (ASA) resins, commercialized initially by BASF and subsequently by Styrolution and others, are normally produced by the graft copolymerization of styrene-acrylonitrile copolymer (SAN) onto an acrylic rubber (usually polybutylacrylate) via emulsion polymerization. The properties of ASA polymers are similar to those of ABS, exhibiting high impact strength, but unlike ABS, the ASA resins exhibit outstanding weatherability, lasting for a substantially longer service life than ABS. The polybutadiene (PBD) rubber in ABS is known to be prone to oxidative degradation reaction (Eq. 19.2) by the combined effect of atmospheric oxygen and solar radiation.

$$\text{\textbf{www}}\ CH_2CH=CHCH_2\ \text{\textbf{www}} \xrightarrow[\text{UV}]{O_2} \text{\textbf{www}}\ CH_2CH=CHCH\ \text{\textbf{www}} \longrightarrow \text{Chain scission}$$

PBD   oxidized PBD   OOH
Equation 19.2 Oxidative chain scission reaction in polybutadiene phase of ABS

Because of the above oxidative chain scission reaction in PBD phase, ABS gradually loses its impact strength upon exposure to sunlight. The ASA polymers, on the other hand, retain their impact strength and toughness even after prolonged outdoor/UV exposure, significantly better than ABS, due to the presence of the weatherable acrylic elastomer phase, which replaces the unstable PBD phase. The outdoor/UV resistance of ASA and ASA-PC blend vs. ABS is schematically illustrated in Fig. 19.9a.

Hence, ASA and ASA blends are primarily used in the automotive/ transportation, recreational and agricultural vehicle parts requiring long outdoor

weather durability. Typical automotive exterior applications are: mirror housings, radiator grills, center pillar trims, window frames, cowl vent grills, fairings, and lamp housings. Pigmented ASA and ASA blends replace metal, coated, or painted ABS, or SMC materials in exterior parts of many types of vehicles.

ASA resins are generally produced as powders for easy blending with other resins such as PVC. ASA is also supplied as pellets for extrusion or injection molding applications. Compared to ABS, the ASA resins are relatively more expensive, hence used only for specialty applications requiring their very high outdoor weatherability and aging resistance. The following are some of the commercial ASA blends that are gaining increasing uses:

19.3.3.1 ASA/PVC Blends

Most of the ASA produced is used for blending with a lower-cost PVC resin by the end users. The fabricator blends powders of ASA and PVC in the desired ratio using conventional PVC processing equipment. The blend has been used in profile extrusions and coextrusions. Applications for ASA/PVC blend included siding, mobile home skirts, window profiles, vending machine trim, automotive exterior trim, etc. The blend has significantly better impact strength, heat distortion temperature, and color retention than PVC. The blend seems to have some cost advantage over neat ASA. Typical properties of ASA/PVC blends are described in Table 19.10.

19.3.3.2 ASA/PC Blends

In order to take advantage of the high impact strength of polycarbonate and outstanding weatherability of ASA resins, blends of ASA and PC have been developed commercially for exterior automotive applications. Some commercial grades of ASA/PC blends are Geloy® XP4025 from Sabic, Luran® SCKR2801 from Styrolution, Astoloy™ PC/ASA401 from Marplex. Blending polycarbonate with ASA enhances the notched impact strength and DTUL, while maintaining the weatherability, property-retention characteristics of ASA. Black and pigment-colored parts, such as automotive mirror housings, trim, cowl vents, grilles, etc., are some of the key applications for this blend. Typical properties of ASA/PC blend are shown in Table 19.10. In the commercial market, such ASA/PC blends have to compete with the painted or plated ABS/PC blends. However, the overall cost saving by pre-colorability without primer or paint and long-term durability factors will favor the ASA/PC blends in the exterior automotive, transportation, and outdoor equipment applications.

19.3.3.3 ASA/PA Blends

The primary rationale for developing the ASA/polyamide blends is to combine the high UV resistance of ASA resins with high heat and solvent resistance properties of the common semicrystalline polyamides such as PA6. The compatibilization of the ASA/PA6 blends uses the same technical approach as for the ABS/PA6 blends, viz., the use of a maleic anhydride-modified (copolymerized) SAN copolymer as a polyamide-reactive compatibilizer as discussed before under the ABS/PA blends

Table 19.10 Properties of some commercial ASA blends

Property	ASTM	Units	ASA/PVC Geloy 1220[a] Sabic	ASA/PC Geloy XP4025 Sabic	Luran SC KR2861 Styrolution	ASA/PA Terblend S NM-31 Styrolution

[a]Commercial status unknown

section (Sect. 19.3.2.3). Some commercial grades of ASA/PA blends currently available are: Terblend® S (Styrolution), Romiloy® 3020 (Romira GmBH). Key features of the ASA/PA blends are reportedly (a) enhanced UV resistance and color fastness (b) good melt flow for high surface quality appearance and (c) high impact strength. ASA/PA blends are still at an early stage of commercial growth. Since the corresponding ABS/PA blends were commercially known for a longer period of time and yet have not grown in significant volume of applications, it is likely that the growth of ASA/PA may be similarly limited. However, the substantially superior weatherability, color fastness, and chemical resistance of the ASA/PA blends may gain them a more favorable market growth in applications such as unpainted automotive interior parts, trim, outdoor equipment housings.

19.3.4 Styrene-Maleic Anhydride (SMA) Copolymer-Based Blends

Commercial SMA resins (Xiran®, Polyscope Polymers) are amorphous, random copolymers of styrene and maleic anhydride (8–30 %) that exhibit higher glass transition temperatures (20–60 °C higher) and higher heat distortion temperatures than polystyrene. The SMA resins were originally commercialized under the trade name of Dylark® by ARCO and by Nova chemicals but later on discontinued.

Table 19.11 Properties of commercial SMA/elastomer blends (impact modified SMA resins)

Property	Test method	Units	SMA/ Elastomer Xiran® SM200 Polyscope	SMA/ Elastomer Xiran® SM400 Polyscope
Density	ISO1183	kg/m^3	1,070	1,050

HDT at 1.82 MPa	ISO 75	C	100	85
Vicat softening point	ISO 306	C	120	110

Currently, the high-molecular weight injection molding and extrusion-grade SMA resins are available only from Polyscope. The maleic anhydride comonomer imparts rigidity to the styrenic backbone raising its T_g by 2 °C with each 1 wt% increase in the maleic anhydride content. In addition, the maleic anhydride comonomer imparts higher polarity to the styrenic backbone and hence, increasing the modulus, strength, solvent resistance, and adhesion to reinforcing fillers and glass fibers (Wambach 1991). Hence, glass-reinforced SMA resins with high stiffness and strength have been used in many applications. The polarity and the reactivity of the SMA resins have also been utilized for the compatibilization of other polymer blends.

Unmodified SMA resins are quite brittle, like the PS, and hence they are invariably toughened by incorporating suitable rubber dispersions, either by grafting of a polybutadiene rubber during the polymerizations in a manner similar to the HIPS technology, or by blending with styrene-butadiene multiblock copolymer-type elastomers. Rubber-toughened SMA resins (Table 19.11) exhibit somewhat higher heat distortion temperatures than HIPS or ABS, yet have an equivalent toughness. Hence, such elastomer-modified SMA copolymers have found niche application in automotive interior instrument panels, headliners, and in some equipment-housing applications.

Terpolymers of SMA containing small amounts of methyl methacrylate comonomer were found to exhibit good miscibility with SAN (Hall 1982); hence, this technology was used to develop blends of SMA-MMA terpolymers with ABS. These blends exhibited higher DTUL/impact balance compared to ABS (Table 19.10) and reportedly offered processing and cost advantages over PPE/HIPS and ABS/PC blends (Kossoff 1987). However, these SMA blends are now no longer commercial. Similarly, SMA copolymers and terpolymers have also

been used for blending with PVC to improve the heat distortion temperature and processability of PVC. These blends contained a rubbery component for impact modification that is usually a high-rubber ABS or an acrylate core-shell rubber such as MBS. For improved weatherability, acrylic rubber-modified PVC has been used for blending with SMA. These SMA/PVC blends are no longer commercial, because they could not compete with the flame-retarded ABS resins in the business machine housing market.

A commercial blend of SMA and polycarbonate (Arloy®) was offered formerly by ARCO, but later discontinued. The polarity of SMA copolymer may account for the good compatibility between the two resins. The blend contained the polybutadiene rubber normally used in SMA resins for impact strength. It exhibited properties comparable to ABS/PC blend but with no cost advantage. In general, because of the lack of a competitive advantage of SMA compared to ABS in polymer blends, very few blends of SMA could be commercialized. The impact-modified SMA resins are the only commercial SMA blends known today (Table 19.11).

19.4   Vinyl Resin Blends

Poly(vinyl chloride) (PVC) is commercially the most significant member of the family of vinyl resins. The other important members of this group are chlorinated-PVC (CPVC) and poly(vinylidene chloride) (PVDC). PVC is one of the most widely used, commodity-type thermoplastics with an annual consumption of nearly 5 Mt/year in the USA. The excellent versatility of PVC is attributed to its blending capability with a variety of plasticizers, additives, and fillers to yield products ranging from very flexible to very rigid types. In addition, PVC has a low-cost advantage and a reasonably good balance of properties, which include (a) general inertness to many chemicals and aqueous fluids, (b) good dimensional stability, (c) good electrical properties, (d) inherent flame resistance, and (e) good weatherability. These attributes led to its widespread use in building construction, wire/cable, and packaging markets.

PVC, however, suffers from an inherent susceptibility to thermal degradation and hence must invariably be processed with heat stabilizers and careful control of processing temperature. The other important drawbacks of PVC are its brittleness in the absence of a plasticizer (low-notched Izod impact strength) and its low heat distortion temperature (ca. 60 °C) originating from its low glass transition temperature and essentially amorphous character. Hence, the primary motivations for blending PVC with other polymers in rigid applications have been to improve its impact strength (notched Izod), DTUL, and processability. In flexible, plasticizer-free (free from low-molecular-type materials) applications, PVC is blended with low-modulus polymeric modifiers known as flexibilizing modifiers or as polymeric plasticizers. For impact modification of rigid PVC, suitable rubbery impact modifiers are blended. The impact-modified and flexibilized PVC blends together constitute a major fraction of PVC used commercially.

Compounding mixtures of PVC, rubber, or flexibilizing modifiers is usually done by a two-step process involving dry blending followed by melt compounding.

Dry blends are usually made in conventional equipment, such as ribbon blenders and high-speed Henschel mixers. Proper mixing conditions are used to avoid excessive heat generation or agglomeration. For melt compounding, intensive mixing with heat and shear is used to compound PVC and the modifiers. Banbury or continuous mixers such as Buss kneaders, and high-shear twin-screw extruders are generally used for achieving a well-mixed PVC blend product.

19.4.1 PVC/Impact Modifier Blends

In rigid PVC applications (pipes, building, and construction), PVC is compounded with typically 5–15 wt% of the rubber-containing impact modifiers, to improve the notched Izod impact strength without sacrificing tensile strength and modulus. Various commercial impact modifiers effective in toughening the PVC are illustrated in Table 19.12. These are generally core-shell-type rubbers with a controlled particle size, rubbery core (polybutadiene, styrene-butadiene rubber, or poly-n-butylacrylate) grafted to a styrene-acrylonitrile (SAN) or styrene-methyl methacrylate (S-MMA) copolymer or polymethylmethacrylate as a rigid outer shell. These are made by emulsion polymerization of the corresponding monomers using a premade rubber latex as seed or core. The shell (rigid polymer) content in the methacrylate-butadiene-styrene-type (MBS) and the all-acrylic-type core rubbers is usually 20–30 % as compared to 30–50 % SAN in "high rubber" ABS.

The toughening effect of ABS, MBS, and acrylic modifiers is undoubtedly due to the controlled particle size of the elastomer phase (Shaw 1982; Shur and Ranby 1976; Walsh and McKeown 1990). For high impact strength, the particle size should be >0.1 μm but <1 μm. The good degree of compatibility or miscibility between PVC and PMMA or SAN phase also plays an important role in the toughening effect. Hence, a notched Izod impact strength of >1,000 J/m is readily achieved with these impact modifiers. ABS, MBS, and acrylic impact modifiers are available as powders and are usually blended with PVC powder in high-shear intensive mixers prior to fabrication of sheet or profile extrusion (Forger 1977). Precompounded grades of PVC are also sold commercially by all the major producers of PVC. When the particle size of the core-shell rubber is >0.2 μm, the toughened PVC is opaque. The ductile-brittle transition temperature shifts to lower temperature as the rubber particle size is decreased (Hassan and Haworth 2006).

Clear impact modifiers for PVC are controlled particle size grades of MBS, i.e., acrylic core shell rubber ABS. They offer the impact strength improvement as well as maintenance of sufficient optical clarity in the PVC blend. These impact modifiers are designed to match the refractive index of PVC. Controlled particle size (100–300 nm) and sufficient compatibility or solubility of the rigid SAN, S-MMA, or PMMA phase with the PVC account for the clarity of the blends. Some grades of MBS have been designed to have cluster-like structures (Saito 1973), in which the individual rubber particles of very small diameter (50–70 μm) are held together by a styrene-methylmethacrylate graft copolymer or terpolymer. When blended with PVC, these rubber particles are small enough to offer transparency to the blend, but

Table 19.12 Effect of various types of commercial impact modifiers for rigid PVC

Modifier	Advantages	Notched Izod (J/m) at various impact modifier levels (%) →			
		0	3	5	12
"High rubber" ABS (PBD $\geq$ 50 %)	Impact, processability	53	69	203	972
Methacrylate-butadiene-styrene ("MBS") (PMMA-g-SBR)	Clarity, impact and processability	53	64	240	1,335
Acrylate core-shell rubbers (PMMA-g-BuA)	Weatherability, clarity, impact, processability	53	69	192	1,041
Chlorinated polyethylene (CPE)	Weatherability, impact	54	90	235	1,225

the clusters of these particles in PVC matrix are large enough to cause craze toughening. Typical applications for clear impact-modified PVC blends are in clear, calendered sheets or films for packaging and for making blown bottles. Acrylic impact modifiers based on poly(n-butyl acrylate) or poly(2-ethyl hexyl acrylate) rubbery cores offer improved weatherability to PVC due to their saturated backbone. These blends are used for outdoor applications such as siding, window profiles, etc.

Chlorinated polyethylene (CPE) flexibilizes and toughens PVC more by a miscibility mechanism, especially when the chlorine content is >42 % (Donbe and Walsh 1979). However, partial miscibility occurring at chlorine levels of 36 % leads to higher toughening effects. CPE offers also weatherability advantage, which is the major reason for its commercial use. When CPEs are used as impact modifiers, they provide excellent toughness-weatherability balance for the entire range of rigid PVC applications, including vinyl siding, fence, window profiles, and pipes.

19.4.2 PVC/Polymeric, Flexibility Modifier Blends

The use of low-molecular weight plasticizers, such as dioctyl phthalate, to flexibilize PVC has been known and commercially practiced for a long time. Almost 90 % of current liquid plasticizer market is for PVC alone. The plasticizers work via molecular miscibility with PVC, thus lowering the PVC's T_g from ca. 80 °C to well below room temperature. The modulus of PVC is lowered from a high of about 3,000 Mpa to <100 Mpa with the addition of 30–40 wt% plasticizers, thus making it flexible enough for a wide range of applications. The transformation of rigid PVC into high-impact, rigid PVC and flexible PVCs and their key features are illustrated in Table 19.13.

Flexible PVC compounds incorporating the phthalate plasticizers have been used for a long time now in a wide range of tubing, hoses, films, wire, and cable jacketing applications in automotive, building, consumer, and health-care markets. However, the recent controversy over the migratability of phthalate ester

Table 19.13 Key features of various types of commercial PVCs

	Rigid PVC	Rigid, high impact PVC	Semi-rigid PVC	Flexible PVC
Modification	Unmodified	Rubber/impact modifiers	Low plasticizer (std. or polymeric)	High plasticizer (std. or polymeric)
Modulus (Mpa)	>3,000	2,400–2,700	100–1,000	10–100
T_g (°C)	85	80 (matrix)	≤0	<0 to −50
Ductile-brittle transition (°C)	60	0	0 to −20	−20 to −50
Elongation at break (%)	10	100–300	150–360	300 to >500
Notched Izod (J/m)	53	960	NB	NB
Key applications	Siding, pipes	Pipes, ducts, oil/chemical tanks	Films, sheets	Hoses, tubing, jacketing

plasticizers and their potential health concerns have spurred intense investigation into the use of various low-modulus, PVC-compatible polymers as potential "polymeric plasticizer alternatives" to the conventional low-molecular weight plasticizers for PVC (Robeson 1989; Brookman 1989). The high-molecular weight, polymeric plasticizers provide greater permanency than the liquid plasticizers, in maintaining the PVC flexibility, since they are not likely to leach out of the PVC during the service life of the part.

Hence, several types of low-modulus, rubbery polymeric modifiers are now used commercially for blending with PVC in order to make flexible PVC products. Most often, the blending is done directly during the fabrication of the flexible PVC product such as extruded sheet, tubing, or jacketing. These flexibilizing polymeric modifiers for PVC include the ethylene-vinyl acetate copolymers and terpolymers, nitrile rubbers (NBR), chlorinated polyethylenes (CPE), polyolefin elastomers (POE), TPU elastomers, etc. Some commercial flexibilizing modifiers and their key features are given in Table 19.14.

19.4.2.1 PVC/Nitrile Rubber Blends

Historically, nitrile rubber (NBR) blends with PVC were one of the earliest examples of any commercial polymer blends, dating as far back as 1946. In the rubber-rich PVC/NBR blends, PVC was added more as an ozone-resistant additive. In the thermoplastically processable PVC/NBR blends, the NBR was used to flexibilize PVC just enough to be used for "soft" goods, wire jacketing, hoses, gaskets, and seals. When the NBR contains >25 % acrylonitrile, it becomes highly miscible with PVC, and at ≤20 % acrylonitrile level, it is still compatible due to partial miscibility (Matsuo et al. 1969). PVC/NBR alloys are commercially produced (TeknorApex and others) and used in various automotive, industrial, and construction hoses, jacketing, seals, weather stripping, etc., where oil-resistance and low-temperature flexibility is important.

Table 19.14 Various modifiers for PVC flexibilization, their key features and benefits

Modifier	T_g (°C)	Miscibility with PVC	Benefits	Applications
Ethylene-vinylacetate copolymer	−20	Partial	Low-cost flexibilizer	Window profiles, films, cable jacketing
Ethylene-vinyl acetate-carbon monoxide terpolymer (E-VA-CO)	−32	High	Effective flexibilizer	Roofing membranes
			Low smoke generation	Geomembranes
Ethylene-butyl acrylate-carbon monoxide terpol. (E-BA-CO)	−54	High	Best flexibilizer for low temp. (−20 °C) flexibility and weatherability.	Roofing membranes
				Geomembranes
Chlorinated PE (30–40 % Cl)	−16	Partial	Chemical resistance + flexibility	Calendered PVC liners and roofing membranes
Polyolefin elastomers (POE)	−16	Immiscible	Low-density/cost, good toughness, processability	Hoses, tubing, seals and gaskets, boots
Thermoplastic polyurethane (TPU)	−30	Low	Chemical resistance	Shoe soles and heels, gaskets, seals, tubing
			Low temp. toughness	
High-nitrile NBR (45 % AN)	−14	High	Oil resistance, flexibility at low temperatures	Cable jacketing, hoses, tubing, belting, seals, gaskets, shoe soles, etc.
Low-nitrile NBR (20 % AN)	−48	Low		

19.4.2.2 PVC/E-VA-CO or E-BA-CO Terpolymer Blends

From a cost-performance balance point of view, the ethylene-vinyl acetate (EVA) copolymers and subsequently, the more effective ethylene-vinyl acetate-carbon monoxide (E-VA-CO) terpolymers have gained increasing use as "polymeric plasticizers" for PVC. Low cost and good weatherability of these PVC/EVA modifier blends permitted their use in window profiles, roofing, cable jacketing, and other outdoor applications. Although ethylene-vinyl acetate copolymer with 65–75 % vinyl acetate content is quite miscible with PVC exhibiting a single T_g for the blend (Hammer 1971; Ranby 1975; Rellick and Runt 1985), such EVA copolymers were quite difficult to process with PVC. EVA copolymers with ≤45 % vinyl acetate showed only a limited degree of partial miscibility with PVC, basically forming two-phase blends. Although commercial EVA copolymers with 25–30 % vinyl acetate can be used for flexibilizing PVC, their effectiveness is limited by their lack of adequate miscibility with PVC.

However, more recently, the ethylene-vinyl acetate-carbon monoxide (E-VA-CO) terpolymers (T_g = −32 °C), offering a more complete miscibility with PVC, because of the polar keto groups in the terpolymer structure, have replaced the EVA copolymers for flexibilizing the PVC. The E-VA-CO/PVC blends exhibit a single T_g behavior, indicating the complete miscibility (McConnell et al. 2004). Thus, the E-VA-CO terpolymer is more effective as a miscible, polymeric plasticizer for effectively lowering the T_g of PVC to make it more flexible.

Hence, commercial E-VA-CO terpolymers (Elvalloy® 741 and 742, DuPont) are now the more preferred and more commonly used flexibilizing modifiers in PVC blends. For an even better low-temperature flexibility in PVC blends, ethylene-n-butyl acrylate-carbon monoxide (E-BA-CO) (Evalloy® HP, Dupont) is used. The advantage of E-BA-CO terpolymer is its lower T_g (-52 °C). PVC/E-VA-CO blends and PVC/E-BA-CO blends are particularly used in roofing membrane and geomembrane application.

19.4.2.3 PVC/Chlorinated Polyethylene (CPE) Blends

Chlorinated polyethylene (CPE) has been in commercial use for a long time as an impact modifier to rigid PVC to achieve a combination of good impact resistance, ductility, and weatherability for use in the entire range of standard rigid PVC applications, including vinyl siding, fence, window profiles, and pipes. CPE has been used in these semirigid/high-impact PVC applications primarily due to its excellent weatherability. CPE has also been used to replace part of the plasticizer in flexible PVC compounds. However, for complete replacement of low-MW plasticizers, CPE lacks complete miscibility in PVC. Compatibility in the immiscible PVC/CPE blends is only due to a partial miscibility, which occurs only when the Cl content in CPE is >42 % (Donbe and Walsh 1979). Hence, for flexible applications, PVC/CPE blends are not flexible enough unless some plasticizer is included. CPE by itself with a small amount of PVC added as a reinforcement is often used for outdoor flexible roofing membrane applications.

19.4.2.4 PVC/POE Blends

The recent proliferation of metallocene-based polyolefins and polyolefin elastomers have gained their popularity owing to their density, cost, and ease of processability. PVC/POE blends have therefore been investigated as flexible PVC compounds. However, these blends are thermodynamically immiscible and needed suitable compatibilizers such as the chlorinated polyethylenes (Eastman and Dadmun 2002). Since they are not miscible, POEs do not lower the PVC modulus sufficiently unless some plasticizer or a compatible elastomer such as EPE is also added. Commercially, some PVC/POE alloys are offered by TeknorApex under Flexalloy® trade name with a shore A hardness 40–60 and brittle points down to -50 °C. They are claimed to have excellent low-temperature toughness, flexibility, compression set-resistance, and oil resistance. Suitable applications include automotive hoses, seals, gaskets, wire jacketing, etc.

19.4.2.5 PVC/TPU Blends

Many TPU elastomers are compatible with PVC exhibiting only a single T_g, in between that of TPU and PVC, indicating some level of miscibility. Because of the heat sensitivity of PVC, only very soft TPUs (i.e., high soft-segment, low-melting grades) can be melt blended with PVC. Typically, 40–50 % TPU is blended. The key advantage of TPU in the blend is wear and abrasion resistance and low-temperature toughness. The oil resistance of PVC is also improved. However, TPU is relatively more expensive as a blend candidate for PVC. Some plasticizer

may also be used to tailor-make desired softness. A 70/30 blend of PVC/TPU is as flexible as conventional plasticized PVC but with substantially better abrasion resistance and toughness at low temperatures. Commercially, PVC-TPU blends are available or formulated with varying Shore A hardness from various compounders (e.g., Apex® product line from TeknorApex). Specialty niche applications for PVC-TPU blends include shoe soles and heels, gaskets, seals, and tubing.

19.4.3 PVC/Styrenic Blends

Styrenic resins have been blended with some PVC primarily to achieve some degree of flame-retardant characteristics and cost benefits in the styrenic resins. ABS, SMA, and rubber-modified SMA, SMA-MMA copolymers have been used commercially for blending with PVC. These have been discussed under the styrenic blends and illustrated in Table 19.7.

19.4.4 PVC/PMMA Blends

PVC blends with poly(methyl methacrylate) (PMMA) have been commercialized (e.g., Kydex®, Kleerdex Co.) as extruded sheets for thermoforming applications such as chairs, seats, trays, etc. Ease of thermoformability, toughness, resistance to cleaning solvents, and the flame retardancy characteristics of the blends have been the primary features leading to its use. The good level of compatibility between PMMA and PVC is mainly responsible for the toughness characteristics of the blend (Walsh and Cheng 1984; Tremblay and Prud'homme 1984; Jager et al. 1983). Notched Izod impact strength of >600 J/m has been reported, although it is likely that some acrylic rubber modifier may have been used. The inherent flame retardancy and low smoke-generation characteristics of PVC/PMMA blends meet the aircraft fire safety standards. This factor coupled with the low cost, high toughness, and easy processing features of the blend led to its use in aircraft components such as toilet shrouds, floor pans, air diffusers, emergency respirator enclosures, etc.

19.5 Acrylic Blends

Commercial acrylic resins comprise a broad array of polymers and copolymers derived from esters of acrylic acid and methacrylic acid. They range from the homopolymer of methyl methacrylate to a variety of copolymers including both the thermoplastic and thermoset type and ranging from hard and stiff types to soft and elastomeric types. The most common of the thermoplastic acrylic resins are the poly(methyl methacrylate) homopolymer (PMMA) and the copolymers containing predominantly methyl methacrylate but with small amounts of methyl or ethyl acrylate, acrylonitrile, or styrene comonomers added for improved toughness.

The commercial PMMA-based acrylic resins are rigid, amorphous polymers (T_g's ranging from 85 °C to 105 °C) particularly noted for their exceptional clarity and UV resistance. They are therefore widely used for glazing, extruded sheet and thermoforming applications, as well as in several molding applications in which these properties are well utilized.

Since most of the applications of the PMMA-type acrylic resins are based on their high degree of transparency and UV resistance characteristics, there has been very little commercial motivation or interest in developing any significant types of acrylic blends. This is understandable because unless there is complete, molecular-level miscibility between the components, it is not possible to maintain a high-degree clarity in the blends. Nevertheless, several examples of commercial blends of acrylic resins are known. These will be discussed under separate headings.

19.5.1 Impact-Modified Acrylic Resins

Since the homopolymer PMMA as well as the MMA-rich copolymers are quite brittle, exhibiting low elongation to break (≤5 %) and low notched Izod impact strength (typically ≤15 J/m), there was a need to blend suitable impact modifiers that would improve the ductility and impact strength of these resins without sacrificing the transparency, rigidity, and weatherability characteristics.

Two general types of impact-modified acrylic resins have been developed commercially, viz., (a) weatherable, impact-modified, transparent acrylic resins for outdoor use in signs and automobiles; (b) nonweatherable impact-modified, transparent acrylic resins for medical and food packaging applications. The weatherable grades of acrylics are made by blending "all acrylic" core-shell rubbers, viz., PMMA-grafted, cross-linked poly(n-butyl acrylate)-type rubbers (Paraloid®, Rohm Haas). The nonweatherable grades are made by blending poly (methyl methacrylate)-g-butadiene/styrene ("MBS")-type core-shell rubbers. In both cases, due to the small particle size of these core-shell rubbers (≤100 nm) and the miscibility of the shell (PMMA) with the PMMA matrix, the refractive index could be matched and the transparency could be completely maintained. The rubber particles were found to promote localized shear banding in the matrix and hence, the ductility and toughness of the matrix improves (Hooley et al. 1981; Bucknall et al. 1984; Wrotecki et al. 1991).

Commercial impact-modified acrylic resins (Table 19.15) exhibit five- to tenfold improvement in the notched Izod impact strength and the ultimate tensile elongation compared to the neat PMMA resin. These impact-modified acrylics are usually blended captively by the manufacturers of the acrylic resins. The base resin in a typical weatherable grade (Plexiglas DR, Rohm and Haas) could be a methyl methacrylate copolymer with ethylacrylate and styrene, while the rubber additive (ca. 10 %) could be an emulsion-polymerized, PMMA-grafted, cross-linked poly (n-butylacrylate) rubber of controlled particle size (≤200 nm). The nonweatherable impact-modified acrylic (XT, CYRO) typically consists of a MMA/S/AN copolymer with MBS (ca. 10 %) rubber particle dispersions.

Table 19.15 Commercial acrylic polymer blends vs. acrylic polymer

Property	ASTM	Units	PMMA/core-shell rubber blend	PMMA/PVC blend	PMMA/PC blend	PMMA/PLA blend	PMMA
			XT 375	Solarkote® PB/PVC	Cyrex 200-8000	Plexiglas® Rnew PRD-1042	Plexiglas® V045
			Evonik	Arkema	Evonik	Arkema	Arkema

Light transmission	D1003	%	86	Opaque	Opaque	87	92

Generally, the weatherable impact-modified acrylic resin has better color and transparency retention than the nonweatherable grade but the latter shows better toughness. The weatherable grades are used for making outdoor signs, automotive headlight lenses, lighting fixtures, glazing, etc. The nonweatherable, high-impact acrylics are used for medical devices, medical and food packaging, refrigerator trays, etc. Polycarbonate is a competitive threat to the impact-modified acrylic resin markets.

19.5.2 Acrylic/PVC Blends

Since PVC is known to be quite miscible with PMMA (miscibility with an LCST behavior) (Jager et al. 1983) and is also low in cost, some blends of PVC and PMMA have been used in sheet extrusion and thermoforming applications.

However, the acrylic PVC compositions commercially used invariably contain an acrylic core-shell rubber (PMMA-g-n-BuA or MBS-type) to get high toughness, with some PMMA, to reduce the cost/impact performance balance. The role of PVC in these blends is primarily to reduce the cost and impart some degree of flame-retardancy to the acrylic resin. The acrylics definitely help in the processability of PVC. These blends have already been discussed under PVC heading.

19.5.3 Acrylic/PVDF Blends

Poly(vinylidene fluoride) (PVDF) is increasingly used in outdoor applications such as architectural coatings, due to its outstanding chemical and UV resistance and long-lasting weatherability performance. However, the chemical inertness of PVDF prevents good adhesion to substrates and makes it difficult to disperse pigments. Furthermore, the high cost of PVDF makes it indispensable to blend a second polymer component to optimize the performance of PVDF materials. The most widely used class of polymers for blending with PVDF is acrylic resin, such as poly (methyl methacrylate) (PMMA) and its copolymers. Acrylics have good compatibility with PVDF providing clarity coupled with good heat resistance and weatherability. Typically, 30 % acrylic polymer is blended in PVDF architectural coatings (Wood et al. 2005).

PVDF is known to form thermodynamically miscible blends with PMMA exhibiting a single T_g, an indication of a single-phase behavior (Bernstein et al. 1977; Mijovic et al. 1982). The homogeneous PVDF-PMMA blend does not phase-separate until above the lower critical solution temperature (LCST) of around 300 °C. Upon cooling to below the melting temperature at 178 °C, PVDF does tend to crystallize to some degree however, from the homogeneous blend (Bernstein et al. 1977; Wang and Nashi 1977). The melt-cooled solid blend contains some PVDF crystallites, and the remaining PVDF plus the acrylic form a second amorphous, miscible alloy phase. This unique combination of crystalline and amorphous phases gives PVDF-PMMA coatings many of their superior properties, such as flexibility combined with solvent resistance.

A commercial PVDF/PMMA blend film (Fluorex® A, Rexham Corp.) is produced captively by solvent-casting for use in specialty film applications, such as a protective and decorative film overlaminated for automotive parts. It is laminated to metal, followed by fabrication (stamping, rolling) into automotive parts such as rocker panels, hubcaps, pillar posts, door edge guards, etc. The role of PVDF in this blend is to offer chemical resistance coupled with weather resistance.

19.5.4 Acrylic/PC Blends

PMMA/polycarbonate (50/50) blends prepared by melt-mixing are mostly immiscible, exhibiting two glass transition temperatures in DSC, one at the normal T_g of PMMA (ca. 105 °C) and the other for PC at about 8 °C below $\boldsymbol{T_g}$

of **PC** (i.e., 142 °C vs. 150 °C), indicative of, at best, only a small degree of partial miscibility (Chiou 1987). Because of this phase-separated morphology, PMMA-PC blends made by the usual melt compounding techniques are understandably opaque and exhibit lower impact toughness than polycarbonate. However, the impact toughness of PMMA/PC blends were substantially improved by blending a PMMA-grafted EPDM rubber as compatibilizing toughener (Zimmerman 1992). Using such a compatibilizer toughening technology, Cyro Industries (now part of Evonik industries) commercially developed a family of opaque, high-impact, PMMA-PC alloys under the trade name of Cyrex®. The key advantage of Cyrex® PMMA-PC blends is the substantially higher notched Izod impact strength (two to three times higher) than that of PC or ABS/PC, with comparable modulus, strength, and hardness properties. Key properties of a commercial high-impact, PMMA/PC blend are shown in Table 19.15.

Key applications for Cyrex® PC-PMMA alloys include the following markets:
  (i) Appliances
 (ii) Toys
(iii) Furniture
 (iv) Automotive components
  (v) Protective casings
 (vi) Housings for personal electronic devices
(vii) Medical equipment

19.5.5 Acrylic/PLA Blends

Polymethyl methacrylate (PMMA) has been found to form miscible alloys with polylactic acid (PLA), a bio-based, biodegradable polyester (Eguiburu et al. 1998; Zhang et al. 2002). Miscibility also means that PMMA and PLA can be blended at any ratio, keeping the transparency high. Blending of PLA into PMMA improves the ductility and solvent resistance of PMMA while maintaining good transparency. The processability and melt flow characteristics are also improved to allow the molding of more complex and intricate PMMA parts. Blending of PMMA in PLA elevates the heat resistance, hydrolysis, and UV-resistance of PLA.

Some commercial PMMA/PLA blends containing 25–35 % PLA have been recently introduced by Arkema as "Plexiglas® Rnew Biopolymer Alloys" (Naitove 2012). The primary motivation to develop these PMMA blends is the desire to reduce the carbon footprint by incorporating bio-based polymers. By blending >25 % PLA into PMMA, a "bio-based" certification is achievable while simultaneously improving the toughness, solvent-resistance, and processability of PMMA. Transparency is retained due to the mutual miscibility of the two polymers. Properties of a transparent grade of PMMA/PLA blend (Plexiglas® Rnew PRD-1042, Arkema) are included in Table 19.15. Target applications for such transparent PMMA/PLA blends, with improved impact and chemical resistance, appear to be primarily in medical equipment markets.

19.6   Elastomeric Blends

The blending of different types of rubbers and then curing into the final fabricated parts such as automotive tires has long been known in the rubber industry and will not be discussed here. This discussion will deal with the commercial blends containing a high volume fraction of a rubbery polymer and minor amounts of a rigid, amorphous, or crystalline thermoplastic. A major motivation for developing such blends was to combine the elastomeric character of the rubber component with the melt processability of the thermoplastic. Hence, blending has been an alternative and somewhat lower-cost approach to making thermoplastic elastomers compared to the block copolymer approach.

Vulcanized rubbers are distinguished by their characteristically low modulus, high extensibility, and high elastic recovery, i.e., by their ability to return to the original dimensions after stretching to high strain levels and then releasing the applied stress. The elasticity behavior in vulcanized rubbers is related to the cross-linking between the polymer chains. However, in the thermoplastic elastomers, the elasticity originates from the pseudo-cross-links formed by the rigid phase, which is either the hard segment of the block copolymer or the rigid inclusion having high gloss transition temperature, or crystalline polymer phase blended into the elastomer as a fine dispersion.

Blends of metallocene polyolefin elastomer/plastomer materials compounded with EPDM (typically 70/30) are finding several extrusion applications such as flexible hoses, cords, and wire jacketing because of much higher extrusion rates and better heat aging characteristics than EPDM (Sherman 1997). Blends of POEs with ethylene-vinyl acetate copolymers are used as cushioning in sports shoes because of improved resiliency and durability. Blends of POE with PVC are employed in some extruded profiles for refrigerator gaskets, window and garage door seals. Other applications of POE blends include soft-touch handles for handheld tools and for automotive noise, vibration, and harshness (NVH) dampening. As the metallocene olefin copolymers become increasingly more cost-effective, the application of their corresponding blends are expected to proliferate.

19.6.1 Nitrile Rubber/PVC Blends

Blends of butadiene-acrylonitrile copolymer rubber (nitrile rubber or NBR) and PVC are among the oldest known examples of commercial elastomer/thermoplastic blends. The shortage of natural rubber during World War II stimulated research in the USA on the compounding and modification of synthetic polymers to produce rubber-like materials. An outcome of this research was the commercial introduction of NBR/PVC blends by B.F. Goodrich in 1947 under the trade name of Geon® Polyblends (Pittenger and Cohan 1947). The blend showed improved ozone resistance and melt processability compared to the nitrile rubber (Table 19.16).

Table 19.16 Typical properties of nitrile rubber/PVC blends vs. nitrile rubber

Property	NBR/PVC (70/30)	NBR/PVC (55/45)	NBR
Hardness (Shore A)	73	82	63
Modulus (MPa) at 100 %	4.6	7.5	2
at 300 % elongation	12	13.5	10
Tensile strength (MPa)	17	15.8	22
Elongation at break (%)	530	460	600
Compression set (%) (22 h, 100 °C)	48	64	37

Butadiene-acrylonitrile copolymer rubbers containing >25 % acrylonitrile exhibit good miscibility with PVC as evidenced by single T_g behavior of the blend (Zakrzewski 1973; Matsuo et al. 1969), although high-resolution electron microscopy indicated some degree of microheterogeneity with a very fine dispersion size (<10 nm) (Matsuo 1968). This high degree of miscibility, or partial miscibility, between the components accounts for the blend's high compatibility and improved mechanical properties. Commercial nitrile rubber/PVC blends are used in both nonvulcanized and vulcanized forms. A descriptive list of commercially available nitrile rubber/PVC blends can be found under a variety of trademarks in the Nitrile Elastomers section of "The Blue Book, Materials, Compounding Ingredients and Machinery for Rubber," published annually by Bill Communications, Inc. Nitrile rubbers are known for their oil and chemical resistance, and addition of PVC improves the ozone resistance. Use of carboxylated NBR is believed to obviate the necessity of vulcanization. Nitrile rubber/PVC blends have reached a mature stage in their commercial usage. They face increasing competition from other thermoplastic elastomers such as the dynamically vulcanized blends of PP/EPDM and PP/NBR (Santoprene® and Geolast® grades).

19.6.2 Thermoplastic Dynamically Vulcanized Elastomer Blends (TPV Blends)

Another class of thermoplastic elastomer blends, which has gained significant commercial growth in recent years, is the "dynamically vulcanized" or a fully cured elastomer blended in a thermoplastic matrix (Coran 1987). Dynamically vulcanized alloys are produced by melt blending a high volume fraction of an elastomer with a thermoplastic in a high-intensity mixer, with a compatibilizer if necessary, such that a fine dispersion of the elastomer is achieved. The elastomer is then fully cured during the melt mixing through the use of selective cross-linking agents. Since the elastomer is fully cured, the blend achieves a high rubber elasticity character, but since the thermoplastic still remains as an uncross-linked matrix, the blend can be melt processed like a thermoplastic. In order to distinguish from the

simple blends of an elastomer and thermoplastic, the dynamically vulcanized blends have previously been classified as "elastomeric thermoplastic alloys" (ETA), (Wallace 1992) but currently more commonly referred to as the "thermoplastic vulanizates" (TPVs).

Dynamically vulcanized, elastomeric thermoplastic alloys or TPVs display properties as good as or even better than the block copolymers, viz., a high degree of rubber elasticity yet good melt processability. The main advantages of the thermoplastic vulcanizate elastomer blends over the uncured thermoplastic/elastomer blends are

- Improved resistance to compression or tension set
- Improved tensile strength, elongation, and resiliency
- Improved flexural fatigue resistance
- Improved chemical resistance
- Better morphology stability during melt processing
- Improved melt processability and recyclability (regrind reusability)

   The dynamically vulcanized blends are melt-processable elastomers, which can be processed by conventional injection molding, blow molding, and extrusion techniques. Some key factors affecting the performance of a TPV are

   - The degree of cross-linking of the rubber phase. A high level of cross-linking offers more rubbery elasticity and low compression set in the product.
   - The degree of fineness of the rubber dispersion in the thermoplastic matrix. The rubber domains must be in 1–2 μm range, although they may be interconnected.
   - The thermodynamic compatibility between the rubber and matrix polymers. A high inherent compatibility needs no compatibilizer, but those with low inherent compatibility (e.g., NBR rubber/PP) will need compatibilizers to stabilize the interface and improve interfacial adhesion strength.

Examples of commercially important TPV alloys include the dynamically vulcanized blends of PP with high volume fractions of EPDM (Santoprene®) and similarly, the PP/polybutadiene rubber blend (Vyram®), PP/nitrile rubber blend (Geolast®), and PP/butyl rubber (Trefsin®), all of which were initially sold by Advanced Elastomer Systems, which is now owned by Exxon. Among these, the dynamically vulcanized EPDM/PP blend (Santoprene®) has enjoyed the most commercial success and market growth, due to its outstanding properties, ease of processability, and relatively low cost. Hence currently, Exxon and other TPE suppliers have a major focus only on the Santoprene®-type EPDM/PP-based TPV blends. Commercially, another member of the dynamically cured elastomeric thermoplastic alloys, which is gaining some interest, is the blend of PVC with a cross-linked ethylene copolymer (Alcryn®, DuPont). The current global consumption of thermoplastic dynamically vulcanized elastomeric alloys is >100 kt/year, with the EPDM/PP blend (Santoprene®) assuming the dominant (>90 %) market share. Some important applications of the commercial thermoplastic vulcanizate (TPV) blends are

- Automotive seals and weather stripping for windows, hoods, trunks, doors, sun roofs, handle gaskets, window spacers, window guides, lock seals, windshield

wiper pivot seals. The automotive window seal/door weather stripping alone is a high-volume application. Other automotive uses include protective boots, jacketing, hoses, grommets, etc.

- Building and architectural applications also include window-glazing gaskets and weather seals in which TPVs offer the advantages of dimensional stability, low compression set, sealing out the noise, wind, and water, while providing long-term UV resistance.
- Other nonautomotive applications include office equipment, household appliances, toys, products requiring the use of boots, bushings, seals, tubing, and other rubber articles.
- Electrical wire-jacketing applications for use in automotive, construction, industrial, appliance, and many other segments.
- Soft-touch overmolding applications in kitchen appliances and tools (e.g., knife handles), handheld power tools, consumer electronics, etc.

19.6.2.1 Thermoplastic, Dynamically Vulcanized EPDM Rubber/PP Blends

Owing to adequate levels of compatibility between polypropylene and ethylene-propylene copolymers, simple blends of these two polymers have been known for a long time. Impact-modified polypropylene blends containing up to 30 % EPR have already been discussed under polyolefin blends. Blends containing high contents of an uncured or partially cured EPDM in polypropylene have been known (Kresge 1978). However, the advantage of fully cured EPDM/PP blends made by selective cross-linking of the rubber phase during the melt mixing has not been commercially realized until recently (Santoprene®, Exxon; Sarlink®, Teknor Apex). The technology (Coran et al. 1978; Coran and Patel 1980) involved an accelerated sulfur cure of the EPDM rubber ($\geq$70 %) in the presence of minor amounts of polypropylene ($\leq$30 %) while melt compounding under high-shear mixing conditions. The curing agents typically consisted of zinc oxide (5 phr), sulfur (2 phr), tetramethylthiuram disulfide (1 phr), and 2-benzothiazolyl disulfide (0.5 phr). The particle size of cured EPDM dispersions was typically <2 μm, but interconnected to look like a cocontinuous morphology.

Increasing the crosslink density of the elastomer dispersion results in improvements of the strength and tension set of the blend. The difference between the earlier commercial grades of partially cured EPDM/PP blends (TPR, Uniroyal) and the more recent commercial grades of completely cured EPDM/PP blends is in the improved elastomeric properties, viz., reduced compression and tension set and improved flexural fatigue. More important, the chemical resistance and resistance to oil swelling is improved. Typical properties of commercial EPDM/PP TPV blends (Santoprene® and Sarlink®) are shown in Table 19.17.

Nearly all of the EPDM/PP-based TPV's growth has been at the expense of thermosetting rubbers due to this TPV's low cost, easier melt processability,

Table 19.17 Key properties of some typical TPVs based on PP/elastomer blends

Properties	ASTM	PP/EPDM Santoprene® 101-73 ExxonMobil	PP/EPDM Sarlink® 4175 TeknorApex	PP/NBR Geolast® ExxonMobil	PP/ Butyl Trefsin®
Specific gravity (g/cc)	D792	0.97	0.96	1.0	1.2
Shore hardness	D2240	78A	72A	70A	70A
100 % modulus (MPa)	D412	3.6	3.4	3.3	5.2
Tensile strength at break (MPa)	D412	8.8	8.1	6.2	7.6
Elongation at break (%)	D412	490	527	265	250
Tear strength (KN/m)	D624	27	39	33	26
Compression set (%), 70 °C, 22 h	D395B	28	22	29	52
Brittlness temp. (°C)	D746	−60		−40	−60
Oil swell (vol%), 70 h at 100 °C		32		10	

Key attributes: melt processability, rubber elasticity, low compression set, low brittleness temperature

and recyclability. Much of this growth has been in automotive applications such as window and door glazing seals, weather stripping, boots and bellows for steering and suspension, seat belt sleeves, and air induction system ducts. The EPDM/PP-based TPV is also used for window glazing and weather seals in building industry, electrical wire jacketing, and for various soft-touch overmolding applications.

19.6.2.2 Thermoplastic, Dynamically Vulcanized, Nitrile Rubber/PP Blends

The oil resistance and chemical resistance of nitrile rubber (NBR) is generally superior to that of EPDM rubbers. However, the ozone resistance of NBR is poor. The highly polar nature of acrylonitrile comonomer causes high incompatibility between NBR and polypropylene when melt-blended. Hence, the stability of NBR dispersions in PP matrix is relatively poor. Reactive compatibilization technology could be used to improve the blend morphology stability (Coran and Patel 1983). It consisted of blending a small amount of a low-molecular weight amine-terminated butadiene-acrylonitrile copolymer (ATBN, B.F. Goodrich) with the high-molecular weight NBR and a small amount of maleic anhydride-grafted polypropylene (maleated PP) with the high-molecular weight polypropylene and then intimately mixing all the components together. A graft-coupling reaction takes place between the ATBN and maleated PP, and the resulting poly(butadiene/acrylonitrile)-g-polypropylene copolymer compatibilizes the NBR/PP blend.

Typically, a 50/50 blend of nitrile rubber and polypropylene is melt mixed with 5 % maleated PP and 1 % ATBN respectively and then cured with $SnCl_2$ (0.5 %). The resistance to hot oil swell (72 h, 100 °C) of NBR/PP blend was found to be significantly better than that of EPDM/PP blend. Typical properties of the commercial dynamically cured NBR/PP TPV (Geolast®) are compared with other PP-based TPVs in Table 19.16. Commercial applications for this TPV were targeted for automotive seals and gaskets in the oil, fuel, and brake systems. However, this blend has not been as commercially successful as the Santoprene®-type PP/EPDM-based TPV.

19.6.2.3 Thermoplastic, Dynamically Vulcanized Butyl Rubber/PP Blends

The dynamically cured, butyl rubber/polypropylene blends were first developed by Gessler et al. using phenolic-type cross-linking agents. Commercial dynamic vulcanizates are based on halobutyl rubbers and polypropylene cured by zinc oxide-type curatives (Hazelton and Puydak 1987; Kay and Ouhadi 1991; Anonymous 1988). The blend containing a high volume fraction of butyl rubber dispersion in PP exhibits good thermoplastic elastomers with (a) low moisture permeability (b) high vibration damping (c) good heat, UV, and solvent resistance. However, excepting in a few niche medical applications, this TPV has no competitive advantage over Santoprene®-type PP/EPDM-TPV.

19.6.3 Thermoplastic Vulcanizates (TPV) of PVC/Ethylene Terpolymer Blends

Blends of ethylene-butyl acrylate-carbon monoxide (E-BA-CO) terpolymers with PVC, which have been dynamically vulcanized into highly elastomeric yet thermoplastically processable blends, have been available commercially (Alcryn®, DuPont). The principle behind this technology appears to be the selection of proper types of low-T_g, ethylene-acrylate-CO terpolymers, which exhibit high degrees of miscibility with PVC and which can selectively be cross-linked in situ, during the melt mixing with specific curing agents (Loomis and Statz 1986). It has been known that PVC forms miscible or partially miscible blends with certain types of ethylene copolymers such as ethylene-vinyl acetate (EVAc), ethylene-methyl acrylate (EMA), and ethylene-butyl acrylate (EBA) copolymers (Krause 1989). The degree of miscibility depends on the structure of ethylene copolymers. For example, when the vinyl acetate content in EVAc is high (e.g., >65 wt%), the copolymer forms completely miscible blends with PVC (Hammer 1971; Rellick and Runt 1985). At lower levels, the blends are partially miscible. Similarly, ethylene-methyl acrylate and ethylene-butyl acrylate copolymers form miscible to partially miscible blends with PVC (Kalfouglou 1983).

However, ethylene terpolymers containing keto groups, such as the ethylene-butyl acrylate-carbon monoxide (E-BA-CO) terpolymers, exhibit complete miscibility with PVC due to the compatibilizing nature of the polar keto groups. Furthermore, these keto groups in the E-BA-CO terpolymers are useful as a reactive functionality in facilitating the free-radical-induced cross-linking of the ethylene terpolymer rubbers. This concept was applied to a dynamic vulcanization process in a twin-screw extruder to achieve high-volume fraction dispersions of cured E-BA-CO terpolymer rubbers in the thermoplastic matrix of PVC. This technology was initially developed by DuPont in the late 1980s to produce their commercial Alcryn® thermoplastic vulcanizate (TPV) elastomer alloys, also known as "melt processable rubbers" (Alcry® MPR). From the available patent information, these TPVs are blends of PVC with ethylene-n-butylacrylate-carbon monoxide (E-BA-CO) terpolymer systems in which the elastomeric ethylene terpolymer was cross-linked selectively through the use of a combination of peroxide and bis-maleimide-type free-radical cross-linking agents (Loomis and Statz 1986).

In a typical formulation, an ethylene-n-butylacrylate-carbon monoxide (60/30/10) terpolymer (60 wt%) is melt compounded in a twin-screw extruder with PVC (30 wt%) along with an optional, nonvolatile plasticizer such as trioctyl trimellitate (10 wt%) such that the ethylene terpolymer dispersion was cured in situ during the mixing by catalytic amounts of a suitable peroxide (0.3 %) and a bismaleimide crosslink promoter (0.2 %). It is believed that the initial homogeneous miscible melt blend later forms the "micro" phase-separated rubber domains as the selective rubber cross-linking progresses. Currently, such TPV blends are commercially sold as Alcryn® melt-processable rubbers by Advanced Polymer Alloys division of Ferro.

These commercial TPVs composed of E-BA-CO terpolymer/PVC blends can be processed by conventional melt fabrication processes such as profile extrusion, extrusion coating, milling and calendering of sheets, injection, and/or compression molding. The typical properties of a commercial grade of ethylene terpolymer and PVC (Alcryn®) are shown in Table 19.18 as compared to other elastomeric TPVs.

Some key advantages of the ethylene terpolymer/PVC blend-based TPV (Alcryn®) are
- Excellent rubber-like elasticity with high strain recovery
- Excellent low-temperature toughness
- Outstanding weatherability and ozone resistance
- High chemical resistance to oils
- High abrasion resistance
- Melt processability and recyclability

Commercial Alcryn® TPVs are used in various automotive seals and gaskets, weather stripping, noise and vibration dampening, tubing, hoses, wire jacketing, fabric coating, pond linings, soft-touch overmolding, and a variety of other extruded and molded goods applications. These TPVs continue to compete against other lower-cost TPVs using their better low-temperature toughness, oil and

Table 19.18 Comparison of the acrylate rubber based TPV blends vs. PP/EPDM blend based TPVs

Property	PA6/Acrylate rubber TPV (Zeotherm® 100-70)	PVC/E-BA-CO terpolymer TPV (Alcryn® 2070)	PP/EPDM-TPV (Santoprene® 101-73)
Density (kg/m^3)	1,150	1,200	980
Shore hardness	75A	68A	70A
100 % modulus (MPa)	5	4	3.6
Tensile strength (MPa)	8	8.6	7.6
Elongation at break (%)	200	400	470
Compression set (%) at 24 °C	–	16	11
Compression set (%) at 125 °C	60	62	37
Brittleness temperature (°C)	−40	−85	−65
Hot oil resistance	Excellent	Good	Moderate
Weatherability	Good	Excellent	Good

Melting temperature (°C)	220	<120	165

chemical resistance, abrasion resistance, and weatherability as marketing advantages. The growing ecological concerns about PVC and chlorinated polymers in general may limit the market growth of these TPVs.

19.6.4 Thermoplastic Vulcanizates (TPV) of PA6/Acrylic Rubber Blends

Polyamides such as PA6 are engineering thermoplastics with high heat and solvent resistance properties and hence make ideal thermoplastic matrix candidates of choice to make high-performance TPVs with dynamically vulcanized rubber blends. Although nylon blends with low rubber content have been known for a long time as impact-modified nylons, as discussed under Sect. 19.7.1, elastomeric TPV blends of polyamide with high rubber content (≥ 60 %) have not been commercially available until recently. Because of their higher thermal and chemical resistance performance, the polyamide-based TPVs have often been called super-TPVs (Leaversuch 2004).

Currently, a PA6-acrylic rubber-based TPV blend is commercialized by Zeon Chemical under the trade name of "Zeotherm®." Zeotherm is composed predominantly of a heat- and oil-resistant polyacrylate (ACM) elastomer, which has been dynamically vulcanized and well dispersed in a polyamide (PA6) thermoplastic matrix. Based on the patent literature (Aonuma et al. 1991),

the technology is based on blending a mixture of functionalized polyacrylate rubbers such as an epoxy functional, ethyl acrylate-glycidyl methacrylate copolymer and a carboxyl functional, ethyl acrylate-methacrylic acid copolymer. During the melt blending with nylon, the two mutually miscible acrylate rubbers cross-link with each other via the carboxyl-epoxy reaction (Eq. 19.3).

$$\text{Acrylate rubber with carboxy groups} + \text{Acrylate rubber with epoxy groups} \longrightarrow \text{COOCH}_2\text{CHOH} \longrightarrow \text{Cross-linked acrylate rubber}$$

| Acrylate rubber with carboxy groups | Acrylate rubber with epoxy groups | Cross-linked acrylate rubber |
Equation 19.3 Graft-coupling cross-linking reactions in functional acrylate rubber blends

The above selective cross-linking of acrylate rubbers in a polyamide thermoplastic matrix leads to a PA-acrylate rubber-blend TPV with the melt-processing advantages of the PA and the high-performance properties of a thermoset acrylate rubber. The PA matrix provides the high heat resistance and solvent resistance while the cross-linked polyacrylate provides the rubber elasticity coupled with its own excellent weatherability and oil resistance properties to the TPV.

The key properties of commercial PA6-acrylate rubber TPV (Zeotherm®) are shown in Table 19.18. Based on the properties and the available commercial literature, the key advantages of the PA6/acrylate rubber TPVs (Zeotherm®) vs. other TPVs may be summarized as follows:

- Higher heat resistance, i.e., higher property retention in hot air
- Spike temperature resistance to 175 °C; long-term use heat resistance to 150 °C
- Higher chemical resistance (to hot, aggressive automotive fluids)
- Improved weatherability
- Superior overmolding adhesion to rigid nylon parts (nylon-nylon compatibility)
- Low-temperature performance to −40 °C

Hence, from above properties, the PA/acrylate rubber TPV is particularly suited to various automotive under-the-hood applications where high heat and fluid resistance is needed such as in automotive boots (CVJ, rack, and pinion), noise/vibration dampening components, dynamic seals, dust covers, underbody/e-coat plugs, grommets, clean air-intake ducts, transmission oil cooler hose, and so on. The nonautomotive applications take advantage of its better overmolding adhesion to nylons to make soft-touch, nylon parts such as power tool handles, overmolded clips, fasteners, and connectors.

Among the various other types of PA-TPVs investigated in the literature, PA/EPDM rubber-based TPV is interesting. As will be discussed in more detail, under impact-modified polyamides section (Sect. 19.7.1.1), binary blends of PA6 of EPDM rubbers can be compatibilized via reactive extrusion

techniques using maleic anhydride EPDM rubbers. At the high rubber loading ($\geq$60 %) needed to make a PA-matrix-based thermoplastic elastomer, it was found that phase inversion or formation of cocontinuous morphology occurs (Oderkerk 2002). However, by lightly cross-linking the EP rubber with a peroxide in a dynamic vulcanization process, even at 60 wt% EPDM rubber content in the PA blend, the rubber was kept as fine-domain dispersed phase. However, although the morphology stability was achieved, the TPV has not yet achieved desired rubber elastic recovery properties due perhaps to the inefficient cross-linking. Currently, the commercial PA6/acrylate rubber TPV (Zeotherm®) meets several of the high-performance TPV application targets and is likely to enjoy further growth in the automotive under-the-hood application segment.

19.6.5 Thermoplastic Vulcanizates (TPV) of PA6/Silicone Rubber Blends

Dynamically vulcanized silicone rubber-polyamide blends with a high volume fraction of the in situ cross-linked silicone rubber dispersions in a polyamide matrix was developed by Dow Corning as a thermoplastic silicone vulcanizate (Brewer et al. 2003). This technology is based on a selective, catalyzed cross-linking reaction (Eq. 19.4) between a hydride-functional polydimethyl siloxane and a vinyl-functional polydimethyl siloxane rubber during the extruder compounding with PA as shown below. In addition, the interface between the highly incompatible silicone rubber and PA in the blend was stabilized by the addition of a small amount of another silicone polymer, which had a PA-reactive, epoxy-functional group.

$$-Si\text{-}H \quad + \quad H_2C = CH\text{-}Si \quad \longrightarrow \quad SiCH_2CH_2Si$$

crosslinked silicone rubber

$$COOH \quad + \quad \overset{\triangle}{\underset{O}{}} \text{epoxy silicone} \quad \longrightarrow \quad COOCH_2CHOH$$

Polyamide end group   epoxy silicone   PA-silicone graft copolymer at the interface
Equation 19.4 Selective cross-linking reactions in PA6/Silicone rubber TPVs

Commercially, a polyamide (PA6)-based thermoplastic silicone vulcanizate is currently commercialized by Multibase, a Dow Corning company under the trade name TPSiV® 1180-50D. It has been evaluated for automotive brake hose

applications because of its resistance to hot brake-fluids (to 150 °C). In addition, this PA-silicone TPV is reported to have excellent long-term resistance to automotive transmission fluids and regular fuels. However, the high cost of silicones may limit the use of such PA-silicone rubber blends in the automotive market. The commercial status of PA-based thermoplastic silicone vulcanizates is still at an early stage.

19.7 Polyamide Blends

Commercial polyamides, frequently referred to as nylons, are crystalline engineering thermoplastics exhibiting high-performance characteristics such as high melting points, high mechanical strength, ductility, and excellent resistance to solvents, fatigue, and abrasion. Nylon is a generic term used for all synthetic polyamides in which the recurring amide groups (−CONH−) are part of the main polymer chain. These amide groups impart strong hydrogen bonding capability and crystallinity in the polyamides, PA, which account for their outstanding solvent resistance and mechanical properties.

Commercial polyamides are generally of two types: (a) those derived from diamines and dicarboxylic acids and (b) those derived from amino acids or lactams as monomers. The major characteristics of these two types of polyamides are similar since these are determined largely by the hydrogen bonding structure of the amide groups. However, within these two types, a wide variety of polyamides are known, varying in their melting points and moisture absorption characteristics, depending on their structure. Among these, PA-66, a polyamide made by polycondensation of hexamethylene diamine and adipic acid, and PA-6, a polyamide made by the ring-opening polymerization of caprolactam, are the two major nylon-engineering thermoplastics produced commercially. Because of their widespread use in fibers, plastics, and films, both PA-66 and PA-6 are produced on a large scale with an estimated total volume globally to be >7 Mt/year. About 60 % of the global PA6 and 66 consumption is in fiber applications, and the remaining 40 % production volume is used in the engineering plastics and film applications (Nexant 2009). PA66 is predominantly used in the injection molding market while the PA6 is used in both the injection molding and the extrusion markets such as cable jacketing and packaging films because of its wider window of melt processability.

There are a number of other specialty polyamides produced from a combination of other diamines and dicarboxylic acids and/or lactams of varying number of carbon atoms. PA-11 and PA-12 with 11 and 12 methylene units between each repeat amide group are relatively low-melting point (170 °C), but exhibit excellent ductility and moisture resistance. Among the more recent class of polyamides are the high-melting (ca. 300 °C) PA-4,6 and PA-6T copolymers with 6 or 66 or 6T monomer units, known as polyphthalamide (PPA) nylons.

Table 19.19 Effect of various polymer blend components on the properties of polyamides

Polymer blend component	Reasons for blending	Compatibilization method
Elastomers (functionalized EP rubber, acrylate rubber, etc.)	Improve PA's notched Izod impact	Graft-coupling reaction
	Shift the ductile brittle transition in PA to lower temperatures	
Ethylene copolymer ionomers	Improve toughness	Polar interaction
	Lower modulus/increase flexibility	
Polyolefins (LDPE, PP)	Lower cost	Graft-coupling reaction
	Improved dimensional stability with humidity	
ABS	High toughness and strength	Graft-coupling reaction
	Reduce moisture sensitivity (better strength and stiffness retention)	
Polyphenylene ether	Improve DTUL (at 1.8 MPa), unfilled	Graft-coupling reaction
	Improve strength and creep resistance	
	Reduce moisture sensitivity (better strength and stiffness retention)	
Silicone IPN	Improve lubricity and wear	None (IPN cured in situ)
	Reduce shrinkage and warp	
High T_g, amorphous PA or a barrier PA (PA6I/6T, MXD6)	Improve the oxygen barrier of PA at high humidity levels	None (miscibility)
Oxidizable polymers (such as PBD) with cobalt catalyst	Oxygen scavenging (active barrier), i.e., achieve near-zero O_2 permeation	grafting

Because of the high level of crystallinity and high melting points, all PAs generally exhibit high heat distortion temperature at low loads even in unfilled form, and when reinforced with glass fibers, definitely exhibit high heat distortion temperatures at high loads. Most of the commercial polyamides exhibit a common set of property advantages attributable to their crystalline nature and hydrogen bonding character. The main advantages offered by the crystalline polyamides (PA-6, PA-66) in blends with other polymers, are: excellent solvent resistance (e.g., gasoline, oils, paint solvents, etc.), heat resistance, and melt flow characteristics. On the other hand, the primary motivation to blend other thermoplastic polymers with polyamides is for reducing the moisture sensitivity of PA and improving its dimensional stability and toughness. Some of the more important polymer candidates commercially used for blending with polyamides and the major reasons for blending them are listed in Tables 19.19 and 19.20.

Because of their highly polar and hydrogen-bonded structure of the backbone, as a general rule, polyamides are immiscible with most of the commercially known polymer systems. In addition, the high degree of interfacial tension (Wu 1989) between polyamides and other classes of polymers leads to highly phase-separated

Table 19.20 Relative performance rating of polyamides compared to the other key thermoplastic polymers, commercially used for blending with the polyamides

	Polyamides (PA6, PA66, PPA)	Rubbers (EPR, SEBS, PE-ionomers)	PP	ABS	PPE
Melting/softening temperature	High	Low	Moderate	Moderate	Very high
Glass transition temperature	Low	Very low	Low	Moderate	High
Melt processability	Excellent	Excellent	Excellent	Excellent	Poor
Moisture absorption	High	None	None	Low	None
Moisture sensitivity (properties, dimensions)	High	None	None	None	None
Drop weight impact strength	High	Very high	Moderate	High	Moderate
Notched Izod impact	Low	Very high	Low	High	Low
Tensile strength	High (dry) Moderate (wet)	Low	Moderate	Moderate	High
Creep resistance	Good	Low	Low	Moderate	Excellent
Solvent resistance					
Hydrocarbons, oils	Excellent	Poor	Moderate	Moderate	Poor

Alcohols, glycols	Poor	Excellent	Excellent	Excellent	Excellent
Hydrolysis resistance (in acidic or basic aq. fluids)	Poor	Excellent	Excellent	Moderate	Excellent

blends with poor delamination resistance. Hence, simple blends of PA with other commercial polymers generally do not have any practical value. Significant progress has been made over the last several decades for developing techniques for compatibilizing polyamide blends, particularly utilizing the reactivity of polyamide end groups in forming ionic or covalently linked bonds with other polymers at the blend interface. Several commercial blends are based on such reactive compatibilization technology.

The graft copolymer compatibilization technique requires the other polymer component to be already "functionalized," i.e., modified with functionalities such as anhydride or epoxide groups, which are reactive toward the amine or carboxyl end groups of PA respectively. During the melt blending, the reaction between the functionalized polymers and polyamides leads to graft copolymer formation at the interface, which is essential for the compatibilization and stabilization of the blend against delamination. Such a graft copolymer compatibilization mechanism in reactive blending is illustrated for PA/rubber blends in Fig. 19.10 and Eq. 19.5.
Fig. 19.10 Schematic illustration of interfacial graft copolymers in polyamide/reactive rubber blends (Note: Balanced end group PA (1-amine/chain) forms a mono-graft copolymer. A "diamine" terminated PA forms di-graft copolymers. The latter can lead to entanglement at interface. Both graft copolymers stabilize and strengthen the blend interface)
Equation 19.5 Melt-phase reactions during the blending of polyamides with maleated EP or SEBS rubbers

19.7.1 Polyamide/Elastomer Blends

19.7.1.1 Impact-Modified Polyamides

Commercial polyamides such as PA-6 and PA-66 are generally regarded as tough and ductile materials since they exhibit high tensile elongation to break and high drop weight impact strengths. They become even tougher after equilibration with ambient humidity, due to the plasticization effect of the absorbed water. However, under conditions of stress concentration such as in the presence of sharp notches or cracks, polyamides exhibit brittle failure. This property, commonly evaluated as notched Izod or Charpy impact tests, indicates that unmodified polyamides exhibit relatively low energies for crack propagation. To overcome this deficiency, polyamides have been blended with several types of impact modifiers that are typically elastomeric or low-modulus-type olefinic polymers. However, the inherent immiscibility of polyamides with all other polymers and particularly with the olefinic rubbers necessitated the development of proper compatibilization techniques to reduce the interfacial tension and improve the dispensability of the rubber for effective impact modification.

The technology for impact modification of polyamides has evolved significantly over a period of many years through the improved methods of compatibilization and particularly through reactive blending techniques (Kray and Bellet 1968; Murch 1974; Epstein 1979; Mason and Tuller 1983). Commercially, several "impact modifier" polymers are available for blending with polyamides to achieve the desired level of impact modification in polyamides. These include (a) reactive elastomers such as maleic anhydride-grafted ("maleated") EPDM, EPR, or styrene-ethylene/butylene-styrene block copolymer rubbers, and (b) functional ethylene copolymers such as ethylene-ethyl acrylate, ethylene-acrylic acid, ethylene-ethylacrylate-maleic anhydride and ethylene-methacrylic acid ionomers. Table 19.21 lists some of these impact modifiers and their relative features, mechanisms, and efficiencies for PA-impact modification. The reactive toughening chemistry, the relative efficiency of tougheners, and the role of nylon end groups has been extensively studied with particular emphasis on PA6 (Akkapeddi 2001).

Compatibilization of an olefinic rubber dispersion in a polyamide melt blend is achievable through a direct chemical coupling reaction between the polymers at the interface such as through the addition reaction between the amine end groups of polyamide and the anhydride functionality of a maleated EP rubber (Schemes I and II). The graft copolymer formed in situ via this reaction during the melt blending process effectively compatibilizes the blend by reducing the interfacial tension and increasing the adhesion at the phase boundary. Due to the graft copolymer's capability to act as an interfacial agent, the dispersibility of the rubber in the polyamide matrix improves considerably, resulting in well-stabilized, small (≤ 1 μm), rubber particle dispersions and thereby substantially increasing the toughness.

The commercially successful "super-tough" nylon (e.g., Zytel® ST801, DuPont') is based on a reactive blending technology using PA-66 and a maleated (m-) EPDM rubber (Epstein 1979). The resulting PA-66/m-EPDM blend exhibits

Table 19.21 Some common reactive rubber and other types of impact modifiers used for melt-blending and impact modification of polyamides

Reactive rubber/ toughener	Functionality	Reactivity	Other features
Maleic anhydride grafted ("maleated"), ethylene-propylene rubber (m-EPR)	Anhydride (0.3–0.9 % MA)	High reactivity with the amine (NH$_2$) end group of PA	Amorphous rubber, low T$_g$ leads to high impact toughness down to −40 °C
Maleated, styrene-ethylene/butylene-styrene block copolymers (m-SEBS)	Anhydride (0.5–2 % MA)	High reactivity with the amine (NH$_2$) end group of PA	Amorphous rubber, low T$_g$ leads to high impact toughness down to −40 °C
Ethylene-ethyl acrylate-maleic anhydride (E-EA-MA) terpolymer	Anhydride (0.3–3 % MA)	High reactivity with the amine (NH$_2$) end group of PA	Moderate T$_g$ limits the low temp. toughness
Zinc neutralized, ethylene-methacrylic acid copolymer "ionomer"	Zinc carboxylate	Low reactivity with amine but good polar interaction of Zn with amide and amine groups (interfacial complexation)	T$_g$ not low enough, limits low temp. toughness; Good solvent resistance
Zinc neutralized, ethylene-butyl acrylate methacrylic acid terpolymer "ionomer"	Zinc carboxylate	Same as above	Lower T$_g$, higher impact modification efficiency
Ethylene-glycidyl methacrylate copolymer (E-GMA)	Epoxide (3–8 % GMA)	Moderate reactivity with carboxyl group of PA	T$_g$ and hardness limit the achievable toughness; Cross-linking tendency
Etlylene-ethyl acrylate-glycidyl methacrylate terpolymer (E-EA-GMA)	Epoxide (1–8 % GMA)	Moderate reactivity with carboxyl group of PA	Viscosity too high
Ethylene-ethylacrylate or butyl acrylate copolymers	Ester	No reactivity with amine end group of nylon	Do not improve impact but useful as flexibilizers

an excellent notched Izod impact strength ($\geq$900 J/m) that is remarkably insensitive to part thickness and notch radius. Impact modification of PA-6 has also been achieved by blending with such ethylene copolymers as ethylene-ethylacrylate, ethylene-acrylic acid and ethylene-methacrylic acid copolymer, particularly their zinc carboxylate salts commonly known as ionomers. It is believed that favorable, associative interactions involving some type of complexation between the amine end groups of polyamide and the zinc carboxylate groups of the ionomer are responsible for the high compatibility and toughening efficiency of ionomers. Some commercial impact-modified PA-6 blends (Capron® 8253 and 8350, 8351, BASF) are based on such "ethylene copolymer ionomer" tougheners (Mason and Tuller 1983).

There are several other routes to compatibilizing polyamide/elastomer blends for the purpose of impact modification such as through the use of anhydride-modified ABS rubbers (Baer 1988), anhydride-modified S-EB-S block (Gelles et al. 1988)

Fig. 19.11 Morphology of typical polyamide/impact modifier blends – TEM., Phosphotungstic acid stain, *top*: PA-6/ethylene copolymer/ionomer blend (21,000X); *bottom*: PA-6/maleated EPR blend (30,000X) (Akkapeddi 2001)
copolymers, carboxylated core-shell rubbers (MBS or acrylic type) (Liu 1988), and acylcaprolactam-grafted EP rubbers (Akkapeddi et al. 1989). Among these, the more common impact modifiers for PA6 are (a) ethylene-copolymer/terpolymer-based Zn ionomers (b) maleated EPR (c) maleated E-EB-S rubbers.

The outstanding impact toughness of the commercial impact-modified polyamides is attributed to the small particle size of rubber dispersion and their good degree of adhesion to the polyamide matrix. In all of these blends, the rubber particle size is >1,000-fold smaller than would be obtained with a typical unmodified EPR phase even under intensive mixing. Typical morphologies of compatibilized PA-elastomer blends is shown in Fig. 19.11.

The toughening mechanism is believed to involve the internal cavitation and debonding of the rubber, which induces localized shear yielding of the polyamide matrix as the primary energy dissipation processes (Borggreve and Gaymans 1989; Ramsteiner and Heckmann 1985; Borggreve et al. 1988) occurring during the impact deformation. Rubber particle size, distribution, and interparticle distance (Wu 1988) are some of the key parameters that have been correlated to the impact

Table 19.22 Properties of some commercial impact modified polyamides (PA/elastomer blends)

| Property | ASTM | Units | PA66/Elastomer | | PA6/ Elastomer | PPA/ elastomer |
| | | | Zytel 408 | Zytel ST801 | Ultramid 8351 | Amodel AT1001 |

at 0.45 MPa	D648	C	230	216	170	
Melting temperature		C	260	260	220	310
Chemical resistance			← Excellent →			

The key attributes of high impact PA/elastomer blends from above are:
• High notched impact strength with good stiffness and strength
• High heat resistance with high melt/softening temperatures
• High chemical resistance

toughness. The ductile-brittle transition of the polyamide blend is shifted to low temperature, both by choosing a low-T_g rubber, as well as controlling the rubber particle size (≤ 1 μm) and volume fraction. At an equivalent content of the compatibilized rubber, PA-6 tends to show higher impact strength at low temperatures than PA-66.

Commercial impact-modified polyamides typically contain 10–25 % of the reactive or compatible elastomer to maximize the toughening efficiency while retaining a high level of tensile strength and DTUL. Commercial impact-modified PA blends (Table 19.22) indeed offer a unique combination of high notched Izod impact and drop weight impact strengths, coupled with a good balance of modulus, tensile strength, heat, solvent, and abrasion resistance characteristics. These properties are suitable for many engineering and metal replacement applications. Because of their wide range of melt flow characteristics, impact-modified polyamides can be processed by injection molding, extrusion, and blow molding techniques. Currently, the impact-modified nylons enjoy the largest market share among all the commercial nylon blends. Some key applications for the elastomer-toughened polyamides (including glass fiber reinforced) are

(a) Automotive applications such as push-pull cables, clips, fasteners, seat belt restraints, gas cap covers, cooling system shrouds, emission control canisters, oil pans, steering column stone shields, fan blades, blow molded air ducts, resonators, etc.

(b) Nonautomotive applications such as elevator buckets, lawn and garden equipment components, power tool housings, outdoor/sports and recreational equipment such as helmets, hockey masks, golf ball covers, snow boards, ski bindings, snow mobiles, etc.

19.7.1.2 Flexible, Polyamide/Elastomer Blends

Some PA66- or PA6-based blends containing a combination of different types of impact modifiers and elastomers have been specifically designed to achieve low modulus, flexible polyamide blends for extrusion applications such as tubing, hoses, and other profiles. These formulations were developed to compete with other higher-cost PA-11 and PA-12 resins, which are extensively used in specialty extrusion applications. Generally, these flexible blends contain higher levels of these elastomers or impact-modifying polymers than the impact-modified polyamides. Often, the PA/rubber blends are used in combination with some plasticizers to achieve a flexible, low-modulus blend product that still retains much of the polyamide advantages, viz., heat and solvent resistance, particularly permeation resistance to such automotive fluids as gasoline, fluorocarbon-based refrigerants. These blends are often formulated to suit a specific customer or application requirement.

In some commercial, semirigid/flexible nylon formulations, an unextracted PA6 resin, which can contain up to 8 % caprolactam monomer, is used since the residual monomer can serve as a low-cost, built-in, internal plasticizer for PA6. Low-modulus, PA6/ethylene-copolymer blends (e.g., Ultramid® 8254) containing such low-cost nylon formulations are commercial (Table 19.23) as extrusion-grade nylons. They are used in automotive under-the-hood applications such as convoluted tubing, emission tubing, etc.

Another extrusion-grade polyamide blend is a reactively compatibilized PA6/polyolefin (PP or LDPE) alloy with some additional olefinic elastomer present for lowering the modulus (Jacquemet et al. 2000). Such low-modulus PA blends (Orgalloy® LT series, Arkema) have been qualified for use in automotive under-the-hood air-intake systems such as clean air tubes and ducts. Low density, high chemical resistance to oil and greases, heat-age resistance, fatigue, and vibration resistance have been the main criteria for the selection of this blend in automotive air-intake duct applications.

The demand for polyamide-based flexible polymer blends, particularly those "free from plasticizers," seems to be increasing. Flexible polyamide blends (Saltman and Varnell 1988; Saltman 1992) containing <50 % PA-6 or PA-66 and >50 % acrylic elastomers have been commercialized by DuPont (Zytel® FN) as a plasticizer-free, low-modulus composition with good low-temperature toughness, resistance to thermal-aging and solvents (particularly to fluorocarbon refrigerants) (Table 19.23). Although flexible polyamide blends contain <50 % polyamide,

Table 19.23 Properties of commercial, low-modulus, semi-flexible PA6/elastomer blends

Property	ISO	Units	PA66/ Elastomer Zytel FN718 Du Pont	PA6/ Elastomer Ultramid 8254 BASF	PA6/polyolefin/ elastomer Orgalloy LT4060 Arkema
Density	1183	kg/m^3	1,040	1,070	1,040
Flexural modulus	178	MPa (kpsi)	1,050 (152)	750 (107)	500 (72.5)
Tensile strength at break	527	MPa (kpsi)	40 (5.8)	34 (4.9)	30 (4.3)
Tensile strain at break	527	%	125	>100	380
Notched Izod at 23 °C	180/1A	kJ/m^2	NB	NB	NB
Notched Izod at −40 °C	180/1A	kJ/m^2	20	6	
HDT at 1.8 MPa	75	C	50	47	
HDT at 0.45 MPa	75	C	80	124	60
Melting temperature		C	263	220	220

The key attributes of semi-flexible PA6/elastomer blends are:
• Low modulus, low hardness
• High elongation at break and high notched impact resistance
• High melt/softening temperatures

the PA phase is continuous, and the major elastomeric phase (>50 %) is kept as dispersion. It is believed that the morphology was controlled by modifying the viscosity of the elastomer phase during the blending through controlled and selective grafting reactions. By using two mutually compatible, coreactive elastomers, a high viscosity ratio between the elastomer and polyamide phases can be maintained preventing phase inversion even when the total volume fraction of elastomer phase is higher than that of polyamide.

For example, by using an ethylene-butylacrylate-methacrylic acid ionomer (P_1) in combination with an ethylene-butylacrylate-glycidyl methacrylate (E-BA-GMA) terpolymer (P_2), a grafting or cross-linking reaction between the two elastomers via the carboxyl/epoxide addition reaction (Eq. 19.6) is expected to take place during the melt blending with the polyamide.
Equation 19.6 Graft-coupling reactions in polyamide blends with a mixture of epoxy and carboxy functional elastomer blends

The above interpolymer reaction would cause an increase in the melt viscosity of the elastomer phase relative to polyamide, thus preventing a phase inversion

(Saltman 1992; Ohme 1991). At the same time, the compatibility between the ionomer and polyamide as well as some degree of reactive compatibilization between E-BA-GMA and polyamide leads to the stabilization of the dispersions. The key advantage of this stabilized, high-rubber blend dispersion morphology of PA appears to translate into a significant improvement of impact strength and elongation at break, after heat-aging at 150 °C for 14 days. Because of the saturated and polar nature of the rubber and the continuous matrix of polyamide, the blend retains solvent resistance (including refrigerants) and long-term heat-aging resistance. Typical applications are automotive air conditioning hoses, ducts, and air-intake systems.

19.7.2 Polyamide/Polypropylene Blends

Polyamide and polypropylene are both crystalline polymers but are significantly different in their structure and polarity. Hence, they are immiscible. The primary motivations for blending polypropylene with polyamide appear to be based on some cost advantages and some improvements in dimensional stability in the presence of moisture. Although compatibilization of polyamide and polypropylene via grafting with a maleic anhydride-modified polypropylene was known for a long time (Ide and Hasegawa 1974), commercial interest in such polyamide/polypropylene blends has not developed until recently (Girard 1990; Moody 1992).

It is known that polypropylene can be modified by a free radical-catalyzed grafting reaction with maleic anhydride (maleation) in the melt phase under extruder processing conditions The process involves some chain degradation that must be controlled by the amount of peroxide used and the temperature and mixing conditions used. Typically, about 0.5 % maleic anhydride can be grafted to PP. Similarly, other unsaturated anhydrides can be used to modify PP. Melt blending of PA-6 (or 66) with such an anhydride-functionalized polypropylene causes a graft copolymer reaction between the polyamide and PP at the interface, which subsequently compatibilizes the blend.

Some commercial polyamide/polypropylene blends (Orgalloy®, Arkema; Dexlon®, D&S Int.) were developed a few years ago. Some of the PA/PP blend grades have now been discontinued. The advantages of polyamide/PP blends vs. other polyamide blends have not been clearly established commercially. Since both the polyamide and PP are crystalline polymers, one would expect the usual notch sensitivity and brittleness under impact loading conditions, despite the compatibilization. Accordingly, the earlier grades of PA6/PP blends showed about the same low notched Izod impact strengths as the individual components. However, the recent metallocene-based reactor-made impact-PP offered the potential for higher notched Izod impact strength in the polyamide/PP blends. Table 19.24 shows some PA6/PP blend properties. These current commercial-grade PA/PP blends seem to exhibit a desirable level of impact strength.

Polyamide/PP blends exhibit significantly slower rate of moisture absorption compared to the polyamides due to the presence of the moisture-resistant

Table 19.24 Typical properties of commercial PA6/PP blends vs. PP

Property	ISO	Units	PA6/PP Schulablend® PA/PP A. Schulman	Orgalloy® RS6000 Arkema	PP Profax® 6523 LyondellBasell
Density	1183	kg/m³	1,010	1,040	900

Charpy impact, at 23 °C	179	kJ/m²	11	20	6.3
Charpy impact at −30 °C	179	,, ,,	6	14	1.2
HDT at 0.45 MPa	75	C	119	140	84
Chemical resistance			high		moderate

The key attributes of PA/PP blends relative to PP are (a) higher impact and tensile, strength (b) higher heat resistance due to higher melt temperatures and (c) higher chemical resistance

polypropylene phase. The morphology of typical commercial PA/PP blends shows nylon as the continuous phase and polypropylene as the dispersed phase. The blend's improved moisture-dimensional stability over polyamide has led to some applications in automotive, lawn, and power tool markets, particularly using the 30 % glass-fiber reinforced form of the PA6/PP blend.

19.7.3 Polyamide/ABS Blends

As indicated in Table 19.19, the advantages of blending ABS with PA are primarily to improve the impact strength and moisture resistance. Since ABS is an amorphous polymer, its heat resistance is limited by the T_g of the SAN phase, thus the blend would be expected to exhibit lower heat resistance than polyamide. However, by keeping the polyamide as a continuous phase and ABS as the dispersion, blends with high softening point (due to the high melting point of polyamide), high HDT can be achieved. In addition, a polyamide matrix would be advantageous for maintaining solvent resistance in the blend.

Simple blends of ABS and PA are highly immiscible and hence are of little practical value. Compatibilization of ABS with polyamide was accomplished by several methods, most of which involve structural modification of ABS. In one approach, ABS was modified by copolymerization with acrylamide, during the preparation of ABS by the standard emulsion polymerization. The introduction of polar acrylamide units on the SAN backbone of ABS in sufficient concentration caused compatibilization with PA-6 when melt blended, presumably due to favorable hydrogen bonding interactions (Grant 1985).

In another approach, a small amount of maleic anhydride was copolymerized with styrene and acrylonitrile during the preparation of ABS by emulsion polymerization. The "anhydride modified" ABS was then melt blended with polyamide to form a compatibilized ABS/PA blend (Lavengood et al. 1986, 1987; Howe and Wolkowicz 1987). Obviously, a reaction between the anhydride functionality of ABS and the amine end group of polyamide leads to an in situ graft copolymer responsible for compatibilizing this blend. The erstwhile Monsanto's ABS/PA blends sold under the Triax® trade name (now marketed by Ineos ABS of USA) are believed to be based on this reactive compatibilization technology. The polybutadiene rubber content of the ABS used in this blend technology was about 40 %, significantly higher than the standard-grade ABS (10–20 % PBD). Because of the high rubber content and the compatibilization chemistry, the blends exhibited excellent notched Izod impact strengths of >850 J/m at room temperature.

Standard-grade ABS (20 % PBD) could also be directly modified by grafting an anhydride functionality via reactive extrusion with maleic anhydride in the presence of a trace amount of peroxide initiator (Akkapeddi et al. 1990). Such an "extruder-maleated ABS" upon subsequent melt blending with an amine terminated PA-6, gave a compatibilized ABS/PA-6 blend with significantly improved impact strength (Fig. 19.12) and a fine dispersion morphology (Fig. 19.13). Undoubtedly, the chemical coupling between the phases via the amine/anhydride reaction is responsible for the observed compatibilization. A small amount (5 wt%) of maleated EP rubber preblended with the maleated ABS led to substantial improvement in the notched Izod impact strength of the final ABS/PA-6 blend. It was postulated that migration of the maleated EPR to the vicinity of SAN/PA-6 boundary and subsequent graft copolymer reaction with nylon led to substantial toughening of the interphase region (Akkapeddi et al. 1993).

Currently, ABS/PA blends are commercially available primarily from Styrolution under the trade name of Terblend® N and Ineos ABS under the trade name of Triax®. In general, ABS/PA blends exhibit excellent notched Izod impact ($\geq$850 J/m or >65 KJ/m^2)) at room temperature (Table 19.9). These impact properties are equivalent to those of impact-modified polyamide (Table 19.22). However, the DTULs (0.45 MPa) of ABS/PA blends are relatively low compared to those of impact-modified nylons. The key difference being that in ABS/polyamide blends, due to the significant level of ABS, a substantial drop in the modulus occurs at the T_g of ABS (SAN), and hence the blend exhibits lower DTUL at 0.45 MPa than the impact-modified polyamide. The latter blends are polyamide-rich ($\geq$75 %) elastomer blends and hence maintain a higher level of heat resistance due to the higher level of the crystalline PA phase.

Commercial ABS/PA blends compete for the same type of applications as the impact-modified polyamides, primarily in areas where impact strength and chemical resistance are required. Presumably due to their lower heat resistance and slightly inferior low-temperature notched Izod impact strengths, their market growth has been somewhat slower than that of impact-modified polyamide. However, ABS/PA blends exhibit somewhat better dimensional stability and lower warpage characteristics than impact-modified polyamide, which led to some applications.

19.7.4 PPE/Polyamide Blends

Poly (2,6-dimethyl-1,4-phenylene ether) PPE is a high-T_g, amorphous polymer
(Hay 1976). It was originally developed by General Electric Co. which until
recently has been the sole producer of this polymer (Hay 1967). PPE is generally
of homopolymer type, although a copolymer with minor amounts of 2,3,6 trimethyl
phenol is also produced. Although PPE exhibits high mechanical strength, DTUL,
and ductility, it is generally difficult to process as a molding resin due to its high
softening temperature ($T \geq 300$ °C), high melt viscosity and tendency for thermo-
oxidative degradation at the high melt processing temperatures (330 °C). The
discovery that PPE can form highly compatible (miscible) blends with polystyrene
led to the development of PPE/HIPS blends (Cizek 1969) that have been the
commercially most successful to date. The properties of PPE/HIPS blends are
suitable for many applications. However, they lack adequate chemical resistance.
    In order to improve chemical resistance, blends of PPE with crystalline polymers
such as polyamides have been the subject of much investigation. Simple blends of

Compatibilized blend
(10,000X) (Akkapeddi 1993)
PPE and polyamides are highly incompatible, generally leading to brittle and readily delaminating products of low value. Hence, considerable attention was paid in recent years to develop the technology for effective compatibilization and impact modification of these blends. The exact compositions, the nature of grafting agents or compatibilizers used, and the impact modifiers used in commercial PPE/PA blends are kept proprietary, although many patents have been issued.

Research efforts have been focused largely on the methods of improving the compatibility between PPE and polyamides. Several compatibilizer additives were

claimed in the early patent literature (Ueno and Maruyama 1982), which included the use of liquid diene rubbers, epoxies, and unsaturated compounds containing acid, anhydride, amino, imino, or hydroxyl groups. Since polyamides have reactive end groups (amine and carboxyl), it is quite conceivable that the compatibilizing additives may react first with polyamide if all the components are blended together all at once, inhibiting any actual coupling reaction between PPE and polyamide. The latter is more desirable for the effective compatibilization of the blend. Hence, subsequent investigators focused first on the functionalization of PPE with a grafting agent such that suitable functional groups are attached to the PPE backbone (Jalbert and Grant 1987; Akkapeddi et al. 1988). Although functionalization of PPE is possible through solution-phase end-capping reaction with trimellitic anhydride acid chloride (Aycock and Ting 1986), one would prefer to use melt-phase grafting reactions via reactive extrusion techniques for reasons of economics.

Melt-phase reactions of PPE with unsaturated functional reagents such as maleic anhydride, fumaric acid, acrylic acid, and their derivatives, glycidyl methacrylate, and other unsaturated compounds were investigated. This functionalization reaction could be done in extruders, and the functionalized PPE could be isolated and characterized. The functionalization step introduced a reactive functional group on the PPE chain that upon subsequent melt blending with polyamide would react with the amine or carboxyl end groups of nylon forming a graft copolymer of PPE and polyamide at the interface. Since the block and graft copolymers are the best interfacial agents for a blend, the dispensability of PPE in polyamide improves due to decreased interfacial tension, and consequently, the tensile properties (strength, elongation) and toughness of the blend improve considerably. The structure of maleated PPE and the characterization of the graft copolymer was reported (Glans and Akkapeddi 1991; Akkapeddi 1993; Campbell et al. 1990).

Functionalization of PPE with maleic anhydride or fumaric acid could be done by melt blending (ca. 300 °C) in an extruder. This anhydride-functionalized PPE could either be isolated and reextruded with PA-6 or melt blended in a single-pass through downstream addition of the polyamide in a twin-screw extruder. In either case, prefunctionalization of PPE is a necessary and an important step in order to optimize the selective grafting reaction between PPE and polyamide and prevent any premature reaction between polyamide and the maleic anhydride or fumaric acid. The graft-coupling reaction itself is an addition reaction between the amine end group of polyamide and the anhydride group of the functionalized PPE. It was also found that the compatibilization efficiency increased when a PA6 polymer rich in the amine end groups ("amine terminated polyamide") was used (Akkapeddi 1992, 1993). The tensile elongation to break increased considerably, as did also the melt viscosity, the latter indicative of increased polymer-polymer grafting reaction (Fig. 19.14). Typical morphology illustrations obtained by transmission electron microscopy of uncompatibilized vs. reactively compatibilized PPE/PA-6 blend indicated a substantially finer dispersion of PPE in the PA-6 matrix in the compatibilized blend as shown in Fig. 19.15.

Fig. 19.14 Effect of blending amine terminated PA-6 on the tensile elongation and melt flow behavior of reactively compatibilized PPE/PA-6/m-EPR (50/40/10) blends (Akkapeddi et al. 1993)
The heat distortion temperature of the PPE/PA blend at high load (1.8 MPa) increases with the amount of PPE in the blend (Fig. 19.16) (Akkapeddi, unpublished results). However, because of the crystallinity of the polyamide matrix, the heat distortion temperature at low load (0.4 MPa) is relatively less sensitive to the PPE content and is largely determined by the polyamide. This is one significant difference between blends of crystalline/amorphous polymers (PA-6/PPE) vs. blends of amorphous/amorphous (PS/PPE) polymers. In the PPE/polyamide blends, the crystalline PA phase is invariably the continuous phase, because of the large melt viscosity difference between PPE and PA.

Although the binary blends of PPE and polyamides exhibit good ductility (tensile elongation and drop weight impact) after the reactive compatibilization, the notched Izod impact strengths are still relatively low. This is to be expected since the individual resin components, viz., PA-6 (or PA-66) and PPE, exhibit low notched Izod impact strengths (<70 J/m). Hence, commercial PPE/PA blends invariably include an impact modifier component, the exact composition and content of which is kept varied from grade to grade. Commercial impact-modified PPE/PA blends exhibit notched Izod impact strengths ranging from 175 to 700 J/m at room temperature. They also differ in their ductile-brittle transitions and low-temperature impact strength behavior.

The type of nylon used (PA-6 or PA-66 or copolymer type), its end group concentrations and molecular weight, and more importantly, the nature of the rubber modifier used (compatible or reactive type), its content, and manner in which it is added determine the efficiency of notched Izod impact strength improvement and the low-temperature ductility. Hydrogenated styrene-butadiene-styrene block copolymer (S-EB-S) rubbers have been used as impact modifiers in PPE/PA-66 blends (Grant et al. 1988) since they are expected to be compatible and readily dispersible in the PPE phase. Preblending a functionalized rubber (such as a maleic anhydride-modified EP rubber) into the functionalized PPE, followed by melt blending with the polyamide, was found to give a better impact strength

Fig. 19.15 Morphology of PPE/PA-6 (60/40) blends (TEM, phosphotungstic acid stain); *Top*: Uncompatibilized blend (10,000X), *Bottom*: Compatibilized blend (20,000X)
improvement in PPE/PA-6 blends than when the rubber was blended simultaneously with the nylon (Akkapeddi et al. 1988, 1992). An impact-modified PPE/PA blend developed by Hüls in Europe contained polyoctenylene as impact modifier (Doescher et al. 1988).

Commercial PPE/polyamide blends typically contain 40–60 % polyamide and 0–10 % of the impact modifier, each grade being formulated for specific types of applications. Typical properties of some commercial unfilled PPE/PA blends are illustrated in Table 19.25. In general, PPE/polyamide blends offer a unique combination of high heat resistance (DTUL and continuous use temperatures), high impact strength, hygrothermal dimensional stability, and ease of processability. In addition, the blends exhibit better chemical resistance compared to other high-heat, amorphous engineering resins such as PPE/HIPS blend and polycarbonate (Table 19.26). Most of the commercial PPE/PA blends are based either on PA-66, that gives a somewhat higher heat resistance to the blend or PA-6, that gives

somewhat higher impact strength at any given blend ratio. Although other specialty polyamides such as PA-12 and PA-4,6 have also been investigated in PPE blends, they have not gained any commercial interest due to their higher cost. The cost of PPE/PA6 or PPE/PA66 blends can be further lowered by the addition of some polystyrene or HIPS into the PPE phase, taking advantage of their mutual miscibility. However, this results in some sacrifice in DTUL, but gives improved melt flow useful for thin-wall parts.

19.7.4.1 Applications of PPE-Polyamide Blends

Because of their unique combination of chemical resistance, stiffness, and impact resistance properties, PPE/PA blends have found many automotive exterior applications such as in body panels and trim. Typically, PPE/PA blends are used in such exterior automotive parts as the fenders, quarter panels, tail gates, hatchbacks, grilles, tank flaps, wheel covers, and mirror housings. Because of their high heat and chemical resistance, parts made from of PPE/PA blends can be painted "online," attached to the metal frame in the existing automotive paint oven temperatures of ca. 180–200 °C. The parts retain good toughness required in these applications. Conductive grades of PPE/PA blends are used for cost-effective production of large automotive body panels, which can be electrostatically painted online without a primer.

Glass fiber-reinforced PPE/PA blends designed to meet varying demands of stiffness, impact, and heat resistance properties are used in automotive under-the-hood applications such as engine control modules, cooling system parts, power distribution boxes, connectors, lamp sockets, etc. Other applications include lawn and garden tractor hoods, pumps, water meter housings, etc.

19.7.5 Polyamide/Polycarbonate Blends

Polycarbonate has been blended with commercial polyamides (PA-66 and PA-6), in order to improve its poor solvent resistance while maintaining a reasonable level of heat resistance and toughness. However, simple blends of polycarbonate and polyamides were highly incompatible and hence not useful. Several different additives such as phenoxy resins, polyester amide elastomers in combination with maleated polyolefins, polyetheramide block copolymers, and polyamide-polyacrylate block copolymers have been used as potential compatibilizers and impact modifiers.

However, even such compatibilized PA/PC blends could not be successfully commercialized, perhaps due to a lack of a cost-performance advantage over other PA blends.

A developmental grade of PA/PC blend (formerly known as Dexcarb®, now discontinued) was claimed to have a high notched Izod impact strength comparable to that of impact-modified polyamides and polycarbonate. From available patent literature, such blends utilized a polyether-amide and a maleated polypropylene or EPR as the compatibilizing/impact-modifying additives (Perron 1988). Polyamide/polycarbonate blends had only a very limited evaluation in exterior automotive applications such as bumper beams. Their dimensional stability and resistance to paint solvents and automotive fluids may have been some of the reasons for their consideration. However, PA/PC blends were commercially discontinued, due to the competition from PA66/PPE blends, which offered better heat resistance and toughness at a comparable cost.

19.7.6 Polyamide/Silicone Blends

A blend of a thermoplastic polyamide (PA-6 or PA-66) and 5–25 wt% of a cross-linkable silicone, which forms a semi-interpenetrating network (semi-IPN) upon curing, was offered commercially for a brief period in the 1980s under the trade name of Rimplast® (Petrarch, div. of Hüls) (Arkles 1985). These blends were produced by extruding the polyamide with a vinyl-terminated, polydimethyl-siloxane and silicone hydride-terminated dimethyl siloxane in the presence of a platinum catalyst. The siloxanes react with one another forming cured silicone thermoset in the thermoplastic matrix phase of the polyamide. At the low concentrations of 5–10 % silicone, the blend was reported to retain much of its thermoplasticity and processability. This silicone semi-IPN reportedly improved the lubricity, wear, and biocompatibility of polyamide as well as reducing the shrinkage and warpage, although with some sacrifice in strength and elongation.

More recently, a dynamically vulcanized silicone rubber-nylon blend with a high concentration of the cross-linked silicone dispersion in a nylon matrix was developed by Dow Corning as a thermoplastic silicone vulcanizate (Brewer et al. 2003). This technology is also based on the selective, catalyzed cross-linking reaction between a hydride-functional polydimethyl siloxane and a vinyl-functional polydimethyl siloxane rubber during the extruder compounding with nylon as discussed before under the polyamide-silicone rubber thermoplastic vulcanizate section. The interface between the silicone rubber and nylon in the blend was compatbilized by the addition of a small amount of another silicone polymer, which had a nylon-reactive, epoxy-functional group.

Commercially, polyamide (PA6)-based thermoplastic silicone vulcanizates are commercialized by Multibase, a Dow Corning company under the trade name TPSiV® 1180-50D. It was evaluated for automotive brake hose application because of its hot brake fluid resistance (to 150 °C). The high cost of silicones may limit the use of such nylon blends only to specialty niche applications.

19.7.7 Polyamide/Polyamide Blends

Blends of PA-6,6 with some aliphatic-aromatic polyamides of higher T_g such as poly (hexamethylene isophthalamide) (PA-6,I) have been evaluated as fibers, in order to achieve improved modulus and heat resistance in PA-66 tire yarn and consequently reduce the tire flat-spotting tendency (Zimmerman et al. 1973). Although the rate of amide interchange in these polyamide/polyamide blends was found to be quite slow (<3 % interchange based on the aromatic polyamide), the formation of some block copolymer was not ruled out. Nevertheless, the observed improvements in the modulus and T_g were primarily attributable to some degree of compatibility or miscibility between the components of the blend. There have been several other research investigations on the compatibility and phase behavior of polyamide/polyamide blends (e.g., Takyanagi et al. 1980; Ellis 1990; Hirakawa et al. 1985). However, there are no commercially significant polyamide/polyamide blends developed to-date for the injection molding market, although recently, there has been some commercial interest in the packaging films market segment particularly for the blends of PA-6 with aliphatic-aromatic polyamides exhibiting sufficiently good oxygen barrier properties suitable for food packaging applications.

Certain types of aliphatic-aromatic random copolyamides such as those derived from the polymerization of (a) hexamethylene diamine and isophthalic/terephthalic acids (6I/6T) or (b) m-xylylenediamine, isophthalic/terephthalic acids, and caprolactam (MXDI/T,6) exhibit high glass transition temperature, amorphous character, and a high barrier to oxygen permeation (Akkapeddi and Gervasi 1989). The oxygen barrier property of these amorphous polyamides is retained even under high humidities because of their high T_g's. In contrast, semicrystalline polyamides such as PA-6 and PA-66 characteristically exhibit low T_g (ca. 50 °C) that becomes even lower after moisture absorption. As a consequence, the permeability of oxygen in PA-6 and PA-66 increases with humidity. There are several commercial semiaromatic, amorphous polyamides that exhibit good oxygen barrier properties, suitable for packaging applications, e.g., Selar® PA (duPont), Novamid® (Mitsubishi Chemical), Grivory® HB (EMS).

To improve the oxygen barrier properties of PA-6 (and PA-66), high T_g, barrier-type amorphous polyamides such as PA-6I/6T (Selar® PA) have been blended (Krizan et al. 1989; Blatz 1989). These blends exhibit improved barrier to oxygen permeation particularly at high relative humidity (Fig. 19.17), presumably due to a good degree of miscibility. Commercially, PA-6 blends with various amorphous PA grades (such as Selar® PA or Grivory® G21) are used by various packaging film fabricators who melt-blend and fabricate these blend films directly for various food packaging applications. Similar blends of poly(m-xylylene adipamide) (MXD6) with PA-6 have also been used as barrier films. PA-MXD6, produced by Mitsuibishi Gas Chemical Co, is a high oxygen barrier resin particularly useful in multilayer coextrusions (Harada 1988) and blends. In the blends of MXD6 with aliphatic polyamides, interchange reactions may play a role during melt-mixing, particularly at long residence time (Takeda and Paul 1992). However, under the

blend with nanoscale oxygen
scavenger dispersions
(Akkapeddi et al. 2004)

normal commercial melt compounding and extrusion throughput rates, interchange
reactions are minimal and good miscible blend products can be obtained.

More recently, polyamide blend compositions exhibiting high oxygen scaveng-
ing barrier properties have been developed for particular use in multilayer barrier
PET bottles (Akkapeddi et al. 2004). According to the published patents, these
blend compositions contain PA6 or PA6-nanocomposite (ca. 2 % nanoclay)
blended with an amorphous nylon such as PA6I/6T, along with small amounts of
functionalized polybutadiene (PBD) and cobalt catalyst serving as the oxygen
scavengers. The resulting polyamide blend exhibited high oxygen scavenging

barrier while retaining a high degree of clarity because of the morphology with extremely fine, "nanoscale" dispersions of the clay platelets and the oxygen scavenger particles (Fig. 19.18). The nanoclay platelets act as the passive barrier, and the nanoscale dispersion of the PBD provides the oxygen scavenging ("active" barrier) properties to the PA blend. Such barrier PA blends have been commercialized as barrier resins (Aegis® OX, Honeywell), for use in coinjection stretch blow molded multilayer PET bottles with enhanced shelf-life for packaging juices, beer, and other oxygen-sensitive food and beverages.

19.8 Polycarbonate Blends

Commercial polycarbonate is an amorphous engineering thermoplastic characterized by a high glass transition temperature (ca. 150 °C) and an excellent balance of properties such as high toughness, clarity, heat resistance, dimensional stability, and good electrical and ignition-resistance characteristics. Because of this outstanding combination of properties, polycarbonate has become one of the most successful of engineering thermoplastics.

Standard polycarbonate, (PC), is made from bisphenol A and phosgene via an interfacial polymerization process. The polymer backbone has an aromatic polycarbonate structure with a recurring carbonate moiety, which uniquely accounts for the outstanding toughness of the polycarbonate, and the rigid aromatic unit contributes to its high glass transition temperature. Although a large number of applications of polycarbonate have been based on its unique combination of high impact strength, heat resistance, and clarity, there are still a few property deficiencies in the neat polymer, which can be overcome by blending with other polymers or additives. Some deficiencies of polycarbonate are

- High notch sensitivity and part thickness sensitivity in impact strength (Fig. 19.19).
- Lack of an adequate low-temperature notched Izod impact strength.
- Lack of an adequate solvent resistance and stress crack resistance.
- Limited long-term hydrolytic stability at elevated temperatures.
- High melt viscosity compared to crystalline engineering polymers such as PA-6, PBT.

Hence, the development of polycarbonate blends was primarily market driven, with a motivation to extend the applications of polycarbonate into areas where improved chemical resistance and processability are required while still retaining high impact strength. The rationale for the development of commercial PC blends is summarized in Table 19.27. Comparison of the properties of various polycarbonate blends is shown in more detail in Table 19.28. In the development of all these commercial polycarbonate blends, one common goal was to maintain a very high level of impact strength while improving the notch sensitivity of impact, chemical, or solvent resistance properties and the cost balance.

Fig. 19.19 Effect of sample thickness on the notched impact strength of unmodified (I) vs. impact Modified (II) Polycarbonate (Adapted from Freitag et al. 1985)
Table 19.27 Rationale for the development of various commercial polycarbonate blends

Polycarbonate blend	Rationale for blending
Impact modified PC (blends with rubber)	Improve notch sensitivity
	Improve low temperature toughness
	Improve thermal-aging resistance
PC/ABS blend	Improve low temperature toughness
	Improve processability
	Lower cost
PC/ASA blends	Improve the weatherability
PBT/PC, PET/PC	Improve solvent resistance
	Improve the processability
PEI/PC	Lower the cost of PEI
	Improve the processability of PEI

19.8.1 Impact-Modified Polycarbonates

Although polycarbonate is exceptional among engineering resins in exhibiting an outstanding level of toughness, its ductile-brittle transition depends on the temperature, notch sharpness, sample thickness, and thermal aging effects. A sharp ductile-brittle transition (Carhart 1985) for polycarbonate occurs at 0–10 °C, hence its notched Izod impact strength at low temperatures is low, e.g., ≤100 J/m at −30 °C. Another important deficiency of polycarbonate is the sensitivity of its notched impact strength to part thickness and notch radius. The notched Izod impact strength of polycarbonate is reduced from 900 to about 100 J/m when the thickness is increased from 3.2 to 6.4 mm (Jones 1985) These effects are due to the changes in the deformation behavior at the crack tip from shear yielding (plane stress) to crazing and unstable crack propagation. By blending small amounts of elastomeric or low-modulus polymers, the impact

strength of polycarbonate could be readily improved, largely by modifying the crack tip plastic deformation.

Polycarbonate modified with small amounts of low-density polyethylene (ca. 5 %) was found to exhibit a substantially improved notched Izod (>500 J/m) in thick sections (6.4 mm) (Dobkowski 1988; Dobrescu and Cobzaru 1978; Gardlund 1984). Some early grades of commercial impact-modified grades of PC were based on this technology (Freitag et al. 1985). However, it is now believed that the current commercial, nontransparent, impact-modified polycarbonates are made by blending small amounts of a low-T$_g$, elastomeric impact modifier such as the core-shell rubbers, viz., PMMA-g-SBR (MBS), PMMA-g-n-butylacrylate (acrylic core-shell) types, all composed of ≤0.1 μm cross-linked rubbery core particles. These modifiers improve both the thick-section (6.4 mm) and low-temperature notched Izod impact properties of polycarbonate (Witman 1981; Neuray and Ott 1981; Bussink et al. 1977) as illustrated in Figs. 19.19 and 19.20. Impact-modified polycarbonates also show better retention of impact strength with heat-aging. However, such impact-modified polycarbonate grades are opaque.

In order to improve the low-temperature notched impact strength of polycarbonate while still maintaining the transparency, new polycarbonate-poly(dimethyl siloxane) block copolymers were developed (Maruvada et al. 2005). These PC-siloxane block copolymers were transparent as long as the siloxane block length was kept short (<10 units), so that fine siloxane rubber domains (10–40 nm) were
Fig. 19.20 Low temperature Impact Strength of unmodified (I) vs. Impact Modified (II) Polycarbonate (Adapted from Freitag et al. 1985)

achieved. Such a PC-siloxane copolymer exhibited high notched Izod impact retention (>600 J/m) down to −50 °C due to the toughening effect of the small siloxane rubber particles. Transparent blends of such a PC-siloxane copolymer with a standard PC also showed improvement in notched impact as well as some hydrolytic/thermal aging resistance. Some key properties of such commercial impact-modified polycarbonates are shown in Table 19.29.

Commercial impact-modified (elastomer-blended) polycarbonates are used for protective headgear, sporting goods, and bobbins for textile industry. Flame-retarded, impact PC blends are used in electronic and electrical equipment housings requiring high toughness. Impact-modified PC has to compete with the lower-cost ABS/PC blends as well as the more chemical-resistant, high-impact, PBT/PC, PET/PC blends, which will be discussed in the following sections.

19.8.2 ABS/Polycarbonate Blends

Since their introduction in 1967, ABS/polycarbonate blends (Grabowski 1964) have enjoyed a dramatic growth in market volume. They are by far the largest-volume polycarbonate blends used with the current global consumption of almost 1 Mt/year (Reseau-plasturgie 2012). The growth rate of ABS/PC blends is estimated to be about 10 %, somewhat faster than that of polycarbonate or ABS. The major reason for the success of ABS/PC blends is their overall better cost/performance balance relative to PC and impact-modified PC. Particularly noteworthy is their unique, synergistic improvement in the low-temperature notched impact strength (Morbitzer et al. 1983), which is better than the individual

components (Fig. 19.21). The partial miscibility between the SAN and the polycarbonate phases, the intrinsic ductility of polycarbonate matrix, and the presence of small particle size polybutadiene dispersions are the key factors contributing to the overall low-temperature toughness of the blend.

A discussion of the ABS/PC blends comparing with other ABS blends may be found under the ABS blends section (Sect. 19.3.2). The properties of the ABS/PC blends, primarily the DTUL and impact strength, are determined by the ratio of ABS to polycarbonate. The morphology is also dictated by the blend ratio. In blends containing ≥50 % polycarbonate, the continuous phase is formed by the polycarbonate with ABS as the dispersed phase. The rubber particles are primarily located in the SAN phase. Typical properties of some of the commercial ABS/PC blends have already been discussed under the ABS blends section (Sect. 19.3.2) and illustrated in Tables 19.8, 19.9, and 19.28. The blends containing higher levels of polycarbonate exhibit better low-temperature impact strengths.

ABS/PC blends are used in a variety of automotive components such as instrument panels, flaps for glove compartments, dashboards, cladding for steering wheel columns, ventilation ports, spoilers, wheel covers, and protective side trims. Flame-retardant ABS/PC blends are used in office equipment and business machine housings. Chlorine or bromine-free flame-retardant ABS/PC compositions contain organophosphate/PTFE powder dispersions (Freitag et al. 1991). ABS/PC blends have been used in automotive exterior body panels first in the GM's former Saturn

Fig. 19.21 Ductile-brittle transition in ABS/PC blend vs. ABS and PC (Adapted from Freitag et al. 1985)
models. The assembly line for this car was equipped to handle the new waterborne paint systems, which cure at lower temperatures than the normal "E-coat" paint ovens. Due to their excellent low-temperature toughness, dimensional stability, and cost advantages, ABS/PC blends are replacing some of the PPE/HIPS applications and are also competing against some polyamide applications. However, they cannot compete with the impact-modified polyamides and the PPE/PA blends in all those applications, which require higher heat and chemical resistance such as automotive fuel emission canisters, fasteners, connectors, and exterior parts like fenders, etc.

19.8.3 Thermoplastic Polyester/PC Blends (PBT/PC, PET/PC, PCTG/PC)

The second most important class of commercial polycarbonate blends is derived by blending with commercial thermoplastic polyesters such as polybutylene terephthalate (PBT) and polyethylene terephthalate (PET). Both PBT and PET are crystallizable polymers and hence offer the expected chemical resistance advantages of the crystalline polymers in blends with polycarbonate. Among the thermoplastic polyester/polycarbonate blends, the PBT/PC blend has the major commercial volume, followed by the PET/PC blend. A copolymer of 1,4-cyclohexanedimethanol, ethylene glycol, and terephthalic acid (PCTG) forms a miscible blend with polycarbonate. PCTG/PC blend was earlier offered by Eastman (Ektar®) for specialty applications, but it is no longer commercial.

A commercial PBT/polycarbonate blend (Xenoy®) was first introduced in 1980 by General Electric when it initially enjoyed a fast growth in automotive applications, particularly for rigid bumper fascias. The blend was developed to meet the low-temperature impact strength, dimensional stability, and paintability requirements of the rigid bumper fascias (Bertolucci and Delaney 1983), which accounted

Table 19.30 Typical properties of some commercial PBT/PC and PET/PC blends

Property	ASTM	Units	PBT/PC Xenoy 1102 Sabic	PBT/PC Makroblend KU2-7912 Bayer	PET/PC Makroblend DP7645 Bayer	PET/PC Xenoy X2202 Sabic
Density	D792	kg/m^3	1,200	1,200	1,200

for the bulk of the market for this blend during the 1980s and 1990s. With the advent of low-cost TPOs successfully dominating the bumper cover market today, the growth for PBT-PC blends has been somewhat slowed down. The development of commercial PET/PC blends also followed shortly after the initial success of PBT/PC blends. Currently, some commercial blends of both PBT/PC and PET/PC types are available, and their properties are shown in Table 19.30.

All the commercial PBT/PC and PET/PC blends also contain typically 10–20 wt% of an additional elastomeric impact modifier. The exact nature and the content of the impact modifier is kept proprietary and often forms the basis for a particular blend patent. Typically, core-shell rubbers such as poly(methyl methacrylate)-grafted butadiene-styrene rubber (MBS) or an all acrylic core-shell rubber such as poly (MMA-g-n-BuA) are used (Nakamura et al. 1975; Chung et al. 1985). ABS (with high polybutadiene content ≥50 %) or ASA rubber (≥50 % acrylate rubber) have also been used. The presence of such a rubber component is definitely needed to obtain high notched Izod impact strengths (≥500 J/m) in these blends.

The binary blends of polycarbonate with poly(butylene terephthalate) (PBT/PC) or poly(ethylene terephthalate) (PET/PC) are now known to be essentially phase-separated blend systems exhibiting two glass transition temperatures in each case, one for the polycarbonate-rich phase and another for the polyester-rich phase (Murff et al. 1984; Huang and Wang 1986; Wahrmund et al. 1978). The evaluation of the amorphous phase miscibility in these blends was often complicated by the potential of a transesterification reaction between the two polymers during the melt blending, which may in principle lead to a block copolymer and eventually to

a random copolymer with a single-phase, single glass transition temperature behavior (Deveaux et al. 1982; Hobbs et al. 1987; Porter and Wang 1992). Sometimes, different conclusions have appeared in the literature regarding the phase behavior of PET/PC and PBT/PC blends, because different methods were used to prepare the blends.

19.8.3.1 Poly(butylene terephthalate)/Polycarbonate Blends (PBT/PC)

Early investigations of the melt blends of PBT and PC showed two glass transition temperatures indicative of two amorphous phases (Murff et al. 1984). However, the T_g's did not correspond to those of pure components, and in addition, there was a slight depression in the melting point of PBT. A melt-phase reaction was hypothesized to take place. Subsequent studies showed that the melt-phase transesterification reaction between PBT and PC can indeed take place, at these high temperatures (T $\geq$ 260 °C), as followed by NMR spectral changes as a function of melt residence time (Deveaux et al. 1982). The presence of titanium catalyst normally present in PBT also catalyzed this reaction.

Although NMR and IR techniques were used in characterizing these interchange reactions, these techniques are often insufficient to detect small changes in the structure that occurs when only one or few interchanges per chain take place. For example, NMR can detect only gross structural changes that take place after long reaction times ($\geq$30 min at 250 °C). Blends made by solution technique or by normal extruder melt blending process under short residence time exhibited a two-phase structure (Hanrahan et al. 1985; Dekkers et al. 1990). However, the T_g of the PC phase in the melt-blended product was usually lower (by 20 °C) than the PC phase of solution-blended product or neat PC. This was attributed to the effect of a small, although not readily detectable, level of interchange reaction in the melt-blended product.

The transesterification reactions in PBT/PC melt blends could be suppressed by using organophosphites and phosphonates, which probably function by deactivating the titanium or antimony type polymerization catalyst residues present in PBT (Golovoy et al. 1989). Even in the presence of phosphite stabilizers, PBT/PC blends showed dual-phase behavior. However, a partial miscibility was evident since the T_g of PC phase was still reduced from the normal 150 °C to about 140 °C. This partial miscibility between PBT and PC even in the absence of an exchange reaction is responsible for the good compatibility and interfacial strength of the blend.

19.8.3.2 Poly(ethylene terephthalate)/Polycarbonate Blend (PET/PC)

Early work on the PET/PC blends indicated that in blends containing >70 % PET, PC was miscible, and in blends with <70 % PET, the components separated into two phases. Subsequent investigations concluded that the blend was essentially immiscible over the entire composition range. The transesterification reaction between PET and PC in the melt phase was found to be slower than in the case of PBT at 270 °C. However, when the reaction does occur, the newly formed ethylene carbonate linkages, $-CH_2-CH_2O-CO-O-$ in the polymer chain appear to degrade more rapidly than the butylene carbonate units generated with PBT. The divergent

conclusions in the literature on the phase behavior of PET/PC blend are undoubtedly caused by the differing degrees of transesterification reaction occurring under the conditions of melt mixing (temperature, time) and the amount of catalyst residues (Goddard et al. 1986).

Under the normal extrusion blending conditions, PET/PC blend forms a two-phase blend morphology. The melt residence times are short enough such that the interchange reaction does not occur, and the PC can be quantitatively extracted out with methylene chloride. From the observed glass transitions of the PET-rich phase and PC-rich phase, measured by DSC or DMA, the blend can be classified as partially miscible with an estimated interaction parameter of slightly positive ($\chi_{12} \simeq 0.04$). From the measured T_g's, it appears that more PET dissolves in PC phase than PC does in the PET-rich phase (Kim and Burns 1990). Nevertheless, the existence of a partial miscibility, even in the absence of transesterification, accounts for the self-compatibilization effect in the blend. Mutual interpenetration of the components at the phase boundary accounts for the high interfacial strength.

The binary blends of PET/PC and PBT/PC exhibit good ductility and tensile strengths, but the notched Izod impact strengths are still low at all the blend compositions containing $\leq$80 % PC. This is a significant difference from ABS/PC blends, in which the grafted polybutadiene rubber particles of ABS phase contribute to the toughness at all the ABS/PC blend ratios. Hence, commercial PBT/PC and PET/PC blends, by necessity, include a proper level of an effective impact modifier, usually a core-shell rubber of small particle size, such as MBS, ABS, etc. It has been shown that during the melt blending, these rubber particles preferentially migrate to the PC phase due to the known compatibility of the PMMA or SAN component of these rubbers (shell structure) with the polycarbonate (Dekkers et al. 1990). Hence, the blend morphology indicates that the rubber particles are predominantly located in the PC phase (Fig. 19.22).

Commercial PBT/PC and PET/PC blends contain about 15–20 % of such core-shell rubber impact modifiers for maximum toughness, i.e., notched Izod impact strengths of typically $\geq$700 J/m, which is maintained even at low temperature (Table 19.30). The ratio of PBT/PC or PET/PC is usually kept between 50/50 and 40/60 to optimize the ductility in the blend, while still maintaining a continuous or cocontinuous phase of the polyester. A continuous phase of PBT or PET with PC as dispersed phase would be preferred for solvent resistance.

The crystallization of PBT and PET in these blends is somewhat suppressed by the partial miscibility of the PC. However, since PBT crystallizes intrinsically faster than PET, blends of PBT and polycarbonate after injection molding show a crystalline PBT phase in their morphology. Injection-molded PET/PC blends, on the other hand, generally lead to an essentially amorphous PET phase. Short-term annealing at elevated temperatures (120–150 °C) causes this PET phase to crystallize and leads to some loss in ductility especially when the polycarbonate content in the blend is $\leq$30 % (Akkapeddi et al., unpublished results).

Long-term thermal aging of PBT/PC blends is known to lead to severe embrittlement (Bertillson et al. 1988). Phase segregation, secondary crystallization, and changes in the amorphous phase free volume with aging are some of the key factors

Fig. 19.22 Morphology of PET/PC/MBS core-shell elastomer (40/40/20) blends – TEM; RuO4 stain; 15,000X (Akkapeddi et al. 1993)
attributable to the embrittlement phenomenon. Embrittlement of PET/PC blends upon heat-aging is even more likely to occur due to the more brittle nature of crystalline PET phase. Recent work has focused on the use of reactive rubber tougheners to improve the embrittlement resistance of PET/PC blends upon heat-aging (Akkapeddi and Mason 1991; Akkapeddi et al. 1993).

The excellent low-temperature toughness and solvent resistance of PBT/PC and PET/PC blends have found good application in automotive exterior parts such as bumper beams and fascias (mainly PBT/PC), air dams, rocker panels, wheel covers, and mirror housings. Nonautomotive applications included instrument housings, lawn-mower chutes, snow blower components, etc. With the increasing competition from low-cost paintable thermoplastic polyolefins (TPO's) in the automotive bumper and fascia markets, further growth for PBT/PC and PET/PC blends may be limited in this area. Hence, these blends must find other applications where their dimensional stability, chemical resistance, high toughness, and moderate DTUL ($T \leq 100\ °C$) are well suitable.

19.8.3.3 PCTG/PC Blends

The commercial copolyester derived from 1,4-cyclohexane dimethanol, ethylene glycol, and terephthalic acid (PCTG, Ektar® DN003, Eastman Kodak) is an amorphous polymer exhibiting excellent toughness (notched Izod impact strength of ≥ 800 J/m), high clarity, and good chemical resistance characteristics. However, it has a relatively low glass transition temperature (ca. 85 °C) and a low heat distortion temperature (ca. 66 °C at 1.8 MPa).

Hence, a blend of PCTG and polycarbonate was developed, which maintained the high toughness of both components (notched Izod import strength ≥ 800 J/m), yet had a useful combination of DTUL (ca. 95 °C) and chemical resistance. More importantly, the blend maintained a high degree of clarity because of the thermodynamic miscibility between the PCTG and polycarbonate, although some

transesterification cannot be ruled out. The miscibility was confirmed by a single-T_g, single-phase behavior of the blend (Mohn et al. 1979; Smith et al. 1981). Such PCTG/PC blends were commercialized as Ektar® DA series by Eastman, but they are no longer available.

19.8.4 Polycarbonate/ASA Blends

ASA polymers are similar to ABS except that the polybutadiene rubber dispersion in the SAN copolymer matrix is substituted by the more weatherable acrylic-rubber dispersion, as the cross-linked n-butyl acrylate rubber particles grafted with SAN copolymer. Since the withdrawal of EPDM-g-SAN copolymer (formerly AES, Rovel® from Dow) from the market, ASA and ASA blends have assumed increased commercial significance for many outdoor, weatherable applications. The weatherability advantages of ASA can be extended into the polycarbonate blends (Sakano et al. 1980) as long as sufficient ASA is used in the blend (≥ 50 %). The compatibility between ASA and PC follows the same fundamental mechanism as in the ABS/PC blends, viz., the partial miscibility of SAN in PC, which compatibilizes and stabilizes the interface against delamination. Hence, ASA/PC blends uniquely combine high notched Izod impact strengths (>500 J/m) with better UV resistance and weatherability than ABS.

Some current commercial grades of ASA/PC blends include Geloy® XP4025 from Sabic, Luran® SCKR2801 from Styrolution, and Astoloy™ PC/ASA401 from Marplex. The properties of ASA/PC blends have already been discussed under ASA blends section in Table 19.10. The two outstanding advantages of ASA/PC blends are (a) high impact strength down to $-20\ °C$ and (b) high outdoor weatherability. Hence, commercial ASA/PC blends find niche applications in exterior automotive parts such as cowl vents, grills, mirror housings, trim, etc., where the parts can be pigmented (black or color) instead of being painted, unlike the case of ABS/PC. The market for ASA/PC blends is likely to grow because it can compete and replace painted or plated ABS/PC blends. The cost saving due to pre-colorability without the need for primer and paint and overall durability of ASA/PC blends will favor their increased use in exterior automotive/transportation and outdoor equipment applications.

19.8.5 Miscellaneous Other Polycarbonate Blends

19.8.5.1 Specialty Styrenic/PC Blends

Blends of polycarbonate with other specialty styrenic resins such as styrene-maleic anhydride (SMA), styrene-methyl methacrylate (S-MMA) resins were investigated primarily to upgrade the performance of these styrenic resins with regard to their impact strength and to some extent DTUL improvement. A developmental SMA/PC blend (former Arloy®, Arco) contained SMA grafted with polybutadiene as the impact modifier. The properties of SMA/PC blend were similar to ABS/PC blend with comparable impact strength (>500 J/m). However, it was discontinued

from the market due to unfavorable economics relative to ABS/PC blend. The partial miscibility between the SMA and polycarbonate may account for the compatibility of this blend.

Similarly, a developmental S-MMA/PC blend (erstwhile Novacor® SD from Nova Chemical) was reported to have better surface finish and scratch resistance than PC/polyester blends and an equivalent level of impact toughness. It is believed that these formulations also include some acrylic rubber (core-shell type) for impact modification. One would expect a sufficient level of partial miscibility for self-compatibilization between the styrene-methyl methacrylate copolymer (S-MMA) and the polycarbonate, especially at high MMA content of the copolymer, since the binary blends of PMMA and PC are known to be miscible.

19.8.5.2 Polyamide/PC blends

Unlike the thermoplastic polyesters (PBT and PET), the commercial polyamides such as PA-6 or PA-66 are strongly hydrogen-bonded polymers and hence highly immiscible with polycarbonate. Simple blends of polyamide and polycarbonate delaminate readily, as expected, unless a suitable compatibilizer is used. Because of the lack of an efficient compatibilization technique, blends of PA-6 (or PA-66) with polycarbonate have not been successfully commercialized, although there are several patents claiming some improvement in properties. Several years ago, there was an attempt to commercialize a polyamide/polycarbonate blend (former Dexcarb®, Dexter Corp.). According to their patent, the blend was compatibilized by using a combination of a polyesteramide elastomer and a maleated olefinic polymer, such as maleated polypropylene or EP rubber (Perron 1984, 1988). However, the efficiency of compatibilization is questionable, since the added components are not known to be miscible or compatible with the polycarbonate. At the present time, there are no commercially significant polyamide/PC blends.

19.8.5.3 Polyetherimide/PC Blends (PEI/PC)

Polyetherimide (PEI, Ultem®, Sabic) is a high-performance engineering thermoplastic with high heat distortion temperature (>200 °C), high mechanical strength, and inherent flame-retardancy characteristics. Blends of polyetherimide with polycarbonate were primarily developed to lower the cost of the PEI while retaining a high level of heat resistance to be used as thermoformable sheets and as molding compounds. The blend was reported to have about the same impact strength as the polyetherimide, (Mellinger et al. 1985). However, the DTUL and chemical resistance of the blend is better than that of polycarbonate.

Extrusion-grade PEI/PC blend was developed for aircraft applications to meet the federal aviation standards for low flammability, smoke, and toxic gas generation (Skeist 1991). PEI/PC thermoformable sheet has been used for the fabrication of transport aircraft window housings, air ducts, consoles, and other components. PEI/PC sheet is also used as high-temperature paint mask in the automotive industry. PEI/PC molding compounds were also evaluated for microwaveable cookware. However, due to the high cost of PEI, commercially, the blends of PEI and PC have not achieved any significant penetration in the injection molding market.

19.9   Polyoxymethylene Blends

Polyoxymethylene polymers, POM, commonly known as polyacetals or "acetal" resins, are linear thermoplastic polymers containing predominantly the $-CH_2-O-$ repeat unit in their backbone. There are two types of acetal resins available commercially: (1) homopolymers made by the polymerization of formaldehyde, followed by endcapping, (2) copolymers derived from the ring-opening polymerization of trioxane (a cyclic trimer of formaldehyde) and a small amount of a comonomer such as ethylene oxide. Acetal resins are highly crystalline polymers with melting points of 160–175 °C and heat distortion temperatures of 110–125 °C at 1.82 MPa, unfilled. Due to highly crystalline nature, POM resins exhibit excellent rigidity, hardness, and resistance to creep, fatigue, and chemical attack. They also exhibit low wear and friction, high dimensional stability, and good electrical properties. Because of their excellent mechanical properties and moderate cost, acetal resins are among the more widely used engineering resins with an estimated current global consumption of over 370 kt/year.

Owing to their high crystallinity, POM resins are not miscible with any of the commercially available polymers. Unmodified POM resins tend to be brittle, particularly when notched. Due to their lack of reactivity, POMs are generally not amenable to any chemical modification by post-reactions with grafting agents. Hence, there are very few commercial blends based on POM resins, with the exception of impact-modified POMs that are simple blends containing elastomeric/impact modifiers. In order to improve the notched Izod impact strength, several types of impact modifiers have been employed, which included core-shell rubbers of acrylic-type (Kusumgar 1987) poly(methyl methacrylate)-g-styrene/butadiene (Schuett et al. 1986) or poly(methyl methacrylate)-g-polybutadiene type (Burg et al. 1985). Some commercial medium-impact grades with notched Izod impact strengths of 100–150 J/m, may contain such impact modifiers.

A commercial grade of high-impact (notched Izod > 900 J/m) POM resin (Delrin® 100 ST, DuPont) is believed to be a blend of POM with ≥30 wt% of a thermoplastic poly(ester-urethane) elastomer derived from poly(1,4-butane adipate) diol and methylene-bis-(4,4′-diphenyl diisocyanate) (MDI) (Flexman 1989). This blend is reported to have a cocontinuous or semi-interpenetrating network of the elastomer in a matrix of the polyacetal (Flexman et al. 1990). The toughening effect in such a blend of IPN-type morphology was interpreted to occur partly through a rubber band mechanism by which the fracture energy is absorbed. The bands of rubbery domains were believed to span the crack and participate in the deformation process.

Typical properties of commercial impact-modified POM resins are shown in Table 19.31. With the increase in the impact strength of these blends, there is a corresponding decrease in the modulus, strength, and DTUL relative to the neat POM resin. Impact-modified POM blends are still low volume in usage relative to unmodified POM. About 80 % of the impact-modified POMs are used in the automotive area in typical applications such as electrical switches, fuel system components, gears, and hardware. Industrial applications include cams, gears, valves, impellers, pumps, and a variety of plumbing and appliance parts.

Table 19.31 Properties of some commercial polyoxymethylene/impact modifier blends

Blend type			POM/TPU	POM/RUBBER	POM
			Delrin 100ST	Ultraform N2640X	Delrin 500

19.10 Polyphenylene Ether (PPE) Blends

PPE is the generic name for the homopolymer, poly(2,6-dimethyl,1,4-phenylene ether) derived from the oxidative coupling polymerization of 2,6-dimethyl phenol (Hay 1976). Developed in the early 1960s by GE, the polymer had many desirable properties such as a high T_g (205 °C) and DTUL (174 °C at 1.8 MPa), high strength and dimensional stability, moisture and hydrolysis resistance, and inherent flame retardancy. However, because its extremely high melt viscosity dictated melt-processing temperatures of well above 300 °C, at which the polymer tends to degrade or cross-link in the presence of air, its use as a molding resin by itself was severely limited. Commercially, all the PPE that is produced is alloyed with other polymers such as high-impact polystyrene (HIPS), nylons, and polypropylene to produce processable, cost-effective blends, which compete with other engineering thermoplastics in various applications. Currently, the only global producer of PPE homopolymer (trademarked as PPO[®]) and the major producer of the PPE alloys and blends (trademarked as Noryl[®]) is SABIC Innovative Plastics.

A major motivation for blending PPE with other thermoplastic polymers has been to take advantage of PPE's high heat performance and combine with useful melt processability of the other thermoplastic polymer. The average PPE content in commercial PPE alloys is about 45 %. Several PPE blends were investigated prompted by the initial success of PPE/polystyrene blends. Table 19.31 compares the key properties of the various types of commercial PPE blends.

19.10.1 PPE/High-Impact Polystyrene (HIPS) Blends

Since the early discovery of miscibility between the low-cost polystyrene and PPE, several commercial grades of PPE/HIPS have been developed, which offer a wide choice of heat resistance (DTUL), impact strength, and melt processability (Cizek 1969; Fried et al. 1978). This versatility of PPE/HIPS blends led to their unparalleled commercial success, accounting for nearly 50 % of market volume of all engineering polymers commercial blends. PPE/HIPS blends filled the price-performance gap between the styrenic resins (HIPS, ABS) and the engineering resins such as polycarbonate, polyarylate, and polysulfones. The technology of PPE/HIPS blends has already been discussed previously under the styrenic blends section (Sect. 19.3), and the typical blend properties are shown in Tables 19.6 and 19.32.

19.10.2 PPE/Polyamide Blends

Commercial PPE/PA blends were developed by the motivation to combine the high heat resistance characteristics of PPE with the chemical resistance characteristics of the crystalline polyamide polymers (PA-66 and PA-6). Because of the inherent incompatibility between PPE and polyamides, suitable methods of compatibilization and toughening have not been developed until recently. The technology of compatibilized, impact-modified PPE/PA blends have already been discussed under polyamide blends section (Sect. 19.7). Commercial PPE/PA blends are based primarily on the lower-cost polyamide (PA6 and PA66) and most often include a rubbery impact modifier as the third blend component, added for a desired level of toughness (Tables 19.25 and 19.32).

The unique difference between PPE/PA blends and PPE/HIPS blends is illustrated by (a) the differences in DTUL at 0.45 MPa and the DTUL at 1.82 MPa in glass-reinforced compositions (b) the difference in their relative sensitivity or resistance to chemicals, e.g., some common solvents and automotive fluids (Table 19.26). These differences arise from the facts that (a) polyamide is a crystalline polymer unlike HIPS, which is amorphous and (b) due to the large melt viscosity difference between polyamide and PPE at the normal blend ratios, the polyamide forms the continuous phase. Hence, in the molded parts, the polyamide surface offers resistance to solvent permeation and high softening temperature. In PPE/HIPS blends due to the single-phase amorphous character of the matrix, the solvent resistance is limited, and the heat resistance is limited by the T_g of the blend. Because of these differences, PPE/PA blends have found significant application niches.

19.10.3 PPE/Polyester Blends

Thermoplastic polyesters, PET, and PBT also offer the advantages of easy melt processability and good solvent resistance owing to their semicrystalline nature.

Table 19.32 Commercial PPE blends

Blend type ➜			PPE/HIPS	PPE/PA-6,6	PPE/PP
	ASTM		Noryl®	Noryl®	Noryl®
Property	Test Method	Units	731 Sabic	GTX910 Sabic	PPX7110 Sabic

Chemical resistance			Poor	Excellent	Good

Key features: Combination of high heat resistance, dimensional stability, and toughness with an adequate level of chemical resistance

In addition, PET and PBT are relatively moisture insensitive under ambient conditions, unlike the polyamides (PA-6 and PA-66), which can absorb significant levels of moisture. Moisture absorption in polyamides leads to significant growth in dimensions and loss in modulus and strength. Although PPE/PA blends exhibit lower moisture absorption than the standard polyamides, they are still not suitable for some exterior automotive applications such as vertical door panels and many electrical and electronic applications, which require stringent moisture resistance and dimensional stability.

Several research investigations were made to compatibilize PET or PBT with PPE both by reactive and nonreactive routes of compatibilization (Brown et al. 1990, 1991; Akkapeddi and VanBuskirk 1992). Compatibilized binary blends of PPE/polyesters still lacked adequate toughness and invariably required the addition of rubbery impact modifiers (reactive or compatible type) and polycarbonate. The addition of polycarbonate suppresses the crystallization of the PET or PBT phase, due to its partial miscibility and therefore contributes to the overall toughness. It was reported that polycarbonate encapsulated the PPE dispersions in

the PBT matrix and consequently improved the compatibility of the blend (Hobbs et al. 1992). The addition of PC to PPE/PET or PBT blends causes some decrease in heat resistance. Although a developmental grade of PPE/PBT blend (Gemax®, GEC) was announced many years ago, currently, there are no commercially significant PPE/PBT blends available.

19.10.4 PPE/Polypropylene Blends

Several approaches to compatibilizing PPE blends with commercial polyolefins (polypropylene, etc.) have been reported in the literature (Lee 1990; Kirkpatrick et al. 1989). Simultaneous compatibilization and impact modification of PPE/polypropylene blends was achieved by choosing selected types of styrene-ethylene/butylene-styrene block copolymers and PPE resin of low molecular weight (Akkapeddi and VanBuskirk 1992). A family of PPE/polypropylene alloys were commercially launched by G.E. in 2001, under the Noryl® PPX trade name, and these are now sold by Sabic. Typical properties of a commercial PPE/PP blend are shown in Table 19.32. These PPE/PP blends are claimed to offer a balance of cost and performance between the TPOs and other higher-cost engineering thermoplastics such as nylons, modified PET, and PBT resins. Basically, the PPE/PP blends offer a balance of key properties: stiffness, toughness, chemical, and heat resistance.

The high-impact, unfilled PPE/PP blends (Noryl® PPX) are marketed for automotive bumper fascias. Compared with TPOs used in bumper fascias, PPE/PP blend offers both higher heat resistance and about 50 % higher stiffness for the same level of toughness. High stiffness and high flow of PPE/PP blend can allow for thinner walls and faster molding cycles. In addition, the scratch resistance and creep resistance are also superior. These factors coupled with a low density makes the PPE/PP cost-competitive to TPOs for bumper fascia application.

The scratch resistance of polypropylene was improved by blending 20 wt% PPE/HIPS blend (Noryl® PX0844) as a modifier and 5 % styrene-ethylene/propylene diblock copolymer (Kraton® G) as a compatibilizer (Sue 2001, 2002). It appears that the fracture energy dissipation in the PP matrix occurs by craze promotion around the dispersed particles of PPE/HIPS blend and thus preventing crack formation, while the compatibilizer promoted the PP/PPE interfacial adhesion.

Glass-filled PPE/PP blends are targeted for automotive uses, as well as power-tool housings, pump housings, heat exchanger housings, and food-handling trays. Glass-filled PPE/PP blends seem to offer a combination of good chemical resistance and excellent dimensional stability with zero moisture growth, an advantage over nylon, particularly in fluid-handling components such as pump and heat exchanger housings where precise assembly is required, especially in contact with hot water. Glass-filled PPE/PP blends claim good heat resistance of up to 110 °C continuous use, and up to 130 °C peak exposure. Glass-reinforced PPE/PP blend is claimed to

offer good surface quality in power tools and good nonstick properties in industrial food-handling trays.

In the automotive area, short glass fiber-filled PPE/PP blends are used for front-end modules, seat backs, load decks, and underhood parts. PPE-PP blends were also evaluated as a thermoplastic matrix for continuous glass-mat reinforced composites. GM's Chevy Volt concept electric car featured light-weight, compression-molded thermoplastic composite hood and door panels, the core of each panel being made from low-density glass mat (Azdel) reinforced Noryl® PPX grade PPE/PP blend (EV world 2007).

19.10.5 Miscellaneous PPE Blends

19.10.5.1 PPE-PPS Blends

Blends of PPE and PPS (Noryl® GTX APS8740, Sabic; Xyron® DG141, Asahi Kasei) are commercially available as glass fiber-reinforced, high-performance engineering resins (Gabrielle 1992). PPS is a brittle semicrystalline polymer with high heat and chemical resistance and is, of course, incompatible with PPE. However, in the PPS/PPE blend, the semicrystalline PPS forms the matrix phase with the more ductile PPE as the dispersed phase. Hence, the addition of the amorphous PPE can improve the ductility of PPS somewhat, while retaining its high-performance properties in the glass fiber-reinforced form. GF-reinforced PPS-PPE blend exhibits high heat resistance (HDT at 1.8 MPa of ca. 230 °C), flame retardancy, and conductivity permitting electrostatic painting or powder coating. Applications of GF-reinforced PPS/PPE blends will be similar to those of standard GF-PPS resins in electrical/electronic and industrial markets, except that the presence of PPE in PPS matrix reduces the part warpage and improves the toughness.

19.10.5.2 PPE-Epoxy Blends

PPE was also blended with some commercial epoxy resins (Chao et al. 1993) to improve the dielectric properties (lower the dielectric constant), toughness, and moisture resistance of the cured thermoset. These formulations with fiberglass reinforcements were used for the printed circuit boards and other electronic applications. In one formulation of epoxy resin (Epon 825, Shell) cured with aluminum alkoxide, incorporation of 30 % PPE increased the tensile elongation at break for the epoxy thermoset from <2 % to 17 %. The HDT was increased from 60 °C to 195 °C. The dissolution of PPE in the epoxy raised its viscosity from 0.2 to 400 Pa.s. (Anonymous 1991).

19.11 Thermoplastic Polyester Blends

Poly(ethylene terephthalate) (PET) and poly(butylene terephthalate) (PBT) are two of the most important members of a family of commercial thermoplastic polyesters.

Other members of this family include specialty polyesters such as PET copolymers (PETG) and poly(1,4-cyclohexanedimethylene terephthalate) (PCT). Commercially important PET and PBT resins are known for their high crystalline melting points (265 °C and 225 °C), good mechanical properties, and solvent resistance characteristics. Among all polyesters, PET is the largest-volume commercial polyester with an estimated global consumption of over 40 Mt/year in fiber applications alone and nearly 25 Mt/year in the injection stretch-blow-molded iPET bottles and containers applications (Nexant/Chemsystems 2007). In the context of textile fibers, PET is referred to by its common name, "polyester," whereas the acronym "PET" is used in relation to the bottles and thermoformed packaging and film markets.

Due to the slow rate of crystallization, unfilled PET resin is generally not used in the conventional injection molding, engineering plastics applications. However, a large volume of neat PET resin is almost exclusively used in the injection stretch-blow molding market for the production of clear PET bottles and containers, which are widely used in the food, beverage, and consumer packaging markets. The commercial success of the PET bottles in replacing the glass bottles is largely due to the unique combination of light weight, clarity, toughness, and good gas barrier (i.e., barrier to O_2 and CO_2) properties coupled with the recyclability.

The dramatic growth in the use of PET in the soft-drink, beverage, and food packaging markets has indeed spurred considerable activity in the recycling of PET. Hence, PET is a relatively low-cost polymer not only because of large-scale production economics but also due to its availability as a recycled material, thus providing a cost incentive for blending with other polymers. Nevertheless, only a few cases of PET blends are actually used commercially in the conventional injection molding markets again because of the slow crystallization rate of PET as compared to PBT or PBT blends. Most of these commercial PET blends used in injection molding market are made either with PBT or polycarbonate, in combination with impact modifiers and/or reinforcing fillers, in which the role of PET is to improve the surface aesthetics and ductility of the molded part. These engineering plastic-grade PET blends will be discussed in a later section.

In the rigid packaging/PET bottle market, there has been some interest in recent years, to blend small amounts of other barrier polymers ("passive" barrier type) or more importantly, "oxygen scavenger" ("active" barrier type) polymers, to improve the barrier performance of PET. Such commercially important PET-oxygen scavenger blends used as barrier PET containers in the food and beverage packaging markets will also be discussed in a later section.

Poly(butylene terephthalate) (PBT) is produced in a much smaller volume than PET. However, PBT is more widely accepted as an injection-moldable engineering plastic in the large automotive and electronic markets due to its faster crystallization rate (Pratt and Hobbs 1976). Hence, PBT is more commonly employed in the formulation of blends also. PBT has generally been preferred over PET in the engineering plastics arena because of its superior processability, faster crystallization rate, shorter molding cycles, and better properties (DTUL/impact balance) in the molded parts, particularly in the unfilled form. Nevertheless, PET is also used to

a limited extent in glass or mineral reinforced forms admixed with nucleators and crystallization promoters.

The primary motivations for blending a crystalline thermoplastic polyester such as PBT with other polymers are: (a) to improve the solvent resistance and processability of amorphous polymers such as PC, styrenics, PPE, etc.; (b) to reduce the mold shrinkage of the thermoplastic polyesters associated with their crystallization; (c) to increase the DTUL of the unfilled polyesters; and (d) to improve toughness.

The largest-volume polyester blend sold commercially is the PBT/polycarbonate blend. PET/PC blend is also gaining some commercial importance because it is almost similar to PBT/PC blend in properties and moldability but has some cost advantages. Unlike the neat, unfilled PET that is difficult to injection-mold due to its slow crystallization rate (long mold cycle times with hot molds and amorphous parts with cold molds), PET/PC blends can be molded readily using the normal hot molds (ca. 80–100 °C) and fast mold cycles. The presence of PC helps retain high stiffness and strength in the part at the mold temperatures, to enable the demolding of distortion-free parts. The properties and applications of PET/PC blends have already been discussed under the polycarbonate blend section (Sect. 19.8). Other commercial blends of PET and PBT are discussed below.

19.11.1 PBT/PET Blends

These blends take advantage of the low cost of PET and the rapid crystallization rate of PBT. Despite their large difference in the crystallization rates, PET and PBT form stable blends without the need for compatibilizing agents. This was attributed to the amorphous phase miscibility between the two components (Escala and Stein 1979; Mondragon et al. 1989). X-ray, DSC, and IR studies indicated that the two components form separate crystalline phases and a single amorphous phase with a single T_g. Some transesterification was detected in the melt by NMR, especially at long melt residence times ($\geq$6 min) (Mondragon et al. 1989). The extent of transesterification under the fast extruder blending operation is however expected to be low.

Commercial grades of PET/PBT blends are generally glass fiber-reinforced (15–30 wt%). Compared to the glass-reinforced PBT and PET, the heat distortion temperatures of the blends at 264 psi are actually lower indicating the lower level of net crystallinity in the blend, an effect possibly caused either by miscibility or transesterification. The primary reason for developing these blends appears to be the improvement of surface appearance and gloss in the injection-molded parts compared to those made from the individual resins. There is also some cost advantage over PBT.

PBT/PET blends are used for making visible parts of both large and small appliances that need the appeal of smooth and glossy surface along with high stiffness, strength, and DTUL. There are also other electrical and automotive applications. Compared to the neat PBT molding resins, the market for the blend is still relatively small.

19.11.2 PBT/Elastomer Blends

Unmodified PBT is a fairly ductile material exhibiting high elongation at break, even after crystallization. However, as to be expected of all rigid semicrystalline polymers, molded parts of PBT show low notched Izod impact strength indicating that under conditions of stress concentration, the resistance to unstable crack propagation is low. Impact modification of PBT was investigated through the use of several elastomeric modifiers. Commercial PBT/elastomer blends are of two types, viz., (a) high impact strength type, (b) low-modulus, highly flexible types.

Commercial impact-modified PBT grades generally contain 20–30 wt% of controlled particle size (<0.3 μm), core-shell rubber modifiers (Neuray and Ott 1981; Farnham and Goldman 1978; Binsack 1985). Typical impact modifiers are: PMMA-g-SBR (MBS), PMMA-g-poly(n-BuA) (acrylic core-shell rubbers), SAN-g-PBD (high rubber ABS), or SAN-g-poly(n-BuA) (high rubber ASA). Commercial impact-modified PBT grades (Table 19.33) exhibit notched Izod impact strengths in excess of 500 J/m, while retaining a good level of modulus, strength, and DTUL. In these blends, the dispersed rubber particles promote multiple sites for crazing and shear yielding in the PBT matrix, thus providing mechanisms for energy dissipation during impact deformation and hence offering resistance to crack propagation (Hourston et al. 1991).

A commercial blend of PBT with a high-rubber ABS as impact modifier (Pocan S1506, Bayer) has been used in Europe for automotive bumpers, mirror housings, and other exterior parts (Kossoff et al. 1987). The blend was reported to exhibit good heat sag resistance at 135 °C and maintain high notched Izod impact strength >700 J/m even at −29 °C (Table 19.33). Substitution of ABS with ASA (SAN-grafted to cross-linked poly(n-butylacrylate) rubber particles) gives a more weatherable, impact-modified PBT (Ultradur KR4071, BASF). Similarly, a commercial PBT blend containing 25 wt% of MBS-type impact modifier (Vandar® 2100, Ticona) has been used in such exterior automotive applications as under-body rivets, fuel-line clips, etc.

PBT/elastomer blends display a unique combination of high impact strength, dimensional stability (due to their non-hygroscopic nature), excellent resistance to automotive fluids such as gasoline, oils, paint solvent, aqueous salt solutions, and good heat resistance. In addition, their easy processability (low melt viscosities) lends themselves to the fabrication of both small and large parts. High mold shrinkage and tendency to warp are some of the drawbacks resulting from the crystallization, which need to be addressed by proper tools and molding process designs.

19.11.3 PBT/Copoly(ether-ester) Elastomer Blends

Commercial copoly(ether-ester) elastomers (e.g., Hytrel®, DuPont; Riteflex®, Celanese) are segmented block copolymers containing a polyether soft segment such as poly(tetramethylene oxide) and a hard segment that is chemically identical

Table 19.33 Properties of typical, commercial PBT/elastomer blends

Property	ASTM	Units	Vandar® 2100 (Ticona)	Toray PBT 5207X11 (Toray)	Pocan® S1506 (Lanxess)
Density	D792	kg/m^3	1,230	1,200	1,200
Mold shrinkage	D955	%	1.8	2.6	1.8
Flexural modulus	D790	MPa (kpsi)	1,800 (260)	1,660 (235)	1,600 (220)
Flexural strength	D790	MPa (kpsi)	60 (8.7)	54 (7.8)	55 (7.9)
Tensile strength at yield	D638	MPa (kpsi)	40 (5.8)	37 (5.3)	35 (5.1)
Elongation at break	D638	%	>50	250	>50
Notched Izod at 23 °C	D256	J/m (ft.lb/in.)	NB	770 (14)	>900 (18)
HDT at 0.45 MPa	D648	C	110		100
HDT at 1.82 MPa	D648	C	50	50	55

to poly(butylene terephthalate). When the soft segment is ≥50 %, these block copolymers exhibit high degrees of rubbery elasticity, yet they process like thermoplastics and hence appropriately are called thermoplastic elastomers (Adams and Hoeschele 1987).

Because the hard segments crystallize like PBT, these thermoplastic elastomers exhibit high heat resistance with Vicat softening points typically in the range of about 180 °C. The hard segment crystallinity also imparts a good level of solvent resistance in these materials. The low T_g of the soft segment is responsible for the flexibility, resilience, and low-temperature toughness characteristics. Although the poly(ether-ester) block copolymers have been used in many niche applications requiring high-performance thermoplastic elastomer characteristics, their high cost has been a drawback in extending to larger volume applications.

To reduce the cost, these elastomers have been diluted with some PBT homopolymer. Because of the chemical similarity between the hard segment of the copoly(ether-ester) elastomers and the PBT, they form fairly compatible blends. When the hard segment content in the copoly(ether-ester) is >80 wt%, it was found to be completely miscible with PBT, showing a single T_g, amorphous phase and cocrystallization of the PBT segments of the elastomer with PBT homopolymer. As the hard segment content was lowered to ≤60 %, the blend exhibited incomplete miscibility, with two T_g's for two amorphous phases and also two separate crystalline phases (Runt et al. 1989). Nevertheless, a partial miscibility was indicated due to changes in the T_g observed in DSC and dielectric relaxation spectra. The partial miscibility and low interfacial tension between the phases makes the blend very compatible.

Commercial PBT/copoly(ether-ester) blends are generally richer (≥50 %) in the copoly(ether-ester) elastomer content. These blends originally designed for the automotive, flexible bumper fascia market (Bexloy® V, DuPont) appear to be no longer

commercial. They exhibited low moduli ($\leq$800 MPa), high elongation, and toughness needed for bumper application. The purpose of PBT in the blend was to lower the cost and improve the heat sag resistance required for paint oven capability. PBT/copoly (ether-ester) elastomer blend-molded parts also exhibited excellent surface finish and good paint adhesion without the need for primers. Because of the excellent surface esthetics of the blend, molded-in colors were also used to reduce the painting costs. Lower levels ($\leq$20 %) of copoly(ether-ester) elastomers have also been blended with PBT to make high impact strength molding resins (Celanex® grades, Celanese).

19.11.4 Impact-Modified Polyesters (Glass Fiber-Reinforced)

PET/elastomer blends have not been commercialized in the unfilled form, due to the slow rate of crystallization of PET. Unfilled PET and PET/elastomer blends are not easy to injection-mold under normal mold temperatures (ca. 80–100 °C) in fast molding cycles. The parts tend to stick to the mold and distort. Use of cold molds allows molding of amorphous PET parts (1–2 mm) lacking heat resistance (DTUL). Upon annealing at elevated temperatures (ca. 150 °C), one can develop crystallinity in PET parts, but they become brittle even in the presence of a modifier. Lack of proper adhesion between the rubber and the PET after crystallization, in general, seems to be the reason for this embrittlement.

Use of reactive tougheners such as ethylene-glycidyl methacrylate copolymers (Iida et al. 1981) and ethylene-n-butyl methacrylate-glycidyl methacrylate terpolymer (Deyrup 1988) leads to significantly improved toughness, which is retained even after annealing (Akkapeddi and VanBuskirk 1993). However, at present, no commercial PET/elastomer blends are offered in the unfilled form. The compositions such as those described above may be nucleated and glass-filled. An ethylene copolymer rubber-modified, glass-filled PET (Rynite® SST) with improved notched Izod impact strength and elongation is commercially available. A glass-filled PBT, impact modified with SAN-g-poly(n-BuA) core-shell rubbers (ASA), is also available commercially (Ultrablend® S, BASF). Because of the superior weatherability of ASA rubber vs. other rubbers such as ABS, MBS, etc., the PBT/ASA blend is likely to find applications in the exterior automotive applications. Mirror housings, door handles, roof racks are typical exterior, automotive applications.

Some grades of glass/mineral-reinforced, impact-modified PET molding resins have also been developed specifically for automotive exterior body panel applications (Bexloy® K, DuPont). This specific formulation was reported to withstand automotive on-line "E-coat" paint oven temperatures (ca. 200 °C) as well as give low warpage and smooth surface finish in the molded parts. A combination of glass fiber or glass beads and/or mica is believed to be used for reinforcement. The impact modifier is more likely a reactive toughener of the ethylene-n-butylacrylate glycidyl methacrylate terpolymer type or an ionomeric-type ethylene-butylacrylate-methacrylic acid terpolymer.

19.11.5 PET/Oxygen-Scavenging Polymer Blends

An oxygen-scavenging polymer, by definition, is a polymer that is capable of reacting with the oxygen from air, under ambient conditions and at a controlled rate. When used as an integral layer or as a blend in a PET container, an oxygen-scavenging polymer can intercept and scavenge the oxygen that permeates through the walls of the container, thus providing a sufficiently long-lasting, oxygen barrier performance to be useful for extending the shelf-life of the packaging. An alternate technology, normally referred to as "oxygen absorbers," is usually based on inorganic materials such as iron powders or ascorbate salts, for use as sachets or closure liners to scavenge the headspace oxygen in a package (Brody et al. 2001). These will not be discussed here. The barrier enhancement achieved with the oxygen-scavenging polymers is referred to as "active barrier" in contrast to the "passive" diffusional barrier achieved by blending with common oxygen barrier resins. The barrier performance of PET blends with active vs. passive barrier polymers is schematically illustrated in Fig. 19.23.

It may be noted that at low barrier resin loading, a PET/passive barrier resin blend can give only a marginal improvement in the oxygen barrier performance, while the PET/oxygen scavenging resin blend can provide a more substantially improved oxygen barrier. Commercial oxygen-scavenging polymers contain oxidizable functional groups (R) such as those shown below, react with oxygen under ambient conditions in the presence of a cobalt catalyst, to impart high barrier performance in PET blends. The oxygen scavenger lasts until its concentration is depleted, resulting in substantial shelf-life extension in the PET containers.

$$\underline{\text{Functional group (R)}} \qquad \underline{\text{Relative oxidizability}}$$

Allylic ($-CH=CHCH_2-$)

Benzylic ($-Ar-CH_2-$)   Increasing oxidizability ↑

Alkylene ether ($-CH_2-CH_2-O-$)

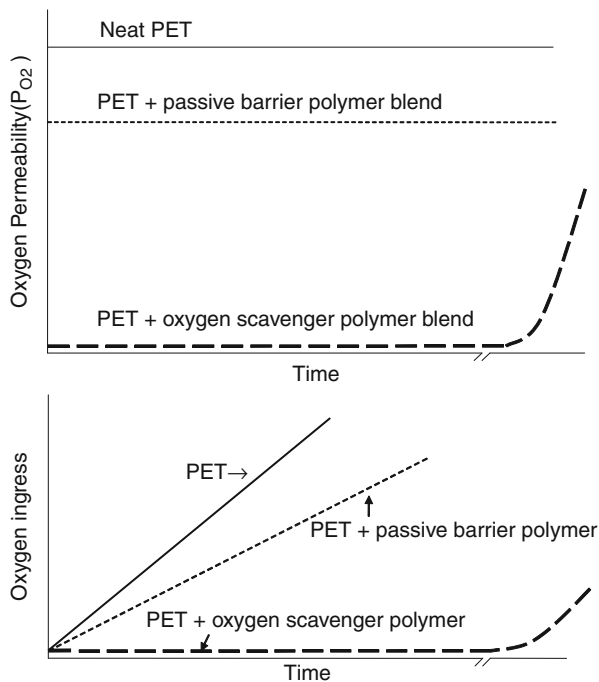
Oxygen scavenging reaction (Cobalt catalyzed oxidation):

$$R\text{-}H + O_2 \rightarrow ROOH$$

Oxygen scavenging rate and capacity $\propto [RH]$

Commercially, the enhanced oxygen barrier PET containers containing the oxygen-scavenging polymers are gaining increased importance, not only for extending the shelf life of standard PET bottles, but more importantly in gaining a larger market share and opportunity in replacing the glass containers traditionally used for packaging oxygen-sensitive foods such tomato-based pasta sauces, salsas, etc., and beverages such as beer and wines. The level of oxygen barrier and the desired shelf life in these containers varies with the type of foods and beverages.

Basically, a high barrier to oxygen ingress in PET containers is needed not only to prevent the microbial growth and spoilage of the food, but also to preserve the quality of taste, aroma, color, and nutritional values such as Vitamin C, all of which are

Fig. 19.23 Schematics of typical O_2 permeability rates (*top*) and the net oxygen ingress in bottles made from PET-O_2 scavenger blends


susceptible to oxidative degradation. For most of the oxygen-sensitive food and beverage products such as tomato-based products, juices, and wines, the total oxygen ingress must be $<5–10$ ppm over the desired shelf-life period of 2 years in a barrier PET container, to prevent browning and deterioration of product taste and quality. For beer, <1 ppm oxygen ingress and >85 % CO_2 retention is needed over the desired shelf life of 6 months. Hence, there is a significant market-driven technical motivation to develop PET-oxygen-scavenger polymer blends to make barrier PET containers. The main advantages of the barrier PET vs. glass containers are

- PET bottles are lighter in weight and more shatter-proof than glass.
- PET bottles are >60 % more energy-efficient than glass bottles.
- PET bottles require less oil to produce than glass bottles.
- PET bottles help in fuel savings in transportation, due to their lower weight.
- PET bottles generate 60 % less atmospheric emissions compared to glass.
- PET bottles generate 70 % less solid waste by weight compared to glass.

The commercially important oxygen-scavenging polymer systems useful for blending with PET are based on oxidizable olefinic polymers such as a polybutadiene block or graft copolymers, oxidizable polyamides, such as PA-MXD6, or oxidizable aliphatic polyether copolymers such as PTMG-b-PET. For the purpose of oxygen scavenging in PET bottles, these oxidizable polymers are always used in combination with a cobalt salt as catalyst, at a level of 50–200 ppm of cobalt.

Table 19.34 Some commercial oxygen scavenger polymers used in barrier PET containers

Oxygen-scavenger system	Oxidizable polymer	Catalyst	Compatibilizer
Amosorb® (*ColorMatrix Corp.*)	PBD-PET block copolymer	Co^{2+}	Block copolymer
Oxbar®, Monoxbar® (*Constar*)	PA-MXD6	Co^{2+}	–
Polyshield® (*Invista*)	PA-MXD6	Co^{2+}	Sulfoisophthalate
Poliprotect® (*M&G corp.*)	PA-MXD6		Sulfoisophthalate
Aegis® OX (*Honeywell*)	PBD-g-PA6 + PA6I/6T blend	Co^{2+}	Graft copolymer
Oxyclear® (*Invista, Indorama*)	PTMG-PET block copolymer	Co^{2+}	Block copolymer

Typically, these oxygen-scavenging polymers are used either as barrier layers in multilayer PET bottles or as blends in monolayer PET bottles. However, the mono-layer PET bottles are preferred because of the lower equipment cost and easier processing compared to the relatively more complex and more expensive coinjection molding processes. There is already a large, globally well-established manufacturing capacity and know-how for making monolayer PET bottles. Hence, there is an economical motivation to make barrier PET blends for monolayer bottles. However, the oxygen scavenger polymers used in these monolayer barrier PET bottles must meet the regulatory requirements for direct food contact safety, not only for the components of the blend but also for the products of oxidation resulting from the oxygen-scavenging reaction. These oxidation byproducts must in principle be nonmigratable or meet the safety threshold limits. Commercial oxygen-scavenging polymers have been designed to meet these requirements and obtain the FDA approvals. Some commercial oxygen-scavenger polymer systems used in the enhanced oxygen barrier PET container applications are listed in Table 19.34.

19.11.5.1 PET/PBD-b-PET Oxygen-Scavenging Blends

Polybutadiene-PET block copolymers (PBD-b-PET) containing about 10 wt% PBD blocks have been developed by a reactive extrusion process via a transesterification reaction between PET and hydroxyterminated polybuadienes using a cobalt salt as a transesterification catalyst (Tibbitt et al. 2007). Such a PBD-b-PET copolymer containing preblended cobalt catalyst is sold commercially as Amosorb® DFC (ColorMatrix USA) resin, for use as an oxygenscavenger concentrate for blending with PET to make enhanced barrier PET bottles.

Typically, this PBD-b-PET copolymer-based oxygen scavenger concentrate is used at 2–5 wt% to blend with PET, to make injection stretch blow-molded bottles with improved oxygen barrier. Such PET/PBD-b-PET blend-based bottles are now commercially used for packaging oxygen-sensitive beverages such as juices, green teas, and wines. These bottles exhibit 6–12 month shelf-life, a two to threefold improvement over the shelf-life of standard PET bottles. However, because of the high reactivity of the allylic groups in PBD, the oxygen-scavenging activity of these bottles can decrease somewhat with the empty bottle storage time. Hence, the PET/PBD-b-PET blend-based bottles must be filled preferably fresh as molded to fully utilize the oxygen-scavenging capacity.

The oxygen-scavenging capacity and consequently the achievable oxygen barrier shelf-life increases steadily with the PBD-b-PET content in the blend. However, due to the inherent phase separation of PBD blocks in PET matrix, the PET blend bottles tend to exhibit some haze particularly at high loading of the PBD-b-PET copolymer. The PBD domains in the PET block copolymers reportedly range from 100 to 1,000 nm, the predominant number of these PBD particles being below 300 nm (Cahill and Chen 2000). The morphology stability of these PBD domains in the PET blend can be attributed to the interfacial compatibilization offered by the covalently bound PBD-PET block copolymer in the PET matrix. Control of bottle clarity or haze will therefore be influenced by the control of the PBD morphology (domain size and distribution) in these PET blends, particularly after the orientation in the bottle.

A blend of PBD-b-PET, PA-MXD6, and cobalt catalyst is also sold under the trade name Amosorb® SolO2 as an oxygen scavenger for blending with PET. Such ternary PET blends can exhibit improved oxygen and CO_2 barrier, suitable for packaging some carbonated beverages.

19.11.5.2 PET/PA-MXD6 Oxygen-Scavenging Blends

Poly(m-xylene adipamide) (PA-MXD6) has gained considerable interest in recent years as a thermoplastic barrier packaging resin. The excellent gas barrier (O_2 and CO_2) properties (ca. 20× improvement over PET), orientability, and melt-processability at as high as the PET processing temperatures, made PA-MXD6 attractive for commercial use in making barrier PET containers of both the multilayer type and the monolayer PET/PA-MXD6 blend type. However, in order to be cost-effective, the PA-MXD6 content in these PET containers is generally limited to $\leq$5 wt%.

PA-MXD6 is also an oxidizable polyamide because of the reactive benzylic groups in its structure. The oxidizability or oxygen-scavenging property of PA-MXD6 was first recognized for its utility in making high oxygen barrier PET containers (Cochran et al. 1981). It was demonstrated that in the presence of a cobalt catalyst, blending as little as 1–4 wt% PA-MXD6 in PET caused an efficient scavenging of the oxygen permeating into the PET bottles, resulting in near-zero O_2 permeability for a considerable period of time (Fig. 19.21). However, the PA-MXD6-Cobalt catalyst-based oxygen scavenger system was initially commercialized in multilayer, barrier PET bottles as Oxbar® (Constar international), SurShot® CPTX-312 (Graham Packaging Co.) systems.

Such multilayer PET containers of three- and five-layer types, containing thin layers of neat PA-MXD6, both as a passive barrier and as an active barrier/oxygen-scavenging type in combination with cobalt catalyst are currently used to some extent in the packaging of oxygen-sensitive beverages (juices, beer, and wines) and some tomato-based food products such as ketchups. However, because of the cost of multilayer coinjection equipment, there has been a significant interest in recent years for developing monolayer barrier PET containers based on PET/PA-MXD6 blends. Hence, several commercial barrier PET technologies were developed for monolayer containers based on PET/PA-MXD6/cobalt catalyst blends, such as Monoxbar® (Constar International), Polyshield® (Invista Corp.), Poliprotect® (M&G USA Corp.), as outlined in Table 19.34.

For optimum barrier performance in PET/MXD6 blends, one needs at least 3–5 wt% PA-MXD6, but even at these low levels, the bottle clarity is invariably compromised due to the inherent incompatibility between the two polymers. The compatibilization in PET/PA-MXD6 blends was found to be somewhat improved by incorporating a small amount of sodium or lithium 5-sulfoisophthalate (SIPA) comonomer units in the PET, thereby reducing the polyamide particle size and reducing the haze in the bottles (Liu et al. 2011; Heater et al. 2007). Without a compatibilizer, the blend morphology consisted of relatively large spherical or ellipsoidal polyamide particles of ca. 2 μm dispersed in the PET matrix. The addition of ca. 0.5 % mol% SIPA to the PET phase reduced the MXD6 particle size to 0.3 μm (Prattipati et al. 2006; Ozen, et al. 2010). It is known from earlier literature that sulfonated ionomers exhibit favorable interaction with nylons via a sulfonate anion-amide complexation mechanism (Feng et al. 1996).

The PET/PA-MXD6 blend-based bottles are relatively more stable and can exhibit longer barrier shelf-life (>1 year) compared to the PBD-b-PET blend-based bottles. Although the bottles exhibit some haze at high PA-MXD6 levels (>5 %), suitable colorants and tints have been employed to mask the haze for use in carbonated and/or oxygen-sensitive beverages such as beers and wines. The market application for PET/PA-MXD6 blends in monolayer PET bottles and jars is still at an early growth stage.

19.11.5.3 PET/PTMG-b-PET Oxygen-Scavenging Blends

Polyethers such as poly(tetramethylene oxide) {PTMO or poly(THF)} are known to be prone to oxidation in air, although not as reactive as polybutadienes. Blends of PET with polyether diols such as poly(tetramethylene oxide)glycol (PTMG) as well as copolymerized polyether-polyester resins were investigated for potential oxygen-scavenging properties, using a cobalt catalyst and photoinitiators (Cyr et al. 2002). Subsequently, some PTMG-PET block copolyether-esters with high PTMG content (ca. 50 wt%) were made via an inreactor copolycondensation process in the presence of a cobalt salt, and the resulting copolyether-ester was evaluated for oxygen-scavenging properties (Chen et al. 2009; Roodvoets 2012). Commercially, a PTMG-b-PET copolyester is marketed as an oxygen scavenger concentrate (Oxyclear® 3500, Invista/Indorama) for use in blending with PET, to make injection stretch-blow molded, oxygen-scavenging PET bottles. Because of the tendency for phase separation of the polyether blocks in the PET, good mixing during the blending and injection molding is critical to get a uniform scavenger dispersion and reduce the bottle haze. Commercial development of this blend is still at an early stage.

19.12 Specialty Polymer Blends

In the plastics industry, specialty polymers are generally considered as high-performance, high-priced resins whose current market volume is still relatively

low compared to the more widely used engineering thermoplastics and commodity thermoplastics. Specialty polymers may be of two types, viz., (a) high-T_g, amorphous engineering thermoplastics such as polysulfones, polyarylates, polyetherimide, polyamideimide, polyimides; (b) high-melting, crystalline thermoplastics such as polyphenylene sulfide, liquid-crystalline polyesters (LCP's), polyetherketones (PEEK, PEK). Both categories of polymers can be classified as high-temperature polymers with long-term service capability at $T \geq 150$ °C and more often at $T \geq 200$ °C, as defined by the U.L. temperature index; i.e., temperature at which ≥ 50 % tensile strength is retained after 10,000 h of heat-aging. A common structural feature of all these high-temperature polymers is their essentially all aromatic backbone structures.

The high-temperature specialty polymers possess certain common property advantages such as (i) high T_g and/or T_m, (ii) inherent flame retardancy, (iii) high thermo-oxidative stability, (iv) high continuous-use temperatures, (v) high mechanical rigidity and strengths, (vi) high dimensional stability (to moisture and temperature) and creep resistance.

The crystalline polymers such as PPS, LCP, PEEK offer the additional advantages of high solvent resistance. Due to the inherently high cost of the specialty polymers, very few blends have been developed for commercial applications. The only driving force for the development of even the few blends of specialty polymers has been the desire to reduce the cost of the base resins by blending with lower-cost engineering plastics, although this invariably results in a lower performance. Some commercially significant specialty polymer blends will be discussed in the following section. The reader may also refer to another chapter of this handbook, viz., ▶ Chap. 16, "High Performance Polymer Alloys and Blends for Special Applications."

19.12.1 Polysulfone Blends

Polysulfones are aromatic high-T_g, amorphous polymers having the rigid aromatic sulfone linkages in the recurring units of their backbone. The three commercially significant polysulfone resins are (1) Polysulfone (PSU; Udel®, Solvay; Ultrason® S, BASF), (2) Polyphenylsulfone (PPSU, Radel® R, Solvay), and (3) Polyethersulfone (PESU-Veradel®, Solvay; PES-Ultrason E, BASF). All are transparent, high-T_g, amorphous ductile engineering resins. The T_g of PSU is 185°CC while that of PPSU and PES are 230 °C and 220 °C respectively. Due to its relatively lower cost, PSU enjoys the major market share by volume (>70 %). Poly(phenyl sulfone) (PPSU) is the highest-performance sulfone with not only a higher T_g (230 °C) but a much better notched impact strength than the more notch-sensitive PSU and PES polysulfones.

Owing to their high T_g and the hydrolytic resistance of the aromatic sulfone backbone structure, polysulfones display reliable long-term performance in hot water and steam even under autoclave conditions. Unlike the other high-T_g, transparent polymers, such as polycarbonate (PC), polycarbonate-ester (PCE), and polyetherimides (PEI), the sulfone polymers are not prone to crazing and failure

Table 19.35 Key properties of a commercial polyphenyl sulfone/polysulfone blend

Property	ASTM	Unit	PPSU/PSU blend (Acudel® Solvay)	PPSU (Radel®, Solvay)
Tensile strength at yield	D-638	MPa	77	69.6
Elongation at break (%)	D-638		50	60
Flexural modulus	D-790	MPa	2,760	2,410
Flexural strength	D-790	MPa	108	91
Notched Izod	D-256	J/m	110	690
HDT at 1.8 MPa	D-648	C	197	207
Transparency			No	Yes
Chlorine resistance			Yes	Yes

in long-term exposure to hot water. Hence, the polysulfones are used in niche specialty applications such as steam-sterilizable medical, dental, and surgical devices, sterilization, and food service trays, hot water/plumbing parts. The inherent flame retardancy and low smoke generation of polysulfones makes them also suitable for aircraft interior applications.

These unique combinations of transparency, hydrolytic, and heat resistance of polysulfones would be lost if other polymers are blended. Hence, there has been very little commercial incentive for blends of polysulfone. Nevertheless, in the early days of polysulfone commercialization, some blends with ABS and PET were developed primarily to lower the cost but also to improve selected properties such as plateability or chemical resistance. A PSU/ABS blend (Mindel® A) was commercially offered for some time but is now no longer available. Additives such as phenoxy resins, styrene-maleic anhydride copolymers have been claimed to improve the compatibility and weld-line strength of the PSU/ABS blends (Robeson 1985). The blend was evaluated for selected appliance, plumbing, and sterilizable equipment plated parts. This blend lacked the heat resistance needed for the vapor phase solderability in electronic applications.

Polysulfone was also blended with PET for the purposes of cost reduction and improvement in solvent stress-crack resistance. The blend was developed in the glass-reinforced forms for applications in electrical and electronic markets (Mindel® B, Amoco). However, the DTUL, flexural strength, and impact strength of this PSU/PET blend were inferior to those of PET at comparable levels of glass reinforcement and hence no longer offered.

Currently, the only commercially available polysulfone blend is a polyphenylsulfone/polysulfone blend (Acudel® PPSU/PSU, Solvay) (Table 19.35). It offers a cost and processing advantage over neat PPSU, while retaining good resistance to hot chlorinated water, useful in plumbing system components such as ball valves, connectors, and housings. The blend is opaque (immiscible) and has a lower notched Izod than PPSU but is more cost-effective.

19.12.2 Polyarylate Blends

Commercial polyarylate is an aromatic polyester of high glass transition temperature (ca. 180 °C) derived from bisphenol A and a mixture of terephthalic and isophthalic acids. It is a transparent, rigid, and tough thermoplastic of high heat distortion temperature (174 °C). Polyarylates face competition from the more established polycarbonate and its higher heat analogs, viz., polyester carbonates, as well as the polysulfone that is superior in hydraulic stability. Although polyarylate has been commercially available for many years, its market growth has been slow due to its high cost/performance balance. Nevertheless, polyarylate's transparency, UV/weather resistance, and high heat distortion temperature properties have found specialty niche applications in automotive taillights, reflectors, etc. Polyarylates have also been used in electrical/electronic connector applications. However, the production volume of polyarylates is still very low. Relatively few blends of polyarylate have been commercialized because blending other polymers results in the loss of the clarity and DTUL advantages of the polyarylate. Currently, the only commercial blend of polyarylate appears to be a blend with polyamide (U-polymer AX-1500, Unitika).

Polyarylate/PET blends prepared by solution or melt blending under short residence times at $T \leq 280$ °C with or without an added ester interchange inhibitor such as triphenylphosphite are essentially phase-separated, exhibiting two glass transition temperatures, one each for a PET phase and a polyarylate-rich phase. From the observed glass transition temperatures, one can conclude that it is a partially miscible blend in which more PET dissolves in the polyarylate phase than polyarylate does in PET. The interaction parameter has been estimated to be slightly positive ($\chi_{12} \cong 0.1$) (Chung and Akkapeddi 1993). The miscibility between polyarylate and PET may be further driven by transesterification reaction within the melt phase (Robeson 1985; Equiazabal et al. 1991). Although polyarylate-PET blends were briefly commercialized (U8000, Unitika; Ardel D-240, Amoco), they are no longer available.

More recently, a polyarylate-polyamide blend with improved chemical, stress-crack resistance is commercially offered (AX1500, Unitika). Due to the inherent immiscibility of polyarylate with polyamide, the blend is opaque and the notched Izod impact is somewhat sacrificed (Table 19.36). Compatibility in polyarylate-PA6 blends could be achieved through addition of ≤ 10 % of a reactive ethylene copolymer such as ethylene-glycidyl methacrylate copolymer (Okamoto et al. 1989).

19.12.3 Polyetherimide Blends

Commercial polyetherimide (PEI; Ultem®, Sabic) is a transparent, amorphous, high-performance engineering thermoplastic with its repeat unit structure containing both the rigid aromatic imide units and the slightly more flexible

Table 19.36 Key properties of a commercial polyarylate/polyamide blend

Property	ASTM	Units	Polyarylate (U100, Unitika)	Polyarylate/PA66 (AX1500, Unitika)

Flexural modulus	D-790	Mpa	2,100	2,600
Notched Izod	D-256	J/m	225	78
HDT at 1.8 MPa	D-648	°C	175	
Transparency			Yes	No

aromatic ether units. Owing to the unique structure of its backbone, polyetherimide exhibits high glass transition temperature ($T_g \simeq 215\ °C$), high mechanical strength and rigidity, yet with a good degree of ductility and melt processability. Its highly aromatic backbone structure also imparts an inherent flame retardancy and low smoke generation characteristics in the polymer. Recently, a new transparent, polyetherimidesulfone (PEIS) copolymer (Ultem® XH6050) with a higher glass transition temperature ($T_g = 247\ °C$) and enhanced hydrolysis-resistance has been developed. Because of the high thermal and mechanical performance characteristics, PEI and PEI copolymers find specialty niche applications in the aerospace, automotive under-the-hood, electronic, food-service, and medical equipment markets.

Very few blends of PEI have been commercialized because blending a lower-cost polymer invariably compromises the transparency and high-performance properties of the neat PEI resin.

Blends of PEI with polycarbonate (PC) form phase-separated morphologies (Chun et al. 1996). Nevertheless, some PEI/PC blends (Ultem® LTX) exhibiting improved melt flow and toughness were commercialized in the 1990s, but now seemed to be discontinued. PEI blended with some PC is used as thermoformable sheets (Ultem® 1668, Sabic) for aircraft interior applications, to meet the processability and the low flammability and low smoke generation requirements.

More recently, blends of PEI with a polycarbonate-ester (PCE) have been introduced by Sabic as Ultem® ATX series (Table 19.37). It was found that the modification of standard bisphenol-A polycarbonate with some resorcinol terephthalate/isophthalate moieties gave a polycarbonate-ester copolymer, which had a surprising miscibility with PEI (Gallucci 2005, 2008). The key advantages of the PEI/PCE blend are (a) high notched impact toughness (b) high melt flow for thin-wall molding (c) metallizability without primer (d) heat-resistance (e) transparency (f) flame-retardant properties. PEI/PCE blend is used in various automotive, aerospace, electrical/electronic components, food-service, and medical equipment applications.

Several years ago, PEI/PET blends with high (>75 %) PEI content and those with very low (<10 %) PEI content were found to exhibit clarity and single-T_g

Table 19.37 Properties of some commercial PEI blends

Property	ASTM	Units	PEI/PC Ultem® LTX100A* Sabic	PEI/PCE Ultem® ATX100 Sabic	PEI/PET Ultem® U-1285 Sabic	PEI/PPSU Ultem® HU1004 Sabic

behavior indicative of miscible blends while other blend ratios from 75/25 to 10/90 showed phase separation behavior (White et al. 1979). An ~85:15 PEI:PET blend was commercialized by GE as Ultem® 1285, but this seems to be no longer available. In a more recent reinvestigation, the use of a lower-molecular weight (0.56 IV vs. 0.84 IV) PET was found to increase the miscibility window in these blends to enable the blending of up to 40 % PET without sacrificing the high modulus, strength, and ductility of PEI and yet retain some transparency (Gallucci 2011). These blends are still not commercial.

To meet the demands in the health care and medical device markets, new transparent PEI blends with improved hydrolysis resistance under the autoclave, steam sterilization conditions, were developed (Sanner 2011). Based on the known superior hydrolytic stability of the sulfone resins and the published patent literature (Kailasam et al. 2009), it is very likely that these clear, hydrolysis-resistant blends are the compatibilized blends of PEI and polyphenylsulfone (PPSU).

It was reported earlier that PEI and PPSU formed a clear "miscible" blend with a single T_g observed by DSC and DMA (Ramiro et al. 2006). However, they could not ascertain the absence of a dispersed phase. This was because the refractive indices of the two components were too close to be differentiated. Later, it was found that the clarity in these blends is likely a result of small domain size of the dispersed phase (<0.5 μm) as determined by TEM (Kailasam et al. 2009). These PEI/PPSU blends are hydrolysis-resistant– capable of >1,000 steam autoclave cycles at 134 °C, while still retaining good ductility, toughness, and transparency (Sanner 2011).

Polyetherimide was also found to be miscible with polyether-ether-ketone (PEEK) exhibiting a single T_g (Chen 1992). Since PEEK is a high-melting, crystalline polymer, the blend should be useful in film and composite applications, but no commercial applications are known to date.

19.12.4 Polyphenylenesulfide (PPS) Blends

Polyphenylenesulfide (PPS) is an aromatic semicrystalline polymer with a recurring sulfide linkage in the backbone. Due to the highly aromatic nature of its structure, PPS is inherently flame-retardant and also exhibits an outstanding level of chemical resistance. PPS is high-melting ($T_m = 285\ °C$), yet its low melt viscosity allows easy processing and high loading of glass or mineral fillers. Since unfilled PPS is too brittle to be used by itself, PPS is generally compounded with reinforcing fillers. Glass-reinforced PPS exhibits high heat distortion temperature (HDT $\cong 265\ °C$) and high continuous use temperature (U.L. index of ca. 200 °C).

Owing to its unique combination of properties, PPS is experiencing a recent growth in the market interest with several producers and suppliers entering this business. Although current worldwide consumption of PPS is still relatively low, a steadily improving cost and supply position of PPS may increase its usage in the future. Since most PPS is used in the glass or mineral reinforced form, blending other polymers generally has no benefits. In addition, the chemical inertness of PPS and the crystallization tendency do not promote any degree of compatibility with other polymers.

Among the few commercial blends of PPS currently being used is the blend of PPS with PTFE. However, in these formulations, PTFE is simply added as a lubricating filler and may not be considered as a blend. These products (Dianippon Ink, Japan) are used for making low-friction gears (for floppy disc drives), bearings, relays, and other moving parts.

Since a major weakness of PPS is its brittleness, some attempts have been made to improve its toughness by blending with other suitable polymers. A commercial impact-modified PPS (Toray) is believed to consist of a blend of PPS with ethylene-glycidylmethacrylate polymer. A grafting reaction is expected to occur if the PPS has active end groups such as –SH or $–S^-Na^+$, which can in principle react with the epoxy group of the ethylene/GMA copolymer.

A PPS blend with liquid crystalline polyesters (LCP) is offered commercially in 40 % glass-filled form (Vectra® V140, Hoechst-Celanese). Since this blend would be considered more as a modified LCP, it will be discussed under the LCP blends section (Sect. 19.12.5). There has been some commercial development activity in the blends of PPS with PPE, in which the PPE is claimed to improve the ductility of PPS, e.g., with an elongation at break of 8 % in a 40 % glass fiber-reinforced blend (Gabriele 1992). The contribution of high ductility, high DTUL of 270 °C, and good processability (low mold shrinkage, warpage, and flash) appears to make this blend to be a significant improvement over glass-filled PPS.

19.12.5 Liquid Crystalline Polyester Blends

Liquid crystalline polyesters (LCP's) are interesting polymers, exhibiting inherently high mechanical strength and modulus due to a high degree of self-orientation; very few commercial blends of LCP are commercial. LCP blends

Table 19.38 Typical properties of commercial LCP/PPS blend (GF-reinforced)

Density (kg/m^3)	1,670
Flexural modulus (MPa)	16,550
Flexural strength (MPa)	248
Tensile strength (MPa)	165
Elongation at break (%)	1.4
DTUL (°C,1.8 MPa)	265
Dielectric constant at 1 kHz	3.7
Dielectric strength (kV/mm)	23.6

have been investigated by many researchers, but their high cost has precluded the successful commercialization of any such blends. The only commercial blends of LCP appear to be those with PPS (Vectra® V140 and V143XL). The liquid crystalline polyester used in this blend is a copolyester of p-hydroxybenzoic acid and 2-hydroxy-6-naphthoic acid. The melting point of this LCP and of PPS closely match, i.e., $T_m = 285–290$ °C. Since there is no compatibility or grafting reaction between the two components, LCP/PPS blend is considered to be a simple mechanical blend. The purpose of blending PPS seems to be simply to lower the cost of LCP without sacrificing the high heat distortion temperature and high melt flow.

In the commercial LCP/PPS blends, it is very likely that due to its low melt viscosity, LCP forms the continuous phase, while PPS may simply be present as a dispersed filler along with the glass fibers. The commercial LCP-PPS blends (Vectra® V140 and Vectra® V143XL, Celanese) are used in electrical, electronic, and industrial components such as connectors, bobbins, housings, switches, breakers, and sensors and other high-tolerance, thin-walled parts. Compared to PPS, the blend offers better flow with no flash into thin-wall part molds at lower injection pressures and lower mold temperatures. Compared to LCP, the blend offers higher weld-line strength and lower warpage. The blends are compatible with lead-free solder and seem to retain the physical and mechanical properties of both the LCP and PPS. Some typical properties of commercial LCP-PPS blend are shown in Table 19.38.

19.12.6 Polyimide Blends

High-performance polyimides (Vespel®, Dupont) and polyamide-imide (Torlon®, Amoco) molding compounds are often mixed with ca. 10 % polytetrafluoroethylene (PTFE) to fabricate a variety of low-friction bearings, bushings, and seals used in automotive, aerospace, and industrial markets. The role of PTFE in these formations is simply to function as a lubricating filler. Hence, these may not be considered as real blends. The PTFE particles are inert and not bonded to the polyimide matrix in the molded part. Because of this heterogeneity, higher amounts of PTFE cannot be tolerated in the polyimide compounds, due to undesirable loss in tensile strength.

19.13 Thermoset Blend Systems

Thermoset systems are, by definition, three-dimensional polymer networks formed by thermal radiation or catalyst-induced polymerization and cross-linking (curing) chemical reactions between multifunctional monomers and/or oligomeric prepolymers. Most often, the thermosetting resin formulation itself consists of a blend of different monomers and prepolymers along with curing agents and other additives. Since a thermosetting resin solidifies upon curing and cannot be remelted or reprocessed, it is necessary to mix all the required ingredients including the reinforcing fillers or fibers, modifiers, stabilizers, and additives during the initial monomeric or prepolymer stage before being fabricated into the final shape by curing. The mixing is facilitated by the low viscosity of the monomer, prepolymer system.

The global thermoset resins market is expected to reach as high as 95 million metric tons by 2016 (Axis Research Mind report 2012). Excluding the alkyd resins, which are used primarily in the coatings, commercially important major types of thermoset resins, along with their relative % market share, estimated from literature (Fosdyke and Starr 2002), can be categorized as follows: Polyurethanes (31 %), Phenolics (18 %), Amino resins (18 %), Unsaturated polyesters (12 %), Epoxies and other specialty/high performance thermosets (12 %), such as silicones, polyimides, bismaleimides (BMI), cyanate ester thermosets, etc.

Commercial thermoset resins offer a range of high heat performance with high glass transition temperatures ranging from 150 °C to >300 °C. When used in conjunction with glass fiber reinforcements and inorganic fillers, the thermoset resin composites invariably offer high heat distortion temperatures (200 °C to >300 °C), high modulus (>20 GPa), and strength (>20 MPa) properties. However, depending on the molecular rigidity of the structural units and the cross-link density, the conventional thermosets exhibit a high tendency for brittleness as generally indicated by their low tensile elongations at break.

Hence, a common goal for making thermoset blends is to improve their toughness without sacrificing their thermal and rigidity characteristics. Additional motivations for thermoset blends are to seek property improvements such as increased heat resistance, moisture resistance, dielectric properties via a cost-effective blending of materials. Figure 19.24 illustrates the typical commercial thermoset types and their blends, comparing their glass transition temperatures with the tensile strains at break, as a relative measure of toughness. As may be seen from Fig. 19.24, the commercial high-performance thermoset blends tend to bridge the gap between the thermal performance, toughness, and cost-effectiveness of the individual components.

A major application for high-performance thermosets and their blends is for making the copper clad laminates (CCL) used in fabricating integrated circuit boards in microelectronic industry. High-performance CCL (HPCCL), which can translate information by high frequency and high speed, has been gaining prominence due to the increased demands from the market. HPCCL must be fabricated by using high-performance resin matrix, with high thermal stability, low dielectric constant and dielectric loss over a wide range of frequency, and easy processability characteristics
Fig. 19.24 T_g vs. Tensile strain at break (%) of various commercial thermosets

at an acceptable price. Hence, there is a strong motivation to modify thermoset polymers via a blend approach to achieve the proper balance of properties and cost.

Many commercial thermosets are often used as complex mixtures of several coreacting monomers and prepolymers, specifically formulated to suit a given end-use application. For example, in coating and adhesive applications, often mixtures of different epoxies, differing in chemical structure and/or molecular weights, are used as required. Even two different thermosetting monomers may be mixed such as in the case of single-package epoxyphenolic molding compounds (Fry et al. 1985). However, even these hybrid thermoset systems are not usually considered as blends. Since the molecular weights of the epoxy and novolaks are low and during curing they become integral parts of the polymer network through coreaction, the system may be called a coreacted or cocured thermoset. Although it is sometimes hard to distinguish some thermoset blends from the coreacting thermosets, thermoset blends can be ideally classified as (a) Thermoset-thermoset blends and interpenetrating networks (IPN's), (b). Rubber-modified thermosets, and (c) Thermoset-thermoplastic blends and semi-IPNs.

An interpenetrating network (IPN) is defined as a combination of two polymer networks, at least one of which is in the presence of the other. The distinction between interpenetrating network and blend may often be based on morphology and the degree of phase separation. If there is a sufficient degree of molecular interaction, the phase separation tendency is suppressed, and a true molecularly or morphologically uniform interpenetrating network can be achieved. Very few systems can form truly homogeneous blend networks and, in reality, some microheterogeneity is invariably observed. Compatible IPNs generally form <5 nm size domains, and incompatible IPNs or blends form domain size >30 nm.

19.13.1 Thermoset/Thermoset Blends

As previously mentioned, several commercial hybrid thermosets are known to be coreacting thermosets; i.e., when the mixture of two different thermosetting monomers or prepolymers is cured, there is a simultaneous graft or coreaction between the components along with the cross-linking reactions. These systems may therefore be considered as copolymerizing thermosets and not as true blends. Examples of such systems are: phenolic novolak/epoxy resin, melamine prepolymer/epoxy resin, carboxyl-terminated unsaturated polyester/epoxy thermosets. The graft or copolymer network reaction involves the reaction between the phenolic $-OH$ or an amine or a carboxyl and the epoxide group.

In a majority of cases, the thermoset/thermoset blends are actually formulated by the fabricator or the end user during the fabrication and processing of such materials as composite prepregs, printed circuit boards, laminates, and adhesives. The formulations and compositions are often kept proprietary and are designed to meet their own individual requirements. The following are some commercially important high-performance thermoset/thermoset blend examples:

- Epoxy/Cyanate ester thermoset blends
- BMI/Cyanate ester thermoset blends
- Epoxy and bismaleimide (BMI) cocured thermosets known as "BT-Epoxy" resins

19.13.1.1 Epoxy/Cyanate Ester Thermoset Blends

Epoxy thermosets are widely used in numerous formulations and forms in the composites applications, particularly in the aircraft-aerospace industry. Epoxy resins are indeed considered the workhorse of the modern day composites. Most of the common epoxies (90 %) are based on bisphenol-A diglycidyl ether, a cross-linkable diepoxide monomer (e.g., Epon™828, Momentive Specialty Chem.). Multifunctional epoxies (Epon™ HPT and SU-8, Momentive) leading to higher cross-link density and higher temperature capability are used in advanced composites. Epoxy resins are used not only in composites for military and civilian aircraft-aerospace but also in such commercial applications as epoxy-reinforced concrete. Glass fiber or carbon fiber-reinforced epoxies are used in building and bridge structures in construction industry and in the printed circuit boards in microelectronic industry. The epoxy formulations used in composites are often modified with toughening or flame-retardant additives. Similarly, to improve moisture resistance and electrical properties, while retaining heat resistance, epoxies are modified by cocuring with other thermosetting resins such as dicyanate esters (Nair et al. 2001).

Aromatic cyanate esters cross-link by catalyst or thermally induced cyclotrimerization to form a cross-linked network of triazine ethers. Cross-linked cyanate ester systems typically exhibit higher glass transition temperatures ($T_g \geq 250\ °C$), lower moisture absorption, and lower dielectric constants than the standard epoxy systems, yet retaining an equivalent level of toughness and elongation at break. Hence, the cyanate esters are considered as high-performance thermosets. Several types of thermosetting cyanate esters are available commercially (AroCy®,Ciba-Geigy; BT-2000/Mitsubishi), and the most common among these is the bisphenol

A dicyanate ester. Due to their high cost, cyanate esters are not used as widely as epoxies but are now being used as blend candidates for improving the properties of epoxy and BMI thermoset resins in composites.

Thus, several properties of the common bisphenol A-diglycidyl ether-based epoxy thermosets can be improved by cocuring with a commercial bisphenol A-dicyanate ester, and the blend is more cost-effective than the cyanate ester alone. Such epoxy/cyanate ester thermoset blends exhibit improvements in processability, toughness, hot-wet performance, and low dielectric properties.

Epoxy/cyanate ester thermoset blend–based composites have low dielectric constant desirable for advanced radomes, microwave antennas, and stealth aircraft composite applications. Other applications include its use in copper clad laminates, semiconductor devices, and fire-resistant aircraft structural composites.

19.13.1.2 Bismaleimide/Cyanate Ester Thermoset Blends

Bismaleimide (BMI) resins are a relatively young class of thermosetting polymers gaining increased acceptance in high-performance composite industry because of their high T_g ($\geq$300 °C) and high retention of physical and electrical properties in hot-wet environment. Typically, bismaleimides are difunctional monomers containing a rigid aromatic unit with two terminal maleimide groups capable of catalyst or thermally induced polymerization resulting in a highly cross-linked rigid thermoset. BMIs bridge the temperature performance gap between epoxies and the high-temperature polyimides. They exhibit epoxy-like processing characteristics, but unlike the polyimides, they cure by an addition, rather than a condensation polymerization reaction. Thus, they avoid the off-gassing issues of polyimides, ensuring high hygrothermal performance.

Commercial bismaleimide thermoset resins are based on aromatic bismaleimides such as 4,4'-bismaleimidodiphenylmethane (Compimid® MDAB, Evonik). Compimid® MDAB, also known in literature as "MDA-BMI" is derived from the condensation reaction between 4,4'-methylene dianiline (MDA) and maleic anhydride, both relatively low-cost monomers. The MDA-BMI is often used as a eutectic mixture with other BMIs such as TDA-BMI, to reduce its melting point for improved impregnation and tackiness in the glass and carbon-fiber-based composite prepregs.

BMI thermosets can be processed basically like the epoxy (177 °C) cure but followed by an elevated temperature post-cure (232 °C), to achieve superior properties. Upon the thermal curing, BMI forms a highly cross-linked rigid thermoset matrix with very high T_g (>300 °C), allowing the continuous use temperatures of upto 250 °C. Such BMI thermosets adequately compete with the high-temperature, multifunctional epoxy-based thermosets in composite applications, primarily due to their better performance and cost advantages. BMI composites are used in electrical printed circuit boards, structural aircraft/aerospace composites, composites for pipes, and other structures for use at high temperature and chemical environments. In these applications, the BMI resin offers high heat resistance, stiffness, and strength but a relatively low elongation at break (<1 %). Hence, BMI needs suitable toughening modifiers to improve its damage tolerance in composites.

For the toughening purposes, BMI monomers have been mixed with different types of coreactive comonomers such as O,O′-diallyl bisphenol A ("DABA" or Compimid® TM124, Evonik) or 4,4′ Bis(2-propenyl phenoxy) benzophenone ("PPB" or Compimid® TM123, Technochemie), to achieve BMI thermoset composites with improved damage tolerance, with unchanged or even enhanced thermal performance. Such a toughened BMI formulation was developed by Cytec as Cycom® 5250-4 ($T_g = 285$ °C; Elongation to break = 4.8 %), for use in advanced carbon-fiber composites in aerospace industry (Boydy et al. 2001). Cycom 5250-4-based BMI composites have been successfully used in Raptor F-22 fighter jets for U.S. Air Force for many years. In addition to such a comonomer approach, the blending of other ductile thermoplastic or thermoset polymers have also been extensively investigated for toughening the BMI composites (Stenzenberger 2006).

Among the candidates to blend with BMI, cyanate esters have the unique advantage of very good processability, low dielectric constant, and adequate toughness with almost a comparable thermal performance of BMI resins (Fig. 19.23). Hence, an obvious approach to combine high thermal stability and easy processability is to blend the two resins. Blends of commercial BMI mixture (i.e., Compimide-353, Evonik) and the commercial bisphenol A dicyanate (AroCy B-30) have been evaluated for high-performance composites (Barton 1996). Such hybrid BMI/cyanate ester blend resins have been commercially available as "BT resins" and the corresponding prepregs and copper clad laminates from Mitsubishi gas chemical. Obviously, the acronym "BT" stands for the bismaleimide-triazine resin blend system. The blend ratio may vary depending on the application. Currently, the BT resins are the most preferred raw materials for making high-speed signal processing, complex high-count multilayer integrated circuit boards used in the tablet computers, motherboards for internet routers, servers, and IC tester devices. The low dielectric constant of the blend is ideal for the high-speed, multilayer circuit boards. The presence of the cross-linked triazine ether network in the matrix of bismaleimide cross-linked network is believed to improve the toughness, reduce the moisture sensitivity, and improve the dielectric properties without a sacrifice in heat resistance.

19.13.1.3 BT-Epoxy Thermoset Blend System

Commercial BT-epoxy resins and laminates (e.g., BT epoxy G200®, Isola group; Nelco® N5000) belong to a growing class of preferred thermoset resins currently used in the printed circuit boards (PCBs) industry. It is a mixture of a standard epoxy resin, a low-cost raw material for PCBs, and the high-temperature BT resins. BT resin itself is a mixture of bismaleimide and cyanate ester as discussed under BMI/cyanate ester blend section. Hence, BT/epoxy may be considered as a ternary blend-based thermoset. The purpose of blending epoxy is simply to lower the cost and improve the toughness of BT resin, while the latter provides the high T_g and low dielectric loss properties retained over a wide temperature range. BT resin also offers excellent electrical insulation resistance even after moisture absorption. BT resin costs about $1.5\times$ that of epoxy, and hence a blend of BT resin and epoxy is more cost-effective and popular in PWB/PCB laminate industry.

The cure reaction for BT-epoxy system occurs similar to epoxy at 180 °C. followed by a post-cure at a higher temperature (upto 250 °C). The cure is catalyzed by strongly basic molecules like Dabco (diazabicyclooctane) and 4-DMAP (4-dimethylaminopyridine). The resulting thermoset products have higher glass transition temperatures of 180–260 °C range and lower dielectric constant (Dk) and dissipation factor (Df) than standard epoxy thermosets. These properties make these materials very attractive and cost-effective enough for use in mass-produced, high-speed printed circuit boards.

19.13.2 Thermoset/Thermoplastic Blends

19.13.2.1 Low-Profile/Low-Shrinkage Polymeric Additives for Unsaturated Polyesters

Unsaturated polyester-based thermosets account for ≥ 70 % of the total global volume of all the glass fiber-reinforced thermosetting composites currently used (Atkins 1978; Majumdar 2008).

Commercial unsaturated polyester thermosets are derived from the polycondensation of glycols such as propylene glycol and maleic anhydride with some phthalic anhydride added to form prepolymers of ca. 800–5,000 number average molecular weight and a controlled degree of unsaturation (ca. 4–20 C=C groups/chain). Such an unsaturated polyester prepolymer is further mixed with styrene as comonomer (ca. 40 %) and then polymerized and cross-linked ("cured") via the use of a preoxyester-type free radical initiator and heat to achieve the final cross-linked thermoset product. Invariably, significant amounts of glass fiber reinforcements and inorganic fillers are also added to the polyester prepolymer-styrene mixture prior to the curing to increase the stiffness, strength, and the impact properties of the thermoset product.

Such glass fiber-reinforced composites based on the unsaturated polyester thermosets are usually fabricated as sheet molding compounds (SMC) and bulk molding compounds (BMC). These are widely used in various metal replacement applications because of their cost-effectiveness, rigidity, light weight, and corrosion resistance properties particularly useful in transportation (cars and trucks), construction, pipe, and tank applications. Automotive and truck body panel and structural component applications of SMC include doors, hatchbacks, hoods, front grilles, etc. Some nonautomotive applications of SMC and BMC include sanitaryware (bathtubs, shower stalls, sinks), appliances, business machine, and electrical components.

Typically, in an SMC composition, chopped glass fiber roving (18–75 mm long) is used, and its content can vary from about 20–40 wt%. In a BMC composition, shorter glass fiber (6–12 mm. long) is used at 15–20 wt%. In both the SMC and BMC compositions, about 40–60 wt% of an inorganic filler such as calcium carbonate (3 μm) is additionally used, primarily to lower the cost of the composites but also to improve the flame retardancy and other physical properties.

In the SMC process, typically the unsaturated polyester resin with styrene monomer along with the fillers, glass fibers, catalyst, and other additives are mixed together

and cast into a sheet sandwiched by polyethylene film. The sheet is then cured at 150 °C by compression molding in a heated, matched-die mold to the required part shapes such as automotive exterior body panels. The SMC composite parts fabricated from reinforced polyester thermosets exhibit excellent rigidity, strength, and toughness. However, the high shrinkage associated with the polymerization and crosslinking of the unsaturated polyester-styrene monomer-curing matrix can cause the following potential defects in the final thermoset composite part:

- Warpage of molded parts preventing the molding of close tolerances.
- Depressions ("sink marks") on the part surface where the ribs or bosses are located.
- Rough, wavy surfaces resulting in a poor surface appearance of the part.

Hence, for parts requiring close tolerance and surface appearance such as automotive body panels, unsaturated polyester-based SMC composites could not be used for a long time, until it was found that blending of suitable high-molecular weight thermoplastic polymers to the formulations helped reduce the shrinkage and produce smooth surfaces (Atkins 1993). Such thermoplastic polymer additives for shrinkage control can be divided into two separate performance categories:

(a) The low-profile additives, which allow an excellent reproduction of the mold surface to give a smooth class "A" surface (<0.05 % to zero shrinkage).
(b) The low-shrink additives, which do not reproduce the mold surface, but reduce the shrinkage moderately and more easily allow internal pigmentability than the low-profile additives.

Some thermoplastic polymers commercially used as the low-profile, low-shrink additives to SMC and BMC composites are

Low-profile additives:
Polycaprolactone (Norsolook® A70091, CCP composites)
Thermoplastic polyurethanes (Neulon® 520, Ashland resins)
Polyvinyl acetate -PVAc (Neulon® T, Ashland; Vinnapas® UW, Wacker Chemie)
Carboxylated PVAc, (Vinnapas® C, Wacker Chemie)

Low-shrink additives:
Polyethylene powders (Microthene® F Lyodell-Basell)
Impact polystyrene (Stypol® AIP, CCP composites)
Poly(methyl methacrylate) (Aropol® Q, Ashland resins)

A typical low-profile SMC recipe consists of ca. 10 % unsaturated polyester, 10 % styrene, 4 % thermoplastic additive, 50 % calcium carbonate, 25 % glass fiber ($>$25 mm) along with 1 % zinc stearate, 0.2 % peroxide catalyst, and small amounts of other additives as needed.

A typical BMC recipe consists of ca. 13 % unsaturated polyester, 12 % styrene, 4 % thermoplastic additive, 55 % calcium carbonate, 15 % glass fiber (6 mm) along with 0.3 % peroxide catalyst, 1 % zinc stearate, and small amounts of other additives as needed.

Among all the thermoplastic additives for SMC and BMC composites, poly (vinyl acetate) was found to be the most effective low-profile, shrinkage-control

Table 19.39 Effect of various polymer additives on the shrinkage of unsaturated polyester SMC

Polymer additive	Linear shrinkage (%)
None	0.5
Polyethylene	0.2
Polystyrene	0.2
Impact polystyrene	0.12
PMMA	0.1
Poly(vinylacetate)	0

additive (Atkins 1998). In general, the relative effectiveness of various polymer additives for shrinkage control in the unsaturated polyester thermoset composites may be summarized as in Table 19.39.

Currently, with the polyvinyl acetate additives, SMC composites can be fabricated at high mold temperatures with zero shrinkage and zero expansion. The resulting parts exhibit excellent, class "A" surface smoothness and dimensional stability without warpage. In addition to this "zero shrink" effect, certain high-temperature SMC processes require effective thickening for easy handling of the composite and good glass-fiber distribution during molding. In such cases, the carboxylated polyvinyl acetates are used in combination with magnesium oxide as the thickening agent and shrinkage control additive for the unsaturated polyester SMC.

It is believed that during the curing of the above type of mixture, the thermo-plastic polymer, which is initially dissolved, becomes phase separated by the reaction-induced spinodal decomposition. The fine domains of the phase-separated thermoplastic then counteract the curing shrinkage in the matrix by thermal expansion and stress relief via microvoid formation mechanisms (Montagne 2005). Thus, a primary requirement for the low-profile polymer additive appears to be that it must be amorphous with a low to moderate T_g and fairly soluble or dispersible in the resin matrix initially, but capable of phase separation during the polymerization to counteract the polymerization shrinkage stresses via thermal expansion and microvoiding. Almost all of the class-A surface SMC composites used currently in the automotive industry are based on the polyvinyl acetate-type low-profile, low-shrinkage additives blended into the unsaturated polyester-styrene-based thermoset recipe.

19.13.2.2 PPE/Epoxy Blends

Poly(2,6-dimethyl 1,4-phenylene ether) (PPE) is a high-T_g (215 °C) ductile polymer with a low dielectric constant and extremely low moisture absorption. Epoxy thermosets exhibit a very good combination of useful properties such as good adhesion, low shrinkage, high electrical resistivity, and good thermal properties. The brittleness and the moisture sensitivity of epoxies can be improved by blending a thermoplastic additive such as PPE. In addition, since PPE has a high T_g, the thermal properties are not sacrificed, but improved. Furthermore, the dielectric constant is lowered. Such blends have been used in glass cloth-reinforced composites form for laminates and printed circuit boards.

In a typical formulation of epoxy resin (Epon 825, Shell) cured with aluminum alkoxide, incorporation of 30 % PPE increased the elongation at break from <2 % to >17 %. The heat distortion temperature increased from 160 °C to 195 °C. The dissolution of PPE in epoxy formulation raised its viscosity at 200 °C from 0.2 to 4 Pa.s. (Anonymous 1991).

19.13.2.3 Thermoplastic/Silicone Semi-IPNs

Although the dynamically vulcanized blends such as EPDM/PP (Santoprene®) and NBR/PP (Geolast®) have sometimes been referred to in the literature as semi-IPNs, we considered them as blends of cross-linked elastomer dispersions in a thermoplastic matrix and as such treated them under the elastomer blends. There is yet another class of thermoplastic/thermoset blend system in which a minor amount of the cross-linkable monomer(s) is allowed to polymerize in the thermoplastic matrix forming a loose network. Examples of such systems are silicone semi-IPNs in thermoplastics that have been recently commercialized (Rimplast®, Petrarch, div. of Hüls) (Anonymous 1983).

The silicone semi-IPNs consist of mixing a hydride-containing silicone prepolymer and a vinyl-functionalized silicone polymer into a thermoplastic matrix such as PA, PBT, thermoplastic polyurethane (TPU), or styrene-ethylene/butylene-styrene (S-EB-S) block copolymer elastomer. The two silicone prepolymers coreact in the thermoplastic matrix during melt extrusion and injection molding to form a partially cross-linked network within the thermoplastic matrix.

The cross-linking reaction may be catalyzed by a small amount of suitable organometallic catalysts. The blends typically contain ca. 5–20 % silicone. Injection-molded or extruded parts are further heat-treated to complete the curing reactions. There is, of course, a significant level of phase separation. In the thermoplastic molding compounds such as glass-filled PA and PBT, addition of the silicone semi-IPN in small amounts (ca. 5–10 %) is reported to reduce the mold shrinkage, improve mold release, and increase wear and friction resistance. Polyamide-silicone blends have already been discussed under PA blends section (Sect. 19.7).

Elastomeric silicone IPN with TPU and S-EB-S thermoplastic elastomer matrices have found some medical applications (Carew and Deisher 1989). The silicone contributes to the excellent release characteristics and to the biocompatibility. Typical applications include medical tubing, catheters, implants, diaphragms, seals, gaskets, etc. The commercial volume for silicone IPNs is, however, still very small.

19.13.3 Rubber-Toughened Thermosets

Most commercial rigid thermosets of high T_g exhibit brittleness and low tensile elongation because of the inherent nature of cross-linked network structures. Addition of rubbery dispersions into the thermoset matrix should improve the ductility and impact strength of the matrix by promoting the absorption of strain energy through multiple crazing and shear deformation sites in the matrix.

Table 19.40 Reactive oligomeric rubbers used in commercial toughened epoxy thermosets

Oligomeric elastomer	Reactive functionality
Polypropylene glycol diglycidyl ether (Riew et al. 1976)	Epoxide end groups
Polyaminoamides (condensation products of polyamines and "dimer" acids) (McAdams 1985)	Amine groups
Liquid polysulfides (McAdams 1985)	Thiol groups
Aliphatic polyesters (Drake 1983)	Carboxyl and −OH groups
Liquids, butadiene-acrylonitrile copolymers (Hycar® ATBN or CTBN) (McGerry 1968; Drake 1975)	Amine or carboxyl end groups

However, dispersion of high-molecular weight rubbers into the monomeric or prepolymer mixtures of the thermosetting resin matrix is usually difficult due to a viscosity mismatch and a lack of solubility or compatibility.

Hence, a low-molecular weight, reactive elastomer is normally used for impact modification of thermosets. The low molecular weight of the rubbery prepolymer aids its easy dissolution or dispensability in the thermosetting resin. The reactive functionality couples the rubber covalently to the growing polymer network during the curing reaction. Hence, the rubber-toughened thermosets may also be considered as coreacted thermosets and not true blends.

Rubber-toughened epoxy resins are the well-known examples of impact-modified thermosets utilizing reactive rubbery prepolymers. Epoxy resins can be toughened or flexibilized by any one of the several types of oligomeric reactive elastomers listed in Table 19.40.

These oligomeric reactive rubbers coreact with the epoxy resins through their corresponding reactive end groups, thus incorporating rubbery blocks into the cross-linked epoxy network. For impact modification, usually 10 wt% of the reactive rubber is used. For flexibilizing the thermoset, higher levels (up to 50 %) are needed. The type and the amount of the oligomeric rubber used depends upon the degree of toughness and flexibility required in the product. The rubbery segments must phase separate after curing into discrete domains for effective impact modification without sacrificing the glass transition temperature or heat resistance of the matrix. Generally, 1–5 μm-size rubber particles promote craze formation while shear deformation is promoted by rubber particles of <0.5 μm. Systems possessing both small and large particles, i.e., bimodal distribution, provide maximum toughness (Riew et al. 1976). Elastomer-modified epoxy resins are primarily used in composites, structural adhesives, and electronics applications.

19.13.4 Miscible Thermoplastic-Toughened Thermoset Blends

Rubber toughening of thermosets can lead to a significant increase in toughness, but this method usually leads to a decrease in the material's stiffness and strength,

which may be undesirable in many applications. The blending of a ductile, thermoplastic polymer that initially dissolves in a thermosetting formulation but subsequently either remains mostly dissolved or has an incipient microphase separation during the curing of the matrix is an alternative approach for toughening the thermoset polymers.

For example, incorporation of 10–20 % polycaprolactone (PCL) in a vinyl ester thermosetting matrix significantly improved the fracture toughness and impact properties while retaining stiffness and thermal properties (Ollier et al. 2012). The interaction between PCL and vinyl ester was strong enough to prevent phase separation as indicated by SEM of the cured blend.

Another interesting case of a thermoplastic-toughened thermoset is the "thermally mendable" thermoset/thermoplastic blend. The principle behind this type of thermoset blend consists of the use of a polymerization-induced phase separation technique to fabricate a "biphasic" blend with a so-called "bricks and mortar" morphology structure in which (a) the major "load-bearing" phase is the cross-linked thermoset providing high stiffness and strength needed for the structural functions and (b) the minor thermoplastic phase provides a "healing" function, upon a short thermal exposure, to repair any crack damage and restore the blend's mechanical integrity.

An example of the "thermally mendable" thermoset blend is the epoxy/polycaprolactone (PCL) blend (Luo et al. 2009). The initially miscible blend composed of 15 wt% PCL undergoes a polymerization-induced phase separation during the cross-linking of the epoxy, yielding a biphasic morphology in which the epoxy phase exists as tightly interconnected spheres ("bricks") interpenetrated with a percolating PCL matrix ("mortar"). The fully cured material is stiff and strong. In the event of an impact or stress-induced damage in the part made from this material, the damage can be thermally mendable with a short heat exposure. A heat-induced "bleeding" behavior of the PCL phase causes a wicking of the molten PCL into the crack or microcrack, thus bridging the crack gap. Upon cooling, the recrystallized PCL in the crack gap is capable of load bearing and thus repairing the crack damage and restoring a significant portion of the initial mechanical strength. Interest in the development of such thermally mendable thermoset-thermoplastic blends continues as they have significant commercial potential.

19.14 Biodegradable Polymer Blends

The generally accepted definition of the term "biopolymer" covers polymers that belong to the following two main categories:

(1) Bio-based polymers, i.e., polymers produced from natural, renewable feedstocks such as the plants and biomass in general. Bio-based polymers are not necessarily biodegradable and quite often include conventional plastic types

such as PE, PET except that they are made from bio-based monomer feed-stocks. The main motivation to use such bio-based polymers is the environmental benefit of reduced carbon dioxide emission.

(2) Biodegradable polymers, i.e., polymers which can be degraded by microorganisms present in the normal soil or composting conditions and must be completely metabolized into CO_2, water, energy, and biomass. Biodegradable polymers can be of three subtypes:

(i) Natural biodegradable polymers such as starch, cellulose, soya protein.

(ii) Biodegradable polymers made from bio-based raw materials,
e.g., Polylactic acid (PLA), Polyhydroxybutyric acid (PHA)

(iii) Biodegradable polymers made from petrochemical raw materials,
e.g., Polycaprolactone (PCL), Polybutylene adipate-*co*-terephthalate (PBAT), Polybutylene succinate (PBS); Polybutylene succinate-*co*-adipate (PBSA)

In general, the growing environmental concerns and the increased consumer awareness of the harmful environmental effects of conventional plastic products is driving the growth of both the bio-based polymers and the biodegradable polymers. However, the public opinion and new legislations are particularly driving toward the development of environment-friendly, fully biodegradable and compostable plastic products. For this purpose, various biodegradable polymers have been developed in recent years (Vroman 2009). Although full biodegradability and compostability are not always readily achievable in thick-wall, injection-molded products, certain plastic wastes from food packaging films and foamed articles, disposable fabrics and agricultural films can be readily managed by the proper use of biodegradable plastics technology.

The demand for consumer products that are truly biodegradable has led to national and international "Definitions and Standards of Biodegradability." Regulatory bodies, such as ASTM (USA) and ISO (international), CEN (Europe), JAS (Japan), have all published such standards and issued logos that certify to meet these standards. Although the definitions, test methods, and certification requirements differ, the following are some common features:

1. A biodegradable polymer in an active composting environment must sufficiently fragment and/or disintegrate so that it completely passes through specifically sized sieve screens within a time frame comparable to kraft paper degradation.
2. In a time frame comparable to kraft paper, usually 6 months, the biodegradable polymer must be completely reduced to carbon dioxide, water, energy, and biomass, in an active composting environment.
3. No toxic residues or toxic monomers should be produced by the composting process.
4. The compost containing the biodegraded polymers must support plant growth.

Hence, the current commercial focus has been on is on the development and application of biodegradable polymers to meet the above biodegradation

Table 19.41 Key properties of commercial biodegradable polyesters

Property	PLA Ingeo® 2003 (NatureWorks)	PCL CAPA® 6800 (Perstorp)	PBSA Bionolle® 3000 (Showa)	PBAT Ecoflex® (BASF)

Biodegradation	←――――――――――― *Complete* ―――――――――――→			

and compostability standards. The market thrust is primarily in the food packaging/food-service markets (films, thermoformed containers, disposable cups, cutlery, etc.), sanitary and disposable fabrics, agriculture/horticulture film markets. Biodegradable polyesters are commercially the most important class of biodegradable polymers (Table 19.41). To achieve faster compostability and better cost benefits, biodegradable polyesters are also used as blends with starch. These blends generally fulfill the range of mechanical properties and compostability requirements in these markets. Although the biodegradable polyesters and starch have also been individually blended with nonbiodegradable conventional polymers such as polyethylene and polypropylene, such "hybrid blends" do not meet the true biodegradability standards and hence will not be discussed. Only the commercially significant, truly biodegradable or compostable polymer blends will be discussed in this chapter.

Among the biodegradable polyesters summarized in Table 19.41, poly(lactic acid) (PLA) has historically received the most commercial attention. The PLA monomer ("lactide") is derived from the low-cost corn starch, and a large-capacity plant has already been built by Natureworks LLC. PLA polymer has mechanical properties somewhat similar to those of polystyrene, and as such it can be used in similar applications. However, its inherent brittleness, low elongation at break, and low impact strength limit a more widespread use of PLA. On the other hand, the more recently developed biodegradable, "aromatic-aliphatic" copolyester "PBAT" (Eastar Bio®, Eastman; Ecoflex®, BASF) is based on conventional petrochemical-based monomers (Haile et al. 2002). Similarly, an aliphatic polyester "PBS" and a copolyester "PBSA" (Bionolle®, Showa Denko) have become available recently as biodegradable polymers. All of these new biodegradable polyesters are soft and flexible with physical properties and processability features similar to LDPE. Hence, these are quite suitable for extruded films and fabrics. Although all these polyesters are fully biodegradable in accordance with ASTM and ISO standards, their rates of biodegradation can be further enhanced for faster compostability. This can be accomplished by blending some thermoplastic starch.

19.14.1 Starch/Biodegradable Polyester Blends

Starch is an inexpensive biodegradable polymer obtained from the abundant renewable plant resources such as corn, wheat, and potato harvests. Natural starch is a complex structure of highly crystalline amylopectin and lesscrystalline amylose polysaccharides, which degrade thermally without melting. Formation of a thermoplastic starch requires the disruption of supramolecular structure and melting of starch crystals with the aid of water (gelatinization) followed by the stabilization of amorphous amylose with other plasticizers or complexing agents. Starch can thus be modified (plasticized and destructurized) with a combination of water, glycerol, polyethylene glycol, or polyvinyl alcohol-type additives for thermoplastic processability (Shanks et al. 2012).

Although such a thermoplastic starch alone can be processed like a traditional plastic, its sensitivity to humidity makes it unsuitable for most applications. Hence, the thermoplastic starch is primarily used in blends with other polymers (Imre and Pukanszky 2013). Blending of a thermoplastic starch with the commercial biodegradable polyesters not only reduces their cost, but also increases their rate of biodegradation for faster compostability. The first commercial example of such a biodegradable polyester/starch blend is the Novamont's Mater-Bi® Z, which is a blend of polycaprolactone (PCL) and thermoplastic starch (Bastioli 1998). More recent examples include Showa-Denko's Bionelle™- Starcla™ series, which are ternary blends of biodegradable polyesters PBSA and PLA with some thermoplastic starch. The composition and mechanical properties of these blends have been balanced to be in the range of LDPE and HDPE for blown film packaging applications while maintaining full biodegradability and compostability.

19.14.2 PLA Blends with Other Biodegradable Polyesters

The other major type of commercial biodegradable polymer blends are the binary and ternary combinations of biodegradable polyester PLA with other synthetic biodegradable polyesters such as the PBAT and PBS, listed in Table 19.41. BASF's Ecovio® series consists of such PLA/PBAT blends. Since PLA is brittle, blending some PBAT improves the toughness and puncture resistance that is needed in rigid and semirigid packaging of thermoformed and foamed structures. On the other hand, PBAT is too soft, and blending of some PLA improves its stiffness and strength while lowering the cost. In all cases, the blends retain full biodegradability and compostability. Some commercial bidegradable polyester blends are listed in Table 19.42, along with their targeted applications. The key properties of some commercial biodegradable polyester blends, used in packaging and agricultural films, are shown in Table 19.43. It is apparent that these biodegradable polymer blends have the processability and properties comparable to LDPE, particularly suitable for film applications, but also have the great environmental benefit of being completely biodegradable and compostable.

Table 19.42 Some commercial types of biodegradable polymer blends

Biodegradable polymer blend	Commercial grades	Key applications
I. Starch/biodegradable polyesters PBSA, PBAT, PLA, etc. – Binary and ternary blends	Mater-Bi®, Novamont Bionolle® Starcla, Showa Biograde®, Biograde Terraloy®, Teknor Apex Compostables®, Cereplast	*Food packaging*: Films, bags, containers, cutlery, etc.
		Agricultural films: Seed mats, ground cover/mulch, erosion control films, etc.
II. PLA blends with other biodegradable polyesters-PBAT, PBSA	Ecovio®, BASF Bio-Flex®, FKuR	*Food packaging*: Films, bags, containers, rigid foam pkg., paper board coating
		Agricultural films: as above

Table 19.43 Key properties of some commercial biodegradable polymer blends

Property	PCL/Starch Mater-By® Z (Novamont)	PLA/PBATEcovio® F (BASF)	PBSA/PLA/Starch Bionelle Starcla™ (Showa Denko)	LDPE
Melting point (C)	65	110–140	93	110
Tensile strength (MPa)	31	35	20	26
Tensile modulus (MPa)	185	750	690	260
Elongation at break (%)	800	300	–	300
Water permeability	High	High	High	Low
Compostability	←——————— yes ———————→			No

19.14.3 Bio-based, Biodegradable PLA/PBS Blends

Recently, NatureWorks, announced the plans to produce PLA blends with bio-based PBS under its Ingeo trade name, in a joint venture with BioAmber (Anonymous 2012). As already discussed before, PBS is a biodegradable polyester made from succinic acid and butane diol (BDO), both normally petrochemical-based. However, BioAmber currently produces bio-based succinic acid by a fermentation process from wheat starch. They also plan to make bio-based BDO from the bio-based succinic acid, thus making a completely bio-based PBS. Unlike pure PLA, which is stiff and brittle like polystyrene, pure PBS is more ductile like polyethylene. Hence, PLA/PBS blends exhibit good flexibility, toughness, and heat resistance, resembling PP and HIPS. Two developmental, thermoforming, and injection grades are available. The injection molding grade (Ingeo AW 300D) is aimed at tableware used with hot foods and drinks. The thermoforming grade (Ingeo AW 240D) is targeted for food-service ware such as

Table 19.44 Key properties of bio-based, biodegradable PLA/PBS blends

	Injection moldable PLA/PBS (*Ingeo*® *AW300*)	Thermoformable PLA/PBS (*Ingeo*® *AW240D*)
Specific gravity	1.34	1.48
Flexural modulus (MPa)	2,485	1,670
Notched Izod, (J/m)	34	–
Vicat softening point, °C	107	105

hot and cold drink cup lids, vending cups, trays, plates, and bowls. Both are opaque materials meeting the FDA requirements. Both these bio-based polymer blends are completely biodegradable and meet the industrial composting standards (Table 19.44).

19.15 Conclusions and Future Trends

Polymer blends will continue to play a significant role in the commercial development and application of plastic materials because of their desirable overall cost/performance balance and their ability to fill the performance gaps between existing single resins. In many cases, polymer blends have provided unique combinations of properties and processability advantages not available in single resins. While further growth in commercial polymer blends will undoubtedly be strongly driven by global economic conditions and economic growth rates, specific market needs and applications, there are also several technological factors, which can drive and sustain this growth. Although the general global economic slowdown in 2009 caused a negative effect on the polymer blends and alloys market growth, it is now on the upswing again since 2012, mainly due to the high growth of the electronics applications and a recovery in the automotive markets.

In the near future, electronic housing and computer-related applications appear to be the main development areas for polymer blends, especially for polycarbonate blends. The electronic housing industry, including housings for information technology-related products such as personal computers, tablets, etc., will be the major growth driver for the polymer blends and alloys market globally. It is expected that bio-based and biodegradable polymer blends will also have a growth potential since increasing environmental concerns and government regulations are driving the demand for sustainable products that can be used for engineering applications.

Polymer blend manufacturers continue to identify new application areas for polymer blends by working closely with the customers to identify the niche opportunities. Hence, engineering design and application developments are currently the major thrust areas in polymer blends. Engineering polymer blends tend to be more expensive than commodity polymers, due to higher processing and material costs. Hence, for high-volume applications like automotive, there is

a continuing trend to move toward modified commodity polymers like long glass fiber-reinforced PP or ABS. These polymers often offer nearly the same performance as polymer blends. Thus, it is necessary to identify niche applications in which commodity polymers cannot replace polymer blends.

The following key factors will likely influence the future growth of commercial polymer blends:

1. Use of low-cost recycled polymer feedstocks of acceptable quality.
2. New compatibilization/reactive alloying strategies for immiscible polymer blends, which fulfill the desired economic, safety, and productivity targets.
3. Improved technology for obtaining reproducible and stable morphologies under commercial extrusion and molding conditions, ensuring blend product quality and reliability.
4. Novel melt-blending technologies such as "chaotic advection mixing" process to make structured morphologies (e.g., micro- or nanolayered) containing blend products.
5. Better understanding of the correlations between rheology, morphology, and mechanical properties to help optimize polymer blend design.
6. Development of efficient toughening technology (impact strength, fracture toughness, and ductile/brittle transition temperature) without sacrificing flexural modulus, strength, and HDT of the blend products.
7. Improving the long-term service life and performance of polymer blends (thermal aging and embrittlement resistance, creep and fatigue resistance, weatherability, and so on).
8. Developing cost-effective processing (compounding and post-fabrication) technology.
9. Improving the recyclability and reprocessability aspects of polymer blends, particularly with respect to the retention of properties after multiple processing histories, to increase the efficiency of regrind reuse.
10. Development of cost-effective technology for polymer blends that can continue to bridge the performance gaps between the commodity, engineering, and specialty polymers.
11. Development of nanocomposite polymer blends to achieve higher levels of stiffness/strength and toughness balance while retaining a low specific gravity desirable for making light-weight parts for the transportation industry.
12. Bio-based and biodegradable polymer blends technology will be a major growth area, as growing environmental awareness and government regulations fuel the demand for sustainable products that can be used for engineering applications.

ASA   Acrylonitrile-*co*-styrene-*co*-acrylate polymer
BMC   Bulk molding compound
BMI   Bismaleimide
DMA   Dynamic mechanical analyzer
DSC   Differential scanning calorimeter
DTUL   Distortion temperature under load
EPDM   Ethylene-*co*-propylene-*co*-diene terpolymer rubber
EPR   Ethylene propylene copolymer rubber
EVA   Ethylene-vinylacetate copolymer
EVOH   Ethylene vinyl alcohol copolymer
HDPE   High density polyethylene
HDT   Heat distortion temperature
HIPS   High impact polystyrene
IPN   Interpenetrating network
LCP   Liquid crystal polyester
LCST   Lower critical solution temperature
LDPE   Low density polyethylene
LLDPE   Linear low density polyethylene
MBS   Methyl methacrylate-butadiene-styrene terpolymer rubber
Mt   Million metric tons
NBR   Acrylonitrile-*co*-butadiene rubber
PA   Polyamide
PBAT   Poly(butylene adipate-*co*-terephthalate)
PBD   Polybutadiene
PBS   Poly(butylene succinate)
PBT   Poly(butylene terephthalate)
PC   Polycarbonate
PCL   Polycaprolactone
PCTG   Poly (cyclohexane dimethanol-*co*-ethylene glycol terephthalate)
PEI   Polyetherimide
PET   Poly(ethylene terephthalate)
PHB   Poly(hydroxybutyric acid)
PLA   Poly(lactic acid)
PMMA   Poly(methyl methacrylate)
POE   Polyolefin elastomer
POM   Polyoxymethylene

PP   Polypropylene
PPA   Polyphthalamide
PPE   Poly(phenylene ether)
PPS   Poly(phenylene sulfide)
PPSU   Poly(phenyl sulfone)
PSU   Polysulfone
PVC   Poly(vinyl chloride)
SAN   Styrene-acrylonitrile copolymer
SBC   Styrene-butadiene block copolymer
SBR   Styrene-butadiene rubber
SEBS   Styrene-ethylene/butane-styrene block copolymer
SMA   Styrene-maleic anhydride copolymer
SMMA   Styrene-*co*-methyl methacrylate polymer
TPE   Thermoplastic elastomer
TPO   Thermoplastic polyolefin
TPU   Thermoplastic polyurethane
TPV   Thermoplastic vulcanizate

Recycling Polymer Blends

20

Francesco Paolo La Mantia and Roberto Scaffaro

Contents

Abstract

Starting with the second half of the 1970s, polymer recycling was extensively adopted to reuse plastics otherwise destined for landfills with the goal to avoid the consequent net loss of money and energy. The simple idea to reintroduce scraps or post-consumer plastics in the processing lines actually revealed complications because even adding the recycled polymer to the same virgin material often led to secondary materials due to differences in the molecular weight, branching, and difference of density. The situation appeared more complicated in the recycling of commingled plastics. In this case, the chemical nature and

F.P. La Mantia (✉) • R. Scaffaro

structures of the different components produce secondary materials with poor properties, thus inhibiting any possible practical application. Nevertheless, enforcement of the law about mandatory collection of post-consumer plastic and the repeated economic crises pushed toward the implementation of recycling of polymer blends in industrial processes, especially if the same processing equipments/methods used for virgin materials can be adopted. In this chapter a review of the recycling technologies of plastic blends is presented. In particular, the mechanical recycling of single polymers in the same virgin materials (the so-called "homopolymer" blends), typical in the on-site reuse of industrial scraps, and, in another section, the strategies that can be pursued to recycle directly a stream of commingled post-consumer plastics to obtain secondary materials with properties suitable for practical applications are analyzed.

20.1 General Introduction

It is commonly accepted that material recycling is a consequence of the strong environmental movement that arose throughout the world in the second half of the 1970s. Actually, especially before the advent of the industrial age in the nineteenth century, a payback way to get raw materials was just recycling and reuse. With the rapid growth of mass-production industrial activities in the twentieth century – particularly during the economic boom of the 1960s – and the optimization of the processes, it was very cheap to produce items and it appeared much more economically advantageous to throw away old objects replacing them with brand-new ones. In the following, the repeated energy crises and the growth of an environmental consciousness for the invading and pollutant landfills induced industries to reconsider the throw-away politic toward a greener recycling one. Beyond metal, paper, glass, or other fine chemicals used in processes (catalysts, solvents), particular attention was paid to plastic recycling as plastic waste, probably much more than other materials, invaded and saturated landfills representing a net loss of money in terms of energy and raw materials (Andrews and Subramanian 1992; La Mantia 1993b; Brandrup et al. 1995; Scheirs 1998; La Mantia 2002).

The initial enthusiasm about the possibility to reprocess plastic waste, thus recovering the added value of the material, was frozen by the decrease – sometime dramatic – of the overall properties/performance of reprocessed plastic. Moreover, even adding recycled polymers to the same virgin material often leads to forms of incompatibility between the two, because of several reasons such as different molecular weights or branching levels, different size/shape of the scraps, different apparent density, and different crystallinity.

Of course, the situation is more complicated in the recycling of commingled plastics, like those coming from post-consumer household items or of polymer blends. In this case, in fact, the different chemical natures and structures of the multicomponent stream make it, in some cases, impossible to get materials that can

be still used for practical applications. Nevertheless, after an initial resistance both on the industrial and on the consumers' side, plastic recycling volumes are generally increasing from year to year, as a result of the implementation and optimization of processes and additives carried out by academia in conjugation with industrial needs, thus making recycled materials economically convenient and with performances fully accepted by the end users. The way to recycling is also accelerated by law enforcement on the mandatory collection of post-consumer plastics and about minimum amounts of recycled materials to be used to produce brand-new items.

From a technical–industrial point of view, recycling is generally referred to as a series of processing operations to obtain secondary materials that can be used to produce the same or different articles. It is evident that, when the segregation level in a mix of different plastic is high, the recycling operation will be simpler than in mixtures in which the single components coexist together. Moreover, while the preventive separation of commingled plastic is generally recommended to get secondary materials with better final properties, in some cases it is not possible or it is not economically advantageous to perform this kind of pretreatment.

This chapter will analyze the application of mechanical recycling technologies to polymer blends, describing the use of recycled materials as a blend's second component or the direct recycling of mixed plastic waste.

20.2   Basic Concepts on Plastic Recycling

Plastic recycling is a general procedure related to processing both for basic theoretical aspects and for applications. In particular, getting monomers from a waste polymer is, of course, a form of recycling (chemical recycling) as well as is incineration (in this case the energy is "recycled"). When discussing plastic recycling issues, people implicitly refer to mechanical recycling, i.e., to a class of processes able to transform waste into secondary materials. Usually, one of more steps of recycling occurs in the melt using equipment and know-how of the parent polymers forming the waste stream. The plastics targeted by mechanical recycling can be conveniently divided into two main categories:

– Mixed plastic from post-consumer mass household applications
– Industrial plastic scraps and post-consumer other than mass household

The first class includes films and sheets for packaging, thermoformed trays, bottles and jars, cookware plastic bags, and other accessories, generally single use or with a short life. Polyolefins and polyesters cover almost all the uses while polyamides are less represented. The second category refers to medium- to long-life articles such as car bumpers and interiors, furniture, and appliances. However in all the cases, it is more correct to look at the plastic recycling as a process regarding blends. The recyclates are materials with properties different from the original virgin polymers; even adding a recycled polymer to its corresponding parent – for instance, in the primary recycling of industrial scraps – generates a new material with new properties, often showing an antagonist effect between the two

components. This feature requires the use of specific additives (compatibilizers, surfactants, coupling agents) to overcome this problem and get a material valid for the preparation of brand-new articles. This is more evident when reprocessing together different polymers such that, without an adequate compatibilizing system, a new material is obtained with very poor properties and often unusable for further applications.

Another important role is played by the degradation of plastic both prior to recycling and during recycling operations. This issue is, of course, even more dramatic for polymer blends (La Mantia 1992). During their first forming process, plastics undergo thermo-mechanical degradation, and during their lifetime they are degraded by the combined effect of humidity, UV light, chemical oxidation, and other environmental factors. Degradation effects are generally more intense in multiphase polymeric systems with obvious consequences on the properties of the secondary materials. To counterbalance the negative effect of degradation occurring during the first processing, the lifetime, and the second processing, it is necessary to add stabilizing systems and, in some cases, change the processing conditions with respect to those adopted for the parent polymers. In fact, beyond a simple chain scission causing the decrease of the molecular weight, degradation may induce other relevant changes in the molecular weight distribution, in the formation of short- and long-chain branches, in the chemical composition (appearance of oxygenated groups or unsaturations). When these changes are important, only milder processing conditions and appropriate additives will allow one to obtain good secondary materials.

In the recycling of polymer blends, another important issue is the difference of the melting points of the different components. Of course, the reprocessing temperature must be set as high as necessary to process the highest melting point material, but this temperature can be too high for lower melting point materials, with a sharp increase of the degradation rate, which is difficult to manage.

The problems of recycled materials do not end with processing. Compatibilizers and stabilizers are necessary to obtain secondary materials with adequate properties, but they must also protect the new objects made from secondary materials from environmental degradation during the second life of plastic. Similar to what occurs during processing, recycled plastics are often "weaker" if compared with the virgin components. As a consequence, the additive system must take into account not only the accelerated thermal and thermo-oxidative degradation typical of plastic reprocessing, but also the higher sensitivity of the secondary materials to environmental degradation.

Another important need when recycling mixed plastic is to ensure adequate mixing. In fact, while in single polymer processing or reprocessing this is not a relevant parameter, in multiphase systems having a fine dispersion of the different phases, it is critical to achieve good final properties. Increasing the mixing speed, of course, will cause an increase of cost but also an intensification of mechanical degradation processes. Therefore, the compatibilizing system, the stabilizing additives, and the processing conditions must be strictly integrated and designed for a successful recycling operation.

A possible answer to these issues could be the preventive separation of the different plastics prior to processing. Actually, since recycling has attracted the interest of industry, the separation processes are becoming more numerous and efficient achieving almost total segregation of the different plastic fractions. However, despite the improvement of the effectiveness of the pretreatment steps, there is still the possibility to find other polymers as contaminants in a main stream, and even at those low amounts, they can disturb the regularity of the recycling operation.

In some situations, the recycled plastic is voluntarily added to a virgin material to form a sort of hybrid virgin-recycled blend. This practice is common for recycling of plastic scraps forming homopolymer (also known as monopolymer) virgin recycling blends, but when applied to heteropolymer virgin-recycled blends, it is possible to obtain good materials, thereby widening the possible uses of plastic wastes.

The above considerations indicate that recycling is far from being close to a final optimization typical of mature processes. Knowing the processing–properties–structure relationships, essential in polymer science, is much more complex in plastic recycling where the number of variables is higher and rarely the streams can be considered composed by a single material. In the same direction, the investigation of the behavior of recycled commingled plastics is particularly attractive both from a scientific and from an industrial point of view as a comprehensive method regarding the reuse of mixed post-consumer objects would imply lower costs and easier waste collection.

20.3   Recycling of Commingled Plastics

20.3.1 With a Compatibilizing Method

While a generic stream of mixed plastics may have a variable composition both in the kind and in the amount of each single component, municipal waste streams consist of three types of polyethylenes (HDPE, LLDPE, LDPE), PET, and, in lower amounts, PP, PVC, PS, and polyamides. In this case, the processing temperature of the whole stream must be as high as that necessary for melting the PET and PP fractions with the consequent need to protect other thermosensitive fractions like PVC, PS, and the polyethylenes. Of course, an appropriate compatibilizer must be used to improve the phase adhesion and dispersion between all these polymers that form highly incompatible systems. One of the first materials used as general compatibilizing agent was chlorinated polyethylene (Paul et al. 1972, 1973a; Park et al. 1996a) followed by several other polymers modified with carboxyl or other polar groups, styrene block copolymers (Paul et al. 1973a; Nosker et al. 1990; La Mantia 1992b, 1993b; Hope et al. 1994; Xanthos et al. 1994, 1995), or maleated polymers (Martinez et al. 2008). The main effect of adding such compatibilizers is a general improvement of the mechanical properties and especially of impact strength and elongation at break. Even if the effects of PVC degradation were

difficult to control with the typical yellowing of the recycled materials, UV irradiation prior to processing was found helpful in forming more compatible blends due to the formation of oxygenated groups that generated in situ compatibilizer copolymers by reactive processing (Martinez et al. 2008).

In another study (Equiza et al. 2007) SEBS/EPR and SBR/EPR were used as binary compatibilizing systems of a mixed PE/PP/PS/HIPS stream. In the same study, beyond the effect of the presence of the compatibilizers, the important effect of the processing conditions in relationship with the final properties was also investigated. It was found that the best parameters set for the whole system are 190 °C, 14 min processing, and 3.5 % of SEBS/EPR. This was found to be more effective than using SBR/EPR. The mechanical properties are better in the presence of the compatibilizing system as well as the morphology that was modeled as a couple of two co-continuous phases containing PE/PP and PE/PS with a small amount of a secondary PP/PS phase. The morphological results were consistent with the PE/PP/PS theoretical ternary phase diagram with the compatibilizer granting good adhesion between the different phases. A similar system composed by HDPE/PP/PS/PVC commingled waste, with HDPE as major phase, was melt reprocessed in the presence of CPE, SEP, or a mix of the two as compatibilizing agents (Ha et al. 2000). The tensile strength was found slightly decreased, but CPE, SEP, or their combination caused an evident increase of the impact strength. The best morphology in terms of adhesion was shown by the CPE/SEP-added blends, while the SEP-containing ones showed the highest values of impact strength. Interestingly, the elongation at break of the recycled materials did not change by the addition of any of those compatibilizers. CPE was also found to be an effective compatibilizer for post-consumer HDPE/PVC blends (Park et al. 1996a) that show improved interfacial adhesion and superior ultimate stress if compared with uncompatibilized blends. Moreover, EPDM and EPM were successfully used in the recycling of LDPE/PP blends (Bertin and Robin 2002; Fortelny et al. 1996, 2002; Nedkov et al. 2008). These additives have a sharp positive effect on properties such as microhardness, elongation at break, and impact strength and show even better properties when PE-g-MB graft copolymer or liquid PB or PB-MA was used. The first reprocessing is usually protected by the presence of residual antioxidants, while further processing may induce significant changes in the blend (Santos et al. 2001). Adding EVA copolymer to the blend allowed increasing the maximum tolerated PP concentration in order to keep unaltered the impact strength of a recycled LLDPE/LDPE/PP blend.

In other situations, it can be decided to add no compatibilizers/modifier considering the natural chemical affinity of the two components. This is the case of PC/PBT blends that were aged and then reprocessed at 275 °C (Sanchez 2007). The recycled materials showed a significant increase of the elongation at break, while reprocessing did not affect the modulus and the tensile stress despite the likely occurring chain scissions due to thermal degradation. A similar approach was chosen for recycling PC/ABS blends (Reig et al. 2007). In particular, the effect of the different variables was studied using a statistical model applied to an injection molding processing. ABS was kept as a major phase, while PC was added

up to 10 % in order to simulate the presence of this second polymer as contaminant of the main ABS stream. It was found that amounts of PC added as small as 5 % do not imply significant change in the optimum processing conditions compared with 100 % ABS, while at higher PC content the change becomes significant. PC/ABS blends are often found as post-consumer plastic from dismantled cars. PA and PMMA, with the latter coming from taillight, can be present as minor phase/contaminants (Liu and Bertilsson 2000). The use of impact modifiers provides the mixture with better impact properties than any of their individual components. However, PA is highly incompatible with the other polymers – especially if filled with glass fibers – and should be either sorted out of the stream or compatibilized with maleated derivatives such as SEBS-g-MA (Liu et al. 2002; Liu and Bertilsson 1997) that are specifically appropriate to increase the compatibility between ABS and PA6. In any case, the use of maleated rubber led to an increase of the impact strength of the recycled materials. For this system, the use of antioxidants or metal deactivators during the melt reprocessing does not help the recyclates to show better mechanical properties.

If recycling mixed plastic waste can be complicated, when cross-linked fractions are present, the complication level can drastically increase. Attempts were made to recycle mixed plastic waste containing ground tire rubber and post-consumer films from greenhouses (essentially LDPE, LLDPE, and small amounts of EVA and additives) (Scaffaro et al. 2005). In this case, mixed film/rubber blends with different compositions were extruded at high temperatures (up to 300 °C) to induce the chemical de-structuration of the rubber cross-links and at high processing speed (up to 300 rpm). The blends show fairly good properties provided that low GTR concentration (no more than 25 %) and high processing temperature are adopted. However, some good mechanical performances of the blends must be attributed to a sort of filler-like effect due to the partial carbonization of the rubber phase. This approach for treating cross-linked rubbers was followed by several other authors (Grigoryeva et al. 2005; Sonnier et al. 2007; Mészáros et al. 2012; Montagna and Santana 2012; Gugliemotti et al. 2012; Karger-Kocsis et al. 2013) with good results in terms of morphology and mechanical performance. Polyurethane foams are also cross-linked systems that are difficult to reprocess. Blends of PU foam-backed PVC sheets for soundproof applications were reprocessed to obtain materials to be used as PCV plasticizers or modifiers (Grigoryeva et al. 2005). The process occurs in an extruder, where the PU–PVC grains are de-structured, partially destroying the PU phase and preserving the PVC backbone. Monoethanolamine and potassium acetate at temperature of up to 200 °C were used as destructing agents for PU, while the protection of PVC was ensured by the residual stabilizers contained in it. Similar to the recycling of the cross-linked rubber, it was found that the processing temperature plays a vital role in the compatibility of the two components, with an increment of the PU segments mobility and of their compatibility with PVC segments.

A promising technique to obtain good secondary materials from mixed plastic with modifier-free processes is to change the micromorphology of the blend. HDPE/PET blends where recycled in the presence of a stabilizer aiming to get

a particular new morphology without adding other modifiers or compatibilizers (Jiang et al. 2007). More in detail, PET and HDPE were first processed by extrusion with a top temperature of 270 °C and then they were hot-stretched in the molten state to promote the formation of microfibrillar PET within the HDPE main phase and immediately quenched to freeze this morphology. After this stage, they were further processed to get the final object and in this phase the initially aligned PET fibrils formed a random network losing the orientation but keeping the fibrillar shape. The materials prepared in this way showed higher yield stress and unchanged modulus, while in the conventionally reprocessed material these values are lower. Another study (Yam Kit et al. 1998) investigated the optimization of the processing conditions and particularly on the blending temperature, demonstrating that when it is in the range 235–265 °C, modulus and tensile stress have a maximum, while the impact strength is the lowest. In particular, an interesting correlation between the processing temperature and the domain sizes was found which decrease significantly when the temperature is higher. However, when processing PET/polyolefins blends, the use of a compatibilizer always leads to better properties. Several studies on recycled PET/HDPE blends (Ballauri et al. 1993; Pawlak et al. 2002a, b, 57A; Pluta et al. 2001; Park et al. 1996b) demonstrated, in fact, that compatibilizer such as SEBS-g-MA, HDPE-g-MA, or EGMA up to 10 phr led to a dramatic improvement of the morphology and to an increase of the ductility and of the impact strength. Beyond the compatibility, in some cases, e.g., PP/PET, the necessary high processing temperature for PET and the thermosensitivity of PP may cause a dramatic loss of properties of the secondary materials. Multilayer PP/PET/silicon oxide (SiOx) films used for gas barrier applications were reprocessed with and without PP-g-MA as compatibilizer (Wyser et al. 2000). The recycling operation consisted in two steps: (i) extrusion at moderate temperature (maximum 245 °C in the melting zone) followed by cooling and pelletization and (ii) injection molding with a top temperature of 260 °C. While SiOx particles, even if they changed dimension due to the reprocessing steps, did not affect the mechanical behavior of the recyclates, the effect of compatibilizer was dramatic. The tensile strength as a function of the compatibilizer content is reported in Fig. 20.1. It can be clearly seen that at low compatibilizer amounts the effects are negligible, while at higher contents (5–10 %) the tensile strength sharply increases to values up to ten times those measured for the uncompatibilized blend.

The reason for this behavior may be found in the morphological changes induced by the compatibilizer. At low PP-g-MA content, there is only a decrease of the PET phase domains with respect to the uncompatibilized PP/PET blends, Fig. 20.2a–c. At concentrations of compatibilizer as high as 5–10 %, beyond a further reduction of the PET particle size, the increase of adhesion between the two phases can be observed, Fig. 20.2d, e. This adhesion is supposed to be responsible for the propagation of the cracks through the phases rather than around the particle edges with consequent increase of the ultimate stress. Further increasing the PP-g-MA concentration to 20 % weakens the interface, with the cracks that go again around the particle edges and not across them.

Fig. 20.1 Strength of the recycled PP/PET/SiOx as a function of the compatibilizer content (Taken from Y. Wyser, Y. Leterrier, J.-A.E. Månson, Effect of inclusion and blending on the mechanical performance of recycled multilayer PP/PETSiOx films, J. Appl. Polym. Sci. **78**, 910 (2000); Fig. 6. Copyright © 2000 John Wiley & Sons, Inc. Reproduced with permission)
This example makes clear how determinant is the knowledge of the relationships between processing–properties–structure and morphology to control the final performance of the secondary materials. Also PP/PA blends suffer the same thermal incompatibility and need an adequate compatibilizing system that, however, may not be sufficient to grant good properties to the secondary material. In fact, when using PP-g-MA or PP-g-AA copolymers as compatibilizer for that blend, an improvement of the mechanical performance is observed. However, when the blend is reprocessed several times, the degradation effects prevail over compatibilization and a decrease of the ultimate properties occurs (La Mantia and Capizzi 2001). A SEBS-based compatibilizer (SEBS-g-MA) was used for the compatibilization of post-consumer PP/PA blends coming from packaging (Kim et al. 2007). Different from the previous systems, the SEBS rubber contains a reactive functional group (maleic anhydride) that is able to produce, during processing, copolymers with the PA fraction thus enhancing the adhesion between the phases. The morphology was found significantly improved in terms of phase adhesion and dispersion with an increase of impact strength of about three times with respect to the uncompatibilized blend. This effect is correlated with the concurrent improved adhesion to the rubbery state of SEBS-g-MA rather than other maleated compatibilizers (PP-g-MA, PE-g-MA) or neat SEBS, which did not induce significant change of this property.

Reprocessing was found to be effective also in PP/EPDM blends (Lee et al. 2012). In this case, the rubber particles in the PP matrix are progressively smaller with positive influence on the mechanical properties. Moreover, the interfacial tension, estimated by using Palierne and Choi–Schowalter models, was lower in multiple processed materials.

In the same line of recycling plastic waste without the aid of compatibilizers, the family of homogenization and solid-state pulverization processes can be found (Daren 1998; Dubrulle D'Orhcel 1993; La Mantia et al. 1996; Khait et al. 1999; Khait et al. 2001) essentially based on the fractionation of plastic waste into fine particles and formation of cross-polymers induced by shear activated reactions that
Fig. 20.2 Morphology of the rupture surface of the reprocessed PP/PET/SiOx material at various compatibilizer weight fractions: (**a**) 0 %; (**b**) 1 %; (**c**) 2 %; (**d**) 5 %; (**e**) 10 %; (**f**) 20 % (Taken from Y. Wyser, Y. Leterrier, J.-A.E. Månson, Effect of inclusion and blending on the mechanical performance of recycled multilayer PP/PETSiOx films, J. Appl. Polym. Sci. **78**, 910 (2000); Fig. 7. Copyright © 2000 John Wiley & Sons, Inc.)

create a self-compatibilized blend as output. One of these processes, by Newplast, is based on mechanochemical reactions that break mixed-waste polymer backbones at thermodynamically weak points (S–S, O–O bonds), double bonds, cross-links, and entanglement points. The commingled plastic waste is initially shredded and rid of eventual metal fractions and then fed to the homomicronizer – a steel chamber containing a high-speed mechanical rotor with blades – in which the residence time is about 1 min. The resulting alloy is extruded, filtered, degassed, cooled, and pelletized, ready to be used as secondary material. The recycled material shows an
Fig. 20.3 Tensile strength, elongation at break and impact energy as a function of the dose (Reprinted from J.C.M. Suarez, E.B. Mano, Characterization of degradation on gamma-irradiated recycled polyethylene blends by scanning electron microscopy, Polym. Degrad. Stab. **72**, 217 (2001); Fig. 1 with permission of Elsevier. Copyright © 2001 Elsevier)

unprecedented ductility (elongation at break may be 33 % higher than virgin HDPE) and tensile strength together with a fine morphology with small particle dimensions and very high adhesion. Other versions of this kind of technology consider the use of additives to obtain even better performing materials (Mital 1996).

LDPE/HDPE recycled blends, despite the similar chemical structure, show a pronounced incompatibility strongly dependent on which one of the two is the major phase (Laguna et al. 1989), thus needing compatibilizing agents like CPE or EVA to improve the interface adhesion (Laguna et al. 1988). An alternative additive-free method to increase the compatibility between two incompatible phases is the use of gamma irradiation. It was found that increasing the irradiation dose causes a net increase of impact strength, Fig. 20.3, which levels off beyond 1,000 kGy, a moderate increase of the ultimate stress, and a decrease of the elongation at break (Suarez and Mano 2001; Patel and Keller 1975; Aslaniam et al. 1987; Moad and Windzor 1998; Suarez et al. 1999; Suarez and Mano 2000; Suarez et al. 2000a, b). An increment of the mechanical properties was observed in postirradiated GTR/LDPE blends, especially when EVA is added to the system (Mészáros et al. 2012). The mixed plastics were melt processed and then irradiated to obtain the final material that shows mechanical performance generally better than that nonirradiated and even better when high amounts of EVA (up to 30 %) are added.

Another interesting approach to recycling is the upturn of the concept of recycling from downcycling (i.e., a process that yields materials with generically
Fig. 20.4 Improvement of molecular and mechanical properties of reclaimed PA66 by using a repairing stabilizer (Taken from R. Pfaendner, H. Herbst, K. Hoffmann, Innovative concept for the upgrading of recyclates by restabilization and repair molecules, Macromol. Symp. **135**, 97 (1998); Fig. 10 with permission of Elsevier. Copyright © 1998 Elsevier)

inferior properties) to upcycling (La Mantia 2004) and the possible totally closed loop of reuse of plastic waste (La Mantia 2010). In this sense, the use of appropriate additives (stabilizers, compatibilizers, impact modifiers, etc.) can be intended as repair and enhancement of the properties rather than limiting their loss. One of the first attempts in this direction was carried out in the late 1990s (Pospisil et al. 1995; Pfaendner et al. 1995; Pfaendner et al. 1996, 1998) with the use of nitroxyl-based stabilizers that acted as repairing agent for chain scission with significant positive effects on several polymeric materials such as HDPE, LDPE, ABS, and PA66 and blends such as PE/PP, PE/PA6, and PBT/PC or composites containing carbon black. In Fig. 20.4 the improvement of some molecular and mechanical properties by using a repairing additive is evident (Pfaendner et al. 1998).

These concepts were taken back later in some studies regarding the rebuilding of post-consumer polyethylene (Scaffaro et al. 2009; Scaffaro et al. 2006; Chaudhary et al. 2007) in which nitroxyl-based compounds were used as radical generator, in conjugation with peroxides or other coupling agents (e.g., EGMA), observing an upgrading of the properties of the reclaimed materials in terms of rupture properties and of impact and tear resistance. The same approach was used in the recycling of post-consumer polyethylene blends coming from pipes (PCP), stabilized with CGX CR946, an hydroxylamine derivative (Scaffaro et al. 2007) prepared in the frame of the studies reported in Pfaendner et al. (1998) as an alternative to classic peroxide compounds. The rebuilding effect is well evident even at the lowest additive concentrations. In Fig. 20.5 (Scaffaro et al. 2006), the viscosity curves are reported
Fig. 20.5 Flow curves of as-received PCP and of PCP with and without CGX processed at 190 °C (Taken from R. Scaffaro, F.P. La Mantia, N. Dintcheva, Effect of the additive level and of the processing temperature on the re-building of post-consumer pipes from polyethylene blends, Europ. Polym. J. **43**, 2947 (2007); Fig. 2 with permission of Elsevier. Copyright © 2007 Elsevier)

as a function of frequency obtained at 190 °C in a parallel plate rheometer. PCP simply reprocessed with no additive shows a viscosity lower than that of as-received PCP due to some thermal degradation during processing. Adding 0.1 % of CGX causes a sharp increase of the melt viscosity, especially in the low-frequency region, and this phenomenon becomes more and more pronounced on increasing the CGX amount added to the blend. This rheological behavior can be explained considering the structural modification of the polyethylene phase in the presence of the nitroxyl compound. In brief, CGX forms nitroxyl radicals that induce the formation and subsequent recombination of free radicals to form branched and cross-linked structures. This structural change causes, of course, a change in the mechanical behavior. At lower additive concentration, the rebuilding causes an increase of the elastic modulus and of the ultimate properties. Above 0.2 % however, the increase of the cross-linked/branched fraction causes a progressive loss of deformability with worsening of the mechanical performance.

20.3.2 With the Formation of Composites

An interesting way to manage mixed plastic waste is to use it as matrix for composite materials. In this way it is possible to reinforce the otherwise poor secondary material with the potential side advantage of reducing the overall environmental impact by using natural fillers or fibers that can also be chemically

treated or added in the presence of a coupling agent to further improve the interaction with the polymeric matrix.

This method led to good results in the recycling of blends of LDPE/LLDPE coming from milk pouches (Choudory et al. 2007). In that case, coir fibers were added to the blend obtaining materials with properties only slightly inferior to those of the respective virgin materials. When pretreating the fibers with maleated styrene, the mechanical properties further improve together with the thermo-oxidative stability. On the other hand, the presence of natural fibers causes a dramatic increase of humidity sensitivity with obvious negative consequences on the mechanical performance.

Another study regarding composites based on natural filler and a mixed polymeric matrix focuses on the effect of reprocessing on the final properties (Lou et al. 2007). In particular, PET and PP have been blended, added with bamboo charcoal, and reprocessed up to three times to obtain extruded or injection molded materials. Injection molded samples showed the best mechanical properties, and the materials added with bamboo charcoal maintained almost the same mechanical properties even after three cycles of processing. For this system, however, the amount of PET plays a vital role in determining the behavior of the final composite as if it is above 20 %, the phase separation between the PP and the PET phase is predominant on the reinforcing action of the filler.

Other interesting results were found by adding cellulose compound to a commingled plastic stream containing HDPE, PP, PS, and PVC (Sik Ha et al. 1999); in this case a maleated rubber (SEBS-g-MA) was found to promote the compatibility between the phases and to enhance the mechanical performance, the thermal stability, and the aging properties. More in detail, adding 20 % of cellulose together with as low as 5 phr of SEBS-g-MA caused a doubling of the tensile strength that maintained approximately the same values even after 6 months aging at 100 °C.

One of the most appealing challenges in plastic recycling is managing complex systems such as Tetra Pak®. This material is a multicomponent layered composite made of paper, aluminum, and LDPE, with the latter two being kept together by a layer of an ethylene–methacrylic acid copolymer (EMAA). The paper part can be easily separated with water while the LDPE–EMAA–Al (PEAL) part must be processed together. Some authors (Lopes et al. 2004, 2006) studied the properties of directly reprocessed PEAL that is used as self-reinforced material as LDPE acts as a matrix, Al as the filler, and EMAA as coupling agent between the two. In another case (Lopes et al. 2006), PEAL was used in conjugation with another waste stream, i.e., PET coming from beverage bottles. The micromorphology of the composites put into evidence a good adhesion between the polymer and the aluminum, and the mechanical properties are consequently good. When PET is added to the system, impact strength and elongation at break decrease, while the elastic modulus is superior to the corresponding PET/LDPE blend from virgin polymers. In this case, the phase discontinuity of aluminum particles promotes crack propagation thus reducing the ultimate and impact

properties and suggesting, for these materials, use that can exalt the presence of the metallic phase such as in applications requiring thermal or electrical conductivity.

20.4   "In Blend" Recycling

20.4.1 With the Same Virgin Polymer (Homopolymer Blends)

The reuse of plastic scraps in the same processing line is a common industrial practice to reemploy materials with high purity otherwise destined for a landfill, with loss of money and negative environmental impact. It is well established, however, that recycled polymers have inferior properties compared with the virgin counterpart, with a magnitude depending on the chemical nature of the polymer, on the processing conditions, and on the number of reprocessing cycles. Of course, such blends must guarantee the same set of properties of the virgin material or, if they are lower, that the properties are still compatible with its final use.

Despite the chemical nature of the two components of the blend being theoretically similar, the processing may significantly change both the structure (e.g., from linear to branched polymer) and the composition (e.g., introduction of unsaturations or oxygenated moieties) that can prevent the formation of a homogeneous material. Moreover, on reprocessing, the recycled material is more sensitive to degradation and it is often necessary to use a stabilizing system that, of course, must be taken into account in the overall cost of the operation. In this direction, small amount of specific inorganic filler can be added to preserve both the material performance and the economic impact (1B, 94B). In some other cases, beyond the stabilizers, even a compatibilizing system must be added to overcome the incompatibility that arises between the virgin and the recycled polymer. When the use of recycled materials needs too expensive additives, the only way to reuse scraps is to decrease their amount in the blend. On the other hand, when the separation from other plastics is relatively easy, the recycling of post-consumer objects in homopolymer blends may have advantageous industrial applications. This is the case, for instance, of polyolefins (PE, PP) widely used for bottles, films, and packaging.

It was found (Sánchez-Soto et al. 2008) that the introduction of moderate (up to 20 wt%) amounts of HDPE from bottles or injection molded parts to virgin HDPE did not cause relevant changes in the mechanical behavior and better results were obtained adding small quantities of talc. In particular, the composites with r-HDPE showed higher deformation and energy absorption in impact tests especially when the provenance was post-consumer bottles. In any case, the results suggest that the conditions of r-HDPE and the reprocessing parameters generate a homogeneous material. Other authors (Ramırez-Vargas et al. 2006) found that homopolymer blends of r-HDPE/HDPE are substantially a single phase material even at high concentration of r-HDPE (70 wt%) even if a progressive drop of ductility is observed. This phenomenon in polyethylenes is common and due to structural changes that can go

from short-/long-chain branching to cross-linking. In this latter case, the recycled polymer tends to be brittle but adding EVA as modifier (3 %) can bring the mechanical properties back to those observed for virgin HDPE. In any case, the use of virgin polyethylene in blend with recycled polyethylene (also mixed) can guarantee mechanical properties comparable with that of the fresh material.

Recycled materials are often associated with scraps or mass consumer end-life appliances, but an important source of secondary materials comes from agricultural applications. Greenhouse covers are made of polyolefins that undergo a slight degradation during processing but a strong photodegradation during their use. It is well known that a photosensitive component in a polymer blend may sensitize the whole material (La Mantia 1986; La Mantia and Curto 1992; La Mantia 1992; Al-Malaika 2002), thus requesting a specific photostabilizing system for the corresponding monopolymer blends (La Mantia and Dintcheva 2004; Herbst et al. 1992; Pospisil et al. 1995; Pfaendner et al. 1995, 1996; Pospisil et al. 1997; Dintcheva et al. 1997; Pfaendner et al. 1998; Herbst et al. 1999; Kartalis et al. 2000a, b, 2001; Papaspyrides et al. 2001; Pfaender 2001). In this case, in fact, the recyclate behaves as a pro-degradant as the oxygenated groups generated by UV irradiation during the lifetime act as chromophore promoting further photodegradation processes. Commonly, a progressive embrittlement of the material and changes in the crystallinity are observed, especially if the new item is thin (below 1 mm) as the degradation rapidly advance from the skin to the core.

Blends of different r-HDPEs coming from post-consumer objects were prepared in order to obtain specific rheological properties and in particular to control the melt flow index (MFI) aiming at the control of the reprocessing operations (Brown et al. 2010). In another case (Miller et al. 2001), an attempt was made to correlate the relative shear viscosity and the relative stiffness of blends of r-PEs coming from different sources/applications. It was found that the difference of viscosity and stiffness are strictly related to factors such as branching content/length and nature of any side unit. With the same aim, morphological measurements with polarized optical microscopy and SEM were used to generate a model that was used to develop both processability windows and optimum blend conversion costs for a given balance of properties (Adewole et al. 1994).

Another plastic typically present in post-consumer waste streams is PET. This material can be advantageously recycled in homopolymer blends by extrusion, injection molding, spinning, or a combination of different processes. It was found (Pattabiraman et al. 2005) that adding r-PET causes a worsening of the mechanical properties, especially at high temperatures, but another study (Aldi 2010) reports that blends prepared by extrusion showed properties very similar to virgin PET after the addition of up to 50 wt% of r-PET. On the contrary, when injection molding is followed by injection molding, the differences are more relevant, likely due to the more intense degradation phenomena.

Beyond the composition of the homopolymer blends, also the processing conditions are essential for determining the behavior of the materials. In this view, it was reported (La Mantia and Scaffaro 1997) that the rheological and mechanical properties of blends of PET and r-PET remained very close to that of the virgin

material provided that a careful drying is carried out before any melt operation. However, even if the homopolymer blends generally showed properties between those of the two components, when the concentration of the two kinds of PET is almost the same, minima in the property–composition plot were observed. In this case, therefore, by a careful drying and the use of small amounts of r-PET, it is possible to obtain materials with properties substantially equal to those of virgin PET without the use of any other additive, with obvious positive impact from the industrial point of view.

Among the engineering plastics, ABS is widely used in electrical and electronic equipment, in the automotive industry, and in telecommunication instruments. Usually, the recycling of these materials causes only slight changes of the mechanical properties unless a high number of reprocessing cycles (more than 10) is applied (Scaffaro et al. 2012; Brennan et al. 2002; Kim and Kang 1995; Boldizar and Moller 2003; Bai et al. 2007; Karahaliou and Tarantili 2009; Arnold et al. 2009; Boronat et al. 2009; Pérez et al. 2010). However, adding r-ABS to virgin ABS causes different outcomes depending on the property, on the number of reprocessings, and on the amount of r-ABS of the blend. The rheological measurements showed that the viscosity of ABS blends was not substantially different by virgin ABS up to two reprocessing steps. Indeed, the third reprocessing cycle induced a slight decrease of the viscosity of all the blends. Up to two reprocessing steps and the presence of r-ABS did not influence significantly the HDT values of the materials. The tensile properties of ABS/r-ABS blends decreased during the first reprocessing, even by adding the smallest amount of r-ABS. Further increase of PC/ABS amount or further reprocessing did not cause significant changes. This was explained as a results of a balance between the opposite degradation effect of chain scission and cross-linking of the PB phase. On the contrary, the flexural properties were almost unaffected by the r-ABS amount and only slightly influenced by the number of recycling operations. The impact resistance significantly decreased both by adding r-ABS and by increasing the number of reprocessing steps. The worsening of this property was correlated with the photodegradation of the PB phase of r-ABS and further thermal degradation during the reprocessing.

Polyamide homopolymer blends were also studied (Scaffaro and La Mantia 2002) by changing humidity of the material and the presence or not of a stabilizer. Neither dry nor wet stabilized polyamide samples showed significant variations of the molecular weight even if the melt Newtonian viscosity is slightly different from that predicted with the rule of mixtures, despite the same chemical nature of the two components. This holds also even more for humid stabilized samples as its noticeably lower molecular weight implies values lower than those expected on a linearity basis. The situation is different for the mechanical properties. The morphology in the solid state determines a more rigid and brittle material, compared to the pure components, with relevant deviations from linearity for all the recycled samples used to prepare the blends. The blends containing dry and wet stabilized recycled PA6 showed almost the same behavior confirming the reduced degradation of these samples.

20.4.2 With Polymers Different from the Recycled One

As already said in the previous section, when the separation of plastics is simple, it could be extremely convenient to prepare homopolymer blends. When this is not possible or is economically disadvantageous, the polymers are recycled together or used as component in blends with virgin polymers different from the recycled one.

Polyolefins represent more than half of the whole polymer production and therefore their recycling attracts the interests of both industry and academia. The simple reprocessing of polyolefin waste leads to products with low mechanical properties because these polymers are frequently incompatible and contaminated by impurities (Mano et al. 1994). These features are evident even in blends between polyethylenes with different chemical structure (e.g., LDPE, LLDPE, HDPE) and can lead to extremely bad quality materials when processing different polyolefins like PE/PP. In this case, beyond the incompatibility of the couple, the strong thermal degradation sensitivity of PP and the higher density with respect to PE causes loss of the mechanical performance. The use of recycled HDPE in blend with PP was found to accelerate the degradation process at concentrations of r-HDPE higher than 20 % (Albano and Sanchez 1999; Albano et al. 1998), and the same threshold was found critical in terms of compatibility of the polymer couple. The incompatibility was demonstrated also by calorimetric tests (Madi 2013); blends of virgin PP and r-HDPE show two distinct peaks in differential scanning calorimetric tests, confirming the essentially biphasic nature of these blends. Moreover, the presence of PE disturbs the formation of PP crystallites thus causing lower crystallinity and worse crystal quality. Of course, the lack of compatibility has direct consequences on the morphology (gross, with evident separated domains of the two components) (Albano and Sanchez 1999) and on the mechanical properties that are far from the theoretical ones of the rule of mixtures (Madi 2013). The situation is better using EPDM, EPM, or PE-g-(2 methyl butadiene) copolymers as compatibilizing agents (Albano and Sanchez 1999; Albano et al. 1998; Bertin and Robin 2002). In this case the properties of the recycled blends are suitable to applications requiring good mechanical performances, but, of course, the costs of the operation are higher. Actually, an attempt was made (Bonelli et al. 2001) to compatibilize the blend with r-PP extracted by floatation. It was found that PP exposed to random/noncontrolled outdoor conditions provided spontaneous non-oxidative chemical modifications that brought a certain compatibilization action to the PE/PP blends.

Another system that attracts the interest of both industry and academia is PET with polyolefins. The two materials are completely different considering the synthesis method, the structure, the polarity, and the degradation behavior. This latter feature is maybe the most important aspect that must be controlled during reprocessing. PET generally undergoes hydrolytic degradation that results in poor mechanical properties, while polyolefins, especially PP, are extremely sensitive to high temperatures thus making complicated the contextual recycling as requested, for instance, for the heavy fraction of urban waste or in the recycling of caps and

bottles. On the other hand, the presence of polyolefins may have positive influence on processing and on the impact behavior of PET.

Some authors (Inoya et al. 2008; Inoya et al. 2012) studied the effect of the compatibilizer level (SEBS) on the mechanical properties of r-PET/PP blends. The addition of up to 15 phr of compatibilizer resulted in a size reduction of the dispersed phase, while a slight increase in density suggested an improvement on interfacial interactions. As expectable, adding the SEBS rubbery compatibilizer caused an increase of ductility and impact resistance. Since 15 phr of compatibilizer is a too high amount in terms of costs, another way is to change the PP molecular weight (Inoya et al. 2012). In this case, lower molecular weight PP helps with the diffusion of the compatibilizer inside the melt and the maximization of its concentration at the interface, allowing the reduction of the compatibilizer amount.

Blends based on r-HDPE and r-PET were prepared by reactive extrusion in the presence of PE-g-MA as compatibilizer, 4,4′-methylene(phenyl isocyanate) (MDI) as PET chain extender, and SEBS as toughening agent were prepared by high shear mixing (5,000 rpm). Only 2 % of PE-g-MA allowed improving the compatibility of the blends toughened with SEBS. In particular, when r-HDPE is the major phase (70 wt%), the maleated additive causes a significant reduction of the domain size (in the range of micron) with a consequent sharp increase of the impact strength. When r-PET is the major phase, the ultimate and the impact strength were improved by adding MDI through the extension of the PET molecular chains. r-HDPE and r-PET influence each other during crystallization and the presence of PE-g-MA or SEBS reduces the crystalline level of either r-PET or r-HDPE. Excess of MDI did not influence crystallization behavior of r-HDPE while reducing that of r-PET. MDI was also found to increase the thermal stability of the r-HDPE-based blend.

r-PET can be also used either with specific additives/modifiers or in conjugation with other engineering polymers (e.g., PA6, PC). r-PET from fabrics was melt blended with PA6 in the presence of LLDPE-g-MA as compatibilizing promoting agent (Jeziórska 2006). The interfacial adhesion was found improved as well as the static and impact mechanical properties: LLDPE-g-MA bridges the polyester and the polyamide forming in situ copolymers r-PET/LLDPE-g-MA/PA6 that locate at the interface acting as compatibilizers. The same modifier (LLDPE-g-MA) was used alone to improve the properties of r-PET also by adopting a low-temperature solid-state extrusion that consists in processing the r-PET above the cold crystallization temperature but slightly below the melting temperature (Zhang et al. 2008). The use of lower processing temperature allows reducing the hydrolytic degradation or r-PET, while the maleated polyethylene improves the ductility with a level-off above 10 wt%. FTIR demonstrated that r-PET and LLDPE-g-MA formed copolymers and SEM confirms that the adhesion between the two phases is excellent. PET/PC blends from post-consumer bottles show mechanical properties that are better than the respective pure component and similar to those of virgin PET (Fraısse et al. 2005). The presence of PC was found to improve the processability of the blend that needs to be extruded to achieve the desired properties. It cannot be excluded that the two recycled polymers react in the melt forming copolymers that are compatibilizers for the blend.

However, the use of maleated copolymers is common to improve the properties of r-PET/rPE blends. In a study, SEBS-g-MA was used to improve the thermal stability and the mechanical properties of r-PET/LLDPE blends (Zhang et al. 2009). In this case, therefore, instead of using distinct compounds – namely, the maleated one and the impact modifier – the functions of compatibilization and impact modification are committed to only one additive. The addition of maleated SEBS (10 wt%) led to the deformation of the dispersed phase from spherical to fibrous structures, with microfibrils formed at the interface between the two phases. The best compatibility was found when 20 wt% of maleated SEBS with positive effects on the elastic modulus and impact strength in agreement with the other studies (Zhang et al. 2008; Jeziórska 2006). SEBS-g-MA was also used as compatibilizer impact modifier for blends of r-PET with different polyethylenes (LLDPE, LDPE, m-PE) to evaluate the influence of the structural differences of the PE phase on the properties of the material (Zhang et al. 2011). In the work, moreover, the effect of the molecular weight of LLDPE was also evaluated. The authors found that the key factor to achieve a good set of properties was the miscibility/interactivity of SEBS-g-MA with the polyethylene phase. More in detail, when using LDPE, the coupling agent locates at the interface between the r-PET phase and the PE phase thus increasing the adhesion with consequent increase of the impact strength. On the contrary, when the miscibility of SEBS-g-MA is too high (m-PE, lower molecular weight LLDPE) or too low (LLDPE with higher molecular weight), the additive is segregated mainly in one phase and its compatibilizing effect is drastically reduced. The compatibilizer caused a reduction of PET crystallinity. Moreover, due to the massive penetration of the compatibilizer into the m-PE phase, its crystal structure is destroyed and no DSC peak is observed.

Similarly, r-PET from food packaging and bottles was melt blended with ethylene–propylene grafted with maleic anhydride (EP-g-MA) at various amounts ranging from 5 to 40 wt% (Alsewailem 2008). The results showed that EP-g-MA is a good impact modifier for r-PET, due to its rubbery status. In particular, adding 40 wt% of modifier allows producing a material tougher than neat virgin PET. Similarly, EGMA was added as reactive component to modify the morphology and the mechanical characteristics of r-PET. Up to 13.5 wt% EGMA content, the impact strength gradually increases while it drastically increases (to ten times of that measured for neat r-PET) for higher concentrations. SEM morphological analysis demonstrated that ductile deformation at the interface produced local fibrils with high energy absorption during the break. The density of the blends, as expected, progressively decreases with increasing the amount of EGMA.

r-PET was also used in combination with PCL (Malinconico et al. 1997; Qi and Nakayama 2000). In a case (Malinconico et al. 1997), the r-PET was first depolymerized and then copolymerized with PCL to form PET–PCL copolymers. Those copolymers were then used as compatibilizers for r-PET/PCL blends and a significant improvement of the morphology was observed. In another case (Qi and Nakayama 2000), r-PET and PCL was blended and hot drawn. Adding 5–10 wt% of PCL allowed achieving the hot drawing at temperature

10 °C lower than those necessary for preparing r-PET sheets. r-PET orientation increases on increasing the draw ratio, while no orientation was observed for PCL. As regards the thermal properties, PCL crystallization was found independent on the draw ratio, while r-PET crystallization was not affected by the presence of PCL.

PC was also used in blends with r-ABS to recover the mechanical performance of the latter up to that of the virgin polymer (Barthes et al. 2012). The authors found that at the highest concentrations of r-ABS, it is necessary to add up to 5 wt% of PP-g-MA as compatibilizer. However, if r-ABS is obtained from formulations containing flame retardants or if the residence time in the melt is too long (e.g., for multiple reprocessing steps), the efficiency of the compatibilizer is sensibly reduced. The use of maleated ABS had positive effects on the properties of r-PC (Elmaghor et al. 2004). In particular, the toughness of the waste was greatly improved, Fig. 20.6, due to the particular morphology developed in the presence of ABS-g-MA and consisting in domains connected together and forming a network that causes the increase of the energy absorbed during the impact.

The r-PC/r-ABS blends may also include PMMA as a third component (Laverty et al. 1996; Rybnicek et al. 2005). In this case, the chemical composition of the styrene–acrylonitrile matrix of ABS was found to have a dramatic effect on the morphology, while lubricant additives of ABS are adverse to the chemical stability. However, all the compositions rich in PMMA exhibited inferior mechanical performance (Laverty et al. 1996). A more detailed mechanical study (Rybnicek et al. 2005) demonstrated that the transition from ductile elastoplastic behavior to brittle linear elastic fracture behavior occurs when the PMMA is above 10 wt%.

Among the engineering plastics, it is worth mentioning the recycling of PPE (Nerkar et al. 2011). Two recyclates with different content of PPE were reprocessed with an injection molding machine. The molecular weight, the T_g, and the viscosity were found to be unaffected even after ten molding cycles and for both compositions of the blends investigated.

Several studies report on the use of styrenic polymers in blends with recycled polymers. PVC, for instance, may undergo severe degradation during reprocessing with rapid worsening of the mechanical performance (Scott 1993). The combination with other polymers may enhance the performance of the secondary materials and allow industrial applications (Robeson 1984; Maiti et al. 1992; Kulshreshtha 1993). SAN and ABS (virgin or recycled) were added to r-PVC exploring the whole composition range (Garcia et al. 2006). Despite the degradation level of r-PVC was not relevant, the incorporation of styrenic polymers causes, as expectable, an improvement of the impact resistance when using ABS, while it is worse if SAN is added; see Fig. 20.7.

Moreover, the virgin styrenic polymers offer a better performance than the recycled ones. The thermal analysis revealed a partial miscibility between r-PVC and the styrenic part. r-PVC was also used in blends with NBR together with glycidyl methacrylate (GMA) as coupling agent (Supri and Yusof 2005). The addition of GMA significantly improved the tensile stress while reducing the elongation at break. This toughening of the compatibilized blend was ascribed to

Fig. 20.6 TEM micrographs of PC and ABS-g-MA of different grafting degrees. Relative degree of grafting: (**a**) zero, (**b**) 1.75, (**c**) 2.75. PC/ABS-g-MA = 1/0.25 wt/wt (Taken from F. Elmaghor, L. Zhang, R. Fan, H.Li, Recycling of polycarbonate by blending with maleic anhydride grafted ABS, Polymer **45**, 6719 (2004); Fig. 2 with permission of Elsevier. Copyright © 2007 Elsevier)
Fig. 20.7 Variation of Charpy impact strength versus styrenic polymers wt% incorporated to r-PVC (Taken from D. Garcia, R. Balart, J.E. Crespo, J. Juan Lopez, Mechanical properties of recycled PVC blends with styrenic polymers, J. Appl. Polym. Sci. **101**, 2464 (2006); Fig. 7. Copyright © 2000 John Wiley & Sons, Inc. Reproduced with permission)

the improved interfacial adhesion as confirmed by SEM analysis. However, GMA was found to decrease the overall thermal stability. Similar results were obtained for the same system using maleic acid to improve the compatibility between the phases (Ghani et al. 2005).

HIPS was added to r-LDPE aiming to the improvement of the mechanical performance. To achieve this goal, HIPS together with an impact modifier system composed by EPDM and styrene–1butadiene (SB) copolymer and with N,N' 1,4-phenylendiamine as stabilizer were added to LDPE coming from outdoor application (i.e., severely photodegraded) (Pospisil et al. 2005). The combination of the tough HIPS phase with the rubbery EPDM/SB phase and with the stabilizer improves the impact strength of the resulting blend.

PS/HDPE blends were prepared by melt processing using both virgin and recycled polymers (Joshi et al. 2006). The morphology of the blends was fine structured with co-continuity regions and average domain dimensions in the micron range. The blends show mechanical properties nearly obeying the rule of mixtures although the behaviors of virgin and recycled materials are quite different. Recycled blends show significant regions of incompatibility but a synergistic zone at around 40 wt% of PS corresponding with the co-continuity of the blends.

The crystallinity of HDPE is reduced in the recycled blend but not in the virgin ones, while the glass transition temperature of PS increases only in the virgin blends. Some modeling of the system was proposed but the full explanation of this behavior is still under study.

r-PS was also added with styrene–butadiene rubber (SBR) (up to 50 wt%) to modify the mechanical properties of the brittle styrenic phase (KGK-Kautschuk und Gummi Kunststoffe 2000). At 20 wt% of SBR, there is a significant increase of the elongation at break and of the impact strength. Conversely, the tensile stress, the hardness, and the T_g of r-PS decreased with increasing the SBR content. The blends showed a pronounced Newtonian behavior and decreased on increasing the SBR level.

Other challenging field in recycling polymer blends is the use of post-consumer ground tire rubber (GTR). Homogeneous dispersion of HDPE/GTR via solid-state mechanochemical milling (Zhang et al. 2012) showed excellent mechanical properties with an enhancement of the tensile strength of 60 % and an increase of the elongation at break of 14 times that of the conventional melt-mixing processed material. This behavior was correlated to the partial devulcanization of the blend as demonstrated by the decrease of the gel fraction.

In another study (Grigoryeva et al. 2008), the polyethylenic phase (either LDPE or HDPE) was pre-functionalized with maleic anhydride. The rubber component, as well, was functionalized with maleic anhydride or acrylamide using chemical methods or gamma-ray irradiation. Additional coupling agents such as p-phenylenediamine or polyamide fibers were used to produce thermoplastic elastomeric materials. As a result, the impact strength and the elongation at break of the resulting materials were drastically improved.

The effect of particles and matrix properties on the shear viscosity of LDPE/GTR blend was also studied by developing a theoretical model to predict the viscosity of the composites as a function of the rheological properties of the matrix, solid concentration, particle size distribution, particle shape, and deformability (Bhattacharya and Sbarski 1998). The real viscosity measurements were found in good agreement with the values predicted below the maximum packing fraction.

As a general conclusion, it is not possible to predict exactly the physical properties of a mixture containing recycled materials. Consequently, when degraded polymers are used, it is a good idea to add only limited amounts to the virgin material to maintain the mechanical properties of the virgin polymer.

20.5   Conclusions

Recycling aims to recover the added value of scraps or post-consumer materials, otherwise irremediably lost. Technically speaking, even the recycling of materials with an initial identical chemical structure should be considered as a blend recycling. Secondary materials can be obtained by blending with the same virgin polymer (homopolymer blends) or by blending with other polymers (virgin or present in the same post-consumer stream), in the presence, or less, of fillers.

Homopolymer blends represent a simple, effective, and cost-efficient way to reuse scraps. Using relatively low amounts (up to 20 wt% or even more for certain polymers) of scraps or post-consumer plastic with the same virgin polymer does not significantly alter the mechanical performance. If higher amount must be added, either a stabilizing system or the concurrent addition of a filler may grant a good set of final properties.

When the scraps or end-use materials are added to a virgin one, the main problems are as follows: the higher thermal sensitivity to reprocessing, the presence of humidity while reprocessing polycondensation polymers, and the incompatibility between the different phases. In this case a stabilizing and/or compatibilizing system is required to obtain materials with properties adequate for the use in new applications.

Of course, these troubles are exalted when recycling commingled plastics. In this case, beyond the problems highlighted above, there is generally no chance to choose the composition, and the presence of small quantities of contaminants can compromise the whole process. To avoid or at least to reduce these phenomena, stabilizers and compatibilizers are not optional.

Miscible Polymer Blends

21

Suat Hong Goh

Contents

Abstract

Miscible polymer blends were once considered a rarity. However, extensive research has led to the discovery of a large number of miscible polymer blends. This Chapter is a compilation of miscible polymer blends reported in literature up to 2012.

21.1   Introductory Remarks

Miscible polymer blends were once considered a rarity. Flory (1953) wrote the following statement in his book *Principles of Polymer Chemistry*:

> It is permissible to state as a principle of broad generality that two high polymers are mutually compatible with one another only if their free energy of interaction is favorable, i.e., negative. Since the mixing of a pair of polymers, like the mixing of simple liquids, in the great majority of cases is endothermic, incompatibility of chemically dissimilar polymer is observed to be the rule and compatibility is the exception.

S.H. Goh
Department of Chemistry, National University of Singapore, Singapore, Singapore
e-mail: chmgohsh@nus.edu.sg

Indeed, in the early 1970s, only a dozen of miscible polymer blends were known to exist (Krause 1972). However, extensive research has led to the discovery of a large number of miscible polymer blends. By 1995, some 1,320 pairs of miscible polymer blends had been reported (Krause and Goh 2002).

What gives rise to miscibility between two chemically dissimilar polymers? Since the entropy gain upon mixing two polymers is negligibly small, a negative Gibbs energy of mixing requires a negative heat of mixing. Therefore, the formation of a miscible polymer blend requires attractive specific interactions (hydrogen bonding, dipole-dipole, ion-dipole, and charge transfer) between the two constituent polymers. Various spectroscopic techniques such as Fourier transform infrared spectroscopy (Coleman and Painter 1995; He et al. 2004a), nuclear magnetic resonance spectroscopy (Takegoshi 1995), and X-ray photo-electron spectroscopy (Chan and Weng 2000) have shown the existence of interpolymer interactions in miscible polymer blends. When polymer-polymer interaction is stronger than polymer-solvent interaction, the two polymers form interpolymer complexes (or simply complexes) by coprecipitating from their common solvent, in which both polymers are initially soluble. It has been commonly observed that through the introduction of increasing amounts of suitable functional groups to polymer chains, an immiscible polymer blend system can be transformed to a miscible polymer blend system and eventually leads to the formation of complexes (Jiang et al. 1999). For a blend containing one or more copolymers, intramolecular interactions between two different types of segments in a copolymer are also important in determining the miscibility (Kambour et al. 1983; Ten Brinke et al. 1983; Paul and Barlow 1984).

The miscibility of polymer blends is dependent on temperature. There are a large number of miscible polymer blends which undergo phase separation upon heating, showing lower critical solution temperature (LCST) behavior. On the other hand, some immiscible polymer blends at room temperature become miscible upon heating, showing upper critical solution temperature (UCST) behavior. There are also examples of polymer blends showing both LCST and UCST behaviors. While solution casting method is widely used to prepare polymer blends, it should be noted that the choice of solvent can affect the miscibility of the blends. A well-known example is the polystyrene/poly(vinyl methyl ether) system (Bank et al. 1971). Blends cast from toluene or benzene are miscible, but those cast from chloroform or trichloroethane are immiscible. Similarly, the formation of interpolymer complexes is also dependent on the choice of solvent. For example, poly(methacrylic acid) forms complexes with poly (4-vinylpyridine) in ethanol/water (1:1) solution but not in dimethylformamide (Yi and Goh 2001).

21.1.1 Determination of Miscibility

The miscibility of a polymer blend is usually ascertained by studying the optical, morphological, and glass transition behavior of the blend. When two amorphous polymers with different refractive indices mix intimately to form a miscible blend, the refractive index of the blend is uniform, and the blend appears transparent. On the other hand, when the two polymers do not mix intimately, the resulting blend is opaque. It must be cautioned that a two-phase immiscible blend may appear transparent if the refractive indices of the two polymers are closely matched or the domain size is smaller than the wavelength of the visible light. For a blend containing a crystallizable polymer, the blend may appear opaque even when the amorphous phases of the two polymers mix intimately.

The most commonly used method to determine miscibility is the measurements of glass transition temperatures (T_g's) by thermoanalytical techniques such as differential scanning calorimetry and dynamic mechanical thermal analysis. The existence of a single composition-dependent T_g indicates intimate mixing of the two polymers on a scale of about 10–30 nm. The appearance of two T_g's indicates a two-phase immiscible blend. For a blend of two polymers with sufficiently close T_g values (difference less than 10–15 °C), it is often difficult to ascertain whether the observed single glass transition is really one glass transition or two overlapping glass transitions. In this type of situation, examination of the enthalpy recovery behavior of the blend after annealing offers a way to determine miscibility (Ten Brinke et al. 1994). A more stringent criterion for miscibility is based on nuclear magnetic resonance spectroscopy (Takegoshi 1995). If two polymer chains in a blend mix intimately, spin diffusion occurs quickly among the chemically different components, and so single values of spin-lattice relaxation times in the laboratory frame, $T_1(H)$, and in the rotating frame, $T_{1\rho}(H)$, are obtained. A single $T_{1\rho}(H)$ value indicates mixing to a scale of about 1–3 nm, whereas a single $T_1(H)$ value mixing to a scale of about 20–30 nm.

For a blend containing a crystallizable polymer, the melting point depression of the crystalline polymer by the amorphous polymer can be used to evaluate polymer-polymer interaction parameter using the Nishi-Wang equation (Nishi and Wang 1975).

21.1.2 Arrangement of Tables

Lists of miscible polymer blends were previously prepared by Krause (1972, 1978, 1989) and Krause and Goh (1999, 2002). The list appeared in the first edition of this handbook covered literature up to 1995. The present compilation extends the coverage to 2012.

The eight tables in the present compilation adopt the same format as that in the first edition of the handbook. The column labeled Polymer I of is an alphabetical listing. The column labeled Polymer II of is an alphabetical listing of polymers miscible with the appropriate polymer from the first column. Because of space constraint, each table contains a particular polymer mixture only once. Readers are advised to look for the names of both polymers for a particular blend system.

The column labeled Methods briefly lists the method(s) used by the researchers in their works. The Comments column mainly lists the compositions of copolymers and other relevant information. For a polymer blend system reported by a number of research groups, comments on selected works are listed.

The eight tables are the following:

1. Chemically dissimilar polymer pairs miscible in the amorphous state at room temperature. Some of these polymers may be copolymers, but the polymer pairs may not have any monomer units in common. One or both of the polymers may be semicrystalline.
2. Polymer pairs containing one monomer in common (at least one of these must be a copolymer), miscible in the amorphous state at room temperature. One or both of the polymers may be semicrystalline.
3. Chemically dissimilar polymer triads and tetrads miscible in the amorphous state at room temperature.
4. Polymer pairs miscible in the amorphous state at room temperature. Molecular weight dependence investigated. These are usually polymer pairs that are miscible when the molecular weights are low and immiscible as when the molecular weights are increased.
5. Polymer pairs that appear to have high temperature miscibility although immiscible at or below room temperature (upper critical solution temperature [UCST] behavior).
6. Polymer pairs miscible at room temperature that appear to have a lower critical solution temperature (LCST) above room temperature. These polymer pairs are also listed in one of the earlier Tables, usually Table 21.1 or 21.2.
7. Polymer pairs that appear to have both lower and upper critical solution temperatures.
8. Polymer pairs that co-crystallize and form mixed crystals. These blends are generally composed of polymers with similar subunits that can substitute for each other in the same unit cells; this is generally called "isomorphous replacement." This table is probably incomplete even though co-crystallization is expected to be rare.

Table 21.1 Chemically dissimilar polymer pairs miscible in the amorphous state at room temperature

Polymer I of	Polymer II of	Method	Comments	Refs.
Acetoxystyrene	γ-Benzyl-L-glutamate	Single T_g; FTIR; NMR; WAXD	–	Kuo and Chen (2012)
	Novolac	Single T_g; FTIR; NMR	–	Kuo and Chang (2002b)
Acetoxystyrene-co-styrene	Novolac	Single T_g; FTIR	II had >45 mol% acetoxystyrene	Kuo and Chang (2001e)
2-Acrylamido-2-methylpropane sulfonic acid	Hexafluoropropylene-co-vinylidene fluoride	Single T_g; TEM	II had 10 wt% hexafluoropropylene	Gibon et al. (2008)
	Vinylpyridine	Single T_g	II was 2- or 4-vinylpyridine; formed complexes	Huglin and Rego (1990)
Acrylic acid	Acrylamide	FTIR; NMR	Formed complexes	Garces et al. (1994), Moharram et al. (1996)
	Acrylamide-co-N,N-dimethylacrylamide	Fluorescence study	Formed complexes; II had 6.0–55 mol% acrylamide	Wang and Morawetz (1989)
	Caprolactam	Single T_g; WAXD	Semicrystalline	Nishio et al. (1993)
	Dextran	Single T_g; transparency; SEM	–	Cascone et al. (1997)
	N,N-Dimethylacrylamide	Fluorescence study	Formed complexes; II had 6.0–55 mol% acrylamide	Wang and Morawetz (1989)
	Ethylene glycol	Single T_g; FTIR; clear films; NMR	Semicrystalline when >50 % II	Chu and Berner (1993), Jeon and Ree (1988), Lu and Weiss (1995), Maunu et al. (1993), Miyoshi et al. (1997), Smith et al. (1959)
	Hydroxypropylcellulose	Single T_g; SEM	Miscible when blends were prepared by coprecipitation	Khutoryansky et al. (2004)
	Vinyl alcohol	FTIR; T_m-depression; SEM	Semicrystalline	Diniluc et al. (1992), Herrera-Kao and Agular-Vega (1999), Nurkeeva et al. (2005), Vazquez-Torres et al. (1993)
	Vinylmethylether	Single T_g; FTIR; NMR	Formed 1:1 complexes	Cowie et al. (1989b)
	N-Vinyl pyrrolidone	Single T_g; FTIR; NMR	Formed complexes	Lau and Mi (2002), Maunu et al. (1993)
	Vinylpyridine	Single T_g; FTIR; XPS	II was 2- or 4-vinylpyridine; formed complexes	Zhou et al. (1998)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
Acrylic acid-butyl acrylate	Styrene-*co*-4-vinylpyridine	Single T_g	I was K-neutralized; II was quaternized with methyl iodide	Pen and Shen (1998)
Acrylic acid-*co*-ethylene	Caprolactam (PA-6)	Single T_g	I had 19 wt% acrylic acid	Matzner et al. (1979)
Acrylic acid-*co*-isobutyl methacrylate	*N,N*-Dimethylaminoethyl methacrylate-*co*-styrene	Single T_g; IGC	I had 10.5 or 22 mol% acrylic acid; II had 88 mol% styrene	Djadoun et al. (1996), Hadj-Hamou et al. (1997)
Acrylic acid-*co*-methyl methacrylate	*n*-Butyl methacrylate-*co*-4-vinylpyridine	Single T_g; FTIR	II had 26 mol% vinylpyridine	Iguerb et al. (1999)
	Vinyl chloride	Single T_g; FTIR	–	Iguerb et al. (1999)
Acrylic acid-*co*-styrene	Acrylonitrile-*co*-methyl methacrylate	Single T_g	–	Brannock et al. (1990)
	11-Aminoundecanoic acid (PA-11)	Single T_g	I had 20 % acrylic acid	Yu et al. (1991)
	Caprolactam (PA-6)	Single T_g	I had 20 % acrylic acid	Kuphal et al. (1991)
	Caprolactone	Single T_g	I had 11.4–20.8 wt% acrylic acid	Jo and Kim (1991)
	Dimethylacrylamide	Single T_g; FTIR	I had 22 mol% acrylic acid	Hadj-Hamou and Djadoun (2006)
	Ethyl methacrylate	Single T_g	I had 2.65–20 wt% acrylic acid	Brannock et al. (1990), Feraz et al. (1995)
	Ethyl methacrylate-*co*-4-vinylpyridine	Single T_g; IGC	I had 20 mol% acrylic acid; II had 8 mol% vinylpyridine	Feraz et al. (1995)
	Ethylene glycol	Single T_g	I had 21 wt% acrylic acid	Jo et al. (1991b)
	Isobutyl methacrylate-*co*-4-vinylpyridine	Single T_g; IGC; FTIR	I had 20 mol% acrylic acid; II had 32 mol% vinylpyridine	Feraz et al. (1995), Hadj-Hamou (2010)
	Methyl methacrylate	Single T_g	I had 8–20 wt% acrylic acid	Brannock et al. (1990), Jo et al. (1989a, b)
	Lauryllactam (PA-12)	Single T_g	I had 20 % acrylic acid	Yu et al. (1991)

	N-Methyldodecano-12-lactam	Single T_g; FTIR	I had 25.7 wt% acrylic acid	Kratochivil et al. (2005, 2007)
	n-Propyl methacrylate	Single T_g	I had 2.65–8.84 wt% acrylic acid	Bowner and Tondii (1986)
	Vinylmethylether	Single T_g	I had 8–20 wt% acrylic acid	Min and Paul (1988)
Acrylonitrile	Tertiary amide	Single T_g; FTIR	II was dimethylacrylamide, N-methyl-N-vinylacetamide or N-vinylpyrrolidone	Yeo et al. (1997)
	p-Vinylphenol	Single T_g; FTIR; XPS	–	Goh et al. (1999b)
Acrylonitrile-co-butadiene	Cellulose acetate butyrate	Some compositions appeared homogeneous	–	Asimova et al. (1962), Gesner (1969), Kosai and Higashino (1975), Peterson et al. (1969)
	Chloroprene	Single T_g when I had 18 % acrylonitrile; sorption of solvent vapors	Two phases in electron micrograph when I had 18 % acrylonitrile may indicate a crystalline phase; two torsional transitions when I had ≥28 % acrylonitrile	Casper and Morbitzer (1977), Tager et al. (1987)
	Epichlorohydrin	Single T_g	I had 26–54 wt% AN	Cowie and Harris (1994)
	Ethylene, chlorinated	Single T_g	I was hydrogenated and had 36.3 or 49.9 wt% AN; II had 42.1 wt% Cl (Severe and White (2000)); I had 34 wt% AN; and II had 35 wt% Cl (Zhang et al. (2002))	Severe and White (2000), Zhang et al. (2011)
	Nitrocellulose	Transparent films when I had 28.6–44.4 % acrylonitrile	Immiscible when I had 18.4 % acrylonitrile	Casper and Morbitzer (1977), Grose and Friese (1965), Kalinina et al. (1956a, b), Kosai and Higashino (1975)
	Vinyl acetate-co-vinyl chloride	Single loss peak when ≤40 % vinyl acetate in II; clear films for some mixtures of commercial polymers	Two loss peaks when ≥50 % vinyl acetate in II	Grose and Friese (1965), Kosai and Higashino (1975), Manabe et al. (1969), Peterson et al. (1969)

(continued)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
	Vinyl chloride	Single T_g; IGC	I had 29–45 wt% acrylonitrile	Aivazov et al. (1970), Breuers et al. (1954), Buchdahl and Nielson (1955), Cowie and Harris (1992), Dimitrova et al. (1971), Kosai and Higashino (1975), Landi (1974), Livingston and Rongone (1967), Matsuo et al. (1969), Nielson (1955), Nielson and Chinai (1962), Oganesov et al. (1969), Reznikova et al. (1955), Shur and Ranby (1975b), Sen and Mukherjee (1993), Takayanagi et al. (1963), Wang and Chen (1981), Wolff (1957), Zahrzewski (1973)
	Vinyl chloride, head-to-head	Single T_g	I had 23.5–56.6 wt% acrylonitrile; II was made from chlorination of poly (1,4-butadiene)	Cowie et al. (1992d)
Acrylonitrile-*co*-butadiene, hydrogenated	Vinyl chloride	Single T_g; microscopy	I had 38 wt% AN	Sotiropoulou et al. (1993)
Acrylonitrile-*co*-butadiene-methyl acrylate	Ethylene-alt-maleic anhydride	Single T_g; microscopy	I was made from a copolymer of AN/MA (75/25) grafted onto BD/AN (70/30) copolymer	Percec and Melamud (1993)
Acrylonitrile-*co*-butadiene-*co*-styrene	Propylene-*co*-vinyl chloride	Single T_g	I was Blendex 701; II had 3.2 or 3.8 % propylene; electron micrographs may indicate two phases	Cheng and Mantell (1979)
Acrylonitrile-*co*-methyl methacrylate	N,N-Dimethylacrylamide	Single T_g; transparency	I had 70 wt% acrylonitrile (AN)	Percec and Melamud (1990)
	Maleic anhydride	Single T_g; transparency	I had 70 wt% AN	Percec and Melamud (1990)
	Vinyl chloride	Single T_g; transparency	II had 2–17 wt% AN	Lath et al. (1993)
	N-Vinylpyrrolidone	Single T_g; transparency	I had 70 wt% AN	Percec and Melamud (1990)

Acrylonitrile-*co*-methyl methacrylate-*co*-α-methylstyrene	Vinyl chloride	Single T_g	I had 8/58/34/acrylonitrile/methyl methacrylate/-methylstyrene	Casper and Morbitzer (1977)
Acrylonitrile-*co*-α-methylstyrene	Alkyl methacrylate	Single T_g; transparency	I had 30 wt% AN; II had an alkyl group of acetonyl, chloromethyl, 2-chloroethyl, 2-hydroxyethyl, 2-hydroxypropyl, methoxymethyl, methylthiomethyl, or tetrafurfuryl	Goh and Lee (1990d), Goh et al. (1991b, 1992b), Goh and Siow (1986a)
	n-Butyl methacrylate	Single T_g	I had 12 wt% AN	Cowie and Elexpuru (1992)
	n-Butyl methacrylate-*co*-methyl methacrylate	Single T_g; transparency	I had 30 wt% AN; II had 70 wt% methyl methacrylate	Goh et al. (1984)
	Carbonate of tetramethylbisphenol-A	Single T_g	I had 4–16.5 wt% AN	Gan et al. (1994a)
	Ethyl methacrylate	Single T_g	I had 10–28 wt% AN	Cowie and Elexpuru (1992), Goh et al. (1982b)
	Ethyl methacrylate-*co*-methyl methacrylate	Single T_g; transparency	I had 30 wt% AN; II had 30 or 60 wt% methyl methacrylate	Goh et al. (1985)
	Ethylene, chlorinated	Single T_g	Depended on AN and Cl contents	Cowie et al. (1991a)
	Methyl methacrylate	Single T_g; XPS; SALS	I had 10–37 wt% AN; I had 30 wt% AN; and II was atactic or isotactic (Goh et al. (1982b))	Bebin and Prud'homme (2004), Cowie and Elexpuru (1992), Goh et al. (1982b), Gan et al. (1994), Zuo et al. (2006)
	Methyl methacrylate-*co*-2,2,6,6-tetramethyl-piperidinyl methacrylate	Single T_g; transparency	I had 30 wt% AN; II had ≥76.2 wt% methyl methacrylate	Goh et al. (1986b, 1987)

(continued)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
	n-Propyl methacrylate	Single T_g	I had 17–20 wt% AN	Cowie and Elexpuru (1992a)
	Vinyl chloride	Single T_g; FTIR	I had 30 wt% AN; miscible when melt blended or cast from methyl ethyl ketone; immiscible when cast from tetrahydrofuran	Gan et al. (1994a), Kim et al. (1989d, 1996), Moon et al. (2007), Rink et al. (1983)
Acrylonitrile-co-p-methylstyrene	Acetonyl methacrylate	Single T_g; transparency	I had 43–61 wt% AN	Chong and Goh (1992a)
	Alkyl methacrylate	Single T_g	II had an alkyl group of 1-chloroethyl and I had 10–40 wt% AN; II had an alkyl group of 2,2-dichloroethyl and I had 8–44 wt% AN; II had an alkyl group of 2,2,2-trichloroethyl and I had 78–88 wt% AN	Goh et al. (1996c)
	2-Bromoethyl methacrylate	Single T_g; transparency	I had 14–61 wt% AN	Neo and Goh (1991a)
	n-Butyl methacrylate	Single T_g; transparency	I had 13.6 wt% AN	Goh et al. (1991a)
	2-Chloroethyl methacrylate	Single T_g; transparency	I had 18.3–46 wt% AN	Neo et al. (1991a)
	Chloromethyl methacrylate	Single T_g; transparency	I had 13–42 wt% AN	Goh and Lee (1990a)
	Cyclohexyl methacrylate	Single T_g; transparency	I had ≤22 wt% AN	Chong and Goh (1992d)
	2,6-Dimethyl-1,4-phenylene ether	Single T_g; transparency	I had ≤5.0 wt% AN	Goh and Lim (1990)
	Ethyl methacrylate	Single T_g; transparency	I had 12–33 wt% AN	Goh et al. (1991a)
	Methyl methacrylate	Single T_g; transparency	I had 12–34 wt% AN	Goh et al. (1991a)
	Methylthiomethyl methacrylate	Single T_g; transparency	I had 19–34 wt% AN	Goh et al. (1992b)
	n-Propyl methacrylate	Single T_g; transparency	I had 6–28 wt% AN	Goh et al. (1991a)
	Tetrahydrofurfuryl methacrylate	Single T_g; transparency	I had 12–48 wt% AN	Goh et al. (1992a)
	Tetrahydropyranyl-2-methyl methacrylate	Single T_g; transparency	I had 5–29 wt% AN	Chong and Goh (1992b)
Acrylonitrile-co-α-methylstyrene-co-styrene	Vinyl chloride	Single T_g; SEM	I had 25 wt% AN	Zhang et al. (2008a, b)

Acrylonitrile-co-styrene				
Acetonyl methacrylate	Single T_g; transparency	I had 33–58 wt% AN	Chong and Goh (1992c)
Alkyl acrylate-co-methyl methacrylate	Single T_g	II had an alkyl group of ethyl or n-butyl; miscibility depended on compositions of I and II; miscibility increased and then decreased with increasing size of alkyl group of II (Zhao et al. (1991)3)	Chu and Paul (1999)
Alkyl methacrylate	Single T_g	II had an alkyl group of 1-chloroethyl and I had 9–30 wt% AN; II had an alkyl group of 2,2-dichloroethyl and I had 9–41 wt% AN; II had an alkyl group of 2,2,2-trichloroethyl and I had 64–93 wt% AN	Goh et al. (1996c)
Alkyl methacrylate-co-methyl methacrylate	Single T_g	II had an alkyl group of t-butyl, phenyl or cyclohexyl; miscibility depended on compositions of I and II	Chu and Paul (1999)
Arylate	Single T_g	Miscibility the greatest when AN = 25 %	Ahn and Jeong (1987)
Arylate of bisphenol-A-co-arylate of tetramethylbisphenol-A	Single T_g	I had 4.2–17.8 wt% AN	Ahn et al. (1997c)
Arylate of tetrabromobisphenol-A-co-arylate of tetramethylbisphenol-A	Single T_g	Miscibility depended on compositions of I and II	Jeong et al. (1994)
Benzyl methacrylate	Single T_g	I had 3.9–7.8 and 24.3–26.6 wt % AN	Sankarapandian and Kishore (1994), Woo et al. (2000b)
2-Bromoethyl methacrylate	Single T_g; transparency	I had 10–58 wt% AN	Neo and Goh (1991a)

(continued)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
	Butylene adipate	Single T_g	I had 13–32.3 wt% AN	Fernandes et al. (1986a)
	Butylene sebacate	Single T_g	I had 13–20 wt% AN	Fernandes et al. (1986a)
	n-Butyl methacrylate-co-methyl methacrylate	Single T_g; transparency	I had 22 wt% AN; II had 70 wt% methyl methacrylate	Goh et al. (1984a), Kammer (1989)
	t-Butyl methacrylate-co-methyl methacrylate	Single T_g	Miscibility depended on compositions of I and II	Nishimoto et al. (1990)
	Caprolactone	Single T_g; light scattering; FTIR; OM; dielectric spectroscopy	I had 10–30 wt% AN; II was linear or 6-arm star polymer (Gorda and Peiffer 1993)	Fernandes et al. (1986a), Groeninckx et al. (1988), Gorda and Peiffer (1993), Janarthanan et al. (1993), Kressler and Kammer (1988), Keyzlarovi and Saha (1999), Li and Woo (2008c), McMaster (1973), Madbouly et al. (2006), Princi and Vicini (2010), Seefried and Koleske (1976), Schulze et al. (1993)
	Carbon monoxide-alt-propene	Single T_g; transparency	I had 25 wt% AN	De Vos et al. (1999)
	Carbonate of bisphenol-A-co-tetramethylbisphenol-A	Single T_g	I had ≤18 wt% acrylonitrile; II had ≤22 wt% bisphenol-A	Kim and Paul (1992e)
	Carbonate of dimethylbisphenol-A-co-carbonate of tetramethylbisphenol-A	Single T_g	I had 2–24 wt% AN; II had 41–83 wt% tetramethylbisphenol-A	Kim et al. (2003a), Yoo et al. (2003)
	2-Chloroethyl methacrylate	Single T_g; transparency	I had 12.5–43 wt% AN	Neo et al. (1991a)
	Chloromethyl methacrylate	Single T_g; transparency	I had 12–37 wt% AN	Goh and Lee (1990e)
	Cyclohexyl methacrylate	Single T_g; transparency	I had ≤20 wt% AN	Chong and Goh (1992b)
	Cyclohexyl methacrylate-co-methyl methacrylate	Single T_g	Miscibility depended on compositions of I and II	Nishimoto et al. (1990)
	2,6-Dimethyl-1,4-phenylene ether	Single T_g	I had ≤10.5 wt% AN	Gottschalk et al. (1994), Kressler and Kammer (1987)

2,6-Dimethyl-1,4-phenylene ether, benzoylated	Single T_g	I had 18 mol% AN; II had 35 or 86 % benzoylated units	Song et al. (1991)
Ethylene adipate	Single T_g	I had 25–28 wt% AN	Fernandes et al. (1986a)
Ethyl methacrylate	Single T_g; transparency; NMR	I had 5.5–28.0 wt% AN (Fowler et al. (1987)); I had 9–34 wt% AN (Chiou et al. (1982))	Chiou et al. (1982), Fowler et al. (1987), Feng et al. (1996b), Lath et al. (1992)
Ethyl methacrylate-co-methyl methacrylate	Single T_g; transparency	I had 22 wt% AN; II had 30 or 50 wt% methyl methacrylate	Goh et al. (1984b)
Ethyl methacrylate-co-2,2,6,6-tetramethyl-piperidinyl methacrylate	Single T_g; transparency	I had 30 wt% AN; II had $\leq$13.3 wt% 2,2,6,6-tetramethyl-piperidinyl methacrylate	Goh et al. (1987)
2-E thyl-2-oxazoline	Single T_g; transparency	I had 25–40 wt% AN; two T_g's when I had 8, 23.5, or 70 % AN	Keskkula and Paul (1986), Pfennig et al. (1986)
Hexamethylene sebacate	Single T_g	I had 16.2 wt% AN	Fernandes et al. (1986a)
2-Hydroxyethyl methacrylate	Transparency	I had 22 wt% AN	Goh et al. (1982b)
2-Hydroxyethyl methacrylate-co-methyl methacrylate	Single T_g	II had <8wt% hydroxyethyl methacrylate; miscibility depended on composition of I	Chu and Paul (2000)
2-Hydroxypropyl methacrylate	Single T_g; transparency	I had 22 wt% AN	Goh and Siow (1986a)
Isobutene-alt-N-methylmaleimide	Single T_g; transparency	I had 25 or 30 wt% AN	Doi et al. (1997)
4-Methacryloxyethyl trimellitic anhydride-co-methyl methacrylate	Single T_g	II had >97 wt% methyl methacrylate; miscibility depended on composition of I	Chu and Paul (2000)
Methoxymethyl methacrylate	Single T_g; transparency	I had 30 wt% AN	Goh et al. (1992b)

(continued)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
	Methyl methacrylate	Transparency; NMR; AFM; XPS	I had 9.4–34.4 wt% AN (Suess et al. 1987); I had 9.5–28 wt% AN (Fowler et al. 1987); I had 9–39 wt% AN (Cowie et al. 1988); II was atactic or syndiotactic (Hsu 1999)	Bernstein et al. (1977), Cowie et al. (1988), Fowler et al. (1987), Feng et al. (1996b), Hsu (1999), Jung and Stein (1973), McMaster (1975), Naito et al. (1978), Peterson et al. (1969), Ramaswamy and Weber (1973), Robertson and Wilkes (2001a), Shaw (1974), Stein et al. (1974), Suess et al. (1987), Wen et al. (2003)
	Methyl methacrylate-co-itaconic anhydride	Single T_g	–	Bell et al. (1994)
	Methyl methacrylate-co-N-phenylitaconimide	Single T_g	Miscibility depended on compositions of I and II	Cowie et al. (1990b)
	Methyl methacrylate-co-phenyl methacrylate	Single T_g	Miscibility depended on compositions of I and II	Nishimoto et al. (1990)
	Methyl methacrylate-co-phenylmaleimide	Single T_g	Miscibility depended on compositions of I and II	Merfeld et al. (1999)
	Methyl methacrylate-co-tribromophenyl maleimide	Single T_g	Miscibility depended on compositions of I and II	Merfeld et al. (1999)
	Methyl methacrylate-co-2,2,6,6-tetramethyl-piperidinyl methacrylate	Single T_g; transparency	I had 22 or 30 wt% AN; II had ≤31.4 wt% 2,2,6,6-tetramethyl-piperidinyl methacrylate	Goh et al. (1986b), Goh et al. (1987)
	Methylthiomethyl methacrylate	Single T_g; transparency	I had 9–36 wt% AN	Goh et al. (1991c)
	Novolac	Single T_g	I had 25 wt% AN; II was formaldehyde + 13/17/70 mol% p-t-butylphenol/m-cresol/o-cresol	Fahrenhlotz and Kwei (1981)

	Oxy-1,4-phenylene-sulfonyl-1,4-phenylene oxy-2,6-diisopropyl-1,4-phenylene isopropylidene 3,5-diisopropyl-1,4-phenylene	Modulus-temperature	I had 13–16 % AN	R17
	Phenyl acrylate	Single T_g	I had 14.6–34.1 wt% AN; width of miscibility window dependent on choice of solvent (Rana et al. (1993))	Rana et al. (1993), Sankarapandian and Kishore (1991), Sankarapandian and Kishore (1994)
	n-Propyl methacrylate	Single T_g	I had 5.7–19.5 wt% AN	Fowler et al. (1987), Lath and Lathova (1994)
	Tertiary amide	Single T_g	II was N-methyl-N-vinylacetamide and I had 67–88 wt% AN; II was N,N'-dimethylacrylamide and I had 70–88 wt% AN; II was N-vinylpyrrolidone and I had 64–88 wt% AN	Yeo et al. (1996)
	Tetrahydrofurfuryl methacrylate	Single T_g; transparency	I had 9–48 wt% AN	Goh and Siow (1987), Goh et al. (1992a)
	Tetrahydropyranyl-2-methyl methacrylate	Single T_g; transparency	I had ≤31 wt% AN	Chong and Goh (1991a)
	Tetramethyl sulfone	Single T_g	I had 11.5–19.5 wt% AN	Ahn et al. (1994)
	Vinyl acetate-co-vinyl chloride	Single T_g	I had 22 wt% AN; miscibility depended on choice of solvent	Das and Banerjee (1996), Das et al. (1996)
	Vinyl chloride	Single T_g	I had 11.5–26 wt% AN	Kim et al. (1989)
Acrylonitrile-co-styrene-co-p-vinylphenol	Carbonate of bisphenol-A	Single T_g; FTIR	I had 25–80 mol% vinylphenol	Li et al. (2007)
Acrylonitrile-co-p-vinylphenol	Carbonate of bisphenol-A	Single T_g; FTIR	I had 12–50 mol% acrylonitrile	Li et al. (2007)

(continued)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
Acrylonitrile-*co*-vinylidene chloride	Caprolactone	Single T_g	I was usually Saran F (80 % vinylidene chloride); semicrystalline when ≤70 wt% I	Aubin et al. (1983), Varnell et al. (1983), Zhang and Prud'homme (1987)
	Hexamethylene terephthalate	Single T_g	Probably semicrystalline; I was Saran F (80 % vinylidene chloride)	Aubin and Prud'homme (1984)
	Methyl methacrylate	Single T_g; FTIR; NMR	I had 20 wt% AN	Feng et al. (1996c)
N-Acryloyl-*N'*-methylpiperazine	Acid	FTIR; XPS	II was acrylic acid, methacrylic acid, styrenesulfonic acid, or vinylphosphonic acid; formed complexes	Liu et al. (2000)
	p-Vinylphenol	Single T_g; FTIR; XPS	–	Liu et al. (1999)
N-Acryloyl-*N'*-phenylpiperazine	Acid	FTIR; XPS	II was acrylic acid, styrenesulfonic acid, or vinylphosphonic acid; formed complexes	Goh et al. (1999d)
	p-Vinylphenol	Single T_g; FTIR; XPS	–	Goh et al. (1999d)
N-1-Alkylitaconamic acid	*p*-Vinylphenol	Single T_g; FTIR	I had an alkyl group of ethyl, propyl, butyl, hexyl, octyl, decyl, or dodecyl	Urzua et al. (2002)
	2-Vinylpyridine	Single T_g; FTIR	I had an alkyl group of ethyl, propyl, butyl, hexyl, octyl, decyl, or dodecyl	Urzua et al. (2002)

N-1-Alkylitaconamic acid-co-styrene	N-Vinylpyrrolidone	Single T_g; FTIR	I had an alkyl group of ethyl, propyl, butyl, hexyl, octyl, decyl, or dodecyl; I had 50 or 80 wt% styrene	Urzua et al. (2006)
	Vinylpyridine	Single T_g; FTIR	I had an alkyl group of ethyl, propyl, butyl, hexyl, octyl, decyl, or dodecyl; I had 50 or 80 wt% styrene; II was 2- or 4-vinylpyridine	Urzua et al. (2006)
Allyl alcohol-co-styrene	Alkyl methacrylate	Single T_g; FTIR; NMR	I had 5.7 wt% OH; II had an alkyl group of ethyl or methyl	Feng and Feng (1997)
	Ester	Single T_g	I had M_w = 1.4–2.1 kg/mol and had 1.3–7.7 wt% OH groups; II was butylene adipate, butylene sebacate, caprolactone, 1,4-cyclohexane dimethylene succinate, decamethylene sebacate, and 2,2-dimethyl-1,3-propylene adipate of hexamethylene sebacate; high OH content of I favored miscibility	Bamum et al. (1981), Woo et al. (1984a)
Amic acid	3,3-Diamino-4,4'-benzidine isophthalamide	Transparency; FTIR	I was LaRC-TPI	Kim et al. (1993b)
	Phenol-formaldehyde	Clear before and after curing	I was made from 4,4'-methylene-dianiline and pyromellitic dianhydride	Adduci et al. (1981)
	Imide	Single T_g	II was Polyimide Prashantha et al. (2008); miscible over certain composition range	Makhija et al. (1992)

(continued)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
Amide	Ester	Single T_g	I was MXDS made from *m*-xylylenediamine and adipic acid; II was made from hexamethylene diamine and a mixture of iso- and terephthalic acid	Nagasawa et al. (2000)
Amide enaminonitrile	*N*-Vinylpyrrolidone	Single T_g; transparency	–	Moore and Kaur (1998)
	4-Vinylpyridine	Single T_g; transparency	–	Moore and Kaur (1998)
Amideimide	Benzimidazole	Single T_g; FTIR; SEM; POM	I was Torlon 4,000T	Wang et al. (2007)
	Novolac	Single T_g	I was made from rosin	Kundu et al. (1986a)
	Imide	Single T_g; FTIR; SEM; POM	I was Torlon 4,000T; II was Matrimid 5218	Wang et al. (2007)
	Resol	Single T_g	I was made from rosin maleic anhydride Diels–Alder adduct with 4,4′-diaminodiphenylmethane	Kundu et al. (1986b)
	Shellac	Single T_g	I was made from rosin-imidoamino acid with 4,4′-diaminodiphenylmethane	Kuo et al. (1990)
n-Amyl methacrylate	Vinyl chloride	Single T_g; transparency	–	Ha et al. (1990a), Perrin and Prud'homme (1991), Tremblay and Prud'homme (1984), Walsh and McKeown (1980)
	Vinyl chloride, chlorinated	Single T_g; transparency	II had 65 or 68 wt% Cl	Ha et al. (1990a), Trask and Roland (1988)
	Vinyl chloride-*co*-vinylidene chloride	Single T_g; transparency	II was Saran; ≥80 % vinylidene chloride	Kang and Cho (1989), Tremblay and Prud'homme (1984)

Aniline	2-Ethyl-2-oxazoline	Single T_g; XPS	I was doped with p-phenolsulfonic acid; blend had 5–60 wt% I	Ong et al. (1996b)
	Tertiary amide	Single T_g; FTIR	I was doped with p-phenolsulfonic acid or 5-sulfosalicylic acid; blend had $\leq$50 wt% I; II was N-vinylpyrrolidone, N-methyl-N-vinylacetamide, N,N-dimethylacrylamide, or 2-methyl-2-oxazoline	Goh et al. (1998a)
	Vinyl acetate	Single T_g; FTIR; XPS	I was doped with p-phenolsulfonic acid; blend had $\leq$50 wt% I	Goh et al. (1996a)
o-Anisidine	2-Alkyl-2-oxazoline	Single T_g; FTIR	Blend had $\leq$50 wt% I; II had an alkyl group of methyl or ethyl	Ong et al. (1996a)
Aramide	Amide	Single T_g; T_m-depression	I was Trogamid T; II was PA-6, PA-4,6, PA-6,6, PA-6,9, PA-6,10, or PA-11, PA-6,12	Ellis (1988, 1989), Garlund (1993), Myers et al. (1990)
	Butylene terephthalate	Single T_g	I was made from 2,2,4-trimethyl-1,6-hexanediamine and terephthalic acid (Trogamid T); semicrystalline	Nadkarni et al. (1988)
	Caprolactam-co-laurolactam	Single T_g	I was Trogamid T; II had 43.8–55.6 mol% caprolactam; semicrystalline	Ellis (1990a, b)
	Caprolactam-co-2-pyrrolidinone	Single T_g	I was Trogamid T; II had 93.5 mol% caprolactam; semicrystalline	Ellis (1990a, b)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
	Ester	Single T_g	I was Trogamid T; II was made from 1,4-cyclohexanedimethanol/ethylene glycol/terephthalic acid (PETG 6763)	Nadkarni et al. (1988)
	Cycloaliphatic amide	Single T_g	I was Trogamid T; II was made from 1,4- and 1,3-benzenedicarboxylic acids and a mixture of 1,6-hexanediamine and bis (4-aminocyclohexyl)methane (Bexloy AP C-803)	Ellis (1989)
	Ethylene terephthalate	Single T_g	I was Trogamid T; semicrystalline	Nadkarni et al. (1988)
	Amide	Single T_g	II was PA-4,6, PA-6, PA-6,6, or PA-6,9; I was made from 1,6-hexanediamine and a mixture of isophthalic and terephthalic acids (Zytel 330); semicrystalline	Ellis (1989, 1990b)
	Cycloaliphatic amide	Single T_g	I was Zytel 330; II was Bexloy AP C-803	Ellis (1989)
	Vinyl chloride	Single T_g; FTIR; SEM	I was made from 4,4′-oxydianiline and isophthaloyl chloride	Shabbir et al. (2008)
Aryl ether ether ketone	Aryl ether ether ketone	Single T_g; POM; AFM	–	Chen and Yang (2005)
	Etherimide	Single T_g; microscopy	–	Tseng and Woo (1998)

Arylate				
	Aramide	Single T_g	I was made from bisphenol-A and a mixture of terephthalic acid/isophthalic acid/5-t-butyl-isophthalic acid = 44/44/12 (Polyarylate C); II was Trogamid T	Dean (1987b)
	Aramide-S	Single T_g	I was Polyarylate C; II was made from 5-t-butylisophthalic acid/isophthalic acid 90/10 and 1,12-diaminododecane (Aramide-S)	Dean and Harris (1992)
	Aramide-M	Single T_g	I was made from bisphenol-A and a mixture of terephthalic acid/isophthalic acid/5-t-butyl-isophthalic acid = 42.5/42.5/15 (Polyarylate D); II was made from adipic acid and m-xylene-diamine/hexamethylene diamine 80/20 (Aramide-M)	Dean and Harris (1992)
	Aramide	Single T_g	I was Polyarylate D; II was Trogamid T	Dean and Harris (1992)
	Aramide-S	Single T_g	I was Polyarylate D; II was Aramide-S	Dean and Harris (1992)
	Aramide-M	Single T_g	I was made from bisphenol-A and a mixture of terephthalic acid/isophthalic acid/5-t-butyl-isophthalic acid = 37.5/37.5/25 (Polyarylate E); II was Aramide-M	Dean and Harris (1992)
	Aramide	Single T_g	I was Polyarylate E; II was Trogamid T	Dean and Harris (1992)

(continued)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
	Aramide-S	Single T_g	I was Polyarylate E; II was Aramide-S	Dean and Harris (1992)
	Aramide	Single T_g	I was made from bisphenol-A and a mixture of terephthalic acid/5-t-butylisophthalic acid 50/50 (Polyarylate F); II was Trogamid T	Dean and Harris (1992)
	Aramide	Single T_g	I was Polyarylate F; II was Aramide-S	Dean and Harris (1992)
	Carbonate of bisphenol-A	Single T_g	I was made from bisphenol-A and a mixture of terephthalic acid/isophthalic acid 50/50 (Ardel D-100); miscibility arose from transesterification	Robeson (1985)
	Ester	Single T_g	I was Ardel D-100; II was made from cyclohexane dimethanol and terephthalic acid/isophthalic acid (80–87 % tere) (Kodar A-150) and another copolymer with tere/iso ratio of 70/30	Robeson (1985)
	Ester	Single T_g; positron annihilation lifetime spectroscopy	I was Ardel D-100; II was made form cyclohexane dimethanol and 1,4-cyclohexane dicarboxylic acid	Zipper et al. (1995)
	Ester	Single T_g	I was Ardel D-100; II was made from cyclohexane dimethanol, ethylene glycol, and terephthalic acid (molar ratio 1:2:3, PETG-6763)	Golovoy and Cheung (1989), Robeson (1985)

		Methods	Comments	Reference
	1,4-Cyclohexamethylene terephthalate	Single T_g	II was arylate of bisphenol-A and iso/terephthalic acid	Hwang (2000)
	Ethylene terephthalate	Single T_g	I was Ardel D-100; miscibility arose from transesterification	Robeson (1985)
	Hydroxyether of bisphenol-A (Phenoxy)	Single T_g	I was Ardel D-100; miscibility arose from transesterification	Robeson (1985)
Arylate of tetramethylbisphenol-A	Butylene sebacate	Single T_g	Semicrystalline	Ahn et al. (1995)
	Ester	Single T_g; T_m-depression	II was caprolactone, butylene sebacate, hexamethylene sebacate, hexamethylene decamethylene decarboxylate, or decamethylene sebacate	Ahn et al. (1998)
	Hexamethylene sebacate	Single T_g	Semicrystalline	Ahn et al. (1993a)
Aryletherketone	Etherimide	Single T_g	I was made from 4,4′-difluoro-benzophenone and hydroquinone; II was Ultem 1000	Harris and Robeson (1988)
	Etherimide	Single T_g	I was made from p-phenoxybenzoyl chloride; II was Ultem 1000	Harris and Robeson (1988)
Arylsulfone	Imide	Single T_g	I was Radel A; II was XU-218	Jeremic et al. (1992)
	3-Bromo-2,6-dimethyl-1,4-phenylene ether p-bromostyrene	Single T_g; microscopy	–	Kambour et al. (1983)
	p-Bromostyrene-co-styrene	Single T_g; microscopy	II had ≤85 mol% styrene	Kambour et al. (1983)
γ-Benzyl glutamate		Dynamic mechanical methods; DSC	Miscible as random coil, but not as α-helics	Tsujita et al. (1985)
Benzimidazole	Phenylsulfone, sulfonated	Single T_g; FTIR; SEM	II was Na-neutralized	Sun et al. (2004)
	Sulfone, sulfonated	Single T_g; FTIR; SEM	II was Na-neutralized	Sun et al. (2004)
	Vinylidene fluoride	Single T_g; FTIR; T_m-depression	–	Dhamodaran et al. (2008)
Benzyl methacrylate	Phenyl methacrylate	Single T_g; FTIR; transparency; SEM	–	Lee and Woo (2000)

(continued)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
Bismaleimide	Imide	Single T_g; transparency	I was based on bisphenol-A; II was alkyl terminated and hyperbranched	Qin et al. (2006)
Bis(methoxyethoxyethoxy) phosphazene	Acrylic acid-co-methyl methacrylate	Single T_g; transparency	II had 10, 20, or 30 mol% acrylic acid	Landry et al. (1993d)
	Methylic acid-co-methyl methacrylate	Single T_g; transparency	II had 20 mol% methacrylic acid	Landry et al. (1993d)
	Styrene-co-styrene-4-carboxylic acid	Single T_g; transparency	II had 75 mol% styrene	Landry et al. (1993d)
	Styrene-co-p-vinylphenol	Single T_g; transparency	II had 78 mol% styrene	Landry et al. (1993d)
	p-Vinylphenol	Single T_g; transparency	–	Landry et al. (1993d)
Bis(methoxyethox yethoxyethoxy)phosphazene	p-Vinylphenol	Single T_g; transparency	–	Landry et al. (1993d)
3-Bromo-2,6-dimethyl-1,4-phenylene oxide-co-2,6-dimethyl-1,4-phenylene ether	p-Bromostyrene	Single T_g; microscopy	I had $\leq$22 mol% 2,6-dimethyl-1,4-phenylene ether	Kambour et al. (1983)
	Styrene	Single T_g; microscopy	Miscible up to full bromination of I when I had $M_w \leq$40 kg/mol and II had $M_w \leq$30 kg/mol	Kambour et al. (1983), Maconnachie et al. (1984)
2-Bromoethyl methacrylate	Ester	Single T_g	II was ethylene adipate, caprolactone, butylene adipate, 2,2-dimethyl-1,3-propylene adipate, 2,2-dimethyl-1,3-propylene sebacate, or hexamethylene sebacate	Neo and Goh (1993)
	Tetrahydrofurfuryl methacrylate	Single T_g; transparency	–	Neo and Goh (1991c)

Bromohydroquinone-co-4,4'-(decamethylenedioxy) bibenzoic acid	(Decamethylenedioxy)-bibenzoic acid-co-4,4'-(ethylenedioxy) diphenol	Single T_g; microscopy	Transition temperature from a mesophase to an isotopic phase changed continuously and smoothly depending on the composition	Jin et al. (1986)
	p-Hydroxybenzoic acid-co-3-methyl-1,6-hexanediol-terephthalic acid	Single T_g; microscopy	Transition temperature from a mesophase to an isotopic phase changed continuously and smoothly depending on the composition	Jin et al. (1986)
p-Bromostyrene-co-styrene	2,6-Dimethyl-1,4-phenylene ether	Single T_g; microscopy	I had ≥ 53 mol% styrene	Kambour et al. (1983)
Butadiene	Butadiene	Single T_g	I was 1,4-polybutadiene; II had 63 % 1,2-	Roovers and Toporowski (1992)
	Diene-co-ethylene-co-propylene	Single T_g	Commercial samples; many mixtures had two T's	Caspary (1972), Kleintjens "unpublished results", Koningsveld et al. (1974)
	Isoprene	Single T_g; microscopy; light scattering; NMR	Depended on microstructure; immiscible when I and II were both highly cis; I was deuterated (Hasegawa et al. (1991))	Bartenev and Kongarov (1963), Briber and Khoury (1987), Corish (1967), Fujimoto and Yoshimiya (1968), Gesner (1969), Hasegawa et al. (1991), Heffner and Mirau (1994), Kawahara et al. (1994), Livingston and Rongone (1970) Marei and Sidorovich (1965), Marsh et al. (1967, 1968), Shutilin and Vysokomol (1991), Slonimskii (1958), Slonimskii and Komskaia (1956), Struminskii and Slonimskii (1956), Walters and Keyte (1965), Zlatkevich and Nikolskii (1973)

(*continued*)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
Butadiene-*co*-styrene	t-Butylstyrene	Single dynamic mechanical loss peak	I had 25 % styrene; II had $M_w = 835$	Class and Chu (1985a)
	Glycerol ester of hydrogenated rosin	Single dynamic mechanical loss peak	I had 25 % styrene; II had $M_w = 500$	Class and Chu (1985c)
Butadiene-*co*-vinyl ethylene	Hydrogenated terpene resin	Light scattering; SEM	I had 47.4 or 60 wt% vinyl content	Kano et al. (1993)
1-Butene	1-Pentene	Single T_g	–	Decroix and Piloz (1977)
	Propylene	Single T_g; T_m-depression	Semicrystalline	Decroix and Piloz (1977), Lee and Marand (1991), Lee and Chen (1996), Piloz et al. (1976)
Butyl acrylate	Alkyl methacrylate	Single T_g	II had an alkyl group of 1-chloroethyl or dichloroethyl	Peng et al. (1996)
	Ethylene, chlorinated	Single T_g; transparency	II had 49.8 or 62.1 % Cl; immiscible when II had 48.0 % Cl	Chai and Walsh (1983)
	Hexafluoroacetone-*co*-vinylidene fluoride	Single T_g; XPS	II had 8 mol% hexafluoroacetone	Kano et al. (1997b)
	4-Hydroxystyrene-*co*-styrene	Single T_g	I was t-butyl; II had 28–66 mol% 4-hydroxystyrene	Zhu et al. (1990)
	Vinyl chloride	Single T_g; transparency	Some papers showed two T_g's (refs. Tremblay and Prud'homme (1984), Wolf (1963)) or phase separation in solution (Kern (1958))	Kern (1958), Piglowski and Kammer (1990), Tremblay and Prud'homme (1984), Walsh and Cheng (1982, 1984a), Walsh and McKeown (1980), Walsh and Sham (1989), Wolf (1963)
	Vinyl chloride-*co*-vinylidene chloride	Single T_g; transparency	II was Saran ($\geq$80 % vinylidene chloride)	Tremblay and Prud'homme (1984)

Butyl acrylate-*co*-methyl methacrylate	Ethylene, chlorinate	Single T_g; FTIR	I had 13–82 wt% butyl acrylate	Piglowski et al. (1996)
	Vinyl chloride	Single T_g; electron microscopy; FTIR	II was Degalan VanderHart (1994) (90 % methyl methacrylate) (Zelinger et al. (1976)); I had 75 % butyl acrylate (Piglowski (1990)); II was head-to-tail or head-to-head (Piglowski et al. (1996))	Piglowski (1990), Piglowski et al. (1996), Zelinger et al. (1976)
Butyl methacrylate	*p*-(2-Hydroxy-hexafluoroisopropyl) styrene-*co*-styrene	Single T_g; transparency	II had 83.3–98.25 mol% styrene; immiscible when II had 99.0 mol% styrene	Adduci et al. (1981), Chen and Morawetz (1989), Min et al. (1983), Pearce et al. (1984), Ting et al. (1980)
	p-(2-Hydroxy-hexafluoroiso-propyl)-α-methylstyrene-*co*-styrene	NMR	II had 1.5 mol% OH-containing monomer	Campbell et al. (1992)
	Vinyl chloride	Single T_g; transparency; miscible in solution	I was *n*-butyl, isobutyl, or sec-butyl	Ha et al. (1990a), Kern (1958), Perrin and Prud'homme (1991), Piglowski (1988), Walsh and Cheng (1984a), Walsh and McKeown (1980), Trask and Roland (1988)
	Vinyl chloride-*co*-vinylidene chloride	Single T_g; transparency	II was Saran, ≥80 % vinylidene; I was *n*-butyl, isobutyl, or sec-butyl	Kang et al. (1988), Tremblay and Prud'homme (1984)
Butyl methacrylate-*co*-vinylbenzyl thymine	Styrene-*co*-2-vinyl-4,6-diamino-1,3,5-triazine	Single T_g; FTIR	I had <93 mol% butyl methacrylate; II had <93 mol% styrene	Kuo and Hsu (2010)
N-Butyl-3-hydroxymethyl carbazoyl methacrylate	ω-Hydroxybutyl-3,5-dinitrobenzoyl methacrylate	Single T_g	–	Rodriguez-Parada and Percec (1986b)

(continued)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
n-Butyl methacrylate-co-methacrylic acid	N,N-Dimethylacrylamide-co-styrene	Single T_g; FTIR	I had 18 mol% methacrylic acid and II had 17 mol% dimethylacrylamide; formed complexes when II had 32 mol% dimethylacrylamide	Siham and Said (2006)
	Styrene-co-4-vinylpyridine	Single T_g; FTIR	I had 8 or 18 mol% methacrylic acid; II had 15, 22, or 28 mol% 4-vinylpyridine	Djadoun et al. (1996)
n-Butyl methacrylate-co-4-vinylpyridine	Methacrylic acid-co-styrene	Single T_g; FTIR	I had 10.6, 18.9, or 26 mol% 4-vinylpyridine; II had 12, 24, or 29 mol% methacrylic acid (Djadoun et al. (1996)); I had 6.50 mol% 4-vinylpyridine; II had 10.50 mol% methacrylic acid (Djadoun (1983))	Djadoun (1983), Djadoun et al. (1996)
t-Butylstyrene	Cyclohexyl acrylate	Single T_g; transparency	–	Siol (1991)
	Cyclohexyl methacrylate	Single T_g; transparency	–	Siol (1991)
	Isoprene	Single dynamic mechanical loss peak	I had $M_w = 835$; II was natural rubber	Class and Chu (1985a)
	3,3,5-Trimethyl-cyclohexyl methacrylate	Single T_g; transparency	–	Siol (1991)
Butylene adipate	Arylate	WAXD; DMA	–	Huo et al. (1993)
	Epichlorohydrin	Single T_g	Semicrystalline	Fernandes et al. (1984)
	Hydroxyether of bisphenol-A (Phenoxy)	Single T_g; melt transparent; IGC	Semicrystalline when ≤60 wt% II	Harris et al. (1982), Uriate et al. (1995)
	Trifluoroethylene-co-vinylidene fluoride	Single T_g	–	Kim and Kyu (1999), Kim and Kyu (2003)
	Vinyl acetate-co-vinylidene chloride	Single T_g	II was Saran C (≥80 % vinylidene chloride); semicrystalline	Aubin et al. (1983)

	Vinyl bromide	Single T_g	–	Cousin and Prud'homme (1982)
	Vinyl chloride	Single T_g	Semicrystalline when ≤70 wt% II	Ziska et al. (1981)
Butylene dodeca methylene dicarboxylate	Vinylidene fluoride	Single T_g; FTIR	Exhibited double T_m	Penning and Manley (1996)
Butylene 2,6-naphthalate	Vinyl chloride	Single T_g	Semicrystalline	Woo et al. (1985b)
	Etherimide	Single T_g; T_m-depression	–	Huang (2004)
	Ethylene 2,6-naphthalate	Single T_g	Blend had ≥80 wt% I	Yoon et al. (1994)
	Ethylene 2,6-naphthalate, phosphorus containing	Single T_g	Blend had ≤40 wt% and ≥90 wt% II	
Butylene sebacate	Epichlorohydrin	Single T_g	Semicrystalline	Fernandes et al. (1984)
	Vinyl chloride	Single T_g	Semicrystalline	Woo et al. (1985b)
Butylene succinate	Vinylidene fluoride	T_m-Depression; OM	Semicrystalline	Lee et al. (1998c)
Butylene terephthalate	Arylate	Single T_g; FTIR	Semicrystalline	Jang and Won (1998), Lee et al. (2000)
	Arylate	Single T_g; T_m-depression	II was arylate of bisphenol-A and 3 different acids	Liau et al. (1999)
	Arylate	Single T_g; T_m-depression	II was arylate of bisphenol-A and a mixture of isophthalic and terephthalic acid	Liau et al. (2006)
	Arylate of bisphenol-A	Single T_g; T_m-depression	Semicrystalline	Liu et al. (1998)
	Butylene oxide-g-butylene terephthalate	Single T_g; dielectric loss measurements; microscopy	II had 84 wt% butylene terephthalate	Martynowicz-Hans and Runt (1986), Runt et al. (1989)
	Caprolactone	Single T_g; FTIR; OM	Miscible when II was oligomeric	Di Lorenzo et al. (2007), Righetti et al. (2007)
	Decamethylene-4,4'-terephthaloyl dioxydibenzoate	Single T_g; microscopy; T_m-depression	0–50 % II in blend	Pracella et al. (1986, 1987, 1989)
	Epoxy	Single T_g; T_m-depression	–	Zhang et al. (2006b)
	Ester	Single T_g	Semicrystalline when ≥25 wt% I; II was CP-350(bisphenol-A-neopentyl glycol terephthalate)	Slagowski et al. (1981)

(continued)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
	Ester	Single T_g	Semicrystalline; II was made from bisphenol-A and 1/1 or 1/3 terephthaloyl chloride/isophthaloyl chloride	Kimura and Porter (1981), Kimura et al. (1983)
	Ester	Single T_g; SEM	II was made from ethylene glycol and cyclohexane-1,4-dimethanol terephthalate	Papadopoulou and Kalfoglou (1997a)
	Ester carbonate	Single T_g	II had 29.1 wt% carbonate unit	Lee et al. (2000)
	Ester carbonate	Single T_g	II had 42 or 70 mol% aromatic ester group	Rodriguez et al. (1996)
	Ester ether	Single crystallization peak	II was a segmental block copolymer	Gallagher et al. (1993)
	Ethylene naphthalene-2,6-dicarboxylate	Single T_g; T_m-depression; NMR	–	Guo and Zachmann (1997)
	Ethylene terephthalate	Single T_g	Semicrystalline	Avramova (1995), Escala et al. (1978), Escala et al. (1979)
	Hydroxyether of bisphenol-A (Phenoxy)	Single T_g; melt transparent	Semicrystalline	Robeson and Furtek (1977, 1979), Seymour and Zehner (1980)
	Vinyl acetate-co-vinylidene chloride	Single T_g	II had ≥80 % vinylidene chloride	Aubin and Prud'homme (1984)
	Vinyl butyral	Single T_g; FTIR; NMR	Miscible when blend was prepared by in situ polymerization of oligomer I in II	Tripathy et al. (2003)
	Vinyl chloride	Single T_g	Semicrystalline	Aubin and Prud'homme (1984), Robeson (1978)
	Vinyl chloride, chlorinated	Single T_g	Semicrystalline	Aubin and Prud'homme (1984)

Caprolactam (PA-6)	Acrylic acid	Single T_g	Semicrystalline	Jiang et al. (1986)
	Amide	Single T_g; OM	II was made from hexamethylene diamine with tere and isophthalic acid	Siciliano et al. (1996)
	Aramide	Single T_g	II was aramide from 5-(4-aminobenzoylamino) isophthalic acid	Monticelli et al. (2003)
	Aramide, hyperbranched	Single T_g; T_m-depression	–	Monticelli et al. (2005)
	Etheretherketone, sulfonated	Single T_g; FTIR	II had 19.2 mol% sulfonation	Lu and Weiss (1996a)
	Etheretherketone, sulfonated and metal-neutralized	Single T_g; FTIR	II had 19.2 mol% sulfonation and neutralized with Li or Zn	Lu and Weiss (1996a)
	Hexamethylene adipamide	Single T_g; enthalpy recovery kinetics	Semicrystalline	Ellis (1992), Tomova et al. (2000), Verma et al. (1986), Wei et al. (2004)
	Maleic anhydride-*co*-vinyl acetate	Single T_g; FTIR, transparency; WAXD	II was hydroxylated	Lee et al. (1996a)
	Methacrylic acid	SAXS	Semicrystalline	Janicke and Wlochowicz (1989)
	Novolac	Single T_g; SAXS	II was chlorinated	Huang et al. (2001)
	Styrene, sulfonated and Li-neutralized	Single T_g	II had 9,8 mol% sulfonated groups; semicrystalline	Molner and Eisenberg (1991), Molner and Eisenberg (1992)
	Styrene, sulfonated and Mn-neutralized	Single T_g; T_m-depression	II had 10.2 mol% sulfonated groups; semicrystalline	Lu and Weiss (1991)
	Styrene, sulfonated and Zn-neutralized	Single T_g; T_m-depression	II had 10.1 mol% sulfonated groups; semicrystalline	Lu and Weiss (1992)
	Vinyl alcohol	Single T_g; T_m-depression	Blend had ≤50 wt% II (Kang et al. (1989))	Cui et al. (2008), Koulouri and Kallitsis (1998)
	Vinyl butyral	Single T_g	Semicrystalline; II had 50–65 vol% residual vinyl alcohol unit	Jeong et al. (2000a)
	p-Vinylphenol	Single T_g; SAXS	Semicrystalline	Huang et al. (2001)
	m-Xylene adipamide	T_m-Depression	Semicrystalline	Shibayama et al. (1995)

(*continued*)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
Caprolactone	Acrylonitrile-*co*-t-butylstyrene	Single T_g; SALS; microscopy	II had 19.8–39.6 wt% acrylonitrile	Hseih and Peiffer (1993)
	Benzoxazine	Single T_g; FTIR; NMR	–	Ishida and Lee (2001), Huang and Yang (2005)
	Benzyl methacrylate	OM	–	Woo et al. (2000d)
	3,3-Bis(chloromethyl)oxetane	Single T_g	Semicrystalline; II was Penton	Guo (1990c), Koleske (1978)
	Bisphenol-A	Single T_g; FTIR	Semicrystalline	He et al. (2001)
	t-Butylphenol	Single T_g; FTIR	Semicrystalline	He et al. (2001)
	Caprolactone-*co*-ethylene terephthalate	Single T_g	II had 13 or 28 wt% ethylene terephthalate	Ma et al. (1996)
	Cellulose alkyl ester	Single T_g; transparency	II was cellulose butyrate, cellulose propionate, or cellulose valerate	Kusumi et al. (2008)
	Chlorostyrene	Single T_g; FTIR; SEM; T_m-depression	II was *o*-chlorostyrene or mixed *o*- and *p*-isomers; semicrystalline when ≥21 % I	Allard (1982), Aubin et al. (1982), Aroguz et al. (2007)
	4,4′-Dihydroxydiphenyl ether	Single T_g; FTIR; T_m-depression	–	Li et al. (2006)
	Epichlorohydrin	Single T_g	Semicrystalline	Brode and Koleske (1972), Fernandes et al. (1984)
	Epoxy	Single T_g; FTIR; NMR	Miscible before and after curing with 2,2′-bis[4-(4-aminophenoxy)phenyl] propane (Zheng et al. (2003d))	Guo nad Groeninckx (2001), Ni and Zheng (2005), Zheng et al. (2003a, c, d)
	Ester	DSC; SALS; X-ray diffraction; microscopy	II was made from terephthaloyl chloride and 4,4′-bis (6-hydroxyhexyloxy)biphenyl	Van Ende et al. (1992)
	Ester, unsaturated	Single T_g; FTIR; T_m-depression	–	Salom et al. (2006)

Ethylene, chlorinated	Single T_g; WAXS; SAXS; TEM	Semicrystalline when ≤90 % II; II had ≥30 % Cl; two T_g's when II had 25 % Cl	Aubin et al. (1982), Belorgey and Prud'homme (1982), Defieuw et al. (1989c), Groeninckx et al. (1988), Plivelic et al. (2007)
Hydroxyether of bisphenol-A (Phenoxy)	Single T_g; melt transparent; IGC; FTIR	Semicrystalline when >50 wt% I	Brode and Koleske (1972), Defieuw et al. (1989b), De Juann et al. (1994), Harris et al. (1982), Kuo et al. (2001a)
Hydroxyether of bisphenol-A, partially acetylated	Single T_g; T_m-depression, FTIR	I had a degree of acetylation of 5–90 mol%	Ma et al. (1999), Zheng et al. (1997c)
Methoxystyrene-*co*-*p*-vinylphenol	Single T_g; T_m-depression, FTIR	I had 60 mol% methoxystyrene	Sanchis et al. (1998)
Nitrocellulose	Single T_g	≥50 % I; semicrystalline when ≥50 % I	Brode and Koleske (1972), Hubbell and Copper (1977, 1979)
Novolac	Single T_g; T_m-depression, FTIR	–	Kuo and Chang (2001a), Kuo et al. (2001a)
Phenol catechin	Single T_g; T_m-depression, FTIR	–	Zhu et al. (2003)
Phenyl methacrylate	Single T_g; FTIR; OM	–	Woo and Mandal (1999), Woo et al. (2000d)
Propylene, chlorinated	Single T_g	I had 66 wt% Cl; semicrystalline when ≥50 wt% I	Allard and Prud'homme (1982), Aubin et al. (1982)
Vinyl acetate-*co*-vinylidene chloride	Single T_g	II was Saran C (≥80 mol% vinylidene chloride); semicrystalline	Aubin et al. (1983), Chiu and Min (2000), Zhang and Prud'homme (1987)
Vinyl bromide	Single T_g	Semicrystalline when >30 % I	Coleman et al. (1991a), Vogl et al. (1997)

(continued)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
	Vinyl chloride	Single T_g; NMR; FTIR; T_m-depression	Semicrystalline when ≥ 30 % I; II was head-to-head or head-to-tail (Vogl et al. (1997))	Brode and Koleske (1972), Chiu and Min (2000), Hubbell and Copper (1977, 1979), Koleske and Lundberg (1969), Kwak (1994), Ma et al. (1999), Nojima et al. (1986a), Ong and Price (1978), Vogl et al. (1997), Woo et al. (1985b), Ziska et al. (1981)
	Vinyl chloride, chlorinated	Single T_g	II had 67.2 wt% Cl; semicrystalline when ≥ 50 wt% I	Belorgey et al. (1982)
	Vinyl chloride-co-vinylidene chloride	Single T_g	Semicrystalline; II had 79 % or 88 % vinylidene chloride; some samples of II were Saran B	Aubin et al. (1983), Varnell et al. (1983), Woo et al. (1983, 1986), Zhang and Prud'homme (1987)
	Vinylidene fluoride	T_m-Depression	Semicrystalline	Jo et al. (1992b)
Caprolactone-co-ethylene terephthalate	Carbonate of bisphenol-A	Single T_g	I had <60 wt% ethylene terephthalate	Ma et al. (1995)
	Ethylene, chlorinated	Single T_g	I had 33–89 wt% ethylene terephthalate; II had 67.2 wt% Cl	Ma and Prud'homme (1990), Zhao et al. (1991)
	Hydroxyether of bisphenol-A	Single T_g; FTIR	I had 48, 58, 72, and 82 wt% ethylene terephthalate	Zhang et al. (1995b)
	Vinyl chloride	Single T_g	I had 33 or 44 wt% ethylene terephthalate	Ma and Prud'homme (1990)
	Vinyl chloride, chlorinated	Single T_g	I had 33 wt% ethylene terephthalate	Ma and Prud'homme (1990)

Carbon monoxide-*co*-ethyl acrylate-*co*-ethylene	Vinyl chloride	Single T_g	Semicrystalline when I had >60 % ethylene; I had 4.0–19.6 % carbon monoxide, 5.5–35.4 % ethyl acetate, and 34.2–79.6 % ethylene	Robeson and McGrath (1977)
Carbon monoxide-*co*-2-ethylhexyl acrylate-*co*-ethylene	Vinyl chloride	Single T_g	I had 17.8/34.2/47.9 or 18.6/ 39.6/41.8 = carbon monoxide/ 2-ethylhexyl acrylate/ethylene	Robeson and McGrath (1977)
Carbon monoxide-*co*-ethylene-*co*-vinyl acetate	Chlorostyrene	Single T_g	I was Elvaloy 741; II was a mixture of *o*- and *p*- isomers	Allard and Prud'homme (1982)
	Propylene, chlorinated	Single T_g	I was Elvaloy 741	Allard and Prud'homme (1982)
	Vinyl chloride	Single T_g	Semicrystalline when I had >60 % ethylene; I was Elvaloy 741 or 10.5/66.7/22.8 or 10.2/ 58.2/31.5 = carbon monoxide/ ethylene/vinyl acetate	Anderson et al. (1979), Bair et al. (1978), Robeson and McGrath (1977)
Carbon monoxide-alt-phenylacetylene	Caprolactone	Single T_g	Semicrystalline	Chen et al. (1996)
	Styrene	Single T_g	–	Chen et al. (1996)
Carbonate of bisphenol-A	Benzoyl paraphenylene	Single T_g; SEM	–	Ha et al. (2001)
	Biphenyl-4,4'ylene sebacate	Single T_g	Up to 40 wt% II in blend	Jo et al. (1992a)
	p-t-Butylphenol formaldehyde	Single T_g	–	Kalkar and Roy (1993)
	Butylene adipate	Single T_g; FTIR	Semicrystalline	Cruz et al. (1979b, c), Mishra and Venkidusamy (1995)
	Caprolactone	Single T_g; SAXS; SANS; NMR; T_m-depression	Semicrystalline, especially when ≥25 wt% II	Balsamo et al. (2001), Cruz et al. (1979b, c), Cheung and Stein (1994), Cheung et al. (1993, 1994), Chun et al. (2000), Herrera et al. (2005), Ma et al. (1999), Paul et al. (1977)
	Caprolactone-*co*-ethylene terephthalate	Single T_g	II had 48 or 58 wt% ethylene terephthalate	Zhang et al. (1995c)

(continued)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
	Carbonate	Single T_g; transparency	II was carbonate of bisphenol-E, bisphenol-F, bisphenol-Z, bisphenol chloral, dimethylbisphenol-A, dimethylbisphenol-A, or tetramethylbisphenol-F	Kim and Paul (1992a)
	1,4-Cyclohexane-dimethylene succinate	Single T_g	Semicrystalline	Cruz et al. (1979c, 1980)
	1,4-Cyclohexane-dimethylene terephthalate	Single T_g; melt transparent	Semicrystalline	Cruz et al. (1979c), Landry and Hendrichs (1989), Mohn et al. (1979)
	Cyclohexyl methacrylate-co-methyl methacrylate	Single T_g; NMR	II had 6.1–43.8 wt% cyclohexyl methacrylate	Hung et al. (1994), Min et al. (1990), Nishimoto et al. (1991)
	Cyclohexyl methacrylate-co-methyl methacrylate-co-2,4,6-tribromophenyl methacrylate	Single T_g; light scattering	II had 70 mol%methyl methacrylate and 10 mol% cyclohexyl methacrylate	Ohnaga et al. (1997)
	Ester	Single T_g; melt transparent	Semicrystalline when cast form solvent up to 80 wt% II; II was prepared from bisphenol-A and 1/1 = terephthalic/isophthalic acid	Mondragon et al. (1983)
	Ester	Single T_g; FTIR	II was prepared from bisphenol-A and 1/1 = terephthalic/isophthalic acid	Sakar et al. (2010)

Ester	Single T_g	II was made from terephthalic acid and 1,4-cyclohexanedimethanol and up to 60 mol% ethylene glycol	A23
Ester	Single T_g; melt transparent	Semicrystalline; II was KODAR Alexandrovich et al. (1980)0, made from 1,4-cyclohexanedimethanol and 1/4 = isophthalic/terephthalic acid	Cruz et al. (1979c), Lee et al. (2006), Masi et al. (1980), Mohn et al. (1979), Zipper et al. (1995)
Ester	Single T_g	II was Hytrel 5556, a multiblock copolymer with poly(tetramethylene ether) glycol terephthalate soft segment and tetramethylene terephthalate hard segment	Gaztelumendi et al. (1988)
Ester	Single T_g; positron annihilation lifetime spectroscopy	II was made from 1,4-cyclohexanedimethanol and 1,4-cyclohexanedicarboxylic acid	Zipper et al. (1995)
Ester	Single T_g	4 different polyesters	Kollodge and Porter (1993)
Ester	Single T_g	I had 2–7 methylene segment per ester group	Ellis (1998)
Ester, liquid crystalline	Single T_g; positron annihilation lifetime spectroscopy; SEM	II was made from p-hydroxybenzoic acid and phenylene isophthalate	Hsieh et al. (1999)
Ethylene adipate	Single T_g	Semicrystalline	Cruz et al. (1979b, c)
Ethylene succinate	Single T_g	Semicrystalline	Cruz et al. (1979b, c)

(continued)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
	Ethylene terephthalate	Single T_g	Semicrystalline; ≥50 or 75 % II; two T_g's when ≤60 % II	Hendrichs et al. (1988), Murff et al. (1984), Nassar et al. (1979), Pellow-Jarman et al. (1995)
	p-(2-Hydroxy-hexafluoroisopropyl) styrene-co-styrene	Single T_g; transparency	II had 29–78 mol% styrene; immiscible when II had 83 mol % styrene	Min and Pearce (1981), Pearce et al. (1984), Ting et al. (1980)
	Maleic anhydride-co-styrene	Light scattering	II had 8 % maleic anhydride	Saito and Inoue (1987)
	Methacrylic acid-co-styrene	Single T_g	II had 2–23 wt% methacrylic acid	Akiyama et al. (1987, 1991)
	Methyl methacrylate	Single T_g; WAXD; NMR	Blends prepared by precipitation of THF solutions in n-heptane or cast from hot THF solutions; phase behavior governed by kinetics of solvent evaporation rate (Woo and Su (1996b))	Asano et al. (1992), Chiow et al. (1987), Kyu and Saldanha (1988, 1989), Landry and Hendrichs (1989), Park and Hong (1998), Saldanha and Kyu (1987), Uyar et al. (2005), Woo and Su (1996a, b)
	Methyl methacrylate-co-p-methylstyrene	Single T_g	II had ≥70 wt% methyl methacrylate	Ikawa and Hosoda (1991)
	Methyl methacrylate-co-N-phenylmaleimide	Single T_g	II had ≥70 wt% methyl methacrylate	Ikawa and Hosoda (1991), Merfeld et al. (1999)
	Methyl methacrylate-co-phenyl methacrylate	Single T_g	II had 16–63 wt% phenyl methacrylate	Nishimoto et al. (1991), Ohnaga et al. (1997)
	Methyl methacrylate-co-styrene	Single T_g	II had ≤14 wt% styrene	Min and Paul (1989)
	Methyl methacrylate-co-2,4,6-tribromophenyl methacrylate	Single T_g; light scattering	II had 52.3–90 wt% methyl methacrylate	Ohnaga et al. (1997), Merfeld et al. (1999)

Novolac	Single T_g	II had $M_w = 1$ kg/mol and was made from formaldehyde and 13/17/70 mol% = p-t-butylphenyl/m-cresol/o-cresol	Fahrenhlotz and Kwei (1981)
Phenyl methacrylate	Single T_g	–	Kyu et al. (1992), Nishimoto et al. (1991)
Pyrrole	Single T_g	Blend had 7 % II	Wang et al. (1990)
Styrene, sulfonated and metal neutralized	Single T_g; FTIR	II had various degrees of sulfonation and neutralized by Na or Li	Lu and Weiss (1996b)
Urethane	Single T_g	II was based on 3,3'-diphenylmethane diisocyanate and aliphatic polycarbonate diols and/or polytetramethylene glycol	Fambri et al. (1997)
Vinyl acetate	Single T_g; WAXD; NMR	Formed by coalescence of gamma-cyclodextrin inclusion complex	Uyar et al. (2005)
Vinylidene chloride-co-vinyl chloride	Single T_g	II had 13.5 wt% vinyl chloride; semicrystalline when ≤25 wt% I	Woo et al. (1985a)
Carbonate of bisphenol-A, cyclic oligomer			
Acrylonitrile-co-styrene	Single T_g; transparency	II had 16–35 wt% acrylonitrile	Kambour et al. (1994)
Carbonate of bisphenol chloral	Single T_g; transparency	–	Kambour et al. (1994)
Carbonate of tetramethylbisphenol-A	Single T_g; transparency	–	Kambour et al. (1994)
Ethersulfone	Single T_g; transparency	–	Kambour et al. (1994)
Etherimide	Single T_g; transparency	–	Kambour et al. (1994)
Formal of bisphenol-A	Single T_g; transparency	–	Kambour et al. (1994)
Methyl methacrylate	Single T_g; transparency	–	Kambour et al. (1994)
Phenyl sulfone	Single T_g; transparency	–	Kambour et al. (1994)
Sulfone	Single T_g; transparency	–	Kambour et al. (1994)
Vinyl acetate	Single T_g; transparency	–	Kambour et al. (1994)
Xylylene ether	Single T_g; transparency	–	Kambour et al. (1994)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
Carbonate of dimethylbisphenol-A	Styrene	Single T_g	–	Park et al. (2001b)
Carbonate of hexafluorobisphenol-A	Ethyl methacrylate	Single T_g; transparency	–	Fernandes et al. (1986d)
	Isopropyl methacrylate	Single T_g; transparency	$\leq$70 wt% I in blend	Kim and Paul (1992d)
	Methyl methacrylate	Single T_g; transparency	–	Kim and Paul (1992d)
	n-Propyl methacrylate	Single T_g; transparency	–	Kim and Paul (1992d)
Carbonate of 2,2-propane-bis(4-(2-methylphenyl))-co-carbonate of 2,2-propane-bis(4-(2,6-dimethylphenyl))	Methyl methacrylate-co-styrene	Single T_g	I had $\geq$60 wt% carbonate of 2,2-propane-bis(4-(2,6-dimethylphenyl)); II had $\leq$37 wt% methyl methacrylate	Yoo and Kim (2004a)
Carbonate of tetrachlorobisphenol-A	Vinyl chloride	Single T_g	–	Neill and Karasz (2000)
	Vinyl chloride, chlorinated	Single T_g	II had $\leq$70.2 wt% Cl	Neill and Karasz (2000)
Carbonate of tetramethylbisphenol-A	Acrylonitrile-co-styrene	Single T_g; FTIR	II had <13 % acrylonitrile	Ahn et al. (1991b), Fernandes et al. (1986d), Kim et al. (1993a)
	Alkyl methacrylate-co-styrene	Single T_g	II had an alkyl group of methyl, ethyl, n-propyl, n-butyl, cyclohexyl, or phenyl	Kim et al. (2002c), Moon et al. (2002)
	Allyl alcohol-co-styrene	Single T_g	II had <19.1 wt% allyl alcohol	Fernandes et al. (1986d)
	Butylene sebacate	Single T_g	Semicrystalline	Fernandes et al. (1986e)
	Caprolactone	Single T_g; dielectric spectroscopy	Semicrystalline	Fernandes et al. (1986e), Madbouly et al. (2006)
	Carbonate of bisphenol-A	Single T_g; transparency	–	Belaribi et al. (1986), Kim and Paul (1992a)

	Carbonate of bisphenol-AP	Single T_g; transparency; dielectric spectroscopy	–	Kim and Paul (1992a), Mansour and Madbouly (1995)
	Carbonate	Single T_g; transparency	II was carbonate of bisphenol-E, bisphenol-F, bisphenol-S, bisphenol-Z, bisphenol chloral, dimethylbisphenol-A, dimethylbisphenol-Z, norbornane, tetramethylbisphenol-F, or tetramethylbisphenol-P	Kim and Paul (1992a)
	Ester	Single T_g	II was decamethylene decamethylene dicarboxylate, decamethylene sebacate, ethylene adipate, hexamethylene decamethylene dicarboxylate, or hexamethylene sebacate	Fernandes et al. (1986e)
	Maleic anhydride-co-styrene	Single T_g	II had 8 % maleic anhydride	Fernandes et al. (1986d)
	Methyl methacrylate-co-styrene	Single T_g	II had <50 wt% methyl methacrylate	Min and Paul (1987), Yu et al. (1991)
	α-Methylstyrene	Single T_g	–	Fernandes et al. (1986e)
	p-Methylstyrene-co-tetrahydrofurfuryl methacrylate	Single T_g	II had ≤50 mol% tetrahydrofurfuryl methacrylate	Goh et al. (1992c)
	Styrene-co-tetrahydrofurfuryl methacrylate	Single T_g	II had ≤53 mol% tetrahydrofurfuryl methacrylate	Goh et al. (1992c)
3-Carboxypropylmethyl siloxane	Vinylpyridine	Single T_g, FTIR; XPS	II was 2- or 4-vinylpyridine	Li et al. (2001b)
3-Carboxypropylmethyl siloxane-co-dimethylsiloxane	Vinylpyridine	Single T_g, FTIR; XPS	II was 2- or 4-vinylpyridine; I had ≥23 mol% acid groups	Li et al. (2001b)

(continued)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
Cellulose	Acrylonitrile	NMR; single T_g; microscopy; WAXD	–	Masson and Manley (1992), Nishio et al. (1987), VanderHart et al. (1994)
	Caprolactone	NMR	–	Masi et al. (1980)
	Ethylene glycol	Single T_g; FTIR; WAXD	–	Guo and Liang (1999), Kondo et al. (1994), Nishio et al. (1989a)
	Vinyl acetate	Single T_g	≥70 % I in blend	Nishio and Manley (1988)
	Vinyl alcohol	NMR; FTIR; T_m-depression	–	Kondo et al. (1994), Masson and Manley (1992), Nishio et al. (1989b), Radloff et al. (1996), Shibayama et al. (1991), Schartel et al. (1996)
	4-Vinylpyridine	Single T_g; NMR	–	Masson and Manley (1991), VanderHart et al. (1994)
Cellulose acetate	2,6-Dimethyl-1,4-phenylene ether, phosphonate derivative	Single T_g	II had 9.5 % P	Cabasso et al. (1977)
	2,6-Dimethyl-3-bromo-1,4-phenylene ether, phosphonate derivative	Single T_g	II had 10.5 % P	Cabasso et al. (1977)
	Ethylene succinate	Single T_g; NMR	Blend had ≥70 % I	Buchanan et al. (1997)
	Methyl methacrylate	Single T_g	I had a degree of substitution of 2.95	Ohno and Nishio (2007)
	Methyl methacrylate-co-N-vinylpyrrolidone	FTIR; NMR	Miscibility depended on degree of substitution of I and composition of II	Ohno and Nishio (2007)
	Styrene, phosphonate derivative	Single T_g	II had 8.0 % P	Cabasso et al. (1977)
	Styrene, phosphorylated	Single T_g	II had more than 1 phosphoryl group per 4 styrene units	Martuscelli et al. (1991)

	Styrenephosphonate ester	Single T_g	Blend initially prepared was heterogeneous and became miscible when annealed above T_g	Sun et al. (1989)
	Vinylidene chloride-co-styrene, phosphonylated, chloromethylated	Single T_g; electron microscopy	I was Eastman 394-45; II had 7 % P, 14.5 % Cl	Cabasso et al. (1974)
	Vinylidene chloride-co-styrene, phosphonylated	Single T_g	II had 8.6 % P	Cabasso et al. (1977)
	Vinyl acetate-co-N-vinylpyrrolidone	Single T_g; FTIR	II had >25 mol% vinylpyrrolidone	Miyashita et al. (2002), Ohno et al. (2005)
	N-Vinylpyrrolidone	Single T_g; FTIR	–	Miyashita et al. (2002), Ohno et al. (2005)
	4-Vinylpyridine	Single T_g; cast films transparent	Semicrystalline; I had 39.4 % acetyl content or had 10H/2 glucose	Aptel and Cabasso (1980), Cabasso (1981)
Cellulose acetate butyrate	Ethylene-co-vinyl acetate	Single T_g; transparent films	I had 18.5/45 = acetic acid/ butyric acid and II had 80 % vinyl acetate; two T_g's when II had 70 % vinyl acetate	Casper and Morbitzer (1977), Kosai and Higashino (1975)
	Ethylene glycol	Single T_g; OM; SAXS	–	Park and Kim (2002)
	Hydroxybutyrate-co-valerate	Single T_g; WAXD; NMR	II had 10 mol% valerate; miscible when blend had 20–50 % II, and partially miscible when blend had 60–80 % II	Buchannan et al. (1992)
	Vinyl acetate-co-N-vinylpyrrolidone	Single T_g; transparency	Miscibility depended on degree of substitution of I and composition of II	Ohno and Nishio (2006)
	p-Vinylphenol	Single T_g; FTIR	–	Gaibler et al. (2004)
Cellulose acetate hydrogen phthalate	Methyl methacrylate	Single T_g	–	Rao et al. (1999)
	N-Vinylpyrrolidone	Single T_g	–	Rao et al. (2000)

(continued)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
Cellulose butyrate	Vinyl acetate-*co*-*N*-vinylpyrrolidone	Single T_g; transparency	II had >80 mol% vinylpyrrolidone	Ohno and Nishio (2006)
	N-Vinylpyrrolidone	Single T_g; transparency	I had a degree of substitution of 2.41; immiscible if degree of substitution >2.5	Ohno and Nishio (2006)
Cellulose acetate propionate	Alkylene glutarate	Single T_g; transparency	The alkylene group was ethylene, diethylene, hexamethylene, pentamethylene, tetramethylene, or trimethylene	Buchanan et al. (1993)
	Epichlorohydrin	Single T_g; transparency	–	Yamaguchi and Masuzawa (2008)
	p-Vinylphenol	Single T_g; FTIR	–	Gaibler et al. (2004)
Cellulose diacetate	*N*-Vinyl pyrrolidone	Single T_g	–	Yin et al. (1997)
Cellulose triacetate	Cyanoethyl cellulose	Single T_g; SEM; FTIR	–	Guo et al. (1993b)
Chitin	Glycidyl methacrylate	Single T_g	–	Miyashita et al. (1997)
	2-Hydroxyethyl methacrylate	Single T_g; FTIR	–	Castro et al. (2005)
	Tertiary amide	Single T_g; transparency	I was 47 % deacetylated; II was *N*-vinylpyrrolidone, *N*-vinylacetamide, or acrylamide	Nishio et al. (1999)
	Vinyl acetate	FTIR; transparency	–	Lee et al. (1996b)
	Vinyl alcohol	Single T_g; T_m-depression	I had a degree of deacetylation of 28 %	Castro et al. (2005), Cho et al. (2001)
	N-Vinylpyrrolidone	Single T_g; FTIR; transparency	–	Miyashita et al. (1995)
Chitin, acyl derivative	Caprolactone	Single T_g; FTIR	Miscibility depended on the nature of carbon atoms in acyl group	Sugimoto et al. (2010)
Chitin-g-2-methyl-2-oxazoline	Vinyl chloride	Single T_g; FTIR	Blend had ≤10 wt% I	Aoi et al. (1995a)

			Formed complexes	
Chitosan	2-Acryloylamino-2-methylpropane sulfonic acid	–		Stoilova et al. (1999)
	Caprolactone	Single T_g; T_m-depression	–	Sarasam and Madihally (2005)
	Ethylene glycol	T_m-Depression; FTIR; WAXD	–	Rakkapao et al. (2011), Zhao et al. (1995)
	Tertiary amide	Single T_g; FTIR	II was N-vinylpyrrolidone, N-methyl-N-vinylacetamide, 2-ethyl-2-oxazoline, or 2-methyl-2-oxazoline	Fang and Goh (2000)
	N-Vinylpyrrolidone	FTIR; transparency; WAXD	–	Cao et al. (1999), Demirci et al. (2009), Sakurai et al. (2000), Yilmaz et al. (2005)
Chitosan acetate	Ethylene glycol	FTIR; SEM	–	Wrzyszczynski et al. (1995)
p-Chloro-(3-ethenoxypropyl) cinnamate	p-Methoxy-(6-ethenoxyhexyl) cinnamate	Single T_g	–	Lin et al. (1989)
	p-Methoxy-(6-ethenoxypropyl) cinnamate	Single T_g	–	Lin et al. (1989)
	p-Methyl-(3-ethenoxypropyl) cinnamate	Single T_g	–	Lin et al. (1989)
1-Chloroethyl methacrylate	Alkyl methacrylate	Single T_g; transparency	II had an alkyl group of methyl, ethyl, n-propyl, isopropyl, n-butyl, or tetrahydrofurfuryl	Peng et al. (1993)
	Ester	Single T_g; transparent melt	II was butylene adipate, caprolactone, 2,2-dimethyl-1,3-propylene adipate, 2,2-dimethyl-1,3-propylene sebacate, ethylene adipate, or hexamethylene sebacate	Peng et al. (1993, 1994a)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
2-Chloroethyl methacrylate	Alkyl methacrylate	Single T_g; transparent melt	II had an alkyl group of methyl, ethyl, or tetrahydrofurfuryl	Neo et al. (1991b)
	Ester	Single T_g; transparent melt	II was butylene adipate, caprolactone, 2,2-dimethyl-1,3-propylene adipate, 2,2-dimethyl-1,3-propylene sebacate, ethylene adipate, or hexamethylene sebacate	Neo and Goh (1991b, 1992b)
	N-Vinylpyrrolidone	Single T_g	–	Neo and Goh (1991d)
Chloromethyl methacrylate	Alkyl methacrylate	Single T_g	II had an alkyl group of methyl, ethyl, n-propyl, isopropyl, acetonyl, or tetrahydrofurfuryl	Chong et al. (1990b), Goh et al. (1990a)
	Carbonate of bisphenol-A	Single T_g	Miscibility depended on method of preparation	Goh et al. (1990b)
	Ester	Single T_g; transparent melt	II was butylene adipate, caprolactone, 2,2-dimethyl-1,3-propylene adipate, 2,2-dimethyl-1,3-propylene sebacate, 2,2-dimethyl-1,3-propylene succinate, ethylene succinate, ethylene adipate, ethylene succinate, or hexamethylene sebacate	Neo and Goh (1991b, 1992b)
	N-Vinylpyrrolidone	Single T_g	–	Neo and Goh (1991d)
Chloroprene	Ethylene-co-methyl acrylate	Single T_g; phase contrast microscopy; WAXD	Semicrystalline; II had 21 wt% methyl acrylate (Kundu et al. (1996c))	Kalfoglou and Margaritis (1984), Kundu et al. (1996a), Kundu et al. (1996c)
	Isoprene, epoxidized	Single T_g; FTIR	II had 50 mol% epoxidation (Kim et al. (1998))	Kim et al. (1998), Nagode and Roland (1991)

3-Chloropropyl methacrylate	Acrylonitrile-*co*-*p*-methylstyrene	Single T_g	II had 15–33 wt% AN	Low et al. (1993a)
	Acrylonitrile-*co*-styrene	Single T_g	II had 12–35 wt% AN	Low et al. (1993a)
	Ester	Single T_g	II was butylene adipate, caprolactone, 2,2-dimethyl-1,1,3-propylene adipate, or hexamethylene sebacate	Low et al. (1994c)
	Tetrahydrofurfuryl methacrylate	Single T_g	–	Low et al. (1993c)
o-Chlorostyrene	Styrene	Single T_g	–	Kalfoglou and Margaritis (1984)
o-Chlorostyrene-*co*-*p*-chlorostyrene	2,6-Dimethyl-1,4-phenylene ether	Single T_g; transparency	I had 23–64 % *p*-chlorostyrene	Alexandrovich et al. (1977)
	Styrene	Single T_g	After quenching from 145 °C; I had 71–92 mol% *o*-chlorostyrene; two T_g's when I had $\leq$62 mol% *o*-chlorostyrene	Cimmino et al. (1992), Ten Brinke et al. (1984)
o-Chlorostyrene-*co*-*o*-fluorostyrene	2,6-Dimethyl-1,4-phenylene ether	Single T_g; transparency; NMR	I had 14–40 mol% *o*-chlorostyrene; two T_g's when I had >36 mol% *o*-chlorostyrene	Andreis et al. (1992), Vukovic et al. (1982a), Vukovic et al. (1983c)
p-Chlorostyrene-*co*-*o*-fluorostyrene	2,6-Dimethyl-1,4-phenylene ether	Single T_g; transparency; NMR	I had 13–74 mol% *p*-chlorostyrene; two T_g's when I had >74 mol% *p*-chlorostyrene	Andreis et al. (1992), Vukovic et al. (1982a), Vukovic et al. (1983c)
p-Chlorostyrene-*co*-styrene	2,6-Dimethyl-1,4-phenylene ether	Single T_g	I had $\geq$34.7 mol% styrene; two T_g's when I had <34.7 mol% styrene	Fried et al. (1978), Karasz et al. (1974), Shultz and Beach (1974)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
Cinnamic acid-*co*-styrene	2-Diaminomethylaminoethyl methacrylate	Single T_g; FTIR	I had 5, 8, or 23 mol% cinnamic acid	Boulash et al. (1999b)
	Ethyl methacrylate	Single T_g; IGC	I had 5, 8, or 23 mol% cinnamic acid	Boulash and Amrani (2001)
	Ethyl methacrylate-*co*-4-vinylpyridine	Single T_g	I had 5, 8, or 21 mol% cinnamic acid; II had 13 or 23 mol% vinylpyridine	Boulash et al. (1999a)
	Methyl methacrylate	Single T_g; FTIR	I had 23 mol% cinnamic acid	Boulash and Amrani (2007)
	Methyl methacrylate-*co*-vinylpyridine	Single T_g; FTIR	I had 23 mol% cinnamic acid; II was 2- or 4-vinylpyridine; II had 15 or 16 mol% vinylpyridine	Boulash and Amrani (2007)
	4-Vinylpyridine	Single T_g; FTIR	Formed complexes	Boulash et al. (2008)
Collagen hydrolysate	Ethyl acrylate	Single T_g	–	Mindru et al. (1983)
2-Cyanoethyl methacrylate	Alkyl methacrylate	Single T_g	II had an alkyl group of methyl, acetonyl, 2-hydroxyethyl, 2-hydroxypropyl, or tetrahydrofurfuryl	Yeo et al. (1994a, b, 1995a)
	2-Ethyl-2-oxazoline	Single T_g; FTIR	Blend had >80 wt% I	Yeo et al. (1995b)
	Tertiary amide	Single T_g; FTIR	II was *N*-vinylpyrrolidone, *N*, *N*-dimethylacrylamide, or *N*-methyl-*N*-vinylacetamide; formed complexes	Yeo et al. (1995b)
Cyanomethyl methacrylate	Alkyl methacrylate	Single T_g; FTIR	II had an alkyl group of acetonyl, 2-hydroxyethyl, or 2-hydroxypropyl	Yeo et al. (1995a)
	2-Ethyl-2-oxazoline	Single T_g	Blend had ≥60 wt% I	Yeo et al. (1995b)
	Tertiary amide	Single T_g	II was *N*-vinylpyrrolidone, *N*, *N*-dimethylacrylamide, or *N*-methyl-*N*-vinylacetamide; formed complexes	Yeo et al. (1995b)

Component 1	Component 2	Method	Comments	Reference
Cyclohexyl methacrylate-co-methyl methacrylate	Carbonate of bisphenol-A	Single T_g	I had 9.5–40.4 wt% CHMA	Park et al. (2001)
	Carbonate of dimethylbisphenol-A	Single T_g	I had 28.5–66.7 wt% CHMA	Park et al. (2001)
	Carbonate of tetramethylbisphenol-A	Single T_g	I had 0–36.7 wt% CHMA	Park et al. (2001)
1,4-Cyclohexane dimethylene succinate	Epichlorohydrin	Single T_g	Semicrystalline	Fernandes et al. (1984)
	Vinyl chloride-co-vinylidene chloride	Transparent melt; large T_m-depression	II was Saran (86.5 % vinylidene chloride)	Woo et al. (1983)
	Hydroxyether of bisphenol-A (Phenoxy)	Single T_g; transparent melt	Semicrystalline ≥50 wt% I	Harris et al. (1982)
	Vinyl chloride	Single T_g	Semicrystalline ≤30 wt% II	Zhuang et al. (1988)
Cyclohexyl methacrylate	Methyl methacrylate-co-styrene	Single T_g	–	Pomposo et al. (1998)
	Vinyl chloride	Single T_g; NMR	–	Parmer et al. (1988)
	Vinyl chloride-co-vinylidene chloride	Single T_g	Semicrystalline ≥75 % II; II had 86.5 wt% vinylidene chloride	Kang et al. (1988), Woo et al. (1984b)
	2-Vinylnaphthalene	Single T_g; excimer fluorescence	I had low M_w; II had M_w = 70 kg/mol	Frank and Zin (1987)
Decamethylene decamethylene dicarboxylate	Vinyl chloride	Single T_g	Semicrystalline	Woo et al. (1985b)
Decamethylene sebacate	Epichlorohydrin	Single T_g	Semicrystalline	Fernandes et al. (1984)
2,6-Dibromo-1,4-phenylene ether	Styrene, sulfonated and metal neutralized	Single T_g; SEM	II had 3.8 mol% sulfonation and Zn- or Mn-neutralized	Alkan and Aras (2001)
2,3-Dichloro-1-propyl acrylate	Ethyl acrylate-co-glycidyl methacrylate	Single T_g	II had 65 % ethyl acrylate	Davis et al. (1981)
2,2-Dichloroethyl methacrylate	Alkyl methacrylate	Single T_g; transparency	II had an alkyl group of methyl, ethyl, n-propyl, isopropyl, n-butyl, isoamyl, cyclohexyl, or tetrahydrofurfuryl	Low et al. (1994b)
2,6-Dichloro-1,4-phenylene ether	Styrene, sulfonated and metal-neutralized	Single T_g	II had 4.8 mol% sulfonation and Zn-neutralized	Mfih et al. (2003)

(continued)

Table 21.1 (continued)

Polymer 1 of	Polymer II of	Method	Comments	Refs.
2,6-Diethyl-1,4-phenylene ether	Styrene	Single T_g	–	Cizek (1968)
N,N-Dimethyl acrylamide	Alkyl methacrylate	Single T_g; FTIR	II had an alkyl group of chloromethyl, 2-chloroethyl, 3-chloropropyl, 2-bromoethyl, or 2-iodoethyl	Low et al. (1994d)
	Ethylene-co-vinyl alcohol	Single T_g; FTIR	II had 56, 68, or 78 mol% vinyl alcohol	Katime et al. (2000)
	Monoalkyl itaconate	Single T_g; FTIR	II had an alkyl group of methyl, ethyl, propyl, butyl, pentyl, hexyl, decyl, or dodecyl	Meaurio et al. (1997, 1998)
	Vinyl acetate-co-vinyl alcohol	Single T_g; FTIR	II had 15–84 mol% vinyl alcohol	Parada et al. (1998b)
	Vinyl alcohol	Single T_g; FTIR	–	Parada et al. (1998b)
	Vinylidene fluoride	Single T_g	Semicrystalline $\geq$60 wt% II	Galin (1984)
N,N-Dimethylacrylamide-co-ethylene	Vinyl chloride	Single T_g	I had 71.4 or 73.1 wt% ethylene; two T_g's when I had $\geq$75.1 wt% ethylene	Matzner et al. (1982)
2,6-Dimethyl-1,4-phenylene ether	Acrylic acid-co-t-butyl acrylate-co-potassium acrylate-co-styrene	Single T_g	II had 1.53 mol% butyl acrylate, 2.14 mol% acrylic acid, and 0.52 mol% potassium acrylate	Leung et al. (2001)
	Acrylic acid-co-styrene	Single T_g	II had 4.7–8.5 wt% acrylic acid	Benabdelghani et al. (1995), Gottschalk et al. (1994)
	p-Bromostyrene	Single T_g; transparency	Blend had $\leq$25 et% II	Aroguz and Baysal (2000)
	p-Bromostyrene-co-fluorostyrene	Single T_g; FTIR	II had 11–73 mol% p-bromostyrene	Mariam et al. (1986), Vukovic et al. (1988)
	t-Butyl acrylate-co-styrene	Single T_g	II had $\geq$76.6 mol% styrene	Leung et al. (2001)
	Cyclohexylmaleimide-co-styrene	Light scattering	I had 83 wt% styrene	Saito and Inoue (1987)

Dinitrostyrene-*co*-styrene	Single T_g	II had 3–14 mol% dinitrostyrene	Fernandez et al. (1997)
Ester	Single T_g; IGC	II was made from bisphenol-A and a mixture of isophthalic acid and terephthalic acid	Sakar et al. (2009)
o-Fluorostyrene-*co*-*p*-fluorostyrene	Single T_g; transparency	II had 10–38 % para isomer; two T_g's when II had 5 or ≥43 % para isomer	Karasz and MacKnight (1986), Vukovic et al. (1983b)
o-Fluorostyrene-*co*-styrene	Single T_g; transparency	II had ≥9 mol% styrene	Vukovic et al. (1981, 1982, 1983a)
p-Fluorostyrene-*co*-styrene	Single T_g; transparency	II had ≥44 mol% styrene	Maeda et al. (1986, 1989), Vukovic et al. (1981, 1982, 1983a)
p-(2-Hydroxy-hexafluoroisopropyl) styrene-*co*-styrene	Single T_g	II had 77.9–90.3 mol% styrene	Min and Pearce (1981), Min et al. (1983), Pearce et al. (1984), Ting et al. (1980)
Luloylmaleimide-*co*-styrene	Light scattering	II had 81 wt% styrene	Saito and Inoue (1987)
Maleic anhydride-*co*-styrene	Single T_g; transparency	II had 8 wt% maleic anhydride; two T_g's when II had 14 wt% maleic anhydride	Fried and Hanna (1982), Fried et al. (1982), Gottschalk et al. (1994), Witteler et al. (1993)
Methacrylic acid-*co*-styrene	DMA; FTIR: OM; IGC	II had 5.9 mol% methacrylic acid; immiscible when II had ≥7.2 mol% methacrylic acid	Akiba et al. (2000), Benabdelghani et al. (1995, 2006), Bazuin et al. (1993)
2-Methyl-6-benzyl-1,4-phenylene ether	Single T_g; transparency	–	Shultz and Gendron (1973)
Methyl methacrylate-*co*-styrene	Single T_g	II had ≤16.5 wt% methyl methacrylate	Goh and Lee (1988b), Gottschalk et al. (1994), Kressler et al. (1990b)
2-Methyl-6-phenyl-1,4-phenylene ether	Single T_g	–	Shultz and Gendron (1974a, b)

(*continued*)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
	α-Methylstyrene	Single T_g	–	Cizek (1968), Kressler et al. (1990a), Robeson et al. (1974)
	α-Methylstyrene-co-styrene	Single T_g	All compositions of II	Kressler et al. (1990a), Shultz and Young (1983)
	o-Methylstyrene	NMR	NMR showed heterogeneity on a 3-nm scale	Dickinson et al. (1987)
	p-Methylstyrene	Single T_g	–	Dickinson et al. (1987), Fried et al. (1985), Su and Fried (1986)
	p-Nitrostyrene-co-styrene	Single T_g	II had <22 mol% nitrostyrene	Cowie et al. (1992a)
	Phenylmaleimide-co-styrene	Light scattering	II had 84 wt% styrene	Lokaj et al. (1995), Saito and Inoue (1987)
	Styrene	Single T_g; transparency; NMR; XPS	Older work showed some ambiguous results; II was syndiotactic (Duff et al. (2001))	Bair (1970), Balsamo et al. (2001), Drioli et al. (1978), Duff et al. (2001), Goh et al. (1999a), MacKnight et al. (1971), Mucha et al. (1981), Prest and Porter (1972), Shultz and Gendron (1972), Shultz and Gendron (1974a, b), Stoelting et al. (1970), VanderHart (1994), Wu and Woo (1999)
	Styrene, head-to-head	Single T_g	–	Kryszewski et al. (1982)
	Styrene, iodinated	Single T_g	II had ≤47 % iodination	Goh and Lee (1989b)
	Styrene, sulfonated and metal-neutralized	Single T_g	II had up to 7.8 mol% sulfonation (Register and Bell (1992)); metal was Zn, Mn, or Ni	Mih et al. (2003), Register and Bell (1992), Tomita and Register (1993)
	Styrene, syndiotactic	Single T_g	–	Cimmino et al. (1993)

	Styrene-b-isoprene-b-styrene	II had block M_w 15-51-17 and 78-52-80 kg/mol	Single T_g; with styrene blocks of II	Meyer and Tritscher (1978)
	2,2,6,6-Tetramethyl-piperidinyl methacrylate-co-styrene	II had ≤24 wt% 2,2,6,6-tetramethylpiperidinyl methacrylate	Single T_g	Goh and Lee (1987)
2,6-Dimethyl-1,4-phenylene ether, carboxylated	Urethane acrylate	I and II formed interpenetrating network	Single T_g; FTIR	Mengujoh and Frisch (1989)
	Styrene	11.8 mol% of repeat units in I carboxylated; two T_g's when 35.0 mol% repeat units in I carboxylated	Single T_g; FTIR	Liao et al. (1996), Xie et al. (1984)
	Styrene, sulfonated and metal-neutralized	II was neutralized with Li, Na, or Cs; miscible when I and II had similar amounts of functional groups	Single T_g	Pan et al. (1997)
2,6-Dimethyl-1,4-phenylene ether, brominated phosphonylated	Cellulose acetate	II was Eastman 394-45	Single T_g; electron microscopy	Cabasso et al. (1974)
2,6-Dimethyl-1,4-phenylene ether, modified	Epichlorohydrin, modified	Both I and II had at least 25 % carbazolyl or 3,5-dinitrobenzoyl groups	Single T_g	Pugh and Percec (1986)
2,6-Dimethyl-1,4-phenylene ether, modified with C_{60}	Acrylonitrile-co-styrene	I had 6.9 or 19.5 wt% C_{60}; II had ≤6.3 wt% AN	Single T_g	Goh et al. (2000a)
	p-Methylstyrene-co-styrene	I had 6.9 or 19.5 wt% C_{60}	Single T_g	Goh et al. (2000a)
	Styrenic monomer	I had 6.9 or 19.5 wt% C_{60}; II was styrene, α-methylstyrene, or p-methylstyrene	Single T_g	Goh et al. (2000a)
2,6-Dimethyl-1,4-phenylene ether, phenylsulfonated	o-Bromostyrene-co-styrene	I had 10.9–88 mol% o-bromostyrene	Single T_g	Vukovic et al. (1998)
	p-Bromostyrene-co-styrene	I had 10.6–90.4 mol% p-bromostyrene	Single T_g	Vukovic et al. (1998)
	p-Chlorostyrene-co-o-fluorostyrene	–	Single T_g	Vukovic et al. (1995)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
	o-Chlorostyrene-*co*-*p*-fluorostyrene	Single T_g	–	Vukovic et al. (1995)
	o-Fluorostyrene-*co*-*p*-fluorostyrene	Single T_g	I had a degree of phenylsulfonation of 4–92 mol %; II had 14–93 mol% *o*-fluorostyrene	Vukovic et al. (1994a)
2,6-Dimethyl-1,4-phenylene ether, sulfonylated	Acrylonitrile-*co*-styrene	Single T_g	I had 20–26 wt% sulfonylation	Kang et al. (1987)
	p-Bromostyrene	Single T_g	I had >12 mol% sulfonylation	Vukovic et al. (1994c)
	o-Bromostyrene-*co*-*p*-bromostyrene	Single T_g	High *p*-bromostyrene content and high degree of sulfonylation favored miscibility	Vukovic et al. (1996b)
	o-Bromostyrene-*co*-*o*-fluorostyrene	Single T_g	Miscibility depended on compositions of I and II	Vukovic et al. (1996b)
	o-Bromostyrene-*co*-*p*-fluorostyrene	Single T_g	Miscibility depended on compositions of I and II	Vukovic et al. (1996b)
	p-Bromostyrene-*co*-*o*-fluorostyrene	Single T_g	Miscibility depended on compositions of I and II	Vukovic et al. (1996b)
	p-Bromostyrene-*co*-*p*-fluorostyrene	Single T_g	Miscibility depended on compositions of I and II	Vukovic et al. (1996b)
	o-Chlorostyrene-*co*-*p*-chlorostyrene	Single T_g	Miscibility not favored when I had high degree of sulfonylation and II had high *o*-chlorostyrene content	Vukovic et al. (1994b)
	o-Chlorostyrene-*co*-*p*-fluorostyrene	Single T_g	Miscibility depended on compositions of I and II	Vukovic et al. (1996a)
	p-Chlorostyrene	Single T_g	Degree of sulfonylation = 4–17 mol%	Vukovic et al. (1993, 1994b, 1996a)
	o-Fluorostyrene	Single T_g	Degree of sulfonylation = 4–17 mol%	Vukovic et al. (1993)

	Component	Method	Notes	References
	p-Fluorostyrene	Single T_g	Degree of sulfonylation = 4–17 mol%	Vukovic et al. (1993, 1996a)
	p-Fluorostyrene-co-styrene	Single T_g	I had 20–26 wt% sulfonylation	Kang et al. (1987)
	Phenylvinyl sec-butyl ether-alt-N-phenylmaleimide	Single T_g	I had 68–87 % sulfonylation	Vukovic et al. (1994d)
	Phenylvinyl ethyl ether-alt-N-phenylmaleimide	Single T_g	I had 61–91 % sulfonylation	Vukovic et al. (1994d)
	Styrene	Single T_g	I had <31 wt% sulfonylation	Kang et al. (1987)
	Styrene-co-4-vinylpyridine	Single T_g; FTIR; NMR	I had 3–12 mol% sulfonation; II had 3–10 mol% vinylpyridine; formed complexes when I had 12 mol% sulfonation and II had 10 mol% vinylpyridine (Pan et al. (2001))	Pan et al. (2001), Pan and Xue (2001)
α,α-Dimethyl-β-propiolactone (pivalolactone)	Vinyl chloride	T_m-Depression	Semicrystalline	Aubin et al. (1982), Aubin and Prud'homme (1980)
Dimethylsiloxane	Ethylene-co-methyl acrylate	Single T_g; FTIR	II had 21 wt% methyl acrylate; I had a small amount of vinyl groups	Santra et al. (1993a)
Dimethylsiloxane, modified	Butyl methacrylate	Single T_g; FTIR	One of the methyl groups in the repeating unit of I was changed to 4-hydroxy-4,4-bis (trifluoromethyl) butyl group	Chu et al. (1991)
	Ethylene glycol	Single T_g; FTIR	One of the methyl groups in the repeating unit of I was changed to 4-hydroxy-4,4-bis (trifluoromethyl) butyl group	Chu et al. (1991)
2,6-Dimethyl-4-vinylphenol	Alkyl methacrylate	Single T_g; FTIR	II had an alkyl group of ethyl, n-propyl, n-hexyl, or n-butyl	Coleman et al. (1996), Pehlert et al. (1996)
	Ethylene-co-vinyl acetate	Single T_g; FTIR	II had 45 or 70 wt% vinyl acetate	Coleman et al. (1996), Pehlert et al. (1996)
	Vinyl acetate	Single T_g; FTIR	–	Coleman et al. (1996), Pehlert et al. (1996)

(continued)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
2,6-Diisopropyl-4-vinylphenol	Alkyl methacrylate	Single T_g; FTIR	II had an alkyl group of ethyl, *n*-butyl, *n*-hexyl, *n*-octyl, or *n*-decyl	Coleman et al. (1996), Pehlert et al. (1996)
	Ethylene-*co*-vinyl acetate	Single T_g; FTIR	II had 33, 45, or 70 wt% vinyl acetate	Coleman et al. (1996), Pehlert et al. (1996)
	Vinyl acetate	Single T_g; FTIR	–	Coleman et al. (1996), Pehlert et al. (1996)
2,6-Dipropyl-1,4-phenylene ether	Styrene	Single T_g	–	Cizek (1968)
Dodecamethylene adipamide, *N*, *N*-dimethyl substituted	*p*-(2-Hydroxy-hexafluoroisopropyl) styrene-*co*-styrene	Single T_g	Semicrystalline when ≤50 % substitution on I	Kotzev et al. (1984)
Dodecamethylene adipate	Epichlorohydrin	Single T_g	Semicrystalline	Fernandes et al. (1984)
	Vinyl chloride	Single T_g	Semicrystalline	Woo et al. (1985b)
Dodecamethylene decamethylene dicarboxylate	Vinyl chloride	Single T_g	Semicrystalline	Woo et al. (1985b)
Dodecamethylene dodecamethylene dicarboxylate	Vinyl chloride	Single T_g	Semicrystalline	Woo et al. (1985b)
Enaminonitrile	Ethylene glycol	Single T_g	–	Moore and Kim (1992)
	Tertiary amide	Single T_g	II was *N*, *N*-dimethylacrylamide, 2-ethyl-2-oxazoline, or *N*-vinylpyrrolidone	Moore and Kim (1992)
	4-Vinylpyridine	Single T_g	–	Moore and Kim (1992)
Epichlorohydrin	Acrylonitrile-*co*-styrene	Single T_g	II had 18 or 25 wt% acrylonitrile	Guo (1991)
	Alkyl acrylate	Single T_g	II had an alkyl group of ethyl or *n*-propyl	Fernandes et al. (1986b, c)
	Alkyl methacrylate	Single T_g	II had an alkyl group of ethyl, *n*-propyl, *n*-butyl, or cyclohexyl	Fernandes et al. (1986b)
	Butyl acrylate rubber	Single T_g	II was Hycar 4043	Fernandes et al. (1986c)

	Ester	Single T_g; T_m-depression	II was made from aliphatic glycols and aliphatic dicarboxylic acids	Fernandes et al. (1984), Kim et al. (1999b), Wetton and Williams (1988)
	Ethyl acrylate rubber	Single T_g	II was Hycar 4051EP	Fernandes et al. (1986c)
	Glycidyl methacrylate	Single T_g	–	Wetton and Williams (1988)
	Glycidyl methacrylate-co-methyl methacrylate	Single T_g	II had 76 % glycidyl methacrylate	Wetton and Williams (1988)
	Methacrylonitrile-co-methyl methacrylate	Single T_g	II had 30–40 mol% methacrylonitrile	Wetton and Williams (1988)
	Methyl methacrylate	Single T_g	Broad T_g might be due to separate phases with differing T_g's within the mixture	Akiyama et al. (1987), Clark et al. (1992), Fernandes et al. (1986b)
	Neopentyl glycol adipate	Single T_g; transparency	–	Fernandes et al. (1984), Goh et al. (1982a)
	Vinyl acetate	Single T_g; NMR; FTIR	–	Cheung et al. (2000), El Shafee (2002b), Guo (1990a)
Epichlorohydrin-co-ethylene glycol	Neopentyl glycol adipate	Transparency	I was Hydrin 200; refractive indices not equal in the temperature range investigated	Goh et al. (1984b)
Ester	Ester	Single T_g; microscopy	I and II were various linear aliphatic polyesters (13 miscible blend systems)	Braun et al. (1993)
	Ester	Melting behavior	Both polymers I and II were liquid crystalline; II had one more ethylene unit in the main chain	Darragas et al. (1994)
Ester, hyperbranched and 3,5-dihydroxyphenyl-terminated	Amide	Single T_g	II was PA-6	Massa et al. (1995)
	Aramide	Single T_g	II was Trogamid T or MXD-6	Massa et al. (1995)
	Butylene adipate	Single T_g	–	Massa et al. (1995)
Ester, hyperbranched and 3,5-diacetoxylphenyl-terminated	Butylene terephthalate	Single T_g	–	Massa et al. (1995)
	Ester	Single T_g	II was made from terephthalic acid and a mixture of ethylene glycol and 1,4-cyclohexane dimethanol	Massa et al. (1995)

(continued)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
4-Ethenylpheno lmethylsiloxane	Acrylonitrile-*co*-styrene	Single T_g; AFM; transparency; XPS	II had 24–31 wt% acrylonitrile	Duan et al. (2001)
	N,N-Dimethylacrylamide	Single T_g; AFM; transparency; XPS	–	Duan et al. (2001)
	N-Vinylpyrrolidone	Single T_g; AFM; transparency; XPS	–	Duan et al. (2001)
	4-Vinylpyridine	Single T_g; AFM; transparency; XPS	–	Duan et al. (2001)
Etheretherketone	Aryl ether ketone	Single T_g; WAXD; FTRI; SEM	–	Woo and Tseng (1999)
	Arylketone	Single T_g	II had 25, 50, or 57 % ketone content	Harris and Robeson (1987)
	Etherdiphenyl ether ketone	Single T_g; WAXD	–	Jo et al. (1994c)
	Etherketone	Single T_g	I was poly(oxy-1,4-phenyleneoxy-1,4-phenylenecarbonyl-1,4-phenylene); II was poly (oxy-1,4-phenylenecarbonyl-1,4-phenylene); semicrystalline	Sham et al. (1988a)
	Etherimide	Single T_g	I was Victrex 450G; II was Ultem 1000; semicrystalline	Crevecoeur and Groeninckx (1991), Chen and Porter (1993), Chun et al. (1999), Goodwin and Simon (1996), Hsiao and Sauer (1993), Jenkins (2001), Lee and Kim (1997), Sauer and Hsiao (1993a)
	Ethersulfone	Single T_g	–	Yu et al. (1990)
	Ethylene terephthalate-*co*-*p*-hydroxybenzoic acid	Single T_g	–	Acierno and Naddo (1994)
	Imide	Single T_g	II was YS-30 (Kong et al. 1998)	Kong et al. (1998), Kong et al. (1996)

Etheretherketone, sulfamidated	Amideimide	Single T_g; FTIR	I had a degree of sulfamidation of 1.33; II was Torlon 4,000T	Karcha and Porter (1993)
Etheretherketone, sulfonated	Amideimide	Single T_g; FTIR	I had a degree of sulfonation of 0.42, 0.53, and 1.00; II was Torlon 4,000T	Karcha and Porter (1989), Karcha and Porter (1993)
	Etherimide	Single T_g	II was Ultem 1000	Karcha and Porter (1989), Karcha and Porter (1993)
Etherethersulfone	Epoxy	Single T_g; microscopy	Miscible when II was cured by amine; immiscible when cured by anhydride	Guo (1993)
Etherimide	Amideimide	Single T_g	I was Ultem 1000; II was Torlon; 4,203 L; miscible when blend had 15, 60, 70, 75, or 85 wt% I; immiscible when blend had 25, 30, or 50 wt% I	Palsule and Cowie (1994), Ryu et al. (2000)
	Arylate	Single T_g	I was Ultem 1000; blend had 10 or 20 wt% II	Bastida et al. (1996a, b)
	Benzimidazole	Single T_g; FTIR	II was nitro-substituted	Cho et al. (2001b)
	Butylene naphthalate	Single T_g; FTIR; SEM	–	Lin and Wang (2001)
	Butylene terephthalate	Single T_g; OM	–	Woo and Yau (1997)
	Ether diphenylether ketone	Single T_g; FTIR	–	Huang and Woo (2000)
	Etheretherketoneketone	Single T_g	Semicrystalline	Shibata et al. (2001)
	Etherimide	Single T_g	I was Ultem 1000; II was made from isophthaloyl chloride and bis-[(4-aminophenoxy)-4-phenyl]propane	Etxeberria et al. (1998)
	Ethylene-1,6-naphthalene dicarboxylate	Single T_g; OM	I was Ultem 1000	Chen et al. (1998c)
	Ethylene terephthalate	Single T_g; T_m-depression; OM; SAXS	I was Ultem 1000	Chen (1995), Chen and Hsiao (1998), Jo et al. (1994c), Martinez et al. (1993)

(continued)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
	Imide	Single T_g	I was Ultem 1000; II was made from diphenylpyromellitic dianhydride (DPPMDA) and 4,4'-diaminodiphenylether	Fukai et al. (1992)
	Imide	Single T_g	I was Ultem 1000; II was made from DPPMDA and 6,6'-perfluoromethylbenzidine	Fukai et al. (1992)
	Imide	Single T_g	I was Ultem 1000; II was made from DPPMDA and 3,3'-dimethoxybenzidine	Fukai et al. (1992)
	Phenylsulfone	Single T_g; SEM	–	Ramiro et al. (2006)
	Trimethylene terephthalate	Single T_g; SEM	–	Huang and Chang (2002), Kuo et al. (2001b)
Etherimide ether	Thioetherimide ether	NMR	–	Feng et al. (1995a)
Etherketone	Terephthaloylimide	Single T_g; WAXS; SAXS	Semicrystalline	Cser and Goodwin (2001)
Etherketoneketone	Etherimide	Single T_g; WAXD; microscopy	II was Ultem 1000	Hsiao and Sauer (1993), Sauer and Hsiao (1993a)
	Imide	Single T_g	II was made from 3,4'-oxydianiline and oxydiphthalic dianhydride	Sauer and Hsiao (1993a)
	Imide	Single T_g	II was made from 4,4'-bis (3-aminophenoxy)biphenyl and pyromellitic anhydride	Sauer et al. (1996)
	Imide	Single T_g; WAXD; FTIR	–	Chun and Weiss (2004)
Ethersulfone	Aramide	Single T_g	II was made from isophthaloyl chloride and bis (4-aminophenyl) ether	Matsuura et al. (1992), Nakata et al. (1990)
	Epoxy	Single T_g; SEM; transparency	–	Francis et al. (2006)
	Etheretherketone	Single T_g; SEM	–	Nandan et al. (2002)

	Imide	Single T_g; NMR	II was Polyimide XUeda and Karasz (1985)18	Janusz et al. (1990)
	Imide	Single T_g; transparency	II was Matrimide	Cha et al. (1994)
	Imide	Single T_g	II was Matrimide 5218; miscibility was a metastable phenomenon achieved by rapid solvent removal	Liang et al. (1992)
	N,N'-(Oxydi-p-phenylene) isophthalamide	Single T_g; transparency	I was Victrex PES 300P	Hayashi et al. (1993)
	Phenylene ether ether ketone	Single T_g	–	Schneider et al. (1995)
	Phenylene ether sulfone ketone	Single T_g	–	Schneider et al. (1995)
	Phenylene sulfone ether sulfone ketone	Single T_g	–	Schneider et al. (1995)
	Phenylene thioether ether ketone	Single T_g	–	Schneider et al. (1995)
	Tertiary amide	Single T_g	II was N-methyl-N-vinylacetamide or N,N-dimethylacrylamide	Goh et al. (1997)
Ethersulfoneetherketone	Epoxy	Single T_g; SEM; transparency	–	Francis et al. (2006)
Ether urethane	Vinyl chloride	Single T_g	20 or 40 wt% II; I was Adiprene L-100 and 4,4'-methylene-bis-2-chloroaniline	Hourston and Hughes (1981)
3-Ethenoxypropyl cinnamate	p-Methyl-(3-ethenoxypropyl) cinnamate	Single T_g	–	Lin et al. (1989)

(continued)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
Ethyl acrylate	Alkyl methacrylate	Single T_g	II had an alkyl group of chloromethyl, 1-chloroethyl, 2-chloroethyl, 2,2-dichloroethyl, 2,2,2-trichloroethyl, or 1,3-difluoroisopropyl	Peng et al. (1996)
	Novolac	Single T_g	II had M_w about 1 kg/mol; II was formaldehyde and 13/17/70 mol% = p-t-butylphenol/m-cresol/o-cresol or formaldehyde and 15/17/68 mol% = 2-t-butylphenol/m-cresol/o-cresol	Fahrenhlotz and Kwei (1981)
	Hexafluoroacetone-co-vinylidene fluoride	Single T_g; XPS	II had 8 mol% hexafluoroacetone	Kano and Akiyama (1992), Kano et al. (1997a)
	Styrene, sulfonated	Single T_g; FTIR	Degree of sulfonation of II = 7.2 %	Taylor-Smith and Register (1993)
	Styrene-co-p-vinylphenol	Single T_g; FTIR	II had >4.46 mol% vinylphenol	Taylor-Smith and Register (1993)
	Vinyl chloride	Single T_g	In situ polymerized II; other mixtures formed two phases (e.g., refs. Grose and Friese (1965), Keskkula and Paul (1986))	Grose and Friese (1965), Keskkula and Paul (1986), Walsh and Cheng (1984a)
	Vinyl chloride-co-vinylidene chloride	Single T_g; transparency	II was Saran ($\leq$80 % vinylidene chloride); I had $M_w = 50$ kg/mol; two T_g's when I had $M_w = 140$ kg/mol; and II was Saran (86.5 wt% vinylidene chloride)	Tremblay and Prud'homme (1984), Woo et al. (1984b)
	Vinylidene fluoride	Single T_g; transparency	Semicrystalline $\geq$25 wt% II	Bernstein et al. (1977), Briber and Khoury (1987), Wahrmund et al. (1978)

Ethyl acrylate, modified with C$_{60}$	Vinylidene fluoride	Single T_g; T_m-depression	I had 19.3 wt% C$_{60}$	Zheng et al. (2001)
Ethyl acrylate-co-methacrylonitrile-co-α-methylstyrene	Vinyl chloride	Single T_g; transparency	I had 2/40/58 = ethyl acrylate/methacrylonitrile/-methylstyrene or unknown composition	Kenney (1976, 1977)
Ethyl acrylate-co-methyl methacrylate	Vinyl chloride	Single T_g; electron microscopy	I was Polaroid Kammer (1989) 0N (95 % methyl methacrylate)	Zelinger et al. (1976)
Ethyl acrylate-co-4-vinylpyridine	Perfluorinated acid copolymer	FTIR	I had 5–21 mol% vinylpyridine; II was Nafion	Tannenbaum et al. (2003)
	Styrene-co-styrene sulfonic acid	Single T_g; transparency	I and II both ≥5 % of second monomer (data obtained ≤10 % substitution)	Eisenberg et al. (1982), Smith and Eisenberg (1983)
	Vinyl chloride	Single T_g	I had 2–14 mol% 4-vinylpyridine	Clas and Eisenberg (1984)
	Vinyl chloride, sulfonated	Single T_g	I had 6.2 mol% 4-vinylpyridine; II had 3.7 mol% sulfonic acid	Clas and Eisenberg (1984)
(N-Ethylcarbazole-3-yl)methyl acrylate	2-(3,5-Dinitrobenzoyl) oxyethyl methacrylate	Single T_g; NMR	–	Simmons and Natansohn (1992a)
(N-Ethylcarbazole-3-yl)methyl methacrylate	2-(3,5-Dinitrobenzoyl) oxyethyl methacrylate	Single T_g; NMR	–	Simmons and Natansohn (1992b)
Ethyl cellulose	Amide	Single T_g; FTIR	II was a copolyamide with PA-6, PA-6,6, and PA-10,10 units	Zhang et al. (2012b)
Ethyl methacrylate	Novolac	Single T_g; FTIR	II had M_w about 1 kg/mol and was formaldehyde and 13/17/70 mol% = p-t-butylphenol/m-cresol/o-cresol	Fahrenhlotz and Kwei (1981), Kim et al. (1991)
	Butyl acrylate-co-styrene	Single T_g	II had 23–63 wt% styrene	Rana et al. (2000)
	Ethyl acrylate	Single T_g	–	Cowie et al. (1992f)
	p-(2-Hydroxy-hexafluoroisopropyl) styrene-co-styrene	Single T_g; transparency	II had 90.3–98.9 mol% styrene	Chen and Morawetz (1989), Min and Pearce (1981), Pearce et al. (1984)

(continued)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
	Vinyl acetate	Transparency	Transparent film when I <25 wt% or when content of I toward 100 wt%	Olayemi and Ibiyeye (1986)
	Vinyl chloride	Single T_g; transparency	–	Fried et al. (1978), Ha et al. (1990a), Perrin and Prud'homme (1991), Tremblay and Prud'homme (1984), Walsh and Cheng (1984a)
	Vinyl chloride-co-vinylidene chloride	Single T_g; transparency	II was Saran (≥80 % vinylidene chloride) or 86.5 wt% vinylidene chloride; semicrystalline ≤30 % I	Kang et al. (1988), Tremblay and Prud'homme (1984), Woo et al. (1984b)
	Vinylidene fluoride	Single T_g	Semicrystalline when ≥40 % II; two T_g's when >60 % II	Galin and Maslinko (1987), Imken et al. (1976), Kwei et al. (1976), Noland et al. (1971), Roerdink and Challa (1980)
Ethyl methacrylate, modified with C_{60}	Vinylidene fluoride	Single T_g; T_m-depression	I had 4.9–14.8 wt% C_{60}	Zheng et al. (2001)
Ethylene, chlorinated	Acrylonitrile-co-butadiene	Single T_g	Depended on Cl content and acrylonitrile content	Chai and Karasz (1992), Cowie and Harris (1992)
	Caprolactam-co-caprolactone	Single T_g	I had 35.2 wt% Cl; II had 17 mol% caprolactam	Van Ekenstein et al. (1997)
	Hexamethylene terephthalate	Single T_g	I had 48 % Cl; immiscible with I had 36 % Cl	Aubin and Prud'homme (1984)
	Methyl methacrylate	Single T_g; transparency; electron microscopy	I had ≥50 wt% Cl; two T_g's when I had 48 wt% Cl	Chai et al. (1983), Grose and Friese (1965), Tremblay and Prud'homme (1984), Walsh et al. (1982)

Polymer I	Polymer II	Method	Comment	Reference
	Neopentyl glycol adipate	Single T_g	I had 42 or 48 wt% Cl; immiscible when I had ≤36 wt% Cl	Goh et al. (1984b)
	Vinyl chloride, chlorinated	Single T_g	I and II with identical chlorine content were immiscible	Ueda and Karasz (1992)
Ethylene, chlorosulfonated	Vinyl chloride	Single T_g	I had 1 % S as SO_2Cl and 42 wt % Cl; stated immiscible when I had 30 wt% Cl in Grose and Friese (1965)	Doube and Walsh (1979)
Ethylene adipate	Hydroxyether of bisphenol-A (Phenoxy)	Single T_g; transparent melt	Semicrystalline when ≥50 wt% I	Harris et al. (1982)
Ethylene-co-methacrylic acid	Ethylene glycol	FTIR	I had 55 wt% methacrylic acid	Coleman et al. (1989b)
	Ethylene glycol-co-propylene glycol	Single T_g; FTIR	I had 18, 32, 44, or 55 wt% methacrylic acid; II had 70 wt% ethylene oxide	Lee et al. (1988c)
	Ethyloxazoline	FTIR	I had 44 wt% methacrylic acid	Lichkus et al. (1988)
	Styrene-co-2-vinylpyridine	FTIR	I had 32 wt% methacrylic acid; II had 70 wt% 2-vinylpyridine	Lee et al. (1988d)
	Tetramethylene glycol	FTIR	I had 55 wt% methacrylic acid	Lee et al. (1988c)
	Vinylethylether	FTIR	I had 55 wt% methacrylic acid	Lee et al. (1988c)
	Vinylmethylether	Single T_g; FTIR	I had 18, 32, 44, or 55 wt% methacrylic acid	Lee et al. (1988a)
	2-Vinylpyridine	FTIR	Miscible when I had 18 wt% methacrylic acid and formed complexes when I had 44 or 55 wt% methacrylic acid; formed complexes when I had 32 wt% methacrylic acid and was ≤35 % I in blend	Lee et al. (1988a)
Ethylene-co-methacrylic acid, zinc neutralized	Vinylmethylether	FTIR	I had 44 wt% methacrylic acid	Serman et al. (1988)
	4-Vinylpyridine	NMR	I had 15 wt% methacrylic acid and 60 % zinc-neutralized	Belfiore (1988)

(continued)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
Ethylene-*co*-methyl acrylate-*co*-unspecified acid	Vinyl chloride	Single T_g	I was Vamac *N*-123	Kalfoglou (1983)
Ethylene-2,6-naphthalene dicarboxylate	Ester	Single T_g; T_m-depression	II was made from hydroxybenzoic acid and ethylene terephthalate	Park and Kim (2003)
	Oxybenzoate-*co*-ethylene terephthalate	Single T_g; T_m-depression	II had 40 mol% ethylene terephthalate	Ho et al. (2000)
Ethylene orthophthalate	Vinyl acetate	Single T_g	–	Vazquez-Torres and Cruz-Ramos (1986)
Ethylene glycol	Acetoxystyrene	Single T_g; T_m-depression; FTIR	–	Kuo et al. (2004b)
	Benzoxazine	Single T_g; T_m-depression	Miscible before curing; phase separation after curing	Lu and Zheng (2003)
	Benzyl methacrylate	Single T_g; FTIR; SEM; OM; NMR	Semicrystalline	Lin et al. (2001), Maekawa et al. (1999)
	Bisphenol-A-*co*-epichlorohydrin	Single T_g; T_m-depression; FTIR	–	Rocco et al. (2003b)
	n-Butyl methacrylate	Single T_g	–	El Shafee and Ueda (2002)
	Butylene adipate-*co*-butylene succinate	Single T_g; T_m-depression; OM	–	Ikehara et al. (2005)
	Butylene succinate	Single T_g; T_m-depression; WAXD, SAXS; NMR; AFM		He et al. (2004b), Hexig et al. (2005), Ikehara et al. (2009), Qiu et al. (2003b)
	Copolyester-polyurethane	Single T_g	–	Iriarte et al. (1991)
	Diethylene glycol-*co*-ethylene terephthalate	Single T_g	II had 37 mol% diethylene glycol	Barcellos et al. (1998)
	Epichlorohydrin	Single T_g; T_m-depression	–	Silva et al. (1988)
	Epoxy resin	Single T_g; FTIR	Miscible when II was uncured; immiscible when II was cured (Guo et al. (1991b)); miscible before and after curing (Luo et al. (1994))	Guo et al. (1991b, 2001), Chen et al. (2008), Hu et al. (2004), Luo et al. (1994, 1995a), Zheng et al. (2003c)

Ester	Single T_g; T_m-depression; POM	II was ethylene adipate, propylene adipate, butylene adipate, or ethylene azelate	Lin and Woo (2006)
Ethersulfone	Single T_g; light scattering; SAX; OM	–	Dreezen et al. (1999), Guo and Higgins (1991), Maejima et al. (1988), Shibanov and Radzhabov (1988)
Ethyl methacrylate	Single T_g	–	Chung et al. (1991)
Ethyl methacrylate-co-methyl methacrylate	Single T_g; NMR	Blend had ≤20 wt% I	Pomposo et al. (1996)
Ethylene-co-vinyl acetate	Single T_g	II had 87.1 wt% vinyl acetate (Cimmino et al. (1991)); II had 73.4 wt% vinyl acetate, miscible with I of $M_w = 20$ and 100 kg/mol (Han et al. (1992))	Cimmino et al. (1991), Han et al. (1992)
Ethylene succinate	Single T_g	–	Lu et al. (2008)
Hydroxyether of bisphenol-A (Phenoxy)	Single T_g; NMR	Semicrystalline when >40 % I	Iriarte et al. (1989, 1991), Robeson et al. (1981)
Hydroxyether terephthalate ester	Single T_g; T_m-depression; FTIR	–	Liu et al. (2005b)
p-(2-Hydroxy-hexafluoroiso-propyl)-α-methylstyrene-co-styrene	ESR	II had 4.88–27.28 mol% OH	Chen et al. (2004a)
p-(2-Hydroxy-hexafluoroisopropyl) styrene-co-styrene	Single T_g	II had 77.9 mol% styrene, and I/II was 1/8–1/2; semicrystalline and no amorphous phase	T80
Hydroxyether sulfone	Single T_g; OM; FTIR; NMR	–	H194
2-Hydroxyethyl methacrylate	Single T_g	–	Prashantha et al. (2008)
2-Hydroxyethyl methacrylate-co-p-vinylphenol	T_m-Depression; WAXD; SAXS	II had 55 mol% vinylphenol (Silva et al. (2009))	Pereira and Rocco (2005), Silva et al. (2009)
3-Hydroxypropionate	Single T_g; NMR	Semicrystalline	He et al. (2000)
Lactide	Single T_g; OM; T_m-depression	Blend had up to 50 wt% I	Lai et al. (2004), Nijenhuis et al. (1996), Yang et al. (1997)

(continued)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
	Maleic acid-alt-methylvinylether	Single T_g; FTIR	Semicrystalline	Rocco et al. (2001)
	Maleic anhydride-co-styrene	Single T_g; T_m-depression	Semicrystalline	Al-Salah (2000), Al-Salah and Qudah (1997)
	Methacrylic acid	Single T_g; NMR	Formed complexes in water and dimethylsulfoxide	Jeon and Ree (1988), Maunu et al. (1993), Miyoshi et al. (1996)
	Methacrylic acid-co-styrene	FTIR	II had 5.6, 11.0, or 17.9 mol% acid and Na-neutralized	Lim et al. (1994)
	Methyl methacrylate	Single T_g; NMR; SAXS; dielectric spectroscopy	I was miscible with atactic or syndiotactic II and immiscible with isotactic II; semicrystalline when >20 wt% I	Baldrian et al. (1999), Chow (1990), John and Ree (1990), Jin et al. (2004b), Liberman et al. (1984), Martuscelli and Demma (1980), Martuscelli et al. (1986), Silvestre et al. (1987), Straka et al. (1995)
	Methyl methacrylate-co-p-vinylphenol	Single T_g; T_m-depression; FTIR; NMR	I had 51 mol% vinylphenol (Kuo and Chang (2001b)); I had 30–92 mol% vinylphenol (Lin et al. (2006b))	Kuo and Chang (2001b), Lin et al. (2006b)
	Phenyl methacrylate	Single T_g; FTIR; SEM	Semicrystalline	Woo et al. (2000c)
	Resorcinol	NMR	–	Belaribi et al. (1986)
	Styrene, sodium salt of sulfonated polystyrene	Single T_g	II had 2.9–8.8 mol% sulfonation; miscible when blend had low I content	Lee et al. (1991)
	Styrene-co-p-vinylphenol	Single T_g; ESR; dielectric spectroscopy	II had 13.1 mol% styrene, and I/II was 1/8-1/1; semicrystalline at higher I content and no amorphous phase miscibility; II had 2.1–48.4 mol% vinylphenol (Tan et al. 2004)	Jin et al. (2004a), Ting et al. (1981), Tan et al. (2004)

Styrene-*co*-vinylphenol trifluoromethyl carbinol	Single T_g	II had 84.4 mol% styrene and I/II had 54.5 mol% styrene and I/II was 1/8–1/4 or II had 1/8–1/2; semicrystalline at higher I content and no amorphous phase miscibility	Ting et al. (1981)
Sulfone	Transparency; light scattering	I had M_n = 3.5–4.0 kg/mol; immiscible when I had M_n = 200 kg/mol	Swinyard et al. (1987)
Vinyl acetate	Single T_g	Kalfoglou et al. (1988) stated miscible when ≥40 wt% II in blend; Guo et al. (1990b) stated completely miscible if I had M_w = 20 kg/mol, and miscible up to 50 wt% II if I had M_w = 100 kg/mol	Chen et al. (1999), Guo et al. (1990b), Kalfoglou et al. (1988), Martuscelli et al. (1985)
Vinyl alcohol	T_m-Depression; FTIR; WAXD; OM	II was hydroxypropylated	Sawatari and Kondo (1999)
Vinyl chloride	T_m-Depression; NMR; IGC	Semicrystalline	Castro et al. (2003), Etxeberria et al. (1993), Katsaros et al. (1986), Marco et al. (1993), Marentette and Brown (1998)
Vinylmethylether	Single T_g; FTIR	–	Pedrosa et al. (1994)
Vinylnaphthalene	Single T_g	Semicrystalline when >50 % I; two amorphous phases when 25–50 % I	Cuddkhy et al. (1965), Moacanin et al. (1965), Rembaum et al. (1963)
p-Vinylphenol	Single T_g; FTIR; NMR; WAXD; POM	–	Lin et al. (2006a), Pedrosa et al. (1995), Qin et al. (1990), Sotele et al. (1997), Tang and Liau (2000), Zhang and Hikichi (1992)
Vinylphosphonic acid	Single T_g; OM	–	Jiang et al. (2010)

(*continued*)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
Ethylene glycol, modified with C_{60}	Acrylic acid	Single T_g; FTIR	I was linear or 4-arm and end-capped with C_{60}	Song et al. (2002)
	Lactide	Single T_g	I was capped with C_{60} at both ends	Kai et al. (2006)
	Methacrylic acid	Single T_g; FTIR	I was end-capped with C_{60}; formed complexes	Huang and Goh (2000)
	Vinyl chloride	Single T_g; T_m-depression; XPS	One or both ends of I were end-capped with C_{60}	Huang and Goh (2002)
	p-Vinylphenol	Single T_g; FTIR	I was end-capped with C_{60}	Huang et al. (2000)
Ethylene succinate	p-Dioxanone	Single T_g; T_m-depression; WAXD; POM	–	Zeng et al. (2010)
	Propylene succinate	Single T_g; T_m-depression; WAXD; POM	–	Papageorgious and Bikiaris (2006)
Ethylene-co-sulfur dioxide-co-vinyl acetate	Vinyl chloride	Single T_g; transparency	I had 72.7/8.8/18.5 = ethylene/sulfur dioxide/vinyl acetate; immiscible when I had 89.0/3.2/7.8 = ethylene/sulfur dioxide/vinyl acetate	Hickman and Ikeda (1973)
Ethylene terephthalate	Ester-carbonate	Single T_g	I was from 1/2 = terephthalate/bisphenol-A with ester and carbonate linkages	Aharoni (1983)
	Ethylene-co-cyclohexane 1,4-dimethanol terephthalate	Single T_g	–	Papadopoulou and Kalfoglou (1997b)
	Ethylene-2,6-naphthalene dicarboxylate	Single T_g; WAXD; NMR	Miscibility arose from transesterification	Andresen and Zechmann (1994), Ihn et al. (1996), Shi and Jabarin (2001)
	Hydroxyether of 4,4′-dihydroxy-α-methylstilbene	Single T_g	Blend had I:II = 1:1	Bruggeman and Tinnemans (1999)
	Hydroxyether of bisphenol-A (Phenoxy)	Single T_g	T_g's of I and II were close; semicrystalline	Robeson and Furtek (1979)

	Ester, liquid crystalline	Single T_g	II was made from ethylene terephthalate (40 %) and hydroxybenzoic acid (60 %) (Zhuang et al. (1988)) or segmental block copolyester (Lin et al. (1983))	Lin et al. (1993), Park and Kim (2003), Zhuang et al. (1988)
	Trimethylene terephthalate	Single T_g; T_m-depression; SEM	–	Liang et al. (2008)
	Vinylidene fluoride	Single T_g, T_m-depression	–	Rahman and Nandi (2002)
Ethylene-co-vinyl acetate	Acrylic acid-co-alkyl acrylate	Single T_g	II had an alkyl group of n-butyl, ethyl, ethylhexyl, or methyl; miscibility depended on compositions of I and II	Bott et al. (1995)
	Alkylthiophene	Microscopy	II had an alkyl group of 3-octyl or 3-dodecyl; I had 20 mol% vinyl acetate; miscible when blend had <30 wtt II	Ho et al. (1993)
	Aniline, N-octadeceylated	OM; T_m-depression	I had 20 wt% vinyl acetate; II had a degree of alkylation of 60.2 wt%	Zheng et al. (1995)
	Chloroprene	Single T_g; SEM; NMR; FTIR	I had 28 wt% vinyl acetate	Kundu et al. (1996b), Kundo et al. (1995)
	2,2-Dimethylbutadiene-co-p-vinylphenol	Single T_g; FTIR	–	Pehlert et al. (1997)
	Hexafluoroacetone-co-vinylidene fluoride	Single T_g	I had $\geq$70 % vinyl acetate; II had 8.9 mol% hexafluoroacetone	Hasegawa and Akiyama (1988)
	Lactide	Single T_g; T_m-depression	II had 85 wt% vinyl acetate	Yoon et al. (1999)
	Novolac	Single T_g; FTIR	I had 14–50 wt% vinyl acetate	Mekhilef and Hadjiandreou (1995)
	3-Octylthiophene	UV-vis spectroscopy; NMR; T_m-depression	I had 20 mol% vinyl acetate	Leung and Lo (1995), Monedero et al. (1999)

(continued)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
	Propylene, chlorinated	Single T_g	I had 40, 44.3, or 45 wt% vinyl acetate; II had 40 or 50 wt% Cl	Lee et al. (1988a, 1989a)
	Vinyl chloride	Single T_g; T_m-depression; SEM	I had 65–75 wt% vinyl acetate; two T_g's when I had 40–45 wt% vinyl acetate; ambiguous when I had 45–65 wt% vinyl acetate	Corradini et al. (1997), Da Silva Neiro et al. (2000), Elmqvist and Svanson (1975), Feldman and Rusu (1974), Hammer (1971), Hardt (1969), Kosai and Higashino (1975), Marcincin et al. (1972), Ranby (1975), Shur and Ranby (1975a), Thaumaturgo and Monteiro (1997a, b)
	Vinyl chloride, chlorinated	Single T_g	Stated that there was a miscible region when I had 0.4–0.75 mol% ethylene and II had 0.4–0.8 mol% vinyl chloride	Shiomi et al. (1986b)
Ethylene-*co*-vinyl acetate-*co*-unnamed monomer	Vinyl chloride	Single T_g	Semicrystalline; I was du Pont de Nemours PBosma et al. (1988)41 (>60 % ethylene)	Bair et al. (1977)
Ethylene-*co*-vinyl alcohol	Alkyl methacrylate	Single T_g; FTIR	I had 21 mol% vinyl alcohol; II had an alkyl group of methyl, *n*-octyl, or *n*-decyl	Coleman et al. (1993b)
	Amide	Single T_g; FTIR; WAXD	II was PA-4,6, PA-6, PA-6,12, PA-12, or copolyamide of PA-6 and PA-12	Ahn and Jeong (1987), Akiba and Akiyama (1994), Ha et al. (1997), Yamaguchi et al. (1996)
	n-Butyl methacrylate	Single T_g; FTIR	I had 56 mol% vinyl alcohol	Keskin and Elliot (2003)
	N-Vinylpyrrolidone	Single T_g; FTIR	I had 45 or 57 mol% vinyl alcohol	Ahn and Jeong (1998)
	4-Vinylpyridine	Single T_g; FTIR	I had 68 mol% vinyl alcohol (Isasi et al. (1994)) or 56 mol% vinyl alcohol (Keskin and Elliot (2003))	Isasi et al. (1994) , Keskin and Elliot (2003)

Polymer I	Polymer II	Methods	Comments	Reference
2-Ethylhexyl methacrylate	Styrene-co-hexyl methacrylate	Single T_g	I had 3–5 % acrylic acid; II had 30 % styrene and 5–15 % 3-(dimethylamino)-2,2-dimethylpropyl methacrylate	Siol and Terbrack (1991)
N-Ethyl-3-hydroxymethylcarbazoyl methacrylate	o-Hydroxyalkyl-3,5-dinitrobenzoyl methacrylate	Single T_g	II had an alkyl group of butyl, hexyl, pentyl, or propyl	Rodriguez-Parada and Percec (1986a)
2-Ethyl-2-oxazoline	Acrylic acid	Single T_g	Formed complexes in water, methanol, or dioxane	Lin et al. (1988)
	Acrylic acid-co-ethylene	Single T_g	II had 20 wt% acrylic acid	Nuno-Donlucas et al. (2001b)
	Acrylic acid-co-styrene	Single T_g	II had 74 mol% acrylic acid	Lin et al. (1988)
	Alkyl methacrylate	Single T_g; FTIR	II had an alkyl group of 2-hydroxyethyl or 2-hydroxypropyl	Isasi et al. (1996)
	Allyl alcohol-co-styrene	Single T_g; FTIR	II had 4.5 or 6.5 wt% OH	Dai et al. (1994b)
	Aramide	Optical microscopy; light scattering	–	Maejima et al. (1989)
	Ethersulfone	Light scattering, transparency	–	Nakamura et al. (1990)
	Ethylene-co-vinyl alcohol	Single T_g; FTIR	II had 68 or 78 mol% vinyl alcohol	Parada et al. (1998a)
	Hydroxyether of bisphenol-A (Phenoxy)	Single T_g; transparency; FTIR; NMR	–	Keskkula and Paul (1986), Lau et al. (1998)
	Maleimide-co-styrene	Single T_g	II had 9.5–48.2 mol% maleimide	Dean (1987b)
	Monoalkyl itaconate	Single T_g; FTIR	II had an alkyl group of methyl, ethyl, propyl, butyl, pentyl, hexyl, decyl, or dodecyl	Meaurio et al. (1997, 1998)
	Novolac	Single T_g	Formed complexes in methanol or acetone	Lin et al. (1988)
	Styrenesulfonic acid, Zn-neutralized	Single T_g; FTIR; XPS	–	G144
	Sulfone, carboxylated	Single T_g	II had $\geq$0.93° of carboxylation	Goh et al. (1991e)

(continued)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
	Vinyl acetate-*co-co*-vinyl alcohol	Single T_g; FTIR	II had 15.3–84.4 mol% vinyl alcohol	Parada et al. (1997)
	Vinyl alcohol	Single T_g; FTIR	–	Aoi et al. (1998)
	p-Vinylphenol	Single T_g; NMR	Formed complexes in dioxane	Lin et al. (1988), Wang et al. (1991, 2001b)
	Vinylidene fluoride	Single T_g	>50 wt% II	Galin (1987b)
2-Ethyl-6-propyl-1,4-phenylene ether	Styrene	Single T_g	–	Cizek (1968)
2-Fluoroethyl methacrylate	Alkyl methacrylate	Single T_g	II had an alkyl group of methyl or ethyl	Peng et al. (1993)
3-Fluoropropyl methacrylate	Alkyl methacrylate	Single T_g	II had an alkyl group of methyl or tetrahydrofurfuryl	Peng et al. (1995)
	Ester	Single T_g	II was butylene adipate, 2,2-dimethyl-1,3-propylene adipate	Peng et al. (1995)
Glutarimide	Maleic anhydride-*co-co*-styrene	Single T_g; SEM	II had 8 wt% maleic anhydride	Bikiaris et al. (2004)
Glycidyl methacrylate	Acrylonitrile-*co*-styrene	Single T_g	II had 32.3–58.8 wt% AN	Gan and Paul (1994b)
	Methyl methacrylate	Single T_g	II had $M_w \leq 4.25$ kg/mol	Gan and Paul (1994b)
	α-Methylstyrene	Single T_g	II had $M_w = 3.5$ kg/mol	Gan and Paul (1994b)
Glycidyl methacrylate-*co*-methyl methacrylate	Acrylonitrile-*co*-styrene	Single T_g	Miscibility depended on compositions of I and II	Gan and Paul (1994b)
	Vinylidene fluoride	Single T_g	Semicrystalline	Gan and Paul (1995)
Glycidyl methacrylate-*co*-styrene	Carbonate of tetramethylbisphenol-A	Single T_g	I had 1.6–37.1 wt% GMA	Gan and Paul (1994b)
	2,6-Dimethyl-1,4-phenylene ether	Single T_g	I had 1.6–18.6 wt% GMA	Gan and Paul (1994b)

Glycolide-co-lactide	(Ethyl glycinato)(p-methylphenoxy)phosphazene	Single T_g; SEM	II had 3 different ratios of ethyl glycinato to p-methylphenoxy	Ibim et al. (1997)
	(Ethyl alanato) (p-phenylp henoxy) phosphazene	Single T_g; SEM	I had 15 mol% glycolide; blend had 25 wt% I	Deng et al. (2008)
	Phosphazene	Single T_g	I had 15 or 50 mol% glycolide; II was choline-substituted	Weikel et al. (2010)
	Phosphazene	Single T_g; SEM	I had 15 or 50 mol% clycolide; II contained alanyl glycine ethyl ester group	Krogman et al. (2010)
Heptamethylene terephthalate	Hexamethylene terephthalate	Single T_g; POM	–	Yen et al. (2009)
	Pentamethylene terephthalate	POM; T_m-depression	–	Yen and Woo (2009)
Hexadecamethylene dodecamethylene dicarboxylate	Vinyl chloride	Single T_g	Semicrystalline	Woo et al. (1985b)
Hexafluoroisopropanol-modified vinyl ether-alt-tetrafluoroethylene	Alkyl methacrylate	Single T_g; FTIR	II had an alkyl group of methyl, ethyl, or n-butyl	Guigley et al. (2002)
	Ethylene-co-vinyl acetate	Single T_g; FTIR	II had 70 wt% vinyl acetate	Guigley et al. (2002)
Hexafluoroisopropyl methacrylate	Alkyl methacrylate	Single T_g	II had an alkyl group of methyl or ethyl	Peng et al. (1993)
Hexamethylene adipamide (PA-6,6)	Ethylene terephthalate	FTIR; NMR	Blends prepared by coprecipitation; blends prepared by melt blending showed no sign of hydrogen bonding	Pillon et al. (1987)
Hexamethylene isophthalamide	Amide	Single T_g	II was PA-6,5, PA-6,7, PA-6,8, or PA-6,9	Cote and Brisson (1994)
	Caprolactam-co-caprolactone	Single T_g	II had varying composition	Ellis (1997)
Hexamethylene sebacate	Vinyl acetate-co-vinylidene chloride	Single T_g	Semicrystalline; II was Saran C ($\geq$80 % vinylidene chloride)	Aubin et al. (1983)
	Vinyl bromide	Single T_g	–	Cousin and Prud'homme (1982)
	Vinyl chloride	Single T_g	Semicrystalline when $\geq$50 % I	Woo et al. (1985b), Ziska et al. (1981)

(continued)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
Hexamethylene terephthalate	Hydroxyether of bisphenol-A (Phenoxy)	Single T_g	Semicrystalline when ≥75 % I	Seymour and Zehner (1980)
	Pentamethylene terephthalate	Single T_g; POM; WAXD; SAXS	–	Yan et al. (2007)
	Vinyl chloride	Single T_g	Semicrystalline; deposited from some solvents as two phases	Aubin and Prud'homme (1984)
Hexanoyl chitosan	Lactide	Single T_g; T_m-depression	Semicrystalline	Peesan et al. (2005)
1-Hexene	1-Pentene	Single T_g	–	Decroix and Piloz (1977), Peesan et al. (2007)
Hexyl methacrylate	Vinyl chloride	Single T_g; transparency	Especially when II was polymerized in situ (Walsh and Cheng (1984a)); stated as immiscible in Tremblay and Prud'homme (1984)	Walsh and Cheng (1984a), Walsh and McKeown (1980)
	Vinyl chloride-co-vinylidene chloride	Single T_g; transparency	II was Saran (≥80 % vinylidene chloride)	Kang et al. (1988), Tremblay and Prud'homme (1984)
3-Hydroxybutyrate	Acrylonitrile-co-vinylidene chloride	Single T_g; T_m-depression	II had 20 wt% (Lee et al. (1997)) or 32 mol% (Gonzalez et al. (2002)) acrylonitrile	Gonzalez et al. (2002), Lee et al. (1997)
	Caprolactone-co-lactide	Single T_g	II had 41 or 68 mol% lactide	Koyama and Doi (1996)
	Cellulose acetate butyrate	Single T_g; OM; SAXS; T_m-depression	Semicrystalline	Ceccorulli et al. (1993), El Shafee et al. (2001), Scandola et al. (1992), Scandola (1995)
	Cellulose acetate-proprionate	Single T_g; microscopy	Semicrystalline	Scandola et al. (1992), Scandola (1995)
	Cellulose proprionate	Single T_g; microscopy; T_m-depression	Semicrystalline	Maekawa et al. (1999)
	Cellulose tributyrate	Single T_g; microscopy	–	Scandola (1995)
	Chitosan	Single T_g; T_m-depression; NMR	–	Cheung et al. (2002)

Epichlorohydrin	Single T_g; microscopy; T_m-depression; dielectric spectroscopy	Semicrystalline	Dubini Paglia et al. (1993), El Shafee (2002a), Finelli et al. (1997), Scandola (1995), Tsukada et al. (1992)
Epichlorohydrin-*co*-ethylene glycol	Single T_g; T_m-depression	II had 30 wt% ethylene glycol (Gonzalez et al. (2003)); II had 48 mol% ethylene glycol (Zhang et al. (2000))	Gonzalez et al. (2003), Zhang et al. (2000)
Ethylene glycol	Single T_g; SAXS	Semicrystalline	Avella and Martuscelli (1988), Chiu and You (2003), He et al. (2000), Kumagai and Doi (1992a), Yoon et al. (1993), You et al. (2003)
Ethylene succinate	Single T_g; microscopy; T_m-depression	Semicrystalline	Al-Salah (1998b)
Ethylene-*co*-vinyl acetate	Single T_g; T_m-depression; POM	Semicrystalline; II had 9–91 mol% vinyl acetate	Ellis (1993), Yoon et al. (1998)
Ethyl cellulose	Single T_g; SEM	Semicrystalline	Zhang et al. (1997)
Hydroxyether of bisphenol-A	Single T_g; FTIR	Semicrystalline; blend had ≤20 wt% I	Yuan and Ruckenstein (1998)
2-Hydroxyethyl methacrylate-*co*-4-vinylphenol	Single T_g; FTIR; OM	II had 55 mol% vinylphenol	Rocco et al. (2003a)
Lactide	Single T_g; microscopy; WAXD	Miscible when II had M_n = 1,759 kg/mol, immiscible when II had M_n = 159.4 kg/mol (Blumm and Owen (1995)); I had M_w = 650 kg/mol, and II had M_w <18 kg/mol (Koyama and Doi (1997))	Blumm and Owen (1995), Focarete et al. (2002), Koyama and Doi (1995, 1997), Ohkoshi et al. (2000), Zhang et al. (2006b)
Methyl acrylate	Single T_g; T_m-depression	–	An et al. (2000)
Methyl methacrylate	Single T_g	Miscible when blend had <20 wt% I	Ceccorulli and Scandola (1999), Cimmino et al. (2000), Lotti et al. (1993)

(continued)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
	Styrene-*co*-*p*-vinylphenol	Single T_g; T_m-depression; FTIR; NMR	II had 20–80 mol% vinylphenol	Gonzalez et al. (2004a, b), Kuo and Liu (2011)
	Vinyl acetate	Single T_g	Semicrystalline	Grece and Martuscelli (1989), Hay and Sharma (2000), Kumagai and Doi (1992b)
	Vinyl acetate-*co*-vinyl alcohol	Single T_g; OM; SASX; WAXD	II had 9, 15, or 22 mol% vinyl alcohol	Xing et al. (1998b)
	Vinyl alcohol	Single T_g; FTIR; NMR	II was 80 % hydrolyzed (Huang et al. (2005)); blend had large amount of II (Yoshie et al. (1995))	Huang et al. (2005), Yoshie et al. (1995)
	Vinylidene fluoride	Single T_g; T_m-depression; SAXS	Semicrystalline	Chiu et al. (2001), Kang and Cho (1989), Karcha and Porter (1989), Liu et al. (2005c)
	p-Vinylphenol	Single T_g; FTIR; WAXD; SAXS; T_m-depression	–	Ding et al. (2011), Guo et al. (2010, 2011), Iriondo et al. (1995, 1996), Xing et al. (1997), Zhang et al. (1999)
3-Hydroxybutyrate-*co*-3-hydroxyhexanoate	Butylene succinate	Single T_g; T_m-depression; FTIR	I had 4 mol% hydroxyhexanoate	Lim et al. (2008)
	Ethylene glycol	Single T_g; FTIR	I had 7.5, 12.3, or 31.2 mol% hydroxyhexanoate; miscible when blend had <17 wt% II	Yu et al. (2010)
3-Hydroxybutyrate-*co*-hydroxyvalerate	Acrylonitrile-*co*-butadiene-*co*-styrene	Single T_g	I had 16 % hydroxyvalerate	Dave et al. (1990)
	Caprolactone	Single T_g; T_m-depression; FTIR	I had 18 mol% hydroxyvalerate	Cho et al. (2001a)
	Chitosan	Single T_g; T_m-depression; NMR	I had 30 mol% hydroxyvalerate	Cheung et al. (2002)
	Epichlorohydrin-*co*-ethylene glycol	Single T_g; T_m-depression	I had 14 mol% hydroxyvalerate and II had 48 mol% ethylene glycol	Zhang et al. (2000)

Ethylene glycol	Single T_g; T_m-depression	II had 12 mol% hydroxyvalerate	Tan et al. (2006)
Methyl methacrylate	Single T_g; T_m-depression; OM; SAXS	I had 10 mol% hydroxyvalerate	Chiu (2004), Chiu and Shu (2005)
Novolac	Single T_g; T_m-depression; POM	I had 5 wt% hydroxyvalerate	Yang et al. (2012)
Vinyl acetate	Single T_g; T_m-depression; FTIR; POM; AFM	I had 9 or 10 mol% hydroxyvalerate	Chang et al. (2011), Chiu (2006), Kwang et al. (1998)
Vinyl chloride	Single T_g	I had 16 % hydroxyvalerate	Dave et al. (1990)
Vinylidene fluoride	OM	I had 14 mol% hydroxyvalerate	Qiu et al. (2004)
p-Vinylphenol	Single T_g; T_m-depression; FTIR; POM; NMR	I had 15 or 20 mol% hydroxyvalerate	Alata et al. (2007), Cai et al. (2012), Xing et al. (1998a)
Hydroxyether of bisphenol-A (Phenoxy) Aryleneetherphenyl phosphine oxide-co-sulfone	Single T_g; FTIR	II was based on bisphenol-A or hydroquinone	Wang et al. (1999b)
Biphenol poly(arylene ether phenyl phosphine oxide)	Single T_g; FTIR; NMR	–	Wang et al. (2001a)
n-Butyl methacrylate-co-methyl methacrylate	Single T_g	II had 18 wt% butyl methacrylate	Erro et al. (2000)
2,2-Dichloroethyl methacrylate	Single T_g; FTIR	–	Goh et al. (1994b)
2,2-Dichloroethyl methacrylate-co-methyl methacrylate	Single T_g; FTIR	II had ≤62 wt% methyl methacrylate	Goh et al. (1994b)
Ester	Single T_g	I was cyclohexylene dimethylene tere/isophthalate	Robeson and Furtek (1979)
Etherester	Single T_g	Interchange reaction took place	Gan and Paul (1995)
Etheretherketone-co-phenolphthalein etheretherketone	Single T_g; FTIR	II had 6.2 or 12.3 mol% etheretherketone	Guo et al. (1996c)
Ethylene oxide-co-propylene oxide	Single T_g	II had >22 mol% ethylene oxide	Guo et al. (1993a)
Ethersulfone	Light scattering	–	Saito et al. (1990)
Hexafluorobisphenol-A poly (arylene ether phenyl phosphine oxide)	Single T_g; FTIR; NMR	–	Wang et al. (2001a)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
	1,1,1,3,3,3-Hexafluoroisopropyl methacrylate	Single T_g; FTIR; XPS; ToF-SIMS	–	Huang et al. (2004b)
	Imide	Single T_g; FTIR; NMR	II were two different imides	Wang et al. (2001a)
	Methyl acrylate-*co*-methyl methacrylate	Single T_g; FTIR	II had 72 or 91 mol% methyl methacrylate	Wu et al. (1998)
	Methyl methacrylate	Single T_g; NMR; FTIR; Raman spectroscopy	II was atactic, isotactic, or syndiotactic (Alberdi et al. (1994), Hsu and Yeh (2000b))	Alberdi et al. (1994), Chiou et al. (1982), Erro et al. (1992, 2000), Hsu and Yeh (2000b), Kim and Choi (1996), Soh (1992b), Ward and Mi (1999)
	Tertiary amide	Single T_g; FTIR	II was *N*-methyl-*N*-vinylacetamide, *N*, *N*-dimethylacrylamide, or 2-methyl-2-oxazoline; formed complexes	Dai et al. (1996)
	Thiodithiophenol poly(arylene ether phenyl phosphine oxide)	Single T_g; FTIR; NMR	–	Wang et al. (2001a)
	Vinylmethylether	Single T_g; IGC	–	Etxeberria et al. (1994, 1995), Robeson et al. (1981), Uriarte et al. (1987, 1989)
	Vinylpyridine	Single T_g; FTIR; NMR	II was 2- or 4-vinylpyridine	De Ilarduya et al. (1993), Zheng and Mi (2003)

Component 1	Component 2	Method	Comments	References
	N-Vinylpyrrolidone	Single T_g; transparency; FTIR; NMR	–	De Ilarduya et al. (1995), Eguiazabal et al. (1984), Zheng et al. (1999a)
	Urethane	Single T_g	II was made from 1/1/2 = polycaprolactone diol (M_n = 2.1 kg/mol)/1,4-butanediol/4,4′-diphenylmethane diisocyanate	Seefried et al. (1976)
Hydroxyether of bisphenol-A, benzoylated	N-Vinylpyrrolidone	Single T_g; FTIR	–	Fernandez-Berridi et al. (1993)
Hydroxyether of bisphenol-A, modified	2-Vinylpyridine	Single T_g; FTIR	OH groups in I were converted to benzoate, acetate, or methoxy	Eguiburu et al. (1994)
Hydroxyether of phenolphthalein	Butylene terephthalate	Single T_g	–	Guo et al. (1990d)
	Carbonate of bisphenol-A	Single T_g	–	Guo et al. (1990d)
	Ethersulfone	Single T_g; FTIR	–	Guo (1992b)
	Ethylene glycol	Single T_g	–	Guo et al. (1990c)
Hydroxyethyl cellulose	Maleic acid-alt-methylvinylether	Single T_g; FTIR	–	Khutoryanskaya et al. (2005)
β-Hydroxyethyl-3,5-dinitrobenzoyl methacrylate	N-Alkyl-3-hydroxymethylcarbazoyl methacrylate	Single T_g	II had an alkyl group of butyl, decyl, dodecyl, ethyl, hexadecyl, hexyl, methyl, octyl, or tetradecyl	Rodriguez-Parada and Percec (1986b)
	N-(2-Hydroxyethyl)carbazoyl methacrylate	Single T_g	–	Rodriguez-Parada and Percec (1986b)
2-Hydroxyethyl methacrylate	Acrylamide-co-styrene	Single T_g; NRET	II had 40, 47, 52, or 57 mol% acrylamide	Chu and Ji (1995), Zhu et al. (1995)
	Dialkyl itaconate-co-styrene	Single T_g	II had an alkyl group of methyl or ethyl; II had 18–80 wt% styrene	Opazo et al. (1996)
	Methacrylic acid	Single T_g; NMR	–	Asano et al. (1999), Eguchi et al. (1998)

(continued)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
2-Hydroxyethyl methacrylate, modified	1-Vinylimidazole	Single T_g; FTIR	I had 0.6–2.6 wt% C_{60}	Goh et al. (2002a, b)
	4-Vinylpyridine	Single T_g; FTIR	I had 0.6–2.6 wt% C_{60}	Goh et al. (2002a, b)
p-(2-Hydroxy-hexafluoroisopropyl)-α-methylstyrene-co-styrene	Butyl acrylate	Single T_g	I had ≥1.2 mol% OH-containing monomer	Cao et al. (1989)
	Methyl methacrylate	Single T_g; NRET; NMR	I had ≥1.9 mol% OH-containing monomer; formed complexes when I had 24 mol% OH	Cao et al. (1989), Jiang et al. (1995c), Qiu and Jiang (1994)
	Methyl methacrylate-co-2-vinylpyridine	Single T_g	I had ≥6 mol% OH-containing monomer	Jiang et al. (1989)
	Propyl carbonate	ESR	I had 19.4 or 27.28 mol% OH	Chen et al. (2004c)
	4-Vinylpyridine	Single T_g; XPS; TOF-SIMS; AFM	Miscible when I had ≥5.1 mol % OH; formed complexes when I had ≥8.3 mol% OH	Liu et al. (2002), Liu et al. (2004a)
p-(2-Hydroxy-hexafluoroisopropyl) styrene	Ethylene-co-vinyl acetate	Single T_g; FTIR; dielectric spectroscopy	II had 45 or 70 mol% vinyl acetate	Masser et al. (2010)
	Vinyl acetate	Single T_g; FTIR; dielectric spectroscopy	–	Masser et al. (2010)
p-(2-Hydroxy-hexafluoroisopropyl) styrene-co-styrene	Aramide	Single T_g; transparency	I had 60 mol% styrene; two T_g's when I had 83 mol% styrene; II was poly(iminotrimethylhexa-methyleneiminoterephthaloyl)	Min and Pearce (1981), Pearce et al. (1984)
	n-Butyl methacrylate	Single T_g; NRET	Miscible with I had 1 mol% OH; formed complexes when I had 18 mol% OH	Qiu and Jiang (1995)

	Ester	Single T_g; transparency	II was KODAR PETG (made from terephthalic and isophthalic acid and ethylene glycol and 1,4-dihydroxymethyl cyclohexane); II had 60 mol% styrene; immiscible when II han >83 mol% styrene	Min and Pearce (1981), Pearce et al. (1984)
	Ester	Single T_g; transparency	I was VITEL PE-307; II had 83–90.3 mol% styrene	Pearce et al. (1984)
	Ester	Single T_g	I was VITEL VPE-5545; II had 83 mol% styrene; immiscible when II had 90.3 mol% styrene	Pearce et al. (1984)
	Hexanediamine-*co*-,-decanedicarboxylic acid	Single T_g	Semicrystalline	Kotzev et al. (1984)
	Hydroxypropyl L-glutamine	Single T_g; light scattering; microscopy	Blend had >50 vol% II	Dadmun and Han (1993)
	Methyl methacrylate	Single T_g; transparency; NMR; FTIR; WAXD; NRET	I had >8 mol% OH; formed complexes when I had 24 mol% OH; II was syndiotactic or isotactic (Luo et al. (1995))	Luo et al. (1993, 1995b), Min and Pearce (1981), Pearce et al. (1984),
	Vinyl acetate	Single T_g; transparency	I had 90.3 mol% styrene	Min and Pearce (1981), Pearce et al. (1984)
	Vinylmethylether	Single T_g; transparency	I had 83.3–99.9 mol% styrene	Min and Pearce (1981), Min et al. (1983), Pearce et al. (1984)
	Vinylmethylketone	Transparency	I had 90.3 mol% styrene	Mengujoh and Frisch (1989)
2-Hydroxypropyl methacrylate	Tertiary amide	Single T_g; FTIR	Formed complexes; II was dimethylacrylamide, *N*-methyl-*N*-vinylacetamide, or 2-ethyl-2-oxazoline	Dai et al. (1994a)
	N-Vinylpyrrolidone-*co*-4-vinylpyridine	Single T_g	–	Radic et al. (2001)
	N-Vinylpyrrolidone-*co*-vinyltrimethylsilane	Single T_g	II had <25 wt% VTMS	Radic et al. (2001)

(continued)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
Hydroxypropyl methyl cellulose	Vinyl acetate-*co*-1-vinylpyrrolidone	Single T_g; FTIR	II had 43 mol% vinyl acetate	Zaccaron et al. (2005)
Imide	Amide	Single T_g; SEM	I was made from 1,6-hexamethylenediamine and a mixture of isophthalic acid and terephthalic acid; II was two different amides	Endo et al. (2006)
	Benzimidazole	Single T_g; FTIR	I was 8 different types of imides	Ahn et al. (1997b)
	Ether ketone	Single T_g	I was made from pyromellitic dianhydride and 4,4'-bis(3-aminophenoxy)biphenyl; II was Victrex 220P	Sauer and Hsiao (1993b)
	Ether ketone ketone	Single T_g	I was the same as the previous system	Sauer and Hsiao (1993b)
	Imide	X-ray diffraction	I was made from pyromellitic dianhydride (PMDA) and oxydianiline; II was made from PMDA and *p*-phenylenediamine; <90 % II in blend	Jou and Huang (1990)
	Imide	Single T_g	I was made from PMDA and 1,4-phenylenediamine; II was made from 6FDA and 2,2'-bis[4-(4-aminophenoxy)phenyl]propane	Tong et al. (2001)

Imide	Single T_g	I was made from 2,2′-bis(3,4′-dicarboxyphenyl)hexafluoro-propane dianhydride (6FDA) and 2,2′-bis(3-aminophenyl)hexafluoropropane (3,3′-6 F-diamine); II was made from 6FDA and 2,2′-bis(4-aminophenyl)hexafluoropropane (4,4′-6F-diamine)	Chung et al. (1991)
Imide	Single T_g	I was made from 4,4′-biphthalic anhydride (BPDA) and 3,3′-6F-diamine; II was made from BPDA and 4,4′-6F-diamine	Chung et al. (1991)
Imide	Single T_g	I was made from 3,3′4,4′-benzophenonetetra-carboxylic dianhydride (BTDA) and 3,3′-6F-diamine; II was made from BTDA and 4,4′-6F-diamine	Chung et al. (1991)
Imide	Single T_g	I was made from 3,3′4,4′-diphenylet hercarboxylic dianhydride (OPDA) and 3,3′-6F-diamine; II was made from OPDA and 4,4′-6F-diamine	Chung et al. (1991)
Imide	Single T_g	I was made from PMDA/BPDA/3,3′-6F-diamine = 25/25/50; II was made from PMDA/BPDA/4,4′-6F-diamine = 25/25/50	Chung et al. (1991)

(continued)

Table 21.1 (continued)

Polymer 1 of	Polymer II of	Method	Comments	Refs.
	Imide	Single T_g	I was made from PMDA/BTDA/3,3'-6F-diamine = 25/25/50; II was made from PMDA/BTDA/4,4'-6F-diamine = 25/25/50	Chung et al. (1991)
	Imide	Single T_g	I was made from PMDA/OPDA/3,3'-6F-diamine = 25/25/50; II was made from PMDA/BTDA/4,4'-6F-diamine = 25/25/50	Chung et al. (1991)
	Imide	Single T_g; WAXD, SAXS	I was made from 3,4:3'4'-biphenyltetra carboxylic dianhydride and 4,4'-oxydianiline; II was made from 4,4'-thiophthalic anhydride and 4,4'oxydianiline	Zhang et al. (1993)
	Imide	Single T_g	I and II were isomeric; 3 blend systems	Coleman et al. (1993a)
	Imide	Single T_g	I and II were different imides, but both had hexafluoroisopropylidene group	Chung and Kafchinski (1996)
	Imide	Single T_g	I and II were different imides	Tang et al. (1997)
	Imide	Single T_g	I was a liquid crystalline imide	Konda et al. (1998)
	Imide	Single T_g	Two pairs of different imides	Khalid et al. (2007)
2-Iodoethyl methacrylate	Acrylonitrile-co-p-methylstyrene	Single T_g	I had 21–42 wt% AN	Low et al. (1993b)
	Acrylonitrile-co-styrene	Single T_g	I had 13–51 wt% AN	Low et al. (1993b)
	Ester	Single T_g	II was butylene adipate, caprolactone, 2,2-dimethyl-1,3-propylene adipate, or hexamethylene sebacate	Low et al. (1994c)
	Tetrahydrofurfuryl methacrylate	Single T_g	–	Low et al. (1993d)

Isobutylene	Dimethylsilylenemethylene	Single T_g; OM	–	Maier et al. (1998)
	Propylene	NMR	II was head-to-head	Wachowicz and White (2007), Walak and White (2005)
Cis-isoprene	Butadiene-*co*-1,2-vinylbutadiene	Single T_g	II had $\geq$32.3 % vinylbutadiene	Kawahara et al. (1989)
	Cis-pentenamer	Single T_g	–	Braun and Rehage (1985)
	Vinylethylene	Single T_g; NMR	II had 86 % 1,2-butadiene	Miller et al. (1990), Roland (1987), Roland and Trask (1989), Trask and Roland (1988), Trask and Roland (1989)
Isoprene, chlorinated	Ethylene-*co*-vinyl acetate	Single T_g; transparency	Semicrystalline; commercial samples	Leffingwell et al. (1973), Purcell and Thies (1968)
Isoprene, modified by hexafluoroisopropanol group	Alkyl methacrylate	Single T_g; FTIR	II had an alkyl group of methyl or *n*-butyl	Coleman et al. (1994)
	Ethylene-*co*-methyl acrylate	Single T_g; FTIR	II had 40 or 75 wt% methyl acrylate	Coleman et al. (1994)
	Ethylene-*co*-methyl methacrylate	Single T_g; FTIR	II had 50 wt% methyl methacrylate	Coleman et al. (1994)
	Ethylene-*co*-vinyl acetate	Single T_g; FTIR	II had 35 or 70 wt% vinyl acetate	Coleman et al. (1994)
	Methyl acrylate	Single T_g; FTIR	–	Coleman et al. (1994)
	Methyl acrylate-*co*-styrene	Single T_g; FTIR	II had 28 wt% methyl acrylate	Coleman et al. (1994)
Isoprene-stat-*N*-(2-hydroxyethyl) carbazole methacrylate	*N*-Itaconimidyl-3,5-dinitrobenzoate-*co*-styrene	Single T_g	I and II had at least 20 mol% of electron donor or acceptor	Cowie and Demaude (1994)
Isoprene-*co*-b-methyl methacrylate	Acrylonitrile-*co*-styrene	Single T_g; TEM	II had 22 wt% AN	Jiang et al. (1995b)
	p-(2-Hydroxyhexafluoroiso-propyl)-α-methystyrene-*co*-styrene	TEM	II had >1.6 mol% OH	Jiang et al. (1995a)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
N-Isopropylacrylamide	Acrylic acid	Single T_g; SEM; FTIR	Formed complexes	Garay et al. (1997, 2000), Mano et al. (2004b), Mayo-Pedrosa et al. (2004)
	Ethylene-co-vinyl alcohol	Single T_g; SEM; T_m-depression	II had 60 mol% vinyl alcohol	Mano et al. (2004a)
	2-Hydroxyethyl methacrylate	Single T_g	–	Garay et al. (2004)
	Methacrylic acid	Single T_g	Formed complexes	Garay et al. (1997, 2000)
	p-Vinylphenol	Single T_g	Formed complexes	Garay et al. (2004)
Isopropyl acrylate	Isopropyl methacrylate	Single T_g; transparency	–	Kosai et al. (1977)
Lactide	Butylene carbonate-co-butyl succinate	Single T_g; POM	–	Hirano et al. (2002)
	Butylene succinate	Single T_g; WAXD; SAXD	Semicrystalline	Park and Im (2002)
	Diethylene adipate	Single T_g; SEM	I had $\leq$20 wt% II	Okamoto et al. (2009)
	Ethylene adipate	Single T_g; SEM	I had $\leq$20 wt% II	Okamoto et al. (2009)
	Hydroxyesterether	Single T_g	Miscibility achieved after several heating-cooling cycles	Cao et al. (2003)
	Methyl acrylate	Single T_g	–	Eguiburu et al. (1998)
	Methyl methacrylate	Single T_g	–	Eguiburu et al. (1998), Shirahase et al. (2006)
	Sebacic anhydride	Single T_g; surface analysis	I had M_w less than 3 kg/mol	Davies et al. (1996)
	Vinyl acetate-co-vinyl alcohol	Single T_g; T_m-depression	II had 11.7–31.4 mol% vinyl alcohol	Park and Im (2003)
Maleic anhydride-alt-α-methylstyrene	2,6-Dimethyl-1,4-phenylene ether, sulfonylated	Single T_g	II had <55 mol% sulfonylation	Vukovic et al. (1992b)
Maleic anhydride-co-styrene	Caprolactone	Single T_g; T_m-depression; WAXD; TEM	I had 14 or 25 wt% maleic anhydride; semicrystalline	Balsamo et al. (2006), Defieuw et al. (1989a)
	Carbonate of bisphenol-A-co-carbonate of tetramethylbisphenol-A	Single T_g	I had 9, 10.7, or 12.2 wt% maleic anhydride	Merfeld and Paul (1998)

	Carbonate of tetramethylbisphenol-A	Single T_g	I had <12 mol% MA	Gan and Paul (1994a)
	2,6-Dimethyl-1,4-phenylene ether	Single T_g	I had <10 mol% MA	Gan and Paul (1994a)
	2,6-Dimethyl-1,4-phenylene ether, sulfonylated	Single T_g	I was alternating copolymer and had <55 mol% sulfonylation	Vukovic et al. (1992b)
	Ethyl methacrylate	Single T_g	I had 0–33 wt% maleic anhydride	Brannock et al. (1991)
	Glutarimide	Single T_g; FTIR; OM	I had 25, 33, or 50 mol% maleic anhydride	Prinos et al. (1999)
	N-Methyl-glutarimide	Single T_g; FTIR	I had 14 wt% maleic anhydride	Prinos et al. (1997)
	Methyl methacrylate	Single T_g; FTIR; NMR	I had 8–33 wt% maleic anhydride	Brannock et al. (1991), Fang et al. (2007), Feng et al. (1995b)
	n-Propyl methacrylate	Single T_g	I had 0–18.1 wt% maleic anhydride	Brannock et al. (1991)
	Methyl methacrylate-co-phenylmaleimide	Single T_g	Miscibility depended on compositions of I and II	Merfeld et al. (1999)
	Methyl methacrylate-co-tribromophenyl maleimide	Single T_g	Miscibility depended on compositions of I and II	Merfeld et al. (1999)
	Vinylmethylether	Single T_g	I had 4.7 wt% maleic anhydride	Wendland et al. (1989)
Maleimide-co-methyl methacrylate	7-(2-Methacryloyloxy)ethyl adenine	Single T_g	I and II had ≥15 mol% hydrogen bonding unit site	Cowie and Love (2001)
Maleimide-alt-α-methylstyrene	2,6-Dimethyl-1,4-phenylene ether, sulfonylated	Single T_g	Depended on degree of sulfonylation of II	Vukovic et al. (1992a)
Maleimide-co-methyl acrylate	Acrylonitrile-co-styrene-co-vinyl 2,4-diamino-1,3, 5-triazine	Single T_g	I had 9–14 mol% maleimide; II had ≥ triazine unit	Cowie and Cocton (1999)
Methacrylate, liquid crystalline	Methacrylate, liquid crystalline	Single T_g, microscopy	I had electron-donating group; II had electron accepting group	Kosaka and Uryu (1995)
Methacrylic acid	Ester of dehydrated castor oil	Single T_g; SEM	Blend had ≤40 wt% I	Ashraf et al. (2007)
	4-Vinylpyridine	NMR	–	Yi and Goh (2001b)
	Vinylpyridine	Single T_g; FTIR; XPS	II was 2- or 4-vinylpyrdine; formed complexes in ethanol/water (1:1)	Zhou et al. (1998)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
Methacrylic acid-*co*-α-methylstyrene	Butyl methacrylate-*co*-4-vinylpyridine	Single T_g; FTIR	I had 50.6 mol% methacrylic acid (MA); II had 18 or 26 mol % vinylpyridine (VP)	Metref and Djadoun (1995)
	Ethyl methacrylate-*co*-4-vinylpyridine	Single T_g; FTIR	I had 50.6 mol% MA; II had 23 mol% VP	Metref and Djadoun (1995)
	Methyl methacrylate-*co*-4-vinylpyridine	Single T_g; FTIR	I had 50.6 mol% MA; II had 8 mol% VP	Metref and Djadoun (1995)
Methacrylic acid-*co*-styrene	Ethyl methacrylate	Single T_g	I had 22 mol% methacrylic acid	Abdellaoui and Djadoun (2005)
	Isobutyl methacrylate-*co*-2-(N,N'-dimethylamino)ethyl methacrylate	Single T_g; IGC	I had 12–45 mol% methacrylic acid; II had 12 or 20 mol% dimethylaminoethyl methacrylate	Habi and Djadoun (1999)
	Isobutyl methacrylate-*co*-4-vinylpyridine	Single T_g; IGC; FTIR	I had 12–45 mol% methacrylic acid; II had 10 mol% vinylpyridine	Habi and Djadoun (1999, 2008)
	Tetrahydrofuran	FTIR	I had 9 mol% methacrylic acid	Cleveland et al. (2000)
Methacrylonitrile-*co*-α-methylstyrene	Vinyl chloride	Single T_g	I was azeotropic; I had 31–43 wt% MAN (Kim et al. (1996))	Kenney (1974), Kim et al. (1996)
Methacrylonitrile-*co*-*p*-methylstyrene	*n*-Butyl methacrylate	Single T_g	I had 12–28 wt% MAN	Chen and Porter (1993)
	Ethyl methacrylate	Single T_g	I had 12–55 wt% MAN	Chen and Porter (1993)
	Methyl methacrylate	Single T_g	I had 19–70 wt% MAN	Chen and Porter (1993)
	Isopropyl methacrylate	Single T_g	I had 19–34 wt% MAN when II had $M_n = 161$ kg/mol; I had 16–34 wt% MAN when II had $M_n = 41.6$ kg/mol	Chen and Porter (1993)
	n-Propyl methacrylate	Single T_g	I had 12–43 wt% MAN	Chen and Porter (1993)
	Vinyl chloride	Single T_g	I had 20–43 wt% methacrylonitrile	Chen et al. (1998d)

Methacrylonitrile-co-styrene	t-Butyl methacrylate-co-methyl methacrylate	Single T_g	Miscibility depended on compositions of I and II	Nishimoto et al. (1995)
	Cyclohexyl methacrylate-co-methyl methacrylate	Single T_g	Miscibility depended on compositions of I and II	Nishimoto et al. (1995)
	Ethyl methacrylate	Single T_g	I had 4.5–44 wt% methacrylonitrile (MAN)	Chen et al. (1994)
	Methyl methacrylate	Single T_g; transparency; fluorescence spectroscopy	Miscibility range varied in various studies especially at low MAN end	Dong et al. (1994), Goh et al. (1993), Nishimoto et al. (1995)
	Isopropyl methacrylate	Single T_g	I had 12–38 wt% MAN when II had $M_n = 161$ kg/mol; I had 8–43 wt% MAN when II had $M_n = 41.6$ kg/mol	Chen et al. (1994)
	n-Propyl methacrylate	Single T_g	I had 2–32 wt% MAN	Chen et al. (1994)
4-[[6-(Methacryloyloxy)hexyl]oxy]-N-[9-methyl-2-carbazolyl]methylene]aniline	4-[[6-(Methacryloyloxy)hexyl]oxy-N-(4'-nitrobenzylidene)aniline	Single T_g	Both polymers I and II were liquid crystalline	Kosaka and Uryu (1994)
4-[[1-[(4-Methoxyphenyl)azo]phenyl-4]oxy-3-propyl]oxy]styrene	[4-[-[[(4-Cyanobiphenyl)-4']oxy]-3-propyl]oxy]styrene	Single T_g	Blends showed liquid crystallinity	Imrie and Paterson (1994)
p-Methoxystyrene-co-p-vinylphenol	Alkyl acrylate	Single T_g; FTIR	II had an alkyl group of methyl or ethyl	Sanchis et al. (1995)
	Vinyl acetate	Single T_g; FTIR	–	Sanchis et al. (1995)
Methyl acrylate	Alkyl methacrylate	Single T_g	II had an alkyl group from 2-chloroethyl, 2-fluoroethyl, 1,3-difluoroisopropyl	Peng et al. (1996)
	Epichlorohydrin	Single T_g; IGC	–	Etxeberria et al. (1995), Fernandes et al. (1986c)
	Epichlorohydrin-co-ethylene glycol	Single T_g	I had 50 mol% epichlorohydrin (Hydrin 200)	Fernandes et al. (1986c)
	Ethylene glycol	Single T_g	–	Fernandes et al. (1986c)
	Hexafluoroacetone-co-vinylidene fluoride	Single T_g; XPS	II had 8 mol% of hexafluoroacetone	Kano et al. (1997c)

(continued)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
	p-Methoxystyrene-co-p-vinylphenol	Dielectric analysis	II had 67 mol% methoxystyrene	Prolongo et al. (1997)
	Nitrocellulose	Single T_g	–	Kargin (1963)
	Vinyl acetate	Single T_g; transparency; NMR	Probably formed two phases when deposited from some solvents (Refs. Nandi et al. (1985), Djadoun (1983))	Casarino et al. (1996), Nandi et al. (1985), Nielson and Chinai (1962), Kosai et al. (1977), Song et al. (1999), Takegoshi et al. (1995)
	Vinyl chloride-co-vinylidene chloride	Single T_g; transparency	II was Saran ($\geq$80 % vinylidene chloride); I had $M_w = 1.0$ kg/mol; two T_g's when I had $M_w = 576$ kg/mol in Woo et al. (1984b)	Tremblay and Prud'homme (1984)
	Vinylidene fluoride	Single T_g; transparent melt	Semicrystalline	Maiti and Nandi (1995), Wahrmund et al. (1978)
Methyl acrylate, modified with C_{60}	Vinylidene fluoride	Single T_g; T_m-depression	I had 10.1 or 19.8 wt% C_{60}	Zheng et al. (2001)
Methyl acrylate-co-vinylcarbazole	Methyl methacrylate-co-2(3,5-dinitrobenzoyl)oxyethyl methacrylate	Single T_g	Both I and II had >27 mol% monomer with interactive groups	Russell et al. (1991)
	Styrene-co-2(3,5-dinitrobenzoyl) oxyethyl methacrylate	Single T_g	Both I and II had >12 mol% monomer with interactive groups	Crone and Natansohn (1991)
Methyl 1-bicyclobutane-carboxylate	Acrylonitrile-co-styrene	Single T_g; transparency	II had 24–38 wt% acrylonitrile	Drujon et al. (1992)
	Ethylene glycol	Single T_g; transparency	$\leq$20 wt% II	Drujon et al. (1992)
2-Methyl-6-ethyl-1,4-phenylene ether	Styrene	Single T_g	–	Cizek (1968)
α-Methyl-α-ethyl-β- propiolactone	Vinyl chloride	Single T_g	Semicrystalline when 75 % I	Aubin and Prud'homme (1980)

Methyl methacrylate	Acrylonitrile-*co*-methyl methacrylate-*co*-styrene	Single T_g	II had 40/39.1/20.9 or 61.1/19.6/19.3 = styrene/methyl methacrylate/acrylonitrile	Nishimoto et al. (1989)
	4'-[[2-(Acryloyloxy)ethyl] ethylamino]-3-chloro-4-nitroazobenzene	Single T_g; NMR	–	Xie et al. (1994)
	4'-[[2-(Acryloyloxy)ethyl] ethylamino]-4-nitroazobenzene	Single T_g; NMR	–	Xie et al. (1994)
	p-t-Butylphenol formaldehyde	Single T_g; FTIR; WAXD	II had M_n = 1,500–1,600	Kalkar et al. (1995)
	Carbon monoxide-alt-propylene	Single T_g; FTIR; NMR	–	Xu and Chien (1994)
	Carbonate of bisphenol-A-*co*-hexafluorobisphenol-A	Single T_g; transparency	II had 4.5–14.0 wt% hexafluorobisphenol-A	Kim and Paul (1992d)
	Carbonate of bisphenol-F	Single T_g; transparency	–	Keskkula and Paul (1986)
	Carbonate of bisphenol-AF	Single T_g; transparency	–	Keskkula and Paul (1986)
	Carbonate of bisphenol chloral	Single T_g; NMR	–	Chiou and Paul (1987), De Los Santos Jones et al. (1984), Keskkula and Paul (1986), Raymond and Paul (1990)
	Epichlorohydrin-*co*-ethylene glycol	Single T_g	–	Fernandes et al. (1986b)
	Ethyl acrylate	Single T_g	–	Cowie et al. (1992f)
	Ethyl methacrylate	Single T_g	Made from slurries of poly (ethyl methacrylate) and methyl methacrylate; inherently unstable, phase separation upon heating	Singh et al. (1988)
	Ethylene, chlorinated	Single T_g	I was atactic, syndiotactic, or isotactic	Ueda and Karasz (1994)
	Formaldehyde-*co*-*p*-tert-butylphenol	Single T_g; FTIR	–	Pennacchia et al. (1986)
	Formaldehyde-*co*-*p*-chlorophenol	Single T_g; FTIR	–	Pennacchia et al. (1986)

(continued)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
	Formaldehyde-*co*-*p*-nitrophenol	Single T_g; FTIR	–	Pennacchia et al. (1986)
	Formaldehyde-*co*-phenol	Single T_g; FTIR	–	Pennacchia et al. (1986)
	Hexafluoropropene-*co*-vinylidene fluoride	Single T_g	II had 10 or 20 mol% hexafluoropropene	Jauannet et al. (1997)
	N-Maleimide-*co*-styrene	Single T_g; FTIR	II had 45 wt% *N*-maleimide	Vermeesch and Groeninckz (1995)
	Methacrylic acid	Single T_g; FTIR; NMR	–	Huang and Chang (2003)
	Methoxymethyl methacrylate	Single T_g	–	Goh and Lee (1990c)
	Methyl acrylate	Single T_g	–	Cowie et al. (1992f)
	α-Methylstyrene	Single T_g	–	Cowie and Miachon (1992), Siol (1991)
	Nitrocellulose	No phase separation in solution or films	–	Dobry and Boyer-Kawenoki (1974), Grose and Friese (1965), Kosai and Higashino (1975), Peterson et al. (1969)
	Novolac	Single T_g; FTIR; NMR	II had M_w about 1.0 kg/mol and was formaldehyde and 13/17/70 mol% = *p*-t-butylphenol/ *m*-cresol/*o*-cresol or formaldehyde and 15/17/68 mol% = 2-t-butylphenol/ *m*-cresol/*o*-cresol; I was isotactic, atactic, or syndiotactic	Fahrenhlotz and Kwei (1981), Huang et al. (2004d), Kim et al. (1991), Kwei (1984)
	Propylene glycol	Single T_g; SAXS	I had M_w = 550 kg/mol; II had M_w = 1.0–3.9 kg/mol	Macchi et al. (1986)
	Silyl ether	Single T_g; NMR	–	Zheng et al. (2003e)
	Trifluoroethylene-*co*-vinylidene fluoride	Single T_g	II had 25 or 50 mol% trifluoroethylene	Jauannet et al. (1997)
	Trifluoroethylene-*co*-vinylidene fluoride	FTIR; T_m-depression	II had 25 mol% trifluoroethylene	Kim et al. (1993c)

Tetrafluoroethylene-*co*-vinylidene fluoride	Single T_g; T_m-depression	II had 80 mol% vinylidene fluoride	Cho (1991), Hamazaki et al. (1991)
Trifluoroethylene-*co*-vinylidene fluoride	Single T_g; T_m-depression; light scattering	II had 58 mol% vinylidene fluoride	Faria and Moreira (1999), Saito et al. (1988)
Vinyl acetate	Single T_g; FTIR; NMR	Miscible when cast from chloroform or cyclohexanone; immiscible when cast from tetrahydrofuran or melt blended	Crispim et al. (1999), Crispim et al. (2000), Guo (1990e), Lee and Ha (1994a), Nandi et al. (1986), Schnek et al. (1990), Song et al. (1990), Song and Long (1991), Uyar et al. (2005)
Vinyl acetate-*co*-vinyl chloride	Single T_g; transparency	II had 5.9–15.1 vol% vinyl acetate	Friese (1968), Grose and Friese (1965), Kosai and Higashino (1975), Lee et al. (1992), Peterson et al. (1969)
Vinyl alcohol	T_m-Depression	Blend had 60, 80, or 90 wt% II	Adoor et al. (2006)
Vinyl chloride	Single T_g; transparency; NMR	Especially when II was polymerized in situ (Walsh and Cheng 1984a); I of all tacticities miscible with II (Hendrioulle-Granville et al. 1990); increase in isotactic content and mol. wt. of I reduced miscibility with II (Zhao and Prud'homme 1990)	Bosma et al. (1988b), Hendrioulle-Granville et al. (1990), Jager et al. (1983), Kamira and Naima (2006), Karlou and Schneider (2000), Lau and Mi (2001), Parmer et al. (1986, 1988), Piglowski (1988), Tremblay and Prud'homme (1984), Walsh and Cheng (1984a), Walsh and McKeown (1980), Zhao et al. (1991), Zhao and Prud'homme (1990), Zheng and Kyu (1992)

(*continued*)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
	Vinyl chloride, chlorinated	Single T_g; FTIR	II had 63–68 wt% Cl; I was atactic, isotactic, or syndiotactic (Ueda and Karasz (1994))	Lemieux et al. (1988), Ueda and Karasz (1994), Voremkamp and Challa (1988)
	Vinyl chloride-*co*-vinylidene chloride	Single T_g; transparency	II was Saran (>80 % vinylidene chloride) or 86.5 wt% vinylidene chloride; semicrystalline when ≥20 % II and I was isotactic and when ≥75 % II and I was atactic for the second II	Kang et al. (1988), Lemieux et al. (1988), Tremblay and Prud'homme (1984), Woo et al. (1984b)
	Vinyl chloroacetate	Single T_g	–	Das and Rodriguez (1987)
	Vinylidene fluoride	Single T_g; NMR; dielectric study; T_m-depression; Raman spectroscopy	Semicrystalline when >35–65 % II; I was isotactic, atactic, or syndiotactic; I was linear or 4-arm (Fan and Zheng (2007))	Aihara et al. (1998), Chow (1990), Fan and Zheng (2007), Grinsted and Koenig (1990), Hahn and Wendroff (1985), Hourston and Hughes (1977b), Imken et al. (1976), Mijovic et al. (1982), Nishi and Wang (1975), Noland et al. (1971), Patterson et al. (1976), Paul et al. (1975), Roerdink and Challa (1978), Walker et al. (2003), Zhou and Cakmak (2007)
	Vinylidene fluoride-*co*-hexafluoroacetone	Single T_g	–	Kobayashi et al. (1987)
Methyl methacrylate, imidized	Acrylonitrile-*co*-styrene	Single T_g	I had 53–91 wt% imidized units; II had 5.7–33 wt% acrylonitrile; miscibility depended on extent of imidization of I and acrylonitrile content of II	Fowler et al. (1989), Majumdar et al. (1994)
	Vinyl chloride	Single T_g	I had 53–85 wt% imidized units	Fowler et al. (1989)

Methyl methacrylate, modified with C_{60}	Vinylidene fluoride	Single T_g; T_m-depression	I had 2.6 or 7.4 wt% C_{60}	Zheng et al. (2000)
Methyl methacrylate-*co*-styrene	Carbonate of bisphenol-A-*co*-tetramethylbisphenol-A	Single T_g; transparency	I had ≤33 wt% methyl methacrylate; II had ≤15 wt% bisphenol-A	Kim and Paul (1992e)
	Carbonate of hexafluorobisphenol-A-*co*-tetramethylbisphenol-A	Single T_g	I had 9, 20, or 33 wt% methyl methacrylate; II had 20 wt% hexafluorobisphenol-A	Takakuwa et al. (1994)
Methyl methacrylate-*co*-2,4,5-tribromostyrene	Acrylonitrile-*co*-styrene	Single T_g	I had ≤51 wt% tribromostyrene; II had 10–30 wt% AN	Chu et al. (2000)
	Maleic anhydride-*co*-styrene	Single T_g	I had ≤51 wt% tribromostyrene; II had 10–33 wt% maleic anhydride	Chu et al. (2000)
Methyl methacrylate-*co*-trifluoroethyl methacrylate	Hexafluoropropene-*co*-vinylidene fluoride	Single T_g	I had 33 or 66 mol% trifluoroethyl methacrylate: II had 10 or 20 mol% hexafluoropropene	Jauannet et al. (1997)
	Vinylidene fluoride	Single T_g	I had 33 or 66 mol% trifluoroethyl methacrylate	Jauannet et al. (1997)
Methyl methacrylate-*co*-vinylpyridine	Acrylic acid-*co*-butyl acrylate	Single T_g; FTIR	I had 13–20 mol% vinylpyridine; II had 13–20 mol % acrylic acid	Jo et al. (1989b)
Methyl methacrylate-*co*-4-vinylpyridine	Triphenylene oxide	Single T_g; FTIR	I had 11 mol% vinylpyridine; II was sulfonated or phenylated	Rajagopalan et al. (2003)
2-Methyl-2-oxazoline	Allyl-*co*-styrene	Single T_g; FTIR	II had 6.5 wt% OH	Dai et al. (1995a)
	Hexamethylene sulfoxide	Single T_g	Blend had 20 wt% I	Oyama et al. (1998)
	Hydroxyether of bisphenol-A	Single T_g; FTIR	–	Dai et al. (1995a)
	2-Hydroxypropyl methacrylate	Single T_g; FTIR	–	Dai et al. (1995a)
	Vinyl alcohol	Single T_g; FTIR	–	Aoi et al. (1995b)
	Vinyl chloride	Single T_g	I <50 wt% in blend	Kobayashi et al. (1988)
	Vinyl fluoride	Single T_g	I <50 wt% in blend	Kobayashi et al. (1988)
	p-Vinylphenol	Single T_g; FTIR	–	Dai et al. (1995a)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
2-Methyl-1-pentene sulfone	Novolac	Single T_g	II had $M_w = 1.0$ kg/mol and was formaldehyde and 13/17/ 70 mol% = p-t-butylphenol/ m-cresol/o-cresol or formaldehyde and 15/17/68 mol % = 2-t-butylphenol/m-cresol/ o-cresol	Fahrenhlotz and Kwei (1981)
N-Methyl-4-piperidinyl methacrylate	Acid	Single T_g, FTIR; XPS	II was acrylic acid, methacrylic acid, styrenesulfonic acid, or vinylphosphonic acid	Luo et al. (1998)
	p-Vinylphenol	Single T_g; FTIR; XPS	–	Goh et al. (2001)
2-Methyl-6-propyl-1,4-phenylene ether	Styrene	Single T_g		Cizek (1968)
α-Methyl-α-n-propyl-β-propiolactone	Vinyl chloride	Single T_g	Semicrystalline when >50 % I	Aubin et al. (1982), Aubin and Prud'homme (1980)
α-Methylstyrene	Cyclohexyl acrylate	Single T_g, transparency	–	Siol (1991)
	Cyclohexyl methacrylate	Single T_g, transparency	–	Chong and Goh (1991a), Chang and Woo (2001b), Siol (1991)
	Ethyl methacrylate	Single T_g, transparency	–	Siol (1991)
	n-Propyl methacrylate	Single T_g, transparency	–	Siol (1991)
p-Methylstyrene	Cyclohexyl acrylate	Single T_g, transparency	–	Siol (1991)
	Cyclohexyl methacrylate	Single T_g, transparency; OM	–	Chong and Goh (1991a), Siol (1991), Woo and Jang (1999)
	2,6-Dimethyl-1,4-phenylene ether, bromobenzylated	Single T_g, transparency	II had 9, 16, or 37 % bromination	Goh and Lee (1989b)
4-Methyl-5-vinylthiazole	Acrylic acid	Single T_g; FTIR; XPS	–	Luo et al. (2003)
	p-Vinylphenol	Single T_g; FTIR; XPS	–	Luo et al. (2003)
	Vinylphosphonic	Single T_g; FTIR; XPS	–	Luo et al. (2003)

N-1-Monoalkyl itaconamide	2-Hydroxypropyl methacrylate	Single T_g; FTIR	I had an alkyl group of butyl, hexyl, or octyl	Urzua et al. (2000)
	4-Vinylpyridine	Single T_g; FTIR	I had an alkyl group of butyl, hexyl, or octyl	Urzua et al. (2000)
Monomethyl itaconate	Thiocarbonate	Single T_g	II had methyl, ethyl, or propyl side groups	Radic and Gargallo (1991)
α-Methylstyrene-co-4-(2-hydroxyethyl)-α-methylstyrene	Alkyl acrylate	Single T_g	I had 6, 41, 72, or 89 mol% α-methylstyrene; II had alkyl group of methyl, ethyl, or t-butyl	Cowie and Reilly (1993a)
	Alkyl methacrylate	Single T_g	I had 6, 41, 72, or 89 mol% α-methylstyrene; II had alkyl group of methyl, ethyl, or t-butyl	Cowie and Reilly (1993a)
	Dialkyl itaconate	Single T_g	I had 6, 41, 72, or 89 mol% α-methylstyrene; II had dialkyl group of dimethyl, diethyl, or di-t-butyl or di-n-propyl	Cowie and Reilly (1993a)
	Vinyl acetate	Single T_g	I had 6, 41, 72, or 89 mol% α-methylstyrene	Cowie and Reilly (1993b)
	4-Vinylpyridine	Single T_g	I had 6, 41, 72, or 89 mol% α-methylstyrene	Cowie and Reilly (1993b)
	N-Vinyl pyrrolidone	Single T_g	I had 6, 41, 72, or 89 mol% α-methylstyrene	Cowie and Reilly (1993b)
α-Methylstyrene-co-4-(1,1,1-trifluoro-2-hydroxyethyl)-α-methylstyrene	Alkyl acrylate	Single T_g	I had 23, 47, 60, 84, or 93 mol% α-methylstyrene; II had an alkyl group of methyl, ethyl, or t-butyl	Cowie and Reilly (1993a)
	Alkyl methacrylate	Single T_g	I had 23, 47, 60, 84, or 93 mol% α-methylstyrene; II had an alkyl group of methyl, ethyl, or t-butyl	Cowie and Reilly (1993a)

(continued)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
	Dialkyl itaconate	Single T_g	I had 23, 47, 60, 84, or 93 mol% α-methylstyrene; II had dialkyl group of dimethyl, diethyl, or di-t-butyl or di-n-propyl	Cowie and Reilly (1993a)
	Vinyl acetate	Single T_g	I had 23, 47, 60, 84, or 93 mol% α-methylstyrene	Cowie and Reilly (1993b)
	4-Vinylpyridine	Single T_g	I had 23, 47, 60, 84, or 93 mol% α-methylstyrene	Cowie and Reilly (1993b)
	N-Vinyl pyrrolidone	Single T_g	I had 23, 47, 60, 84, or 93 mol% α-methylstyrene	Cowie and Reilly (1993b)
Methylthiomethyl methacrylate	Vinyl alcohol	Single T_g; FTIR; XPS; NMR	–	Yi and Goh (2003)
N-Methyl-N-vinylacetamide	Allyl alcohol-co-styrene	Single T_g; FTIR	II had 4.5 or 6.5 wt% OH; formed complexes in butanone	Dai et al. (1994b)
Mono-n-alkyl itaconate	Vinylpyridine	Single T_g; FTIR	I had an alkyl group of methyl, ethyl, n-propyl, n-butyl, n-pentyl, or n-hexyl; II was 2- or 4-vinylpyridine	Velada et al. (1996a, b)
Monomethyl itaconate	Tertiary amide	Single T_g	II was N,N-dimethylacrylamide or 2-ethyl-2-oxazoline; formed complexes	Meaurio et al. (1996)
2,2'-(2,6-Naphthalene) bisbenzimidazole	Imide	Single T_g; FTIR	II was made from 1,4-phenylene and 3,3',4,4'-benzo-phenolic dianhydride	Kao and Chen (1997)
Natural rubber, epoxidized	Acrylic acid-co-ethylene	Single T_g	I had 50 mol% epoxidation; II had 6 wt% acrylic acid	Mohanty et al. (1995, 1996)
	Ethylene, chlorinated	Single T_g	I had 50 mol% epoxidation; II had 25 or 48 % Cl	Margaritis et al. (1987)
	Ethylene, chlorosulfonated	Single T_g	I had 25 mol% epoxidation; II was Hypalon 40	Mukhopadhyay and De (1990)
	Novolac	Single T_g	I had 50 mol% epoxidation	Kallistsis and Kalfoglou (1989)

Neopentyl glycol adipate (2,2-dimethyl-1,3-propylene adipate)	Propylene, chlorinated	Single T_g	I had 50 mol% epoxidation	Kallistsis and Kalfoglou (1987)
	Vinyl chloride	Single T_g	I had 50 mol% epoxidation	Leung et al. (1986), Varughese et al. (1986, 1989)
	Vinyl chloride, plasticized	Single T_g	I had 50 mol% epoxidation; II had 40 phr dioctyl phthalate	Varughese (1990)
	Vinylidene chloride-*co*-alkyl acrylate	Single T_g	I had 50 mol% epoxidation; II had 10 % alkyl acrylate	Kallistsis and Kalfoglou (1987)
	Hydroxyether of bisphenol-A (Phenoxy)	Single T_g; transparency	–	Harris et al. (1982)
	Vinyl acetate-*co*-vinyl chloride	Single T_g; transparency	II had 2 or 17 wt% vinyl acetate	Goh et al. (1984c)
	Vinyl chloride	Single T_g; transparency	–	Goh et al. (1982b)
	Vinyl chloride-*co*-vinylidene chloride	Single T_g	Semicrystalline; II was Saran (86.5 wt% vinylidene chloride)	Woo et al. (1983)
	Vinylidene fluoride	Clear melt although refractive indices very different; T_{m}-depression	Semicrystalline	Goh et al. (1985)
Neopentyl glycol succinate (2,2-dimethyl-1,3-propylene succinate)	Epichlorohydrin	Single T_g; transparency	–	Fernandes et al. (1984)
	Hydroxyether of bisphenol-A (Phenoxy)	Single T_g; transparency	Semicrystalline ≤20 wt% II	Harris et al. (1982)
	Vinyl chloride	Single T_g; transparency	–	Ziska et al. (1981)
	Vinyl chloride-*co*-vinylidene chloride	Single T_g	≤60 wt% I; possible second T_g when >60 wt% I; semicrystalline	Woo et al. (1983)
Nitrocellulose	Butylene adipate	Single T_g; FTIR	I had 12.62 or 13.42 % N	Jutier et al. (1988)
	Caprolactone	Single T_g; FTIR	I had 12.62 or 13.42 % N	Jutier et al. (1988)
	Ethylene adipate	Single T_g; FTIR	I had 12.62 or 13.42 % N	Jutier et al. (1988)
	Valerolactone	Single T_g; FTIR	I had 12.62 or 13.42 % N	Jutier et al. (1988)
	Vinyl acetate	Single T_g; clear films	–	Friese (1968), Kawai (1956), Kosai and Higashino (1975)

(*continued*)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
Norbornene	Carbonate of bisphenol-A	Single T_g, FTIR	I was hydrogenated	Yang and Han (2008)
	Styrene-*co-p*-vinylphenol	Single T_g, FTIR	II had 5–28 mol% vinylphenol	Tanaka et al. (2009)
	2-Vinylpyridine	Single T_g, FTIR	I was hydrogenated	Yang and Han (2008)
Novolac	Amide	Single T_g, FTIR	II was PA-6 or PA-6,6	Wang et al. (1999a)
	n-Butyl methacrylate	Single T_g, FTIR	–	Kim et al. (1991)
	Butylene adipate	FTIR	–	Ma et al. (1997b)
	Dimethylsiloxane adipamide	Single T_g, FTIR	–	Hung et al. (2002)
	Ethylene adipate	FTIR	–	Ma et al. (1997b)
	Ethylene glycol	Single T_g, FTIR; T_m-depression	–	Ma and Wu (2001), Sotele et al. (1997), Zhong and Guo (1998)
	Vinyl acetate	Single T_g	I had M_w about 1.0 kg/mol and was formaldehyde and 15/17/68 mol% = 2-t-butylphenol/*m*-cresol/*o*-cresol	Fahrenhlotz and Kwei (1981)
	Vinylmethylether	Single T_g	I had M_w about 1.0 kg/mol and was formaldehyde and 13/17/70 mol% = *p*-t-butylphenol/*m*-cresol/*o*-cresol	Fahrenhlotz and Kwei (1981)
	Vinylpyridine	Single T_g, FTIR	II was 2- or 4-vinylpyridine	Kuo et al. (2002b)
(2-Oxo-1,3-dioxolan-4-yl)methyl methacrylate	Ethyl acrylate-*co*-methyl methacrylate	Single T_g, FTIR; transparency	II had 2 or 5 wt% ethyl acrylate	Park et al. (2001a)
(2-Oxo-1,3-dioxolan-4-yl)methyl methacrylate-*co*-acrylonitrile	Ethyl acrylate-*co*-methyl methacrylate	Single T_g, transparency	I had 24.5 wt% AN; II had 7 wt % ethyl acrylate	Park et al. (2002a)
(2-Oxo-1,3-dioxolan-4-yl)methyl methacrylate-*co*-ethyl acrylate	Methyl methacrylate	Single T_g, FTIR; transparency	I had 19.7 wt% ethyl acrylate	Park et al. (2001c)
(2-Oxo-1,3-dioxolan-4-yl)methyl methacrylate-*co*-ethyl acrylate	Vinyl chloride	Single T_g, FTIR; transparency	I had 19.7 wt% ethyl acrylate	Park et al. (2001c)
(2-Oxo-1,3-dioxolan-4-yl)methyl methacrylate-*co*-styrene	Vinyl chloride	Single T_g, FTIR; transparency	I had 19.5 wt% styrene	Park et al. (2002b)

(2-Oxo-1,3-dioxolan-4-yl)methyl vinyl ether-co-N-phenylmaleimide	Acrylonitrile-co-styrene	Single T_g; transparency	I had 67.7 wt% N-phenylmaleimide; II had 40 wt% acrylonitrile	Moon et al. (2000)
	Vinyl chloride	Single T_g; transparency	–	Moon et al. (2000)
Oxy-2,2-bis(butylsulfonylmethyl)-trimethylene	Oxy-(alkylsulfonylmethyl)ethylene-co-oxyethylene	Single T_g	II had an alkyl group of n-butyl or pentyl	Lee et al. (1998b)
	Oxy-(pentylsulfonylmethyl)ethylene	Single T_g	–	Lee et al. (1998b)
Oxy-2,2-bis(ethylsulfonylmethyl)-trimethylene	Oxy-(alkylsulfonylmethyl)ethylene	Single T_g	II had an alkyl group of ethyl, n-propyl, or isopropyl	Lee et al. (1998b)
	Oxy-(alkylsulfonylmethyl)ethylene-co-oxyethylene	Single T_g	II had an alkyl group of methyl, ethyl, n-propyl, or isopropyl	Lee et al. (1998b)
Oxy-2,2-bis(isopropylsulfonylmethyl)-trimethylene	Oxy-(2-alkylsulfonylmethyl)-ethylene-co-oxyethylene	Single T_g	II had an alkyl group of n-butyl, 2-butyl, or isopropyl	Lee et al. (1998b)
	Oxy-(2-butylsulfonylmethyl)ethylene	Single T_g	–	Lee et al. (1998b)
Oxy-2,2-bis(methylsulfonylmethyl)-trimethylene	Epichlorohydrin	Single T_g	–	Lee and Litt (2001)
	Epichlorohydrin-co-oxy(methylsulfonylmethyl)ethylene	Single T_g	II had 34, 18, or 0 mol% epichlorohydrin	Lee and Litt (2001)
	Oxy(methylsulfonylmethyl)ethylene-co-oxyethylene	Single T_g	–	Lee et al. (2001)
Oxy-2,2-bis(n-propylsulfonylmethyl)-trimethylene	Oxy-(alkylsulfonylmethyl)ethylene	Single T_g	II had an alkyl group of n-butyl or 2-butyl	Lee et al. (1998b)
	Oxy-(alkylsulfonylmethyl)ethylene-co-oxyethylene	Single T_g	II had an alkyl group of n-propyl, isopropyl, n-butyl, 2-butyl, or pentyl	Lee et al. (1998b)
Oxy(methylsulfonylmethyl)ethylene-co-oxyethylene	Epichlorohydrin-co-oxy(methylsulfonylmethyl)ethylene	Single T_g	II had 34 or 46 mol% epichlorohydrin	Lee and Litt (2001)
Pentabromobenzyl methacrylate-co-methyl methacrylate	Acrylonitrile-co-styrene	Single T_g	Miscibility depended on compositions of I and II	Merfeld et al. (2000)
	Maleic anhydride-co-co-styrene	Single T_g		Merfeld et al. (2000)

(continued)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
Pentabromobenzyl methacrylate-co-styrene	Carbonate of tetramethylbisphenol-A	Single T_g; light scattering	II had ≤33.9 wt% pentabromobenzyl methacrylate	Merfeld et al. (2000)
	2,6-Dimethyl-1,6-phenylene ether	Single T_g; light scattering	I had ≤54 wt% pentabromobenzyl methacrylate	Merfeld et al. (2000)
	Methyl methacrylate	Single T_g; light scattering	Miscibility depended on M_w of II and blend composition	Merfeld et al. (2000)
	Styrene	Single T_g; light scattering	Miscibility depended on M_w of II and blend composition	Merfeld et al. (2000)
2,2,3,3,3-Pentafluoropropyl methacrylate-co-4-vinylpyridine	Methacrylic acid co-methyl methacrylate	Single T_g; FTIR; XPS; ToF-SIMS	I had 28–54 mol% vinypyridine	Huang et al. (2004a, c)
Phenolphthalein polyaryletherketone	Ethylene glycol	Single T_g	–	Zheng et al. (2004)
Phenolphthalein polyetheretherketone	Epoxy	Single T_g; FTIR; SEM	–	Guo et al. (1991a), Song et al. (2001), Zhong and Guo (1998)
	Hydroxyether of bisphenol-A (Phenoxy)	Single T_g	–	Guo et al. (1988, 1991a)
	Sulfone	Single T_g	–	Guo et al. (1988, 1990b)
	N-Vinylpyrrolidone	Single T_g	–	Guo (1992a)
Phenolphthalein polyetherethersulfone	Ethylene glycol	Single T_g		
	N-Vinylpyrrolidone	Single T_g	–	Guo (1992a)
Phenolphthalein polyetherketone	Imide	Single T_g	Blend had <90 wt% I	Tang et al. (1996)
Phenolphthalein polyethersulfone	Hydroxyether of bisphenol-A	Single T_g; FTIR; SEM	–	Zheng et al. (2003b)

Phenol-formaldehyde	N,N-Dimethylacrylamide	Single T_g	Formed complexes from acetone, dioxane, and ethyl acetate	Yang et al. (1989)
	Methyl methacrylate-co-styrene	Single T_g	II had >20 wt% methyl methacrylate	Kim et al. (1989a)
Phenyl acrylate	Vinyl benzoate	Single T_g; transparency	–	Maiti et al. (1988)
N-phenyl-2-hydroxytrimethylene amine	Caprolactone	Single T_g; FTIR	Semicrystalline	Guo et al. (1997)
	Ethylene glycol	Single T_g; FTIR	Semicrystalline	Guo et al. (1997)
	Vinylmethylether	Single T_g; FTIR	–	Guo et al. (1997)
Phenylene	Phenyl sulfone	Single T_g; AFM	I was made from phenylketone-substituted p-phenylene and m-phenylene	J76
Phenylene, sulfonated	Ethyl acrylate-co-4-vinylpyridine	Single T_g	–	Murali et al. (1986)
2,2-(m-Phenylene)-5,5'-bisbenzimidazole	Arylate	Single T_g	–	Christiansen et al. (1987)
	Carbonate of bisphenol-A	FTIR	–	Musto et al. (1991)
	Imide	Single T_g; FTIR	II was made from 3,3',4,4'-benzophenone-tetracarboxylic dianhydride (BDTA) and 3,3'-diaminobenzophenone (LARC TPI)	Guerra et al. (1988a)
	Imide	Single T_g; FTIR; transparency	II was made from BDTA and 2,4-toluenediamine or 4,4'-methylene dianiline	Ahn and Choe (1995)
	Imide	Single T_g; FTIR	II was poly[2,2'-bis(3,4-dicarboxyphenoxy) phenylpropane-2-phenylene bisimide] (Ultem 1000)	Leung et al. (1986), Liang et al. (1991), Shiomi et al. (1989), Vanderhart et al. (1992)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
	Imide	Single T_g; FTIR	II was made from 3,3',4,4'-benzophenonetetra-carboxylic dianhydride and 5,6-amino-1-(4'-aminophenyl)-1,3,3'-trimethylindane (XU 218)	Choe et al. (1987), Leung et al. (1986), Shiomi et al. (1989)
	Imide	Single T_g; FTIR	II was made from benzophenone-tetracarboxylic dianhydride and 4/1 mixture of 2,4-toluenediisocyanate and 4,4'-diphenylmeth anediisocyanate (PI 2080)	Leung et al. (1986), Stankovic et al. (1988)
	Imide sulfone	Single T_g; FTIR	II was made from 3,3',4,4'-benzophenonetetra-carboxylic dianhydride and 3,3'-diaminodiphenyl sulfone	Chen et al. (1988b), Janarthanan et al. (1992), Lee and Quin (1989)
	Imide sulfone, fluorinated	Single T_g; FTIR	≥80 % I	Janarthanan et al. (1992)
	Siloxaneimide, segmental copolymer	Single loss tangent peak	II was 3,3',4,4'-benzophenonetetra-carboxylic dianhydride and 3,3'-diaminodiphenyl sulfone-based polyimide and dimethylsiloxane segmental copolymer	Chen et al. (1988a)
m-Phenylene-isophthalamide	Aramide	Single T_g	II was a copolyamide Ultramid T or Selar 3426	Ellis (1995)
	Ethersulfone	Single T_g; transparency	–	Hayashi et al. (1995)
	Hexamethylene isophthalamide	Single T_g	Semicrystalline	Brisson and Breault (1991), Ellis (1995)
	Heptamethylene isophthalamide	Single T_g	Semicrystalline	Brisson and Breault (1991)
	m-Xylene adipamide	Single T_g	Semicrystalline	Ellis (1995)

Phenylene sulfide	Phenylene sulfide ether	Single T_g	Semicrystalline	Brostow et al. (1995)
p-Phenylene terephthalamide	Caprolactam (nylon 6)	Single T_g; FTIR	Semicrystalline	Kyu et al. (1989b)
	Hexamethylene adipamide (nylon 6,6)	Single T_g; FTIR	Semicrystalline	Kyu et al. (1989b)
	p-Phenylene 1,3,4-oxadiazole	OM; FTIR	–	Kummerlowe et al. (1993)
	4-Vinylpyridine	Single T_g; TEM	N atom of I was modified to propanesulfonate or n-propyl group	Parker and Hara (1997)
o-Phenylphenol	Ethyl acrylate-co-methyl acrylate	Single T_g	II had 37 or 81 wt% ethyl acrylate	Kim et al. (1998)
Phosphazene	Glycolide-co-lactide	Single T_g; FTIR; SEM	II had 50 or 85 mol% lactide	Krogman et al. (2007)
n-Propyl acrylate	Alkyl methacrylate	Single T_g	II had an alkyl group of chloromethyl, 1-chloroethyl, 2-chloroethyl, dichloroethyl, or trichloroethyl	Peng et al. (1996)
	Vinyl chloride	Single T_g; transparency	–	Walsh and McKeown (1980)
n-Propyl methacrylate	Vinyl alcohol	Single T_g; FTIR; NMR	–	Yi and Goh (2005)
	Vinyl chloride	Single T_g; transparency	–	Ha et al. (1990a), Perrin and Prud'homme (1991), Tremblay and Prud'homme (1984), Walsh and McKeown (1980)
	Vinyl chloride-co-vinylidene chloride	Single T_g; transparency	Semicrystalline when $\geq$65 % II; II was Saran ($\geq$80 % vinylidene chloride) or 86.6 wt% vinylidene chloride	Kang et al. (1988), Tremblay and Prud'homme (1984), Woo et al. (1984b)
Propyloxazoline	Styrene	Single T_g	<25 wt% I in blend	Kobayashi et al. (1988)
Propylene	1-Butene-co-ethylene	NMR	I was atactic; II had 66 mol% butene	Wachowicz et al. (2008)
	Hydrogenated oligocyclopentadiene	Melting point depression; WAXS; SANS	–	Martuscelli et al. (1991)
Propylene, chlorinated	Neopentyl glycol adipate	Single T_g; transparency	I had 67 wt% Cl	Goh et al. (1985)
Rubber, chlorinated	Vinylmethylether	Phase diagram	–	Gevorkyan et al. (1978)

(continued)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
Sebacic anhydride	2,2-Dimethyltrimethylene carbonate	T_m-Depression	Semicrystalline	Wang et al. (2002a)
	Tetramethylene carbonate	T_m-Depression	Semicrystalline	Wang et al. (2002a)
Styrene	5-Acetyl-2,6-dimethyl-1,4-phenylene ether	Single T_g; transparency; FTIR; light scattering	–	Liu et al. (2000)
	5-Benzoyl-2,6-dimethyl-1,4-phenylene ether	Single T_g; transparency; FTIR; light scattering	–	Liu et al. (2000)
	Carbonate of bisphenol-A	Single T_g; SEM	–	Jang and Lee (2003)
	Carbonate of tetramethylbisphenol-A	Single T_g; light scattering; FTIR	Semicrystalline after long annealing	Guo and Higgins (1990), Iler et al. (1984), Kim and Paul (1992b), Koh et al. (1998), Liu et al. (1995), Shaw (1974),Yang et al. (1993a, b)
	Carbonate of bisphenol-A-co-tetramethylbisphenol-A	Single T_g; transparency	II had ≥85 wt% tetramethylbisphenol-A	Kim and Paul (1992e)
	2-Chlorostyrene	Negative volume change of mixing	–	Tsujita et al. (1987)
	Cyclohexyl acrylate	Single T_g	–	Siol (1991)
	Cyclohexyl methacrylate	Single T_g; transparency; NMR	I was isotactic (Chang and Woo 2003b, Chang et al. 2004a)	Chong and Goh (1991a), Chang and Woo (2003b), Chang et al. (2004b), Friedrich et al. (1996), Nishimoto et al. (1990), Siol (1991), Wu et al. (2002)
	Cyclohexyl methacrylate-co-methyl methacrylate	Single T_g	II had ≥21.6 % cyclohexyl methacrylate	Nishimoto et al. (1990), Pomposo et al. (1998)
	2,6-Dimethyl-1,4-phenylene ether, bromobenzylated	Single T_g	II had ≤76 % bromination	Goh and Lee (1988a)
	2,6-Dimethyl-1,4-phenylene ether, sulfonated	Single T_g	II had <1.9 % sulfonation	Hsieh and Peiffer (1992)

2,6-Dimethyl-1,4-phenylene ether-co-2,3,6-trimethyl-1,4-phenylene oxide	Single T_g	I was atactic or isotactic; II had <20 mol% 2,3,6-trimethyl-1,4-phenylene oxide	Paduchewit et al. (1989)
Dimethylsilphenylene	Single T_g	–	Werlang et al. (1997)
Ethyl methacrylate	Single T_g	Miscible when melt blended	Brannock et al. (1990)
α-Methylstyrene	Single T_g	–	Saeki et al. (1983), Schneider and Dilger (1989), Van Tam Bui et al. (1988), Widmaier and Mignard (1987), Yang et al. (1991)
n-Propyl methacrylate	Single T_g	Miscible when melt blended	Brannock et al. (1990)
Sila-α-methylstyrene	Single T_g; OM	–	Maier et al. (1996)
Vinylmethylether	Single T_g; transparency; NMR; SANS	Two phases when deposited from some solvents	Asano et al. (1995), Bank et al. (1971, 1972), Bhowmick et al. (1986), Beaucage and Stein (1993), Chu et al. (1988), Cowie et al. (1993a), Hikichi et al. (1998), Kwei et al. (1974), McMaster (1973), Mandal and Woo (1999c), Nishi and Kwei (1975), Tezuka et al. (1995)
Styrene, modified with C$_{60}$			
2,6-Dimethyl-1,4-phenylene ether	Single T_g	I had 1.9–13.6 wt% C$_{60}$	Zheng et al. (1997a)
Vinylmethylether	Single T_g	I had 1.9 or 9.9 wt% C$_{60}$	Zheng et al. (1997a)
Styrene, sulfonated			
Amine-terminated polyalkylene glycol	FTIR	I had 4.5 mol% sulfonation; II had M_n = 900 (Jeffamine ED-900)	Gracia (1986)
Benzyl methacrylate-co-4-vinylpyridine	Single T_g; FTIR	I had 4–10.2 mol% sulfonation; II had 3.7–11.2 mol% 4-vinylpyridine	Sankarapandian and Kishore (1996a)
N,N-Dimethylacrylamide	Transparency	I had 12 mol% sulfonation	Landry and Teegarden (1991)

(continued)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
	2,6-Dimethyl-1,4-phenylene ether	Single T_g	I had <2.6 % sulfonation	Hsieh and Peiffer (1992)
	Ethylene glycol	Single T_g	I had 1.35 or 4.51 mol% SOlayemi and Ibiyeye (1986)H; II end-capped with propylamine groups	Weiss et al. (1990)
	Methyl methacrylate	Single T_g; transparency	I had 12 mol% sulfonation	Landry and Teegarden (1991)
	Methyl methacrylate-*co*-4-vinylpyridine	FTIR; TEM; NMR	I had 6 mol% sulfonation and II had 6 mol% vinylpyridine (Chen et al. (2004b)); I had 9.9 % sulfonation; II had 11.1 % vinylpyridine (Natansohn and Eisenberg (1986))	Chen et al. (2004b), Natansohn and Eisenberg (1986)
	Phenylsilsesquioxane	Single T_g; SEM; WAXD	–	Li et al. (1996)
	Urethane	FTIR	I had 7.9 mol% sulfonation	Tannanbaum et al. (1986)
	Vinylpyridine	Single T_g; FTIR; XPS	II was 2- or 4-vinylpyridine	Zhou et al. (1997c)
Styrene, sulfonated and metal-neutralized	Amide	Single T_g; NMR; FTIR	I had 9.8 mol% sulfonation and Li-neutralized; II was PA-6,6 or PA-6,10 (Molnar and Eisenberg (1993)); II was PA-6 and I was Zn-neutralized or not neutralized (Kwei et al. (1993)); I had 5.4 or 9.8 mol% sulfonation and Li-neutralized, II was PA-6 (Rajagopalan et al. (1995))	Kwei et al. (1993), Molnar and Eisenberg (1993), Rajagopalan et al. (1995)
	Amide	Single T_g; WAXD	I had 9.7 mol% sulfonation and Li-neutralized; II was PA-4	Ng et al. (1994)
	Amide	Single T_g; FTIR; SAXS	I had 5.4 or 9.8 mol% sulfonation and Li-neutralized; II was PA-6	Weiss and Lu (1994)

	Amide	Single T_g; FTIR; NMR; SAXS	I had 6.5–9.0 mol% sulfonation and Zn-neutralized; II was PA-6	Weiss and Lu (1994)
	Amide	T_m–Depression	I had 20, 44, or 70 mol% sulfonation and Na-neutralized; II was PA-11	Deimede et al. (2000)
	N,N′-Dimethylene sebacamide	Single T_g; light scattering; NMR; SANS	I had 13.7 mol% sulfonation and neutralized by Zn, Cu, Mn, Cd, or Li	Feng et al. (1996a, e)
	N,N′-Dimethylethylene sebacamide	Single T_g	I had 7.4 mol% sulfonation and Li-neutralized	Feng et al. (1996d)
	Ester, liquid crystalline	Single T_g	I had 5 mol% sulfonation and Zn-neutralized	Dutta et al. (1996)
	Ester, liquid crystalline	Single T_g; FTIR; SEM	I had 6.9 mol% sulfonation and neutralized with Li, Na, Mn, or Zn; II was made from hydroxybenzoic acid and ethylene terephthalate (60:40)	He and Liu (1999)
	Ester, liquid crystalline	Single T_g; FTIR; SEM	I had 5.3 mol% sulfonation and Zn-neutralized; II was made from hydroxybenzoic acid and hydroxynaphthoic acid	Weiss et al. (2000)
	Ethyl acrylate-co-4-vinylpyridine	FTIR	I had 2.1–7.3 mol% sulfonation and Zn-neutralized; II had 2.4–10.6 mol% vinylpyridine	Sakurai et al. (1993)
	N-Methyl-4-piperidyl methacrylate	FTIR; XPS	I was neutralized with Zn; formed complexes	Goh et al. (2000b)
	4-Vinylpyridine	Single T_g; FTIR; XPS	I was Li- or Zn-neutralized; formed complexes	Goh et al. (1998b)
Styrene-co-o-acetyl-1,6-diisopropyl-4-vinylphenol	Ethylene glycol	Single T_g; FTIR	I had 7 mol% OH	Coleman et al. (1999)
	Vinylmethylether	Single T_g; FTIR;	I had 7 mol% OH	Coleman et al. (1999)
Styrene-co-p-(2-hydroxypropan-2-yl)styrene	n-Butyl methacrylate-co-4-vinylpyridine	Single T_g; light scattering	I had 8–58 mol% OH; II had 4.7–68 mol% vinylpyridine; formed complexes when OH and pyridine contents were high	Zhu et al. (1998a)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
Styrene-*co*-maleic acid	Vinyl butyral	Transparency	I was Daidou Kogyo Styrite HS-2	Kosai and Higashino (1975)
Styrene-*co*-methacrylic acid	Ethyl methacrylate	Single T_g; fluorescence study	Miscible when cast from toluene or dioxane; immiscible when cast from chloroform; I had 93.4–96.7 mol% styrene	Chen and Morawetz (1989)
Styrene-*co*-methacryloyl glycine	Ethyl methacrylate	Fluorescence study	Miscible when cast from toluene; immiscible when cast from chloroform; I had 93.8–97.2 mol% styrene	Chen and Morawetz (1989)
Styrene-*co*-styrene-4-carboxylic acid	*N,N*-Dimethylacrylamide	Single T_g; transparency	I had 25 or 54 mol% acid groups	Landry and Teegarden (1991)
	Methyl methacrylate	Single T_g; transparency	I had 25 mol% acid units	Landry and Teegarden (1991)
Styrene-*co*-*p*-(2,2,2-trifluoro-1-hydroxy-1-trifluoromethyl) ethyl-α-methylstyrene	Caprolactone	Single T_g	I had $\geq$5 mol% OH	Zhou et al. (1997a)
	p-(Tert-butyl)phenylene fumarate	Single T_g	I had 3.9 or 8.0 mol% OH	Chen et al. (1998a)
Styrene-*co*-4-vinylbenzene phosphonic acid	Vinylmethylether	Single T_g; FTIR	I had 7.5 or 13.3 mol% VPBA;	Zhuang et al. (1995)
Styrene-*co*-4-vinylbenzoic acid	*n*-Butyl methacrylate-*co*-4-vinylpyridine	Single T_g	I had 1–20 mol% acid group; II had 4.7–68 mol% vinylpyridine; formed complexes when acid and pyridine contents were high	Zhu et al. (1998a)
	Ethyl methacrylate-*co*-4-vinylpyridine	Single T_g; FTIR	I had 7.4 mol% acid; II had 12.5 mol% vinylpyridine	Hammachin et al. (1999), Ourdani and Amrani (2000)
Styrene-*co*-4-vinylbenzoic acid, K-neutralized	5,7-Dodecadiyne-1,12-dicarboxylic acid, K-neutralized	Single T_g	I had 26 mol% acid group	Eisenbach et al. (1994a)
Styrene-*co*-4-vinylbenzoic acid, triethylammonium ionomer	5,7-Dodecadiyne-1,12-dicarboxylic acid, triethylammonium ionomer	Single T_g	I had 26 mol% acid group	Eisenbach et al. (1994a, b)

Styrene-*co*-*p*-vinylphenol	Acetoxystyrene	Single T_g; FTIR	I had 16–50 mol% vinylphenol	Kuo and Chang (2002a)
	Benzyl methacrylate	Single T_g; FTIR	II had 4.9, 9.2, or 23 mol% vinylphenol	Sankarapandian and Kishore (1996a)
	n-Butyl methacrylate	Transparency; FTIR; fluorescence study	I had 8, 25, 43, or 75 wt% vinylphenol	Chen and Morawetz (1989), Xu et al. (1991)
	N,N-Dimethylacrylamide	Transparency; FTIR; single T_g	I had 22, 42, or 82 mol% vinylphenol	Landry and Teegarden (1991)
	Caprolactone	Single T_g; FTIR	I had 10, 12.2, 15.4, or 20.4 wt% vinylphenol	Ahn et al. (1993b), Kuo and Chang (2001d), Vaidya et al. (1995)
	Carbonate of bisphenol-A	Single T_g; FTIR	I had 54 or 63 mol% vinylphenol	Li et al. (1999a)
	Carbonate of tetramethylbisphenol-A	Single T_g; FTIR	I had 20, 44, 55, or 100 mol% vinylphenol	Li et al. (1999a)
	Cyclohexyl methacrylate	Single T_g; FTIR; NMR	I had 16–50 mol% vinylphenol	Kuo and Chang (2002a), Mugica et al. (2005)
	Ethyl methacrylate	Transparency; fluorescence study; light scattering	I had >0.93 mol% vinylphenol; formed complexes when I had >9 mol% OH (Xiang et al. (1997b))	Chen and Morawetz (1989), Xiang et al. (1997b)
	n-Hexyl methacrylate	FTIR; light scattering	I had 8, 25, or 43 wt% vinylphenol	Bhagwagar et al. (1994), Xu et al. (1991)
	Lactide	Single T_g; FTIR; SEM	I had 16 or 33 mol% vinylphenol	Zuza et al. (2008)
	Methyl methacrylate	Single T_g; transparency; fluorescence study; FTIR	I had >0.93 mol% vinylphenol; II was syndiotactic (Jong et al. (1993)); I had 15 mol% vinylphenol, and II was atactic, isotactic, or syndiotactic (Hsu and Yeh (1999a))	Chen and Morawetz (1989), Hsu and Yeh (1999a), Jong et al. (1993), Landry and Teegarden (1991)
	Phenylimino-1,4-phenyleneoxyterephthaloyl	Single T_g; FTIR	I had 46 mol% vinylphenol	Cowie et al. (1996)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
	Vinyl cinnamate	Single T_g	Miscible after I was thermally cross-linked	Hsu (2008)
	Vinylbutylether	FTIR	I had 48 wt% vinylphenol	Serman et al. (1991b)
	4-Vinylpyridine	Single T_g	I had 50 mol% vinylphenol	Vivas de Meftahi and Frechet (1988)
	N-Vinyl pyrrolidone	Single T_g; FTIR	II had >11 mol% OH; formed complexes in THF when I had >25 mol% vinylphenol (Prinos et al. (1998))	Prinos et al. (1998), Zhu et al. (1994)
Styrene-co-4-vinylphenyldimethylsilanol	n-Butyl methacrylate	Single T_g; FTIR	II had 9, 11, 18, or 34 mol% silanol group; formed complexes when II had 34, 60, 81, or 100 mol% VDPMS	Lu et al. (1994, 1995a, b)
Styrene-co-4-vinylphenylmethyl-phenylsilanol	n-Butyl methacrylate	Single T_g; FTIR	II had 9–56 mol% OH	Lu et al. (1996a)
	N-Vinylpyrrolidone	Single T_g; FTIR	Miscible when I had 9–18 mol% OH; formed complexes when I had 31–74 mol% OH	Lu et al. (1996b)
Styrene-co-2-vinylpyridine	n-Butyl methacrylate-co-p-vinylphenol	Single T_g; FTIR	I had 27 wt% vinylpyridine; II had 54 wt% vinylphenol	Coleman et al. (1998a)
	2,3-Dimethylbutadiene-co-p-vinylphenol	Single T_g; transparency	I had 17, 26, or 40 mol% 2-vinylpyridine; II had 38 mol% p-vinylphenol	Motzer et al. (2001a)
Styrene-co-4-vinylpyridine	2,6-Dimethyl-1,4-phenylene ether	Single T_g; SEM	I had 5 or 15 mol% 4-vinylpyridine	Benabdelghani et al. (2008)
	Isoprene, sulfonated	Single T_g; transparency	II had 5–10 % substituted and partly cyclized; immiscible when II had 2 % substituted	Eisenberg et al. (1982), Zhou and Eisenberg (1983)
	Methyl methacrylate-co-p-vinylphenol	Single T_g; FTIR; SEM	I had ≥30 mol% vinylpyridine; II had 50 mol% vinylphenol	Belabed et al. (2012)

N,N′-(Sulfo-p-phenylene terephthalamide)	Vinyl alcohol	Single T_g	–	Dai et al. (1994)
	Vinyl pyridine	Single T_g; NMR	II was 2- or 4-vinylpyridine	Dai et al. (1994)
Sulfone	Etheretherketone-co-phenolphthalein etheretherketone	Single T_g; FTIR	II had 6.2 mol% etheretherketone	Guo et al. (1996c)
	Styrene-co-1-vinylpyrrolidone	Single T_g; transparency	II had 12–32 wt% styrene	Kim et al. (2002b, 2003b)
1,2,2,2-Tetrachloroethyl methacrylate	Cyclohexyl methacrylate	Single T_g	–	Goh et al. (1997a)
	Ester	Single T_g	II was caprolactone or 2,2-dimethyl-1,3-propylene adipate	Goh et al. (1997a)
Tetrafluoroethylene, sulfonated	Ethyl acrylate-co-4-vinylpyridine	Single T_g	I had equivalent weight of 1155	Murali and Eisenberg (1988)
Tetrafluoroethylene-alt-vinyl alcohol	Alkyl methacrylate	Single T_g; FTIR	II had an alkyl group of methyl or ethyl	Coleman et al. (1993c)
	Methyl acrylate	Single T_g; FTIR	–	Coleman et al. (1993c)
	Vinyl acetate	Single T_g; FTIR	–	Coleman et al. (1993c)
Tetrahydrofurfuryl methacrylate	Allyl alcohol-co-styrene	Transparency	II had 5.4–6.0 % OH	Goh (1987)
	Epichlorohydrin	Single T_g; transparency	–	Chong and Goh (1991b)
	Hydroxyether of bisphenol-A (Phenoxy)	Single T_g; transparency	–	Goh (1987)
	Vinyl chloride	Single T_g; transparency	–	Goh and Siow (1987)
	Vinyl chloride-co-vinylidene chloride	Single T_g	II had 88 % vinylidene chloride	Chong and Goh (1991b)
Tetrahydropyranyl-2-methyl methacrylate	Allyl alcohol-co-styrene	Transparency	II had 5.4–6.0 wt% OH	Chong and Goh (1992a)
	Epichlorohydrin	Single T_g; transparency	–	Chong and Goh (1991b)
	Hydroxyether of bisphenol-A (Phenoxy)	Single T_g; transparency	–	Chong and Goh (1992a)
	Vinyl chloride	Single T_g; transparency	–	Chong and Goh (1991b)
	Vinyl chloride-co-vinylidene chloride	Single T_g	II had 88 % vinylidene chloride	Chong and Goh (1991b)
	p-Vinyl phenol	Single T_g; transparency	–	Chong and Goh (1992a)

(*continued*)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
2,4,5-Tribromostyrene-*co*-styrene	Carbonate of tetramethylbisphenol-A	Single T_g	≤38.8 wt% tribromostyrene	Chu et al. (2000)
	2,6-Dimethyl-1,4-phenylene ether	Single T_g	I had ≤48.8 wt% tribromostyrene	Chu et al. (2000)
2,2,2-Trichloroethyl methacrylate	Alkyl methacrylate	Single T_g; transparency	II had an alkyl group of methyl, ethyl, *n*-propyl, isopropyl, cyclohexyl, or tetrahydrofurfuryl	Low et al. (1994b)
3,3,5-Trimethyl cyclohexyl methacrylate	3,3,5-Trimethyl-cyclohexyl acrylate	Single T_g; transparency	–	Siol (1991)
Trifluoroethylene	Vinylidene fluoride	Single T_g	Semicrystalline	Godovskii et al. (1981)
2,2,4-Trimethylhexamethylene terephthalamide	Caprolactam-*co*-caprolactone	Single T_g	II had varying composition	Ellis (1997)
Trimethylene adipate	Vinyl chloride	Single T_g; transparency	When ≥75 % II	Woo et al. (1985b)
Trimethylene terephthalate	Ester	Single T_g; microscopy; WAXD	II was ethylene terephthalate or butylene terephthalate	Chiu (2007), Kuo and Woo (2003), Supaphol et al. (2004)
	Ethylene naphthalate	Single T_g; T_m-depression	Semicrystalline	Krutphun and Supaphol (2005), Run et al. (2006)
	Carbonate of bisphenol-A	Single T_g; FTIR	Initially immiscible, became miscible after annealing	El Shafee et al. (2008), Lee and Woo (2004a)
4-Trimethylsilyl Styrene	Isoprene	Single T_g; SANS; OM	–	Harada et al. (2005a, b)
Urethane	Carbonate of bisphenol-A	Single T_g	Miscible when blend had 10–20 wt% I	Fambri et al. (1993)
	Ethylene-*co*-methacrylic acid-*co*-isobutyl acrylate	Single T_g; FTIR; OM	I was Desmopan 359; II had 78 mol% ethylene and 10 mol% methacrylic acid: II was 70 % neutralized with Zn	Papadopoulou and Kalfoglou (1998)
	Ethylene-*co*-methyl acrylate	Single T_g; FTIR	I was Estane 58311; II had 21 wt% methyl acrylate	Santra et al. (1993b)

Ethylene glycol	FTIR	I was made from a mixture of 2,4- and 2,6-tolyldiisocyanate and 1,4-butanediol	Coleman et al. (1988a), Hu et al. (1988)
Ethylene glycol-*co*-propylene glycol	Single T_g; FTIR	I was made from a mixture of 2,4- and 2,6-tolyldiisocyanate and 1,4-butanediol; II had 70 wt% ethylene glycol	Coleman et al. (1988b)
Methacrylic acid-*co*-styrene	Single T_g	I had polyether segment with M_w = 1.0 or 2.0 kg/mol; II had 10.5 % methacrylic acid, Li-neutralized	Rutkowska and Eisenberg (1984)
Styrene-*co*-p-vinylphenol	FTIR; SANS; FTIR	II had 5–50 mol% vinylphenol; I was liquid crystalline	Metha and Dadmun (2006), Viswanathan and Dadmun (2004)
Urethane	Single T_g	I and II were separate polymers; I was 4,4'-diisocyanate diphenyl methane (MDI)/dipropylene glycol = 9/10 mol ratio; II was poly Groeninckx et al. (1988)-56 polyoxyethylene-*co*-oxypropylene, 45 % ethylene oxide, M_w = 2000/MDI/1/1	Lockwood and Alberino (1981)
N-Vinylpyrrolidone	Single T_g; for II with hard segments of I; soft segment T_g's also observed; clear films	I was segmented, made from methylene bis(4-phenyl isocyanate) and poly(ethylene glycol) and *cis*-2-butene-1,4-diol and butane-1,4-diol	Egboh (1983)

(continued)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
Urethane, functionalized	Styrene-*co*-2-methyl-5-vinylpyridine	Single T_g	I carried pendant carboxylated groups neutralized by ammonium ion	Rutkowska (1991)
	Styrene-*co*-acrylic acid	Single loss peak; microscopy	I had tertiary amine group; II had 15 or 30 mol% acrylic acid; linear blend of I and II or interpenetrating polymer network of I and II	Hsieh and Chou (1989)
Valerolactone	Vinyl acetate-*co*-vinylidene chloride	Single T_g	Semicrystalline; II was Saran C (≥80 % vinylidene chloride)	Aubin et al. (1983)
	Vinyl bromide	Single T_g	–	Cousin and Prud'homme (1982)
	Vinyl chloride	Single T_g	Semicrystalline when ≥50 % I	Aubin et al. (1982), Aubin and Prud'homme (1981a, b)
Vinyl acetate	Alkyl acrylate	Single T_g; FTIR	I had an alkyl group of methyl, ethyl, or butyl	Princi et al. (2009)
	2-Bromoethyl methacrylate	Single T_g; transparency	Miscible when cast from methyl ethyl ketone; immiscible when cast from tetrahydrofuran	Neo and Goh (1992a)
	2-Chloroethyl methacrylate	Single T_g; transparency	–	Neo and Goh (1992a)
	Chloromethyl methacrylate	Single T_g; transparency	–	Neo and Goh (1992a)
	Ester	Single T_g; SEM; OM	II was ethylene adipate, propylene adipate, or butylene adipate	Chang et al. (2006)
	Formaldehyde-melamine resin	Single T_g; FTIR; NMR	–	Kim and Kim (2007)
	Hexafluoroacetone-*co*-vinylidene fluoride	Single T_g	II had 8.9 mol% hexafluoroacetone	Shiomi et al. (1989)
	Lactide	Single T_g	–	Gajria et al. (1996)
	Methacrylic acid	NMR	–	Asano (2004), Asano et al. (2002)
	Novolac	Single T_g; FTIR; NMR	–	Huang et al. (2002b)

		Method	Comments	Reference
	Styrene-alt-maleic anhydride, hydrolyzed	Single T_g	1.8–43 % hydrolyzed	Bosma et al. (1988a)
	Trifluoroethylene-co-vinylidene fluoride	Single T_g; T_m-depression	II had 32 mol% trifluoroethylene	Tang and Scheinbeim (2003)
	Vinyl nitrate	Single T_g; phase contrast microscopy	–	Akiyama et al. (1969)
	Vinylidene fluoride	Single T_g	Semicrystalline	Belke and Cabasso (1988), Bernstein et al. (1978b)
Vinyl acetate-co-vinyl chloride	n-Butyl methacrylate-co-isobutyl methacrylate	Single T_g	Miscibility range depended on compositions of I and II; I had ≥81 wt% vinyl chloride	Shiomi et al. (1989)
	Hexyl acrylate-co-methyl acrylate	Single T_g	I had 5–23.7 vol% vinyl acetate; II had 15–88 vol% hexyl acrylate; miscibility depended on compositions of I and II	Jin et al. (1992)
	n-Butyl methacrylate	Single T_g	I had 5.9–15.1 wt% vinyl acetate	Lee et al. (1992)
Vinyl acetate-co-vinyl alcohol	4-Vinylpyridine	Single T_g; FTIR; OM	I had 35–70 mol% vinyl alcohol	Isasi et al. (1995), Lee et al. (1998a)
Vinyl acetate-co-N-vinylpyrrolidone	Methyl methacrylate-co-p-vinylphenol	Single T_g	Formed complexes	Akiba et al. (2002)
Vinyl alcohol	Acrylamide	Single T_g	–	El-Din et al. (2003)
	Ethylene imine	Single T_g; T_m-depression	Semicrystalline	Guo (1995)
	N-Methylglycine	Single T_g; FTIR; SEM; transparency	Blend had ≤40 wt% II	Aoi et al. (2000)
	Pyrrole	FTIR; SEM; X-ray	Blend lost crystallinity when less than 15–20 % II was present	Wang and Fernandez (1992)
	Sodium α,β-D,L-aspartate	FTIR; SEM; X-ray	–	Takasu et al. (1997)
	Sodium-4-styrenesulfonate	Single T_g; FTIR; SEM	–	Mbareck et al. (2009)
Vinyl alkanoate	Vinyl alkanoate	Single T_g; microscopy	The alkanoate was butyrate, caprate, caproate, caprylate, or laurate	Braun et al. (1993)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
Vinyl butyral	N-Vinylpyrrolidone	Single T_g; transparency	≤50 % II	Eguiazabal et al. (1984)
	Urethane elastomer	Single T_g	II from methylene bisdiphenyl diurethane and polytetramethylene ether glycol; miscible with hard segment	Sincock and David (1992)
Vinyl chloride	Acetonyl methacrylate	Single T_g; transparency	–	Chong et al. (1990a, b)
	Acrylic acid-co-carbitylacrylate-co-methylstyrene-co-styrene	Single T_g	II was an oligomer with M_n = 1.07 and M_w = 3.32 kg/mol	Rim and Orler (1987)
	Acrylonitrile-co-n-butyl acrylate	Optical microscopy	II had 53, 67, or 84 mol% butyl acrylate	Piglowski and Kammer (1990)
	Acrylonitrile-co-methyl methacrylate-co-α-methylstyrene	Single T_g	II had 32.3 wt% AN and 8.1 wt% MMA	Kovacic et al. (1994)
	Arylate of tetramethylbisphenol-S	Single T_g; FTIR	–	Choi et al. (1998)
	Butadiene, epoxidized	Single T_g	II had 50 mol% epoxidation	Margaritis and kalfoglou (1988)
	Butadiene-co-styrene, epoxidized	Single T_g	II had 45 wt% styrene; epoxidation >40 mol%	Margaritis et al. (1989)
	Butyl acrylate-co-ethyl acrylate	Single T_g	II had 22.9, 43.5, or 52.8 % butyl acrylate	Walsh and Sham (1989)
	Butyl acrylate-co-hexyl acrylate	Single T_g	II had 47.8 % butyl acrylate	Walsh and Sham (1989)
	Butyl acrylate-co-methyl acrylate	Single T_g	II had 44.6 % butyl acrylate	Walsh and Sham (1989)
	Butyl methacrylate-co-methyl methacrylate	Single T_g	II had 30 or 70 % methyl methacrylate	Yang et al. (1986a)
	Butylene adipate	FTIR	II has linear of branched	Lindstrom and Hakkarainen (2007)
	Butylene adipate-co-terephthalate	Single T_g; FTIR	–	Ibrahim et al. (2011)

Caprolactam-*co*-caprolactone	Single T_g	II had 12.8 mol% caprolactam	Van Ekenstein et al. (1997)
Caprolactone-*co*-L-lactide	Single T_g	II had $\leq$40 wt% lactide	Vion et al. (1986)
Caprolactone-*co*-lignin	Single T_g; SEM; TEM	II was a 7-arm starlike polymer containing 20 wt% lignin derivative	De Oliveira and Glasser (1994)
Caprolactone-*co*-methylcaprolactone	Single T_g	Whatever composition of II	Vion et al. (1986)
Carbonate, liquid crystalline	Single T_g; SEM; FTIR	–	Sato and Ujiie (1996a)
Cyclohexyl methacrylate	Single T_g	–	Ha et al. (1990a)
2,2-Dimethyl-1,3-propylene sebacate	Single T_g; transparency	–	Neo and Goh (1992b)
Ester	Single T_g; FTIR	II was made from 1,4-butanediol and a mixture of isophthalic acid and adipic acid	Andrcic et al. (2006)
Ester	Single T_g	II was made from 1,4-butanediol and a mixture of terephthalic acid and adipic acid	Andrcic et al. (2008)
Ester	Single T_g; for I with soft segments of I	II was Hytrel, a multiblock copolymer with poly(tetramethylene ether) glycol terephthalate soft segments and tetramethylene terephthalate hard segments; hard segments crystalline; two T_g's after 130 °C annealing; Hourston and Hughes (1977a), Hourston and Hughes (1981) showed single T_g to 50 or 60 wt% I	Hourston and Hughes (1977a, 1981), Nishi et al. (1975a)

(*continued*)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
	Ester	Single T_g	I was made from adipic acid, hexane-1,6-diol and neopentanediol and had M_n = 2 kg/mol	Hardt et al. (1982)
	Ester, liquid crystalline	Single T_g	II was made from p-hydroxybenzoic acid and ethylene terephthalate (60:40)	Meng and Tjong (1999)
	Ester carbonate	Single T_g	I was made from adipic acid and hexane-1,6-diol and neopentane-diol and diphenyl carbonate	Hardt et al. (1982)
	Ethyl acrylate-co-hexyl acrylate	Single T_g	II had 41.7 or 43.2 % ethyl acrylate	Walsh and Sham (1989)
	Ethyl acrylate-co-methyl methacrylate	Single T_g	II had 10 % ethyl acrylate	Xu et al. (1987)
	Ethylene-co-vinyl acetate	Permittivity measurements; single T_g and negative enthalpy of mixing (Righetti et al. (2002))	II had 70 % vinyl acetate; composition dependent; miscible when blend contained ≥25 % II	Rellick and Runt (1986), Righetti et al. (2002)
	Isopropyl methacrylate	Single T_g	–	Ha et al. (1990a)
	Methyl acrylate-co-hexyl acrylate	Single T_g	II had 9.7 % methyl acrylate	Walsh and Sham (1989)
	Methyl methacrylate-b-styrene	–	No gross phase separation when I had M_n = 43 kg/mol; PMMA and PS block had the same M_n = 40 kg/mol in II	Jerome et al. (1986)
	Methyl methacrylate-co-styrene	Single T_g, FTIR	II had 0–30 wt% styrene	Dompas et al. (1997)
	Methyl methacrylate-co-4-vinylpyridine	Single T_g, FTIR	II had 15 wt% vinylpyridine	Benmerad et al. (2011)
	Nitrile rubber, carboxylated	Single T_g	II was Krynac-221	Ramesh et al. (1993)
	Pentyl acrylate	Single T_g	–	Walsh and Sham (1989)

	Phenyl acrylate	Single T_g; NMR	—	Sankarapandian and Kishore (1996b)
	Propyl acrylate	Single T_g	—	Walsh and Sham (1989)
	Pentyl acrylate-*co*-propyl acrylate	Single T_g	II had 48.1 % propyl acrylate	Walsh and Sham (1989)
	Styrene	Single T_g; SEM	Blends were prepared by in situ polymerization of styrene in PVC with supercritical carbon dioxide as swelling agent	Dai et al. (2002)
	Urethane	Single T_g	II was a thermoplastic PU elastomer	Kim et al. (1994b)
	Vinyl acetate	Single T_g	Bhagwagar et al. (1989) stated miscible when cast from methyl ethyl ketone and immiscible when cast from tetrahydrofuran; De Jager and Ten Brinke (1991) stated blends cast from both THF and MEK were immiscible	De Jager and Ten Brinke (1991), Bhagwagar et al. (1989)
Vinyl chloride, chlorinated	Butadiene, epoxidized	Single T_g	II had 20 or 43 mol% epoxidation	Sotiropoulou et al. (1992)
	Butadiene-*co*-acrylonitrile	Single T_g	Depended on Cl-content and acrylonitrile content	Chai and Karasz (1992), Cowie and Elexpuru (1992), Huh and Karasz (1989, 1992)
	n-Butyl methacrylate	Single T_g; transparency	I had 65 or 68 wt% Cl	Ha et al. (1990a), Tremblay and Prud'homme (1984)
	Cyclohexyl methacrylate	Single T_g	I had 68 wt% Cl	Ha et al. (1990a)
	Ethyl methacrylate	Single T_g; transparency	I had 65 or 68 wt% Cl	Ha et al. (1990a), Tremblay and Prud'homme (1984)
	Ethylene terephthalate	Single T_g	Probably semicrystalline	Aubin and Prud'homme (1984)
	Hexamethylene sebacate	Single T_g	I had 67.2 wt% Cl; semicrystalline when ≥50 wt% II	Belorgey et al. (1982)
	Hexamethylene terephthalate	Single T_g	Semicrystalline	Aubin and Prud'homme (1984)

(*continued*)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
	Isopropyl methacrylate	Single T_g	I had 68 wt% Cl	Ha et al. (1990a)
	n-Hexyl methacrylate	Single T_g	–	Ha et al. (1990a)
	Maleic anhydride-ran-styrene	Single T_g	I was Goodrich CPVC 3010; II had 86 % styrene	Bourland (1988), Bowland and Braunstein (1986)
	α-Methyl-α-n-propyl-β-propiolactone	Single T_g	I had 67.2 wt% Cl	Belorgey et al. (1982)
	n-Propyl methacrylate	Single T_g, transparency	I had 65 or 68 wt% Cl	Ha et al. (1990a), Tremblay and Prud'homme (1984)
	Urethane	Single T_g	I had 67 wt% Cl; II had a soft poly(tetramethylene adipate) segment capped with 2-hydroxyethyl acrylate	Gracia (1986), Wu et al. (1999)
	Valerolactone	Single T_g	I had 67.2 wt% Cl	Belorgey et al. (1982)
Vinyl chloride-co-vinylidene chloride	Ester	Single T_g	I had 13.5 wt% vinyl chloride; semicrystalline; II was butylene adipate, butylene sebacate, dodecamethylene adipate, dodecamethylene decamethylene dicarboxylate, dodecamethylene dodecamethylene dicarboxylate, hexadecamethylene dodecamethylene dicarboxylate, or hexamethylene sebacate	Woo et al. (1986)
	Phenyl methacrylate	Single T_g	I had 12 % vinyl chloride; semicrystalline	Kang et al. (1988)
	Isopropyl methacrylate	Single T_g	I had 12 % vinyl chloride; semicrystalline	Kang et al. (1988)
Vinyl cinnamate-co-ethylene	Dimethylbutadiene-co-p-vinylphenol	Single T_g, FTIR	I had 82 mol% ethylene; II had 18 mol% vinylphenol	Hu et al. (2002)

Polymer	Component	Method	Comment	Reference
Vinyl cinnamate-co-vinyl acetate	Dimethylbutadiene-co-p-vinylphenol	Single T_g; FTIR	I had 83, 90, or 96 mol% vinyl acetate; II had 33 mol% vinylphenol	Hu et al. (2002)
Vinyl fluoride	Vinylidene fluoride	Single T_g	Semicrystalline; later work found the blends immiscible (Guerra et al. (1986))	Godovskii et al. (1981), Guerra et al. (1986)
Vinyl p-methoxycinnamate	p-Chloro-(3-ethenoxypropyl) cinnamate	Single T_g	–	Lin et al. (1989)
	Vinyl p-chlorocinnamate	Single T_g	–	Lin et al. (1989)
	Vinyl cinnamate	Single T_g	–	Lin et al. (1989)
Vinyl p-methylcinnamate	Vinyl cinnamate	Single T_g	–	Lin et al. (1989)
	p-Chloro-(3-ethenoxypropyl) cinnamate	Single T_g	–	Lin et al. (1989)
	p-Cyano-(3-ethenoxypropyl) cinnamate	Single T_g	–	Lin et al. (1989)
	3-Ethyoxypropyl cinnamate	Single T_g	–	Lin et al. (1989)
	Vinyl p-chlorocinnamate	Single T_g	–	Lin et al. (1989)
N-Vinylimidazole	Acrylic acid	Single T_g, FTIR	Formed complexes	Luo et al. (1999)
	3-Carboxyprop ylmethylsiloxane-co-dimethylsiloxane	Single T_g, FTIR; XPS	II had 77 mol% dimethylsiloxane	Li et al. (2001a)
	2-Hydroxypropyl methacrylate	Single T_g; FTIR	Formed complexes	Luo et al. (1999b)
	Methacrylic acid	NMR	–	Ruhnau and Veeman (1996)
	Styrenesulfonic acid	FTIR; XPS	Formed complexes	Luo et al. (1999a)
	Styrenesulfonic acid, Zn-neutralized	FTIR; XPS	Formed complexes	Luo et al. (1999a)
	p-Vinylphenol	Single T_g; FTIR	Formed complexes	Luo et al. (1999b)
Vinylethylether	Butyl acrylate	Single T_g; FTIR; OM	–	Woo and Juang (2007)
Vinylmethylether	Alkyl acrylate	Single T_g	II had an alkyl of ethyl, n-propyl, or n-butyl	Chakraborty et al. (1993)
	Acrylonitrile-co-styrene	Single T_g	–	Lin et al. (1989)
	Benzyl methacrylate	Single T_g; FTIR; OM	–	Mandal and Woo (1999a)

(continued)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
	Butadiene-*co*-styrene	Light scattering	II had 60 or 68 wt% styrene	Ahn et al. (1997d)
	Caprolactone	Single T_g; FTIR; OM	–	Bisso et al. (1998, 1999), Woo et al. (2010)
	2-Chlorostyrene	Single T_g; FTIR; light scattering; dielectric studies	–	Tran-Cong et al. (1994), Urakawa et al. (2001)
	Dinitrostyrene-*co*-styrene	Single T_g	II had 3–14 mol% dinitrostyrene	Fernandez et al. (1997)
	Epichlorohydrin	NMR; dielectric spectroscopy	–	Alegria et al. (1994, 1995) McGrath and Roland (1994)
	Ester	Single T_g; FTIR; OM	II was ethylene succinate, ethylene adipate, butylene adipate, trimethylene adipate, ethylene azelate, or hexamethylene sebacate	Chiang and Woo (2007)
	Ethyl methacrylate	Single T_g; transparency	–	Woo and Juang (2007)
	Hexamethylene adipate	Single T_g; OM; T_m-depression	–	Woo et al. (2010)
	Hydroxybutyrate	Single T_g; FTIR; OM	–	Chiang and Woo (2007)
	Hydroxyether of bisphenol-A	Single T_g	II was 11.7–42.3 mol% methylated or 7.5–30.1 mol% benzoylated	Etxeberria et al. (2001)
	Lactide	Single T_g; FTIR; OM	–	Chiang and Woo (2007)
	Maleic anhydride-*co*-styrene	Single T_g	II had <10–11 % acrylonitrile	Min and Paul (1988)
	Methyl methacrylate-*co*-styrene	Single T_g	II had 15 % maleic anhydride	Min and Paul (1988)
	α-Methylstyrene	Light scattering	II had <60 mol% methyl methacrylate	Halary et al. (1991), Chien et al. (1988)
	α-Methylstyrene-*co*-4-(2-hydroxyethyl)-α- methylstyrene	Single T_g	II had 6–89 mol% methylstyrene	Cowie and Reilly (1992), Ha et al. (1990b)
	α-Methylstyrene-*co*-4-(1,1,1-trifluoro-2-hydroxyethyl)-methylstyrene	Single T_g	II had 0–96 mol% methylstyrene	Cowie and Reilly (1992)

	α-Methylstyrene-co-styrene	Light scattering; FTIR;	II had 77.5 or 88 wt% styrene	Ha et al. (1990b, 1993)
	p-Methylstyrene-co-styrene	Light scattering; FTIR; single T_g	II had 78.5 or 87.3 wt% styrene; II had ≥61 mol% styrene (Goh et al. (1994))	Goh et al. (1994), Ha et al. (1990b, 1993)
	m-Methylstyrene-co-styrene	Light scattering; FTIR	II had 76.5 or 87.5 wt% styrene	Ha et al. (1993)
	Nitrostyrene-co-styrene	Single T_g	II had ≤25.6 mol% nitrostyrene	Cowie et al. (1990a), Defieuw et al. (1989a)
	Styrene-co-1-vinylnaphthalene	Light scattering	II had 17.4, 23, 50, or 80 wt% styrene; depended on composition of blend	Ha et al. (1990b), Kanakalatha et al. (1983)
	Styrene-co-2-vinylnaphthalene	Light scattering	II had 19.2, 51, or 84 wt% styrene	Ha et al. (1990b), Ryu et al. (2000)
	Vinyl alkanoate	Single T_g; IGC; transparency	II was vinyl propionate or vinyl butyrate	Dutta et al. (1993)
	1-Vinylnaphthalene	Single T_g; FTIR	II had M_n = 5.4 kg/mol; blend contained 65–85 wt% II	Kang and Cho (1989)
Vinylmethylketone	Epichlorohydrin	Single T_g; FTIR	–	Guo et al. (1996a)
	2-Hydroxyethyl methacrylate	Single T_g; FTIR	–	Guo et al. (1996a)
	Vinyl nitrate	Single T_g; FTIR	–	Kondo et al. (2002)
	Vinylidene fluoride	Single T_g; transparent melt	Semicrystalline	Bernstein et al. (1978a)
Vinylphenylketone, hydrogenated	2,6-Dimetyl-1,4-phenylene ether	Single T_g; FTIR	Blend had 10–40 wt% and 60–90 wt% II	Maldonado-Santoyo et al. (2004c)
	2-Ethyl-2-oxazoline	Single T_g; FTIR	–	Maldonado-Santoyo et al. (2004a)
	Styrene-co-4-vinylpyridine	Single T_g; FTIR	II had 50 wt% vinylpyridine	Maldonado-Santoyo et al. (2004b)
p-Vinylphenol	Acetonyl methacrylate	Single T_g; transparency	–	Chong and Goh (1992a)
	4-Acetoxystyrene	Single T_g; FTIR	–	Himuro et al. (1992)
	N-Acryloylmorphine	Single T_g; FTIR; XPS; NMR	–	Yi and Goh (2002)
	N-Acryloylthiomorphine	Single T_g; FTIR; XPS	–	Yi et al. (2001a)
	Amide	Single T_g	II PA-6, PA-6,6, or PA-11	Landry et al. (1993b)
	Butyl acrylate-co-t-butyl acrylate	Single T_g	II had 64 mol% butyl acrylate	Zhu et al. (1990)

(continued)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
	Butylene adipate	Single T_g; NMR; WAXD	Semicrystalline	Belfiore et al. (1993), Landry et al. (1993b, c), Qin and Belfiore (1990), Sun et al. (2011)
	Butylene adipate-co-butylene succinate	Single T_g; T_m-depression; WAXD; SAXS	–	Yang et al. (2009)
	Butylene adipate-co-butylene terephthalate	Single T_g; FTIR	II had 44 mol% butylene terephthalate	Lee et al. (2010)
	Butylene 2,6-naphthalate	Single T_g; T_m-depression; FTIR	–	Lee and Han (2004), Lee and Yan (2002)
	Butylene succinate	Single T_g; T_m-depression	–	Qiu et al. (2003a)
	Butylene terephthalate	Single T_g; FTIR	Semicrystalline	Landry et al. (1993b)
	Caprolactone	Single T_g; FTIR; NMR; IGC	Semicrystalline	Belfiore et al. (1993), Coleman et al. (1989a), Kuo et al. (2001a), Lezcano et al. (1995, 1996), Qin and Belfiore (1990), Wang et al. (2002b)
	Cellulose tripropionate	Single T_g	–	Landry et al. (1993b)
	Copolyester	Single T_g; FTIR	Five different copolyesters	Landry et al. (1993c)
	Dialkyl itaconate	Single T_g; FTIR	II had a dialkyl group of methyl, ethyl, bis [2-[2-(2-methoxyethoxy) ethoxy]ethyl], or bis [2-(2-methoxyethoxy)ethyl]	Hong et al. (1995b), Landry et al. (1993a)
	N,N-Dimethylacrylamide	Single T_g	Formed complexes in dioxane or acetone	Landry and Teegarden (1991), Landry et al. (1993b), Suzuki et al. (1992), Wang et al. (1991)
	2-(Dimethylamino)ethyl methacrylate	Single T_g; FTIR; XPS	Formed complexes	Huang et al. (1999)
	2,2-Dimethylpropylene terephthalate	Single T_g; FTIR	–	Landry et al. (1993b, c)

Epoxy	Single T_g; FTIR; NMR	–	Huang and Woo et al. (2002)
Ester, liquid crystalline	Single T_g	II contained lateral pyridyl group	Sato et al. (1996b)
Ethoxyethyl methacrylate	Single T_g; FTIR; NMR	–	Hill et al. (1999)
Ethyl acrylate	FTIR	–	Coleman et al. (1989a), Parmer et al. (1988)
γ-Ethyl L-glutamate	FTIR; microscopy	–	Painter et al. (1991), Zucco and Painter (1988)
Ethyl methacrylate	Single T_g; FTIR	–	Coleman et al. (1991b), Goh and Siow (1988a), Pomposo et al. (1993b), Serman et al. (1991a)
Ethyl methacrylate-co-methyl methacrylate	Single T_g; FTIR	II had 30, 60, or 70 mol% MMA	Pomposo et al. (1993b, 1994a)
Ethylene adipate	Single T_g; NMR	Semicrystalline	Belfiore et al. (1993), Qin and Belfiore (1990)
Ethylene azelate	Single T_g; T_m-depression; FTIR	–	Woo and Chang (2004)
Ethylene imine	Single T_g; FTIR; OM	Formed complexes	Huang et al. (1997)
Ethylene sebacate	Single T_g; T_m-depression; FTIR	–	Papageorgiou et al. (2011)
Ethylene succinate	Single T_g; NMR	Semicrystalline	Belfiore et al. (1993)
Ethylene terephthalate	Single T_g; FTIR	–	Gestoso and Brisson (2003), Landry et al. (1993c)
Ethylene glycol-b-2-vinylpyridine	Single T_g; FTIR; NMR; TEM	–	Lee et al. (2006a)
Ethylene 2,6-naphthalenedicarboxylate	Single T_g; FTIR	–	Landry et al. (1993b, c)
Ethylene-co-vinyl acetate	Single T_g; FTIR	II had 70 % vinyl acetate	Coleman et al. (1989a), Coleman et al. (1987), Moskala et al. (1986)
Hexamethylene adipate	Single T_g	–	Chiang and Woo (2006)
Hexamethylene sebacate	Single T_g; T_m-depression; FTIR	Semicrystalline	Qin and Belfiore (1990), Woo and Chang (2004)

(continued)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
	n-Hexyl methacrylate-co-methyl methacrylate	Single T_g; FTIR	II had 20, 38, or 48 wt% hexyl methacrylate	Coleman et al. (1993b)
	Hexylene-m-xylenedicarboxamide	Single T_g	–	Landry et al. (1993b)
	Hydroxyether of bisphenol-A	Single T_g; FTIR; NMR	–	Kuo et al. (2003)
	Isopropyl methacrylate	Single T_g	–	Goh and Siow (1986b)
	Lactide	Single T_g; T_m-depression; FTIR; SAXS; NMR	–	Chen et al. (2000), Meaurio et al. (2005a, b), Shirahase et al. (2007), Zhang et al. (1998), Zuza et al. (2006)
	γ-Methyl L-glutamate	FTIR; microscopy	–	Painter et al. (1991), Zucco and Painter (1988)
	Methyl acrylate	FTIR; NMR	–	Coleman et al. (1989a), Li and Brisson (1996), Parmer et al. (1988a), Prolongo et al. (1997), Takegoshi and Hikichi (1994), White and Mirau (1994), Zhang et al. (1991a), Zhao and Prud'homme (1991)
	Methyl methacrylate	Single T_g; FTIR	II was atactic, isotactic, or syndiotactic (Hsu et al. (1997, 2002a)	Coleman et al. (1991b), Goh and Siow (1988a), Hsu et al. (1997, 2002a), Landry and Teegarden (1991), Pomposo et al. (1993b), Serman et al. (1991a), White and Mirau (1994)
	Methyl methacrylate-b-N-vinylpyrrolidone	Single T_g; FTIR; NMR; TEM	Immiscible when blend had 2–60 wt% vinylphenol	Lee et al. (2006b)
	N-Methyl-4-piperidinyl methacrylate	Single T_g; FTIR; XPS	Formed complexes	Luo et al. (1997)
	Methylthiomethyl methacrylate	Single T_g; FTIR; XPS; NMR	–	Yi et al. (2001b)

n-Propyl acrylate	FTIR	–	Coleman et al. (1989a), Parmer et al. (1988)
2,2,3,3,3-Pentafluoropropyl methacrylate-co-4-vinylpyridine	Single T_g; FTIR; XPS	II had 28, 40, or 54 mol% vinylpyridine	Huang et al. (2002a)
Propylene carbonate	Single T_g; FTIR; XPS	–	Zhang et al. (2002)
n-Propyl methacrylate	Single T_g; FTIR	–	Coleman et al. (1991b), Goh and Siow (1988a), Serman et al. (1991a)
Styrene-co-4-vinylbenzenephosphonic acid diethyl ester	Single T_g; FTIR; NMR	II had >7.5 mol% phosphorus group	Zhuang et al. (1994)
Styrene-co-4-vinylpyridine	Single T_g	II had 50 mol% 4-vinylpyridine	Vivas de Meftahi and Frechet (1988)
Styrene-co-2-vinylpyridine	Single T_g; FTIR	II had 30 mol% styrene; formed complexes	Dai et al. (1994c)
Tetrahydrofuran	FTIR; transparency	–	Serman et al. (1991b)
Tetrahydrofurfuryl methacrylate	Single T_g	–	Goh and Siow (1988a)
2,2,5-Trimethylene terephthalamide	Single T_g	–	Landry et al. (1993b)
Trimethylene terephthalate	Single T_g; T_m-depression; FTIR	–	Lee and Woo (2004b)
Vinyl acetate	Single T_g; FTIR	–	Coleman et al. (1987, 1989a), Moskala et al. (1986)
Vinyl cinnamate	Single T_g; FTIR	–	Coleman et al. (1998b)
Vinylethylether	Single T_g; dielectric spectroscopy	–	Mpoukouvalas et al. (2005)
1-Vinylimidazole	Single T_g; FTIR	–	Goh et al. (1996)
Vinylmethylether	Single T_g; FTIR; IGC	–	Pedrosa et al. (1994), Lezcano et al. (1998)

(continued)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
	Vinylphenylketone	Single T_g; FTIR	–	Rodriguez-Castro et al. (2006)
	Vinylpyridine	Single T_g; FTIR; NMR; XPS	Formed complexes; II was 2- or 4-pyridine	Dai et al. (1994c), Vivas de Meftahi and Frechet (1988), Wang et al. (2001c), Zhou et al. (1997b)
	N-Vinylpyrrolidone	Single T_g; FTIR; NMR	–	Akiba and Akiyama (2001), Kuo and Chang (2001c)
p-Vinylphenol, brominated	Caprolactone	Single T_g; T_m-depression	–	Prolongo et al. (2002)
	Vinylmethylether	Single T_g; T_m-depression	–	Prolongo et al. (2002)
Vinyl propionate	N-Vinylpyrrolidone	Single T_g	Formed complexes from methanol	Wang et al. (1991)
N-Vinylpyrrolidone	Acrylic acid-co-ethylene	FTIR; dielectric analysis	Blend had 12, 20, 30, 40, 50, or 90 wt% N-vinylpyrrolidone	Nuno-Donlucas et al. (2001a)
	Acrylonitrile	Single T_g	–	Guo et al. (1996b)
	N-1-Alkyl itaconic acid	Single T_g	II had an alkyl group of butyl, hexyl, or octyl	Urzua et al. (1998)
	Allyl alcohol-co-styrene	Single T_g; transparency	II had 5.4–6.0 or 7.3–8.0 wt% OH	Dai et al. (1995b), Goh and Siow (1990)
	Amide	Single T_g; FTIR; POM	–	Neelakandan and Kyu (2009)
	Amide	Single T_g	II had 1/1/1 = caprolactam/hexamethylene adipamide/hexamethylene sebacamide structural unit	Guo et al. (1992)
	Aramide	Single T_g; transparency	Five different aramides	Cherdron et al. (1994)
	Benzimidazole	Single T_g; transparency	–	Cherdron et al. (1994)
	n-Butyl methacrylate-co-2-hydroxyethyl methacrylate	Single T_g; transparency	II had ≥20.9 mol% 2-hydroxyethyl methacrylate	Lee et al. (1991c)
	Carbonate of bisphenol-A	NMR	–	Da Silva and Tavares (1998a)
	Chitosan acetate salt	FTIR; transparency	–	Cao et al. (1998)

2-Cyano-1,4-phenylene terephthalamide	FTIR; NMR	—	Oh et al. (2009)
Dialkyl itaconate	Single T_g	II had an alkyl group of methyl, 2-chloroethyl or 3-chloropropyl	Opazo et al. (1994)
Dialkyl itaconate-co-styrene	Single T_g	II had an alkyl group of methyl or ethyl	Opazo et al. (1996)
Epoxy resin	Single T_g; FTIR	—	Janarthanan and Thyagarajan (1992)
Ether amide	Single T_g; transparency	Studied up to 30 % II; I was made from isophthaloyl chloride and cis-4,4'-diamino-dibenzo-18-crown-6	Schchori and Jagur-Grodzinski (1976)
Ethersulfone	Single T_g	—	Guo (1992a)
Ethyl acrylate	Single T_g; transparency; IGC	—	Bhattacharyya et al. (1986, 1989)
Ethylene glycol	Single T_g; NMR	I had $M_w = 360$ kg/mol; II had $M_w = 0.3$ kg/mol	Da Silva and Tavares (1998b), Spindler and Shriver (1986)
Epichlorohydrin	Single T_g; NMR	—	C514, Guo (1990d)
Ethyl methacrylate-co-2-hydroxyethyl methacrylate	Single T_g; transparency	II had ≥ 7.5 mol% 2-hydroxyethyl methacrylate	Goh and Lee (1990b)
Haloalkyl methacrylate	Single T_g; FTIR	II had a haloalkyl group of chloromethyl, 2-chloroethyl, 3-chloropropyl, 2-bromoethyl, or 2-iodoethyl	Low et al. (1994a), Opazo et al. (1994)
Hydroxyether of bisphenol-A	Single T_g; FTIR	Formed complexes	Dai et al. (1995b)
Hydroxyether benzoate	Single T_g; FTIR	—	Wang et al. (2008)
Hydroxyether of phenolphthalein	Single T_g; FTIR	—	Guo et al. (1996b)
Hydroxyether terephthalate ester	Single T_g; FTIR	—	Wang et al. (2008)
2-Hydroxyethyl methacrylate	Single T_g; transparency	—	Goh and Siow (1990)
2-Hydroxyethyl methacrylate-co-methyl methacrylate	Single T_g; transparency	II had ≥ 1.9 mol% 2-hydroxyethyl methacrylate	Lee et al. (1991c)

(continued)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
	2-Hydroxypropyl methacrylate	Single T_g; transparency	Formed complexes	Dai et al. (1995b), Goh and Siow (1990), Kuo et al. (2004a)
	Hydroxypropyl cellulose	T_m-Depression; SEM; FRIT; WAXD	–	Reddy et al. (2012)
	Hydroxypropylmethyl cellulose	Single T_g	–	Karavas et al. (2006)
	Isopropenyl methyl ketone	Single T_g; FTIR; NMR	–	Hong et al. (1995a)
	Methacrylic acid	NMR	Formed complexes	Maunu et al. (1993)
	Methyl methacrylate	Single T_g	II was atactic or syndiotactic	Hsu (2001)
	Monobenzyl itaconate	FTIR	Formed complexes	Cesteros et al. (1990)
	Monoethyl itaconate	FTIR	Formed complexes	Cesteros et al. (1994b)
	N-Phenyl-2-hydroxytrimethylene amine	Single T_g; NMR	–	Zhang and Mi (1999)
	Sulfone	Single T_g; transparency	–	Goh et al. (1991d)
	Sulfone, carboxylated	Single T_g; transparency	II had degree of carboxylation 0.43–1.93	Goh et al. (1991d)
	Vinyl alcohol	Single T_g; NMR; XPS; FTIR	–	Cassu and Felisberti (1997, 1999), Feng et al. (1993), Lewandowska (2005), Li et al. (1998b), Nishio et al. (1990), Ping et al. (1990), Thyagarajan and Janarthanan (1989), Wang et al. (1990)
	Vinyl alcohol, modified	Single T_g; FTIR	II was grafted with lactic acid, glycolic acid, or hydroxybutyric acid	Lejardi et al. (2011)
	Vinyl alcohol-co-vinyl acetate	Single T_g	II had ≥70 % vinyl alcohol	Eguiazabal et al. (1986a)
	Vinyl chloride	Single T_g; FTIR; NMR	–	Guo (1990d), Zheng et al. (1999b)
	Vinyl formal	Single T_g; FTIR	–	Huang and Guo (1990), Isasi et al. (1993)

Vinylidene fluoride	Acetonyl methacrylate	Single T_g	Semicrystalline	C37
	Acrylic acid-co-methyl methacrylate	Single T_g; T_m-depression	II had 5.7 mol% acrylic acid	Moussaif and Jerome (1999)
	Butylene succinate-co-butylene adipate	T_m-Depression; POM; WAXD	II had 20 mol% butylene adipate	Qiu et al. (2007a, b)
	N,N-Dimethylacrylamide	Single T_g	Semicrystalline	Galin (1987a)
	Ethyl 2-cyanoacrylate	T_m-Depression; SEM	–	Tiwari et al. (2009)
	Ethyl methacrylate-co-methyl methacrylate	T_m-Depression	II had 16–80 wt% methyl methacrylate	Goh and Siow (1988b)
	Methacrylic acid-co-methyl methacrylate	Single T_g; T_m-depression	II had 2.2–9.5 mol% methacrylic acid and K-neutralized	Leung and Lo (1995)
	Methyl methacrylate-co-styrene	Single T_g	II had <13 vol% styrene	Jo et al. (1991a)
	2-Methyl-2-oxazoline	Single T_g; T_m-depression	Miscible when II was a star polymer; immiscible when II was a linear polymer	Shen and Zheng (2006)
	N-Methyl-N-vinylacetamide	Single T_g	Semicrystalline	Galin (1987a)
	Methoxymethyl methacrylate	Single T_g	Semicrystalline	Goh et al. (1991c)
	Pivalolactone	T_m-Depression		Huang et al. (1994)
	Thiophene-g-methyl methacrylate	Single T_g; FTIR; WAXD; POM		Mandai and Nandi (2011)
	N-Vinylpyrrolidone	Single T_g	Semicrystalline	Alfonso et al. (1989), Ceccorulli et al. (1989), Galin (1984), Kang et al. (1989)
Vinylphosphonic acid	Vinylpyridine	Single T_g; FTIR; XPS	II was 2- or 4-vinylpyridine	Zhou et al. (1997d)
Vinylpyridine	Hydroxyalkyl methacrylate	Single T_g; FTIR	I was 2- or 4-vinylpyridine; II had an alkyl group of 2-hydroxyethyl or 3-hydropropyl	Cesteros et al. (1994a)
	Monoalkyl itaconate	T_g difficult to detect	I was 2- or 4- vinylpyridine; II had an alkyl group of methyl or ethyl	Gargallo et al. (1994)
	Monoethyl itaconate	FTIR	I was 2- or 4-vinylpyridine; formed complexes in ethanol	Cesteros et al. (1995), Velada et al. (1995)

(continued)

Table 21.1 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
2-Vinylpyridine	Aramide	Single T_g; FTIR	II was made from hexamethylenediamine and a mixture of terephthaloyl and isophthaloyl dichlorides	Skrovanek and Coleman (1987)
4-Vinylpyridine	Benzimidazole	Single T_g; FTIR	–	Pu (2003)
	N-Cyclohexyl methacrylamide	Single T_g; FTIR; NMR	–	Lin et al. (2010)
	Ethylene-alt-maleic acid	FTIR	–	Villar et al. (2003)
	Hydroxyether ketone	Single T_g; T_m-depression; FTIR	–	Zhu et al. (2012)
	Hydroxyether terephthalate ester	Single T_g; FTIR	–	Liu et al. (2006b)
	Methylcellulose	Single T_g; NMR	–	Masson and Manley (1991)
	N-Phenyl methacrylamide	Single T_g; FTIR; NMR	–	Lin et al. (2010)
	p-Phenylene terephthalamide	Transparency; microscopy	–	Cowie et al. (1996), Hara and Parker (1992)
	Sulfone, carboxylated	Single T_g; transparency	II had degree of carboxylation 0.43–1.93	Goh et al. (1992d)
	Tyrosine	Single T_g; FTIR; WAXD; NMR	–	Lu et al. (2012)
	Vinyl acetate-*co*-vinyl alcohol	Single T_g; FTIR	II had 29–38 mol% vinyl alcohol	Cesteros et al. (1993, 1994c, d)
4-Vinylpyridinium chloride	Sodium (2-acrylamido-2-methyl propane sulfonate)	–	Formed complexes in dilute aqueous solutions; T_g difficult to detect	Huglin et al. (1996)
	Sodium phosphate	–	Formed complexes in aqueous solution	Acar and Tulun (1996)
2,3-Xylenyl methacrylate	2,6-Xylenyl methacrylate	Single T_g	–	Petrovic-Djakov et al. (1993)

Table 21.2 Polymer pairs containing one monomer in common, miscible in the amorphous state at room temperature

Polymer I of	Polymer II of	Method	Comments	Refs.
Acrylic acid-*co*-styrene	Dimethylacrylamide-*co*-styrene	Single T_g; FTIR	I had 27 mol% acrylic acid; II had 17 or 32 mol% dimethylacrylamide	El Miloudi et al. (2008, 2009) Hadj-Hamou and Djadoun (2006), Hadj-Hamou et al. (2009)
	Styrene-*co*-4-vinylpyridine	Single T_g	I had 14 mol% acrylic acid; II had 15 mol% vinylpyridine	El Miloudi et al. (2009)
Acrylonitrile-*co*-butadiene	Acrylonitrile-*co*-butadiene	Single T_g; clear films; electron microscopy	Difference in composition between I and II ≤22 % acrylonitrile	Ambler (1973), Bartenev and Kongarov (1963), Chandler and Collins (1969), Cheng and Kardos (1969), Corish (1967), Jorgenson et al. (1973), Kosai and Higashino (1975)
	Acrylonitrile-*co*-styrene	Single T_g	–	Cowie et al. (1992c)
	Acrylonitrile-*co*-vinylidene fluoride	Single T_g	I had 23.6–49.6 vol%AN; II had 19 wt% AN	Cowie and Harris (1994)
Acrylonitrile-*co*-maleic anhydride-*co*-styrene	Acrylonitrile-*co*-styrene	Single T_g	Miscibility dependent on compositions of I and II	Cowie et al. (1994b)
	Maleic anhydride-*co*-styrene	Single T_g	Miscibility dependent on compositions of I and II	Cowie et al. (1994b)
Acrylonitrile-*co*-methyl methacrylate	Acrylonitrile-*co*-N-phenylitaconimide	Single T_g	–	Cowie et al. (1990c)
	Methyl methacrylate-*co*-itaconic anhydride	Single T_g	Miscibility dependent on compositions of I and II	Bell et al. (1994)
	Methyl methacrylate-*co*-N-phenylitaconimide	Single T_g	–	Cowie et al. (1990c)
Acrylonitrile-*co*-methyl methacrylate-*co*-methylstyrene	Methyl methacrylate	Single T_g	I had 20/20/60 = acrylonitrile/methyl methacrylate/-methylstyrene	Olabisi and Farnham (1979)
Acrylonitrile-*co*-methyl methacrylate-*co*-styrene	Acrylonitrile-*co*-styrene	Light scattering	–	Ikawa and Hosoda (1990)
	Methyl methacrylate	Light scattering	–	Ikawa and Hosoda (1990)

Polymer I of	Polymer II of	Method	Comments	Refs.
Acrylonitrile-co-α-methylstyrene	Acrylonitrile-co-methyl methacrylate	Single T_g	–	Cowie and Elexpuru (1992)
	Acrylonitrile-co-styrene	Single T_g; NMR	I had 32.3 wt% acrylonitrile; II had 27 wt% acrylonitrile	Aoki (2000), Cowie et al. (1992a), Ikawa et al. (1993), Lath et al. (2000), Rink et al. (1983)
Acrylonitrile-co-methylstyrene-co-styrene	Acrylonitrile-co-methylstyrene-co-styrene	Clear films	Difference in composition between I and II <12 % acrylonitrile	Slocombe (1957)
Acrylonitrile-co-styrene	Acrylic acid-co-styrene	Single T_g	–	Jin et al. (1986)
	Acrylonitrile-co-benzyl methacrylate	Single T_g	Miscibility dependent on compositions of I and II	Sankarapandian and Kishore (1994)
	Acrylonitrile-fumaronitrile-styrene	Single T_g	I had 32–40 wt% AN; II had 11–17 wt% fumaronitrile	Warakomski and Dion (1992)
	Acrylonitrile-co-methyl methacrylate	Single T_g	–	Cowie et al. (1988), Nishimoto et al. (1989)
	Acrylonitrile-co-(2-oxo-1,3-dioxolane-4-yl)methyl methacrylate	Single T_g	I had 25 wt% AN; II had 24.5 wt% AN	Park et al. (2002a)
	Acrylonitrile-co-N-phenylitaconimide	Single T_g	–	Cowie et al. (1990c)
	Acrylonitrile-co-styrene	Single T_g; no visible phase separation	Difference in composition between I and II <3.5 % acrylonitrile	Landi (1972), Molau (1965)
	Acrylonitrile-co-vinylidene chloride	Single T_g	I had 25 wt% AN; II had 20 wt% AN	Hsu (2004a)
	Benzyl methacrylate-co-styrene	Single T_g	Miscibility dependent on compositions of I and II	Sankarapandian and Kishore (1994)
	p-(2-Hydroxy-hexafluoro-isopropyl)styrene-co-styrene	Single T_g; clear film	I had 70 % styrene; II had 90.3 % styrene	Min and Pearce (1981), Pearce et al. (1984)

	Itaconic anhydride-stat-styrene	Single T_g	Miscibility dependent on compositions of I and II	Bell et al. (1994)
	Maleic anhydride-co-styrene	Single T_g	I had 44.4–94.6 wt% styrene; II had 50–91.5 wt% styrene	Aoki (1988), Heinen et al. (1998), Kressler et al. (1988), Martynowicz-Hans and Runt (1986), Shiomi et al. (1986a), Wastlund et al. (1998)
	Methyl methacrylate-co-styrene	Light scattering	–	Tang et al. (2002)
	N-Phenylitaconimide-co-styrene	Single T_g	–	Cowie et al. (1988)
	N-Phenylmaleimide-co-styrene	Single T_g	–	Aoki (1988, 1990)
	Styrene-co-p-vinylphenol	Single T_g; FTIR	I had 6–30 wt% acrylonitrile; II had 27–92 wt% vinylphenol; miscibility depended on compositions of I and II	Ahn et al. (1997a)
3-Bromo-2,6-dimethyl-1,4-phenylene ether	3-Bromo-2,6-dimethyl-1,4-phenylene ether-co-2,6-dimethyl-1,4-phenylene ether	Single T_g; microscopy	II had ≥48 mol% 3-bromo-2,6-dimethyl-1,4-phenylene oxide	Kambour et al. (1983)
3-Bromo-2,6-dimethyl-1,4-phenylene ether-co-2,6-dimethyl-1,4-phenylene ether	2,6-Dimethyl-1,4-phenylene ether	Single T_g; microscopy	I had ≥62 mol% 2,6-dimethyl-1,4-phenylene ether	Kambour et al. (1983)
p-Bromostyrene-co-styrene	Styrene	Single T_g	I had ≥90 mol% styrene	Kambour et al. (1983), Strobl et al. (1986)
Butadiene	Butadiene	Single T_g	Semicrystalline; I was SKD (87 % cis-1,4) and II was SKBM (Godovskii et al. (1979); I had 50 % vinyl-1,2, 35 % cis-1,4, and 15 % trans-1,4, and II had 98 % cis-1,4 (Shah et al. (1988)); I had 50 % vinyl-1,2, 35 % cis-1,4, and 15 % trans-1,4, and II had 55 % trans-1,4, 35 % cis-1,4, and 10 % vinyl-1,2 (Shah et al. (1988))	Godovskii et al. (1979), Shah et al. (1988)

(continued)

Table 21.2 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
Butadiene-*co*-styrene	Butadiene-*co*-styrene	Single T_g	II had >70 % butadiene; immiscible when II had <60 % butadiene	Caspary (1972), Corish (1967), De Decker and Sabatine (1967), Fujimoto and Yoshimiya (1968a, b), Livingston and Rongone (1967), Marsh et al. (1967), Marsh et al. (1968), Shah et al. (1989), Slonimskii (1958), Slonimskii and Komskaia (1956), Struminskii and Slonimskii (1956), Yoshimura et al. (1968)
Butadiene-*co*-styrene	Butadiene-*co*-styrene	Single T_g; microscopy	Difference in composition between I and II <20 % styrene; two T_g's when composition difference >20 %	De Decker and Sabatine (1967), Livingston and Brown (1968, 1970), Livingston and Rongone (1967), Kraus and Rollman (1971), Shutilin and Vysokomol (1991), Slonimskii and Komskaia (1956)
	Styrene	Single dynamic mechanical loss peak	I had 25 % styrene; II had M_w ≤917; ≤50 % II; two loss peaks when 75 % II	Class and Chu (1985a, c)
Butene-*co*-ethylene	Ethylene-*co*-styrene	Phase contrast optical microscopy	I had 15 mol% butane; II had 1.0–3.9 mol% styrene	Hu et al. (2005)
Butyl acrylate-*co*-butyl methacrylate	Butyl acrylate-*co*-butyl methacrylate	Clear films	Difference in composition between I and II 25 % butyl acrylate; immiscible when composition difference 50 % butyl acrylate	Kosai et al. (1977)
Butyl acrylate-*co*-N-hydroxyethylcarbozolyl acrylate	Butyl acrylate-*co*-β-hydroxyethyl-3,5-dinitrobenzoyl acrylate	Single T_g	I had 6 or 48 mol% electron donating carbozoyl groups; II had 10 or 63 mol% electron withdrawing dinitrobenzoyl groups	Schneider et al. (1992)

Butyl acrylate-co-ethyl acrylate	Butyl acrylate-co-ethyl acrylate	Clear films	Difference in composition between I and II 25 % ethyl acrylate; immiscible when composition difference 50 % ethyl acrylate	Kosai et al. (1977)
	Ethyl acrylate	Clear films	I had 75 % ethyl acrylate; immiscible when I had ≤50 % ethyl acrylate	Kosai et al. (1977)
Butyl acrylate-co-methyl methacrylate	Butyl acrylate-co-methyl methacrylate	Single T_g; clear films	Difference in composition between I and II ≤10 % methyl methacrylate	Kollinsky and Markert (1969, 1971)
n-Butyl methacrylate	n-Butyl methacrylate-co-styrene	Single T_g; clear films	II had ≥90 wt% n-butyl methacrylate	Fujimoto and yoshimura (1968)
n-Butyl methacrylate-co-p-chlorostyrene	n-Butyl methacrylate-co-p-chlorostyrene	Single T_g; microscopy	–	Braun et al. (1992)
n-Butyl methacrylate-co-N-hydroxyethylcarbazoyl acrylate	n-Butyl methacrylate-co-hydroxyethyl-3,5-dinitrobenzoyl acrylate	Single T_g	I had 9 mol% carbazoyl groups; II had 9 mol% dinitrobenzoyl groups	Schneider et al. (1992)
Butyl methacrylate-co-methacrylic acid	Methacrylic acid-co-styrene	Single T_g	MAA contents of I and II were 20.2 and 13.7 mol%, respectively; MAA was Na-neutralized	Jiang et al. (1993)
Butyl methacrylate-co-methyl methacrylate	Butyl methacrylate-co-methyl methacrylate	Clear films	Difference in composition between I and II ≤20–30 % butyl methacrylate, depending on compositions of I and II	Braun et al. (1992), Kollinsky and Markert (1969)
n-Butyl methacrylate-co-styrene	n-Butyl methacrylate-co-styrene	Single T_g; microscopy	–	Braun et al. (1992)
	Styrene	Single T_g; microscopy	II had ≥90 wt% styrene	Fujioka et al. (1984)
Caprolactam-co-caprolactone-co-laurolactam	Caprolactam-co-laurolactam	Single T_g	I and II had varying compositions	Ellis (1993)
Caprolactone	Butylene terephthalate-co-caprolactone	Single T_g; microscopy	II had <60 mol%butylene terephthalate	Ma et al. (1997a)
Carbonate of bisphenol-A	Carbonate of bisphenol-A-co-1,1-bis(4-hydroxyphenyl)-3,3,5-trimethylcyclohexane	Single T_g; transparency	II had 36–89 wt% bisphenol-A	Haggard and Paul (2004)

(continued)

Table 21.2 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
p-Chlorostyrene-co-hexyl methacrylate	p-Chlorostyrene-co-hexyl methacrylate	OM	Closely match compositions of I and II favored miscibility	Sato et al. (2004)
Cyclohexyl methacrylate-co-methyl methacrylate	Cyclohexyl methacrylate-co-methyl methacrylate	Single T_g	Miscibility depended on compositions of I and II	Pomposo et al. (1998)
Cinnamic acid-co-styrene	Styrene-co-4-vinylpyridine	Single T_g; FTIR	I had 15 mol% cinnamic acid; II had 16.6 mol% 4-vinylpyridine	Boulash et al. (2008)
	Methyl methacrylate-co-styrene	Single T_g		Pomposo et al. (1998)
1,8-Dibromooctane-co-bisphenol-A	1,8-Dibromooctane-co-4,4′-(hexafluoroisopropylidene) diphenol	Single T_g; AFM; XPS; TOF-SIMS	I:II = 80:20 in blend	Lei et al. (2003)
2,6-Dimethyl-1,4-phenylene ether, sulfonylated	2,6-Dimethyl-1,4-phenylene ether, sulfonylated	Single T_g	Difference in degree of sulfonylation between I and II in the range of 20–26 wt%	Kang et al. (1987)
2,3-Dimethylbutadiene-stat-p-vinylphenol	2,3-Dimethylbutadiene-stat-alkyl methacrylate	Single T_g; transparency	II had an alkyl group of methyl, ethyl, n-propyl, n-butyl, n-decyl, or n-hexadecyl	Pehlert et al. (1998)
Dimethylsiloxane, functionalized	Dimethylsiloxane, functionalized	Single T_g	I had 4–15 mol% electron-donating carbazoyl or N-methylaniline groups; II had 4–15 mol% electron-accepting dinitrobenzoyl groups; donor/acceptor = 1/1	Schneider et al. (1992)
Epichlorohydrin	Epichlorohydrin-co-ethylene glycol	Single T_g	I was Hydrin 100; II was Hydrin 200	Jaroszynska and Gaczynski (1976)
Etheretherketone	Etheretherketone	Single T_g	I was linear and II was hyperbranched	Li et al. (2011)
Ethyl acrylate-co-ethyl methacrylate	Ethyl acrylate-co-ethyl methacrylate	Clear films	I and II had 25, 50, or 75 % ethyl acrylate	Kosai et al. (1977)
	Ethyl methacrylate	Clear films	I had 75 wt% ethyl methacrylate; immiscible when I had ≤50 wt% ethyl methacrylate	Kosai et al. (1977)

Polymer I	Polymer II	Method	Comments	References
Ethyl acrylate-*co*-methyl methacrylate	Ethyl acrylate-*co*-methyl methacrylate	Clear films	Difference in composition between I and II <20–27 % ethyl acrylate depending on compositions of I and II	Kollinsky and Markert (1969)
Ethylene	Ethylene	Rheological studies; IGC	I and II were LDPE, HDPE, or LLDPE; miscibility depended on branch content and composition distribution	Hameed and Hussein (2004), Hussein (2003), Hussein et al. (2003), Hussein and William (2004a, b), Zhao and Choi (2004)
Ethylene-*co*-propylene	Ethylene-*co*-propylene	AFM	Difference in ethylene content in I and II was less than 18 mol%	Kamdar et al. (2006)
Ethylene, chlorinated	Ethylene, chlorinated	Single T_g; clear films	Difference in composition between I and II $\leq$1.2–13.3 wt% Cl depending on compositions of I and II	Chai and Sun (1983), Chai et al. (1992), Oswald and Kubu (1963), Ueda and Karasz (1990a)
	Ethylene-*co*-methyl acrylate	Single T_g; phase contrast microscopy	Semicrystalline when I had 25 wt% Cl; I had 25 or 48 wt% Cl	Kalfoglou and Margaritis (1984)
	Ethylene-*co*-vinyl acetate	Single T_g; microscopy	I had 35.4–52.6 wt% Cl; II had 50–60 wt% ethylene	Walsh et al. (1983)
	Ethylene-*co*-styrene	Single T_g	Miscible when the difference in styrene content was less than 10 wt%	Cheung and Guest (2000)
Ethylene-*co*-vinyl acetate	Ethylene, low density	Single T_g	I:II = 50:50	Ray et al. (1993)
	Ethylene acetate-*co*-vinyl acetate	Single T_g; microscopy	I and II had 7–100 wt% vinyl acetate	Braun et al. (1993)
	Ethylene-*co*-vinyl alcohol	Single T_g; FTIR	I and 21 mol% vinyl acetate; II had 21 mol% vinyl alcohol	Coleman et al. (1993b)
	Vinyl acetate-*co*-vinyl chloride	Single T_g	–	Shiomi et al. (1986, 1990)
Ethylene-*co*-vinyl alcohol	Ethylene-alt-maleic anhydride	Single T_g; T_m-depression	I had 38 mol% ethylene	Aouak et al. (2012)
Ethylene-*co*-vinyl chloride	Ethylene-*co*-vinyl chloride	Single T_g	Difference in vinyl chloride or ethylene content of I and II <15 mol%	Bowmer and Tondli (1986a, b)
Vinyl chloride	Vinyl chloride	Single T_g; T_m-depression	I had >80 mol% vinyl chloride	Bowmer and Tondli (1986a)
Ethylene glycol	Epichlorohydrin-*co*-ethylene glycol	Single T_g; T_m-depression	–	Silva et al. (1988)
Ethylene naphthalene-2,6-dicarboxylate	Ethylene naphthalene-2,6-dicarboxylate-*co*-4-hydroxybenzoate	NMR	II had 20 mol% 4-hydroxybenzoate	Guo and Zachmann (1993)
Ethyl methacrylate-*co*-methyl methacrylate	Ethyl methacrylate-*co*-methyl methacrylate	Single T_g	–	Chai et al. (1992)

(*continued*)

Table 21.2 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
o-Fluorostyrene-co-p-styrene	o-Fluorostyrene-co-p-styrene	Single T_g	I and II had 10 and 23 mol% p-fluorostyrene, respectively	Oudhuis et al. (1993)
o-Fluorostyrene-co-styrene	o-Fluorostyrene-co-styrene	Single T_g	I had 18 or 49 % o-fluorostyrene; II had 40 or 77 % o-fluorostyrene	Oudhuis et al. (1993), Salomons et al. (1991)
	Styrene	Single T_g	I had 18, 40, or 49 % o-fluorostyrene and II had M_n = 15 kg/mol; I had 18 % o-fluorostyrene and II had M_n = 110 kg/mol	Oudhuis et al. (1993), Salomons et al. (1991)
p-Fluorostyrene-co-styrene	Styrene	Single T_g	I had 8 or 16 mol% p-fluorostyrene; II had M_n = 40 or 326 kg/mol	Oudhuis et al. (1993)
Hexyl methacrylate-co-methyl methacrylate	Hexyl methacrylate-co-methyl methacrylate	OM	Closely match compositions of I and II favored miscibility	Sato et al. (2004)
Hexyl methacrylate-co-styrene	Hexyl methacrylate-co-styrene	OM	Closely match compositions of I and II favored miscibility	Sato et al. (2004)
Hydrocarbon polymer, chlorinated	Hydrocarbon polymer, chlorinated	Clear films	One series derived from reduction of polyvinyl chloride and one series derived from chlorination of polyethylene	Braun et al. (1989)
p-Hydroxybenzoic acid-co-6-hydroxy-2-naphthoic acid-co-terephthalic acid-co-hydroquinone	p-Hydroxybenzoic acid-co-6-hydroxy-2-naphthoic acid	Single T_g; X-ray diffraction	X-ray diffraction showed no significant transesterification occurred in the mixture	DeMeuse and Jaffe (1989)
Hydroxybutyrate	Hydroxybutyrate	OM; SAXS	I was isotactic. II was atactic	Abe et al. (1994)
	3-Hydroxybutyrate-co-4-hydroxybutyrate	Single T_g; FTIR	I had 41 mol% 4-hydroxybutyrate; miscible when blend had 1- = 50 wt% II	Luo et al. (2007)
	Hydroxybutyrate-co-hydroxyhexanoate	Single T_g	II had 10 or 20 mol% hydroxyhexanoate	Feng et al. (2003)
	Hydroxybutyrate-co-hydroxyvalerate	Microscopy; melting behavior; WAXS	II had 3.8–22.3 mol% hydroxyvalerate	Organ (1994), Organ and Barham (1993), Scandola et al. (1997)

Hydroxybutyrate-co-hydroxyhexanoate	Hydroxybutyrate-co-hydroxyhexanoate	Single T_g	Hydroxyhexanoate contents of I and II were 10 and 20 mol%, respectively	Feng et al. (2003)
3-Hydroxybutyrate-co-hydroxypropionate	3-Hdroxybutyrate-co-hydroxypropionate	Single T_g	II had hydroxypropionate content less than 40 mol%	Na et al. (2001)
Imide	Imide	Single T_g; transparency	I and II had a common monomer but different flexibility	Cosutchi et al. (2012)
Isoprene	Isoprene-styrene block copolymer	Electron microscopy	I had M_n = 6.5–53.9 kg/mol; II was diblock, triblock, or four-arm star copolymer having total M_n = 26–622 kg/mol	Jiang et al. (1986)
Maleic anhydride-co-styrene	Acrylonitrile-co-styrene	Single T_g, transparency, microscopy	I had 15.3 wt% maleic anhydride; II had 15.0, 19.5, or 25.0 wt% acrylonitrile	Gan and Paul (1994a) Kim et al. (1989b), Maruta et al. (1988)
	Maleic anhydride-co-styrene	Single T_g	Miscible when the difference in MA content of I and II was less than 2.5 vol %	Pinoit and Prud'homme (2002)
	Methyl methacrylate-co-styrene	Single T_g	Miscibility dependent on compositions of I and II	Gan and Paul (1994a)
	Styrene-co-4-vinylpyridine	Single T_g; FTIR	I had 28 or 50 mol% maleic anhydride; II had 32 mol% vinylpyridine	Haddadine-Rahmoun et al. (2008)
N-Maleimide-co-methyl methacrylate	Methyl methacrylate-co-7-[2-methacryloyloxy]ethyladenine	Single T_g	I and II had ≥10 mol% hydrogen bonding unit site	Cowie and Love (2001)
N-Maleimide-co-styrene	Styrene-co-2-vinylpyridine	Single T_g; FTIR	II had 30 wt% styrene	Vermeesch et al. (1993)
Methacrylic acid-co-methyl methacrylate	Methyl methacrylate-co-4-vinylpyridine	Phase diagram	I had 91.48 or 77.7 mol% methyl methacrylate; II had 80.2 mol% methyl methacrylate	Djadoun (1983)

(continued)

Table 21.2 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
Methacrylic acid-*co*-styrene	2-(*N*,*N*-Dimethylamino)ethyl methacrylate-*co*-styrene	Single T_g	Formed complexes when I had 22 mol% acid and II had 79 or 88 mol% styrene	Abdellaoui and Djadoun (2005)
	Styrene-*co*-4-vinylpyridine	Single T_g; phase diagram; FTIR	Formed complexes when I had 12 or 29 mol% acid and II had 6 or 15 mol% vinylpyridine (Bennour et al. (2005)); I had 89.5 mol% styrene; II had 83.9 mol% styrene (Djadoun (1983))	Benabdelghani et al. (2008), Benabdelghani and Etxeberria (2011), Bennour et al. (2005), Djadoun (1983)
	Styrene-*co*-2-vinylpyridine	Single T_g; FTIR	I had 9 mol% methacrylic acid; II had 17 mol% vinylpyridine	Motzer et al. (2001b)
	Styrene-*co*-N-vinylpyrrolidone	Single T_g; FTIR	I had 9 mol% methacrylic acid; II had 13 mol% N-vinylpyrrolidone	Motzer et al. (2001b)
[4-(Methacryloyloxy)-butyl] pentamethyldisiloxane	[4-(Methacryloyloxy)-butyl] pentamethyldisiloxane-*co*-methyl methacrylate	Single T_g; clear films	II had 67 % methyl methacrylate	Blahovici et al. (1982)
[4-(Methacryloyloxy)-butyl] pentamethyldisiloxane-*co*-methyl methacrylate	Methyl methacrylate	Single T_g; clear films	I had 67 or 75 % methyl methacrylate	Blahovici et al. (1982)
Methacrylonitrile-*co*-styrene	Methacrylonitrile-*co*-methyl methacrylate	Single T_g	Miscibility dependent on compositions of I and II	Cowie et al. (1993b)
	Methacrylonitrile-*co*-styrene	Single T_g	Miscibility dependent on compositions of I and II	Cowie et al. (1993b)
Methyl acrylate	Methyl acrylate-*co*-vinyl acetate	Clear films	II had 25–75 % methyl acrylate	Kosai et al. (1977)
Methyl acrylate-*co*-methyl methacrylate	Methyl acrylate-*co*-methyl methacrylate	Clear films	Difference in composition between I and II 28–48 % methyl acrylate when I and II had degree of polymerization = 400 and 20–35 % methyl acrylate when I and II had degree of polymerization = 3,000, depending on compositions of I and II	Kollinsky and Markert (1969)

Methyl acrylate-*co*-vinyl acetate	Vinyl acetate	Clear films	I had 25–75 % vinyl acetate	Kosai et al. (1977)
Methyl methacrylate	Ethyl methacrylate-*co*-methyl methacrylate	Single T_g	I was isotactic; II had ≤45 % ethyl methacrylate	Schroeder et al. (1985)
	Methyl methacrylate	Single T_g	I was isotactic; II was syndiotactic; I and II were atactic, isotactic, or syndiotactic (Chang and Woo (2010))	Chang and Woo (2010), Ragupathy et al. (2007), Schroeder et al. (1985)
	Methyl methacrylate-*co*-phenylmaleimide	Single T_g	Miscibility depended on M_w of I and composition of II	Merfeld et al. (1999)
	Methyl methacrylate-*co*-tribromophenyl maleimide	Single T_g	Miscibility depended on M_w of I and composition of II	Merfeld et al. (1999)
	Methyl methacrylate-*alt*-styrene	Single T_g; TEM	–	Galvin et al. (1994)
Methyl methacrylate-*co*-2-[(3,5-dinitrobenzoyl)oxy] ethyl methacrylate	Methyl methacrylate-*co*-(N-ethylcarbazole-3-yl)methyl methacrylate	Single T_g	I was mixed with II with similar acceptor or donor content and D:A = 1	Pionteck et al. (1995)
Methyl methacrylate-*co*-styrene	Acrylonitrile-*co*-styrene	Single T_g	–	Cowie and Lath (1988), Kammer et al. (1989)
	Maleic anhydride-*co*-styrene	Single T_g	–	Kammer et al. (1989)
	Methyl methacrylate-*co*-N-phenylitaconimide	Single T_g	–	Cowie et al. (1990c)
	Methyl methacrylate-*co*-styrene	Single T_g; microscopy	Miscibility depended on compositions of I and II	Braun et al. (1992), Kohl et al. (1990), Zhu and Paul (2003)
	Methyl methacrylate-*co*-2,4,5-tribromostyrene	Single T_g	I had ≤29.1 wt% styrene; II had ≤13.6 wt% tribromostyrene	Chu et al. (2000)
	N-Phenylitaconimide-*co*-styrene	Single T_g	–	Cowie et al. (1990c)
Methyl methacrylate-*co*-trifluoroethyl methacrylate	Trifluoroethyl methacrylate-*co*-vinylidene fluoride	Single T_g	I had 33 or 66 mol% trifluoroethyl methacrylate; II had 25 or 50 mol% trifluoroethyl methacrylate	Jauannet et al. (1997)
α-Methylstyrene	*p*-Methylstyrene	Single T_g; SEM	I had M_w = 70 kg/mol; miscible when II had M_w = 7.5 kg/mol, immiscible when II had M_w = 31.4 kg/mol	Chang and Woo (2000)
p-Nitrostyrene-*co*-styrene	*p*-Nitrostyrene-*co*-styrene	Single T_g	–	Cowie et al. (1992d)

Table 21.2 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
Novolac resin	Novolac resin	Single T_g	I was formaldehyde and 13/17/70 mol% = p-t-butyl phenol/m-cresol/o-cresol; II was formaldehyde and 15/85 mol% = 2-t-butyl phenol/o-cresol; I and II had M_w 0.8–1.6 kg/mol	Fahrenhlotz and Kwei (1981)
2,2,3,3,3-Pentafluoropropyl methacrylate-co-4-vinylpyridine	2,2,2-Trifluoroethyl methacrylate-co-4-vinylpyridine	Single T_g; FTIR; XPS; ToF-SIMS	I had 28–54 mol% pyridine; II had 27 or 42 mol% vinylpyridine	Huang et al. (2004a)
N-Phenylmaleimide-co-styrene	4-Cyanostyrene-co-styrene	Single T_g	I had 39 wt% styrene; II had 58.5–83.1 mol% styrene	Dean (1987a)
	2-Cyanostyrene-co-4-cyanostyrene-co-styrene	Single T_g	II had 23.5 or 22.7 mol% styrene; ratios of 2-cyanostyrene/4-cyano-styrene were 25:75 or 78:22	Dean (1987a)
Propylene	Ethylene-co-propylene	Single T_g	Miscible when I and II had low M_w	Lohse et al. (1993)
	Propylene	T_m-Depression; OM	I and II had different tacticities	Woo et al. (2007)
Styrene	Alkyl methacrylate-co-styrene	Single T_g	II had an alkyl group of methyl or ethyl; II had 22 mol% styrene; blend had 5, 20, or 95 wt% II	De Andrade and Atvars (2004)
	α-Methylstyrene-co-styrene	Single T_g; T_m-depression	I was syndiotactic; II had 44 wt% styrene	Chiu and Li (2003)
	2-Oxo-1,3-dioxolane-4-yl)methyl methacrylate-co-styrene	Single T_g	II had 19.5 wt% styrene	Park et al. (2002b)
	Styrene	Single T_g	I had M_w = 0.8 kg/mol; II had M_w = 8420 kg/mol; I/II = 31.7/68.5	Chang (1988)
	Styrene	Single T_g	I was linear; II was multibranched	Tsukahara et al. (1994)
	Styrene	Single T_g; OM; T_m-depression	I and II had different tacticity	Ahn et al. (1997e), Bonnet et al. (1998), Hong et al. (1998), Li and Woo (2006), Wang et al. (2005), Woo et al. (2000a), Wu and Woo (1999)

Styrene-*co*-styrenesulfonic acid	Styrene, iodinated	Transparency	II had a degree of iodination of 6 or 15 %	Goh and Lee (1989b)
	Styrene-*co*-*p*-vinylphenol	FTIR; NMR	I had 86 mol% styrene; II had 22 mol% vinylphenol	Huang and Guo (1990), Kelts et al. (1993), Landry et al. (1993a)
	Styrene-*co*-4-vinylpyridine	FTIR; XPS	I had 1.8–9.9 mol% acid; II had 1.9–9.9 mol% pyridine (Smith and Eisenberg (1994); I had 17 or 27 mol % acid and II had 17 or 30 mol% vinylpyridine (Goh et al. (1996b))	Goh et al. (1996b), Smith and Eisenberg (1994)
Styrene-*co*-2,4,5-tribromostyrene	Acrylonitrile-*co*-styrene	Single T_g	I had $\leq$29 wt% tribromostyrene; II had $\leq$6.3 wt% acrylonitrile	Chu et al. (2000)
	Maleic anhydride-*co*-styrene	Single T_g	I had $\leq$29 wt% tribromostyrene; II had $\leq$8 wt% maleic anhydride	Chu et al. (2000)
Styrene-*co*-*p*-vinylphenol	Styrene-*co*-4-vinylpyridine	Light scattering; NRET; XPS; TOF-SIMA	I had 3–70 mol% vinylphenol; II had 14–75 mol% vinylpyridine; formed complexes	Li et al. (1998a), Liu et al. (2004b, 2005a), Xiang et al. (1997a)
Sulfone	Sulfone, carboxylated	Single T_g	Degree of carboxylation of II <1.3	Lau et al. (1993)
Vinyl acetate-*co*-vinyl chloride	Vinyl chloride	Single T_g; microscopy of fibers	I had 78 or 86 wt% vinyl chloride	Kolowski and Laskawski (1980)
	Vinyl chloride, chlorinated	Single T_g	–	Shiomi et al. (1986)
Vinyl acetate-*co*-vinyl stearate	Vinyl acetate-*co*-vinyl stearate	Single T_g; microscopy	I and II had 21–98 wt% vinyl acetate	Braun et al. (1993)
Vinyl chloride	Propylene-*co*-vinyl chloride	Single T_g; microscopy of fibers	II had 89 or 91 wt% vinyl chloride	Kolowski and Laskawski (1980)
Vinyl chloride, chlorinated	Vinyl chloride	Single T_g	Up to 61.3 or 65.2 % Cl in I with dependence on mol% CCl_2 groups	Carmoin et al. (1977), Lehr (1985, 1986)
	Vinyl chloride, chlorinated	Single T_g	Difference in composition between I and II $\leq$3–4 % Cl depending on composition of I and II with dependence on number of CCl2 groups	Chai et al. (1992), Lehr (1985)

Table 21.3 Chemically dissimilar polymer triads (and tetrads) miscible in the amorphous state at room temperature

Polymer I of	Polymer II of	Polymer III of and Polymer IV of	Method	Comments	Refs.
Acetoxystyrene	Ethylene glycol	p-Vinylphenol	Single T_g; FTIR	Existence of an immiscibility loop	Kuo et al. (2005b)
Acrylic acid-co-methyl methacrylate	n-Butyl methacrylate-co-4-vinylpyridine	Vinyl chloride	Single T_g	Miscible when blend had >50 wt% II	Iguerb et al. (1999)
Acrylic acid-co-styrene	N,N-Dimethylacrylamide-co-styrene	Styrene-co-4-vinylpyridine	Single T_g	I had 14 mol% acrylic acid; II had 25 mol% dimethylacrylamide; III had 15 mol% vinylpyridine	El Miloudi et al. (2009)
	Ethylene glycol	Methyl methacrylate	Single T_g	I had 12.2, 20.8, or 33.1 mol% acrylic acid	Jo et al. (1991b)
Acrylonitrile-co-butadiene	Vinyl chloride	Vinyl chloride-co-vinylidene chloride	Single T_g	Semicrystalline; I had 30 or 40 wt% acrylonitrile; III had 65 wt% vinylidene chloride	Wang and Chen (1981)
Acrylonitrile-co-butadiene-co-styrene	Carbonate of bisphenol-A	Propylene-co-vinyl chloride	Single T_g	I was Blendex 701; II was Merlon Matzner et al. (1982), M-60; III had 3.2 or 3.8 % propylene; I/II/III = 1/1/2; two T_g's when I/II/III = 3/7/10	Cheng and Mantell (1979)
Acrylonitrile-co-methyl acrylate	Ethylene glycol	2-Hydroxyethyl methacrylate-co-4-vinylphenol	Single T_g; T_m-depression; FTIR	III had 55 mol% vinylphenol	Silva et al. (2009)
Acrylonitrile-co-methyl methacrylate	Acrylonitrile-co-styrene	Maleic anhydride-co-styrene	Single T_g	I had 12 % acrylonitrile; II had 25 % acrylonitrile; III had 25 % maleic anhydride	Brannock and Paul (1990)
	Acrylonitrile-co-styrene	Methyl methacrylate-co-styrene	Single T_g	I had 2.7–7.4 vol% acrylonitrile; II had 14.5–49.5 vol% acrylonitrile; III had 11.2–16.0 vol% styrene	Cowie and Lath (1987), Cowie et al. (1992b)
	Acrylonitrile-co-styrene	Methyl methacrylate-co-N-phenylitaconimide	Single T_g	I had 68 or 95 vol% MMA; II had 63 or 70 vol% styrene; II had 12 or 45 vol% MMA	Cowie et al. (1994a)

Acrylonitrile-co-methylstyrene	Vinyl chloride	Single T_g	I had 32.3 wt% acrylonitrile; II had 27 wt% acrylonitrile; >25 % I	Rink et al. (1983)
	Ethyl methacrylate	Single T_g	I had 30 wt% acrylonitrile	Goh et al. (1986a)
Acrylonitrile-co-N-phenylitaconimide	Acrylonitrile-co-styrene	Single T_g	I had 6 or 9 vol% acrylonitrile; II had 22, 44, or 65 vol% acrylonitrile; III had 12 or 42 vol% styrene	Cowie et al. (1991b)
Acrylonitrile-co-styrene	Maleic anhydride-co-styrene	Single T_g	I and I had different compositions; III had 22–34 mol% maleic anhydride	Tacx et al. (2002)
	Butylene adipate	Single T_g	I had 12 or 25 % acrylonitrile	Shah et al. (1986)
	Caprolactone	Single T_g	–	Shah et al. (1986)
	Hydroxyether of bisphenol-A	Single T_g	I had 15 wt% AN	Jo et al. (1994a), Vanneste and Groeninckx (1994), Vanneste et al. (1997)
	Maleic anhydride-co-styrene	Single T_g; transparency	I had 15 wt% AN; II had 14 wt % MA	Vanneste and Groeninckx (1995)
	Caprolactone	Single T_g	Miscible when I/II/III = 68/16/16	Huang et al. (1988b)
	Cyclohexane dimethylene succinate	Single T_g	–	Shah et al. (1986)
	Carbonate of tetramethylbisphenol-A	Single T_g	All blends were miscible and exhibited LCST	Yoo and Kim (2004b), Yoo et al. (2003)
	Maleic anhydride-co-styrene	Single T_g	Miscible at all blend compositions	Reichelt et al. (1996a, b)
	Maleic anhydride-co-styrene	Single T_g	I had 25 % acrylonitrile; III had 14–25 % acrylonitrile	Brannock and Paul (1990)
	Methyl methacrylate	Single T_g	I had 30 wt% acrylonitrile; some blends showed LCST	Goh and Siow (1986b)
Ethylene-co-vinyl acetate	Vinyl chloride	Single T_g; SEM; PALS	I had 25 wt% AN; II had 45 wt % vinyl acetate	Meghala and Ranganathaiah (2012)
	Methyl methacrylate	Single T_g	II was atactic; III was isotactic	Hsu and Yeh (1999b)

(continued)

Table 21.3 (continued)

Polymer I of	Polymer II of	Polymer III of and Polymer IV of	Method	Comments	Refs.
	Methyl methacrylate	Vinyl chloride	Single T_g	I had 23 or 25 wt% acrylonitrile	Huang and Guo (1990), Meghala and Ranganathaiah (2012)
Acrylonitrile-*co*-vinylidene chloride	Methyl methacrylate	Methyl methacrylate	Single T_g	I had 20 wt% AN; I and II were atactic and isotactic, respectively	Hsu and Yeh (2000a)
	Methyl methacrylate	*p*-Vinylphenol	Single T_g	Miscible when blend had ≤20 wt% III	Hsu (2004a)
Acrylonitrile-*co*-vinylidene fluoride	Methyl methacrylate	Methyl methacrylate	Single T_g	II and II were atactic and sydiotactic, respectively; blend had >12.5 wt% II	Hsu (2000)
Amide	Methyl methacrylate	*p*-Vinylphenol	Single T_g; FTIR	I was amorphous; miscibility required a high content of III	Hosokawa and Akiyama (1999)
n-Amyl methacrylate	*n*-Butyl methacrylate	Vinyl chloride	Single T_g	Miscible when blend had >30 wt% III	Perrin and Prud'homme (1993)
n-Amyl methacrylate	*n*-Propyl methacrylate	Vinyl chloride	Single T_g	Miscible when blend had >70 wt% III	Perrin and Prud'homme (1993)
Arylate	Butylene terephthalate	Hydroxyether of bisphenol-A (Phenoxy)	Single T_g	I was Arilef U-100; III >30 wt%	Ahn et al. (1990), Eguiazabal et al. (1986b), Iruin et al. (1989)
Benzyl methacrylate	Caprolactone	Acrylonitrile-*co*-styrene	Single T_g; microscopy	III had 17 or 25 wt% AN; blend exhibited LCST	Su et al. (2003)
	Caprolactone	Phenyl methacrylate	Single T_g	Miscible at all compositions; all blends exhibited LCST	Lee and Woo (2002)
	Caprolactone	Vinylmethylether	Single T_g; microscopy	Blend exhibited LCST	Woo et al. (2003b)

3-Bromo-2,6-dimethyl-1,4-phenylene ether-co-2,6-dimethyl-1,4-phenylene ether	2,6-Dimethyl-1,4-phenylene ether	Single T_g; microscopy	≤37 mol% brominated monomer in I and II	Kambour et al. (1983)
	Styrene	Single T_g; microscopy	≤16 mol% brominated monomer in I and II	Kambour et al. (1983)
	Styrene	Single T_g; microscopy	≤45 mol% brominated monomer in I	Kambour et al. (1983)
	2,6-Dimethyl-1,4-phenylene ether	Single T_g; microscopy	≤26 mol% brominated monomer in I and in II	Kambour et al. (1983)
Bromostyrene	2,6-Dimethyl-1,4-phenylene ether (polymer IV of styrene)	Single T_g	Blend had ≥33 wt% II	Aroguz and Baysal (2000)
p-Bromostyrene-co-styrene	Styrene	Single T_g; microscopy	≤29 mol% p-bromostyrene in I	Kambour et al. (1983)
n-Butyl methacrylate	Propylene glycol	Transparency	–	Duffy et al. (2005)
Butylene adipate	p-Vinylphenol	Single T_g; OM: FTIR	Blend had ≥60 wt% III	Lee et al. (2010)
Butylene succinate	Ethylene succinate	Single T_g; OM	–	Ikehara et al. (2010)
	Hydroxybutyrate-co-hydroxyvalerate	Single T_g; SEM; TEM	–	Zhang et al. (2012a)
Butylene terephthalate	Carbonate of bisphenol-A (Phenoxy)	Single T_g	Blend had ≥33 wt% II	Remiro and Nazabal (1991a, b)
	Etherimide	Single T_g	–	Yau and Woo (1996)
	Etherimide	Single T_g	–	Woo and Lee (2003)
	Ethylene terephthalate (polymer IV of trimethylene adipate)	Single T_g	Completely miscible (Woo and Kuo (2003))	Run et al. (2007), Woo and Kuo (2003)
Ethylene terephthalate	Trimethylene terephthalate	Single T_g	Completely miscible	Lee et al. (2006)
Ethylene terephthalate	p-Vinylphenol	Single T_g; T_m-depression; FTIR	Completely miscible	Lee et al. (2006)
Trimethylene terephthalate	p-Vinylphenol	Single T_g; T_m-depression; FTIR		
Hydroxyether of bisphenol-A	Methyl methacrylate	Single T_g; SEM	Miscible when blend had >50 wt% III	Jo et al. (1994b)

(continued)

Table 21.3 (continued)

Polymer I of	Polymer II of	Polymer III of and Polymer IV of	Method	Comments	Refs.
Caprolactam	Vinyl alcohol	Vinyl butyral	Single T_g; SEM	Miscible when blend had 40–60 wt% II	Jeong et al. (2000b)
Caprolactone	Ethylene glycol	Hydroxybutyrate	Light scattering	–	Chee et al. (2004)
	Ethylene glycol	Lactide	Single T_g; OM	–	Buddhiranon et al. (2011)
	Ethylene glycol	Novolac	Single T_g; FTIR;	3 Miscible binary pairs; existence of an immiscibility loop	Kuo et al. (2002a)
	Hydroxyether of bisphenol-A (Phenoxy)	Novolac	Single T_g; FTIR;	Miscible at all compositions	Kuo et al. (2005a)
	Hydroxyether of bisphenol-A (Phenoxy)	Vinylmethylether	Single T_g	Miscible at all compositions; all blends showed LCST	Guo (1990a)
	Carbonate of bisphenol-A	Hydroxyether of bisphenol-A (Phenoxy)	Single T_g	Generally miscible when >60 wt% I in blend	Christiansen et al. (1987)
	Carbonate of bisphenol-A	Carbonate of tetramethylbisphenol-A	Single T_g	Miscible at all compositions	Kim and Paul (1994)
	Vinyl chloride	Vinyl chloride, chlorinated	Single T_g	II had 67.2 wt% Cl; generally miscible when I >40 % at high II/III ratio and miscible when I >26 % at low II/III ratio	Ameduri and Prud'homme (1988)
Carbonate of bisphenol-A	Carbonate of bisphenol chloral	Methyl methacrylate	Single T_g	–	Kim and Paul (1992a)
	Carbonate of tetramethylbisphenol-A	Acrylonitrile-co-styrene	Single T_g	III had 2.7–19.7 wt% AN	Kim et al. (1994a)
	Carbonate of tetramethylbisphenol-A	Methyl methacrylate-co-styrene	Single T_g	III had 4.5–58.5 wt% MMA	Kim et al. (1994a)
	Carbonate of tetramethylbisphenol-A	Styrene	Single T_g	–	Kim et al. (1994a), Landry et al. (1991)
	Methyl methacrylate	Vinyl acetate	Single T_g; NMR	I:II:III = 1:4.5:4.5	Rusa et al. (2004)

Carbonate of dimethylbisphenol-A	Styrene	Single T_g; OM	–	Kim et al. (2005)
Carbonate of tetramethylbisphenol-A	Methyl methacrylate-co-styrene	Single T_g; OM	III had 15 or 30 wt% methyl methacrylate	Kim et al. (2005)
Carbonate of tetramethylbisphenol-A	Methyl methacrylate-co-styrene	Single T_g	–	Yu et al. (1991)
2-Chlorostyrene	Styrene	Single T_g; light scattering	Three miscible binary blend systems; existence of an immiscibility loop in the ternary system	Rabeony et al. (1994)
o-Chlorostyrene-co-p-chlorostyrene	Styrene	Single T_g	I had 50 mol% p-chlorostyrene; miscible when blend had $\geq$10 wt% II	Aroguz and Karasz (2004)
Copolyester	Hydroxyether of bisphenol-A (Phenoxy)	Single T_g; microscopy	II/III = 1/1; I was made from 65/30/5 = terephthalate/isophthalate/sebacate and 70/20/10 = ethylene glycol/resorcinol di-(hydroxy ethyl) ether/poly(tetra-methylene ether)glycol; II was 4/1 by wt = Araldite 6099/Araldite 6010	Aharoni (1978)
Cyclohexyl methacrylate	p-Methylstyrene	Single T_g; OM; SEM	Immiscibility loop present at the center of the phase diagram; all blends exhibited LCST	Chang and Woo (2003c)
	Methyl methacrylate	SIMS	–	Harton et al. (2005)
	Styrene	Single T_g; POM	II was atactic; III was isotactic; miscible at all compositions; blends exhibited LCST	Chang et al. (2004a)

(continued)

Table 21.3 (continued)

Polymer I of	Polymer II of	Polymer III of and Polymer IV of	Method	Comments	Refs.
2,6-Dimethyl-1,4-phenylene ether	Methacrylic acid-co-styrene	Styrene-co-4-vinylpyridine	Single T_g; SEM	I:II:III = 25:25:50; II had 20 mol% methacrylic acid and III had 15 mol% vinylpyridine	Benabdelghani et al. (2008)
	Styrene	Styrene	Single T_g; POM	II was atactic; III was isotactic; miscible at all compositions	Chang et al. (2004a)
Epichlorohydrin	Ethylene glycol	3-Hydroxybutyrate	Single T_g	Miscible at all compositions	Goh and Ni (1999)
	Ethylene glycol	Methyl methacrylate	Single T_g	Miscible at all compositions	Min et al. (1987)
	Methyl methacrylate	Vinyl acetate	Single T_g	Miscible at all compositions; all blends showed LCST	Guo (1990b), Pinoit and Prud'homme (2002)
Etherimide	Amideimide	Etheretherketone, sulfonated	Single T_g	I was Ultem 1000; II was Torlon 4,000T; III had a degree of sulfonation of 0.53 or 1.00	Karcha and Porter (1992)
	Etheretherketone	Etherdiphenyletherketone	Single T_g; FTIR;	–	Woo and Tseng (2000)
	Etheretherketone	Liquid crystalline polymer	Single T_g	I was Ultem 1000; II was Victrex 450G; III was HXiang et al. (1997)000	Bretas and Baird (1992), Morales and Bretas (1996a, b)
	Ethylene naphthalate	Pentamethylene naphthalate	Single T_g; OM; WAXD	Miscible after annealing	Su and Shih (2006)
Ether urethane	Oxytetramethylene-co-oxyditetramethylene-co-terephthalic acid	Vinyl chloride	Single T_g	I was Adiprene L-100 and 4,4'-methylene-bis-2-chloroaniline; I/II/III = 1/1/2; two T_g's when I/II/III = 1/2/1 and 1/1/1	Hourston and Hughes (1981)
Ethyl methacrylate	Methyl methacrylate	Styrene-co-p-vinylphenol	Single T_g	III had 5 or 15 mol% vinylphenol	Hsu (2003)
	Methyl methacrylate	p-Vinylphenol	Single T_g; FTIR; microscopy	Blend had >60 wt% III	Pomposo et al. (1993a, 1994b)
	Vinyl acetate	p-Vinylphenol	Single T_g	–	Hsu (2006a)

Ethylene, chlorinated	Natural rubber, epoxidized	Vinyl chloride	Single T_g	II was 50 mol% epoxidized	Kaklas et al. (1991)
Ethylene, chlorosulfonated	Natural rubber, epoxidized	Nitrile rubber, carboxylated	Single T_g	I had 35 % Cl and 1 % S (Hypalon-40); II was 50 mol % epoxidized; III was Krynac-211	Roychoudhury et al. (1992)
Ethyl methacrylate	Methyl methacrylate	Vinylidene fluoride	Single T_g	>30 and <80 wt% III	Kwei et al. (1977)
Ethylene glycol	Ethyl acrylate-co-methacrylic acid	N-Vinylpyrrolidone	Single T_g; FTIR	–	Kireeva et al. (2007)
	Hydroxyether of bisphenol-A	Vinylethylether	Single T_g; FTIR	–	Rocco et al. (2010)
	Vinyl acetate	p-Vinyl phenol	Single T_g; FTIR	Existence of an immiscibility loop (Zhang et al. (1994))	Le Menestrel et al. (1992), Zhang et al. (1994)
	p-Vinylphenol	2-Vinylpyridine	Single T_g; SEM; NMR; FTIR	I:III = 22:77; blend had 20, 30, 50, or 80 wt% II	Lee et al. (2006a)
	Hydroxyether of bisphenol-A	Methyl methacrylate	Single T_g	Three miscible binary pairs; existence of an immiscibility loop	Hong et al. (1997)
Ethylene-2,6-naphthalene	Etheretherketone	Etherimide	Single T_g; SEM	–	Bicakci and Cakmak (1998)
Ethylene terephthalate	Trimethylene terephthalate	p-Vinylphenol	Single T_g; T_m-depression; FTIR	Completely miscible	Lee and Woo (2006)
Hexafluoroacetone-co-vinylidene fluoride	Methyl methacrylate	Vinyl acetate	Single T_g	I had 9 mol% hexafluoroacetone	Kobayashi et al. (1994)
Imide	Imide	Imide	Single T_g	I, II, and III were different	Chung et al. (1997)
Hydroxyether of bisphenol-A	Methyl methacrylate	p-Vinylphenol	Single T_g	II was atactic, isotactic, or syndiotactic	Hsu (2002b)
	Novolac	p-Vinylphenol	Single T_g; OM; FTIR	–	Kuo (2009)
Maleic acid-co-maleic anhydride-co-styrene	Urethane	Vinyl chloride	Single T_g	I had 6.25 wt% maleic acid and 25 wt% maleic anhydride	Al-Salah (1998a)
Methyl acrylate	Vinyl acetate	p-Vinyl phenol	Single T_g	Completely miscible at all compositions	Zhang et al. (1994)

(continued)

Table 21.3 (continued)

Polymer I of	Polymer II of	Polymer III of and Polymer IV of	Method	Comments	Refs.
Methyl acrylate-*co*-styrene	Vinyl acetate	*p*-Vinyl phenol	Single T_g	–	Zhang et al. (1994)
Methyl methacrylate	Methyl methacrylate-*co*-styrene	Styrene	Single T_g	–	Winey et al. (1966)
	Methyl methacrylate-alt-styrene	Styrene	Single T_g	–	Winey et al. (1966)
	Styrene-*co*-*p*-vinylphenol	N-Vinylpyrrolidone	Single T_g	II had 5 or 15 mol% vinylphenol	Hsu (2005)
	Vinyl acetate	Vinylidene fluoride	Single T_g	All ternary blends showed LCST (Guo (1996))	Classen et al. (1995), Guo (1996)
	Vinyl acetate	*p*-Vinylphenol	Single T_g; FTIR	I was isotactic or syndiotactic (Hsu (2006b))	Hsu (2004b, 2006b), Liu et al. (2006a)
	Vinyl cinnamate	*p*-Vinylphenol	Single T_g	Three miscible binary pairs; existence of an immiscibility loop	Hsu (2007)
	N-Vinylpyrrolidone	Vinylidene fluoride	Single T_g; FTIR; WAXD	–	Cheng et al. (2012)
α-Methylstyrene	*p*-Methylstyrene	Styrene	Single T_g; OM; NMR	Miscibility at high I (≥80 wt%) content	Chang et al. (2004c)
Natural rubber, epoxidized	Nitrile rubber, carboxylated	Chloroprene	Single T_g	I was 50 mol% epoxidized; II was Krynac-211; I/II/III =1/1/1	Alex et al. (1990)
Natural rubber, epoxidized	Nitrile rubber, carboxylated	Vinyl chloride	Single T_g	I was 50 mol% epoxidized; II was Krynac-211	Ramesh and De (1993)
Neopentyl glycol adipate	Vinyl chloride	Vinylidene fluoride	Single T_g	III <50 wt%	Lau et al. (1988)
Styrene-*co*-4-vinylpyridine	Vinyl acetate	*p*-Vinyl phenol	Single T_g	I had 70 wt% vinylpyridine	Zhang et al. (1994)

Table 21.4 Polymer pairs miscible in the amorphous state at room temperature. Molecular weight dependence investigated

Polymer I of	Polymer II of	Method	Comments	Refs.
Acrylonitrile-co-α-methylstyrene	Carbonate of bisphenol-A	Single T_g; transparency	I had 9–12 wt% AN; miscible when II had $M_w = 3.8$ kg/mol, immiscible when II had $M_w = 9.9$ kg/mol	Callaghan and Paul (1994a)
	Maleic anhydride-co-styrene	Single T_g	Region of miscibility was sensitive to M_w	Gan et al. (1994b)
Acrylonitrile-co-styrene	Carbonate of bisphenol-A	Single T_g; transparency	I had 24.6 wt% AN and II had $M_w = 3.8$ kg/mol; miscible when I had $M_w = 3.317$ kg/mol and immiscible when I had $M_w = 6.085$ kg/mol	Callaghan et al. (1993)
	Acrylonitrile-co-α-methylstyrene	Single T_g	Region of miscibility was sensitive to M_w	Gan et al. (1994b)
3-Bromo-2,6-dimethyl-1,4-phenylene ether	Styrene	Single T_g; transparency	I had $M_w \leq 40$ kg/mol; II had $M_w \leq 30$ kg/mol	Machado and French (1992b)
n-Butyl methacrylate	Styrene	Single T_g; transparency	I had $M_w = 320$ kg/mol; II had $M_w = 1.71$ kg/mol; two T_g's when II had $M_w = 1,100$ kg/mol	Defieuw et al. (1989b)
Carbonate of bisphenol-A	Ester	Single T_g	II was made from 4,4′ (2-norbornylidene)diphenol and terephthalic acid and azelaic acid; miscible when I had $M_w = 28.1$ kg.mol; immiscible when I had $M_w = 73.2$ kg/mol	Yang and Yetter (1994)
2,6-Dimethyl-1,4-phenylene ether	Alkylstyrene	Transparency	I had $M_w = 5$ to 500 kg/mol, and II was a ring-alkyl (with various carbon atoms) styrene. Raising M_w of II eventually produced a transition from clear to hazy or cloudy films in each system except that containing poly-α-methylstyrene. With this resin, clear single-T_g films were obtained even with M_w of I = 500 kg/mol and M_w of II = 800 kg/mol	Kambour et al. (1988)
	p-Bromostyrene	Transparency	II had $M_n = 29.1$ kg/mol and $M_w = 32$ kg/mol; M_w limit for miscibility in 50/50 blend of I with II was 6.2 ± 2.4 kg/mol. When II had $M_n = 6.4$ kg/mol and $M_w = 7.04$ kg/mol, M_w limit for miscibility of I was 14.0 ± 4.0 kg/mol	Kambour et al. (1988)

(continued)

Table 21.4 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
	p-Tert-butylstyrene	Transparency	II had $M_n = 113$ kg/mol and $M_w = 289$ kg/mol; M_w limit for miscibility in 50/50 blend of I with II was 4.50 ± 0.7 kg/mol	Kambour et al. (1988)
	4-Ethylstyrene	Transparency	II had $M_n = 139$ kg/mol and $M_w = 158$ kg/mol; M_w limit for miscibility in 50/50 blend of I with II was 22.4 kg/mol	Kambour et al. (1988)
	4-Methoxystyrene	Transparency	II had $M_n = 282$ kg/mol and $M_w = 457$ kg/mol; M_w limit for miscibility in 50/50 blend of I with II was 3.6 kg/mol	Kambour et al. (1988)
	4-Methylstyrene	Transparency	II had $M_n = 118$ kg/mol and $M_w = 265$ kg/mol; M_w limit for miscibility in 50/50 blend of I with II was 35.5 kg/mol	Kambour et al. (1988)
	4-n-Propylstyrene	Transparency	II had M_n 128 kg/mol and $M_w = 267$ kg/mol; M_w limit for miscibility in 50/50 blend of I with II was 14.0 ± 4.0 kg/mol	Kambour et al. (1988)
	Vinylbenzylchloride	Transparency	II had $M_n = 16.8$ kg/mol and $M_w = 29.3$ kg/mol; M_w limit for miscibility in 50/50 blend of I with II was 14.0 ± 4.0 kg/mol	Kambour et al. (1988)
	4-Vinylbiphenyl	Transparency	II had $M_n = 79$ kg/mol and $M_w = 153$ kg/mol; M_w limit for miscibility in 50/50 blend of I with II was 7.0 ± 1.6 kg/mol	Kambour et al. (1988)
	Vinylnaphthalene	Transparency	II had $M_n = 13$ kg/mol and $M_w = 32.6$ kg/mol; M_w limit for miscibility in 50/50 blend of I with II was 10.2 kg/mol	Kambour et al. (1988)
	Vinyltoluene	Transparency	II had $M_n = 20.7$ and $M_w = 40.4$ kg/mol; M_w limit for miscibility in 50/50 blend of I with II was 69 ± 25 kg/mol	Kambour et al. (1988)
Ethylene	Dimethylsiloxane	Cloud point curve	I was oligomeric polyethylene with $M_w = 0.254$–2.234 kg/mol, and II was oligomeric polydimethylsiloxane with $M_w = 0.505$–4.5 kg/mol	Molner and Eisenberg (1992)

Table 21.4 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
Ethylene glycol	Propylene glycol	Miscibility stated	I and II both had $M_w <1,000$	Booth and Pickles (1973)
	Vinyl acetate	Single T_g	I had $M_w = 20$ kg/mol miscible with II; I had $M_w = 100$ kg/mol miscible with II when blend had ≤ 50 % II	Han et al. (1992)
	Sulfone	Scattering turbidimetry	Blends with II >40 wt% were homogeneous when I had $M_w = 3.5–4.5$ kg/mol and II had $M_w = 35.6$ kg/mol. Blends were heterogeneous at all compositions when I had $M_w = 200$ kg/mol	Swinyard et al. (1987)
Hydroxybutyrate	Lactide	Microscopy	Miscible when II had $M_n = 1.759$ kg/mol; immiscible when II had $M_n = 159.4$ kg/mol	Blumm and Owen (1995)
Cis-isoprene	Styrene	Single dynamic mechanical loss peak	I was natural rubber; II had $M_w \leq 0.375$ kg/mol; two peaks when II had $M_w \geq 0.600$ kg/mol	Class and Chu (1985b)
	Vinyl cyclohexane	Single dynamic mechanical loss peak	I was natural rubber; II had $M_w \leq 0.375$ kg/mol; two peaks when II had $M_w \geq 0.65$ kg/mol	Class and Chu (1985b)
Methyl methacrylate	Carbonate of bisphenol-A	Single T_g; transparency	Miscible when M_w of I/II were 2.4/38, 10.55/38, 60/9.9, and 105/99 kg/mol; immiscible when M_w of I/II were 20.3/38, 33.5/25.9, 33.5/38, and 60/38 kg/mol	Callaghan and Paul (1994a)
	Carbonate of hexafluor obisphenol-A-co-carbonate of tetramethy lbisphenol-A	Single T_g; transparency	II had 60 wt% HFPC and $M_w = 33$ kg/mol, and miscible when I had $M_w = 4–99$ kg/mol; when II had $M_w = 103$ kg/mol, it was miscible with I having $M_w = 4$ and 11 kg/mol only	Takakuwa et al. (1994)
	Styrene	Transparency	I was "high" M_w; ≤ 15 or 20 wt% II when II had $M_n = 2.1$ kg/mol; ≤ 5 or 10 wt% II when II had $M_n = 3.1$ kg/mol	Parent and Thompson (1978), Thompson (1980)
Methyl methacrylate-co-styrene	Styrene	Single T_g; transparency	I had 26 % styrene and II had 0.6 kg/mol or I had 62.6 % styrene and II had $M_w \leq 2.1$ kg/mol or I had 80 % styrene and II had $M_w \leq 4.0$ kg/mol	Massa (1979), Thompson (1980)

(continued)

Table 21.4 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
α-Methylstyrene	Styrene	Single T_g; transparency; neutron scattering	I had M_n = 4–80 kg/mol; II had M_n = 55–300 kg/mol	Baer (1964), Ballard et al. (1976), Black and Worsfold (1974), Cowie et al. (1992e), Dunn and Krause (1974), Robeson et al. (1974), Saeki et al. (1983), Schelten et al. (1976), Van Tam Bui et al. (1988), Widmaier and Mignard (1987)
	Styrene, deuterated	Single T_g	I had M_n = 25.8–78.3 kg/mol; II had M_n = 36.1–84.1 kg/mol	Rameau et al. (1989)
α-Methylstyrene-co-styrene	Styrene	Single T_g	I had M_n = 59–818 kg/mol; II had 3–79 mol% α-methylstyrene	Cowie et al. (1992e)
Styrene	Carbonate of bisphenol-A	Single T_g; transparency	I had M_w = 0.58, 0.68, 0.95, or 2.95 kg/mol; II had M_w = 3.8, 9, 25.9, or 38 kg/mol; miscibility depended on M_w and blend composition	Callaghan and Paul (1994a)
	Carbonate of tetramethylbisphenol-A	Single T_g; transparency	II had M_w = 30 kg/mol; miscible when I had M_w = 0.58, 0.68, or 9.5 kg/mol; immiscible when I had M_w = 2.95 kg/mol	Callaghan and Paul (1994a)
	Carbonate of tetramethylbisphenol-P	Single T_g; transparency	II had M_w = 31 kg/mol; miscible when I had M_w = 2.95 kg/mol; partially miscible when I had M_w = 9.2 or 17.5 kg/mol; immiscible when I had M_w = 341 kg/mol	Callaghan and Paul (1994a)
	o-Chlorostyrene-co-p-chlorostyrene	Single T_g	I had M_n = 2.2–93 kg/mol; II had 7–100 mol% o-chlorostyrene	Cimmino et al. (1992)
	Vinylmethylether	Single T_g	I had mol. wt. 0.8–233 kg/mol; II had MW 1.0–97.5 kg/mol	Yang et al. (1991), Schneider and Leikauf (1987)
	2-Vinyl naphthalene	Single T_g	I had M_w = 2.2 kg/mol; II had M_w ≤70 kg/mol	Semerek and Frank (1984)
p-Vinylphenol	Diethyl itaconate	Single T_g	II had M_w = 9.4 kg/mol and was miscible with I having M_w = 1.5–7, 9–11, 22, or 30 kg/mol; II had M_w = 61 kg/mol and was miscible with I having M_w = 1.5–7 and 9–11 kg/mol	Hong et al. (1995b)

Table 21.5 Polymer pairs that appear to have high temperature miscibility although immiscible at or below room temperature (UCST behavior)

Polymer I of	Polymer II of	Comments	Refs.
Acrylonitrile-co-styrene	N-Phenylmaleimide-co-styrene	I had 22–28 wt% AN and II had 56.2 wt% N-phenylmaleimide; I had 20–24 wt% AN and II had 49 wt% N-phenylmaleimide	Park et al. (2008)
	Styrene	I had 4–20 vol% acrylonitrile	Yang et al. (2004)
	Sulfone of tetramethylbisphenol-A	I had 9 wt% AN and II had M_w = 4.8 kg/mol; I had 11 wt% AN and II had M_w = 12.4 kg/mol	Callaghan and Paul (1994b), Pfefferkorn et al. (2012)
Aramide	Imide	I was Aramide 34I and II was polyimide UR	Nakata et al. (1993)
2-Bromoethyl methacrylate	2,2-Dimethyl-1,3-propylene sebacate	–	Neo and Goh (1993)
Butadiene	Butadiene	I had 98 % cis-1,4; II had 71 % vinyl-1,2 and 19 % trans-1,4	Shah et al. (1988)
	Butadiene, perdeuterated	Both I and II were cis-1,4	Bates et al. (1986)
	Butadiene-co-styrene	I was cis-1,4; II had 23–30 wt% styrene	Inoue et al. (1985), Maier et al. (1994), Pestov et al. (1978), Shah et al. (1989), Tager et al. (1987)
	Styrene	II was hydrogenated or partly deuterated; I and II had M_w = 2.0 kg/mol (Lin et al. 1985); I had M_w = 0.96 kg/mol and II had M_w = 9.0 kg/mol (Tomlins and Higgins 1989)	Lin et al. (1985), Lipson et al. (2003), Tomlins and Higgins (1989)
	Terpene, hydrogenated	I had 10–70.4 % 1,2-content	Kawahara and Akiyama (1993)
Butadiene-co-styrene	Styrene	II was hydrogenated or partly deuterated; II was 68.4 wt% styrene and had M_w of 10 kg/mol and II had M_w of 100 kg/mol	Lin et al. (1985)
n-Butyl methacrylate	n-Butyl methacrylate-co-methyl methacrylate	II had 29, 56, or 71 mol% methyl methacrylate	Sato et al. (1996a)
	Isobutyl methacrylate-co-methyl methacrylate	II had 23, 42, 58, or 75 mol% methyl methacrylate	Sato et al. (1996a)
Isobutyl methacrylate	n-Butyl methacrylate-co-methyl methacrylate	II had 29, 56, or 71 mol% methyl methacrylate	Sato et al. (1996a)
	Isobutyl methacrylate-co-methyl methacrylate	II had 23, 42, 58, or 75 mol% methyl methacrylate	Sato et al. (1996a)

Table 21.5 (continued)

Polymer I of	Polymer II of	Comments	Refs.
n-Butyl methacrylate-*co*-isobutyl methacrylate	Isobutyl methacrylate-*co*-methyl methacrylate	I had 13–87 mol% isobutyl methacrylate; II had 75 mol% methyl methacrylate	Sato et al. (1996b)
Caprolactone	Ester	II was made from adipoyl chloride and 4,4′-bis (6-hydrohexyloxy) biphenyl	Van Ende et al. (1992)
Carbonate of bisphenol-A	Biphenyl-4,4′ylene sebacate	II was liquid crystalline and blend had 50–80 wt % II	Jo et al. (1992a)
	1,4-Dimethylcyclohexane-*co*-ethylene terephthalate	II had 32–80 mol% dimethylcyclohexane	Kim et al. (2006)
	Etherester	II had a hard tetramethylene terephthalate segment and a soft polytetramethylene ether-glycol terephthalate segment	Gaztelumendi and Nazabal (1995)
	Methacrylic acid-*co*-styrene	II had 4–23 wt% methacrylic acid	Akiyama et al. (1991, 2001)
	Styrene	I had M_w = 6 kg/mol; II had M_w = 2.7 kg/mol; blend had 10–30 wt% I	Li et al. (1999b)
	Styrene, sulfonated	II had 6.5 mol% sulfonation and Li-neutralized	Lu and Weiss (1996b)
2-Chloroethyl methacrylate	2,2-Dimethyl-1,3-propylene sebacate	–	Neo and Goh (1992b)
3-Chloropropyl methacrylate	2,2-Dimetyl-1,3-propylene sebacate	–	Low et al. (1994c)
Chlorostyrene-*co*-styrene	2,6-Dimethyl-1,4-phenylene ether	I had 32.9 mol% styrene	Fried et al. (1978), Wetton et al. (1978)
Cyclohexyl methacrylate	Cyclohexyl acrylate	–	Siol (1991)
2,6-Dimethyl-1,4-phenylene ether	*p*-Methylstyrene	–	Woo et al. (2002)
	p-Methylstyrene + styrene	The ternary blend system exhibited UCST	Chou et al. (2002)
Dimethylsiloxane	Hexylmethylsiloxane	–	Stammer and Wolff (1998)
	Methylethylsiloxane	–	Horiuchi et al. (1991)
	Phenylmethylsiloxane	–	Kuo and Clarson (1990)
Epoxy	Acrylonitrile-*co*-butadiene, carboxyl terminated	I was Epon 828, M_n = 380; II had 17 wt% acrylonitrile, M_n = 3,500	Lee and Quin (1989)
	2,6-Dimethyl-1,4-phenylene ether	Optical and electron microscopy	Pearson and Yee (1993)

(*continued*)

Table 21.5 (continued)

Polymer I of	Polymer II of	Comments	Refs.
Etherethersulfone	Etheretherketone-*co*-etherethersulfone	II had 50 % etherethersulfone	Sham et al. (1988a)
Etherimide	Butylene terephthalate	–	Chen et al. (1997)
	Ethylene naphthalate-*co*-ethylene terephthalate	The higher the ethylene naphthalate content in II, the lower the UCST	Kinami et al. (1995)
Etherketone	Imide, thermoplastic	–	Sauer et al. (1996)
Ethyl methacrylate	*n*-Butyl acrylate-*co*-styrene	II had 63 wt% styrene	Rana et al. (2000)
	Ethyl acrylate	–	Siol and Terbrack (1991)
Ethylene	Butane-*co*-ethylene	I was LLDPE; II had 26 mol% butene	Li et al. (2004)
	Ethylene	I was HDPE; II was LLDPE containing 5.3 mol% octene	Stephens et al. (2003)
	Ethylene-*co*-propylene	II was alternate copolymer (Choi et al. (2006))	Choi et al. (2006), Lipson et al. (2003)
	Propylene	II was atactic; no UCST when II was isotactic; from high temperature phase diagrams (Kosai and Higashino (1975)); II was head-to-head (Lipson et al. (2003)); I was LLDPE (Lo et al. (2004))	Kosai and Higashino (1975), Lipson et al. (2003), Lo et al. (2004)
Ethylene, chlorinated	Ethylene, chlorinated	Cl contents = 40–50 wt%	Ueda and Karasz (1985)
Ethylene glycol	Caprolactone	–	Chuang et al. (2005)
	2-Ethylhexyl methacrylate-*co*-methyl methacrylate	II had 7.7–31.0 mol% 2-ethylhexyl methacrylate	Takeshita et al. (2005)
	n-Hexyl methacrylate-*co*-methyl methacrylate	II had 7.8–21.1 mol% *n*-hexyl methacrylate	Takeshita et al. (2005)
Hemicellulose	Lignin	Blend had 10, 80, or 90 vol% of II	Shiyematsu et al. (1994)
3-Hydroxybutyrate	Ethylene adipate	–	Hsieh and Woo (2011)
	Ethylene succinate	–	Hsieh and Woo (2011)
2-Iodoethyl methacrylate	2,2-Dimethyl-1,3-propylene sebacate	–	Low et al. (1994c)
Isophthalamide-6I (iminoisophthaloyl-iminohexamethylene)	Hexamethylene adipamide	Interchange reaction slow	Zimmerman et al. (1973)
Isoprene	Vinylethylene	II was syndiotactic and had 92 % vinyl-1,2-	Iriarte et al. (1991)
Lactide	Ethylene succinate	–	Hsieh et al. (2012)
	Trimethylene adipate	–	Hsieh et al. (2012)
Maleic anhydride-*co*-styrene	Sulfone of tetramethylbisphenol-A	I had 14 wt% maleic anhydride; II had $M_w = 4.8$ kg/mol	Callaghan and Paul (1994b)
	Alkyl methacrylate	I had an alkyl group of *n*-butyl or isobutyl	Sato et al. (1996a)

(*continued*)

Table 21.5 (continued)

Polymer I of	Polymer II of	Comments	Refs.
Methyl methacrylate	Carbonate of bisphenol-A	I had M_w = 1.21 or 2.4 kg/mol; II had M_w = 33 kg/mol	Callaghan and Paul (1994a)
	Carbonate of tetrachlorobisphenol-A	I had M_w = 1.21 kg/mol; II had M_w = 41 kg/mol	Callaghan and Paul (1994a)
	Carbonate of tetramethylbisphenol-P	I had M_w = 1.21 or 2.4 kg/mol; II had M_w = 31 kg/mol	Callaghan and Paul (1994a)
	Ester	II was ethylene adipate, 1,3-trimethylene adipate, 1,4-butylene adipate, ethylene azelate, caprolactone, or hexamethylene adipate	Li and Woo (2008a)
	Hydroxybutyrate	–	Siciliano et al. (1995)
	Lactide	I was atactic or syndiotactic	Li and Woo (2008c)
	Styrene	II had M_n = 600; M_w of I was 1,950, 2,950, or 9,200 and M_w of II was 2,030, 2,400, 4,250, 10,550, or 60,000 (Callaghan and Paul (1993))	Callaghan and Paul (1993), Ougizawa and Walsh (1993), Massa (1988)
	Sulfone of tetramethylbisphenol-A	I had M_w = 1.21 or 2.4 kg/mol; II had M_w = 4.8 or 12.4 kg/mol	Callaghan and Paul (1994b)
	Sulfone of tetramethylhexafluorobisphenol-A	I had M_w = 1.21 kg/mol; I had M_w = 40 kg/mol	Callaghan and Paul (1994b)
	Sulfone of tetramethylbisphenol-P	I had M_w = 1.21 kg/mol; II had M_w = 40 kg/mol	Callaghan and Paul (1994b)
	Vinyl butyral	–	Chen et al. (2001)
	Vinyl chloride	–	Razinskaya et al. (1985)
Methyl methacrylate-co-styrene	Ethylene glycol	–	Sato et al. (1998)
	Styrene	–	Sato et al. (1998)
1,3-Phenylene adipamide	Hexamethylene adipamide	I was made from m-phenylenediamine and adipic acid; interchange reaction slow	Zimmerman et al. (1973)
Propylene	Propylene	I and II had different tacticities	Woo et al. (2007)
Sebacic acid	1,6-Bis(p-carboxyphenoxy) hexane	–	Kipper et al. (2004)
Styrene	3-Alkylthiophene	II had an alkyl group of butyl, hexyl, octyl, or dodecyl	Lee et al. (2009)
	Caprolactone	I had M_n = 950	Nojima et al. (1986b)
	Carbonate of bisphenol-A	I was sulfonated and Zn-neutralized; I had 8.7–13.7 mol% sulfonation	Xie and Weiss (1998)

<div align="right">(continued)</div>

Table 21.5 (continued)

Polymer I of	Polymer II of	Comments	Refs.
	Carbonate of bisphenol chloral	I had M_w = 0.58 or 0.68 kg/mol; II had M_w = 30 kg/mol	Callaghan and Paul (1994a)
	Isoprene	I had low M.W.; UCST was depressed in the presence of supercritical carbon dioxide	Walker et al. (1999)
	α-Methylstyrene	UCST increased with molecular weight	Lim and Roe (1988)
	o-Methylstyrene	–	Antonietti et al. (1986)
	p-Methylstyrene	–	Antonietti et al. (1986), Chang and Woo (2001a, 2003a), Stroeks et al. (1991)
	m-Methylstyrene	–	Antonietti et al. (1986)
	Styrene, brominated	II had 27 or 29 mol% brominated units	Stoelting et al. (1970)
	Styrene, deuterated	–	Bates and Wignall (1968), Yang et al. (1986b)
	Styrene, sulfonated	II had 0.7 mol% sulfonated and neutralized with Na, Ba, or Zn	Zhou et al. (2007)
	Sulfone of tetramethylbisphenol-A	I had M_w = 1.21 or 2.4 kg/mol; II had M_w = 4.8 or 12.4 kg/mol	Callaghan and Paul (1994b)
	Sulfone of tetramethylbisphenol-P	I had M_w = 1.21 kg/mol; II had M_w = 40 kg/mol	Callaghan and Paul (1994b)
	Sulfone of tetramethylhexafluorobisphenol-A	I had M_w = 1.21 kg/mol; II had M_w = 40 kg/mol	Callaghan and Paul (1994b)
	Vinylmethylether	By SANS and by extrapolation of solution data	Cowie et al. (1990c), Kim et al. (2002b)
Urethane	Styrene-co-p-vinylphenol	I was liquid crystalline; II had 5–50 mol% vinylphenol	Viswanathan and Dadmun (2003)
Vinyl chloride	Acrylonitrile-co-methyl methacrylate-co-α-methylstyrene	II had 32.3 wt% AN, 8.1 wt% MMA; blend had 50–80 wt% II	Kovacic et al. (1994)
Vinylidene fluoride	Methyl methacrylate	–	Tomura et al. (1992)
Vinylidene fluoride-co-tetrafluoroethylene	Vinylidene fluoride-co-hexafluoroacetone	I had 80 mol% vinylidene fluoride; II had 92 mol% vinylidene fluoride	Cho et al. (1993)
Vinylmethylether	Alkyl methacrylate	II had an alkyl group of n-propyl or isopropyl	Woo and Juang (2007)

Table 21.6 Polymer pairs miscible at room temperature that appear to have a lower critical solution temperature (LCST) above room temperature

Polymer I of	Polymer II of	Comments	Refs.
Acrylic acid, Li-neutralized	Ethylene glycol	0.1–0.4 mol fraction of I was neutralized	Lu and Weiss (1995)
Acrylic acid-*co*-styrene	Ethyl methacrylate	I had 8.84 wt% acrylic acid	Brannock et al. (1990)
	Methyl methacrylate	I had 2.65–20.0 wt% acrylic acid	Wang et al. (1990), Jo et al. (1991b)
	n-Propyl methacrylate	I had 2.65–8.84 wt% acrylic acid	Wang et al. (1990)
Acrylonitrile-butadiene-methyl acrylate	Ethylene-alt-maleic anhydride	I was Barex 210	Percec and Melamud (1993)
Acrylonitrile-*co*-α-methylstyrene	Acetonyl methacrylate	I had 30 wt% acrylonitrile (AN)	Goh and Lee (1990d)
	Acrylonitrile-*co*-styrene	II had 28–40 wt% AN	Aoki (2000), Lath et al. (2000)
	n-Butyl methacrylate	I had 12 wt% AN	Cowie and Elexpuru (1992)
	n-Butyl methacrylate-*co*-methyl methacrylate	I had 30 wt% AN; II had 70 wt% methyl methacrylate	Goh et al. (1984a)
	Carbonate of tetramethylbisphenol-A	I had 4–16.5 wt% AN	Gan et al. (1994a)
	Ethyl methacrylate	I had 30 wt% AN (Goh et al. 1982b); II had 10–28 wt% AN (Cowie and Elexpuru (1992))	Cowie and Elexpuru (1992), Goh et al. (1982b)
	Ethyl methacrylate-*co*-methyl methacrylate	I had 30 wt% AN; II had 60 wt% methyl methacrylate	Goh et al. (1984a)
	Methoxymethyl methacrylate	I had 30 wt% AN	Goh and Lee (1990d)
	Methyl methacrylate	I had 30 wt% AN and II was atactic or isotactic (Goh et al. 1982b); I had 31.3, 33.1, 34.8, or 41.3 wt% AN (Suess et al. 1986); I had 10–37 wt% AN (Cowie et al. 1991a)	Cowie and Elexpuru (1992), Goh et al. (1982b), Gan et al. (1994a), Suess et al. (1986)
	Methyl methacrylate-*co*-2,2,6,6-tetramethylpiperidinyl methacrylate	I had 30 wt% AN; II had ≥76.2 wt% methyl methacrylate	Goh et al. (1986b, 1987)
	Methylthiomethyl methacrylate	I had 30 wt% AN	Goh et al. (1991b)
	n-Propyl methacrylate	I had 17–20 wt% AN	Cowie and Elexpuru (1992)
	Tetrahydrofurfuryl methacrylate	I had 30 wt% AN	Goh and Siow (1987)
	Vinyl chloride	I had 11.9–30 wt% AN	Gan et al. (1994a)

Acrylonitrile-*co*-*p*-methylstyrene	Acetonyl methacrylate	I had 43.0–61.0 wt% AN	Chong and Goh (1992c)
	Alkyl methacrylate	II had an alkyl group of 1-chloroethyl and I had 10–40 wt% AN; II had an alkyl group of 2,2-dichloroethyl and I had 8–44 wt% AN	Goh et al. (1996c)
	n-Butyl methacrylate	I had 13.6 wt% AN	Goh et al. (1991a)
	Cyclohexyl methacrylate	I had 15.8–21.3 wt% AN	Chong and Goh (1992d)
	Ethyl methacrylate	I had 26.5–32.3 wt% AN	Goh et al. (1991a)
	n-Propyl methacrylate	I had 21.3–26.5 wt% AN	Goh et al. (1991a)
	Tetrahydrofurfuryl methacrylate	I had 32.3–46.5 wt% AN	Goh et al. (1991a)
	Tetrahydropyranyl-2-methyl methacrylate	I had 23.8–26.5 wt% AN	Chong and Goh (1992b)
Acrylonitrile-*co*-styrene	Copolycarbonate of bisphenol-A and tetramethylbisphenol-A	Some blends showed LCST, depending on compositions of I and II	Kim and Paul (1992e)
	Acetonyl methacrylate	I had 33–58 wt% AN	Chong and Goh (1992c)
	Acrylonitrile-*co*-methyl methacrylate	Some blends showed LCST	Nishimoto et al. (1989)
	Alkyl methacrylate	II had an alkyl group of 1-chloroethyl and I had 9–30 wt% AN; II had an alkyl group of 2,2-dichloroethyl and I had 9–41 wt% AN	Goh et al. (1996c)
	Benzyl methacrylate	I had 3.5–24.4 wt% AN	Woo et al. (2000b)
	Butyl methacrylate-*co*-methyl methacrylate	Some blends showed LCST	Kammer and Piglowski (1989)
	Caprolactone	I had 28 % AN	McMaster (1973), Madbouly et al. (2006), Oudhuis et al. (1994)
	Carbonate of dimethylbisphenol-A-*co*-carbonate of tetramethylbisphenol-A	I had 2, 10, or 15 wt% AN; II had 60, 74, or 83 wt% tetramethylbisphenol-A	Kim et al. (2003a)
	Cyclohexyl methacrylate	I had 13.4–19.8 wt% AN	Chong and Goh (1992d)

(continued)

Table 21.6 (continued)

Polymer I of	Polymer II of	Comments	Refs.
	2,6-Dimethyl-1,4-phenylene ether, benzoylated	I and 18 mol% AN; II had 35 % benzoylated unit	Song et al. (1991)
	Ethyl methacrylate	I had 5.5–28 wt% AN	Fowler et al. (1987), Lath et al. (1992)
	2-Hydroxyethyl methacrylate	I had 28.4 or 30 wt% AN; II had 1.4 or 2 wt% hydroxyethyl methacrylate	Chu and Paul (2000)
	Maleic anhydride-*co*-styrene	Some blends showed LCST	Fang et al. (2007), Kim et al. (1989b), Kressler et al. (1988), Maruta et al. (1988)
	Methoxymethyl methacrylate	I had 30 wt% AN	Goh and Lee (1988b)
	Methyl methacrylate	I had 9.4, 9.8, 27.0, 28.2, 30.5, or 34.4 wt% AN (Lemieux et al. 1988); I had 29.4–39.3 wt% AN (Cowie et al. 1988)	Bernstein et al. (1977), Cowie et al. (1988), Kressler et al. (1986), Lemieux et al. (1988), McMaster (1975)
	Methyl methacrylate-*co*-2,2,6,6-tetramethylpiperidinyl methacrylate	I had 22 or 30 wt% AN; II had 69, 74, or 85.5 wt% methyl methacrylate	Goh et al. (1986b, 1987)
	Methyl methacrylate-*co*-N-phenylmaleimide	I had 24.6 wt% AN; II had 23.5 wt% N-phenylmaleimide	DeMeuse and Jaffe (1989)
	Methyl methacrylate-*co*-2,4,5-tribromostyrene	I had 33 wt% AN; II had 8 or 14 wt% tribromostyrene	Chu et al. (2000)
	Methylthiomethyl methacrylate	I had 34.5 wt% AN	Goh et al. (1992b)
	Phenyl acrylate	I had 14.6, 29.9, or 34.1 wt% AN	Sankarapandian and Kishore (1991), Rana et al. (1993)
	n-Propyl methacrylate	I had 5.7–19.5 wt% AN	Fowler et al. (1987), Lath and Lathova (1994)
	Tetrahydrofurfuryl methacrylate	I had 34.5–46.6 wt% AN	Goh et al. (1992a)
	Tetrahydropyranyl-2-methyl methacrylate	I had 2.2 or 22–30.5 wt% AN	Chong and Goh (1992b)
	Vinyl chloride	I had 11.5–26 wt% AN	Kim et al. (1989)

Aramide	Caprolactam-*co*-laurolactam	I was Trogamid T; II had 43.8 mol% caprolactam	Ellis (1990b)
Arylsulfone	Imide	I was Radel A; II was XU 218	Jeremic et al. (1992)
2-Bromoethyl methacrylate	Vinyl acetate	Blends cast from methyl ethyl ketone	Neo and Goh (1992a)
Butadiene	Butadiene	I had 50 % vinyl-1,2, 35 % *cis*-1,4, and 15 % *trans*-1,4; II had 55 % *cis*-1,4, 35 % *trans*-1,4, and 10 % vinyl-1,2	Shah et al. (1988)
	Isoprene	I had £ 59 % 1,4 content and II was *cis*-1,4 isomer (Trask and Roland 1988); I was deuterated and II was protonated (Hasegawa et al. 1991); I had 32.3 mol% 1,2 (Kawahara et al. 2002)	Hasegawa et al. (1991), Kawahara et al. (2002), Trask and Roland (1988)
Butyl acrylate	Alkyl methacrylate	II had an alkyl group of 1-chloroethyl or dichloroethyl	Peng et al. (1996)
	Ethylene, chlorinated	–	Chai and Walsh (1983)
	Hexafluoroacetone-*co*-vinylidene fluoride	–	Kano et al. (1997b)
	Vinyl chloride	–	Piglowski and Kammer (1990), Walsh and Cheng (1982), Walsh and McKeown (1980), Walsh and Sham (1989)
Butyl methacrylate	*p*-(2-Hydroxy hexafluoroisopropyl) styrene-*co*-styrene	II had 90.3–90.8 mol% styrene	Pearce et al. (1984)
N-Butyl-3-hydroxymethyl-carbazoyl methacrylate	o-Hydroxybutyl-3,5-dinitrobenzoyl methacrylate	–	Guerra et al. (1986)
Butylene adipate	Trifluoroethylene-*co*-vinylidene fluoride	–	Kim and Kyu (1999, 2003)
	Vinylidene fluoride	–	Penning and Manley (1996)
p-Tert-butylstyrene	1,2-Butadiene	–	Yurekli and Krishnamoorti (2004)
	Cyclohexyl acrylate	–	Siol (1991)
	Cyclohexyl methacrylate	–	Siol (1991)
	Isoprene	–	Yurekli and Krishnamoorti (2004)

(*continued*)

Table 21.6 (continued)

Polymer I of	Polymer II of	Comments	Refs.
Caprolactone	Benzyl methacrylate	–	Mandal and Woo (1998, 1999c)
	Ethylene, chlorinated	II had 30 or 42.1 wt% Cl	Belke and Cabasso (1988), Defieuw et al. (1989c)
	Lactide	–	Meredith and Amis (2000)
	Vinylidene fluoride	Blends rich in I showed LCST	Jo et al. (1992b)
Carbon monoxide-*co*-ethyl acrylate-*co*-ethylene	Vinyl chloride	I had 13.8/7.41/78.8 = carbon monoxide/ethyl acrylate/ethylene	Robeson and McGrath (1977)
Carbonate of bisphenol-A	Benzoyl methacrylate	–	Ha et al. (2001)
	Caprolactone	Thermal diffusivity measurements (Tsutsumi and Kano 1999)	Bernstein et al. (1977), Cruz et al. (1979a), Paul et al. (1977), Tsutsumi and Kano (1999)
	Cyclohexyl methacrylate-*co*-methyl methacrylate	II had £ 3.3 wt% cyclohexyl methacrylate (Min et al. 1990); II had 14.7–34.3 wt% cyclohexyl methacrylate (Brisson and Breault 1991)	Brisson and Breault (1991), Min et al. (1990)
	Cyclohexyl methacrylate-*co*-methyl methacrylate-*co*-2,4,6-tribromophenyl methacrylate	II had 70 wt% methyl methacrylate, and 10 wt% cyclohexyl methacrylate	Ohnaga et al. (1997)
	Methyl methacrylate	Blends prepared by precipitation of tetrahydrofuran solutions by *n*-heptane or by solution casting from tetrahydrofuran at high temperature	Chiow et al. (1987), Landry and Hendrichs (1989), Kyu and Saldanha (1988)
	Methyl methacrylate-*co*-*p*-methylstyrene	II had $\geq$70 wt% methyl methacrylate	Ikawa and Hosoda (1991)
	Methyl methacrylate-*co*-*N*-phenylmaleimide	II had $\geq$70 wt% methyl methacrylate	Ikawa and Hosoda (1991)
	Methyl methacrylate-*co*-phenyl methacrylate	II had 16–63 wt% phenyl methacrylate	Brisson and Breault (1991), Ohnaga et al. (1997)

	Methyl methacrylate-co-styrene	II had £ 14 wt% styrene	Min and Paul (1989)
	Methyl methacrylate-co-2,4,6-tribromophenyl methacrylate	II had 52.3–90 wt% methyl methacrylate	Ohnaga et al. (1997)
Carbonate of dimethylbisphenol-A	Styrene	Blend had <60 wt% I	Park et al. (2001b)
Carbonate of hexafluorobisphenol-A	Alkyl methacrylate	II had an alkyl group of ethyl, n-propyl, or isopropyl	Kim and Paul (1992a, d)
Carbonate of 2,2-propane-bis(4-(2-methylphenyl))-co-carbonate of 2,2-propane-bis(4-(2,6-dimethylphenyl))	Methyl methacrylate-co-styrene	I had $\geq$60 wt% carbonate of 2,2-propane-bis(4-(2,6-dimethylphenyl)); II had $\leq$37 wt% methyl methacrylate	Yoo and Kim (2004a)
Carbonate of tetramethylbisphenol-A	Acrylonitrile-co-styrene	II had 2 or 11.5 % acrylonitrile	Fernandes et al. (1986d)
	Methyl methacrylate-co-styrene	II had 4.5, 32.5, 33.5, or 35 wt% methyl methacrylate (Min and Paul 1987); II had 4.5–33.5 wt% methyl methacrylate (Kim and Paul 1992c)	Kim and Paul (1992c), Min and Paul (1987), Yu et al. (1991)
	Pentabromobenzyl acrylate-co-styrene methacrylate	II had 19.8 or 33.9 wt% pentabromobenzyl methacrylate	Merfeld and Paul (2000)
	Styrene	I had M_w = 341 kg/mol; II had M_w = 33 kg/mol (Callaghan and Paul 1994a)	Callaghan and Paul (1994a), Iller et al. (1984), Kim and Paul (1992b), Shaw (1974)
Carbonate of tetramethylbisphenol-P	Styrene	I had M_w = 9.2 kg/mol; II had M_w = 31 kg/mol	Callaghan and Paul (1994a)
Cellulose acetate	4-Vinyl pyridine	I was 10H/2 glucose	Cabasso (1981)
Cellulose acetate butyrate	Ethylene glycol	–	Park and Kim (2002)
1-Chloroethyl methacrylate	Alkyl methacrylate	The alkyl group of II was ethyl, n-propyl, isopropyl, or n-butyl	Peng et al. (1993)
2-Chloroethyl methacrylate	Ethyl methacrylate	–	Neo et al. (1991b)
Chloromethyl methacrylate	Alkyl methacrylate	II had an alkyl group of ethyl, n-propyl, or isopropyl	Goh et al. (1990a)
o-Chlorostyrene	Styrene	–	Alexandrovich et al. (1980)
o-Chlorostyrene-co-p-chlorostyrene	2,6-Dimethyl-1,4-phenylene ether	–	Alexandrovich et al. (1977)
	Styrene	I had 71–92 mol% ortho isomer	Ten Brinke et al. (1984)

(continued)

Table 21.6 (continued)

Polymer I of	Polymer II of	Comments	Refs.
o-Chlorostyrene-co-o-fluorostyrene	2,6-Dimethyl-1,4-phenylene ether	I had about 14–40 mol% ortho-chloro isomer	Vukovic et al. (1982a, 1985)
p-Chlorostyrene-co-o-fluorostyrene	2,6-Dimethyl-1,4-phenylene ether	I had 66–74 mol% para isomer	Vukovic et al. (1982a, 1985)
Cyclohexyl methacrylate-co-methyl methacrylate	Carbonate of bisphenol-A	I had 9.5–40.4 wt% CHMA	Park et al. (2001b)
	Carbonate of dimethylbisphenol-A	I had 28.5–66.7 wt% CHMA	Park et al. (2001b)
	Carbonate of tetramethylbisphenol-A	I had 0–36.7 wt% CHMA	Park et al. (2001b)
2,2-Dichloroethyl methacrylate	Alkyl methacrylate	II had an alkyl group of n-propyl, isopropyl, n-butyl, or isoamyl	Low et al. (1994b)
2,6-Dimethyl-1,4-phenylene ether	Acrylic acid-co-styrene	II had 6.3 or 8.5 wt% acrylic acid	Gottschalk et al. (1994)
	Acrylonitrile-co-styrene	II had 6.3 wt% acrylonitrile	Gottschalk et al. (1994)
	o-Fluorostyrene-co-p-fluorostyrene	II had 10–38 % para isomer	Vukovic et al. (1983b)
	o-Fluorostyrene-co-p-bromostyrene	II had 68 or 73 mol% bromostyrene	Vukovic et al. (1988)
	o-Fluorostyrene-co-styrene	II had 9–20 mol% styrene	Vukovic et al. (1981, 1982)
	p-Fluorostyrene-co-styrene	II had about 22–54 mol% styrene	Maeda et al. (1989), Vukovic et al. (1981, 1982)
	Maleic anhydride-co-styrene	II had 4.6, 8.0, or 9.9 wt% maleic anhydride (Witteler et al. (1993)); II had 7.3, 8.5, 10, or 12.5 wt% maleic anhydride (Gottschalk et al. (1994))	Gottschalk et al. (1994), Witteler et al. (1993)
	Methyl methacrylate-co-styrene	II had 12.5, 15, or 20 wt% methyl methacrylate	Gottschalk et al. (1994)
	α-Methylstyrene	–	Woo et al. (2003a)
2,6-Dimethyl-1,4-phenylene ether, sulfonylated	Phenylvinyl sec-butyl ether-alt-N-phenylmaleimide	I had 87 % sulfonylation	Vukovic et al. (1994d)
	Phenylvinyl ethyl ether-alt-N-phenylmaleimide	I had 87 or 91 % sulfonylation	Vukovic et al. (1994d)
Dodecamethylene decamethylene dicarboxylate	Vinyl chloride	–	Woo et al. (1985b)
Dodecamethylene dodecamethylene dicarboxylate	Vinyl chloride	–	Woo et al. (1985b)
	Vinyl chloride-co-vinylidene chloride	II had 13.5 wt% vinyl chloride	Woo et al. (1986)

Epichlorohydrin	Alkyl acrylate	II had an alkyl group of ethyl or n-propyl	Fernandes et al. (1986c)
	Alkyl methacrylate	II had an alkyl group of methyl, ethyl, n-propyl, n-butyl, or cyclohexyl	Fernandes et al. (1986b)
	Vinyl acetate	–	El Shafee (2002b), Guo (1991)
	N-Vinylpyrrolidone	–	Guo (1990d)
Etherimide	Amideimide	Examined by thermo-optical analysis	Ryu et al. (2000)
	Etheretherketone	–	Nandan et al. (2002)
	Ethylene glycol	Examined by thermo-optical analysis	Ryu et al. (2000)
	Styrene	Examined by thermo-optical analysis	Ryu et al. (2000)
Ethersulfone	N,N-Dimethylacrylamide	–	Goh et al. (1997)
	Imide	II was Matrimide 5218	Liang et al. (1992)
Ethyl acrylate	Alkyl methacrylate	II had an alkyl group of chloromethyl, 1-chloroethyl, 2-chloroethyl, 1,3-difluoroisopropyl	Peng et al. (1996)
	Vinylidene fluoride	–	Bernstein et al. (1977), Wahrmund et al. (1978)
	Hexafluoroacetone-co-vinylidene fluoride	II had 8 mol% hexafluoroacetone	Kano and Akiyama (1992), Kano et al. (1995), Kano et al. (1997a)
2-Ethylhexyl methacrylate	Hexyl methacrylate-co-styrene	I had 3–5 % acrylic acid; II had 30 % styrene and 5–15 % 3-(dimethylamino) 2,2-dimethylpropyl methacrylate	Siol and Terbrack (1991)
N-Ethyl-3-hydroxymethylcarbazoyl methacrylate	ω-Hydroxyalkyl-3,5-dinitrobenzoyl methacrylate	II had an alkyl group of butyl, hexyl, propyl of pentyl	Rodriguez-Parada and Percec (1986a)
Ethyl methacrylate	n-Butyl methacrylate-co-styrene	II had 23 or 34 wt% styrene	Rana et al. (2000)
	p-(2-Hydroxy hexafluoroisopropyl) styrene-co-styrene	II had 90.3–98.8 mol% styrene	Pearce et al. (1984)
	Vinyl chloride-co-vinylidene chloride	II had 86.5 wt% vinylidene fluoride	Woo et al. (1984b)
	Vinylidene fluoride	I was syndiotactic or atactic; LCST below T_m of II if I had high M_w isotactic	Bernstein et al. (1977), Roerdink and Challa

Table 21.6 (continued)

Polymer I of	Polymer II of	Comments	Refs.
			(1980), Ten Brinke et al. (1982)
2-Ethyl-2-oxazoline	Aramide	–	Maeda et al. (1986)
	Ethersulfone	–	Nakamura et al. (1990)
Ethylene, chlorinated	Ethylene-co-vinyl acetate	I had 35.4–52.6 wt% Cl; II had 40–45 wt% vinyl acetate	Walsh et al. (1983)
	Methyl methacrylate	I had 50–52 wt% Cl	Chai et al. (1983), Walsh et al. (1982)
Ethylene orthophthalate	Vinyl acetate	I had M_n = 9.5 kg/mol; no LCST when I had M_n = 5.1 kg/mol	Vazquez-Torres and Cruz-Ramos (1986)
Ethylene glycol	n-Butyl methacrylate	–	El Shafee and Ueda (2002)
	Enaminonitrile	–	Mondragon et al. (1983)
	Ethersulfone	–	Dreezen et al. (1991), Guo and Higgins (1991), Maejima et al. (1998), Shibanov and Radzhabov (1988), Walsh and Singh (1984)
	Ethylene-co-vinyl acetate	–	Chung and Chen (1990)
	Hydroxyether sulfone	–	H194
	Sulfone	M_n of I = 3,500–4,500; II was Udel Piglowski (1990)00	Swinyard et al. (1987)
	Vinyl acetate	LCST decreased with increasing M_w of II	Chen et al. (1999)
	Vinylphosphonic acid	Blend had ≤50 wt% I	Jiang et al. (2010)
Ethylene-co-vinyl acetate	Aniline, N-octadecylated	I had 20 wt% vinyl acetate; II had a degree of alkylation of 60.2 wt%	Zheng et al. (1995)
	Hexafluoroacetone-co-vinylidene fluoride	I had 70 % vinyl acetate; II had 8.9 mol% hexafluoroacetone	Hasegawa and Akiyama (1988)
	Vinyl chloride	I had 30 or 37 wt% ethylene	Nolley et al. (1979), Rellick and Runt (1986), Thaumaturgo and Monteiro (1997b)

Ethylene-*co*-vinyl alcohol	Amide	II was a copolyamide of PA-6 and PA-12	Akiba and Akiyama (1994)
2-Fluoroethyl methacrylate	Alkyl methacrylate	II had an alkyl group of methyl or ethyl	Peng et al. (1993)
3-Fluoropropyl methacrylate	Methyl methacrylate	–	Peng et al. (1995)
Hexadecamethylene dodecamethylene dicarboxylate	Vinyl chloride	–	Woo et al. (1985b)
Hydroxyether of bisphenol-A (Phenoxy)	Alkyl methacrylate	II had an alkyl group of methyl, tetrahydrofurfuryl or tetradropyranyl-2-methyl	Chiou and Paul (1991), Chong and Goh (1992a), Goh (1987)
	Ester	II was neopentyl glycol adipate or neopentyl glycol succinate	Harris et al. (1982)
	Ethersulfone	–	Saito et al. (1990), Singh and Walsh (1986)
	Ethylene oxide-*co*-propylene oxide	EO content of II = 22, 50, or 56 mol%	Guo et al. (1993a)
	Vinylmethylether	–	Ueda and Karasz (1992)
Hydroxyether of phenolphthalein	Butylene terephthalate	–	Guo et al. (1990d)
	Ethersulfone	–	Guo (1992b)
	Ethylene glycol	–	Guo et al. (1990c)
β-Hydroxyethyl-3,5-dinitrobenzoyl methacrylate	*N*-Alkyl-3-hydroxymethylcarbazoyl methacrylate	II had an alkyl group of butyl, decyl, dodecyl, ethyl, hexadecyl, hexyl, octyl, or tetradecyl	Rodriguez-Parada and Percec (1986b)
2-(Hydroxyl-hexafluoroisopropyl) styrene-*co*-styrene	Hydroxypropyl L-glutamine	I had 98.5 mol% styrene; blend had <50 vol% II	Dadmun and Han (1993)
	Methyl methacrylate	I had 90.3–96.1 mol% styrene	Pearce et al. (1984)
	Vinylmethylether	I had 90.3–99.9 mol% styrene	Pearce et al. (1984)
2-Iodoethyl methacrylate	Tetrahydrofurfuryl methacrylate	–	Low et al. (1993d)
Isoprene	*Cis*-butadiene-*co*-1,2-vinylbutadiene	II had £ 24.3 % vinylbutadiene	Kawahara et al. (1989)
Maleic anhydride-*co*-styrene	Ethyl methacrylate	I had 0–33 wt% maleic anhydride	Brannock et al. (1991)
	N-Methyl glutarimide	I had 14 wt% maleic anhydride	Prinos et al. (1997)
	Methyl methacrylate	I had 8, 10, 13, or 33 wt% maleic anhydride	Brannock et al. (1991)
	n-Propyl methacrylate	I had 0–18.1 wt% maleic anhydride	Brannock et al. (1991)

(continued)

Table 21.6 (continued)

Polymer I of	Polymer II of	Comments	Refs.
Methacrylonitrile-*co-p*-methylstyrene	*n*-Butyl methacrylate	I had 15, 17, 22, 23, or 25 wt% methacrylonitrile (MAN)	Chen and Porter (1993)
	Ethyl methacrylate	I had 40, 46, or 53 wt% MAN	Chen and Porter (1993)
	Isopropyl methacrylate	I had 22, 23, 25, or 31 wt% MAN when II had $M_n = 161$ kg/mol; I had 17, 22, 23, 25, or 31 wt% MAN when II had $M_n = 41.6$ kg/mol	Chen and Porter (1993)
	Methyl methacrylate	I had 34, 53, 56, or 68 wt% MAN	Chen and Porter (1993)
	n-Propyl methacrylate	I had 37 or 40 wt% MAN	Chen and Porter (1993)
Methacrylonitrile-*co*-styrene	Methyl methacrylate	I had 46.6–62.8 wt% MAN	Goh et al. (1993)
	n-Propyl methacrylate	I had 2–32 wt% methacrylonitrile	Chen et al. (1994)
Methyl acrylate	1,3-Difluoroisopropyl methacrylate	–	Peng et al. (1996)
	Hexafluoroacetone-*co*-vinylidene fluoride	II had 8 mol% hexafluoroacetone	Kano et al. (1997c)
	Vinylidene fluoride	–	Bernstein et al. (1977), Wahrmund et al. (1978)
Methyl methacrylate	Acrylonitrile-*co*-methyl methacrylate-*co*-styrene	II had 40.0/39.1/20.9 or 61.1/19.6/19.3 of S/MMA/AN	Nishimoto et al. (1989)
	Carbonate of bisphenol-A-*co*-hexafluorobisphenol-A	II had 5.3–14 wt% hexafluorobisphenol-A	Kim and Paul (1992d)
	Carbonate of bisphenol chloral	–	Chiou and Paul (1987), Callaghan and Paul (1994a)
	Epichlorohydrin-*co*-ethylene glycol	II had 50 mol% ethylene glycol	Fernandes et al. (1986b)
	Ethylene, chlorinated	I had 56–68 wt% Cl	Ueda and Karasz (1994)
	Ethylene glycol	–	Fernandes et al. (1986b)
	Hexafluoroacetone-*co*-vinylidene fluoride	–	Kobayashi et al. (1987)
	Maleic anhydride-*co*-styrene	–	Chopra et al. (1998)

	N-Maleimide-co-styrene	II had 45 wt% N-maleimide	Vermeesch and Groeninckx (1995)
	Tetrafluoroethylene-co-vinylidene fluoride	II had 80 mol% vinylidene fluoride	Hamazaki et al. (1991)
	Vinyl acetate	Blends cast from chloroform and cyclohexanone	Burdin and Tager (1993), Guo (1990e), Lee and Ha (1994a), Song et al. (1990), Song and Long (1991)
	Vinyl chloride	–	Jager et al. (1983), Lemieux et al. (1988), Piglowski (1988), Shen and Torkelson (1992)
	Vinyl chloride, chlorinated	II had 63, 65, or 68 wt% Cl	Lemieux et al. (1988), Ueda and Karasz (1994), Voremkamp and Challa (1988)
	Vinyl chloride-co-vinylidene chloride	I was atactic or isotactic; II had 86.5 wt% vinylidene chloride	Lemieux et al. (1988), Woo et al. (1983, 1984b)
	Vinylidene fluoride	LCST above decomposition temperature of I	Belorgey and Prud'homme (1982)
Methyl methacrylate, imidized	Acrylonitrile-co-styrene	I had 53–91 wt% imidized unit; II had 5.7–33 wt% acrylonitrile; some blends showed LCST	Fowler et al. (1989)
Methyl methacrylate-co-styrene	Vinylmethylether	–	Sato et al. (1998)
α-Methylstyrene	Carbonate of bisphenol-A	I had M_w = 3.5 or 6.7 kg/mol; II had M_w = 33 kg/mol	Callaghan and Paul (1994a)
	Carbonate of bisphenol-P	I had M_w = 3.5 or 6.7 kg/mol; II had M_w = 31 kg/mol	Callaghan and Paul (1994a)
	Cyclohexyl methacrylate	–	Chang and Woo (2001b)
	Ethyl methacrylate	–	Siol (1991)
	Methyl methacrylate	Effect of M_w on LCST was reported in Callaghan and Paul (1993)	Cowie and Miachon (1992), Callaghan and Paul (1993), Siol (1991)

(continued)

Table 21.6 (continued)

Polymer I of	Polymer II of	Comments	Refs.
	p-Methylstyrene	–	Chang and Woo (2000)
	n-Propyl methacrylate	–	Siol (1991)
	Styrene	–	Saeki et al. (1983), Schneider and Dilger (1989), Widmaier and Mignard (1987)
	Tetrahydropyranyl-2-methyl methacrylate	–	Chong and Goh (1991a)
p-Methylstyrene	Cyclohexyl methacrylate	–	Woo and Jang (1999)
α-Methylstyrene-co-4-(2-hydroxyethyl)-α-methylstyrene	Alkyl acrylate	I had an alkyl group of methyl, ethyl, or t-butyl	Cowie and Reilly (1993a)
	Alkyl methacrylate	I had an alkyl group of methyl, ethyl, or t-butyl	Cowie and Reilly (1993a)
	Dialkyl itaconate	I had an alkyl group of methyl, ethyl, n-propyl, n-butyl, or t-butyl	Cowie and Reilly (1993a)
	Vinyl acetate	–	Cowie and Reilly (1993b)
	4-Vinylpyridine	–	Cowie and Reilly (1993b)
	N-Vinyl pyrrolidone	–	Cowie and Reilly (1993b)
α-Methylstyrene-co-4-(1,1,1-trifluoro-2-hydroxyethyl)-α-methylstyrene	Alkyl acrylate	I had an alkyl group of methyl, ethyl, or t-butyl	Cowie and Reilly (1993a)
	Alkyl methacrylate	I had an alkyl group of methyl, ethyl, or t-butyl	Cowie and Reilly (1993a)
	Dialkyl itaconate	I had an alkyl group of methyl, ethyl, n-butyl, or t-butyl	Cowie and Reilly (1993a)
	Vinyl acetate	–	Cowie and Reilly (1993b)
	4-Vinylpyridine	–	Cowie and Reilly (1993b)
	N-Vinyl pyrrolidone	–	Cowie and Reilly (1993b)
Novolac	Ethylene-co-vinyl acetate	II had 50 wt% vinyl acetate; LCST decreased with increasing degree of cure	Chen et al. (1998b)
Oxymethylene	Novolac	–	Wang et al. (1991b)
Pentabromobenzyl methacrylate-co-methyl methacrylate	Carbonate of bisphenol-A	II had ≤23.7 wt% pentabromobenzyl methacrylate	Merfeld et al. (2000)

Pentabromobenzyl methacrylate-*co*-styrene	Carbonate of tetramethylbisphenol-A	I had ≤33.9 wt% pentabromobenzyl methacrylate	Merfeld et al. (2000)
	2,6-Dimethyl-1,4-phenylene ether	I had 54 or 44.9 wt% pentabromobenzyl methacrylate	Merfeld et al. (2000)
Phenol-formaldehyde	Methyl methacrylate-*co*-styrene	II had 30.4–83.5 % MMA	Kim et al. (1989a)
Phenolphthalein polyaryletherketone	Ethylene glycol	–	Zheng et al. (2004)
Phenolphthalein polyetherethersulfone	Ethylene glycol	–	Zheng et al. (1997a)
p-Phenylene benzobisoxazole	Amide	II was PA-6,6 (Kyu and Chen (1993)) or an amorphous polyamide Zytel 330 (Chen and Kyu (1993))	Chen and Kyu (1993), Kyu and Chen (1993)
2,2′-(*m*-Phenylene)- 5,5′-bisbenzimidazole	Imide	II was Ultem 1000	Choe et al. (1988)
	Imide	II was XU 218	Choe et al. (1988)
o-Phenylphenol	Ethyl acrylate-*co*-methyl methacrylate	II had 37 or 81 wt% ethyl acrylate	Kim et al. (1998)
n-Propyl acrylate	Alkyl methacrylate	II had an alkyl group of chloromethyl, 1-chloroethyl, 2-chloroethyl, dichloroethyl. or trichloethyl	Peng et al. (1996)
n-Propyl methacrylate	Vinyl chloride-*co*-vinylidene chloride	II had 86.5 wt% vinylidene chloride	Woo et al. (1984b)
Styrene	5-Acetyl-2,6-dimethyl-1,4-phenylene ether	–	Kim et al. (1993c)
	5-Benzoyl-2,6-dimethyl-1,4-phenylene ether	–	Kim et al. (1993c)
	Carbonate of bisphenol-A-*co*-tetramethylbisphenol-A	II had ≥85 wt% tetramethylbisphenol-A	Kim and Paul (1992e)
	Carbonate of dimethylbisphenol-A-*co*-carbonate of bisphenol-A	II had 60–90 wt% tetramethylbisphenol-A	Kim et al. (2003a)
	Cyclohexyl methacrylate	I was isotactic (Chang and Woo (2003b))	Chang and Woo (2003b), Friedrich et al. (1996)
	o-Fluorostyrene-*co*-*p*-fluorostyrene	II had 10 or 23 mol% *p*-fluorostyrene	Oudhuis et al. (1991, 1993)
	Vinylmethylether	–	Mandal and Woo (1999c)
Styrene, sulfonated	Caprolactam (PA-6)	I had 6.5, 8.1, or 9.0 mol% sulfonated unit and Zn-neutralized	Kwei et al. (1993)
Styrene, modified with C$_{60}$	Vinylmethylether	I had 1.9 or 9.9 wt% C$_{60}$	Zheng et al. (1997b)

(continued)

Table 21.6 (continued)

Polymer I of	Polymer II of	Comments	Refs.
Styrene, sulfonated and metal-neutralized	Caprolactam (PA-6)	I was neutralized by Li, Mg, or Zn	Weiss and Lu (1994)
	N,N′-Dimethylene sebacamide	I had 4.0, 5.2, or 9.5 mol% sulfonation and neutralized by Li	Feng et al. (1996a, e), Tucker et al. (2003)
	N,N′-Dimethylethylene sebacamide	I had 7.4 mol% sulfonation and Li neutralized	Feng et al. (1996d)
Styrene-*co*-*p*-(2,2,2-trifluoro-1-hydroxy-1-trifluoromethyl)ethyl-*α*-methylstyrene	*p*-(Tert-butyl)phenylene fumarate	I had 3.9 or 8.0 mol% OH	Chen et al. (1998a)
Styrene-*co*-vinylphenol	Caprolactone	I had 10 wt% vinylphenol	Ahn et al. (1993)
	n-Hexyl methacrylate	–	Bhagwagar et al. (1994)
	Methyl methacrylate	I had 5 mol% vinylphenol; II was syndiotactic	Jong et al. (1993)
Sulfone	Styrene-*co*-1-vinylpyrrolidone	II had 12–32 wt% styrene	Kim et al. (2003b)
1,2,2,2-Tetrachloroethyl methacrylate	Ester	II was caprolactone or 2,2-dimethyl-1,3-propylene adipate	Goh et al. (1997a)
4-Trimethylsilylstyrene	Isoprene	–	Harada et al. (2005a, b)
Vinyl acetate	Maleic anhydride-alt-styrene, hydrolyzed	II was 1.8–43 % hydrolyzed; LCST increased with increasing degree of hydrolysis	Bosma et al. (1988a)
Vinyl acetate-*co*-vinyl chloride	*n*-Butyl methacrylate	I had 5.9–15.1 vol% vinyl acetate	Lee et al. (1992)
	Hexyl acrylate-*co*-methyl acrylate	I had 5–23.7 vol% vinyl acetate; II had 15–88 vol% hexyl acrylate; some blends showed LCST	Jin et al. (1992)
	Methyl methacrylate	I had 5.9–15.1 vol% vinyl acetate	Lee et al. (1992)
	4-Vinylpyridine	I had 32–55 mol% vinyl alcohol	Isasi et al. (1995)
Vinyl alcohol	Amide	I composed of 1:1:1 (wt%) of PA-6, PA-6,6, and PA-6,10 units	Zheng et al. (1996)
Vinyl butyral	Vinylpyridine	II was 2- or 4-pyridine	Franzen et al. (1995)

Vinyl chloride	Acrylonitrile-*co*-*n*-butyl acrylate	II had 53, 67 or 84 mol% butyl acrylate	Piglowski and Kammer (1990)
	n-Amyl methacrylate	–	Perrin and Prud'homme (1991), Piglowski (1988)
	Butyl acrylate-*co*-ethyl acrylate	II had 22.9, 43.5, or 52.8 % butyl acrylate	Walsh and Sham (1989)
	Butyl acrylate-*co*-hexyl acrylate	II had 47.8 % butyl acrylate	Walsh and Sham (1989)
	Butyl acrylate-*co*-methyl acrylate	II had 44.6 % butyl acrylate	Walsh and Sham (1989)
	Butyl acrylate-*co*-methyl methacrylate	II had 75 % butyl acrylate	Piglowski (1990)
	n-Butyl methacrylate	–	Perrin and Prud'homme (1991), Piglowski (1988)
	Butyl methacrylate-*co*-methyl methacrylate	II had 30 or 70 % methyl methacrylate	Piglowski (1988)
	Ethyl acrylate-*co*-hexyl acrylate	II had 41.7 or 43.2 % ethyl acrylate	Walsh and Sham (1989)
	Methyl acrylate-*co*-hexyl acrylate	II had 9.7 % methyl acrylate	Walsh and Sham (1989)
	Methyl methacrylate-*co*-styrene	II had 30 wt% styrene	Dompas et al. (1997)
	Pentyl acrylate	–	Walsh and Sham (1989)
	Pentyl acrylate-*co*-propyl acrylate	II had 48.1 % propyl acrylate	Walsh and Sham (1989)
	Propyl acrylate	–	Walsh and Sham (1989)
Vinyl chloride-*co*-vinylidene chloride	Neopentyl glycol succinate	I was Saran with 86.5 wt% vinylidene chloride; LCST above T_m when blend had ≤50 wt% II	Cowie and Reilly (1993a)
Vinylmethylether	Acrylonitrile-*co*-styrene	II had £ 10–11 % acrylonitrile	Min and Paul (1987)

(continued)

Table 21.6 (continued)

Polymer I of	Polymer II of	Comments	Refs.
	Alkyl acrylate	II had an alkyl group of ethyl or *n*-propyl	Chakraborty et al. (1993)
	Benzyl methacrylate	–	Mandal and Woo (1999a)
	Butadiene-*co*-styrene	II had 60 or 68 wt% styrene	Ahn et al. (1997d)
	Caprolactone	–	Bisso et al. (1998), Bisso et al. (1999), Oudhuis et al. (1994)
	2-Chlorostyrene	–	Tran-Cong et al. (1994), Urakawa et al. (2001)
	Dinitrostyrene-*co*-styrene	II had 3–14 mol% dinitrostyrene	Fernandez et al. (1997)
	Hydrogenous-block-deuterated styrene	–	Gomez-Elvira et al. (1994)
	Maleic anhydride-*co*-styrene	II had <15 % maleic anhydride	Min and Paul (1987)
	Hydroxyether of bisphenol-A	II was 11.7–42.3 mol% methylated or 7.5–30.1 mol % benzoylated	Etxeberria et al. (2001)
	α-Methylstyrene	–	Ha et al. (1990b)
	α-Methylstyrene-*co*-4-(2-hydroxyethyl)–methylstyrene	II had 6–89 mol% methylstyrene	Cowie and Reilly (1992)
	α-Methylstyrene-*co*-4-(1,1,1-trifluoro-2-hydroxyethyl)-methylstyrene	II had 0–93 mol% methylstyrene	Cowie and Reilly (1992)
	α-Methylstyrene-*co*-styrene	II had 77.5 or 88 wt% styrene	Ha et al. (1990b, 1993)
	p-Methylstyrene-*co*-styrene	II had 78.5 or 87.3 wt% styrene; II had 61, 72, 80, 90, or 95 mol% styrene (Goh et al. (1994a))	Goh et al. (1994a), Ha et al. (1990b, 1993)
	m-Methylstyrene-*co*-styrene	II had 76.5 or 87.5 wt% styrene	Ha et al. (1993)
	o-Methylstyrene-*co*-styrene	II had 76.2 or 86.8 wt% styrene	Ha et al. (1993)
	Methyl methacrylate-*co*-styrene	II had <60 mol% methyl methacrylate	Chien et al. (1988)
	Nitrostyrene-*co*-styrene	II had £ 25.6 mol% nitrostyrene	Cowie et al. (1992b), Defieuw et al. (1989a)
	Styrene-*co*-1-vinyl naphthalene	II had 17.4 wt% styrene	Ha et al. (1990b)
	Styrene-*co*-2-vinyl naphthalene	II had 19.2 wt% styrene	Ha et al. (1990b)
	Trimethylene adipate	–	Chiang and Woo (2007)

Vinylmethylketone	Styrene-*co*-4-vinylstilbene	Cloud point was sensitive to the *cis*-fraction of 4-stilbenzyl groups	Irie and Iga (1986)
p-Vinylphenol	4-Acetoxystyrene	–	Himuro et al. (1992)
	Trimethylene terephthalate	–	Lee and Woo (2004b)
2-Vinylpyridine	Aramide	II made from hexamethylenediamine and a mixture of isomers of phthalic acid	Skrovanek and Coleman (1987)
	2-Hydroxyethyl methacrylate	–	Cesteros et al. (1994a)
Vinylidene fluoride	Butylene adipate	–	Lee et al. (2008)
	Methoxymethyl methacrylate	–	Goh et al. (1991c)
	Pentamethylene adipate	–	Li and Woo (2008b)
	Trimethylene adipate	–	Li and Woo (2008b)

Table 21.7 Polymer pairs appear to have both a lower critical solution temperature and an upper critical solution temperature

Polymer I of	Polymer II of	Comments	Refs.
Acrylonitrile-*co*-styrene	Acrylonitrile-*co*-butadiene	I had 25 wt% acrylonitrile; II had 40 wt% acrylonitrile	Oswald and Kubu (1963)
	Caprolactone	II had 12.4–26.4 wt% AN; blends showed an LCST-UCST loop	Svoboda et al. (1994)
	Carbonate of bisphenol-A	I had 25 wt% AN; II had $M_w = 6$ kg/mol; blend had 20–25 wt% II	Li et al. (1999b)
Butadiene	Butadiene-*co*-styrene	II had 45 wt% styrene	Tager et al. (1987)
4-t-Butoxystyrene-stat-4-t-butylstyrene	Isoprene	I had 30–66 mol% t-butylstyrene	Rahman et al. (2009)
Carbonate of bisphenol-A	Methyl methacrylate	Blends showed an LCST-UCST loop	Brannock et al. (1990), Kyu and Lim (1989), Kyu et al. (1993)
Dimethylsiloxane	Methylphenylsiloxane	–	kundu et al. (1986c)
Etherimide	Imide	II was made from 4,4′-bis(3,3′-aminophenoxy)biphenyl and pyromellitic anhydride	Ma and Takahashi (1996)
2-Hydroxyethyl acrylate-*co*-liquid crystalline acrylate	2-Hydroxyethyl acrylate-*co*-liquid crystalline acrylate	Both I and II had 6 % 2-hydroxyethyl acrylate; the liquid crystalline acrylate of I and II had different space groups	Guo and Mitchell (1994)
o-Methylated phenol formaldehyde	Methyl methacrylate	I had 20 or 50 % of OH group methylated	Kim et al. (1989b)
	Methyl methacrylate-*co*-styrene	I had 20 or 50 % of OH group methylated; II had 50 or 60 % methyl methacrylate	Kim et al. (1989b)
Styrene	2,6-dimethyl-1,4-phenylene ether, carboxylated	II had 8.0–10.3 mol% carboxyl group	Cong et al. (1986)
	n-Pentyl methacrylate	–	Kim et al. (2004)

Table 21.8 Polymer pairs that co-crystallize

Polymer I of	Polymer II of	Method	Comments	Refs.
Butylene terephthalate	Butylene glycol-b-butylene terephthalate	T_g and T_m by DSC, dielectric loss measurements	Two T_g's when I was Valox 310 (General Electric) having $M_n = 20$ kg/mol and II contained 44–67 wt% butylene terephthalate; single T_g and single T_m when II contained 85 wt% butylene terephthalate; single T_m indicated that only one type of crystal was present	Martynowicz-Hans and Runt (1986)
	Butylene glycol-b-butylene terephthalate	T_g and T_m by DSC, dielectric loss measurements, microscopy	Single T_g and single T_m when I was Valox 310 (General Electric) with $M_n = 33$ kg/mol, II contained 84 wt% butylene terephthalate and I/II = 1/3–3/1; thermal analysis and morphological evidence pointed to extensive co-crystallization in this mixture; two T_g's when II contained 50 wt% butylene terephthalate	Runt et al. (1989)
	Ester–ether segmented polymer	Dielectric loss peak and T_m by DSC	I was Valox 310 (General Electric) with $M_n = 20$ kg/mol; II was comprised of a poly(butylene oxide) soft segment and a hard segment 4GT-butylene terephthalate and had total $M_w = 25$–30 kg/mol; single beta dielectric loss peak and single T_m were found when II was 44 or 67 wt% 4GT; single T_m between the T_ms of the pure components indicated co-crystallization; two dielectric loss peaks and two T_m when II was 84 wt% 4GT	Runt et al. (1987)
Etheretherketone	Ether ether ether ketone	T_g and T_m by DSC	Single T_g and single T_m when I contained 33 % ketone linkages and had melt flow = 3.0 dg/min at 400° C and II had melt flow = 10 dg/min; I/II = 1/1	Harris and Robeson (1987)
	Etheretherketone ketone	T_g and T_m by DSC	Single T_g and single T_m when I contained 33 % ketone linkages and had melt flow = 3.0 dg/min at 400° C and II contained 50 % ketone linkages and had melt flow = 4.0 dg/min; I/II = 1/1	Harris and Robeson (1987)
	Ether ketone	T_g and T_m by DSC	Single T_g and single T_m when I contained 33 % ketone linkages and had melt flow = 3.0 dg/min and II contained 50 % ketone linkages and had melt flow = 1.5 dg/min; I/II = 1/1	Harris and Robeson (1987), Nandan et al. (2001)

(continued)

Table 21.8 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
	Ether ketone	T_g and T_m by DSC; WAXD	Single composition-dependent melting endotherms obtained upon quenching when I had intrinsic viscosity = 1.124 dl/g in sulfuric acid at 30° C and II had intrinsic viscosity = 1.107 dl/g in sulfuric acid at 30° C, but it did not happen when other thermal histories were imposed	Sham et al. (1988b)
	Ether-*co*-ketone	T_g and T_m by DSC	Single T_g and single T_m when I contained 33 % ketone linkages and had melt flow = 3.0 dg/min and II contained 57 % ketone linkages and had melt flow = 1.5 dg/min; I/II = 1/1	Harris and Robeson (1987)
	Ether ketone (polymer II), etherimide (polymer III)	T_g and T_m by DSC	I had reduced viscosity = 1.05 dl/g in 1 wt% conc. sulfuric acid at 23° C; II had reduced viscosity = 1.9 dl/g in the same condition as for I; III was Ultem 1000 from GE with reduced viscosity = 0.5 dl/g in 0.2 wt% chloroform at 25° C; single T_g and single T_m for I/II/III = 25/25/50	Harris and Robeson (1988)
Ethylene	Butadiene, hydrogenated	DSC, SALS, and SEM	I was narrow M_w fraction with M_w = 113 kg/mol and M_n = 105 kg/mol; II contained 2.2–5.5 mol% ethyl branches and had M_w = 103–420 kg/mol and M_n = 83–156 kg/mol; stated that I and II co-crystallized upon rapid crystallization from the melt when II contained up to 2 mol% of ethyl branches	Alamo et al. (1988)
Ethylene	Ethylene	DSC and SALS	I was polyethylene and II was UHMWPE with M_w = 5,000 kg/mol; I was LLDPE (GRSN-7047 from Union Carbide with M_w = 134 kg/mol and M_w/M_n = 4), or I was HDPE (Chemplex 6186 with M_w = 134.8 kg/mol and M_w/M_n = 7.4); only a single composition-dependent T_m was observed; SALS showed the co-crystallization took place; but when I was LDPE (M_w = 114 kg/mol and M_w/M_n = 5.2), separate crystals were formed	Kyu and Vadhar (1986)

Ethylene	DSC, SAXS, and X-ray diffraction	I was linear LLDPE and II was HDPE; co-crystallization was evidenced by a single T_m by DSC; stated that X-ray diffraction peak width, SAXS and Raman spectra were all consistent with a single crystallizing species; but for HDPE/LDPE and LLDPE/LDPE, separate crystals were seen with two T_ms being found by DSC	Stein et al. (1989)
Ethylene	DSC, SAXS, and X-ray diffraction	I was HDPE with $M_w = 100$ kg/mol and $M_n = 11$ kg/mol and II was LLDPE with $M_w = 350$ kg/mol and $M_n = 16$ kg/mol; after the blend with I/II $= 25/75$ by weight was cross-linked either by irradiation or by peroxides in the liquid state above a critical degree of cross-linkage, the DSC curve of the blend showed only one single melting point on heating and only one single crystallization peak on cooling; references B8, Hahn and Wendroff (1985)1, Machado and French (1992b)5, Kallistis and Kalfoglou (1989)5, and R8 also discussed the miscibility of PE/PE blends	Illers and Koehnlein (1986)
Ethylene	DSC; SANS; SAXS	I was HDPE and II was LDPE; blends were homogeneous in the melt	Wignall et al. (1995)
Ethylene	SANS	I was LDPE and II was LLDPE	Shin et al. (2009)
Ethylene, deuterated	T_m by DSC	Single T_m varying smoothly with composition and no gross segregation occurred	English et al. (1985)
Ethylene-co-vinyl acetate	DSC, SALS, and SEM	I was narrow M_w fraction with $M_w = 113$ kg/mol and $M_n = 105$ kg/mol; II contained 1.12–6.6 mol% of acetate branches and had $M_w = 60.3$–105 kg/mol and $M_n = 23.5$–43.6 kg/mol; stated that I and II co-crystallized upon rapid crystallization from the melt contained up to 2 mol% of acetate branches	Alamo et al. (1988)
Ethylene-co-vinyl acetate	Ethylene-co-vinyl acetate	DSC, SALS, and SEM	I and II had $M_w = 60.3$–105 kg/mol, $M_n = 23.5$–43.6 kg/mol, and they were different in the content of acetate branches; stated that these copolymers containing about 1–2 mol% of acetate branches were found to co-crystallize with one another	Alamo et al. (1988)

Table 21.8 (continued)

Polymer I of	Polymer II of	Method	Comments	Refs.
Glutamate	Glutamate	Dynamic mechanical measurements, X-ray diffraction	I or II was poly(L-glutamate) or poly(D-glutamate) having m number of methylene group in the ester group of a general formula as -CH$_2$CH$_2$COO-(CH$_2$)$_m$-C$_6$H$_5$-, m might be 1, 2, or 3, so the component polymer would be represented as L_m or D_m; the M_w of both components were 135–380 kg/mol and M_w/M_n = 1.1–1.2; stated that binary blends of Landi (1972), Dave et al. (1990), Landry and Hendrichs (1989), and Davis et al. (1981) were miscible and formed isomorphous mixed crystals at all compositions, whereas other pairs, with the exception of Landi (1974)/Das and Rodriguez (1987), were immiscible	Sankarapandian and Kishore (1991)
Hexafluoroacetone-co-vinylidene fluoride	Tetrafluoroethylene-co-vinylidene fluoride	DSC	I had 92 mol% VDF and II had 80 mol% VDF; blends of difference compositions showed single melting peak	Cho et al. (1993)
Hexafluoropropylene-co-tetrafluoroethylene	Perfluoromethyl vinyl ether-co-tetrafluoroethylene	DSC	I had 1 mol% hexafluoropropylene; II had 2 mol% perfluoromethyl vinyl ether	Pucciariello and Angioletti (1999)
Isopropylvinylether, isotactic	Sec-butylvinylether, isotactic	Unit cell dimension from X-ray diffraction	Co-crystallization at all compositions	Natta et al. (1969)
Lactide	Lactide	DSC	I was linear and II was branched; I and II co-crystallized in one lamellae type	Zuideveld et al. (2006)
4-Methyl-1-hexene, isotactic	4-Methyl-1-pentene, isotactic	Unit cell dimensions from X-ray diffraction	Co-crystallization only below 25 wt% I and above 75 wt% I	Natta et al. (1969)
Propylene	Ethylene-co-propylene	–	I was isotactic	Kim et al. (1999a)
Tetrafluoroethylene	Tetrafluoroethylene-co-perfluoroalkyl vinyl ether	Dynamic mechanical studies	II had 98 or 99 mol% tetrafluoroethylene	Runt et al. (1995)
	Tetrafluoroethylene-co-perfluoropropyl vinyl ether	WAXD; SEM	II had 98 mol% tetrafluoroethylene	Endo et al. (2000)

Trifluoroethylene-co-vinylidene fluoride	Trifluoroethylene-co-vinylidene fluoride	DSC, X-ray, and phase-contrast microscopy	No phase separation by phase-contrast microscopy, a sharp single X-ray peak, intermediate in spacing between those of the individual copolymers, and clearly different from their superposition, and only one ferroelectric transition and only one melting point by DSC, indicated co-crystallization within the same lattice when I was 52/48 mol% vinylidene fluoride (VDF)/trifluoroethylene (TFE), II was 65/35 mol% VDF/TFE, or I was 65/35 mol% VDF/TFE, and II was 73/27 mol% VDF/TFE; but two X-ray peaks and two ferroelectric transitions and two melting points when I was 52/48 and II was 73/27 mol% VDF/TFE	Tanaka and Lovinger (1987)
Vinyl alcohol	Vinyl alcohol	DSC	I and II had a diad syndiotacticity of 54 and 58 mol%, respectively	Tanigami et al. (1994)
Vinylidene fluoride	Tetrafluoroethylene-co-vinylidene fluoride	DSC	II had 9.1, 14.3, or 17.6 mol% tetrafluoroethylene	Datta and nandi (1996)

Notations and Abbreviations

AFM Atomic force microscopy
DSC Differential scanning calorimetry
FTIR Fourier transform infrared spectroscopy
HDPE High-density polyethylene
IGC Inverse gas chromatography
LCST Lower critical solution temperature
LDPE Low-density polyethylene
LLDPE Linear low-density polyethylene
M_n Number-average molecular weight
M_w Weight-average molecular weight
NMR Nuclear magnetic resonance spectroscopy
NRET Non-radiative energy transfer
OM Optical microscopy
PA Polyamide
PALS Positron annihilation light spectroscopy
POM Polarized optical microscopy
SALS Small angle light scattering
SANS Small angle neutron scattering
SAXS Small angle X-ray scattering
SEM Scanning electron microscopy
T_g Glass transition temperature
T_m Melting temperature
TEM Transmission electron microscopy
ToF-SIMS Top of flight secondary ion mass spectrometry
UCST Upper critical solution temperature
UHMWPE Ultra high molecular weight polyethylene
WAXD Wide angle X-ray diffraction
XPS X-ray photoelectron spectroscopy

Appendices

Appendix I: International Abbreviations for Polymers and Polymer Processing

AA	Acrylic acid (monomer)
AAS, ASA	Copolymer of acrylonitrile, acrylate (ester), and styrene
ABA	Acrylonitrile-butadiene-acrylate copolymer
ABM	Copolymer of acrylonitrile-butadiene-methyl acrylate
ABMA	Copolymer of acrylonitrile-butadiene-methacrylic acid
ABR	Elastomeric copolymer from an acrylate (ester) and butadiene, a rubber
ABS	Thermoplastic terpolymer, an acrylonitrile-butadiene-styrene copolymer
ABSM	Graft copolymer of acrylonitrile-butadiene-styrene-methyl methacrylate
ABSMA	Graft copolymer of acrylonitrile-butadiene-styrene-maleic anhydride
ABS-MA	Maleated acrylonitrile-butadiene-styrene copolymer
ABVC	Thermoplastic terpolymer, an acrylonitrile-butadiene-vinyl chloride copolymer
ACM	Acrylate rubber, based on ethyl acrylate with other acrylics
ACM	Acrylic elastomer, e.g., alkyl acrylate-2-chloroethyl vinyl ether copolymer
ACPES	Acrylonitrile-chlorinated polyethylene-styrene copolymer
ACRYL	Poly- or copoly-methyl methacrylate (acrylic)
ACS	Thermoplastic blend of acrylonitrile-styrene-chlorinated PE terpolymer
ACS, ACPES	Acrylonitrile-chlorinated polyethylene-styrene copolymer
AEM	Elastomeric ethyl (or other) acrylate-ethylene copolymer
AES	Terpolymer from acrylonitrile, ethylene-propylene elastomer, and styrene
AF	Aniline-formaldehyde molding resins

AFMU	Terpolymer of tetrafluoroethylene, trifluoro-nitrosomethane, and nitrosoperfluorobutyric acid
AK	Alkyd resin
AMAB	Copolymer from acrylonitrile, methyl acrylate, and butadiene rubber
AMC	Alkyd molding compound
AMMA	Thermoplastic copolymer from acrylonitrile and methyl methacrylate
AMS	α-Methyl styrene
AN	Acrylonitrile
ANM	Acrylate rubber, based on ethyl acrylate with acrylonitrile
AP, APR	Elastomeric ethylene-propylene-diene copolymer, now EPDM
APET	Amorphous polyethyleneterephthalate
aPP	Amorphous polypropylene
aPP	Atactic PP
AR	Elastomeric copolymer from acrylates and olefins
ARP	Polyarylterephthalate liquid crystal copolymers, also PAT
AS	Acrylonitrile-styrene copolymer (see also SAN)
ASA, AAS	Thermoplastic copolymer from acrylonitrile, styrene, and acrylates
ASR	Alkylene sulfide rubber
AU	Elastomeric polyester or polyurethane with polyester segments
BA, PBA	Polybutylacrylate (incorrectly used for acrylic elastomer, ACM)
BAAN	Butyl acrylate-acrylonitrile copolymer
BAMM	Butyl acrylate-methyl methacrylate copolymer
BFE	Bromotrifluoroethylene polymers
BIIR	Brominated elastomer from isobutene and isoprene, bromobutyl rubber
BMC	Bulk molding compound (UP resins)
BMI	Bismaleimide
BMMM	Butyl methacrylate-methyl methacrylate copolymer
BOPP	Biaxially oriented polypropylene film
BP, BR	Polybutadiene or an isobutene-isoprene copolymer, butyl or butadiene rubber
BPA	Bisphenol-A
bPC	Branched polycarbonate of bisphenol-A
BR	Butadiene rubber
Bu-ABS	Graft copolymer of butylacrylate and triallyl isocyanurate on polybutadiene, in turn emulsion grafted with styrene and acrylonitrile

CA	Cellulose acetate
CAB	Cellulose acetate-butyrate
CAN	Cellulose acetate-nitrate
CAP	Cellulose acetate-propionate
CB	Cellulose butyrate (also carbon black reinforcing pigment)
CBR	Chlorinated butadiene rubber
CDB	Conjugated diene butyl elastomer
CE	Cellulose plastics in general
CEM	Polychlorotrifluoroethylene (also CFM, CTFEP, PCTFE)
CF	Cresol-formaldehyde resins (also reinforcing carbon fiber)
CFM	Polychlorotrifluoroethylene (also CEM, CTFEP, PCTFE)
CHR	Elastomeric copolymer from epichlorohydrin and ethylene oxide
CIIR	Post chlorinated elastomeric copolymer from isobutene and isoprene
CM	Chloro-polyethylene (also compression molding)
CMC	Carboxymethyl cellulose (or critical micelle concentration)
CMHEC	Carboxymethyl hydroxyethyl cellulose
CMPS	Poly(chloromethyl styrene)
CN	Cellulose nitrate (celluloid)
CNR	Elastomeric terpolymer from tetrafluoroethylene, trifluoronitrosomethane, and a small amount of an unsaturated monomer, e.g., nitrosoperfluorobutyric acid and nitroso or carboxy nitroso rubber
CO	Polychloromethyl oxirane elastomer, epichlorohydrin rubber
COP	Cycloolefin polymers or copolymers
CO-PAI	Copolyamideimide
COPE	Copolyester elastomer
CO-PI	Copolyimide
COPO	Poly(carbon monoxide-co- polyolefin), a linear, alternating terpolymer: ethylene-co- propylene-co-carbon monoxide
COX	Carboxylic rubber
CP	Cellulose propionate, or chlorinated polyethylene, also CPE
CP2	Alternating copolymer from vinyl ether and maleic acid
CP4	Copolymer from acrylic acid and maleic acid
CPE	Chlorinated polyethylene
CPET	Crystallizable (or chlorinated) polyethyleneterephthalate
CPI	*cis*-Polyisoprene, also IR
CPVC	Chlorinated polyvinyl chloride
CR	Chloroprene, or neoprene, rubber
CRM	Chlorosulfonated polyethylene
CRP	Carbon fiber reinforced plastics
CS	Casein

CSM, CSPE	Chlorosulfonated polyethylene, also CSPE or CSR
CSR	Chlorosulfonated polyethylene (also CSPE or CSM)
CT, CTA	Cellulose triacetate
CTBN	Carboxy-terminated nitrile rubber
CTFE	Polychlorotrifluoroethylene
CTFEP	Polychlorotrifluoroethylene (also CFM, CEM, PCTFE)
CUT	Continuous use temperature
CV	Viscose, also VI
DAC	Diallylchlorendate
DAF	Diallylfumarate
DAIP	Diallylisophthalate
DAP	Diallylphthalate
DCA	Dichloroacetic acid
DMA	Dynamic mechanical analysis
DMC	Dough molding compound
DMF	*N*,*N*-dimethylformamide (solvent, also DMT)
DMSO	Dimethyl sulfoxide (solvent)
DSC	Differential scanning calorimetry
E/B	Copolymers of ethylene and 1-butene
E/P	Ethylene-propylene copolymer EA
EAA	Ethylene acrylic acid copolymer
EAM	Elastomeric copolymer of ethylene and vinyl acetate
EBA	Ethylene-butyl acrylate copolymer
EBA-AA	Ethylene-butyl acrylate-acrylic acid copolymer
EBA-GMA	Ethylene-butyl acrylate-glycidyl methacrylate copolymer
EBA-MA	Ethylene (50–90 parts)-co-butyl acrylate (5 to 49 parts)-co-maleic anhydride (0.5 to 10 parts) copolymer
EBM	Extrusion blow molding
EC	Ethyl cellulose
ECA	Ethylene-carbonate copolymer
ECB	Blends from ethylene copolymers with bitumen
ECO, CO	Elastomeric copolymer from ethylene oxide and epichlorohydrin (also EO-ECH)
ECPE	Extended chain polyethylene
ECTF, ECTFE	Poly(ethylene-co-chlorotrifluoroethylene)
EEA	Elastomeric copolymer from ethylene and ethyl acrylate
EEAAA	Polyethylene grafted with ethyl acrylate and acrylic acid
EEA-GMA	Ethylene-ethyl acrylate-glycidyl methacrylate copolymer
EGMA	Ethylene-glycidyl methacrylate copolymer
EHEC	Hydroxyethyl cellulose
ELAST	Elastomer
EMA	Copolymer from ethylene and maleic anhydride or ethylene-methyl acrylate
EMAc	Copolymer from ethylene and methacrylic acid

EMAC	Ethylene methacrylate copolymer
EMI	Electromagnetic interference
EMM	Copolymer from ethylene and methyl methacrylate
EMP	Ethylene-propylene copolymers (ethylene-modified polypropylene)
ENR	Epoxidized natural rubber
EO-ECH	Copolymer of ethylene oxide and epichlorohydrin (also ECO, CO)
EP	Epoxy resins
EPD	Ethylene-propylene-diene copolymer
EPD, EPDM	Elastomeric terpolymer from ethylene, propylene, and a non-conjugated diene
EPDM-MA	Maleic anhydride-modified ethylene-propylene-diene terpolymer
EPE	Ester of an epoxy resin
EP-G-G	Prepreg from epoxy resin and glass fabric (German literature)
EP-K-L	Prepreg from epoxy resin and carbon fiber fabric (German literature)
EPR, EPM	Elastomeric copolymer of ethylene and propylene
EPR-MA	Maleated ethylene-propylene rubber, EPR
EPS	Polystyrene foam, expanded PS
EPT, EPTR	Ethylene, propylene, and a non-conjugated diene terpolymer, also EPDM
E-PVC	Emulsion polyvinyl chloride, PVC polymerized in emulsion
ES	Ethylene-styrene block copolymer
E-SBR	Polymerized in emulsion styrene/butadiene copolymer
ESCR	Environmental stress crack resistance
ESD	Electrostatic dissipation
ETE	Engineering thermoplastic elastomer
ETFE	Copolymer from ethylene and tetrafluoroethylene
EtOH	Ethanol
EU	Polyether urethane
EVA	Ethylene-vinyl acetal copolymer
EVAc	Copolymer from ethylene and vinyl acetate
EVAc-AA	Ethylene-vinyl acetate-acrylic acid graft copolymer
EVAc-CO	Ethylene-vinyl acetate-carbon monoxide copolymer
EVAc-MA	Copolymer from ethylene, vinyl acetate, and methacrylic acid
EVA-GMA	Ethylene-vinyl acetate-glycidyl methacrylate copolymer
EVAl, EVAL	Copolymer of ethylene and vinyl alcohol
EVAVC	Ethylene-vinyl acetate-vinyl chloride copolymer
EVC	Copolymer from ethylene and vinylene carbonate
EVE	Ethylene-vinyl ether copolymer
EVM	Ethylene-vinyl acetate copolymer, a thermoplastic elastomer
EVOH	Ethylene-vinyl alcohol copolymer (also EVAl, EVAL)

EVP	Ethylene-vinyl pyrrolidinone copolymer
FA	Formic acid
FE	Fluorine-containing elastomer
FEP	Fluorinated EPR, tetrafluoroethylene/hexa-fluoro propylene rubber
FF	Resin from furan and formaldehyde
FFKM	Perfluoro rubbers of the polymethylene type, having all substituent fluoro, perfluoroalkyl, or perfluoroalkoxy groups on the polymer chain
FK, FRP, GRP	Fiber reinforced plastic
FKM	Hexa-fluoro propylene- vinylidene fluoride copolymer
FMQ	Methyl fluoro silicone rubber
FP	Fluoroplastic
FPM	Vinylidene fluoride/hexa-fluoro propylene elastomer, rubbers with fluoro and fluoroalkyl or fluoroalkoxy groups
FPVC	Flexible PVC film
FQ	Elastomeric silicone with fluorine-containing substituents
FRE	Fiber reinforced epoxy
FRP, GRP, FK	Glass fiber reinforced polyester
FTIR	Fourier transform infrared spectroscopy
FVMQ	Silicone rubber with fluorine, vinyl, and methyl substituents
GC	Gas chromatograph
GECO	Epichlorohydrin-ethylene glycol- glycidyl ether elastomeric copolymer
GEP	Glass fiber reinforced epoxy resin
GF	Glass fiber, or glass fiber reinforced plastic
GF-PF	Glass fiber reinforced phenolic resin
GF-UP	Glass fiber reinforced unsaturated polyester resin
GMA	Glycidyl methacrylate (monomer)
GMT	Glass mat reinforced plastics
GP	Gutta-percha
GPC	Gel permeation chromatograph (now: size exclusion chromatography, SEC)
GPO	Elastomeric copolymer from propylene oxide and allyl glycidyl ether
GPPS	General-purpose polystyrene (also PS)
GPSMA	General-purpose styrene-maleic anhydride copolymer (also SMA)
GR	Government rubber from state-owned factories in the USA during the Second World War
GR-1	Butyl rubber
GR-N	Nitrile rubber, now NBR
GR-S	Styrene-butadiene rubber

GRP	Glass reinforced polyester (thermoset)
GUR	Ultrahigh molecular weight polyethylene (UHMWPE)
HALS	Hindered amines (antioxidants)
HAO	Higher alpha-olefins
HBV	Poly(3-hydroxy butyrate- co-valerate)
HDPE	High-density polyethylene (ca. 960 kg/m^3)
HDT	Heat deflection temperature
HEC	Hydroxyethyl cellulose
HIPS	High-impact polystyrene
HISMA	High-impact styrene-maleic anhydride copolymer
HM	Hot melt adhesive
HMC	Sheet molding compound with high glass fiber content
HMW	High molecular weight
HMW-PE	Polyethylene with high molecular weight
H-NBR, HNBR	Hydrogenated acrylonitrile- butadiene elastomer
HPC	Hydroxy propyl cellulose
HPMC	Hydroxy propyl-methyl cellulose
HR	High resiliency foams
HTE	Hydroxyl-terminated polyether
ICP	Intrinsically conductive (or connecting) polymer
IEN	Interpenetrating elastomeric network
IGC	Inverse gas chromatograph
IHPN	Interpenetrating homopolymer network
IIR	Isobutene-isoprene rubber (butyl rubber)
IM	Polyisobutene, also PIB
IO	Ionomer
IPN	Interpenetrating polymer network
IPS	Impact resistant polystyrene
IR	Synthetic *cis*-1,4-polyisoprene, synthetic isoprene rubber
IR, FTIR	Infrared spectroscopy (or Fourier transform infrared spectroscopy)
LCP	Liquid crystal polymer
LDPE	Low-density polyethylene (ca. 918 kg/m^3)
LIM	Liquid impingement molding (now reactive injection molding, RIM)
LIPN	Latex interpenetrating polymer network
LLDPE	Linear low-density polyethylene
LMDPE	Linear medium-density polyethylene
LPE	Linear polyethylene
LRM	Liquid reaction molding (now reactive injection molding, RIM)
LRMR	Reinforced liquid reaction molding (now reinforced reactive injection molding, RRIM)
L-SBR	Solution-polymerized SBR

LSR	Liquid silicone rubber
LTG	Low-temperature zinc phosphate glasses
MA or MAH	Maleic anhydride (monomer)
MABS	Copolymer from methyl methacrylate, acrylonitrile, butadiene, and styrene
MAN	Copolymer from methyl methacrylate and acrylonitrile
MAS	Copolymer from methyl methacrylate, acrylonitrile, and styrene
MBA	Copolymer from methyl methacrylate, butadiene, and acrylonitrile
MBS	Copolymer from methyl methacrylate, butadiene, and styrene
MC	Methyl cellulose
MC	Methylene chloride (solvent)
MDI	Methyl di-isocyanate
MDPE	Medium-density polyethylene (ca. 930 to 940 kg/m^3)
MEK	Methyl ethyl ketone (solvent)
MeSAN	Copolymer from α-methyl styrene and acrylonitrile
MF	Melamine-formaldehyde resins
MFI	Melt flow index
MFK	Metal fiber reinforced plastic
MFQ	Silicone rubbers with methyl and fluorine substituent groups, also FMQ
MFR	Melt flow rate
MI	Melt index
MIPS	Medium-impact-strength polystyrene
MMA	Methyl methacrylate (monomer)
MMA-MAc-EA	Copolymer of methyl methacrylate, methacrylic acid, and ethyl acrylate
MMBA	Copolymer from methyl methacrylate and butyl acrylate
MMBA-TPT	Copolymer from methyl methacrylate, butyl acrylate, diallyl maleate, and trimethylol propane triacrylate
MMEA	Methyl methacrylate-ethyl acrylate copolymer
MMMA	Methyl methacrylate-methyl acrylate copolymer
MMPMI	Methyl methacrylate-co-*N*-phenylmaleimide copolymer
MMS	Copolymer from methyl methacrylate and α-methyl styrene
MMVAc	Methyl methacrylate-vinyl acetate copolymer
MMVAc-AA	Copolymer of methyl methacrylate, vinyl acetate, and acrylic acid
MMW	Medium molecular weight
MPC	Tetramethyl polycarbonate (also TMPC, TMBPA-PC)
MPF	Melamine-phenol-formaldehyde resin
MPQ	Silicone rubbers having both methyl and phenyl substituent groups, also PMQ
MPR	Melt-processable rubber poly(α-methyl styrene)

M-PVC	Polymerized in bulk polyvinyl chloride
MPVQ	Silicone rubbers with methyl, phenyl, and vinyl groups, also PVMQ
MQ	Elastomeric silicones with methyl substituents
MSABS	Methylstyrene-styrene-acrylonitrile-grafted polybutadiene
MSAN	Thermoplastic copolymer from α-methyl styrene and acrylonitrile
MSMA	Copolymer of methyl methacrylate, *p*-methyl-styrene, and maleic anhydride
MVQ	Silicone rubbers having both methyl and vinyl substituent groups, also VMQ
MWR	Molding with rotation
n-C$_6$	n-Hexane
n-C$_7$	n-Heptane
n-C$_{10}$	n-Decane
NBR	Elastomeric copolymer from butadiene and acrylonitrile, nitrile rubber
NC	Cellulose nitrate, also CN
NCR	Elastomeric copolymer from acrylonitrile and chloroprene
NDPE	Low-density polyethylene (see also LDPE)
NIR	Elastomeric copolymer from acrylonitrile and isoprene
NK	Natural rubber, also NR
NP	Network polymer
NR	Natural rubber, also NK
OEP	Oil-extended polymer
OPET	Oriented polyethyleneterephthalate
OPP	Oriented polypropylene, film, or bottles, also PP
OPR	Elastomeric polymer from propylene oxide
OPS	Oriented polystyrene films
OPVC	Oriented polyvinyl chloride
OSA	Olefin-modified styrene-acrylonitrile copolymer
P3FE	Poly(trifluoroethylene)
PA	Polyamide; the abbreviation PA is normally followed by a number, a combination of numbers, a letter, or a combination of letters and numbers. A single number refers to the polyamide from an α,ω-amino acid or its lactam. A combination of two numbers is often separated by a comma. The first number following the symbol PA indicates the number of methylene groups of aliphatic diamines and the second number the number of carbon atoms of aliphatic dicarboxylic acids. An I stands for isophthalic acid and a T for terephthalic acid. For example, co-polyamide from caprolactam, hexamethylenediamine condensed with isophthalic and terephthalic acids

	is abbreviated as PA-6IT6, or that from caprolactam, m-xylylenediamine, and adipic acid as PA-mXD6, etc.
PA-6	Poly-ε-caprolactam
PA-46	Poly(tetramethylene adipamide), also PTA
PA-66	Poly(hexamethylenediamine-adipic acid), polyhexa-methylene adipamide
PA-6IT6	Poly(caprolactam-co-hexamethylenediamine-isophthalic and terephthalic acids)
PAA	Polyacrylic acid
PAAE	Polyarylamide-polyether
PAAM	Polyacrylamide
PABM	Polyaminobismaleimide
PAC	Polyacrylonitrile fiber (also PAN), polyacrylate
PACE	Polyacetylene
PADC	Poly(allyl diglycol carbonate)
PAE	Polyarylether
PAEB	Poly(*p*-aminoethyl benzoate)
PAEI	Polyacrylic ester imide
PAEK	Polyaryletherketone
PAES	Polyarylethersulfone
PAI	Polyamide-imide
PAK	Polyester alkyd
PALL	Polyallomer – a block copolymer of propylene, ethylene (1.5 to 3%), butene (8%), and hexene (5%)
PAMS	Poly-α-methyl styrene
PA-mXD	Poly(*m*-xylylene adipamide)
PA-mXD6	Poly(*m*-xylylenediamine and adipic acid-co-caprolactam)
PAN	Polyacrylonitrile
PANI	Polyaniline
PAPA	Polyazelaic polyanhydride
PAPI	Polymethylenepolyphenylene isocyanate, also PMPPI
PAr, PAR	Polyarylate $[-\varphi\text{-}C(CH_3)_2\text{-}\varphi\text{-}CO_2-\varphi\text{-}CO_2\text{-}]_n$, amorphous polyester of bisphenol-A with isophthalic and terephthalic acids
PARA	Polyaryl amide (aromatic, usually amorphous polyamide)
PARS	Polyaryloxysiloxane
PArSi	Poly(aryloxysiloxane), e.g., poly(dimethylsiloxane biphenylene-oxide)
PAS	Polyarylsulfide copolymers (esp. in German and Japanese literature)
PAS, PASU	Polyarylsulfone $[-\varphi\text{-}SO_2\text{-}\ \varphi\text{-}O-]_{0.875}\ [-\varphi\text{-}O-]_{0.125}$
PAT	Polyaminotriazole, also polyarylterephthalate, aromatic LCP polyester
PAUR	Polyester urethane
PB	Poly-1-butene, polybutylene, elastic polydiene fiber

PBA	Polybutylacrylate, also poly(1,4- benzamide)
PBAN	Poly(butadiene-co-acrylonitrile)
PBCD	Poly(butylene cyclohexane dicarboxylate)
PBD	Polybutadiene
PBE	Poly(1-butene-co-ethylene)
PBG	Polybutylene glycol, also known as polytetrahydrofuran, PTHF
PBI	Polybenzimidazoles
PBMA	Poly-*n*-butyl methacrylate
PBMI	Polybismaleimide
PBN	Poly(butylene-2,6-naphthalene dicarboxylate)
PBNDC	Poly(butylene-2,5-naphthalene dicarboxylate)
PBO	Polybutylene oxide
PBR	Copolymer from butadiene and vinyl pyridine
PBS	Copolymer from butadiene and styrene (see also GR-S, SBR)
PB-SMA	Styrene-maleic anhydride-grafted polybutadiene
PBT, PBTP	Polybutyleneterephthalate
PBT-PBG	Copolymer of 1,4-butanediol- polybutylene glycol-terephthalic acid
PBZ	Polybenzobisoxazole
PBzMA	Poly(benzyl methacrylate)
PBZT	Poly(p-phenylenebenzobisthiazole)
PC	Polycarbonate of bisphenol-A
PCA	Polycarbonate-acrylic
PCD	Polycarbodiimide
PCDP	Polydicyclopentadiene
PCDT	Poly(1,4-cyclohexylene dimethylene terephthalate)
PCE	Polycycloenes
PCF	Polychlorotrifluoroethylene fiber
PCHMA	Polycyclohexyl methacrylate
PCI	Poly(1,4-cyclohexylenedimethylene isophthalate)
PCME	Poly(2,2-dichloro- methyltrimethylene ether)
PCN	Poly(2-cyano-5-norbornene)
PCO	Polycycloolefin
PC-Ph	Co-polycarbonate from phosgene with bisphenol-A and phenolphthalein
PCT, PCTG	Poly(cyclohexane terephthalate- glycol), copolymer of cyclohexanedimethanol (66 mol%), ethylene glycol, (34 mol%), and terephthalic acid
PCTFE	Polychlorotrifluoroethylene (also CEM, CFM, CTFE)
PCU	Polyvinyl chloride (old German literature)
PDAP	Polydiallylphthalate (also DAP, FDAP)
PDCP	Polydicyclopentadiene
PDMDPhS	Poly(dimethyl-diphenylsiloxane)

PDMS	Polydimethylsiloxane
PDPS	Polydiphenylsiloxane
PE	Polyethylene
PEA	Polyetheramide
PEAc	Polyethylacrylate
PEB	Polyethylene-*p*-oxybenzoate
PEBA	Thermoplastic elastomer, polyether block amide
PEC	Polyestercarbonate or chlorinated polyethylene, usually CPE
PeCe	Chlorinated PVC (also CPVC, PC, PVCC)
PECO	Polyethylene carbonate
PEE	Polyester ether fibers (containing diol and *p*-hydroxy benzoate units, e.g., polyethylene-*p*-oxybenzoate
PEEI	Polyesteretherimide
PEEK	Polyetheretherketone
PEG	Polyethyleneglycol
PEH	High-density polyethylene, also HDPE
PEI	Polyetherimide
PEIE	Polyetherimide ester copolymer
PEIm	Polyetherimine
PEK	Polyetherketone
PEKEKK	Poly(ether-ketone-ether-ketone-ketone)
PEL	Low-density polyethylene, also LDPE
PEM	Medium-density polyethylene, also MDPE
PENDC, PEN	Poly(ethylene 2,6-naphthalene dicarboxylate) or polyethylenenaphthalate
PENi	Polyethernitrile
PEO	Polyethylene glycol, usually PEG
PEOX	Poly(2-ethyl-2-oxazoline)
PEP	Thermoplastic copolymer from ethylene and propylene
PEPA	Polyether-polyamide copolymer
PES	Polyethersulfone $[-\varphi\text{-}SO_2\text{-}\varphi\text{-}O\text{--}]_n$
PEsA	Polyesteramide
PESK	Polyarylenethioetherketone
PEST	Thermoplastic polyesters, e.g., PBT, PET, also TPES
PET, PETP	Polyethyleneterephthalate
PETG	Polyethyleneterephthalate glycol, copolymer with 66 mol% ethylene glycol and 34 mol% cyclohexylene dimethanol
PEtI	Polyethyleneimine
PEUR	Polyether urethane
PF	Phenol-formaldehyde resin
PFA	Polyfluoroalcoxyalkane, copolymer of tetrafluoroethylene and perfluorinated
PFEP	Copolymer from tetrafluoroethylene and hexa-fluoro propylene, also FEP

PFF	Phenol-furfural resin
PG	Poly-α-hydroxy acrylic acid
PGI	Polyglutarimide
PH	Phenolics
PHB, POB	Poly(p-hydroxybenzoic acid)
PHBA	Poly(β-hydroxybutyric acid)
PHEMA	Poly-2-hydroxyethyl methacrylate
PHIT	Poly(hexylene-isophthalate-terephthalate)
PHMT, PHT	Polyhexamethylene terephthalate PHP Physiological hydrophilic polymers PhPS Poly(p-phenyl styrene)
PHP	Physiological hydrophilic polymers
PhPS	Poly(p-phenyl styrene)
PHT, PHMT	Polyhexamethylene terephthalate
PHZ	Polyphosphazene
PI	Polyimide but also *trans*-1,4- polyisoprene, gutta-percha (UK)
PIAN	Isoprene – acrylonitrile oil-resistant elastomer
PIB	Polyisobutene
PIBI	Copolymer from isobutene and isoprene, butyl rubber (also butyl, GR-I, IIR)
PIBO	Polyisobuteneoxide
PIP	Synthetic *cis*-1,4-polyisoprene (also CPI, IR)
PIPO	Polyimidazipyrolone
PIR	Polyisocyanurate (foam) PIS Polyisobutylene
PISU	Polyimidesulfone
PL	Polyethylene (EWG), also PE
PLA	Polylactic acid
PMA	Polymethyl acrylate
PMAC	Polymethoxy acetal
PMAN	Polymethyl acrylonitrile
PMB	Poly-methylenebenzoate
PMCA	Polymethyl-α-chloro acrylate
PMI	Polymethacrylimide
PMMA- GMA	Poly(methyl methacrylate-co-glycidyl methacrylate)
PMMA	Polymethyl methacrylate
PMMA-MA	Poly(methyl methacrylate-co-acrylic acid)
PMMI	Polypyromellitimide
PMP	Poly-4-methyl-1-pentene (see also TPX)
PMPhS	Polymethylphenylsiloxane
PMPPI	Polymethylenepolyphenylene isocyanate, also PAPI
PMQ	Silicone rubbers with methyl and phenyl substituents
PMS	Poly-α-methyl styrene
PNA	Polynuclear aromatics
PNF	Polyfluoroalcoxyphosphazene
PNR	Polynorbornene rubber

PO	Polyolefin but also elastomeric polypropylene oxide and phenoxy resin
POB, PHB	Poly-*p*-hydroxy benzoate
POBA	Polyoxybenzoyl acid, rigid-rod polymer
POBI	Polyoxadiazobenzimidazole
POCA	Poly(oxy(cyanoarylene)) or polyoxycyanoarylene
POD	Polyoctadecene
PODZ	Poly(*p*-phenylene 1,3,4-oxadiaxole)
POM	Polyoxymethylene, polyformaldehyde, polyacetal, or "acetal resin"
POMA	Poly(oxetane methacrylate)
POP	Polyoxypropylene, usually PPG
POR	Elastomeric copolymer from propylene oxide and allyl glycidyl ether
POT	Polyoctyl thiophene
PP	Polypropylene or oriented polypropylene (see also OPP)
PPA	Polyphthalamide, also polypropyleneadipate
PPAc	Polypropyl acrylate
PPBA	Polyparabanic acid
PPC	Chlorinated polypropylene
PPC	Polyphthalate-carbonate, High heat PC with HDT $= 160°C$
PPCA	Poly(polycyclic (meth)acrylate)
PPD-T, PPTA	Poly(*p*-phenylene terephthalamide) Kevlar™
PPE	Poly(2,6-dimethyl 1,4-phenylene ether) (see also PPO)
PPeA	Poly(*n*-pentyl acrylate)
PPE-MA	Maleic anhydride-modified poly(2,6-dimethyl 1,4-phenylene ether)
PPG	Polypropylene glycol
PPhA	Polyphthalamide
PPI	Polymeric polyisocyanate
PP-MA	Maleic anhydride-modified polypropylene
PPMA	Poly(phenyl methacrylate)
PPMS, PpMS	Poly(*para*-methyl styrene)
PPO	GE Co., Polymer Products Operation, trade name for poly (2,6-dimethyl 1,4-phenylene ether) (see PPE)
PPOEA	Poly(phenoxyethoxyethyl acrylate)
PPOX, PPO	Polypropylene glycol, usually PPG
PPP	Poly-*p*-phenylene
PPR	Polypyrrole
PPrA	Poly(*n*-propyl acrylate)
PPS	Polyphenylsulfide
PPSK, PKS	Polyketonesulfide $[-φ-S-φ-CO-]_n$
PPSS	Polyphenylenesulfidesulfone
PPS-S	polythioethersulfone

PPSU, PSF, PSO	Polyphenylene sulfone, polysulfone
PPT, PPTP	Polypropyleneterephthalate; (see also PTT)
PPTA, PPD-T	Poly(1,4-phenylene terephthalamide)
PPX	Poly(*p*-xylylene)
PPy	Polypyrrole
PPZ	Polyorganophosphazene
PQ	Elastomeric silicone with phenyl substituents
PS	Polystyrene
P-S, PSA	Pressure-sensitive adhesive
PSAB	Copolymer from styrene and butadiene (also SB, S/B)
PSAN	Thermoplastic copolymer from styrene and acrylonitrile, also SAN
PSB	Styrene-butadiene rubber, also GS-R, SBR
PSBR	Elastomeric terpolymer from vinyl pyridine, styrene, and butadiene
PSF	Polysulfone, also PSUL, PSU, PSO
PS-GMA	Styrene-glycidyl methacrylate copolymer
PSI	Polymethylphenylsiloxane
PSL	Polyspirodilactone
PS-MA	Styrene-maleic anhydrite copolymer
PSO	Polysulfone, also PSUL, PSU, PSF
PSOX	Styrene polymer having reactive (2-oxazoline) groups
PST	Polystyrene fiber with at least 85% styrene units
PS-TSG	Polystyrene foam, processed by injection (German literature)
PSU	Polysulfone $[-\varphi\text{-}SO_2\text{-}\varphi\text{-}O\text{--}\varphi\text{-}C(CH_3)_2\text{-}\varphi\text{-}O\text{--}]_n$
PSUL	Polysulfone, also PSF, PSU, PSO
PS-VPh	Poly(styrene-b-vinyl phenol) block copolymer
PTA	Polytetramethylene adipamide
PTF	Polytetrafluoroethylene fiber
PTFE	Polytetrafluoroethylene (also TFE)
PTHF	Polytetrahydrofuran [also known as polybutylene glycol, PBG]
PTMA	Polytetramethyleneadipate
PTMC	Poly(trimethylene carbonate)
PTMEG	Poly(tetramethylene ether glycol)
PTMG	Polytetramethylene glycol
PTMT	Poly(tetramethylene terephthalate) or polybutyleneterephthalate, PBT
PTO	Polytransoctanylene
PTR	Polysulfide rubber
PTT	Poly(trimethylene terephthalate), also PPT
PU, PUR	Polyurethane elastomer
PVA	Polyvinyl acetal
PVAc, PVAC	Polyvinyl acetate

PVAl, PVAL	Polyvinyl alcohol
PVBO	Polyvinyl butyral
PVBu	Polyvinyl butyrate
PVC	Polyvinyl chloride
PVCA, PVCAc	Copolymer from vinyl chloride and vinyl acetate
PVCC	Chlorinated PVC, also CPVC, PeCe
PVC-DC	Poly(vinyl chloride-co-vinylidene chloride)
PVD	Polyvinylidene chloride fiber with 50 wt% vinylidene chloride
PVDC	Polyvinylidene chloride, also PVC_2
PVDF	Polyvinylidene fluoride, also PVF_2
PVE	Polyvinylethylene
PVF	Polyvinyl fluoride
PVFM, PVFO	Polyvinyl formal
PVI	Poly(vinyl isobutyl ether)
PVID	Polyvinylidenecyanide
PVIE	Polyvinyl isobutyl ether
PVK	Poly-*N*-vinylcarbazole
PVM	Copolymer from vinyl chloride and vinyl methyl ether
PVME	Polyvinyl methyl ether
PVMQ	Silicone rubber with methyl, phenyl, and vinyl substituents
PVOH	Polyvinyl alcohol (also PVAL, PVAl)
PVP	Poly-*N*-vinylpyrrolidone
PVPh	Poly(4-vinylphenol), poly(*p*-hydroxy styrene)
PVSI	Polydimethylsiloxane with phenyl and vinyl substituents
PY	Unsaturated polyester resins, also UP
Q	Silicone elastomer
QA	Quality assurance
QC	Quality control
QDS	Quality data statistics
QMC	Quick molding change
RAM	Restricted area molding
RCF	Refractory ceramic fiber
REX	Reactive extrusion
RF	Resorcinol-formaldehyde resin
RH	Relative humidity (in %)
RHB	Reheat blow molding
RIM	Reaction injection molding
RLM	Reactive liquid polymer
RMPS	Rubber-modified polystyrene
RP, RTP	Reinforced plastics, reinforced thermoplastic, also RP/C
RPBT	Reinforced polybutyleneterephthalate
RPET	Reinforced polyethyleneterephthalate
RPVC	Rigid PVC film

RRIM	Reinforced reaction injection molding
RTD	Residence time distribution
RTM	Resin transfer molding
RTP	Reinforced thermoplastic
RTPO	Reactor-blended thermoplastic olefinic elastomer
RTS	Reinforced thermoset
RTV	Room temperature vulcanization (of silicone rubber)
RUC	Chlorinated rubber
SAA	Styrene-acrylic acid copolymer
SAMA	Styrene-acrylonitrile-methacrylic acid copolymer
SAN	Styrene-acrylonitrile
SAN	Thermoplastic copolymer from styrene and acrylonitrile, also AS, PSAN
SANGMA	Styrene-acrylonitrile-glycidyl methacrylate copolymer
SANMA	Styrene-acrylonitrile-maleic anhydride copolymer
SAXS	Small-angle X-ray scattering
SB, SBR	Thermoplastic copolymer from styrene and butadiene, also PASB, S/B
SB/BA	Styrene-butadiene-butyl acrylate copolymer
SBCL	Styrene-butadiene-caprolactone copolymer
SBMA	Styrene-butadiene-maleic anhydride copolymer
SBMI	Styrene-butadiene-maleimide
SBP	Styrene-butadiene polymer
SBR	Styrene-butadiene elastomer
SBS	Styrene-butadiene-styrene
SBS	Styrene-butadiene-styrene triblock polymer
SCR	Elastomeric copolymer from styrene and chloroprene
SEBS	Styrene-ethylene/butylene-styrene triblock polymer
SEM	Scanning electron microscopy
SEP	Styrene-ethylene-propylene block copolymer
S-EPDM	Sulfonated ethylene- propylene-diene terpolymer
SF, SFM	Structural foam, structural foam molding
SFK	Synthetic fiber reinforced plastic (German literature)
SFP	Scrapless forming process
SHIPS	Super-high-impact polystyrene
SI	Thermoplastic silicone
SIN	Simultaneous interpenetrating network or semi-interpenetrating network
SIPN	Sequential interpenetrating polymer network
SIR	Elastomeric copolymer from styrene and isoprene
SIS	Styrene-isoprene-styrene triblock polymer
SMA	Copolymer from styrene and maleic anhydride
SMAA	Copolymer from styrene and methacrylic acid
SMA-AA	Styrene-maleic anhydride-acrylic acid copolymer

SMC	Sheet molding compound
SMI	Copolymer from styrene and maleimide
SMMA, SMM	Styrene-methyl methacrylate copolymer
SMM-GM	Styrene-methyl methacrylate- glycidyl methacrylate copolymer
SMM-MA	Styrene-methyl methacrylate-maleic anhydride copolymer
SMS	Copolymer from styrene and α-methyl styrene
SP	Saturated polyester plastics
SPC	Statistical process control
sPP	Syndiotactic polypropylene
SPPF	Solid-phase pressure forming
SPSF	Solid-phase stretch forming
S-PVC	Suspension PVC
SR	Synthetic rubber, polysulfide rubber
SRIM	Structural reactive injection molding
SRP	Styrene-rubber plastics
SSE	Single-screw extruder
SVA	Styrene-vinyl-acrylonitrile copolymer
SVPh	Styrene-*p*-vinyl phenol copolymer
SWP	Solvent-welded plastics pipe
TA	Cellulose triacetate, also CT, CTA
TC	Technically classified natural rubber
TCE	Tetrachloroethane
TDI	Toluene di-isocyanate
TE	Thermoplastic elastomer of any type
TEEE	Thermoplastic elastomer, ether-ester
TEO	Thermoplastic elastomer, olefinic
TES	Thermoplastic elastomer, styrenic
TFE	Polytetrafluoroethylene (also PTFE)
TGA	Thermogravimetric analysis
TGIC	Triglycidyl isocyanurate
THF	Tetrahydrofuran (solvent)
TM	Thioplasts, transfer molding
TMA	Thermomechanical analyzer
TMBA-PC	Tetramethyl bisphenol-A polycarbonate (or MPC, TMPC)
TMC	Thick molding compound
TMPC	Tetramethyl bisphenol-A polycarbonate (TMBPA-PC)
TOR	*Trans*-polyoctenamer rubber TP Thermoplastic
TPA, TPR	1,5-*trans*-polypentenamer
TPE, TPEL	Thermoplastic elastomer
TPE-A	Thermoplastic elastomer-amide
TPE-E	Thermoplastic elastomer-ester
TPE-S	Thermoplastic elastomer-polystyrene
TPES	Thermoplastic polyesters, e.g., PBT, PET (see also PEST)

TPI	Thermoplastic polyimide
TPO	Thermoplastic olefinic elastomer
TPS	Toughened PS (in the UK for HIPS)
TPU, TPUR	Thermoplastic urethanes
TPV	Thermoplastic vulcanizate
TPX	Poly(4-methyl-1-pentene) (see also PMP)
TR	Thermoplastic elastomer or thio rubber (UK)
TREF	Temperature-rising elution fractionation
TS	Thermoset
TSE	Thermoset elastomer
TSI	Thermoset polyimide
TSUR	Thermoset polyurethane
UE	Polyurethane elastomer
UF	Urea-formaldehyde resin
UFS	Urea-formaldehyde foam
UHMW-PE	Ultrahigh molecular weight polyethylene (over 3 Mg/mol)
ULDPE	Ultralow-density polyethylene (ca. 900–915 kg/m^3)
UP	Unsaturated polyester
UP-G-G	Prepreg from unsaturated polyesters and textile glass fibers
UP-G-M	Prepreg from unsaturated polyesters and textile glass mats
UP-G-R	Prepreg from unsaturated polyesters and textile glass rovings
UPVC	Unplasticized PVC
UR	Polyurethane elastomers, also UP
VAc	Vinyl acetate
VAc-AN	Copolymer from vinyl acetate and acrylonitrile
VAcE	Vinyl acetate-ethylene copolymer
VC/E, VCE	Vinyl chloride-ethylene copolymer
VCE	Copolymer from ethylene and vinyl chloride
VCEMA	Copolymer from vinyl chloride, ethylene, and methyl acrylate (or maleic anhydride)
VCEV	Copolymer from vinyl chloride, ethylene, and vinyl acetate
VCM	Vinyl chloride (monomer), also VC
VCMA	Copolymer from vinyl chloride and methyl acrylate
VCMMA	Copolymer from vinyl chloride and methyl methacrylate
VCOA	Copolymer from vinyl chloride and octyl acrylate
VCVAc	Copolymer from vinyl chloride and vinyl acetate
VCVDC	Copolymer from vinyl chloride and vinylidene chloride
VDC	Vinylidene chloride
VDC/AN	Copolymer from vinylidene chloride and acrylonitrile
VF/HFP	Copolymer from vinylidene fluoride and hexa-fluoro propylene
VLDPE	Very low-density polyethylene (ca. 885 kg/m^3)
VMQ	Silicone rubber with methyl and vinyl substituents
VOC	Volatile organic compound

VPE	Vulcanized (cross-linked) polyethylene, also XLPE
VQ	Elastomeric silicone with vinyl substituents
VSI	Polydimethylsiloxane with vinyl groups
WAXS	Wide-angle X-ray scattering
WR	Woven rovings
XABS	Acrylonitrile-butadiene-styrene/acidic monomer, an elastomeric copolymer
XLPE	Cross-linked polyethylene
XMC	Extra-strength molding compound
XNBR	Acrylonitrile-butadiene/acidic monomer, an elastomeric copolymer
XPS	Expandable or expanded PS
XSBR	Butadiene-styrene/acidic monomer, an elastomeric copolymer
YBPO	Elastomeric polyetherester: $[((CH_2)_4\text{-}O)_n\text{-}CO\text{-}\phi\ CO\text{-}O\text{-}]_m$
YSBR	Thermoplastic, elastomeric block copolymer from styrene and butadiene
YXSBR	Block copolymer from styrene and butadiene containing carboxylic groups

Note: This list is based on the nomenclature proposed by diverse standardizing organizations, as well as on the acronyms used in technical literature, viz., American Society for Testing Materials, Standard Terminology for Abbreviated Terms Relating to Plastics, ASTM D1418-01a, ASTM D1600-99, and their referenced standards; British Standards, schedule of common names, and abbreviations for plastics and rubbers, BS 3502–1978; Deutsches Institut für Normung, plastics, symbols and codes for polymers and their special characteristics, DIN 7728 Teil 1 01.88; symbols for reinforced plastics, DIN 7728 Teil 2 03.80; plastics molding materials DIN 7742 Teil 1 01.88; molding techniques for molding materials, definitions, DIN 16700 09.67; Association Française de Normalisation, plastics, vocabulary, T 50–100 08.90; plastics, symbols, T 50-050-1, T 50-050-2, T 50-050-3 06.89; International Organization for Standardization, plastics, symbols, ISO 1043–1; 1987, ISO 1043–2; 1988, ISO 1043–3; International Union for Pure and Applied Chemistry, Pure Appl. Chem. **18**, 583 (1969); Pure Appl. Chem. **40**, 473 (1974).

Appendix II: Examples of Commercial Polymer Blends

	Polymer				
No.	A	B	Name	Supplier	Comments
1.	PS	PB(BR) or PE	Hostyren	Hoechst	The blends are formulated for extrusion, injection and blow molding
			Limera R	Dainippon Ink and Chemicals	They show excellent processability, low moisture absorption and shrinkage, improved impact strength. Composition-dependent modulus, toughness, ductility, transparency, and gloss
			Polysar	Bayer Miles	
			Polystyrol	BASF AG	
			Styroblend	BASF AG	
			Styroplus	BASF AG	
2.	ABS or ASA	Elastomer or SMA*	Cadon*	Monsanto Chem.	Blends of ABS or ASA with either acrylic rubber (800) or PB (900 series) were formulated for extrusion, thermoforming, injection, and blow molding. They show excellent processability, weatherability, impact strength, HDT, scratch resistance, paintability, and plateability
			Centrex	Monsanto Chem.	
			Luran S	BASF AG	
			Magnum	Dow Chem. Co.	
			Rovel	Uniroyal	
			Starflam ABS	Ferro Plastics	
			Terluran	BASF AG	

No.	Polymer A	B	Name	Supplier	Comments
3.	TPU	ABS	Prevail	Dow Chem. Co.	The blends can be injection molded, extruded, blow molded, or thermoformed. Transfer or compression molding, calendering, and solid state may also be used. They show hardness between that of TPU and ABS, superb toughness, chemical resistance, appearance
			Techniace TU	Sumitomo Dow	
4.	LDPE	PIB	Lupolen O 250	BASF AG	The 1:1 blends are flexible and resistant to cracking under stress and show good water-vapor properties. The blends are formulated for extrusion, injection, and blow molding. The weld-line strength, resistance to warpage, and shrinkage depend on processing conditions
			Pax-Plus	Paxon Polymer Co.	
5.	NBR	EPDM or CPE or PVC	Geolast JSR NE *	Monsanto JSR	The blends are formulated for extrusion, calendering, injection, and blow molding. They have either co-continuous or (less frequently) dispersed morphology. They show good processability; ozone, oil, and heat resistance; low compression set; low-temperature flexibility; nearly total elastic recovery; and excellent weather resistance. Principal use includes automotive weather stripping, interior moldings, tubings, hoses, seals, gaskets, expansion joints, cable sheathings, conveying belts, roofing, pond liners, geomembranes, floorings, etc.
			Chemigum TPE[#]	Goodyear Tire & Rubber Co.	
			Krynac NV	Polysar, Inc.	
			[#]Nipol	Nippon Zeon	
			[#]Paracril OZO	Uniroyal Chemical	

	Polymer				
No.	A	B	Name	Supplier	Comments
6.	PP	TPO or EPR or EPDM	BK 891	Mitsui Chemical	The blends are formulated mainly for injection molding, but they can also be extruded, thermo- or vacuum-formed (e.g., Optum), compression or transfer molded, calendered, and blow molded. Several have dynamic properties, viz., hardness and heat resistance. Some blends are vulcanized, showing toughness, and are composition dependent (30 wt%) (e.g., Kelburon) and reactor made. Reinforced and filled grades (containing glass fiber, talc, $CaCO_3$, or mineral filler) are available. These blends show good processability, low-temperature modulus and impact strength, dimensional stability, low shrinkage, good mechanical properties at temperatures from −40 to 150 °C, ozone resistance, dynamic fatigue and abrasion resistance, as well as high good weather ability (especially carbon-black filled grades) tear strength and paintability. Over 200 applications have been found for these materials, e.g., they are used in appliances, hardware and plumbing, automotive industry (arm rests, pillar trim, door panels, radiator grilles, dashboards, children seats, side protectors, bumpers, spoilers), etc.
			Deflex	A. Schulman	
			Dynaflex	JSR	
			Ferrolene	Ferro Plastics	
			Ferro Flex	Ferro Plastics	
			HiFax	Himont Adv. Mat.	
			Hostalen PP	Hoechst	
			IPCL JSA1986	IPCL	
			Kelburon, Keltan TP	DSM Polymer International	
			Milastomer	Mitsui Petrochem.	
			Modylen	Tiszagi Vergi Kom.	
			Moplen SP	Himont	
			Oleflex	Showa Denko Co.	
			Optum	Ferro Plastics	
			Polytrope	A. Schulman, Inc.	
			Propathene	ICI	
			PU-21713	Ferro Plastics	
			RPI 507 EP	Research Polym.	
			RxLOY	Ferro Plastics	
			Santoprene	Monsanto	
			Sarlink	Novacor	
			Sumitomo TPE	Sumitomo Chem.	
			Thermolan 2000	Mitsubishi Petrochemicals	
			TPO 900	Reichhold Chem.	
			Vestolen EM	Hüls A.-G.	

	Polymer				
No.	A	B	Name	Supplier	Comments
7.	PVC	Acrylics	Acrylivin	General Tire & Rubber	Suspension PVC modified by 5–15 wt% acrylic elastomer. The blends are are formulated for extrusion, injection, and blow molding, vacuum- or thermoforming, and calendering. They show high impact strength, rigidity, resilience, dimensional stability, flame retardancy, excellent outdoor performance, and good flame, abrasion, electrical, chemical, and solvent resistance. These blends are used in industrial, commercial, consumer (e.g., as wall coverings, corner guards, column covers, shelving, counter laminates, ceiling tiles), medical, food or beverage equipment, aircraft or mass transit interior components, and applications requiring good resistance to weathering
			Cladux	R. Daleman	
			Decoloy	GE Plastics	
			Fiberloc HTX	The Geon Company	
			Haibulen	Nippon Zeon	
			Kane-ace	Kanegafuchi Chem.	
			Kydex	Rohm and Haas	
			Metabulen	Mitsubishi Rayon	
			Polycast	Royalite	
			Sunloid KD	Tsutsunaka	
			Vinidur	BASF AG	
8.	PVC	NBR	Carloy	Cary Chem. Inc.	These blends (containing 30–60 wt% PVC) are formulated mainly for extrusion and calendering, but injection, blow, compression, and transfer molding can also be used. They show good processability, fast calendering and extrusion, impact and tear strength, and oil, fuel, improved chemical, abrasion, weathering, ozone, antistatic, flame, and moisture resistance. Their applications include cables and hoses, printing plates and rollers, shoe soles, bottles for cosmetics and edible oils, profiles, etc.
			Geon/Hycar	B. F. Goodrich	
			Denka LCS	Showa Denko Co.	
			JSR NV	Jap. Synth. Rub.	
			Krynac NV	Miles-Polysar	
			Nipol	Nippon Zeon	
			Oxyblend	OxyChem	
			Paracril OZO	Uniroyal Chem.	
			Vynite	Alpha Chem. Plast.	

No.	Polymer A	B	Name	Supplier	Comments
9.	PVC	ABS or ASA*	Abson 042	Abtec Chem. Co.	These blends are formulated for injection molding, extrusion, and thermo-or vacuum forming, but calendering can also be used. The blends show superior processability to component polymers, impact strength, flame retardance, and cost-to-performance ratio. The blends with ASA show superior weatherability, while those containing SMA high HDT. The main use is for business machines, electrical and electronic equipment housings, automotive applications, swimming pool fittings, irrigation, etc.
			Cycovin K-29	The Geon Co.	
			Denka Taimel.	Denki Kagaku	
			*Geloy XP2003	GE Plastics	
			Kaneka Enplex	Kanegafuchi Corp.	
			Kralastic	Uniroyal/Sumitomo	
			Lustran ABS 860	Monsanto Chem.	
			Nipeon AL	Zeon Kasei Co.	
			Polyman 500	A. Schulman, Inc. DSM	
			Ronfaloy V	DSM	
			Tufrex VB	Mittsubishi	
			Triax CBE (discontinued)	Monsanto Chem.	
10.	PA-6		Grilon BT	EMS-Chemie	Miscible blends show improved processability, solvent resistance, elongation, low-temperature impact and tensile strength
		PA	Wellamid MR	Wellman, Inc.	
			Zytel 3100	E. I. du Pont	
11.	PA	PA	Akuloy RM	DSM Eng. Plast.	The blends are formulated mainly for injection molding and extrusion. Polyamides PA-6, PA-66, PA-mXD6, and PARA. In most blends PA is the matrix phase, but those with PP as a matrix are also available (e.g., from Solvay). The blends show good processability; reduced water absorption; dimensional stability; low density (i.e., low cost per volume); low liquid and vapor permeability; moderate impact strength; good resistance to alcohols, glycols, and gasohol; improved heat aging; primer-less paintability; and resistance to cracking when exposed to metal halides (e.g., CaCl$_2$). Some grades are reinforced. Principal blend uses include appliances, automotive, tools, building, furniture, and industrial
			Dexpro, Dexlon	Dexter Corp.	
			Eref	Solvay	
			Flexloy	Sumitomo Chem.	
			Gapex	Ferro Plastics	
			LAX 23	Ube, Inc.	
			MCX-Q	Mitsui Petrochem.	
			NB	Toyobo	
			Novamid AC	Mitsubishi Chem.	
			Orgalloy R-6	Atochem	
			Poliblend NH	Poliresins SA	
			Snialoy	Nylon Corp. Amer.	
			Systemer S	Showa Denko Co.	
			Thermocomp	LNP	
			Ube Alloy CA	Ube Inc.	
			Ultramid KR	BASF AG	
			UTX	Unitika	

No.	Polymer A	B	Name	Supplier	Comments
12.	PA-6, P PA-66, PARA, or PA-666	E, EPR, acrylic elastomers, or ionomers	Albis	Albis Plastics	The blends are formulated for extrusion, co-extrusion, injection, compression, transfer, and blow molding. They can also be thermoformed. Grades containing up to 40 wt% mineral or glass fibers are available. Some may contain PTFE. The blends have good processability, low-temperature impact strength, rigidity, stiffness, high heat resistance, lower service temperature. The molded articles can suppress vibration, even when dry and at sub-zero temperatures. The blends find use in a broad range of applications, viz., automotive (stone and splash guards, under-the-hood moldings, seals, hoses, tubes, clips, fasteners, fuel doors, gears), appliances, sport (e.g., ski bindings, roller skates), business equipment, consumer products (office chair seats, housings, casters, wheels, rollers, pulleys, gears), etc.
			Bexloy C	E. I. du Pont	
			Brilion BT-40	Emser Ind.	
			Capron	AlliedSignal	
			Durethan	Bayer A.-G	
			Dynyl	Rhône Poulenc

			Vydyne	Monsanto Chem.	
			Wellamid 22 L	Wellman Inc.	
			Zytel ST	E. I. du Pont	
			Zytel 300, 400	E. I. du Pont	
13.	PA-66, or PA-6	Brominated PS	Akulon K228	DSM	These fire-resistant, unreinforced blends designed for injection molding or extrusion are used in automotive and electrical applications. They show good flame retardance, mechanical properties, and dimensional stability
			Latamid 66	Lati	
			Starflam PA6	Ferro Plastics	
			Ultramid A3X	BASF AG	
			Zytel FR	E. I. du Pont	

No.	Polymer A	Polymer B	Name	Supplier	Comments
14.	PA-6 or PA-66	ABS	Alphaloy MPA	Kanegafuchi Chem.	The compatibilized blends (with either PA as matrix or co-continuity of both phases) are formulated for injection molding, extrusion, and thermoforming, but blow and compression molding also can be used. The blends show good processability and flow; high heat and chemical resistance; high resistance to oil, wear, and abrasion; dimensional stability; low-temperature impact strength; reduced moisture sensitivity; and economy. Main application is in automotive, chemical, electrical, customer, and sport industries. Some grades are glass fiber reinforced. The material has been also used in anti-vibration damping structures
			Elemid	GE Plastics	
			Diaaloy N	Mitsubishi Rayon	
			Kane ace MUH	Kanegafuchi Chem.	
			Malecca S	Denki Kagaku K.

			Toyolac alloy	Toray Ind., Inc.	
			Triax 1000	Monsanto	
			Ultramid	BASF AG	
15.	PA	Cyclic - PO	Elmit ZF	Mitsui Petrochemicals	Processability, impact strength, moisture insensitivity
16.	PA	PC	Dexcarb	D & S Int.	Processability, HDT > 200 °C, impact strength, low mold shrinkage, solvent, and moisture sensitivity
			Iupilon	Mitsubishi Gas	
			SC 720	Idemitsu	
			Petrochemicals		
17.	PC	TPU	Texin 3000	Bayer/Miles	PC blends with polyester urethane were designed for extrusion or molding articles used in automotive and consumer goods' industries
			Texin 4000		
18.	PC	Elastomer	Idemitsu SC-150	Idemitsu Petrochemicals	The blends for extrusion or injection molding contain < 6 wt% elastomer (e.g., butyl acrylate-co-methacrylate) and thus are opaque. They show low temperature toughness, high impact strength, good weld-line strength, and HDT
			Makrolon T-78	Bayer/Miles	
			Novarex AM	Mitsubishi Chem.	

No.	Polymer A	B	Name	Supplier	Comments
19.	PC	ABS (and SAN in some blends)	Alphaloy	Kanegafuchi Chem.	The blends are formulated for injection molding, extrusion, and thermo-or vacuum forming, but they can also be compression or transfer molded. They show good processability, excellent plating, HDT and impact strength, high stiffness and strength, dimensional stability, toughness, delamination resistance, low-temperature impact strength, good weld-line strength, and solvent and chemical resistance. These are three-phase blends, with 30–65 wt% PC usually being the matrix. Grades with glass fiber reinforcement are available. The blends are used for housings of computers, business machines and electrical appliances, electrical and electronic parts, connectors, carriages, switches, fans, power and agricul-tural, garden and lawn tools, cameras, optical instruments, exterior automotive components, electronic or telecommunication parts, sporting goods, etc.
			Bayblend T	Bayer/Miles

			Terblend B	BASF AG	
			Triax 2000	Monsanto Chem.	
			ABS/PC 7901	Diamond Polymers	
20.	PC	ASA, or AAS*	Baitaloy*	Hitachi Chem. high-	High impact strength, thermal stability, improved resistance to temperature aging and UV degradation, excellent weatherability, rigidity, and dimensional stability. The blends are formulated mainly for extrusion, injection molding, and thermoforming
			Dialoy A	Mitsubishi Rayon	
			Geloy XP4001	GE Plastics	
			Terblend S	BASF AG	
21.	PC	PS	Novadol	Mitsubishi Chem.	Impact strength, thermal stability, and weatherability
			SC 200	Idemitsu Petrochemicals	

No.	Polymer A	B	Name	Supplier	Comments
22.	PC	SMA	Arloy 1000	ARCO Chem. Co.	The blends are designed for extrusion, thermoforming, or injection molding. They show excellent processability, toughness, and heat resistance
			Ektar MB	Eastman Kodak	
			R4 9900	Thermofil Inc.	
23.	PC	PBT or PET or PCTG (and 10–20 wt% impact modifier)	Azloy	Azdel, Inc.	The blends are formulated for injection molding, extrusion, and blow molding, but they can be transfer or compression molded, formed in solid state, or thermoformed. In most blends PC is the matrix phase. The impact modifier can be PE, ABS, or acrylic copolymer, e.g., MBS. The blends show good processability; heat resistance; ductility; HDT; high modulus, impact, tensile, and flexural strength over a wide temperature range; good adhesion; solvent, chemical, and UV resistance. They can be painted, hot stamped, metallized, and plated. Some blends (containing polybutadiene as impact modifier) may have poor weather-ability. The blends are mainly used in automotive industry

24.	PET	Elastomer or SMA*	Arloy 2000*	ARCO Chem. Co.	The blends are formulated for extrusion, injection, compression, blow, and transfer molding. The blends contain up to 35 wt% glass fiber. They show good processability, rigidity, impact and tensile strength, as well as excellent weatherability
			Celanex	Celanese Eng. Res.	
			Rynite	E. I. du Pont	
			SC-150	Idemitsu Petrochemicals	
25.	PET or PCTG*	PC (and 15–20 wt% impact modifier)	*Ektar MB	Eastman	These blends can be injection molded or extruded. They are partially miscible, with co-continuous morphology showing improved processability, solvent resistance, elongation, low-temperature impact and tensile strength (possible reduction of crystallinity upon blending) Ektar resins are based on poly(cyclohexane-terephthalate-glycol) mixed with PC and/or with SMA. They are primarily used in business machines, appliances, consumer goods, garden tools, lightning, automotive, sports equipment, fluid handling, etc.
			Hyperlite	Kanegafuchi Chem.

29.	PBT	ABS or AAS*	A, AN	Teijin	The blends contain 0–30 wt% glass fiber or mineral fillers. They are formulated for injection molding but can be extruded, thermoformed, or solid state formed. They show excellent processability, high gloss, stiffness at high temperature, good electrical properties, thermal stability, mechanical strength, HDT, low shrinkage, good dimensional stability, impact strength, as well as solvent (e.g., to gasoline and motor oils) and chemical resistance. The main consumption includes electronics, automotive and electrical industry, as well as office, sports, and household equipment

30.	PAr	PET or PC	Ardel D-240	Amoco Corp.	Processability, high HDT, tough, high impact strength
			U-8000	Unitika	
31.	POM	PBT	Duraloy	Celanese	HDT, toughness, softness, high impact strength
			Lynex T	Asahi Chem.	
32.	POM	TPU	Celcon	Celanese Eng. Res.	The blends are formulated for extrusion, injection, compression, blow, and transfer molding. They show excellent processability; rigidity; high impact strength; high fatigue, flexural, and tensile strength; high toughness; low water absorbency; gloss; and resistance to chemicals. In most blends POM is impact-modified with 10–30 wt% TPU. Some grades contain PTFE. Co-continuous morphology gives especially good performance. These blends find use in sports equipment, plumbing, electronic/mechanical parts, automotive, appliances, hinges, etc.

33.	PPE	PS (HIPS, SBS, SEBS, ABS, SB,. . .)	Gepax	GE Plastics	These blends, with 25–60 wt% PPE, were designed for injection or blow molding, calendering, thermoforming, and extrusion. Some grades are rein-forced with < 30 wt% glass fibers. They show good processability, heat resistance, HDT = 90–150 °C, toughness, good dimensional stability, resistance to hot water, flame retardance, low density, cost/performance ratio, and low moisture absorption
			Luranyl	BASF AG	
			Noryl	GE Plastics	
			Prevex	GE Plastics

37.	PVDF	PMMA	Polycast	Royalite	Used for electrets or as outdoor films with good clarity and chemical and UV stability
38.	PSF	ABS	Arylon	Uniroyal	The blends can be either extruded or injection molded. They show good processability, toughness, dimensional stability, high HDT, hot water resistance, plateability, and paintability. The applications include plumbing, food service, and fiber optics controlled system
			Mindel A	Amoco Corp.	
39.	PSF	PET	Mindel B	Amoco Corp.	The blends can be either extruded or injection molded. They show improved processability and impact strength, low shrinkage and warpage, high HDT, good stress crack chemical and solvent resistance, and good economy. The blends find applications as molded electrical parts, viz., connectors, relays, switches, motor starters, control housings, etc.
40.	PSF	PA	Reo-alloy	Riken Vinyl	Processability, low viscosity, and low water absorption
41.	SMI	SAN	Malecca A	Denka	High heat and impact resistanc
42.	SMI	ABS	Malecca K	Denka	High heat and impact resistance
43.	SMI	PA	Malecca N	Denka	High heat, solvent, and impact resistance
44.	PEEK	PES	Sumiploy SK	Sumitomo Chem.	The blends are designed for injection molding, but extrusion, compression molding, or thermoforming can also be used. SK 1660 grade contains glass fibers. The materials show good processability, excellent high temperature, and chemical and hot water resistance

45.	PEEK	LCP	Sumiploy EK	Sumitomo Chem.	The blends are designed for injection molding, but extrusion, compression molding, or thermoforming can also be used. They show good process- ability, high strength, modulus, and HDT
46.	PEI	PC	Ultem LTX	GE Plastics	Designed for injection molding and extrusion. Processability; HDT; flexural, tensile, and impact strength; flame retardancy; long-term hydrolytic stability; stain and chemical resistance; and lower cost than PEI
47.	PI	LCP	Aurum	Mitsui Toatsu	Good processability, low viscosity, HDT, and low water absorption
48.	HIPS	Hydrophilic polymer		Toray	Permanent antistatic properties

Appendix III: Dictionary of Terms Used in Polymer Science and Technology

A-, B-, and C-stages	Expressions used by Baekeland to differentiate polymerization steps of phenolic resins. A-stage, initial; resins are still fusible and soluble. B-stage, advanced degree of condensation; resins are still capable of swelling but no longer soluble. C-stage; complete cross-linking and insolubility.
AB, AABB polymerization	Step-growth polymerization, in which the two types of functional group (A and B) are attached to the same or two different monomers, viz., hydroxy acid (AB) and diol-diacid (AABB).
Ablation	Decomposition of a material caused by heat friction.
Abrasion	The wearing away of some surface area by its contact with another material.
Abrasion resistance	Ability of material to withstand mechanical action such as rubbing, scraping, or erosion that tends to progressively remove material from its surface; to resist surface wear.
ABS	A thermoplastic classified as an elastomer-modified styrene-acrylonitrile copolymer.
Accelerated aging	Aging by artificial means to obtain an indication on how a material will behave under normal conditions over long period. Also tests in which conditions are intensified to reduce the time required to obtain deteriorating effects, similar to these resulting from normal service conditions.
Accelerated weathering	Duplicating or reproducing weather conditions by machine-made means. Test in which the normal weathering conditions are accelerated by means of a device.

Accumulator	A device for conserving energy in hydraulic systems of molding equipment, or an auxiliary ram extruder used to provide fast material delivery in a molding machine.
Acetal resins	Polyoxymethylene – a crystalline thermoplastic material made from formaldehyde, viz., Delrin™ or Celcon™.
Acrylic elastomer	An elastomer based on polyethylacrylate and/or poly-n-butylacrylate with thermal stability up to T = 200 °C, usually cross-linked by heating with peroxides or with alkali. To improve the solvent resistance, 20–50 wt% of ethoxy or methoxyethyl-acrylate may be added.
Acrylics	Name given to plastics produced by the polymerization of acrylic acid derivatives, usually including methyl methacrylate. An amorphous thermoplastic material. In technological jargon polymethylmethacrylate (PMMA) or polyacrylonitrile fiber with at least 85 wt% of PAN.
Adapter	A mechanical reducing mechanism between the barrel and either a nozzle or a die.
Additive	A material added to a polymer during the final synthesis stages or in subsequent processing to improve or alter some characteristics of the polymer. Additives, as a class of materials, are not intended to increase strength properties. Examples of additive include pigments, lubricants, antistatic agents, flame retardants, and plasticizers.
Adhesion	The state in which two surfaces are held together at an interface by mechanical or chemical forces, by interlocking action, etc.
Adhesive	A substrate capable of holding two materials together by surface attachment. Adhesive can be in film, liquid, or paste form.
Advanced composites	Composite materials that are reinforced with continuous fibers having a modulus higher than that of glass fibers. The term includes polymeric matrix, metal matrix, and ceramic matrix composites, as well as carbon-carbon composites.
Aging	The change of a material over time under defined natural or synthetic environmental conditions, leading to improvement or deterioration of properties. Also, changes caused by exposure to physical and chemical factors (viz., light, temperature, chemicals, weather), leading to irreversible deterioration. A process of exposing plastics to natural or artificial environmental

	conditions for a prolonged time. See also "Accelerated aging," "Artificial aging," "Chemical aging," and "Physical aging."
Alkyd resins	Name given to synthetic, thermosetting resins processed from polyhydric alcohols and polybasic acid or anhydrides. These unsaturated polyesters are prepared by esterification of a polyfunctional alcohol (e.g., glycerin) with phthalic anhydride in combination with fatty acids or rosin acids (molecular weight about 2,000 to 5,000). These resins are frequently modified by incorporation of, e.g., nitrocellulose, NC, or phenolics. Alkyds are used mainly as lacquers.
Alloy	A material made by blending polymers or copolymers with other polymers or elastomers under selected conditions, e.g., styrene-acrylonitrile copolymer (SAN) blended with butadiene-acrylonitrile elastomer (NBR). A mixture of two chemically different polymers to form a material having properties different from but often comprising those of the original resins. Also see "Polymer alloy."
Allyl resin	Low-molecular-weight polymerization product of allyl monomer, $CH_2 = CHCH_2X$, where, for example, $X = -OH, -OOCCH_3$.
Ambient temperature	Temperature of the medium surrounding an object. Used to denote prevailing room temperature (RT).
Amino resin	Collective term for resins that are capable of being cross-linked. Terms, aminoplast and amino plastic, are also used. The materials are based on compounds containing NH_2 group and formaldehyde. The representatives are urea-, melamine-, and dicyanodiamide-based resins used for laminating and molding.
Amorphous polymer	A noncrystalline polymeric material that has no definite order or crystallinity. A polymer in which the macromolecular chain has a random conformation in solid (glassy or rubbery) state. On the one hand, an amorphous polymer may show a short range order, while on the other, a crystalline polymer may be quenched to the amorphous state (viz., polyethylene terephthalate (PET)).
Amplitude	The maximum value of a periodically varying function, e.g., used to describe the energy transmitted from the ultrasonic welding horn to the weld joint.
Analysis of variance	A statistical technique where the total variation of the investigated response is being analyzed or divided into meaningful components, such as a portion due to regression and a portion due to error.

Anionic polymerization	Chain polymerization in which the active center is an anion, usually carbanion. The method is mostly used to polymerize vinyl monomers carrying electron-withdrawing substituents (e.g., $-CN$, $-COOR$, $-COR$, $-aryl$). The polymerization is frequently initiated by n-butyllithium.
Anisometry	The difference in the magnitude of the dimensions of a particle that depend on the direction. Thus, sphere is isometric – it has a minimum of anisometry. It is customary to define anisometry in terms of the aspect ratio, p. For platelets, p is defined as the thickness divided by the longest orthogonal dimension; thus, for platelets, $p \leq 1$. By contrast, for fiber-like particles, p is the length-to-diameter ratio, i.e., $p \geq 1$. Macromolecules show high anisometry with a typical value $p = 1,000$.
Anisotropy	The material properties being dependent on the direction. Most multiphase polymeric systems show some degree of anisometry. The mechanical performance in the machine direction can be as much as a hundred times higher than those in the transverse direction. In homopolymers, the anisotropy is a reflection of the molecular orientation in either a glassy or a semicrystalline state (see "Birefringence").
Annealing	To heat a molded plastic article to a predetermined temperature and slowly cool it to relieve stresses. Annealing of molded or machined parts may be done dry, as in an oven, or wet, as in a heated tank of mineral oil. To relieve the stresses without introducing major change of the molecular structure in the formed article, the annealing is frequently carried out at a temperature being few degrees *below* the glass transition temperature, T_g. The treatment is also used to increase polymer crystallinity. The process requires keeping the polymer at a temperature $T < T_d$ (where T_d is the thermal degradation temperature). The best results are usually obtained when $(T_g + T_m)/2 \leq T < T_m$, where T_m is the melting temperature.
Antioxidant	A substance that, when added in small quantities to the resin during mixing, prevents its oxidative degradation and contributes to the maintenance of its properties.
Antiplasticization	An increase of stiffness, tensile strength, and/or the glass transition temperature and a decrease of the elongation at break caused by addition of small amount of a plasticizer. For example, maximum hardness of

	polyvinylchloride was observed at 5–10 phr of diethylhexyl phthalate, PVC/DOP, and minimum impact strength at 12 phr. Antiplasticization occurs in many polymers, viz., PVC, polymethylmethacrylate (PMMA), polystyrene (PS), polycarbonate (PC), polyamides (PA), and silk (by water).
Antistatic agents (antistats)	Substances that, when added to the molding material or applied on the surface of the molded part, make it less able to store static electrical charge.
Apparent or bulk density	Weight of unit volume of material including voids (air) inherent in the material.
Arc resistance	The time required for a given electrical current to render the plastic surface of a material conductive because of carbonization by the arc flame. Also ability to resist the action of a high voltage electrical arc, usually in terms of time required to render the material electrically conductive. The total time (in sec) that intermittent arc may play across the plastic surface with rendering the surface conductive.
Aromatic	Description used for chemicals that have at least one ring structure derived from benzene in their chemical structure. Benzene rings are made by six carbon atoms forming a hexagonal structure with alternating single and double bonds. The description is general and covers a wide range of chemicals. The word "aromatic" is used because of the strong smell of benzene. Many of the chemicals classified as aromatics have a very different smell or no smell at all. A benzene ring structure with one bonding site is a "phenyl" ring or group. See also "Benzene."
Aromatic polymer	A polymer containing aromatic ring structures, viz., polyamides, polyesters, polyethers, polysulfides, polysulfones, polysiloxanes.
Artificial aging	The exposure of a plastic to conditions that accelerate the effects of time, such as heating, exposure to cold, flexing, application of electrical field, immersion in water, exposure to chemicals and solvents, ultraviolet, light stability, and resistance to fatigue. The accelerated testing of plastic specimens to determine their changes in properties carried out over a short time. The tests indicate what may be expected of a material under service conditions over extended periods. Typical investigations include those for dimensional stability, mechanical fatigue, chemical resistance, stress cracking resistance, dielectric strength, and so forth, under the

	conditions that reflect the conditions under which the article will be used. Usually, the time the article is exposed to these test conditions is relatively short. See also "Aging."
Ashing	The reduction of a polymer by high heat to yield any inorganic material, e.g., fillers or reinforcements, used to verify the percentage of nonorganic content in the resin.
Aspect ratio	The relative comparison of one dimension of an object to another. For fibers, the aspect ratio is the length divided by the diameter. For mica, it is the shorter of the length and width of a platelet to its thickness. For complex objects like a particle of clay, it is a relative number approximating the ratio of the longer of two dimensions to the shorter. This ratio is key in how effective a reinforcement is within a matrix of polymer molecules. Given uniform composition and coupling agents, higher aspect ratio reinforcement results in a higher increase in strength. The aspect ratio determines how much stress can be transferred to the fibers or platelets before being transferred back into polymer matrix.
ASTM	Abbreviation for American Society for Testing and Materials.
Atactic polymer	A polymer in which at least one chain atom in a mer can exhibit stereoisomerism (e.g., $-CH_2C*HX-$), but has no preference for one particular configuration, e.g., atactic vinyl polymers (PVC or PS), atactic polypropylene, and PP.
Atom	The most basic compositional unit of the elements composed of protons, electrons, and neutrons. Elements are any substance composed solely of chemically identical atoms, viz., carbon, hydrogen, oxygen, sulfur, nitrogen, iron, and aluminum.
Attenuation	The diminution of vibrations or energy over time or distance. The term is also used to describe a process of making thin and slender articles, e.g., the formation of fiber from molten glass.
Autoclave	A closed vessel for conducting either a chemical reaction or other operation (e.g., cooling) under pressure and heat. Autoclaves are widely used for bonding and curing reinforced plastic laminates.
Autoclave molding	A process in which after lay-up, winding, or warping, an entire assembly is placed in a heated autoclave, usually at 340–1,380 kPa (50–200 psi). The pressure results in higher density and improved removal of volatiles.

	The lay-ups are usually vacuum bagged with a bleeder and release cloth.
Automatic mold	A mold or die in injection or compression molding that repeatedly goes through the entire cycle without human assistance.
Auxiliary equipment	Refers to equipment, other than the principal processing unit (e.g., an extruder or an injection molding machine), required to ensure that the manufactured part would be made correctly. The auxiliary equipment comprises dryers, chillers, material and part conveyors, robots, process monitoring and controlling units, etc.
Average molecular weight	Summation over the distribution of molecular weights of a polymeric substance, e.g., with respect to the number, M_n, weight, M_w, or higher moments. Depending on the method of determination, M_n, M_w, or higher average molecular weight is obtained.
Back pressure	A pressure against the free flow of material during extrusion that causes the material to have a high mixing action. Also resistance of a material caused by its viscosity to flow when mold is closing.
Back taper or draft	Reverse draft used in mold to prevent molded articles from drawing freely.
Backing plate	In mold construction, a plate used as a support for the cavity blocks, guide pins, bushings, etc.
Ball valve	A screw melt seal or valve, similar to a check ring valve, but designed differently. Uses a roundball to seal off the melt so it does not flow back over the screw flights during the injection cycle.
Banbury	An internal mixer for compounding, composed of a pair of counterrotating rotors that masticate the materials.
Barrel	In extrusion, injection molding, or blow molding machine a hollow tube in which the plastic material is gradually heated and melted and from which it is extruded.
Batch	A quantity of materials formed during the same process or in one continuous process and having identical characteristics throughout.
Benzene	A chemical structure composed of six carbon atoms arranged in a stable cyclic structure. Each carbon atom is single bonded to the next carbon atom on one side and double bonded to the carbon atom on the other side. Each also has a hydrogen atom bonded to it. Phenyl groups are benzene rings where one of the carbon atoms is bonded to another molecule, making the entire cyclic structure a substituent or side group of that molecule.

Bezel	A grooved rim or flange.
Binder	The resin or a cementing constituent that holds the other components together. The agent applied to mats or preforms to bond the fibers before molding.
Binomial distribution	A discrete probability distribution based on two possible outcomes, which may be labeled success (with probability p) or failure (with probability q = 1 − p); the probability function expresses the number of X successes in n independent trials.
Bimodal distribution	A probability distribution in which the differential distribution function has two maxima.
Biopolymer	Polymer produced by biosynthesis in nature, viz., polysaccharides, nucleic acids, proteins, cellulose, lignin, and natural rubber.
Binodal	The line on the temperature vs. composition phase diagram for a mixture of two components, which separates the metastable region from the single-phase regions. Hence, it represents the limits of stability in a two-phase system, viz., a polymer solution or polymer blend.
Birefringence (double refraction)	The difference between index of refraction in two directions, measured with polarized light. The birefringence originates in the molecular orientation in either a glassy or crystalline phase. Positive birefringence occurs when the principal optic axis lies along the chain and negative when it is perpendicular. See also "Dichroism."
Bleed	To give up color when in contact with water or a solvent. Also a "migration," undesired movement of additives in a plastic (e.g., plasticizers in PVC) to the surface of the finished article or into an adjacent material. The term is also used to describe a passage at the parting line of a mold (such as a vent, but deeper) that makes it possible for the material to escape or bleed.
Bleeding	Diffusion of an additive in or out of a plastic part. See "Bleed."
Blending	Preparation of polymer blends or alloys, usually involving mixing of two polymeric liquids.
Blends	see "Polymer blends."
Blister	A raised area on the surface of a molded part caused by the pressure of gases inside it.
Blister packaging	Packaging method based on sealing articles inside thermoformed, transparent cases.
Block copolymers	Copolymer synthesized from two or more monomers in such a way that monomers of the same kind are arranged in homopolymeric blocks.

Block polymerization	An older expression for bulk or mass polymerization.
Blocking	The adhesion between layers of plastic that may develop under pressure during storage or use.
Bloom	A visible exudation or efflorescence on the surface of a plastic – it may be caused by lubricant, plasticizer, etc.
Blow film extrusion	Techniques for making film by extruding the plastic through a circular die, followed by expansion (by the pressure of internal air admitted though the center of the mandrel), cooling, and collapsing the bubble.
Blow molding	A molding process used to produce hollow objects in which a hollow tube (parison) is forced into a shape of the mold cavity using internal air pressure. The two primary types are injection blow molding and extrusion blow molding. Blow molding is a method of fabrication in which a warm plastic parison is placed between the two halves of a mold and forced to assume the shape of that mold cavity by use of air pressure introduced through the inside of the parison that forces the melt against the surface of the mold.
Blow pin	A hollow pin inserted or made to contact the blowing mold so that the blowing media can be introduced into the parison or hollow form and expanded to conform to the mold cavity.
Blowing agent	Additive capable of producing a cellular structure in a plastic or rubber mass.
Blueing off	Checking the accuracy of mold cutoff surfaces by putting a thin coating of Prussian blue on one-half and checking the blue transfer to the other half.
Blush	The tendency of a plastic to turn white or chalky in areas that are highly stressed (viz., gate blush).
Bonds	Forces between atoms that hold them in relative proximity to each other resulting in larger structures called molecules. Primary bonds result from the sharing of two electrons of two atoms of the same molecule and are strongest. Secondary bonds are between atoms of different molecules or remote sections of the same molecule. They are the result of attractions due to polarity, induced polarity due to displaced electrons, and temporary polarity due to vibration and spinning. These bond forces are weak in comparison to primary bonds.
Boss	A projection on a plastic part designed to add strength, facilitate alignment during assembly, and provide for fastening.
Bottom plate	Part of the mold containing the heel radius and push-up.

Branched chains	Side chains attached to the main, original chain.
Branched polymer	A nonlinear polymer in which the molecules consist of linear main chain to which there are randomly attached secondary chain branches, viz., low density polyethylene. A fraction of repeat units in a polymer that statistically contain one branch is defined as the branching density: $\lambda = \alpha b/n$, where α is the branching coefficient (dependent on functionality of the branch point), b is the number of branch points, and n is the number of repeat units.
Breaker plate	A perforated plate located at the end of an extruder or at the nozzle end of an injection cylinder. It often supports the screens that prevent foreign particles from entering the die.
Breathing or degassing	The opening and closing of a mold to allow gases to escape early in the molding cycle. When referring to plastic film, "breathing" indicates permeability.
Brittle failure	Failure resulting from inability of material to absorb energy, resulting in instant fracture upon mechanical loading.
Brittle or brittleness temperature	Temperature at which plastics and elastomers exhibit brittle failure under impact conditions – the lowest temperature at which the material withstands given condition without failure.
Brittle point	The highest temperature at which a material fractures in a prescribed impact test procedure.
Buckling	Crimping of the fibers in a composite material, often occurring in glass-reinforced thermosets due to resin shrinkage during cure.
Bulk or apparent density	Average density of material in a loose or powdered form of plastic (granular, nodular, etc.) expressed as a ratio of weight to volume.
Bulk factor	Ratio of volume of any given quantity of the loose plastic material to the volume of the same quantity of the material after molding or forming. It is a measure of volume change that may be expected in fabrication.
Bulk polymerization	Polymerization where only the monomer and initiator (or catalyst) are involved. Owing to heat of polymerization and difficulty of safe dissipation of generated heat, the conversion rarely exceeds 50 %. Older terms: block or mass polymerization.
Burning	Overheating the resin in the barrel causing discoloration and, if long enough, charring the material. Burning can be caused by trapped gases in poor or nonvented area of the mold. The gases may ignite, due to pressure and

temperature (as in a diesel engine) and discolor or char the part.

Burst strength	The internal pressure required to break a pressure vessel such as a pipe or fitting. The pressure (and therefore the burst strength) varies with the rate of pressure buildup and the time during which the pressure is held.
Butadiene	A common name of a synthetic elastomer, polybutadiene – BR, e.g., used in butadiene-styrene, butadiene-acrylonitrile, and acrylonitrile-butadiene-styrene copolymers.
Butt fusion	A method of joining similar forms of thermoplastic materials using heat.
Buttress thread	A type of thread used for transmitting power in only one direction. It has the efficiency of the square thread and the strength of the V-thread.
Calendering	The passing of sheet materials between sets of pressure rollers to produce a smooth finish sheet of desired thickness.
Calorimeter	An instrument capable of making absolute measurements of energy absorbed in a material by measuring changes of temperature.
Capillary rheometer	Instrument for measuring the flow properties (viscosity) of polymer melts. Composed of a capillary tube of specified diameter and length, means for applying a pressure to force molten polymer through the capillary, means for maintaining the desired temperature of the apparatus, and means for measuring differential pressures and flow rates.
Carbon black	A black pigment or filler produced by the incomplete burning of natural gas or oil. It is widely used in the rubber industry and for wire/cable applications. Since it possesses ultraviolet protective properties, it is also used in formulations intended for outside weathering applications.
Carbon fiber	Fibers produced by the pyrolysis of organic precursor fibers, such as rayon, polyacrylonitrile (PAN), and pitch, in an inert environment. The term is often used interchangeably with the term graphite; however, carbon fibers and graphite fibers differ. The differences lie in the temperature at which the fibers are made and heat-treated, as well as in the amount of elemental carbon produced. Carbon fibers typically are carbonized at around 1,315 °C and contain 94 $\pm$ 1 % carbon, while graphite fibers are graphitized at 1,900–2,480 °C and contain 99 % carbon.

Carborane polymer | A polymer containing carborane structures, viz., $-C(B_{10}H_{10})C-$, known for their high decomposition temperature $T_d \S 500\ °C$. Owing to the hydrogen presence, the oxidative stability is limited to about 300 °C.

Carreau-Yasuda equation | Relation between viscosity, η, and the deformation rate, y, was originally derived for monodisperse polymers:

$$\eta = \eta_0 \left[1 + (\tau y)^2 \right]^{-(1-n)/2}$$

where η_o is the zero-shear viscosity, τ is the principal relaxation time, and n is the power-law exponent. For polydispersed systems, the above equation was later modified by other authors to read:

$$\eta = \eta_0 \left[1 + (\tau y)^{m_1} \right]^{-m_2}$$

where m_1 and m_2 are polydispersity parameters:

$$n = 1 - m_1 \cdot m_2$$

Cartridge heaters | Electrical heaters enclosed in a jacket that can be selectively located to heat the surrounding metal.

Catalyst | A substrate that changes the rate of a chemical reaction without itself undergoing permanent change in composition or becoming a part of the molecular structure of the product. By contrast, either curing agents or hardeners may not only catalyze the reaction but also participate in it. Also accelerator, curing agent, hardener, inhibitor, and promoter.

Cationic polymerization | Chain polymerization in which the active center is a cation, usually carbonium ion, $-C^+$. Generally, the method is used to polymerize vinyl monomers carrying electron-releasing substituents (e.g., alkyl or alkoxy groups). The polymerization is initiated by an initiator and co-initiator, viz., $BH_3 + H_2O$.

Cavity | A depression in the mold that usually forms the outer surface of the part. Depending on the number of such depressions, molds are designated as a single cavity, a multicavity, or a family cavity mold.

Cavity number | A sequential number engraved in a mold cavity and reproduced on the molded part for later reference in case a problem ever occurs with the part.

Cavity retainer plates | Plates in a mold that hold the cavities and usually contain the guide pins and bushings.

Ceiling temperature	Temperature at which the free polymerization energy is zero. Thus, above this temperature, no further polymerization takes place.
Cellular plastic	A plastic with greatly decreased density because of the presence of numerous cells or bubbles dispersed throughout its mass. Also foamed plastics and synthetic cellular plastics.
Cellulose acetate	An acetic acid ester of cellulose, obtained by the action of acetic acid or acetic anhydride on purified cellulose (e.g., from cotton linters). All three hydroxyl groups of each glucose unit can be acetylated. For plastics' applications, it is usual to acetylate fully and then lower the acetyl value to 54 ± 2 % by partial hydrolysis.
Cellulosic plastics	Plastics based on cellulose derivatives, such as esters (cellulose acetate) or ethers (ethyl cellulose).
Cementing	A process of joining two similar plastic materials to themselves or to dissimilar materials by means of solvents.
Center-gated mold	An injection or transfer mold in which the cavity is filled with molding material through a sprue or gate directly into the center of the part.
Chain member number	Number of atoms involved in building a macromolecule.
Chain polymerization	An addition polymerization in which a monomer is converted to polymer in a chain reaction. Here initiator activates the monomer to which other monomers are added:

$$I^* + M \rightarrow IM^*$$
$$IM^* + M \rightarrow IMM^*$$
	preserving the active status of the terminal mer. The active center may be a free radical, an anion or a cation.
Chalking	A dry, whitish, powdery chalk-like appearance or deposit on the surface of a plastic caused by material degradation (usually from weather). See also "Haze" and "Bloom."
Change request	A request to modify or alter the dimensions, material, tolerances, or manufacture of a part now in or soon to be in production. Used to ensure all interested and involved department personnel are informed and can comment and approve or disapprove of the pending change.
Charpy	A common name of a type of pendulum tests for toughness.
Charpy impact test	A test for shock loading in which a centrally notched sample bar is held at both ends and broken by striking

	the back face in the same plane as the notch. A destructive test measuring impact resistance, consisting of placing the specimen in a horizontal position between two supports, then striking the specimen with a pendulum striker swung from a fixed height. The magnitude of the blow is increased until specimen breaks.
Check ring	A material shutoff ring mounted on the front of the screw, behind the screw tip, that allows melt to flow past it when the screw is retracting so that a supply of melt builds up in front of the screw. When the screw moves forward to inject melt into the mold, the check ring moves rearward and seals off the screw flights so that the melt is pushed into the mold.
Chemical aging	The long-term deleterious effects on a material under defined natural or artificial environmental conditions (viz., light, temperature, humidity), leading to irreversible deterioration of properties. A process of exposing plastics to natural or artificial factors for prolonged time. See also "Aging," "Accelerated aging," "Artificial aging," and "Physical aging."
Chemical resistance	Ability of a material to retain utility and appearance following contact with chemical agents.
Chi-square (χ^2) test	Test of normality of distribution or a goodness of fit.
Chromatography	The separation, especially of closely related compounds, caused by allowing a solution or mixture to seep through an absorbent, such that each compound becomes adsorbed in a separate layer.
Chromium plating	An electrolytic process that deposits a hard film of chromium metal onto working surfaces of other metals. Used when resistance to corrosion, abrasion, and/or erosion is needed.
Clamping area	The largest rate molding area an injection or transfer press can hold closed under full molding pressure.
Clamping force or pressure	In injection molding, the pressure applied to the mold to keep it closed despite the fluid pressure of the compressed molding material within the cavity and runner system.
Clamping plate	A plate used to fasten the mold to a molding machine.
Clarity or transparency	Frequently considered as evidence of blends miscibility or at least that of fine domains. This, however, is misleading when the refractive indices of the two polymers approach each other. Also material clearness or lack of haze.
Closed loop	A feedback system used with microprocessor for control of a processing unit operation.

Coefficient of expansion or thermal expansion	The fractional change in a specified dimension or volume of a material for a unit change in temperature. Values for plastics range from 10 to 200 ppm per 1 °C (ASTM D696).
Coefficient of friction	A measure of the resistance to sliding of one surface in contact with another. The value calculated under a known set of conditions, such as pressure, surface, speed, temperature, and material, to develop a number, either static or dynamic, of the resistance of the material to slide – the lower the value, the higher the material's lubricity.
Coefficient of linear expansion	A measure of the change in dimension of an object caused by a change in temperature; specifically measured by the increase in length of an object per one degree.
Coefficient of regression, or coefficient of correlation, R	Measure of the degree of relationship between a model obtained by regression (curve fitting) and the independent variables; if reported as $100R^2$ (%), it can be interpreted as the percentage variation explained by the postulated model.
Coefficient of thermal expansion	The change in volume per unit volume produced by a one degree rise in temperature.
Coining	The peening over or compressing of a material to change its original shape or form.
Cold flow	A plastic exhibits cold flow when it does not return to its original dimensions after being subjected to stress. See also "Creep."
Cold shot	Incomplete parts formed while cycling a molding machine during heating.
Cold slug	The first material to enter an injection mold so called because in passing through sprue orifice, it is cooled below the effective molding temperature.
Cold slug well	Space provided directly opposite the sprue opening in an injection mold to trap the cold slug.
Colloid	A system in which at least one component exists in state of fine dispersion with particle diameter d = 1 to 1,000 nm. Three types, colloidal dispersions, lyophilic colloids, and colloidal associations, are distinguished.
Colloidal molecules	A discrete macromolecule is the colloidal particle.
Color concentrate	A mixture of a measured amount of dye or pigment and a specific plastic material base. A more precise color can be obtained using concentrates than using neat colors. Note: Care should be taken to verify that the color concentrate base is miscible with the plastic it is to color. Color concentrate may contain up to 60 wt% of

	pigment and it is normally used at 1–4 % of the plastic material to be colored.
Color standard	The exact color a plastic resin or part must match to be acceptable. Resin suppliers often submit color chip samples of the matched resin color to be compared to the molded part. The color chip, or standard, is usually 51 × 76 mm with one polished surface and various textured surfaces on the opposite side. Suppliers use similar standards to verify the color of each lot of resin shipped to their customer.
Colorfast	The ability to resist change in color.
Colorimeter	Instrument for matching colors with results approximately the same as those of visual inspection but more consistently.
Commodity resin	The term associated with the high-volume low-price resins having low-to-medium physical properties, used for less critical applications. The principal five resin types are polyethylenes (PE), polypropylenes (PP), styrenics (PS, HIPS, ABS, MBS, etc.), acrylics, and vinyls (PVC, EVAc, etc.).
Compatibility	Ill-defined term pertaining to ability of one material to coexist with another without undesirable effects – to be avoided.
Compatibilization	A process of modification of interfacial properties of an immiscible polymer blend, leading to creation of a polymer alloy.
Compatible polymer blend	Ill-defined, utilitarian term indicating a commercially attractive polymer mixture, normally homogenous to the eye, frequently with enhanced physical properties over the constituent polymers – to be avoided.
Complex modulus	The ratio of stress to strain in which each is a vector that may be represented by a complex number. It may be measured in tension or flexure, E*; compression, K*; or shear, G*.
Compliance	Tensile compliance is the reciprocal of Young's modulus. Shear compliance is the reciprocal of shear modulus. The term is also used in the evaluation of stiffness and deflection.
Composites	Any solid material that consists of a combination of two or more types retaining their separate identity. In polymer technology, the term is reserved for these polymeric systems in which additions of solid particles result in reinforcing effect. The composites are divided into reinforced filled systems (with a particle size:

	d = 50 nm), short fiber composites, long fiber composites, and continuous fiber composites.
Compound	A mixture of polymer(s) with all materials necessary for the finished product. In reinforced plastics and composites, the intimate admixture of a polymer with other ingredients, such as fillers, softeners, plasticizers, reinforcements, catalysts, pigments, dyes, etc.
Compounding	Preparation of a compound.
Compression molding	A molding technique in which the preheated compound is placed in the heated open mold cavity, the mold is closed, pressurized (what causes the material to flow and fill the cavity), and then pressure is held until the material has cured.
Compression ratio	In an extruder is a ratio of volume available in the first flight (at the feed) to the last flight at the end of the screw (near the die).
Compressive strength	The ability of a material to resist a compressive force. It is expressed as maximum load sustained by a test specimen in a compressive test divided by original cross-sectional area of the specimen or, in other words, a crushing load at the failure divided by the original sectional area of the specimen (ASTM D695).
Concentricity	The relationship of all circular surfaces with the same center. Deviation from concentricity is often referred to as a runout.
Condensation polymer	A polymer obtained in step-growth polymerization, often accompanied by elimination of small molecules (e.g., water). Polyesters, polyamides, phenol-, melamine-, and urea-formaldehyde resins are typical condensation polymers.
Conditioning	The subjection of a material to standard environmental and/or stress history before testing, so that it will respond in a uniform way to subsequent testing or processing. The term is frequently used to refer to the treatment given before testing. ASTM standard conditions for a plastic testing laboratory are 23 ± 2 °C and 50 + 5 % relative humidity.
Conditioning chamber	An enclosure used to prepare parts for their next step in the assembly or decorating process. Parts can be stress relieved, humidity or moisture conditioned, or impregnated with another element.
Configuration	Spatial arrangement of atoms in a molecule. The chemical constitution of a polymer chain, which can be changed only by breaking the chemical bonds.

Conformation	Arrangements of the chain elements in space, which may be changed by rotation about bonds. The conformation depends on the internal and external forces, e.g., interactions, pressure, temperature, and stresses. For polymers with the carbon-carbon main chain, two conformations are important: trans or t and gauche or g:

gauche   trans
	The helical conformations are defined by the long sequences of these two, viz., tgtgtgtgtgt and tggtggtggtggt.
Conjugated polymer	A polymer with sequence of conjugated double bonds, such as polyacetylene, polyphenylene, and dehydrogenated polyvinyl chloride.
Continuous use temperature (CUT)	Maximum temperature at which material may be subjected to continuous use without fear of premature thermal degradation.
Cooling channels	Passageways within the body of a mold through which a cooling or heating medium (e.g., chilled water, steam, hot oil, or other fluids) can be circulated to control temperature on the mold surface.
Cooling or shrink fixture	A block of steel, wood, or composite material that is similar to the shape of the molded piece. The hot molded part is taken from the mold, placed on it, and allowed to cool, without distorting.
Cooling time	The time required after the gate freezes for the part to cool and becomes rigid enough for ejection from the mold cavity.
Copolycondensation	Polycondensation of different monomers having either a different constitution or different functional groups following different reaction mechanisms.
Copolymer	A polymer obtained from polymerization of two or more monomers, where the repeating structural units of both are present within each molecule, thus comprising more than one chemical species. In most cases, the term refers

	to a polymer containing two monomer types, e.g., styrene and butadiene (SBR). When a copolymer contains three or four different mer species terms, terpolymer, tetrapolymer, or multipolymer may be used. Seven types of copolymers are recognized: statistical, random, alternating, periodic, graft, block, and core-shell. The copolymers may be prepared in reactive blending, with properties intermittent between those of polymers of the two composing monomers.
Copolymerization parameter	Ratio of the velocity constants during copolymerization.
Copolymerization	Polymerization with more than one species of monomer, which can react with one another, forming a copolymer.
Core	Either a male element in die that produces a hole or recess in a part, a part of a complex mold that molds undercut parts (cores are usually withdrawn to one side before the main sections of the mold open), a channel in a mold for circulation of a heat-transfer medium or the central part of a laminate.
Coring	Removal of excess material from the cross section of a molded part to attain a more uniform wall thickness.
Corona treatment	Exposing a plastic part to a corona discharge increases receptivity to inks, lacquers, paints, and adhesives. See also "Surface treatment."
Corrosion	Material that is eaten away by chemical reactions at the surface.
Corrosion resistance	The ability of a material to withstand contact with ambient natural factors or those of a particular artificially created atmosphere.
Coupling agent	A material used to improve the interfacial properties between two phases. The term most frequently refers to the material used to improve an adhesion between polymer matrix and filler or reinforcing particles.
Covalent bond	A bond where electrons are equally shared between two atoms producing a stable electron configuration and a very stable molecule. Covalent bonds are the strongest of the molecular bonds.
Crack	A fracture, a separation of material, visible on opposite surfaces of the part, and extending through the thickness.
Crazing	A series of or the forming of very fine cracks in the surface of a material, usually a polymeric substance. The cracks may extend in a network on or under the surface or through a layer of plastic material. These are

	undesirable defects, characterized by distinct cracks or minute, frost-like internal cracks, resulting from stresses within the article. These stresses result from molding shrinkage, machining, flexing, impact shocks, temperature changes, or action of solvents. Crazing is generally caused by chemical attack or other degrading agents such as ultraviolet radiation.
Creep	The change in dimension of a plastic under load over a period of time (excluding the initial instantaneous elastic deformation). Owing to viscoelastic nature, a plastic subjected to a load for a period of time tends to deform more than it would from the same load released immediately after application. The degree of this deformation depends on the load duration. Creep is the permanent deformation resulting from prolonged application of stress below the elastic limit. Data obtained in creep test are presented as creep vs. time, with stress and temperature constant. Slope of the curve is the creep rate, and the end point of the curve is the time for rupture. Creep at room temperature is called cold flow (ASTM D674).
Creep modulus (apparent modulus)	Ratio of initial applied stress to creep strain.
Creep rupture strength	Stress required to cause fracture in a creep test.
Creep strength	Maximum stress required to cause specific creep in specific time.
Cross-links	Covalent bonds, or a short sequence of chemical bonds, joining two macromolecules to form a cross-linked or network polymer.
Cross-linking	The chemical reaction between polymeric molecules to form covalently bonded three-dimensional macromolecules. The reaction progresses from a linear chain to branched elastomeric macromolecules, than to hard and brittle resin. When extensive, as in most thermosetting resins, cross-linking engenders a single, infusible supermolecule of all the chains. Cross-linking can be achieved by irradiation with high energy electron beams or by chemical means.
Cross-linked polymer	A polymer in which initially linear macromolecules are joined by a covalent bond or a short sequence of chemical bonds either during the polymerization [e.g., poly(styrene-co-divinylbenzene)] or in a post-polymerization cross-linking reaction (cross-linking, curing, or vulcanization). The cross-linked materials are insoluble and they do not flow when heated.

Crystalline polymer	A material having an internal structure in which the atoms are arranged in an orderly three-dimensional configuration. More accurately a semicrystalline polymer, since only a portion of the macromolecules is in crystalline form.
Crystallinity	A state of molecular structure attributed to existence of solid crystals with a definite geometric form. Such structures are characterized by uniformity and compactness. A regular arrangement of the atoms of a solid in space.
	In most polymers, including cellulose, this state is imperfect. The crystalline regions are submicroscopic volumes in which there is a degree of regularity sufficient to obtain X-ray diffraction patterns. High crystallinity causes a polymer to be less transparent or opaque.
Cup flow test	Test for measuring the flow properties of thermosetting materials. A standard mold is charged with preweighed material, and the mold is closed using sufficient pressure to form a required cup. Minimum pressures required to mold a standard cup and the time required to close the mold fully are determined.
Cup viscosity test	Test for making flow comparison under strictly comparable conditions. The cup viscosity test employs a cup-shaped gravity device that permits the timed flow of a known volume of liquid passing through an orifice located at the bottom of the cup.
Cure	That portion of the molding cycle during which the plastic material in the mold becomes sufficiently rigid to permit ejection.
Curing	Cross-linking or vulcanizing a polymer to improve such properties as modulus, strength, thermal stability, etc.
Cushion	The 5–10 mm of resin in front of the screw tip that remains at the end of the injection cycle. It is used to maintain packing pressure on the melt until the cavity gate freezes.
Curing time	The time between the end of injection pressure and the opening of the mold.
Cycle	Complete, repetitive sequence of operations in a process or part of a process. In molding, the cycle time is the period, between a certain point in one cycle and the same point in the next.
Cyclopolymerization	Polymerization leading to ring structures, with usually low molecular weight and low viscosity. These prepolymers or cyclomers can be used at a higher temperature in the subsequent catalyzed reaction to generate a high molecular weight, linear polymers, viz.,

	polycarbonates and polyesters. The cyclomer technology facilitates preparation of polymer alloys, composites, or nanocomposites.
Damping	The loss in energy, as dissipated heat, that results when a material system is subjected to an oscillatory load or displacement.
Daylight opening	Clearance between two platens of a press in the open position. Mold daylight describes the opening distance of mold halves for part removal.
Deboss(ed)	Indent or cut in design, or lettering of a surface.
Decompression	The removal of the melt pressure by an increase in screw flight depth and a positive vent opening in the barrel of a vented barrel extruder or injection molding machine.
Deflashing	The term is used for a variety of finishing methods used to remove the flash (excess, unwanted material), viz., filing, sanding, milling, tumbling, and vibrating.
Deflection temperature under load (DTUL)	The temperature at which a simple beam has deflected a given amount under load (formerly called heat distortion temperature (HDT)).
Deformation	Any change of form or shape in a body, in particular a linear change of dimension of a body in a given direction produced by the action of external forces.
Degating	The removal of the part from the runner system.
Degradation	A deleterious change in the chemical structure, physical properties, and/or appearance of a plastic, usually caused by exposure to heat. Also any undesirable change of polymer chemical structure leading to deleterious change of properties, viz., thermal, hydrolytic, oxidative, photo, bio, and radiation.
Degree of polymerization	The number of mers in a macromolecule, i.e., the number of repeat units in the chain of a molecule, DP. In a condensation polymer, a repeating unit is composed of a monomer group from each reactive species.
Delaminate	To split or separate a laminated plastic material along the plane of its layers.
Density	The weight per unit volume of a substance, expressed in kilograms per cubic meter.
Depropagation or unzipping	A degradation reaction in which the consecutive mers are gradually removed from one macromolecular chain end to another. Few polymers undergo this reverse kinetics process, viz., PMMA, POM, and PTFE.
Desiccant	A substance that can be used for drying purposes because of its affinity to water.
Design of experiments (DOE)	Process of planning the experiment so that sufficient data will be collected for the statistical analysis, to

provide valid and objective conclusions. It includes the choice of the factors, levels, and treatments, as well as the use of certain tools called randomization and replication. The term is frequently used to indicate a problem-solving technique developed by Taguchi, i.e., by using a testing process with an orthogonal array to analyze data and determine the main contributing factors in the solution to the problem.

Degree of freedom	The number of degree of freedom in statistical analysis is the number of independent elements used in the computation of that statistic.
Design stress	The long-term stress, including creep factors and safety factors, that is used in designing structural fabrication.
Destaticization	Treating plastic materials to minimize their accumulation of static electricity.
Destructive test	Any test performed on a part in an attempt to destroy it; often performed to see how much abuse the part can tolerate without failing.
Deterioration	Permanent change in the physical properties of a plastic evidenced by impairment of these properties.
Devolatilization	The removal of volatile components during processing.
Diaphragm gate	The gate used in molding annular or tubular articles that forms a solid web across the opening of the part.
Diblock copolymer	A block copolymer made of two blocks, one having a chain of AAAAA mers and the other of BBBBB to form AAAAAA BBBBBBB polymer. The two block copolymers are used as compatibilizers in the poly-A + poly-B mixtures.
Dichroism	The dependence of absorbency of polarized radiation on the direction of polarization. For polymers the magnitude of dichroism, expressed as dichroic ratio, depends on the orientation of the radiation absorbing groups, thus the macromolecules. In consequence, the infrared dichroism is a powerful method to measure the molecular orientation.
Dichroic ratio	The ratio of absorbencies of polarized radiation, usually the infrared region. The dichroic ratio is used as a measure of molecular orientation in oriented polymers. The dichroic ratio may provide information on the orientation in the glassy and at the same time in the crystalline phase.
Die	A metal form in making or punching plastic products.
Die adapter	The part of an extrusion die that holds the die block.
Die drips	Carbonized resin drool formed on the face of an extrusion die face during the resin production cycle. If the die

	face is not kept clean, it can solidify, break off, and contaminate the product.
Dielectric constant or permittivity	Normally the relative dielectric constant, in practice, a ratio of the capacitance of a given configuration of electrodes with a material as dielectric to the capacitance of the same electrodes' configuration with a vacuum or air as dielectric. A relative measure of nonconductance. Capacitance is the ability of a material to store electrical charge when exposed to electrical current. A low dielectric constant is desired for plastic components used to insulate and isolate electrical components from each other. High dielectric constant materials are desirable for use as the insulator portion of capacitors, so that the electrical energy can be stored in as small a volume of material as possible.
Dielectric heating (also electronic, or R.F. heating)	The plastic to be heated forms the dielectric of a condenser to which a high frequency (20–80 MHz) voltage is applied. Dielectric loss in the material is the basis of the process (e.g., used for sealing vinyl films).
Dielectric strength	The maximum electrical voltage a material can sustain before it is broken down, or "arced through." Also an electrical voltage gradient at which an insulating material is broken down or "arced through."
Dielectrometry	An electrical technique to measure changes in loss factor and capacitance during cure of the resin. Also called dielectric spectroscopy.
Differential scanning calorimetry (DSC)	Thermal analysis technique that measures the quantity of energy absorbed or evolved (given off by a specimen as its temperature is changed). Also measurements of the energy absorbed (endotherm) or produced (exotherm) while undergoing glass transition, melting, crystallizing, curing, evaporating of solvents, and other processes involving energy change.
Differential shrinkage	Nonuniform material shrinkage in part caused by nonuniform distribution of stresses, thus orientation.
Differential thermal analysis (DTA)	An analytical method in which a specimen and a control are simultaneously heated and the difference in their temperatures is monitored. The difference provides information on the relative heat capacities, presence of solvents, changes in structure, and chemical reactions. See also DSC.
Diffusion	The movement of a material, such as a gas or liquid, in the body of a polymer. If the gas or liquid is adsorbed on one side of a test piece and given off on the other, the phenomenon is related to permeability. Diffusion and

	permeability are controlled by the chemical not physical mechanisms.
Digital device	Numerical output device that must index from the initial to the final output reading. More accurate than a similar analog device, but slower.
Dimensional stability	Ability to retain the precise shape to which it was molded, cast, or otherwise fabricated.
Discoloration	Either a change from an initial color possessed by a plastic or lack of uniformity in color over the whole area of an object caused either by overheating, light exposure, irradiation, or chemical attack.
Dished	Showing a symmetrical distortion of a flat or curved section of a plastic object, so that as normally viewed, it appears concave or more concave than intended. See "Warpage."
Dispersion	Finely divided particles of one material suspended in another.
Dispersive mixing	A mixing process in which agglomerates are reduced in size by fracture due to stresses generated during mixing and/or drops of the dispersed phase are deformed and broken.
Dissipation factor	Ratio of the conductance of a capacitor in which the material is dielectric to its substance, or the ratio of its parallel reactivity to its parallel resistance. Most plastics have a low dissipation factor, a desirable property because it minimizes the waste of electrical energy as heat.
Distribution	A method of describing the variation of a stable system, in which individual values are not predictable but in which the outcome as a group forms a pattern that can be described in terms of its location, spread, and shape.
Distribution function	A differential or integral description of population. For the polymer molecular weight a mathematical description of the polydispersity.
Distributive mixing	A mixing process in which the dispersed phase domains are uniformly distributed – a reduction of nonuniformity.
Domain	A morphological term used in noncrystalline systems, such as block copolymers, in which the chemically different sections of the chain separate, generating amorphous phases.
Domed	Showing a symmetrical distortion of a flat or curved section of a plastic object, so that as normally viewed, it appears convex or more convex than intended. See "Warpage."

Double strand polymer	Rigid rod "ladder polymer," consisting of two parallel chains of polymer regularly joined by covalent bonding, viz., pyrrones, polyquinoxalines, and polyphenylsilsesquioxane.
Double-shot molding	A method of producing two-color pieces in thermoplastic materials by successive injection molding operations.
Draft	A taper or slope in a mold that facilitates removal of the molded piece. The opposite of this is called back draft, q.v.
Drool	Melt oozing from a nozzle that is not correctly temperature controlled, or presence of drip on the face of extruder die.
Drop impact test	Impact resistance test in which a predetermined weight is allowed to fall freely onto the specimen from varying heights.
Dry as molded (DAM)	Term used to describe a part immediately after it is removed from a mold and allowed cooling down. All physical, chemical, and electrical property tests are performed on nonconditioned test bars and the results recorded on the data sheets. Parts and test bars in this DAM state are felt to be their weakest in some properties as they have not had time to condition or relieve the molded-in stresses.
Dry blend	Molding compound containing all necessary ingredients mixed in a way that produces a dry, free flowing, particulate material (commonly used for PVC formulations).
Dry coloring	A method commonly used to color plastic by tumble blending uncolored particles of the plastic material with selected dyes and pigments.
Dryers	Auxiliary equipment used to dry resins before processing to ensure that surface properties are within manufacturer specifications. There are several styles of dryers, including ovens, microwave, hot-air desiccant bed, and refrigeration types.
Ductility	The amount of plastic strain that a material can withstand without fracturing, the extent to which a solid material can be drawn into a thinner cross section without breaking. Also, the ability of material to deform plastically before fracturing.
Duromer	Old German name for thermosets, i.e., strongly cross-linked, insoluble polymer.
Durometer hardness	Measure of the indentation hardness of plastics, usually understood as hardness measured by the Shore

	Durometer as an extent to which a spring-loaded steel indenter protrudes into the material.
Dwell	A pause in the application of pressure to a mold, just before the mold is completely closed, to allow the escape of gas from the thermoset molding material. Also the time between when the injection ram is fully forward holding pressure on the material within the mold and the time the ram retracts.
Dyes	Intensely colored synthetics or natural chemicals that are soluble in most common solvents and can be dissolved in a resin to impart color. Dyes are characterized by good transparency, high tinctorial strength, and low specific gravity.
Dynamic mechanical measurement	A technique in which either the modulus or damping of a substance under oscillatory load or displacement is measured as a function of temperature, frequency, time, or their combination.
Ebonite	A material consisting of rubber cured with large quantity with sulfur (one sulfur atom per 4–8 main chain carbons).
Ejection	The removal by mechanical means of the finished part from the mold cavity.
Ejection time	Time in the cycle when the mold opens, the part is ejected, the mold closes, and clamping pressure is applied.
Ejector pin (ejector sleeve)	A rod, pin, or sleeve that pushes a molding off a core or out of a cavity. It is attached to an ejector bar or plate that can be activated by the ejector rod(s) or the press or by auxiliary hydraulic or air cylinders.
Ejector pin retainer Plate	A retainer plate onto which ejector pins are assembled.
Ejector return pins	Projections that push the ejector assembly back as the mold closes. Also called safety pins or position push backs.
Ejector rod or bar	A bar that activates the ejector assembly when the mold is open.
Elastic deformation	A deformation in which a substance returns to its original dimensions on release of the deforming stress – any portion of the total deformation of a body that occurs immediately when load is applied and disappears immediately and completely when the load is removed.
Elastic limit	The greatest stress a material is capable of sustaining without permanent strain remaining after the complete release of the stress. A material is said to have passed its

	elastic limit when the load is sufficient to initiate plastic, or non-recoverable, deformation.
Elastic recovery	The fraction of a given deformation that behaves elastically. A perfectly elastic material has an elastic recovery of one, while a perfectly plastic material has an elastic recovery of zero.
Elasticity	That property of plastic materials because of which they tend to recover their original size and shape after removal of a force causing deformation. If the strain is proportional to the applied stress, the material is said to exhibit Hookean or ideal elasticity.
Elastomers	A customary name for substances showing the plastic–elastic behavior, characteristic for vulcanized rubberlike synthetic or natural polymers, viz., rubbers and weakly cross-linked polyether and polyester urethanes.
Elastomeric	The property of a material that at room temperature can be stretched under low stress to at least twice its original length and, upon immediate release of the stress, will return with force to its approximate original length.
Electric discharge machining (EDM)	A metal-working process applicable to mold construction in which controlled sparking is used to erode the workpiece.
Electrical strength [dielectric strength]	That property of an insulating material that enables it to withstand electrical stress. The electrical strength is defined as the highest electrical stress that an insulating material can withstand for a specified time without the occurrence of electrical breakdown.
Electroformed molds	A mold made by electroplating metal on the reverse pattern of the cavity. Molten steel may be then sprayed on the back of the mold to increase its strength.
Electronic data interchange (EDI)	Exchange of data by customer and supplier computers, usually through a third neutral company that safeguards the host computers from unwanted entry. Used for order placement, shipment, receiving, billing, and payment.
Electroplating	A deposition of metals on certain plastics and mold for finish.
Elongation at break	Elongation recorded at the moment of rupture of a specimen, often expressed as a fraction or percentage of the original length.
Elongation	Deformation caused by stretching, or fractional increase in length of a material in tension, expressed as a percentage difference between the original length and the length at the moment of the break – higher elongation indicates higher ductility.

Embossing	Techniques used to create depressions of a specific pattern in plastics' films or sheeting. Also development of surface patterns on the molded part by photoengraving or a similar process.
Embrittlement	Reduction in ductility due to physical or chemical changes.
Emulsion	A stable dispersion of one liquid in another created in the presence of an emulsifying agent (that has affinity with both phases). The emulsifying agent, discontinuous phase, and continuous phase produce the third phase, the interphase, which serves as an enveloping protective layer around each dispersed drop.
Emulsion polymerization	Free radical polymerization of an emulsion, consisting of aqueous phase containing an initiator and emulsified oil phase containing the monomer.
Endothermic	An action or reaction that absorbs heat.
Endurance or fatigue lifetime	Maximum fluctuating stress a material can endure for infinite number of cycles – determined from the S-N diagram.
End use	Function the part or assembly was originally designed and manufactured to perform.
Engineering polymer alloy	A processable engineering material containing two or more compatibilized polymers, capable of being formed to precise and stable dimensions, exhibiting high performance at the continuous use temperature above 100 °C, and having tensile strength exceeding 40 MPa.
Engineering polymer	A processable polymeric material capable of being formed to precise and stable dimensions, exhibiting high performance at high temperature and high tensile strength. Usually to qualify for the term, the material must have the continuous use temperature above 100 °C and the strength exceeding 40 MPa. Five types of polymers are customarily qualified as engineering resins: polyamide (PA), polycarbonates (PC), thermoplastic polyesters (EST), polyoxymethylene (POM), and modified polyphenylene ethers (PPE).
Engineering polymer blend	A polymer blend either containing engineering polymer(s) or having properties of an engineering polymer.
Engineering resin	Term associated with plastics having medium to high physical properties used for structural and demanding applications. Five types of resins belong to this group: PA, PEST (viz., PBT, PET, PAr), PC, PPE, and POM.
Environmental stress cracking (ESC)	The susceptibility of a thermoplastic resin to crack or craze when in the presence of surface-active agents or other environments, e.g., under the influence of certain chemicals or aging, weather, and stress.

Epoxide	A compound containing 1,2-epoxide, $CH_2(O)CH–R$, or its derivative.
Epoxy plastics	A thermoset polymer containing one or more epoxide groups and curable by reaction with amines, alcohols, phenols, carboxylic acids, acid anhydrides, and mercaptans. It has been primarily used as a matrix resin in composites and adhesives.
Epoxy resin	An oligomer containing two or more epoxide groups per molecule cross-linked with a hardener, usually diglycidyl ether of bisphenol A or pentaerythritol:

$$RH + CH(O)CH- \rightarrow -C(R)H - C(OH)H-$$
	The OH group may further react with the hardener, which leads to highly cross-linked thermoset polymer.
Etch	To treat with an acid, leaving parts of the surface in relief to form the desired design.
Ethylene plastics	Plastics based on polymers of ethylene or copolymers of ethylene with other monomer, the ethylene being in greatest amount by mass.
Ethylene-propylene rubber (EPR)	An elastomeric copolymer based on ethylene and propylene prepared in Ziegler-Natta polymerization. When small amount of a diene monomer is added, the resulting polymer becomes ethylene-propylene terpolymer, EPDM.
Ethylene-vinyl acetate (EVAc)	A thermoplastic copolymer made from ethylene and vinyl acetate. This copolymer is similar to polyethylene but has considerably increased flexibility.
Exfoliated clay	Individual clay platelets dispersed in a matrix polymer with the interlayer distance $d_{001} > 8.8$ nm. The platelets can be randomly dispersed individually or as short stacks or tactoids.
Exfoliation	Chemical and/or mechanical means of dispersing clay platelets in a polymer matrix. The process usually starts with intercalated clay (q.v.).
Exothermic	Pertaining to an action or reaction that gives off heat.
Extensibility (or extendibility)	The ability of a material to extend or elongate upon application of sufficient force, expressed as a percentage of the original length.
Extensometer	Instrument for measuring changes in linear dimensions (also called strain gauge).
Extrudate swell (sometimes improperly called die swell)	The ratio of the outer parison diameter to the inner diameter of the die. The swell is influenced by polymer nature, die construction, land length, extrusion speed, additives (viz., external lubricants), and temperature.

Extruder	A machine that accepts solid (pellets or powder) or liquid feed, conveys it through a surrounding barrel by means of a rotating screw(s), and pumps it, under pressure, through an orifice called "die."
Extrusion blow molding	Most often the process, in which a parison is extruded from a polymeric melt and is then entrapped between the halves of a mold. The parison is expanded by compressed air against the mold cavity, and then it is cooled, removed, and trimmed.
Extrusion	Compacting a plastic material (powders or granules) into a uniform melt and forcing it through an orifice in a continuous fashion to yield a desired shape. While held in the desired shape, the melt must be cooled to solidify. The term also describes plasticization of a resin in an extruder (barrel-and-screw or plunger assembly) and forcing of the molten material or extrudate through a die or into a mold. Extrusion is the initial part of the molding process.
Extrusion plastometer or melt indexer	A primitive viscometer used for determining the melt flow index, MFI. It is composed of a vertical cylinder with two longitudinal bored holes (one for measuring temperature and one for containing the specimen, the latter having an orifice of stipulated diameter at the bottom and a plunger from the top). The cylinder is heated by external bands, and weight is placed on the plunger to force the polymer specimen through the orifice. The result is reported in g/10 min. See also "Melt index."
Exudation	Formation of liquid plasticizer on the surface of a plasticized (usually PVC) resin.
Fabricate	To work a material into a finished form by machining, forming, or other operation. In the broadest sense, it means to manufacture.
Fading	Any lightning of an initial color possessed by a plastic.
Fadometer	Apparatus for determining the resistance of materials to fading by exposing them to ultraviolet rays of approximately the same wavelength as those found in sunlight.
Family mold	A multicavity mold in which each cavity forms a part that often has a direct relationship in usage to the other parts in the mold. Family molds can have more than one cavity making the same part, but they will still always have the same direct relationship to usage. The term is often applied to molds in which parts for different customers are grouped for economy of production. Sometimes called a combination mold.

Fan gate	A shallow gate somewhat wider than the runner from which it originates.
Fatigue	Permanent structural changes that occur in a material subjected to fluctuating stress and strain, which cause decay of mechanical properties. See "S-N diagram."
Fatigue ductility	The ability of a material to plastically deform before fracturing in constant strain amplitude and low-cycle fatigue tests. See "S-N diagram."
Fatigue failure	The failure or rupture of a plastic under repeated cyclic stress, at a point below the normal static breaking strength. See "S-N diagram."
Fatigue limit	The stress below which a material can be stressed cyclically for an infinite number of times without failure. See "S-N diagram."
Fatigue strength	Magnitude of fluctuating stress required to cause failure in a fatigue test specimen after specified number of cyclic loading – determined from the S-N diagram. Also the maximum cyclic stress a material can withstand for a given number of cycles before failure. The residual strength after being subjected to fatigue. See "S-N diagram."
Feathered thread	A thread that is thin at one end and does not end abruptly. Usually found in screw machine parts.
Feed throat	The section of the hopper mounted on the extruder to feed resin into the feed section of the barrel and screw.
Feedback	Information returned to a system or process to maintain the output within specified limits. See also "Closed loop."
Fiber	Often the term is used synonymously with filament having a finite length, $L = 100d$, where the diameter is typically $d = 100–130$ μm. In most cases, it is prepared by drawing from a molten bath, spinning, or depositing on a substrate. Fibers can be continuous, long (10–50 mm) or short (about 3 mm). In the plastics industry almost synonymous with thin strands of glass used to reinforce both thermoplastic and thermosetting materials.
Fiber-reinforced plastic (FRP)	A general term for a plastic that is reinforced with cloth, mats, strands, or any other fiber form.
Fiberglass	Filaments made by drawing molten glass. Continuous filaments have indefinite length. Staple fiber mat is made of glass fibers of the length generally 430 mm, the length depending on the forming or spinning process used.
Fiberglass reinforcement	Major material used to reinforce plastic, available as mat, roving, fabric, and so forth. It is incorporated into both thermosets and thermoplastics.

Filament	The smallest unit of a fibrous material. The basic units formed during drawing and spinning, which are gathered into strands of fiber for use as reinforcements. Filaments usually are of great length and small diameter, $d < 25$ μm.
Filler	A relatively inert substance added to plastics to improve their physical, mechanical, thermal, electrical, or other properties or to lower cost or density. A compound or substance added to a polymer during the initial synthesis process or in subsequent processing to decrease the volume of resin needed to produce a given product. Fillers are generally much lower in cost than the resins they are used in, thus reducing resin cost per part. Fillers or extenders are generally not used with engineering resins.
Fillet	A rounded inside corner of a plastic piece. The rounded outside corner is called a bevel.
Fines	Small particles mixed in with larger particles.
Finish	The secondary work on a part so that it is ready for use: filing, deflashing, buffing, drilling, tapping, and degating are commonly called finishing operations.
Finite element analysis	A stress analysis technique of a part using a computer-generated model that can take finite sections of the part for analysis of the forces and loads the part will experience in service. It generates a part-section analysis that shows the force concentrations in the section and determines if the material selected will be suitable for the part.
First surface	The front surface of a plastic part, nearest the eye.
Fisheye	A small, globular mass that has not completely blended into the surrounding polymeric material. This condition is particularly evident in a transparent or translucent film, fiber, or sheet.
Fishbone diagram	A problem analysis technique used to list all the variables and steps in the solution to a problem. All contributing elements are associated with each factor and taken back to their starting point to ensure that all variable elements are considered.
Fissure	A narrow opening crack in a material.
Fixture	Means of holding a part during a machine or other operation.
Flakes	A term used to describe resin residue formed on the inside of pipes during material transfer, created by the friction of the pellets against the surface of the transfer piping. With time, they build up, flake off, and can cause feed problems at the throat of the extruder.

Flame resistance	Ability of a material to extinguish flame once the source of heat is removed.
Flame retardants	Chemicals used to reduce the tendency of a polymer to burn.
Flame retarded	A resin modified by flame-inhibiting additives so that exposure to a flame will not burn or will self-extinguish. Some resins will not burn and others can be modified to meet flame burning specifications, while others may not be able to be modified.
Flame treatment	A type of surface treatment that oxidizes a plastic surface for better reception of paint, inks, and adhesives. See also "Surface treatment."
Flammability	Measure of the extent to which a material will support combustion.
Flash	Extra plastic attached to a molding along the parting line. Under most conditions, it is objectionable and must be removed before parts are judged acceptable.
Flash gate	Usually a long gate extending from a runner parallel to an edge of a molded part along the flash or parting line of the mold.
Flash line	A raised line appearing on the surface of a mold and formed at the junction of mold faces. "See Parting line."
Flash mold	A mold in which the faces are perpendicular to the clamping action of the press. The higher the clamping force, the tighter the mold seam.
Flash trap	A molded-in lip or blind recess on a part that is used for trapping excess molten material during an assembly operation. It negates flash trimming secondary operations.
Flex life	The time of heat aging that an insulating material can withstand before failure when bent around a specific radius (used to evaluate thermal endurance).
Flexural modulus	The ratio within the elastic limit of the applied stress to specimen's strain during flexural deformation mode testing – a measure of relative stiffness.
Flexural strength	Ability of a material to flex without permanent distortion or breaking. The resistance of a material to being broken by bending stresses.
Flock	Short fibers of cotton, wood, glass, etc., used as inexpensive filler.
Flocking	A decorating and/or sound-deadening technique where fibers of different materials are attached to the surface of a plastic part. Fibers can be oriented in specific directions and patterns determined by the techniques used, and adhesive patterns lay down on the surface of the part.

Flow	A qualitative description of the fluidity of a plastic material during processing. A quantitative value of fluidity may be expressed by the flow curve, melt index (MI), or melt flow index (MFI).
Flow chart	A line chart that traces the whole process.
Flow curve	A log-log plot of the isothermal viscosity as a function of the deformation rate.
Flow length	The actual distance a material will flow under a set of molding machine conditions. Influenced by the processing and mold design variables, the composition of the polymer, and any additives in the polymer.
Flow line	A mark on a molded piece made by the meeting of two flow fronts during molding. Also called weld line or weld mark.
Flow marks	Wavy surface appearance of an object molded from thermoplastic resins, caused by improper flow of the resin into the mold. Also see "Splay marks."
Flow coating	A painting process in which the article to be painted is drenched under a curtain of lacquer. The part is withdrawn and rotated until the coating dries.
Fluidized bed coating	Process in which small particles of a thermoplastic resin are suspended in a gas stream (generally air) and behave like a liquid. A heated article is immersed in this fluidized bed of powder. The particles melt and fuse to the heated surface, forming a smooth coating.
Fluoropolymer	A polymer whose mers contain fluorine, F.
Fluoropolymers	The family of fluorinated polymers that include polytetrafluoroethylene, (PTFE), polychlorotrifluoroethylene (PCTFE), polyvinylidenefluoride (PVDF), and fluorinated ethylene-propylene. These resins are characterized by good thermal and chemical resistance, nonadhesiveness, low dissipation factor, and low dielectric constant. They are available in a variety of forms, such as moldings, extrudates, dispersions, films, or tapes.
Foamed plastics or cellular plastics	Plastics with numerous cells disposed throughout its mass. Cells are formed by a blowing agent or by the reaction of the constituents. Resins in sponge form may be flexible or rigid; the cells may be open or closed.
Foil decorating	Molding paper, textile, or plastic foils printed with compatible inks directly onto a plastic part so that the foil is visible below the surface of the part as an integral decoration.
Force	That which changes the state of rest or motion in matter, measured by the rate of change of momentum.

Forming	The term usually applied to a process in which the shape of plastic pieces such as sheets, rods, or tubes is changed to a desired form. Usually the term does not include extrusion, molding, or casting, in which forms are made from molten polymers or solutions.
Fourier transform	An analytical method used in advanced forms of spectroscopic analysis such as infrared and nuclear magnetic resonance spectroscopy.
Fractionation	Experimental methods for separating and isolating fractions, each with the more uniform molecular weight, and thus of low polydispersity. The process also serves for ascertaining the distribution function.
Fracture strength	The normal stress at the beginning of fracture. Calculated from the load at the beginning of fracture during a tension test, and the original cross-sectional area of the specimen.
Fracture	The separation of a body, defined both as rupture of the surface without complete separation of the laminate and as complete separation of a body because of external or internal forces.
Free radical polymerization	Polymerization in which the active centers of reaction are radicals. The polymerization can be initiated by thermally activated or redox initiator, by irradiation, or through thermal activation of monomer.
Freeze drying	A method of removing volatiles from solidified material at low temperatures.
Freeze-off	Refers to the gate area when polymer solidifies, as well as any area in the flow system when the melt becomes too cool to flow and solidifies.
Frequency	The number of times a specified phenomenon occurs within a specified interval, e.g., number of completed energy transmissions imparted to the welding horn in a vibratory motion.
Friction welding	A means of assembling thermoplastic parts by melting them along their line of contact through friction. See also "Spin welding."
Full IPN	Any material containing two or more polymers in an intimate network form without induced cross-links between the individual polymers.
Fusion bond	The joining of two melt fronts that meet and solidify in a mold cavity. A bond formed during the assembly operation where the joint line is melted before assembly. See "Hot-plate welding," "Induction welding," and "Ultrasonic sealing."

Fusion	Heating of a vinyl dispersion to produce a homogeneous material.
Galling	A surface area that is worn away by another by rubbing against it.
Gas-assisted injection molding (GAM)	An injection molding process that introduces a gas (usually nitrogen) into the plasticized material, to form voids in strategic locations.
Gaseous blowing agent	A compressed gas, such as compressed air or nitrogen, used to create a cellular structure or controlled voids in a rubber or plastic's mass.
Gate	In injection and transfer molding, the orifice through which the melt enters the cavity.
Gauges	Measuring devices used to determine if the part meets customer specifications, including micrometers and vernier calipers.
Gaussian (or normal) distribution	A symmetrical, bell-shaped distribution function: $$y = \left[1/\sigma(2\pi)^{1/2}\right]\exp\left\{-[(x-\bar{x})/\sigma]^2/2\right\}$$ where x is a variable and σ is the standard deviation.
Gaylord	A term used to identify a box of resin vs. a bag or drum. Box size and weight of resin can vary depending on the density of the resin and the supplier's box size. Box size usually conforms to the size of a standard pallet on which it is shipped.
Gel or Trommsdorff effect	Auto-acceleration at the end of chain growth polymerization. With increasing size of the macroradicals, their mobility decreases and terminations are less frequent. However, the diffusion of the monomer remains unhindered and the polymerization proceeds exothermally, resulting in auto-acceleration.
Gel permeation chromatography (GPC, more recently size exclusion chromatography, SEC)	A form of liquid chromatography in which the polymers are separated by their ability or inability to penetrate the material in the separation columns. Column chromatography technique employing a series of columns containing closely packed rigid gel particles. The polymer to be analyzed is introduced at the top of the column and then is eluted with a solvent. The polymer molecules diffuse through the gel at rates depending on their molecular size. As they emerge from the columns, they are detected by differential refractometer, viscometer, FTIR device, etc. From the output of these detectors, a molecular weight distribution curve can be obtained.

Gel point	The stage at which a liquid begins to exhibit pseudo-elastic properties. Also known as "gel time."
Gel solutions	Concentrated solutions; intermediate state between gel and sol.
Gel	That cross-linked part of polymer in liquid state, which having its network character may swell but not dissolve.
Generic	Descriptive of an entire type or class of plastic resins. The base resin is one of a family of polymers, but there may be hundreds of product combinations.
Glass	A material that solidifies from the molten state without crystallization, a supercooled liquid whose shear viscosity is $\eta \geq 10^{12.5}$ Pas, a liquid whose rigidity is great enough to be put to use, or a glassy state of matter. A typical glassy material is hard and brittle (tensile modulus E § 70 GPa, tensile strength σ § 0.5 GPa). Typical polymeric glasses are atactic polystyrene, atactic polymethylmethacrylate, polycarbonate, etc.
Glass-mat thermoplastics, (GMT)	A mat consisting of long glass fibers that are impregnated with a thermoplastic resin to produce a flat, homogeneous, semifinished composite blank.
Glass transition temperature, or glass transition point, T_g	The center of the temperature range in which a noncrystalline solid changes from being glass brittle to being viscous or rubbery. The temperature, or a range of temperatures, separating the rigid (glassy) from elastic (rubbery or liquid) state of a polymer. For the transition to occur, 20 to 50 main chain atoms must be able to move in a cooperative manner. For the organic polymers -160 "T_g" 400 °C depending on the intrinsic flexibility of the polymeric chain and its molecular weight. Since the transition is kinetic in nature, it depends on the rate or frequency. The measured T_g value depends considerably on the test rate, frequency, or mechanical deformation.
Gloss	Brightness or luster of a plastic resulting from a smooth surface. The shine or luster of the surface of a material (ASTM D 673). See "Specular gloss" and "Surface finish."
Grades	Polymers that belong to the same chemical family and are produced by the same manufacturer. They may vary in processing or performance due to differences in molecular weight, additives, or other structural features. For example, a supplier of PC may have flame-resistant grades, glass fiber-reinforced grades, a conductive grade, and easy flowing grades.

Graft copolymers	A copolymer whose macromolecules consist of two or more macromolecular parts of different composition, covalently joined in such a way that one of the parts forms the main chain (polymer A) and the other(s) the side chains (polymer B). In a sense the block copolymers are graft copolymers in which the graft block B is attached to the end of main chain A. Graft copolymers are frequently used as compatibilizers.
Graining	The term refers to wood graining on plastics. This can be done by hand, roller coating, hot stamping, or printing.
Graphite	A crystalline allotropic form of carbon.
Graphite fiber	A fiber from either pitch or polyacrylonitrile (PAN) precursor by an oxidation, carbonization, and graphitization processes. See also "Carbon fiber."
Grinder or granulator	A machine (in many sizes, styles, and capacities) with a series of knife blades and a sizing screen to chop up plastic materials for reuse.
Grit blasted	A surface treatment of a mold in which grit or sand materials are blown onto the walls of the cavity to produce a roughened surface. Air escape from mold is improved and special appearance of the molded article is often obtained by this method.
Guide or leader pins	Devices that maintain proper alignment of parts.
Guideway	Usually a T-shaped slot in a mold.
Gusset	An angular piece of material used to support or strengthen two adjoining walls.
Hand molds	Molds that are removed from the press by the operator, who opens the mold and extracts the part by hand.
Hardenable substance	Thermoset resin that, under the influence of temperature and/or reactive agent, undergoes cross-linking that irreversibly changes the chemical constitution and thereby physical properties.
Hardeners	Polyfunctional substances that are able to cause cross-linking in thermosets.
Hardening, curing	A chemical cross-linking of material, initially soft or that can be made so by warming, into a more viscous form or hard solid.
Hardness	The resistance to compression and surface indentation, usually measured by the depth of penetration of a blunt point under a given load using a particular instrument according to a prescribed procedure. Among the most important methods of testing are Barcol hardness, Brinell hardness, Knoop hardness, Mohs hardness, Rockwell hardness, and Shore hardness.

Haze	The degree of cloudiness in a plastic material. The cloudy or turbid aspect of appearance of an otherwise transparent specimen caused by light scattered from within the specimen or from its surface.
Head	The end section of the molding machine that consists of the core, die, mandrel, mold, and other parts necessary to form the plastic.
Head-to-head structure	A structure of the type $-CH_2CHX-CHXCH_2-$ in polymers where the monomer placement in the growing chain has two isomeric possibilities: head-to-head (as shown) or head-to-tail, viz., $-CH_2CHX-CH_2CHX-$. The latter structure predominates.
Heading	The mechanical, thermal, or ultrasonic deformation of a pin to form a locking attachment.
Heat resistance	The property or ability of plastics and elastomers to resist the deteriorating effects of elevated temperatures.
Heat sealing	A process of joining two or more thermoplastic films or sheets by heat.
Heat stability	The resistance of a plastic material to chemical deterioration caused by exposure to heat during processing.
Heat stabilizer	An ingredient added to a polymer to improve its processing or end-use resistance to elevated temperatures. The term is used in different contexts depending on the benefit to be derived from the additive. For processing, it retards changes of color. For end use, it protects the surface of the part exposed to elevated temperatures. It does not imply that a resin can be used beyond its recommended end-use temperature rating if it is heat stabilized.
Heat distortion temperature (HDT)	The temperature at which a standard test bar deflects by an arbitrary value under a stated load. In ASTM D648, it is defined as a total deflection of 250 μm in a rectangular bar supported at both ends under a load of 0.5 or 1.8 MPa. The temperature is increased at a rate 2 °C/min.
Heated manifold mold	A hot-runner mold that is both heated and insulated; an insulated mold is a hot-runner mold that does not contain heaters.
Heater bands	The heat source for the barrel and nozzle. The temperature control is usually divided into rear, middle, front, and nozzle sections. The bands are accurate resistance heaters with high heat output.
Heating chamber	In injection molding that part of the machine in which the cold feed is reduced to a hot melt. Also called heating cylinder.

Helix	A helical conformation of polymeric chain in which all main chain atoms can be placed on a cylindrical surface in such a way that all elements on that surface are cut at constant angle or, in other words, that the conformation is exactly repeated at constant intervals. For example, 31 helix in polypropylene has three repeating units per one helix turn.
Hermetic	As in seal, to form a bond that is pressure tight, so that air or gases cannot enter or escape.
Heterogeneous	Materials consisting of identifiable dissimilar constituents separated by internal boundaries. It is noteworthy that not all nonhomogeneous materials are necessarily heterogeneous.
Hiding power	The opacity that can be effected with a coating.
High-density polyethylene (HDPE)	Linear polyethylene copolymers with low branching, having density $\rho = 940$–960 kg/m^3. The regular structure engenders material with greater strength, rigidity, chemical resistance, and higher softening temperature than the branched one.
High-impact polystyrene (HIPS)	A thermoplastic resin from a styrene and elastomer. It has good dimensional stability and low-temperature impact strength, high rigidity, and ease of processing.
Histogram	A bar chart with the height of each bar indicating how many data points were collected within certain interval. The width of the bar provides a measure of the interval.
Hob	A master model in hardened steel used to sink the shape of a mold cavity into a soft steel block.
Hobbing	Forming multiple mold cavities by forcing a hob into soft steel cavity blanks. Also called sinking.
Holding pressure	The pressure maintained on the melt after the cavity is filled until the gate is filled and freezes.
Homologous polymer blend	A mixture of two or more homologous polymers, usually narrow molecular weight distribution fractions of the same polymer.
Homologous polymers	Polymers identical in structure and composition and differing only in molecular weight. A polydispersed polymer is a miscible blend of homologous polymers.
Homopolymer	The product of the polymerization of a single monomer, i.e., a polymer containing one type of repeating units, viz.

$$-[\mathrm{CH_2CHX - CH_2CHX}]_n^-.$$
Hone, honing, honed	To impart a precise accuracy to the surface finish by using a fine-grained whetstone.

Hooke's solid	An ideal elastic material where stress is directly proportional to strain.
Hoop stress	The circumferential stress in a material of cylindrical form subjected to internal or external pressure.
Hopper	A conical reservoir from which the molding powders or pellets are fed into the extruder.
Hopper feeder	Usually part of the resin drying system that also can be an independent unit, to convey material to the machine's feed hopper using vacuum or pressure.
Hot stamping or branding	Engraving operation in which roll leaf is stamped with heated metal dies onto the face of the plastics.
Hot tip	The precise controller and gating mechanism of a hot-runner mold.
Hot-plate welding	The use of a heated tool to cause surface melting of a part at the joint area. It is then removed before the joint surfaces being pressed together to form a fusion bond.
Hot-runner mold	A thermoplastic injection mold in which the runners are insulated from the chilled cavities and remain hot so that the center of the runner never cools in normal cycle operation. Runners are not usually ejected with the molded pieces.
Hot/heated manifold mold	A thermoplastic injection mold in which the mold that contains the runner system has its own heating elements to keep the molding material in a plastic state ready for injection into the cavities, from which the manifold is insulated.
Hydrolysis	Chemical decomposition of a substance involving the addition of water.
Hydrophilic	Capable of absorbing water.
Hydrophobic	Capable of repelling water.
Hygroscopic	Material capable of absorbing and retaining atmospheric moisture from air. Plastics such as PA, PEST, or ABS are hygroscopic and must be dried before molding.
Hysteresis	The failure of a property that has been changed to return to its original value when the cause of the change was removed. The cyclic noncoincidence of the elastic loading and the unloading curves under cyclic stressing. The area of the resulting elliptical hysteresis loop is equal to the heat generated in the system.
Immiscible polymer blend	Any polymer blend whose free energy of mixing is positive: $\Delta G_m > 0$.
Impact strength	The ability of a material to withstand shock loading, expressed as an amount of energy required to fracture a specimen subjected to impact. The work done in fracturing, under shock loading, using a specified test

	specimen and a specified procedure. Also, the relative susceptibility of plastic articles to fracture under stress applied at high speeds.
Impact test	Often associated with the Gardner (ball or falling dart) test, with a known weight falling at a known distance and hitting a part, thereby subjecting it to an instantaneous high load. ASTM impact tests for material properties are the Izod, Charpy, and tensile impact tests. The test can also be a pendulum type.
Induction welding	The use of radio, magnetic, or electrical energy to form a melt through the application of a foreign medium at the joint line to form a fusion bond.
Inert pigment	A pigment that does not react with any component of paint.
Infrared (IR or FTIR)	Pertaining to that part of the electromagnetic spectrum between the visible light range and the radar range. Radiant heat is in this range, and infrared heaters are frequently used in the thermoforming and curing of plastics and composites. Infrared analysis is used for identification of polymer constituents. The powerful Fourier transform infrared spectroscopy, FTIR, uses a method of splitting a beam into two waves, and the spectral information is obtained from the phase difference between the two waves, recombining them in the Michelson interferometer. The interferogram is obtained by digitizing the detector signal and transforming it from the time domain by means of the Fourier transform operation into a conventional IR spectrum. See "Infrared spectroscopy."
Infrared spectroscopy or spectrometry	A technique used to observe the wavelengths in the electromagnetic spectrum lying beyond the red, from about 750 nm to a few mm.
Inhibitor	A substance that reacts with the active polymerization site either to form a totally nonreactive product or to reduce the system reactivity. In radical polymerization, the radical scavengers, viz., diphenylpicrylhydrazyl and quinones, are used as inhibitors.
Initiator	Either an additive mixed in a material to cause a chemical or physical reaction in the melt or a substance able to engender reaction of a monomer, radical or ionic.
Injection blow molding	Blow molding in which the parison is directly formed by injection molding.
Injection molding	A method of forming a plastic to the desired shape by forcing the softened plastic into a relative cool cavity

	using a screw or ram – used with thermoplastics or thermosets. See "Thermoplastic injection molding" and "Thermoset injection molding."
Injection pressure	The pressure in the mold during the injection of plasticized material into the mold cavity.
Injection ram	See "Ram."
Injection time	The time it takes for the screw's forward motion to fill the mold cavity with melt.
Inorganic	A mineral compound not composed of carbon atoms.
Inorganic pigments	Natural or synthetic metallic oxides, sulfides, and other salts that impart color, as well as heat and light stability, and weathering resistance.
Inorganic polymer	A polymer with high proportions of non-carbon atoms. In principle, most inorganic materials can be considered inorganic polymers, viz., silicates. In polymer science, the inorganic materials containing organic groups are considered inorganic polymers, e.g., polysiloxanes (silicones), phosphonitrilic elastomers, polycarboranes, organometallic polymers, polymetaphosphates, polyphosphazenes, and sulfurnitride polymers. See also "Organic polymers."
Insert	An integral part of plastics molding. It consists of metal or other material that may be molded into position or may be pressed into the molding after the molding is completed. Also a removable or interchangeable component of the mold.
Intercalated clay	Clay having organic or inorganic molecules inserted between its platelets, thus increasing the interlayer spacing between them to at least 1.5 nm.
Intercalation	Process of inserting organic or inorganic molecules between platelets of a layered material, thus increasing the interlayer spacing.
Interface	The boundary or surface between two different, physically distinguishable media. With fibers, the contact area between the fibers and sizing or finish. In laminates, the contact area between the reinforcements and the laminating resin.
Interpenetrating polymer network, (IPN)	Historically, any material containing two or more polymers, each in network form, without induced cross-links between the individual polymers, usually produced by polymerizing and/or cross-linking at least one component in the immediate presence of the other, thus thermoset in character. Currently, the term IPN encompasses the thermoplastic co-continuous polymer blends, as well as ionomers and block and graft

	copolymers. The later materials are known as thermoplastic IPN.
Interphase	The boundary region between two phases in polymer blends, the matrix polymer and the dispersed phase, or (in case of phase co-continuity) between two polymeric phases. In compatibilized blends, the interphase contains the compatibilizer as well as low-molecular-weight additives and fractions.
Intrinsic viscosity	The limiting value (at infinite dilution) of the ratio of specific viscosity of the polymer solution to concentration.
Ion exchange resins	Cross-linked polymers that form salts with ions from aqueous solutions.
Ionic polymers or ionomers	Polymers of linear or network structure with ionic groups which by addition of the appropriate counterions can be ionically cross-linked. A copolymer of ethylene and acrylic acid is used as a compatibilizer in polyamide blends. Converted to ethylene-zinc acrylate copolymer, Surlyn™ is used as packaging film. Other ionic polymers are applied as polyelectrolytes, ion exchange resin, etc.
Ionomer	Polyethylene that contains both covalent and ionic bonds. The polymer exhibits strong interchain ionic forces. The anions hang from the hydrocarbon chain, and the cations are metallic, e.g., Na, K, Li, Zn, and Mg. The resins have similar properties as polyethylenes, with high transparency, tenacity, resilience, and increased resistance to oils, greases, and solvents.
Ishakawa	See Fishbone diagram.
Isomeric polymers	Polymers that are basically homogeneous but in which, by secondary alterations or by a small number of different kinds of linking of the primary molecules (e.g., branching), variations are introduced.
Isotactic polymer	A polymer in which the constitutional repeating units have the same stereochemical configuration, for example, isotactic polypropylene.
Izod impact test	A type of pendulum impact test in which a notched sample bar is held at one end and broken by a blow. This is a test for shock loading.
Izod impact strength	Determination of the resistance of a plastic material to a shock loading, in which a notched specimen bar is held at one end and broken by striking, and the energy absorbed is measured.
Jetting	Turbulent flow of plastic from an undersized gate or thin section into a thicker mold section, as opposed to

	laminar flow of material progressing radially from a gate to the extremities of the cavity. May also result from shooting material into a mold cavity where there is no core or immediate cavity wall to break up the flow of the material coming through the gate.
Just-in-time (JIT)	A practice developed to minimize customer inventory. The supplier provides the product, at predetermined intervals, so that it can proceed directly to the customer's assembly line. This practice demands excellent quality control and production schedules. Customers who use JIT must demand the same care and treatment from their own suppliers. Suppliers and customers are usually located within a few hours shipping time of each other.
Kirksite	An alloy of aluminum and zinc used for the construction of prototype molds. It imparts a high degree of heat conductivity to the mold
Kneading elements, kneading blocks	Three types of elements are used to assemble screws in a twin-screw extruder: kneading, mixing, and transporting. The kneading elements are mostly two- or three-lobe self-wiping that mainly provide for the dispersive mixing by pressing, stretching, and folding actions. An assembly of kneading elements is known as a kneading block, characterized by the individual disk length, number of disks, and stagger angle between the disks in the kneading block. See also "Mixing elements."
Knit line	A line on a part where opposing melt fronts meet. Created by material flow around obstructions or multiple gating. See "Weld line."
Knockout or ejector pin	A pin that pushes a cured molded article out of a mold.
Kurtosis	The state or quality of peakedness or flatness of the graphic representation of a statistical distribution expressed as $\alpha_4 = m_4/m_2^2$, where m_4 and m_2 are the fourth and second moment of the distribution function. The excess of kurtosis is given as $\alpha_4 - 3$. The kurtosis is large when on a distribution function there is a relatively high concentration in the middle and out on the tails, with a relatively steep drop in between.
Lack of fill-out	An area occurring usually at the edge of a laminated plastic, where the reinforcement has not been wetted with resin.
Ladder polymer	A rigid rod polymer, consisting of two parallel macromolecular chains regularly joined by covalent bonding, forming a sequence of interconnecting rings, e.g.,

	pyrrone, polyquinoxalines, polyphenylsilsesquioxane, and poly(bisbenzimid-azobenzo-phenanthroline).
Lamella	The basic morphological unit of a crystalline polymer, usually ribbonlike or platelike in shape. Generally (if ribbonlike), about 10–50 nm thick, 100 nm wide, and 1,000 nm long.
Lamellar thickness	A characteristic morphological parameter, usually estimated from X-ray studies or electron microscopy, usually 10–50 nm.
Laminar flow	Flow of thermoplastic resins accompanied by solidification of the layer in contact with the mold surface that acts as an insulating tube through which material flows to fill the remainder of the cavity. This type of flow is essential to duplication of the mold surface.
Land	Either a horizontal bearing surface of a semipositive or flash mold by which excess material escapes, a bearing surface along the top of the flights of a screw in an extruder, or the surface of an extrusion die parallel to the direction of the melt flow. In injection molding, the gate, when entering a part, has always the length of the gate itself that is called the land.
Latex, lattices	Aqueous dispersion of polymeric particles, a polymer emulsion, a product of emulsion polymerization used in paints, adhesives, coatings, etc.
LCST (lower critical solution temperature)	The lowest temperature of immiscibility, where binodal and spinodal curves meet. This type of phase separation predominates in polymer blends.
Let-down ratio	The quantity of one ingredient to be mixed with a base material to obtain the desired results.
Level of significance, "a"	The probability of committing the error of rejecting a given hypothesis when it is true; "a" is usually set to 0.05 for most of the statistical tests.
Light resistance	The ability of a plastic material to resist fading after exposure to sunlight or ultraviolet light (ASTM D1501). Light stability is the measure of this resistance.
Limit switch	An electromechanical switch positioned to stop or start an action. It is operated by mechanical action on a movable control arm.
Liquid crystal polymer (LCP)	A thermoplastic polymer (polyamide or polyester) that contains primarily benzene rings in its backbone, is melt processable, and can be highly oriented during processing. Available with or without fiber reinforcement.
Living polymer	An ionic polymer in which, in the absence of a monomer, the active centers of polymerization are

	preserved. Formation of living polymers in anionic or Ziegler-Natta polymerizations makes it possible to produce block copolymers.
Loading or charging tray	A device used to load the charge of material or metal inserts simultaneously into each cavity of a multicavity mold by the withdrawal of a sliding bottom from the tray.
London dispersion forces	Weak intermolecular forces based on dipole-dipole interactions.
Long chain branching	Branches of comparable length as the main polymer chain as in low-density polyethylene, polyvinylchloride, etc.
Loss modulus	A quantitative measure of energy dissipation, defined as the ratio of stress $90°$ out of phase with oscillating strain to the magnitude of strain. The loss modulus may be measured in tension of flexure, E", compression, K", or shear, G" (see also "Complex modulus").
Lubricants	Processing aids to assist material flow during extrusion or injection molding. The internal and external lubricants are recognized. Internally lubricated resins use oils, Teflon™, MoS_2, or other materials to give the molded part a lower coefficient of friction. The external lubricant can be a solid, such as sodium or zinc stearate, a fluoropolymer, or silicone resin or liquid.
Macbeth	A lighting system used for checking color.
Macromer	An oligomeric or telomeric chain capable of entering into a polymerization reaction.
Macromolecule	A large molecule in which neither the end groups nor the substitution of a group has any significant influence on the material properties.
Manifold	A pipe channel, or mold, with several inlets or outlets.
Mass spectrometer	An instrument capable of separating ionized molecules of different mass/charge ratios and measuring the respective ion currents.
Master curve	The acceptable or required curve that all subsequent test curves must match.
Matched metal, or die, molding	A method of molding reinforced plastics between two close-fitting metal molds mounted in a press.
Matrix	Either the base resin used for a molded part or the main phase in polymer blends.
Matte finish	A type of dull, nonreflective finish. See "Surface finish."
Mean or average	The sum of values divided by their number.
Mechanical properties	The properties related to the relationships between stress and strain, such as compressive and tensile strengths and moduli, associated with elastic and inelastic reaction to the applied force.

Median	The middle value when all values are arrayed in order of magnitude.
Melt fracture	An elastic strain set up in a molten polymer as the polymer flows through the die. It may show up as irregularities on the surface of the plastic. Several stages (and different mechanisms responsible for these) are recognized, viz., shark skin, pressure oscillation (or spurt), and gross distortions.
Melt front	The exposed surface of molten resin as it flows into a mold. The melt front advances as the molten resin is continuously pushed through its center section.
Melt index (MI), melt flow index (MFI), or melt flow rate (MFR)	The amount in grams of a thermoplastic resin forced through a 2.10 mm (0.0825 in. orifice when subjected to the prescribed force, e.g., 2.16 kg force during 10 min at the prescribed temperature ($^{\circ}$C) using an extrusion plastometer (ASTM D1238). It is customary to refer to the flow rate of polyethylene as "melt index." However, for all other materials, the term "melt flow rate" should be used.
Melt strength	The strength of a plastic while in the molten state.
Melt temperature	The temperature at which a resin melts or softens and begins to flow. The temperature of resin melt taken with a pyrometer melt probe.
Melting point	The temperature at which a resin changes from a solid to a liquid.
Metal plating	The process of plating a plastic part by chemically etching the surface to accept a base metal on which the subsequent layers of metal are deposited. Usually a multistep process. Not all plastics can be metallized.
Metallizing	A general term used to cover all processes by which plastics are coated with metal.
Metallocenes	Metallo-organic sandwich compounds in which two cyclopentadienlidene, Cp, rings form a sandwich around a metallic ion of, e.g., Fe, Co, Ni, Cr, Ti, V, and Zr. They have been used to catalyze the coordination polymerization of olefinic or vinylic monomers into highly regular macromolecules, viz., with narrow molecular weight, high regularity of comonomer placement, and/or high tactic purity. For example, ethylene was catalyzed with $R'_s(Cp)_2MeQ$ [Me is metal from group 4b, 5b, or 6b (preferably Zr); R' is a C_1–C_4 alkylene radical, a dialkyl germanium, or silicone; Q is an alkylidene radical having from 1 to about 20 carbon atoms, s = 0–1, p = 0–2, m = 4–5], in combination with alumoxanes.

Meter	SI length unit equal to 100 cm molecular dimension, or 39.37 in.
Metering equipment	A machine or system to accurately meter additives to the machine's hopper or feed throat. Comes in many sizes and types to suit each particular application, including augers, shuttle plates, photoelectric eyes, and positive or negative weight loss belt feeders.
Metering screw	An extrusion or injection molding screw that has constant shallow depth and pitch section, usually over the last three to four flights.
Micelle colloids	Low-molecular-weight, mainly homogeneous molecules, held together by secondary forces to form a colloidal particle.
Microcracking	Cracks formed when local stresses exceed the strength of the matrix. In composites, because microcracks do not penetrate the reinforcing fibers, in cross-ply or cloth prepreg tape laminates, they are usually limited to the thickness of a single ply.
Micro-morphology	Structural constitution on a submicron scale as related to crystallinity, viz., crystalline unit cells, lamellae shape and size, and stress-induced shish kebab crystals.
Microprocessor	Computer system that stores, analyzes, and adjusts the controls of a machine based on the parameters established during the operation of the machine it is controlling. It continuously analyzes output data to adjust and maintain the machine's cycle within programmed limits. Can also store data and output it as directed by programming.
Microstructure	The molecular structural features of a single polymer chain: tacticity, isomerism, chain branching, structural irregularities, etc.
Migration of plasticizer	Loss of plasticizer from a polymeric compound, with subsequent absorption by an adjacent medium that lowers its concentration and induces brittleness.
Migration	The transfer of a material from a plastic to other contacting solids.
Mil	English unit of length equal to 0.001 in. or 25.4 μm.
Miscible polymer blend	A polymer blend, homogenous down to the molecular level, in which the domain size is comparable to macromolecular dimension, associated with the negative value of the free energy and heat of mixing, ΔG_m and $\Delta H_m < 0$, and $\partial^2 \Delta G_m / \partial \varphi^2 > 0$. Operationally, it is a blend whose domain size is comparable to the dimension of the macromolecular statistical segment.

Mixing	General term associated with the physical act of homogenization (e.g., mixing of fractions). Mixing of liquids is usually called blending (e.g., preparation of polymer blends or alloys), while incorporation of solids into molten polymer is usually called compounding (e.g., preparation of a compound).
Mixing elements	Three types of elements are used to assemble screws in a twin-screw extruder: kneading, mixing, and transporting. The mixing elements of different types are provided by the equipment manufacturers, viz., turbine, gear, notched disk, and blister rings. Depending on the type, these elements are responsible for either or for both the distributive and dispersive actions. Several authors consider kneading and mixing elements as belonging to the same class, alternatively labeled as kneading or as mixing blocks. See also "Kneading elements."
Modified natural products	Plastics or fibers that are prepared by chemical transformation of natural substances, e.g., cellulose nitrate or acetate and casein or gelatin hardened by formaldehyde.
Modifiers	Any additive that improves the processing or end-use properties of the polymer, e.g., PVC plasticizers added to make it soft and pliable and improve its impact strength. Almost all plastic resins use different modifiers to meet desired product requirements.
Modulus of elasticity	The ratio of the stress to the strain produced in a material that is elastically deformed (ASTM D790). If a tensile stress of 20 MPa results in an elongation of 1 %, the modulus of elasticity is 2 GPa.
Modulus of resilience	The energy that can be absorbed per unit volume without creating a permanent distortion. Calculated by integrating the stress–strain curve from zero to the elastic limit and dividing by the original volume of the specimen.
Moisture absorption	The pickup of water vapor from the atmosphere by bulk of a material. It relates only to vapor withdrawn from the air by a material and must be distinguished from water absorption, which is the gain in weight due to the take-up of water by immersion.
Moisture adsorption	Surface retention of moisture from the atmosphere.
Moisture vapor transmission rate (MVTR)	The rate at which water vapor permeates through a plastic film or wall at a specified temperature and relative humidity (ASTM E96).

Mold deposits	Material build up on a cavity's surface due to plate out of resin, usually in a gaseous state. Can be attributed to additives in a resin adhering to the mold's surface.
Mold release agent	A lubricant, liquid, or powder (often silicon oils and waxes) used to coat a mold cavity to prevent the molded piece from sticking to it, thereby facilitating its removal from the mold. Additives put into a material to serve as a mold release.
Mold shrinkage	Shrinking a molded part while it is removed from a mold and cooled to room temperature. The difference in dimensions between a piece and the mold cavity. The incremental difference between the dimensions of the molding and the mold from which it was made, expressed as percentage of the mold dimensions.
Molding	A group of plastics processes used to form polymers or composites into solids with shape and size defined by the mold cavity, by the application of pressure and heat for a given time.
Molding cycle	The time required to complete a cycle and produce a part.
Molding compound powder or material	Plastic material, often comprising resin, filler, pigments, plasticizers, and other ingredients, ready for molding operation.
Molding pressure	The pressure applied directly or indirectly on the compound to allow the complete transformation to a solid dense part. The pressure developed by a ram or screw to push molten plastic into a mold cavity. See "Injection pressure."
Molding shrinkage	See "Mold shrinkage."
Molecular weight, or an average molecular weight (MW)	The sum of the atomic masses of the elements forming the molecule expressed in units of 1/12 the mass of ^{12}C atom, or a mass of one mole of the substance (kg/mol), indicating the relative size typical chain length of the polymer molecule. Owing to polydispersity the molecular weight of a polymer is expressed as an average:

$$M_k = \frac{\sum_i N_i M_i^{k+1}}{\sum_i N_i M_i^k}$$

For $k = 1$, the number average; for $k = 2$, the weight average; for $k = 3$, the z-average; for $k = 4$ ($z + 1$), average molecular weight is generated; etc. (viz., M_n, M_w, M_z, $M_z + 1$, respectively).

Molecularly homogeneous	A polymer in which all the molecules possess the same chemical structure.
Molecular weight distribution (MWD)	A statistical description of the sizes and frequency of occurrence of different molecular chain lengths within a given sample or lot of polymers, i.e., the distribution of molecular sizes in a polydispersed polymer. Several analytical functions f(M) have been proposed. Some of them are general statistical expressions (e.g., log-normal distribution, q.v.) and the others are based on assumed kinetics of polymerization (e.g., Schultz-Flory distribution). MWD is normally determined using a size exclusion chromatography, SEC (an old GPC). Wide and skewed distributions result in significant variation of properties. Narrow distributions are more consistent.
Molecule	A group of atoms bonded together which forms the fundamental structural unit of most organic substances. The number of atoms can range from two to millions. A molecule is the smallest unit of a substance that still retains the properties of that substance.
Monomer (monomer = single unit)'	A small molecule of an organic substance capable of entering into a polymerization reaction with itself or with other similar molecules or compounds, viz., vinyl monomers, dienes, α,ω-lactams, and diamines. A low-molecular-weight-reactive chemical that polymerizes to form a polymer. Monomers are generally gases or liquids. When bonded together in long chains, they form solid materials or polymers.
Morphology	The study of the physical form and structure of a material. The overall physical form of the physical structure of a material on a submicron and micron scale. Common units are dispersed phase domains, lamellae, spherulites, etc. The term comprises notion of the global structure (e.g., stress-induced skin core), as well as shape, size, orientation, and distribution of the dispersed phase (solid, liquid, or gaseous).
Mottle	The desired or accidental mixture of colors or shades of a color giving approximately distinct or complicated patterns or specks, spots, or streaks of color.
Movable platen	The moving platen of an injection or compression molding machine to which half of the mold is secured during operation. The platen is moved either by a hydraulic ram or a toggle mechanism.
Multiblock copolymer	A block copolymer with more than three blocks, e.g., $-[AB]_n-$.

Multicavity mold	A mold having more than one cavity or impression for forming finished items during one machine cycle.
Multichain polymer	A polymer with more than two chains extending from a center, e.g., comb or star polymer.
Multiple-screw extruder	An extruder machine that has two or more screws, as contrasted with conventional single-screw extruders.
Nanocomposite (NC)	A matrix material (metallic, ceramic, or polymeric in nature) having dispersed particles, with at least one dimension that does not exceed 10 nm. Polymeric nanocomposites (PNC) of commercial interest comprise 2–5 wt% of exfoliated clay.
Necking	Localized reduction in cross section that may occur in a material under tensile loading during a tensile test. Necking is disregarded in calculation of the engineering stress, but is taken into account in determining the true stress.
Network polymer	A cross-linked polymer forming infinite network, obtained in a step-growth polymerization with multifunctional monomers.
Newtonian fluid	An ideal fluid characterized by a constant ration of the shear stress to the rate of shearing in a simple shear deformation and with zero normal stress difference (nonelastic).
Nondestructive evaluation (NDE) or nondestructive inspection (NDI)	An analysis to determine whether the material is acceptable for its function.
Nondestructive inspection (NDI)	A process or procedure, such as ultrasonic or radiographic inspection, for determining the quality or characteristics of a material, part, or assembly, without permanently altering the subject or its properties. Used to find internal anomalies in a structure without degrading its properties.
Nonpolar	Incapable of having a significant dielectric loss. Polystyrene and polyethylene are nonpolar.
Nonreturn valve	See "Ball or checking valve."
Nonrigid plastic	A plastic that has a modulus of elasticity (either in flexure or in tension) of not over 69 MPa (10,000 psi) at 25 °C and 50 % relative humidity (ASTM D747).
Normal distribution	See "Gaussian distribution."
Notch sensitive	A plastic material is said to be notch sensitive if it will break when it has been scratched, notched, or cracked. Glass is considered to be highly notch sensitive.
Notch sensitivity	A measure of reduction in load-carrying ability caused by stress concentration in a specimen. Brittle plastics are more notch sensitive than ductile.

Nozzle	A hollow metal nose screwed into the extrusion end of either the heating cylinder of an injection machine or a transfer chamber (where this is a separate structure).
Nuclear magnetic resonance (NMR)	Relates to the radio frequency-induced transitions between magnetic energy levels of atomic nuclei. NMR instrument consists essentially of a magnet, radio frequency accelerator, sample holder, and detector, capable of producing an oscilloscope image or line recording of NMR spectrum. See also "Nuclear magnetic resonance spectroscopy."
Nuclear magnetic resonance (NMR) spectroscopy	When an organic molecule containing certain atoms (e.g., ^{13}C, H, D, F) is placed in a strong magnetic field and irradiated with radio frequency, transition between different nuclear spin orientational states takes place, and energy is absorbed at specific frequencies. Several different types of NMR measurements have been developed for characterization of polymer molecules, viz., high-resolution NMR of polymer solutions, wide-line solid-state NMR, magic-angle spinning NMR, and pulse-induced NMR.
Nucleating agent	A foreign substance, often crystalline, usually added to a crystallizable polymer to increase its rate of solidification and reduce size of spherulites.
Nucleation	Any additive that assists or acts as a starting site for crystallization of a polymer. These initiators can reduce cycle time by speeding up the crystalline formations, thereby causing the part to solidify faster so its ejection from the mold can occur sooner.
Nylon™	A generic term for polyamides (a trademark of E. I. du Pont de Nemours, adduct of New York and London). To be avoided – use polyamide, PA, instead.
Olefins	Plastics produced from olefins, viz., polyethylene or polypropylene.
Oligomer	Low-molecular-weight polymeric material with the degree of polymerization, $10 < DP < 50$; from Greek oligos = few, little.
Opalescence	Limited clarity of vision through a sheet of transparent plastic at any angle, caused by light scattering within or on the surface of the plastic.
Opaque	A material that will not transmit light and is not transparent.
Open-hole insert	An insert having a hole drilled completely through it.
Optical comparator	An inspection machine using optics to compare the outline of a part to its required dimensions on a graphic screen.

Optical distortion	Any apparent alteration of the geometric pattern of an object when observed through a plastic or as reflection from a plastic surface.
Orange peel	An unintentional rugged surface that gives an appearance resembling the skin of an orange.
Ordered polymer	A polymer with monomers arranged in regular sequence, viz., alternating or block copolymers.
Organic	The term refers to a general class of substances whose composition is based on the element carbon. Organic infers some relationship to materials, which at some point in time were alive.
Organosol	Fine PVC suspension in a volatile, organic liquid. At room temperature, the resin is swollen, but not appreciably dissolved. At elevated temperatures, the liquid evaporates, and the residue upon cooling forms homogenous plastics. Plasticizers may be dissolved in the volatile liquid. See also "Plastisols."
Orientation	The alignment of the molecular structure in polymeric materials to produce anisometric material properties. It can be accomplished by drawing or stretching during fabrication, especially at low temperatures.
Orifice	An opening in a die or other metal piece used to meter the flow of fluid material.
Out-of-round	Nonuniform radius or diameter.
Overflow Tab	A small, localized extension of a part at a weld-line junction to allow a longer material flow path for the purpose of obtaining a better fusion bond of the meeting melt fronts.
Overlay sheet	See "Foil decorating."
Oxidation	Any chemical reaction in which electrons are transferred. The chemical reaction involving oxygen to form an oxide; the deterioration of an adhesive film due to atmospheric exposure; the breakdown of a hot melt adhesive due to prolonged heating and oxide formation. Degradation of a material through contact with air. A chemical reaction involving a combination with oxygen to form new compounds.
Oxygen index	The minimum concentration oxygen expressed as a volume percentage in a mixture of oxygen and nitrogen that will just support flaming combustion of a material initially at room temperature under the specified conditions. An indication of flammability.
Pack time	The amount of time that packing pressure is kept on the screw until the gate freezes. It takes time immediately after the injection stroke ends.

Packing pressure	The pressure applied just before the part cavity fills, which is about 50 % of the injection pressure required to continue filling the mold without flashing it. Packing pressure is maintained until the gate freezes.
Pad	See "Cushion."
Paint line	The point where two colors meet.
Paint step	Break in a smooth surface that allows a mask to rest.
Parallel to the draw	The axis of the cored position or insert parallel to the up-and-down movement of the mold as it opens and closes.
Parallels (risers or support fillers)	The support spacers between the mold and press platen or clamping plate.
Pareto analysis	An analytical and statistical technique used to determine part defect type and quantity. Ranks each type of defect as a percentage of the total number of defects found, based on the quantity of each type of defect.
Parison	Hollow plastic tube from which a part is blow molded.
Part separator	A machine or system used to automatically separate parts from the runner system after molding. Separated parts go to their next station and the runner moves to a granulator for reuse if permitted. The system may use blades, rigid pins, or a degating station with parts placed by a robot for separation.
Parting agent	See "Mold release."
Parting line	The point in the mold where two or more metal surfaces meet creating a shutoff. Mark on a molding or casting where halves of a mold met in closing.
Partitioned mold cooling	See "Bubbler."
Pastel	A tint, a tone to which white has been added.
Paucimolecular	Polymers that consist of only a few different molecular weight components. Also called the paucidisperse polymers.
Peak exothermic temperature	The maximum temperature reached by reacting thermosetting plastic composition is called peak exothermic temperature.
Permeability	The passage or diffusion of a gas, vapor, liquid, or solid through a barrier without affecting it. The rate of the passage.
pH	Negative logarithm of concentration of hydrogen ions, $-\log [H^+]$, a measure of the acidity or alkalinity of a substance. Acid solutions have $pH < 7$, at neutrality $pH = 7$, and in alkaline solutions $pH > 7$.
Phase	A separate, but not necessarily separable, portion of a system.

Phenolic resins	Cross-linked resins based on phenol and formaldehyde of a complex, not fully known, structure.
Photodegradation	Degradation caused by long wavelength ultraviolet radiation that is the main cause of outdoor weathering.
Photoelasticity	Experimental technique for the measurement of stresses and strains in material objects by means of the mechanical birefringence.
Physical aging	The relaxation process that takes place in plastics after fabrication. Upon cooling a melt, the molecular mobility decreases, and when the relaxation time exceeds the experimental time scale, the melt becomes a glass in nonequilibrium thermodynamic state (density, enthalpy, etc.). Thus, the value of the thermodynamic parameters continues to change toward an equilibrium state. The process may lead to development of cracks and crazes that initiate critical failure. See also "Aging," "Accelerated aging," "Artificial aging," and "Chemical aging."
Physical cross-link	A physical bond that joins two or more chains together. They may arise from crystalline portions of a semicrystalline polymer, the glassy or crystalline portion of a block copolymer, or the ionic portion of an ionomer. The physical cross-link forces are affected by the temperature.
Physical cross-linking	An existence of restraining force between polymer chains other than covalent bonding; viz., entanglements, presence of microcrystallinity, and glassy blocks in block copolymer.
Piece part price	Calculated finished part cost based on material, processing, assembly, decorating, and packaging, including productivity and overhead costs.
Pigment	Imparts color to plastic while remaining a dispersion of undissolved particles.
Pigmented	A plastic resin comprising pigments to produce a desired color after molding. The pigments can be either organic or inorganic based.
Pinpoint or restricted gate	A restricted orifice through which molten plastic flows into a mold cavity.
Pit	Small regular or irregular crater in the surface of a plastic, usually with width approximately of the same order of magnitude as its depth.
Pitch	With respect to extruder or injection molding, the distance from any point on the flight of a screw line to the corresponding point on an adjacent flight, measured parallel to the axis of the screw line or threading.

Plastic	A synthetic or natural organic substance (exclusive of adhesives and rubbers) formable or pliable at some stage during its formation or subsequent manufacturing process, thus a polymeric material that is capable of being shaped through plastic flow under influence of deforming forces, a thermoplastic or thermoset material. It either melts and flows with heat and pressure, as with a thermoplastic, or it chemically "sets," as with a thermoset material. Many materials, such as glass, become plastic under the right conditions.
Plastic deformation	Any portion of the total deformation of a body that occurs immediately when load is applied but that remains permanently when the load is removed. The deformation of a material under load that is not recoverable after the load is removed. Opposite of elastic deformation.
Plastic memory	A phenomenon of a plastic to return, in some degree, to its original form upon heating.
Plasticate	To soften by heating and/or kneading.
Plasticating extruder	An extruder fed with solid polymer that melts and plasticates it while conveying toward the die.
Plasticity	A property of plastics that upon the application of a force allows the material to be deformed continuously and permanently without rupture (the opposite of "elasticity").
Plasticization	Softening, enhancement of flexibility engendered by incorporation of low-molecular-weight liquid, a plasticizer, such as 2-ethylhexylphthalate (DOP).
Plasticize	To make a material soft and moldable with the addition of heat, pressure, or a plasticizer.
Plasticizer	A material incorporated in a thermoplastic to reduce its glass transition temperature, thus to increase its flexibility.
Plastisols	Mixtures of PVC and plasticizers that can be molded, cast, or converted to continuous films by the application of heat. The mixtures that contain volatile thinners are known as organosols, q.v.
Plate dispersion plug	See "Breaker plate."
Platens	The mounting plates of a press to which the entire mold assembly is bolted.
Plunger	The part of a transfer or injection press that applies pressure to the unmelted plastic material to push it into the chamber. This, in turn, forces the melt out through the nozzle.
Poisson distribution	Discrete probability function, derived by Simeon Poisson in 1837, for the situation when the probability

	of a single event is very small, but the number of events approaches infinity.
Poisson's ratio, r	The ratio of lateral strain to the corresponding axial strain in axially loaded specimens, below the proportional limit. It is a material constant that relates the modulus of rigidity, G, to Young's modulus, E, in the relation: $E = 2G(r + 1)$, viz., ASTM E1321.
Polarized light	Polarized electromagnetic radiation whose frequency is in the optical region.
Polarizer	A medium or a device used to polarize the incoherent light.
Polyacrylonitrile (PAN)	Product of free radical polymerization in solution or suspension. Used primarily for production of fibers (it may contain up to 10 % comonomer to improve dyeability). Homopolymer of PAN is a base material in the manufacture of carbon fibers.
Polyaddition	A step-growth polymerization from two types of bi- or polyfunctional primary molecules, e.g., polyurethane formation. This irreversible, rapid process is caused, usually through heteroatoms, by bond displacement without the splitting off any component.
Polyallomers	Crystalline thermoplastic polymers made from two or more different monomers, usually ethylene and propylene.
Polyamide-imide (PAI)	A family of polymers based on the combination of trimellitic anhydride with aromatic diamines. In the uncured form (ortho-amic acid), the polymers are soluble in polar organic solvents. The imide linkage is formed by heating, producing an infusible resin with thermal stability up to 290 °C. These resins are used for laminates, prepregs, and electrical components.
Polyamides (PA)	A group of semicrystalline thermoplastics containing the amide group (−NHCO−) in the main chain, resulting from polycondensation of either α,ω-lactam or a diacid with a diamine. Natural polyamides, polypeptides, and synthetic polyamides belong to this family.
Polyarylates (PAr)	Wholly aromatic polyesters from dihydric phenols and dicarboxylic acid chlorides. They are characterized by high melting point (up to 500 °C), good thermal stability, and solubility in chlorinated solvents. Commercial polymers are produced by polycondensation of iso- and terephthalic acids with bisphenol A, having glass transition temperatures near 170 °C and the continuous use temperature of 140–150 °C.
Polyarylsulfone (PAS)	Alternative name for aromatic polyethersulfone. See "Polyethersulfone."

Polybenzimidazole (PBI)	The polycondensation product of tetraaminobiphenyl with terephthalic acid has the highest thermal stability of all commercial organic polymers. Its continuous use temperature is 400 °C, and it has good chemical stability.
Polybutylene terephthalate (PBT)	Polycondensation product of dimethylterephthalate and 1,4 butanediol, with melting temperature T_m § 224 °C. PBT can be easily blended with number of other thermoplastics. Major uses include automotive parts (interior, under-the-hood, and exterior), electrical connectors, small appliances, and pump housings.
Polybutylenes, BR	A group of polymers consisting of isotactic, stereoregular, highly crystalline polymers based on butene-1. Their properties are similar to those of polypropylene and linear polyethylene, with superior toughness, creep resistance, and flexibility.
Polycarbonate (PC)	An amorphous thermoplastic derived from the direct reaction between aromatic and aliphatic dihydroxy compounds with phosgene or by the ester exchange reaction with appropriate phosgene-derived precursors. Highest impact resistance of any transparent plastic. It is transparent and can be injection molded, extruded, thermoformed, or blow molded (esp. branched PC).
Polycondensation	A polymer synthesis from bi- or multifunctional monomers with liberation of a low-molecular, volatile by-product.
Polyesters	Polymers containing the ester group (−COO−) in the main chain, products of polycondensation of α,ω-lactones or diacid with diols. Both unsaturated (alkyd) polyesters and thermoplastic polyesters (including PC, PET, PBT, and PNT) enjoy wide commercial use.
Polyether-imide (PEI)	An aromatic polymer containing both ether and imide groups in the polymeric chain. It has a heat distortion temperature of 200 °C, continuous use temperature of 170 °C, and low flammability. It can be blended with several engineering thermoplastics for a wide range of properties and applications (mainly in automotive and electronic/electrical industries).
Polyethersulfone (PES)	An aromatic polymer containing benzene rings linked by both ether and sulfone groups in the polymeric chain. Several commercial products of this type have been developed. Their glass transition temperature varies from 190 to 285 °C. The materials have high rigidity, low creep, high electrical resistance, transparent, self-extinguishing, and low flammability. They can be

	blended with several engineering thermoplastics. The applications include printed circuit boards, TV components, and diverse electronic/electrical parts.
Polyethylenes (PE)	Thermoplastic materials composed of ethylene units. They are normally translucent, tough, waxy solids that are unaffected by water and by a large range of chemicals. These plastics have >85 % ethylene and >95 % of total olefins.
Polyethylene terephthalate (PET)	Polycondensation product of dimethylterephthalate and ethylene glycol, with $T_m = 260$–270 °C. Oriented PET has outstanding tensile strength. Its principal use includes bottles, X-ray films, electrical insulation, and food packaging.
Polyimide (PI)	Polymer produced by reacting an aromatic dianhydride with an aromatic diamine. It is highly heat-resistant (at $T = 315$ °C) resin, similar to a polyamide, differing only in the number of hydrogen atoms per mer. The polymer is suitable for the use a binder or adhesive and may be either a thermoplastic or a thermoset. Initially, it could not be processed by conventional molding methods. The polymer has rings of four carbon atoms tightly bound together. It has excellent resistance to heat.
Poly-liner	A perforated, longitudinally ribbed sleeve that fits inside the cylinder of an injection molding machine. Used as a replacement for conventional injection cylinder torpedoes/older machines. Also a plastic bag placed inside a carbon or box to prevent material contamination during shipment.
Polymer	Material composed of many (Greek poly) units (Greek meros). A high molecular weight organic compound – natural or synthetic, formed by a chemical reaction in which two or more small organic units join to form large units composed of repeating small units. Its structure can be represented by repeated small units, the mers. Synthetic polymers are formed by addition or condensation polymerization of monomers. Some polymers are elastomeric, and others thermoplastic or thermoset. The term was coined by Berzelius in 1832 to describe hydrocarbons of a general formula $(CH_2)_n$ with $n = 1$ to 4 (sic!). Today a substance may be called polymer if it shows high degree of polymerization, DP >50.
Polymer alloy	An immiscible polymer blend having a modified interface and/or morphology.

Polymer blend	A mixture of at least two macromolecular materials: two or more polymers, polymer with copolymers, two or more copolymers, etc. Polymer blends are either miscible or immiscible. See "Miscible polymer blend" and "Immiscible polymer blend."
Polymer conversion	Preparation of polymer derivatives during which the number of macromolecules or the degree of polymerization is preserved.
Polymerization	The process or chemical reaction in which the molecules of a monomer are linked together to form macromolecules whose molecular weight is a multiple of that of the original substance $nM \rightarrow [M]_n$, where n is a degree of polymerization, DP. It is said that the polymerization leads to oligomer if $10 < DP < 50$ and to polymer if $DP > 50$. When two or more monomers are involved, the process is called copolymerization. Most polymerization processes are classified as condensation (step) reactions or addition (chain) reactions.
Polymethylme-thacrylate (PMMA)	Crystal-clear radical polymerization product of methyl methacrylate. PMMA has the glass transition temperature of 105 °C, excellent weatherability, and scratch resistance, as well as useful combination of stiffness, density, and toughness. It can be easily modified by co-reacting or blending.
Polymolecularity	Practically all polymers are mixtures of impossible to separate homologues or fractions. Mathematically the polymolecularity is expressed by a molecular weight distribution, MWD, q.v.
Polyphenylene ether (PPE)	An amorphous thermoplastic with useful temperature range that depending on composition varies from 135°C to 190 °C.
Polypropylenes (PP)	A crystalline thermoplastic made by polymerizing propylene gas. It has the lowest density of all plastics, except methylpentene. Tough, lightweight thermoplastics made by the polymerization of propylene in the presence of an organometallic catalyst at relatively low pressures and temperatures.
Polystyrenes (PS)	An amorphous thermoplastic made by polymerizing styrene. Thermoplastics produced by the polymerization of styrene, having outstanding electrical properties and good thermal and dimensional stability. Because it is somewhat brittle, it is often copolymerized or blended with other materials to obtain desired properties (see HIPS).

Polysulfones (PSF or PSU)	A family of engineering thermoplastics with excellent high-temperature properties, high strength, high service temperature, low creep, and self-extinguishing properties, produced either by a Friedel-Crafts reaction of sulfonyl chloride groups with aromatic nuclei or by reacting dichlorosulfone with diphenyls. The continuous use temperature is about 160 °C. They can be formed by extrusion and molding method, directly competing with metals and more expensive materials for electronic circuitry.
Polytetrafluoroethylenes (PTFE)	A linear polymer obtained by radical polymerization of tetrafluoroethylene. PTFE has a melting point of 327 °C and outstanding resistance to chemical attacks or dissolution. Its uses include liners for chemical processing equipment, high-temperature cable insulation, bushings, seals, and nonstick surfaces.
Polyurethanes (PU)	Polymers containing urethane groups ($-$NHCOO$-$) in the main chain. Thermoplastic or thermoset materials made from isocyanates and polyols. The linear polyurethanes (thermoplastic polyurethanes, TPU) are formulated with rigid and soft segments, thus (as block copolymers) showing interesting elastomeric character. However, most polyurethanes are produced as cured rubbers (polyurethane rubber, PUR) by means of combining isocyanate having functionality about 2.7 with diols. The principal use of PUR is in manufacture of rigid and flexible foams.
Polyvinyl chloride (PVC)	A thermoplastic material composed of polymers of vinyl chloride. It is a colorless solid with outstanding resistance to water, alcohols, and concentrated acids and alkalis. It is obtainable as granules, solutions, lattices, and pastes. Compounded with plasticizers, it yields a flexible material superior to rubber in aging properties. It is widely used for cable and wire coverings, in chemical plants, and in the manufacture of protective garments. The pure polymer is brittle and difficult to process. It yields a flexible material when compounded with plasticizers.
Polyvinylidene chloride (PVDC)	A thermoplastic material composed of polymers of vinylidene chloride. Its principal uses are in flexible films and coatings.
Porosity	A condition of trapped pockets of air, gas, or vacuum within a solid material, expressed as percentage of the total nonsolid volume to the total volume.

Post annealing	Stress relieving of molded parts by external means, hot air or oil, humidity chambers, or submersion in a fluid.
Post mold shrinkage	The shrinkage occurring after a part has been removed from the mold is influenced by the material properties of the resin and its molding conditions.
Post-forming	A process used to impart a shape to a previously molded article.
Pot life	The time span during which a cross-linking resin-hardener system can still be processed.
Potentiometer	An electrical control device that senses changes in voltage or a potential difference by comparison to a standard voltage and can transmit a signal to a control switch.
Preplastication	Technique of premelting injection molding powders in a separate chamber and then transferring the melt to the injection cylinder. The device used for preplastication is known as a preplasticizer.
Prepolymer	A chemical intermediate with a molecular weight between that of the monomer or monomers and the final polymer.
Press fit	An interference assembly between two mating parts, with friction holding the parts together under considerable stress.
Pressure drop	The decrease in pressure of a fluid related to the number of turns it has to make and the distance it must flow to fill a cavity.
Pressure gradient lines	A hypothetical set of pressure lines in a part created by the material's pressure drop as the part is filled. The further the material flows from the gate, the lower the packing pressure.
Pressure pads	Reinforcements distributed around the dead areas in the faces of a mold to help the land absorb the final pressure of closing.
Primary molecule, monomer	The smallest molecular unit from which the macromolecule is built.
Printing on plastics	The decoration of plastics by means of various printing processes, e.g., offset, silk screen, letterpress, electrostatic, or photographic methods.
Process control procedures	A separate document, often included as an attachment to the quality control manual that provides detailed description of the methods to be followed in the manufacture of a product. A copy may be attached to the work order for reference and revision as required should changes in the product occur.
Processing aid	An additive that improves processing characteristics.

Product certification	The certificate or letter stating that the material or product meets or exceeds customer requirements. Values are often listed for the tested or measured results. To be signed by a key representative of the company to verify accuracy.
Projected surface area	The exposed resin area of a mold on the parting line that transmits the injection pressure on the closed mold halves. It includes part, runner, and sprue surfaces.
Propagation	A series of reaction steps in a chain polymerization in which the monomers are being added to the active polymerization center.
Proportional limit	The greatest stress that a material is capable of sustaining without deviation from proportionality of stress and strain (Hooke's law).
Prototype mold	A simplified mold construction often made from a light metal casting alloy or from an epoxy resin to obtain information for the final mold and/or part design.
Pseudo-IPN	Simultaneous IPN in which one polymer is in network form and the other linear.
Pultrusion	A continuous process for manufacturing composites that have a constant cross-sectional shape. The process consists of pulling a fiber-reinforcing material through a resin impregnation bath and then through a shaping die, where the resin is subsequently cured.
Purging	Cleaning one color or type of material from the processing machine by forcing it out with the new color or material to be used in subsequent production. Special purging materials are also available.
Pyrometer	An electrical thermometer for measuring high temperatures. The units come with two probes to measure melt and surface temperatures.
Quality assurance	A separate department established to direct the quality function of the business areas. Major efforts are directed to assisting and auditing the activities of the quality control department in their efforts to ensure that quality products are manufactured.
Quality circles	A quality analysis group consisting of employees with specific departmental knowledge used to provide suggestions and ways to solve a procedural or manufacturing quality problem. If found acceptable, the group's findings and solutions are then passed on to upper management for implementation.
Quality control (QC)	A department set up to be technically involved in the control of product quality. Involved in the principal

	inspection and testing of a product, with limited systems responsibility.
Quality control manual	A document that states the company's quality objectives, and how they will be implemented, documented, and followed in the manufacture of products.
Quality rated	See "Approved supplier."
Quenching	A method of rapidly cooling thermoplastic parts when they are removed from the mold, usually by submerging the parts in water.
Radical polymerization	Polymerization in which the active centers of reaction are radicals. The polymerization can be initiated by thermally activated or redox initiator, irradiation, or through thermal activation of monomer (also known as free radical polymerization).
Radio frequency, RF, preheating	A method of preheating used to mold materials to facilitate the molding operation and/or reduce the molding cycle. The frequencies commonly used are between 10 and 100 MHz/s.
Ram	The press member that enters the cavity block and exerts pressure on the molding compound designated as the "top force" or "bottom force" by position in the assembly. See "Plunger."
Ram travel	Distance ram moves during a complete molding cycle.
Random copolymer	A copolymer in which the different monomers are randomly placed in the main chain. A perfectly random copolymer is produced by polymerization of different mers having identical reactivity ratios, $r_A = r_B = r_C$.
Randomness	A condition in which individual values are not predictable, although they may come from a definable distribution.
Reactive extrusion	Execution of chemical reactions during extrusion of polymers and/or polymerizable monomers. The reactants must be in a physical form suitable for extrusion processing. Reactions have been performed on molten polymers, on liquefied or dispersed monomers, or on polymers dissolved or suspended in or plasticized by a solvent (also reactive compounding or reactive processing).
Reactive injection molding (RIM)	A semicontinuous manufacturing process in which two liquid components are metered in the calculated ratio by high pressure piston pumps, mixed by impingement mixing and injected into a mold cavity or cavities, where the reactants are polymerized or cured. The process has been used to polymerize polyamides, elastomeric polyurethanes, and polyurethane foams.

Reactivity ratio	A ratio of two kinetic constants $r = k_{AA}/k_{AB}$ where k_{AA} represents the self-propagation and k_{AB} the transfer from A* active center to B* active center caused by addition of monomer-B to a growing copolymer chain.
Real time	The present time or as an activity is occurring.
Reciprocating screw	A combination injection and plasticizing unit in which an extrusion device with a reciprocating screw is used to plasticize the material. Injection of material into a mold can take place by direct extrusion into the mold, by reciprocating the screw as an injection plunger, or by a combination of the two. When the screw serves as an injection plunger, this unit acts as a holding, measuring, and injection chamber.
Recycled plastics	A plastic material prepared from previously used or processed plastic materials that have been cleaned and reground.
Redox initiator	An initiator capable of generating free radicals at low temperature by oxidation-reduction reaction between two components, viz., $H_2O_2 + FeSO_4$.
Regrind	Waste material from industrial operations that has been reclaimed by shredding or granulating. Regrind is usually incorporated, at a predetermined percentage, with virgin material.
Reinforced molding compound	A material reinforced with special fillers to meet specific requirements, such as rag or glass.
Reinforced polypropylene	Polypropylene that is reinforced with mineral fillers, such as talc, mica, and calcium carbonate, as well as with glass and carbon fibers. The maximum concentration is about 5 wt%, although concentrates with higher levels of filler or reinforcement are available.
Reinforcement	A substance or material added to a polymer during the final synthesis stages or in subsequent processing to improve the strength properties of the polymer. Usually, a high strength material bonded into a matrix to improve its mechanical properties. Reinforcements are usually long fibers (glass, carbon or aramid), chopped fibers, whiskers, particulates (glass beads, mica, clay, and organic fibers), and so forth. The term is *not* synonymous with filler.
Relative viscosity	Ratio of the kinematic viscosity of a polymer solution to the kinematic viscosity of the pure solvent.
Relaxation time	The time required for a stress under a sustained constant strain to diminish by a stated fraction of its initial value.
Release agent	See "Mold release."

Release or parting agent	A material that is applied in a thin film to the surface of a mold to keep the resin from bonding (also mold release agent).
Relief angle	The angle of the cutaway portion of the pinch-off blade from a line parallel to the pinch-off land. In a mold, the angle between the pitch-off land and the cutaway portion adjacent to the pinch-off land.
Repeatability	The variation obtained when one person measures the same quantity several times using the same instrument.
Reprocessed plastic	A thermoplastic material, prepared from melt-processed scrap or reject parts, or from nonstandard or nonuniform virgin material. The term scrap does not necessarily connote feedstock that is less desirable or usable than the virgin material from which it may have been generated. Reprocessed plastic may or may not be reformulated by the addition of fillers, plasticizers, stabilizers, or pigments.
Reproducibility	The variation in measured averages obtained when several persons measure the quantity using the same instrument or when one person measures the quantity using different instruments.
Residence time	Time a resin spends in a given processing machine (an extruder, injection molding unit, etc.) and is subjected to heat and stress.
Residence time distribution	The distribution of residence time provides information how long different parts of the resin reside in the processing equipment. The spread of the residence times reflects, on the one hand, the uniformity of flow inside the processing unit and, on the other, the quality of the product, the degree of mixing, or the extent of a chemical reaction.
Residual stress	The stresses remaining in a plastic part as a result of thermal or mechanical treatment.
Resin	An organic material, usually of high molecular weight, that tends to flow when subjected to stress. Any of a large class of synthetic substances that have some of the properties of natural resin (or rosin) but differ chemically. "Resin" is often used as a general term for polymers or plastics and denotes a class of material. It usually has a softening or melting range and fractures conchoidally. Most resins are polymers. Also any of a class of solid or semisolid organic products of natural or synthetic origin, generally of high molecular weight with no definite melting point (also see "Polymer").

	In reinforced plastics, the material used to bind together the reinforcement material; the matrix.
Resin pocket	An apparent accumulation of excess resin in a small localized section that is visible on cut edges of molded surfaces. Also called resin segregation.
Resin transfer molding (RTM)	A fabrication process that involves the transfer of catalyzed resin into an enclosed mold cavity containing a previously positioned reinforcement preform. The process has been used for manufacturing from components consisting of glass fiber mats and polyester resins.
Restricted gate	Sometimes referred to as pinpoint gate. A small opening between the runner and cavity in an injection or transfer mold.
Retainer plate	The plate, usually drilled for steam or water, on which demontable pieces, such as mold cavities, ejector pins, guide pins, and bushings, are mounted.
Retaining pin	A pin on which an insert is placed and located before molding.
Rheology	The study of the deformation and flow of materials of the interrelations between the force and its effects. The science considers deformation of all materials from the elastic deformation of Hookean solids to the flow of Newtonian liquids.
Rib	An object designed into a plastic part to provide lateral, longitudinal, or horizontal support.
Rigid plastics	A plastic that has a modulus of elasticity either in flexure or in tension greater than 690 MPa at 23 °C and 50 % relative humidity, RH.
Ring gate	A gate or annular opening that circles around a core pin or molded part.
Rockwell hardness	A common method of testing materials for resistance to indentation in which a diamond or steel ball, under pressure, is used to pierce the test specimen.
Rubbers	Cross-linked polymers having glass transition temperatures below the room temperature that exhibit highly elastic deformation and have high elongation.
Runner	In an injection or transfer mold, the channel that connects the sprue with the gate to the cavity.
Runner system	The sprues, runners, and gates that lead the material from the nozzle of an injection machine to the mold cavity.
Rupture	A cleavage or break resulting from physical stress. Work of rupture is the integral under the stress–strain curve between the origin and the point of rupture.

Salt and pepper blends	Resin blends of different concentrate additives, in pellet form, mixed with virgin resin to make a different product. Usually associated with color concentrate blends, that, when melted and mixed by the injection molding machine's screw, yield a uniform colored melt for a part.
SAN	An abbreviation for styrene-acrylonitrile copolymers.
Scanning electron microscopy (SEM)	Electron microscopy that uses the secondary emission of electrons from a surface when bombarded with an electron beam. The main advantage is the depth of field. Technique in which the surface of a specimen is scanned, point by point, with a finely focused electron beam. Image formation is made by detecting the secondary electrons emitted by the specimen's surface. Even though resolution in modern SEM can be as high as 4 nm, the main advantage of SEM over the other microscopy techniques is its very large depth of field.
Scanning probe microscopy (SPM)	a microscopy technique in which the surface of a specimen is scanned, point by point, using a very sharp probe (d = 10 nm). Accurate piezoelectric devices are utilized to maintain the separation distance between the lowest atom on the probe tip and the highest atom on the specimen constant and in the range of 1–100 nm. In this range of tip-to-sample spacing, phenomena like tunneling current (scanning tunneling microscopy (STM)) or interatomic repulsion/attraction (atomic force microscopy (AFM)) can be used for determining specimen topography with resolution ranging from a few microns, down to atomic level.
Scanning transmission electron microscopy (STEM)	a microscopy technique in which an ultrathin specimen is scanned, point by point, with a finely focused electron beam. Image formation is made by detecting the electrons transmitted through the specimen.
Scrap	A product or material that is out of specification to the point of being unusable.
Screw plasticating injection molding	See "Injection molding."
Screw	The main component of the "reciprocating screw" injection molding machine. It may have various sizes, lengths, and compression ratios. It is used to feed, compress, melt, and meter the resin for injecting into the mold cavity. Basically divided into 3 major sections: feed section, deep screw depths to convey the resin into the next screw's section; transition section, gradually decreasing screw depths when resin is compressed, forced against the barrel's surface, and melts; and

	metering section, the molten melt that is further compressed in a shallow, uniform screw depth conveying forward as the screw turns.
Scuff mark	An imperfection on a part's show surface caused by dragging the part against the mold's surface during ejection from the mold cavity.
Sealant	A material applied to a joint in paste or liquid form that hardens or cures in place, forming a seal.
Sealing diameter	That portion of a metal insert that is free of knurl and is allowed to enter the mold to prevent the flow of plastic material.
Secant modulus	The ratio of total stress to corresponding strain at any specific point on the stress–strain curve.
Second-surface decorating	A method of decorating a transparent plastic part from the back or reverse side. The decoration is visible through the part, but is not exposed.
Semiautomatic molding machine	A molding machine in which only part of the operation is controlled by direct human action. The automatic part of the operation is controlled by the machine according to a predetermined program.
Semi-I IPN	An intimate combination of two polymers in network form. Sequential IPN in which polymer-1 is cross-linked and polymer-2 linear.
Semi-II IPN	An intimate combination of two polymers in network form. Sequential IPN in which polymer-1 is linear and polymer-2 cross-linked.
Semicrystalline	Polymers that exhibit localized, partial crystallinity (see "Crystalline plastic").
Sequential polymerization	Formation of an alternating or block copolymer through careful control of addition of different monomers at specific stages of the reaction.
Sequential IPN (SIPN)	An intimate combination of two polymers in network form. During preparation of SIPN, the first polymer-A is swollen in a mixture of monomer-B, cross-linking agent, and initiator and then polymerizing in situ.
Servomotor	An electrical motor or hydraulic piston that supplies power to a feedback system that consists of a sensing element and an amplifier used in the automatic control of a mechanical device.
Shear heat	The rise in temperature created by the compression and longitudinal pressure on the resin in the barrel by the screw's pumping action.
Shear joint	An ultrasonic welding joint design where the welding action is parallel to each part surface.

Shear rate	The overall velocity over the cross section of a channel with which molten polymer layers is gliding along each other or along the wall in laminar flow. A change of shear strain within one second.
Shear strain	Deformation relative to the reference configuration of length, area, or volume. Tangent of the angular change, caused by a force between two lines originally perpendicular to each other through a point in a body is called angular strain.
Shear strength	The maximum shear stress that a material is capable of sustaining. The maximum load required to shear a specimen in such a volume manner that the resulting pieces are completely clear of each other. Shear strength (engineering) is calculated from the maximum load during a shear or torsion test and is based on the original cross-sectional area of the specimen.
Shear stress	Stress developed because of the action of the layers in the material attempting to glide against or separate in a parallel direction. In other words, the stress developed in a polymer melt when the layers in a cross section are gliding along each other or along the wall of the channel (in laminar flow).
Shearing	Breaking caused by the action of equal and opposed forces, located in the same plane.
Shelf-life	The time a material, such as a molding compound, can be stored without loss of its original physical or functional properties.
Shore hardness	A method of determining the hardness of a plastic material using a scleroscope or sclerometer. The device consists of a small conical hammer fitted with a diamond point and acting in a glass tube. The hammer is made to strike the material under test and the degree of rebound is noted on a graduated scale. Generally, the harder the material, the greater the rebound (ASTM D2240).
Short or short shot	A molded part produced when the mold has not been filled completely.
Shot capacity	The maximum volume of material that a machine can produce from one forward motion of the plunger or screw.
Shot peening	Impacting the surface of the material with hard, small, round beads of materials to disrupt the surface flatness. Used to stress relieve welds and to improve the release of plastic resins on smooth core surfaces.
Shot	The yield from one complete molding cycle, including cull, runner, and flash.

Shrink fixture	See "Cooling fixture."
Shrinkage allowance	The additional dimensions that must be added to a mold to compensate for shrinkage of a plastic material on cooling.
Shrinkage	In a plastic, the reduction in dimensions after cooling. The relative change in dimension from the length measured on the mold when it is cold to the length of the molded object 24 h after it has taken out of the mold.
SI units	International System of Units.
Side actions (side coring or side draw pins)	An action built into a mold that operates at an angle to the normal open-and-close action and facilitates the removal of parts that would not clear a cavity or core on the normal press action. Projections used to core a hole in a direction other than the line of closing of a mold and which must be withdrawn before the part is ejected.
Sigma (σ)	The Greek letter used to indicate the standard deviation of a population, defined as the square root of the variance, e.g., for the normal (Gaussian) distribution:

$$y = \left[1/\sigma(2\pi)^{1/2}\right]\exp\left\{-[(x - \bar{x})/\sigma]^2/2\right\}$$
$$\text{Variance} \equiv \sigma^2 = \Sigma(x - \bar{x})/(N - 1)$$

Silicones	Chemicals derived from silica used in molding as a release agent and general lubricant. A silicon-based thermoset plastic material. Polyorganosiloxanes of different composition (e.g., polydimethylsiloxane, silicone rubber), structures (linear or network), and molecular weight, used as "high-temperature oil," resin, or elastomer.
Silk screen printing	In its basic form, it involves laying a pattern of an insoluble material, in outline, on a finely woven fabric. When ink is drawn across the material, it passes through the screen only in the designed areas. Also called screen process decorating.
Simultaneous IPN (SIN)	IPN is prepared by mixing together the two monomers, their respective cross-linking agents, and initiators and then polymerizing simultaneously by way of noninterfering modes.
Sink mark	A depression or dimple on the surface of an injection molded part formed as a result of collapsing of the surface following local internal shrinkage after the gate seals. May also be an incipient short shot.

Size exclusion chromatography, SEC	Recent name for what has been known as gel permeation chromatography, GPC, q.v.
Skewness	The degree to which a distribution is asymmetrical; negative or positive skewness is observed when the distribution peak is shifted to the upper or lower side.
Skins	See "Flakes."
Slides	Sections of a mold cavity that form complex three-dimensional parts that must move before the molding can be ejected. Used to form openings and sections of parts 90° to the part's release from the mold cavity.
S-N diagram	Plot of stress, S, vs. number of cycles, N, required to cause failure of similar specimens in fatigue test. Data for each curve on the S-N diagram are obtained by determining fatigue life of a number of specimens subjected to various amounts of fluctuating stress. The stress axis may represent stress amplitude, maximum stress, or minimum stress. A log scale is usually used, especially for the N-axis.
Snap fit	An assembly of two mating parts, with one or both parts deflecting under stress, mating the parts together.
Softening temperature	Temperature at which amorphous polymer (or the amorphous part of crystalline polymer) passes from the hard glass to the soft elastic or liquid state.
Sol solutions	Solutions of macromolecules so diluted that they do not hinder each other free rotation. The limiting concentration depends on the hydrodynamic volume of the macromolecule, usually expressed by the intrinsic viscosity, $[\eta]$.
Solid-state polymerization	Polymerization of crystalline monomer, usually vinyl, using high energy radiation. Topochemical, topotactic, and canal polymers belong to this group.
Solvent	Any substance, but usually a liquid, that dissolves other substance.
Solvent welding, cementing, or bonding	A method of bonding thermoplastic articles of like materials to each other by using a solvent capable of softening the surfaces to be bonded. Thermoplastic materials that can be bonded by this method are ABS, PA, PC, PS, acrylics, cellulosics, and vinyls.
Solvent casting	A process that consists of mixing and dissolving the ingredients in a suitable carrier that conveys the solution of "dope" through a drier where the solvent is subsequently evaporated; the resulting film is removed from the substrate surfaces and wound into rolls.
Specific gravity	The ratio of the mass of a given volume of a substance to the mass of an equal volume of a reference substance,

	usually water, at a specified temperature (ASTM D792). Also, dimensionless ratio of a substance density to that of a reference material.
Specific heat	The quantity of heat required to raise the temperature of a unit mass of a substance by one degree (1 °C) at constant pressure or volume.
Specific volume	Reciprocal of density.
Specification	A written statement that dictates the material, dimensions, and workmanship of a manufactured product.
Spectrometry	A method based on designation of the wavelengths within a particular portion of a range of radiation or absorption, for example, ultraviolet (UV), emission, and absorption spectrometry.
Spectrophotometer	An instrument that measures transmission of apparent reflectance of visible light as a function of wavelength, permitting accurate analysis of color or accurate comparison of luminous intensities of two sources of specific wavelengths.
Spectroscopy	The study of spectra using an instrument for dispersing radiation for visual observation of emission or absorption. See also "Infrared," "Nuclear magnetic resonance," "NMR," and "Spectroscopy."
Specular gloss	The relative luminous reflectance factor of a specimen at the specular direction.
Spherocolloids	The colloidal particle has a spherical shape, formed either by single macro-molecule or an association of low-molecular weight species.
Spider gate	Multi-gating of a part through a system of radial runners from the sprue.
Spin welding	The process of fusing two objects by forcing them together while one of the pair is spinning, until frictional heat melts the interface. Spinning is then stopped and pressure held until they are frozen together.
Spinodal	The line on the temperature vs. composition phase diagram for a mixture of two components, which separates the region from the two-phase regions. Hence, with binodal, it represents the limits of metastability of a two-phase system, viz., in polymer solutions or polymer blends. See also "Binodal."
Spinodal decomposition	The phase separation that occurs when the single-phase system is abruptly brought into the spinodal region of phase diagram, by either a rapid change of temperature, pressure, or flash evaporation of a solvent, viz., in polymer blends. Owing to spontaneous phase separation in

the system (no nucleation!), the morphology generated is co-continuous.

Spiral flow test
A method for determining the flow properties of a plastic material based on the distance it will flow under controlled conditions, pressure, and temperature along the path of a spiral cavity using a controlled charge. The length of the material that flows into the cavity and its weight gives a relative indication of the flow properties of the resin.

Splay marks or splay
Marks or lines found on the surface of the part after molding that may be caused by overheating the material, moisture in the material, or flow paths in the part. Usually white, silver, or gold in color. Also called silver streaking.

Split cavity
A cavity of a mold that has been made in sections.

Split-ring mold
A mold in which a split cavity block is assembled in a chase to permit the forming of undercuts in a molded piece. These parts are ejected from the mold and then separated from the molded piece.

Spot welding
The localized fusion bonding of two adjacent plastic parts that does not require a molded protrusion or hole in the parts. To be effective, use where two parallel and flat surfaces meet.

Spray drying
The transformation of feed from a fluid state into a dried particulate form by spraying the feed into a hot drying medium. It is used for the continuous production of dry solids in powder, granulate, or agglomerate form from liquid feedstocks as solutions, emulsions, pastes, and pumpable suspensions, viz., PVC lattices.

Spreader/torpedo
A streamlined metal block placed in the path of flow of the plastics material in the heating cylinder of extruders and injection molding machines to spread it into intimate contact with the heating areas.

Sprue bushing
A hardened steel insert in an injection mold that contains the tapered sprue hole and has a suitable seat for the nozzle of the injection cylinder. Sometimes called an adapter.

Sprue
Feed opening provided in the injection or transfer mold. Also, a slug formed at this hole.

Sprue gate
A passageway through which molten plastic flows from the nozzle to the mold cavity.

Sprue lock or puller
In injection molding, a portion of the plastic composition held in the cold slug well by an undercut, used to pull the sprue out of the bushing as the mold is opened.

	The sprue lock itself is pushed out of the mold by an ejector pin.
Stabilizer	An ingredient used in the formulation of some plastics to assist in maintaining the physical and chemical properties of the compounded materials at their initial values throughout the processing and service life of the material.
Staking	A term used in fastening – forming of a head on a protruding stud to hold component parts together. Staking may be done by cold staking, hot staking, or ultrasonic heating.
Standard deviation, or sigma (σ)	The standard deviation of a population, labeled as the Greek letter sigma, is defined as the square root of the variance:

$$\sigma \equiv (\text{Variance})^{1/2} = \sqrt{\Sigma(x - \bar{x})/(N-1)}$$

Starve feeding	A method of feeding an extruder where the polymer is metered in a rate below the full capability of the machine. Thus, the output is determined by the feeder not the extruder or process variables. The controlled metering of resin into the machine's feed section to fill the screw flights is not necessarily from the hopper, but from auger, feed belt, or by hand.
Stationary platen	The plate of an injection or compression molding machine to which the front plate of the mold is secured during operation. This platen does not move during the normal operation.
Statistical chain (Kuhn)	Hypothetical free rotating polymer chain units with length ls, defined to reproduce the chain length; viz., the square end-to-end distance can be expressed as:

$$< r^2 > = N_s l_s^2$$

Statistical process control (SPC)	The use of statistical methods to monitor and control a process.
Stereolithography	A three-dimensional printing process that produces copies of solid or surface models in plastic. This process uses a moving laser beam, directed by computer, to print or draw across sections of the model onto the surface of photo-curable liquid plastic.
Stereoregular polymers	Tactic polymers exhibiting tacticity, i.e., regularity in the stereochemical configuration of its constitutional repeating units: isotactic, syndiotactic, erythro, and threo.

Storage life	See "Shelf-life."
Storage modulus	A quantitative measure of elastic properties, defined as the ratio of the stress inphase with strain, to the magnitude of the strain. The storage modulus may be measured in tension or flexure, E', compression, K', or shear, G'.
Strain	The charge in length per unit of original length, expressed as a fraction of the original length, $\lambda = (L - L_o)/L_o$, in percent, $\Delta l = 100\lambda$, or in extensional flow as $\varepsilon = (L - L_o)/L$. The dimensionless numbers that characterize the change of dimensions of a specimen during controlled deformation. In tensile testing, the elongation divided by the original gage length of the test specimen.
Strength of material	Refers to the structural engineering analysis of a part to determine its strength properties.
Stress concentration	Magnification of the level of applied stress in the region of a notch, crack, void, inclusion, or other stress raisers. Sections or areas in a part where the molded-in or physical forces are high or magnified – all sharp corners have high stresses.
Stress concentration factor (SCF)	Ratio of the maximum stress in the region of a notch, or another stress raiser, to the nominal corresponding stress. SCF is a theoretical indication of the effect of stress concentration on mechanical behavior. Since it does not take into account the stress relief due to plastic deformation, its value is usually larger than the empirical fatigue notch factor or strength reducing ratio.
Stress crack	External or internal cracks in a plastic caused by imposed stresses.
Stress cracking	A process of cracking under induced mechanical stress. Stress cracking generally starts with microscopic surface cracks, caused by chemical attack or other degrading influence such as ultraviolet radiation. Under mechanical stress, the microcracks propagate eventually producing a localized failure.
Stress optical sensitivity	The ability of materials to exhibit double refraction of light when placed under stress.
Stress relaxation	The gradual decrease in stress with time under a constant deformation (strain) and temperature. Stress relaxation is determined in creep test. Data is often presented as stress vs. time plot. The stress relaxation rate is given by the slope of the curve at any point.
Stress	The force applied to produce a deformation in the material. The ratio of applied load to the original

	cross-sectional area of a test specimen, or force per unit area that resists a change in size or shape of a body.
Stress-induced crystallization	The production of crystals in a polymer by the action of stress, usually in the form of an elongation. It occurs in fiber spinning, or during rubber elongation, and is responsible for enhanced mechanical properties.
Stress–strain curve	Simultaneous readings of load and deformation, converted to stress and strain, plotted as ordinates and abscissas, respectively, to obtain a stress–strain diagram.
Stress–strain diagram	Graph of stress as a function of strain constructed from data obtained in any mechanical test in which a load is applied to a material and continuous measurements of stress and strain are made simultaneously. It is constructed for tensile, creep, or torsional loadings.
Striation	A separation of colors resulting in a linear effect or color variation. In blow molding, the rippling of thick parisons. Also a longitudinal line in a plastic created by a disturbance in the melt path.
Stripper-Plate	A plate that strips a molded piece from core pins or cores.
Structural reaction injection molding (SRIM)	A molding process that is similar in practice to resin transfer molding, RTM. SRIM derives its name from the RIM process from which the resin chemistry and injection techniques have added to indicate the reinforced nature of the composite components manufactured by this process.
Styrene-acrylonitrile copolymers (SAN)	A thermoplastic copolymer of styrene and acrylonitrile. If it comprises either SAN-grafted butadiene or is blended with nitrile rubber, NBR, a terpolymer is known as ABS.
Styrenics	A group of plastic materials that are either whole or partially polymerized from styrene monomer.
Submarine gate	A type of edge gate where the opening from the runner into the mold is located below the parting line or mold surface, as opposed to conventional edge gating where the opening is machined into the surface of the mold. With submarine gates, the item is broken from the runner system on opening of the mold or ejection from the mold.
Substituted macromolecules	Linear macromolecules with the side chains consisting of definite and usually homogeneous substituents. (In branched macromolecules, the side chains consist of the same primary molecules as in the main chain and are of varied length and irregularly arranged.)

Substrate	A material upon the surface of which an adhesive-containing substance is spread for any purpose, such as bonding or coating.
Suck-back	A slight retracting of the screw, usually no more than 5–7 mm as the mold opens to suck-back any resin that might have drooled out of the nozzle after the sprue was pulled. Correct nozzle type and temperature control can eliminate a need for this step, even when using very fluid resins.
Surface finish	Finish of a molded product. Refer to the SPI-SPE Mold Finishes Comparison Kit.
Surface treatments	Any method of treating a material so as to alter the surface and render it receptive to inks, paints, lacquers, and adhesives such as chemical, flame, and electronic treatments.
Surfactant	A compound that affects (usually reduces) interfacial tension between two liquids.
Surging	Unstable pressure buildup in an extruder leading to variable throughput.
Suspension polymerization	Chain polymerization of vinyl monomer dispersed in form of large drops in aqueous medium. The polymerization is initiated by monomer-soluble initiator; thus, each drop can be treated as individual bulk polymerizing volume.
Swaging	An assembly technique, similar to heading, where the plastic material is deformed to a specific shape to assemble one or more parts.
Sweating	Exudation of drops of liquid, usually a plasticizer, on the surface of a plastic part.
Swell	A dimensional increase caused by exposure to liquids and/or vapors.
Swelling	Swelling is the ability of a body to take up liquids. It depends on the size and shape of the macromolecule. Linear or lightly branched polymers immersed in a good solvent first swell without limit and then dissolve. The cross-linked polymers show limited swelling capability.
Syndiotactic polymer	A stereoregular polymer in which at least one monomeric carbon atom exhibits stereochemical configurational isomerism and in which the configurations alternate between the neighboring units, viz., syndiotactic PVC and isotactic or syndiotactic PP.
Tab gated	A small removable tab of approximately the same thickness as the mold item, usually located perpendicular to the item. The tab is used as a site for edge gate location, usually on items with large flat areas.

Tacticity	A regularity of configurational isomeric unit placement in the polymeric chain. See "Isotactic, stereoregular, and syndiotactic polymer."
Taguchi method	Problem-solving technique developed by Taguchi, which employs a testing process with an orthogonal array to analyze data and determine the main contributing factors in the solution of the problem.
Tapered block copolymer	Gradient block copolymer in which there is a gradual change of composition at the junction between the two blocks from pure AAAAAAAA type to pure BBBBBBBB type. The tapered block copolymers are reported to be more efficient than pure AB block copolymers as compatibilizers of polymer blends. Tapping cutting threads in the walls of a circular hole.
Tear resistance	The force required to tear completely across a notched specimen tested according to prescribed procedures, expressed in pounds per inch of specimen thickness.
Telechelic polymer	A polymer with purposely introduced chain end groups of a specific type, e.g., ionic, hydroxyl, acidic, etc.
Telomer	Low-molecular-weight radical polymerization product obtained in a reaction in which extensive chain transfer to a solvent (or specifically introduced chain transfer agent) has occurred, so that the telomer contains fragments of these reactants as end groups.
Telomerization	Primarily, a radical solution polymerization with high transfer constant, leading to products of relatively low molecular weight (telomers, with MW § 10,000) containing built-in fragments of the solvent.
Temperature gradient	The slope of a temperature curve. An increasing or decreasing temperature profile on the barrel of the molding machine is an example.
Tensile impact energy	The energy required to break a plastic specimen in tension by a single swing of a calibrated pendulum.
Tensile impact test	A test whereby the sample is clamped in a fixture attached to a swinging pendulum. The swinging pendulum strikes a stationary anvil causing the test sample to rupture. This is similar to the Izod test.
Tensile strength	The pulling stress at any given point on the stress vs. strain curve, usually just before the material tears or breaks. Area used in computing the engineering strength is the original, rather than the necked-down area.
Tensile strength or stress	The maximum tensile load per unit area of original cross section, within the gage boundaries, sustained by the

	specimen during a tension test. Ultimate strength of a material subjected to tensile loading.
Terpolymers	A copolymer composed of three different repeat units or monomers, where the repeating structural units of all three are present within each molecule. The influence of all three types of monomer is evident in the property profile of the polymer. Common terpolymers include ABS and ASA.
Tetrapolymers	Copolymers that contain four different monomers.
Texturizing	The etching or cutting of a pattern on a mold surface to be reproduced on the molded part.
Thermal conductivity	Ability of a material to conduct heat. The coefficient of thermal conductivity is expressed as the quantity of heat that passes through a unit cube of the substance in a given unit of time when the difference in temperature of the two faces is 1 °C.
Thermal degradation	Degradation caused by exposure to an elevated temperature. In the absence of oxygen, the term pyrolysis, while in its presence, the term thermo-oxidative are frequently used.
Thermal expansion	The linear rate at which a material expands or contracts due to a rise or fall in temperature. Each material is unique and has its own rate of expansion and contraction.
Thermal polymerization	Free radical polymerization initiated either by thermal homolysis of an initiator (e.g., azo compound) or caused by action of heat on the monomer itself.
Thermal stress cracking (TSC)	Crazing and cracking of some thermoplastic resins that results from overexposure to elevated temperatures.
Thermocouple	A thermoelectric heat-sensing element mounted in or on machinery and the mold to transmit accurate temperature signals to a control and readout unit.
Thermoelasticity	Rubberlike elasticity exhibited by a rigid plastic and resulting from an increase of temperature.
Thermoforming	The process of forming a thermoplastic sheet into a three-dimensional shape after heating it to the point at which it is soft and flowable and then applying differential pressure to make the sheet conform to the shape of a mold or die positioned below the frame. Thermoforming variations include vacuum forming, air-assist vacuum forming, plug-assist forming, drape forming, plug-and-ring forming, ridge forming, slip forming, bubble forming, matched-mold forming, and scrapless thermoforming.

Thermogravimetric analysis (TGA)	The study of the change in mass of a material, either in oxygen, air, or an inert atmosphere. The test can be conducted under various conditions of time, temperature, and pressure. A testing procedure in which changes in the weight of a specimen are recorded as the specimen is progressively heated.
Thermomechanical analysis (TMA)	An analytical technique consisting of measuring physical dimensions of a material or changes in its moduli as a function of temperature and/or frequency.
Thermoplastics (TP)	A class of plastic materials that is capable of being repeatedly softened by heating and hardened by cooling, viz., ABS, PVC, PS, and PE. Generally, a polymer that, upon heating softens, changing from a solid into elastic or liquid moldable state without having undergone chemical changes. The process is reversible and can be repeated many times.
Thermoplastic elastomer (TPR)	An elastomer which upon heating turns into regularly behaving linear polymer. Polystyrene-polybutadiene block copolymers, polypropylene blends with ethylene-propylene-diene terpolymer provide examples.
Thermoplastic injection molding	A process in which melted plastic is injected into a mold cavity, where it cools and takes the shape of the cavity. Bosses, screw threads, ribs, and other details can be integrated, which allows the molding operation to be accomplished in one step. The finished part usually does not require additional work before assembling.
Thermoplastic (IPN)	Any IPN in which the individual polymers are thermoplastic. The polymers may contain physical cross-links as in ionomers where ionic clusters join two or more chains together. Nowadays, phase-separated polymeric systems, e.g., block and graft copolymers or thermoplastic polyurethanes, are frequently considered thermoplastic IPNs.
Thermoplasticity	The ability of material to be deformed without breaking with a relatively fast flow, when (at a suitable temperature) this material is properly stressed.
Thermosets (TS)	Materials that undergo a chemical reaction by the action of heat and pressure, catalysts, ultraviolet light, etc., leading to a relatively infusible state. Typical of the plastics in the thermosetting family are the amines (melamine and urea), unsaturated polyesters, alkyds, epoxies, and phenolics. A common thermoset goes through three stages.
	A-stage An early stage when the material is soluble in certain liquids and fusible and will flow.

| | B-stage | An intermediate stage at which the material softens when heated and swells in contact with certain liquids, but does not dissolve or fuse. Molding compound resins are in this stage. |
| | C-stage | The final stage is the TS reaction when the material is insoluble, infusible, and cured. |

Thermoset injection molding
A process in which thermoset material that has been heated to a liquid state is caused to flow into a cavity or several cavities and held at an elevated temperature for a specific time. After cross-linking is complete, the hardened part is removed from the open mold.

Thermosetting plastics
See "Thermosets."

Thinner
A liquid that can extend a solution, but not reduce the power of the solvent.

Thixotropy
A decrease of apparent viscosity under shear stress, followed by a gradual recovery when the stress is removed. The effect is time dependent. Its antonym is rheopexy.

Thread plug, ring, or core
A part of the mold that shapes a thread.

Tie bars
Bars that provide structural rigidity to the clamping mechanism of an injection molding press and usually guide platen movement.

Toggle or toggle action
A mechanism that exerts pressure developed by the application of force on a knee joint. It is used as a method of closing presses and serves to apply pressure at the same time.

Tolerance
A specified allowance for deviation in weighing and measuring or for deviations from the standard dimensions of weight.

Topochemical polymerization
Solid-state polymerization of crystalline monomer without any intermediate loss of order. The topotactic oligomers have been produced, but the order is lost as the polymerization progresses beyond a low degree of polymerization.

Torsion pendulum
Test equipment used for determining the dynamic mechanical properties of plastics.

Torsion
Stress caused by twisting a material.

Torsional
The twisting or turning motion of a part. Torsional stress is created when one end of a part is twisted in one direction while the other is held rigid or twisted in the other direction.

Toughness
The extent to which a material absorbs energy without fracture. A measure of the ability of a material to absorb energy. The actual work per unit volume or unit mass of

	material that is required to rupture it. Toughness is proportional to the area under the load-elongation curve from the origin to the breaking point.
Transesterification	An ester interchange reaction occurring when ester is heated in the presence of hydroxy compound (alcoholysis) or acid compound (acidolysis). Since esterification is reversible, the transesterification occurs between mixed esters in the presence of (thermally activated) low concentration of volatile reaction by-products. Ester-amide exchange can also be accomplished by similar (catalyzed) process.
Transfer molding	A method of molding thermosetting materials in which the plastic is first softened by heat and pressure in a transfer chamber and then forced by high pressure through suitable spruces, runners, and gates into a closed mold for final shaping and curing.
Translucent	The quality of transmitting light without being transparent.
Transmission electron microscopy (TEM)	a microscopy technique in which an ultrathin specimen is illuminated by an electron beam. Image formation is made by detecting the electrons transmitted through the specimen. The short wavelength of electrons allows a much higher resolution in TEM (0.2 nm) than in its visible light analogous: the optical microscopy
Transparent	A material with a high degree of light transmission that can be easily seen through.
Triblock polymer	A block copolymer consisting of three $A_nB_mA_n$ blocks.
Tristimulus colorimeter	The instrument for color measurement based on spectral tristimulus values. The color is expressed in terms of three primary colors: red, green, and blue.
Tumbling	Finishing operation for small plastic article by which gates, flash, and fins are removed and/or surfaces are polished by rotating them in a barrel together with wooden pegs, sawdust, and polishing compounds. Adding color to a material through tumble blending.
Tunneling	Release of longitudinal portions of the substrate in incompletely bonded laminates and deformation of these portions to form tunnellike structures.
UCST (upper critical solution temperature)	The highest temperature of immiscibility, where binodal and spinodal curves meet. This type of phase separation predominates in solutions.
Ultimate strength	Strength at the break point in tensile test.
Ultimate tensile strength	The highest stress sustained by a specimen in a tension test. Rupture and ultimate stress may *not* be the same.

Ultrasonic insertion	The inserting of metal into a thermoplastic part by the application of vibratory mechanical pressure at ultrasonic frequencies.
Ultrasonic sealing, bonding, or welding	A method in which sealing is accomplished through the application of vibratory mechanical pressure at ultrasonic frequencies (16–4,000 kHz). Electrical energy is converted to ultrasonic vibrations through the use of a piezoelectric transducer. The vibratory pressures at the interface in the sealing area develop localized heat losses that melt the plastic surfaces effecting the seal.
Ultrasonic testing	Measurement of ultrasonic velocity and absorption (dissipation of sonic energy as a result of conversion to heat) to determine such structure-related factors as glass transition temperature, cross-link density, branching, morphology, composition, etc. Also a nondestructive test applied to materials to locate internal flaws or structural discontinuities by high-frequency reflection or attenuation ultrasonic beam.
Ultrasonics	Branch of acoustics dealing with periodic waves with frequencies above the audible range, i.e., greater than 16 kHz.
Ultraviolet, UV	The region of the electromagnetic spectrum between the violet end of visible light and the X-ray region, including wavelengths from 10 to 390 nm. Because UV wavelengths are shorter than visible wavelengths, their photons have more energy, which initiates some chemical reactions and degrades most plastics, particularly aramids and polypropylenes.
Unbalanced mold	A nonuniform layout of mold cavities and runner system, fill rate, packing pressure, and part quality will vary from cavity to cavity. Used only for noncritical, stand-alone parts.
Undercut	Having a protuberance or indentation that impedes withdrawal from a mold in its normal open/closed movement. Flexible materials can be ejected intact even with slight undercuts.
Unimodal distribution	Distribution with a single peak.
Unit mold	Mold designed for quick-changing interchangeable cavity parts. A mold that comprises only a single cavity, frequently a pilot for the production set of molds.
Universal testing machine	A machine used to determine tensile, flexural, or compressive properties.
Unsaturated polyester	A low-molecular-weight polyester with unsaturated, double bonds able to enter into cross-linking reaction

	with added unsaturated monomer by the radical mechanism. The latter reaction is usually initiated by solution of methyl ethyl ketone peroxide. Also a family of polyesters characterized by vinyl unsaturation in the polyester backbone, which enables subsequent hardening or curing by copolymerization with a reactive monomer in which the polyester constituent has been dissolved.
Unzipping	Depropagation – a degradation reaction in which the consecutive mers are gradually removed from one macromolecular chain end to another. Few polymers undergo such a reverse propagation reaction, viz., PMMA, POM, and PTFE.
UV stabilizer	Any chemical compound that, when added to thermoplastic material, selectively absorbs ultraviolet rays.
Vacuum metallizing	Process in which surfaces are thinly coated with metal by exposing them to the vapor of metal that has been evaporated under vacuum (one millionth of normal atmospheric pressure).
Variance	See "Standard deviation."
Vent	In a mold, a shallow channel or minute hole cut in the cavity to allow air to escape as the melt enters.
Vertical flash ring	The clearance between the force plug and the vertical wall of the cavity in a positive or semipositive mold. Also the ring of excess material that escapes from the cavity into this clearance space.
Vicat softening point	The temperature at which a flat-ended needle of 1 mm, circular or square cross section, will penetrate a thermoplastic specimen to a depth of 1 mm under a specified load using a uniform rate of temperature rise. The temperature at which a plastic is penetrated to 1 mm depth by a flat-ended circular metal pin, while in a controlled temperature silicone fluid bath.
Vinyl	Usually polyvinyl chloride, PVC, but may be used to identify other polyvinyl plastics.
Vinyl chloride plastics	Plastics based on polyvinyl chloride, PVC, or copolymers of vinyl chloride with other monomers, the vinyl chloride being the major component.
Virgin plastics or virgin material	A material not previously used or processed and meeting manufacturer's specifications.
Viscoelasticity	A property involving a combination of elastic and viscous behavior. A material having this property is considered to combine the features of an elastic solid and Newtonian liquid.

Viscosity	The property of resistance to flow exhibited within the body of a material, expressed in terms of relationship between applied shearing stress and resulting rate of strain in shear. A measurement of resistance of flow due to internal friction when one layer of fluid is caused to move in relationship to another layer. Viscosity is quantitatively defined as a ratio of shear stress to shear rate.
Viscometer	An instrument used for measuring the viscosity and flow properties of fluids.
Viscous deformation	Any portion of the total deformation of a body that remains permanently when the load is removed, also referred to as nonelastic deformation.
Void	A void or bubble occurring in the center of a heavy thermoplastic part, usually caused by excessive shrinkage.
Volume resistivity	The electrical resistance between opposite faces of a 1 cm cube of insulating material. It is measured under prescribed conditions using a direct current potential after a specified time of electrification. Also called specific insulation resistance (ASTM D257).
Vulcanization	Process of converting of raw rubber compounds into lightly cross-linked network elastomer. Vulcanization of diene rubbers involves compounding it with sulfur or sulfur compounds and then heating at about 140 °C for sometimes several hours. The process can be sped up by addition of catalyst, viz., ZnO.
Warpage	Dimensional distortion in a plastic object after molding.
Water absorption	The amount of water absorbed by a polymer when immersed in water for stipulated periods of time.
Weathering	A term encompassing exposure of polymers to solar or ultraviolet light, temperature, oxygen, humidity, snow, wind, pollutants (e.g., ozone, NO_2, CO_2), cyclical changes of temperature and moisture, etc. Outdoor degradation of material, exposed to adverse weather factors.
Weatherometer	An instrument used for studying the accelerated effects of weather on plastics, using artificial light sources and simulated weather conditions.
Weibull distribution function:	$$y = (\beta/\alpha)(x - y)^{b-1} \exp\left\{ -(x - \gamma)^{\beta/\alpha} \right\}$$ $$\text{for} : x \geq \gamma; y = 0$$ $$\text{for} : x \leq \gamma$$ where x is a variable and α, β, and γ are the distribution parameters.

Welding	Joining thermoplastic pieces by one of several heat-softening processes. Butt fusion, spin welding, ultrasonic, and hot gas are examples of such methods.
Welding horn	The sonic-energy transmission and pressure-transmitting tool used for ultrasonic welding. Each welding horn is tuned to specific amplitudes to efficiently perform the welding operation.
Wetting agent	An ingredient or solution used to lower the surface tension between two materials, so that good coverage and bonding occur.
Wheel abrading	Deflashing molded parts by abrasion with small particles at high velocity.
Witness lines	Lines left on a molded part by poor mating and fit of side action cores.
WLF equation	Williams-Landel-Ferry equation that relates the value of the shift factor, a_T (associated with time-temperature superposition of viscoelastic data), required to bring log-modulus (or log-compliance) vs. time or frequency curves measured at different temperatures onto a master curve at a particular reference temperature, T_0, usually taken at 50 °C above the glass transition temperature ($T_0 = T_g + 50$ °C): $$a_T = \frac{C_1(T - T_0)}{[C_2 + (T - T_0)]}$$ where the constants, C_1 and C_2, are approximately identical for all polymers: -8.86 and 101.6 K, respectively. Later, the WLF equation has been interpreted in terms of the Doolittle's free volume theory.
Yellowness index	Measure of the tendency of plastics to turn yellow upon long-term exposure to light.
Yield point elongation	In materials that exhibit a yield point, the difference between the elongation at the completion and the start of discontinuous yielding.
Yield point	The point at which permanent deformation of a stressed specimen begins to take place. Stress at which strain increases without accompanying increase in stress. Only materials that exhibit yielding have a yield point.
Yield strength	The stress at the yield point – stress at which a material exhibits a specified limiting deviation from the proportionality of stress to strain or the lowest stress at which a material undergoes plastic deformation. When the material is elastic at lower stresses and viscoelastic at higher, unless otherwise specified, the stress at the

	border of this change is the yield stress. Yield stress is often defined as the stress needed to produce a specified amount of plastic deformation, usually a 0.2 % change in length. In tensile testing, the yield stress is taken as that at which there is no increase in stress with a corresponding increase in strain – usually the first peak on the curve. It may also be defined as a specific limiting deviation from the proportional stress–strain curve.
Young's modulus	The ratio of normal stress to corresponding strain under tensile or compressive loading at stresses below the linearity limit of the material (also modulus of elasticity).
Zero defects	A quality control method where anyone in the production cycle who discovers a quality problem can stop the assembly line or manufacturing process until it is corrected. The problem associated with this method is that upper management is often never made aware that a problem occurred. This lack of knowledge may prevent a complete repair from being initiated and the problem continues to occur.
Ziegler-Natta polymerization	Chain polymerization on a Ziegler-Natta catalyst, Z-N. The Z-N catalysts are based either on $TiCl_4$, VCl_5, or $CoCl_3$ mixed with either $Al(C_2H_5)_3$ or $Al(C_2H_5)_2Cl$, e.g., reacting AlR_3 (R is an alkyl group) with crystalline $TICl_3$ in an inert solvent. For example, three catalytic systems led to polymerization of high-density polyethylene, HDPE, (1) molybdena-alumina, (2) hexavalent CrO_3 on silica, and (3) aluminum trialkyl (e.g., $AlEt_3$) with $TiCl_4$. The polymerization occurs at relatively mild conditions. Z-N polymerization is frequently used to obtain stereoregular polymers, viz., either to an isotactic or a syndiotactic polypropylene.

Appendix IV: Trade Names of Polymers and Their Blends

A		
A-C	Low molecular weight polyethylene, PE	Allied-Signal Inc.
A-FAX	Amorphous polypropylene, PP	Himont
A-fax	Polypropylene, PP	Himont
A-Tell	Polyethylene-*p*-oxybenzoate for fibers	ICI
Abbey #100	Poly(vinyl chloride) compound, PVC	Abbey Plastic Corp.
Abbey #400	Polypropylene, PP	Abbey Plastic Corp.
Absafil	Acrylonitrile-butadiene-styrene terpolymer, ABS	Fiberfil/Akzo/DSM
Abson	ABS/PVC blends	Abtec/BF Goodrich
Abstrene	Acrylonitrile-butadiene-styrene terpolymer, ABS	Distillers
Accpro	Polypropylene blends	Amoco Chemical
Acctuf	High-impact ethylene-propylene copolymers	Amoco Chemical
Acculloy	Polymer alloys	Aclo Compounders
Accutech	Reinforced resins	Aclo Compounders
Acetabel	Cellulose acetate, CA	Ponceblanc
Acetron GP Acetal	POM reinforced or not (rods or sheets)	Polymer Corp.
Acetron NS Acetal	POM. lubricated (rods or sheets)	Polymer Corp.
Achieve	Metallocene-grade isotactic polypropylene, PP	Exxon
Acihr	Fluoropolymer film	Allied-Signal Inc.
Aclar, Aclon	Fluorocarbon PCTFE film	Allied-Signal Inc.
Aclyn	Low molecular weight EVAc ionomers	Allied-Signal Inc.
Acme	Epoxy resins and molding compounds	Allied Products Corp.
Acpol	Acrylic or thermoset polyesters; acrylic/urethane/styrene IPN	Freeman Chem Co.
Acraldon	Ethylene-vinyl acetate copolymer, EVAc	Bayer AG

(*continued*)

Acralen	Elastomers	Bayer AG
Acrifix	PMMA, poly(methyl methacrylate)	Röhm AG
Acrilan	Polyacrylonitrile, PAN	Chemstrand Corp.
Acronal	Acrylic esters; homo- and copolymers	BASF Plastics
Acrylafil	Glass fiber-reinforced SAN	Akzo/DSM
Acrylan	Acrylic fiber	Monsanto
Acrylan-Rubber	Butyl acrylate-acrylonitrile copolymer	Monomer Corp.
Acrylite	Acrylic (PMMA)	Cyro Industries
Acrylite FF	Poly(methyl methacrylate) powder, sheets, PMMA	Cyro Industries
Acrylite GP	Cast acrylic sheet, PMMA	Chemacryl Plastics, Ltd.
Acrylite SDP	Double-skinned acrylic sheet, PMMA	Chemacryl Plastics, Ltd.
Acrylivin	Poly(vinyl chloride)/Acrylic alloy	Gen. Tire & Rubber
Acryloid	Poly(methyl methacrylate)-butadiene-styrene	Rohm and Haas
Acrylyn	Melt-processable rubber	E. I. du Pont de Nemours
Acrypanel	PMMA, poly(methyl methacrylate)	Mitsubishi Rayon Co.
Acrypoly	Acrylic extruded sheet, PMMA	Chi Mei Ind. Co. Ltd.
Acryrex	Acrylic resin, PMMA	Chi Mei Ind. Co. Ltd.
ACS	Chlorinated polyolefins, e.g., PE, cross-linked or not	Showa Denko K. K.
ACS Resin NS	Styrene-acrylonitrile copolymer, SAN	Biddle Sawyer Corp.
Acsium	Alkylated chlorosulfonated polyethylene, CSR	DuPont/Safic-Alcan
ACter	Low molecular weight terpolymers	Allied-Signal Inc.
ACumist	Micronized polyolefins, PO	Allied-Signal Inc.
ACX	Polyoxymethylene, POM	United Composites
Addylene	Polypropylene, PP	Addiplast
Addylon	Polyamides, PA	Addiplast
Adell A, B	Polyamide-6 or polyamide-66; reinforced or not, PA-6	Adell Plastics, Inc.
Adell F	Polypropylene; reinforced or not, PP	Adell Plastics, Inc.
Adell H	Poly(butylene terephthalate); reinforced or not, PBT	Adell Plastics, Inc.
Adell K	Polyethylene; reinforced or not, PE	Adell Plastics, Inc.
Adflex	Reactor PP alloy; soft PP/EP copolymer	Himont Inc.
Adion A	ABS/hydrophilic-PA; antistatic, for medical uses	Asahi Chemical Ind.
Adion H	HIPS/hydrophilic-PA; antistatic, for cassettes	Asahi Chemical Ind.
Adiprene	Diisocyanates, polyurethanes, PU	E. I. du Pont de Nemours
Admer	Polyolefins, PO	Mitsui Petrochem.
Adpro AP	Reactor olefinic thermoplastic elastomers, RTPO	Genesis Polymers
Adpro	Polypropylene, PP	Novacor/Genesis Polymers
Adstif	Rigid polypropylene made in *Catalloy* process	Himont Inc.
Aerolam, Aerolite	Epoxy resin and molding compounds	Ciba-Geigy Ltd.
Aeroweb, Aracast	Honeycomb materials	
Afcolène	Styrene-acrylonitrile copolymer, SAN	Rhône Poulenc

Afcoryl	Acrylonitrile-butadiene-styrene terpolymer, ABS	Pechiney-Saint-Gobain
Affinity	Polyolefin plastomer, containing 0–20 wt% comonomer based on Insite™ metallocene technology, with long chain branching	Dow Chem. Co.
Aflas FA	Fluoropolymers	3M Ind. Chem.
Aflas	PTFE + PP + cure site monomer terpolymer	Asahi Glass
Aflon	Poly(tetrafluoroethylene-co-ethylene)	Asahi Glass
Ahane	Ultra low-density polyethylene, ULDPE	Dow Chem. Co.
Aim	–	Dow Plastics
Airflex	Ethylene-vinyl acetate copolymer, EVAc	AP&C
Akulon	PA-6, PA-66, blends with PO, reinforced or not	Akzo/DSM Plastics
Akuloy J	Polyamide-66 with PP and 30 % glass fiber	DSM Plastics Int.
Akuloy RM	Polyamide-6 or polyamide-66 blend with functionalized-PP; glass fiber or mineral filled or not	DSM Plastics Int.
Akuloy XT	Polyamide-6/thermoset elastomer alloy	DSM Plastics Int.
Alathon	Polyethylene resins, PE	Occidental
Alathon	Polyethylenes, PE	Cain Chem. Inc.
Albertol	Phenol-formaldehyde resins, PF	Chem. Werke Albert
Albidur	Thermosetting resins; PU, epoxides, polyesters	OFACI
Albis	Polyamide-6/Polyolefin (10 %) blend	Albis Plastics
Alcotex	Poly(vinyl alcohol), PVAl	Revertex
Alcryn	Chlorinated olefin/EVAl/acrylate ester blends; PVC/ethylene-carbon monoxide-vinyl chloride copolymer; TP elastomers	E. I. du Pont de Nemours
Alcudia	Polyethylene, PE	Repsol Quimica SA
Alcupol	Polyols, polyurethanes, PU	Repsol Quimica SA
Alfon Cop.	Modified ethylenetetrafluoroethylene copolymer	Asahi Glass
Alftalat	Alkyd resins	Chem. Werke Albert
Algoflon	Fluorinated resins	Enimont
Algoflon	Polytetrafluoroethylene, PTFE	Montecatini/Ausimont
Alkapols	Polyfunctional PPO polyols	Rhône-Poulenc
Alkathene	High-density polyethylene, HDPE	ICI Adv. Mater.
Alkox	Polyethylene oxide	Meisei Chemical Works
Alkydal	Alkyd, polyester resins, UP	Bayer AG/Miles
Alkyde	Polyester polyurethanes, TPU	Synres-Almoco
Alkynol	Polyester resins for paints and varnishes, UP	Bayer
Allied CM-X	Polytetrafluoroethylene, PTFE	Allied-Signal Corp.
Allobec	Polyesterimide, PEI	Dr. Beck & Co.
Alloprene	Chlorinated rubber	ICI Adv. Mater.
Alpha-PVC	Flexible PVC – CPD	Alpha Chem. & Plastics
Alphaseal	TPO elastomer for packaging	Alpha Chem. & Plastics

(*continued*)

Alphatec	TPE for medical products	Alpha Chem. & Plastics
Alphon	Fluoroelastomer, PTFE/elastomer blends	Custom M.P.
Alton	Poly(phenylene sulfide)/polytetrafluoroethylene	Intl. Polym. Corp.
Altuchoc	Polycarbonate, PC	Societe Altulor SA
Altuglas	Acrylic, poly(methyl methacrylate), PMMA; sheets	Societe Altulor SA/ Elf Atochem
Altuglas	PUR/PMMA interpenetrating polymer networks	Elf Atochem
Altulite	Poly(methyl methacrylate); powder, PMMA	Societe Altulor SA
Alulon	Polyamide-66, PA-66	Akzo/DSM
Amberlite	Synthetic ion exchanger	Rohm and Haas
Ameripol CB	Polybutadiene, PB	BF Goodrich
Ameripol	Polyisoprene, CPI	Firestone
Ameripol	Polyisoprene, CPI	Firestone
Ameripol SM	cis-1,4-Polyisoprene, CPI	Firestone
Amidel	Polyamide, amorphous, transparent	Union Carbide
Amidel	Polyamide-6, PA-6	Toray Industries
Amilan	Glass fiber- or mineral-reinforced polyamide-6	Toray Industries
Amilon	Polyamide-6 or polyamide-66, PA-6 or PA-66	Toray Industries
Amoco 10	Polypropylenes, PP	Amoco Chem. Corp.
Amoco 20	Polyethylenes, PE	Amoco Chem. Corp.
Amoco A-I	Polyimide; insulative and conductive coatings	Amoco Chem. Corp.
Amoco G	Polystyrene, PS	Amoco Chem. Corp.
Amodel A-	Polyphthalamide, reinforced	Amoco Performance Products
Amodel AD-	Polyphthalamide, PPA, semicrystalline-PA	Amoco Performance Products
Amodel ET-	Polyphthalamide, impact modified	Amoco Performance Products
Amoron	Polythioethersulfone, block copolymer with 53 % PPS and poly(phenylene sulfide)sulfone, PPSS, filled with 0, 30, and 40 wt% glass and PTFE	Dainippon Ink & Chem.
Ampal	Polyester, unsaturated, UP	Ciba-Geigy Ltd.
Ampec	Ethyl cellulose, EC	American Polymers
Ampol	Cellulose propionate, CP, or cellulose acetate-butyrate, CAB	American Polymers
Antron	Polyamide fiber	E. I. du Pont de Nemours
Apec	Aromatic, "high heat," polyester carbonate, PEC	Bayer AG/Miles
Apex	Poly(vinyl chloride) compounds; PVC	Teknor Apex
Apiax	Polyether compound	Polymix
Apiflex	Poly(vinyl chloride), semirigid, plastified; PVC	Polymix
Apilon	Polyurethanes, PU, or poly(vinyl chloride), PVC	Polymix
Aplical	Polyimide film, PI	Allied Signal Inc.
APP	Polypropylenes, PP	Reichhold Chem., Inc.
Applied Comp 8000	Thermoset polyester-based composites, UP	Applied Composites

(*continued*)

Appryl	Polypropylene, PP	Elf Atochem
Apscom	Speciality thermoplastics (ABS, Acrylics, SAN, Akzo/DSM POM, PC, PEI, PP, PPE, PPS, etc.)	
Aqua Keep	Superabsorbent polymers	Elf Atochem
Aqualoy 100	Polypropylenes, PP	CoAlloy Intl. Corp.
Aqualoy 600	Polyamide-66	CoAlloy Intl. Corp.
Aquathene	Polyethylene	Quantum
Arakote	Thermoset polyesters, UP	Ciba-Geigy Corp.
Araldite	Epoxy resins, EP	Ciba-Geigy Ltd.
Arcel	Polyethylene copolymers	ARCO Chemical
Arcol	Polyols	ARCO Chemical
Ardel D-100	Polyarylate, bisphenol-A iso-/terephthalate	Amoco Chem. Co.
Ardel	PAr/PET blends	Amoco Chem. Co.
Areca	Reinforced polypropylene, PP	SPCI
Ariloks	Poly(phenylene ether)/HIPS; PPE/HIPS blends	USSR
Arimax	Polyurethanes, PU	Ashland Chem. Co
Aristech	Polypropylene, PP	Aristech Chem Corp.
Arlon	Polyetheretherketone; reinforced or not, PEEK	Du Pont/Green, Tweed
Arloy 1000	Polycarbonate, PC/SMA blend	Arco Chem. Co.
Arloy 2000	Styrene maleic anhydride, SMA/PET alloys	Arco Chem. Co.
Arloy	PC/SMA/HIPS blends	Amoco
Arnel	Cellulose triacetate	Celanese
Arnite PBTP	Poly(butylene terephthalate), reinforced or not	Akzo/DSM
Arnite	Poly(ethylene terephthalate), reinforced or not	Akzo/DSM
Arnitel	Thermoplastic ether-ester elastomer, TPE	Akzo/DSM
Aropol	Unsaturated polyesters, UP	Ashland Chem.
Aroset	Acrylic copolymers (P-sensitive adhesives)	Ashland Chem.
Arpak/Arpro	Polyethylene-expanded beads	ARCO Chemical/JSP
Arpro/Arpak	Polypropylene-expanded beads	ARCO Chemical/JSP
Arradur	Acrylonitrile-butadiene-styrene terpolymer, ABS	Elf Atochem
Arum	Polyimide for injection molding	Mitsui Toatsu Chem., Inc.
Arylef	Polyarylate	Solvay
Arylon	Polyarylate, PAr, PET blends	E. I. du Pont de Nemours
Asahi PPS RE	Poly(phenylene sulfide), PPS alloy	Asahi Glass
Ashlene	Polyamide-6, polyamide-612, or polyamide-66; reinforced or not	Ashley Polymers Inc
Aspect	Thermoplastic polyester; PET-based blends	Phillips 66 Co.
Asplit	Phenol-formaldehyde resins, PF	Hoechst
Aspun	Fiber-grade polyethylene resins, PE	Dow Chem. Co.
Asterite	Acrylic dispersion	ICI Chem. Polym. Ltd.
Astrel	Polyarylethersulfone, PAES, $[-\phi-O-\phi-SO_2-\phi-\phi-SO_2-]$	Carborundum
Astryn	Filled polypropylene, PP	Himont

(*continued*)

Astyr	Butadiene rubber, BR	Montecatini
Atlac	Unsaturated polyester resin, UP	DSM/Koppers Co., Inc.
Atlantic Polybead	Expanded polystyrene, PS	Atlantic Gypsum
Atlas	Acrylate and methacrylate resins	Degussa
Attane	Ultra low-density linear polyethylene copolymers	Dow Chem. Co.
Aurum	Polyimide; for injection molding, recyclable	Mitsui Toatsu
Avimid	Thermoplastic polyimide	E.I. du Pont de Nemours
AVP	Engineering thermoplastic resins and blends	Polymerland, Inc.
AVP Resin	Recycled thermoplastic resins	Polymerland, Inc.
Avron	Acrylic dispersion	ICI Chem. Polym. Ltd.
Avtel	Advanced composites	Phillips 66 Co.
AX-500	Amorphous polyarylate/PA-6 alloy + 40 % glass	Unitika
Azdel	Continuous glass fiber-filled PP	Azdel Inc.
Azloy	Continuous glass fiber-reinforced PC/PBT blends	Azdel Inc.
Azmet	Crystalline polyester-based composite	Azdel Inc.
B		
Bakelite DFD	Polyethylenes, PE	Bakelite/Union Carbide
Bakelite DHDA	Ethylene-vinyl acetate copolymers, EVAc	Bakelite/Union Carbide
Bakelite DPD	Acrylic resins	Bakelite/Union Carbide
Bakelite DQDA	Ethylene-vinyl acetate copolymers, EVAc	Bakelite/Union Carbide
Bakelite ERL, ERR	Epoxy resins, EP	Bakelite/Union Carbide
Bakelite HFD	Polyethylenes, PE	Bakelite/Union Carbide
Bapolan 1000	Polyethylenes; reinforced or not, PE	Bamberg Polymers
Bapolan 4000, 5000	Polypropylenes, PP	Bamberg Polymers
Bapolan 6000	Polystyrenes, PS	Bamberg Polymers
Bapolan 7000	Styrene-acrylonitrile copolymer, SAN	Bamberg Polymers
Bapolan 8445	Acrylonitrile-butadiene-styrene terpolymer, ABS	Bamberg Polymers
Bapolene	Polyethylene	Bamberger
Barex	Polyacrylonitrile and acrylonitrile copolymers transparent for bottles, films, etc.	BP Chemicals, Intl.
Basopor	Urea-formaldehyde resin, UF	BASF Plastics
Basotect	Elastic melamine foam, MPF	BASF Plastics
Bayblend DP2	PC/ABS alloy; molding, structural foam, etc.	Bayer AG/Miles
Bayblend	PC/ABS alloys, reinforced, flame retard or not	Bayer AG/Miles
Baycoll/Baymer	Polyurethanes, PU	Bayer AG/Miles
Baycomp	Fiber-reinforced plastic	Bay Mills
Baydur	Polyurethanes, PU	Bayer AG/Miles
Bayer LCP	Liquid crystal polymers, LCP	Bayer AG/Miles

Bayer Silicone	Silicones	Bayer AG/Miles
Bayfill/Bayfit	Polyurethanes, PU	Bayer AG/Miles
Bayflex	Polyurea for reactive injection molding, RIM	Bayer AG/Miles
Bayfol CR	PC/PBT blends	Bayer AG/Miles
Bayfol	Films made of PC blends	Bayer AG/Miles
Baygal/Baymidur	Polyurethane casting resins, PU	Bayer AG/Miles
Baylon	Ethylene-vinyl acetate copolymer, EVAc	Bayer AG/Miles
Baylon	Polycarbonate PC	Bayer AG/Miles
Baylon	Polyamide-66	Bay Resins
Baymer/Baysport	Polyurethanes, PU	Bayer AG/Miles
Baymoflex	Acrylonitrile-styrene-acrylic rubber blend	Bayer AG/Miles
Baynat/Baytec	Polyurethane, PU	Bayer AG/Miles
Baypren	Chloroprene rubber, CR; for molding	Polysar/Bayer AG
Baypren Latex	Anionic lattices of chloroprene rubber, CR	Polysar/Bayer AG
Baypren/Bystal	Polychloroprene elastomers	Bayer AG/Miles
Baysilone	Silicones	Bayer AG/Miles
Baytac	Laminating adhesives (hot melt)	IGI Baychem, Inc.
Baytec 800	Polyurethanes, PU	Bayer AG/Miles
Beckacite	Phenol-formaldehyde resins, PF	Reichhold Ltd.
Beckopox	Epoxy resins, EP	Reichhold Ltd.
Beetle	α-cellulose-reinforced urea-formaldehyde, UF	BIP Chemicals Ltd.
Beetle	PBT, PET compounds	BIP Chemicals Ltd.
Beetle	Polyamide-6, polyamide-66 compounds, PA-6	BIP Chemicals Ltd.
Beetle	Polycarbonate compounds, PC	BIP Chemicals Ltd.
Beetle	Polyester compounds (PMC)	BIP Chemicals Ltd.
Beetle	Polyoxymethylene, POM	BIP Chemicals Ltd.
Beetle	Unsaturated polyester resins, UP	BIP Chemicals Ltd.
Beetle	Urea-formaldehyde molding powders UF	BIP Chemicals Ltd.
Benvic	PVC blends with ABS, NBR, MBS, CPE, etc. with glass fiber or not	Solvay & Cie SA
Bergacell	Cellulose acetates, CA	Th. Bergmann
Bergadur	Thermoplastic polyesters	Th. Bergmann
Bergamid	Polyamides reinforced or not, PA	Th. Bergmann
Bergaprop	Reinforced polypropylene, PP	Th. Bergmann
Beta	–	Beta Polymers
Bexel	SAN/acrylic alloys	Bakelite Xylonite
Bexloy	Automotive engineering resins (an ionomer)	E. I. du Pont de Nemours
Bexloy C	Amorphous polyamide blend, PA	E. I. du Pont de Nemours
Bexloy J	Poly(butylenes terephthalate), PBT, blend	E. I. du Pont de Nemours
Bexloy K	Reinforced PET blend	E. I. du Pont de Nemours
Bexloy M	Aromatic polyester blend	E. I. du Pont de Nemours

(*continued*)

Bexloy	Polyarylate, PAr, PET blends	E. I. du Pont de Nemours
Bexloy V	Thermoplastic copolyester elastomer blend	E. I. du Pont de Nemours
Bexloy W	Ionomer engineering blend	E. I. du Pont de Nemours
Bexoid	Cellulose acetate, CA	British Xylonite
Bexone F	Poly(vinyl formal), PVFM	British Xylonite
Bextrene	Polystyrene, PS	British Xylonite
Bioform	Acrylic-based IPN for artificial teeth	Dentsply International
Biopol	Poly(β-hydroxybutyric acid), PHBA	
Biresin	Thermoset resins, UP	SPCI
Blane	Poly(vinyl chloride), PVC; with clay or not	BP Performance
Blendex	ABS modifier/processing aid for rigid PVC	GE Speciality Chemicals
Blendur	PU-based thermoset blend	Bayer AG/Miles
Blendur-E	Epoxides, EP	Bayer AG/Miles
Blueboard	Plastic foam insulation	Dow Chem. Co.
BMC	Unsaturated polyester; reinforced or not, UP	BMC Inc.
Boltaron	Poly(vinyl chloride)/acrylic alloy sheets	GenCorp Polymer Prod.
Bond 811B	Epoxy resins, EP	Furane Products
Bonoplex	Poly(methyl methacrylate), PMMA	AB Bofors, Sweden
Bonvic	Rigid PVC formulation based on emulsion resin	Solvay & Cie SA
Bovidur/Bovil	Poly(vinyl chloride) compounds, PVC	Maprac
BP D, H	Polyethylenes, PE	BP Chemicals Ltd.
BP Polystyrene	Polystyrene, PS	BP Chemicals Ltd.
BR	Poly(phenylene sulfide), PPS/PTFE blend	Phillips 66 Co.
Brilion BT 40	Polyamide alloys, PA	EMS
Bristrend	Poly(vinyl chloride)/Poly(vinyl acetate)	Polymers Inc.
Bromo XP-50	Brominated poly(isobutylene-*co*-*p*-methylstyrene)	Exxon Chem.
Bromobutyl	Elastomers	Exxon Chem.
BT resin	Thermosetting polyimide	Mitsubishi Gas Chem.
Budd Cast	Polyamide-6, PA-6	Budd Co.
Budene	*cis*-1,4-Polybutadiene, PB	Goodyear, USA
Buna AP	Thermoplastic elastomers: EPR or EPDM	Bunawerke Hüls
Buna BL	Styrene-butadiene block copolymer, for impact modification of PS, leading to HIPS	Polysar/Bayer AG
Buna CB	Butadiene rubber, BR; polymerized with Ti-, Nd-, or Li-based catalyst	Polysar/Bayer AG
Buna EM	Expandable SBR, E-SBR	Bunawerke Hüls
Buna Hüls butacryl	Butadiene-acrylonitrile copolymer, MBR	Plastugil, France
Buna N	Poly(butadiene-*co*-acrylonitrile), MBR	Chem. Werke Hüls
Buna	Polybutadiene, PB	Buna AG
Buna S	Butadiene-styrene copolymer, SB	Chem. Werke Hüls

Bur-A-Loy	PVC/nitrile rubber blends	Mach-1 Compounding
Butacite	Poly(vinyl butyral) sheeting; safety glass sheeting E. I. du Pont de Nemours	
Butaclor	Polychloroprene, CR	Distugil
Butacon	Butadiene copolymers	ICI
Butaprene	Styrene-butadiene copolymers	Firestone
Buton	Cross-linked butadiene-styrene copolymer	Exxon, GB
Butvar	Poly(vinyl butyral)	Shawinigan Chemicals
Butylkautschuk	Polyisobutylene with 5 % isoprene, PIB	Bayer AG/Miles
BVC	Poly(vinyl chloride), PVC	Bayshore Vinyl
BXL	Polysulfone, PSU	Union Carbide Co., Inc.
Bynel (CXA)	Coextrudable adhesive resins	E. I. du Pont de Nemours
C		
C-020	Polypropylene, PP	Aristech Chem.
C-Flex	Thermoplastic elastomers; SEBS/PDMS blends	Concept Polymer
Cadon	SMA and SMA/ABS elastomeric blends with glass fibers or not	Monsanto Chem. Co.
Calatrava	High-density polyethylene, HDPE	Repsol Quimica
Caleprene	Elastomers	Repsol Quimica
Calibre	Polycarbonate, PC, and its blends	Dow Chem. Co.
Calibre CR	PC blended with PBT and PET	Sumitomo Dow Ltd.
Calibre IM	PC blended with an elastomer	Sumitomo Dow Ltd.
Calprene	Synthetic rubber	Repsol Quimica SA
Capran	Polyamide-6; resins, films, fibers, laminates, PA	Allied-Signal Inc.
Caprolan	Thermoplastic elastomers	Elastogran
Capron	Polyamide-6 and blends; reinforced or not, PA	Allied-Signal Inc.
Capron	Polyamide/PO or elastomer blend	Allied-Signal Inc.
Capron AB	Polyamide-6/elastomer; food grade barrier resin	Allied-Signal Inc.
Caradate	Polyurethanes, isocyanates, PU	Shell Chem. Co.
Caradol	Polyols for PU	Shell Chem. Co.
Carapor	Additive for polyurethane	Shell Chem. Co.
Carbopol	Acrylic acid polymers, PAA	BF Goodrich
Carboset	Acrylic polymers	BF Goodrich
Carbowax	Poly(ethylene glycol), PEO	Union Carbide Co., Inc.
Carbres	Reinforced polypropylene, PP	SIC Plastic
Cardura	Chemical intermediates	Shell Chem. Co.
Cariflex I	*cis*-1,4-Polyisoprene	Shell Chem. Co.
Cariflex	Styrene-butadiene block copolymer, SB	Shell Chem. Co.
Caril	Poly(phenylene ether), PPE blend	Shell Chem. Co.
Carilon	Linear, alternating olefin/CO copolymer, COPO, engineering resin with good barrier properties [based on Pd catalyst; introduced in 1995]	Shell Chem. Co.

(continued)

Carina	Poly(vinyl chloride), PVC	Shell Chem. Co.
Carinex	Polystyrene, PS	Shell Chem. Co.
Caristar	Plastic packaging material	Shell Chem. Co.
Carloy	Poly(vinyl chloride), PVC/elastomer blend	Cary Chem. Inc.
Cast Nylon	Polyamide, PA	Commercial Plastic
Castethane	Elastomer systems	Dow Chem. Co.
Catalloy	Polypropylene copolymer alloy	Himont
Cefor	Polypropylene	Shell Chem. Co.
Celanese Nylon 6	Polyamide-6, PA-6 impact modified	Hoechst Celanese Corp.
Celanese Nylon 6/6	Polyamide-66 and polyamide-66/TPU alloys glass fiber reinforced or not	Hoechst Celanese Corp.
Celanese	Polyamide-6, polyamide-66, PA-6 or PA-66	Hoechst Celanese Corp.
Celanex	PBT/elastomer; blends reinforced or not	Hoechst Celanese Corp.
Celanex	PBT/PET/elastomer; blends reinforced or not	Hoechst Celanese Corp.
Celazole	Thermoplastic polyimides, reinforced or not	Hoechst Celanese Corp.
Celcon	Copolyoxymethylene, POM, glass-reinforced, impact-modified elastomer blends	Hoechst Celanese Corp.
Celion	Carbon fibers	BASF Plastics
Cellasto	Cellular PUR elastomers	BASF Plastics
Cellatherm	Polyesterimide, PEI	Reichhold Chemie
Cellidor B	Cellulose acetate-butyrate, CAB	Bayer AG/Miles
Cellidor CP	Cellulose propionate, CP	Bayer AG/Miles
Cellit	Cellulose acetate or cellulose propionate	Bayer AG/Miles
Cellon	Cellulose acetate, CA	Dynamit Nobel
Cellophan	Cellulose hydrate from pulp	Kalle
Cellosize	Hydroxyethyl cellulose	Union Carbide
Celltrek 3000	Polyol for PU foam without CFC	Dow Europe
Celluloid	Cellulose nitrate plasticized with camphor, CN	Hoechst Celanese
Celstran	Long glass fiber-reinforced thermoplastics, viz., POM, PBT, PET, PA, etc.	Hoechst Celanese Corp.
Centrex 800	ASA-based, weatherable polymers	Monsanto Chem. Co.
Centrex	Acrylonitrile-styrene-acrylate copolymers, ASA/AES rubber modified blends	Monsanto Chem. Co.
Cevian	ABS	Hoechst Celanese Co.
Chem-AD	Epoxy and polyurethane industrial adhesive	Chemque
Chem-POT	Encapsulating resins of epoxy and polyurethane	Chemque
Chemfluor	Polytetrafluoroethylene compounds, PTFE	Norton Performance
Chemigum	Nitrile rubber, NBR; TP elastomers	Goodyear Chem.
Chemigum TPE	NBR blend with PVC, CPE, TPU, and/or PA	Goodyear Chem.
Chemorset	Epoxy adhesives, EP	Chemor Inc
Chemplex 1000, 3000	Polyethylenes, PE	Norchem, Inc.

Chemplex 5000, 6000	Polyethylenes, PE	Norchem, Inc.
Chemplex EVA	EVAc for extrusion coating, laminating	Norchem, Inc.
Chemplex PE	EVAc for tough film applications	Norchem, Inc.
Chen-Lon	Polyimide, PI, adhesive	Chemtronics
Chevron	Polypropylene, PP	Chevron
Chlorkautschuk	Chlorinated natural rubber	Bayer AG/Miles
Chlorobutyl	Elastomers	Exxon Chem.
Cibamin	UF, MF-lacquer resins	Ciba-Geigy Ltd.
Cibanoid	Urea-formaldehyde, UF, molding material	Ciba-Geigy Ltd.
CIL 100	Low-density polyethylenes and copolymers	CIL Inc.
CIL 1000	Ethylene-vinyl acetate copolymers, EVAc	CIL Inc.
Cis-4	*cis*-1,4-Polyisoprene	Phillips
Cladlux	Acrylic/PVC alloy	Richard Daleman
Claradex	ABS	Shin-A
Clarene	Poly(ethylene-*co*-vinyl alcohol); EVAl or EVOH	Solvay & Cie SA
Clariflex TR	Styrene-butadiene-styrene copolymer, SBS	Shell Chem. Co.
Clear 01	PVC alloy with glutarimide acrylic copolymer for hot-fill bottles	Georgia Gulf
Cleartuf 7000	Poly(ethylene terephthalate), PET	Goodyear
Clysar	PO shrink films	E. I. du Pont de Nemours
Cobex	Poly(vinyl chloride)	Bakelite Xylonite
Codabs	ABS reinforced or not	Codiplast
Codica	Reinforced polypropylene, PP	Codiplast
Codimel	Reinforced poly(vinyl chloride), PVC	Codiplast
Codix	Polypropylene, PP	Codiplast
Comalloy 110	Polypropylenes; reinforced or not, PP	Comalloy Intl. Corp.
Comalloy 210	Polystyrenes; reinforced or not, PS	Comalloy Intl. Corp.
Comalloy 220	ABS; reinforced	Comalloy Intl. Corp.
Comalloy 240	SAN; glass fiber reinforced	Comalloy Intl. Corp.
Comalloy 260	Polystyrene; glass fiber reinforced, PS	Comalloy Intl. Corp.
Comalloy 310	Poly(vinyl chloride); glass fiber reinforced, PVC	Comalloy Intl. Corp.
Comalloy 410	Poly(butylene terephthalate); glass fiber reinforced	Comalloy Intl. Corp.
Comalloy 510	Polycarbonate; mineral/glass fiber reinforced	Comalloy Intl. Corp.
Comalloy 610	Polyamide-6; glass fiber reinforced, PA-6	Comalloy Intl. Corp.
Comalloy 620	Polyamide-66; glass fiber reinforced, PA-66	Comalloy Intl. Corp.
Comalloy 640	Polyamide-612; glass fiber reinforced, PA-612	Comalloy Intl. Corp.
Comalloy 710	Poly(phenylene sulfide); mineral/GF reinforced	Comalloy Intl. Corp.
Comalloy 740	Polysulfone; glass fiber reinforced, PSU	Comalloy Intl. Corp.
Comalloy 832	ABS/PVC alloy	Comalloy Intl. Corp.
Comalloy 862	Polyamide-66; glass fiber reinforced, PA-66	Comalloy Intl. Corp.
Comalloy 940	Polypropylene; 50 % copper filled, PP	Comalloy Intl. Corp.
Comalloy	Polycarbonates, PC	Comalloy Intl. Corp.
Comco Nylon 6	Polyamide-6, PA-6	Commercial Plastic
Comco Nylon 6	Polyamide-6, PA-6	Commercial Plastic

(*continued*)

Comco Nylon 6/6	Polyamide-66, PA-66	Commercial Plastic
Comco PVC	Poly(vinyl chloride), PVC	Commercial Plastic
Comco UHMW-PE	Ultrahigh molecular weight PE, UHMWPE	Commercial Plastic
Comp Armor	Unsaturated polyester, UP	Haysite Reinforced Plastics
Compodic	Polyamides, PA	DIC Trading
Compound No. 1000	Unsaturated polyester, UP	Resinoid Engr. Corp.
Comshield	Filled polypropylene, PP	Comalloy Intl. Corp.
Comtuf 100	Reinforced polypropylene, PP	Comalloy Intl. Corp.
Comtuf 400	Reinforced polyesters, PBT, PET	Comalloy Intl. Corp.
Comtuf 600	Reinforced polyamides-6, PA-612, or PA-66	Comalloy Intl. Corp.
Conap CE-1132	Unsaturated polyesters, UP	Conap, Inc.
Conap CE-1170	Acrylic resins	Conap, Inc.
Conap UC-21	Polyurethanes, PU	Conap, Inc.
Conapoxy	Epoxy resins, reinforced or not, EP	Conap, Inc.
Conathane	Polyurethanes (TS)	Conap, Inc.
Condux 8000A	Poly(vinyl chloride)/ABS alloy, PVC/ABS	Advanced Dynamics
Conex	Aramid	Teijin/Hoechst
Conoptic	Polyurethanes (TS)	Conap, Inc.
Contrex	Acrylonitrile-styrene-acrylate terpolymer, ASA	Monsanto Europe SA
Coral rubber	*cis*-1,4-Polyisoprene	BF Goodrich
Cordura	Polyamide fiber	DuPont de Nemours
Corezyn	Unsaturated vinyl esters or polyesters, UP	Interplastic Corp.
Corovin	Polypropylene, PP	J. H. Benecke
Corton	Mineral-filled resins	PolyPacific
Corvic	Poly(vinyl chloride) polymers, PVC	European Vinyls Corp.
Cosmic DAP	Diallyl phthalate (TS), DAP	Cosmic Plastics
Courlene	Polyethylene, PE fiber	Courtaulds Fibers Ltd.
Courlene PY	Polypropylene, PP-fiber	Courtaulds Fibers Ltd.
Courtelle	Polyacrylonitrile, PAN	Courtaulds Fibers Ltd.
CP 41	Acrylates	Continental Poly.
CP D33	Diallyl phthalate (TS); reinforced or not, DAP	Cosmic Plastics
CP	PMMA/elastomer blend	Continental
CPP30GF	Mineral-reinforced polypropylene, PP	Ferro Corp.
Crastin	Poly(butylene terephthalate), PBT	Ciba-Geigy Ltd.
Crastin	Poly(ethylene terephthalate), PET	Ciba-Geigy Ltd.
Crastin XMB	Poly(butylene terephthalate)/ABS blends	DuPont
Crastone	Poly(ethylene sulfide), PES	Ciba-Geigy/Phillips
Crealan	Thermoset resins	Bayer
Creslan	Acrylic fiber	Cyanamid
CRI	Polyamide-6, PA-6	Custom Resins
Crystalor PMP	Poly(4-methylpentene-1), PMP	Phillips 66 Co.
Crystic	Unsaturated polyesters, UP	Ashland Chem
CTE	Acrylics	Richardson Polymer
CTI AN	Glass fiber-reinforced polyamide, PA	CTI

CTI AS	Glass fiber-reinforced ABS	CTI
CTI AT	Glass fiber-reinforced polyoxymethylene, POM	CTI
CTI ES	Glass fiber-reinforced polyethersulfone, PES	CTI
CTI NH	Glass fiber-reinforced polyamide-11, PA-11	CTI
CTI NI	Glass fiber-reinforced polyamide-610, PA-610	CTI
CTI NJ	Glass fiber-reinforced polyamide-12, PA-12	CTI
CTI NL	Glass fiber-reinforced polyamide-612, PA-612	CTI
CTI NN	Glass fiber-reinforced polyamide-66, PA-66	CTI
CTI NY	Glass fiber-reinforced polyamide-6, PA-6	CTI
CTI PC	Fiber-reinforced polycarbonate, PC	CTI
CTI PF	Fiber-reinforced polysulfone, PSU	CTI
CTI PI	Fiber-reinforced polyetherimide, PEI	CTI
CTI PK	Fiber-reinforced polyetheretherketone, PEEK	CTI
CTI PS	Glass fiber-reinforced poly(butylenes terephthalate)	CTI
CTI SF	Glass fiber-reinforced poly(phenylene sulfide), PPS	CTI
CTI SN	Glass fiber-reinforced SAN	CTI
Cyanacryl	Alkyl-*co*-alkoxyalkyl acrylates, elastomers	Akzo/DSM
Cyanaprene	Castable urethane, PU	Cyanamid Co.
Cycogel	ABS	Nova Polymers
Cycolac	Acrylonitrile-butadiene-styrene terpolymers, ABS	GE Plastics
Cycolac EHA	ABS/PC alloys	GE Plastics
Cycolac G	ABS/PBT	GE Plastics
Cycolac GCT/M	ABS/PBT automotive blends	GE Plastics
Cycolac SDB	ABS/engineering polymer blends	GE Plastics
Cycolac SDM	ABS/electrostatic dissipation polymer blends	GE Plastics
Cycolin	ABS/PBT alloy	GE Plastics
Cycoloy	ABS/PC; ABS/PVC; or ABS/TPU blends	GE Plastics
Cycoloy EHA	PC/ABS alloys with varying PC content	GE Plastics
Cycoloy LG9000	PC/ABS low-gloss alloy	GE Plastics
Cycopac	Acrylonitrile-butadiene-styrene terpolymers, ABS	GE Plastics
Cycovin	Acrylonitrile-butadiene-styrene terpolymer, ABS	BF Goodrich
Cycovin K25	Poly(vinyl chloride)/ABS high impact alloy	BF Goodrich
Cycovin KAB	ABS/PVC alloys	BF Goodrich
Cyglas	Unsaturated polyesters; reinforced or not	American Cyanamid
Cymel	Alpha cellulose-reinforced melamine-formaldehyde	American Cyanamid
Cyrex 200	PMMA/PC opaque, high-impact-strength alloys	Cyro Industries
Cyrex	SAN/PC opaque blends	Cyro Industries
Cyrolite	Acrylic-based, impact-modified highly transparent multipolymer	Cyro Industries
D		
D-007	Polypropylene, PP	Aristech Chem.
D-10FG	Glass fiber-reinforced ABS	Thermofil, Inc.
D.E.R.	Epoxy resins, EP	Dow Chem. Co.
D7	Acrylonitrile-butadiene-styrene terpolymer, ABS	Thermofil, Inc.

(*continued*)

D8	Styrene-acrylonitrile copolymer, SAN	Thermofil, Inc.
Dacron	Poly(ethylene terephthalate), PET fibers	E. I. du Pont de Nemours
Dai El	PTFE/PHFP/PVDF or PVDF/PHFP elastomers	Daikin/Chevassus
Daki Polistyren	Styrene-butadiene copolymer, SBR	INA
Dalpen	Polyolefins: PE or PP	Kingsley & Keith/PCD
Daltoflex I	Polyurethane rubber	ICI
Dalvor	Fluorinated EPR rubber, FEP	Dow Chem. Co.
Dapex RX	Diallyl phthalate, DAP	Rogers Corp.
Daplen	LDPE, HDPE, PP, GMT, PCD	Polymere Gesellschaft
Dapon	Diallyl phthalate resin	FMC Corp.
Daramelt	Hot melt adhesives/sealants	W R Grace
Dararay	Microwave fluxed plastisols	W R Grace
Daraseal	Poly(vinyl chloride) plastisols, PVC	W R Grace
Darawave	Microwave curable plastisols, PVC	W R Grace
Daron 40	Unsaturated polyester/polyurethane thermosetting blends for fiber-filled systems	DSM
Daron	Hybrid polyester resin; HT resistance	DSM
Dart PS-100	Polystyrene, PS	Dart Polymers, Inc.
Darvic	Poly(vinyl chloride)	ICI
Decaplast	Polyamide-6, -10, PA-610	Montefibre
Decargias	Extruded polycarbonate sheet, PC	Degussa AG
Decoloy	Acrylic/PVC alloy	Borg-Warner/Ube
Deerlon	Polyamides	Deer Polymer
Defsan	Polycarbonate, PC/PET alloy	USSR
Degalan	Acrylates and methacrylates, PMMA powder	Degussa AG
Deglas	Extruded acrylic sheet, PMMA	Degussa AG
Delrin	Polyoxymethylene (*acetal*) resins, POM, some grades contain PTFE	E. I. du Pont de Nemours
Delrin T, ST	POM toughened by addition of TPU elastomer	E. I. du Pont de Nemours
Demospan	Polyurethanes	Bayer
DEN	Epoxy resins, EP	Dow Chem.
Denka HS	Acrylonitrile-butadiene-styrene terpolymer/PC	Denki Kagaku
Denka LCS	Poly(vinyl chloride)/NBR blends	Denki Kagaku/Chevassus
Denka Taimelan	Acrylonitrile-butadiene-styrene terpolymer/PVC	Denki Kagaku
DER	Epoxy resins, EP	Dow Chem. Co.
Derakane	Thermoset vinyl ester epoxy resins	Dow Chem. Co.
Desmodur	Polyurethanes, isocyanates	Bayer AG/Miles
Desmopan	Polycarbonate, PC, with TPU blends	Bayer AG/Miles
Desmopan	Thermoplastic polyurethanes, TPU, isocyanates	Bayer AG/Miles
Desmophen A	TPU ether or ester elastomers	Bayer AG/Miles
Dexcarb	Polycarbonate/polyamide, PC/PA alloys	Dexter Corp.
Dexter RPI	Polycarbonate/ABS alloys	Dexter Corp.

(*continued*)

Dexel	Cellulose acetate	Courtaulds Fibers Ltd.
Dexflex	PO alloys	Dexter Corp.
Dexlon	Polyamide/polypropylene, PA/PP alloy	Dexter Corp.
Dexloy	Customized alloys	Dexter Corp.
Dexpro	Polypropylene/polyamide, PP/PA alloy	Dexter Corp.
Dexter RPI 101EP	Polypropylene/polyolefins, PP/PO alloy	Dexter Corp.
Dexter RPI 101EP	Polypropylene/polyolefins; reinforced or not	Dexter Corp.
Dexter RPI 201EP	Acrylonitrile-butadiene-styrene terpolymer, ABS	Dexter Corp.
Dexter RPI 207EP	ABS/polycarbonate alloys	Dexter Corp.
Dexter RPI 310	Poly(butylene terephthalate); reinforced or not, PBT	Dexter Corp.
Dexter RPI 424, 600	Glass fiber-reinforced polyamide-6 or polyamide-66, PA	Dexter Corp.
Dexter RPI 500EP	Polycarbonates; reinforced or not, PC	Dexter Corp.
Dexter RPI BEE-15	Polyesters	Dexter Corp.
Dexter RPI BEE-18	Polyamides, PA	Dexter Corp.
Dexter RPI BEE-23	Polyesters	Dexter Corp.
Dia Alloy	ABS/PC alloys	Mitsubishi Rayon
Diacon	PMMA, acrylic/elastomer blends (powder)	ICI Adv. Mater.
Diamond	–	Diamond Polymers
Diarex	Styrene-butadiene copolymer, SBR	Mitsubishi Monsanto
Diathon	Acrylic coatings	ICI Polyurethanes
DIC-PPS SE-730	Poly(phenylene sulfide), PPS, alloys with PPE for high HDT and low flash	Dainippon Ink &Chem.
Dielectrite	Unsaturated polyesters, UP	Industrial Dielect.
Diene	Polybutadiene	Firestone
Difan	Poly(vinylidene chloride), PVDC	BASF A.-G.
Dimension	PA-6 blends with PPE; reinforced or not with up to 30 wt% GF	AlliedSignal
Diolen	Poly(ethylene terephthalate), PET	ENKA-Glanzstoff
Dion	Unsaturated vinyl esters, UP	Koppers Co., Inc.
Dispercoll	Polyurethanes, water dispersions	Bayer
Distifoam/Distitron	Polyester resins, UP	Maprac
Distugil	Polyurethane elastomers, PUR	Arnaud Promecome
DK	Epoxy resins, EP	Dexter Corp.
DKE 450	Poly(methyl methacrylate)/PVC alloy	E. I. du Pont de Nemours
Dolan	Polyacrylonitrile, PAN	Südd. Zellwolle
Dorlastan	Spandex fiber	Bayer
Dow ABS	Acrylonitrile-butadiene-styrene terpolymer, ABS	Dow Chem. Co.
Dow CG	Polyethylenes, PE	Dow Chem. Co.
Dow Corning 1	Silicones	Dow Corning
Dow D.E.H./D.E.R.	Epoxy resins, EP	Dow Chem. Co.
Dow HDPE	High-density polyethylene, HDPE	Dow Chem. Co.
Dow LDPE	Low-density polyethylene, LDPE	Dow Chem. Co.
Dow SAN	Styrene-acrylonitrile copolymer, SAN	Dow Chem. Co.

(*continued*)

Dow Tyrin	Chlorinated polyethylene, CPE	Dow Chem. Co.
Dowex	Ion-exchange resin	Dow Chem. Co.
Dowlex IP-2580	Linear low-density polyethylene, LLDPE	Dow Chem. Co.
Dowlex IP-90	High-density polyethylene, HDPE	Dow Chem. Co.
Dowlex	Linear low-density polyethylene, LLDPE	Dow Chem. Co.
Dowlex NG	Poly(ethylene-*co*-octene) LLDPEs	Dow Chem. Co.
Dralon	Polyacrylonitrile, PAN, fiber	Bayer AG/Miles
Drexflex	TP elastomer	D&S Plastics
Driscopipe pipe	Polyethylene pipe, PE	Phillips 66 Co.
DS6CO1K	Polypropylene, PP	Shell Chem. Co.
Dualite	Poly(vinylidene chloride), PVDC, microspheres	Pierce & Stevens
Duct 2.5	Epoxy resins, EP	Furane Products
Duethan BC	Elastomer modified PA-6 blends	Bayer AG/Miles
Duocel	Epoxy coating, EP	Duochem Inc.
Duoclad	Epoxy flooring systems, EP	Duochem Inc.
Duodeck	Polyurethane membrane, PU	Duochem Inc.
Duolite	Ion-exchange resin	Chemical Processing Co.
DuPont LCP	Liquid crystal polymers, LCP	E. I. du Pont de Nemours
Duracon	Polyoxymethylene, POM	Daicel-Polyplastics
Duracryn	TPE: ethylene interpolymers/PP or PE	E. I. du Pont de Nemours
Duraflex	Polyisobutylene, PIB	Shell Chem.
Duraflex 8000	Polyethylenes, PE	Shell Chem.
Dural	Reinforced rigid poly(vinyl chloride), CPD	Dexter Corp./Alpha Chemical
Dural 776/X6	Poly(vinyl chloride)/ABS high impact alloy	Alpha Chem. & Plastics
Duralex	Poly(vinyl chloride)/PU/NBR alloy	Alpha Chem. & Plastics
Duralon	Polyamide-11, PA-11	Thermoclad Co.
Duraloy 1000	Polyoxymethylene, POM, with elastomer	Hoechst Celanese Corp.
Duraloy 2000	Poly(butylene terephthalate), PBT, with elastomer	Hoechst Celanese Corp.
Duraloy	PBT blended with elastomers or POM	Hoechst Celanese Corp.
Duraloy/Vandar	POM/TPU or PBT/elastomer blends	Hoechst Celanese Corp.
Durastrength	Acrylic impact modifier for outdoor PVC siding and window profiles	Elf Atochem
Duratop	Industrial coatings	Thermoclad Co.
Duravin	Poly(vinyl chloride), PVC	Thermoclad Co.
Durel	Polyarylate, PAr, and PAr/PBT blends, glass fiber reinforced or not	Hoechst Celanese Corp.

Durethan	PA-6, PA-66, blended with PO or elastomer, modified and/or reinforced	Bayer AG/Miles Inc.
Durethan BC	PA-6 blended with ethylene-butyl acrylate-acrylic acid	Bayer AG/Miles Inc.
Durethan RM	PA-6 blended with methacrylate-butyl acrylate-bisphenol-A copolymer, with glass fiber or not	Bayer AG/Miles Inc.
Durethan U	Polyurethane, thermoplastic, TPU	Bayer AG/Miles Inc.
Durez 111	Thermoset phenolic compounds; filled or not	Cain Chem. Inc.
Durez SI-75	Thermoset diallyl phthalate compounds, DAP	Cain Chem. Inc.
Durodet	GRP application and SMC	Mitras Kunstoffe
Durolito	GRP syntactical foam	Mitras Kunstoffe
Durolon	Polycarbonate, PC	Polymix
Dutral	EPR copolymers	Himont/Enimont
Dutralene	Thermoplastic elastomer, TPO	Himont/Montedison
Duval	Polypropylene, PP, graft for high-temperature steel pipes	E. I. du Pont de Nemours
Dycryl	Photopolymer system	DuPont de Nemours
Dyflor 2000	Poly(vinylidene fluoride), PVDF	Dynamit Nobel
DYGL	Styrene maleic anhydride copolymer, SMA	Polymer Composites
Dylark	SMA and its blends (with, e.g., PBT, HIPS)	Arco Chem. Co.
Dylene	Polystyrene, PS; styrene-butadiene rubber, SBR	Arco Chem. Co.
Dylite	Polystyrene – expandable, EPS	Arco Chem. Co.
Dylite EPS	Polystyrene – expandable, EPS (25 % recycles)	Arco Chem. Co.
Dym	Polyester elastomer	E. I. du Pont de Nemours
Dymetrol	Elastomeric type	E. I. du Pont de Nemours
Dynacoll	Polyesters	Hüls AG
Dynaflex	PP/EPDM/NBR blends	
Dynalit	Poly(butylene terephthalate), PBT	Dynamit Nobel
Dynamar	Fluoroelastomer processing aid for LLDPE film	3M Canada Inc
Dynapol	Polyester resins	Hüls AG
Dynapor	Phenolic resin foams, PF	Dynamit Nobel
Dynaset	Phenolic compounds, PF	Reichhold Ltd.
Dyneema	UHMWPE gel-spun fibers	DSM
Dynel	Vinyl chloride-acrylonitrile copolymer	Union Carbide Co., Inc.
Dynyl	Polyblockamides: PA-66-*mb*-PA-636	Rhône Poulenc
Dyphene	Phenolic resins, PF	PMC Specialties Group
Dytherm	Expandable copolymer for rigid foam	Arco Chem. Co.
Dytherm	Expandable copolymers	Arco Chem. Co.
Dytron XL	Polyolefins/elastomer blends	Monsanto Chem. Co.
E		
E-08, 9900	Reinforced poly(butylene terephthalate), PBT	Thermofil, Inc.
E-260H, 2748	Epoxy; reinforced or not, EP	ICI/Fiberite
E1-	Glass fiber-filled PET/PBT polyesters	Thermofil, Inc.

<div align="right">(continued)</div>

E484	Glass-filled epoxy, EP	Cosmic Plastics
EA 3000	Polystyrene, PS	Chevron Chem.
Eagle Picher EP	Unsaturated polyesters with glass fibers, UP	Eagle Picher Plas.
EB 6000	Polystyrene, PS	Chevron Chem.
Eastalloy DA003	Transparent copolyester/PC alloy	Eastman
Ebaco	Ethylene-vinyl acetate copolymers, EVAc	Neste Chim.
Ebecryl	Acrylates and methacrylates	UCB Soc.
EC 6000	Polystyrene, PS	Chevron Chem.
Ecavyl	Poly(vinyl chloride), PVC	Kuhlmann/Fr.
Eccogel	Epoxy resins, EP	Emerson & Cuming
Eccoseal	Epoxy resins, EP	Emerson & Cuming
Eccothane	Polyurethane, PU	Emerson & Cuming
Econit SHF-MR	Polypropylene/nitrile rubber	Resine Sintet. Adamoli
Econol	Poly(p-hydroxybenzoic acid ester)	Sumitomo Chem.
Ecothene	HDPE containing 28 % postconsumer resin	Quantum Chem. Corp.
Edistir	High-impact polystyrene, HIPS, PS	ECP Enimont Polymeri
Editer	Glass fiber-reinforced ABS	ECP Enimont Polymeri
EE4000	Mineral-filled epoxy, EP	Dexter Corp.
EFK	Aromatic polyester	Sumitomo Chemical
Ekkcel	Aromatic polyester	Carborundum
Ekonol	Poly(p-hydroxybenzoic acid), $T_m = 550\ °C$	Carborundum
Ektar	Thermoplastic polyesters and copolyesters: PET, PBT, PCT, PCTG polyesters	Eastman Chem. Prod.
Ektar DN	Thermoplastic polyesters	Eastman Chem. Prod.
Ektar FB	TP elastomers	Eastman Chem. Prod.
Ektar FB CG	Glass fiber-filled polyarylate	Eastman Chem. Prod.
Ektar FB DG	Glass fiber-filled poly(ethylene terephthalate), PET	Eastman Chem. Prod.
Ektar FB PG	Glass fiber-filled polypropylene, PP	Eastman Chem. Prod.
Ektar MB DA003	PCTG/PC or SMA transparent alloys	Eastman Chem. Prod
Elastalloy	TP elastomers	GLS Corporation
Elastocell	Polyurethane foam compounds, PU	BASF Plastics
Elastocoat	Polyurethane casting systems, PU	BASF Plastics
Elastoflex	Soft PUR foam system	BASF Plastics
Elastofoam	Soft integral-skin PUR foam	BASF Plastics
Elastogran	Family of polyurethanes, PU	BASF Plastics
Elastolan	Thermoplastic polyurethane, TPE	BASF Plastics
Elastolit	Hard integral-skin PUR foam	BASF Plastics
Elastopal	Polyurethane elastomers, PUR	BASF Plastics
Elastopor	Hard PUR foam systems	BASF Plastics
Elastopreg	Semifinished product glass-mat	BASF Plastics
Elastorob	Polyurethane elastomers, PUR	Robbe

(*continued*)

Elastosil	Silicone rubbers	Wacker Chemie
Elastotec	Polyester thermoplastic elastomers	BASF Plastics
Elastron	PU vapor barriers	ICI Polyurethanes
Elastuff	Urethane coatings, PU	ICI Polyurethanes
Electrafil 55-EC	Carbon black-filled EVAc	Akzo/DSM
Electrafil ABS	ABS, aluminum filled	Akzo/DSM
Electrafil CF	Polyamide-66, carbon fiber filled; PA-66	Akzo/DSM
Electrafil	Electrically conductive plastics	Wilson-Fiberfil Inc./ DSM
Electrafil G-1100	Polyethersulfone, stainless steel filled, PES	Akzo/DSM
Electrafil G-50	Polycarbonate, carbon fiber filled, PC	Akzo/DSM
Electrafil J-1	Polyamide-66, carbon fiber filled, PA-66	Akzo/DSM
Electrafil J-1105	Polyetheretherketone, carbon fiber filled, PEEK	Akzo/DSM
Electrafil J-1106	Polyetherimide, carbon fiber filled, PEI	Akzo/DSM
Electrafil J-1200	ABS, carbon fiber filled	Akzo/DSM
Electrafil J-1300	Poly(phenylene sulfide), carbon fiber filled, PPS	Akzo/DSM
Electrafil J-1400	FTFE, carbon fiber filled	Akzo/DSM
Electrafil J-1500	Polysulfone, carbon fiber filled, PSU	Akzo/DSM
Electrafil J-3	Polyamide-6, carbon fiber filled, PA-6	Akzo/DSM
Electrafil J-30	Polystyrene, carbon fiber filled, PS	Akzo/DSM
Electrafil J-50	Polycarbonate, carbon fiber filled, PC	Akzo/DSM
Electrafil J-60	Polypropylene, carbon fiber filled, PP	Akzo/DSM
Electrafil SMA	SMA plastics, aluminum filled	Akzo/DSM
Elemid	ABS/polyamide alloys; PA/ABS	GE Plastics
Elexar	Triblock SEBS or SBS thermoplastic elastomers	Shell Chem.
Elix	Polymer modifiers: elastomer with either PB, SAN, SMA, ASA, or MSAN	Monsanto Chem. Co.
Eltex P	Polypropylenes, PP; also highly isotactic PP	Solvay & Cie SA
Eltex	Polyethylenes, PE	Solvay & Cie SA
Elvacet	Poly(vinyl acetate), PVAc	E. I. du Pont de Nemours
Elvacite	Acrylic resins	E. I. du Pont de Nemours
Elvamide	Polyamide resins, PA	E. I. du Pont de Nemours
Elvanol	PVAl, ethylene-vinyl alcohol copolymers, EVAl	E. I. du Pont de Nemours
Elvax	Ethylene-vinyl acetate copolymers, EVAc	Du Pont/Safic-Alcan
Elvic	Poly(vinyl chloride), PVC	Solvay & Cie SA
EM-7302	Epoxy resins, EP	Industrial Dielect.
Emac	EMA copolymer	Chevron
EMI-X	PA-6 or PA-66 with Al flakes for EMI control	LNP Eng. Plastics
Emiclear	–	Toshiba
EMPEE PE	Polyethylenes, PE	Monmouth Plastics
EMPEE PP	Glass fiber-reinforced polypropylene, PP	Monmouth Plastics
EMPEE PP	Polypropylenes, PP	Monmouth Plastics

(*continued*)

EMPEE PS	Polystyrenes, PS	Monmouth Plastics
Empee	Polyethylene, polypropylene	Monmouth
Enathene	Ethylene butyl acrylate	Quantum
Encron	Polyester fiber	Akzo/DSM
Enduran	High-density PBT resin	GE Plastics
Engage	Poly(ethylene-*co*-octene) a polyolefin elastomer, POE, based on Insite™ metallocene technology	Dow Chem. Co.
Enjay Butyl	Isobutylene-isoprene copolymer, IIR	Enjay
Envex	PI, PI lubricated by PTFE, MoS_2, or graphite	Rogers Corp.
EP Total	EPDM, thermoplastic polyolefins	Total Elastomers
EP Total SL 180	Silicones	Total Elastomers
EP	Unsaturated polyesters, UP	Eagle Picher Plas.
Epalex	–	PolyPacific
EPDM XG 006	Ethylene-propylene oil extended rubber	Polysar-Miles
Epi-Rez	Epoxy resins, EP	Celanese
Epi-Rez	Ethylene-propylene elastomer, EPR	Devoe-Raynolds
Epiall	Epoxy resins, EP	Rogers Corp
Epic	Epoxy/unsaturated polyesters, UP	Epic Resins
Epikote	Epoxy resins, EP	Shell Chem.
Epilox	Ethylene-propylene elastomer, EPR	Soprochim
EPM XF 004	Ethylene-propylene impact modifier for TPO	Polysar-Miles
Epo-Tek	Epoxy resins, EP	Epoxy Technology
Epocast	Ethylene-propylene elastomer, EPR	Elastomer Chem./USA
Epodite	Epoxy resin	Showa Highpolymer
Epolan	Acrylonitrile-butadiene-styrene terpolymer, ABS	Industrial Resistol
Epolene	Oxidized polyolefin, PO	Van Waters & Rogers Ltd.
Epolite	Epoxy; filled or not, EP	Hexcel Corp.
Epon	Epoxy resins, EP	Shell Chem. Co.
Eponite	Epoxy resin-based materials, EP	Shell Chem. Co.
Eposir	Epoxy resins, EP	Kingsley & Keith/SIR
Epoxilrub	Epoxy resins, EP	Furane Products
Epoxylite	Epoxy resins, EP	Epoxylite Corp.
Eraclear	LLDPE and VLLDPE	ECP EniChem Polymeri
Eraclene	High-density polyethylene, HDPE	ECP EniChem Polymeri
Eref LS	PP modified, with 40 % or 50 % glass fiber	Solvay SA
Eref	PA-66 or PA-mXD6 blends with 40–60 % PP; ≤50 % glass fiber	Solvay SA
Ertacetal	Polyoxymethylene (acetal), POM	Polymer Corp.
Ertalon	PA-6, internally lubricated, cast in rods and plates	Polymer Corp.
Ertalyte PET-P	PET rods or plates	Polymer Corp.
ES0002	Epoxy resins, EP	Dexter Corp.
Esall	Polypropylene, PP	Sumitomo Chem. Co.

<div align="right">(continued)</div>

Esbrid	Polyamide-6 with 50 % ceramic and glass reinforced	Thermofil, Inc.
Esbrite	Polystyrene, PS	Sumitomo Chem. Co.
Escalloy	Polypropylene, PP	Comalloy Intl. Corp.
Escor	Ethylene-acrylic acid, EAA, copolymers	Exxon Chem
Escorene Micro	Ethylene-vinyl acetate copolymers, EVAc	Exxon Chem/Esso Chem
Escorene	Polyolefins (PO): LDPE, LLDPE, MDPE, PP	Exxon Chem/Esso Chem.
Escorene Ultra	Ethylene-vinyl acetate copolymers, EVAc	Exxon Chem/Esso Chem
Esso-PVC	Poly(vinyl chloride), PVC	Esso Chemical
Estalloy DA	Polyester/polycarbonate blends	Eastman Kodak
Estane	Thermoplastic polyurethanes, TPU, and TPU/SAN or TPU/ABS blends	BF Goodrich/ Polyplastic
Estar	Polyester film	Eastman Kodak
Esthane	Polyurethane TPE	BF Goodrich
ET-Polymer	Butyl-grafted polyethylene, PE	ABB Polymer Comp.
ET-Semicon	Conductive butyl-grafted PE	ABB Polymer Comp.
ETA-Polymer	PP/EPDM, TPO alloys, thermoplastic elastomers	Republic Plastics
Ethavin	Olefinic/poly(vinyl chloride) alloy	Vi-Chem Corp.
Ethocel	Cellulose ethers: ethyl and methyl	Dow Chem. Co.
Ethofil	Polyethylenes; glass fiber filled, PE	Akzo/DSM
Ethron	Polyethylenes, PE	Dow Chem. Co.
ETP	Polyamide/acrylic thermoplastic elastomer blend	E. I. du Pont de Nemours
Euredur/Eurelon	Polyamide resins, PA	Schering AG
Euremelt	Polyamide and polyester resins	Schering AG
Eurepox	Epoxy resins, EP	Schering AG
Europrene SOL T	Triblock SBS or SIS thermoplastic elastomers	EniChem
Evaclene	Ethylene-vinyl acetate copolymer, EVAc	Anic
Evaco	Ethylene-vinyl acetate copolymers, EVAc	Neste Chim.
Evaflex	Ethylene-vinyl acetate copolymer, EVAc	Mitsui
EVAL	Ethylene-vinyl alcohol copolymers, EVAc	EVAL Co. of America
Evalca	EVA copolymer	EVAL Co. of America
Evatane	Ethylene-vinyl acetate copolymers, EVAc	ICI
Evatate	Ethylene-vinyl alcohol copolymers, EVAl	Sumitomo Chem. Co.
Evathane	Ethylene-vinyl acetate copolymers, EVAc	Elf Atochem
Ever-Flex	Thermoplastic elastomers, TPO formulations	Quality Service Technology
Evoprene	Thermoplastic elastomers, TPE	Evode Plastics Ltd.
Exac CTFE	CTFE fluorocarbon	Norton Performance
Exac ECTFE	ECTFE fluorocarbon	Norton Performance
Exac ETFE	ETFE fluorocarbon	Norton Performance
Exac FEP	FEP fluorocarbon	Norton Performance
Exac PFA	PFA fluorocarbon	Norton Performance
Exac PTFE	PTFE fluorocarbon	Norton Performance

Exac PVDF	PVDF fluorocarbon	Norton Performance
Exact PE	Polyethylene (medical grade) prepared using the metallocene catalyst, Exxpol	Exxon Chem. Co.
Exprima	Rigid poly(vinyl chloride) compounds, PVC	European Vinyls Corp.
Extir	Expandable polystyrene, EPS	ECP Enimont Polymeri
Extron	Glass-filled resins	PolyPacific
Exxelor	Polymeric modifiers	Exxon Chem.
Exxon Butyl 077	IIR, also chlorobutyl and bromobutyl rubbers	Exxon Chem.
Exxtral	Reactor olefinic thermoplastic elastomers, RTPO	Exxon Chem.
F		
F-007	Polypropylene; glass filled or not, PP	Aristech Chem.
F-40MF	Polyethylene; glass filled or not, PE	Aristech Chem.
F-9900	Polyethylenes, PE	Thermofil, Inc.
F6	Glass fiber-filled polyethylenes, PE	Thermofil, Inc.
Fascat	Alkydes, polyesters, silicones	Ceca
Faskene	Poly(vinyl chloride) compounds, PVC	Technicompound
Fastool	Filled epoxy resins, EP	REN Plastics
Fenilin	Poly(*m*-phenyleneisophthalamide), PPA	USSR
Fenochem	Phenol-formaldehyde resins, PF	C.P.R.I.
Ferrene	Filled polyolefins, PO	Ferro Corp.
Ferrex	Mineral-filled polypropylenes, PP	Ferro Corp.
Ferro Flex	Polypropylene, PP, PP/EPDM or EPM blends	Ferro Corp.
Ferrocon	Polypropylenes, PP	Ferro Corp.
Ferroflo	Polyolefins, PO, polystyrene, PS	Ferro Corp.
Ferrolene	PP, rubber modified, containing 20 % mineral	Ferro-Eurostar
Ferrolene TPE	IPN-type PP/EPDM blends	Ferro Corp.
Ferropak	PP/PE alloy	Ferro Corp.
Fertene	Low-density polyethylene, LDPE	Montecatini
FF-020	Polypropylene, PP	Aristech Chem.
Fibercore	Glass-filled unsaturated polyesters, UP	American Cyanamid
Fiberfil	Fiber-reinforced material	DSM
Fiberfil G-1	Polyamide-66 with glass fiber, PA-66	Akzo/DSM
Fiberfil G-1500	Fiber-filled polysulfone, PSU	Akzo/DSM
Fiberfil G-40	Fiber-filled SAN	Akzo/DSM
Fiberfil G-50	Fiber-filled polycarbonate, PC	Akzo/DSM
Fiberfil G-60	Fiber-filled polypropylene, PP	Akzo/DSM
Fiberfil J-1106	Glass fiber-filled polyetherimide, PEI	Akzo/DSM
Fiberfil J-1300	Glass fiber-filled poly(phenylene sulfide), PPS	Akzo/DSM
Fiberfil J-1850	Glass fiber-filled poly(butylene terephthalate), PBT	Akzo/DSM
Fiberfil J-7	Fiber-filled polyamide, PA	Akzo/DSM
Fiberfil NY-12	Glass fiber-filled polyamide-612, PA-6,12	Akzo/DSM
Fiberfil NY-7	Glass fiber-filled polyamide, PA	Akzo/DSM

Fiberfil TN	Polyamide-6, 12 impact modified blends containing PO; GF reinforced or not	Akzo/DSM
Fiberfil VO	Flame-retarded plastics	Wilson-Fiberfil Intl.
Fiberite FM	Phenolic compounds, PF	Fiberite/ICI
Fiberite PI	Graphite-filled polyimide, PI	Fiberite/ICI
Fiberite SI	Filled thermoset silica compounds	Fiberite/ICI
Fiberloc	Poly(vinyl chloride) rigid formulation, PVC fiber reinforced	BF Goodrich/Geon
Fiberstran	Long glass-reinforced thermoplastics	Akzo/DSM
Fiberstran	Long fiber-reinforced material	DSM
Fibredux	Epoxy prepregs, EP	Ciba-Geigy Ltd.
Fibrela	Honeycomb sandwich panels	Ciba-Geigy Ltd.
Filabond	Unsaturated polyester, UP	Reichhold Ltd.
Filmex	Cast film extrusion	Windmoeller/ Hoelscher
Filmon	Cast polyamide, PA, films	SNIA Tecnopolimeri SpA
Fina	Polystyrenes, PS	Fina Oil & Chem.
Finaclear	SBS, linear Poly(styrene-b-butadiene-b-styrene) with 75 wt% styrene (lamellar structure)	Fina Oil & Chem.
Finaprene	Elastomers, TPE	Fina Chem.
Finaprop	Polypropylene, PP	Fina Chem.
Finathene	Polyethylenes: LDPE, MDPE, HDPE	Fina Chem.
Firestone	Polyamide-6, PA-6	Firestone Canada Inc.
Flemion	Carboxylated fluoropolymer	Asahi Glass
Flex-Line	Polyamide monofilaments, PA	Elf Atochem Deutschland
Flexel	Thermoplastic elastomers, TPE	BF Goodrich
Flexomer	Ultra low-density linear polyethylene ULDPE	Union Carbide Co., Inc.
Flexomer DFDA	ULDPE high flow processing aid for injection	Union Carbide Co., Inc.
Flexorob/Flexothane	Polyurethane, PU	Robbe
Flexthane	Urethane-acrylate water-based coatings	Air Products & Chem.
Flo-Well	PP/PVC copolymer blends	Air Products & Chem.
Flovic	Poly(vinyl acetate), PVAc	ICI Adv. Mater.
Fluon	Polytetrafluoroethylene, PTFE	ICI Adv. Mater.
Fluorel	Thermoset fluoropolymers; PVDF/PHFP blend	3M Ind. Chem.
Fluorocomp	60 % bronze-filled PTFE	LNP Engineering
Fluorofil	Carbon/glass-filled PVDF	Akzo/DSM
Fluorogold	Polytetrafluoroethylene filled or not, PTFE	Fluorocarbon
Fluoromelt	Fluoropolymers, melt processable	ICI Adv. Mater.
Fluoromelt FP-CC	ECTFE, glass or carbon fiber filled	LNP Engineering
Fluoromelt FP-EC	FTFE, glass or carbon fiber filled	LNP Engineering
Fluoromelt FP-FC	FEP, glass or carbon fiber filled	LNP Engineering
Fluoromelt FP-PC	PFA, glass or carbon fiber filled	LNP Engineering
Fluoromelt FP-VC	PVDF, glass or carbon fiber filled	LNP Engineering
Fluorosint PTFE	PTFE + mica composites (rods or plates)	Polymer Corp.

<div align="right">(continued)</div>

Fluorotemp 103	Polyetheretherketone, PEEK, filled	Fluorocarbon
Fluorothene	Polychlorotrifluoroethylene, PCTFE	DuPont de Nemours
Fomrez/Formrez	Polyurethane, PU	Witco
Foraflon 51	Fluorocarbon PTFE	Elf Atochem
Foraflon 1000	Fluorocarbon PVDF	Elf Atochem
Foraflon	Poly(vinylidene fluoride), PVDF	Elf Atochem
Formacast	Epoxy/polyurethane casting blends	Formulated Resins
Formaldafil	Polyoxymethylene; filled or not, POM	Akzo/DSM
Formaldafil	Polyoxymethylene, POM/PTFE blend	Fiberfil
Formica	Melamine-formaldehyde resin	Cyanamid
Formion	Ionomer	A. Schulman, Inc.
Formion	Ionomer compounds; PO/ionomer blends	A. Schulman, Inc.
Forprene	Olefinic thermoplastic elastomers, TPO	Ferro Corp.
Forticel	Propyl cellulose, CP	Hoechst Celanese Corp.
Fortiflex	Polyethylenes, PE	Soltex Polymer Co.
Fortiflex	Polyethylenes, PE	Solvay & Cie SA
Fortilene	Polypropylene, PP	Soltex Polymer Co.
Fortilene	Polypropylene, PP	Solvay & Cie SA
Fortron	Poly(phenylene sulfide), linear PPS, glass and mineral reinforced or not	Kureha Chem./ Hoechst Celanese
Fosta Tuf-Flex	Styrene-butadiene copolymer, SBR	Hoechst AG
FP-200	Polypropylene, PP	Aristech Chem.
FPC 18MI	Styrene-acrylonitrile copolymer, SAN	Federal Plastics
FPC 30	Polypropylene, PP	Federal Plastics
FPC 40	Polyethylene, PE	Federal Plastics
FPC 75	Acrylonitrile-butadiene-styrene terpolymer, ABS	Federal Plastics
FPC 500, 600	Polyethylenes, PE	Federal Plastics
FPC	Polystyrene, PS	Federal Plastics
Freshtuff	Ionomer/polyamide alloys	American Can Co.
FT-015	Polypropylene, PP	Aristech Chem.
Fulton 404	POM lubricated with PTFE	LNP Eng. Plastics
FurCarb	Furan-based TS resins; reinforced or not	QC Chem., Inc.
FyRid	Flame-retardant polystyrene, PS	GE Plastics
G		
G-2-	Polyoxymethylene, filled: glass bead, graphite, etc.	Thermofil, Inc.
G-Resin	Polyethylenes, PE	Union Carbide Co., Inc.
G1	Glass fiber-filled polyoxymethylene, POM	Thermofil, Inc.
Gabrite	Phenol-formaldehyde, PF, molding material	Montecatini
Gafite	PBT/elastomer alloys, reinforced or not	GAF Corp.
Gaflex	TPU, ester/ether thermoplastic elastomer	GAF Corp.
Gaflon	Polytetrafluoroethylene, PTFE	Gachot, France
Gaftuf	High-impact PBT/elastomer alloys	GAF Corp.
Galalith	Plastics from milk protein, CS	Int. Galalith-Ges.

Gantrez	Poly(methyl vinyl ether-*co*-maleic anhydride)	GAF Corp
Gapex	PP/PA-6 or PA-66 compatibilized alloy, reinforced or not	Ferro-Eurostar
Garamed	Poly(vinyl chloride), PVC	Ferro Corp.
Garaprene E	Thermoplastic elastomers	Ferro Corp.
Garaprene O	TPO for wire and cable applications	Ferro Corp.
Garaprene	Thermoplastic alloy compounds	Evode Plastics Ltd.
Garaprene	Thermoplastic elastomer	Ferro Corp.
Gary PVC	PVC compounds for cables	Evode Plastics Ltd.
GC 480	Polyurethanes, PU	Gallagher Corp.
GECET	PPE/PS foams	GE Plastics
Gedamine	Unsaturated polyester, UP	Norsolor, France
Gedelite	Phenol-formaldehyde resins, PF	Norsolor, France
Gedex	Polystyrene, PS	Elf Atochem
Gedexcel	Expanded polystyrene, PS	Elf Atochem
Gel 151	Epoxy resins, EP	Furane Products
Gelon	Amorphous polyamide, PA	GE Plastics
Geloy GY1020	Acrylic acid-styrene-acrylonitrile terpolymer, ASA	GE Plastics
Geloy GY1220	ASA/PVC alloys in pellet form	GE Plastics
Geloy SCC 1320	ASA/Poly(methyl methacrylate), PMMA blends	GE Plastics
Geloy XP 2003	ASA/Poly(vinyl chloride), PVC alloy	GE Plastics
Geloy XP 4001	ASA/polycarbonate, PC blends for automobile	GE Plastics
Geloy XP 4025	ASA/PC blends	GE Plastics
Gelvatol	Poly(vinyl alcohol)	Shawinigan Chemicals
Gemax	Poly(phenylene ether)/PBT, PPE/PBT blends	GE Plastics
Gemon	Maleimide	GE Plastics
Geolast	Thermoplastic elastomer blends; NBR/EPDM or PP/NBR blends	Advanced Elastom. Syst.
Geon	Poly(vinyl chloride) and blends, viz., PVC/NBR	BF Goodrich/Geon
Geon HTX	Poly(vinyl chloride)-based high performance alloy	BF Goodrich/Geon
Georgia-Gulf	Poly(vinyl chloride) resins and alloys, PVC	Georgia-Gulf
Gepax	PPE/crystalline PS alloys	GE Plastics
Getem	Amorphous cyclomer-type polymers	GE Plastics
Glaskyd	Thermoset alkyd resins; filled or not, UP	American Cyanamid
Glastic	Unsaturated polyesters; filled or not, UP	Glastic Co.
Glendion/Tercarol	Polyether and polyester polyols	ECP EniChem Polymeri
Glyptal	Alkyd resin, UP	GE Plastics
Goodrite Latex	SB and vinyl pyridine	BF Goodrich
Goodrite	Polyacrylic acid, PAA	BF Goodrich
GPC DELTA	Styrene-acrylonitrile copolymer, SAN	Grand Pacific
GR7	Glass-reinforced Zytel polyamides, PA	Du Pont Canada
Grafoil	Foils of pure graphite	Union Carbide Co., Inc.
Granular Compound	Urea-formaldehyde resin; cellulose filled, UF	Plastics Mfg. Co.

(*continued*)

Granular	Liquid crystal polyester, LCP	Granmont Inc./ Montedison
Granulation Comp.	Filled melamine-formaldehyde resin, MF	Plastics Mfg. Co.
Grilamid	Polyamide-12, reinforced or not, PA-12; also blends with aromatic-aliphatic polyamides	EMS-American Grilon
Grilamid ELY-60	Polyetheramide, PEA	EMS-American Grilon
Grilamid TR	Polyamide, transparent, amorphous	EMS-American Grilon
Grilesta	Powder coating resins	EMS-American Grilon
Grilet	PBT-extrusion and PET-molding resins	EMS-American Grilon
Grilon	PA-6 or PA-612 blended with PB or EPR	EMS-American Grilon
Grilon A	Polyamide-6, PA-6, with PB or EPR; filled or not	Emser Ind.
Grilon BT	PA-6/aromatic-aliphatic polyamide, PA alloys	EMS-American Grilon
Grilon T	Polyamide-66, PA-66	EMS-Chemie AG
Grilon XE	Polyamide-66/610 copolymer	EMS-Chemie AG
Grilon XE3404	Polyamide-polyethylene blend	EMS-Chemie AG
Grilonit	Ethylene-propylene copolymers, EPR	Emser-Werke
Grilpet	PET, PBT; reinforced or not	EMS-Chemie AG
Griltex	Copolyamides, copolyesters	EMS-Chemie AG
Grivory	Amorphous engineering resin, reinforced or not	EMS-American Grilon
Grivory G	Amorphous polyamide, PA	EMS-Chemie AG
Grilamid TR	Amorphous polyamide, PA	EMS-Chemie AG
Grilesta	Copolyester resin for powder coating	EMS-Chemie AG
Gumiplast	Poly(vinyl chloride) compounds, PVC	Saplast
GX-200	ASA/polycarbonate, PC, alloys	GE Plastics
H		
H-Film	PI (pyromellitic anhydride/ diaminodiphenylether)	E. I. du Pont de Nemours
Halar	ECTFE fluoropolymers	Ausimont Inc.
Halon	Fluoropolymer	Ausimont Inc.
Halon 1000R	Polytetrafluoroethylene, ETFE; glass fiber filled	Ausimont Inc.
Halon 2000R	Polytetrafluoroethylene, ETFE; graphite filled	Ausimont Inc.
Halon 3000R	Polytetrafluoroethylene, ETFE; bronze filled	Ausimont Inc.
Halon 4000R	Polytetrafluoroethylene, ETFE; graphite filled	Ausimont Inc.
Halon ET	Filled ETFE fluorocarbon	Ausimont Inc.
Hanalac	ABS	Miwon
Hannam ABS	Acrylonitrile-butadiene-styrene terpolymer, ABS	Hannam
Haysite BMC	Unsaturated polyesters, glass filled, UP	Haysite Reinforced Plastics
HC-3	Polyethylene; filled, PE	CCA Compounding
HCPP	High crystallinity polypropylene with isotacticity ≤99 %, broad MWD	Chiso Corp.
HDPEX	Auto cross-linkable PE	ABB Polymer Comp.
Heatlok	Polyurethane elastomer, PUR resins	ICI Polyurethanes
Herclor	Elastomers	Hercules
Hercocel	Cellulose acetate, CA	Hercules

(*continued*)

Hercules K-type	Ethyl cellulose, EC	Hercules
Herculoid	Cellulose nitrate, CN	Hercules
Hercuprene	Thermoplastic rubber, TPE	J-Von
Hetron	Unsaturated polyester, UP	Ashland Chem. Co.
Hevea-Plus	NR/PMMA interpenetrating polymer networks	Malaysia
HF-2230	Poly(vinyl chloride), PVC/ABS blends	Georgia Gulf
HHW, HHP	Poly(vinyl chloride) rigid formulations, PVC	Georgia Gulf
Hi-D	Polyethylenes, PE	Chevron Chem.
Hi-Fax	High-density polyethylene, HDPE	Hercules
Hi-Zex	Polyethylenes, PE	Mitsui Petrochem.
Hicond-2000	HDPE/PP electrically conductive alloy	United Composites
Hicond-X	Polyethylene, PE	United Composites
HiFax	Reactor olefinic thermoplastic elastomers, RTPO	Himont Adv. Materials
HiGlass	Glass-filled polypropylene Himont	
Hiloy 100	Glass fiber filled polypropylene, PP	Comalloy Intl. Corp.
Hiloy 400	Glass fiber filled poly(butylene terephthalate), PBT	Comalloy Intl. Corp.
Hiloy 440	Glass fiber filled poly(ethylene terephthalate), PET	Comalloy Intl. Corp.
Hiloy 600	Glass fiber-filled polyamide-6, polyamide-612 or polyamide-66, PA	Comalloy Intl. Corp.
Himod PU GL	Thermoplastic polyurethane, TPU, alloys	Polymer Compos.
Histat-X	Electrically conductive polyethylenes, PE	United Composites
Hitalex	Polyethylene	Hitachi
Hitanol	Phenol-formaldehyde resin	Hitachi
HiVal	Polyethylenes, HDPE	General Polymers
HMS 1000	Conductive styrenic alloy	HMS Compounds, Inc.
Hoslapren	Chlorinated polyethylene, CPE	Hoechst Celanese Corp.
Hostacom	Filled or reinforced polypropylene, PP	Hoechst Celanese Corp.
Hostadur	Poly(ethylene terephthalate), PET	Hoechst Celanese Corp.
Hostadur X	PBT/PET alloy	Hoechst Celanese Corp.
Hostaflon	Fluoropolymers (PTFE, PFA, ETFE)	Hoechst Celanese Corp.
Hostaflon C2	Polychlorotrifluoroethylene	Hoechst Celanese Corp.
Hostaflon ET	Ethylene-*co*-tetrafluoroethylene, ETFE	Hoechst Celanese Corp.
Hostaflon FEP	Tetrafluoroethylene-*co*-hexafluoropropylene	Hoechst Celanese Corp.
Hostaflon TF	Polytetrafluoroethylene, PTFE	Hoechst Celanese Corp.
Hostaflon TFM	Modified suspension PTFE	Hoechst Celanese Corp.

(*continued*)

Hostaform C	POM/TPU alloys	Hoechst Celanese Corp.
Hostaform	POM copolymer, impact modified, reinforced, etc.	Hoechst Celanese Corp.
Hostalen GUR	Ultrahigh molecular weight PE, UHMWPE	Hoechst Celanese Corp.
Hostalen	UHMWPE, HDPE, PP/EPDM, resins and prod.	Hoechst Celanese Corp.
Hostalen PP	Polypropylene, PP	Hoechst Celanese Corp.
Hostalit	Poly(vinyl chloride), PVC	Hoechst Celanese Corp.
Hostalit Z	High-impact PVC/CPE blends	Hoechst Celanese Corp.
Hostalloy 731	Polyolefin alloy, with high abrasion resistance	Hoechst Celanese Corp.
Hostamid	Polyamide, transparent, amorphous	Hoechst Celanese Corp.
Hostaphan	Poly(ethylene terephthalate), PET	Kalle, Germany
Hostapren	Chlorinated polyethylene, CPE	Hoechst Celanese Corp.
Hostatec	Polyetheretherketoneketone, PEK	Hoechst Celanese Corp.
Hostyren	Polystyrene, PS; PS/elastomer blends	Hoechst Celanese Corp.
HPP30GR	Mineral/glass fiber-filled polypropylene, PP	Ferro Corp.
HTX	Polyetherketone	ICI
Hycar PA	Modified acrylic elastomers	BF Goodrich
Hycar	PVC/nitrile rubber	BF Goodrich
Hydrin	Polyepichlorohydrin elastomer, can be blended with any elastomer, sulfur or peroxide curable	Zeon Chemicals, Inc.
Hylar 5000	Poly(vinylidene fluoride), PVDF	Ausimont
Hylar	Poly(ethylene terephthalate), PET	E. I. du Pont de Nemours
Hypalon	Chlorosulfonated PE (CSM) synthetic rubber	E. I. du Pont de Nemours
HyTemp	Polyacrylate elastomer, curable or not	Nippon Zeon Co., Ltd.
Hytrel	Thermoplastic polyether-ester block copolymer elastomers, 1,4-butanediol-polybutylene glycol-terephthalic acid copolymer, TPE	E. I. du Pont de Nemours
Hytrel HA	Copolyester/polyacrylate/PET	E. I. du Pont de Nemours
I		
Icdal Ti40	Polyesterimide	Dynamit Nobel
Idemitsu LCP	Liquid crystal polyester, LCP	Idemitsu Petro Chem
Idemitsu Polycarb.	Polycarbonates, PC	Idemitsu Petro Chem
Idemitsu SC	PC/ABS, PES blends	Idemitsu Petro Chem
Igelit	Poly(vinyl chloride), PVC	Bitterfeld, Germany

(*continued*)

Illen	Poly(butylene terephthalate), PBT/elastomer blend	Dr. Illing GmbH
Imidex	Polyesterimide, PEI	General Electric Co.
Impet	Poly(ethylene terephthalate), PET, glass reinforced	Hoechst Celanese Corp.
Implex	High-impact acrylic blends	Rohm and Haas
Imprez	Resins	ICI Polymers
Indopol	Polybutenes, PB	Amoco Chem. Co.
Innovex	Linear low-density polyethylene, LLDPE	BP Chem. Ltd.
Inprima	Rigid poly(vinyl chloride), PVC	European Vinyls Corp.
Insite	Ethylene/octene copolymers prepared using the *constrained-geometry* metallocene catalyst	Dow Plastics
Instant-Set Polym.	Thermosetting polyurethane, PU	Dow Chem. Co.
Insultruc P-	Unsaturated polyesters with glass fiber, UP	Industrial Dielect.
Intene/Intex	Elastomers	Enimont
Intol/Intolene	Elastomers	Enimont
Ionac	Ion-exchange resin	Ionac
Iotek	Ionomers	Exxon Chem.
IPC	Glass fiber-filled poly(phenylene sulfide), PPS	IPC
IPN-Compound	Interpenetrating polymer	ABB Polymer Comp.
Iporka	Urea-formaldehyde, UF, plastic foam	BASF Plastics
Iropol	Polyester resin	Armkem Iroquois Chem.
Irostic	Polyurethane, TPU-adhesive resins	Monon International Inc
IRPS	Polystyrene, PS	Huntsman Chem.
Irrathene	Polyethylenes cross-linked by radiation, XLPE	GE Plastics
Isobam	Copolymer of isobutylene and maleic anhydride water soluble (protective colloids)	Kuraray Co., Ltd.
Isolic	Acrylic resins	Great Eastern
Isomid	Polyesterimide, PEI	Schenectady Chem.
Isoplast	Polyurethanes	Dow Plastics
Isorob/Isothanne	Polyurethanes, PU	Robbe
Isplen	Polypropylene, PP	Repsol Quimica
Isplen	Polypropylene, PP	Repsol Quimica SA
ITP	PU/polyester/polystyrene IPN	ICI
Iupiace	PPE alloys	Mitsubishi
Iupilon	Polycarbonate, PC	Mitsubishi Gas
Iupilon Polym. All.	Polycarbonate/ABS alloys	Mitsubishi Gas
Iupirex	Polyimide	Ube Industries
Iupital F40-03	Polyoxymethylene, POM	Mitsubishi Gas Chem.
Iupital-FL	Polyoxymethylene, POM, fluoropolymer blends	Mitsubishi Gas Chem./Franklin
Iupital-FU	Polyoxymethylene, POM, elastomer blends	Mitsubishi Gas Chem./Franklin
Ixan	Poly(vinylidene chloride) copolymers, PVDC	Solvay & Cie SA

(*continued*)

Ixef	Semi-aromatic polyamide, PA, polyarylamides, with GF or mineral	Solvay & Cie SA
Ixol	Polyetherpolyol halogened (for PU)	Solvay & Cie SA
Iztavil	Poly(vinyl chloride), PVC	Polimeros de Mexico
J		
J-Plast.	Thermoplastic elastomer, TPE	J-Von
Jet-Flex	Acrylonitrile-ethylene/propylene-styrene copolymer	Multibase, Inc.
Jonylon	Polyamide-6, polyamide-66, PA	BIP Chem. Ltd./ Polymix
JSR Excelloy CB	ABS/polycarbonate, alloys	Japan Synth. Rubber
JSR Excelloy GE	Polycarbonate/AES, alloys	Japan Synth. Rubber
JSR NE	NBR/EPDM blends	Japan Synth. Rubber
JSR NV	NBR/poly(vinyl chloride), alloys	Japan Synth. Rubber
Jupilon	Polycarbonate, PC MBS (now *Paraloid*™)	Mitsubishi Chem.
K		
K-15NF	Graphite fiber-filled polyethersulfone, PES	Thermofil, Inc.
K-20NF	Glass fiber-filled polyethersulfone, PES	Thermofil, Inc.
K-Resin	Butadiene-styrene copolymer, SBR	Phillips Chemicals
K-Resin SB Plastic	Styrene-butadiene copolymer, SB	Phillips 66 Co.
K-Resin	Styrene-butadiene copolymer, SB	Phillips Petrol. Chem.
K-Resin	Styrene/butadiene bl. copolymer Phillips	
K2-30FG	Glass-reinforced polyetheretherketone, PEEK	Thermofil, Inc.
K2-30NF	Graphite fiber-reinforced polyetheretherketone	Thermofil, Inc.
K2-50FG	Graphite fiber-reinforced polyetheretherketone	Thermofil, Inc.
Kadel	Polyetherketone, aromatic, PEAK	Amoco Performance Products
Kadon	ABS/SMA blends	Monsanto Chem. Co.
Kaladex	Poly(ethylene 2,6-naphthalene dicarboxylate)	ICI Films
Kalrez	Perfluoro elastomer parts, TFE/PVME blend	E. I. du Pont de Nemours
Kamax	Polyacrylates, polymethacrylates, and imidized poly(methyl methacrylate)s	Rohm and Haas/Ato Haas
Kane Ace B	Methacrylate-butadiene-styrene, MBS, modifiers for clear PVC (impact strength improvers)	Kanegafuchi Chemicals
Kane Ace	MBS acrylics	Kanegafuchi Chemicals
Kane Ace PA	Acrylic processing aids	Kanegafuchi Chemicals
Kane Ace	Polyamide chlorinated	Kanegafuchi Chemicals
Kane Ace XEL	Poly(vinyl chloride) cross-linked, XLPVC	Kanegafuchi Chemicals
Kane Ace-FM	Acrylic low gloss impact modifiers for PVC	Kanegafuchi Chemicals
Kaneka CPVC	Poly(vinyl chloride) chlorinated resins, XLPVC	Kanegafuchi Chemicals

Kaneka Enplex	ABS/PVC alloys compatibilized with α-methyl styrene-methyl methacrylate copolymer	Kanegafuchi Chemicals
Kaneka	Poly(vinyl chloride) chlorinated resins, XLPVC	Kanegafuchi Chemicals
Kaneka	Teralloy, PVC HDT modifiers	Kanegafuchi Chemicals
Kapton 300H	Polyimide, PI, electrical and thermal insul. film	E. I. du Pont de Nemours
Kapton H	PI, (pyromellitic anhydride/diaminodiphenylether)	E. I. du Pont de Nemours
Kasobond	Polyurethane elastomers for adhesives, PUR	Lu-Kas Polym. Chemie
Kasothan	Polyurethane thermoplastic, TPU	Lu-Kas Polym. Chemie
Kaurit-Leim	Urea-formaldehyde glue, UF	BASF Plastics
Kayocel	Cellulose compounds	Henley-McKenzie Feimann
KC 1257	PVC alloy with glutarimide acrylic copolymer for hot-fill bottles	Keysor-Century
KC1000	Poly(vinyl chloride), PVC, rigid, high impact	Keysor-Century
Kel-F Elastomer	Poly(vinylidene fluoride/chlorotrifluoroethylene)	Kellogg, USA
Kel-F	PCTFE fluoroelastomer	3M Ind. Chem.
Kel-F	Polychlorotrifluoroethylene, PCTFE	3M
Kel-F	PVDF/PCTFE blend	3M
Kelanex	Glass-filled poly(butylene terephthalate), PBT	Hoechst Celanese Corp.
Kelburon	Reactor-blended PP/EPDM; RTPO for self-supporting car bumpers	DSM Polymers Int.
Keldax	Filled polyethylenes, PE	E. I. du Pont de Nemours
Kelon	Mineral-reinforced polyamides, PA	Lati Eng. Thermoplast.
Kelprox	Thermoplastic olefinic elastomers, TPO	DSM Polymers Int.
Kelrinal	Chlorinated, rubber (CM)	DSM Polymers Int.
Keltan	Thermoplastic elastomers, EPDM, PP/EPDM	DSM Polymers Int.
Keltan TP	PP/EPDM blends with fillers	DSM Polymers Int.
Kematal	Polyoxymethylene (acetal), POM	Hoechst Celanese Corp.
Kenflex	Hydrocarbon resins	Kenrich
Kerimide	Polyimide, PI, for laminating and molding (TS)	Nippon Polyimide
Keripol	Polyester resins	Vynckier
Kermel	Poly(m-phenyleneisophthalamide), PPA	Rhône Poulenc
Kermel	Polyamide-imide; fibers, PAI	Rhône Poulenc
Kevlar	Poly(p-phenylene terephthalamide); fibers, resins	E. I. du Pont de Nemours
Keysor	Poly(vinyl chloride), PVC	Keysor-Century
KF Polymer	Poly(vinylidene fluoride), PVDF	Kureha
Kibisan PN	Acrylonitrile-styrene-acrylate copolymer, ASA	Chi Mei Ind. Co. Ltd.

(continued)

Kibisan	Styrene-acrylonitrile copolymer, SAN	Chi Mei Ind. Co. Ltd.
Kinel	Filled *bis*-maleimide-based molding polyimides	Rhône-Poulenc
KN-220	Polyethylenes, PE	Chevron Chem.
Koblend	Polycarbonate/AES and PC/ABS alloys	ECP Enimont Polym./ EniChem
Koblend PCA	Polycarbonate/ABS blends	Montedipe Milano
Kodapak PET	Poly(ethylene terephthalate), PET	Eastman Chem. Prod.
Kodapak	Poly(butylene terephthalate), PBT	Eastman Chem. Prod.
Kodar PETG	PETG, a thermoplastic copolyester of 1,4 cyclohexylene glycol and mixture of iso- and terephthalic acids	Eastman Chem.
Kodar	Thermoplastic polyesters	Eastman Chem.
Kodel	Polyester fiber	Eastman Chem.
Kodel-10	Poly(ethylene terephthalate), PET	Eastman Chem.
Kodel-2	Polybishydroxymethylcyclohexaneterephthalate	Eastman Chem.
Kollidon	Polyvinylpyrrolidone, PVP	BASF Plastics
Koppers	Unsaturated polyesters, UP	Koppers Co., Inc.
Koroseal	Poly(vinyl chloride)/PVF blends	BF Goodrich
Korton	Thermoplastic fluoropolymer alloy	Norton Performance Plast.
Kostil BV	Styrene-acrylonitrile copolymer, SAN, reinforced	Montepôlimeri
Kostil	Styrene-acrylonitrile copolymer, SAN	Montepôlimeri
Kralastic	Acrylonitrile-butadiene-styrene terpolymers, ABS	Uniroyal
Kralastic FVM	ABS/Poly(vinyl chloride) alloys	Uniroyal/Sumitomo
Kraton	Thermoplastic elastomers, TPE	Shell Chem. Co.
Kraton D1101	SBS three block thermoplastic elastomer	Shell Chem. Co.
Kraton D1107	SIS three block thermoplastic elastomer	Shell Chem. Co.
Kraton D1116	$(SB)_n$ multi block thermoplastic elastomer	Shell Chem. Co.
Kraton D1320X	$(SI)_n$ multi block thermoplastic elastomer	Shell Chem. Co.
Kraton D2103	SBS/HIPS alloys	Shell Chem. Co.
Kraton FG	SEBS functionalized with maleic or succinic anhydride (a PA impact modifier)	Shell Chem. Co.
Kraton G	SEBS blends	Shell Chem. Co.
Kraton G1650	SEBS three block thermoplastic elastomer	Shell Chem. Co.
Kraton G1701	SEP three block thermoplastic elastomer	Shell Chem. Co.
K-Resin	Styrene/butadiene block copolymer	Phillips Petrol.
Krystaltite	Poly(vinyl chloride) film, PVC	Allied Signal Inc
Krynac	Nitrile rubber, NBR; AN = 19–50 %	Polysar/Bayer AG
Krynac NV	NBR/Poly(vinyl chloride) alloys (34 % AN)	Polysar/Bayer AG
Krynac Xi	Carboxylated NBR with i = 1–9 % carboxylic	Polysar/Bayer AG
Krynac XN	NBR lightly cross-linked with AN = 29–35 %	Polysar/Bayer AG
KUI	Liquid crystal polyester, LCP	Bayer
Kureha KF	PVDF fluorocarbon, poly(vinylidene fluoride)	Kureha Corp.
Kydene/Kydex	Poly(vinyl chloride)/Poly(methyl methacrylate) alloys	Rohm and Haas

(continued)

Kydex lOO	Poly(vinyl chloride)/acrylic alloy sheets	Kleerdex Co.
Kynar	Poly(vinylidene fluoride), PVDF	Elf Atochem
L		
L-030 Z	Polypropylene, PP	Aristech Chem.
L-20 FG	Poly(phenylene ether), PPE, glass fiber filled	Thermofil, Inc.
L-20 NF	Poly(phenylene ether), PPE, graphite filled	Thermofil, Inc.
L-30 FG	Poly(phenylene ether), PPE, glass fiber filled	Thermofil, Inc.
L-30 NF	Poly(phenylene ether), PPE, graphite filled	Thermofil, Inc.
L-40 AF	Poly(phenylene ether), PPE, aluminum filled	Thermofil, Inc.
L-9900	Poly(phenylene ether), PPE, filled	Thermofil, Inc.
L.C.P.	Liquid crystal polymers, LCP	E. I. du Pont de Nemours
L1, L2. L3	Poly(phenylene ether), PPE, glass fiber filled	Thermofil, Inc.
Lacovyl	Poly(vinyl chloride), PVC, bulk polymerized	Elf Atochem
Lacovyl	Poly(vinyl chloride), PVC, emulsion polymerized	Elf Atochem
Lacovyl	Poly(vinyl chloride), PVC, suspension polymerized	Elf Atochem
Lacovyl	Vinyl chlorine-*co*-vinyl acetate, VC/VAc	Elf Atochem
Lacqrene	Crystal, high-impact polystyrene, HIPS	Elf Atochem
Lacqrene	Polystyrene, PS	Elf Atochem
Lacqrene	Styrene-acrylonitrile copolymer, SAN	Elf Atochem
Lacqsan	Styrene-acrylonitrile copolymer, SAN	Aquitaine, France
Lacqtene HD	High-density polyethylene, HDPE	Elf Atochem
Lacqtene	Low-density polyethylene, LDPE	Elf Atochem
Lacqtene LX	Linear low-density polyethylene, LLDPE	Elf Atochem
Lacqvyl	Polyvinylchloride, PVC	Elf Atochem
Ladene	LLDPE, MDPE, PS resins (all grades)	SABIC Marketing Ltd.
Laminac	Polyester resin	Cyanamid
Lanital	Fiber from milk protein, CS	SNIA Viscosa, Italy
LARC-TPI	Polyimides, PI	NASA/Mitsui Toatsu Chem.
LARC-13	Polyimides, PI, for structural adhesives to metal	NASA Langley RC
Laril	Modified poly(phenylene ether), *m*-PPE, alloys	Lati Eng. Thermoplast.
Larodur	Acrylic resins	BASF Plastics
Larton	Reinforced poly(phenylene sulfide), PPS	Lati Eng. Thermoplast.
Lastane	Polyurethane elastomers, PUR	Lati Eng. Thermoplast.
Lastiflex	Poly(vinyl chloride)/terpolymer alloy	Lati Eng. Thermoplast.
Lastil	SAN; reinforced or not	Lati Eng. Thermoplast.
Lastilac 09-11	ABS/polycarbonate alloy	Lati Eng. Thermoplast.
Lastilac	ABS; reinforced or not	Lati Eng. Thermoplast.
Lastirol	Polystyrene, HIPS	Lati Eng. Thermoplast.
Lasulf	Polysulfone, PSU	Lati Eng. Thermoplast.
Latamid 6	Polyamide-6; reinforced or not, PA-6	Lati Eng. Thermoplast.
Latamid 12	Polyamide-12; reinforced or not, PA-12	Lati Eng. Thermoplast.
Latamid 66	Polyamide-66; reinforced or not, PA-66	Lati Eng. Thermoplast.
Latamid 68	Polyamide-68; reinforced or not, PA-68	Lati Eng. Thermoplast.

Latan	Polyoxymethylene; reinforced or not, POM	Lati Eng. Thermoplast.
Latene EP	Impact modified polypropylene, PP	Lati Eng. Thermoplast.
Latene HD	High-density polyethylene, HDPE	Lati Eng. Thermoplast.
Latene	Polypropylene; reinforced or not, PP	Lati Eng. Thermoplast.
Later	Reinforced polyester resins	Lati Eng. Thermoplast.
Latilon	Polycarbonate; reinforced or not, PC	Lati Eng. Thermoplast.
Lavasint	Ethylene-vinyl alcohol copolymer, EVAl	Bayer AG
LCP	Liquid crystal polymers, LCP	RTP Co.
LDPE	Low-density polyethylene, LDPE	Dow Chem. Co.
Le Vinychlore	Poly(vinyl chloride) compounds, PVC	Saplast
Leacril	Polyacrylonitrile, PAN	ACSA, Italy
Leguval	Unsaturated polyester, UP, for SMC or BMC	Bayer AG/Miles
Leguval	Unsaturated polyester resin, UP	DSM
Leguval	Unsaturated polyester, UP	Bayer AG/Miles
Lekutherm	Epoxy resins, EP	Bayer AG/Miles
Leona HR100	Polyamide-6,6, foam grade + 30 % glass fiber	Asahi Chemical
Levaflex	Thermoplastic elastomers, TPE	Bayer AG/Miles
Levapren	Ethylene-vinyl acetate copolymer, EVAc	Polysar/Bayer AG
Lewatit	Ion-exchange resins	Bayer AG/Miles
Lexan	Polycarbonate resins or blends, toughened by PO or elastomers; reinforced or not	GE Plastics
Lexan PPC	Polyphthalate-carbonate resins or blends, PPC	GE Plastics
Lexan WR	Fluorocarbon polytetrafluoroethylene, PTFE	GE Plastics
Lexan XT	Poly(carbonate-*co*-silicone) copolymer	GE Plastics
LF-1	Thermoplastic polyesters	GE Plastics
Limera	Styrenic blends with a variety of polymers: PS, PVC, PMMA, ABS, PPE; reinforced or not	Dainippon Ink & Chem.
LISA	Polycarbonate-based light conducting polymers	Bayer AG/Miles
Litrex	Low-density polyethylene, LDPE	PCD France
LLD	Linear low-density polyethylene, LLDPE	Dow Chem. Co.
Lomod	Copolyetherimide esters elastomer blends, PBT/SBS, TPE	GE Plastics
Lonox	Polyethylene, PE	Union Carbide Co., Inc.
Lotader AX	EEVA-glycidylmethacrylate, E-EA-GMA GMA content ca. 8 wt%	Norsolor/Elf Atochem
Lotader	Ethylene-ethylacrylate-vinyl acetate, EEVA	Norsolor/Elf Atochem
Lotrene	Low-density polyethylene, LDPE	S.F.PE
Lotrex	LLDPE and VLLDPE	S.F.PE
Lotryl	EBA and EDA copolymers	Elf Atochem
LP	Polyethylenes, PE	Aristech Chem.
LPP	Calcium carbonate-filled polypropylene, PP	Ferro Corp.
LR 3320	Thermoplastic elastomer, TPE	GE Plastics
Lubricom	–	Comalloy
Lubricomp	Lubricated, wear-resistant engineering polymers, filled or not, viz., PAs	ICI/LNP Eng. Plastics

(continued)

Lubricomp A	ABS/PTFE or PDMS with 0–30 % glass fiber	ICI/LNP Eng. Plastics
Lubricomp Fulton/K	POM + 0–25 PTFE, 0–2 % PDMS, filler	ICI/LNP Eng. Plastics
Lubriloy	Internally lubricated resins	ICI/LNP Eng. Plastics
Lucalen	Ethylene/acrylic acid/acrylate copolymers, EAA	BASF Plastics
Lucalor	Chlorinated poly(vinyl chloride), CPVC	Elf Atochem
Lucel	Polyoxymethylene (acetal), POM	S.P.C.I.
Lucite	Poly(methyl methacrylate) and copolymers, PMMA	E. I. du Pont de Nemours
Lucky ABS	Acrylonitrile-butadiene-styrene terpolymer, ABS	Standard Polymers
Lucobit	Ethylene copolymer/bitumen blend	BASF Plastics
Lucoflex	Poly(vinyl chloride), PVC	Péchiney, France
Lucolene/Lucorex	Poly(vinyl chloride) compounds, PVC	Elf Atochem
Lucovyl	Poly(vinyl chloride) resin, PVC	Elf Atochem Canada
Lucryl	Poly(methyl methacrylate), PMMA	BASF Plastics
Luparen	Polypropylene, PP	BASF Plastics
Luphen	Phenol-formaldehyde resins, PF	BASF Plastics
Lupolen	Ethylene-vinyl acetate copolymer, EVAc	BASF A.-G.
Lupolen O 250H	LDPE blends with polyisobutylene	BASF Plastics
Lupolen	Polyethylenes: LDPE, LLDPE, MDPE, HDPE	BASF Plastics
Lupox	Thermoplastic polyesters; reinforced or not	S.P.C.I.
Lupoy	ABS alloys	S.P.C.I.
Lupragen/Lupranat	Polyurethanes, PU	Elastogran France
Lupranol/Lupraphen	Polyurethanes, PU	Elastogran France
Luprenal	Acrylic resin	BASF Plastics
Luran	Styrene-acrylonitrile copolymers and blends, SAN, ASA	BASF Plastics
Luran S	SAN blended with grafted acrylic ester elastomer, ASA, and its blends	BASF Plastics
Luranyl	PPE/styrene-butadiene copolymer blend, reinforced with up to 30 wt% glass fiber or not	BASF Plastics
Lustran	ABS, SAN, alloys with PVC, etc.	Monsanto Chem. Co.
Lustran ABS	Acrylonitrile-butadiene-styrene terpolymer, ABS, high gloss, general purpose	Monsanto Chem. Co.
Lustran Elite	ABS, low gloss, high flow grades	Monsanto Chem. Co.
Lustran FRABS	ABS, flame-retardant grades	Monsanto Chem. Co.
Lustran SAN	Styrene-acrylonitrile copolymer	Monsanto Chem. Co.
Lustran Ultra	ABS, for injection molding	Monsanto Chem. Co.
Lustrex	Polystyrene, PS	Monsanto Chem. Co.
Lustropak	Acrylonitrile-butadiene-styrene terpolymers, ABS	Monsanto Chem. Co.
Lutonal	Polyvinyl ethers	BASF Plastics
Luvican	Polyvinylcarbazole, PVK	BASF Plastics
Luvitherm	Poly(vinyl chloride) foil, PVC	BASF Plastics
Luxis	Polyamides, PA-66	Westover Color Chem.
Lycra	Diisocyanates/polyether elastomeric fibers	E. I. du Pont de Nemours
Lynex	PPE/polyamide blends	Asahi Chemical

(continued)

M

M-2014	Thermoset melamine, MF	ICI/Fiberite
M-511, M-521	MBS modifiers for PC, PEST, PVC	Kaneka
MA 5000	Polystyrene, PS	Chevron Chem.
Mablex	ABS/polycarbonate alloys	Mazzucchelli Cell.
MABS	Glass fiber-reinforced ABS	Modified Plastics
MAC	Glass fiber-reinforced polyoxymethylene, POM	Modified Plastics
Macepreg	Preimpregnated polyesters	Mecelec Holding
Maflex	Butadiene-styrene copolymer, SB	Sic Plastics France
Magnacomp	Polyamide-6 filled with barium ferrite	LNP Engineering
Magnum	Acrylonitrile-butadiene-styrene terpolymer, ABS	Dow Chem. Co.
Makroblend DP	Polycarbonate/PET/HDPE alloys; general purpose	Bayer AG/Miles, Inc.
Makroblend EC 900	PVC/elastomer, high-impact blends	Bayer AG/Miles, Inc.
Makroblend	PBT/elastomer	Bayer AG/Miles, Inc.
Makroblend PR	Polycarbonate/PBT or PET alloys	Bayer AG/Miles, Inc.
Makroblend UT	Polycarbonate/PET/ABS alloys, filled or not	Bayer AG/Miles, Inc.
Makrofol	Polycarbonate films, PC or PC/PVF	Bayer AG/Miles, Inc.
Makrolon	Polycarbonate, PC, and impact-modified PC, containing <6 % butyl acrylate-methacrylate elastomer; blends reinforced or not	Bayer AG/Miles, Inc.
Malecca	SMI blends with ABS or PBT	Denki Kagaku
Malon	Thermoplastic polyesters	MA Industries
Maragla	Epoxy resins, EP	Acme Div. of Allied
Maranyl	Impact modified, PA-66 or PA-6/elastomer blends, mineral filled	ICI Adv. Mater.
Marlex	Polyethylenes, PE	Phillips 66 Co.
Marlex BMN	Polyethylene, PE	Phillips 66 Co.
Marlex CL	Polyethylene, PE	Phillips 66 Co.
Marlex CP	Polypropylene, PP	Phillips 66 Co.
Marlex EHM	Polyethylene, PE	Phillips 66 Co.
Marlex ER	Mineral-filled polyethylene, PE	Phillips 66 Co.
Marlex GP	Polypropylene, PP	Phillips 66 Co.
Marlex HGL	Polypropylene, PP	Phillips 66 Co.
Marlex PE	Polyethylene, PE	Phillips 66 Co.
Marnyte	Poly(ethylene terephthalate); glass filled or not, PET	Bamberger Polymers
Marvalloy	Acrylic-modified polystyrene	Marval Industries
Marvylan	Poly(vinyl chloride) compounds, PVC	L.V.M. France
Marvyloy	ABS/poly(vinyl chloride) alloys	DSM
MAT-20FG	Glass fiber-filled polyoxymethylene, POM	Modified Plastics
Mater-Bi	Starch-based biodegradable thermoplastics	Novamont
MB 1000	Unsaturated polyesters, UP	Mar Bal Inc.
MC 2100	Polystyrene, PS	Chevron Chem.
MDI	Polyurethane, PU	Dow
Megarad	Polycarbonate, PC	Dow Chem. Co.
Megol	Elastomeric compounds	Polymix

Melacoll	Melamine-formaldehyde resins, MF	Piesteritz
Melan	Melamine-formaldehyde, urea-formaldehyde	Henke
Meldin 2001	Polyimide, PI; for high-temperature electrical parts	Furon Dixon
Meldin 2021	PI + 15 % graphite; high-temperature applications	Furon Dixon
Meldin 2030	PI + 30 % PTFE; high-temperature bearings	Furon Dixon
Melinar PET	Poly(ethylene terephthalate), PET	ICI Adv. Mater.
Melinex	Poly(ethylene terephthalate) films, PET	ICI Films
Melinite	Poly(ethylene terephthalate), PET	ICI Adv. Mater.
Melmex	Melamine-formaldehyde molding powders, MF	BIP Chemicals Ltd.
Melochem	Melamine-formaldehyde, MF	C.P.R.I.
Melolam	Melamine-formaldehyde laminating resins, MF	Ciba-Geigy Ltd.
Melopas	Melamine molding compound, MF	Ciba-Geigy Ltd.
Meraklon	Polypropylene, PP	Montecatini
Merlon	Polycarbonate, PC; PC/PO blends	Bayer AG/Miles
Mertex	TPU blends	Bayer AG/Miles
Metablen P-522	Acrylic processing aid for PVC blow molding	Mitsubishi Rayon Co., Metco
Metablen P-570	Acrylic processing aid for PVC siding	Mitsubishi Rayon Co., Metco
Metamarble	Polycarbonate/PMMA alloy	Teijin Chem. Ltd.
Methafil	Mica- or glass fiber-filled polymethylpentene	Akzo/DSM
Methocel	Ethyl and methyl cellulose	Dow
Methylon	Phenolic resin, PF	Cain Chem. Inc.
MG-6	Silica-filled epoxy resins, EP	Dexter Corp.
Mikrothene FE, MU	Ethylene-vinyl acetate copolymer, EVAc	Quantum Chem.
Mikrothene FN	Polyolefins, PO	Quantum Chem.
Mikrothene HD, MD	Polyethylenes, PE	Quantum Chem.
Milastomer	TP elastomer	Mitsui
Milkon	PPS/PTFE blend	Tribol. Ind. Inc.
Millathane	Thermoplastic polyurethane elastomer, TPE	TSE Industries, Inc.
Mindel	Polysulfone, PSF or PSO, blends; filled or not	Amoco Performance Product
Mindel A	Polysulfone/ABS blends; filled or not	Amoco Chem. Co.
Mindel B	Polysulfone/PET blends; filled or not	Amoco Chem. Co.
Minlon	PA-66 or PA-66/ionomer alloy + mineral/glass	E. I. du Pont de Nemours
Mipolam	Poly(vinyl chloride), PVC	Dynamit Nobel
Miramid	Polyamides, PA	Soprochim
Miraspin	Polyethylenes, PE	Mitsui Petrochem.
Mirathen	Low-density polyethylene, LDPE	Soprochim
Mirlon	Polyamide, PA	Viscose Suisse
MN-6	Glass fiber-filled polyamide-6, PA-6	Modified Plastics
MN-6/6	Glass fiber-filled polyamide-66, PA-66	Modified Plastics
Moatek	Ethylene-butene-1, or octene-1, copolymer	Idemitsu Petrochem.

(*continued*)

Mobil MX	Polystyrenes, PS	Mobil Chem. Co.
Mobil	Polyethylenes, PE	Mobil Chem. Co.
Mobil PS	Polystyrenes, PS	Mobil Chem. Co.
Modar	Urethane-modified acrylic resin	ICI Chem. Polym.
Modylen	PP copolymer/EPDM blends	Tiszai Vegyi Komb.
Moldex A	ABS/polycarbonate alloy	Anic
Moltopren	Foam material based on polyurethane, PU	Bayer AG/Miles
Monkalloy P	PC/ABS alloys with glass fiber	Monsanto-Kasei Co.
Monocast	PA directly polymerized into shapes	Polymer Corp.
Moplen	PP homopolymers and copolymers with ethylene	Himont/Montedison
Mor-Thane	Thermoplastic polyurethanes, TPU	Morton Thiokol
Morthane	Thermoplastic polyurethane, TPU	Morton International, Inc
Morvanflex	Thermoplastic elastomers, TPE	S.P.2.I
Mowicoll	Poly(vinyl acetate) dispersions, PVAc	Hoechst Celanese Corp.
Mowilith	Poly(vinyl acetate), PVAc	Hoechst Celanese Corp.
Mowiol	Poly(vinyl alcohol), PVAl	Hoechst Celanese Corp.
Mowital	Poly(vinyl butyral), PVB	Hoechst Celanese Corp.
MPBT-FG	Glass fiber-filled polybutylene terephthalate, PBT	Modified Plastics
MPC	Phenolic resin, PF	Rogers Corp
MPC-FG	Glass fiber filled polycarbonate, PC	Modified Plastics
MPP-FG	Glass fiber filled polypropylene, PC	Modified Plastics
MPPE	PA/PPE alloys	Asahi Chem. Ind.
MPPO-FG	Glass fiber-filled poly(phenylene ether), PPE	Modified Plastics
MPSL-FG	Glass fiber-filled polysulfone, PSU	Modified Plastics
Multi-Flam	Polypropylene	Multibase, Inc.
Multi-Flex	SEBS (Kraton G)-based TPEs	Multibase, Inc.
Multi-Hips	Polystyrene, PS, HIPS	Multibase, Inc.
Multi-Pro	Polypropylene	Multibase, Inc.
Multi-San	SAN copolymer	Multibase, Inc.
Multibase ABS	Acrylonitrile-butadiene-styrene copolymer	Multibase, Inc.
Multibase	ABS	Multibase, Inc.
Multibase	Reinforced polypropylene, PP	Multibase, Inc.
MultiChem	Vinyl compounds	Colorite Plastics
Multilon	Polycarbonates and PC/ABS alloys	Teijin Chem. Ltd.
Multipet	Polyethylene-polyester multilayer film	Wihuri Oy Wipak
MX-5350	Polystyrene/elastomer blends	Mobil
Mylar	Poly(ethylene terephthalate) film, PET	E. I. du Pont de Nemours

N

N05FG	Polyamide-6 with 5 % glass fiber, PA-6	Thermofil, Inc.
N15-40NF	Polyamide-610 with 40 % graphite fiber, PA-610	Thermofil, Inc.
N3-20FG	Polyamide-66 with 20 % glass fiber, PA-66	Thermofil, Inc.
N40fm	Polyamide-6 with 40 % glass fiber and mineral	Thermofil, Inc.
N40MF	Polyamide-6 with 40 % mineral, PA-6	Thermofil, Inc.
N5	PA/ABS alloys containing up to 30 wt% GF	Thermofil, Inc.
N6-30MF	Polyamide-612 with 30 % mineral, PA-612	Thermofil, Inc.
N66G-30	Polyamide-66 with 30 % glass fiber, PA-66	Polymer Composites
N8-30FG	Polyamide-11 with 30 % glass fiber, PA-11	Thermofil, Inc.
N9-30FG	Polyamide-12 with 30 % glass fiber, PA-12	Thermofil, Inc.
Nafion	Perfluorinated membranes	E. I. du Pont de Nemours
Nalcite	Ion-exchange resin	National Aluminate
NAP	Polyarylate, amorphous; 3,3′, 5,5′-tetramethyl-dihydroxydiphenylmethane copolymer	Kanegafuchi Chem.
Napryl	Polypropylene, PP	Péchiney, France
NAS 30	Poly(styrene-*co*-methyl methacrylate), transparent	Novacor Chemicals
NAS 50	Poly(methyl methacrylate-*co*-styrene), transparent	Novacor Chemicals
Natene	Polyethylenes, PE	Péchiney, France
Natsyn	Polyisoprene	Goodyear
Naxell	Polycarbonate (recycled)	MRC Polymers
Naxols/Naxoreses	Polyester resins for paints and varnishes	Convert
NCH	"Nylon-Clay Hybrid"; polyamide-6 with montmorillonite particles 0.1–0.2 nm diameter; *nanometer composite* developed by Toyota Research Corp.	Ube Industries, Ltd.
Neo Cis	Elastomers	Enimont/Safic-Alcan
Neo-zex	Polyethylenes, PE	Mitsui Petrochem.
Neoflon FEP	Fluorinated ethylene-propylene, FEP	Daikin
Neoflon PCTFE	Polychlorotrifluoroethylene, PCTFE	Daikin
Neoflon PFE	Perfluoroalkoxyether, PFE	Daikin
Neoflon PVDF	Poly(vinylidene fluoride), PVDF	Daikin
Neopolen	PE/polypropylene foam	BASF Plastics
Neopolen	Polystyrene/polyethylene, PS/PE, blend	BASF Plastics
Neoprene	Polychloroprene, CR	E. I. du Pont de Nemours
Neoprene	Synthetic polychloroprene rubber	E. I. du Pont de Nemours
Neosepta F	Ionic fluoropolymer membrane	Tokoyama Soda
Neoxil	Unsaturated polyester resin, UP	DSM
Neste Oxo	Plastisols, PVC	Neste Chim.
Neste Polystyrene	Polystyrene, PS	Neste Chim.
Neste PP	Polypropylene, PP	Neste Chim.

Newcon	Reactor made TPO/PP alloys for car bumpers	Chiso Corp.
New TPI	Polyimides; reinforced or not, PI	S.P.C.I.
Niax	Polyether from glycerin or hexane-1,2,6-triol	Union Carbide Co.
Nike	Cellulose nitrate, CN	Punda Inc.
Nipoflex	Ethylene-vinyl acetate copolymer	Toyo Soda
Niopolon	Polyethylene	Toyo Soda
Nipeon AL	ABS/poly(vinyl chloride) (50 %) alloy	Zeon Kasei Co.
Nipol AR	Polyacrylate elastomers	Nippon Zeon Co., Ltd.
Nipol Carboxylated	Nitrile rubbers lightly carboxylated, NBR	Nippon Zeon Co., Ltd.
Nipol DP 5120P	NBR modifiers for clear PVC	Nippon Zeon Co., Ltd.
Nipol	Nitrile elastomers, NBR, AN = 21–51 % also liquids, powders, or crumbs	Nippon Zeon Co., Ltd.
Nipol Polyblends	NBR/PVC (30–50 %) elastomeric alloys plasticized or not	Nippon Zeon Co., Ltd.
Nipol Terpolymer	Acrylonitrile-butadiene-isoprene elastomers; grade DN-224 contains 50 % DOP	Nippon Zeon Co., Ltd.
Nissan 1000–3000	Polyethylenes, PE	Nissan Chem. Ind.
Nitriflex	Acrylonitrile-butadiene-styrene copolymer, ABS	A. Schulman, Inc.
Nitrilene	Poly(vinyl chloride)/BR/ABS alloys	Rhein Chemie
Nitron	Cellulose nitrate, CN	Monsanto Chem. Co.
Nitrovin	Nitrile or polyurethane rubber/PVC, alloys	Vi-Chem Corp.
Nivionplast	Polyamides, PA-6, PA-66	ECP Enimont Polymeri
Nivionplast	Polyamide-6, PA-6	EniChem
Noblen	Polypropylene, PP	Mitsubishi Petrochem.
Noblen	Polypropylene; filled or not, PP	Sumitomo Chem. Co.
Nolimid 32	Polyimides; for junction coatings, PI	Rhône-Poulenc
Nomex	Poly(*m*-phenyleneisophthalamide) fibers, PPA	E. I. du Pont de Nemours
Norasol	Polycarboxylate, water soluble	Elf Atochem
Norchem	Polyethylenes, PE	Quantum Chem.
Norchem	Polyethylenes, reinforced or not, PE	Norchem, Inc.
Norchem	Polyolefins: LDPE, HDPE, LLDPE, PP	Enron Chem. Co.
Nordbak 7451	Epoxy or polyurethane	Rexnord Chem.
Nordel	EPDM, hydrocarbon rubbers	E. I. du Pont de Nemours
Norsodyne	Polyester resins	Norsolor/Please
Norsoflex	Polyethylenes: LLDPE and VLLDPE	S.F.PE
Norsolene	C-9 hydrocarbon resins, PE	Elf Atochem
Norsomix	Polyester resin compounds	Norsolor
Norsophen	Phenol-formaldehyde resins, PF	Norsolor
Norsorex	Polynorbornene elastomers	Cyanamid/Atochem/ Nippon Zeon Co.
Nortuff	Polypropylene, PP	Quantum Chem. Co.
Norvinyl	Poly(vinyl chloride), PVC	Norsk Hydro/Hydro PLast

(*continued*)

Noryl	PPE thermoplastic blends, reinforced or not	GE Plastics
Noryl BN	PPE/HIPS alloys; reinforced or not	GE Plastics
Noryl FN	Foamable PPE/HIPS alloys	GE Plastics
Noryl GFN	Glass fiber-filled PPE/HIPS alloys	GE Plastics
Noryl GTX	PA/PPE(30 %) blend, reinforced or not	GE Plastics
Noryl Plus	PPE/HIPS/PA alloys	GE Plastics
Nova PC	Polycarbonate, PC; with flame retardant or not	Nova Polymers, Inc.
Novablend	Poly(vinyl chloride), PVC; rigid	Novcor
Novablend 4510	PVC alloy with glutarimide acrylic copolymer for hot-fill bottles	Novatech Plastics & Chem.
Novacor	–	Novacor
Novaccurate	Liquid crystal polyester with glass fiber or not	Mitsubishi Chem.
Novadur	Poly(butylene terephthalate), PBT	Mitsubishi Chem.
Novadur ST520	Poly(butylene terephthalate) with 20 % acrylic rubber	Mitsubishi Chem.
Novalar	Elastomeric grafting copolymer to be used in ABS, PVC, PC, PBT, TPU, EP, acrylics, etc., for improvement of impact strength and ductility	Nova Polymers, Inc.
Novalast	Thermoplastic olefins, TPE	Nova Polymers, Inc.
Novalene	TPO compound from recycled PE or PP; 50–90 Shore A durometer	Nova Polymers, Inc.
Novalene RF	TPO/TPE impact modifier for PE or PP	Nova Polymers, Inc.
Novalloy 9000	Poly(vinyl chloride)/ABS alloy, PVC/ABS	Novatech Plastics & Chem.
Novalloy-A	PA-6 or PA-66 blends with ABS	Daicel Chem. Ind., Ltd.
Novalloy-B	PBT blends with ABS, reinforced or not	Daicel Chem. Ind., Ltd.
Novalloy-S	ABS/polycarbonate blends, reinforced or not	Daicel Chem. Ind., Ltd.
Novamate A	AAS/polycarbonate blends	Mitsubishi Chem.
Novamate B	ABS/polycarbonate blends	Mitsubishi Chem.
Novamid	Polyamides	Mitsubishi Chem.
Novamid ST220	Polyamide/elastomer blends	Mitsubishi Chem.
Novamid X21	Semi-aromatic amorphous polyamide	Mitsubishi Chem.
Novapet	Poly(ethylene terephthalate) with glass fiber or not	Mitsubishi Chem.
Novapol	Polyethylenes	Novacor
Novapol LD	Low-density polyethylene, LDPE	Novacor
Novapol LL	Linear low-density polyethylene, LLDPE	Novacor
Novapol, HD	High-density polyethylene, HDPE	Novacor
Novapps	Poly(phenylene sulfide) blends	Mitsubishi Chem.
Novarex AM	PC/elastomer with glass fiber or not	Mitsubishi Chem.
Novarex	Polycarbonates, PC	Mitsubishi Chem.
Novatec P	Polypropylenes, PP	Mitsubishi Chem.
Novatec	Polyethylenes, PE	Mitsubishi Chem.
Novex	Low-density polyethylene, LDPE	BP Chemicals Limited
Novimide	Epoxy resins, EP	Furane Products
Novodur	Acrylonitrile-butadiene-styrene terpolymer, ABS	Bayer AG/Miles
Novolac	Phenol-formaldehyde resins, PF	Perstorp Bakelite S.A.

Novolen KR	Polypropylene/EPR blend	BASF Plastics
Novolen	Polypropylene, PP, also filled and reinforced	BASF Plastics
Novolen	Rubber modified PP/PE blend	BASF Plastics
Novon	Based on starch, biodegradable polymers for extrusion, injection molding, or thermoforming	Warner-Lambert/ Novon Co.
Nucrel	Ethylene-methacrylic acid copolymer, EMAA	E. I. du Pont de Nemours
Nupol	Thermoset acrylics	Freeman Chem. Corp.
NX-7000	PPE/PA-6 alloys for automobile applications	Mitsubishi Gas Chem.
NX-9000	PPE/polyamide-66 alloys	Mitsubishi Gas Chem.
Ny-Kon	PA-6 or PA-66 internally lubricated with MoS_2	LNP Eng. Plastics
Nybex	Polyamides, PA-6,PA-66, impact modified	Ferro Corp.
Nycoa 1485	Polyamide-6 with PE toughened blends	Nylon Corp. of America
Nycoa 2084	Polyamide-6 with EEA toughened blends	Nylon Corp. of America
Nycoa 7551	Polyamide-6 with EPR toughened blends	Nylon Corp. of America
Nydur	Polyamide, PA/PO blends, fiber reinforced or not	Bayer AG/Miles
Nylafil G	Polyamide-6/elastomer; glass or carbon fibers	Akzo/DSM/Wilson-Fiberfil
Nylafil J-1	Polyamide-66/elastomer; glass or carbon fibers	Akzo/DSM/Wilson-Fiberfil
Nylafil J-2	Polyamide-610/elastomer blend; glass fibers	Akzo/DSM/Wilson-Fiberfil
Nylamid	Polyamide-6 or polyamide-66; reinforced or not, PA	Polymer Service
Nylatron GS Nylon	Polyamides; glass, mineral, or MoS_2, in shapes	Polymer Corp.
Nylon 6T	Poly(hexamethylenediamine-terephthalic acid)	Hoechst Celanese Corp.
Nylon 7000	Polyamide/elastomer blend	Hoechst Celanese Corp.
Nylon Celanese	Polyamides; reinforced or not, PA	Hoechst Celanese Corp.
Nylon	Generic name for polyamides, PA	E. I. du Pont de Nemours
Nylon MXD	Polyamides, PA	Mitsubishi Gas
Nyltex	Polyamides, PA	Vecoplas
Nypel	Polyamide-6; reinforced or not, PA-6	Allied Signal Inc
Nyref	Semicrystalline polyamides N-MXD6, PA-N	Solvay & Cie SA
Nyrim	PA-block copolymers	DSM
O		
Oldodur	Integral-skin-rigid foams	Buesting & Fasch Co.
Oldofill	Packing foams	Buesting & Fasch Co.
Oldoflex	Integral skin, flexible foams	Buesting & Fasch Co.
Oldotherm	Rigid foams	Buesting & Fasch Co.

Oleflex	TPO blend of PE, PP, and α-olefin random copolymer.	Showa Denko K. K.
Olehard	Filled polypropylene	Chiso America
Ontex ABX, APE	PP/EPDM – elastomer/binder blends	Dexter Corporation.
Oppanol B	Polyisobutylene, PIB	BASF Plastics.
Oppanol C	Polyvinylisobutyl ether, PVI	BASF Plastics.
Oppanol O	Isobutylene-styrene copolymer (9:1)	BASF Plastics
Oppanol	Polyisobutylene, PIB	BASF Plastics
Optema	Ethylene-maleic anhydride, EMA copolymers	Exxon Chem.
Optix	Acrylic resins	Plaskolite
Opto 90	Epoxy resins, EP	ICI/Fiberite
Optum	Polypropylene/TPO alloys, reinforced	Ferro Corp.
Orevac	Ethylene-vinyl acetate copolymers, EVAc	Elf Atochem
Orgablend	Polyamide/polypropylene recycled alloys, PA/PP	Elf Atochem
Orgaflex	Polyphosphazene	Elf Atochem
Orgalan	Polycarbonate, PC	Elf Atochem
Orgalloy R 60ES	Polypropylene/polyamide-6, CO_2, H_2O barrier	Elf Atochem
Orgalloy R 6000	Polypropylene/polyamide-6 alloys, PP/PA-6 with up to 30 wt% GF	Elf Atochem
Orgalloy R 6600	Polypropylene/polyamide-66 alloys, PP/PA-66	Elf Atochem
Orgamide	Polyamide-6, PA-6	Elf Atochem
Orgasol	Ultrafine powder polyamides, PA	Elf Atochem
Orgater	PBT, PBT/EVA/PEBA alloys	Elf Atochem
Orlon	Polyacrylonitrile, PAN	E. I. du Pont de Nemours
Oroglas	Polyacrylates and polymethacrylates	Rohm and Haas
OS0100	Epoxy resins, EP	Dexter Corp.
OS2000	Epoxy resins, EP	Dexter Corp.
Owens-Corning E-	Unsaturated polyesters, UP	Owens/Corning
Oxy 3700	Poly(vinyl chloride), PVC	Occidental Chem. Corp.
Oxyblend	Poly(vinyl chloride), PVC, elastomer blends	Occidental Chem. Corp.
Oxyclear	Poly(vinyl chloride) rigid formulation, PVC	Occidental Chem. Corp.
Oxyclear 4190	PVC alloy with glutarimide acrylic copolymer for hot-fill bottles	Occidental Chem. Corp.
Oxyester	Polyurethanes, PU	Hüls AG
Oxytuf	Poly(vinyl chloride), PVC/EPDM blends	Occidental Chem. Corp.
P		
P-2000	Unsaturated polyesters, UP	Industrial Dielect.
P-9900-	Polypropylene; filled or not, PP	Thermofil, Inc.
P-xyBG	Polypropylene with xy wt% glass beads, PP	Thermofil, Inc.
P-xyCC	Polypropylene with xy wt% $CaCO_3$, PP	Thermofil, Inc.
P-xyFG	Polypropylene with xy wt% glass fibers, PP	Thermofil, Inc.

P-xyMF	Polypropylene with xy wt% mineral, PP	Thermofil, Inc.
P-xyMI	Polypropylene with xy wt% mica, PP	Thermofil, Inc.
P-xyTC	Polypropylene with xy wt% talc, PP	Thermofil, Inc.
P.M.C.	Gel coats	Synres-Almoco
P1-xyFG	Polypropylene with xy wt% of glass fiber, PP	Thermofil, Inc.
P1120	Polypropylene filled with mineral and glass, PP	MA Industries
PA66-110	Polyamide-66; filled or not, PA-66	MRC Polymers Inc.
PAF-200 to 600	Polyoxymethylene with 10–30 wt% glass, POM	Polyfil, Inc.
Palapreg	SMC/BMC resins, resin system	BASF Plastics
Palatal	Unsaturated polyester resins, UP	BASF Plastics
Palesit	Silicones	S.P.C.I.
Panapol	Polybutylene, PB	Exxon Chem.
Panlite	Polycarbonates; filled or not, PC	Teijin Chem. Ltd.
Pantalast	Poly(vinyl chloride), PVC/EVAc alloys	Pantasote Inc.
Paracril AZO	Nitrile rubber/Poly(vinyl chloride), NBR/PVC alloy	Uniroyal Chemical
Parad	Photopolymer, resistant and dielectric	E. I. du Pont de Nemours
Paraglas	Cast acrylic sheet, PMMA	Degussa AG
Paralac	Polyester resin, UP	ICI Adv. Mater.
Paraloid EXL-3361	Acrylic impact modifier for PC and its blends	Rohm and Haas
Paraloid EXL-3657	MBS impact modifier for PC and its blends	Rohm and Haas
Paraloid EXL-4151	Polyglutarimide for alloying PC with polyamide	Rohm and Haas
Paraloid HT-510	Polyacrylic-imide modifier for PVC bottles	Rohm and Haas
Paraloid	Poly(methyl methacrylate-butadiene-styrene) MBS (old *Acryloid*™)	Rohm and Haas
Paraplast 8000	Epoxy resins, EP	Hexcel Corp.
Paraplex	Polyester resin	Rohm and Haas
Parastyren	Styrene-butadiene copolymer, SBR	Paraisten Kalkki Oy
Parel	Polypropylene oxide elastomers	Nippon Zeon Co., Ltd.
Parlon	Chlorinated rubber, RUC	Hercules
Parylene C	Poly(monochloro-*p*-xylene)	Union Carbide Co., Inc.
Parylene D	Poly(dichloro-*p*-xylene)	Union Carbide Co., Inc.
Parylene N	Polyparaxylene	Union Carbide Co., Inc.
PAS-2	Polyphenylsulfide-sulfone	Phillips
Pax-Plus	HDPE/polyisobutylene blends	Allied-Signal Corp.
Paxon	Polyethylene/polyisobutylene, PE/PIB, blends	Allied-Signal Corp./ Paxon
Paxon Pax-Plus	PE/elastomer blends	Allied-Signal Corp./ Paxon
PBF-300	Poly(butylene terephthalate), glass filled, PBT	Polyfil, Inc.
PBT-5008	Poly(butylene terephthalate); filled or not, PBT	Mitsubishi Chem.
PBTGL-30	Poly(butylene terephthalate), 30 % glass filled, PBT	Polymer Compos.
PC-00B	Polycarbonate; filled or not, PC	Plastic Materials
PC-100	Polycarbonate; filled or not, PC	MRC Polymers, Inc.
PC-12	Epoxy resins, EP	Dexter Corp.

<div align="right">(continued)</div>

PCC-800	Polycarbonate; carbon fiber filled, PC	Polyfil, Inc.
PCCE-5154	Thermoplastic polyester	Eastman Chem. Prod.
PCF-800	Polycarbonate; glass fiber filled, PC	Polyfil, Inc.
PCGL-30	Polycarbonate, 30 % glass filled, PC	Polymer Compos.
PDC-400	Poly(phenylene sulfide) with carbon fibers, PPS	Polyfil, Inc.
PDF-400	Poly(phenylene sulfide) with glass fibers, PPS	Polyfil, Inc.
PE-1007 to 5976	Polyethylenes, PE	Chevron Chem.
PE-2FR	Polyethylenes; filled or not, PE	Reichhold Chem., Inc.
Pebar	Blends of polyolefins (HDPE, PP) with high nitrile resin, _Barex_™	BP Chemicals
Pebax	TPE polyether block amide; GF filled or not	Elf Atochem
Pedigree 433	Unsaturated polyester, UP	P. D. George Co.
PEF-400	Polyethylene with glass fibers, PE	Polyfil, Inc.
Pekema	Poly(vinyl chloride), PVC	Punda Inc.
Pelaspan	Polystyrene, expandable	Dow Chem. Co.
Pellethane	Polyurethane TPU, ABS/TPU, TPE	Upjohn/Dow Chem.
Pellethane 2102	Polyester-polycaprolactone	Dow Chem. Co.
Pellethane 2103	Polyether TPU	Dow Chem. Co.
Pellethane 2352	Thermoplastic elastomer, TPU	Dow Chem. Co.
Pellethane 2355	Polyester TPU	Dow Chem. Co.
Pellethane 2363	Thermoplastic polyurethane, TPU	Dow Chem. Co.
Pellets	Polyurethane, TPU	Fimor
Pelprene	Aliphatic-b-aromatic polyester copolymer	Toyobo Corp.
Pensrene EN	IPN of poly(phenylene sulfide) and TS resin	Dainippon Ink & Chem.
Penton	Poly(2,2-dichloromethyltrimethylene ether)	Hercules
PEO	Polyethylene oxide	Seitetsu Kagaku
Perbunan C	Polychloroprene elastomer, CR	Bayer AG/Miles
Perbunan N Latex	Anionic latices of nitrile rubber, NBR; 45–50 % solids; AN = 18–48 %	Polysar/Bayer AG
Perbunan N	Nitrile rubber, NBR; AN = 18–48 %	Polysar/Bayer AG
Pergut	Diverse resins	Bayer AG
Periston	Polyvinylpyrrolidone	Bayer AG/Miles
Perlenka	Polyamide-6, PA-6	AKU, Netherlands
Perlon	Generic name for polyamide-6, PA-6	Bayer AG/Miles
Perlon U	Polyurethane, PU	Bayer AG/Miles
PermaStat 100	Polypropylene, with 0 % and 10 % glass fiber	RTP Co.
PermaStat 2500	Polycarbonate/ABS alloys	RTP Co.
PermaStat 2700	Styrenic elastomer resins	RTP Co.
PermaStat 4000	Polyphthalamide with 0 % and 30 % glass fiber	RTP Co.
Permutit	Ion-exchange resin	Permutit Co.
Perspex	Cast, extruded PMMA sheet	ICI Chem. Polym. Ltd.
Perstorp Grade 151	Urea-formaldehyde, UF	Perstorp, Inc.
Perstorp Grade 751	Melamine-formaldehyde, MF	Perstorp, Inc.

PET Azdel	Polypropylene with 35 % glass fiber, PP	Azdel Inc.
Pet	Thermoplastic polyesters	ICI
PETGL-30	Poly(ethylene terephthalate), 30 % glass filled, PET	Polymer Compos.
Petlon	Poly(ethylene terephthalate) glass/mineral filled	Bayer AG/Miles
Petra	Poly(ethylene terephthalate), PET	Allied Signal Inc
Petra 130	Poly(ethylene terephthalate), glass filled, PET	Allied Signal Inc
Petra 230	Poly(ethylene terephthalate), glass/mineral filled	Allied-Signal Inc.
Petrarch PTFP	Polytetrafluoroethylene, PTFE	Petrarch Systems
Petron	Poly(ethylene terephthalate)	Mobay
Petrothene	LDPE, LLDPE, HDPE, PP, EVAc; filled or not	Quantum Chem. Co.
Petsar	PET/PC/acrylic blends with 30 % glass fiber	Novacor Chemicals Inc.
Pevalon	Poly(vinyl alcohol)	May & Baker
Pevikon	Poly(vinyl chloride) resins, PVC	Norsk Hydro/Hydro PLast
PGF-400	Glass-filled poly(phenylene ether), PPE	Polyfil, Inc.
PHC-600	Carbon fiber-filled polysulfone, PSU	Polyfil, Inc.
Phenoxy	Bisphenol-A/epichlorohydrin copolymer	Amoco Performance
PHF-400	Glass-filled polysulfone, PSU	Polyfil, Inc.
Philprene	Styrene-butadiene thermoplastic copolymer, SBR	Phillips 66 Co.
PI-730	Polyimide; glass or carbon fiber filled, PI	ICI/Fiberite
Pibiflex	Poly(butylene terephthalate), PBT copolymers	Enimont
Pibiter	PBT homopolymers or blends; filled or not	Montepolimeri/ EniChem
Pioloform	Polyvinyl acetal, butyral, and formal	Wacker-Chemie
PIQ	Polyimide, electronic coatings, PI	Hitachi
PKF-400	Glass-filled ABS	Polyfil, Inc.
PL-25	Acrylics	Plaskolite, Inc.
Plaper	Styrene-butadiene copolymer, SBR	Mitsubishi Monsanto
Plaskon	Thermoset resins: alkyd, DAP, epoxy, phenolic	Plaskon Electronic
Plaslube	Lubricated resins	Akzo/DSM
Plaslube AC	Polyoxymethylene with 15 % fluorocarbon, POM	Akzo/DSM
Plaslube J	PC, PA-66, PSU; lubricated materials with GF	Akzo/DSM
Plaslube NY	Polyamide-66 with 5 % MoS_2, PA-66	Akzo/DSM
Plastadur	Phenol-formaldehyde, PF	Soprochim
Plastalloy	Polysulfone alloys with short glass fiber, PSU	Akzo/DSM
Plastylene	Polyethylene, PE	Pichney-Saint-Gobain
Platabond	Copolyamides, hot melts	Elf Atochem
Platamid	Copolyamides, hot melts	Elf Atochem
Plathen	Polyethylene hot melt, PE	Elf Atochem Deutschland
Platherm	Copolyamides, hot melts	Elf Atochem
Platilon	TPU and nylon films	Elf Atochem Deutschland
Platon	PET, polyamide-6 monofilaments	Elf Atochem Deutschland

(*continued*)

Plenco	Diallyl phthalate, phenolics, polyesters	Plastics Engineering Co.
Plexalloy	PMMA/ABS alloys	Rohm and Haas
Plexar	PO-based adhesives	DSM
Plexidur	Poly(acrylonitrile-*co*-methyl methacrylate)	Rohm and Haas
Plexiglas	Acrylic, methacrylic resins and blends	Roehm GmbH/ AtoHaas
Plexiglas G, V, MC	Acrylic, methacrylic resins and copolymers	Rohm and Haas
Plexigum	Acrylate and methacrylate resins	Rohm and Haas
Pliocord VP Latex	Vinylpyridine copolymer	Goodyear Chemicals
Pliofilm	Hydrochloride rubber	Goodyear Chemicals
Pliogrip	Polyurethane adhesives, PU	Ashland Chemicals
Pliolite	Styrene-butadiene copolymers	Goodyear Chemicals
Pluracol	Polyether polyols	BASF Plastics
Pluronics	Ethylene oxide-propylene oxide copolymers, EPO	Wyandotte Chem.
Plyophen	Phenolic resin,	Cain Chem. Inc.
PMF-400	Glass-filled polyamide-66, PA-66	Polyfil, Inc.
PNC-400	Carbon fiber-filled polyamide-66, PA-66	Polyfil, Inc.
PO	Polypropylene, PP	MA Industries
Pocan 7913	PBT/PC/elastomer alloys	Bayer AG/Miles
Pocan	Poly(butylene terephthalate), PBT, PBT/ABS	Bayer AG/Miles/Albis
Pocan-S	PBT/elastomer blends	Bayer AG/Miles
POF-400	Glass-filled polyamide-6, PA-6	Polyfil, Inc.
Polane T, HST	Urethane coatings	Sherwin-Williams Co
Poliblend NH	Polypropylene/polyamide blend; reinforced or not	Poliresins SpA
Polidux	ABS, SAN, polystyrenes	Aiscondel
Polifil	Polypropylene + mineral, talc, calcium carbonate	Polifil, Inc.
Pollopas	Urea-formaldehyde resins, UF	Dynamit Nobel
Polloplas	Urea-based cellulose-containing compound	Dynamit Nobel
Poly BD	Polybutene, hydroxyl terminated	Elf Atochem
Poly G	Specialty polyols	Olin Chemicals
Poly-Dap	Diallyl phthalate; glass or mineral filled	Industrial Dielect.
Poly-Eth	Polyethylene, PE	Gulf Oil
Polyac	Acrylonitrile-butadiene-styrene terpolymer, ABS	Primex
Polybatch	PE, PP, PVC, PA, ABS color concentrates	A. Schulman, Inc.
Polyblak	Carbon black concentrates	A. Schulman, Inc.
Polybond	Chemically modified POs	PB Performance Polymers
Polycarbafil G	Polycarbonate; filled with glass, metal, carbon	Akzo/DSM
Polycast	Poly(vinylidene fluoride)/poly(methyl methacrylate) blends for electrets	Royalite
Polychem 100	Phenolic resins filled with glass, wood, etc.	Budd Co.
Polyclear	Polyethylene terephthalate, PET	Hoechst Celanese Corp.
Polycol	Poly(vinyl chloride) compound, PVC	Elf Atochem

<div align="right">(continued)</div>

Polycomp	PPS or PET/PTFE blends	LNP Corp.
Polycomp	PTFE filled with PPS or PAr blends	LNP Corp.
Polydene	Poly(methyl methacrylate)/PVC alloy	A. Schulman, Inc.
Polydet	GRP plates (polyester)	Mitras Kunstoffe GmbH
Polydur	Thermoplastic polyurethane, TPU	Dynamit Nobel/A. Schulman
Polyfil	–	Polyfil
Polyfine	–	Tokuyama Soda
Polyflam X	Flame-retarded resins; X = ABS, PS, PE, PP, etc.	A. Schulman, Inc.
Polyflon	Polytetrafluoroethylene, PTFE	Daikin
Polyfort	Polypropylene; filled with mineral, glass, PP	A Schulman Inc.
Polyimide	Polyimide, PI	Upjohn Co.
Polylac	Acrylonitrile-butadiene-styrene terpolymer, ABS	Chi Mei Industrial Co.
Polylite	Unsaturated polyester resin, UP	Reichhold Ltd.
Polyloy	Polyamide-6 or polyamide-6,6/PO or TPO blends	Dr. Illing GmbH
Polyman	ABS or SAN/PVC compounds	A. Schulman, Inc.
Polyman *506, 509*, etc.	Poly(vinyl chloride)/ABS high-temperature alloys	A. Schulman, Inc.
Polyman *551*	Polyolefin, PO	A. Schulman, Inc.
Polyman *552*	SAN/PO blends	A. Schulman, Inc.
Polymer XE *3055*	Polyamide blends, PA	EMS-Chemie AG
Polymin	Polyethyleneimine	BASF Plastics
Polyox	Polyethylene oxide	Union Carbide
Polypenco Acrylic	Cast acrylic rods	Polymer Corp.
Polypenco Nylon 101	PA-66 reinforced or not (rods or sheets)	Polymer Corp.
Polypenco Q200.5	Cross-linked PS (rods or sheets)	Polymer Corp.
Polypenco Torlon	Polyamide-imide in rods or plates	Polymer Corp.
Polypro J	Polypropylene; filled or not, PP	Mitsui Petrochem.
Polypro KS	Polypropylene; filled or not, PP	Tokuyama Soda Co.
Polypur APU	Long fiber-reinforced TPU alloys	A. Schulman, Inc.
Polyrex P	Polystyrene, PS	Chi Mei Industrial
Polyrite PP	Unsaturated polyester with glass fiber, UP	Polyply, Inc.
Polysar Bromobutyl	Bromobutyl rubber, BIIR	Polysar/Bayer AG
Polysar Butyl	Butyl rubber, BR	Polysar/Bayer AG
Polysar Chlorobutyl	Chlorobutyl rubber, CIIR	Polysar/Bayer AG
Polysar EPDM	EPDM rubbers with ethylene/propylene ratio = 58/42 to 75/25	Polysar/Bayer AG
Polysar	Polystyrene, PS	Novacor
Polysar	PS with 4–8 % polybutadiene blend	Novacor
Polysar S	Emulsion SBR with 23.5 % bound styrene	Polysar/Bayer AG
Polysar SS	Emulsion SBR with 64 % bound styrene	Polysar/Bayer AG
Polysizer	Poly(vinyl alcohol), PVAl	Showa Highpolymer
Polystyrol	Polystyrene/polybutadiene alloys, HIPS, styrene-butadiene copolymer, SBR, etc.	BASF Plastics
Polysulfon	Poly(bisphenol-A/dichlorodiphenylsulfone)	Shell Chem. Co.

<div align="right">(continued)</div>

Polythene	Polyethylenes, PE (high pressure)	E. I. du Pont de Nemours
Polytron	Electroconductive Poly(vinyl chloride) alloys	BF Goodrich
Polytrope TPP	TPO alloys, PP/EPDM	A. Schulman, Inc.
Polyval	Poly(vinyl alcohol), PVAl	Unitika Kasei
Polyvest	Polybutadiene, PB	Hüls AG
Polyvin	Poly(vinyl chloride) compounds, PVC	A. Schulman, Inc.
Polyviol	Poly(vinyl alcohol), PVAl	Wacker-Chemie
Poticon	PA-66, POM, PBT, PA-6 with potassium titanate	Biddle Sawyer Corp.
PP-C1CC	Polypropylene with calcium carbonate, PP	Reichhold Chem., Inc.
PP-C2TF	Polypropylene with talc, PP	Reichhold Chem., Inc.
PP-G2MF	Polypropylene with mica, PP	Reichhold Chem., Inc.
PP-HFG	Polypropylene with glass fiber, PP	Reichhold Chem., Inc.
PPO	Poly(2,6-dimethyl-phenyl ether), PPE	GE Plastics
Prester	Polyester polyurethanes, TPU	SPRA Neste Polyesters
Prevail	TPU/ABS alloys	Dow Plastics
Prevex	PPE alloys	GE Plastics
Prevex P2A, V3A	PA/PPE-copolymer blends with glass fiber	GE Plastics
Prevex PMA, PQA	PPE-copolymer-based blends with HIPS	GE Plastics
Prevex *S33*	Polyamide/PPE-copolymer alloys	GE Plastics
Primacor	EAA copolymer, EEA-type adhesives	Dow Chem. Co.
Primef	Poly(phenylene sulfide), PPS, with GF, CF, or mineral fillers	Solvay & Cie SA
Primex	Poly(vinyl chloride), PVC	Primex
PRL-ABS	ABS; glass filled or not	Polymer Resources
PRL-Acetal	Acetal; glass filled or not, POM	Polymer Resources
PRL-Nylon	Polyamide-6 or polyamide-66; glass filled or not, PA	Polymer Resources
PRL-PC	Polycarbonate; glass filled or not, PC	Polymer Resources
PRM	Polymer reflective material; PC/acrylic multilayer metallic-like sheets	Dow Plastics
Pro-Fax	PP homopolymers, copolymers with ethylene and PP/EPR blends	Himont Canada
Pro-Seal	Epoxy resins, EP	Prod. Res.& Chem.
Procom	Polypropylene, PP, PP/PA semi-IPNs	ICI Materials – Plast.
Procond-H	Polypropylene, PP	United Composites
Profil	Polypropylene + $CaCO_3$, talc, mica, carbon, etc.	Wilson-Fiberfil
Profil	Polypropylene with glass or carbon fiber, PP	Akzo/DSM
Proloy	ABS/polycarbonate alloys	GE Plastics
Propafilm	Oriented PP film, OPP	ICI Films
Propak	Polypropylene	PolyPacific
Propathene	Polypropylene, PP, toughened PP/EPR blends	ICI Materials – Plast.
Propathene PP	Polypropylene, PP	ICI Materials – Plast.
Propiofan	Polyvinylpropionate	BASF Plastics
PS 50	Polystyrene, PS	Huntsman Chem.

(*continued*)

PSF	Styrene-acrylonitrile copolymer with glass, SAN	Polyfil, Inc.
PU-21713	Polypropylene, PP, rubber modified alloy	Ferro-Eurostar
PUGL	Polyurethane with glass fiber, TPU	Polymer Composites
Pulse	Polycarbonate/ABS, PC/ABS (30 %) alloy	Sumitomo Dow Ltd.
PVC-Semicon	Conductive PVC	ABB Polymer Comp.
PVC360	Poly(vinyl chloride), PVC	Exxon Chem.
PXM	Polyetherketone	Amoco
Pyralin	Polyimide; laminates and electronics coating, PI	E. I. du Pont de Nemours
Pyratex	Elastomers	Bayer
Pyre-ML	Polyimide, PI; wire enamel	E. I. du Pont de Nemours
Pyrotex	Phenolic resins with asbestos	Raymark Indust. Div.
Q		
Q 2	PA from 1,4-bis-aminomethylcyclohexane and suberic acid	Eastman/USA
Q-TEL	Encapsulating EP or PU resins	Chemque
QuaCorr Resin	Thermoset furan resins with glass fiber	QC Chem., Inc
Quatrex	Electronic grade epoxy resins, EP	Dow Chem. Co.
Quiana	Polyamide fiber from trans, trans diamino-dicyclohexylmethane and dodecanedioic acid	E. I. du Pont de Nemours
Quimcel	Cellulose nitrate, CN	Punda Inc.
Quirvil	Poly(vinyl chloride), PVC	Rumianca SpA
R		
R-570	Acrylic resins	Richardson Polymer
R-9900	Polycarbonate, PC	Thermofil, Inc.
R-xyAF	Polycarbonate with xy wt% aluminum, PC	Thermofil, Inc.
R-xyFG	Polycarbonate with xy wt% glass fiber, PC	Thermofil, Inc.
R-xyMF	Polycarbonate with xy wt% mineral, PC	Thermofil, Inc.
R-xyNF	Polycarbonate with xy wt% graphite fiber, PC	Thermofil, Inc.
R2-9900	Polycarbonate, PC/PBT alloy	Thermofil, Inc.
R2-xyFG	Polycarbonate with xy wt% glass fiber, PC	Thermofil, Inc.
R2-xyNF	Polycarbonate with xy wt% graphite fiber, PC	Thermofil, Inc.
R4-9900	Polycarbonate, PC/SMA alloy	Thermofil, Inc.
R9-2039	Epoxy resins, EP	Dexter Corp.
RA-059	Polyolefin, PO	Himont, Inc.
Radel A	Polyarylethersulfone, PAES, $[-\phi-O-\phi-SO_2-\phi-\phi-SO_2-]$	Amoco Performance Products
Radel AG	Polyarylsulfone; filled, PAS	Amoco Performance Products
Radel R	Polyphenylsulfone, PSU	Amoco Performance Products
Radlite	Glass fiber-reinforced PC/PBT blends	Azdel Inc.
Raplan	Elastomers	Polymix
Ravemul	Poly(vinyl acetate), PVAc	Enimont
Ravikral	Acrylonitrile-butadiene-styrene terpolymer, ABS	EniChem

Ravinil	Poly(vinyl chloride), PVC, suspension polymers	European Vinyls Corp.
RBC 2000	Epoxy resins, EP; filled or not	RBC Ind.
RDZ	Acrylics/PC opaque blends	Cyro Industries
RE2038/9	Epoxy resins, EP	Dexter Corp.
Reapox	Epoxy resins, EP	Rea Industrie
Regulus	Thermoplastic polyimides; thermoformable film	Mitsui Toatsu Chem., Inc.
Reichhold TPR	Thermoplastic elastomers: PO/EPDM blend	Reichhold Chem., Inc.
Ren RP-1774	Epoxy resins, EP; filled or not	Dexter Corp.
Ren-Flex	Thermoplastic elastomers, TPO, PP/EPDM	Dexter Corp.
Ren-Flex-726	Polyolefins, PO	Dexter Corp.
Renalal	Acetal copolymer, POM	Hoechst Celanese Corp.
Reny	Polyamides, PA-66	Mitsubishi
Replay	Polystyrene	Huntsman
Repolem, Ecocryl	Acrylic and vinylic emulsions	Elf Atochem
Reprean	Ethylene copolymers	Discas
Resarit	Poly(methyl methacrylate), PMMA powder	Resart-IHM AG
Resartglas	Poly(methyl methacrylate), PMMA sheets	Resart-IHM AG
Resiglas	Unsaturated polyester with glass fiber, UP	Kristal Kraft, Inc.
Resin 18	Poly-alpha-methylstyrene	Amoco Chem. Co.
Resin PVC	Poly(vinyl chloride), PVC	Georgia Gulf
Resin S, trans, etc.	Epoxy resins, EP; filled or not	Furane Products
Resinmec	Polyamides, polypropylene	Amoco Chem. Co.
Resinol Type A, F, etc.	Polyethylenes, PE	Allied Resinous
Resolite	Urea-formaldehyde, UF	Ciba-Geigy, GB
Restirolo	Polystyrene, PS	Societa Italiana Resine
Retain	Polyethylene/polystyrene-based recycled blends	Dow Plastics
Revinex	Carboxylated rubber	Doverstrand
Rex Flex-D	Thermoplastic elastomers; filled or not, TPO	Dexter Corp.
Rexene PE	Polyethylenes, PE	Rexene/El Paso Prod.
Rexene PP	Polypropylenes, PP	Rexene/El Paso Prod.
Rexflex	Polypropylene	Rexene
Rhodester	Cellulose acetate, CA	Rhône-Poulenc
Rhodia	Cellulose-2.5 acetate, CA	Soc. Rhodiaceta, France
Rhodiaceta-nylon	Polyamide-6,6, PA-66	Soc. Rhodiaceta, France
Rhodopas	Styrene-butadiene copolymer, SBR	Rhône-Poulenc
Rhodorsil	Silicones	Rhône-Poulenc
Rhodoviol	Poly(vinyl alcohol), PVAl	Rhône-Poulenc
Rhovyl	Poly(vinyl chloride), PVC	Soc. Rhodiaceta, France

(*continued*)

Riblene	Ethylene-vinyl acetate copolymers, EVA	ECP EniChem Polymeri
Riblene	Polyethylenes: LDPE, LLDPE, and VLLDPE	ECP EniChem Polymeri
Rigidex	High-density polyethylene, HDPE	BP Chemicals Limited
Rigidite	Carbon, aramid, glass fiber filled	BASF PLASTICS
Rigipore	Expandable polystyrene, PS	BP Chemicals Limited
Rigolac	Polyester resins	Showa Highpolymer
Rilsan A	Polyamide-12, PA-12, or blends with PEBA	Elf Atochem
Rilsan AVR	Polyamide-11 with $T_m = 175\ °C$ (rotomolding)	Elf Atochem
Rilsan B	Polyamide-11, PA-11	Elf Atochem
Rilsan ESY	Polyamide-11 for electrostatic spraying	Elf Atochem
Rilsan	Polyamide-11, polyamide-12, PA-6.6/PEBA	Elf Atochem
Rimplast	PA-6,6 or PA-12/silicone, reinforced or not	LNP Corp./Petrarch Sys.
Rimplast	Polyurethane/silicone IPN, reinforced or not	LNP Corp./Petrarch Sys.
Rimplast PTUE	Silicone-modified TPU, aromatic ether	Hüls AG
Risilan AZM	Polyamide-12 with glass/graphite fibers, PA-12	Elf Atochem
Risilan BZM	Polyamide-11 with glass/graphite fibers, PA-11	Elf Atochem
Riston	Photopolymer film resistant	E. I. du Pont de Nemours
Riteflex	Thermoplastic elastomer and blends	Hoechst Celanese Corp.
Riteflex BP	Poly(butylene terephthalate), PBT, alloys with a thermoplastic elastomer	Hoechst Celanese Corp.
RNYxy	Polyamide-6 with xy wt% glass fiber, PA-6	Ferro Corp.
Robetanche	Polyurethanes, PU	Robbe
Robfill/Robflex	Polyurethanes, PU	Robbe
Robinsectisol	Polyurethanes, PU	Robbe
Rocalene	Reinforced polypropylene, PP	R.M.P.
Rodran	Liquid crystal polyester, LCP	Unitika
Rogers HT	Phenolics with glass fiber	Rogers Corp.
Rogers RX 1	Diallyl phthalate with filler, DAP	Rogers Corp.
Rogers RX 300	Phenolics; filled with glass, wood, mineral, etc.	Rogers Corp.
Ronfalin	Acrylonitrile-butadiene-styrene copolymer, ABS	DSM
Ronfalin	Acrylonitrile-butadiene-styrene/polycarbonate	DSM
Ronfaloy E	Acrylonitrile-butadiene-styrene/EPDM alloy	DSM
Ronfaloy P	Acrylonitrile-butadiene-styrene/PET alloy	DSM
Ronfaloy V	Acrylonitrile-butadiene-styrene/Poly(vinyl chloride)	DSM
Ropet	Poly(ethylene terephthalate), PET/PMMA alloys	Rohm and Haas
Rosite 3250 BMC	Unsaturated polyester with glass fiber, UP	Rostone Corp.
Roskydal	UP lacquer resins	Bayer AG/Miles
Roto Flame	Polyethylene, PE	Rototron Corp.
Rotothene R-	Polyethylenes; filled or not, PE	Rototron Corp.

Rotothon XP-I	Polypropylene, PP for rotational molding	Rototron Corp
Rovel 747	Polycarbonate, PC/AES blends	Dow Chem. Co.
Rovel	Styrene-acrylonitrile copolymer, SAN, blended with saturated olefinic elastomer, EPR	Dow Chem. Co.
Royalcast	Elastomers	Safic-Alcan
Royalcast	Polyurethanes, thermoset (TS)	Uniroyal Chemical
Royalene	EPDM for modification of HDPE	Uniroyal Chemical
Royalene	Polyethylene, PE, or polypropylene, PP	US-Rubber, USA
Royalite	Acrylonitrile-butadiene-styrene terpolymers, ABS	Uniroyal Chemical
Royalite	Poly(vinyl chloride)/PMMA alloys	Uniroyal Chemical
Royalite R 11	Polycarbonate/ABS alloys	Uniroyal Chemical
Royaltherm	EPDM modified with silicone	Uniroyal Chemical
Royaltuf 372	EPDM grafted with SAN	Uniroyal Chemical
Royaltuf 465	EPDM functionalized with maleic anhydride	Uniroyal Chemical
Royaltuf	Modified EPDM	Uniroyal Chemical
Royaltuf XN6G	EPDM grafted with polyamide-6	Uniroyal Chemical
Roylar A-863	Polyether-polyurethenes, PU	Uniroyal Chemical
RPC-440	Acrylic, PMMA	Richardson Polymer
RPI 504 EP	Polycarbonate-based alloys	Research Polymers Intl.
RPI 507 EP	Polypropylene/EPDM-type TPO blends	Dexter Corp.
RPI 602 EP	Polyamide-66-based alloys	Research Polymers Intl.
RPI	Polyolefin, PO/EPDM blends	Dexter Corp.
RPPxy	Polypropylene with xy wt% glass fiber, PP	Ferro Corp.
RPS	Polystyrene, PS-reactive	Dow Chem. Co.
RT 700	Cellulose (Viscose)	Glanzstoff, Germany
RT/duroid	Polytetrafluoroethylene with glass fiber, PTFE	Rogers Corp.
RTA-Polymer	Rigid TP alloys	Republic Plast. Co.
RTD	Impact-modified acrylics	Cyro Industries
RTP 200 TFE	Polyamide-66/PTFE/PDMS; filled or not	RTP Co.
RTP 200C	Polyamide-11/PTFE (20 %); filled or not	RTP Co.
RTP 200D	Polyamide-612/PTFE ($\leq$ 20 %); filled or not	RTP Co.
RTP 200H	Polyamide/PTFE ($\leq$ 20 %); filled or not	RTP Co.
RTP 300 TFE	Polycarbonate/PTFE/PDMS; filled or not	RTP Co.
RTP 600	ABS/PTFE or PDMS; filled or not	RTP Co.
RTP 800	POM/PTFE or PDMS; filled or not	RTP Co.
RTP 900	PSF/PTFE (15 %); filled or not	RTP Co.
RTP 1000	PBT/PTFE(15 %); filled or not	RTP Co.
RTP 1300	PPS/PTFE ($\leq$ 20 %); filled or not	RTP Co.
RTP ESD	Polyarylsulfone with glass fiber	RTP Co.
RTP PWB	Polyarylsulfone with glass fiber	RTP Co.
Rucon	Poly(vinyl chloride), PVC	Hooker
Rucothane	TPU, polyurethane thermoplastic elastomers	Hooker Chem. Corp.

Rulan	Polyethylene with filler, PE	E. I. du Pont de Nemours
Rumiten	Polyethylenes, PE	Rumianca SpA
Runite SST	Poly(ethylene terephthalate) + 35 wt% glass, PET	E. I. du Pont de Nemours
Rütaform	Aminoplasts: MF, MPF, melamine-polyester, etc.	Hoechst Celanese Corp.
Rutapal	Polyester resins, UP	Bakelite GmbH
Rutaphen	Phenol-formaldehyde, resorcinol-formaldehyde	Bakelite GmbH
Rutapox	Epoxy resins, EP	Bakelite GmbH
Rutapur	Polyurethane resins, PU	Bakelite GmbH
RX	Acrylonitrile-butadiene-styrene copolymer, ABS	Resin Exchange
RX ENG. TS	Phenolic and diallyl phthalate molding materials	Rogers Corp
RX	Poly(phenylene sulfide), PPS/PTFE blend	Intl. Polym. Corp.
RxLoy	Polyolefin alloys for medical applications	Ferro Corp.
Rylon	Polyphenylene sulfide, PPS	Phillips Petrol. Co.
Rylon PPS	Polyphenylene sulfide, PPS	Phillips Petrol. Co.
Rynite PBT	Poly(butylene terephthalate)/elastomer alloys with up to 30 wt% glass fibers	E. I. du Pont de Nemours
Rynite	PBT or PET/elastomer with up to 35 wt% mica and glass fibers	E. I. du Pont de Nemours
Rynite SST	Poly(ethylene terephthalate)/elastomer alloys	E. I. du Pont de Nemours
Ryton	Poly(*p*-phenylene sulfide); filled or not, PPS	Phillips Petrol. Co.
Ryulex C	Polycarbonate/acrylonitrile-butadiene-styrene	Dainippon Ink & Chem.
S		
S-660	Unsaturated polyester with glass fiber, UP	ICI/Fiberite
S-xyFG	Polysulfone with xy wt% glass fiber, PSU	Thermofil, Inc.
S-xyMF	Polysulfone with xy wt% mineral, PSU	Thermofil, Inc.
S-xyNF	Polysulfone with xy wt% graphite fiber, PSU	Thermofil, Inc.
Sabre	Polycarbonate, PC, alloys with PET or PBT	Dow Chem. Co.
Sadisol	Polyurethanes, polyols, isocyanates	Robbe
Saflex	Polyvinylacetal, PVAc	Monsanto, USA
Sanrex	Styrene-acrylonitrile copolymer, SAN	Mitsubishi Monsanto
Santoprene	Polypropylene/EPDM or EPM, dynamically vulcanized thermoplastic elastomers, TPO	Monsanto Chem. Co.
Sapedur	Poly(vinyl chloride) compounds, PVC	Saplast
Saran	PVDC with at least 80 % vinylidene chloride	(generic name)
Saran	PVDC with at least 80 % vinylidene chloride	Dow Chem. Co.
Saranex	Poly(vinylidene chloride), PVDC, and PVDC/PO	Dow Chem. Co.
Sarlink 1000	TPE; oil-resistant PP/PB blends	DSM; Novacor
Sarlink 2000	TPE; low permeability PP/BR blends	DSM; Novacor
Sarlink 3000	TPE; multipurpose PP/EPDM	DSM; Novacor
Sarlink TPE	Thermoplastic elastomers, TPE	DSM; Novacor
Sarnylene	Poly(vinyl chloride) compounds, PVC	Plastic Auvergne

Sarnymousse	Poly(vinyl chloride) compounds, PVC	Plastic Auvergne
Satellite	HDPE blown film system	Filmaster Inc.
Satinflex	Poly(vinyl chloride) super elastomers, PVC	Alpha Chem. & Plastics
Scarab	Urea-formaldehyde, UF, molding powders	BIP Chemicals Ltd.
Schulamid GB	Polyamide-6 with glass beads, PA-6	A. Schulman, Inc.
Schulamid GF	Polyamide-6 or polyamide-66 with glass fibers, PA-6 or PA-66	A. Schulman, Inc.
Schulamid MF	Polyamide-66 with mineral, PA-66	A. Schulman, Inc.
Schulamid MWG	Polyamide-6 with glass fiber/mineral, PA-6	A. Schulman, Inc.
Schulman 9HD	Polyethylene resins, PE	A. Schulman, Inc.
Schulman 9PE	Polyethylene resins, PE	A. Schulman, Inc.
Schulman ABS	Acrylonitrile-butadiene-styrene copolymer, ABS	A. Schulman, Inc.
Schulman CP	Polyethylene resins, PE	A. Schulman, Inc.
Sclair	Polyethylene resins, PE	Du Pont Canada
Sclar	Polyamide/polyolefin, PA/PO, blends	Du Pont Canada
Scolefin	High-density polyethylene, HDPE	Buna AG
Sconapor	Polystyrene foam, EPS	Buna AG
Sconatex	Acrylonitrile-butadiene-styrene copolymer, ABS	Buna AG
Scopyrol	Polystyrene, PS	Buna AG
Scotch-Grip	Adhesives	3M Canada Inc
Scotchcast	Epoxy resins, EP	3M, USA
Scotchcote	Epoxy resin, EP	3M Canada Inc
Scotchpak	Polyester film	3M Canada Inc
Scovinat	Poly(vinyl acetate), PVAc	Buna AG
Scovinyl	Poly(vinyl chloride), PVC	Buna AG
Scuranate	Polyurethanes, isocyanates	Rhône-Poulenc
SEBS-Compound	Thermoplastic elastomer, TPE	ABB Polymer Comp.
SEBS-Semicon	Conductive TPE	ABB Polymer Comp.
Selar Barrier Resin	Polyamide blend	E. I. du Pont de Nemours
Selar OH	EVAl resins for oxygen barrier film (blend)	E. I. du Pont de Nemours
Selar PA	Amorphous PA for oxygen barrier film (blend)	E. I. du Pont de Nemours
Selar PT	Polyester resins for barrier films (blend)	E. I. du Pont de Nemours
Selar PT	Polyethylene terephthalate blend, PET, (blend)	E. I. du Pont de Nemours
Selar RB	PA/HDPE concentrates for O_2 barrier PO films	E. I. du Pont de Nemours
SFP	Polystyrene, PS	Huntsman Chem.
Shell DP	Polyisobutylene resins, PIB	Shell Chim.
Shell	PP, PS, PVC resins	Shell Chim.
Shinko-Lac G	Poly(butylene terephthalate); filled or not, PBT	Mitsubishi Rayon Co.
Shinko-Lac GH	Acrylonitrile-butadiene-styrene copolymer, ABS	Mitsubishi Rayon Co.

(*continued*)

Shinkolite A	Acrylic sheets, PMMA	Mitsubishi Rayon Co.
Sholex	Polyethylene	Showa Denko K. K.
Shore	Polyester elastomers, TPE	E. I. du Pont de Nemours
Shuman 500	Polypropylene, PP	Philip Shuman & Sons
Shuman 700	Acrylonitrile-butadiene-styrene copolymers, ABS	Philip Shuman & Sons
Shuman 780	Poly(vinyl chloride)/ABS alloy, PVC/ABS	Philip Shuman & Sons
Shuman 800	Polystyrene, PS	Philip Shuman & Sons
Shuman 900	Polycarbonate, PC	Philip Shuman & Sons
Shuman 6000	Polyethylene, PE	Philip Shuman & Sons
Shuman SP	Poly(phenylene ether), PPE alloy	Philip Shuman & Sons
Shutane	Poly(vinyl chloride)/TPU alloy	Reichhold Chem., Inc.
Shuvinite	Poly(vinyl chloride)/ABS alloy	Reichhold Chem., Inc.
Sicalit	Cellulose acetate, CA	Sic Plastics
Sicoflex	Acrylonitrile-butadiene-styrene copolymers, ABS	Sic Plastics
Sicol	Plastisols, PVC	Enimont
Sicostrol	Polystyrene; reinforced or not, PS	Sic Plastics
Sicron	Poly(vinyl chloride) compositions, PVC	European Vinyls/ Montedison
Silastic	Silicones	Dow Chem. Co.
Silastomer	Silicones	Dow Chem. Co.
Silflex	Silicone, TS	Furane Products
Silixol	Silicones, MQ	Convert
Silmar	Unsaturated polyesters, UP	Silmar
Silopren	Silicone rubber, MQ	Bayer AG/Miles
Siltem	Siloxane-etherimide copolymers and blends	GE Plastics
Sinkral	Acrylonitrile-butadiene-styrene copolymers, ABS	ECP Enimont Polym./ EniChem
Sinvet	Polycarbonate, PC	Anic; ECP EniChem Polymeri
Sirester	Polyester resins	SIR France
Sirester	Polyester resins	SIR France
Sirfen	Phenol-formaldehyde resins, PF	SIR France
Sirit	Urea-formaldehyde resins, UF	SIR France
Siritle	Urea-formaldehyde resins, UF	SIR France
Sirotherm	Ampholytic polyelectrolyte	ICI
Sirtene	Polyethylene, PE	Societa Italiana Resine
SKS	Copolymers from butadiene	USSR
Skybond 700	Polyimides; laminating varnish, PI	Monsanto
Skygreen	Biodegradable polyethylene succinate/adipate for injection or extrusion	Sukyong Industries
Skyprene	CR elastomers	Tosoh, Harcros Chemicals
SMA	Styrene maleic anhydride, SMA	Elf Atochem
Snevyl	Poly(vinyl chloride) compositions, PVC	Sebuca

Snialene	Polypropylene, PP	SNIA Tecnopolimeri SpA
Snialoy AP06	Polyamide-66 with PP toughened blends	Nylon Corp. of America
Snialoy BP06	Polyamide-6 with PP toughened blends	Nylon Corp. of America
Sniamid	Polyamide-6, polyamide-66, PA-6, PA-66	SNIA Tecnopolimeri SpA
Sniater	Poly(butylene terephthalate), PBT	SNIA Tecnopolimeri SpA
Snissan	Acrylonitrile-butadiene-styrene copolymer, ABS	SNIA Tecnopolimeri SpA
Snlatal	Polyoxymethylene (acetal), POM	SNIA Tecnopolimeri SpA
Soablen/Soarlex	Ethylene-vinyl acetate copolymer, EVAc	Nippon Synthetic
Soarnol	EVA copolymer	Nichimen
Soarnol EVOH SF	Ethylene-vinyl alcohol, EVAl	Elf Atochem
Soetene	Low-density polyethylene, LDPE	Sogo
Sokalan CP2	Polyelectrolyte	BASF
Sol T	SBS and SIS block copolymers	Enarco Elastomers Co.
Solef 1000	Poly(vinylidene fluoride), PVDF	Solvay & Cie SA
Solef 8800	Poly(vinylidene fluoride), PVDF, with filler	Soltex/Solvay & Cie SA
Solimide	Polyimide foam, PI	Ethyl Corp
Solprene	Branched $(SB)_n$ or $(SI)_n$ block copolymers	Phillips Petrol.
Solucryl	Acrylates and methacrylates	UCB Soc.
Solvic	Poly(vinyl chloride), PVC	Solvay & Cie SA
Somel	TPO thermoplastic elastomer, PP/EPDM	Colonial
Soreflon	Polytetrafluoroethylene, PTFE	Rhône-Poulenc
Sowpren	Polychloroprene, CR	USSR
Spandex	Elastic PU fibers	(generic name)
Spanzelle	Spandex fiber	Courtaulds
Specflex	PU elastomer	Dow Chem. Co.
Spectra	UHMWPE gel-spun fibers	AlliedSignal Inc.
Spectrim HF	Thermoplastic polyurea	Dow Chem. Co.
Spectrim HF-80	Thermoplastic polyurethane, TPU	Dow Chem. Co.
Spectrim HT	Thermoplastic polyurea	Dow Chem. Co.
Spectrim RD	Polyurethane; filled or not, TPU	Dow Chem. Co.
SPX	PP/EPR elastomer	Mitsubishi
SRIM	Polyurethane, PU	Mobay Corp.
ST-801	Polyamide elastomer blends	DuPont
ST-Nylon	Polyamide/ionomer(?) blends	Toray
Stabar	PES and PEEK films	ICI Films
Stadlite	Phenol-formaldehyde resin, PF	Hitachi
Staloy N	Acrylonitrile-butadiene-styrene/PA alloys	DSM Polymer Int.
Stamylan HD or LD	High or low-density polyethylene, PE	DSM Polymer Int.

(*continued*)

Stamylan LD	Low-density polyethylene, LDPE	DSM Polymer Int.
Stamylan P	Polypropylene, PP	DSM Polymer Int.
Stamylex	Linear low-density polyethylene, LLDPE	DSM Polymer Int.
Stamyroid	Modified amorphous polypropylene, PP	DSM Polymer Int.
Stanuloy ST	Poly(ethylene terephthalate), PET, modified or blended with polycarbonate	MRC Polymers, Inc.
Stanyl	Polyamide-4,6 and its blends, PA-46	DSM Polymer Int.
Stapron	Rubber-modified SMA polymers	DSM Polymer Int.
Stapron C	Polycarbonate/acrylonitrile-butadiene-styrene	DSM Polymer Int.
Stapron E	Polycarbonate/PET or PBT with PB as impact-modifier; for interior automobile door panels	DSM Polymer Int.
Stapron N	Polyamide-6, PA-6, alloys with ABS with impact-modified PA-phase	DSM Polymer Int.
Stapron S	Rubber modified amorphous SMA with glass fiber reinforcements or not	DSM Polymer Int.
Star	Reinforced thermoplastic resins, e.g., ABS, SAN	Ferro-Eurostar
Star X	PA-6,PA-46, or PA-66 with an impact modifier, glass fiber reinforced or not	Ferro-Eurostar
Staramide-Glass	Glass fiber-filled polyamide-6, PA-6	Ferro Corp.
Staramide-Mineral	Mineral-filled polyamide-6, PA-6	Ferro Corp.
Starcoat	Gel-coat	Chanet Paints
Starflam ABS	ABS blend, flame retarded, glass reinforced or not	Ferro-Eurostar
Starflam PA6; PA66	PA-6 or PA-66/brominated polystyrene, impact modified, glass or mineral reinforced or not	Ferro-Eurostar
Starflam PBT	PBT blend, flame retarded, glass reinforced	Ferro-Eurostar
Starglas ABS	Acrylonitrile-butadiene-styrene with glass fiber	Ferro Corp.
Starglas PBT	Glass fiber filled poly(butylene terephthalate), PBT	Ferro Corp.
Starglas PC	Glass fiber filled polycarbonate, PC	Ferro Corp.
Starglas PE	Glass fiber filled HDPE	Ferro Corp.
Starglas POM	Reinforced polyoxymethylene, POM	Ferro Corp.
Starglas PSU	Glass fiber-filled polysulfone, PSU	Ferro Corp.
Starglas SAN	Reinforced SAN	Ferro Corp.
Starpylen	Glass fiber-filled thermoplastic resins	Ferro-Eurostar
Stat-Kon M	PP with electrostatic discharge	LNP Eng. Plastics
Statcon	Electrostatic dissipative materials	LNP
Stereon	Triblock SBS thermoplastic elastomer	Firestone Co.
Stilon	Acrylonitrile-butadiene-styrene/polycarbonate	USSR
Strathox	Epoxy resins, EP	Technibat
Stratyl	Unsaturated polyester, UP	Péchiney, France
Stycast	Epoxy; filled or not, EP	Emerson & Cuming
Stycone	Polystyrene, PS alloys	United Compos.
Sterpon	Polyester resins, UP	Convert
Stypol	Unsaturated polyesters; filled or not, UP	Freeman Chem. Corp.
Styrafil	Polystyrene with fillers, PS	Akzo/DSM
Styroblend	Polystyrene, PS, blends with PE or PB	BASF Plastics
Styrocell	Expandable polystyrene, EPS	Shell Chem.

Styrodur	Extruded rigid polystyrene, PS	BASF Plastics
Styroflex	PS fiber	Ndd. Seekabelwerke
Styrofoam	Polystyrene, PS plastic foam	Dow Chem. Co.
Styrol	Polystyrene, PS	Idemitsu
Styrolux	Styrene-butadiene copolymer, SBR	BASF Plastics
Styron	Polystyrene, PS, and impact-modified PS, HIPS	Dow Chem. Co.
Styroplus	Polystyrene, PS, blends with polybutadiene, PB	BASF Plastics
Styropol	Styrene-butadiene copolymer, SBR	Carl Gordon Ind.
Styropor	Expandable polystyrene, EPS	BASF Plastics
Styruvex	Styrene-acrylonitrile copolymer, SAN	Coplex
Sulfil G	Polysulfone with long glass fibers, PSU	Akzo/DSM
Sulfil J-1100	Polyethersulfone with glass fibers, PES	Akzo/DSM
Sulfil J-1300	Poly(phenylene sulfide) with fillers, PPS	Akzo/DSM
Sulfil J-1800	PET or PBT with glass fibers	Akzo/DSM
Sumigraft	Poly(vinyl chloride), PVC	Sumitomo Chem. Co.
Sumikathene	Polyethylenes, PE	Sumitomo Chem. Co.
Sumikon	Epoxy resins	Sumitomo Bakelite
Sumilit SX	Poly(vinyl chloride), PVC	Sumitomo Chem. Co.
Sumipex	Acrylic resins, PMMA	Sumitomo Chem. Co.
Sumiploy	PES, PES/PEEK-modified blends	Sumitomo Chem. Co.
Sunloid	Acrylonitrile-butadiene-styrene terpolymers, ABS	Tsutsunaka Plastics
Sunloid KD	Poly(vinyl chloride)/PMMA alloy	Tsutsunaka Plastics
Sunloid New Ace	Poly(vinyl chloride) sheets, PVC	Tsutsunaka Plastics
Sunloid PC	Polycarbonate, PC sheet, films	Tsutsunaka Plastics
Sunprene	Poly(vinyl chloride)-based elastomers, PVC/elastomer	Mitsubishi Kasei/A. Schulman
Suntec	Polyethylene	Asahi Chemical Co.
Suntra	Poly(phenylene sulfide), PPS resin	Sunk Yong
Supec	Poly(phenylene sulfide) and blends with PEI, PPE	GE Plastics/Toso Susteel
Supec CTX530	Poly(phenylene sulfide)/PEI blends with 30 % GF	GE Plastics
Supec CTX540	Poly(phenylene sulfide)/PEI blends with 40 % GF	GE Plastics
Superec P	Acrylonitrile-butadiene-styrene/polycarbonate	Mitsubishi-Monsanto
Supec W331	Poly(phenylene sulfide)/PTFE blends with 30 % GF	GE Plastics
Superohm	Ethylene-propylene copolymer, EPR	A. Schulman, Inc.
Supralen	Polyethylenes, PE (pipes)	Mannesmann, Germany
Supraplast	Thermoset resins: resorcinol-formaldehyde, etc.	O.F.A.C.I.
Suprel	Styrene-acrylonitrile grafted on PVC, SAN or ABS/PVC alloys	Vista Chemical Co.
Suprel SVA	Poly(vinyl chloride)/α-methyl styrene-ABS	Vista Chemical Co.
Surlyn	Ionomer resins	E. I. du Pont de Nemours
Surlyn 7930	Lithium grade ionomer resin	E. I. du Pont de Nemours

(*continued*)

Surlyn 8020	Sodium grade ionomer resin	E. I. du Pont de Nemours
Surlyn 9020	Zink grade ionomer resin	E. I. du Pont de Nemours
Surlyn A	Ionomer, ethylene-acrylic acid copolymer	E. I. du Pont de Nemours
Susteel	Poly(phenylene sulfide), PPS	Toso Susteel
SVM	Aromatic polyamides	USSR
Sylon FX	Fluoropolymer, thermoset (TS)	3M Ind. Chem.
Syn-Flex	Polyolefin compounds, PO	Synergistics Ind
Synergy	Polyamide-6/PPE blends	Allied-Signal Inc.
Synolite	Unsaturated polyester resin, UP	DSM Plastics
Synprene	Thermoplastic rubber compounds, TPE	Synergistics Ind
Synres	Specialty olefins, PO	Quality Service Technology
Syntewax	Acrylonitrile-butadiene-styrene terpolymer, ABS	Comiel SpA
Synthetic ABS	Polypropylene with calcium carbonate, PP	Reichhold Chem., Inc.
Syspur/Systanat	Polyurethane, PU	Soprochim
Systemer S	Polypropylene/polyamides, reinforced or not	Showa Denko K. K.
Systol	Polyurethane, PU	Soprochim
T		
T-xyCF	Polyphenylene sulfide, PPS + xy% graphite fiber	Thermofil, Inc.
T-xyCG	Polyphenylene sulfide with xy% carbon/glass	Thermofil, Inc.
T-xyFG	Polyphenylene sulfide with xy wt% glass fiber	Thermofil, Inc.
T-xyNF	Polyphenylene sulfide with xy wt% graphite fiber	Thermofil, Inc.
T-xyNG	Polyphenylene sulfide with xy% glass/graphite	Thermofil, Inc.
Tactix	High performance EP elastomeric resins	Dow Chem. Co.
Taffen	Thermoplastic composites	Exxon Chem.
Taflite	Polystyrene, PS-g-EPDM blends	Mitsui Toatsu
Tafmer	Metallocene-made linear low-density polyolefin with strictly controlled comonomer placement	Mitsui Petrochemicals
Tafmer A	Metallocene-made linear low-density polyolefin with 1 % acidic groups, used for compatibilization	Mitsui Petrochemicals
Taitalac	Acrylonitrile-butadiene-styrene terpolymer, ABS	Taita Chem. Co.
Taktene	Butadiene rubber, BR; based on co-catalyst	Polysar/Bayer AG
Tallerand	Poly(vinyl chloride), PVC	Tallerand Chem.
Tamcin PP	Polypropylene, PP	Reichhold Chem., Inc.
TAP-MR	Polyisocyanate thermoplastics	Urylon Development
Tarpee	Polyethylene laminated sheet, PE	Hagihara Industries Inc.
TDI	Polyurethane, PU	Dow
TE-1004	Epoxy with metallic fillers, EP	Dexter Corp.
Techniace TA	Polyamide/ABS alloys	Sumitomo Dow, Ltd.
Techniace TB	Poly(butylene terephthalate)/ABS alloys	Sumitomo Dow, Ltd.

Techniace TC	ABS/polycarbonate alloys, T-series = heat and impact resistant, H-series = high heat and impact resistant, W-series = weather and impact resistant, F-series = flame and impact resistant	Sumitomo Dow, Ltd.
Techniace TU	Thermoplastic polyurethane/ABS alloys	Sumitomo Dow, Ltd.
Technora	Poly(p-phenylene diphenylether terephthalamide)	Teijin Ltd.
Technyl A	Polyamide-66/elastomer, with filler or not, PA-66	Rhône Poulenc
Technyl B	Polyamide-66, 6/elastomer, with filler or not	Rhône Poulenc
Technyl C	Polyamide-6/elastomer, with filler or not	Rhône Poulenc
Technyl D	Polyamide-610/elastomer, with filler or not	Rhône Poulenc
Technyl	Polyamide-6, polyamide-66, polyamide-610 impact modified, glass fiber or mineral reinforced or not	Rhône Poulenc
Techster	Polyesters: PBT, PET, and blends	Rhône Poulenc
Techster T	Poly(butylene terephthalate), PBT/elastomer blends	Rhône Poulenc
Techtron PPS	Polyphenylene sulfide, PPS rods or plates	Polymer Corp.
Tecnoflon	Fluoroelastomers; PVDF/PHFP blends	Enimont
Tecnoprene	Glass fiber-reinforced polypropylene	Enimont
Tecoflex	Polyurethane, PU	Thermedics, Inc.
Tecolite KM	Phenolic-filled thermosets, PF	Toshiba Chem. Prod.
Tediflex/Tedilast	Polyurethane, PU, formulated systems	ECP Enimont Polymeri
Tedipur	Polyurethane, PU, formulated systems	ECP Enimont Polymeri
Teditherm/Tedirim	Polyurethane, PU, formulated systems	ECP Enimont Polymeri
Tedlar	Polyvinyl fluoride, PVF, film	E. I. du Pont de Nemours
Tedur	Polyphenylene sulfide, PPS, with glass/mineral	Bayer AG/Miles
Tefabloc/Tefaprene	Elastomers	Thermoplastiques C. T.
Tefanyl	Poly(vinyl chloride) compounds, PVC	Thermoplastiques C. T.
Teflon	Fluoropolymers; PTFE, PFA, FEP	E. I. du Pont de Nemours
Teflon FEP	Tetrafluoroethylene-co-hexafluoropropylene, FEP	E. I. du Pont de Nemours
Teflon PFA	Fluorocarbon, perfluoroalkoxy resin, PFA	E. I. du Pont de Nemours
Teflon TFE	Polytetrafluoroethylene, PTFE	E. I. du Pont de Nemours
Tefzel	Modified ethylenetetrafluoroethylene copolymer	E. I. du Pont de Nemours
Teijinconex	Poly(m-phenyleneisophthalamide), PPA	Teijin, Ltd.
Teknor Apex	Poly(vinyl chloride), PVC	Teknor Apex
Telcar	PP/EPDM, TPO elastomeric blends	Teknor Apex
Tempalloy	Polypropylene with fillers, PP	Comalloy Intl. Corp.
Temprene	Poly(vinyl chloride)/nitrile rubber (15–40 phr)	Piltec Group
TempRite	Chlorinated PVC, CPVC	BF Goodrich

(*continued*)

Temprite LC	Poly(vinyl chloride) compounds, PVC	Polyplastic
Tenac	Polyoxymethylene, POM	Asahi Chemical Ind.
Tenite	Polyolefins, cellulosics, CAB	Eastman Chem. Prod.
Tenite 000	Cellulose acetate, CA	Eastman Chem. Prod.
Tenite 200	Cellulose butyrate, CB	Eastman Chem. Prod.
Tenite 300	Cellulose propionate, CP	Eastman Chem. Prod.
Tenite 5000	Polyallomer	Eastman Chem. Prod.
Tenite Acetate	Cellulose acetate, CA	Eastman Chem. Prod.
Tenite Butyrate	Cellulose acetate-butyrate, CAB	Eastman Chem. Prod.
Tenite P7673	Polyallomer	Eastman Chem. Prod.
Tenite Pet	Thermoplastic polyesters, PET	Eastman Chem. Prod.
Tenite Polypropion	Cellulose acetate-propionate, CAP	Eastman Chem. Prod.
Tenite Propionate	Cellulose propionate, CP	Eastman Chem. Prod.
Tenite PTMT	Polytetramethylene terephthalate, PTMT	Eastman Chem. Prod.
Tenite	PVAc, PVB, PVPr	Eastman Chem. Prod.
Tenneco 2710	Polyallomer	Tenneco Polymers
Tenneco	Poly(vinyl chloride)/EVA blends	Tenneco Polymers
Teracol	Polyoxytetramethylene glycol	E. I. du Pont de Nemours
Terathane	Polyether glycol, PEO	E. I. du Pont de Nemours
Terblend B	ABS/polycarbonate, PC, blend	BASF Plastics
Terblend S	ASA/polycarbonate, PC, blend	BASF Plastics
Terblend	Styrene copolymer blends	BASF Plastics
Terital	Poly(ethylene terephthalate), PET	Montefibre, Italy
Teritherm	Polyesterimide, PEI	P. D. GeorgeÉ. Co.
Terlenka	Poly(ethylene terephthalate), PET	AKU, Netherlands
Terluran	ABS blends with acrylic rubber	BASF Plastics
Terluran	Acrylonitrile-butadiene-styrene terpolymers, ABS	BASF Plastics
Terlux	Clear methyl methacrylate-acrylonitrile-butadiene-styrene, MABS	BASF Plastics
Terphane	Polyester film	Rhône Poulenc
Terylene	Poly(ethylene terephthalate), PET	ICI Adv. Mater.
Tetra-Temp PEEK	Polyetheretherketone, PEEK	Tetrafluor, Inc.
Tetrafil J-1800	Poly(ethylene terephthalate) filled, PET	Akzo/DSM
Tetrafluor	Polytetrafluoroethylene, PTFE	Tetrafluor, Inc.
Tetralene UHMW	Polyethylene, PE	Tetrafluor, Inc.
Texalon/Texapol	Polyamide-6; PA-66, with filler or not, PA-6; PA-66	Texapol Corp.
Texicote	Poly(vinyl acetate)	Scott Bader
Texigels	Acrylic polyelectrolyte	Scott Bader
Texin	Polyurethanes	Bayer AG/Miles, Inc.
Texin 3000	Polycarbonate/polyester-PU, PC/TPU alloys	Bayer AG/Miles, Inc.
Texin 4000	Polyester-PU alloys with PC	Bayer AG/Miles, Inc.
Therban/Tornac	Fully or partially hydrogenated nitrile rubber, NR, with AN = 33–43 %	Polysar/Bayer A

<div align="right">(continued)</div>

Therban	Elastomers	Bayer
Thermaflo	Poly(vinyl chloride) footwear compounds, PVC	Evode Plastics Ltd.
Thermaflo	Thiorubber, TR, compound	Evode Plastics Ltd.
Thermalloy	Acrylonitrile-butadiene-styrene, ABS blends	CdF Chimie
Thermid IP-600	Polyimide, PI, structural adhesive	Nat. Starch @ Chem.
Thermocomp	Reinforced engineering polymer compounds with either glass or carbon fibers	LNP Engineering
Thermocomp AF	Acrylonitrile-butadiene-styrene, ABS, with fillers	LNP Corp.
Thermocomp BF	Styrene-acrylonitrile cop., ABS, with fillers	LNP Corp.
Thermocomp DL	Polycarbonate, PC/PTFE 13 %/silicone 2 %	LNP Corp.
Thermocomp PDX	PEEK/PTFE (20 %) alloys	LNP Corp.
Thermocomp RFL	Polyamide-66/silicone 5 % blends	LNP Corp.
Thermocomp RL	Polyamide-66/PTFE 13 %/Rimplast	LNP Corp.
Thermolan 2000	Polypropylene/EPDM blends	Mitsubishi Petrochem.
Thermolan 3000	EPDM/polypropylene blends	Mitsubishi Petrochem.
Thermomanto	Extruded EPS insulation boards	Dow Europe
Thermoset	Epoxy resins with fillers, EP	Thermoset Plastics
Thiokol	Poly(ethylene chloride-*co*-sodium sulfide)	E. I. du Pont de Nemours
Thornel	Graphite yarn	Union Carbide Co.
THV-Fluoroplastic	Terpolymer of tetrafluoroethylene, hexafluoropropylene and vinylidene fluoride (processing at 130 °C)	3M
TI-4000	Polypropylene, PP	Aristech Chem.
Tinolex	Poly(vinyl chloride); rigid, calendered, PVC	Tins Ind. Co. Ltd.
Tivar (Series)	Ultrahigh molecular weight PE, UHMWPE	Menasha Corporation
Tivar-Thane	Polyurethane sheet, PU	Menasha Corporation
Tonen Polyeth	Polyethylenes, filled or not, PE	Tonen Petrochem./ TCA Plastics
Tool WDC	Epoxy resin with aluminum, EP	Furane Products
Topalloy	–	TCA Plastics
Topas	Cyclic, amorphous *co*-polyolefin, COC, optical grade for compact disks (metallocene based)	Hoechst/Mitsui Petrochemicals
Toplex	Polycarbonate/ABS alloy	Multibase, Inc.
Toprene	Poly(phenylene sulfide), PPS	Tonen Petrochem.
Toray PBT	Poly(butylene terephthalate), with glass or not, PBT	Toray Industries
Torelina	Poly(phenylene sulfide), PPS	Toray Industries
Torlon	Polyamide-imide, PAI; modified PAI with PTFE, for electrical connectors, valves, bushings, parts, etc.	Amoco Chem. Co.
Torlon 4000	Polyamide-imide + PTFE + graphite	Amoco Chem. Co.
Torlon 7000	Polyamide-imide + PTFE + glass/graphite fiber	Amoco Chem. Co.
Torolithes	Thermoset polyester resins, UP	Routhan Soc. Nouv.
Toso LCP	Liquid crystal polyester, LCP	Toso

(continued)

Total Butyl	Elastomers	Total Chim.
Total Plast	Thermoplastic elastomers; EPDM/PO blends, etc.	Total Chim.
Toyarac	Acrylonitrile-butadiene-styrene, ABS	Toyo, Japan
Toyoflon	Polytetrafluoroethylene, PTFE	Toyo, Japan
Toyolac	Acrylonitrile-butadiene-styrene, ABS also polycarbonate/ABS	Toray Industries
Toyolac ASG20	Styrene-acrylonitrile, SAN with glass fiber	Toray Industries
TPO 900	Polypropylene/EPDM blends	Reichhold Chem., Inc.
TPP 10GB	Polypropylene alloy with talc, paintable	Ferro Corp.
TPR	Thermoplastic cross-linked rubber for PP	Uniroyal Chemical
TPX	Polymethylpentene, PMP	Mitsui Petrochem.
Trans-4	*trans*-1,4-Polybutadiene	Phillips
Traytuf	Poly(ethylene terephthalate) with TiO_2, PET	Goodyear
Trefsin	Thermoplastic elastomers, TPR, PP/BR	Advanced Elastomer Systems
Trespaphane	Biaxially oriented polypropylene film, BOPP	Hoechst Celanese Corp.
Trevira	Poly(ethylene terephthalate) fiber, PET	Hoechst
Triax 1000	Polyamide-6 or polyamide-66, PA-6 or PA-66 blends with acrylonitrile-butadiene-styrene, ABS	Monsanto Chem. Co.
Triax 1120	Polyamide-6/ABS blends	Monsanto Chem. Co.
Triax 1125	Polyamide-66/ABS = 1:1 blends	Monsanto Chem. Co.
Triax 1180	Polyamide-6,66/acrylonitrile-butadiene-styrene	Monsanto Chem. Co.
Triax 2000	PC/acrylonitrile-butadiene-styrene, ABS	Monsanto Chem. Co.
Triax CBE	Poly(vinyl chloride)/α-methyl styrene-ABS (available as Suprel SVA from Vista Chemical Co.)	Monsanto Chem. Co.
Tribolon	Polyimide/polytetrafluoroethylene, PI/PTFE	Tribol. Ind. Inc.
Tribolon XT	Poly(phenylene sulfide)/polytetrafluoroethylene	Tribol. Ind. Inc.
Tricel	Cellulose acetate, CA	Bayer AG/Miles
Triplus TPR 178	Silicone-based paints and coatings	GE Plastics
Typlax	–	Typlax
Trivin	Poly(vinyl chloride) alloys, PVC	Vi-Chem
Trogamid	Polyamide resins, PA	Kingsley & Keith
Trogamid	Polyamide-63-T, PA-63-T	Hüls AG
Trogamid T	Poly(trimethylhexamethylene terephthalamide)	Dynamit Nobel
Trolen	Polyethylene, PE	Dynamit Nobel
Trolit AE	Cellulose ether	Dynamit Nobel
Trolit F	Cellulose nitrate, CN	Dynamit Nobel
Trolitan	Phenol-formaldehyde resins, PF	Dynamit Nobel
Trolitul	Polystyrene, PS	Dynamit Nobel
Trolon	Phenolic resins	Hüls AG
Trolon	Phenolic-based binder	Dynamit Nobel
Trosiplast	Poly(vinyl chloride), rigid or plasticized, PVC	Dynamit Nobel
Trovicel	Poly(vinyl chloride), foamed, PVC	Hüls AG
Trovidur	Poly(vinyl chloride), PVC	Dynamit Nobel

(*continued*)

Trovitherm	Poly(vinyl chloride) sheets, PVC	Dynamit Nobel
Trubyte	Acrylic-based IPN for artificial teeth	Dentsply International
Tuffak	Polycarbonate sheet, PC	Rohm and Haas
Tuffax	Polycarbonate, PC	Rohm and Haas
Tuflin	Second-generation Unipol-type LLDPE	Union Carbide
Tufpet	Poly(ethylene terephthalate)	Toyobo Corp.
Tufprene	Triblock SBS thermoplastic elastomer	Asahi
Tufrex VB	ABS/Poly(vinyl chloride), PVC alloys	Mitsubishi-Monsanto
Twaron	Poly(p-phenyleneisophthalamide), PPA	Akzo NV
Tybrene	Acrylonitrile-butadiene-styrene terpolymer	Dow Chem. Co.
Tylac	Poly(vinyl chloride), PVC/BR blends	Standard Brands Chemicals
Tylose	Cellulose ether	Kalle, Germany
Tynex	Polyamide-6,6, PA-66	E. I. du Pont de Nemours
Typlax	Thermoplastic Elastomers	Typlax Products
Tyril	Styrene-acrylonitrile copolymer, SAN	Dow Chem. Co.
Tyrin	Chlorinated PE elastomers and resins, CPE	Dow Chem. Co.
Tyvek	Spunbonded olefin fiber, PO	E. I. du Pont de Nemours
U		
U-Polymer	Polyarylate, amorphous	Unitika
U-polymer	Polyarylate	Unitika
U-xyFG	Polyurethane with xy wt% glass fiber, PU	Thermofil, Inc.
Ube	–	Ube Industries Inc.
Ube 3000	Polyamide-12, modified, PA-12	Ube Industries Inc.
Ube Alloy CA700	Polypropylene/polyamide, PP/PA blend	Ube Industries Inc.
Ube Nylon	Polyamide-6 or polyamide-66, modified, PA-6, PA-66	Ube Industries Inc.
Ube Polypro	Polypropylene, PP	Ube Industries Inc.
Ube, Ubec	Polyethylenes, PE	Ube Industries Inc.
Ucardel P4174	Polysulfone/SAN blend	Amoco Performance
Ucecoat	Polyurethane, PU	UCB Soc. Com.
Ucecryl	Acrylates and methacrylates	UCB Soc. Com.
Ucefix	Polyurethane, PU	UCB Soc. Com.
Uceflex	Polyurethane, PU	UCB Soc. Com.
Udel	Bisphenol-A polysulfone, PSF (or PSO)	Amoco Chem. Co.
Udel GF	Polysulfone with glass fiber, PSF	Amoco Chem. Co.
Udel P	Bisphenol-A polysulfone, PSF	Amoco Chem. Co.
Udel P-1700	PSF + 10 % anhydride-terminated PSF + 50 % PA-6 (or PA-66), with PA being the matrix	Amoco Chem. Co.
Udel-X	PSU/PA-6 or PA-66 experimental alloys, with 10 wt% anhydride-terminated PSU	Amoco Chem. Co.
Ugikral	Acrylonitrile-butadiene-styrene copolymer, ABS	GE Plastics
UHMWPE 900	Ultrahigh molecular weight PE, UHMWPE	Himont

Ultem	Polyetherimide, PEI, and its blends, e.g., with PC, TP	GE Plastics
Ultem 2000	Polyetherimide with glass fiber, PEI	GE Plastics
Ultem 5000	Polyetherimide copolymer, PEI	GE Plastics
Ultem 6000	Polyetherimide copolymer, PEI	GE Plastics
Ultem 8000	Polyetherimide/polycarbonate alloy, PEI/PC	GE Plastics
Ultem LTX	PEI/PC blends (unreinforced)	GE Plastics
Ultem ATX	PEI/PC blends (unreinforced)	GE Plastics
Ultem HTX	PEI/PPC blends (unreinforced)	GE Plastics
Ultem PEI/PPO	PEI blends with polyphenylene ether	GE Plastics
Ultra-Wear	Polyethylene, PE	Polymer Corp.
Ultrablend	ASA/PBT blend	BASF Plastics
Ultrablend KR	PET or PBT/PC/elastomer blends	BASF Plastics
Ultrablend S	PBT/SAN, ABS, or ASA blends, with up to 30 wt% glass fiber	BASF Plastics
Ultradur B	Poly(butylene terephthalate), PBT, and impact-modified PBT	BASF Plastics
Ultraform	Polyoxymethylene, POM, acetal	BASF
Ultraform	Polyoxymethylene/thermoplastic polyurethane, POM/TPU, alloys, with 10–30 wt% TPU	BASF Plastics
Ultralastic	Polyurethane sheet, PU	Menasha Corporation
Ultramid A	Polyamide-66, PA-66/elastomer, with glass fiber, mineral filler or not	BASF Plastics
Ultramid B	Polyamide-6, PA-6/elastomer; with glass fiber, mineral filler or not	BASF Plastics
Ultramid C	Copolyamide-6/66, PA-6,66/elastomer; 15 or 30 wt% mineral filled	BASF Plastics
Ultramid Lurans	Polyamide, PA-66/ASA alloys	BASF Plastics
Ultramid	PA-6, PA-66, PA-610; blends, reinforced	BASF Plastics
Ultramid S	Polyamide-610; with glass fiber or not	BASF Plastics
Ultramid T	Semi-aromatic polyamide-6/66, PA-66 T, or PARA with elastomer; 30 wt% glass fiber or mineral filled	BASF Plastics
Ultramid Terluran	Polyamide, PA-66/ABS alloys	BASF Plastics
Ultranyl	PA-66/PPE alloys, reinforced or not	BASF Plastics
Ultrapas	Melamine-based molding compound	Dynamit Nobel
Ultrapek	Polyaryletherketone, PAEK (PEKEKK, PEK)	BASF Plastics
Ultrason E	Polyether sulfone, PES	BASF
Ultrason S	Polysulfone, PSF (or PSO)	BASF
Ultrason E	Polyethersulfone, ≤30 wt% glass fiber, PES	BASF Plastics
Ultrason	Polyethersulfone, PES, alloys	BASF Plastics
Ultrason S	Polysulfone, ≤30 wt% glass fiber, PSU	BASF Plastics
Ultrastyr OSA	SAN-EPDM/ABS or PC alloys	ECP Enimont Polymeri
Ultrastyr	Special styrene copolymers	ECP Enimont Polymeri

Ultrathene	Ethylene-vinyl acetate, reinforced or not, EVAc	USI Chemicals Co./ Quantum
Ultrax	Liquid crystal polymers, LCP	BASF Plastics
Ultryl	Poly(vinyl chloride)	Phillips
Ultzex	Ethylene-4-methylpentene-1 copolymer	Mitsui Petrochem
Unichem	Poly(vinyl chloride); with glass fiber or not, PVC	Colorite Plastics
Unidene	Elastomers	Enimont
Union Carbide	Polyethylenes; with carbon fibers or not	Union Carbide Co., Inc. Corp.
Unipol PP	Polypropylene, PP	Shell Chem. Co.
Unirez	Polyacrylic resin emulsions	Unocal
Unitika	Polyamide-6, filled or not, PA-6	Unitika Co.
Unival DMDA	Polyethylene; PE	Union Carbide Co., Inc. Corp.
UP	Polyarylate/Poly(ethylene terephthalate) blend	Unitika
Upilex	Polyimide films; PI	ICI Films
Uradil	Polyester resins for paints (aqu. dispersions), UP	DSM
Urafil J	Polyurethane; glass or carbon fiber filled, PU	Akzo/DSM
Uraflex	Polyester resins for paints, UP	DSM
Uralac	Polyester resins for paints, UP	DSM
Uralite	Polyurethane prepolymer resin, PU	Kingsley & Keith
Uramex	Polyester resins for paints, UP	DSM
Uramul	Poly(vinyl acetate) latices for paints, PVAc	DSM
Uravin	TPU/PVC alloy	Vi-Chem
Urecoll	Urea-formaldehyde, UF	BASF Plastics
Ureol	Polyurethane resins, PU	Ciba-Geigy Ltd.
Urepan	Polyurethane, PU	Bayer
Urochem	Urea-formaldehyde resins, UF	C.P.R.I.
Urtal	Acrylonitrile-butadiene-styrene copolymer, ABS	Montepolimeri
Urylon	Polyisocyanate thermoplastic, PPI	Urylon Development
US0028	Polyurethane; filled or not, PU	Dexter Corp.
Uvecryl	Acrylic and methacrylic resins	UCB Soc. Com.
V		
V440	Poly(vinyl chloride) compounds, PVC	Vi-Chem Corp.
Vacrel	Photopolymer film soldermask	E. I. du Pont de Nemours
Valox	PBT or PET or PCT, resins or blends	GE Plastics
Valox 200	Poly(butylene terephthalate); unreinforced, PBT	GE Plastics
Valox 300	Poly(butylene terephthalate); unreinforced, PBT	GE Plastics
Valox 400	Poly(butylene terephthalate); glass reinforced, PBT	GE Plastics
Valox 500	PBT/PET alloy; glass reinforced	GE Plastics
Valox 700	Poly(butylene terephthalate); glass/mineral filled	GE Plastics
Valox 800	Poly(butylene terephthalate) alloy; glass reinforced	GE Plastics
Valox 815	PBT/PET alloy; with glass fiber or not	GE Plastics
Valox 9000	Poly(ethylene terephthalate); glass reinforced, PBT	GE Plastics

Valox 9700	Polycyclohexyleneterephthalate; glass reinforced	GE Plastics
Valox HV7000	Poly(butylene terephthalate) alloy; mineral filled	GE Plastics
Valox VCT	PBT or PET toughened with elastomer	GE Plastics
Valtel, Valtec	Polypropylene, PP	Himont
Valtra	Polystyrene, PS, and blends	Chevron Chemicals
Valtra 7023	Rubber-modified styrenic blends	Chevron Chemicals
Valtra HG-200	Styrenic copolymer for injection molding	Chevron Chemicals
Vamac	Ethylene-acrylic elastomer, curable with diamines	E. I. du Pont de Nemours & Co.
Vandar	PBT/acrylic alloys, reinforced or not	Hoechst Celanese Corp.
VB-510	Polypropylene with talc, PP	Reichhold Chem., Inc.
VC	Poly(vinyl chloride), PVC	Borden Chem.
VE	Unsaturated vinyl ester, with glass or carbon fiber	ICI/Fiberite
Vector 6000	SB, SBS, SI, and SIS block copolymers	Dexco Polymers
Vectra A	Liquid crystal polymer, LCP; reinforced or not a copolyester from hydroxy benzoic acid with hydroxynaphthoic acid	Hoechst Celanese Corp.
Vectra B950	LCP copolymer comprising 20 mol% of terephthalic acid, 20 mol% 4-aminophenol, and 60 mol% of 2-hydroxy-6-naphthoic acid	Hoechst Celanese Corp.
Vectra V140	LCP/PPS blends for electrical/electronic parts	Hoechst Celanese Corp.
Vedril	Poly(methyl methacrylate)s powder, sheets, PMMA	Montedison SpA
Vekton 6	Polyamide-6; filled or not, PA-6	Norton Performance
Vekton 11	Polyamide-11, PA-11	Norton Performance
Vekton 66	Polyamide-66; filled or not, PA-66	Norton Performance
Velponyl/Velporex	Printing resins	DSM
Venyl	Polyamides; reinforced or not, PA	Vecoplas
Versamid	Polyamide; vegetable oils condensed with amines	General Mills
Versamid	Polyamides, PA	Henkel Corp
Versicol	Acrylic polyelectrolyte	Allied Colloids
Verton	Long fiber reinforced resins	ICI Materials – Plast./ LNP
Verton DF	Long fiber reinforced polyamide-66	ICI Materials – Plast./ LNP
Verton KA	Long fiber reinforced polyoxymethylene, POM	ICI Materials – Plast./ LNP
Verton NF	Long fiber reinforced SMA	ICI Materials – Plast./ LNP
Verton OF	Long fiber reinforced poly(phenylene sulfide), PPS	ICI Materials – Plast./ LNP
Verton PF	Long fiber reinforced polyamide-66, PA-66	ICI Materials – Plast./ LNP
Verton QA	Long fiber reinforced polyamide-610	ICI Materials – Plast./ LNP

Verton RF	Long fiber reinforced polyamide-66	ICI Materials – Plast./LNP
Verton TF	Long fiber reinforced polyurethane, PU	ICI Materials – Plast./LNP
Verton WF	Long fiber reinforced poly(butylene terephthalate)	ICI Materials – Plast./LNP
Verton YA	Long fiber reinforced polycarbonate, PC	ICI Materials – Plast./LNP
Verton YF	Long fiber reinforced polyester	ICI Materials – Plast./LNP
Vespel ST	Super-tough polyimide with high-impact strength	E. I. du Pont de Nemours
Vespel-SP	Polyimide (polypyromellitimide); electrical parts	E. I. du Pont de Nemours
Vestamelt	Copolyesters	Hüls AG
Vestamid	Polyamide-12, polyamide-6,12, PA-12 elastomer	Hüls AG
Vestamid D; X	Polyamide-612; filled or not, PA-612	Hüls AG
Vestamid L	Polyamide-12; filled or not	Hüls AG
Vestenamer	*Trans*-polyoctenamer, thermoplastic elastomer	Hüls AG
Vestoblend	Polyamide/PPE alloys, reinforced or not	Hüls/Nuodex Inc.
Vestodur	Poly(butylene terephthalate), PBT; reinforced or not	Hüls AG
Vestolen A	High-density polyethylene, HDPE	Hüls AG
Vestolen BT	Polybutene, PB	Hüls AG
Vestolen EM	EPR- or EPDM-modified polypropylene, PP, containing talc, $CaCO_3$, glass fibers, mineral, or not	Hüls AG
Vestolen P	Polypropylene, PP	Hüls AG
Vestolit	Poly(vinyl chloride), PVC, rigid and flexible	Hüls AG
Vestopal	Unsaturated polyester resins, UP	Hüls AG
Vestoplast	Amorphous olefin copolymers, TPO	Hüls AG
Vestopren	Polyolefin impact modifier, PO	Hüls AG
Vestoran	PPE blends with HIPS and elastomer	Hüls AG
Vestosint	Polyamides, PA	Hüls AG
Vestypor	Expandable polystyrene, EPS	Hüls AG
Vestyron	GP-PS, HIPS	Hüls AG
VFR-10248	Poly(ethylene terephthalate) with TiO_2, PET	Goodyear
Vibraspray	Elastomers	Safic-Alcan
Vibrathane	Urethane prepolymers, TS	Uniroyal Chemical Ltd.
Vibrin	Polyester resins, UP	Fiberglas Canada
Viclan	Vinylidene chloride copolymers, PVDC	ICI
Vicotex 260	Phenolic prepreg resins	Ciba-Geigy
Vicotex	Epoxy preimpregnates, EP	Brochier
Victrex D	Polyetheretherketone, with glass or carbon fiber	ICI Materials – Plastics/Victrex
Victrex J	Polyethersulfone, PES; filled	ICI/LNP Eng. Plastics
Victrex PEEK	Polyetheretherketone, PEEK; reinforced or not	ICI/LNP Eng. Plastics

Victrex PES	Polyethersulfone, PES; filled, lubricated	ICI/LNP Eng. Plastics
Victrex SRP	Liquid crystal polyester, LCP	ICI Materials – Plast.
Victrex VKT	Polyetheretherketone, PEEK/PTFE blend	ICI Materials – Plast.
Victrex VST	Polyethersulfone, PES/PTFE blends	ICI Materials – Plast.
Vidar	Poly(vinylidene fluoride), PVDF coating powders	Solvay & Cie SA
Vifnen VN	AAS/Poly(vinyl chloride), PVC alloys	Hitachi Chem.
Vilit	Poly(vinylidene chloride) copolymers, PVDC	Hüls A.-G
Vinapas	Poly(vinyl acetate), PVAc	Wacker Chemie
Vinavil	Poly(vinyl acetate), PVAc	Montecatini
Vinavol	Poly(vinyl alcohol), PVAl	Hoechst AG
Vinex	Poly(vinyl alcohol), PVAl	Air Products & Chem.
Vinidur	Poly(vinyl chloride), PVC, and impact-modified PVC with 5–15 wt% acrylate-graft copolymer	BASF Plastics
Vinika	Poly(vinyl chloride)-based elastomers, PVC	A. Schulman, Inc.
Viniproz	Poly(vinyl chloride)/PMMA alloys	USSR
Vinnapas	Poly(vinyl acetate), PVAc	Wacker-Chemie
Vinnol	Poly(vinyl chloride), *homo*, *g* and *r* copolymer., PVC	Wacker-Chemie
Vinoflex	Poly(vinyl chloride), suspension grade, PVC	BASF Plastics
Vinoflex	Vinyl chloride-vinyl ether copolymer, PVCAc	BASF Plastics
Vinuran	MBS modifier for poly(vinyl chloride)	BASF Plastics
Vipla	Poly(vinyl chloride) paste polymers, PVC	European Vinyls Corp.
Viplast	Poly(vinyl chloride) compositions, PVC	European Vinyls Corp.
Viscose	Fibers from cellulose	(generic name)
Vista	Poly(vinyl chloride); filled or not, PVC	Vista Chem. Co.
Vistaflex	Thermoplastic elastomers, TPO, PP/EPDM	Advanced Elastomer System
Vistalon 404	Ethylene-propylene copolymer, EPM	Exxon Chem.
Vistalon 2504	EPDM terpolymer	Exxon Chem.
Vistanex	Polyisobutene, PIB	Exxon Chem.
Vistel	Rigid PVC blends for injection molding	Vista Chemical Co.
Vithane	Polyurethanes, PU	Goodyear
Viton A	Vinylidene fluoride/fluoridehexafluoropropylene	E. I. du Pont de Nemours
Viton B	PTFE/PHFP/PVDF	E. I. du Pont de Nemours
Viton	Fluoroelastomers	E. I. du Pont de Nemours
Vitrofi	Vetrotex trademark for tissue	Vetrotex International
Vituf	Poly(ethylene terephthalate), PET; with TiO_2	Goodyear
Vivypak/Lighter	Poly(ethylene terephthalate), PET bottle grades	ECP EniChem Polymeri
Vixrex PES	Polyethersulfone, PES; glass/mineral filled	LNP Engineering
Vodcum	Phenolic resin, PF	Cain Chem. Inc.
Volara	EVA/PP or PE blends	Seiksui/Voltek
Volex 410	Poly(butylene terephthalate), PBT; glass/mineral	Comalloy Intl. Corp.

(*continued*)

Volex 440	Poly(ethylene terephthalate), PET; glass/mineral	Comalloy Intl. Corp.
Volex 600	Polyamides-6, polyamide-66, polyamide-612, PA; with glass/mineral	Comalloy Intl. Corp.
Voloy 100	Polypropylene; with glass/mineral, PP	Comalloy Intl. Corp.
Voloy 680	Polyamide-6,6; with glass/mineral, PA-66	Comalloy Intl. Corp.
Voltalef 300	Polychlorotrifluoroethylene, PCTFE	Elf Atochem
Voralast	Tailored PU elastomers	Dow Chem. Co.
Voranol	Polyether PU elastomers	Dow Chem. Co.
Vulcaprene	Polyurethanes, PU	ICI
Vulkollan	Polyurethanes, PU	Bayer AG/Miles
Vulta Foam	Rigid urethane foam, EPU	General Latex
Vultex	Latex and compounds	General Latex
Vybak	Poly(vinyl chloride), PVC	Bakelite Xylonite
Vydyne	Polyamide-66 or polyamide-69	Monsanto Chem. Co.
Vydyne M	Polyamide-66, PA-66	Monsanto Chem. Co.
Vydyne R	Polyamide-66 with glass or mineral, PA-66	Monsanto Chem. Co.
Vygen	Poly(vinyl chloride), PVC	Vygen Corp.
Vynathene	Ethylene-vinyl acetate copolymer, EVAc	Quantum Chem.
Vyncolite	Phenol-formaldehyde resins, PF	Vynckier
Vynite	Poly(vinyl chloride)/nitrile rubber alloy	Dexter Corp.
Vyram	PP/diene – TPE elastomeric blends	Advanced Elastomers
Vythene	Poly(vinyl chloride), PVC/PU alloy	Dexter Corp.
W		
W-xyFG	Polyetherimide with xy wt% glass fiber, PEI	Thermofil, Inc.
W-xyNF	Polyetherimide with xy wt% graphite fiber, PEI	Thermofil, Inc.
Wacke VAE	Ethylene-vinyl acetate copolymer, EVAc	Wacker Chimie A.-G.
Wacker PU	Polyurethane or silicone elastomers, PU	Arnaud Promecome
Wellamid	Polyamide-6, polyamide-66, PA-66	Wellman Inc.
Wellamid 22 LHI	Polyamide-66/elastomer, PA-66 blend	Wellman Inc.
Wellamid FR	Polyamide-66 with glass spheres, PA-66	Wellman Inc.
Wellamid GF	Polyamide-6 or polyamide-66 with glass fiber, PA-6, PA-66	Wellman Inc.
Wellamid MR	Polyamide-6 or polyamide-66 with glass or mineral, PA-66	Wellman Inc.
Wellamid MR	Polyamide-66/polyamide-6, PA-6 alloys	Wellman Inc.
Wellite	Poly(butylene terephthalate), PBT; with glass	Wellman Inc.
Wellpet GF	Poly(butylene terephthalate), PBT; with glass	Wellman Inc.
Welvic	Poly(vinyl chloride) compositions, PVC	European Vinyls Corp.
Wingtack	Synthetic polyterpene	Goodyear Chem. Eur.
Witcast	Polyurethane elastomers, PUR	Witco
Witcothane	Polyurethane elastomers, PUR	Witco
Wofatit	Ion-exchange resin	VEB Farbenfabrik
WRM	Elastomers	Safic-Alcan
WRS	Polypropylene, PP	Shell Chem. Co.
Wydyne	Polyamides; reinforced or not, PA	Monsanto

X

X-28057	Epoxy resins with mineral, EP	ICI/Fiberite
Xantar	Polycarbonate, PC	DSM
XB-4000	Polyamide-6 with or without glass, PA-6	Allied Signal Corp.
Xenoy	PC/PBT/MBA alloys, reinforced or not	GE Plastics
Xenoy 1000, 5000	Polycarbonate, PC:PBT = 1:1 alloys	GE Plastics
Xenoy 2000	Polycarbonate, PC/PET/MBA alloys	GE Plastics
Xenoy 3000	Polycarbonate, PC/TPE alloy	GE Plastics
Xenoy 6125	PET/PC, impact mod.; 0–30 wt% glass fiber	GE Plastics
Xenoy DX6302	Polycarbonate/polyester alloy with carbon fiber	GE Plastics
XL-030	Polypropylene, PP	Aristech Chem.
XP-50	Poly(*p*-methylstyrene-*co*-isobutylene)-based compatibilizing system	Exxon Chem. Co.
XT	Acrylic-based multipolymer blends	Cyro Industries
XT 3055	Polyamide alloys, PA	EMS-American Grilon
XT Polymer	Acrylic-based transparent, high-impact blend	Cyro Industries
Xtcon	Polyester/polyurethane hybrid resin	Amoco Chem. Co.
XTPE	Cross-linkable elastomers and olefins	Quality Service Technology
XTPL NFR-6000	Thermoplastic elastomer, TPE	E. I. du Pont de Nemours
XU	TPU/acrylonitrile-butadiene-styrene, ABS alloys	Dow Chem. Co.
XU61513	Polyethylene, PE	Dow Chem. Co.
Xycon	TPEs/TPU alloys	Amoco Chem. Co.
Xydar	Liquid crystal polymer, LCP	Amoco Performance Products
Xydar FC	Liquid crystal polymer, LCP; glass/mineral	Amoco Chem. Co.
Xydar FSR-315	Liquid crystal polymer, LCP; 50 % talc	Amoco Chem. Co.
Xydar RC	Liquid crystal polymer, LCP; glass/mineral	Amoco Chem. Co.
Xylok	Aralkyl thermoset resins	O.F.A.C.I.
Xylon	Polyamide-66 with a filler, PA-66	Akzo/DSM
Xyron 200	Poly(phenylene ether) PPE/HIPS alloys	Asahi Chem. Ind.
Xyron A	Polyamide/PPE/alloys, reinforced or not	Asahi Chem. Ind.
Xyron G	Polyamide/poly(phenylene ether) PPE alloys	Asahi Chem. Ind.

Y

Y-xyFG	Polystyrene with xy wt% glass fiber, PS	Thermofil, Inc.
Y1-xyFG	Polystyrene with xy wt% glass fiber, PS	Thermofil, Inc.
Yukalon	Polyethylenes, PE	Mitsubishi Petrochem.

Z

Zemid	–	E. I. du Pont de Nemours
Zenite	Polyamide-66, with glass fiber, PA-66	E. I. du Pont de Nemours
Zenite	Wholly aromatic polyester, LCP, HDT = 295 °C	E. I. du Pont de Nemours

(*continued*)

Zeo-karb	Ion-exchange resin	Permutit Co.
Zeonex	Polymethylpentene, PMP	Nippon Zeon
Zeonex	Polyolefin, amorphous, transparent for optical applications: disks, lenses, prism, LCD films, etc.	Nippon Zeon Co., Ltd.
Zeospan	Polyether elastomer	Nippon Zeon Co., Ltd.
Zerlon	Polystyrene, PS/PMMA alloys	Dow Chem. Co.
Zetabond	Plastic clad metal for fiber optic cables	Dow Europe
Zetafin	Ethylene-vinyl acetate copolymer, EVAc	Dow Chem. Co.
Zetpol	Hydrogenated, nitrile elastomer (HNBR), highly saturated for fuel and solvent resistance	Nippon Zeon Co., Ltd.
Zetpol PBZ	HNBR/PVC blends	Nippon Zeon Co., Ltd.
Zitex G	PTFE porous films	Norton Performance Plast.
Zylar	High transparency acrylic terpolymers	Novacor Chemicals Inc.
Zylar ST	SAN/polybutadiene high transparency alloy	Novacor Chemicals Inc.
Zytel	Polyamide-6,10, PA-610	E. I. du Pont de Nemours
Zytel 71G	Polyamide-66/ionomer, PA-66 alloys	E. I. du Pont de Nemours
Zytel 77G	Polyamide-6,12/ionomer, PA-612 alloys	E. I. du Pont de Nemours
Zytel 101	Polyamide-66, PA-66	E. I. du Pont de Nemours
Zytel 105	Polyamide-66, with carbon black, PA-66	E. I. du Pont de Nemours
Zytel 150	Polyamide-6,12, PA-612	E. I. du Pont de Nemours
Zytel 300, 400	Polyamide-6,6/ionomer, PA-66 alloys	E. I. du Pont de Nemours
Zytel 3100	Polyamide-6/polyamide-66 alloys	E. I. du Pont de Nemours
Zytel FN	Flexible polyamide alloys	E. I. du Pont de Nemours
Zytel GRZ	Glass fiber-reinforced PA-66 or PA-612	E. I. du Pont de Nemours
Zytel ST	Impact-modified PA-6 or PA-66	E. I. du Pont de Nemours
Zytel ST-350	Polyamide-612/elastomer, PA-612 alloys	E. I. du Pont de Nemours

Appendix V: Commercialization Dates of Selected Polymers

Year	Code	Polymer	Producer
1868	NC	Cellulose nitrate; *Nixon*	Hyatt Bros.
1900	CS	Casein; *Galalith*	Kritische (France)
1909	PF	Phenol-formaldehyde; *Bakelit*	Bakelit Gesellschaft
1915	PS	Polystyrene; *Trolitul*	I. G. Farbenindustrie
1926	AK	Alkyd resins; *Glyptal*	General Electric Company
1927	CA	Cellulose acetate fibers; *Lumarith*	Canadian Celanese/Eastman
1927	PMA	Poly(methyl acrylate)	O. Röhm
1928	PVAc	Poly(vinyl acetate); *Elvacet*	Shawinigan Chemical Ltd.
1928	PVC/Ac	Poly(vinyl chloride-co-vinyl acetate)	I. G. Farbenindustrie
1928	PMMA	Poly(methyl methacrylate), *Plexiglas*	Röhm and Haas
1929	GRS/SBR	Styrene-butadiene rubber; *Styrolux*	I. G. Farbenindustrie
1929	UF	Urea/formaldehyde resins; *Pollopas*	Stein Hall Mfg. Company
1930	PAN	Polyacrylonitrile	I. G. Farbenindustrie
1930	CR	Chloroprene rubber; *Neoprene*	E. I. du Pont de Nemours & Co.
1930	TR	Polysulfide rubbers; *Thiokol*	Thiokol Chemical Corporation
1931	PVC	Poly(vinyl chloride); *Trovidur, Vestolit*	I. G. Farbenindustrie
1931	PEG	Poly(ethylene glycol)	I. G. Farbenindustrie
1931	PVAl	Poly(vinyl alcohol)/formaldehyde fibers	I. G. Farbenindustrie
1932	Buna-S	Styrene-butadiene rubber	I. G. Farbenindustrie
1932	Buna-N	Acrylonitrile-butadiene rubber	I. G. Farbenindustrie

(continued)

Year	Code	Polymer	Producer
1932	UM	Urea/melamine	American Cyanamid Company
1933	PEMA	Poly(ethyl methacrylate)	Röhm and Haas
1933	EC	Ethyl cellulose; *Methocel*	ICI
1933	AF	Aniline/formaldehyde resins; *Cibanite*	Ciba
1934	PCTFE	Polychlorotrifluoroethylene; *Hostaflon*	I. G. Hoechst
1934	PVFO	Poly(vinyl formal)	Shawinigan Chemical Ltd.
1935	PVBO	Poly(vinyl butyral)	Shawinigan Chemical Ltd.
1936	ABS-A	Acrylonitrile-butadiene-styrene; *Royalite*	Naugatuck Chemical Company
1936	MF	Melamine/formaldehyde resins	Ciba
1937	PA-66	Polyamide-66; *Nylon*	E. I. du Pont de Nemours & Co.
1937	SAN	Styrene-acrylonitrile copolymer; *Luran*	I. G. Farbenindustrie
1937	TPU	Thermoplastic polyurethane elastomers	O. Bayer
1937	TS	Thermoset polyesters	Marco Chemical Company
1937	PVK	Poly-N-vinylcarbazole; *Luvican*	I. G. Farbenindustrie (BASF)
1938	MF	Melamine-formaldehyde resin; *Resart*	Henkel AG
1938	CAB	Cellulose acetate butyrate; *Tenite*	Eastman Kodak Company
1938	PA-6	Poly-ε-caprolactam; *Perlon*	I. G. Farbenindustrie
1938	PA-66	Polyhexamethyleneadipamide; *Nylon*	E. I. du Pont de Nemours & Co.
1939	LDPE	Low-density polyethylene; *Alketh*	ICI Ltd.
1939	PVDC	Poly(vinylidene chloride); *Saran*	Dow Chemical Company
1939	PVP	Poly-N-vinylpyrrolidone	Farbenindustrie
1939	PU	Polyurethane fibers, *Perlon U*	I. G. Farbenindustrie, Wolfen
1940	DAC	Diallyl glycol carbonate; *CR-38*	PPG Company
1942	UP	Unsaturated polyester; *Vestopal*	United States Rubber Company
1942	PTFE	Polytetrafluoroethylene; *Teflon TFE*	E. I. du Pont de Nemours & Co.
1943	EP	Epoxy; *Araldite*	Ciba-Geigy
1943	BR	Butyl rubber	St. Claire Processing Corporation
1943	HDPE	High-density polyethylene; *Vestolen*	BASF A.-G.
1943	PDMS	Polydimethylsiloxane; *Dow Corning*	Dow Corning Corporation
1943	PVAl	Poly(vinyl alcohol); *Vinaviol*	Shawinigan Chemical Ltd.

Year	Code	Polymer	Producer
1943	PVCAc	Vinyl copolymers; *Vinidur*	Shawinigan Chemical Ltd.
1945	CP	Cellulose propionate; *Forticel*	Celanese
1947	PU	Polyurethanes; *Perlon U*	Bayer A.-G.
1948	ABS-G	Acrylonitrile-butadiene-styrene latex	Röhm & Haas
1948	ACM	Acrylic elastomer; *Hycar PA*	B. F. Goodrich Chemical Co.
1950	EVA	Ethylene-vinyl acetate copolymer	ICI
1950	CSR	Chlorosulfonated PE; *Hypalon*	E. I. du Pont de Nemours & Co.
1950	PCTFE	Polychlorotrifluoroethylene	Hoechst A.-G.
1952	OPET	Oriented polyethyleneterephthalate film	E. I. du Pont de Nemours & Co.
1953	PET	Poly(ethylene terephthalate); *Melinite*	ICI
1954	PVAc/Ph	Poly(vinyl acetate)/phthalate	C. E. Frosst & Company
1955	PA-11	Polyamide-11; *Risilan*	Thann & Mulhouse
1956	PC	Bisphenol-A polycarbonate; *Macrolon*	Bayer A.-G.; General Electric Co.
1956	PCME	Polydichloromethyltrimethylene ether; *Penton*	Hercules
1957	PEG	Poly(ethylene glycol); *Carbowax*	Union Carbide Canada Ltd.
1957	PP	Isotactic Polypropylene; *Pro-Fax*	Hoechst/Montecatini/Hercules
1958	DAP/DAIP	Allyl unsaturated polyester; *Dapon*	FMC Corporation
1958	SMM	Poly(styrene-co-methylmethacrylate); *Kamax*	Röhm & Haas A.-G.
1958	UHMWPE	Ultrahigh molecular weight polyethylene; *Hostalen GUR*	Hoechst A.-G./Himont
1959	CPE	Chlorinated polyethylene; *Hostapren*	Hoechst A.-G.
1959	POM	Polyoxymethylene (Acetal); *Delrin*	E. I. du Pont de Nemours & Co.
1959	POM	Poly(oxymethylene/ethylene); *Celcon*	Celanese
1959	TPU	Thermoplastic polyurethane; *Estane*	B. F. Goodrich
1960	EVAc	Ethylene-vinyl acetate; *Elvacet*	E. I. du Pont de Nemours & Co.
1960	CAP	Cellulose acetate propionate; *Tenite*	Eastman Kodak
1960	CBR	Chlorobutyl rubber; *Exxon Butyl*	Exxon
1960	EPR	Ethylene-propylene elastomer; *Vistalon*	Exxon
1960	LLDPE	Linear low-density polyethylene; *Sclair*	DuPont-Canada
1960	–	Chlorinated polyether; *Penton*	Hercules Inc.
1961	–	Polyamide-epichlorohydrin; *Hydrin*	Hercules Powder Company
1961	Aramid	Poly(m-phenyleneisophthalamide); *Nomex*	E. I. du Pont de Nemours & Co.

<div align="right">(continued)</div>

Year	Code	Polymer	Producer
1961	FEP	Fluorinated-ethylene propylene; *Teflon FEP*	E. I. du Pont de Nemours & Co.
1961	PVDF	Poly(vinylidene fluoride); *Kynar*	Pennwalt Chemical Company
1962	SB	Styrene-butadiene block copolymer	Phillips
1962	ACM	Acrylate rubber	Polymer Corp. Ltd. (Polysar)
1962	Phenoxy	Polyhydroxyether of bisphenol-A; *Phenoxy*	Union Carbide
1962	PI	Polyimides; *Kapton*	E. I. du Pont de Nemours & Co.
1963	EPDM	Ethylene-propylene-diene; *Nordel*	E. I. du Pont de Nemours & Co.
1963	SMA	Styrene-maleic anhydride; *Dylark*	Sinclair Petrochemicals Company
1963	IO	Ethylene copolymer ionomers; *Surlyn*	E. I. du Pont de Nemours & Co.
1964	EVAc	Ethylene-vinyl acetate copolymer; *Elvax*	E. I. du Pont de Nemours & Co.
1964	EVAc	Ethylene-vinyl acetate cop.; *Ultrathene*	U. S. Industrial Chemicals
1964	PIAN	Isoprene/acrylonitrile rubber	Polymer Corp. Ltd. (Polysar)
1964	PPE	Poly(phenylene ether); *PPE*	General Electric Company
1964	PB	Polybutylene, *Vestolen BT*	Hüls A.-G.
1965	PAI	Polyamide-imide; *Torlon*	Amoco Chemical Corporation
1965	PBIA	Polybenzimidazole	Naramco, Materials Div.
1965	PSF	Polysulfone of bisphenol-A; *Udel*	Union Carbide Corp./ Amoco
1965	SBS	Poly(styrene-b-butadiene); *Kraton D*	Shell Chemical Company
1965	EP	Poly(ethylene-b-propylene); *Polyallomer*	Eastman Chemical Products
1965	(blend)	PU/polyester; *Corfam*	E. I. du Pont de Nemours & Co.
1965	PPX	Polyparaxylene; *Parylene*	Union Carbide Company, Inc.
1965	PMP	Poly-4-methyl pentene-1; *TPX*	ICI/Mitsui Petrochemical Ind.
1966	PPE blend	Poly(phenylene ether); *Noryl*	General Electric Company
1966	PA-12	Polyamide-12; *Vestamid*	Hüls A.-G./Emser Werke
1969	–	Amorphous, aromatic PARA; *Trogamid*	Dynamit Nobel
1969	PB	Polybutene-1; *Duraflex*	Hüls A.-G.

Year	Code	Polymer	Producer
1969	PBT	Poly(butylene terephthalate); *Celanex*	Celanese
1969	PBT	Poly(butylene terephthalate); *Hostadur*	Hoechst A.-G.
1970	PO	*Unipol process*	Union Carbide Company, Inc.
1970	LCP	Poly(p-oxybenzoyl); *Ekonol*	Carborundum
1970	BIIR	Bromobutyl rubber	Polysar
1970	PA-612	Polyamide-6,12; *Zytel 150*	E. I. du Pont de Nemours & Co.
1970	Aramid	Poly(p-phenyleneisophthalamide); *Kevlar*	E. I. du Pont de Nemours & Co.
1971	PASU	Polyarylsulfone; *Astrel*	3M Company
1971	PPS	Poly(phenylene sulfide); *Rayton R*	Phillips Petroleum Company
1971	PAE	Polyarylether; *Arylon T*	Uniroyal
1972	EVAl	Ethylene-vinyl alcohol; *Elvanol*	Kuraray Company Ltd.
1972	LCP	Liquid crystal polymers; *Ekkcel I-2000*	Carborundum
1972	PES	Polyethersulfone; *Victrex*	ICI Ltd.
1972	PFA	Perfluoro alkoxy polymer; *Teflon PFA*	E. I. du Pont de Nemours & Co.
1972	ETFE	Poly(ethylene-co-tetrafluoroethylene); *Tefzel*	E. I. du Pont de Nemours & Co.
1972	SB	Styrene-butadiene blocks; *K-resin*	Phillips Petroleum Company
1972	SEBS	Poly(styrene-b-ethylene butylene); *Kraton G*	Shell Chemical Company
1973	PVDF	Poly(vinylidene fluoride); *Dyflon*	Dynamit Nobel
1973	PAr	Polyarylate (mixture of *i*- and *t*-phthalic acid with bisphenol-A); *U-polymer*	Unitika
1976	PPSU	Polyphenylsulfone; *BXL, Radel R*	Union Carbide/Amoco
1978	PEEK	Polyetheretherketone; *Victrex*	ICI Ltd.
1980	APEC	Aromatic polyestercarbonate; *Apec*	Chemical Werke Albert; Bayer
1981	PEBA	Polyether-block-amide; *Pebax*	Atochem
1981	TPO	Dynamically vulcanized PO blend; *Santoprene*	Monsanto Company
1982	PEI	Polyetherimide; *Ultem*	General Electric Company
1983	PAS	Polyarylsulfone; *Radel*	Amoco
1983	PBI	Polybenzimidazole; *PBI*	Celanese Corporation
1985	PAE	Polyarylether; *Parylen*	Union Carbide
1985	MPR	Melt-processable rubber; *Acrylyn*	E. I. du Pont de Nemours & Co.
1986	PISO	Polyimidesulfone	Celanese
1987	PTES	Polythioethersulfone; *Amoroon*	Dainippon Ink & Chemicals
1987	PA-46	Polyamide-4,6; *Stanyl*	DSM
1987	PPMB	Poly-*p*-methylenebenzoate	Amoco

Year	Code	Polymer	Producer
1989	sPS	Syndiotactic polystyrene	Idemitsu/Dow
1991	PPA	Polyphthalamide; *Amodel*	Amoco
1992	sPP	Syndiotactic polypropylene	Sumitomo Chemical
1994	PENi	Polyethernitrile	Idemitsu Materials Company
1995	COPO	Ethylene-carbon monoxide copolymer	Shell Chemicals

Appendix VI: Notation and Symbols

The following list of commonly used notation and symbols is used in the *Encyclopedia*. They are based on those listed in *American National Standard Abbreviations for Use on Drawings and in Text (ANSI Yl.l)*, *American National Standard Letter Symbols for Units in Science and Technology (ANSI Y10)*, and *The Society of Rheology [J. Rheol., 28, 181 (1984)]*.

Abbreviations

A	Amorphous polymer
a-c	Alternating current
abs	Absolute
aq	Aqueous
av	Average
BC	Block copolymer
bcc	Body-centered cubic
bct	Body-centered tetragonal
bp	Boiling point
C	Crystalline polymer
ca	Circa (about as much)
cgs	Old units: centimeter-gram-second
CH	Centrifugal homogenizer
CMC	Critical micelle concentration
conc	Concentration
cp	Chemically pure
CPC	Cloud point curve
cryst	Crystalline
CST	Critical solution temperature
CTM	Cavity transfer mixer

d-c	Direct current, adj.
dB	Decibel
dec	Decompose
detd	Determined
detn	Determination
dia	Diameter
dil	Diluted
dl -; DL-	Racemic
DMA	Dimethylacetamide
DMF	Dimethylformamide
DMG	Dimethylglyoxime
DMSO	Dimethyl sulfoxide
DP	Degree of polymerization
dp	Dew point
DPH	Diamond pyramid hardness
DR	Draw ratio
DS	Degree of substitution
dsc	Differential scanning calorimetry
dta	Differential thermal analysis
ECU	Electrochemical unit
ED	Effective dose
ed.	Edited, edition, editor
em	Electron microscopy
emf	Electromotive force
emu	Electron magnetic unit
EP	Engineering polymer
EPB	Engineering polymer blends
epr	Electron paramagnetic resonance
Eq	Equation
esca	Electron-spectroscopy for chemical analysis
esp	Especially
esr	Electron-spin resonance
est(d)	Estimate(d)
estn	Estimation
esu	Electrostatic unit
exp	Experiment, experimental
ext(d)	Extract(ed)
fcc	Face-centered cubic
fp	Freezing point
frz	Freezing
FTIR	Fourier transform IR
g-mol	Gram-molecular weight
gc	Gas chromatography
glc	Gas–liquid chromatography

gpc	In old terminology, gel-permeation chromatography; modern term, size exclusion chromatography, sec, should be used instead
grd	Ground
hcp	Hexagonal close-packed
hex	Hexagonal
HPB	Homologous polymer blend
hplc	High-pressure liquid chromatography
HRC	Rockwell hardness (C scale)
HV	Vickers hardness number
hyg	Hygroscopic
ICT	International Critical Table
ID	Inside diameter
Im	Imaginary part of a complex function
im	Immiscible
intl.	International
ir	Infrared
IU	International Unit
IUPAC	International Union of Pure and Applied Chemistry
l.c.	Lower case (in printing)
LALLS	Low-angle laser light scattering
LCB	Long-chain branching
LCD	Liquid crystal display
LCST	Lower critical solution temperature
LED	Light-emitting diode
liq	Liquid
ln	Logarithm (natural)
log	Logarithm (common)
m	Miscible
max	Maximum
MEK	Methyl ethyl ketone
meq	Milliequivalent
mfd	Manufactured
mfg	Manufacturing
mfr	Manufacturer
MIBC	Methyl isobutyl carbinol
MIBK	Methyl isobutyl ketone
min	Minute; minimum
mol	Mole
mol wt	Molecular weight
mp	Melting point (also T_m)
MPB	Miscible polymer blend
ms	Mass spectrum
MTT	Melt titration technique
MW	Molecular weight

MWD	Distribution of MW
mxt	Mixture
na	Not available
nat	Natural
NDB	Negatively deviating blends
neg	Negative
NG	Nucleation-and-growth
NI	Notched Izod impact strength
NIRT	Notched Izod impact strength at room temperature
nmr	Nuclear magnetic resonance
no.	Number
NRET	Non-radiative energy transfer
NTP	Normal temperature and pressure (25 °C and 101.3 kPa or 1 atm)
o-	Ortho
OD	Outside diameter
OM	Optical microscopy
p-	Para
p-i-n	Positive-intrinsic-negative
p., pp.	Page, pages
PAB	Polymer alloys and blends
PDB	Positively deviating blends
Pe	Peclet number
pH	Negative logarithm of the effective hydrogen ion concentration
phr	Concentration in parts per hundred of resin
PICS	Pulse-induced critical scattering
pm	Partially miscible
pmr	Proton magnetic resonance
PNDB	Positively and negatively deviating blends (sigmoidal)
pos	Positive
ppb	Parts per billion (10^9)
pph	Parts per hundred
ppm	Parts per million (10^6)
ppmv	Parts per million by volume
ppmwt	Parts per million by weight
PRC	Particular rheological composition
pt	Point; part
pwd	Powder
qv	Quod vide (which see)
r-f, rf	Radio frequency; adj. and n., respectively
rad	Radian
rds	Rate-determining step
Re	Real part of complex function
Ref.	Reference
rh	Relative humidity

rms	Root-mean square
rpm	Rotations per minute
rps	Revolutions per second
RT	Room temperature
SANS	Small-angle neutron scattering
satn	Saturation
SAXS	Small-angle X-ray scattering
SCB	Short-chain branching
SCF	Self-consistent field
SD	Spinodal decomposition
SEC	Size-exclusion chromatography
SEM	Scanning electron microscope
SH	Strain hardening
SI	Le Système International d'Unités (International System of Units)
SIS	Solvent-induced shift
sol	Soluble
soln	Solution
soly	Solubility
sp	Specific
sp gr	Specific gravity
sr	Steradian
std	Standard
TEM	Transmission electron microscopy
tex	Tex, linear density
THF	Tetrahydrofuran
tlc	Thin-layer chromatography
trans	Isomer in which substituents are on opposite sides of double $C = C$ bond
TREF	Temperature rising elution fractionation
TW	Glass temperature width (°C)
UCST	Upper critical solution temperature
uv	Ultraviolet
v sol	Very soluble
var	Variable
vol	Volume
vs.	Versus, against
WAXS	Wide-angle X-ray scattering
yr	Year

Notation: Roman Letters

A	Chemical affinity
a	Drop curvature

A_2	Second virial coefficient
a_c, a_T	Concentration and temperature shift factors
A_j, a_j	Equation constants
a_s	Distance from spinodal condition; $a_s = 2[(\chi N)_s - (\chi N)]$
B	Thermodynamic interaction parameter; $B = \chi_{12} RT/V_{1u}$
B	Mobility
B, B_o	Extrudate swell and its value for Newtonian liquid
$C = \omega/\dot{\gamma}$	Sprigg's constant
c_i^o	Universal constants in WLF equation
c_2, C	Concentration (g/dl)
C_p	Heat capacity at constant pressure
C_v	Heat capacity at constant volume
$c \times 3$, $(3c)$	Number of external degrees of freedom per macromolecular segment
D^c	Cahn-Hilliard diffusion constant
D	Droplet deformability; $D = (l-b)/(l+b)$
D	Diffusion coefficient
D	Tensile compliance
$D(t, \sigma_E)$	Tensile creep compliance
d, d_i	Diameter, diameter of ith generation of particles in polydisperse suspensions
D_c, D_e	Capillary and extrudate diameter, respectively
D_E	Droplet deformability in extensional flow
D_r	Rotational Brownian diffusion coefficient
$D_s(\sigma_E)$	Steady-state tensile compliance
$d_{v/s}$	Volume-to-surface average particle diameter
E	Elasticity of the interphase
E_i	Interaction energy
E	Tensile, or Young's, modulus
e	Electron
$E(t)$	Tensile relaxation modulus
$E(t, \varepsilon)$	Tensile stress relaxation modulus
E^+	Threshold energy of coagulation
E_j	Activation energy
E_{ij}	Exchange energy of i-j contact
F	Helmholtz free energy (F = E—TS)
f	Free volume fraction
$f(x)$	Function of a parameter x
f_O	Onsager coefficient
G	Gibb's free energy (G = E — TS + pV = H — TS)
G	Shear modulus (modulus of rigidity)
G	Gravitational constant, G = 6.67 3 1011 N m^2/kg^2
Gy	Gray
g	Acceleration due to gravity; g = 9.80621 m/s^2 (see level, lat. 45°)
g^*	Concentration gradient at the interface

$G'(\omega)$	Shear storage modulus
G'_y, G''_y	Yield values for G' and G''
$G(t)$	Shear relaxation modulus
$G(t, \gamma)$	Shear stress relaxation modulus
$G''(\omega)$	Shear loss modulus
$G^*(\omega)$	Complex shear modulus
H	Enthalpy
H	Henry
h	Hydrodynamic shielding parameter
$H(t)$	Relaxation spectrum
h_c	Critical separation distance for drop coalescence
$\tilde{H}_G$	Reduced Gross relaxation spectrum
h_g	Partial (or specific) molar enthalpy of component g
$H_G(s)$	Gross frequency relaxation spectrum
h_T	Vertical time-temperature shift factor
Hz	Hertz
I	Scattering intensity ratio
I_D, I_M	Intensity of emission of the excimer and monomer
J	Hear compliance
J	Joule
$J'(\omega)$	Shear storage compliance
$J(t)$	Shear creep compliance
$J(t, \sigma)$	Shear creep compliance
$J''(\omega)$	Shear loss compliance
$J^*(\omega)$	Complex shear compliance
J, J_o, J_c°	Creep compliance, its value at t = 0 and at steady state
J_e	Equilibrium shear compliance
J_s	Steady-state shear compliance
$J_s(\sigma)$	Steady-state compliance
K	Bulk modulus
K	Kelvin
k_B	Boltzmann s universal constant
k	Rate constants
k_H, k_M	Huggins, Martin constants of solution viscosity
L	Length of a dispersed particle
$L(t)$	Retardation spectrum
L, L*	Lamellar thickness
l, b	Prolate drop half length and half width
M	Mobility constant
m	Strain ratio in asymmetric extension
M, M_w, M_n	Molecular weight and its weight and number averages
M_e	Entanglement molecular weight
M_n	Number-average molecular weight
M_v	Viscosity-average molecular weight

$\mathbf{M_w}$	Weight-average molecular weight
$\mathbf{N_e}$	Number of polymer segments between entanglements
$\mathbf{N}$	Newton (force)
n_i^D	Index of refraction (for 20 °C and sodium light)
$\mathbf{n}$	"Power law" exponent between melt viscosity and the deformation rate
N_1, N_2	First and second normal stress difference, respectively
$N_1^+(t, \dot{\gamma})$	First normal stress growth function
$N_1^-(t, \dot{\gamma})$	First normal stress decay function
$N_1(t, \dot{\gamma})$	First normal stress relaxation function
$N_2(t, \dot{\gamma})$	Second normal stress relaxation function
$N_2^+(t, \dot{\gamma})$	Second normal stress growth function
$N_2^-(t, \dot{\gamma})$	Second normal stress decay function
$\mathbf{P}$	Pressure
P	Probability
$\mathbf{P(q)}$	One-particle scatter function
$\mathbf{p, p^*}$	Anisometric particle aspect ratio and its generalized value
$\mathbf{Pa}$	Pascal (pressure)
P_e	Entrance-exit pressure drop in capillary flow
$\mathbf{Q}$	Heat received by the system
$\mathbf{q}$	Wavevector
R, r	Radius, position variable radius
$\mathbf{R}$	Universal gas constant; 8.31432 J/mol deg
$\mathbf{r^2}$	Correlation coefficient squared, precision of data
$\mathbf{kr^2l}$	Mean square end-to-end distance
$R(t, \sigma)$	Ecoil function, $R(t, \sigma) = \gamma_r/\sigma$
$\mathbf{r, r_c}$	Radial position of a particle and its critical value
$\mathbf{R_c}$	Particle diameter-to-capillary diameter ratio
$\mathbf{Re}$	Reynolds number
$\mathbf{R_R}$	Rao constant
R_T	Trouton ratio; ratio of the extensional to shear viscosity
$\mathbf{R_g}$	Radius of gyration
$R_\infty(\sigma)$	Ultimate recoil function
$\mathbf{S}$	Entropy
$\mathbf{S}$	Siemens
$\mathbf{s}$	Number of statistical segments per macromolecule
$\mathbf{s}$	Second
$S(t, \sigma_E)$	Tensile recoil coefficient; $S(t, \sigma_E) = \varepsilon_r/\sigma_E$
$\mathbf{s_g}$	Specific molar entropy of g
S_i	Initial slope of the stress growth function in uniaxial extension
$\mathbf{s_i}$	Specific surface area of ith particle
$\mathbf{S_v}$	Entropy per unit volume
T	Temperature
t	Time

T_g	Glass transition temperature
T_m, T_g	Melting point; glass transition temperature
t_p	Period of rotation for anisometric particles
U	Total energy of the system
V	Volume
v	Specific volume
v_g	Partial molar (or specific) volume of g
v_i	Velocity in direction i
V_L, V_S	Ultrasonic velocity; transverse and shear
W	Heat flow (components W_i, i = x, y, z)
w	Weight fraction
w_i	Weight fraction of specimen i
x	Variable
x_1 or x	Direction of flow
x_2 or y	Direction of velocity gradient
x_3 or z	Neutral direction
x_i	Mole fraction
z	Coordination number

Greek Alphabet (Lower Case, Capital Letter)

α, ς	alpha	ν, N	nu
β, B	beta	ξ, Ξ	xi
γ, Γ	gamma	π, Π	pi
δ, Δ	delta	ρ, P	rho
ε, E	epsilon	σ, Σ	sigma
ζ, Z	zeta	τ, T	tau
η, H	eta	φ, (ω), Φ	phi
θ, (ϑ), Θ	theta	χ, X	chi
κ, K	kappa	ψ, Ψ	psi
λ, Λ	lambda	ω, Ω	omega
μ, M	mu		

Notation: Greek Letters

α_i	Thermal expansion coefficient
2α	Convergence angle
β_{12}	Slip factor in Lin's equation
Γ_{ij}	Nonrandomness parameter for ij segment placement
Γ_o	Critical parameter for droplet breakup

$\boldsymbol{\gamma}$	Shear strain
$\dot{\boldsymbol{\gamma}}_c, \dot{\boldsymbol{\gamma}}_y$	Critical value of $\dot{\gamma}$ for onset of dilatancy or yield
$\boldsymbol{\gamma}_R$	Recoverable shear strain
$\dot{\boldsymbol{\gamma}}$	Shear rate
$\boldsymbol{\gamma}_r(t, \boldsymbol{\sigma})$	Recoil strain
$\boldsymbol{\gamma}_\infty(\boldsymbol{\sigma})$	Ultimate recoil
$\boldsymbol{\Delta}$	Increment
$\boldsymbol{\Delta E_\eta}$	Activation energy of flow
$\boldsymbol{\Delta G_m}, \boldsymbol{\Delta G_{el}}$	Gibbs free energy of mixing and an elastic contribution
$\boldsymbol{\Delta H_m}$	Heat of mixing
$\boldsymbol{\Delta l}$	Thickness of the interphase
$\boldsymbol{\delta}$	Solubility parameter
$\boldsymbol{\varepsilon}$	Dielectric parameter
$\boldsymbol{\varepsilon}$	Tensile Hencky strain
$\dot{\boldsymbol{\varepsilon}}$	Strain rate (≥ 0)
$\boldsymbol{\varepsilon}_b$	Maximum Hencky strain at break
$\boldsymbol{\varepsilon}_{\max}$	Maximum filament shrinkage
$\boldsymbol{\varepsilon}_r(t, \dot{\boldsymbol{\varepsilon}})$	Tensile recoil function
$\boldsymbol{\varepsilon}_\infty(\boldsymbol{\sigma}_E)$	Ultimate tensile recoil
$\boldsymbol{\varepsilon}_B/\dot{\boldsymbol{\varepsilon}}_B$	Biaxial strain/strain rate (≥ 0)
$\boldsymbol{\zeta}$	Correlation length; domain size
$\boldsymbol{\eta}$	Viscosity
$\boldsymbol{\eta}_o$	Limiting viscosity at zero shear rate, i.e., at the upper Newtonian plateau
$\boldsymbol{\eta}_\infty$	Limiting viscosity at infinite shear rate, i.e., at the lower Newtonian plateau
$\boldsymbol{\eta}_s$	Viscosity of solvent or of continuous medium
$\boldsymbol{\eta}_r$	Relative viscosity (η/η_s)
$\boldsymbol{\eta}_{sp}$	Specific viscosity ($\eta_r - 1$)
$[\boldsymbol{\eta}]$	Intrinsic viscosity
$[\boldsymbol{\eta}]_E, [\boldsymbol{\eta}]_{E,d}$	Emulsion and deformable droplet emulsion intrinsic viscosity, respectively
$\boldsymbol{\eta}_d, \boldsymbol{\eta}_m$	Viscosity of dispersed and matrix liquid; also η_1, η_2, respectively
$\boldsymbol{\eta}_i, \boldsymbol{\eta}_{si}, \boldsymbol{\eta}_{ei}$	Interface viscosity and its shear and extensional components
$\boldsymbol{\eta}_{app}$	Apparent viscosity
$\boldsymbol{\eta}_{o,M}$	Maxwellian viscosity
$\boldsymbol{\eta}^*(\boldsymbol{\omega})$	Complex viscosity
$\boldsymbol{\eta}'(\boldsymbol{\omega})$	Dynamic viscosity
$\boldsymbol{\eta}''(\boldsymbol{\omega})$	Out-of-phase component of complex viscosity
$\boldsymbol{\eta}^+(t, \dot{\boldsymbol{\gamma}})$	Shear stress growth coefficient
$\boldsymbol{\eta}^-(t, \dot{\boldsymbol{\gamma}})$	Shear stress decay coefficient
$\boldsymbol{\eta}_E^+(t, \dot{\boldsymbol{\varepsilon}})$	Tensile stress growth coefficient
$\boldsymbol{\eta}_E^-(t, \dot{\boldsymbol{\varepsilon}})$	Tensile stress decay coefficient

$\boldsymbol{\eta_E}$	Elongational or tensile viscosity
$\boldsymbol{\eta_B}$	Biaxial extensional viscosity
$\boldsymbol{\eta_B^+(t, \dot{\varepsilon}_B)}$	Biaxial stress growth coefficient
$\boldsymbol{\eta_B^-(t, \dot{\varepsilon}_B)}$	Biaxial stress decay coefficient
$\boldsymbol{\Theta}$	Scattering angle
$\boldsymbol{\vartheta}$	Distortion wavelength in capillary instability
$\boldsymbol{\kappa}$	Ratio of rheological to interface forces; capillarity factor $\kappa = \sigma d / v$
$\boldsymbol{\Lambda}$	Wavelength
$\boldsymbol{\lambda}$	Thermal conductivity
$\boldsymbol{\lambda = \eta_d / \eta_m}$	Viscosity ratio of the dispersed to the matrix phase liquids in polymer blend flow
$\boldsymbol{\mu}$	Chemical potential
$\boldsymbol{\mu_i}$	Chemical potential of i
$\boldsymbol{\mu}$	Poisson ratio
$\boldsymbol{\nu}$	Interfacial tension coefficient
$\boldsymbol{\nu, \nu_o}$	Dynamic interfacial tension coefficient and its equilibrium value
$\boldsymbol{\nu_s, \nu_e}$	Side and interfacial energies of a polymeric crystal
$\boldsymbol{\sigma}$	Shear stress
$\boldsymbol{\sigma_{ij}}$ ij	component of the stress tensor
$\boldsymbol{\sigma_y, \sigma_{yc}, \sigma_{yE}}$	Yield shear stress, its value in compression and extension
$\boldsymbol{\sigma_c}$	Critical shear stress for droplet break-up
$\boldsymbol{\sigma_m}$	Critical shear stress for melt fracture
$\boldsymbol{\sigma^+(t, \dot{\gamma})}$	Shear stress growth function
$\boldsymbol{\sigma^-(t, \dot{\gamma})}$	Shear stress decay function
$\boldsymbol{\sigma(t, \gamma)}$	Shear stress relaxation function
$\boldsymbol{\sigma_E}$	Net tensile stress
$\boldsymbol{\sigma_B^+(t, \dot{\varepsilon})}$	Tensile stress growth function
$\boldsymbol{\sigma_B^-(t, \dot{\varepsilon})}$	Tensile stress decay function
$\boldsymbol{\sigma_E^-}$	Tensile stress decay coefficient
$\boldsymbol{\sigma_B}$	Net stretching stress
$\boldsymbol{\rho}$	Density
$\boldsymbol{\tau}$	Relaxation time
$\boldsymbol{\tau_y}$	Characteristic time of the yield cluster
$\boldsymbol{\tau_\zeta}$	Lifetime of the density fluctuation
$\boldsymbol{\Phi_\iota}$	Farris volume fraction of component i in the mixture
$\boldsymbol{\phi, \phi_m}$	Volume fraction; maximum packing volume fraction
$\boldsymbol{\phi_{mo}, \phi_{m\infty}}$	Maximum packing volume fraction at shear stress $\sigma \to 0$ and $\sigma \to \infty$
$\boldsymbol{\chi_{ij}}$	Thermodynamic interaction coefficient between species i and j
$\boldsymbol{\Psi(t)}$	Retardation function
$\boldsymbol{\Psi_1}$	First normal stress coefficient
$\boldsymbol{\Psi_2}$	Second normal stress coefficient
$\boldsymbol{\psi_1^+(t, \dot{\gamma})}$	First normal stress growth coefficient
$\boldsymbol{\psi_2^+(t, \dot{\gamma})}$	Second normal stress growth coefficient

$\psi_1^-(t, \dot{\gamma})$	First normal stress decay coefficient
$\psi_2^-(t, \dot{\gamma})$	Second normal stress decay coefficient
Ω	Distortion wavelength
Ω	Vorticity
ω	Frequency (rad/s)

Subscripts

app, a	Apparent
B	Binodal
E	Uniaxial extension
g	Glass
i	Counting subscript, inversion or dispersed phase
L	Linear viscoelastic function
m	Mixing, melt, matrix
R	Reference variable
S	Strain hardening
S	Spinodal
s	Suspension
y	Yield

Superscripts

E	Excess value
L	Lattice gas model
+	Stress growth function
−	Decay function
∼ (tilde)	Reduced variable
*	Complex or reducing variable

Mathematical Symbols

<>	Average
Π	Multiplication
π	3.1415926536
Σ	Summation

Index
