Contents

Volume 1

Part I Professions and Professional Practice

1	Professionalism, Profession and Professional Conduct: Towards a Basic Logical and Ethical Geography	5
	David Carr	
2	The Concept of Professionalism: Professional Work, Professional Practice and Learning.....	29
	Julia Evetts	
3	Moral Aspects of Professions and Professional Practice	57
	Gerhard Minnameier	
4	Professional Work and Knowledge.....	79
	Lina Markauskaite and Peter Goodyear	
5	Conceptions of Professional Competence	107
	Martin Mulder	
6	Becoming a Practitioner: Professional Learning as a Social Practice.....	139
	Silvia Gherardi and Manuela Perrotta	
7	Productive Systems of Professional Formation.....	163
	Jim Hordern	

Part II Research Paradigms

8	Understanding Learning for the Professions: How Theories of Learning Explain Coping with Rapid Change.....	199
	Erno Lehtinen, Kai Hakkarainen, and Tuire Palonen	

9	Understanding Learning for Work: Contributions from Discourse and Interaction Analysis	225
	Laurent Filliettaz	
10	Research Paradigms of Practice, Work and Learning	257
	Paul Gibbs	
11	A Phenomenological Perspective on Researching Work and Learning	279
	Gloria Dall’Alba and Jörgen Sandberg	
12	The Neuronal Base of Perceptual Learning and Skill Acquisition	305
	Mark W. Greenlee	
13	Hierarchical Linear Models for Research on Professional Learning: Relevance and Implications	337
	Eva Kyndt and Patrick Onghena	
14	The Anthropological Paradigm of Practice-Based Learning	369
	Catherine Hasse	
 Part III Educational Institutions and Systems		
15	Professional Education Between School and Practice Settings: The German Dual System as an Example	397
	Peter F.E. Sloane	
16	The Dual System of Vocational Education and Training in Germany – What Can Be Learnt About Education for (Other) Professions	427
	Bärbel Fürstenau, Matthias Pilz, and Philipp Gonon	
17	From University to Professional Practice: Students as Journeymen Between Cultures of Education and Work	461
	Madeleine Abrandt Dahlgren, Tone Dyrdal Solbrekke, Berit Karseth, and Sofia Nyström	
18	Integrating Professional Learning Experiences Across University and Practice Settings	485
	Stephen Billett and Sarojni Choy	
19	Transitions to Working Life: Securing Professional Competence	513
	Päivi Tynjälä and Jennifer M. Newton	
20	Interprofessional Education in the Health Workplace	535
	Elizabeth Katherine Molloy, Louise Greenstock, Patrick Fiddes, Catriona Fraser, and Peter Brooks	
21	Medical Education	561
	Tim Dornan and Pim W. Teunissen	

22 A Phenomenographic Way of Seeing and Developing Professional Learning 591
 Ming Fai Pang

23 Changing Cultures of Knowledge and Professional Learning 611
 Monika Nerland and Karen Jensen

Volume 2

Part IV Practice-Based Learning Activities

24 Identity and Agency in Professional Learning 645
 Anneli Eteläpelto, Katja Vähäsantanen, Päivi Hökkä,
 and Susanna Paloniemi

25 Simulation Learning 673
 Jan Breckwoldt, Hans Gruber, and Andreas Wittmann

26 Learning from Errors at Work 699
 Christian Harteis and Johannes Bauer

27 Learning in the Circumstances of Professional Practice 733
 Stephen Billett and Raymond Smith

28 Apprenticeship as a Model for Learning in and Through Professional Practice 759
 Geoffrey Gowlland

29 Implicit Knowledge and Work Performance 781
 Britta Herbig and Andreas Müller

30 Intuition in Professional and Practice-Based Learning 807
 Eugene Sadler-Smith

31 An Organisational Perspective on Professionals’ Learning 835
 Bente Elkjaer and Ulrik Brandi

32 Professional Learning in the Ambulance Service 857
 Morten Sommer

33 Mimetic Learning at Work: Learning Through and Across Professional Working Lives 887
 Stephen Billett

Part V Implementing and Supporting Professional Learning

34 Professional Development and the Profession 915
 Anton Havnes and Jens-Christian Smeby

35 The Real Professional is a Learning Professional 955
 P. Robert-Jan Simons and Manon C.P. Ruijters

36	Team Learning in Education and Professional Organisations	987
	Filip Dochy, David Gijbels, Elisabeth Raes, and Eva Kyndt	
37	Teams, Communities of Practice, and Knowledge Networks as Locations for Learning Professional Practice	1021

Introduction

The need for both a thorough and robust initial preparation as well as provision supporting ongoing learning has become essential for the professions within the last decades. This is because the requirements for occupational practice continue to become more complex and demanding, and more frequently transform as labour markets have dramatically changed, and the requirements for practice continually change. Moreover, across western countries with advanced industrial economies, the key growth in employment can be found in occupations that are referred to as para-professional and professional occupations. Hence, there is a growing demand for both initial learning and ongoing development for professional occupations. In all, increases in demand for occupational development, transitions in individuals' occupational careers, and changing requirements for occupational activities and tasks make for both thorough initial preparation and ongoing learning throughout professionals' working lives essential now. Furthermore, as changes in these occupations' requirements for performance are usually manifested in particular set of everyday work tasks, both initial preparation and professional development provisions wholly located in educational institutions decrease in their salience. Correspondingly, learning and development experiences in and as part of professional activities has increased in their salience, and are often included within both initial and professional development programs. Consequently, educational provisions for the professions now focus increasingly on the analysis and the support of learning for, within and throughout professional lives, and often include practice-based experiences. It follows, therefore, that research on professional and practice-based learning is emerging as a crucial topic within educational enquiry, and one whose findings requires to be broadly considered, widely disseminated and acted upon in educational programs seeking to prepare individuals for professional occupations and then sustaining their employability across lengthening professional lives.

Associated with these educational goals are a range of scientific challenges and important focuses within the field of professional learning that warrant being further understood. These include understanding and making explicit the complex and massive knowledge that is required for professional practice and identifying ways in which this knowledge can best be initially learnt and developed further across

professional lives. For instance, conceptually, major issues for a handbook on research in professional and practice-based learning are analytical explications of those processes that support learning at an individual and an organisational level. Associated procedural issues include understanding how learning experiences and educational processes might best be aligned or integrated to support this professional learning, again at the individual workers' level as well as on organisational level of enterprises.

However, the increase in numbers and concentration of professional workers, and their need for ongoing development, demands a comprehensive handbook comprising contributions that speak directly to theoretical and empirical research on professional learning issues, and that can be considered as key reference for international scientific and educational community. Therefore, given these growing needs and sets of important educational challenges, it is only now necessary and timely to bring together what is currently known about professional work, processes for initial and ongoing development of the capacities required for effective professional practice and a specific consideration on practice-based learning in the form of a comprehensive handbook. This handbook aims to fill this gap, and, thereby, augment the existing Springer series (i.e. International Handbooks of Education). The intention with this handbook is to establish a strong research-based platform for informed discussion of the variety of concepts and practices associated with professional education and professionals' learning that focus on both the individual development of professionals and the organisation of professional life and educational experiences to support and sustain that learning, and with a particular emphasis on that learning arising through practice-based experiences. The key premise of this handbook is that during both initial and ongoing professional development, individual learning processes are influenced and shaped through their professional environment and practices. Moreover, in turn, the practice and processes of learning through practice are shaped by their development, all of which are required to be understood through a range of research orientations, methods and findings. All of this means this handbook necessarily engages a wide range of scholars whose research orientations, disciplines and perspectives are quite diverse. Contributions reporting research on the individual development in professional contexts are incorporated into the handbook as is research on the social embedding of practice in professional domains. The need to engage with this range of distinct contributions as well as being comprehensive required careful scoping and selection of contributors who are able to provide chapters that comprehensively inform the particular area or issue they address and which in turn have informed the development of the structure and organisation of the handbook's content.

Moreover, there are no restrictions in the area of relevant occupations or conceptual or procedural approaches to conform to those of the editors. Instead, an inclusive approach towards the project of research in professional learning is necessary and is adopted in selecting appropriate contributors and secure comprehensive and well-developed responses from them. In these ways, the handbook brings together the contributions of key international researchers across its two volumes of consolidated work. For this purpose, researchers from a range of disciplines make

contributions that are integrated into the text. The contributors include those from education, studies of the professions, anthropology, sociology, cognitive and social psychology, amongst others. Moreover, the book seeks to be inclusive in its scope. In this way, the handbook also aims at addressing professional learning in institutions of higher and vocational education as well as the practice settings where professionals work and learn, focussing on both initial and ongoing development. In all, the handbook provides a platform for between almost 50 contributions from selected and invited researchers in associated fields to present and discuss research highly focused and detailed analyses through their chapters.

The handbook comprises two volumes, with six sections each with distinct themes, three each per volume, with a total of 48 chapters. Each of these two volumes has an overarching purpose and the parts within them are directed towards describing, elaborating and articulating key aspects of that purpose. The contributors to this Handbook are drawn from across a range of countries and continents, languages, disciplines and fields of study. These volumes and the contributing sectors are now briefly introduced.

Volume 1 – Scientific and Institutional Framework

The first volume sets out the scientific institutional framework through which professions can be understood, their purposes identified and investigated, the kinds of practices that are organised and enacted to develop the capacities required to practice them. Central to these practices are the provision of practice-based experiences which are central to developing the kinds of capacities required for effective professional practice. The three parts comprising this volume are entitled: (i) Professions and professional practice; (ii) Research paradigms; and (iii) Educational institutions and systems. The focuses for those parts are briefly outlined below.

Professions and professional practice: This part comprises contributions that advance accounts of what constitutes the professions, professional practice and how the practice of professions is enacted in the workplace. These contributions explicitly address what constitutes professions and professional practice, including its ethical dimensions. Considerations are also given here to the formation of professions and the way professional associations and professionals serve and sustain the standing of the professions. In doing so, this part sets out something of the concepts, thematic issues and premises for considering what constitutes the professions and their formation.

Research paradigms: This part comprises contributions outlining the diverse theoretical and conceptual accounts of understanding both professions and professional learning, and that indicate the scope of methodological approaches to investigating both the professions and professional learning. These approaches are represented by accounts of methods and paradigms which are used to engage in scientific enquiry associated with what constitutes professional work and its learning. Key and contrasting methods are included, illustrated and discussed in this part.

Educational institutions and systems: This part comprises contributions identifying the educational purposes and processes (i.e. curriculum and pedagogy) used by educational institutions to prepare professionals and then maintain their competence across their working lives. Featured here are selected accounts of the way educational systems have been organised and enacted to secure professional learning outcomes and what kinds of conceptions of curriculum and curriculum practices are utilised in securing effective professional capacities through educational institutions and systems.

Volume 2 – Learning, Education and Assessment in and for the Professions

This second volume focuses on procedural issues associated with learning for and through professional practice. This includes a necessary but central consideration of the role which practice-based learning experiences play in the formation of national capacities. Moreover, attention is given to the design and implementation of experiences that support professional learning both through initial preparation and ongoing development across professional lives. Concluding here is also a set of considerations about the assessment of learning experiences and the evaluation of professional education provisions. The three parts comprising this volume are entitled: (i) Practice-based learning activities; (ii) Implementing and supporting professional learning; and (iii) Assessing professional learning.

Practice-based learning activities: This part comprises reviews and analyses of the current state of research on work related learning activities occurring outside educational institutions – e.g. workplaces, everyday life, private environments – covering intentional as well as incidental learning. Central to this part is understanding, illustrating and elaborating the roles which practice-based learning activities play in the development of occupational identity and capacities as well as being utilised as sites for ongoing professional learning across lengthening working lives. Included here are contributions that utilise the educational lexicon and discourse to understand, legitimate and illustrate the ways which practice-based activities and experiences are central to professional formation.

Implementing and supporting professional learning: This part comprises research reporting on processes of and practices for the ongoing development of professional competence, with a particular emphasis on how this kind of learning arises through practice-based strategies. The strategies comprise a range of curriculum and pedagogies practices which can be used to secure professional capacities and identities. These include considerations of the goals and purposes for professional education and further development, and the way in which practices such as mentoring, the use of teams and the actions of professionals themselves are central to securing initial and ongoing professional competence.

Assessing professional learning: This part addresses research on issues of judging, evaluating, monitoring, and assessing professional learning. The chapters address evaluation processes on the micro-, meso-, and macro level of analysis by exploring methodological and normative issues of work related judgement processes. Research which reports the ways in which professional learning can be assessed and the means by which the assessment progresses feature within this final part. This featuring largely focuses on making judgements about what constitutes professional competence, means for validly and reliably assessing that learning, and extends through to considerations and practices associated with the evaluation of education programs, provisions of educational institutions and other kinds of experiences that seek to secure, certify and order professional knowledge.

Through the focus of these volumes and the structuring of these contributions, what is provided within this International Handbook of Research into professional and Practice Based Learning is an attempt to provide a comprehensive, albeit not exhaustive, resource which provides an informed account of the field which builds upon a scientific and institutional heritage and seeks to use that heritage to inform how provisions for the initial and ongoing learning professionals can be ordered, enacted, supported and assessed.

Part I

Professions and Professional Practice

This first part comprises contributions that advance accounts of what constitutes the professions, professional practice and how the practice of professions is enacted in workplaces. In doing so, they set out and elaborate the objects of what efforts associated with learning for the professions and through practice-based considerations are directed. In his chapter – *Professionalism, profession and professional conduct: Towards a basic logic and ethical geography* (Chap. 1) – David Carr explores the current broadly based interest in professions and professionalism. Both the attraction of high status occupations and characteristics of occupations performed to the highest standard, including ethical conduct have broadly attracted much interest. Yet, such premises require clear understandings about and distinctions amongst what constitutes a profession, being professional and the broader conservation of professionalism. He proposes that whilst many occupations have and are characterised by the need for moral conduct, that professions are distinguishable by inherent ethical nature and the status of their enactment. These distinguishing qualities then become central concern for professional education, with the object of securing a professional phronesis. Adopting a sociological stance Julia Evetts in her chapter – *The concept of professionalism: Professional work, professional practice and learning* (Chap. 2) – elaborates changing conceptions of professionalism from those largely associated with the organisation of work practice as undertaken and exercised by an individual professional, through to a form of work which is increasingly subject to the constraints and expectations of large organisations, where professionals increasingly work. To delineate this trajectory, she examines how the conception of professionalism arose and has been transformed in contemporary times. In particular, she refers to how the practice of the professions within organisations whilst being increasingly common, positions professionalism and professionals discretion in decision-making within an organisational context, which could have either private or public sector goals. Adopting a similar theme, Gerhard Minnameier proposes that the sets of standards which are used to guide the preparation of professionals needs to both include the moral aspects of professional practice, and how those aspects and professional practice more broadly are shaped by situational clues and

what constitutes situationally appropriate professional practice. In his aptly entitled contribution – *Moral aspects of professions and professional practice* (Chap. 3) – he argues for the use of a broader set of standards as guidelines for developing professional practice and that these guidelines need to address both moral and situational adjustments to more broadly encompass that practice.

In their chapter – *Professional work and knowledge* (Chap. 4) – Peter Goodyear and Lina Markauskaite explore perspectives of relations between professional work and the knowledge which supports it. Their review is informed by emerging theories that make specific references to both contributions from working and learning in work settings which are captured through the conception of an extended mind. This consideration is augmented by accounts and conceptions that emphasise the active nature of perception as possessed and deployed by human actors. They suggest that the reliance upon explicit and conceptual knowledge as emphasised within the educational discourse needs to be moderated by one which is more broadly inclusive of a wider range of ways of knowing, acting and the circumstances in which these can be more effectively enacted. For instance, the emphasis on experiences within work settings and how these might be related to those within educational institutions is a central consideration. In his chapter – *Conceptions of professional competence* (Chap. 5) – Martin Mulder proposes that conceptions of professional competence have been helpful in understanding the requirements for learning these occupations and through practice-based experiences. His emphases in making such claims is that through coming to understand what constitutes professional competence and that what constitutes professional competence has a range of dimensions and characteristics which then can lead to informed views about how such competence can be developed initially and extended across professionals' working life. In advancing the case he links competence to considerations of motivation, intelligence as well as performance. From these, a number of specific and non-domain specific elements of competence are proposed as needing to be developed. He then proposes schemes by which professional competence can be generated and evaluated, and provides examples of how this has been enacted across a range of occupations.

Adopting a sociological perspective, Silvia Gherardi and Manuela Perrotta in their chapter – *Becoming a practitioner: Professional learning as a social practice* (Chap. 6) – discuss another kind of trajectory. That is, of individuals becoming socialised as professional practitioners, through their participation in professional practice, and socialisation into the particular profession. They identify a dual process of individuals being inducted into a particular circumstance of practice and at the same time being seduced into the particular profession. Hence, they give much attention to the issue of being inducted into professional practice and professional work. Basing their analyses on professionals' engagement in fertility clinics, they propose processes of becoming a professional is not concluded when commencing as a professional, but continues across working life as does the tensions in negotiations of contradictions amongst the management of professional work, its conduct and professionals' identity as workers. Finally, in the chapter entitled – *Productive systems of professional formation* (Chap. 7) – Jim Hordern examines ways that pathways towards and processes of professional formation recognition are shaped

by the relations amongst professional associations, educational institutions and employing organisations. These relations give rise to not only to what constitutes professional knowledge, but also the organisation of professional work. Adopting a sociological perspective of knowledge and identity formation, and drawing findings from distinct kinds of professional practice, this chapter illuminates how these processes are enacted and appropriated by those engaged in professional work.

Across this opening part, then, these contributions explicitly address what constitutes professions and professional practice, including the ethical dimensions of occupational practice. Considerations are also given here to the formation of professions and the way professional associations and professionals serve and sustain the standing of the professions. In doing so, these contributions set out something of the concepts, thematic issues and premises for considering what constitutes the professions and their formation that are the central focus of this Handbook.

Chapter 1

Professionalism, Profession and Professional Conduct: Towards a Basic Logical and Ethical Geography

David Carr

Abstract For various reasons, concepts of profession, professionalism and professional conduct are of considerable political interest and concern, especially in modern liberal democratic contexts and economies. For one thing, the idea of profession has become the modern gold standard of occupational status: for another, insofar as ideas of profession or professionalism have been associated with notions of enhanced occupational standards, to regard workplace conduct as ‘professional’ is to consider it to have been performed according to the highest moral and technical standards. That said, it seems that such notions are liable to unhelpful confusions between different and distinguishable senses of such terms as ‘profession’, ‘professional’ and ‘professionalism’. From this viewpoint, the first aim of this chapter to distinguish and clarify different senses of professionalism and profession – in particular, to distinguish ‘profession’ as a term for a particular type or category of human occupation from a broader notion of ‘professional’ as a more general term of normative appraisal. Following this, however, the chapter turns to deeper exploration of profession, arguing that while other occupations can and often are conducted morally, what mainly distinguishes professions from other occupations is their inherently ethical nature and status. Further to this, the chapter also aspires to give a distinctively ‘virtue ethical’ account of such status focused on the development of ‘professional phronesis’.

Keywords Professionalism • Professional • Profession • Ethics • Moral virtue • *Phronesis* • Practical wisdom

1.1 Diverse Senses of ‘Profession’ and ‘Professional’

Concepts of profession, professionalism and professional conduct are of considerable public interest and concern, especially in modern liberal democratic contexts and economies. For the moment, we may mention two broad reasons for such interest. First, the idea of profession – or the aspiration to ‘professional’ recognition – has become the modern gold standard of occupational status: occupations already widely regarded as professions guard such status with jealous pride, and those presently lacking such recognition aspire no less enviously to such status. Secondly, however, ideas of profession or professionalism have usually implied or been associated with enhanced occupational standards – so that, as we shall see, to describe an episode of workplace conduct as ‘professional’ is usually to regard it as having been performed to the very highest moral and technical standards. That said, to whatever extent at least the aspiration to such standards may capture part of what we commonly mean by such terms as ‘profession’ ‘professional’ and ‘professionalism’ these also seem to be caught in a web of confusions between rather different ideas or concepts that it is part of our present purpose to untangle (For some history of social development of notions of profession and professionalism, see Larson 1977: for previous treatments by the present author of the conceptual issues, see Carr 1999, 2000).

In what follows, I will assume that most modern non-English counterparts of such terms as ‘profession’, ‘professional’ and ‘professionalism’ – given the relatively recent global currency of such terms – reflect or exhibit much the same nuances and associations that they have in common or standard Anglophone usage. At all events, it should first be clear that such terms are used in a range of different ways – not all of which are entirely consistent with one another. In this regard, perhaps the loosest usage concerns the term ‘professional’ as such. Indeed, grammatically speaking, we might first note that while this term is often – perhaps mainly or primarily – used adjectivally, it is nowadays also much employed as a *noun*. Thus, to refer to someone as ‘a professional’ may be to signify that he or she belongs to one (or more) of a certain class or category of human occupations – commonly called ‘professions’ – or, more modestly, that he or she (doctor, teacher, plumber, office cleaner or whatever) is a person who has actually some training, expertise or experience with regard to the task (s)he is performing. Clearly, however, someone may be considered a professional in the second of these senses without being, or being considered to be, a professional in the first. Moreover, while any converse mismatch is less likely – since one might hope for or trust in some degree of relevant training or experience on the part of general practitioners or lawyers – one might still intelligibly observe of some professional practitioner, on some occasion, that although (s)he was a professional in the first sense (s)he was not much of one in the second.

That said, the term ‘professional’ seems no less prone to ambiguity in its perhaps more familiar adjectival sense. To begin with, there is a familiar enough sense of ‘professional’ indicating little more than that those engaged in this or that

occupation receive payment for what they do. In this sense, in referring to someone as a professional footballer (for example), the implied contrast is with all those who are (unpaid) amateurs. (We shall not here pause to consider more recent blurring of this distinction as the in notion of the professional amateur or ‘pro-am’: but see Leadbeater and Miller 2004.) However, this is clearly a different sense of ‘professional’ from that whereby we commend someone for a job well done. Thus, if a plumber comes to my house and makes an expert job of installing the washing machine, I may recommend his or her services to my neighbour as highly professional; whereas if the builder makes a terrible mess of repairing the garage, I am likely to dismiss him (or her) as ‘unprofessional’. In this sense, the terms ‘professional’ and ‘unprofessional’ are just very general terms of normative appraisal: as such, they are used to signify whether or not a provider of this or that service has performed it to competent or exemplary standards. But given that the sense of professional as contrasted with ‘unprofessional’ is *different* from that which contrasts with ‘amateur’, there can be no contradiction in stating that an agent who performs professionally in one sense does not do so in another. Thus, we may – without the least whiff of self-contradiction or paradox – judge that this professional footballer has played unprofessionally, whereas the playing of that amateur is extremely professional. To complicate things yet further, however, while we have already noted a common contemporary use of ‘professional’ to refer to members of professions, it should be clear that we might consider paid workers who give satisfactory service to be professional in these senses without regarding them as member of *professions*.

In this light, to speak of agents as professionals in the sense of members of professions is to place them in a particular occupational category that has traditionally included doctors, lawyers and architects, but excluded joiners, plumbers and electricians. To be sure, the question of which occupations should be included in the general category of profession is a matter of some dispute. Indeed, it seems nowadays widely held – under the influence of modern ‘constructivist’ social theory that there is little more to any distinctions between so-called professions and other occupations than considerations of social standing and no grounds other than status mongering and snobbery for regarding general medical practice and law as professions and refusing so to recognise teachers, nurses or electricians. That said, it hardly does much to explain the different social status of diverse occupations, to say that it is because people or societies have come to regard them in this way. Thus, without denying that status mongering and snobbery are, or have often been, involved in claims to professional membership, it should be admitted that there *are* significant economic and other differences between human occupations that are not just differences of social regard – so that the more interesting question might be that of why, in the light of such differences, occupations have attracted different social status. Indeed, it is of some interest here that despite latter day aspirations of such groups as ministers, teachers and nurses to the status of profession, these occupations have traditionally merited much social esteem as ‘vocations’ rather than professions. (For a thought-provoking critique of the present author’s position, which – despite some misunderstanding – gives broader occupational and vocational application to

present points, see Winch 2002.) At all events, we shall now examine the question of what, if anything, *might* distinguish the occupational category of profession from such other groupings as (for example) vocation, trade or service industry.

1.2 Criteria of ‘Profession’ and/or Professionalism

Much latter day (particularly sociological) literature on professions and professionalism has sought to ‘define’ such notions – or, at any rate, to specify criteria for the correct application of the terms in question. In the event, many such attempts seem to have been bedevilled by aforementioned confusions between notions of profession and professional – since (for one thing) alleged criteria of ‘professionalism’ have usually looked more like criteria for professional membership. Indeed, perhaps compounding such confusion, it has been common to refer to occupations such as nursing, teaching and ministry as ‘semi-professions’ (see, primarily, Etzioni 1969) largely on the grounds that they do not meet all suggested criteria of full professionalism – some of which would only strictly apply, as it were, to traditional professions. Still, such confusion aside, we may take the most frequently cited criteria of profession or professionalism as useful starting points for exploration of the contours of both profession and the normative character of much professional service. While such lists of criteria vary somewhat between sources, the following conditions of profession/professionalism are routinely specified (see, for example, Humes 1986): (i) that the occupation in question provides important or valued public service; (ii) that it requires substantial knowledge and skill involving extensive education and/or training; (iii) that it embodies something like a moral or ethical code spelling out the nature of professional duties; (iv) that its workers have appropriate scope for the exercise of independent (‘autonomous’) thought and judgement in complex circumstances; (v) that it is organised on a self-regulating basis for purposes of recruitment and discipline. In the rest of this chapter, we shall submit the more fundamental (mainly the first four) of these conditions to closer examination.

The trouble with the first, ‘important professional service’, criterion is that it seems far too vague or imprecise for any useful purpose. First, as previously noted, since what may count as an important service must depend somewhat on an agent’s needs at this or that particular moment, almost any human occupation is likely to be of pressing importance at some time or another: if I am up to my eyes in water in the kitchen or my rubbish has not been collected for the past month, I am likely to regard the services of plumbers or garbage collectors as more urgent than those of lawyers or GPs. That said, it seems possible to put a rather finer point on this idea as at least contributory to the definition of such established professions a medicine and law. For example, one point that might be made about medical and legal services is that they are concerned to address needs – in such cases for health care and civil liberty – that are quite basic to human flourishing in any tolerable human society. Indeed, such needs are so basic to human welfare or benefit – in anything that we should want to call a civil society – that some institutional provision for such needs tends to be

regarded as something like a *moral* right or entitlement. Thus, while it might sound odd to speak of someone having a right to a new car, a smart suit of clothes or a good bottle of wine, it may seem more apt to speak of someone as having a right to (at least basic) medical treatment or legal aid. That said, many other human occupations such as teaching, nursing and ministry – not always included in traditional lists of professions – might well be regarded as fulfilling this condition of profession.

In particular, it might be said that education in the form of institutionalised schooling seeks – along with medicine and law – to provide a necessary condition of flourishing or survival in the complex circumstances of modern civil societies. For just as citizens are unlikely to fare well in the absence of those civil liberties that a legal system is (at least in principle) designed to uphold or defend, or in the absence of the basic health-care that institutionalised medical care exists to provide, so individuals are unlikely to prosper in technologically advanced modern societies without the basic knowledge and expertise – literacy, numeracy and employable skills – that state schooling aims to promote. From this viewpoint, education (or at least institutionalised schooling), along with law and medicine, might be regarded as providing a basic triple bulwark against perennial human evils of disease, injustice and ignorance. That said, something along these lines (if with slightly less clout) might also be said on behalf of services that other human occupations aim to provide. For, to be sure, it also makes much sense to speak of civil rights or entitlements to some (basic) affordable housing, clean water, energy supply, postal delivery, public transport, refuse collection – as distinct from private transport, free holidays or local entertainment – and so on (again, see Winch 2002). All the same, as we shall shortly see, some such moral discourse of rights, obligations and/or (corresponding) public accountability would seem to be significantly implicated in any significant definition of profession or professional service.

Moreover, the important public service criterion is only proposed as *one* feature of profession or professionalism – as a *necessary* rather than sufficient condition – and as such needs to be reinforced by other aforementioned criteria. So what, then, of the second criterion of substantial knowledge and skill involving extended education and training? Again, this requirement is rather vague as it stands, and – without some further specification – might well apply to many occupations that would not widely be considered professions. Still, perhaps the key point at issue here is that not any kind of knowledge, or any sort of education – such as the extensive craft knowledge acquired through even lengthy apprenticeship to a trade – would qualify in this regard. The expertise in question here would seem to be precisely academic or research-based knowledge and understanding normally acquired through graduate and/or postgraduate study. (However, for some interesting questions about the role and status of professional ‘experts’ and ‘expertise’ in the face of information technology and contemporary ‘knowledge society’, see Weinberger 2011.) From this viewpoint, the kinds of formal academic education associated with such acknowledged professions as law and medicine would best exemplify the epistemic criterion of profession/professionalism. However, this does fairly sharply separate the professional sheep from the non-professional goats for many if not most human occupations, since the practical hands-on knowledge acquired over the course of

even lengthy apprenticeship would not serve to raise such trades as plumbing or joinery to the status of profession – although, of course, we might still regard certain forms of practical or technical failure or dereliction as ‘unprofessional’ in the wider normative sense of this term.

That said, the professional knowledge condition does raise problems for certain occupations that have gained some contemporary credibility as professions – partly by dint of extensive or recently extended professional training and preparation. Indeed, one such ‘problematic’ occupation is *teaching*. To be sure, one general difficulty about evaluating the professional status of teaching is that there are different sectors of teaching that require different levels or depths of expertise. It is clear, for example, that lecturers in universities or other institutions of higher education, as well as many subject specialists in secondary schooling, will usually have undergone extensive in-depth education and training in this or that field of knowledge and understanding in order to qualify for university, college or secondary teaching. Most contemporary secondary school teachers, as well as some university or college lecturers, will also have acquired some kind of training in professional conduct or technique via postgraduate diplomas of education (UK PGDE’s) or other vocational qualifications. But for legions of teachers working in early or primary education the situation is often different. Indeed, in the United Kingdom and elsewhere, the history of elementary teacher training is largely a tale of fairly rudimentary initiation – often via little more than apprenticeship – into basic instructional methods, for which little in the way of advanced personal education would be required. For well into post-WWII years, the academic fare of teacher training colleges was little more than a rag-bag of loosely connected scraps of educational history, ‘philosophy’ and psychological theory, and it was not until the late 1960s that a serious attempt was made to make degree level purses out of the sows’ ears of pre-service teacher training courses. (For the development of British teacher education, see Dent 1977; and Thomas 1990).

Moreover, despite much professional effort during the early decades of post WWII settlement towards transforming elementary teaching into an all-graduate profession in Britain and elsewhere, political and professional doubts have continued to surface about whether lengthy academic training – particularly in the academically suspect realms of so-called educational theory – is the best route to producing teachers, and there have been regular calls to return to something more like school-based training of teachers in classroom skills or ‘competences’. The basic idea here is that beyond the possession of adequate subject knowledge – which, for primary teachers, would really mean no more than the general knowledge acquired during compulsory primary and secondary schooling – all there really is to good teaching is the mastery of a repertoire of effective techniques of classroom management and communication. From this viewpoint, what has been derided as ‘barmy’ educational theory (Clarke 1991) – usually a rather uncertain mixture of psychology, sociology, philosophy and history of education – has been dismissed as not only redundant, but actually impedimental to the efficient promotion of effective school learning. Indeed, calls by British political and educational conservatives to abolish both educational theory and the training institutions in which it is taught have

been fuelled by various events in which the college teaching of educational studies, influenced by radical (Marxist, anarchist and other) social theory, has allegedly undermined school order and discipline and created local social unrest and division (see Davis 2002 on the infamous British ‘William Tyndale’ affair). There can also be little doubt that the Dewey influenced progressivism of the professional education academy of the USA has been viewed with similar scepticism and distrust by American political and educational conservatives.

In short, given the enormous public significance of schooling as a formative influence on the character and attitudes of citizens, it is hardly surprising that any and all untoward social developments in which such schooling may seem to have been implicated have been of larger political concern: that, indeed, such events have usually inclined to tighter central control over the pre-service training of teachers and the conduct of public education. Indeed, it is now a part of the received professional wisdom of British teacher educators that recent tighter central control over both the content and methods of state schooling has followed directly from political and public perceptions of declining standards in primary schools – widely imputed to the so-called ‘progressive’ educational innovations of the 1960s and the influence of radical (usually neo-Marxist) social theory on the college training of teachers in the 1960s and 1970s. Subsequent state educational ‘reforms’ have taken the forms: first, of direct central control of the school curriculum through the imposition of national curricula – determining *what* teachers are allowed to teach; secondarily, of the imposition of various ‘competence’ and other models of teacher training – prescribing fairly precisely *how* teachers should teach (see Carr 2000; Hyland 1993). While such developments were invariably promoted in the name of enhanced or improved teacher ‘professionalism’, they have been widely perceived by teachers and teacher educators as ‘de-professionalizing’: on this view, such initiatives significantly restrict teachers’ individual autonomy and initiative, reducing them to ‘classroom technicians’ whose main role is to follow the directives of various line-managers. At this point, indeed, we may note that such scepticism about whether teaching satisfies the ‘epistemic’ criterion of professionalism (or of teaching profession) – more particularly, about whether there is any theoretically significant professional knowledge or expertise that teachers might be said to possess – have precisely fuelled doubts about the fourth criterion of professionalism as applied to teaching (or, again, about the status of teaching as a profession): that teaching might be considered the kind of occupation that requires, or allows much scope for, individual judgement or *autonomy*.

1.3 The Moral Basis of Profession and Normative Professionalism

At this point, however, perhaps the precise implications of the epistemic or knowledge condition of profession or professionalism would benefit from closer scrutiny. For the assumption so far seems to be that the status of an occupation as a profession or

as professional depends primarily on extent of the in-depth theoretical or (in some cases) technical knowledge that it requires of practitioners. In this light, a medical consultant or surgeon will count as highly professional insofar as (s)he possesses cutting-edge knowledge of the latest developments in medicine, and university teaching would count as more of a profession – or as more professional – than infant teaching just to the extent that it requires an academically deeper level of subject knowledge. On this view, teaching becomes more professional, or more of a profession, the more specialised the knowledge that it transmits becomes, and as the age of the students to whom that knowledge is instructed increases – so that tutoring adults would have to count as more of a profession or more professional than teaching (or nurturing) children in the nursery classroom. But although teachers themselves may often have been guilty of viewing the matter in this light, there would seem to be something objectionable about any such viewpoint. For even though the kind of knowledge generally associated with professions may be of a highly sophisticated academic or technical nature, and while some professional shortcomings may well relate to deficiencies of academic and technical knowledge, such deficiencies are not obviously the only or the most significant grounds on which we might judge this or that practice to be *unprofessional*. Indeed, it may be that we would not necessarily fault a doctor or a lawyer for lacking some item of academic knowledge or some skill as such, unless such lack directly undermined this or that obligation of justice or care towards patient or client: on the other hand, we may readily impute professional failures to teachers of early years even though such teachers would not be expected to profess high levels of academic or technical skill. In short, those knowledge-related deficiencies for which practitioners are likely to be judged unprofessional seem to turn more on failures to appreciate what is required for appropriate association or transaction with those they are employed to serve.

To be sure, in the broad normative sense that entails failure to rise to the highest standards of any given occupation, charges of unprofessionalism – notably in the case of such trades and crafts as building, joinery and plumbing – are more likely to turn on lack of knowledge of the principles of building, joinery or plumbing, or of the trade skills required for building or plumbing, than on considerations related more to the complexities of human relationship or association. In crude terms, we are more likely to regard a builder as unprofessional on the grounds that he lacks knowledge of how the roof is constructed, or the skills to repair it, than because he fails to respect confidences, charges some more than others for the same job, is rude or offhand to clients, or (even) sleeps with their wives. A builder may be guilty all of these offences and yet pass muster as a professionally commendable – in the general occupational requirement sense of ‘professional’ – artisan. Of course, we may prefer to employ trades-people who do not behave in such humanly disreputable ways; it may well be bad business (given the ill repute they are likely to acquire) for them so to conduct themselves; and it is clear enough that many trades-people are of highly praiseworthy character and conduct. The present point is only that it is mainly by their craft knowledge and skills that we judge such trades-people to be professional or unprofessional. Many who are highly professional in the ‘job-well-done’ sense are notorious for poor time-keeping, avoiding clients they

find uncongenial or giving variable estimates (perhaps on the basis of on-the-spot judgements about what this or that client seems able to afford). But we are less liable on these accounts to question their professional competence. Still, ironically, it may be just on such grounds that people have traditionally been *disinclined* to include building, plumbing and other trades in the 'higher' occupational category of 'profession'.

From this viewpoint, it begins to look as though the kind of knowledge, expertise or wisdom on which the professionalism of professions mainly turns could not be academic or technical knowledge quite divorced from other human capacities. While we do expect members of professions – taking these, for the moment, to include such 'white collar' occupations as medicine, law, teaching, ministry and architecture – to be well-educated people, it is not upon such academic learning *per se* that their professional status depends, but upon their capacity to engage – albeit in the light of such learning – in civilised and/or morally principled association: indeed, despite a common assumption that members of professions must possess highly specialist knowledge of particular fields of academic study or enquiry, this may not always be so (in the case of, say, generalist primary teachers). So, what might we expect of good ('professional') doctors is that they are able to judge what is the right course of treatment in these circumstances for this particular (anxiety-prone) patient; of good lawyers that they are able to distance themselves, in the interests of just and impartial treatment, from personal sympathies or antipathies towards those they are required to prosecute or defend; and of good teachers that they are able to instil character-forming discipline, or provide necessary support to under-confident or vulnerable pupils, as and when circumstances indicate the need for this. In short, it is not the possession of bodies of academic knowledge or of sophisticated technical skill *as such* that members of professions need for professional conduct: what is rather required is the *education* – displayed, amongst other things, in a grasp of principles of just and equitable human association and in qualities of reflective character – to appreciate how such occupational knowledge and technique might or should be utilised for individual or common good.

Since it ought already to be evident that such appreciation is deeply implicated in considerations of fairness, equal regard and right action, it should now be clear that our exploration of the nature of profession and (higher) professionalism has taken a distinctively *moral* turn – and that it is now time to look more closely at the third 'moral' criterion of profession. (For a useful overview of the ethics of profession and professionalism, see Koehn 1994.) In this light, we have already noted that such professional services as health care, legal aid and education are naturally spoken of as benefits to which people have *rights*. To be sure, rights talk is not exclusive to professional services or always even significantly moral: thus, if I purchase a faulty television set, such purchase will usually carry a supplier's guarantee of my right to return the item – and to a refund of my money – if the item is faulty. But, first, such rights – and any derivative obligations – are evidently not *universally* applicable – since they are clearly relative to the terms of this or that specific contract. Moreover, though we may say that a company that refuses refund for faulty goods or services is culpable or unfair, such unfairness may appear only

minimally or restrictedly moral – or, perhaps, to be more a legal than a moral matter. On the other hand, for some moral theorists – such as, notably, Kant (1967) – the two ideas of morality and universality have been inseparably linked. On this view, a moral right is one that is owed to all by virtue of a common human (rational) condition – rather than as a matter of local commercial or other contract – and a moral duty is one that all human agents owe to others by that same token of common (rational) humanity. Kant’s various formulations of the *categorical* (or moral) imperative, specify that a moral (as opposed to prudential) law or prescription is ‘universalizable’ – in other words, one to which we might will the obedience of all without exception – as well as one that advocates treatment of any and all human agents as ends in themselves rather than as means to this or that particular end.

Interestingly, it seems to be much the spirit of this Kantian account of morality that lies at the heart of the most enduring – and certainly the earliest – western conception of professional ethics. This conception, ascribed to the fourth century BC Greek physician Hippocrates, insists that the human needs which those of his profession are called upon to meet are so basic and common (perhaps, more strongly, universal) as to place doctors under a clear moral obligation to address them. This means, amongst other things, that doctors should always put the interests of patients above their own and never exploit them for their own advantage or profit. In its original formulation, the Hippocratic code runs as follows:

I swear by Apollo Physician and Asclepius and Hygieia and Panacea and all the gods and goddesses, making them my witnesses, that I will fulfil according to my ability and judgment this oath and this covenant:

To hold him who has taught me this art as equal to my parents and to live my life in partnership with him, and if he is in need of money to give him a share of mine, and to regard his offspring as equal to my brothers in male lineage and to teach them this art – if they desire to learn it – without fee and covenant; to give a share of precepts and oral instruction and all the other learning to my sons and to the sons of him who has instructed me and to pupils who have signed the covenant and have taken an oath according to the medical law, but no one else.

I will apply dietetic measures for the benefit of the sick according to my ability and judgment; I will keep them from harm and injustice.

I will neither give a deadly drug to anybody who asked for it, nor will I make a suggestion to this effect. Similarly I will not give to a woman an abortive remedy. In purity and holiness I will guard my life and my art.

I will not use the knife, not even on sufferers from stone, but will withdraw in favour of such men as are engaged in this work.

Whatever houses I may visit, I will come for the benefit of the sick, remaining free of all intentional injustice, of all mischief and in particular of sexual relations with both female and male persons, be they free or slaves.

What I may see or hear in the course of the treatment or even outside of the treatment in regard to the life of men, which on no account one must spread abroad, I will keep to myself, holding such things shameful to be spoken about.

If I fulfil this oath and do not violate it, may it be granted to me to enjoy life and art, being honoured with fame among all men for all time to come; if I transgress it and swear falsely, may the opposite of all this be my lot (Edelstein 1943).

The spirit of this code has governed western medical ethics down to the present day and survives in modern dress as the ‘Hippocratic oath’ that doctors are required

to swear (in an appropriately updated version) as rite of professional passage. Mirroring precisely Kant's general account of moral agency as obedience to duty, the Hippocratic oath conceives medical ethics in terms of a universal or absolute obligation to meet the health needs of patients wherever and whenever possible, requiring doctors to treat patients always as ends and never as means to personal interest or advantage. The 'Kantian' heart of this ethics of professional duty – the core of its universalizability – lies in the allegedly 'reciprocal' character of moral rules. Kant's idea – anticipated by Rousseau (1973) and followed in modern times by quasi-Kantian contractarian moral and social theorists (such as Rawls 1999) – is that some human needs (for care, respect, freedom and so on) are so common and basic that no rational agent could do other than wish to have these guaranteed as a matter of *right*. However, the only way in which such needs might be effectively secured as rights, is if *all* rational agents see themselves as bound by duty to respect the claims to these self-same rights of others. For Kant, there is blatant irrationality in failing to feel so bound. If, for example, I claim freedom from slavery as a human *right*, I cannot rationally avoid a corresponding duty to respect the right of the next person to that same freedom: in short, slave owners seem caught in downright incoherence and contradiction if they claim personal freedom as a right, yet deny this to others. By the same token, the Hippocratic claim is that in respect of the common human needs for relief from the suffering and injury of disease that it is the business of physicians to address, no professionally reputable doctor could wish other than that all those in his or her position should feel *duty bound* to meet such needs whenever possible.

Insofar, it would appear that the primal obligation of professions to address common and basic human needs – regardless of any (professionally irrelevant) individual differences of those in need – generally tends towards a *deontological* (perhaps primarily Kantian) account of professional ethics: on this view, a moral duty to equal treatment of clients or patients is written into the very idea of good professional practice. More pointedly, the Hippocratic code requires doctors to address the needs of patients in a spirit of disinterested *impartiality* – without, as it were, fear or favour: generally, professional practitioners should eschew bias or prejudice, avoiding preference of this client over that one on grounds of wealth, race, colour, class or gender. That said, such impartiality – as the very hallmark of professionalism – has often been equated with *impersonality*: as, precisely, precluding any and all personal relations between professional practitioners and clients. In this light, good doctors, lawyers, architects, teachers or ministers are required to avoid all contact or involvement with clients, patients or pupils that might suggest that one person has been preferred over another for this or that personal motive. But this may also appear somewhat counterintuitive. To begin with, it might be asked, is it really the case that I can only be – professionally or otherwise – just or fair to others by treating them alike? Indeed, on the level of everyday personal association, it would seem fairly obvious that I may *not* be acting fairly or justly towards my two daughters in buying them the same book for their birthdays if one is interested in the topic of the book and the other has no interest in it whatsoever. In this case, it might be said either: (1) that I cared for the one (who appreciated the book) more than the

other; or (2) that I cared for neither (if, say, I did not care whether either valued the book) in a spirit of complete indifference to the needs or interests of either. In general appreciation of this point, Aristotle (1941a) famously argued that it is no less unjust to treat unequals equally than it is to treat equals unequally.

All the same, does not the deontological construal of professional ethics precisely aim to distinguish the kind of non-professional relations I might have with my own children from the professional relations I *should* have with those of other people? But there seem to be at least two problems with any such broad distinction. The first of these is to hold, *contra* Aristotle, that the *only* kind or level of justice in any human affairs *is* that involved treating equals equally – in that sense of impartiality that implies avoidance of bias or prejudice, fear or favour. However, the second is precisely to make the fairly common mistake of supposing – as in the previous paragraph – that impartiality logically entails *impersonality*, understood as avoiding any and all personal human association. Avoiding these errors, we may recognise that although we should want doctors, lawyers, nurses and teachers who are not biased towards or against patients, clients or pupils on grounds of race, class, religion, intellectual ability or physical disability – or who are not actually inclined to personal favouritism – this need not preclude personal relations of a more professionally positive or constructive kind. Indeed, it should be clear that good practitioners are precisely those capable of entering into professionally *appropriate* personal relations with clients, patients or pupils. Thus, we might expect a good teacher to be the one who is sensitive to the different emotional characters of pupils that may incline them to react differently to different types of motivation; or a good doctor to be one who is similarly able to distinguish sensitively between the emotional vulnerability of this patient and the more stoical or ‘no-nonsense’ attitude of that one.

So while professional conduct may need to be understood or defined at least partly in deontological terms – as a matter of disregarding professionally irrelevant individual differences – this cannot be the whole story of professional ethics, or of the normative deliberations in which professional practitioners need to engage to respond adequately to the diverse needs or interests of clients, patients or pupils. As already noticed, Kant conceived the main aim of moral reflection and deliberation as the formulation of general obligations or duties regarding the promotion of justice as equal respect for persons that are liable to be compromised by the less altruistic urgings of self-interest. And, to be sure, much professional reflection and deliberation seems to be of this ‘universalising’ kind. Much is concerned, in line with the Hippocratic conception of professional ethics, with the formulation of rules and principles – the do’s and don’t’s – of professional conduct, that usually find their way into those so-called codes of professional ethics designed to govern the conduct of many recognised professions. Such are the basic rules of professional engagement that professional practitioners ignore at their peril. These may, precisely, rule strictly and absolutely against certain kinds of conduct – inappropriate personal liaisons between professionals and clients, breaches of confidence, the misuse or misappropriation of professional time and resources for personal advantage or purposes and so on – that court professional censure if not deregistration or dismissal. And, in

accordance with such deontological principles, much professional conduct will be – at least to that extent – a matter of observing and following set procedures or ‘going by the book’. However, most if not all received literature on professions and professionalism emphasises another significant aspect or quality of professional conduct – that of personal ‘autonomy’ – which is invariably invoked to contrast professions with the mechanical rule-following of many other human occupations.

1.4 Extended and Restricted Professionalism

To be sure, one might measure and/or contrast human occupations in terms of the levels of individual responsibility they demand of practitioners. Insofar, while all occupations – however prestigious – are likely to involve variable mixtures of individual responsibility and submission to some authority, we can easily think of jobs that are higher on the obedience spectrum or lower on the responsibility scale than others. To say this is not necessarily, if at all, to offer a negative evaluation of more routine, compliant or ‘subservient’ occupations. For one thing, there would appear to be some human occupations, such as soldier or monk (without denying that good soldiers and monks will need to exercise individual initiative and responsibility in some contexts) in which an occupationally significant degree of obedience is a clear *virtue*, and disobedience tantamount to (occupational) *vice*. Further to this, there are clearly many jobs in private and public service sectors – from factory production to hotel room cleaning – with regard to which reliable routine rather than creative imagination is the order of the day. Again, given natural variations of human temperament, it is not uncommon to find that occupations of low responsibility and high-obedience are often sought by those who prefer working lives of relatively low stress in which the burdens of responsibility are carried by others in higher managerial positions. In many important spheres of public service, then, the main role will be to do (well) what one is told to do rather than to exercise – at least to any great degree – one’s individual initiative. And such jobs and roles are none the worse for that.

It should be no less clear, however, that other jobs or occupations cannot be – of their very nature – of such submissive or conforming character. Here, to be sure, the contrast is not primarily between the ‘line-managed’ whose role it is to execute the orders of others and the ‘line-managerial’ who are the source of such orders – since it may be that the office boss is no less constrained by rules and regulations than those (s)he is charged with managing. The contrast is rather between those roles and occupations in which there are clear or unambiguous rules and guidelines of correct procedure and those in which there are not or cannot be – at least, in any very clearly specifiable or predictable sense. Thus, whereas there may be only one way to wash a stair or fry chips – or, at any rate, where any creative variations of such tasks are likely to count as unwelcome departures from some prescribed and largely agreed ideal – there are many possible ways to treat a patient, care for the elderly, nurse the sick, minister to a parish, or teach a child. Again the key point is not just that more

alternative courses of action may be available in these occupational roles, so that it may be harder – and therefore require more deliberation and skill – to find the right way of proceeding. It is rather that there is likely to be less general agreement – even within the occupations or professions in question – about what *counts* as the right thing to do in this or that circumstance. Thus, the essence of the undoubted complexity of medical practice, social work or teaching is that the basic goals and values of such occupations are – as it seems nowadays fashionable to put this – ‘essentially contested’.

To be sure, one needs to be careful with this kind of talk in such professional spheres as medicine, social work and education – and I have elsewhere criticized some latter day incautious and dangerously relativistic conceptions of essential contestation in such fields (Carr 2010). Thus, to say that the aims of this or that profession are contested *cannot* be to say that anything we (individually or collectively) *choose* may count as medicine, law or education, or that there cannot be plainly mistaken approaches to professional conduct in such fields. On the contrary, there is quite obviously significant and substantial agreement among sane and sensible practitioners about the general purposes, aims and values of medicine, law and education. Notwithstanding such fundamental agreement, however, individual doctors, lawyers, nurses, social workers and teachers may daily have to face hard decisions about how best to secure the medical health or progress of this patient, ensure the safety of these children at risk, or address the behavioural problems of that pupil. It is faced with such potentially life changing, even life or death, challenges that the need for some informed professional initiative becomes all too apparent. Two social workers may agree substantially about what it is for Mary to live a psychologically and physically healthy and flourishing life: what may be less clear is whether this is best assisted by taking her away from her parents and into care, or by leaving her with her parents. Moreover, although it may be all too tragically clear that Mary’s prospects of short or long term flourishing are liable to be dim in some respects whatever the decision, it is all the more, rather than less, important for the professional social worker to make the most informed and considered decision that (s)he can based on the most thorough possible knowledge of her circumstances.

Still, while issues and challenges of this complex kind would seem to be the stuff of such professional practices as medicine, law, social work, nursing and teaching they are hardly, if at all, characteristic of office cleaning, hamburger grilling or auto-assembly. Indeed, much recent debate about professions and professionalism has turned on this consideration. In this connection, while we have already indicated that such occupations as teaching, nursing and social work have sometimes been regarded (by sociologists) as ‘semi-professions’ – because they do not seem to satisfy all the professional criteria of standard professions – a related distinction has been drawn between ‘restricted’ and ‘extended’ profession(alism) (Hoyle 1974; see also Kirk 1988). Basically, this registers a difference between those clerical and other ‘white collar’ jobs in which workers observe 9–5 routines and take only minimum ‘jobs-worth’ responsibility for the further development of the professional practice in which they are now engaged, and those occupations in which workers are directly involved in the wider development of professional values, aims and objectives

way beyond the call of strict requirement or duty. The latter, so-called 'extended professional', is the professionally pro-active agent who is prepared to take time – outside any and all minimally prescribed working hours – to engage in discussion, enquiry and research regarding the progressive development of professional principles and procedures, to attend professional conferences and seminars, to assist with the education and training of junior colleagues, to take individual responsibility and initiative (rather than passing the buck) in circumstances of professional uncertainty and dilemma, and so on. As already noted, one of the most evident bones of contention regarding (for example) teacher professionalism has concerned recent political attempts in the United Kingdom and elsewhere to 'de-professionalize' teachers mainly via the imposition of state mandated (national) curricula and so-called 'competence' models of professional training that aim for tight prescription of educational content and methods. In the face of such narrow definition and direction of educational aims and content, the teacher – so it is complained – is reduced to the level of a 'classroom technician' whose only role is obedience to the *de haut en bas* dictates of others (including extra-professional politicians and civil servants).

Not surprisingly, teacher unions, professional associations and theorists of teacher education have vigorously resisted the 'restricted' model of teacher professionalism of political imposition and prescription. At the level of principle and theory, it has been pointed out that teaching cannot be a matter of such simple compliance and prescription and that the kind of decisions with which teachers are daily faced are such as to call for educated, sensitive – and highly contextualised – judgement that defies reduction to mechanical rule following. Any informed or 'insider' perspective on the actual practice of teaching shows clearly that it is a highly complex and challenging activity involving sophisticated levels of educational insight and interpersonal sensitivity that cannot be boiled down to routine skills or techniques. At the level of professional practice this has more recently led (in many countries) to professional and political efforts to improve the initial or pre-service quality of teacher education and training – in terms of both content and duration (by, for example, raising college training courses to university undergraduate status) – and to continue or extend the professional development of teachers into post-training employment via so-called CPD (continuing professional development) courses that aim to 'refresh' teachers with new research-based theoretical and practical knowledge of teaching. Indeed, practising teachers may also be involved in the development of new educational curricula and teaching methods or strategies and encouraged to mentor new recruits to the profession. A recent initiative, taking in-service professional development of teachers to a significantly higher level, has been the introduction (in, for example, Scotland) of a new university Masters' degree in teaching, leading to the award of 'Chartered teacher' and bringing higher professional status and further remuneration to non-promoted teachers who wish to improve their professional understanding and craft skills without having to leave the 'chalk face' for more managerial or administrative positions.

It is precisely in view of such considerations about 'extended' professionalism, however, that we may seem to need a new model of reflection and deliberation

through which the normative complexities and uncertainties of the contemporary professional lives of doctors, lawyers, nurses, social workers and teachers might be addressed. While we have seen that a broadly Kantian-Hippocratic conception of practical reason serves well enough to define the basic moral contours of professional conduct that are indispensable to both restricted and extended professionalism – such as the definition of client rights and professional obligations and the marking of those moral boundaries that members of professions should not overstep – it would also seem that a deontological account is less well able to explain the difference between the ‘jobs-worth’ rule-following of restricted professionals and the capacity of extended professionals for more flexible and pro-active judgement and deliberation in uncertain and contextually-sensitive circumstances. What is also needed is an account of professional judgement and deliberation that may assist professional practitioners to effective action in circumstances: (i) in which there may be no clear rule or precedent for present procedure; (ii) in which certain fundamental professional values, principles or prescriptions may actually be in some tension or conflict; or (iii) in which some judicious departure from established rules or procedures may be in order in the interest of fair or virtuous practice. It would be an added bonus of such an account if it could also help to show – as deontological accounts do not – the significant place of affect as well as cognition in the working lives of such professional practitioners as (particularly) nurses, social workers and teachers. We may now turn to Aristotle’s conception of ‘*phronesis*’ or practical wisdom for an account of moral deliberation more fitted to this purpose.

1.5 Professional ‘Phronesis’

Whereas Kant is arguably the master modern theorist of the various types and limits of human reason, Aristotle is no less evidently the master theorist of rationality of antiquity. In the first pages of his *Nicomachean Ethics*, Aristotle (1941b, book 1, chapter 6, p. 940) takes his own master Plato to task for mistakenly assimilating practical deliberation concerning the nature of human good or virtue to the theoretical reason of Platonic dialectic – arguing that it is not the purpose of moral deliberation to discover definitions of the good, but to help us become good or virtuous agents. In the sixth book of that work, he offers a complex taxonomy of human rationality that distinguishes five main types of reason by reference to their different and relatively distinct aims and purposes. For present purposes, however, we may focus on two presently relevant Aristotelian distinctions. First, he distinguishes theoretical rationality (*episteme*) – broadly the sorts of enquiries that are primarily concerned with the discovery of (in his terms, *necessary*) truths about the nature of reality – from those more practical kinds of reasoning directed towards the achievement of certain good, worthwhile or effective ends in the world. But secondly, he distinguishes within the sphere of practical reason between *techne* or productive deliberation – the kind of reasoning involved in the development and exercise of techniques or skills for the making of (say) works of art – and the moral deliberation that he calls *phronesis*

or practical wisdom. Basically, Aristotle distinguishes these different kinds or modes of human reason or reflection in terms of their purposes and/or objects: whereas the aim of theoretical reason (in the sciences and elsewhere) is the discovery of *truth*, and the aim of technical reasoning is the efficient *production* of artefacts or artworks, the aim of *phronesis* or practical wisdom is the cultivation of sound moral character and conduct. As Aristotle puts it, practical wisdom aims to make us good persons or agents (Aristotle 1941b, book 2, chapter 2, p. 953).

It should be clear enough from what has been said so far that – notwithstanding any and all theoretical or technical knowledge or expertise required for effective professional practice or conduct – such conduct is no less deeply implicated in moral principle, judgement and deliberation. Indeed, it is the present view that the very idea of professional service is a fundamentally *moral* one; that issues and questions about the promotion of this or that aspect of human good or flourishing are central to the conduct of any and all occupations meriting professional status; and that any theoretical or technical knowledge which professional agents may indeed require for the effective prosecution of the various moral ends or goals of professional service are at least *normatively* secondary to or subservient of such ends. In short, doctors do not just need medical knowledge or surgical skills, but the wisdom to employ these in the best interests of patients' health; lawyers need not just legal knowledge, but the judgement to ensure that such knowledge conduces to the benefit of clients; teachers need not just the academic knowledge and pedagogical skills required for effective practice, but some understanding of how, when and where to use such knowledge and skills to the ultimate educational welfare of each and every pupil in their care. As we have seen, a deontological (Kantian-Hippocratic) account of the logic of moral principles – in terms of universal obligations to meet fundamental human needs – goes some way to explaining the ethical basis of certain general professional duties, requirements or prohibitions, but it fares less well in accounting for those aspects of professional life and practice in which practitioners may need to make *particular* judgements about what to do in circumstances where there can be no easy or mechanical resort to general rules.

In this regard, Aristotelian practical wisdom may be variously contrasted with Kantian practical reason. To be sure, one way in which Aristotle's account of moral reason is commonly contrasted with Kant's is as an ethics of *judgement* rather than an ethics of *principle*. But this is misleading insofar as Aristotle recognises no less than Kant the importance of definite rules and principles in moral deliberation – even though his account of why such rules are normatively unexceptionable is somewhat different from Kant's. To be sure, he recognises well enough that actions such as adultery, murder and lying are always bad or wrong – even though there may be some circumstances in which we may be forced to *do* the wrong thing as the lesser of competing evils (such as lying to save lives). It may therefore be more accurate to say that Aristotle's conception of moral wisdom is rather broader than Kant's account of practical reason insofar as it *also* tries to explain how moral agents deliberate to judgements in circumstances where there is no obvious covering rule – or, perhaps, some conflict between more general rules (see Carr 2003). It is, however, still more accurate to contrast the general ethics in which Aristotle's notion

of *phronesis* is implicated as an *aretaic* ethics (or ethics of character) rather than a *deontological* ethics (or ethics of duty). On the former view, the key point is that the more particular deliberations and judgements required for complex moral decision making presuppose the development of a range of personal qualities of good character that have been generally termed – since the Greeks – moral *virtues*. Since such virtues involve aspects of human nature that are not only or exclusively cognitive, another way of expressing this would be to say that in order to be a competent moral agent one needs not just moral reasoning skills (even if it is coherent so to speak), but to be a certain kind of *person*. This, to be sure, is essentially the position of so-called *virtue ethics*.

The virtues of (neo-Aristotelian and other) virtue ethics are such moral traits as honesty, justice, courage, persistence, temperance (self-control), generosity, patience, loyalty, industry and so forth. At one level, such virtues are – as Aristotle famously argued in his *Nicomachean Ethics* – primarily developed as practical dispositions, which may not seem to require much reflection or deliberation at all: the courageous agent is (s)he who may be counted on to leap to save the drowning child without a moment's thought. However, Aristotle was no less clear that – at a more mature or developed level – virtues require to be rationally informed or guided: in short, for him, all so-called moral virtues need to be grounded in or informed by the intellectual virtue of *phronesis* or moral wisdom. More precisely, *phronesis* involves judicious observance in each morally demanding circumstance of Aristotle's famous principle of the *mean* – whereby all virtuous actions should aim to avoid certain excesses or defects of feeling, appetite and/or desire. Hence, in contrast to some conceptions of virtue as a matter of the rational control, suppression or even elimination of affective or appetitive life, courageous agents are not those who lack fear and temperate agents may still enjoy (appropriate) appetites: indeed, agents without fear are not virtuous but reckless – and, similarly, any lack of normal human appetite would presumably be sub-human or pathological rather than virtuous. So to be virtuous is to have ordered one's affective, appetitive or desiderative life in a humanly beneficial way: as the present author has elsewhere, put this, virtues are more or less equivalent to states of states of emotion, feeling or appetite ordered in accordance with some deliberative ideal of practical wisdom (Carr 2009). The key task of the rational capacity of *phronesis* or practical wisdom, then, is to order and inform the affective and appetitive aspects of human experience and to determine the appropriate degree of level of exercise and expression of these on this or that occasion. However, if we now ask how we may know whether it is appropriate to indulge this or that appetite (say, sexual desire) or feeling (say, anger) on any given occasion, the general answer is that it must depend on wise adjudication of the precise – but ever variable – context: in Aristotelian terms, morally wise agents are those capable of acting appropriately towards the right agents, with the right motives, in the right place, at the right time, in the right way, and so on.

It should also here be noted that much of the talk so far of reason *and* feeling, or of *phronesis* as intellectual virtue and other virtues as moral virtues, suggests distinctions or dichotomies that Aristotle does not accept or rejects. Or, at least, we should recognise that on his view any emotions implicated in the exercise of virtue

are no mere episodes of (brute) affect, but feelings deeply informed by judgements or evaluations. In more recent philosophical parlance, Aristotelian emotions are inherently (if not exclusively) cognitive or 'intentional': any humanly significant anger is therefore *about* this or that hurt or injustice; our jealousy is *about* attention paid by the object of our affections to another; our compassion or pity is *in respect of* the plight of another; and so on. What this also means, of course, is that insofar as any emotions implicated in *phronesis* entail judgements, they can be *wrong* or erroneous no less than right: the tragedy of Shakespeare's Othello turns precisely on the fact that the Moor's jealousy is quite mistaken or misplaced. That said, one should not conclude that what are sometimes called 'negative' emotions such as fear, anger or jealousy are *always* wrong or mistaken and therefore to be eliminated or suppressed (as some eastern and western spiritualities have occasionally maintained). On the contrary, as Aristotle insisted, the courageous are those who feel appropriate fear and the just are those capable of feeling righteous anger in circumstances in which moral outrage is appropriate. The key point is that effective moral agency is a matter of the cultivation of practical wisdom as sensitive and appropriately attuned cognitive-affective response to the complexities of human experience and association. But then it would seem to follow that insofar as professional judgement and conduct are species – or particular expressions or applications – of basic moral agency, the 'phronetic' cultivation of character should also be part of professional development at least in those occupations commonly regarded as professions. On this view, to be a good or effective doctor, lawyer, social worker, teacher or nurse, one requires capacities for deliberation and judgement grounded in affectively measured and stable character. In sum, to be professionally effective – in the sense of exemplifying the virtues traditionally associated with profession – more is needed than just the knowledge, skills or expertise of a particular occupation; as previously noted, one also needs to be a particular kind of moral agent or *person*.

The key point is that in those human occupations that have traditionally been considered professions – or in some cases, perhaps, as the 'people professions' (see Bondi et al. 2011) of so-called 'vocation' – there is arguably need for more significant occupational continuity between the pre-professional moral agency of admirable character or personhood and exemplary professional practice than in other human occupations and services. On this view, it seems to matter what kind of person (speaking primarily in terms of character) a practitioner of medicine, law, teaching, social work or nursing is in a way that it does not in the case of check-out girls, auto-mechanics, builders, office cleaners or painters and decorators. To be sure, this point should not be overdrawn or misunderstood. Of course many mechanics, builders, cleaners, painters and shop assistants are also admirable people and we may rightly respect them for their personal qualities of character. Their virtues may also contribute to the quality of the service they provide – and, in any case, employers are likely to dispense with their services if their employees are dishonest, lazy or unduly rude or abusive to customers or clients. At all events, we have every reason to encourage – on various grounds and for various purposes – the cultivation of a wide variety of humanly positive characteristics in all sorts of private and public employees. The present point is rather that such virtues or other personal

characteristics seem to be related to such occupations, as it were, only *externally* or *contingently*. The employer wants the employee to be honest or hard-working because this is good for business; the customer may not care much whether the shop assistant is off-hand or surly as long as she gets good advice or a bargain; and the car owner, likewise, wants an efficiently serviced car irrespective of the mechanic's temper. To this extent, we may understand what counts as efficient or effective service in such occupations – not least since refraining from stealing from the till for fear of dismissal does not necessarily indicate an honest person – independently of qualities of character. On the other hand, there is an important sense in which the moral virtues or qualities of character of what we would want to call good or exemplary doctors, lawyers, teachers, nurses or social workers are *internal* or *integral* to the proper professional pursuit of their respective practices.

In short, what we *mean* by effective or exemplary practice in the aforementioned 'professions' can hardly be understood apart from the exercise of virtues of good character. For the Geeks – and in the virtue-ethical tradition generally – the key human virtues were (are) the four so-called 'cardinal' virtues (virtues to which all other virtues may be reduced but which are not themselves reducible to others) of wisdom, courage, temperance and justice. Clearly, for Aristotle, wisdom – as largely exhibited in *phronesis* – is the lynchpin of complete or mature moral virtue. As we have seen, it is hard to understand the moral agency of professional practice without reference to the deliberations of *phronesis*, insofar as the judgement required for such practice cannot be a matter of mechanical rule-following and needs to be sensitive to the complexities of particular context. However, it should be clear that insofar as it is a key aim of such judgements to avoid unequal or partial treatment *and* – where appropriate – to give due weight to professionally relevant individual differences, such practical wisdom operates primarily in the service of that justice which is also a pre-eminent concern of Kantian, Hippocratic and other deontological accounts of professional ethics. But then it should be no less clear that professional practitioners will often require the courage to defend and uphold such judgements and principles of justice when external pressures – of variously interested political or public opinion – may pressure them to compromise such principles. Many professional 'scandals' have revolved around the failures of integrity of those in high professional office to stick to their guns in the face of intimidation from outside political or corporate commercial agencies driven by less than just motives. But, likewise, professional scandals have also turned on the failure of practitioners to uphold the highest professional principles of other-directed fairness and justice due to their own greed and self-interest – in short, through manifest failures of temperance or self-control.

To be sure, even this way of putting things might suggest that the role of the traditional virtues of pre-professional moral agency is a predominantly instrumental one: that one needs practical wisdom, justice, temperance and courage in order to pursue the ends of medicine, law, teaching, social, work, ministry or nursing, which nevertheless might be specified independently in terms of certain sorts of academic or technical expertise (such as surgical or teaching skills). However, as I have argued elsewhere (Carr 2000, 2007), it seems hardly possible in the case of many

professional practices to specify such professional knowledge and skill independently of moral virtues: or, to put it even more strongly, what are often widely canvassed as professional skills or techniques in some of these professional fields do not appear – on closer scrutiny – to be (morally neutral) techniques or skills at all (see Carr 2007). Thus, taking one example from the field of professional teaching, one indispensable requirement of effective practice for classroom teachers is the capacity to maintain order and control in the classroom – which has been widely viewed in professional literature in terms of the mastery of skills, techniques or competencies (Department of Education and Science and the Welsh Office 1989). In fact, however, given the diverse contexts of classroom teaching, it may seriously be doubted that there are any such competences or skills – in the sense of one-size-fits-all techniques that will suit all circumstances. Even where something resembling such techniques might be identified (for a given context) it seems clear that these are seldom *sufficient* for classroom order and that what teachers require is a *moral authority* grounded in deep ‘phronetic’ appreciation of the complexities of human association. The reason why young teachers are so often poor at classroom management may well be less because they lack off-the-peg management techniques, and more because they lack the personal knowledge and appreciation of pupils and their circumstances – as individuals, no less than groups – that facilitates healthy association. But what is here true of teaching, also clearly goes for many aspects of general medical practice, nursing, social work, ministry and counselling: moral virtues are not just useful *means* to the job; they actually *are* the job.

Lack of further space precludes more than a mention here of the fifth commonly cited criterion of profession or professionalism that emphasises the need for professional bodies for the oversight, monitoring and regulation of professional practice in the interests of proper recruitment, public accountability and discipline of practitioners. On the one hand, such professional organisations do clearly have a positive role to play in upholding the basic standards of professions and as a bulwark against various political and private interests that might seek to control or manipulate professions for non-professional ends. (One may think here, of recent political attempts to control or manipulate hospitals and schools for non-professional ends.) In this regard, medical, teaching and other councils in Britain and elsewhere have sought reasonably successfully to maintain fundamental professional standards and values and to protect the interests of their professional members. On the other hand, however, there is the ever-present danger that such organisations may themselves take an unduly narrow or restricted view of professional standards, values and practices that may itself impede or restrict professional creativity or innovation. One issue that has been much discussed and debated in this connection is that of the value or utility of those codes of professional ethics whereby various professions have sought to specify precise rules of professional conduct or competence for practitioners. Given the complexities of professional life to which we have alluded – that require scope for individual (‘phronetic’) deliberation and judgement – the problem with such codes is that of finding a meaningful *via media* between largely vacuous generalities (the obvious ‘do and don’t’ presuppositions of everyday professional practice) on the one hand, and the unhelpful constraint of precise prescription on the

other. But achieving this all-important Aristotelian middle way is clearly the holy grail of sane and sensible professional engagement as such.

Presently limited space also precludes much exploration of the all-important topic of professional *education* – particularly of the question of how the professionally crucial quality or capacity of *phronesis* might be cultivated. For one thing, if *phronesis* or practical wisdom requires or presupposes understanding or appreciation of others and their motives – and of the chemistry of human association generally – it should be clear that this cannot be acquired exclusively via the acquisition of occupational knowledge and skills (knowledge of the law or surgical techniques). Thus, it has been customary in many of the so-called ‘people professions’ such as teaching, social work and ministry to include courses on psychology or sociology – and even (more recently) ethics or moral theory – in the training of teachers, ministers and social workers. That said, one may also doubt that the kind of knowledge of human behaviour or association available via the study of the various social and moral sciences is really appropriate to understanding other *people* as required for effective professional communication and engagement. Indeed, although Aristotle himself did seem to think that knowledge of more theoretical kinds could contribute something to our understanding of human psychological and social life, it seems fairly clear that for him the cultivation of *phronesis* depended upon a broad general or *liberal* education to which the arts might make as much contribution as the sciences. Thus, in his *Poetics*, Aristotle clearly regards the works of creative imagination of the great tragic poets of his day as having a large contribution to make to the education of the all-important emotional dimensions of *phronesis*. In short, although professional practitioners of social work, teaching or medicine might well be urged to read books in order to help them acquire the kind of knowledge of others and their interests and motives that might help them to become better professional practitioners, it is arguable that a broader educational acquaintance with the wider literary inheritance of human culture(s) than has often been apparent in courses of professional training might also assist professional development: that, in short, practitioners of social work, medicine or teaching (of anything) might benefit professionally from acquaintance with Euripides Shakespeare, Tolstoy, Hardy or Joyce no less than from textbooks of law, medical science or psychology.

Chapter 2

The Concept of Professionalism: Professional Work, Professional Practice and Learning

Julia Evetts

Abstract For a long time, the sociological analysis of professional work has differentiated professionalism as a special means of organizing work and controlling workers and in contrast to the hierarchical, bureaucratic and managerial controls of industrial and commercial organizations. But professional work is changing and being changed as increasingly professionals (such as doctors, nurses, teachers, social workers) now work in employing organizations; lawyers and accountants in large professional service firms (PSFs) and sometimes in international and commercial organizations; pharmacists in national (retailing) companies; and engineers, journalists, performing artists, the armed forces and police find occupational control of their work and discretionary decision-making increasingly difficult to sustain.

The paper begins with a section on defining the field of professional work, professional practice and its learning. The paper continues with a second section on the concept of professionalism, its history and current developments. The third section of the paper considers the changes, challenges and opportunities of the practice of professional work within employing organizations. The fourth section of the paper identifies some of the important contributions made by researchers on professional work to public policy developments, assessment and evaluation.

Keywords Professionalism • Professional work • Professional practice • Learning

For a long time, the sociological analysis of professional work has differentiated professionalism, as a special means of organizing work and controlling workers, and in contrast to the hierarchical, bureaucratic and managerial controls of industrial and commercial organizations. Change is a constant feature of professional work but the speed and prominence of change is growing as increasingly professionals

(such as doctors, nurses, teachers, social workers) now work in employing organizations; lawyers and accountants in large professional service firms (PSFs) and sometimes in international and commercial organizations; pharmacists in national (retailing) companies; and engineers, journalists, performing artists, the armed forces and police find occupational control of their work and discretionary decision-making increasingly difficult to sustain (Adler et al. 2008; Brante 2010; Champy 2011). How, then, are current changes affecting perceptions of professionalism, professional practice and learning?

There also have been a number of policy and societal developments and changes, and increased complexities in the contexts and environments for professions. This makes it necessary to look again at the theories and concepts used to explain and interpret this category of occupational work. Some long-established differences are becoming blurred. For example, there is no longer a clear differentiation between the public and the private sectors of professional employment. Private funding is now operational in public sector work places and PPP (public/private partnerships) (e.g. in schools, universities and hospitals) enables the promotion of new capital as well as other policy developments (Farrell and Morris 2003; Kuhlmann 2006).

Another complication and variation is the increased emphasis on and calls for professionalism in the voluntary sector, charities and non-governmental organizations (NGOs) (Langer and Schröer 2011). Wherever trust, transparency and accountability need to be demonstrated, then increased regulation, audit and assessment seem to follow (e.g. social work and aid agencies, national and international). In addition, there is wider accessibility to internet knowledge which renders the importance of professional and expert, tacit and experiential knowledge and expertise more open to challenge (Olofsson 2009; Verpraet 2009).

The role of the nation-state, has always been critical in theorizing about professions and, in particular, differentiating between Anglo-American and European systems of professions (Burrage and Torstendahl 1990a, b). The role of the nation-state had been seen to be paramount because states had granted legitimacy, for example, by licensing professional activity, setting standards of practice and regulation, acting as guarantor of professional education (not least by giving public funds for academic education and scientific research), and by paying for services provided by professional experts and practitioners. But the internationalization of markets required the reconceptualization of traditional professional jurisdictions. In addition, the increased mobility of professional practitioners between nation-states necessitated recognition and acceptability of other states licensing, education and training requirements (Evetts 2008; Orzack 1998). Again, the convergence of professional systems and of regulatory states has required the reconceptualization as well as new theoretical and interpretational developments in the sociology of professional occupational groups (Brint 2006; Noordegraaf 2007; Svensson and Evetts 2003, 2010).

The chapter begins with a section on defining the field of professional work, professional practice and its learning. Three concepts (profession, professionalization and professionalism) will be identified and explored. The difficulties associated with the concepts of profession and professionalization will be indicated and

the advantages of the concept of professionalism will be explained. The chapter continues with a second section on the concept of professionalism, its history and current developments. Three phases will be identified: an early phase which defined professionalism as an occupational or normative value; a second negative phase of critique when professionalism was dismissed as ideological and promoted in the interests of professional practitioners themselves; the third phase which constitutes a reappraisal and a return to professionalism and combines both the ideological critique and the normative value interpretations of professionalism. In this third phase professionalism is defined as a discourse, used by managers in organizations, and reclaimed as an important and distinctively different way of organizing service sector work, which is in the best interests of customers and clients as well as practitioner workers themselves. Professionalism, like professional work and learning, is changing and being changed particularly in the organizational contexts in which practitioners currently practice.

The third section of the chapter considers the changes, challenges and opportunities of the practice of professional work within employing organizations. The need to reconnect professional occupations and professional organizations will be identified and the challenges this presents to professionalism as a normative value, which implies occupational control of the work practices and procedures, will be explained. The opportunities presented for professional practitioners working in organizations will also be discussed.

The fourth section of the chapter identifies some of the important contributions made by researchers on professional work to public policy developments, assessment and evaluation. The idea of professionalism as an occupational and normative value can be linked with public policy concerns about competences at all levels of occupational work. Perhaps the reclaiming and recreation of professionalism in work and occupations will be one of the most important tasks for policy makers and practitioners over the next few years.

2.1 Defining the Field and Clarifying Concepts

The concept of profession is much disputed (Sciulli 2005 and Evetts' 2006 response) and this is a difficulty for defining the field of professional work, professional practice and professional learning. For a period in the 1950s and 1960s, researchers shifted the focus of analysis onto the concept of profession as a particular kind of occupation, or an institution with special characteristics. The difficulties of defining the special characteristics and clarifying the differences between professions and other occupations (particularly other expert occupations) troubled analysts and researchers during this period (e.g. Greenwood 1957; Etzioni 1969; Wilensky 1964). It is generally the case, however, that definitional precision is now regarded more as a time-wasting diversion, in that it did nothing to assist understanding of the power of particular occupational groups (such as law and medicine, historically) or of the contemporary appeal of the discourse of professionalism in all occupations (Champy 2009). To most researchers

in the field (e.g. Brint 2001; Olgiati et al. 1998; Sciulli 2005) it no longer seems important to draw a hard and fast line between professions and occupations but, instead, to regard both as similar social forms which share many common characteristics (Olofsson 2009).

Hughes (1958) was probably the first sociologist to argue that the differences between professions and occupations were differences of degree rather than kind. For Hughes not only do professions and occupations presume to tell the rest of their society what is good and right for it, but also they determine the ways of thinking about problems which fall in their domain (Dingwall and Lewis 1983: 5). Professionalism in occupations and professions implies the importance of trust in economic relations in modern societies with an advanced division of labour. In other words, lay people have to place their trust in professional workers (electricians and plumbers as well as lawyers and doctors) and some professionals must acquire confidential knowledge. Professionalism, therefore, requires those working as professionals to be worthy of that trust, to put clients first, to maintain confidentiality and not use their knowledge for fraudulent purposes. In return for professionalism in client relations, some professionals are rewarded with authority, privileged rewards and high status. Subsequent analysis has interpreted high rewards to be the result of occupational powers rather than professionalism, but this was one result of the rather peculiar focus on medicine and law as the archetypal professions in Anglo-American analysis, rather than a more realistic assessment of the large differences in power resources of most occupational groups (Freidson 1983; Hanlon 1999; Johnson 1992).

The comparative work of Hughes, and his linking of professions and occupations, also constitutes the starting point for many micro level ethnographic studies of professional socialization in work places (e.g. hospitals and schools) and the development (in new) and maintenance (in existing) workers of shared professional identities. This shared professional identity (which has been a major research focus for French researchers) is associated with a sense of common experiences, understandings and expertise, shared ways of perceiving problems and their possible solutions. This common identity is produced and reproduced through occupational and professional socialization, by means of shared educational backgrounds, professional training and vocational experiences, and by membership of professional associations (local, regional, national and international) and institutes where practitioners develop and maintain a shared work culture.

One result of all these factors is similarities in work practices and procedures, common ways of perceiving problems and their possible solutions, and shared ways of perceiving and interacting with customers and clients. In these ways the normative value system of professionalism in work, and how to behave, respond and advise, is reproduced at the micro level in individual practitioners and in the work places in which they work (Abbott 1988; Hughes 1958). Some of the differences in occupational socialization between occupations have been identified, but the general process of shared occupational identity development via work cultures, training and experience was regarded as similar across occupations and between societies. Research into occupational identities has been prominent in

French analyses (e.g. Dubar 2000) because the rather peculiar emphasis on occupational privileges and powers, in Anglo-American research, has had less influence on the definition of the field in France.

Many researchers focus on a particular case study professional/occupational group and handle the definitional problem in different ways. Some avoid giving a definition of profession and instead offer a list of relevant occupational groups (e.g. Hanlon 1998 claimed to be following Abbott 1988). Others have used the disagreements and continuing uncertainties about precisely what is a profession, to dismiss the separateness of the intellectual field, although not necessarily to dispute the relevance of current analytical debates. Crompton (1990), for example, considered how paradoxes and contradictions within the sociological debates about professions actually reflected wider and more general tensions in the sociologies of work, occupations and employment.

For most researchers, professions are regarded as essentially the knowledge-based category of service occupations which usually follow a period of tertiary education and vocational training and experience. A different way of categorizing professions is to see them as the structural, occupational and institutional arrangements for work associated with the uncertainties of modern lives in risk societies. Professionals are extensively engaged in dealing with risk, with risk assessment and, through the use of expert knowledge, enabling customers and clients to deal with uncertainty. To paraphrase and adapt a list in Olgiati and colleagues (1998), professions are involved in birth, survival, physical and emotional health, dispute resolution and law-based social order, finance and credit information, educational attainment and socialization, physical constructs and the built environment, military engagement, peace-keeping and security, entertainment, the arts and leisure, religion and our negotiations with the next world.

In general, however, it no longer seems important to draw a hard definitional line between professions and other (expert) occupations (see Svensson and Evetts 2003). The operational definition of profession can be highly pragmatic. The field includes the study of occupations which are predominantly service sector and knowledge-based and achieved sometimes following years of higher/further education and specified years of vocational training and experience. Sometimes professional groups are also elites with strong political links and connections, and some professional practitioners are licensed as a mechanism of market closure and the occupational control of the work. They are primarily middle-class occupations sometimes characterised as the service class (Goldthorpe 1982).

In sociological research on professional groups, three concepts have been prominent in the development of explanations: (i) profession, (ii) professionalization, (iii) professionalism. The concept of profession represents a distinct and generic category of occupational work. Definitions of 'profession' have been frequently attempted but sociologists have been unsuccessful in clarifying the differences between professions and other occupations and identifying what makes professions distinctive. Definitions of professions as institutional remain unresolved though particular generic occupational groups continue to form the case studies in which to examine and test sociological theories and explanations.

The concept of professionalization is regarded as the process to achieve the status of profession. It has been interpreted as the process to pursue, develop and maintain the closure of the occupational group, in order to maintain practitioners own occupational self-interests in terms of their salary, status and power, as well as the monopoly protection of the occupational jurisdiction (Larson 1977; Abbott 1988). This interpretation was prominent in the field in the 1970s and 1980s and was associated with a critique of professions as ideological constructs (Johnson 1972). This interpretation has declined in popularity recently (e.g. see themes of papers presented at recent international conferences) although sociologists interested in gender issues and differences continue to critique the idea of profession as a gendered (historical) construct (Davies 1995; Witz 1992), and sometimes as the opposite – as a process that has benefited particularly female-dominated occupational groups (e.g. midwifery) in competition with medical dominance (Bourgeault et al. 2004). In addition, the concept of professionalization continues to be important in the analysis of newly emerging occupations (e.g. IT consultancy, human resources management, psychology and social care work), perhaps seeking status and recognition for the importance of the work, often by standardization of the education, training and qualification for practice (Brint 2001; Ruiz Ben 2009).

A third concept is professionalism which has had a long history in the disciplinary sub-field and is examined in the next section. Professionalism was usually interpreted as an occupational or normative value, as something worth preserving and promoting in work and by and for workers. Then later developments interpreted professionalism as a discourse and, to an extent, this has combined the occupational value and the ideological interpretations. Certainly there are real advantages in the analysis of professionalism as the key analytical concept in explanations and interpretations about professional knowledge-based work, occupations and practitioners.

In current work and employment contexts (such as professional work in organizations) it is the increased use of the discourse of professionalism, in a wide range of occupations and work places, which is important and in need of further analysis and understanding. The discourse of professionalism is used as a marketing slogan (e.g. ‘have the job done by professionals’) and in advertising to attract new recruits (e.g. ‘join the professionals’ – the army) as well as customers (Fournier 1999). It is used in occupational recruitment campaigns, in company mission statements and organizational aims and objectives to motivate employees. The discourse of professionalism has entered the managerial literature and been embodied in training manuals. Even occupational regulation and control (both internal and external forms) are now explained and justified as means to improve professionalism in work. The concept of professionalism has an appeal to and for practitioners, employees and managers in the development and maintenance of work identities, career decisions and senses of self.

If the focus of analysis is shifted away from the concepts of profession (as a distinct and generic category of occupational work), and professionalization (as the process to pursue, develop and maintain the closure of the occupational group), and towards the concept of professionalism, then different kinds of explanatory theory become apparent. Then the discourse of professionalism can be analyzed as a

powerful instrument of occupational change and social control at macro, meso and micro levels and in a wide range of occupations in very different work, organizational and employment relations, contexts and conditions.

2.2 Professionalism : History and Current Developments

The concept of professionalism has a long history particularly in Anglo-American sociology. In Europe the concept has been less prominent until recently. The continental functional proximity between state government bureaucracies, public state universities and professions created a minority of free professions ('freie Berufen' and 'professions liberals') and favoured sociology of class and organization to the disadvantage of sociology of professions (Burrage and Torstendahl 1990a). The Anglo-American systems of less centralized state governments, private or at least relatively independent universities and free professions, on the other hand, created a majority of market-related professions and an elaborate and detailed sociology of professions, which has had strong impact worldwide.

When considering the history of the concept of professionalism, three phases can be identified: an early phase which defined professionalism as an occupational or normative value; a second negative phase of critique when professionalism was regarded as ideological and promoted in the interests of professional practitioners themselves; a third phase which combines both the ideological critique and the normative value interpretations of professionalism. These three phases are considered next.

2.2.1 Early Phase: Professionalism as a Normative Value

In early British sociological analysis, the key concept was 'professionalism' and the emphasis was on the importance of professionalism for the stability and civility of social systems (e.g. Tawney 1921; Carr-Saunders and Wilson 1933; Marshall 1950). Tawney perceived professionalism as a force capable of subjecting rampant individualism to the needs of the community. Carr-Saunders and Wilson (1933) saw professionalism as a force for stability and freedom against the threat of encroaching industrial and governmental bureaucracies. Marshall (1950) emphasized altruism or the 'service' orientation of professionalism and how professionalism might form a bulwark against threats to stable democratic processes. In these interpretations professionalism was regarded as an important and highly desirable occupational value and professional relations were characterized as collegial, co-operative and mutually supportive. Similarly, relations of trust characterized practitioner/client and practitioner/management interactions since competencies were assumed to be guaranteed by education, training and sometimes by licensing.

The early American sociological theorists of professions also developed similar interpretations and again the key concept was the occupational value of professionalism based on trust, competence, a strong occupational identity and co-operation. The best known, though perhaps most frequently mis-quoted, attempt to clarify the special characteristics of professionalism, its central values and its contribution to social order and stability, was that of Parsons (1939). Parsons recognized and was one of the first theorists to show how the capitalist economy, the rational-legal social order (of Weber), and the modern professions were all interrelated and mutually balancing in the maintenance and stability of a fragile normative social order. He demonstrated how the authority of the professions and of bureaucratic hierarchical organizations both rested on the same principles (for example of functional specificity, restriction of the power domain, application of universalistic, impersonal standards). The professions, however, by means of their collegial organization and shared identity demonstrated an alternative approach (compared with the managerial hierarchy of bureaucratic organizations) towards the shared normative end.

The work of Parsons has subsequently been subject to heavy criticism mainly because of its links with functionalism (Dingwall and Lewis 1983). However, the differences between professionalism and rational-legal, bureaucratic ways of organizing work have been examined in Freidson's (2001) analysis. He examined the logics of three different ways of organizing work in contemporary societies: (i) the market, (ii) organization and (iii) profession and illustrated the respective advantages and disadvantages of each for clients and practitioners. In this analysis he also demonstrated the continuing importance of maintaining professionalism (with some changes) as the main organizing principle for service sector work. Freidson does not use the term 'occupational value' and instead focused on the importance of knowledge and expertise, but he maintained that occupational control of the work (by practitioners themselves) is of real importance for the maintenance of professionalism. Practitioner occupational control is important because the complexities of the work are such that only the practitioners can understand the organizational needs of the work, its processes, procedures, testing and outcomes. It is by means of extensive (and expensive) systems of work place training and socialization that new recruits develop the expertise to put theoretical knowledge into practice and to use and control the work systems and procedures.

This interpretation represents what might be termed the optimistic view of what professionalism and the process of professionalization of work entails. It is based on the principle that the work is of importance either to the public or to the interests of the state or an elite (Freidson 2001: 214). According to Freidson, 'the ideal typical position of professionalism is founded on the official belief that the knowledge and skill of a particular specialization requires a foundation in abstract concepts and formal learning' (2001: 34/5). Education, training and experience are fundamental requirements but once achieved (and sometimes licensed) then the exercise of discretion (i.e. discretionary decision-making rather than autonomy) based on competences is central and deserving of special status. The practitioners have special knowledge and skill and, because of complexity, it is often necessary to trust professionals' intentions. One consequence is that externally imposed rules (from states or

organizations) governing the work are minimized and the exercise of discretionary decision-making and good judgment, often in highly complex situations and circumstances, and based on recognized competences is maximized.

It can also be argued that professionalism represents a distinctive form of decentralized occupational control and regulation which constitutes an important component of civil society. Professions create and maintain distinct professional values or moral obligations (e.g. codes of ethics), which restrain excessive competition by encouraging cooperation as well as practitioner pride and satisfaction in work performance – a form of individualized self-regulation. Indeed it could be argued that professional commitment (professionalism) has frequently covered for the various failures of statutory and organizational forms of work regulation. Where statutory and organizational forms have been seen to impoverish the quality of work, and increase the bureaucracy, professionalism can be defended as a uniquely desirable method of regulating, monitoring and providing complex services to the public (Freidson 2001).

2.2.2 Critical Phase: Professionalism as Ideology

There is a second more pessimistic interpretation of professionalism, however, which grew out of the more critical literature on professions, which was prominent in Anglo-American analyses, in the 1970s and 1980s. During this period professionalism came to be dismissed as a successful ideology (Johnson 1972), and professionalization as a process of market closure and monopoly control of work (Larson 1977), and occupational dominance (Larkin 1983). Professionalization was intended to promote professional practitioners' own occupational self interests in terms of their salary, status and power as well as the monopoly protection of an occupational jurisdiction (Abbott 1988). This was seen to be a process largely initiated and controlled by the practitioners themselves and mainly in their own interests although it could also be argued to be in the public interest (Saks 1995).

Critical attacks on professions in general as powerful, privileged, self-interested monopolies, that were prominent in the neo-Weberian research literature of the 1970s and 1980s, resulted in a general skepticism about the whole idea of professionalism as a normative value. Johnson, for example, dismissed professionalism as a successful ideology which had entered the political vocabulary of a wide range of occupational groups in their claims and competition for status and income (1972: 32). More recently Davies (1996) has urged researchers to abandon claims to professionalism and instead to recognize the links between such claims and a specific historical and cultural construction of masculinity which fits uneasily with newer and more feminized professions.

During the 1970s and 1980s, when sociological analysis of professions was dominated by various forms of professionalism as ideology theorizing, one concept that became prominent was the 'professional project'. The concept was developed by Larson (1977) and included a detailed and scholarly historical

account of the processes and developments whereby a distinct occupational group sought a monopoly in the market for its service, and status and upward mobility (collective as well as individual) in the social order. The idea of a professional project was developed in a different way by Abbott (1988) who examined the carving out and maintenance of a jurisdiction through competition and the requisite cultural and other work that was necessary to establish the legitimacy of the monopoly practice.

Larson's work is still frequently cited and MacDonald's textbook on professions (1995) continued to use and to support her analysis in his examination of the professional field of accountancy. The outcome of the successful professional project was a 'monopoly of competence legitimised by officially sanctioned "expertise", and a monopoly of credibility with the public' (Larson 1977: 38). This interpretation has not gone unchallenged. Freidson (1982) preferred market 'shelters' to complete monopolies in professional service provision, which indicated the incomplete nature of most market closure projects. It is also the case that Larson's (1977) careful analysis has been oversimplified by enthusiastic supporters such that some researchers talk about the professional project, as if professions and professional associations do nothing else apart from protecting the market monopoly for their expertise.

Another version of the professionalism as ideology interpretation has been the notion of professions as powerful occupational groups, who not only closed markets and dominated and controlled other occupations in the field, but also could 'capture' states and negotiate 'regulative bargains' (Cooper et al. 1988) with states in the interests of their own practitioners. Again this was an aspect of theorizing about professions in Anglo-American societies which began in the 1970s (e.g. Johnson 1972) and which focused on medicine and law. It has been a particular feature of analysis of the medical profession (e.g. Larkin 1983) where researchers have interpreted relations between health professionals as an aspect of medical dominance as well as gender relations (e.g. Davies 1995).

Since the mid-1980s, the flaws in the more extreme versions of this professionalism as ideology view have become apparent. Annandale (1998) has queried aspects of medical dominance and has linked this with diversity, restratification and growing hierarchy within the medical profession itself – namely only some doctors can become dominant, along with some nurses and some midwives. More generally, it has turned out that radical governments could successfully challenge the professions. Professions do sometimes initiate projects and influence governments but, as often, professions are responding to external demands for change, which can be political, economic, cultural and social. This has resulted in a reappraisal of the historical evidence, which is still incomplete. One line of development has been the view that the demand-led theory of professionalization needs to be complemented by an understanding of the supply side (Dingwall 1996). Instead of the question – How do professions capture states? – the central question should be – Why do states create professions, or at least permit professions to flourish? This has resulted in a renewed interest in professionalism as normative values interpretation, and in the historical evidence about the parallel processes of the creation of modern

nation-states in the second half of the nineteenth century and of modern professions in the same period. It is suggested, for example, that professions might be one aspect of a state founded on liberal principles, one way of regulating certain spheres of economic life without developing an oppressive central bureaucracy. The work of the English sociologist Herbert Spencer has provided a useful starting point for this analysis (Dingwall and King 1995) and Dingwall (1996) takes this argument further by considering the need for social order in the rapidly developing global economies and international markets, and how professions might make a normative and value contribution in meeting this need.

In the 1990s researchers began to reassess the significance of professionalism and its positive (as well as negative) contributions both for customers and clients, as well as for social systems. This re-examination indicates a return to the professionalism as normative value system interpretation. One result of this return and re-appraisal is a more balanced assessment, however, (Dingwall 2008; Evetts 2003; Fournier 1999). Thus, in addition to protecting their own market position through controlling the license to practice and protecting their elite positions, professionalism might also represent a distinctive form of decentralized occupational control which is important in civil society (Durkheim 1992). It has also been argued that the public interest and professional self-interest are not necessarily at opposite ends of a continuum and that the pursuit of self-interests may be compatible with advancing the public interest (Saks 1995). Professionalism might also work to create and represent distinct professional values or moral obligations which restrain excessive competition and encourage co-operation (Dingwall 1996).

The claim is now being made (for example, Freidson 1994, 2001) that professionalism is a unique form of occupational control of work which has distinct advantages over market, organizational and bureaucratic forms of control. In assessing the political, economic and ideological forces that are exerting enormous pressure on the professions today, Freidson (1994) has defended professionalism as a desirable way of providing complex, discretionary services to the public. He argues that market-based or organizational and bureaucratic methods impoverish and standardize the quality of service to consumers and demotivates practitioners, and he goes on to suggest how the virtues of professionalism can be reinforced. Thus, professions might need to close markets in order to be able to endorse and guarantee the education, training, experience and tacit knowledge of licensed practitioners, but once achieved the profession might then be able to concentrate more fully on developing the service-orientated and performance-related aspects of their work (Evetts 1998; Halliday 1987). The process of occupational closure will also result in the monopoly supply of the expertise and the service, and probably also to privileged access to salary and status as well as to definitional and control rewards for practitioners. In respect of these privileges, it is necessary to remember the dual character of professions which include both the provision of a service (and the development of an autonomous form of governance) as well as the use of knowledge and power for economic gain and monopoly control (which pose a threat to civility). The pursuit of private interests is not always in opposition to the pursuit of the public interest, however, and indeed both can be developed simultaneously (Saks 1995).

Halliday (1987) also argued that the emphasis on market monopolies underestimated the breadth of professionalism, especially concerning professional influences on states and legislative bodies. For Halliday the closure of markets might only be an issue during the early stages of professional development. In his analysis of the Chicago Bar Association, the preoccupation with market dominance was confined to early developmental stages and, once completed, its importance declined. In the later phase of 'established professionalism' the professional projects are different and a broader range of work is undertaken. Indeed, he (1987: 354) stated that 'if it can secure its occupational niche and protect its vital economic interests, then a profession's resources can be freed from market concerns for other causes'.

In general, then, some recent Anglo-American analyses of professions have involved the re-interpretation of the concept of professionalism as a normative value system in the socialization of new workers, in the preservation and predictability of normative social order in work and occupations, and in the maintenance and stability of a fragile normative order in state and increasingly international markets. This current interpretation has built on earlier (perhaps less critical) analyses but the result is now a more balanced and cautious reappraisal. There is due recognition, for example, of the power and self-interests of some professional groups in wanting to preserve and indeed promote professionalism as normative value system. This current interpretation of professionalism as value system involves a re-evaluation of the importance of trust in client/practitioner relations (Karpik 1989), of discretion (Hawkins 1992) as well as analysis of risk (Grelon 1996) and expert judgement (Milburn 1996; Trépos 1996). It also includes a reassessment of quality of service and of professional performance in the best interests of both customers (in order to avoid further standardization of service provision) and practitioners (in order to protect discretion in service work decision-making) (Freidson 1994).

2.2.3 Third Phase: Professionalism as a Discourse

A third development involved the analysis of professionalism as a discourse of occupational change and control – this time in work organizations where the discourse is increasingly applied and utilized by managers. This third interpretation is a combination of the previous two and includes both occupational value and ideological elements. Fournier (1999) considered the appeal to 'professionalism' as a disciplinary mechanism in new occupational contexts. She suggested how the use of the discourse of professionalism, in a large privatized service company of managerial labour, worked to inculcate 'appropriate' work identities, conducts and practices. She considered this to be 'a disciplinary logic which inscribes "autonomous" professional practice within a network of accountability and governs professional conduct at a distance' (1999: 280).

It is also the case that the use of the discourse of professionalism varies between different occupational groups. It is possible to use McClelland's categorization (1990: 170) to differentiate between professionalization 'from within' (that is,

successful manipulation of the market by the group e.g. medicine and law) and 'from above' (that is, domination of forces external to the group e.g. engineering and social work). In this interpretation, where the appeal to professionalism is made and used by the occupational group itself, 'from within', then the returns to the group (in terms of salary, status and authority) can be substantial. In these cases, historically, the group has been able to use the discourse in constructing its occupational identity, promoting its image with clients and customers, and bargaining with states to secure and maintain its (sometimes self) regulatory responsibilities. In these instances the occupation is using the discourse partly in its own occupational and practitioner interests but sometimes also as a way of promoting and protecting the public interest (e.g. medicine).

In the case of most contemporary public service occupations and professionals now practicing in organizations, however, professionalism is being constructed and imposed 'from above' and for the most part this means by the employers and managers of the public service organizations in which these 'professionals' work. Here the discourse (of dedicated service and autonomous decision making) is part of the appeal (or the ideology) of professionalism. This idea of service and autonomy are what make professionalism attractive to aspiring occupational groups. When the discourse is constructed 'from above', then often it is imposed and a false or selective discourse, because autonomy and occupational control of the work are seldom included. Rather, the discourse is used to promote and facilitate occupational change (rationalization) and as a disciplinary mechanism of autonomous subjects exercising appropriate conduct.

This discourse of professionalism is grasped and welcomed by the occupational group since it is perceived to be a way of improving the occupations status and rewards collectively and individually (e.g. aspiring caring occupations). It is a powerful ideology and the idea of becoming and being a 'professional worker' has appealed to many new and existing occupational groups particularly during the second half of the twentieth century (e.g. social work and social care occupations throughout Europe and North America).

However, the realities of professionalism 'from above' are very different. The effects are not the occupational control of the work by the worker/practitioners. Instead the emphasis is control by the organizational managers and supervisors (e.g. health and social care work). Organizational objectives, which are sometimes political, define practitioner/client relations, set achievement targets and performance indicators. In these ways organizational objectives regulate and replace occupational control of the practitioner/client work interactions, thereby limiting the exercise of discretionary decision-making, and preventing the service ethic that has been so important in professional work. Organizational professionalism is clearly of relevance to the forms of public management currently being developed in the UK, Europe, North America and more widely, in educational institutions (schools and universities), hospitals and primary care practices.

The appeal to professionalism can and has been interpreted as a powerful motivating force of control 'at a distance' (Burchell et al. 1991; Miller and Rose 1990). It is also effective at the micro level where essentially it is a form of inner-directed control

or self-control where close managerial supervision is not required – professional workers do not need supervisors. Organizational professionalism will be achieved through increased occupational training and the certification of the workers/employees – a process labelled as credentialism by Collins (1979, 1981). In these cases the appeal to professionalism is a powerful mechanism for promoting occupational change and social control.

But the appeal to the discourse by managers in work organizations is to a myth or an ideology of professionalism (Evetts 2003). The myth includes aspects such as exclusive ownership of an area of expertise, increased status and salary, autonomy and discretion in work practices and the occupational control of the work. The reality of the professionalism is actually very different. The appeal to professionalism by managers most often includes (i) the substitution of organizational for professional values; (ii) bureaucratic, hierarchical and managerial controls rather than collegial relations; (iii) managerial and organizational objectives rather than client trust and autonomy based on competencies and expertise; (iv) budgetary restrictions and financial rationalizations; (v) the standardization of work practices rather than discretion; and (vi) performance targets, accountability and sometimes increased political control.

The use of the discourse of professionalism as operationalized by managers in work organizations is also a discourse of self-control which enables self-motivation and sometimes even self-exploitation. Born (1995) illustrates this process in the work context of French professional music practice and it is present more generally in the work culture of artists, actors and musicians in general. Once self-defined as a professional artist, imposing time or other limits on one's efforts are rendered illegitimate. This is also the case with professionals in general. The expectations by self and others of the professional have no limits. For the professional, of all kinds, the needs and demands of audiences, patients, clients, students and children become paramount. Professionals are expected and expect themselves to be committed, even to be morally involved in the work. Hence managers in organizations can use the discourse of professionalism to self-motivate, inner-direct and sometimes to exploit professionals in the organization.

The analysis of professionalism has, then, involved different interpretations – sometimes positive, sometimes negative, and in the latest interpretation combined – of what the professionalization of an occupational group entails. The characteristics of occupational professionalism which made it distinctive and different to organizational means of controlling work and workers were somewhat idealistic (probably ideological) and based on a model and image of historical relations probably in the medical and legal professions in predominantly Anglo-American societies in the nineteenth century. The image was of the doctor, lawyer and clergyman, who were independent gentlemen, and could be trusted as a result of their competence and experience to provide altruistic advice within a community of mutually dependent middle and upper class clients. The legacy of this image, whether in fact or fiction, has provided a powerful incentive for many aspiring occupational groups throughout the twentieth century and helps to explain the appeal of professionalism as a managerial tool.

The image or the ideology of professionalism as an occupational value that is so appealing involves a number of different aspects. Some might never have been operational; some might have been operational for short periods in a limited number of occupational groups. The range of aspects include:

- control of the work systems, processes, procedures, priorities to be determined primarily by the practitioner/s;
- professional institutions/associations as the main providers of codes of ethics, constructors of the discourse of professionalism, providers of licensing and admission procedures, controllers of competences and their acquisition and maintenance, overseeing discipline, due investigation of complaints and appropriate sanctions in cases of professional incompetence;
- collegial authority, legitimacy, mutual support and cooperation;
- common and lengthy (probably expensive) periods of shared education, training, apprenticeship;
- development of strong occupational identities and work cultures;
- strong sense of purpose and of the importance, function, contribution and significance of the work;
- discretionary judgment, assessment, evaluation and decision-making, often in highly complex cases, and of confidential advice-giving, treatment, and means of taking forward; and
- trust and confidence characterize the relations between practitioner/client, practitioner/employer and fellow practitioners.

These aspects are not intended to be regarded as the defining characteristics of a profession. Rather these are aspects of the image and the ideology of professionalism which can account for the attraction and appeal of professionalism as an occupational value and increasingly as a managerial tool in work organizations. In previous publications I have referred to these aspects as ideal-types of occupational professionalism and contrasted these with organizational aspects of professionalism (Evetts 2006). But professionalism is changing and being changed. The next section examines some of the changes to the occupational value aspects of professionalism.

2.3 A New Professionalism? Changes and Continuities

Professionalism has undergone change and these changes have been seen as part of a governmental project to promote commercialized (Hanlon 1998) and organizational (Evetts 2006, 2009) forms of professionalism. Within this context Brint (1994) has discussed an epochal shift from the rhetoric of trusteeship to the rhetoric of expertise. Organizational principles, strategies and methods are deeply affecting most professional occupations and expert groups, transforming their identities, structures and practices. Whether a 'new' form of professionalism is emerging is debatable since there are elements of continuity as well as of change. It is important,

therefore, to clarify what exactly has changed and what continues in order to be able to assess the likelihood (or otherwise) of professionalism surviving as an occupational value.

Aspects of change certainly include elements of hierarchy, bureaucracy, output and performance measures and even the standardization of work practices, all of which are more characteristic of organizational rather than professional forms of occupational control. When service sector professionals have proved enduringly difficult to manage and resistant to change, then an important part of the strategy became to recreate professionals as managers and to manage by normative techniques. The discourse of enterprise becomes linked with discourses of professionalism, quality, customer service and care. Professionals are also tempted by the ideological components of empowerment, innovation, autonomy and discretion. Furthermore, attempts to measure and demonstrate professionalism actually increase the demand for explicit auditing and accounting of professional competences. Thus, managerial demands for quality control and audit, target setting and performance review become reinterpreted as the promotion of professionalism. It is necessary to recognize, however, that output and performance measures also represent a 'discourse of competition' (Hoggett 1996: 15) or what Broadbent et al. (1999) termed 'individualization'. The danger is that social cohesion and institutional action are undermined whilst competition threatens both team working and collegial support. Thus, the quest for professionalism and accountability is highly competitive and individualistic, but it is also a bureaucratic means of regaining and exercising control of a market-directed enterprise staffed by professionals.

In addition there are other characteristics (particularly the professionalism developed under the guise of New Public Service Management (NPSM)) which seem to point to a new and distinct variant of professionalism. The emphasis on governance and community controls, the negotiations between complex numbers of agencies and interests, and the recreation of professionals themselves as managers, are all examples of these variants. Thus, in public sector professions, control is increasingly achieved by means of normative values and self-regulated motivation. In professional services firms a discourse of enterprise is fitted alongside the language of quality and customer care and the ideologies of empowerment, innovation, autonomy and discretion. In addition, this is also a discourse of individualization and competition where individual performance is linked to the success or failure of the organization. These factors all constitute powerful mechanisms of worker/employee control in which the occupational values of professionalism are used to promote the efficient management of the organization.

In numerous ways centralizing, regulatory governments, intent on demonstrating value from public service budgets seem to be redefining professionalism and accountability as measurable. But before we acknowledge the decline (and possible demise) of occupational forms of professionalism, it is necessary also to acknowledge some of the ways in which occupational professionalism still continues to operate. Adler et al. (2008) argue that the market, hierarchy and community are not necessarily mutually exclusive but can be mutually supportive. More market pressures often lead to more community based practices such as multi-disciplinary

teams and cooperative working which are consistent with occupational forms of professionalism.

In addition the occupational control of work is still important in some traditional professions such as law (though less so for medicine). It is also of increased importance in some newly powerful professional groups such as international accountancy. The organization can provide new territories and opportunities for professionalization (e.g. management and personnel management) and there are examples of attempts by some occupational groups to reclaim professionalism. In these cases both national institutions and European professional federations are involved in aspects of the regulation of the occupational groups including the development of performance criteria, target setting and continuing professional development (CPD). In assisting governments to define and construct these regulatory systems, these national professional institutions and European federations are continuing to exercise occupational control over work whilst constituting a form of moral community based on occupational membership. In addition there are also examples of the sharing, modification and adaptation of particular regulatory regimes between different professional institutions and federations (Evetts 1994; Flood 2011).

Other continuities characteristic of occupational professionalism remain and seem resistant to change, sometimes despite clear policies and incentives for change. Gender differences in professional careers and occupational specialisms, continue, although some interesting variants are emerging and situations are complex. Women are entering established professions in larger numbers and proportions, and men are entering female professions, and many are successfully developing careers. Other professionalizing occupations (often where women are numerically dominant) have utilized professionalism in order to secure new tasks, responsibilities and recognition. Women are increasingly becoming managers, but management itself is being changed and standardized such that it might be the case that men are leaving this (less interesting and powerful) field and moving upwards where they can and sideways (e.g. into consultancy or private practice) when they cannot.

The following table summarizes aspects of change and continuity in the interpretation of professionalism as an occupational value in service professions. This is a simplification of what is, in fact, a highly complex, variable and changing situation. Professional occupations are different both within and between nation-states and contexts are constantly changing as new nation-state and European policies emerge, develop and are adapted and modified in practice and in local work places. Used with care and due caution, these aspects might enable an assessment of the prominence of organizational and occupational professionalism to be made in different occupations and work places (Table 2.1).

These changes and continuities include both structural and relationship aspects and characteristics, although, importantly, the changes are more structural while the continuities tend to focus on relations. In addition these changes and continuities have been identified and illustrated at macro (i.e. societal) and mezo (i.e. institutional/organizational) levels of analysis but there might also be significant micro (i.e. work place) variations in different places of work and local organizational contexts (Liljegren 2012).

Table 2.1 Changes and continuities in professionalism as occupational value

Changes	Continuities
Governance	Authority
Management	Legitimacy
External forms of regulation	Prestige, status, power, dominance
Audit and measurement	Competence, knowledge
Targets and performance indicators	Identity and work culture
Work standardization, financial control	Discretion to deal with complex issues, respect, trust
Competition, individualism, stratification	Collegial relations and jurisdictional competitions
Organizational control of the work priorities.	Gender differences in careers and strategies
Possible range of solutions/procedures defined by the organization	Procedures and solutions discussed and agreed within specialist teams

What, then, are the consequences for practitioners and clients? Is occupational professionalism worth preserving as a distinct alternative and contrasting way of controlling work and workers (compared with organizations and markets) and with value for both practitioners and their clients? What are the challenges and opportunities of changing aspects of professionalism as an occupational value?

2.3.1 Consequence and Challenges

The consequences of, and challenges to professionalism as an occupational value, are being documented by researchers interested in different occupational groups in Europe and North America (e.g. Bolton 2005; Bourgeault and Benoit 2009; Boussard 2008; Champy 2008; Dent et al. 2008; Schepers 2006; Wrede 2008;) and research links with sociologists of organizations are strengthening (Faulconbridge and Muzio 2008). There are also some early indications of what might be a retreat from or a substantial redefinition of certain aspects of managerialism and New Public Service Management (NPSM) by policy-makers in respect of some service work (e.g. Dahl and Hanne 2008). There is, as yet, no established causal link between the organizational changes and challenges to occupational professionalism and a deterioration of professional values so, as yet, any linkage remains speculative. Also there are several complicating factors which make a causal link difficult to establish. Complicating context factors (some general, some nation-specific) include the demystification of aspects of professional knowledge and expertise; cases of practitioner malpractice and ‘unprofessional’ behaviour; media exaggeration and oversimplification; political interference; large fee and salary increases in particular professional sectors; and divisions between commercial (corporate clients) and social service (state-funded) practitioners; increasing trade union activism on behalf of professionals; all of which carry a perception of self rather than public interest.

It is also the case that powerful professionals have often been resistant to managerial intervention and organizational controls. Many organizations in the public services (e.g. hospitals and universities) are complex professional bureaucracies (Mintzberg 1983) characterized by the involvement of a number of different professional groups. These groups have a history of relative autonomy over their working practices and often have high status which gives them both power and authority. In addition, the 'outputs' of these organizations (and the professionals in them) are not easily standardized and measurable. When the ability to define and standardize the nature of the work process is limited, and the definition of the outputs of the work (and what constitutes success) is problematic, then such service work would seem to be unsuitable for both market and organizational controls.

A decline in occupational professionalism and the possible expansion of organizational forms of professionalism is, then, one of a number of complicating factors (also see an alternative interpretation in Adler et al. 2008). It can be stated, however, that organizational techniques for controlling employees have affected the work of practitioners in professional organizations. The imposition of targets in teaching and medical work – and indeed for the police (see Boussard 2008) – have had 'unintended' consequences on the prioritization and ordering of work activities, and have brought a focus on target achievement to the detriment or neglect of other less-measurable tasks and responsibilities. Bureaucracy, increased regulation and form filling take time which might arguably be devoted to clients. The standardization of work procedures, perhaps using software programmes, is an important check on the underachieving practitioner but can be a disincentive to the creative, innovative, and inspirational professional.

It is important to remember also that the way professionals regard their service work and their working relationships are also being changed and this is an important consequence of redefining the occupational value aspects of professionalism. An emphasis on internal as well as external markets, on enterprise and economic contracting, are changing professionalism. In tendering, accounting and audit management, professionalism requires practitioners to codify their competence for contracts and evaluations (du Gay and Salaman 1992; Freidson 2001; Lane 2000). 'Professional work is defined as service products to be marketed, price-tagged and individually evaluated and remunerated; it is, in that sense, commodified' (Svensson and Evetts 2003: 11). Professional service work organizations are converting into enterprises in terms of identity, hierarchy and rationality. Possible solutions to client problems and difficulties are defined by the organization (rather than the ethical codes of the professional institution) and limited by financial constraints. The role of organizations as institutional entrepreneurs has also been identified and includes the lobbying of the state by professional institutions in order to change professional regulation in their favour.

The commodification of professional service work entails changes in professional work relations. When practitioners become organizational employees then the traditional relationship of employer/professional trust is changed to one necessitating supervision, assessment and audit. Relationships between professionals and clients are also being converted into customer relations through the establishment of

quasi-markets, customer satisfaction surveys and evaluations, as well as quality measures and payment by results. The production, publication and diffusion of quality and target measurements are critical indicators for changing welfare services into a market (Considine 2001). The service itself is increasingly focused, modeled on equivalents provided by other producers, shaped by the interests of the consumers and increasingly standardized. The increasing focus on marketing and selling expert solutions (Brint 1994) connects professionals more to their work organization than to their professional institutions and associations. Clients are converted into customers and professional work competencies become primarily related to, defined and assessed by, the work organization.

2.3.2 Opportunities

The challenges to professionalism as an occupational value seem numerous but are there any opportunities associated with these changes which might improve both the conduct and the practice of professional service work and be advantageous for both practitioners and their clients? Are there some advantages in the combination of professional and organizational logics, of hybrid organizations and organizationally located professional projects, for controlling work and workers?

Using the list of changes and continuities already identified, it would seem important to try to retain some form of occupational control both of work processes and relations. All aspects would need evaluation and assessment by research but it is possible to argue that identity, work culture, specialist team working, discussions among specialists, knowledge and expertise formation and its maintenance all improve the conduct of professional work and its practice while being of benefit to both practitioners and their clients. Other items apparently of importance to organizations would seem to be of less relevance and indeed to have a detrimental affect on professional control of their work. These include auditing measurement, targets and performance indicators. In several instances, these aspects have been shown to distort work processes, procedures and work priorities producing 'unintended' consequences for practitioners and clients. Other aspects of organizational change, including credentialism, governance and external forms of regulation, would seem to produce some benefits (for example of transparency and control of more extreme professional powers) while, at the same time, resulting in detrimental effects such as increased bureaucracy, form-filling and paper-work. These all take time which, arguably, could be better spent in client contact and service work as defined by the profession itself rather than by the work organization. These aspects would seem to have benefits and costs, therefore, and their appropriateness for professional work would need to be monitored over time.

There are other opportunities which might prove to be more beneficial from the combination of the logics of professionalism and the organization which might prove advantageous. One of these is the incorporation of Human Resource Management (HRM) from the organization into professional employment practices,

processes and procedures. Job contracts, job descriptions, formal interview and selection procedures, employment rights and benefits, appeals procedures, sickness benefit and cover, maternity, caring and other absences, are all examples which have benefited the majority of professionals working in organizations and have for the most part replaced less formalized social networking and informal recommendation procedures. Indeed, human resources procedures have contributed to the spectacular growth in professional employment over the last 20 years and have improved diversity and equal opportunities.

Standardization and formalization of selection, retention and career development procedures have also increased the transparency of what were often hidden, even 'mysterious' arrangements in respect of promotion, career progress and departmental relationships and links within the organization. Less formalized procedures benefited only a select few privileged practitioners and were perceived as unfair and inequitable by the majority. Increased transparency can then result in more emphasis on career choices, dependent on personal circumstances, rather than the sponsorship of the privileged few. Career inequalities clearly continue (including in respect of gender and ethnicity), as well as some reliance on networking, informal advice and recommendations but, in general, the incorporation of HRM procedures and regulations from the organization into professional employment practices have been an opportunity and of benefit for practitioners and their work.

Other opportunities would seem to be explained by the increased recognition that organizational management and managerialism is not only complex but is also multi-layered and multi-dimensional. Management is being used to control, and sometimes limit, the work of practitioners in organizations but, in addition, management is being used by practitioners and by professional associations themselves as a strategy both in the career development of particular practitioners and in order to improve the status and respect of a professional occupation and its standing.

As a micro-level strategy, there is some evidence, particularly from health professionals such as nursing and midwifery (Carvalho 2008; Bourgeault et al. 2004) but also now from medical doctors (Kuhlmann 2008) and teachers (Gewirtz et al. 2009), of individual practitioners acquiring qualifications in management (e.g. the MBA or other professional doctorates) with the clear intention of furthering their careers. In the case of health professionals, such as nurses and midwives, this can also be interpreted as a collective mobility strategy as increasingly hospital management at middle and senior levels is perceived as a career opening for those with appropriate management credentials, experience and motivation.

As a mezo level strategy, it is also interesting to note the work of Langer (2008) in respect of social work in Germany. Masters level programmes for social workers in Germany are incorporating management training as a way of increasing the status, standing, reputation and respect for social work as a professional occupation in the field of social services work. Following European Union attempts to standardize higher education levels in Europe, in Germany there is a large development of Masters programmes which qualify (in this case) social workers to apply for leadership positions in non-profit organizations and social services departments. These

developments can be interpreted, therefore, as both micro and mezo level strategies in respect of social work.

In addition, organizations can constitute sites for (and objects of) professional control and domination. Jurisdictional disputes and negotiations were originally described by Abbott (1988) but now they are being played out within organizations rather than in the wider arena of labour markets and education systems. Within organizations, occupations seek to process and control tasks and task divisions to suit their own occupational interests. The medical profession can continue to use its cultural authority and legitimacy to maintain dominance (Coburn 2006; Freidson 2001; Larkin 1983) but other professionals need to use competition, particularly in respect of competences, to acquire dominance in decision-making in the organization. Armstrong (1985) describes competition between professionals in management (accountancy, engineering and personnel) in colonizing key positions, roles and decision-making within large organizations. In these ways organizations constitute arenas for inter-professional competitions as well as professional conquests.

2.4 Policy Relevance, Assessment and Evaluation

In this section I identify some of the important contributions made by researchers on professional work to public policy developments, assessment and evaluation. The idea of professionalism as an occupational and normative value can be linked with public policy concerns about competences at all levels of occupational work.

In the field of sociology of professional groups a number of policy initiatives have been examined by researchers producing reports for policy-makers at both nation-state and regional (European) levels. Health policies particularly in respect of occupations in medicine, nursing, midwifery and alternative medicine and the regulation of these groups of workers have been of interest and have been debated and discussed by researchers. Discussion has also focused on changing modes of governance and of how best to administer professional groups and, in particular, the significance of managerialism and of organizations in public sector social service work (e.g. teaching and social work). Policies focused on recruitment and retention of key groups of service-sector workers, as well as issues to do with migration for both exporting and importing countries and their practitioners, have featured strongly in recent discussions and publications.

Professional work is generally perceived to be service-sector and essentially knowledge-based and where practitioner expertise and experience, both substantive and tacit, are valued and rewarded. The education and training of such practitioners, their credentialing and sometimes their licensing, and continuing professional development, are also policy-relevant issues. The production and certification of expertise, and the promotion of abilities to make expert judgments and assessments in highly complex cases, are regarded as extremely important in all occupations and professions. Yet these abilities are difficult to promote and encourage other than by means of long and expensive education, training and apprenticeships. Most of these

apprenticeships are, of necessity, perceived as vocationally specific. However a recent European focus on work and workplace competences seems to be attempting a more general focus (see Pavlin et al. 2010). Policy initiatives in respect of competences and where these are best facilitated and developed (e.g. in education, higher education or in work) are currently of interest to policy-makers and governments. In Europe, the Bologna Accord (which focused on educational mobility in Europe) and subsequent developments (e.g. in Lisbon) are also encouraging the standardization and regularization of higher education credentials and levels in order both to encourage mobility within the European Union as well as to promote higher education itself as a marketable commodity in international markets.

There are a number of other policy-relevant issues and questions in need of attention as systems of higher education expand and the numbers and proportions of educated individuals increase world-wide. Some of these can be listed and are being discussed by researchers in the field of sociology of professional groups. Examples include the following: what are the connections and linkages between the concepts of expertise, competence and professionalism? In the context of mass academic certification, the certified individual is not necessarily an expert whose judgment can be relied on to take decisions. Is trust in professionals worth preserving? Is professionalism as an occupational value worth protecting and promoting, and even expanding to all kinds of occupational work and workers? Are we able to define and categorize the notion of occupational competence and how do the different discourses of employers, managers, workers and customers vary in respect of how competences are perceived? If the occupational values of competences and professionalism are linked and worth promoting then in which institutional locations and stages of career are these best developed – in educational institutions such as schools and universities, in workplace organizations, or in vocational and training courses separate from schools and work? What is the function and purpose of professional institutes and associations? Are these of value and importance, and worth promoting and developing in societies where none have existed? Alternatively have these institutions become too powerful in closing markets and protecting jurisdictions from competition and other market effects? Where are the ethical dimensions of work and occupations best developed and maintained? Are customer complaints a good measure or indicator of the extent of professionalism in the workplace? Is the occupation (via its institute, guild or association) the best regulator of the work and workplace practice?

In general, then, service-sector occupations and knowledge-based work are increasingly seen to be marketable products in the global economy. Knowledge-based occupations are also the expanding employment categories and the growth sectors of labour markets particularly in developed societies but also in transitional and developing economies. Professions are essentially the knowledge-based category of occupations which usually follow a period of tertiary education and vocational training and experience. A different way of categorizing these occupations is to see them as work associated with the uncertainties of modern lives in risk societies. Professional workers are extensively engaged in dealing with risk, with risk assessment and, through the use of expert knowledge, enabling customers and

clients to deal with uncertainty. Sociologists of professional groups are increasingly involved in the evaluation and assessment of risk in social and public policy.

In conclusion, this chapter has explained professionalism as an occupational value and argued the importance of retaining and perhaps recreating this interpretation for service sector professional and occupational work. But professionalism is changing and being changed as service professionals now increasingly work in large-scale organizational work places and sometimes in international professional firms. The chapter examined the changes to and the continuities in the construction of professionalism in these organizational contexts. Also examined were some of the changes and challenges to professionalism as an occupational value as well as some of the opportunities for practitioner-workers and their clients in service work. It is important to remember that the redefinition of professionalism and its links with management present opportunities and benefits for professional work and workers as well as important challenges. Perhaps continuities, challenges and opportunities, for the maintenance of professionalism as an occupational value is one of the most important tasks for professional institutions and for governments over the next few years. Professionalism as an occupational and normative value is arguably fundamental for professional work, professional practice and learning.

Chapter 3

Moral Aspects of Professions and Professional Practice

Gerhard Minnameier

Abstract Professions are usually defined as occupations that require expert training at an academic level and are built on a set of standards that have to be met by members of a given profession. These standards not only apply to certain kinds of expert knowledge that are expected of professionals but also ethical standards in relation to the usage of this expert knowledge. However, apart from possible failures to meet these requirements, professionals, like anybody else, normally do not always act according to one guideline alone. Their actions are rather tuned to different situational cues. The article explores what kind of situations can be distinguished on a theoretical basis, how far such differentiations are acceptable or even appropriate and where they are not, and how situational adaptation works. The paper ends with deriving implications for professional practice and vocational education and training.

Keywords Professional ethics • Business ethics • Moral development • Developmental stages • Situation specificity • Moral functioning • Moral motivation

3.1 Introduction

Professions are usually defined as occupations that require expert training at an academic level and are built on a set of standards that have to be met by members of a given profession (Abbott 1988, 1991; Freidson 2001). These standards not only relate to certain kinds of expert knowledge, but also to ethical guidelines and principles. And the more professionalised a certain area is, the more difficult it is for their social environment (e.g. customers and clients) to know what is best for them and

e-mail: minnameier@econ.uni-frankfurt.de

what is morally appropriate. Think, e.g., of the medical and judicial professions, where clients have to rely on the professionals' honesty and integrity.

However, today ethical codes also apply to lower ranking professionals and, in fact, to all staff of a company or organisation. The reason behind this is that autonomy and responsibility have become key elements in the modern organisation of work, and with more autonomy of the personnel the moral responsibility also increases. This not only includes the problem of furthering one's own interests – staff theft or disengagement at work – but also the issue of conflicts of loyalty to the company and to the customer, or conflicts between seeking the company's benefit and social or environmental concerns.

Apart from particular moral problems that may arise in specific areas – e.g. security issues for those in the airline industry; biotechnological aspects in health professions and so on – all professionals have the problem of mediating between their professional aims and duties on the one hand, and their personal views and values on the other. Furthermore, with respect to social and environmental concerns and other stakeholder interests, there is no clear dividing line between the professional and the private point of view, since stakeholder management and corporate social responsibility have become key areas of business management (see e.g. Freeman et al. 2004) and since the proper understanding of the social responsibility of a profession is also a key element of the very idea of professionalism (see e.g. Abbott 1988; Beck 1997; Kutscha 2008; Parsons 1968).

Professional identities can take three forms: undifferentiated, segmented, and integrated (Nyström 2009). According to Nyström, these forms constitute a developmental sequence, beginning with an undifferentiated identity, where the (previously formed) personal identity is transferred to the professional life. Segmentation means that a new and separate professional identity is formed, so that the individual has two different identities: one professional, one private. At the final stage, the personal and the professional identity are integrated.

However, it is still an open question whether professional and personal identities can always be integrated and how an integrated identity would work, especially with respect to ethical issues. There is ample evidence today, both from research in moral psychology (see Krebs and Denton 2005, for an overview) and in business ethics for situation-specific moral judgement and action (see e.g. Church et al. 2005; Forsythe et al. 1994; Greenberg 2002; Hoffman et al. 1994; Johns 2001, 2006; O'Fallon and Butterfield 2005; Ross and Robertson 2000; Schminke and Priesemuth 2012; Tenbrunsel and Smith-Crowe 2008; Treviño et al. 2006). It is widely accepted today, that moral judgement and action are adapted to situational affordances and constraints, so that there is a great deal of situation-specificity in moral functioning. However, it is not only unclear, how this situational adjustment actually functions, but also, whether it should be welcomed as flexible and intelligent adaptation or condemned as opportunistic orientation and trimming one's sails to the wind.

Whether one view or the other is correct will depend on the way in which situation-specificity comes about and is handled by the individual. As already mentioned above, one possibility is segmentation or separation, so that the individual lives in different worlds with different principles and action-orientations for a critique of the so-called separation thesis (see Wicks 1996, see also Sandberg 2008;

Harris and Freeman 2008; conversely Bragues 2005). The other possibility is a specific problem orientation, so that situation-specificity depends on specific types of problems that evoke specific moral principles and reactions that are suited to master that situation. The former is the more problematic interpretation implying some kind of split personality. The latter relates to the positive view of an integrated identity that allows for suitable differentiations in moral functioning.

To determine which view ought to be endorsed, I will first consider the types of problems that professionals may encounter and what conflicts these problems may induce with respect to the differentiation of a personal and a professional identity (Sect. 3.2). It will also be discussed what kind of moral principles are suitable to deal with the respective problems, and it turns out that quite different stage principles seem to be appropriate in different situations. Therefore, I will attend to the processes of moral functioning in Sect. 3.3 and discuss an inferential approach which yields an extended view of the processes of moral judgement. According to this analysis much of what we perceive as situation-specific adjustment follows a coherent logic, indeed, which speaks against the idea of simple segmentation and also against the widely-held view that heterogeneous moral orientations are to be equated with insufficient moral motivation in certain situations. As most scholars not only consider situational factors but also personal factors to be relevant for determining moral action orientation, a section on the moral self and its role in moral functioning is also included (Sect. 3.3.3). Finally, in Sect. 3.4, implications for professional practice and vocational education and training will be discussed.

3.2 Moral Problems and Solutions in the Context of Professional Practice

3.2.1 Moral Problems at Work

Moral problems at work arise at all levels and for both employees and entrepreneurs (see e.g. Crane and Matten 2010; Clarke and Holt 2010; Ferrell et al. 2008; Hannafey 2003; Harris et al. 2009; Heinrichs et al. 2014; Valentine and Hollingworth 2012). Moral conflicts arise, because individuals have quite different responsibilities and interests which may coincide, but which may also conflict. In their role as employee or entrepreneur they have to act in the interest of their company or business. As members of professions they are also committed to ethical codes or standards of their profession. As experts in their professional activity, they are indebted to their customers or clients who (have to) trust them. As human beings, they have friends, relatives and their families whom they have to care for. And as members of society they will also be concerned about broader social and environmental issues. Last but not least, their duties may also conflict with their valid self-interest, which also constitutes an important and perhaps neglected moral problem (Maitland 2002).

The company's interest is violated in all cases of employee theft and company-related fraud, but also if staff merely work to rule and do not really care for doing a

good job. In this respect, therefore, one has to be committed to the company as such (i.e. as a social whole) rather than merely following one's self-interest and being motivated only by avoiding punishment, by prospects for better pay and promotion.

Professional standards may be violated for personal reasons or for the sake of the company in order to make an extra profit or to save costs. Therefore, people in the medical professions commit themselves first of all to the well-being of their patients. Engineers should put safety and proper work first in order to prevent accidents and damages. Advertisers ought to extol goods, but not to deceive consumers. Financial advisors direct their clients to comparatively high returns, but they also have to inform them about the risks they run when investing their money in a particular way. By the same token it is important for all professions that their members keep to the standards and act within ethical boundaries, because otherwise the profession itself could fall into disrepute.

Issues of *valid* self-interest, e. g., are questions of how one's work is rewarded (especially, how it is remunerated), and how far one has to be indebted to the company (when it comes to helping out or working for the company in one's free time). However, not only the employee can be the victim, but also the employer. Consider the case of junior employees who are offered 2-year specialised training and then receive tempting job offers at the end of this period. On the one hand, they have benefited from the employer's investment, yet, on the other hand, it could also be argued that they have to seize such opportunities.

As a consequence, there are what economists call "moral hazards" on all sides. Customers as well as one's own company may be deceived and professions as a whole may be discredited by what they consider 'immoral' members of a profession and dishonest behaviour. Moral hazards are based on information asymmetries, and these typically increase with the level of professionalisation of a certain field. Such hazards arise where so-called principals engage agents for some kind of task, and where agents have information that they might conceal to the detriment of the principal. Think of employees whose employer does not know how much effort these employees actually put into their work. Or, consider a seller of used cars (agent) who knows more about a car's actual condition than the customer (client) (see Mankiw 2011, 468–473, for an overview).

Thus, on the one hand, professionals have to meet many moral requirements in a wide variety of contexts. They have to have the necessary moral understanding and motivation, and they have to be sensitive to situation-specific demands. On the other hand, however, they also have to be aware of the moral hazards they face, especially when their morality is likely to be exploited. Therefore, types of situations and (moral) means to handle them, are of great importance for adequate moral functioning.

3.2.2 *A Taxonomy of Types of Situations*

As explained above, situations differ in terms of who is concerned and what is at stake. Apart from different types of groups or individual functions, however, we can also distinguish different kinds of moral tasks. For instance, a team of young

Table 3.1 Description of the four stage-related types of situations according to Beck

Situation (stage)	Description
<i>Competition (Stage 2)</i>	Competitive situations are marked by a clash of interests in which one either has to pursue one's own (or one's company's) interests or engage in negotiations in order to strike a deal and stick to that in the mutual interest of the parties involved.
<i>Cooperation (Stage 3)</i>	In cooperative situations people have to be aware of the social roles they play or have taken on and have to consider what is best for their group, their family or their company.
<i>Coordination (Stage 4)</i>	In the larger context or where group orientations and role expectations conflict, one has to rely on generally agreed (especially democratically established) rules like laws and other regulations.
<i>Constitution (Stage 5)</i>	Constitutive situations are about inventing or setting rules for coordination. As such, these situations require a prior-to-society perspective and principles according to which laws can or should be made.

entrepreneurs may have to convince their bank to give them a loan and, therefore, conceal some disadvantageous information. Or, job applicants put themselves in very positive light, or a salesperson does not inform a customer about a slight defect of the desired product. All these actions are motivated by self-interest, so they are all of one type, irrespective of the specific context.

However, a quite different kind of moral problem arises when a manager of a middle-sized firm stresses the team character of the company, or when employees have to cooperate to determine who goes on holiday when or how to split up a complex order into small work packages. Whereas the issues mentioned first are situated in a framework of *competition*, those latter issues focus on *cooperation*. Beck (1999, 2008) has made this distinction and added two more types: *coordination* and *constitution*, which he also matches with specific Kohlberg stages (see Table 3.1). On his view, Stage 2 is appropriate for competitive situations, Stage 3 for cooperative situations, Stage 4 for problems of normative coordination, and Stage 5 for constitutional situations. *Coordination* in his understanding means that larger social entities that consist of concrete groups (of people how know each other, work or live together) have to coordinate their activities based on established and accepted procedures or by democratic decision-making. The organisation of a larger company is one example, deciding where to best build a certain road and other questions concerning infra-structure are another. *Constitutional* situations go even beyond mere coordination, because they concern the establishment of coordinative rules and procedures in terms of guiding principles (e.g. in the sense of a Rawlsian social contract).

Thus, the four categories described in Table 3.1 constitute very general types of situations, which differ from each other in that each requires a specific kind of moral reasoning in terms of 'Kohlberg stages'. However, this also means, contrary to Kohlberg, that the highest (or a higher) stage is not always appropriate. Rather, if situations belong to a certain type, they have to be matched with the respective moral stage principle.

As the examples already suggest, the four different types characterise *abstract* modes of social interaction that may appear in different *concrete* contexts, so that competition, cooperation, coordination, and constitution may all be relevant for the internal interaction among members of a company, the relations with customers and suppliers and with society as a whole. This extended view yields the two-dimensional classification of situations shown in Table 3.2. The single cells contain examples of concrete problems representing the categories. For instance, *competition* appears in personal relations within the company, in the interaction between the company (or its members) and customers or suppliers, and as a principle of interaction on the level of society as a whole (where, e.g., tax-payers try to keep their personal burden low even though they accept taxation as such for the society). The examples also show that issues of all stage-related types can be found in all of addressee-related types (in the lines of Table 3.2).

Depending on one's position and tasks, some of these moral aspects are more relevant, others less. However, to some extent they will play a role in the professional lives of virtually anyone, because everyone is part of a social system – indeed, various social systems that may also be embedded into one another. Therefore, every employee and every employer can perceive their roles and actions from different moral points of view. What these points of view are, and how they may become relevant in actual practice, is perhaps better understood within a neo-Kohlbergian framework of moral stages that I will sketch in the following section.

3.2.3 A Neo-Kohlbergian Taxonomy of Moral Stages

As far as the Kohlberg stages are concerned, they have long been criticized for their vagueness and their weak systematic foundation (see e.g. Tomlinson 1986; Gibbs 2010). However, these deficiencies might have been overcome with a neo-Kohlbergian taxonomy which is more detailed and theoretically more stringent (see Minnameier 2000, 2001, 2005, 2009, 2010a, b, c). Kohlberg's theory may work as makeshift to some extent. However, when it comes to the problem of situational adaptation, it is no longer appropriate, as will become apparent further below. The neo-Kohlbergian taxonomy can enhance our understanding of morality related to the different contexts, and it also accommodates much of what is in the Kohlberg model, e.g. his idea of A- and B-types of each stage (Kohlberg differentiated A- and B-types; the neo-Kohlbergian taxonomy distinguishes three substages, A, B, and C, for each stage).¹

The neo-Kohlbergian taxonomy (see Fig. 3.1) is based on a dialectic developmental theory that was originally suggested by Piaget and Garcia (1989). According to their

¹ Kohlberg first introduced these forms as “sub-stages” (see e.g. 1984), but played them down later and spoke of “types”, because he noticed anomalies in the developmental sequence (Colby and Kohlberg 1987). From the point of view of the neo-Kohlbergian taxonomy, however, these anomalies are integrated and therefore constitute no systematic problem anymore.

Table 3.2 Types and examples of moral issues

Addressee-related types	Stage-related types			Constitution
	Competition	Cooperation	Coordination	
<i>Company</i>	Conflicts of interest between employer and employee	Teamwork; company loyalty; living up to one's concrete role in the job	Respecting organization and internal procedures	Discussing the company's philosophy and human relations
<i>Customer/supplier</i>	Buying and selling	Friends/relatives as customers/suppliers; regular customers	Securing customers' /suppliers' legal rights	Developing consumer protection
<i>Society</i>	Business in a market economy; the individual as tax payer	Cooperation in industrial associations;	Complying with existing rules on wage negotiations with unions	Developing regulations for sustainable production

Levels	I						II						III																	
Stages	1			2			3			4			5			6			7			8			9					
Substages	A	B	C	A	B	C	A	B	C	A	B	C	A	B	C	A	B	C	A	B	C	A	B	C	A	B	C	A	B	C

Fig. 3.1 Overview of the neo-Kohlbergian stage taxonomy

approach development proceeds across the dialectical triad of intra-, inter-, and trans-stages. “Intra” means that certain claims (of individuals or groups) are recognised as such, but can as yet not be balanced in a principled way. Consider the relevance of personal interests. According to Kohlberg, people at Stage 2 realise that everybody has interests to pursue. Thus, interests of others are recognised and accepted (this is Stage 2A in the neo-Kohlbergian framework).² However, when interests clash, everybody just has to pursue his or her own personal interest.

At the “inter”-stage, however, it is possible to mediate between those interests, especially through mutual agreements (promises or contracts), by which the different interests are matched in such a way that an agreement is reached and accepted by both parties. This type of moral reasoning also belongs to Kohlberg’s Stage 2, although it is quite different from the first type. It is labelled Stage 2B in the present framework.

Eventually, at the “trans-stage”, one may even go beyond negotiating exchange values, when one becomes aware of the fact that sometimes you are forced into unjust and disadvantageous deals. This is possible in the sense of the Golden Rule (in its simplest form), where one considers the others’ and one’s own interests from an outside perspective (Stage 2C). This kind of thinking plays an important role when salespersons act in favour of the customers and at the expense of their own or their company’s profit, because they are considerate and value the customer’s interest as such, not just strategically. According to Kohlberg’s taxonomy this reasoning would already belong to Stage 3. However, it still takes place in the context of dealing with conflicting interests, whereas the neo-Kohlbergian Stage 3 relates to the perspective of a social whole like e. g. taking the perspective of one’s company or one’s department.

This differentiation within – broadly speaking – the entire “Kohlberg-stages” thus covers important additional aspects of how to suitably address different moral problems at work. For reasons of brevity I cannot go into more detail here, but the examples given will suffice to give the reader an idea of what kinds of different moral principles may be relevant in specific situations (for additional examples and explanations see Heinrichs et al. 2014).

²In some earlier presentations of the taxonomy the stages were called levels and numbered only 1–3 recursively (following the hierarchically integrated dialectical structure; see Minnameier 2000). However, in order to make the main relations to Kohlberg’s stages more salient, they are numbered 1 through 9 here. This also indicates that there are forms of ethical reflection that are not included in Kohlberg’s stages at all and that go beyond his framework (for more details and the explication of stages and differences to Kohlberg’s view see Minnameier 2000, 2001).

In this section, it has been shown, how forms or moral reasoning are connected in terms of higher complexity, where higher stages solve the problems that appear at the lower ones. Based on this, the next section explores how moral stages are used in situations, according to the level of complexity as it is perceived.

3.3 Moral Functioning and Situational Adjustment

3.3.1 *Situation-Specific Adaptation*

Today, there is hardly any doubt that professional morality has to do justice to the specificity of situations rather than lumping everything and everyone together under one “cure-all” moral principle. Many have claimed this (quite recently) in business ethics (Church et al. 2005; Crane and Matten 2010, 160–176; Greenberg 2002; Johns 2001, 2006; O’Fallon and Butterfield 2005; Schminke and Priesemuth 2012), and moral psychologists have produced impressive empirical evidence of situation-specific variability of moral judgement (for an overview see Krebs and Denton 2005; see also Beck et al. 2002; Beck and Parche-Kawik 2004; DeScioli and Kurzban 2013). Following Krebs and Denton (2005) I also believe that while people acquire increasingly sophisticated structures of moral reasoning in the course of their development, they “retain their old forms of moral reasoning and invoke them to solve the problems that they are equipped to solve. Simple problems can be solved perfectly adequately with simple forms of thought” (2005, 673). The question, however, is what kinds of situational adaptations are appropriate and how they are to be explained. The latter question will be addressed in this section, and I shall discuss the former in the following section.

Situation specificity has long been a problem for moral psychologists, Firstly, Kohlberg has always held that moral stages are structured wholes that include and transcend the stages below them so that the highest reached stage is always the best one and is used in any situation (see e.g. Colby and Kohlberg 1987, 6–8; Lapsley 2006). Secondly, the deviation from a moral judgement has been interpreted as a lack of moral motivation (esp. by Rest 1983, and subsequently in the research on the so-called “happy victimizer phenomenon”; see e.g. Nunner-Winkler 2007; Nunner-Winkler and Sodian 1988; see also Minnameier 2010b, 2013). Similarly, Kohlberg and Candee (1984) have employed Blasi’s (1983) concept of “judgements of responsibility” to address this problem and held that by way of those judgements individuals have to commit themselves to what they have already identified as their moral duties (see Fig. 3.2).

Given this, attuning one’s decisions and actions to the affordances and constraints of different situations arouses the suspicion that one just lacks moral motivation (or moral responsibility, with respect to Fig. 3.2) to live up to one’s duties, being self-righteous and trimming one’s sails to the wind. However, if situational adaptation is taken seriously, as something that is positive and even required of

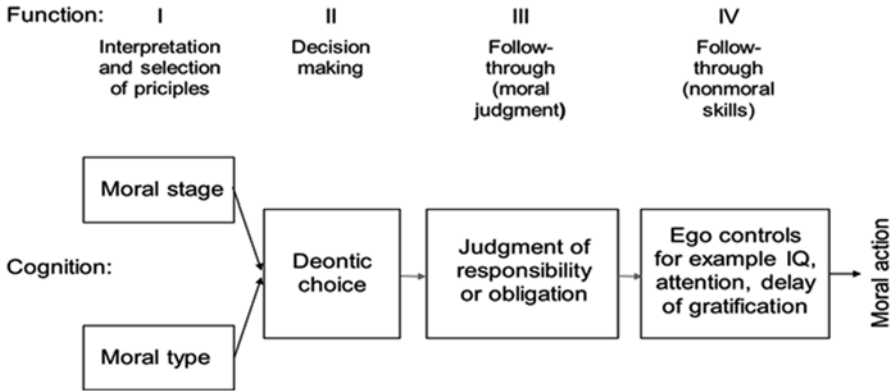

Fig. 3.2 Model of the relationship of moral judgment to moral action (Kohlberg and Candee 1984, 71)

professionals, we have to reinterpret the processes of moral functioning as modelled by Kohlberg and Candee (1984) and by Rest (1983, 1984; also Rest et al. 1999).

This is all the more important, because moral motivation and moral responsibility have not only been discussed with respect to moral function in everyday situations, but have also been championed in the field of business ethics where, however, Rest's four-component model became embedded into a larger model including also so-called person-situation interaction (see e.g. Crane and Matten 2010, 143–145; Ferrell and Gresham 1985; Hunt and Vitell 1986; Jones 1991; Treviño 1986; Treviño et al. 2006).

Criticism of the Restian view of moral motivation is based on systematic reasons, i.e. problems with the very notion of moral motivation (Minnameier 2010a, b, c, 2013) and the already mentioned influence of situational factors on top aspects of the moral personality (Crane and Matten 2010, 143–145), e.g. that one and the same person cooperates in one team, but refuses to cooperate in another team, where freeriding prevails. I will not go into the criticisms here, but rather explain how the logic of situational adaptation might work, based on an inferential approach which distinguishes between abduction, deduction, and induction. In the subsequent section, I will discuss how personal influences might come into play.

3.3.2 *Inferences and the Explanation of Situational Differentiation and Adaptation*

Rest's four-component model of moral functioning distinguishes between 'moral sensitivity', 'moral judgment', 'moral motivation', and 'moral character' (see Rest 1983, 1984; Rest et al. 1999). According to this model, there is obviously only one distinctively cognitive component: *moral judgment*. The other processes are

thought to frame, process, possibly distort or suppress this cognitive activity or its outcome.

While Kohlberg and Candee's (1984) model looks similar on the surface, there are marked (and remarkable) differences between them. In particular, Rest clearly divorces moral judgement from moral motivation (see also Rest 1983, 564; Rest 1984, 27, 32), whereas Kohlberg and Candee "hypothesize that there are two distinguishable but related modes or kinds of moral judgment" (1984, 56). In their view, moral judgment as a whole is divided up into two parts, a deontic judgement and a judgment of responsibility (see *ibid.*, 57). On top of this, the first step according to Kohlberg and Candee consists in activating a suitable stage-principle based on the situational input. All this suggests that "deontic choice", the second step in their model, is but one cognitive process which is sided by additional cognitive processes.³

In particular, it can be argued that the overall process of moral judgement splits up into three distinctive types of judgment or inferences that cover the first three processes of Kohlberg and Candee's (1984) model. These inferences can be distinguished and explicated in the framework of C. S. Peirce's approach to scientific reasoning, which is discussed and applied, today, in different disciplines contexts (see e.g. Aliseda 2006; Campos 2011; Gabbay and Woods 2005; Magnani 2009; Minnameier 2004a, 2010c; Schurz 2008).

Peirce (1903/1934) goes beyond the classical distinction of *deduction* and *induction* and introduces a third type of inference called *abduction*. On his account, and opposed to the classical view still common in today's common sense understanding, induction cannot produce any new items of knowledge but only establish a conviction about the factual truth (in the pragmatist sense). In Peirce's own words, the inferences are described as follows:

Abduction is the process of forming an explanatory hypothesis. It is the only logical operation which introduces any new idea; for induction does nothing but determine a value, and deduction merely evolves the necessary consequences of a pure hypothesis. Deduction proves that something *must* be; Induction shows that something *actually is* operative; Abduction merely suggests that something *may be*. Its only justification is that from its suggestion deduction can draw a prediction which can be tested by induction, and that, if we are ever to learn anything or to understand phenomena at all, it must be by abduction that this is to be brought about. (Peirce 1903/1934, 106 [CP 5.171])

These three inferences constitute a dynamic and recursive structure illustrated in Fig. 3.3. *Abduction* begins with a situational problematic that needs to be addressed by some theory. The problem can be explanatory (this is the common framing), but also technological (i.e. how to solve a practical problem) or moral. In all these fields, abduction marks the creative process of either inventing new concepts and principles or activating already existing ones. The premises of the abductive inference are the problematic facts that need to be addressed, and the result is the suggested theoretical approach. In the moral domain, this theoretical approach consists in the moral principle according to which the moral problem might be solved

³To be sure, Kohlberg and Candee's account is not free from inconsistencies that are revealed and discussed in Minnameier (2013).

Fig. 3.3 The dynamical interaction of abduction, deduction, and induction

(e.g. “everybody has to care for themselves” [Stage 2A], “tit for tat” [Stage 2B], the ‘golden rule’ [Stage 2C], or “every employee has, as member of the company, to act in the company’s interest” [Stage 3A]).

Since any inference can be correct or incorrect, there has to be a criterion for the validity of abduction. Generally speaking, the abduced concept or theory has to be able to accommodate the (problematic) facts. Thus, explanatory theories have to provide a plausible explanation. An explanation can be true or false – this has to be established by way of deduction and induction, – but abduction as such merely has to determine whether a given theory solves the explanatory problem at least in principle. Similarly, a suitable moral principle must fit the moral problem at hand and allow us to decide which course of action is morally right and which is morally wrong. Again, whether we should ultimately accept the moral outcome of the application of our principle is a different question to be treated by the other inferences.

Deduction is the process that produces the outcome of the application of a moral principle to a situation. Consider the example of the shop assistant who has to decide whether or not to inform a customer about a slight defect of a certain good (this is the moral problem). They consider the ‘golden rule’ (by way of abduction), and now they work out what the principle requires them to do in this situation. The golden rule requires them to consider what they would want, if they were in the customer’s shoes, as an additional premise. From this rule and the situational and additional premises the resulting course of action can then be deduced straight away.

However, we are not forced to accept this outcome. Logical truths are not factual truths, and deductive consequences of moral principles merely tell us what we *would* have to do if we accepted the principle. After all, we first have to know these deductive consequences before we can establish whether they are practically appropriate. This is where *induction* comes in assist to decide whether one should do practically what has been derived theoretically. There may always be side effects or specific risks that may prevent the individual from following the deduced course of action. For instance, the shop assistant may realise that while the ‘golden rule’ is generally applicable, it is insensitive to the different roles of customer and salesperson.

Induction leads back to the problematic facts, because it determines – based on past experience or newly gathered experience e.g. from experiments – whether to accept or reject the theoretical approach for the problematic situation at hand. However, the inductive result is not restricted to this one situation only, but rather applies to all relevantly similar situations, past, present, or future. In this way, existing moral orientations may either be reinforced (if the commonly activated principle is also accepted in the present situation) or may be changed as a result of newly encountered conflicts or negative aspects.

Based on the types of situations differentiated and classified in this paper, we can assume that the more experienced we are and the more expertise we have acquired in those situations, the more naturally we will abduce to situation-specific moral principles (if we undergo explicit reasoning at all, especially within in routinized action-schemes). What is more, our situational selectivity is, on the inferential account, neither hardwired nor based on rigid categorisation or segmentation, but is always controlled, reinforced or weakened by inductive evaluation, which secures flexibility and adaptivity in the sense of controlling and developing our situational differentiations: in the way we perceive situations, in the principles we deem appropriate, and in the personal responsibilities to which we feel committed (as individuals or as members of an organisation). This has also been revealed in a study on students of management science (Minnameier and Schmidt 2013).

To sum up, abduction, deduction, and induction, cover the whole process of moral reasoning and allow us to integrate the processes of activating moral principles, of determining what action would follow from a certain principle, and the evaluation of this action in terms of a responsibility judgement. This yields a broader and more comprehensive notion of moral judgement. In this respect, the three inferences are not only meant to explain how moral-cognitive development proceeds, but also how stages are activated and used in actual moral practice and how moral judgement can be attuned to situational affordances and constraints.

3.3.3 The Moral Self and Moral Functioning

As already explained, scholars from the field of business ethics have proposed a model of interaction of individual factors and situational factors. Whereas the situational factors and how they influence moral judgement have been sufficiently treated in the previous sections, the role of individual factors still has to be discussed. What are these individual factors? Of course, the ability of moral judgement is a key element in this respect. Church et al. (2005) even take it as the only truly important aspect. On top of it, however, Treviño includes ego strength, field dependence, and locus of control (1986, 602), and in later publications also moral awareness, moral disengagement and other cognitive biases (Treviño et al. 2006). Such biases currently receive much attention (see, e.g., Ariely 2012; Bazerman and Tenrunsel 2011)

From a theoretical point of view it is still an open question, how all these factors hang together conceptually and in relation to the above-mentioned models of moral

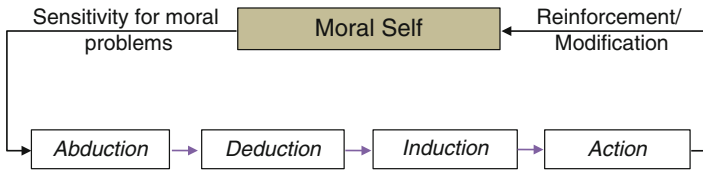

Fig. 3.4 The moral self and moral functioning

functioning. They are often discussed in connection with the so-called ‘moral self’ (see Bandura 1999; Blasi 1995, 2004; Shao et al. 2008). With respect to the inferential analysis described in the previous section, however, it becomes obvious that, at least to some extent, these moral biases refer to processes of moral reasoning, i.e. to ways of taking moral decisions and justifying one’s decisions and actions.

Originally, the moral self was associated primarily with judgements of responsibility (and moral motivation), and a lack of responsibility or moral motivation was explained in terms of a weak or insufficiently developed moral self. Meanwhile, the concept of the moral self has been extended and includes moral identity, moral responsibility, and a tendency to strive for self-consistence (see Shao et al. 2008, 514, who summarise Augusto Blasi’s contributions to the theory of the moral self and distinguish three different “components”). Without being able to explicate this in detail in the present context, it seems that Blasi’s “moral identity” is associated with Rest et al.’s (1999) first component (‘moral sensitivity’) and “strife for self-consistency” with the fourth (‘moral character’). If and insofar as this is true, one may be tempted to suspect even a fourth component of the moral self in the sense of *the degree to which one wants to be just and know what is right*. And this component could be associated with ‘moral judgement’ in the narrow sense. In other words, the moral self, which is meant to explain specific aspects of moral functioning, boils down to a reiteration of those very aspects (the four components).

However, the moral self is said to be of a ubiquitous relevance to almost all aspects of moral functioning (see Blasi 1995; Frimer and Walker 2008). Now, instead of assuming four separate “components” of the moral self, these “components” might just as well be conceived of as mere aspects of one integrated moral self, i.e. how the (single) moral self affects the different processes of moral functioning, especially the abductive, deductive, and inductive processes of moral reasoning (as illustrated in Fig. 3.4). This view leads us to an understanding in which the moral self might be constituted of underlying personality traits that are operative within and across the processes of moral functioning.

The question of how to conceptualise the moral self, especially at the intersection of moral cognition and other aspects of moral functioning, has been considered as a still open, yet most important one (see e.g. Hardy and Carlo 2005; Frimer and Walker 2008). The above account at least provides a possible and plausible solution.

Let us now consider, in the context of the four phases according to Kohlberg and Candee (1984, 71), how the moral self might influence the four processes of moral functioning ('interpretation and selection of principles', 'decision making', 'follow-through (moral judgment)', 'follow-through (nonmoral skills)'), especially how it interacts with situation-specific inferential moral reasoning.

1. "Interpretation and selection of principles": First, the individual must become aware of a moral problem in the ordinary flow of events. If moral centrality (see e.g. Blasi 1995, 2004; Frimer and Walker 2009; Frimer et al. 2011) is high, it is assumed that individuals have a greater propensity to attend to moral aspects. If they identify a moral situation and attend to it, however, the cognitive process of abduction starts, in which one first gathers the relevant situational features and comes to a preliminary solution in the form a principle that might fit.
2. "Decision making": Deduction in the context of moral reasoning yields a course of action as the necessary consequence of applying a principle to situational premises. This is a process that might be labelled "cold cognition". However, it is heated up by the previous motivation to reason about the situation. And when it comes to moral values that are central and constitute the moral self, these values may also include the principle itself, so that its activation based on the situation may be emotionally propped up by its very meaning for the self.
3. "Follow-through (moral judgment)": Above, I have stressed the cognitive aspect of this part of moral judgement and identified it with inductive reasoning in the Peircean sense. In this process one judges the acceptability for the self (or another agent) to act in a particular way. In determining this one not only has to consider objective side conditions and outcomes, but also the characteristics of the agent him- or herself. If helping others is a central motive and a feature of the self, it will be right for such persons to help even at significant personal costs.
4. "Follow-through (nonmoral skills)": A strong moral self will increase the individual's compliance with his or her moral decisions, because the remorse or bad conscience must be all the greater.

A strong moral self in this sense should make people attend more than others to moral aspects in their daily practice, it could make them reflect moral problems further (i.e. at higher stages) than others, feel responsible to a greater extent than others and stick more to their principles rather than betraying them.

In summary, these qualities are considered to be positive. However, in the business context one might suspect that a weaker moral self might be better for business. In a way this may even be true. Nonetheless, as will be argued in the following concluding section, higher moral stages and a strong moral self may also be relevant in business practice in all occupational contexts, and therefore situational sensitivity and adaptivity might be the real thing to go for in vocational education and training in order to bring about appropriate professional attitudes and actions.

3.4 Implications for Professional Practice and Vocational Education and Training

Professionals of all kinds may be confronted with a wide range of moral problems that they have to handle. To judge those situations properly, they need to be able to distinguish different types of situations and tune their actions accordingly, rather than acting from an abstract god-like perspective, from which situational constraints might be irrelevant (especially consequences for the self). However, this judgement is not enough. They have to at least consider two further aspects.

The first is that they do not act as individuals like they do in their private lives, but as representatives of a company or organisation. And as such, their responsibility goes beyond mere loyalty toward the company. In fact, companies – like other organisations – are integral parts of our overall societal organisation. In particular, a market economy is built on the principle of competition. In this competitive framework businesses are not only meant to adapt to people's needs and satisfy those needs, but also to do this efficiently in order to save resources and direct them where they are needed most (see e.g. Hayek 1976; Vanberg 2001). This is the main and the moral function of competitive markets. In this view, cost-saving controllers and top-selling merchants are, at least in principle, not just acting in their own or their company's interest, but also fulfil an important socio-economic function. Every worker, every employee, every manager and every entrepreneur has to be aware of this role within the society at large that he or she plays when acting on behalf of a company or organisation (see also Clark and Lee 2011).

However, companies or the responsible managers may also engage in dysfunctional activities such as evading taxes, ignoring safety regulations or duping their customers. Responsible professionals, therefore, do not simply have to fulfil their superiors' demands and boost profits, but they also have to live up to the standards of their professions (irrespective of their particular job in their particular company). Moral hazards, which derive from information asymmetries, have been discussed above. They exist especially where professionals have expert knowledge and where their clients have to rely on their expertise, and this is not restricted to what we call 'professions' in the narrow sense (including engineers, architects, medical and judicial professions, and possibly teachers and trainers), but to everybody who works for somebody else either by producing something or by giving counsel. Consider e.g. the work of craftsmen or of financial advisers. Advantageous and dishonest behaviour produces mistrust, and if this happens at a sufficiently large scale, it constitutes a problem not only for individual companies or self-employed persons (whose reputation is spoiled), but also for the professions at large and as such.

As a consequence, professionals have to adopt professional moral standards, yet be able to analyse and distinguish situations and develop differentiated action strategies. On the one hand, they have to staunchly adhere to their professional standards, especially because there will always be loopholes that they should not use. In particular they should refrain from misusing their informational superiority for illicit purposes. Furthermore, economists know the principles of incomplete contracts,

i.e. that there will always be ways to cheat on one's counterpart, if one likes to do so. Apart from the fact that one's partners might 'strike back' in some way, basic trust and trustworthiness are needed in the sense that everybody plays by the rules (be they explicit or tacit).

An additional aspect of professional ethics relates to behavioural standards in day to day business. Professionals have to remain friendly and considerate even when their counterparts are not. And, conversely, they have to stick to their ordinary rules and practices, even when they deal with friends or relatives as clients. In this sense, they have to be "situation-insensitive" in their attitudes and homogeneous in their actions.

In sum, all professionals, i.e. even those in lower ranking occupations, have to adopt fairly high moral stages to be competent and reliable agents in all relevant situations. Note that what has just been called "playing by the rules" refers to Stages 3B and 3C in terms of the neo-Kohlbergian taxonomy mentioned above, and would also have to be classified at least as "Stage 3" in Kohlberg's terms. Yet at the same time, professionals have to be sensitive to constraints, especially their counterparts play different moral games at lower moral stages (i.e. when they change the rules of the game). If one is exploited or underpaid by one's principal, one is certainly justified seek one's benefit if it is not possible just to leave the firm and work somewhere else. If competitors successfully and to a large extent manage to circumvent regulations, a company cannot keep on as if nothing were happening, because this leaves the unethical companies with a cost benefit and would ultimately lead to the survival of the black sheep and the extinction of the white ones, which is clearly dysfunctional and unacceptable. Therefore, professionals not only have to play by the (agreed or common) rules, but also know and adapt to the rules of the games actually played.

As far as loopholes, illegal practices or external effects are present, professionals and companies, as agents in a market economy, have some kind of split responsibility. On the one hand, they have to take situational circumstances seriously in the way just explained. However, they also have an ethical role to play as members of organisations that have specific functions in society. Adapting to situational constraints is one thing, working towards changing inappropriate incentive structures and dysfunctionalities is another (Beck 2008; Beck et al. 1999, 2002; Minnameier 2004b, 2008, 2011). In other words: While one has to play by the rules of all kinds of games actually played in order to survive in competitive markets, one can – and possibly should – engage in the improvement and transformation of those rules. This applies especially to powerful multinational companies, because they sometimes have even more regulatory power than governments (Homann 2002), but also to professions with high and specialised expertise, because they know better than others, what moral problems, perils, and pitfalls we have to deal with in the relevant contexts.

All in all it is of vital importance for professionals to realise that they actually act in different roles, even if we only focus their role as professionals (!), and in multitude of systematically different situations. However, one major difficulty, and therefore also one major task, with respect to situational adaptation is to distinguish between appropriate situational adjustment on the one hand, and moral biases (as described by Bazerman and Tenbrunsel 2011) on the other hand.

Chapter 4

Professional Work and Knowledge

Lina Markauskaite and Peter Goodyear

Abstract This chapter provides an overview of some influential perspectives on the relationships between professional work and professional knowledge. We build upon a number of recent developments in theories of knowledge, skill, expertise, capability and action to help reframe understandings of professional knowledge as culturally and socially situated and materially grounded. We draw on ideas from cognitive ecology and developmental psychology to argue that effective professional action often depends upon tools and resources that come to hand in the workplace – it is the accomplishment of an “extended mind”. We also use recent research on the active nature of perception to argue that professional expertise is often highly dependent on “conceptual perception” and “sensory intelligence”. We suggest that employers and providers of professional education, and quite possibly students themselves, expect too much from the kinds of knowledge that can most readily be acquired in formal education settings: explicit, conceptual and principles-based knowledge. When employers comment negatively on the sharp contrast between the practical capabilities of new graduates and the capabilities of their more experienced workers, part of what they are noticing is – we argue – emergent from, and constitutively entangled with, the workplace setting. A richer understanding of how effective and innovative professional practitioners do what they do is needed, to make progress in the design and evaluation of professional education programs.

Keywords Professional knowledge and knowing • Professional work • Professional education • Professional vision • Epistemic fluency • Extended mind • Perception-action • Grounded cognition • Epistemic environments

4.1 Introduction

4.1.1 *Aims of the Chapter: Harmonising Multiple Views on Professional Knowledge to Illuminate Persistent Problems in Professional Education*

This chapter provides an overview of a number of influential perspectives on the relationships between professional work and professional knowledge. Its ideas are relevant to researchers specialising in this field and also to people with a serious stake in the organisation of professional education, including employers and those in higher education who provide programs preparing students to work in the professions.

We provide a brief review of some perspectives on professional knowledge that have become quite established in the last 40 years or so. However, our main contribution is to use a number of recent developments in theories of knowledge, skill, expertise, capability and action to help reframe understandings of professional knowledge as culturally and socially situated and materially grounded. We draw on ideas from cognitive ecology and developmental psychology to argue that effective professional action often depends upon tools and resources that come to hand in the workplace – it is the accomplishment of an “extended mind”. We also use recent research on the active nature of perception to argue that professional expertise is often highly dependent on “conceptual perception” and “sensory intelligence”. We are coming to the view that employers and providers of professional education, and quite possibly students themselves, expect too much, and too many different things, from the kinds of knowledge that can most readily be acquired in formal education settings: the kinds of explicit, conceptual and principles-based knowledge that can be shared in lectures and through textbooks. When employers comment negatively on the sharp contrast between the practical capabilities of new graduates and the capabilities of their more experienced workers, *part* of what they are noticing is (we argue) emergent from, and constitutively entangled with, the workplace setting. Further, no one will dispute the fact that it takes some time to *learn* local working practices, even for an experienced professional who has moved into a new organisation. But our sense is that much of what enables fluent professional practice *in situ* has been hazy, if not invisible, and underestimated. The chapter aims to redress the balance, and thereby raises some questions about what could be a more reasonable set of expectations from initial professional education programs, about transitions to work (and between workplaces), and about what all parties – universities, accrediting bodies and employing organisations – need to contribute to a more effective regime of professional preparation. It does this by highlighting one kind of knowledge that we see as particularly useful for making transitions – knowledge for creating epistemic environments to support one’s learning and cognition.

4.1.2 *Structure of the Chapter*

The rest of this chapter falls into eight sections. We start with a brief review of the central place given to specialist knowledge in accounts of professional work. Then we introduce some basic conceptual building blocks and key terminology that prove necessary for an understanding of the main arguments that are developed in the rest of the chapter. We make some distinctions, and draw some relations, between public, organisational and personal knowledge; learning to understand and learning to do; knowledge as a possession and knowing in action.

In the next section of the chapter we introduce the core idea of *epistemic fluency in professional practice* (Markauskaite and Goodyear [forthcoming](#)). We do this by describing four *epistemic projects* – a term that we use to capture what we hope will be recognisable genres of working with knowledge in professional activity. We sketch each of these epistemic projects in turn, making links to some of the key writings on professional knowledge as we do so. The next two sections of the chapter introduce a fifth epistemic project and revisit some of the earlier ideas about the nature of knowledge, bringing in some recent research on embodiment and grounded cognition. This part of the chapter introduces some contemporary ideas about the interdependence of knowledge, perception and action, sketching aspects of professional work and knowledge in a way that captures professional action as the accomplishment of an extended mind. The chapter concludes with a summary of some implications for the organisation of professional education.

4.2 Professional Work and Workplaces

It is not easy to pin down the meanings of the terms ‘profession’, ‘professional’ and ‘professional knowledge’. The core term – profession – has denoted different occupations at different times and in different places. Its interpretation is strongly coloured by its association with medicine and law – fields often seen, in the literature and in higher education, as the archetypal professions (Glazer 1974). In recent years, in Western countries, other occupations/fields have been added to the list: engineer, architect, scientist, for example. Others have pushed to join the club. Some have succeeded. Some have been consoled with titles like ‘para-profession’ or ‘minor profession’. Moreover, the very idea of profession has to be seen as both historically and spatially located. If one traces the history of occupational fields in China, India or other non-Western countries, different ideas about professions and professional hierarchy emerge.

In twentieth century western sociological accounts of the professions, definitions tended to focus on two aspects of this area of work: knowledge, and the relationship between the professional and the client. For example, Carr-Saunders and Wilson (1933) speak of “prolonged and specialised intellectual training which

allows a particular service to be rendered” (p. 478). Talcott Parson’s classic analysis defines professional work as entailing provision of a service, based upon a body of expert, scientific knowledge (e.g. Parsons 1968). While the nature of the relationship between professional and client may have changed substantially, the insistence on *expertise* as a distinguishing mark of the professional has not (Jensen et al. 2012).

Professional knowledge, more narrowly defined, has long been used to locate professions in a hierarchy.

One of the major differences between the major and minor professions is that practitioners of the minor professions do not possess knowledge at the same level of technical complexity and of the same importance to an individual’s life as that possessed by the classic major professions (Glazer 1974, p. 348).

we find that the knowledge and skills requisite for an occupation is the best single predictor of the prestige assigned to it. Value to society ... has no predictive value of prestige over and above the other dimensions considered (Adler and Kraus 1985, p. 36).

Early forms of professional work (e.g. in medicine or law) normally involved provision of a service by an individual rather than an organisation, though some professionals came together in arrangements which allowed some sharing of costs and resources. These days, services are more commonly offered through organisations than by independent professionals. While specialist knowledge continues to be seen as crucial to the provision of professional services, one can argue that the forms of knowledge and ways of knowing now needed by professionals have become more complex, diffuse and specialised. For good or ill, a doctor working in today’s public health service needs a broader range of knowledge (e.g. how to get things done, how to utilise the expertise of others, how to make a career in the health system) than was the case with independent practitioners in the nineteenth century.

Just as the tendency for professional work to be enacted in more complex organisational contexts has required the acquisition of knowledge specific to the employing organisation, so changes in the material setting of professional work have extended the range of knowledge required. (Professional work has, therefore, to be understood as both socially/organisationally situated and physically/materially situated.) The material changes in professional work are both vivid and subtle. For example, many professionals now have a much richer array of technologies to use in the workplace. But in some aspects of their work, communications technologies redistribute labour, moving parts of the job (or of the “workflow” or value chain) to distant sites.

Professions share some characteristics, but there are important differences between them. Also, the range of activities *within* any one person’s professional practice can be very varied – with concomitant variations in the relations between what they are doing (moment-by-moment) and what they know. It is important to bring this variability to mind, when thinking of the nature of professional work and knowledge, lest an undifferentiated conception, or a too dominant image, oversimplify both the work and its relationship to what is known.

4.3 What Is Knowledge?

It is impossible to classify ideas about professional knowledge in a simple, uniform way. The fundamental message that comes from research on professional knowledge is quite consistent. Professional workers, especially experts, draw on a *variety* of knowledge types and they learn this knowledge and draw upon it in their professional practice in a *variety* of ways (Argyris 1993; Bereiter 2002; Collins and Evans 2007; Collins 2010; Davenport 2005; Eraut 1985, 1994, 2010; Ericsson 2009; Farrell 2006; Harper 1987; Hoffmann and Roth 2005; Schön 1983). Moreover, while there is some agreement in the literature about some aspects of professional knowledge – including a reasonable consensus on the importance of specialist, personal, applicable knowledge – there are some deep differences about what knowledge is, and about how it connects to perception and action.

4.3.1 Knowledge, Broadly Understood

We use the term “knowledge” in the broadest sense, to include justified propositions, hunches, beliefs and other constructs of human thought; tacit as well as explicit; conceptual and procedural; abstract and concrete; personal and public (Hoy and Murphy 2001; Murphy and Mason 2006; Southerland et al. 2001; Bereiter 2002). Human thought is composed of different kinds of epistemic entities, such as knowledge, beliefs, values and moral judgements. These epistemic entities have different features, come together in different relationships, and have different kinds of implications in discussions of what is true and how things might be known. For example, “knowledge” often refers to factual, externally verified and logically organised ideas; whereas “belief” usually refers to propositions and ideas that individuals feel to be true irrespective of external validation or justification (Hoy and Murphy 2001). However, as Southerland et al. state:

Distinctions between knowledge and belief, complex and confusing at the theoretical level, seem to become hopelessly blurred at the empirical level (Southerland et al. 2001, p. 348).

Towards the end of the chapter, we revisit some of the fundamental ideas about knowledge, action and perception, with the aim of sharpening their application to understanding the area of professional expertise and professional education.

4.4 Public, Personal and Organisational Knowledge

In this next section, we distinguish between public knowledge and personal knowledge and then introduce the idea of organisational knowledge as a kind of knowledge that emerges at the intersection between, and as an entanglement of, the public and the personal. All three – and their interactions – are required in a comprehensive picture of the relations between professional work and knowledge.

4.4.1 *Public Knowledge*

Public knowledge is knowledge that is made available by culture – what Bereiter (2002) calls “knowledge outside the mind” (p. 56). It includes both codified and non-codified knowledge.

Codified public knowledge includes all the knowledge that is represented in some *inscribed form*; thus, it can be shared and used beyond the immediate communities, sites and people who produced it. For Eraut (2010, p. 38) codified public knowledge is most typically made available through books and journals, particularly those involving a review process which bestows the status of “acceptance” – allowing it to be incorporated into a profession’s knowledge base. Codified public knowledge also includes other kinds of knowledge embedded in material inscriptions that are available to members of a professional community, including formal educational resources, qualification standards, professional databases and informal resource collections. Broadly, this knowledge has the qualities of what Bereiter calls “conceptual artefacts” (2002, p. 64).

Non-codified public knowledge includes knowledge that is *embedded* in cultural practices rather than inscribed in some tangible form. Professionals learn such knowledge through participation in working practices. Some non-codified public knowledge is embedded in the discourses and other practices of professional communities. Some of it is situated and emerges from engagement in local activities – involving relationships among the people, tools, artefacts, historical and cultural material and the social and physical environment in which practice takes place. In both cases, this knowledge is not available (in its original non-codified, non-inscribed form) beyond those communities and practices and so it can only be acquired through direct personal engagement and socialisation.

4.4.2 *Personal Knowledge*

Personal knowledge or “knowledgeability” (Bereiter 2002, p. 193) can be defined as what an individual knows and is able to accomplish. It refers to personal attributes, capacities and other qualities, and, as Eraut suggests, it can be described as “the individual-centered counterpart to cultural knowledge” (Eraut 2010, p. 37). In specific professional contexts, it can be described more narrowly – “what individual persons bring to the situation that enables them to think, interact and perform” (Eraut 2010, p. 37); or what Yinger and Hendricks-Lee, drawing on Harper (1987), call “working knowledge”: the kind of knowledge that is “particularly useful to get things accomplished in practical situations” (Yinger and Hendricks-Lee 1993, p. 100). Other terms have been used for similar kinds of knowledge and knowing, such as “knowing in action” (Schön 1983), “actionable knowledge” (Argyris 1993), “action-oriented understanding”, “personal practical knowledge” (Clandinin 1985) and “*metis*” (Baumard 1999).

Personal knowledge involves different kinds of mental constructs. For example, some such knowledge may be concrete – facts, stories, or episodic experiences; other knowledge is abstract – involving concepts, schemata, procedures and principles.

Some of this knowledge may be *explicit* – available to consciousness – and some is *tacit* or *implicit*. (One may be able to do something, without knowing that one has, or being able to say how.) Explicit and tacit could be seen as individual (embodied and embrained) counterparts of codified and non-codified knowledge: the former is available to consciousness, reflection or discourse; the latter is enacted in doing. When it comes to professional knowledgeability, tacit knowledge often attracts most attention as something essential, but hard to teach and learn.

4.4.3 Organisational Knowledge

There are some other kinds of knowledge that occupy a large space between public and private knowledge: such as community knowledge, organisational knowledge and group knowledge. Given this chapter's concern with professional work and the fact that much professional activity occurs within organisational settings, we refer to this category of knowledge as "organisational knowledge." Organisational knowledge can be seen as an assemblage of personal knowledge and a subset of cultural knowledge that is made available to everyone within an organisation or group. It will normally include both tacit and explicit elements. It may take the form of shared symbolic artefacts, such as rules, codes, organisational routines and codified propositions embedded in organisational artefacts. As Argyris and Schön put it:

When organizations are large and complex, their members cannot rely entirely on face-to-face contact to help them compare and adjust their private images of organizational theory-in-use. Even in face-to-face contact, private images of the organization often diverge. Individuals need external references to guide their private adjustments. Such reference functions are fulfilled by organizational maps, memories, and programs... Artefacts such as these describe existing patterns of activity and serve as guides to future action (Argyris and Schön 1996, p. 16).

In short, organisational knowledge can be seen as an internal property of an organisation. Organisational knowledge is not the mere aggregation of the knowledge of the individuals who work for the organisation. Tsoukas and Vladimirov (2001) note,

organizational knowledge is the set of *collective* understandings embedded in a firm, which enable it to put its resources to particular uses (Tsoukas and Vladimirov 2001, p. 981, emphasis added).

However, Tsoukas and Vladimirov (2001) also observe that the open-endedness of the world "gives knowledge its not-as-yet-formed character" (p. 989). They argue that it is individuals who put organisational knowledge into action and there is always an improvisational element in how individuals make sense of organisational propositions and how they enact this organisational knowledge in specific contexts and situations (see also Cook and Brown 1999; Orlikowski 2002, 2007; Weick 1995, 2001; Weick et al. 2005).

From this point of view, organisational knowledge can be seen as involving the collective capability of members to make sense of situations and carry out their work. Thus, use of organisational knowledge *depends on* individual understandings, but it cannot be seen as a static property of one individual's mind (or of an aggregate of minds). Rather, in its totality, it is a dynamic property of individuals and groups that emerges in performance, across contexts and situations over time.

4.5 Knowledge and Professional Action: Foundational Ideas

Discussions about professional learning are sometimes bedevilled by a set of apparently simple tensions between “theory” and “practice”, “academia” and the “workplace”, “knowing that” and “knowing how”, “knowledge” and “knowing”, “tacit” and “explicit”, “stability” and “flexibility”, “routine” and “change”. In this section we attempt to pin down some key ideas about knowledge that are needed to understand its relationships with professional action. We cover (a) doing and understanding; (b) knowledge and knowing (c) commonalities and differences in professional ways of knowing.

4.5.1 *Learning to Do and Learning to Understand*

If successful task performance were impossible without correct understanding, human culture could not have gotten started. ...In fact, all the technologies that brought the human race out of subsistence – metal working, leather preparation, the manufacture of cloth and glass, navigation, waterwheels and windmills, sailing boats, bread baking, brick making – had to be invented and developed in the absence of deep understanding, because such understanding has only become available since the scientific revolution, three centuries or so ago (Ohlsson 1995, p. 49).

Ohlsson (1995) provides a useful set of distinctions and relations between practical knowledge and declarative knowledge. *Practical knowledge* is the knowledge needed for accomplishing something in an efficient way. Such knowledge includes sensorimotor skills (e.g. driving a car) and cognitive skills (e.g. calculating, playing chess). The main outcome of mastering such knowledge is *competence* and, as Ohlsson argues, acquiring competence starts from general methods (e.g. analogical reasoning) and becomes an increasingly specific and automatic (“proceduralised”) skill. Such “know how” is generally acquired through mimesis (imitation) and by extensive practice. The medium for it is action.

In contrast, *declarative knowledge* includes concrete facts and higher order abstract knowledge of concepts, ideas, theories, schemas, principles and propositions. Ohlsson argues that learning “higher-order” knowledge proceeds in the opposite direction from that taken in the development of practical knowledge. It starts from knowledge which is taken for granted and increasingly becomes more

conscious, explicit, elaborate and abstract. The main outcome of mastering such knowledge is *understanding* or “knowing that”. Such knowledge is acquired mainly through reflection, and the medium for it is discourse. As Ohlsson notes, one can act successfully without understanding what one is doing, and understanding does not guarantee successful action.

4.5.2 *Knowledge and Knowing*

Ohlsson’s (1995) distinction between competence and understanding is relatively clear cut. However, once one looks at action and understanding in professional work in organisational settings, the relationships become more complex.

Cook and Brown (1999) make a useful distinction between the “epistemology of possession” and “epistemology of practice.” Knowledge is sometimes treated as something people or organisations *possess*. While such knowledge is important, it does not account for what one *can do*. For example, when a mechanic fixes a car, her knowledge involves not only what she possesses and applies, but also what she is doing. Cook and Brown extend the view of *knowledge as possessed* with the view of *knowing as a part of action*.

understanding of the epistemological dimension of individual and group action requires us to speak about both knowledge *used in* action and knowing as *part of* action (Cook and Brown 1999, p. 53, original emphasis).

The former focuses on *knowledge* employed in understanding and action; the latter focuses on *ways of knowing* employed for understanding in action. Cook and Brown point out that tacit and explicit, individual and collective types of knowledge are not mutually substitutable and neither do they sit in a hierarchical relationship: rather each of them makes a distinct contribution to knowing in action. Further, actionable professional knowledge involves what is already known, but it is also involves practice, and some epistemic work is inevitably done in action and by action. That is, knowledgeable action demands fusions between understanding and doing, and knowledge as possessed and knowing in practice.

4.5.3 *Generic Thinking Skill and Professional Episteme*

Do professions differ in what they know, or also in their ways of knowing and thinking? Classic studies of professional expertise have tended to the latter view. The military, science, law, medicine, design and other professions have been described as involving distinct forms of thinking and reasoning with distinct “shapes” to their professional knowledge (Ericsson et al. 2006; Holyoak and Morrison 2005). Other, more “mundane” or “minor” professions, are now also described as having special ways of working with knowledge: “thinking like a teacher” or “thinking like an

accountant” for example (Sternberg and Horvath 1999). However, if we look closely at the literature that tries to describe those distinct forms, we notice more similarities than differences. Consider law and medicine. Studies of legal reasoning focus on two main methods: deductive or rule-based reasoning and analogical or case-based reasoning (Ellsworth 2005). Research on medical diagnosis distinguishes between forward (data-driven) and backward (hypothesis-driven) reasoning strategies. However, it also commonly makes a distinction between two ways of thinking that have similar forms in legal reasoning: causal-analytical reasoning, which employs basic medical (or legal) knowledge and rule-based logic, and exemplar-based reasoning, which draws on the recognition of similarities between new and previously-encountered cases (Norman et al. 2006; Patel et al. 2005).

Cognitive strategies do not seem to be unique to specific professions, rather, distinctions arise in the ways of thinking, sensing and doing that emerge from the assemblages of cognitive strategies, declarative knowledge, tools, aims and contexts in which professional actions and knowing takes place – that is “professional epistemes”. (A range of synonyms is used for this idea: “constitutive entanglements” (Orlikowski 2007), “knowledge assemblages” (Turnbull 2000), “meshes” (Ingold 2011)).

Ellsworth (2005) provides a nice illustration of the sources of this complexity by comparing legal decision-making with that of scientists:

Science demands no final decision; it is an ongoing process. If the evidence is murky, scientists can wait, can reserve judgement until they can conduct further research. And they can figure out what further research needs to be done to answer the question, and do it. Judges can neither reserve judgement nor go beyond the data presented in court, however ambiguous those data might be. They cannot carry out further research, nor wait until others have done so; they must decide. And the judge’s decision, whether the evidence is conclusive or completely inadequate, has the same precedential force. It is final. The scientist’s conclusions are never final, always tentative. The judge must also decide for the one side or the other; the scientist’s decision that the true lies somewhere between the extreme points is typically not available to the judge (Ellsworth 2005, p. 696).

So as Ellsworth points out, the process and form of legal and scientific reasoning are not so different – the two professions share many analytic strategies. Nevertheless, “the context, the raw materials to which the processes are applied, and the nature of the rules” are very distinct to each profession (p. 686).

4.6 Epistemic Fluency and Professional Knowledge: Tracing Four Epistemic Projects

Our research on the kinds of assessment tasks that students are given in the course of preparation for their professions reveals four distinguishable kinds of task, each of which can be traced back to an underlying “epistemic project” (Markauskaite and Goodyear [forthcoming](#)).

Drawing on Pickering (1995) and Mulcahy (2011) we contrast two views of professional learning: the *representational* and the *performative*. Each of these

involves distinct kinds of “epistemic tricks” that students need to master. We call them “self-representation” and “self-performance”. The former links the *doing* implied in professional action and skill with *knowing* (or indeed professional identity/being *as knowing*). The latter links *doing* with *being* (or indeed professional knowing *as being*). We also suggest that students find themselves challenged to go beyond the individual, beyond self-representation and self-performance in the here and now. They are challenged to engage in professional tasks on the boundaries of their professions. One set of boundaries is *temporal* – extending doing and knowing from the past and present into the future. The other set of boundaries is territorial or *spatial* – extending doing and being from “assembling the professional self” (Mulcahy 2011) to crafting new professional assemblages and dwelling in inter-professional, trans-epistemic spaces. We argue that professional learning for such a dynamic professional world involves mastering the fusion of all four epistemic tricks – self-representation and self-performance within and across the spatial, temporal and material boundaries of one’s profession. We call the resulting capacity “epistemic fluency” (Morrison and Collins 1996; Goodyear and Ellis 2007; Goodyear and Zenios 2007; Goodyear and Markauskaite 2009).

This section provides a brief summary of the four main epistemic projects. Each is presented in terms of the development of ideas, rather than as a static position. After the fourth description, we introduce a relatively novel, fifth, more grounded, notion of professional knowledge.

4.6.1 The Reflective-Rational Project: From Rational Knowledge to Reflective Practice to Rational Reflection

In real-world practice, problems do not present themselves to practitioners as givens. They must be constructed from the materials of problematic situations that are puzzling, troubling, and uncertain. In order to convert a problematic situation to a problem, a practitioner must do a certain kind of work. He must make sense of an uncertain situation that initially makes no sense (Schön 2002, p. 47).

This epistemic project becomes familiar when traced back to the intersection of two lines of thinking about (i) the connections between theory and practice and (ii) reflection (Schön 1983; Eraut 1994). Schön (1983) critiqued the dominant positivist idea of an epistemic canon of professional knowledge and made a distinction between technical rationality and reflective thinking (reflection in action and reflection on action). From the technical rationality perspective, practical knowledge is a form of applied science. Thus professionals should learn an extensive, coherent network of codified declarative knowledge, provided to them by basic science, and a number of general problem-solving heuristics. Then they

should develop the skills of applying these principles in rigorous, proceduralised ways to the problems they encounter. Schön opposed this view, pointing to uncertainty, uniqueness, value conflicts and other epistemic complexities encountered in professional practice. He argued that practical knowledge involves a capacity to *frame* encountered situations as problems. The epistemology of practice involves doing and thinking “on one’s feet”. Relevance, not just rigour, should be the basis for professional knowledge.

Schön was primarily interested in designers’ work and “designerly” ways of knowing-in-action that could be seen as “thin” and “slow” on the physical plane of action, but “thick” on the epistemic plane of mental work. Such thinking and action are not characteristic features of all professions. Eraut (1994) and some others (e.g. Usher et al. 1997) have wondered whether and how reflection in action may happen in other areas of professional practice, arguing that Schön essentially overlooks some psychological realities of reflective thinking, and worrying especially about the possibilities of reflection in action when time is critical. Eraut (1994) noted that many practical decisions have to be made in a short time and the scope for reflective thought is extremely limited in such situations. In these conditions, as Eraut argued,

reflection is best seen as a metacognitive process in which the practitioner is alerted to a problem, rapidly reads the situation, decides what to do and proceeds in a state of continuing alertness (Eraut 1994, p. 145).

Schön also argued that professionals reflect not only “in action”, but also “on action”, suggesting that there is another layer of professional knowledge and knowing, such as general principles, which is different from the knowledge involved in the rapid decisions of concrete problem-solving and which requires a different kind of reflection. In both cases, Schön opposed the notion of “the systematic knowledge base of a profession” – specialised, firmly bounded, scientific and standardised (Schön 2002, p. 41).

Eraut (1994) also questions Schön’s assertions about the limited use of propositional knowledge in practical situations.

the use of such theoretical knowledge may not always be in the application mode stressed by the technical rationality model, but in the interpretative mode where it is more difficult to detect. Moreover, just because busy professionals do not use a particular idea, does not imply that they should not: that remains to be argued (Eraut 1994, pp. 103–104).

Eraut (1994) also insists that there is no clear cut distinction between theory and practice. He agrees that the knowledge and knowing that underpin professional action should be of central importance in professional learning. He also agrees that the use of theoretical (propositional) knowledge in practical decisions requires considerable time and significant intellectual effort. In contrast, he argues that propositional knowledge must undergo significant transformation before it enters practice. Thus, the process of interpreting and personalising theoretical propositions needs considerable support in professional education.

4.6.2 *The Reflective-Embodied Project: From Knowing to Being*

...we do not primarily access things conceptually or intellectually, but, instead, through being constantly immersed in activities, projects and practices with things and others. We organise entities and creatures within these projects: breed livestock and prepare food for our families, for example. We also alter or construct things, such as fell trees and build houses, or re-orient streams and rivers. To be this way requires that we are open to the possibilities of things – the qualities of timber or fresh produce, for example, and what those qualities enable. Things, in turn, need to be receptive to our manipulations (Dall’Alba and Barnacle 2007, p. 681).

A more radical turn, not only away from technical rationality, but also away from the “intellect” (cognitive capacities) as a *basis* for professional action can be observed in other recent writing on the topic. The turn is towards the ontological project of “being” (Barnett 2004; Dall’Alba 2009; Dall’Alba and Barnacle 2007) and “becoming” (Scanlon 2011).

These writings have different roots, ranging broadly from Heidegger’s existentialist ideas about “receptive spontaneity,” (e.g. Dall’Alba 2009) to accounts that are more grounded in the physical world, in socio-materialist practices of “assembling the professional self” (Mulcahy 2011). This move is based on the assumption that the knowledge and skills needed for future workplaces cannot be known in detail or with any great certainty. Thus, attention to “knowing the world” and the skills for doing so provides an unproductive focus for educating future professionals in higher education. Rather, “being-in-the-world,” pulling disparate elements of practice together into one “assemblage of self”, provides a more defensible centre for professional education.

Dall’Alba and Barnacle (2007) question whether there is a universal form of knowledge, disconnected from experience. They argue that: (a) the current emphasis on knowledge and skills in higher education, decontextualised from the practices to which they relate, is flawed; (b) there is no one absolute universal knowledge, rather there are knowledges that are situated, localised, and “socially constructed in relation to specific knowledge interests” (Dall’Alba and Barnacle 2007, p. 680). This view challenges the primary focus of higher education on intellect, knowledge and transfer, and suggests an alternative account of knowing that dislocates mind and reason from a privileged, detached, position:

Where a conventional account of knowing has treated it as restricted to an ideal realm of thoughts, ideas and concepts, we want to situate knowing within the materiality, and spatial and temporal specificity, of being-in-the-world. In other words, knowing is not reducible to thought or the discursive. Instead, knowing is always situated within a personal, social, historical and cultural setting, and thus transforms from the merely intellectual to something inhabited and enacted: a way of thinking, making and acting. Indeed, a way of being (Dall’Alba and Barnacle 2007, p. 682).

This line of thinking holds that professional education has become too concerned with epistemology, at the expense of ontology (understood as a concern

for the nature of being and of existence). Dall’Alba and Barnacle’s “ontological turn” is not so much from epistemology to ontology, but to more ontological forms of knowing:

from epistemology in itself to epistemology in the service of ontology... In other words, learning is not confined to the heads of individuals, but involves *integrating ways of knowing, acting and being* within a broad range of practices (Dall’Alba and Barnacle 2007, p. 683, emphasis added).

Others have extended this ontological twist to speak of lifelong learning; from “being” to “becoming” (e.g. Scanlon 2011).

It is important to note that this view of knowledge does not deny, in any strong sense, the existence of a professional knowledge base, skills and competences.

Aspiring professionals need to develop necessary knowledge, routines and procedures for entering into appropriate care relations with those whom they provide a service; ontology and epistemology are both implicated. For example, accountants need to develop knowledge and skills in accounting in order to provide ethical accounting services that respect the needs of their clients (Dall’Alba 2009, p. 141).

What is more at stake is the question of *what else* is needed to provide a sufficient basis for acting effectively as a professional practitioner.

The main pedagogical suggestion that underpins this onto-epistemic project is that curriculum should be organised around core practices, meaning-making, reflexivity and identity: “Allowing students to encounter and reflexively dwell in this dynamism and complexity” (Dall’Alba and Barnacle 2007, p. 688). There are several variants on this line of thinking about professional knowledge. Nevertheless, the core pedagogical proposition is underpinned by a shared leitmotif of action or of performance: getting, body, mind and hands (and heart) to act together in a coherent dynamic ensemble with the environment and the ongoing action of others.

4.6.3 The Relational Project: From Individualistic to Relational Expertise

All learning involves boundaries. Whether we speak of learning as the change from novice to expert in a particular domain or as the development from legitimate peripheral participation to being a full member of a particular community (Lave and Wenger 1991), the boundary of the domain or community is constitutive of what counts as expertise or as central participation. When we consider learning in terms of identity development, a key question is the distinction between what is part of me versus what is not (yet) part of me (Akkerman and Bakker 2011, p. 132).

The discontinuities and tensions discussed in relation to the first two accounts (above), have emerged *within* the epistemological boundaries of professional domains. Whether these consist of socio-cultural discontinuities between university and workplace settings, or between different kinds of knowledge that constitute the internal workings and knowledge base of the profession, or between theory

and practice, knowing, doing and being – these boundaries are *within the epistemic space of the profession*, thus internal to a broader notion of becoming an expert practitioner within one’s professional domain. Crossing these “internal boundaries” – between school and work, learning and doing, etc. – have dominated the literature on professional learning in higher and vocational education for decades (Billett 2010; Eraut 1994; Sternberg and Horvath 1999; Tuomi-Grohn and Engeström 2003).

However, as Akkerman and Bakker (2011) note,

various types of professional work ... are heterogeneous in that they involve multiple actors representing different professional cultures... Hence, working and learning are not only about becoming an expert in a particular bounded domain but also about *crossing boundaries* (Akkerman and Bakker 2011, p. 143; emphasis added).

The expanding scale of such boundary work has been demonstrated in numerous studies of inter-disciplinary, inter-professional, lay-professional and other kinds of joint work (e.g. Derry et al. 2005; Engeström 2008; Hutchins 1995; Star and Griesemer 1989). In some domains, such as architecture, design, media, healthcare, social work and other public services, this kind of boundary expertise is not restricted to a specific group of people (such as sales people or customer care staff), but is a core part of professional competence. New accounts of professional expertise that deal with this capacity to work on epistemic boundaries have been emerging in variety of professional and scientific domains (e.g. Collins and Evans 2007; Edwards 2010). Thus, the notion of professional learning has to be expanded to include the capacities needed to work on the epistemic boundaries of professional expertise.

Edwards (2010) has offered the idea of “relational agency” or “relational expertise” and defined it as,

an additional form of expertise which makes it possible to work with others to expand understandings of the work problem as an object of joint activity, and the ability to attune one’s responses to the enhanced interpretations of those being made by other professionals (Edwards 2010, p. 13).

She explains that this kind of expertise primarily arises from two dynamically interrelated sources: (a) recognising other professionals as resources – what is salient for them and what they bring when they interpret the joint object of activity; and (b) aligning one’s own responses and actions to the emergent interpretations and actions of others. Edwards argues that relational expertise involves a purposeful inter-professional activity as well as “weaving” clients’ private knowledge into professional decisions (2010, p. 15). While such decision-making does not necessarily involve established procedures or pre-existing ideas, it can be learnt. Edwards is, nevertheless, convinced that core professional expertise is essential and warns against “the dilution of personal specialist expertise” (Edwards 2010, p. 15).

Learning to work across the (spatial/territorial) boundaries of one’s home profession has a temporal complement – learning to push at the frontiers of knowledge and extend them, through innovations in practice. We now turn to this fourth area.

4.6.4 *The Knowledge Building Project: From Practice as Knowledge Transfer to Knowing as Epistemic Practice*

new knowledge is created also by professionals in practice, though this is often of a different kind from that created by researchers. Moreover, in some professions nearly all new practice is both invented and developed in the field, with the role of academics being confined to that of dissemination, evaluation and post-hoc construction of theoretical rationales. In others, knowledge is developed by practitioners ‘solving’ individual cases and problems, contributing to their personal store of experience and possibly that of their colleagues but not being codified, published or widely disseminated (Eraut 1985, p. 129).

It is now widely acknowledged that a range of professional innovations and organisational knowledge emerge from professional practices and problem-focussed design activity rather than developmental work driven by basic research. Knowledge creation, innovation and transformation capacities have been seen as important qualities of successful practitioners and organisations (Argyris and Schön 1996; Engeström 2008; Nonaka 2004).

Some professions, such as architecture, engineering or computer programming, claim that such knowledge-building work is a part of everyday practice (Ewenstein and Whyte 2009). Other professions try to create similar practical knowledge, by trying to render current practices into codified forms that have the status of “knowledge” (Falconer and Littlejohn 2009; Goodyear and Steeples 1998; Szymanski and Whalen 2011). The nature and form of knowledge that emerges from practice-based innovation is different from the normative accounts of scientific knowledge; and the process through which such practical knowledge is created is distinct from the orderly systematic knowledge creation processes that underpin normative models of inquiry for producing scientific theories.

It is often assumed that practical innovation and knowledge-creation largely rest either on chance or on substantial amounts of experience. The ability to help transform an organisation’s ways of working therefore depends on skills which are hard to acquire and knowledge that cannot be expected of a new recruit to the profession. Nonaka and Takeuchi (1995) and Nonaka and Toyama (2007) suggest that innovation depends on the conversion of knowledge from tacit to explicit. Such knowledge gets created through continuous social interaction, and is articulated, codified and made available for use in other settings.

Bereiter, Argyris, Schön, Engeström and others suggest that knowledge creation might be a more mundane activity, not very different in kind from individual, group and organisational learning (Argyris and Schön 1996; Bereiter 2002; Engeström and Sannino 2012; Miettinen and Virkkunen 2005). On this view, knowledge creation can guide learning and be learnt (e.g. Bereiter 2002; Paavola et al. 2004).

While the theoretical starting points for these various authors differ significantly (see e.g. Engeström and Sannino 2010), they nevertheless share a common position with respect to the idea that knowledge is not only the property of an individual mind, but is also embedded in mediating or conceptual artefacts (such as plans, theories, ideas and models).

Learning could be understood as a collaborative effort directed toward developing some mediated artefacts, broadly defined as including knowledge, ideas, practices, and material and conceptual artefacts. The interaction among different forms of knowledge or between knowledge and other activities is emphasised as a requirement for this kind of innovativeness in learning and knowledge creation (Paavola et al. 2004, pp. 569–570).

Some kinds of knowledge-building products have a “tool like” character. They are not only a solution to a specific problem, and not only a product of knowledge use. They both use knowledge and extend it. Such tools might be created for a person’s own future use; they might also be shared, tweaked and integrated into new assemblages, reused and improved. A classic example of this kind of professional knowledge and knowing can be seen in software engineering, particularly in open source communities, where people build on each other’s program code (Nerland and Jensen 2010). It is also observable in less mundane cases, where professionals come together to solve distinct shared problems encountered in their work to create new procedures, standards or other elements of infrastructure that make shared work possible (Engeström 2008; Miettinen and Virkkunen 2005; Virkkunen and Ristimäki 2012; Star and Griesemer 1989; Star 1989).

We now turn to outline a fifth perspective – one which we have not so far seen documented in the main body of literature on professional learning, though it has some roots in anthropological research into the nature of skill, perception and practice.

4.7 From Rational Thought and Embodied Material Skill to Grounded Professional Knowledge

In a recent paper, Jean Lave (2012) draws on Tim Ingold’s (2000) distinction between “*technology, language and intelligence*” and “*craftsmanship, song and imagination*.” Lave is talking about practice in general, but we think the distinction can be particularly powerful in thinking about the nature of professional expertise, as a counterweight to the mainstreams of cognitive science research on expert knowledge.

neo-Darwinian biology, cognitive science and psycholinguistics have conspired to produce an extremely powerful approach to understanding the relations, in human evolution, between technology, language and intelligence. ... Suppose, to pursue my alternative claim, that we set ourselves the task of examining the relation, in human evolution, not between technology, language and intelligence, but between craftsmanship, song and imagination. The resulting account, I suspect, would be very different (Ingold 2000, pp. 406–407).

Ingold’s writings on craftsmanship are strong on the notion of embodied skill, vividly tracing the perception-action loops that enable the skilled person to work with subtle variations in materials and adjust to subtle changes in the world, more generally. Many of Ingold’s examples come from his anthropological research and describe what might seem esoteric skills traditional within remote communities.

But he also speaks of craftsmanship in ways that illuminate discursive work in professional settings. For example,

We ‘feel’ each other’s presence in verbal discourse as the craftsman feels, with his tools, the material on which he works; and as with the craftsman’s handling of tools, so is our handling of words sensitive to the nuances of our relationships with the felt environment (Ingold 2000, p. 411).

Of the four accounts of professional knowledge and knowing sketched above, two emphasise “thinking” or “reasoning” like a lawyer (doctor, engineer, etc.) (views 1 and 4) and two emphasise “acting like” a lawyer (doctor, engineer, etc.) (views 2 and 3). In short, the literature tends to the view that expertise is either strongly associated with thinking, reasoning and the mind or deeply embedded in skills, dispositions and the material context. It is as if there is a Cartesian divide between knowledge and skill, mind and context. Then again, there is a contrast between views which privilege rational thought and fine-tuned, embrained skills (on the one hand) and views which imply that social and material context and practices matter more than minds and brains (on the other hand).

In contrast, we want to take seriously the mind and practice, and also the body (in which the brain and mind are embodied) and contexts (in which practices are embedded). Mind, body, perception, action and matter all matter. From this perspective, knowledge and knowing involve fine-tuned coordination: “thinking like”, “acting like”, “seeing like” and “touching like” a professional.

Though Goodwin’s (1994) writing focuses on professional discourse, his notion of “professional vision” can help us advance a more general argument.

Discursive practices are used by members of a profession to shape events in the domains subject to their professional scrutiny. The shaping process creates the objects of knowledge that become the insignia of a profession’s craft: the theories, artifacts, and *bodies of expertise* that distinguish it from other professions. Analysis of the methods used by members of a community to build and contest the events that structure their lifeworld contributes to the development of a practice-based theory of *knowledge and action* (Goodwin 1994, p. 606, our emphasis).

Goodwin focuses on three distinctive professional practices:

(1) *coding*, which transforms phenomena observed in a specific setting into the objects of knowledge that animate the discourse of a profession; (2) *highlighting*, which makes specific phenomena in a complex perceptual field salient by marking them in some fashion; and (3) producing and articulating material representation. By applying such practices to phenomena in the domain of scrutiny, participants build and contest *professional vision*, which consists of socially organized ways of seeing and understanding events that are answerable to the distinctive interests of a particular social group (Goodwin 1994, p. 606, original emphasis).

Goodwin offers a clear statement that human knowing and action are not limited to language, but are “constructed by assembling diverse materials” including language, prosody, visible embodied displays, tools, and material environments. In short, the focus of expert knowing shifts from cognitive operations – what is in ones’ mind – to fluent use of semiotic and material tools, body and environment (Goodwin 2013).

For example, Hindmarsh and Pilnick (2007) have studied the skilful interweaving of professional action among anaesthesia teams during operations. Their descriptions capture our point about professional knowing as entailing the coordination of seeing, feeling and action.

The tight coordination of action among the anaesthetic team of anaesthetist and ODA [operating department assistant] rests on an intimate understanding of the possible trajectories of delicate shifts in bodily conduct by both anaesthetist and ODA – treated as indicating the need for assistance and the availability of help. Moreover, the resources for the two colleagues to assist are not simply verbal, or even a combination of the verbal and the visual, but rather bring together verbal, visual and tactile resources. The import of tactile knowing in the production, and moreover the interactional organization, of work practice is often overlooked and yet this fragment highlights the critical resource that touch, in the form of finger pressure on a colleague's hand, provides for the anaesthetist in organizing and coordinating the conduct of her colleague (Hindmarsh and Pilnick 2007, p. 1408).

This knowing is not to be mistaken for a shapeless, moment-to-moment improvisation by the anaesthesia team. Rather, it is an intelligent fine-tuned coordination of manual and perceptual skills with deep understanding of what is happening now and what comes next.

Knowing the scene rests on understanding the character and sequence of action in the anaesthetic room and recognizing a 'trajectory of action' that he can contribute to. ... In addition, as he does not explicitly request the instrument, the anaesthetist can be seen to expect or rely on the ODA knowing what comes next and that he will pass the instrument at just the appropriate moment. However, the timing of the instrument being passed is not all that is relevant here. Indeed the way in which the ODA presents and positions the different instruments to the anaesthetist displays understanding of the other's prospective embodied conduct as well; that is to say, through the manner of the passing of the instrument the ODA displays a sensitivity to what it takes to use a laryngoscope and later to insert a tracheal tube (Hindmarsh and Pilnick 2007, p. 1404).

This richer, more extensive view of knowledge and knowing (as revealed in perception and action) is nicely captured by both Ingold (2011) and Del Mar (2010).

it is in the very 'tuning' of movement in response to the ever changing conditions of an unfolding task that the skill of any bodily technique ultimately resides (Ingold 2011, p. 46).

Each of our senses – and also the numerous different complexes of them (e.g., hearing-touch) – are skills that can be (perhaps infinitely) improved. Each does already, and can ever more (if it is trained), contribute to our understanding; indeed, understanding consists, *at least to a large extent, in the intelligence of the senses* (Del Mar 2010, p. 1, our emphasis).

Thinking about pedagogical implications of this fifth view, Del Mar (2010, 2011) provides the best example we know of an interpretation of professional education (in the law) that reflects Ingold's "craftsmanship, song and imagination".

students must be given the opportunity to experience the making of such judgements, i.e., of having such experiences as 'Ah, I see that', or 'Ah, I see that as.' They also need to come to understand the dynamics of legal knowledge, i.e., that the rules themselves do not delimit or determine anything. What is vital is the activity of seeing, and thus also respecting the potentiality of any rule or any image. It is not students that are 'stupid' if they cannot make the judgement that we want them to make: it is we, the teachers, who are failing to provide them with the right conditions for making judgements for themselves (Del Mar 2010, p. 15).

We return to some practical implications for professional education shortly. Just before doing so, we need to make one final pass over the question we asked at the beginning: what is knowledge?

4.8 What Is Knowledge, Revisited: Dynamic Knowledge, Grounded Concepts and Embodied Epistemic Environments

Much of the intellectual space mapped by people who study professional knowledge involves theoretical accounts in which the mind has a non-trivial role. Accounts of what the mind is, how it contributes to intelligent performance, how it learns and can be taught, and how it becomes capable of innovation are therefore very salient. Various conceptualisations of professional knowledge have aimed to propose how professionals *think in action* and *in context*, but not all of them – indeed rather few – have provided explicit accounts of how actually the *mind works, changes and relates* to skill, movement, and social and material context. Some scholars write about expertise from a strong psychological perspective can be accused of adopting rather rationalist views of mind (Chi et al. 1988; Clark 2008; Ohlsson 2011). As a rule they draw a clear division between “higher order” conscious thought (cognition, metacognition) involving abstract, systematically organised knowledge constructs (concepts, theories, schemas, etc.), and “lower order” cognitive operations (senses, perception, actions, emotions, etc.) which provide an interface with the external world. On this view, the “higher order” capabilities do the real intellectual work, the rest are mere inputs for rational expert thinking.

Some scholars who have tried to give a more central role to environment, and the human senses, in professional work have turned away from mentalist models of cognition, but in so doing have also turned away from serious consideration of a psychological basis for human knowing in general. As a rule, they have dismissed the central role of concepts, theories and other systematically organised knowledge constructs as a basis for expertise, but have said relatively little about what kinds of alternative mental elements and processes may underpin experts’ thinking and performance.

In our view, it is time to find a rapprochement – one that gives due weight to mind and context and which acknowledges the dynamic nature of human intellect and its dependence on grounding in experiences and environments (Barsalou et al. 2007; Barsalou 2008; Hutchins 2010; Smith 2005; Smith and Sheya 2010; Smith and Thelen 2003). In the space remaining, we can only offer a sketch of three core facets of this perspective: (a) how knowledge emerges; (b) the nature of conceptual knowledge; (c) how the environment supports knowing. The interested reader will find a more extensive treatment in Markauskaite and Goodyear (forthcoming).

4.8.1 How Knowledge Emerges: Intelligent Action as Coordinated Cognition and Non-cognition

Traditional modal theories of cognition commonly focus on stability and rational logical behaviour, but intelligent professional action requires not a stable repetition of behaviour, but coherence and flexibility in responding to a changing world. Smith (2005) notes that a traditional way to explain stability in behaviour across situations or over the time was to look for stability in the mind and especially for one central unit that could coordinate all actions. Typical resources for such stability are things like “concepts” and other relatively firm mental representations – theories, mental models, beliefs, frameworks, etc. – that guide behaviour, but exist independently of perception and action. In contrast, Smith argues that much of the apparent stability in human behaviour emerges from the variability and coupling of individual elements distributed across the mind, the body and the world. Smith illustrates this with an example of a cat’s locomotion:

cats walk backward, forward, on grass, on hills, on rubble. They side step objects; they walk when one limb is in a cast. The alternating limb pattern is apparent in all these cases but the variability to make this same pattern is remarkable (Smith 2005, p. 280).

An apparently stable pattern of alternating limbs when the animal moves through terrain cannot be explained by the existence of a stable central “pattern generator” that is capable of producing similar, alternating movements of four limbs. Variability in the movements is essential and extraordinary – as each move requires very different muscle firing to keep the general pattern of limb alternation stable when the cat moves across real terrains.

Smith claims that such apparently stable behaviour can best be understood as a dynamic system – there is no one central control mechanism that has a causal priority (be it a stable concept, theory or plan). An apparently coherent pattern emerges from the interaction and self-organisation of many elements of the system – from the coordinated relationships among diverse components distributed across mind, body and world.

The intelligence that makes alternating leg movements is not strictly in the brain, not in the body, nor the world but in interaction of a particularly structured body in a particularly structured world (Smith 2005, p. 286).

Empirical research is providing more evidence to support this view, demonstrating that creativity, anticipation and intuition are not just a result of independent processes created by a mind; they emerge from the interactions among many other basic systems in the brain, such as perception, goal management, action, motivation, emotions, and learning (Barsalou 1999).

Humans probably learn important things more often through social interaction than they do from isolated individual interactions with inanimate stimuli. Furthermore, these socially acquired skills are intrinsic to coordinated activity in division-of-labour settings, and also in competitive activity in conflict situations (Barsalou et al. 2007, p. 82).

This view shifts the focus of what is central in knowledgeable performance from stable constructs that can (ostensibly) control knowledgeable actions (stable concepts, theories, mental models, etc.) to rich relationships and interactions between elements of a system that spans mind, body and world.

4.8.2 Grounded Concepts: Situated Knowing and Non-situated Knowledge

What then is the role of concepts, theories and other similar well organised knowledge constructs that have commonly played a role in defining professional knowledge bases and in organising programs of professional education? A grounded cognition view suggests that mental representations (i.e., conceptual knowledge) do have a central role in human cognition (Barsalou 1999, 2009). However, this conceptual system is *unlikely* to be composed of abstract self-contained elements operating in a closed system independently from the external world and experiences. Cognition is embedded in actions and the physical world and this world is the main source of resources from which humans construct and organise their conceptual systems. Along these lines, Barsalou (2009) proposes an alternative view of the human conceptual system and argues that human conceptual knowledge is inherently situated and grounded in experiences. He shows how human conceptual knowledge remains tightly linked with background situations, experiences and actions.

viewing a picture of a manipulable object (e.g., HAMMER) for a few seconds and naming it does not simply activate visual and linguistic areas, it also activates the grasping circuit in the brain, indicating that the brain is preparing for situated action with the object (Barsalou 2009, p. 250, in which he draws on Chao and Martin 2000).

According to this view, conceptual categories are stored with at least four types of situated information: (a) selected properties of the conceptual category relevant to the situation; (b) information about the background settings; (c) possible actions that could be taken; (d) perceptions of internal states that one might have experienced during previous encounters with the conceptual phenomena, such as affects, motivations, cognitive states and operations. Such a conceptual system is not abstract and detached from the situated experiences, rather it is grounded in perception and “constructs situated conceptualizations dynamically, tailoring them to the current needs of situated action” (Barsalou 2009, p. 251). These “conceptual packages” prepare humans for situated action and guide goal-directed activity. Multiple modalities of the phenomena experienced in the world via vision, touch, smell, audition, emotion, etc. are an integral part of knowledge representations and processes through which knowing becomes possible. Such conceptual understanding is not organised around abstract categories, but around the interface between perception and action – understanding the concept is “being there conceptually”.

4.8.3 *How Environments Support Knowing: Embodied Epistemic Environments and Professional Knowledge Work*

This grounded view of conceptual knowledge gives us an insight into why professionals find it so hard to bridge between the conceptual knowledge learnt in university settings and the practical problems encountered in workplaces. It is unlikely that gaps between “knowledge to understand” and “knowledge to do” create these difficulties. Rather, disconnections between the contexts and situations in which the “theoretical concepts” are learnt and the “practical concepts” are encountered cause the “conceptual divisions”. Students do not “see” learnt concepts as professionals do, because educators and employers rarely succeed in creating conditions that allow students to ground concepts in situations that fuse theoretical and practical professional experiences.

What kind of environments may be productive for learning grounded conceptual knowledge and taking knowledgeable action informed by theoretical understanding? Clark (2011) and many others (e.g. see Hutchins 1995, 2010; Nersessian 2012) point to the mutual role of environment, language and embodied interaction, not only for situating, but also *for enhancing* intelligent mind-body-world connections.

the linguistic tools enable us to deliberately and systematically sculpt and modify our own processes of selective attention” (Clark 2011, p. 48); “the intelligent use of space and the intelligent use of language form a mutually reinforcing pair, pursuing a common cognitive agenda (Clark 2011, p. 65).

The environments of human thinking are not “natural” environments. They are artificial through and through. Humans create their cognitive powers by creating the environments in which they exercise those powers (Hutchins 1995, p. 169).

Ingold (2000) prompts us to make one further step beyond the initial contact between “learning to understand” and “learning to do,” and look into how this relationship may evolve with practice:

The novice becomes skilled not through the acquisition of rules and representations, but at the point where he or she is able to dispense with them. They are like the map of an unfamiliar territory, which can be discarded once you have learned to attend to the features of the landscape, and can place yourself in relation to them. The map can be a help in beginning to know the country, but the aim is to learn the country not the map (Ingold 2000, p. 415).

However, if we step beyond the territory of *established* professional practices into the territories that are occupied by pioneering “knowledge workers” then we have quite a different learning challenge. The features of the landscape should be discovered, and the map should be created, simultaneously. Andy Clark’s (2011) reminder about the central role of language (and symbolic artefacts) in experts’ simultaneous self-engineering of the mind and environment gives us an opportunity to make this further move in the argument:

Coming to grips with our own special cognitive nature demands that we take seriously the material reality of language: its existence as an additional, actively created, and effortfully maintained structure in our internal and external environment. From sounds in the air to inscriptions on the printed page, the material structures of language both reflect, and then systematically transform, our thinking and reasoning about the world. ... Linguistic forms and structures are first encountered as simply objects (additional structure) in our world. But they then form a potent overlay that effectively, and iteratively, reconfigures the space for biological reason and self-control. The cumulative complexity here is genuinely quite staggering. We do not just self-engineer better worlds to think in. We self-engineer ourselves to think and perform better in the worlds we find ourselves in. We self-engineer worlds in which to build better worlds to think in. We build better tools to think with and to use these very tools to discover still better tools to think with. We tune the way we use these tools by building educational practices to train ourselves to use our best cognitive tools better (Clark 2011, p. 59).

This richly recursive conception of “self-engineering” provides both resources and challenges for those involved in rethinking professional education.

4.9 Concluding Comments: Some Practical Implications

As we said at the start of the chapter, preparation for the professions is bedevilled by confusions about the nature of capability in the workplace, and about how an appropriate blend of academic and workplace experiences can be crafted so as to overcome some of the problems recognised by employers, academic teachers and students alike. Employers typically push for longer periods of practical experience (though not at their own expense). Academic teachers want to make sure that students are trained for the uncertainties of future practice, arguing that workplace readiness is not enough. Students juggle what seem to them to be conflicting priorities – emanating from a clash of cultures between academia and the workplace. A deeper analysis of the capacities that distinguish effective, innovative professional workers from novices or the hidebound can provide *part* of the solution. We end by mentioning a few implications of the analysis provided above.

One of the key implications of the grounded account of knowledge and knowing is that perception and action are inseparable from, and equally important as, processes in the mind. So professional education cannot be solely concerned with processes in the mind nor solely with actions in the world. It must embrace the coordination of what the mind does with perception and action. If we believe in the usefulness of propositional knowledge in knowledgeable action then the educational challenge becomes how to link the “grammar” that underpins these theoretical constructs with the multi-modal experiential constructs on which human cognition naturally operates. In short, the focus of attention has to shift from knowledge (concepts, theories) and skill (perception, action) to the constructs, processes and environments for *coordinating* mind-body-world experiences – constructs for knowing, for conceptually perceiving, for intelligently sensing.

If we take multiple modalities seriously, then there is no sense in trying to decide which of the five accounts is right, or best. All are needed for a comprehensive

account of professional knowledge. If one takes a grounded view, and the notion that much conceptual knowledge is organised around the interface between body-world, perception-action, and coordination, then it is extraordinary that neither higher education nor employers do much to enable the learning of *actionable (conceptual)* knowledge, i.e., making concepts grounded; “*educating*” “*conceptual perception*” in action, in the material environment, in the cultural environment, etc. Constructing productive learning-epistemic environments is key. And – if we are serious about seeing professionals as innovating knowledge workers – developing graduates’ capacities to construct congenial environments for their own epistemic work is also vitally important.

Chapter 5

Conceptions of Professional Competence

Martin Mulder

Abstract Professional and practice-based learning is a process which manifests itself in many different forms. It differs by personal characteristics of the learners, levels of their professions, fields of practice, intentionality of their learning, and formalisation of the learning activities. Notions of competence have entered this diverse practice in many ways. The question is whether conceptions of professional competence have helped the practice of professional and practice-based learning. In this chapter it is argued that this is indeed the case. Although various attempts to implement competence-based professional learning programmes were heavily criticized, later developments in competence theory and research gave new insights which emphasized the integrative meaning of competence within professional practice. It helped in mapping professional fields from a domain-specific as well as a generic behavioural perspective. This chapter goes into the roots of the competence movement, and evaluates the contributions of these to the field of professional and practice-based learning. This is further illustrated with examples of different professions in which competence models have been and still are an effective means to map requirements for professional practice and to guide the evaluation and development of professional and practice-based learning programmes. What worked and did not work is then explained by distinguishing three approaches of conceptualizing competence which have been used in different contexts, and which have wide implications for professional and practice-based learning. The chapter concludes with the claim that current competence conceptions help mapping, focusing and assessing professional and practice-based learning.

5.1 Introduction

The concept of competence is probably as old as humankind. Homo sapiens have always been desiring to master skills and to find ways to solve practical, professional and scientific challenges. Certain individuals always received the prerogative to perform certain activities which had a highly symbolic meaning. The attribution of authority was originally strongly related to tradition but that gradually moved to cognition and ability. In the current meritocratic society, people are generally allocated to jobs based on educational achievement and their profile of capabilities and other personal characteristics. The drive of individuals to learn to perform in certain fields of activities, however, never changed, and is to a large extent based on eagerness to master certain skills, become independent and get recognition. This is very well visible in babies and toddlers when they want to turn in their cradle, crawl on the floor and walk in the room, stimulated by their parents who are cheering when the first steps are taken. Young children constantly move around until they are able to do what they desperately want at the end of the day: to gain independence; or: to become competent. For gaining an independent position in society nowadays, individuals need to pass through formal education trajectories and complete examinations. The higher the education levels students achieve, the higher their chances of getting a good position at the labour market and an appointment in a better-paid and stable job. Independence, however, is a relative notion. In society, people are interdependent by definition, but individual ego development is necessary for getting a personal identity in the first place and a professional identity later in life, for which recognition is needed, by getting an appropriate education qualification, and subsequently by being appointed in a job, being promoted, rewarded, and having a career perspective. Development opportunities are often the top priority of graduates from higher education and considered to be a major labour condition. Because of the massification of education, it has become an industry. And because of its limited innovation capacity, it somehow alienated from society. Getting a diploma became a goal in itself, many educational institutions were not well-aligned to societal demands anymore, and became pedagogical islands. Sometimes, this process is called the ‘diploma disease’. Yet, it can also be named the ‘competence crisis’,

as the big issue was whether graduates who were qualified really were able to perform according to standards in the profession and expectations in the working situation. Having a college degree was no guarantee for being able to perform well on the job or in society.

The disconnection between education and the labour market was the main cause of the competence movement (Grant et al. 1979). Therefore, professional associations began to articulate performance requirements and develop competence profiles with which candidates had to comply to enter the profession. Educational institutes reworked their curricula to adjust them to what was expressed as being important by professional associations and industry organisations. However, as the concept of intelligence, the concept of competence was multi-dimensional, and various conceptions of professional competence emerged. Sometimes, the concept was praised and, at other times, it was cursed because of the differences between its intrinsic meaning, quality promises and disappointing application and results (Mulder 2011). Nevertheless, at present, the concept of competence is institutionalized, for instance in the European Qualification Framework, and, thereby, in national qualification frameworks of EU member states, where competence is seen as the ability to apply knowledge and skills at a certain level of independency and autonomy (Mulder 2012). It is also used in education or training profiles for certain professional groups such as medical specialists, and in the design of educational programs, especially in vocational education and training. Although these applications are quite straightforward, different theoretical insights have developed, which contradict one another on several dimensions. Certain authors stress the importance of the integral nature of the concept of competence, while others separate knowledge, skills and attitudes. Another major issue is the distinction between competence-oriented and competence-based education which has major implications for the extent that principles of competence development are implemented in education programs.

In this chapter, the concept of competence is placed in the context of professional and practice-based learning. This learning is a process which manifests itself in many different forms. It differs by personal characteristics of the learners, levels of their professions, fields of practice, intentionality of their learning, and formalisation of the learning activities. Notions of competence have entered this diverse practice in many ways. The main question in this chapter is whether conceptions of professional competence have helped the practice of professional and practice-based learning. In this chapter it is argued that this is indeed the case. Although various attempts to implement competence-based professional learning programmes were heavily criticized (Mulder et al. 2007b; Weigel et al. 2007), later developments in competence theory and research gave new insights (Biemans et al. 2004) which emphasized the integral meaning of competence (Wesselink 2010) within professional practice. It helped in mapping professional fields from a domain-specific as well as a generic behavioural perspective. This chapter goes into the roots of the competence movement, and evaluates the contributions of these to the field of professional and practice-based learning. Examples of competence models will be given; these models have been and still are an effective means to map requirements for professional practice and to guide the evaluation and development of professional

and practice-based learning programmes. What worked and did not work is then explained by distinguishing three approaches of conceptualizing competence which have been used in different contexts, and which have wide implications for professional and practice-based learning.

To link the concept of competence to professional and practice-based learning, the chapter commences with a review of the historical roots of the concept of professional competence, which are related to competence *motivation*, human *intelligence*, professional *performance* and professional *education*. This description will show that the concept of competence was used in the context of learning and performance from the outset, and that competence and professional and practice-based learning are intrinsically related to one another. The next section, on competence and professions, will make that even clearer. Various professional fields are selected, in which competence profiles have helped to improve professional and practice-based learning in terms of learner assessment, selection, education, training and development. The fields which are selected are *management*, *human resource development*, *medicine*, and *purchasing*. This selection is not meant as being complete but serves as an example of ways in which the competence movement has entered professions and professional development. This section is concluded with a description of an attempt to capture all competence in one behavioural competency framework, which can be used for implementing processes for professional and practice-based learning and self-reflection and development.

The link between competence and professional practice however differs by the way in which competence is defined. Three broad approaches of competence and professional development are distinguished here: (1) Competence and behaviouristic functionalism, which stresses the importance to specifically determine the discrepancies between actual and desired competence, leading to training of sometimes miniscule skills; an important pitfall of this approach is fragmentizing learning; (2) Competence as integrated occupationalism, which is visible in the present qualification frameworks and competence-based education approaches in which it is stressed that knowledge, skills and attitudes should be integrated in the curriculum, teaching, learning and testing; (3) Competence as situated professionalism, which indicates that competence only gets meaning in a certain context; an important pitfall here is holism, when details of competence are covered under generic expressions of abilities of people, which may be sufficient in personal development processes, but not for professional certification purposes (Mulder 2011). Although these three different approaches have distinct implications for professional and practice-based learning, we contend that in all three there are strengths and weaknesses, and that they can be combined in practice. The optimum mix depends on the purpose and the specific context of the professional learning, which can vary from learning to change winter tyres to leading an open heart surgery team. Related to the latter, there is another fundamental difference in the relationship between competence and professional practice which has important implications for professional and practice-based learning, which is the difference between generic competence and task-oriented competence. An example of the first is the communication capability of a medical expert, whereas an example of the second would be the

ability to make the right diagnosis given a series of certain medical examinations. Again, we contend that both are important in professional practice and for professional and practice-based learning.

The chapter concludes with the claim that current competence conceptions help mapping, focusing and assessing professional and practice-based learning. But first we go into the meaning of the concept of competence.

5.2 What Is Professional Competence?

Professionals are competent when they act responsibly and effectively according to given standards of performance. They are held to possess sufficient competence. Professional competence is seen as the generic, integrated and internalized capability to deliver sustainable effective (worthy) performance (including problem solving, realizing innovation, and creating transformation) in a certain professional domain, job, role, organisational context, and task situation.

Competence consists of various competencies. A competency is a part of generic competence; it is a coherent cluster of knowledge, skills and attitudes which can be utilized in real performance contexts. For instance, in a crime scene investigation a forensic expert needs to produce a DNA profile of a piece of evidence. This requires knowledge (e.g. disciplinary knowledge), skills (e.g. working with artefacts) and attitudes (e.g. accuracy, coping with pressure, integrity). Together these constitute professional competence. To take another example, traders at a flower auction require knowledge (about the products, quality indicators, market developments, prices), skills (e.g. multi-tasking, processing information, instant decision making), and attitudes (stress-tolerance, feeling for sales). These are elements of professional competence as well.

What has not yet been discussed often is the twofold meaning of competence in terms of capabilities and rights. These two are different, yet go together. Competence as capabilities is the field professionals feel comfortable with. Because of their education and experience in practice they have gained a certain level of competence, which goes together with a feeling of confidence, self-efficacy and professional identity. But educational institutions have declared graduates to be competent by approving their completions. The diploma is the formal piece of evidence of the competence level of the graduate, which is nowadays more transparent because of the education levels specified in the European Qualification Framework and printed on diplomas or in diploma supplements. Professional associations also declare individuals as competent when they comply with certain standards. Educational institutes and professional associations have the right to do so if they are acknowledged by the relevant institutions. We can also say that educational institutions have the competence to take decisions regarding the licensure of candidates who complete educational programs. Other institutions may have other rights, such as law courts and European institutions. Examples of institutional competencies of law courts were already described in the dissertations of Viruly (1890) and Roes (1885) at the

University of Leiden in the Netherlands. (Both dissertations counted 31 and 41 pages respectively). Individuals who have received a professional licence of an educational institute or a professional association, or the state, also have certain rights to act (e.g. as teacher), perform interventions (e.g. as medical expert), and take decisions (as lawyer). Citizens also have their rights (e.g. to vote, to raise children, to move in freedom), but if there are grounded reasons to do so, the legal system can also deny these rights by declaring people incompetent.

The meaning of competence discussed above is mainly related to professional competence, as used in key competencies, competence domains, competence clusters, enabling competencies, and competency dimensions or competency components. However, there is also a branch of literature in which organizational competence is being discussed. The most prominent source of this is probably the work of Prahalad and Hamel (1990) on the core competence of organisations. Core competencies are capabilities of organisations in which they excel, with which they earn most of their profits, and which cannot easily be copied by competitors. This is an interesting line of research, and at organisational level core competencies should be included in the corporate strategy, which should be aligned with corporate human resources management strategy, which in turn should be related to the corporate competence development strategy.

The relationship between competence and professional performance is complicated. There are multiple connections between the two at various levels of aggregation and relationships between detailed competencies and specific performance results are not exclusive. Utilizing criterion differentiation and canonical correlation in the search for common dimension of competence and performance as suggested by Bartram (op cit.) is nevertheless useful.

5.3 Theoretical Notions Regarding Competence and Competence Development

Historically, there has been a close link between the concept of competence and professional practice. This already appears from the work of Dewey (1916), who used the term various times in his book 'Democracy and Education'. Examples are: 'Translated into specific aims, social efficiency indicates the importance of industrial competency. Persons cannot live without means of subsistence' (p. 125), 'A democratic criterion requires us to develop capacity to the point of competency to choose and make its own career' (p. 119), 'It is, of course, arbitrary to separate industrial competency from capacity in good citizenship' (p. 68), and 'But there is a great difference between a proficiency limited to immediate work, and a competency extended to insight into its social bearings; between efficiency in carrying out the plans of others and in one forming one's own' (Dewey 1916, p. 214). From these citations, it appears that Dewey saw competency as the general public did, as the ability to create a livelihood, but also as the minimum requirement to enable the pursuit of an independent career that is chosen in freedom, the broad mastery

of professionalism which needs to be related to citizenship, which enables people to participate in the democratic society and a vocation or profession in a self-determined way.

Citations like these can be found in more places in publications in the early twentieth century, such as in the report of Childs (1910). This report is of a delegation of agricultural education experts from the United Kingdom who went to the USA and Canada in the first decade of the 1900s. They studied agriculture and agricultural education in those countries in different places, and prepared a report in which they, as Dewey, used the concept of competence in various ways. The most meaningful quotes are about the following issues: ‘... competence of professionals (i.e. farmers), competence in professional tasks and responsibilities (e.g. manual farm operations), competence in professional practice (e.g. scientific agriculture), competence of teachers and competence of researchers as teachers, competence of assessors, competence management (e.g. enabling and securing good working conditions), and last but not least: incompetence of all mentioned above’ (Mulder and Pachau 2011, p. 397).

These examples show the early concerns with the competence of students in, graduates of, teachers in and administrators of education, or the level of their professional knowledge in practice. However, in these writings competence development was not yet a professional practice in itself. It took nearly half a century for the concept of competence to move beyond general use and to enter the literature as a concept that was being studied as a theme.

5.3.1 Competence and Motivation

As far as we know White (1959) was the first to introduce the concept of competence in the psychological literature on motivation and then to conceptualise it as a key notion to explain behaviour. Until that time, the use of the concept was not thematic but more instrumental, and related to day-to-day use of it. White voiced the discontent with personality psychology of Freud and others in which ‘drives’ were perceived as being the central concept by which human behaviour could be explained. Instead, he proposed ‘competence’ as the central concept by which he meant ‘...an organism’s capacity to interact effectively with its environment.’ (op cit., p. 297). He believed that competence in human beings was not the result of a natural maturation process, but that it ‘... is slowly attained through prolonged feats of learning’ (op cit., p. 287). White (1959) provided examples from biological experiments and underlined research that showed that behaviour motivation is much more complex than responding to certain drives. For instance, he mentioned research from which it appeared that dogs which need certain nutrients are going to search for specific food that contains these, and hormone levels in lead to more complex sexual behaviour than was accounted for in the theories of drive-reduction, insights that were breakthroughs in the fifties of the last century. After various other examples from general psychology and child psychology he proposed to conceive

of competence as a 'motivational concept'; '... there is a *competence motivation* as well as competence in its more familiar sense of achieved capacity.' (op cit., p. 318). White (1959) called the motivation to become competent 'effectance'. He did not believe that drives were not sufficient to explain activities that are carried out to become competent. 'Such activities in the ultimate service of competence must, therefore, be conceived to be motivated in their own right. It is proposed to designate this motivation by the term effectance, and to characterize the experience produced as a feeling of efficacy' (op cit., p. 329). This line of thinking still prevails in current debates on competence. Children, students and professionals in general are motivated to learn to understand more or less complex phenomena and master certain skills to make the able to effectively function in their environment. To capture this motivation in education, performance motivation tests were developed, which included tests on failure anxiety, which appeared to be a major barrier for in making educational tests and education achievement in general. When a problem is complex or a performance situation is demanding, becoming competent and, thus, confident that one understands the problem and can effectively perform in a given situation is rewarding, and still seen as self-efficacy (Bandura 1977).

The insight of competence being performance motivation has been essential in the field of learning in general and professional learning in particular. It is helped to understand that without performance motivation, or the will to master a certain level of professional skill, there would be no professional learning at all.

5.3.2 *Competence and Intelligence*

Next to motivation, intelligence was another central concept by which behaviour was explained. The criticism of this concept has also been severe, and was aimed at disputing the invariability and one-dimensionality of it, which ultimately resulted in the notion of multiple intelligence (Gardner 1983). If competence is seen as being able to effectively interact with the (social and intellectual) environment and the result of intensive and continuous learning, professional education has to obviously prepare for that. To do so, curricula need to be adjusted to essential competence domains, teaching and learning materials need to be in place, teaching staff need to be prepared to implement these curricula, and educational tests need to be aligned to the curriculum and course objectives, course content and learning tasks. However, McClelland (1973) stated that education was testing more for intelligence than for competence, whereas intelligence tests did not predict job success very well. He cited a work of Thorndike and Hagen (1959) in which 12,000 correlations were reported of more than 10,000 respondents. That study showed that the relationship between aptitude testing and job success was insignificant. He also cited work of other researchers like Berg (1970) and Taylor, Smith and Ghiselin (1963) who demonstrated that job performance and educational success were poorly related. McClelland suggested that educational tests should be based on competence: 'How would one test for competence, if I may use that word as a symbol for an alternative

approach to traditional intelligence testing?’ (op cit., p. 7). More specifically, he proposed the following competence-oriented testing principles (op cit., pp. 7–12): (1) Use criterion sampling; (2) Test change in what has been learned; (3) Make publicly and explicitly known how one can improve on the characteristic that is tested; (4) Competencies which are part of ‘clusters of life outcomes’ should be sampled and included in assessments; (5) Tests should not only rely on asking responses on clearly defined problem statements but also on vague instructions as real-life situations are in most instances not well-structured (this distinction is named ‘respondent’ versus ‘operant’ behaviour); (6) Item sampling should be aimed at operant thought patterns, as these are more general and of a higher level than small skills, and therefore enable better generalization.

So, whereas White (1959) was emphasizing the importance of the motivation to learn and to perform, McClelland (1973) was stressing that assessment of learning needed to be more relevant. It should go beyond the measurement of small skills, which does not have sufficient predictive validity for life and job success. This emphasis has direct implications for the design of professional education and professional development. Next to motivation, appropriate assessment was seen as essential for the preparation of graduates for the world of work.

5.3.3 *Competence and Performance*

Next to motivation and assessment, there was another influential development which tried to link systems thinking and learning with competence and performance. Commencing in the 1960s, the movement of performance improvement grew which was not only aimed at explaining behaviour, assessing competence, and training and development, it was dedicated to productivity improvement and performance in practice. The systems approach implied that it was insufficient to look at individual behaviour. Instead, workplaces with their group dynamics, work units with their organisational constellations and people management policies and practices, organisations themselves in their environment and societal context were conceptualized as mutually dependent. Performance improvement technology was developed to assist the industrial society to become more efficient and effective.

Gilbert (1978) strongly linked competence and performance, which appears from the title of his influential book called ‘Human Competence: Engineering Worthy Performance’. During this time, the belief that performance could be ‘engineered’, or that societies and organizations could be made, was still prevalent. Systems theory became popular: Von Bertalanffy (1969) had developed systems thinking originating from biology, but which was applied in a wide range of disciplines, including psychology, sociology and education.

Gilbert (1978) proposed three theorems, which he calls ‘Leisurely Theorems’; he uses ‘leisure’ as ‘...a synonym for human capital, which is the product of time and opportunity’ (op cit., p. 15). His first theorem is that performance is the effect of behaviour leading to consequences. But that not all consequences of behaviour are

valuable or socially acceptable. So he moves on to defining performance as the effect of behaviour leading to accomplishment, this being a consequence of desirable value. However, accomplishments are being reached by behaviour that can be too excessive and too costly, which would imply that the performance is not worthy: the costs would be too high, and the accomplishments too expensive. Therefore, Gilbert introduces the worth ratio: worth equals value divided by costs. He then links this to competence: 'Roughly speaking, *competent* people are those who can create valuable results without using excessively costly behaviour' (op cit., p. 17). This line of reasoning results in his first leisurely theorem: 'Human competence is a function of worthy performance (W), which is a function of the ratio of valuable accomplishments (A) to costly behaviour (B)' (op cit., p. 18). This first theorem and its explanation show that competence is the capability to realise worthy performance. This means that Gilbert distinguishes competence as a capability, behaviour and valuable results of that behaviour, of in his words, he distinguishes behaviour and accomplishment (which as a certain value).

It is also interesting to note that introducing his second theorem Gilbert states that '...performance alone is not competence. Competence is a social concept, a comparative judgement about the worth of performance' (op cit., p. 29). He speaks about a social standard for being able to measure competence. The second theorem is about the potential for improving performance, or the PIP. It is defined as '...the ratio of exemplary performance to typical performance' (op cit., p. 30). Exemplary performance is the best performance of a certain activity over time, in other words a historical record. It is noteworthy to see that Gilbert states that it is only meaningful to calculate PIPs for specific or identifiable accomplishments, as '...there is no "general quality of competence"' (ibid.). Elsewhere he also speaks about the context in which worthy performance gets meaning. Examples of values of PIPs Gilbert gives are 1.5 or less for professional athletes, 3 for management professionals, and 10 or more for sales professionals. He also gives examples of PIPs he found for reading teachers (10) and 'teaching certain mathematics topics' (30) (op cit., p. 43). Gilbert contends that PIPs have the advantage of showing potential or opportunity, and are thus much more positive than IQ measures which can have a stigmatizing effect. 'Poor performers usually have great potential' (op cit., p. 31).

The third leisurely theorem Gilbert presents, is seen by him as the 'management theorem', which is about selection of professionals, arranging their working environment, specifying standards of performance, performance monitoring, rewarding and problem analysis. The point Gilbert makes is that for establishing accomplishments, professionals need a certain behavioural repertory (P) and an environment (E) that enables worthy performance; examples are production tools and support systems, but appropriate reward schemes are also needed. Employers need to pay for both: the repertory and the environment, so the costs of behaviour are the sum of P and E. From this follows that worthy performance, that was defined as the ratio of (value of) accomplishment and (costs of) behaviour can be refined as the ratio of accomplishment and the sum of the cost of the repertory (the remuneration of the professional) and the environment, or $W = A/(P + E)$. Management also incurs costs, so the formula should read as $W = A/(P + E + M)$ (op cit., p. 139). Gilbert notes that

performance problems can be the result of limited competence of a professional, insufficient support systems, limited rewarding, poor motivation or other personal problems like disease. But, overall, Gilbert attributes performance problems to management problems: 'For any given accomplishment, a deficiency in performance always has as its immediate cause a deficiency in behaviour repertoire (*P*), or in the environment that supports the repertoire (*E*), or in both. But its ultimate cause will be found in a deficiency of the management system (*M*)' (op cit., p. 76). He shows that information, instrumentation and motivation both in the repertoire of professionals (*P*) and their environment (*E*) serve as essential components of and conditions for effective behaviour. The sequence of analysing performance problems is first to look at the information, responses and motivation in the environmental support (i.e. is the information given sufficient, are the instruments to enable performance available, are there sufficient incentives provided), and then at the factors in the professional repertoire (i.e. does the professional have sufficient knowledge, is there sufficient capacity to respond to challenges in the workplace and is the motivation to perform present?) (op. cit., p. 92).

So, next to competence as performance motivation and assessment object, Gilbert (1978) has emphasized the issue of competence engineering. The engineering perspective he advocates is not one that is purely technological, nor is the notion of competence, as we have seen already. By definition competence is related to worthy performance and valued accomplishments. This is also the implication of the engineering framework Gilbert uses in his work, which he distinguished from pure science. Engineers always have to take value considerations into account as to how to construct new solutions, like bridges or buildings. The process of production and construction is always constrained by social conventions, legal regulations or values. This is also visible in the model he proposes for performance analysis, which has several layers, the philosophical (i.e. about ideals), the cultural (i.e. about goals), the policy/institutional (about missions), strategic (i.e. about responsibilities), tactics/tasks (i.e. about duties) and logistics level (i.e. about schedules). At all levels, there are performance measures, such as integrity, conformity, worth, value, cost and material need, and methods, such as commitment, policy, programs, strategies, tools and supplies (op cit., p. 132).

The contribution of Gilbert (1978) to the field of professional development cannot easily be over-rated. His theorems look somewhat rigid and quasi-mathematical, but are in fact essential lessons for the practice of professional education and development. First: his notion that all individuals have a potential for performance improvement is very positive; much more positive than the notion that all persons have an intelligence score: half, or maybe even more than half, of the tested population feel bad, because of the intelligence score they received. Second: performance should not be achieved at excessive costs. This means that professionals should be competent enough to conduct certain professional tasks at acceptable costs. Third: if individuals show poor performance, attention should be paid first to the working conditions of these individuals: is there a healthy working culture, is there effective employee management, are the tasks and expectations clear, are workers allowed to use their competence to its full potential, are effective motivation and reward

schemes in place, are the tools and instruments available which are needed for effective performance? In reality, it happens too often that these factors are not taken into account, and that performance problems are tried to be 'solved' by letting workers go to professional training programs.

5.3.4 Competence and Higher Education

The concept of competence gradually made its way into higher education. Grant, Elbow, Ewens, Gamson, Kholi, Neumann, Olesen and Riesman (1979) published a series of case studies on competence-based education programs in the United States which were implemented in the 1970s. The case studies were conducted with a grant of the Fund for the Improvement of Postsecondary Education of the United States Department of Health, Education and Welfare. The same fund supported higher education institutes to redesign their curricula in the direction of competence-based education. Concerns with the *competency* movement in the USA that was spreading around at that time can be read through the lines in the Preface, where Grant is saying that the book does not touch upon the 'minimum competency testing' (in elementary and secondary schools on reading and mathematics for example where student has to pass standardized tests), 'competency-based teacher education' (which were aimed at training specific teaching skills) and 'competency-based certification' movements (op cit., p. X). Apparently, there was already significant discontent with these approaches. These concerns were amplified by Gamson (1979), who stated that 'competence-based programs have had a high mortality rate', meaning that the programs were not well-received by students and faculty at various colleges, especially those with tenure. Their natural tendency was to maintain the status quo and teach the subjects they liked according to their personal preferences.

The book of Grant et al. (1979) is aimed at describing competence-based curriculum development projects at undergraduate college level in various liberal arts and non-teaching professions. It starts with reviewing the reasons as to why American colleges were invited to convert their programs into competence-based programs. The reasons mentioned signal a sense of urgency to improve the quality of undergraduate education. Riesman (1979) points at the international competition that in certain fields scores better than the USA, for instance in the automobile industry, and at problems regarding the environment, over-population, food security, and nuclear terror, that requires higher education to prepare young people for being able to cope with this essential challenges. Grant et al. (1979) tried to define competence-based education, but were not especially satisfied with it, since the author team could list several objections against this definition. Nevertheless, the following definition was proposed in the book: 'Competence-based education tends to be a form of education that derives a curriculum from an analysis of a prospective or actual role in modern society and that attempts to certify student progress on the basis of demonstrated performance in some or all aspects of that role.'

Theoretically, such demonstrations of competence are independent of time served in formal educational settings' (op cit., p. 6).

In summary, the work of White, McClelland, Gilbert and Grant et al., have contributed significantly to the understanding of what the concept of competence means for the practice of professional learning. It shows the importance of competence in relation to performance motivation, assessment, performance improvement and education innovation. These are all essential in establishing professional and practice-based learning of good quality. To make the general observations a bit more practical, the next section considers competence in a number of professions. There have been and still are numerous examples of competence models that have served standardization in professions, certification, licensure and professional development and assessment.

5.4 Competence and Professions

As noted above, there are a number of professions for which and organizations in which competence models have been developed. A wide overview with examples is given by Rosier (1994). In the four Volumes of his handbook (binders with numerous competency models) he has included core competency models, leadership, managerial, professional, sales and marketing, finance, information systems, operations/logistics, human services competency models and competency tools and applications. Apart from professional domains there are other domains in which competence plays an important role are language and communication (Chomsky 1965, 1968; Canale and Swain 1980), mathematics (Gelman and Green 1989), intercultural communication (Hampden-Turner and Trompenaars 2000), and life (Rychen and Salganik 2001, 2003). The examples which will be given below are oriented towards professions, and are documented in the scientific literature. They have all been used in a wider context than in one organisation.

5.4.1 Management

Management was one of the first domains in which competence models were developed to assist the selection and training of professionals. Boyatzis (1982) presented a competency model consisting of various clusters: (1) the human resources management cluster (including the use of socialized power, managing group processes, accurate self-assessment and positive regard), (2) the leadership cluster (including self-confidence, conceptualization, logical thought and use of oral presentations), (3) goal and action management cluster (including efficiency orientation, diagnostic use of concepts, concern with impact and proactivity), (4) directing subordinates cluster (including use of unilateral power, developing others and spontaneity), and perceptual objectivity (op cit., p. 194). Boyatzis starts his account with the notion of

effective performance, just as White was doing in defining competence as effective interaction with the environment. He speaks about attaining specific results through specific actions which have to be consistent with organizational policies, procedures and conditions (op cit., p. 12). Effective specific actions or behaviour are at the intersection of the competencies of the individual, the demands of the job, and the environment of the organization (op cit., p. 13). Boyatzis defines competence following Klemp (1980) as ‘...an underlying characteristic of a persons which results in effective and/or superior performance in a job’ (op cit., pp. 20–21). He further describes the underlying characteristic as being a ‘motive, trait, skill, aspect of one’s self-image or social role, or a body of knowledge...’ If the work of White is interpreted well, motives, traits and aspects of one’s self-image or social role are not competencies. Motives are drivers of behaviour, and competence effectiveness is one of these. Traits are rather permanent personality characteristics, such as the big five. Self-image is the result of competence, and related to self-efficacy. Social roles are positions on the labour market to which certain activities, rights and responsibilities are attributed in social interaction, perception and agreements. Competence of professionals is part of that, because without competence the professional would not be able to play the role in question. But that is not the same as saying that the role is an underlying characteristic of competence. It is rather the other way around. Competencies are performance requirements without which professionals would not be able to effectively function in their professional situations. Knowledge, skills and attitudes are components of competence. We will come back to that.

Boyatzis used a five-step method to arrive at the competency model (op cit., p. 42): (1) Identification of the criterion measure (this is about choosing an appropriate measure of job performance and data collection, resulting in job performance data of managers); (2) Job element analysis (this is about identifying characteristics in clusters which lead to effective or superior performance as perceived by managers); (3) Behavioural event interviews (this is about interviewing, coding interviews for characteristics, relating these to job performance data, and listing validated competencies); (4) Tests and measures (this is about choosing and administering tests to assess competencies and relating them to job performance data); (5) Competency model (determine causal relationships between competencies and job performance, which lead to the validated competency model). Boyatzis is stating that there are three differences between this approach and traditional task and function analyses (op cit., p. 43): during the analysis the focus is not only on the job but also on the person, the process results in a competency model and not just a laundry list of unrelated competencies, and the model is validated by performance data. A major concern in this approach is establishing a valid relationship between competence and job performance data. Boyatzis acknowledges that, in certain professions, there are no clear performance criteria. Education is a good example of that profession, although there is a strong tendency to make teaching performance more results-oriented. But one of the difficulties is that the performance of one teacher can depend on the performance of a teacher in another subject. For instance: the performance of a teacher in chemistry or physics is depending on the performance of a teacher in mathematics. The same holds for teachers in languages. The quality of language

teaching in the mother tongue is to a certain extent influencing the learning of other languages, especially regarding sentence parsing. Also: there does not seem to be a linear and unidimensional relationship between competence and performance. One can perform tasks within acceptable but different ways and yet arrive at desired performance results. This is very well visible in doing research and teaching. Faculty can do their work in various ways, comply with standards of performance and still get positive student evaluations, sufficient credits for publications and desired promotions. Bartram (2005) points at this issue when he, just like McClelland (op cit.), calls for criterion differentiation. Without sufficient specification of competence in terms of relevant professional acting, it is difficult to grasp the meaning of professional development.

Quinn et al. (1996) also produced a competency framework for managers, although they used an approach of theory synthesis. They reviewed and constructed an overview of key management models and defined eight general directions of management roles in a competing value-framework. These directions are defined by four models of management: (i), the rational goal model, (ii) the internal process model, (iii) the human relations model and (iv) the open systems model, and by two dimensions: control-flexibility and internal-external. The eight orientations are aiming at: (i) maintaining the system, (ii) consolidation/continuity, (iii) centralisation/integration, (iv) maximizing outputs, (v) competing position of system, (vi) developing human resources, (vii) decentralisation/differentiation, and (viii) expansion/change. It is interesting to note that the authors promote the creation of multi-orientation teams in organisations because this diversity creates a more solid basis for success than having representatives of one perspective only. This vision relates to the notion of collective competence, by which the composition of the team and the current distribution of competencies is reviewed before a new team member is added to the group. The team member, in many cases, should not be a duplicate of existing team members, but add competencies the team needs and which it does not have yet at the desired level.

5.4.2 Roles and Competencies of HRD Experts

The competency profile of Boyatzis has been used extensively in management assessment, selection and development. The HRD profession in the USA has been using competency profiling for self-assessment purposes. McLagan (1983, 1989) has conducted various studies in which competence models were generated. The first study resulted in an overview of competency statements, based on extensive research within the profession. It is remarkable that this study was called 'models for excellence' because excellence is not synonymous with competence, whereas the rest of the study title is about the competency study which was done. The connection between competence and excellence is located in the fact that both are points at a continuum of professional development. Dreyfus and Dreyfus (1986) pointed at the various stages of this professional development of skill acquisition as

they called it: (1) Novice; (2) Advanced beginner; (3) Competence; (4) Proficiency; (5) Expertise. Although these levels of skill acquisition are generally accepted, the phrasing of these levels is somewhat problematic, given the developments in competence and expertise theory and research. Apart from the fact that levels 1 and 2 are referring to beginning professionals and levels 3–5 are referring to levels of mastery of professional skills, the fundamental problem is that competence itself consists of various levels, as does expertise, and proficiency is a characteristic of mastery at various levels as well. In other words, professionals can have different levels of competence and professional expertise, and are thus differently proficient at these levels. Rather we suggest to use the following phases in the development of professional expertise: (1) Ignorance, referring to novices who by instructions; (2) Nascence, referring to apprentices who work under guidance; (3) Competence in the sense of doing independent work, referring to the basic level professionalism; (4) Excellence, which stands for delivering outstanding performance as by an expert or specialist; (5) Brilliance, which indicates great talent and superb performance, as delivered by stars in the organisation, the profession or society.

Coming back to the work of McLagan (1983, 1989), one could say that competence and excellence models are different things; they represent models of different mastery of knowledge, skills and attitudes in a given domain, in which competence is related to the minimum standards of achievement, and excellence is beyond that level. This difference can easily be understood when one is hit by a life-threatening disease. In such a case one would rather go to an excellent specialist than to one who is competent, although the competent physician may effectively be able to cure the disease. Trust in the ‘excellent’ physician however will be greater and chances are that unforeseen complications will be handled in a better way than by the ‘competent’ colleague who may have less experience with potential complications.

The empirical part of the second study of McLagan (1989) comprised of a review of future forces for the role of HRD professionals, outputs of HRD professionals (products and services), the definition of standards of outputs, the level of expertise of competencies and the formulation of ethical issues which the HRD professionals may encounter.

Since the studies of McLagan (1983, 1989) the American Society of Training and Development has commissioned further studies to make a competency model for the profession, called ‘The ASTD Competency Model. Training & Development Redefined to Create Competitive Advantage’ (ASTD 2013). The model distinguishes foundational competencies (i.e. those that are relevant for success in most occupations, being business skills, global mind-set, industry knowledge, interpersonal skills, personal skills, technology literacy) and training & development areas of expertise, for which is specified what professionals need to be able to do. The areas of expertise are performance improvement, instructional design, training delivery, learning technologies, evaluating learning impact, managing learning programs, integrated talent management, coaching, knowledge management and change management. These fields resemble the HRD-roles (Biddle 1986) defined in 1989, which were: (1) Administrator; (2) Evaluator; (3) HRD manager; (4) HRD materials developer; (5) Individual career development advisor; (6) Instructor or facilitator;

(7) Marketer; (8) Needs analyst; (9) Organization change agent; (10) Program designer; (11) Researcher. They are also related to the roles, (e.g. the learning strategist, the business partner, the project manager and the professional specialist) areas of expertise (e.g. career planning and talent management, coaching, delivering training, designing learning, facilitating organizational change, improving human performance, managing the learning function, managing organizational knowledge, and measuring and evaluating) and foundational competencies are Interpersonal, Business and Management and personal competencies as identified in 2011.

In sum, an interesting difference between the models of Boyatzis and those of the ASTD is that the one of Boyatzis employed assessment and also have been used as foundation of assessment of management candidates and management education and training curriculum design. However, whereas the model of the ASTD was developed for self-assessment and self-development of workplace learning and performance improvement professionals. In general, different professional groups use competence profiles for different reasons; there is a tendency that professions in which errors cause injuries to people, damage to the environment or significant capital losses (such as in operating complex capital-intensive technical systems) use competence profiles for education and training, professional licensure and mandatory retraining.

5.4.3 The Medical Profession

Another current example of a more tight use of a competency model is the CanMEDS 2005 Framework which is used by the medical profession (Frank, Jabbour et al. 2005). This model is developed for medical experts. The roles of expert are defined and elaborated in this Framework, which consists of key competencies and enabling competencies. Medical expertise is the central quality of the physician in the framework. Apart from this role of medical expert, the other roles are communicator, collaborator, manager, health advocate, scholar, and professional.

Key competencies of the medical expert role are amongst others: ‘function effectively as consultants, integrating all of the CanMEDS Roles to provide optimal, ethical and patient-centred medical care’ and ‘establish and maintain clinical knowledge, skills and attitudes appropriate to their practice’ (op cit., p. 1). The key competencies are elaborated systematically into enabling competencies. Examples of enabling competencies for the first key competency are for instance: ‘effectively perform a consultation, including the presentation of well-documented assessments and recommendations in written and/or verbal form in response to a request from another health professional’, ‘demonstrate effective use of all CanMEDS competencies relevant to their practice’, and ‘identify and appropriately respond to relevant ethical issues arising in patient care’ (op cit., p. 1). Examples of key competencies of the role of communicator are ‘develop rapport, trust and ethical therapeutic relationships with patients and families’, ‘accurately elicit and synthesize relevant information and perspectives of patients and families, colleagues and other professionals’,

and ‘accurately convey relevant information and explanations to patients and families, colleagues and other professionals’ (op cit., p. 3). Examples of the first key competence in this role are ‘recognize that being a good communicator is a core clinical skill for physicians, and that effective physician-patient communication can foster patient satisfaction, adherence and improved clinical outcomes’, ‘establish positive therapeutic relationships with patients and their families that are characterized by understanding, trust, respect, honesty and empathy’, and ‘respect patient confidentiality, privacy and autonomy’ (op cit., p. 4).

Key competencies of the role of scholar are for instance: ‘maintain and enhance professional activities through on-going learning’, ‘critically evaluate information and its sources, and apply this appropriately to practice decisions’, and ‘facilitate the learning of patients, families, students, residents, other health professionals, the public, and others, as appropriate’ (op cit., p. 9). This rather elaborate description of the CanMeds 2005 Competency Framework is given (although the whole Framework is over ten full pages) to explain that this competency model is mainly content- or task-driven. This is visible in the wording of the key and enabling competencies of the core role of the medical expert, but also in the other roles, key competencies and enabling competencies. It is all about being able to provide optimal medical care. Some of the key competencies and enabling competencies read as tasks, which the physicians need to be able to do; this is also the format of the competency statements: ‘Physicians are able to ...’. Examples of this competency are establish and maintain clinical knowledge, effectively perform a consultation, accurately elicit and synthesize relevant information, respect patient confidentiality, privacy and autonomy, critically evaluate information and its sources, and facilitate the learning of patients, families and students.

Models or frameworks like those of the management, human resource development and the medical profession certainly help in mapping the domain of professions, and thus developing curricula for professional education and training and development programs for continuing professional development. How much specificity is needed is a question that is difficult to answer. Certainly, overspecialisation should be avoided, but sufficient description is needed to define course and instructional development. The core professional tasks graduates and more experienced professionals are confronted with should be at least included in the education and development programmes. This means that in specifying competence statements for professional learning, ample attention should be paid to the content-matter of the professional tasks.

5.4.4 The Purchasing Profession

An example in which we experienced the necessity of sufficient specification of content-related competence profiles is from the purchasing professions (Mulder et al. 2005). This project also resulted in a predominantly task-driven

competence framework. In this study a variety of research and development strategies were used within an association of purchasing professionals (N of population=3,083; N of pre-survey=806; N of main survey is 261; a test for sector-bias of the main survey given the population distribution was satisfactory). These activities that were conducted are (op cit., pp. 188–189): (1) qualitative multi-perspective iterative interviews for trend analysis in the literature, research and practice about purchasing; (2) stratification discussions regarding the structure of the profession in term of main roles, and group interviews for generating and structuring task and competencies lists; (3) a large-scale task performance survey; (4) a test of sector-specificity of job profiles; (5) job profile mapping; (6) job picture development; (7) competence mapping. The outcomes of the project were an overview of the major trends in the profession, regarding strategic importance of the purchasing function, the importance of internal marketing of the purchasing function, the further development of e-business, the focus on core competencies of the organizations, the emerging necessity of working in multi-disciplinary teams, the urgency of chain management, further globalization of trade, the creation of purchasing alliances, differentiation and specialization within the purchasing function, and the increasing attention for ethics and corporate social responsibility. Four job and competence profiles were developed, for four key competencies: (i) purchasing management, (ii) information and communication, (iii) initial purchasing and (iv) operational purchasing respectively. In total, 105 tasks were formulated which were generated in the different interviews and included in the large-scale survey. Job profiles were composed which consisted of the four roles and task specifications by task domains and activities. An aggregate job profile was constructed for the four roles as well and the four general tasks and thirteen subtasks. A Subtasks in the field of initial purchasing was ‘specifying the purchasing need’, and examples of tasks in that field were ‘Supporting and advising the development of functional and technical specifications of purchasing needs with the internal customer’, ‘verifying whether what has to be purchased measures up to functional and technical specification of the organization’, and ‘evaluation the completeness of the specifications’.

As will be clear, there is a strong relationship between this example and the example of the medical profession. In both examples, roles and tasks are specified and these are used as input for stating that the professional should be able to perform these tasks.

All professional competence models described above have contributed significantly to the professional and practice-based learning in the respective fields. They also all include an overview of the tasks professionals need to be able to perform in their professional field. These tasks may be closed and open, and of reproductive and productive nature. For instance, in the field of innovation professionals may be asked to cope with situations, products and processes, but they also may be expected to contribute to the creation of innovations.

Now after these task- or content-oriented competence frameworks attention will be paid to an approach that emphasises generic competencies which are stated in terms of behaviour.

5.4.5 *A Generic Behavioural Competency Framework*

Above we have raised an important question regarding the specificity of competence models for various professions. This specificity is necessary for the development of relevant and current curricula and professional development programs. But there is also a line of research in which it is tried to explain human behaviour and predict job performance and career success just as White tried to explain motivation and human behaviour. The work of Barrick and Mount (1991) is a clear example of this kind of explanation. They proposed the following five dimensions with which they tried to explain all professional behaviour: (1) openness (inventive/curious versus consistent/cautious); (2) conscientiousness (efficient/organized versus easy-going/careless); (3) extraversion (outgoing/energetic versus solitary/reserved); (4) agreeableness (friendly/compassionate vs. cold/unkind); (5) neuroticism (sensitive/nervous vs. secure/confident). Secondly, they were also very interested in testing the intelligence of candidates, again, to predict their later job performance.

A comparable approach is followed by Bartram (2005). As with the work of Boyatzis (1982), the work of Bartram is from the consultancy world. Bartram conducted a meta-analysis of 29 studies with a total n of 4,861 cases; an impressive number. The studies employed the so-called Great Eight competency factors published earlier (Kurz and Bartram 2002). The Great Eight competencies are: (1) Leading and deciding; (2) Supporting and cooperating; (3) Interacting and presenting; (4) Analysing and interpreting; (5) Creating and conceptualizing; (6) Organizing and executing; (7) Adapting and coping; (8) Enterprising and Performing (Bartram 2005, p. 1187). These competencies are further defined, and the 20 competency dimension as well as the 112 competency components are listed in the appendix with the article. Also, the hypothesized relationships between the competencies and Big Five factors are listed. The purpose of the study is to determine the relationship between competence and job performance. The author states that this relationship has been difficult to prove, because in many studies, job performance was only rated by one item (one score on overall job performance). Therefore, he calls for criterion differentiation: 'The key point of all this work is the demonstration that differentiating the criterion, in only in two broad areas, provides a considerable gain in the clarity of how personality-based predictors relate to performance' (op cit., p. 1187).

The approach presented in the study of Bartram is typical for the quest to try to explain variation in performance by a set of predictors that is a limited as possible. While this is understandable from the perspective of assessment, selection and generic advice on competence development, it is not sufficient for more detailed content-oriented professional development. Whereas the Great Eight competencies and the more detailed competency dimension and competency components are absolutely essential for the management profession, but content-driven professions like medical experts, engineers, scientists, lawyers, but also accountants, operators, nurses, teachers, technicians, logistic professionals and construction workers need a solid basis in competence in terms of knowledge, skills and attitudes that are strongly related to their work environment, and, thus, more content-specific.

So regarding the contribution of the generic behaviour-oriented models of competence, we conclude that these are of limited value for professional and practice-based learning, unless they are further specified for a certain profession and professional contexts.

5.5 Three Fundamental Approaches of Competence and Professional Development

In the preceding sections, an overview of developments is advanced in the use of the competence approach in professional and activity-based learning. As indicated, since the 1950s the concept of competence entered the professional literature. Main developments in the conceptualisation of competence since then have been described. The interim conclusion was that competence models have significantly contributed to the mapping of professions, and to the design and implementation of professional education and development programmes.

The total body of the competence literature however is much richer. For other accounts of the developments in the field of competence theory and research see Rothwell and Lindholm (1999) and Hodge (2007). Rothwell and Lindholm reviewed the competence identification, modelling and assessment literature until the late 1990s, focusing on the literature in the USA; Hodge (2007) reviewed the origins of competency-based training as the theory of vocational education that formed the foundation of the national qualification framework in Australia. Rothwell and Lindholm (1999) reviewed a number of the same authors whose most important competence works have been explained above. They elaborate competency identification, modelling and assessment practices at operational level in greater detail than has been done in this chapter. Hodge's review is limited to the origins of competency-based training, and does not go back as far as this chapter does in exploring the psychological roots of the concept. He refers to Houston (1974), Norton et al. (1978), Tuxworth (1989), and Harris et al. (1995) as sources who describe the origins of the competency-based training approach.

Advocates of the concept (Zemke 1982; Dubois 1993; Spencer and Spencer 1993) have stressed the added value of the concept of competence. However, critics have pointed at its negative properties like conceptual confusion (Westera 2001), standardization of education (Hyland 2006) and lack of measurability. Although it is true that the many attempts of applying competence in professional development (such as in competence-based teacher education) failed, there is no doubt about the importance of professionals being competent in their jobs. Rather, ways of using competence or operationalizing it in practice has raised many questions. However, the right comments on the concept have to be pointed in the right direction. That competence is being used in the debates on enhanced cooperation in education, the creation of one education space, facilitating mobility of students, the Bologna process of higher education, and the enacting of the European Qualification Framework (EQF) within the European Union does not mean students would not need to be educated

to become competent and that professionals would not be needing further professional development. On the contrary, the complexity of the demands for occupational performance in contemporary workplaces is so high that all means must be employed to warrant competence development. And, by denying the added value of the concept of competence in educational planning and professional development, and subsequently including it in a model for competences as sub skills (Westera, op cit., p. 86) only adds to the confusion, and leads to limited operationalization and use in practice. As to the lack of measurability, there is a host of recent literature that addresses competence measurement and assessment (Hartig et al. 2008; Shavelson 2010; Winther 2010; Blömeke et al. 2013).

Although critics have a point in saying that the concept of competence lacks clarity, it cannot be denied that the concept has a long and strong history (Mulder 2007), and that it has achieved a solid position in common language, professional practices and institutional regulations (Mulder 2012), such as in the European Qualification Framework and the competences of the European institutions.

Various authors have proposed different epistemological approaches to conceptualize and study competence. As mentioned already, there is the big difference between task and behaviour orientation, the comprehensive approach, stressing the importance of combining knowledge, skills and attitudes in competence statements (Wesselink 2010), and the interpretative-relationship approach, which is close to naturalistic phenomenology (Velde 1999; Sandberg 2000). The latter approach means that competence only gets meaning in the ‘dynamic conception’ of work and individual’s relationships to it. To capture competence and stimulate professional development, it is important to fully understand the meaning of competence of individuals, which can be achieved by this approach.

As an attempt to create some structure in the enormous amount of publications in the field of competence theory and research, and thus be better able to evaluate the use of competence models for professional and activity-based learning, a trichotomy in approaches of the concept of competence is proposed. The three approaches are: (1) Competence and behaviouristic functionalism; (2) Competence as integrated occupationalism; (3) Competence as situated professionalism (Mulder 2011).

5.5.1 Competence and Behaviouristic Functionalism

Initiatives like competence-based teacher education (CBTE) in the 1970s were heavily influenced by behaviouristic psychology and education philosophies which entailed the preparation of students for certain functions. The basic idea of this approach of education and professional development was to specifically determine the discrepancies between mastery of actual and desired specific competencies, which often resulted in training sometimes miniscule skills; an important pitfall of this approach was over-specification and fragmentation of learning. This approach was heavily criticised by proponents of the humanistic-based teacher education movement, and those who were convinced of the fact that reflection on action is more important than practicing endless small skills. Researchers showed that experience

and personal epistemologies had a stronger influence on professional behaviour than the training of isolated skills. Because of these insights, CBTE and with that many competence-based education initiatives fell out of favour. Nonetheless, via corporate strategy literature and practice as well as human resource management theories and instruments, the competence-based education movement became popular again, but then especially based on the second approach.

5.5.2 Competence as Integrated Occupationalism

Instead of focusing on functions, or narrow job profiles, the approach to stimulate integrated occupationalism was based on notions of holistic, generic and integrated sets of knowledge, skills and attitudes, which are needed in occupational roles and situations. Not only the task content is important, also the way in which tasks are being carried out. For instance, dentists who have to fill holes in teeth of children, reassures the child and performs the necessary actions with care. Current vocational education policy is aimed at implementing competence-based education practices in which it is stressed that knowledge, skills and attitudes should be integrated in the curriculum, teaching, learning and testing. In present qualification frameworks and competence-based education models it can be seen that attempts have been made to link core roles and work situations, work-processes, and competencies. Within the European Union, this process is being stimulated by the development of national qualification frameworks in relation to the European Qualification Framework (Mulder 2012). The approach is called occupationalistic as a lot of weight is attributed to the demand side of education, as part of the neo-liberal theory of market-led economies. The needs in the labour market are considered to be leading in the articulation and definition of the functional specifications of education. So, in many countries, industry defines the needs for education. However, not only do industries find this task difficult, this approach is also fundamentally limited. The problem can easily be understood because not all companies and institutions, large or small, and in different economic sectors, are working with optimal organizational models, nor are they all sufficiently innovating or transforming their business models which is needed given developments in technology, markets and society. So educational institutes themselves have an autonomous role in formulating their educational philosophy on preparing young generations for the future. Balance is needed in the influence of various stakeholders in educational planning and professional development.

5.5.3 Competence as Situated Professionalism

This approach is based on the observation that competence only has meaning in a certain context, in which professionals interact with each other. For instance, when a competence domain of communication is at stake, it means something totally

different for a secretary giving standard information to students than for researchers who are defending a thesis. Also, communication for researchers means two very different things when they are interviewing a respondent or having a job interview. The professional context, on the other, had also enables competence development because of its affordances (Gibson 1979). He conceived of affordance as characteristics of a given context which provide possibilities for professional action and development. Affordances can be perceived and acted upon, given the abilities of agent. These abilities, defined as effectivities by Shaw et al. (1982) who saw these as functions of a being in relation to its context, or formulated a bit wider, as the abilities of an agent. These affordances and effectivities have a lot in common with competence development in context, although the work of Shaw et al. (1982) has a more perceptual base.

Competence also develops during experience with certain activities and in varied situations. This approach of situated professionalism is related to notions of situated cognition: 'Knowledge is situated, being in part a product of the activity, context, and culture in which it is developed and used' (Brown et al. 1989, p. 32). In situated professionalism, the development of a professional identity is also important, which is an idea that is related to the theory of situated cognition. While growing in the role of beginning manager, consecutive experiences of successful performance, positive feedback on successes, and the feeling of learning of and with colleagues, results in a positive self-image of the individual. The work context then takes shape as a community of practice in which players interact and share and negotiate meaning (Lave and Wenger 1991; Wenger 1998; Wenger et al. 2002). It is also closely related to theories and practices of professional development which show that personal epistemologies (Hofer and Pintrich 2002) have a stronger influence on professional behaviour than isolated skills training. It also touches upon the notion that competence is heavily influenced by what important stakeholders expect of the professional in terms of wishful professional action. Professional associations (such as associations of medical specialists or pilots), but also local players (such as hospital directors, chefs de Clinique, and airline executives) have a strong influence on the desired competence fields and the extent to which the professionals need to be proficient in these fields.

The theory of situated cognition (and thereby situated professionalism) has not remained without criticism. Anderson et al. (1996) state that not all learning is necessarily depending on a real context, transfer is possible if tasks are similar, learning of abstractions is possible by giving concrete examples, and not all learning needs to be individual. Nevertheless, social-constructivism learning theory has been quite influential in professional education and development, and as a consequence authentic learning and competence-assessment have become widely distributed in professional learning arrangements. An important pitfall here is holism, when details of competence are covered under generic expressions of abilities of people, which may be sufficient in personal development processes, but not for professional certification purposes.

Evaluating these approaches against their potential use for professional and activity-based learning, it can be said that it is difficult to say which one is most effective.

That mainly depends on the situation and the specific task for and in which a professional has to develop. Training specific behaviour can be very effective in sports and music, but also in medical education. On the other hand, education for certain occupations can be very effective in vocational school settings. Finally, professional development of teachers can be very effective in an in-service-situation. In short, there is added value in all three approaches, and the interim conclusion here is that competence-based initiatives contribute to the quality of professional and activity-based learning. It appears that learning needs (whatever closed or open they are) are being specified, which guide the direction of professional development programmes and activities.

5.6 Conclusions, Discussion and Further Research

The main question in this chapter was whether conceptions of professional competence have helped the practice of professional and practice-based learning. The interim answers on this question throughout the chapter have been positive, and the general balance regarding this question is also positive. Indeed, we think that the development of competence models (frameworks or profiles) help in mapping professions. We also think this should not be done in a rigid way. The reality of professional practice is dynamic, but on the other hand quality requirements in certain professional domains require a certain level of standardization, especially in hazardous occupations and professional domains which have an important influence on health, safety and risks. Approaches of competence development such as those described (in the training, education and development context) have to be made context-specific as their added value is situation-specific. Important variables to take into account are the level of the profession, the field of practice, the intentionality of learning, and the formalisation of learning activities. Professional and activity-based learning practices vary considerably by these variables.

As has become clear in this chapter, many conceptual studies appeared regarding the concept of competence, competency, competencies, competence models, competence systems, competence dictionaries, competence-based management, competency-based education, competence testing, competence assessment, competence centres, etc. The number of empirical studies has been increasing however.

Mulder (2004) established a series of principles of good-quality competence-based education, which was adapted by Wesselink (2010) who constructed a matrix for competence-based vocational education, which consists of eight principles of education and four levels of implementation. Experiences of teachers with the matrix were studied (Wesselink et al. 2010). This model for curriculum design practice was further elaborated and now consists of ten principles of education and five levels of implementation. The model is validated in senior-secondary vocational education, and proven to be useful in assessing and developing competence-based vocational education programs (Sturing et al. 2011). As such, this instrument contributes to the quality of professional and activity-based learning.

Furthermore, Mulder (2006) studied the inclusion of sectoral social partners in European competence development projects, and concluded that this leaves a lot to be desired. Biemans et al. (2009) studied measures to overcome the most common pitfalls of competence-based vocational education and reported on the effects of these measures. There are also advancements regarding authentic student assessment (Gulikers et al. 2010). Gulikers et al. (2009) described evaluations of the quality of competence-based assessments as perceived by curriculum developers, teachers, students and employers. Experiences of education developers, teaching staff and students regarding competence-oriented learning environments have been studied to evaluate the different perceptions of these stakeholders regarding the intentions and practices of this educational innovation (Wesselink et al. 2010). Furthermore competence studies were conducted in various professional domains which were not yet mentioned in this chapter: agricultural extension to develop a competence profile for agricultural instructors (Karbasioun et al. 2007); rural consultancy in the field of HIV/Aids in Africa, in which key competencies for the socially sensitive issue of extension on reproductive practice and the dangers of infection were identified in a participatory way (Brinkman et al. 2007); environmental education for which competencies were identified (Wesselink and Wals 2011); entrepreneurship in greenhouse horticulture (Mulder et al. 2007a; Lans 2009; Lans et al. 2008, 2010a, b; Lans and Gulikers 2010); teacher competence on inquiry-based science teaching (Alake-Tuenter et al. 2012); corporate social responsibility, a field that is just being explored (Osagie et al. 2012).

There is also advancement in the field of competence development and knowledge arrangements. New arrangements for cooperative knowledge creation have been explored (Beers et al. 2010), as well as regional learning arrangements, and competencies for the establishment of regional learning (Oonk et al. 2011), to see whether process-based reflection in multi-stakeholder groups can help overcome the barriers that existed in the older models of knowledge dissemination. Furthermore, there is progress on the acquisition and fostering of interdisciplinary, intercultural and argumentative competence. Many of the problems students and professionals in the natural, life and social sciences encounter in their field of work are related to these issues. Since professionals need to be able to justify their choices and practices in a more and more digitalised working environment, it is also interesting to look at research on learning in advanced digital collaborative learning spaces. Studies were conducted in the domain of interdisciplinarity (Spelt et al. 2009), intercultural learning (Popov et al. 2012) and argumentation-based learning in online collaboration spaces (Noroozi et al. 2011, 2012, 2013a, b).

The relationship between competence and professional performance has not yet been studied intensively. There has been research by Lans (2009) in small and medium sized companies and Du Chatenier (2009) in open innovation teams in large organizations. However, since establishing worthy performance is costly, and performance outcomes (accomplishments) should justify the costs of performance, it seems to be worthwhile to further investigate the effects of competence development on professional performance improvement.

Various competence studies have been based on large surveys on opinions and perceptions of competence as needed in professional practice. Some experiments have been done to study specific aspects of competence development. However, more ecological validity is needed in this type of research. Professionals in given contexts performing certain tasks and exerting certain responsibilities need to be studied to see what is actually going on at the intersection of working and learning. In other words: competence development in workplace learning settings should further be explored. It would also be worthwhile to further study the effects of different competence development strategies in specific domains.

As a final caveat, this chapter is concluded with a general pitfall in competence-management and development practices. Competence-based professional development often starts with modelling professional competence. The development of competence frameworks for professions is informed by empirical research, but in the final stage it is an act of normative decision making. These frameworks are being used as standards within certain professions or organisations with which professionals have to comply, either for registration or for re-registration. Once models for professional competence have been developed and professionals assessed, learning needs can be aligned to these models. This does not automatically happen, since learning processes are taking place anyway, intentional or incidental, organized or informal, conscious or unconscious. The default mechanism for professional development plans is to revert to training. However, in many cases training is not effective for professional learning and other development activities have more potential. Transforming a workplace in a smart collaborative learning place, or creating scripted online knowledge sharing networks with embedded tutoring, may be much more effective. In general, competence development is a socio-constructivist learning process in which social interaction and situation-specific searching for quality improvement of working processes is of utmost importance.

Chapter 6

Becoming a Practitioner: Professional Learning as a Social Practice

Silvia Gherardi and Manuela Perrotta

Abstract A practice-based interpretative framework for reading the process of becoming a professional as a social practice is developed to examine the ecology of the human and non-human actors involved in induction to the organization and seduction by the profession. We argue that professionals undergo induction into the organization while they undergo seduction by the profession. The chapter illustrates the situatedness of this process in relation to different types of organizations (private, public, network) in order to analyse the relation between the induction process and the actors that influence it. Three different models of induction are described: (a) in a professional bureaucracy, socialization precedes selection, and the key actor is the profession; (b) in a small private organization, induction is almost exclusively managed by the community of practice in the form of seduction by the profession; (c) in a large network of organizations, induction is explicitly managed by the organization and becomes a means to transmit the organizational culture.

Because the process of becoming a professional is a continuous process throughout working life, the tensions and contradictions that characterize its accomplishment are discussed in relation to the issues of behaviour control versus professional control, managerialism versus professionalism and identity work.

This chapter proposes that induction is not solely the effect of encounters between individuals and organizations, because two other agents are involved in the process: the profession and the community of practice.

This chapter is the result of an entirely collaborative effort by the two authors. If, however, for academic reasons, individual responsibility must be assigned, Manuela Perrotta wrote Sects. 6.3, 6.4, 6.5, and 6.6, Silvia Gherardi wrote the other sections.

6.1 Introduction

The process of becoming a professional is usually described as a socialization process whereby novices learn how to perform a series of occupational tasks and how to develop appropriate identities as practitioners. Usually, sociology of work and sociology of occupation use the term ‘socialization’ to describe the reciprocal accommodation between an organization and an individual during the life-time of a presumably long-term work relation. Typically, it is the point of view of the individual that is privileged in this analysis, and from this point of view the socialization process resembles a trajectory or a stage model starting with anticipatory socialization. This occurs during the educational process: upon entry into an organization the individual assumes the social position of the novice; then later becomes an insider; and finally gets ready to leave the condition of employee through a process of gradual disinvestment from the working context. More recently, and especially within organization studies, it seems as if the scientific community is seeking to renew its lexicon so that it can continue to reflect on the same phenomenon but with new concepts. The term ‘induction’ seems to have arisen from this dynamic and the organizational point of view, and it is assumed as the main agent of the process.

The strength of the new term ‘induction’ lies in the semantic openness deriving from its scant definition. Whilst studies on socialization (e.g. Van Maanen 1976) have moved through the development of diverse conceptual models and methodologies of analysis including those from socialization as an independent variable affecting numerous organizational factors, through to models privileging the organization/individual relation viewed as a problem-solving process, to a model where socialization is an ongoing process and not an individual trajectory, induction is a notion still to be fully modelled and elaborated. For the initial purposes of this chapter, we adopt the definition of induction put forward by Skeats (1991: 16) as “any arrangement made to familiarise the new employee with the organization, safety rules, general conditions of employment, and the work of the section or department in which they are employed”. This is a minimal definition, in that ‘any arrangement’ may vary from mere information lasting as long as an interview to a training course of even very long duration. This minimal definition is based on the implicit assumption that induction consists in a series of activities deliberately and formally undertaken by the organization to integrate new employees efficiently and effectively once they have been recruited. Therefore, the main aim of the managerial literature on staff induction is to provide normative advice on how new employees can be better integrated into their new working environment (Major 2000; Ards et al. 2001; Tuttle 2002). At least four dimensions relating to the introduction of new employees have been explored in empirical research: (i) socialization tactics (Ashforth and Saks 1996; Allen 2006), (ii) newcomer adjustment (Cooper-Thomas and Anderson 2002;

Bauer et al. 2007), (iii) newcomer's commitment (Allen and Meyer 1990; Bauer and Green 1994) and (iv) identification (Pratt 2000).

A recent review of empirical research in the field of induction and socialization (Antonacopoulou and Güttel 2010) identifies three main strands. Firstly, the individual and organizational antecedents, i.e. the newcomer's predispositions and the firm's practices which govern staff induction, secondly, the inductee's adjustment and, thirdly, learning behavior over the course of their socialization; the outcomes of staff induction and socialization, especially in terms of person-organization fit. Moreover, Antonacopoulou and Güttel (2010) point out that the majority of researches undertaken are focused on the individual inductee as the main unit of analysis and thus are conducted with a dominant focus on psychological aspects.

Yet, if induction is to be understood in a specific but highly reductive sense, we fail to understand why the term is used synonymously with socialization, and why the management literature has sponsored it, thereby presenting in new guise a worn-out concept disciplinarily connoted in sociological and psychological terms. We are critical of such a narrow definition. For instance, consider the Latin etymology of the term: *in-ducere* is composed of the verb *ducere*, i.e. 'to lead' and the preposition *in*, which denotes place change. Induction thus signifies 'to lead in', i.e. to lead along the right path. The role of leadership is thus foregrounded, together with passivity and the passivization of those inducted. This linkage with the theme of leadership may explain the preference of management scholars for this term. We shall assume the term 'induction' in accordance with the etymological derivation of a process that leads along the right path, but we shall also correlate it with another term only apparently distant from it: seduction. The etymology of *se-ducere* comprises the same verb of motion, but the preposition denotes taking away, i.e. leading away from the straight and narrow path. Hence, seduction is an action that distracts the subject, who – seduced – is induced to follow the seducer away from the right way to the world of their passions. Leadership and seduction are, therefore, not distant or incompatible terms, as Calàs and Smircich (1991) have already noted adopting a deconstructionist methodology.

We shall discuss the process of induction/seduction in terms of the becoming of the relation among an organization, a profession and individual professional identities. The notion of "becoming" draws attention to movements, emergence, flux, process and organizations as "worldmaking" activities (Chia 2003; Carlsen 2006). Becoming denotes the emergence of a sociology of verbs that in organization studies began with Karl Weick's (1979) work, which introduced the terms 'organising' and 'sensemaking'. It continued with the sociology of translation (Law 1994: 103) – that is, a sociology of 'contingent ordering' that interprets society as a relational achievement and ordering effect – and then underwent the 'narrative turn' which emphasised that storytelling – i.e. the performance of stories – is a key aspect of organizational members' work lives (Boje 1991; Czarniawska 1997). The concept of becoming finally underwent what, at present, appears to be its latest turn, the 'practice turn', which has completed the change from knowledge to knowing. This transition from nouns to verbs has produced an epistemological shift to the analysis of processes, temporality, and the negotiation of meanings. Our aim is,

therefore, to elaborate a theoretical framework for the study of induction as a situated practice. The practice-based approach to induction that we propose is grounded in organization studies, and it conceives organizations as flows, as verbs in the process of always becoming (Chia 1995; Clegg et al. 2005; Gherardi 2011). Professional learning is a process of becoming that does not end with the acquisition of the status of insider, nor is it a linear process, nor is it a stable end-state.

Through brief illustration of an empirical research study, we shall show how individuals undergo induction (to the organization) when they undergo seduction (by the profession) within the power structure of a field of situated working practices. Our empirical field is the world of the health-care professions. In particular, three case studies conducted at centres for medically assisted reproduction will illustrate three ideal-typical models of becoming a professional. This empirical field will enable us simultaneously to show the action of the organization and the action of the profession in inducting/seducing newcomers. Before presenting the empirical cases, we shall describe our theoretical-methodological framework, which is situated within practice-based studies (Corradi et al. 2010). We then familiarize the reader with the dynamics of becoming a professional through a fine-grained description of the ecology of forces at play across three case studies before discussing the main sources of tensions that arise through these processes.

6.2 A Practice-Based Approach to Induction/Seduction

Returning for a moment to studies on socialization, we would point out that they connect closely with the idea that, during the socialization process, novices ‘learn’ the tricks of the trade that others ‘teach’ them (Van Maanen and Schein 1979: 211). Also, when socialization is conceived as a continuous process, we find this link, defined as the mobilization of knowledge as a result of interactivity between the newcomer and more experienced members (Danielson 2004). It is, therefore, easy to establish a connection between learning viewed in the context of studies on socialization and the context of studies on situated learning and knowing in practice (Lave and Wenger 1991; Elkjaer 2003; Gherardi 2009). The connection is made by conceiving the learning process as competent participation in work practices and as the simultaneous development and performance of a practitioner identity. Moreover, if we consider the verb form ‘to practise’, practice is seen as “undertaking or engaging fully in a [...] profession” (Brown and Duguid 2001: 203). Becoming a practitioner, therefore, involves the learning and development of competences which are professional in the strict as well as relational and identitarian sense. This process is simultaneously explicit and conscious, and implicit and unconscious. Becoming competent in the working practices of a profession entails mastering the coordinated activities that a community of professionals builds in sustaining the traditions of a profession (including tools, artefacts, discourses) and the practising that re-creates connections in action in the everyday texture of workplace knowing and learning (Gherardi 2006).

The practice of a profession consists of both canonical elements – what we can identify as formal prescriptions of tasks and jobs – and non-canonical ones (Brown and Duguid 2001: 203). While the former can be defined and abstracted within formal prescriptions and, therefore, expressly transmitted through formalized education and training, the latter are transmitted during participation in working practices and in the development of practitioner identity, and they are to a large extent implicit and also unconsciously learned and transmitted. When people become professionals, the socialization process that precedes their actual entry into an employment relation is highly important and controlled by professional associations, by ethical norms, and by the culture of the profession. For example, the socialization process in medicine has received close attention in the literature (Becker et al. 1961; Atkinson 1995; Witman et al. 2010). The way in which future doctors learn to behave according to the non-canonical norms of the profession is considered as important as their formal education. This socialization process has been called ‘the hidden curriculum’ (Hafferty and Franks 1994) through which doctors internalize norms of ethical behaviour, power relations and collegial manners. The medical habitus (with a reference to Bourdieu) is the effect of a socialization process (Luke 2003). It can be seen in the liturgy of the clinic, the meetings, the patient rounds and the medical talk (Atkinson 1995; Freidson 1970). Despite medical practice in different organizations, despite changes in health care, despite generational changes, this pre-organizational socialization to the profession remains quite stable. Becoming a practitioner within a community of practice entails, in fact, recognizing and actively participating in discussion on the professional norms that define what are typical and good professional practices (Lave and Wenger 1991). The competence of the practitioner recognized as a full participant in the professional community is, therefore, a social, technical, as well as discursive competence because the professional community recognizes competence in debating and discussing the canons of correct ethical and aesthetic practices. What is negotiated and contested within a practice, and among practitioners, is not just the effectiveness or efficiency of the practice, but the vision of the world (ethical and aesthetic) that sustains a collective mode of doing. Practitioners have an emotional, aesthetic and ethical attachment to the practices that they support and reproduce. This attachment creates affiliations and celebrates ‘community’ within the community (Gherardi 2009).

In general, these professional norms, values and vocabularies are strongly institutionalized and adopted essentially through socialization processes, mainly pre-organizational and productive of a habitus or a system of dispositions, subconscious schemes of perceptions and appreciations that point the way to practising. We may say that the literature on organizational socialization is informed by especial attention to the internalization of norms, habit, and cultural adaptation of individuals to the profession and to the organization in which they will perform. On the other hand, the literature on communities of practice complements the literature on organizational socialization because it takes a similar point of view.

The work of Lave and Wenger (1991), introduced to an organizational audience by Brown and Duguid (1991), is focused on how learning at a collective level may occur as part of the lived day-to-day organizational activities. Under the label of

'social learning theory' the ideas of learning as participation, legitimate peripheral participation, and community of practice have been explored, developed and contested. If we circumscribe the birth of the idea of community of practice to its historical-cultural context, we note how it differs, on the one hand, from cognitive theories of learning and, on the other, from the conception of learning as individual learning. Hence, by means of this concept a shift was accomplished both with respect to where learning takes place (i.e. in the community, not in the head) and in respect to who learns (i.e. the community as a collective subject, not the individual). However, on adopting a perspective in which induction is viewed as an explicit and conscious activity by the organization which temporally follows the selection process and whose purpose is to facilitate socialization, we may, therefore, wonder how to describe (i.e. assuming that it exists) an organizational practice of induction. To this end, it is necessary to make explicit the theoretical premises of theories of practice compared with those of theories of action.

While theories of action assume a linear model of explanation which privileges the intentionality of actors, from which derives meaningful action, theories of praxis (Cohen 1996) assume an ecological model in which agency is distributed among humans and non-humans and in which the relationality between the social world and materiality reconfigures agency (Latour 2005) as a capacity realized through the associations of humans and materiality. Theories of practice are inscribed within conceptions that can be called 'post-humanist' in that they seek to decentre the human subject (Knorr Cetina 1997) and focus on relationships. A focus on social practice emphasises the relational thinking based on interdependencies between subject and object, person and world, networks and society. They develop their properties only in relation to other subjects, social groups, or networks (Østerlund and Carlile 2005).

Methodologically, an interpretative framework of induction as a social practice within an organization pays attention to the ecology of humans and non-humans involved in the production of induction as a social effect. The intentionality brought into being by the organization in making arrangements and planning organizational routines for induction purposes, therefore, amalgamates with the intentionality and the emotionalism of the subjects about to become practitioners (Gherardi and Perrotta 2010). In turn, the professional communities have a certain way of conceiving and undertaking working practices establish a relationship with newcomers. The effect of this ecology of actions may be a successful or unsuccessful induction, or even a hybrid negotiation of emergent intentionality in which all the relationships at play are modified by and during the process.

To illustrate who are the agents within the ecology of practices that compete in the process of induction and how their power generates the tensions that frame the process of becoming a professional, we shall present three different scenarios that can be taken as ideal types of organizational contexts. In fact, the concept of situatedness is central within a practice-based approach to becoming a professional since we cannot avoid consideration of the contingencies of the field of practices within a specific

organization and a specific community of practices. In other words, the becoming of a professional is necessarily the effect of a texture of situated practices, and every community of practices follows a situated curriculum on admitting a new member.

The concept of ‘situated curriculum’ (Gherardi et al. 1998) denotes the pattern of learning opportunities available to newcomers in their encounter with a specific community inside a specific organization. Whilst the learning curriculum focuses on the learning opportunities related to a specific occupation, the notion of the situated curriculum emphasizes that its content is closely related to the particular set of local material, economic, symbolic, and social characteristics of the system of practices and work activities. Most of the time, the situated curriculum is not fully known to the practitioners that enact it; or it may be part of a negotiated agreement and, therefore, bears many similarities with the hidden curriculum in that it is informal and non-canonical.

The theoretical framework that we have elaborated assumes that induction is produced within an ecology of practices at the moment when the newcomer is seduced by the ecology itself. We shall, therefore, analyse induction as a social practice within this ecology produced in the interaction among organizational induction routines, the emergence of a practitioner identity, and the working practices of the community to which the aspiring practitioner seeks entry. Moreover, we must consider also the professional associations that may exert an influence within that ecology and may take part in generating and solving the tensions and contradictions that pave the way to becoming a professional.

6.3 A Methodological Note

Three different centres for medically assisted reproduction were studied empirically using qualitative data collection and analysis techniques – specifically participant observation and interviews (Perrotta 2008; Gherardi and Perrotta 2010). In accordance with the logic of theoretical sampling (Glaser and Strauss 1967) the three centres were selected because of their different organizational characteristics, with particular regard to the size of the centre and its organizational form. The centres selected were the following: Sisma, a public university centre of medium size (around 300 infertility treatments a year); Beta, a private centre of small size (around 60 treatments a year); and Bioartlife, a network connecting a large centre with six satellite centres of medium and small size (for a total of 1,500 treatments a year, of which half at the main centre).

The next sections will be devoted, not to a detailed description of ordinary activities, but to descriptions of the different textures of induction practices in the three organizations studied. We intend to use the three cases as illustrations of three ideal typical models of induction practice. We, therefore, describe the respective situated practices in order to show the dynamics of interactions and the tensions between agents.

6.4 Sisma: When Socialization Precedes Selection

Sisma is a public assisted reproduction centre. It is part of a university hospital in which the personnel work in close contact with the adjoining gynaecology department. The Assisted Reproduction Technology (henceforth ART) centre has two chief consultants in reproductive medicine (each of them in charge of a team of doctors and trainee specialists); a head of the ART laboratory; a biologist; two anaesthetists in the operating theatre (who also supervise two trainee specialists); four nurses; and two ward attendants.

During the field observation, it was very difficult to determine the positions occupied in the organization. I (MP, the second author) was able to distinguish staff from patients by virtue of their nurse's uniforms or doctor's coats, but I did not have sufficient information to decide who did what. In fact, although some white uniforms had red (for doctors) and green (for nursing staff) badges, a large number of other subjects wore white coats without any type of marker, so that it was not possible to identify the positions of these people at the centre. The markings on white coats differed for a highly symbolic organizational reason: the centre provided white coats for nursing and medical staff; while trainees at the centre had to purchase their own coats regardless of their formal position. This artefact thus performed the function of a material symbol of induction, in that possessing it with a coloured badge signified membership of the organization. By contrast, its personal purchase symbolized the time to wait before being hired.

The white-coated students, in the two teams that I observed, all seemed to have the same position, but as I followed them in their activities and talked to them, I realized that there were differences. The student specialists describe the trajectory followed by novices as a process consisting of three stages:

- Undergraduate: Undergraduates come to the centre in the fourth or fifth year of medicine because they want to write a thesis in gynaecology. Their university supervisors assign the students a thesis topic, arranged for their attendance at the centre (in terms of days per week), and allocated them to an 'expert' trainee clinician (i.e. a fourth- or fifth-year student at postgraduate medical school), who decided what the student should do in the healthcare practice. In this period, the students do not take active part in the centre's activities.
- Intern: after graduation, attendance at the centre became more regular, given that participation in its activities was decisive for those seeking admission to postgraduate medical school. As one of the interns explained: *an intern is a transitory figure hopefully about to enter postgraduate medical school*. The period of time spent at the centre as an intern varied (from a few months to 4 or 5 years) and depended on the individual case: *as 'an aspiring trainee specialist', you sit the entrance examination and wait for a grant for postgraduate medical school, and then you attend for five years*.
- Trainee clinicians: on passing the entrance examination for postgraduate medical school, the students attended the centre for 5 years and took part in its various activities (monitoring, pick-up, transfer, etc.). The trainee clinicians officially

joined the organization and had a well-defined role: they clocked on and off; attended the centre for 36 h a week, had to be on ward duty once a week, and received a bursary which paid for their work.

All three of these positions in the trajectory of becoming a member of the organization preceded the formal moment of selection, but they signalled a hierarchy of rules and competences among newcomers. It emerged from observation and interviews that tasks were assigned to new arrivals (i.e. the undergraduate medical students, the interns beginning attendance at the centre, and the trainee clinicians) according to a situated curriculum. The route followed by students wanting to enter the centre was well defined. While they were writing their theses, assiduity of attendance at the centre was relative, and they were more concerned to develop the topics of their theses. They followed a 'bottom up' training process whereby they gradually participated in the centre's work. When the student became an intern, the 'expert' trainee clinician to whom they had been assigned began giving them elementary tasks: for example making photocopies, or taking test tubes from the operating theatre to the laboratory. Through their participation, the interns began to receive slightly more demanding tasks: compiling the clinical records of patients, for example. When the interns passed the entrance examination to postgraduate medical school, they began to take active part in the centre's activities, but in this phase, too, tasks were assigned gradually. The status of the trainee clinician changed from peripheral participant to actual participant in the 5-year postgraduate medical course. Participation, it was explained to me, progressively increased: *It's gradual. At the beginning you do the [clinical] records, or not even the records because you don't know how to, you make photocopies... then as you get on, you do more professional things; it's not as if as soon as you arrive he [the professor] hands you a scalpel and says 'operate'. But yes, it's gradual, there are also things that you'll never do because they won't let you, but what he doesn't want to do because it's a drag, he lets you do.*

The three phases of the trajectory were pre-specified, but they could be of different durations. The position of undergraduate thesis-writers might last 1 or 2 years, while that of interns might vary from a few months to several years. The interns therefore followed different routes. There were a fixed number of places at postgraduate medical school. An entrance examination was held every year, and those who failed had to wait until the following year to take it again, and there was no guarantee that they would succeed on the second attempt. For this reason, there was fierce competition among the interns. Only postgraduate medical school was of fixed duration (5 years).

During my period of observation, I realized that the two 'expert' trainee specialists had a great deal of autonomy in all the centre's activities, not only the more central ones (for example, clinical work, oocyte extraction, or transfers) but also others (handling relations with medical representatives). Moreover, the 'expert' trainee specialists had the task of supervising the interns at the centre. The relationship between an intern and the supervising trainee specialist was hierarchical – as was that between the trainee practitioner and the chief consultant. The distribution of

power in the group was clearly vertical. Moreover, their relationship was negatively influenced by the competitive environment (at the end of the process only few trainee specialists would be hired by the centre) and characterized by the non-sharing of knowledge.

Summarizing the process by which novice gynaecologists were inducted into the centre, final-year students doing research for their theses cannot be considered members of the organization. On graduation, they spent varying periods of time waiting for admission to postgraduate medical school and attended the centre as 'interns'. Internship could last for even long periods of time, during which participation in the centre's activities grew increasingly intense. It is, therefore, difficult to determine exactly when the interns became full members of the organization.

Additionally, from a formal point of view, the trainee specialists were members of the organization. They clocked on and off, and they received bursaries for their work at the centre. Hence, they were effective members of the working unit, even though temporary ones (postgraduate medical school lasts for 5 years). However, although a sharp distinction between members and non-members can be made in formal terms, from the point of view of participation in the centre's activities it is less straightforward. Not all those who had completed medical school continued to attend the centre. Their decision on whether or not to do so depended on the availability of work at the centre or on contracts taken elsewhere. If they became a permanent member of staff, their change of status was largely formal. Whatever the case may be, they could not be described as newcomers.

This interpretation was confirmed when I asked the head of laboratory how newcomers were inducted. His reply was: *What newcomers? There's nobody new here. New intake has been frozen for years, and there are no new researchers. The last to arrive was, the biologist, and he's been here for years.* He did not believe that the medicine undergraduates, the interns, and the trainee specialists could be considered 'novices' in the organization.

From the medical team's point of view, undergraduates were not novices because they were not directly involved in the ART process and participated marginally in the group's activities. Their constant presence at the centre, first as undergraduates and then as interns, made their participation slow and gradual. These roles also served to enhance their novice status. Hence, when they became trainee specialists they were not regarded as novices because they had already been at the centre for years. The facets and contradictions within the category of novices were reflected in the fact that none of them was perceived as novices; rather they took part in the centre's activities as non-members.

The Sisma case shows how induction is the effect of an ecology in which organizational routines accompany a newcomer's entry are entirely lacking, because when the organization begins the selection process, the newcomer's socialization has already been accomplished. The professional community is instead the actor with complete autonomy in the management of socialization and which, informally, also manages the selection process. Finally, the community of practice, given the competitive nature of its relationships, is an ambivalent actor in a new member's

induction because it is responsible for both transmitting knowledge relative to the tasks that form the situated curriculum and implicitly selecting among the members themselves.

6.5 Beta: When the Profession Seduces

Beta is a private centre of very small size founded more than 20 years ago by Paolo, the gynaecologist who directs it, together with a group of friends and colleagues. These include: Alex, another gynecologist (who no longer works at the centre), Marco, a biologist, and Sara, an anesthetist. In recent years, Alex's place has been taken by Valeria, a young assistant gynecologist who worked with Paolo when she was specializing at university. The final member of the centre's medical staff is Ciro, a recent graduate in medicine waiting to enter a specialization school and Paolo's nephew.

The centre is located on the first floor of a private clinic, from which Paolo leases the premises (i.e. rooms for patients, laboratory, operating theatre, and so on), the personnel (i.e. nursing and administrative staff), and equipment for the laboratory and the operating theatre. All activities relative to the treatment (i.e. oocyte pick up, laboratory operations, sperm self-donation) take place within the centre, while during the initial phase (i.e. first examinations and monitoring) and the phase subsequent to the embryo transfer, patients are treated by Paolo at his private surgery.

Given the limited number of patients and treatments, to minimize costs, work at the centre is organized in "cycles": Paolo groups a certain number of patients (at least ten) and organizes all the interventions in periods of time ranging from a week to 10 days, with intervals of a couple of months between one cycle and the next. As the centre is so small and has developed on the basis of trust relations among the four friends/colleagues, it has no formalized practice of selection and induction; rather, these are the outcomes of an implicit process. This case study is significant because it epitomizes situations which are 'minor' from an organizational point of view but very common numerically and representative of the type of organizations which arise on the basis of trust relations among their members. One does not become a member of such organizations through formal selection, nor because of selection by the professional community, but by participating in a community of practice that is entered on the basis of the (relational and reputational) social capital (Coleman 1988) possessed by newcomers.

For the two most recent newcomers at the centre, Valeria and Ciro, in fact, access was made possible by personal relations which drew on social capital. Valeria, had met Paolo while she was at specialization school and he was working at the university where she was specializing. Their collaboration began externally to the centre and then stabilized and developed within it, when Alex, the second gynecologist, decided to leave the centre and a post fell vacant. Valeria was, therefore, not a novice in the profession when she joined the centre.

The only novice at the Beta centre was *Ciro*, who had been only sporadically present since he began working on his thesis 3 years previously. *Ciro's* position was distinctive, because he was present in the operating theatre as an intern, so that he actively participated in the practice. As *Ciro* specified: "*I am not an assistant. I collaborate with the operating theatre's work*". This specification is important because it highlights *Ciro's* position as a novice with respect to the centre and to the profession. *Ciro*, in fact, was supervised in his learning process through constant explanations of activities and instructions on how to do the work. During the period of observation, *Paolo* – while working in the operating theatre – frequently directed *Ciro's* attention to the monitor on which uterus and endometrium could be seen, showing him their normal shapes and giving advice on how to recognize them.

Learning how to see images on the ecograph monitor, in fact, is one of the practices most difficult to acquire in both reproductive medicine and medicine in general. According to *Ciro*, he had difficulties in recognizing images on the ecograph screen because he only sporadically engaged in the activity: gaining experience in this field meant "getting an eye for it", developing visual skills.

A very similar account was also provided by *Marco* in relation to his experience of learning laboratory practices: "*There are no schools, books or handbooks; these things you only learn with practice. I spent a year and a half watching what they did; but if they don't make you do it, you don't learn*". *Marco* then explained to me that at the beginning of his career he had gone to a centre in London to learn the techniques. However, the manager of the centre had commercial relations with an ART centre in the south of Italy and situated in the same city from where *Marco* came. For this reason, the manager was afraid that, once *Marco* had learned the techniques and returned to Italy, he would open his own centre in the same city and become a direct competitor of the centre with which the manager collaborated. *Marco's* learning process had, instead, been facilitated by his friendly relations with the two biologists at the centre: "*They were a Jamaican and an Australian girl. We made friends, we went out together, we went to the pub, and so on*". In *Marco's* story, it was his personal relationship with the two biologists that enabled him to learn what to 'do': "*One of them suddenly asked me: 'have you ever cleaned an oocyte? No. So clean one'*".

This further episode shows how induction to the profession was closely tied to trust relations established both internally and externally to the centre. It took the form of 'seduction' into the profession by peers. This process of developing a passion for the profession, in fact, seems to be the factor that brings novices into its core (Gherardi et al. 2007).

The induction to the practice described (learning how to 'see' an ecograph or clean an oocyte) is situated in the specific context linked with the performance of the work, and well represented by the concept of situated curriculum. There is a body of practical knowledge required to become an 'expert'. This knowledge is eminently tacit and managed collectively by the community of practitioners where novices learn. Hence, induction to the practices of the gynaecological profession at the ART centre offered an opportunity to become expert in the area, depending on the difficulties inherent in the contingent situation and on the novice's ability to

grasp the learning opportunities offered to him. What novices learn depends on the actual practices where they are involved, and on the quality of their participation. Instructions and micro-explanations are dispensed wholly at random, in the sense that they depend entirely on situations as and when they occur.

6.6 Bioartlife: When the Organization Has a Vision

Bioartlife is a large, private ART centre. It consists of a main centre and six satellite (external) centres, whose work is organized in cycles. This means that while the main centre is always open (including weekends), the satellite centres concentrate the core part of their work (i.e. the surgical part, laboratory fertilization and the transfer) in a single week. The frequency of the cycles depends on the number of cases to be treated by each centre. The satellite centres are situated in private clinics staffed by gynecologists and biologists from Bioartlife (who travel between the clinics) and nurses and ward attendants provided by the host clinics. Bioartlife performs around 1,500 treatments per year, half of them at the main centre. It follows, therefore, that Bioartlife has a large staff (around 50 people). It comprises 15 gynaecologists (working internally and externally), 15 biologists (internal and external), 1 psychologist, andrologist, anesthetist, president, storeperson and administrative director, 3 administrative workers, secretaries and nurses, 2 ward attendants, and 4 receptionists. All the gynecological staff were trained in the same university department and are directed by one of the best-known clinicians in the field, who is also the scientific advisor to the centre and has a private office at the Bioartlife centre.

The professionals who started to work in the satellite centres had acquired previous experience in the field of reproduction. The main part of their induction process was their integration with the internal team, which came about by standardizing ways certain procedures and administrative activities were performed. For instance, as the administrative manager said, at one of the last external centres to enter the network, the clinic concerned already had a team consisting of a doctor and a biologist: *“They were obviously professionals who had already worked in this field for a long time, and so the process was more rapid, but nonetheless they underwent an evaluation phase. In this case, they were only required to attend the centre in order to harmonize ways of doing things.”*

During the observation period at the main centre, the sole newcomer (who had been hired only one month previously) was a person assigned to develop a new kind of network with gynecologists who had not previously worked in the specific field of fertility. The work of the new employee was to establish and maintain new relationships with external gynecologists, to increase the number of potential patients. These external gynecologists had a particular position, because they were not (and probably would never be) members of the organization, but they underwent a kind of induction process to work in partnership with the centre. The main activity required of an external gynecologist was the first phase of ovarian monitoring. The centre wanted to give its patients the opportunity to be supervised in the first part

of the process by their own gynecologist or one near where they lived. For this purpose, the external gynecologist, who did the material work, and the internal one, who decided on the therapy, had to collaborate. External gynecologists were not allowed to interfere with therapy management, because responsibility (and power in the relationship) pertained to the centre. For these reasons, the centre was trying to stabilize the relationship between the centre and internal gynecologists with the external gynecologists through a process whereby they monitored patients in a specific way required by the centre. They had to have some specific technologies; they had to follow the instructions given them by an internal gynecologist; and (possibly) they should have a day of induction into the centre when they were supported by the internal gynecologist who would be their referent.

To sum up, the organization established different kinds of routines for the induction of internal staff and external fixed partners in order to ensure control over desired behaviors and transmission of the organizational culture. For all these people, induction was both the process and outcome of a practice in which the organization, the various professional occupations and the peer group were involved, but the organization sought to exert formal control over both the selection process and socialization. For instance, the centre adhered strictly to the standards required by quality certification. According to the description given by the administrative manager, the certification quality rules converged with the organizational ones prior to them: *“The quality discourse has done nothing but induce us to formalize and better specify things that happened in substantially the same way before. The inception processes of both the doctor and the biologist took a very long time, at least one year. I mean, the specialist gynaecologist expert took around a year to familiarize himself with our work model, with our methods. During that year, he obviously passed through increasing levels of autonomy. However, this is a process that cannot simply be studied in a book; you have to acquire an experience and familiarity with these things, which necessarily take a long time.”*

These standards were required not only of medical staff. A new non-medical member of staff shadowed a colleague for a week when they arrived so that they had time to adjust to the job. At the same time, participation was encouraged at social occasions (such as birthdays or other kinds of celebration), social dinners and parties organized by the centre. Induction to this centre involved a tacit dimension of what being a member of the centre meant: sharing professional behaviours and ethical assumptions embedded in working practices. In many interviews, workers at the centre used expressions such as “we do this...”, “we don’t do this...” to signify their involvement in, participation in, and (at least declared) agreement with the centre.

6.7 Three Models of Becoming a Professional

When the induction process is considered as a social practice – that is, in terms of how it usually takes place in a given organization. It assumes different patterns according to the type of organization, and, therefore, according to the ecology of power relations among the three principal agents of the process.

Table 6.1 A comparison between induction practices

Name of the centre	Type of organization	Size	Main agents in the induction practice	Model of induction
Sisma	Public university centre	Medium	The professional community	Socialization precedes selection
Beta	Private centre	Small	The community of practice	Professional seduction
Bioartlife	Private network organization	Big (network of six centers)	The organization	Organizational routines for specific competences

The three case studies that we have presented illustrate three different models of induction (Table 6.1):

- In the professional bureaucracy (Mintzberg 1979) of a university hospital, the professional community exercised almost complete control over the induction of newcomers, who entered the profession first and only, thereafter, the organization. In this case, socialization preceded selection, and the organization did not envisage a formal trajectory of accompaniment upon entry. Moreover, the community of practice constituted a ‘recalcitrant’ socialization agent because the competitive environment regulating access to selection made the sharing of knowledge more forced than freely available to newcomers.
- In the small private organization created by a professional or a group of professionals, the induction practice was almost exclusively managed by the community, and induction into the organization coincided with induction into the profession. In this type of simple bureaucracy, selection took place on the basis of trust relations, so that the type of social capital possessed by the newcomer was decisive for entry. The professionals also controlled the situated curriculum (as in the previous case) which produced the effect of induction/seduction. Passion for the profession and the professional vision were transmitted through participation in working practices because the work environment was collaborative and, in the absence of competitive power relations among peers, knowledge was freely shared.
- In the large network of organizations, the administrative area predominated over the professional one. In this case, the organization had devised formal routines to favour the induction of all competences (commercial, administrative, and professional) within the organization. These arrangements were deliberately created by the organization in order to transmit the organizational culture and to control the network’s performance from a distance. These arrangements were flanked by induction to the profession, which was undertaken by the professionals, although they were subject to close control through the standardization of procedures via the quality control system. Finally, the community was the main agent of socialization as a tacit process. Organizational identity formation and cooperation among peers might or might not come about because the environment was not competitive. To be noted, however, is that, for the community, provenance from

the same university, and even the same department, meant mutual knowledge and development of a sense of belonging. But this access also signified the existence of an “old boys’ network” and of an organization which had a tacit preference among its selection criteria.

We conclude by pointing out that the ‘same’ practice assumes very different situated features, and that a practice-based approach is able to bring out the ecology of actors that locally stabilize a situated practice and reciprocal power relations.

We now turn to how the tensions and the power games between all the actors in the ecology of professional practices may shape the becoming of a professional.

6.8 Becoming a Professional Within a Field of Tensions

The illustration of three empirical contexts allows us to stress the main limitation of both the organizational socialization and community of practice approaches. Both literatures conceive the learning process in a linear way, be it a trajectory in becoming a competent member, or be it a process of peripheral legitimate participation. The advantage of a practice-based approach, on the contrary, consists in giving primacy neither to the subject, nor to the negotiations that take place within the texture of situated working practices, nor to the tensions and contradictions that are generated in the interactions of all the humans and non-humans involved in the ecology.

The idea that tensions are important triggers for learning is put forward by Elkjaer and Huysman (2008: 171) when they note that ‘learning as participation is oriented towards the inclusion of newcomers into communities of practice, rather than the disruptive and confusing elements of admitting membership to newcomers. This means that the gaze is directed towards processes of adoption and adaptation rather than the tensions that may arise from newcomers’ (and others) participation in organizational life and work’. Similarly, within activity theory, the role of contradiction is central for expansive learning to occur (Engeström 1987; Miettinen and Virkunen 2005). When contradictions generate disturbances, problems or break-downs, practitioners elaborate some working hypothesis for a more advanced form of activity or a zone of proximal development that may solve the contradiction. Therefore, we can say that within both a pragmatist approach to learning and activity theory the active role of the subject who enters the organization and takes part in an activity system is acknowledged; and with it the idea of tensions, contradictions and power games is introduced. A practice-based approach looks at how the becoming of a professional is shaped following the resolution of tensions or their coexistence.

From the illustration of the previous three organizational contexts we can appreciate how the process of becoming a professional is accomplished, depending on the situated curriculum that the local community uses, and how the organizational context may vary according to who is the main agent of socialization for the newcomer.

In any case, we see how misleading is the image of a dyadic organization/individual relation that is traditionally portrayed in the organizational socialization literature. On the contrary, we have seen that at least three main agents are at work: (i) the organization, (ii) the community of practice and (iii) the profession. These do not include the individual as an active actor and the material world of artefacts and technologies. Finally, we should not forget that the becoming of a professional does not begin as these individuals enter an organization, because their educational training is already part of the same socialization process. Nor does that the process take place only within the organizational boundaries, because the social world of a profession is wider and it includes not only the professional associations and their power of control over the professionals and on the educational curriculum, but also the development of a professional ethics and aesthetics that contributes to the institutionalization of a professional power and network of political interests.

We do not have enough space here to fully develop the role of materiality in shaping power relations in intraprofessional networks, nor to illustrate how professions and professional practice change in relation to technological innovation. We have done this elsewhere (Gherardi and Perrotta 2011) for more detailed treatment in relation to assisted medical reproduction technological changes. Here, we discuss how the becoming of a professional takes place within a field of tensions and through the provisional and always unstable resolution of tensions.

We shall discuss the main tensions at the following levels: (i) within the individuals and their positioning in the field; (ii) within organizational control and professional control; (iii) within managerialism and professionalism. Our implicit assumption and our critique of the traditional literature on professionalism is that the process of becoming a professional is inherent to the entire working life of individuals and continues throughout their careers.

The focus on individuals allows us to recall that the concept of becoming has its roots in post-structuralism and Marxism (Carlsen 2006: 133), and to consider the constitutive nature of language and structures of meaning, in collective mobilization of beliefs and habits of action as a result of new experiences obtained through interactions.

In a study of the induction practice for becoming customer service officers in a bank, Bjørkeng and Clegg (2010) propose two concepts that illustrate the dynamics among the newcomers, the organization and the profession. The first is authoring acts – the inductees’ processes of making sense of themselves as practitioners – and the second is performative acts, i.e. all acts constituting the object or process of which they are part.

Becoming a practitioner involves narrating self and practice, and narratives are not one-dimensional representations of a reality (Cunliffe 2001); rather, they are multi-voiced, contextually dependent, ambiguous, equivocal constructions of experience, always negotiated between the inductees, the work, and whatever they try to communicate to someone in a given context. In authoring the bank as a familiar place, and themselves as practitioners, the inductees recognise themselves as such, so that by the end of the induction course they have mastered the formal routines, tools, and methods of their working practices.

Another facet of the authoring act that is seldom addressed concerns becoming a gendered professional. Professions are also marked in terms of masculine/feminine cultures, and practicing gender at work (Martin 2006) means also knowing how to perform gender in appropriate ways, where ‘appropriate’ means in accordance with the professional culture and in accordance with the professional’s gender identity. An example of how a young female consultant – Omega – entered a male-dominated profession and community of practice is reported in Bruni and Gherardi (2001). The tensions on her side and the rent position enjoyed by her (male) colleagues were part of Omega’s becoming a professional and learning what is called ‘gender switching’, i.e. the unconscious choice of adhering to a masculinist gender language and resisting it at the same time through appropriate gender displays. Too often neglected in the discourse on becoming a professional are both the gender identity of the practitioner and the practicing of gender at work and in the professional culture. A profession is also structured along gendered lines and gendered activities that here we mention only in passing (Jones 1998).

What we can interpret through the concepts of authoring and performative acts is the interplay and the tensions between becoming a practitioner and constructing practices. In this process, the aspect of constructing professional practices is also linked with the capacity to imagine practices. By considering ‘becoming’ as the imagining of practice, Carlsen (2006: 135) places the authoring of identities within the lived experience of everyday work and its irreducible present-past and present-future temporality. Imagination of practice refers to:

the manner by which an organizational collective assigns social weight to an act, an event, or a stream of acts and events within their living experience by selective attention, appropriation, extension, and amplification, in sum, the storied construction of shared fields of meaning and engagement. Participating in the imagination of practice is, therefore, a collective act in which the becoming of the professional and the performance of the practice co-evolve in the active reconstruction of the past in light of present circumstances and anticipations of the future. (Carlsen 2006: 135)

The second source of tensions in becoming a practitioner is located within the exercise of control in organizations. In the illustration given in the preceding sections we described how Sisma – a professional bureaucracy – relied mainly on professional control, while Bioartlife made use of control over behaviour.

Controls in organizations are necessary to ensure that organizational members direct their efforts towards organizational goals. A classic source of tension in organizations is the relation between administrative managers and professionals, and the inappropriate use of one form of control may lead to organizational ineffectiveness and conflict in interpersonal relations. The choice between behaviour control and professional control is emblematic of how the becoming of a professional is shaped in the relationship between superior/subordinate and, as we shall see next, in the tension between managerialism and professionalism.

Behaviour control consists in close monitoring and evaluation of subordinates’ actions by superiors. Whilst this control has the advantage of being direct and immediate in giving feedback and correcting deviations, it has the disadvantage of being costly and limited to the superior’s span of control. It may, therefore, become

inefficient, and may even reduce innovation and lead to risk-adverse behaviour (Snell 1992). In particular, if behaviour control is exercised over a long period of time when subordinates expect to be professionally controlled, they will perform at a lower level because controls are not aligned with their expectations (Rowe et al. 2012). Professional control has the following characteristics: (i) organizational reliance on self-enforced control, (ii) features like tacit in-group monitoring, and (iii) the symbolic or explicit social sanctions applied to those who do not respect norms. Professional control is more appropriate than behaviour or output control when intense socialization is present and organization-specific skills have been developed (Rowe et al. 2012: 64).

The becoming of a professional encounters the tensions and the gap in expectations between the different forms of control. In fact, the organizational use of behaviour control or output control when professional control is expected may lead to resentment, frustration, counterproductive behaviours and various forms of resistance. On the other hand, professional control is based on a socialization process rooted in long-term employment, rigorous selection and training. All these circumstances are now at risk because the increasing uncertainty, the severance of the employment relationship, and the rate of turnover induce a preference for behaviour control in organizations. Traditional professional control is also challenged by the tensions between managerialism and professionalism.

The conflict between organization and profession has been widely explored. Nevertheless, the terms of this tension are challenged by the changing organizational context of professional work (Farrell and Morris 2003). The reconfiguration of the two fields has been proposed under the label of 'organized professionalism' (Noordegraaf 2011: 1351), which represents professional practices that embody organizational logic. Professionals may take up organizing roles, and professional workers may develop organizational capacities, in order to deal with changing work circumstances. An emblematic example is provided by health organizations where managerial innovation tends to modify traditional professional practices, assigning them new goals and thus reducing professional autonomy. While some authors have seen a challenge to the decline of medical dominance, Freidson (2001) prefers to see a process of 'restratification' whereby an elite stratum of medical professionals is co-opted into management so that the profession can maintain its power. This dynamic also influences multi-professional teams, where health and social integration care generate conflict over the respective jurisdictions, and different professional cultures generate interprofessional tensions (Tousijn 2012). In multi-professional teams, many professionals carry out managerial work. Therefore, what can be deduced concerns not much the decline of medical dominance as the reconfiguration of the professions both internally and in relation to the changing context of other interrelated professions. The 'new' professionalism is constructed more from within than from above (Evetts 2009, 2011).

A final point to be made in regard to all the tensions reflected in the becoming of a practitioner is to acknowledge the professional associations that are external to the single organization in which the professional works but greatly influence the power that a profession may exert on the culture and the practices of that professional.

Regulative bargains between professional associations and the state have enabled professional groups to regulate their own work by establishing meaningful professional standards. Nevertheless, professional associations are just one actor in the institutionalisation process, and their power is challenged by changing employment relationships (Greenwood et al. 2002; Muzio and Kirkpatrick 2011).

When we consider the field of forces that keep together the individual professional, the organization, the community of practice, and the professional association, we see that the process of becoming a professional is not linear, is not harmoniously developmental, is not simply the effect of a socialization process, and does not end in becoming an expert. The concept of becoming includes the idea of an open-ended process in which tensions and contradictions are collectively elaborated and temporarily resolved within a field of struggles.

6.9 Conclusions

Whereas the lens of socialization focuses on the shared norms, values and standards that the professional newcomer internalises to become a competent member of a professional culture, the lens of the community of practice focuses on their peripheral legitimate participation, and both of them privilege the point of view of the individual in relation to the collective. The lens of induction is positioned instead on the eye of the organization and its mechanisms of selection, training and control. Finally, the lens of professional control makes it possible to consider how the professions may enjoy autonomy within the organization and how, through the regulative bargains of their professional associations with the state, they try to exert control on the educational system and maintain professional boundaries *vis-à-vis* interrelated professions. Different lenses not only represent distinct interpretative frameworks; they also express the points of view and the tensions that shape the field of professional practices.

As individuals become professionals throughout their working lives, their authoring and performing acts are accomplished within a field of practices marked by tensions and contradictions among the main agents just mentioned. The process begins before formal entry into an organization, and it continues with the induction into the organization. However, to author an identity as professionals, these individuals become seduced by the profession and author themselves as individuals who 'are' professionals and adjust to the gendering of the profession. In this process, becoming a practitioner and constructing practices is also linked with the capacity to imagine practices, since the authoring of identities emerges within the lived experience of everyday work and its irreducible present-past and present-future temporality.

Through three empirical examples from the medical field we have argued in favour of the situatedness of the becoming process and the difference that the organizational context exerts in shaping the path of the becoming. We have shown that, in a professional bureaucracy, professional socialization may anticipate the moment of becoming an organizational member, whilst in a small professional organization

it is the community that induces and seduces the newcomer, and that in a large managerially controlled organization, induction may be an explicit practice negotiated with the community of practice and the individual.

A final caveat is necessary in regard to the limits of a practice-based approach to induction. Whilst this approach proves its worth in the interpretation of the situatedness of becoming, it implies that any situated practice has to be described in relation to its context, so that we can generalize about it only through its modelling. On the one hand, we need further research to understand what is common across different organizations. On the other hand, we must further test the theoretical framework that we propose, because a practice-based approach to induction is an innovative contribution to the literature and it should be further confirmed, disconfirmed or refined.

Chapter 7

Productive Systems of Professional Formation

Jim Hordern

Abstract Pathways and processes of professional formation are influenced by relations between professional associations, educational institutions and employing organisations, notions of professional knowledge, and the organisation of professional work. This article advances the use of a productive systems approach to the analysis of professional formation, articulating this with concepts developed in the sociology of educational knowledge and workplace learning that identify how knowledge is appropriated and transformed for professional practice. It is suggested that at different stages of the ‘production’ of professionals the dynamics of formation alter as certain organisations or actors exercise particular influence over a given process or activity. The maintenance of certain forms of social and technical infrastructure, interwoven throughout the stages of production, may facilitate co-operation, aligning goals and reducing tensions in the process of formation. The role of the professional association as a vehicle for formulating the specific logic of the profession, and for brokering relations between key organisations, is examined. Examples from two professions based in the United Kingdom illustrate how the character of professional formation is shaped by how knowledge is valued, the capacity to involve employers in formation processes, the level of engagement that professionals enjoy with other professionals as part of formation, and by the degree of specificity or flexibility legitimated in the pathways constructed.

Keywords Professional formation • Professional associations • Professional knowledge • Productive systems • Recontextualisation

7.1 Introduction

Research has outlined how the development of the professions and the influence of notions of professionalism have led to particular patterns of work and organisation. Attention has been drawn to the tensions between the logics of bureaucracy, market and professionalism (Friedson 2001), the growth of ‘organisational’ and ‘corporate’ modes of professionalism (Evetts 2004; Muzio et al. 2011), struggles for ‘jurisdiction’ between professions (Abbott 1988), and how professionalism is used to exercise control and discipline at work (Fournier 1999). Professions and professionals can be seen as having specific levels of influence in organisational fields (DiMaggio and Powell 1991), initiating or resisting change and institutionalising forms of work and organisational practice (Scott 2008; Suddaby and Viale 2011). Professional associations emerge as key players as professions change (Greenwood et al. 2002; Noordegraaf 2011), formulating and co-ordinating the frameworks through which professionals are qualified and accredited (Millerson 1964), adapting to, and shaping, the prevailing logic in which the profession operates, and managing transitions to new pathways of formation (Lester 2009). Although the basis for professional legitimacy differs with national contexts, models of professional association with Anglo-American origins have strengthened as a consequence of globalising forces and geo-political change (Evetts 2003; Faulconbridge and Muzio 2012), articulating with growth in forms of ‘civil society’, the rise of a global middle class and the expansion of mass higher education (Anheier et al. 2001; Altbach et al. 2009).

With a greater focus on individuals and their work environments, studies of the development of professional capability and competence have often sought to identify ‘stages’ or ‘steps’ that practitioners pass through in order to ‘become’ professionals (Dall’Alba and Sandberg 2006). Drawing on work in psychology, cultural anthropology and micro-sociology, these and similar studies have indicated the importance of the relation between practitioners ‘in formation’ and the practice contexts in which they become increasingly embedded (Brown and Duguid 2001; Guile 2010). Professional formation can here be construed as a question of the development of skill, expertise and identity (Eraut 1994; Beck and Young 2005), a process in which metaphors of ‘acquisition’ and ‘participation’ (Sfard 1998) reflect professional learning, knowing and knowledge development. These insights may, or may not, influence the development of formal pathways of professional formation that are constructed by professional associations, educational institutions, employers and state organisations.

Much professional formation is a combination of periods of time spent both in formal education settings and organisational contexts, resulting in practitioners ‘in formation’ engaging in cultures that may emphasise both ‘acquisitive’ and ‘participative’ modes of learning (Sfard 1998). Research into communities and networks of practice (Lave and Wenger 1991; Brown and Duguid 2001; Fuller et al. 2005) establishes some of the meso-level conditions that may facilitate participative learning in workplaces, and thus provides a framework for analysis of professional development at work. Radical participative models may assert that formal educational contexts are merely other ‘communities’, albeit often hindered by supposedly ‘redundant’

acquisitive metaphors embedded in the culture of educational institutions (Sfard 1998). Some professional associations may thus suggest that formal 'education' has little to offer, developing new frameworks for accrediting professional capability that conceive professional formation solely in terms of workplace experience.

However, retaining a command of the 'abstractions' that provide a resource to tackle the problems encountered by professional work can be considered a necessary condition for the viability of a profession (Abbott 1988). Where a profession has a technical and scientific base, strong connections often exist between the production of knowledge and its use in professional work (Foray and Hargreaves 2003), driven by scientific research, technological advance and the demands of the clients of professionals for increased quality and efficiency. For example, in the healthcare or engineering professions, professional competence is only sustained if practitioners continually engage with new knowledge (Eraut 1994; Becher 1999; Friedson 2001). The growth and sustenance of professional 'networks of practice' (Brown and Duguid 2001) that can refine and nurture expertise is built upon the foundations of formal scientific and technical knowledge that qualify practitioners for participation. The 'rails laid by practice' (Ibid., p. 204) provide the social and technical infrastructure that enables knowledge to circulate and productive networks to form. However, effective participation in a network relies on participants being conversant with a body of knowledge and how this knowledge is utilised in practice. The 'acquisition' of formal knowledge and the availability of opportunities to participate in relevant 'networks' are thus both crucially important for professional formation.

The important relationship between, and different roles of, formal educational knowledge and the 'art of knowing' (Duguid 2005) is not necessarily recognised, or reconciled, in the formalised processes of professional formation. A traditional process of institutionally based education, remote from the world of work, separated from and followed by immersion into practice environments, can lead to problems with recognition of the different roles, purposes, and 'degrees of situatedness' (Young 2006, p. 115) of different types of knowledge. A lack of practice engagement may also underplay the importance of practitioner capacity to appropriate and transform, or 'recontextualise', knowledge for use in new contexts (Evans et al. 2010; Guile 2010). On the other hand, total immersion in practice without the opportunity to access knowledge beyond the immediate work contexts leads to a neglect of the forms of knowledge that enable practice innovation and the making of connections with other disciplines, practices and contexts (Wheeler 2010; Muller 2009). How 'knowledge' and 'knowing' are conceived and articulated by associations, employers and educational institutions has considerable influence on how pathways of professional formation are structured. How different forms of knowledge are 'enmeshed' (Breier 2004) or interrelated in education and practice may or may not be recognised and enacted in the structures, curricula and pedagogy involved in professional formation.

The arguments above suggest that professional formation is constituted through the relation between education and workplace practice, and shaped by the wider context in which professionals operate. This article discusses an approach that can be used to interpret the context of professional formation, drawing on research into

the sociology of professional and workplace knowledge and learning, the changing dynamics of professional practice, and the roles and relations of professional associations. The productive system approach illustrated below is seen to have particular value as a consequence of its capacity to identify changes in levels of mutuality and relative power at different stages of formation, and to scrutinise the roles of key agents and the explicit and implicit contracts they hold with other bodies. Using examples from two professional bodies based in the United Kingdom representing surveyors and human resource professionals the structure and stages of different pathways towards professional accreditation are outlined. It is argued that pathways of formation are influenced by the infrastructure of social and technical relations that support formation, and considerations of what constitutes valuable professional knowledge. Forms of knowledge vary in their significance depending on the pathway, and this is reflected in the attention given to differing sites of knowledge production and processes of workplace and learner recontextualisation. The analysis of a productive system enables scrutiny of the context of formation, and the identification of how different pathways to professional status are predicated on specific conceptions of professional knowledge and competence.

7.2 Pathways to Professional Formation

Certain professions and vocations have structured pathways of formation that, historically, have been mandatory for those who wish to achieve full accreditation as a professional. This is particularly true of the more 'traditional' professions, such as Medicine and Law, where higher level qualifications followed by periods of gaining experience under the supervision of more experienced practitioners have been the norm (Becher 1999; Friedson 2001). In contrast, other occupations, particularly those where professional qualification has not been essential, or where experienced people from other walks of life have been able to demonstrate their competence relatively easily, have operated more flexible processes of recognition. For example, in many of the business related corporate professions the notion of any structured 'formation' may be largely irrelevant, when 'professionalism' is dominated by prevailing organisational or market imperatives (Muzio and Kirkpatrick 2011; Evetts 2004, 2011). In such cases the mode of work organisation may have a greater impact on what is valued as professional knowledge.

With the changing nature of work some professions have struggled to delineate their boundaries with cognate professions that have similar knowledge bases, and to establish routes to accreditation that reflect all routes to professional competence. The notion of 'jurisdiction' is significant here, with professions competing to be recognised as having authority over an aspect of work (Abbott 1988). However, as technological, regulatory and social changes fracture old boundaries, there is a constant need to re-delineate jurisdiction, negotiating to capture a segment of the shifting sands of contemporary economic life. Thus professions may feel compelled to make pathways to professional status more flexible or more restrictive depending on the

changing nature of work, the knowledge required for professional practice and the strength of forces of competition and integration with other professional domains. Greater flexibility may have the advantage of facilitating the recruitment of new members from other professions with similar knowledge bases, whereas restrictiveness may be perceived as maintaining greater exclusivity or may be a necessary response to regulatory change.

Pathways of professional formation may also need to adapt to the level and nature of demand for entry into the profession, to labour market circumstances and changing patterns of formation elsewhere, and to demands for accountability and transparency. If a pathway to formation is considered to require too much personal investment for too little reward in terms of professional status or income, it may be necessary for a profession to consider making changes to maintain the quality and volume of recruitment required. On the other hand, if there is excess demand or a perceived dilution of quality of prospective professional, there may be calls for making entry more difficult, or to make aspects of formation more challenging. The pool of available recruits to the professions is arguably deepening and broadening, with considerable increases in graduate numbers in many countries, and the greater flexibility and mobility of skilled labour in the global economy (Brown and Hesketh 2004; Brown and Lauder 2006). However, levels of demand for entry to a given profession do not only depend on economic prospects, job security, levels of autonomy and difficulty of qualification. Certain professions, for example architecture, retain high status and high demand despite patterns of job insecurity and underemployment (Becher 1999), due perhaps to persistently attractive socially-constructed notions of certain forms of work.

The degree of flexibility available in formation will also depend on whether a 'licence to practice' system regulated by statute or through voluntary agreements exists, with some pathways of formation bound to comply with rules regarding experience and qualification content. Meanwhile, increasing requirements for professional accountability and transparency (Power 1999; Fournier 1999) translate into an onus on professional associations to clearly outline the standards and competences expected of practitioners, and for practitioners to evidence their continuing professional development (Lester 2009; Friedman and Phillips 2004). Transparency can thus provide a guarantee of quality to the profession's 'clients', which may include the public and government, as much as to potential recruits to the profession from universities, schools or the wider labour market. In some professions an academic qualification will be a pre-requisite for, or even designate, professional status, whereas in other professions accreditation processes may be purely based on experience at work. The increased significance of qualifications has been a characteristic of professional life (Millerson 1964; Friedson 2001), and these qualifications can involve various combinations of academic study and workplace experience in an integrated fashion (Lester 2009) that aims to maximise opportunities for the practitioners in-formation to perceive the relation between the professional knowledge base and the contexts of its application.

Lester (2009, p. 228) usefully identifies four categories of professional formation pathways, labelling them 'sequential', 'parallel', 'integrated' and 'experiential' routes.

Sequential routes involve full time study followed by a period of time under supervision in practice, corresponding to the 'traditional' formation pathway for many of the classical professions. The parallel and integrated routes involve concurrent combinations of study and workplace experience over a period of time, with the 'integrated' route specifically focusing on maximising the connection between study and practice. The experiential route, however, is based on learning through practice, with additional independent study or short courses as necessary. Lester (2009) notes how professions differ in the number and type of pathways available, and also in the volumes of recruits using those pathways. Certain assessment and accreditation processes predominate depending on the specificities of the route, including examinations common where formal education and training is involved, and forms of practice-based assessment, which may also be used to ensure ongoing proficiency (Lester 2009). For those professions with more flexible entry standards, the submission of evidence of prior qualification, comparable professional membership or experience may be sufficient.

There is also evidence that pathways to professional formation are being opened to those who have entered the occupational field in supporting roles. These pathways may involve study support if necessary, or new forms of mentoring, short courses and assessment that are specifically designed to support a 'step-up' route to full professional status. The accountancy professional bodies in the U.K. have ensured that a work-based technician route is integrated into pathways to full professional membership, as discussed by Young (2011, pp. 271–273), and the U.K. legal profession is considering opening a new pathway to full professional status via a 'higher apprenticeship' (Skills for Justice 2013), as part of broader trends that challenge traditional models of legal education (Wiseman et al. 2012). U.K. based Professional bodies with global ambitions such as the Chartered Institute of Personnel and Development and the Royal Institute of Chartered Surveyors have recently introduced 'Associate' levels of membership that facilitate progression to full membership. These routes may enable those staff in assistant or technical support roles in a wider range of organisations to access the resources of their professional community, and to broaden practice networks within the professions concerned (i.e. see Goodhead 2010 for discussion for Chartered Surveyors).

Such developments may not be solely about benignly supporting individual career progression, however. New entry pathways can be seen as aligning with the 'professional projects' (Larson 1977) that professions develop in pursuit of greater status, positioning the professional body in the ongoing competition for members between organisations both within an occupational field and between cognate professions. They may also reflect changes in the division of labour that professions feel compelled to adapt to in national contexts where regulatory constraints on occupational change are limited, in contrast to continental European models where the state provides a greater bulwark against change (Karseth and Nerland 2007; Torstendahl and Burrage 1990). A greater diversity of pathways to professional formation can also circumvent or provide alternatives to traditional graduate entry routes, and demand for these alternatives may grow in countries where the cost of higher education is increasing (Altbach et al. 2009; Universities UK 2012). Employers

may also support the expansion of alternatives as they scrutinise the cost of employing graduate level staff, and recognise the potential for engendering commitment to organisational objectives by supporting formation internally. Moreover, the growth of flexible experiential routes that shift the burden of professional formation onto practitioners can be seen to reflect changes towards the 'self-management' of careers (Grey 1994), and the salience of attitudes towards the development of professional knowledge that are 'learner-centred' and routed in social constructivism. This flexibility and learner-centeredness may articulate with an increasing 'genericism' in the professional knowledge base and a concomitant weakening of professional identity (Bernstein 2000; Beck and Young 2005), as relationship management and client-focus skills are foregrounded in professional competency frameworks, overshadowing greater engagement with disciplinary knowledge. Thus, practitioners entering a profession via work-based experiential routes may lack the opportunities to acquire the types of knowledge that enable their full participation in the professional community, and the wider labour market, over the longer term.

7.3 Using Productive Systems to Interpret Professional Formation

Following from the argument developed above, there is a need to develop approaches that can identify and characterise the factors that influence the pathways and structures through which professional formation takes place. The process of professional formation can be interpreted through the lens of a 'productive system' (Wilkinson 2002; Felstead et al. 2009) in which the forces of production 'combine in production' (Wilkinson 2002, p. 2), to create professionals with an acknowledged and valued level of capability. The notion of the productive system was originally developed by Wilkinson (1983; 2002) as a counterbalance to the perceived hegemony of neo-classical approaches to macro-economics. Wilkinson (2002) sought to challenge these on the grounds that a sustainable system of production required co-operation between those involved and some confluence of mutual interests to achieve 'operational and dynamic efficiencies' (Ibid., pp. 2–3). In so doing an analytical approach was developed which could potentially be used to analyse a range of industrial and non-industrial contexts which involved the pursuit of a shared objective of production. Wilkinson foregrounded the role of the social relations of production in 'determining the effectiveness of technical co-operation' (Ibid., p. 3), recognising that both 'mutuality' and 'power asymmetries' (Ibid., p. 4) will have bearing on the character of a given system. The productive system is historically contingent and continuously evolving, with each system 'subject to continuous change from the interactions among the technical, economic, social and political forces to which they are subject' (Ibid., p. 6). Using productive systems to analyse the context of learning at work, Felstead et al. (2009, pp. 19–21) introduced the notion of articulation between the 'structure' and 'stages' of production, with the 'structure' representing

the 'constituent network' (Ibid., p. 20) of actors interested and involved in production, and the stages the various steps involved in a work activity or organisational process.

Whereas Wilkinson (1983; 2002) focused primarily on macro-economic systems and Felstead et al. (2009) on analysing the context of learning at work, the objective of developing a productive system of professional formation is to concentrate on the forces which combine to 'produce' professionals through formal pathways to professional status. Wilkinson's 'forces of production' included 'labour', 'the means of production', 'the social system in which production is organised', 'the structure of ownership and control' and the wider 'social, political and economic framework' (2002, p. 2). Applying these to the context of professional formation suggests that 'labour' may include teachers, trainers or the professional themselves, whereas the 'means of production' may include mechanisms or pathways for education, training and accreditation, and the resources associated with these. The process of production of 'professionals', or what Abel (2003, p. 475) terms the 'production of producers', can be seen to proceed through a series of stages or steps that may involve studying in educational institutions and immersion in the practice of workplaces, usually punctuated by forms of accreditation or recognition of knowledge, skill and competence. Interpretation of the 'articulation' of the 'stages' with the 'structure' of the productive system (Felstead et al. 2009), and the conflict and co-operation which results, is essential to comprehending how and why pathways through the system are constructed, and for ascertaining the flexibility of the pathways, the roles of those involved, and the sustainability of the system. Building on the work of Felstead et al. (2009), the version of productive systems analysis presented here particularly emphasises the extent to which roles and relations change in the structure of productive *within* the course of the productive process as different stages are enacted (Hordern 2012, 2013b).

A structure of production of professional formation thus comprises a constellation of professional bodies, educational institutions, dominant firms and organisations that make decisions about pathways towards professional status. The interactions of these bodies are influenced by the 'norms of appropriateness' that are embedded in routines and practices of the profession and its dominant organisations (March and Olsen 2004; DiMaggio and Powell 1991), much of which may derive from the historical context and tradition of the profession. Together the constellation and the norms provide a structure which articulate with each stage of formation differentially depending on the nature of the stage. In other words, certain bodies, institutions, partnerships and relations may have particular significance at particular stages. Thus, an archetypal productive system of 'traditional' professional formation involving an initial degree qualification and a period of supervised experience, for example in Medicine or Law, could be characterised by high levels of influence from higher education institutions at the early stage followed by greater influence from employing organisations and the professional body at the latter stages. Analysis of the structure of production can also be seen as a means of illuminating the 'soft infrastructure' (Benner 2003; Amin and Roberts 2008) of social and technical relations that support the productive process, highlighting the distribution of trust and opportunities to 'expand learning' beyond the confines of an organisation (Fuller and Unwin 2010).

The configuration of relations in any given system may also lead to certain forms of explicit or implicit contracts which embed relations between particular actors (Friedman and Miles 2002), impacting on whether shared understandings of professional formation develop across the system or remain fragmented. The extent to which shared understanding develops may be particularly important in relations between employers and educational institutions (Reeve and Gallagher 2005; Hordern 2013a).

It would, however, be misleading to assume that the organisations and individuals represented in structures of production are inclined necessarily towards co-operation (Wilkinson 2002; Felstead et al. 2009). The development of agreed process is contingent on the recognition of mutual interests and decisions to pursue them, and these circumstances may be subject to changes in the social, economic and political environment. Thus, for example, employers, professional bodies and higher education institutions may recognise the value of co-operating in processes of formation, but may be reluctant to do so due to political or economic uncertainty. Equally, once pathways of formation become embedded they may acquire a degree of institutionalisation, with forces within the structure of production supporting their continued existence.

Professional formation involves the acquisition, application and transformation of different forms of knowledge, obtained from different sources and used in various contexts (Evans et al. 2010). A practitioner who follows a 'traditional' or 'sequential' route of a full time academic qualification at an educational institution followed by supervised experience and further qualifications in the workplace engages with knowledge differently from a practitioner whose route is entirely work-based or 'experiential' and may be located primarily or entirely within one organisational context. Processes of 'recontextualisation' occur, involving the appropriation and transformation of knowledge, in and between sites of knowledge production, curricula, pedagogy and workplaces (Evans et al. 2010; Bernstein 2000). The knowledge that is 'generated and practiced in one context' is therefore 'put to work in new and different contexts' (Evans et al. 2010, p. 246). Practitioners, as communities of learners or individuals, reshape knowledge for their own practice, bringing their own 'learning territories' or 'personal knowledge' into the context (Eraut 2007; Fuller et al. 2007; Felstead et al. 2009; Evans et al. 2010). Knowledge can be described as technical and cultural, conceptual and contextual, procedural and processual, academic and practical (Becher 1999; Eraut 1994, 2007; Muller 2009). Additionally, it can be explicit or tacit, or partially explicit, embodied in a range of tools, routines and practices (Guile 2010). It can also be specific to an immediate task, or relate to broader conceptions of the work process (Boreham et al. 2002). Pathways of formation therefore entail engagement with particular admixtures of professional knowledge, but individual practitioners may select, appropriate and transform knowledge differently depending on their own personal histories and inclinations.

Much work in the sociology of the professions maintains the importance of the link between academic knowledge production and the professional knowledge base, identifying a role for abstract knowledge in the ascription of social legitimacy to the profession and in providing a resource for meeting the challenges of practice (Abbott 1988; Friedson 2001). Institutional work identifies professions with 'theoretic

cultures' (Donald 2000 cited in Scott 2008) that define the profession and establish professional authority over a jurisdiction (Scott 2008; Abbott 1988). Meanwhile, sociologists of educational knowledge have asserted that knowledge acquired through academic disciplines should be clearly differentiated from knowledge acquired through 'everyday' practice (Young 2008; Muller 2009; Shay 2012). This work builds on Bernstein's (1999, p. 159) delineation between 'systematically principled' and 'context dependent' forms of knowledge, and Durkheim's (2008) identification of the significance of notions of the 'sacred' for the development of abstract thought and social structure. The formation of the professional knowledge base arises through the appropriation and transformation of knowledge from academic disciplines and the domain of practice to meet the requirements of the profession (Bernstein 2000; Barnett 2006; Muller 2009). The 'sacredness' of the professional enterprise is sustained through the formulation and maintenance of a viable theoretic culture that reflects both the socio-cultural hinterland of the profession and its changing role in society. However, the legitimacy this sacred knowledge base provides must be balanced with a functionality that enables knowledge to be 'put to work' successfully in practice contexts (Abbott 1988; Evans et al. 2010; Guile 2010). Professional associations, through the links they maintain with educational institutions, workplaces, and with professionals themselves, have a key role in achieving this balance. The following section examines the influence of professional associations in the process of formation.

7.4 The Role of the Professional Association in the Structure of Production

In systems of professional formation actors in the structure of production may include educational institutions, professional associations, employers, government or regulators, and unions or other representative bodies, some of whom may work in forms of partnership to deliver a particular stage of a formation process. The role of the professional association is posited here as generally having considerable impact on a productive system of professional formation, reflecting models of professionalism that are dominant in a variety of national contexts, and may be reinforced by supra or transnational processes (Faulconbridge and Muzio 2012). Of course this is by no means characteristic of all professions in any national context, as the role of governments or other professions may be particularly prominent in the shaping of formation for specific professions.

Historically considered a defining feature of the Anglo-American model of a profession (Millerson 1964; Abbott 1988), the association or professional body is customarily the vehicle through which professional change is subjected to 'intra-professional legitimation' (Greenwood et al. 2002, p. 61), and the forum through which professional education, culture, behaviour and standards are maintained (Noordegraaf 2011; Millerson 1964). Theories which posit professionalisation as a progressive process have identified the creation of a professional association

as a key indicator of professional organisation (Wilensky 1964). However professional associations are not static, unitary entities that conform to an ideal type. They can be heavily influenced by the interests of key employers within the professional field (Greenwood et al. 2002), causing the association to adapt modes of professionalism to the strategies of those employers and their responses to market conditions or technological change. They may primarily act to reproduce or conserve professional identity, or initiate and lead change to the profession (Greenwood et al. 2002, p. 73; Noordegraaf 2011). Professional associations may negotiate and iterate the pathways to accreditation, stipulating the standards required for professional status, and co-ordinating the contributions of educational institutions, employers and experienced professionals to 'produce' a professional. How the professional association envisages these contributions and partnerships, with an orientation towards inviting structured co-operation, or a tendency towards greater flexibility, reflects how the profession sees its objectives, social role, and connection with sources of knowledge.

In essence the professional association provides the forum through which the particular logic of the profession is maintained, iterated and translated into processes of professional formation, ensuring the 'sustained resilience of professional practices' (Greenwood et al. 2002, p. 62), but also supporting the profession more or less effectively to adjust to jurisdictional or organisational change over which the profession may or may not have some influence. Thus professional associations can both lead and be led by change, facilitating a shared reconceptualization and redefinition of the problems over which the profession has jurisdiction and providing a space for 'theorisation' (Greenwood et al. 2002, p. 74), or complying reactively to pressures from dominant organisations or factions within the profession, or the actions of other professions. The spectrum of available actions available will, in part, reflect inter-professional relations, which may be conflictual, co-operative, or characterised by implicit or explicit hierarchies (Abbott 1988). Changes in the system of professional formation may lag behind reform processes within the profession, as educational institutions and workplace activities struggle to adapt to the dictates of the profession. Thus the 'schooling and socialisation processes' of the profession may fail to cohere with the realities of professional work, and the pressures of organisational life (Noordegraaf 2011, p. 466). Relations between the agents and actors in the productive system of professional formation are therefore a vital factor in negotiating, agreeing and communicating change in the content and structure of formation.

The organisational context of work also matters for professional formation. Within larger organisations, culture and behaviours may vary between functions, and with different workplace practices (Brown and Duguid 2001), and there is the potential for tension between professional and organisational norms (Ackroyd 1996). For those working in smaller organisations, the importance of tapping into the networks of practice that are supported by the profession or by larger organisations often becomes crucially important (Becher 1999). Professionals may have the capacity to ensure that organisational forms and processes reinforce their professional dominance (Suddaby and Viale 2011). However, the nature of this capacity is surely

dependent on the extent of 'organisation' in the profession itself, as reflected by the efficacy of its representative bodies, in addition to the scope for maintaining forms of 'closure', protecting jurisdictions and controlling work within organisations (Abbott 1988; Ackroyd 1996). While doctors, accountants and lawyers may become 'lords of the dance' (Scott 2008) with the capacity to orchestrate work processes, those professionals with less influence are less able to resist the competing logics of the market or bureaucracy, compelled to comply and compromise in the ongoing reformation of their professionalism. Arguably, it is the professional association, representing the 'collective structure' of the profession (Greenwood et al. 2002, p. 75), that has the potential to reconcile the tension between professional and organisation imperatives, expressing this through professional education amongst other mechanisms (Noordegraaf 2011). The examples outlined in the following section demonstrate how professional associations seek to negotiate these tensions and formulate a specific logic that is perceived to meet the needs of their profession and its practitioners.

7.5 Two Professions and Their Productive Systems of Formation

In this section the productive systems of professional formation of two professions are discussed and compared to exemplify and expand on how productive systems operate. This serves to illustrate how various aspects of the social and technical relations interwoven between structures and stages of production promote different types of formation. The social and technical relations of production are influenced by a series of factors. These factors include how knowledge is valued by the profession and the concomitant pressures that arise to sustain the knowledge base, the capacity to tie employers in to professional formation processes, the level of engagement that professionals enjoy with other members of the profession and related professions as part of formation, and by the degree of specificity or flexibility legitimated in the pathways available. The extent to which a given profession can alter the circumstances of formation is also constrained by how the work of that profession is organised.

The two professions discussed here, surveying and human resource management (HRM), are governed by different professional associations and regulative frameworks in different countries. The foregoing discussion focuses primarily on the U.K. context, where the relevant professional bodies are the Royal Institution of Chartered Surveyors (RICS) and the Chartered Institute of Personnel and Development (CIPD). However, the examples also have relevance outside the United Kingdom, as the RICS also has a considerable international presence, including in Asia, Europe and the Middle East, and the CIPD actively recruits internationally and supports the growth of new national associations (Farndale and Brewster 2005). The RICS and the CIPD have much in common and yet differ significantly. Both are 'qualifying associations' that seek to represent and accredit their members, and to engage

actively in marketing the benefits of membership (Millerson 1964). Neither of the two professions are able to claim command of a domain of work, or jurisdiction, that can be legally enforced and thus both have to identify other resources in order to assert their professional authority (Scott 2008), as can be seen through the actions of their professional associations (Hannah et al. 2009; Gilmore and Williams 2007). Both professions are experiencing the pressures of competition from other professions which share aspects of their knowledge base and are under pressure to remodel their professionalism to meet organisational, market and technological imperatives. Concerns around professional competence have led to reforms of membership structures and qualifications, as both associations struggle to maintain coherent bodies of knowledge in the face of economic and occupational change (Karseth and Nerland 2007). This suggests that the professions may be unable to exercise full control over the ‘abstractions’ or the problem definitions that relate to their professional work (Abbott 1988). Such a context suggests that the relations formed between associations, educational institutions and employing organisations in the structure of production are fundamental in managing change and ensuring professional stability and vitality.

Notwithstanding these similarities there are differences in the factors affecting recruitment and employment in the two professions (Hannah et al. 2009; Hollist 2012) and the organisation and character of the work their members perform. It could be argued that surveying maintains some of the characteristics of a classical ‘occupational’ mode of professionalism, including notions of autonomy and independent expertise, whereas human resource work exhibits more of the characteristics of ‘organisational professionalism’ (Evetts 2004), focused on demonstrating its effectiveness as a ‘business partner’ as a means of affirming its value within organisational contexts (Francis and Keegan 2006). (Becher (1999, p. 16) categorised the professions in terms of whether they are generally ‘rule-governed’ (procedural) or dependent on ‘a mastery of process’ (processual), and whether they are technical or non-technical in orientation. Human resource work can be seen as largely non-technical and processual with some procedural elements, although the procedures used may be derived from the organisational context as much as the professional knowledge base. On the other hand, surveying has both technical and non-technical elements that reflect its ‘broad church’ of specialisms and has a processual focus on projects and problem-solving rather than pure procedural application.

Chartered surveying encompasses a wide range of professional areas, from land surveying to valuation, building surveying to project management, with possible duplications of the competences of other professional bodies operating in fields as wide ranging as engineering, architecture, and law. The progressive expansion of surveying specialisms has led to some criticism of the perceived diminution of professional identity (Hannah et al. 2009). The lack of an exclusive ‘licence to practice’ in the U.K., enjoyed by surveyors in some other countries, has ensured a degree of competition for members, and facilitated the reconfiguration of initial professional formation for chartered surveyors (Hannah et al. 2009). In 2000, after some resistance from key stakeholders, the RICS started to implement the Agenda for Change (A4C) (Plimmer 2003). Key developments resulting from this included the

introduction of ‘partnership’ arrangements between the RICS and higher education institutions which are intended to maintain the quality of initial formation and the development of new routes to qualification (RICS 2008a; Plimmer 2003). Currently, most surveyors enter the profession via a related undergraduate or postgraduate degree, followed by 2 years in the workplace to complete the Assessment of Professional Competence (APC) (RICS 2008b). However recent reforms have seen the introduction of an Associate pathway into the profession, as noted above, intended for those employed in technical and supporting roles without relevant degrees, a Professional Experience route to membership, and an Adaption route which is designed for those qualified with other professional bodies who are interested in becoming Chartered Surveyors.

The CIPD has a membership body consisting of professionals involved in human resource management and development. Although the overlaps in competence with other professional bodies are perhaps less obvious than in the case of surveying, there are bodies such as the Institute of Training and Occupational Learning (ITOL) and the British Institute for Learning and Development (BILD), with whom the CIPD may compete for members. A greater difficulty within the CIPD has been to find pathways to professional recognition that maintain a coherent professional identity and yet provide sufficient space for specialisation. In part these difficulties can be seen a legacy of the merger in 1994 of the Institute of Personnel Management and the Institute of Training and Development that created the current body (CIPD 2012a), but also the tension between the ‘welfare’ role of ‘personnel’ and the ‘business partner’ role of HRM (Francis and Keegan 2006). There is an acknowledgement in the CIPD that the profession still has more to do to justify its value, but this appears to increasingly be in terms of organisational value rather than in relation to individual employees (Gilmore and Williams 2007; Bailey 2011). This ‘corporatisation’ of the profession (Muzio et al. 2011), driven by the perceived inevitability of changes in the emphasis of human resource work and the need to appeal to prospective and current practitioners, can provide an explanation for reforms to initial professional formation. New membership categories, qualification structures and pathways to recognition have been introduced recently, including greater potential for gaining membership through specialist qualifications in HRM and HRD that arguably echo the pre-merger distinction between personnel management and training, an Associate grade of membership, and pathways that enable accreditation via the ‘Experience Assessment route’ which does not involve taking a qualification (CIPD 2012b).

7.6 Structure and Stages of Production of Chartered Surveyors

The diagrams below set out the structure and stages of ‘production’ of chartered surveyors that applies in the United Kingdom, and to a considerable extent in the other countries where the RICS is increasingly prominent, including in Asia, parts of Europe and Oceania. Diagram 7.1 outlines the structure of production, sketching the various organisations and institutional influences on the productive process, and

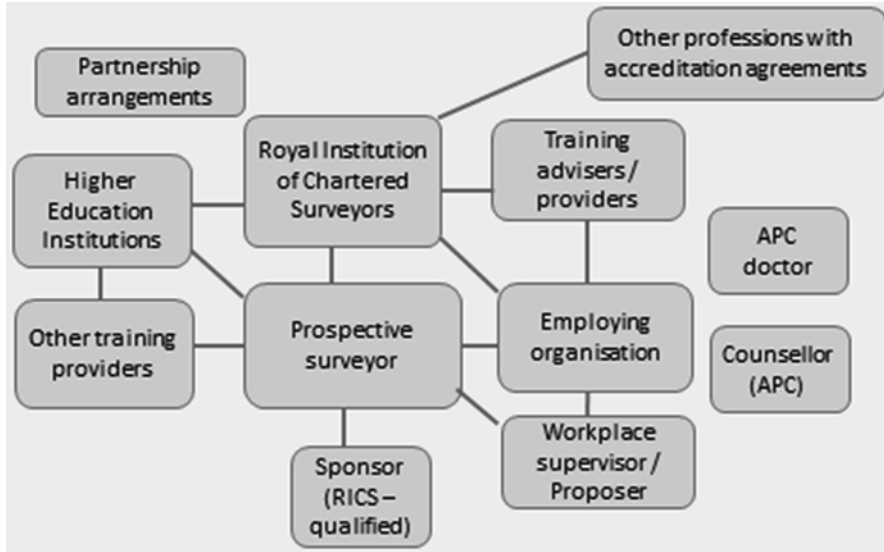

Diagram 7.1 Structure of production (chartered surveyors)

here this also includes individuals (APC Doctor, Counsellor, Workplace Supervisor) who are appointed to particular roles to support prospective surveyors pass the Assessment of Professional Competence (APC) and thus become full members of the RICS. In the case of Chartered Surveying the productive system involves ‘partnership arrangements’ between the RICS and higher education institutions which aim to provide a guarantee of the quality of surveying education (Plimmer 2003), and are designed to ensure there is transparency for all parties around the status of qualifications. As discussed above Chartered Surveying is a profession with multiple competences, many of which ‘overlap’ with other professional bodies, and thus the RICS has relationships of both collaboration and potential competition (Hannah et al. 2009; Ratcliffe 2011). Decisions about professional formation are thus ‘structured’ by concern about these relationships, and changes made by other professional bodies in terms of their membership opportunities. A professional body such as the RICS is concerned about its presence and its reputation, and this will impact on finding an appropriate balance between maintaining rigorous entry standards for membership and ensuring healthy recruitment. In addition, the RICS maintains relationships with many surveying firms, and is responsible for regulating those firms that have over 50 % of partners and directors that are chartered surveyors (RICS 2012a). The RICS Rules of Conduct for firms include a stipulation that all firms have ‘the necessary procedures to ensure that all its staff are properly trained and competent to do their work’ (RICS 2012b, p. 5). This ensures a direct link between the RICS and firms employing prospective surveyors preparing for the APC, and provides the RICS with greater influence in the productive system. It does not, of course, exclude cognate professionals from carrying out work that can be defined as ‘surveying’. Overall the structure of production illustrates the various forms of implicit and explicit contracts made between stakeholders as they combine

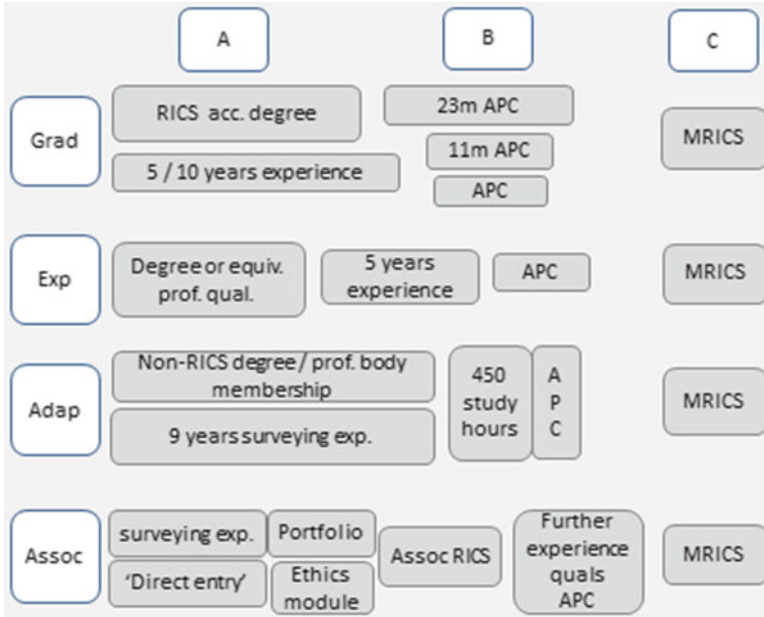

Diagram 7.2 Stages of production (chartered surveyors). *Grad* graduate route, *Exp* professional experience route, *Adap* adaptation route, *Assoc* associate routes (experience and direct entry), *MRICS* member of Royal Institution of Chartered Surveyors

forces to ‘produce’ chartered surveyors, with the RICS playing a key role in ensuring the ‘compatibility’ of relations (Friedman and Miles 2002; Wilkinson 2002).

The pathways that prospective chartered surveyors can take towards professional formation are outlined below. There are a number of routes available, including the graduate, professional experience and adaptation routes towards full membership (MRICS) and the opportunity to achieve an Associate level of membership (Assoc RICS) through qualification or membership of another professional body (direct entry) or by experience and the submission of a portfolio. Whereas the graduate route is the ‘traditional’ and ‘sequential’ route to membership, combining a higher education qualification and a period of structured training towards the APC, the professional experience and adaptation routes provide alternative ‘experiential’ pathways for those practitioners who may have entered surveying employment from other professional backgrounds or have entered surveying via a non-relevant degree. The routes recognise the diversity of surveying employment, and the ‘overlaps’ in competencies with other professions.

Diagram 7.2 above the four pathways of formation are each broken down into two stages which correspond to initial experience and knowledge (stage A) and the process of accreditation for Full or Associate membership (stage B). In the cases of those who take an RICS degree before proceeding to surveying employment on the Graduate route (Grad), the partnership arrangements between the RICS and

higher education institutions have particular influence at Stage A, whereas in the professional experience route or the adaptation route, experiences within the workplace or as part of another professional body have greater bearing on formation. At Stage B on the graduate route a prospective surveyor must generally engage in 23 or 11 months structured training before completing the APC. The training process involves working with, and being supervised by, colleagues, managers and RICS qualified surveyors in the workplace. This contrasts with the greater flexibility on the Adaptation or Professional Experience routes, where the prospective chartered surveyor has greater flexibility in preparation for the APC, although this still involves an assessment process that may result in applicants being asked to acquire further relevant knowledge and experience. Additionally applicants via these routes must have a sponsor who is a member of RICS, and in the professional experience route a proposer, who must be a member of the employing organisation (RICS 2012c; 2011). Although there are now a multiplicity of routes to full membership of the RICS which will open up the potential of membership to a wider spectrum of practitioners, the routes remain specific in terms of the type of knowledge, the extent of experience and the steps that a prospective member must take.

7.7 Structure and Stages of Production of Human Resource Professionals in the U.K.

In the case of the CIPD, as outlined in Diagram 7.3 below, the structure of production of professional formation is less dense than the RICS, with fewer organisations and individuals involved in the processes and minimal contractual activity between stakeholders. This can be seen as a reflection both of the relatively few professional associations that overlap with the competence of the CIPD in the United Kingdom context, and of the pan-sectoral nature of human resource work. Whereas surveying work is located in particular sectors of the economy and tends to be organised in professional service organisations, human resource management and development is involved to some extent in most forms of organisation, although it may not always be a specialist function. Indeed it can be suggested that it is precisely the diffusion of responsibility for many aspects of human resource management to line managers throughout organisations that has undermined the effectiveness of HRM (McGovern et al. 1997; Cunningham and Hyman 1999), and thereby the status of HRM as a profession. A challenge for the CIPD is to make membership attractive to those involved in human resource work, although here it is also helped by the steady demand for employment in HR and for higher qualification levels in the U.K., Ireland and internationally (Hollist 2012; Lengnick-Hall and Aguinis 2012). This can result in organisations using CIPD membership as a means of differentiating between applicants in recruitment processes. Unlike the RICS, the CIPD is not in a position to develop extensive co-operative links with individual employers relating to professional formation, due to the diffusion of human resource professionals across all organisational types, and therefore the

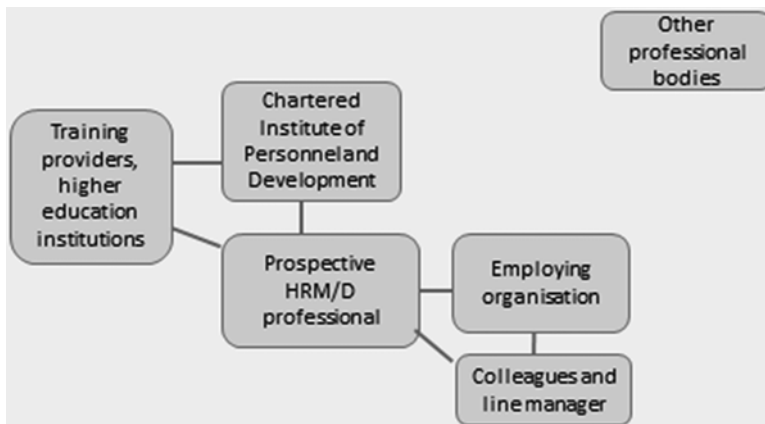

Diagram 7.3 Structure of production (human resource professionals)

development of a registration or regulatory operation for ‘HRM organisations’ is not viable. Diagram 7.3 therefore illustrates a scenario in which a professional association has assumed a pre-eminent role in the structure of production, but the influence that the association might bring to bear on formation processes may be constrained by the lack of viable links with sources of abstract knowledge (i.e. educational institutions) and workplaces (i.e. via organisations).

The stages of professional formation that lead to CIPD membership have recently been substantially revised as part of the CIPD review that has led to the HR profession map, new qualifications at level 3,5 and 7, and a new membership structure. In Lester’s (2009) terms, routes to CIPD membership have characteristically been predominantly ‘parallel’ rather than ‘sequential’ with HR practitioners studying while in work. However the recent reforms have also led to the development of a new more experience based route to membership (EA), and the introduction of greater flexibility through accreditation based primarily on competence rather than qualification, and are justified in terms of the ‘changing needs of the profession and the expectations of employers’ (CIPD 2012c). Arguably this flexibility puts considerable emphasis on the role of the prospective member in managing their own learning and ensuring they access the opportunities to develop the appropriate competences. Such an approach may work well for some prospective members. However, for others there may be difficulties due to the reluctance of employers to offer discretion and challenge at work (Felstead et al. 2009; Gallie et al. 2009). There is no equivalent to the adaptation route offered by the RICS, as there are fewer cognate professional bodies, and those entering from other professions could now use the Experience Assessment route. Although there are many higher education institutions offering CIPD qualifications, prevailing beliefs in the practice orientation of HR knowledge may indicate that stronger engagement with higher education institutions is unnecessary. The CIPD has its own extensive training operation, and thus relations with higher education institutions may be competitive as well as collaborative.

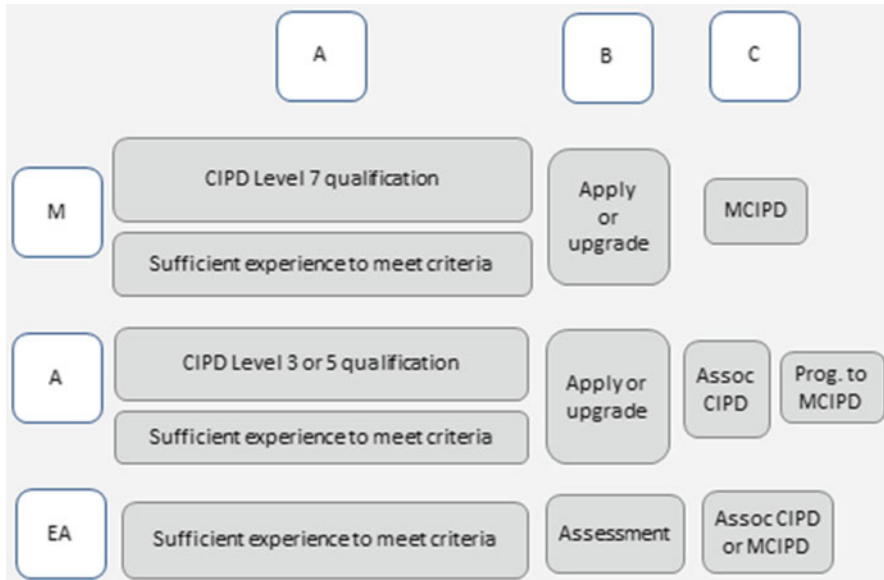

Diagram 7.4 Stages of production (human resource professionals). M=standard route to membership; A=standard route to associate membership; EA=experience assessment route; Assoc CIPD=associate member of the CIPD; MCIPD=Full member of the CIPD

CIPD has introduced an ‘academic’ route to membership, although this is still in its infancy with small numbers of members (138 out of over 134,000 in 2012) (CIPD 2012d, p. 17). Overall, pathways to professional membership of the CIPD lack the structure of the traditional ‘graduate’ routes offered by the RICS and also by ‘classical’ professions such as law and accountancy, and instead prioritise flexibility. This lack of structure may reflect the realities of human resource work and the experiences of HR practitioners.

Diagram 7.4 above differentiates between two stages that lead to accreditation as a full member or Associate of CIPD. Stage A relates to the process of undertaking a CIPD qualification and acquiring sufficient experience to meet the criteria of membership, although in the Experience Assessment route (EA) no specific qualification is required as such. At this stage we can see the potential influence of educational providers, although the CIPD retains control over the specification of qualification content rather than deferring to higher education institutions, and some have argued this has resulted in a ‘technicist’ or ‘de-politicised’ approach to human resource management evident in the suite of texts that the CIPD publishes (Gilmore and Williams 2007). This does not necessarily diminish the influence of higher education institutions, as they may choose to supplement CIPD content with additional elements in the context of an undergraduate or postgraduate programme, or critique the CIPD texts. However, it can be argued that the unilateral approach of the CIPD towards its qualifications reflects its own interests as a provider of training, and, more broadly, its own conception of the human resource profession. Stage B in the diagram consists of the application, upgrading or assessment process, which generally

involves input from colleagues and managers from the prospective member's workplace (CIPD 2012b; c). Here, therefore, the organisational context has particular influence.

7.8 Mutuality and Tensions in Production: The Two Professions Compared

Through the 'articulation' between the structure and stages of production (Felstead et al. 2009) relative levels of influence and the tensions of co-operation become apparent. The influence and role of those who contribute to the structure tends to alter at each stage. For example the graduate route membership of RICS generally involves a 'traditional' pathway consisting first of the initial predominance of degree-based education structured by partnerships between the RICS and the respective institution, before a second stage at which responsibility for formation is shared between the employer, RICS and the prospective surveyor. However, the professional experience route to full membership or the experience-based route to Associate membership rely to a greater extent on practitioner experience, which will have been influenced primarily by the work contexts in which he or she has been employed. Finally, the adaptation route, or the 'direct entry' Associate route rely primarily on the accreditation procedures of the processes of other professional bodies. Notwithstanding this, however, the RICS maintains its influence in all these routes through the Assessment of Professional Competence (APC), with its requirement for evidence of knowledge acquisition and application (RICS 2008b; 2011), in addition to the requirement for a sponsor who is a member of RICS.

In the case of CIPD, the soft infrastructure of social and technical relations is less apparent with an absence of stakeholder relations and partnerships in the process of formation. The stages of production are less dependent on co-operative relationships in the structure of production, enabling greater fluidity and flexibility. This is not to say that CIPD is not active in developing a form of infrastructure for their practitioner base, and in developing links with other organisations, but these do not necessarily impact on formation and appear to have a greater degree of contingency rather than necessity (Friedman and Miles 2002). The comparative absence of a professionally-mandated infrastructure guiding the articulation between stages and structure means that the individual practitioner and the various employment contexts they have experienced often have the greatest influence on formation. CIPD qualifications are increasingly flexible in terms of structure and delivery, and are often taken part time by those already in employment (CIPD 2012d). However, the introduction of the experience assessment route (EA) renders specific qualifications unnecessary for CIPD membership. In all routes to membership, the employment context has substantial influence on the process of formation and membership accreditation, as prospective members must have access to the opportunities to develop their capabilities and provide evidence of their competence. To qualify it is essential to be able to 'demonstrate how you make an impact in the workplace', and

to be able to complete statements that relate to workplace activities (CIPD 2011, pp. 3–7). In the process of upgrading to a new level of membership, two colleague feedback forms must be completed. The first must be completed by a line manager or client and the second by a colleague. However, unlike in the case of RICS, there is no need for these contributors to be CIPD members (CIPD 2011), and thus there is no necessary link to more experienced professionals in the process of formation. The weight attached to this process demonstrates the influence that the employing or contracting organisation has on the process of accreditation.

There is a contrast between a certain level of stringency in the professional formation of chartered surveyors and the relative flexibility of the formation and accreditation of human resource professionals. Indeed, whereas formation has traditionally been seen as an assumption of a shared identity and induction into a community of professionals (Friedson 2001), the acquisition of CIPD membership can potentially be an entirely atomistic individualised process, with minimal or no interaction with other professional members. Such atomisation is less likely to be the case with the surveying profession, due to the requirement to complete the Assessment of professional competence (APC), which entails some involvement with surveyors and probably cognate professionals, thus engendering contact with a network of practitioners.

The capacity to integrate employing organisations with professional formation strongly relates to the degree of flexibility in processes of professional formation. Whereas the RICS operates a mechanism, via its code of conduct (RICS 2012b) that ensures that employers are normatively obliged to support professional formation and ongoing professional development, this aspect of the infrastructure is very difficult for the CIPD to construct. Chartered surveyors, similarly to architects, many engineers, and lawyers, work predominantly within professional organisations that are able to sustain a logic of professionalism and patterns of work organisation that provide an infrastructure for formation within employment. What Billett (2006) describes as a ‘workplace curriculum’ may thus be readily apparent and easily accessible in the context of work, enabling organisations to support the structure of formation at limited cost. However, a guarantee of access to a workplace curriculum is more difficult to achieve with human resource management work, due to an absence of mechanisms through which employing organisations can be ‘tied in’ to the process of HR professional formation, leaving formation subject to the specific dispositions and proclivities of the employer.

7.9 Knowledge and Recontextualisation in the Productive System

The two productive systems discussed above can be further interpreted in terms of the different character of knowledge valued by the professions and how the processes of knowledge recontextualisation embedded in the infrastructure of the system support professional formation. A helpful notion is the knowledge ‘region’

(Bernstein 2000) which is formed through the appropriation and transformation (i.e. recontextualisation) of knowledge from 'singulars', or academic disciplines, 'to support a domain of professional practice' (Muller 2009, p. 213). Singulars and regions are examples of 'performance modes' which 'are based on different principles of text construction, different knowledge bases and on different social organisations' (Bernstein 2000, p. 51). Regions are therefore socio-epistemic entities that represent both the organising fora and the domain within which professional knowledge is validated for the purpose of recontextualisation into curricula and into professional standards. It can be argued that processes within the region are governed not only by the agency of the organisations, institutions and individuals that act within it, but also by the norms and socio-historical context of the profession, and by the structure and character of the knowledge contained in the region. The social dimension of the region thus loosely corresponds to the 'structure of production' (Felstead et al. 2009), while the epistemic dimension consists of the professional knowledge that forms the basis for curricula and recognition of competence. Regions are suspended between 'sacred' disciplinary singulars and the requirements of the 'profane' (Bernstein 2000, p. 52), which for most professions will include society, the market, other professions, and potentially government (Beck and Young 2005).

The notion of maintaining authority over a distinctive knowledge base is a fundamental tenet of most professions (Becher 1999; Beck and Young 2005; Friedson 2001), although this authority can rarely be translated into full 'control'. Professions are subject in some form to developments in knowledge, or its application, in related fields or disciplines (Foray and Hargreaves 2003). For example, medicine is subject to knowledge development in the pure sciences, while arguably chartered surveying is as much subject to developments in other cognate professions, including architecture, engineering and planning, as to breakthroughs in technology that impact on work processes. The dynamics within the region govern the way in which the influx of new knowledge is managed and incorporated into the professional knowledge base. This incorporation may involve 'profane' influences encouraging the prioritisation or reshaping of professional knowledge to suit the exigencies of the market or government, resulting in pressures for qualification reform. Alternatively, the 'profane' concerns with ensuring the sustainability of the professional body, or taking members from other bodies, may encourage actors within the region to recontextualise knowledge differently into curricula and professional standards, with the aim of making professional qualification more or less accessible or demanding. Regions can be seen as the space in which the 'hard applied' and 'soft applied' disciplines or fields of study (Becher 1994; Biglan 1973; Muller 2009) are located, and the variable levels of connectivity that these fields have with the 'hard pure' and 'soft pure' disciplines that form their parent singulars has a further impact on their character. Bernstein conceived the regions as formed from the recontextualisation of singulars (2000, p. 52), but this recontextualising process may or may not be continual, and may incorporate certain 'pure' singular elements to the exclusion of others.

Chartered surveying and human resource work demonstrate many of the qualities of 'hard applied' and 'soft applied' fields respectively. The region of surveying

knowledge has a need to retain relatively close links with other technically-orientated professional knowledge regions in order to maintain a relative level of authority over its professional knowledge in its construction and land specialisms. These regions will include in particular architecture, planning and engineering, which may be subject to pressures to manage constant inflows of new technical knowledge (Karseth and Nerland 2007). However, this connectivity can also entail difficulties with establishing and maintaining the boundaries of the surveying region, a factor that Beck and Young (2005) identify as contributing to weaker professional identities. The overlap of surveying competence with other professions, which have their own regions, means that knowledge is recontextualised both from other regions and from the surveying region's own parent disciplines. Where knowledge is recontextualised from another region this could lead to a 'dilution' in the conceptuality of knowledge (Hamilton 2012, p. 74). This is due to the more distant connection with developments in the academic disciplines from which knowledge is recontextualised into these regions. However, it is likely that many of the 'pure' academic disciplines relevant to surveying will be similar to those that contribute to the regions of architecture, planning and engineering. These disciplines incorporate primarily the physical sciences and 'harder' social sciences, such as geography and economics. The other more commercially orientated branches of surveyors may have greater interest in other business and management orientated regions that recontextualise knowledge from similar disciplines. However, in order to mitigate the 'dilution', the surveying region needs to maintain its capacity to recontextualise for its own purposes. Arguably, the surveying profession had recognised this with the development of partnership arrangements with surveying departments in higher education institutions with high quality research profiles (Plimmer 2003), although the argument above would suggest that it would be necessary to ensure that these departments have sufficient orientation towards disciplinary singulars and not only towards the specificities of practice.

For the non-technical human resource knowledge region it can be argued that there is less evidence for ongoing recontextualisation from what might be considered the 'soft pure' parent disciplines of sociology, psychology and economics. The human resource management disciplinary knowledge base is characterised by a porosity in its boundaries with other disciplines (Hamilton 2012, p. 77), and can be described as a 'weak' region that is subject to the dominance of knowledge from more powerful regions, such as management studies (Ibid., pp. 74–5). The region derives a greater volume of its knowledge from organisational contextualities than from disciplinary singulars, as practice-based knowledge is valued more than knowledge derived from disciplines (Hamilton 2012, pp. 63–73; Beck and Young 2005). The practice orientation can be demonstrated in the offer the CIPD makes to its members in terms of 'knowledge resources' and the mechanisms it uses to accredit its members, which concentrate on 'demonstrating workplace effectiveness'. The CIPD acts as a 'hub' of organisational and professional knowledge, encouraging its members' continual subscription through offering access to a dynamic knowledge base of 'best practice' which attempts to substitute for the disciplinary based knowledge that characterises traditional professions with 'stronger' classical regions

(Bernstein 2000, p. 55). The overall impression is of a profession that is largely disconnected from purer disciplines that might be accessed to support the profession in advancing knowledge and to illuminate challenges of practice. Becher (1999, pp. 179–196) outlines how many of the more technical professions maintain links with higher education departments to tackle difficult problems and to maintain the currency of their knowledge. These technical knowledge regions sustain links with purer disciplines, recontextualising knowledge in ways that is valuable for practice. Where co-operative relationships are less prevalent, as in the case of HRM, academics criticise practitioners for non-engagement with research, and practitioners criticise academics for irrelevant work (Short et al. 2009; Gray et al. 2011). The disengagement is compounded by notions of professional competence which are rooted in evidence of workplace ‘effectiveness’, which can be driven as much by local organisational knowledge and ‘behaviours’ as by the use of professional knowledge. The consequence is a professional knowledge base that adjusts to the whims of the market, with less capacity to access the abstract knowledge resources that would provide both greater professional legitimation and shed light on the challenges of practice. This also results in greater pressure on individual practitioners, in particular to ensure that their professional knowledge meets current workplace demands. The following section brings the resultant impact on practitioners into greater focus.

7.10 Professionals and Recontextualisation at Work

Evans et al. (2010, p. 246) use an interpretation of recontextualisation which differs somewhat from Bernstein’s (2000), incorporating ‘schools of thought, the traditions and norms of practice, the life experiences in which knowledge of different kinds is generated’ into the notion of context while retaining aspects of the focus on appropriation and transformation. This approach draws attention to the multiplicity of factors affecting the outcome for the practitioner, and incorporates both structural and agentic elements. In the model used by Evans et al. (2010) processes of recontextualisation are extended to workplaces and practitioners’ experiences, enabling an analysis of how knowledge is reconstituted as it flows from sites of production and curricula to work contexts, and, when brought together with an analysis of the productive system, an analysis of the extent to which this process is supported by educational institutions, employers and other professionals.

In the case of chartered surveying we can see how most pathways of formation (i.e. Graduate route via a RICS accredited degree and Professional Experience route as outlined in Diagram 7.2) support processes of workplace and learner recontextualisation. These routes provide opportunities for prospective practitioners to use workplace activities as a ‘test bench’ for curriculum knowledge (Evans et al. 2010, p. 247) through a period of structured training. Links are maintained, through curricula, with the original sites of knowledge production in disciplines and workplaces, via the partnership arrangements between RICS and higher education.

The workplace structured training that those on the graduate route to full membership of the RICS enjoy before completing the Assessment of Professional Competence also provides opportunities for a 'learning conversation' that 'recognises, but also expands employees'/learners knowledge and puts it to work' (Evans et al. 2010, p. 249), through the facilitation of the workplace supervisor. The structure provided by the Assessment of Professional Competence enables the developing expertise of the professional in formation to be valued, by the employer, the practitioner and also by the profession, and the co-operation of different actors with supportive roles provides an opportunity for the engendering of high trust relations both within and beyond the workplace (Fuller and Unwin 2010).

On the other hand, development of a version of the Graduate route to Chartered Surveyor status which obviates the need for structured training relies to a greater extent on the learner making sense of their own workplace experience through their own capacity to recontextualise, perhaps with fewer opportunities to 'test bench' knowledge from outside their experience. The Adaptation route to full membership of the surveying profession also lessens the influence of the professional body, and its partnerships with higher education institutions, over the recontextualisation process. In these cases there is greater reliance on processes of workplace and learner recontextualisation being supported by the context of surveying employment, which tends to involve contact and co-operation with other surveyors and cognate professions (Hannah et al. 2009). Thus the 'chains' of recontextualisation (Evans et al. 2010, p. 250) can be strengthened in cohesive networks of practice. However the existence of these networks requires the support of employers through an approach to workforce development that perceives breadth and depth of individual capability as vital for achieving objectives (Fuller and Unwin 2010). The existence of regulatory requirements linking individual surveying firms to the RICS, and rules of conduct that specify the importance of training and CPD should facilitate employer commitment to workforce development and the networks of practice necessary for recontextualisation processes to ensue (RICS 2012b).

In the case of human resource professionals seeking to qualify through the CIPD it is clear that the Experience Assessment route relies heavily on the recontextualisation capabilities of human resource practitioners, who will need to find their own way to 'make sense' of their own learning. It is undeniable that some very experienced practitioners may have the capacity to do this, including through involving critical friends, coaches and mentors inside or outside their workplaces. However, potential problems could be seen to exist due to the lack of structured links between curriculum, pedagogic and workplace recontextualisation where practitioners have not followed an initial CIPD qualification. The link with the sites of knowledge production in relevant disciplines and through research into practice is weaker, further evidence of the disconnect between human resource work and those disciplines that can potentially inform its practice. The formation of a successful human resource professional relies heavily on the existence of workplace opportunities and 'pedagogies of work' (Evans et al. 2010, p. 249; Billett 2002) that practitioners in formation may have limited control over due to the organisation of work (Felstead et al. 2009). The consequence is considerable pressure on the learner

to recontextualise knowledge individually, from a multiplicity of sources, and perhaps with limited guidance in distinguishing between what knowledge is likely to be useful based on rigorous research. It is here that the CIPD can be seen to have identified a gap which they can fill through the provision of member resources, packaging knowledge for the body of practitioners.

7.11 Concluding Remarks

The structure and stages of production of the two professions suggest that the models of professionalism in use differ. Chartered surveying ascribes to a technical and processual model of professionalism (Becher 1999) that has more in common with engineering and the other construction professions, while the CIPD appears to have taken human resource management in the direction of an organisational or corporate model of professionalism (Evetts 2011; Muzio et al. 2011), a step further towards the 'commercialised professionalism' (Hanlon 1998) identified by Gilmore and Williams (2007), and a pragmatic realisation of the role of a professional association in the contemporary context of HRM (Farndale and Brewster 2005). For Chartered Surveying the maintenance of the structures that underpin the professional knowledge 'region' remain important, and this is reinforced by the organisation of surveying work. In the case of human resource professionals the 'region' appears to have detached itself from the notion of a body of knowledge linked to 'pure' disciplinary 'singulars', and knowledge derived from practice that is deemed useful is prioritised. In effect the absence of disciplinary knowledge may lead to the development of a form of generic mode (Bernstein 2000, p. 53), 'directly linked to the instrumentalities of the market' (p. 55). In these circumstances professional bodies have opportunities to assert themselves, and it is clear that the CIPD has an ambitious agenda to develop knowledge resources that are then made available to CIPD subscribing members. The CIPD is filling the vacuum left in the 'region', but in so doing is in danger of defining valuable knowledge in terms of its current perceived applicability rather than its connection with ongoing research within purer disciplines that might inform human resource work.

The development of a wider suite of pathways to professional formation suggest that both professional bodies discussed here recognise the need to provide opportunities for members who may have worked in other fields, or entered the profession through employment based routes. However this expansion of routes could be seen to have stemmed from different impetuses, and have led to different results. The CIPD has streamlined and simplified the process of becoming a member, reduced the number of levels of membership and unilaterally governs its qualification base. It asserts that valid human resource knowledge can be gained through experience in any organisational environment. The result has been routes that offer greater flexibility to enable any prospective member to demonstrate his or her competence. In contrast the RICS recognises how surveying work both overlaps and interconnects with other cognate professions and with developments in the disciplinary knowledge

base. Thus the expansion of pathways and routes to qualification in surveying reflect attempts to secure the surveying profession through greater porosity and collaboration, with the acknowledgement than any attempts to strengthen the boundaries between surveying knowledge and other cognate knowledge bases, for example in architecture, planning or engineering, could result in loss of membership to other professions. However, although there are now more routes to membership, they remain tightly specified, reflecting the dense structure of production in which professional formation of surveyors is located.

Productive systems vary in terms of the extent to which an infrastructure of socio-technical relations is able to bind together the structure and stages of formation. As we have seen in the examples discussed the character of this infrastructure can be influenced by how professional work is organised, pressures to maintain jurisdiction, and by decisions made by professional associations which are constrained by the extent to which professions can form and reform institutions, and thus influence organisational fields to their own advantage (Greenwood et al. 2002; Scott 2008; Suddaby and Viale 2011). The key relations and characteristics within the infrastructure, including relations with higher education guided by conceptions of knowledge value, the capacity to integrate employing organisations, the degree of involvement of fellow professionals, and the tensions between specificity and flexibility in formation pathways, are all influenced by a dynamic interplay between the structural forces impacting on, and permeating through, the productive system, and the decisions made by agents acting within. The professional association, as we have seen here, has a key role in mediating, negotiating and steering the profession, facilitating change in the productive system within the constraints apparent within the wider professional, organisational and societal systems in which the profession is located.

Part II

Research Paradigms

The diverse theoretical and conceptual accounts for understanding both professions and professional learning are this part's key focus. Its contributions indicate something of the scope of methodological approaches identified and adopted to investigate both the professions and professional learning. These approaches are represented by accounts of methods and paradigms which are used to engage in scientific enquiry associated with what constitutes professional work and its learning. For instance, in their chapter – *Understanding learning for the professions: How theories of learning explain coping with rapid change* (Chap. 8) – Erno Lehtinen, Kai Hakkarainen and Tuire Palonen review theories of learning to ascertain their accounting for the ways that the dynamic requirements for professional working life can be initially learnt and then addressed across lengthening professional lives. What they hold is that given the uncertainty about particular kinds of knowledge is necessary to identify which accounts of knowledge and learning furnish helpful advice about proceeding with supporting such development. Throughout, all of these accounts the mediation of knowledge for new generations of professionals was emphasized although how they account for, can tolerate and support the dynamic requirements of evolving professional practice is less clear. A helpful example of how to understand interactions and learning through practice and for professional learning is provided in the chapter by Laurent Filliettaz. Entitled *Understanding learning for work: Contributions from discourse and interaction analysis* (Chap. 9), this contribution highlights the importance of accounting for the discursive and interactional aspects of professional work and its learning. Necessarily interdisciplinary, this chapter illustrates how two distinct fields (i.e. linguistic method and educational research) offer complementarity and augmentation in addressing the specific and complex phenomenon of learning through work. Moreover, methodologically, this contribution illustrates the consonances between social theories of learning and approaches and procedures that are adopted within the fields of discourse and interactional analysis.

The centrality of method is foremost in the contribution from Paul Gibbs – *Research paradigms of practice, work and learning* (Chap. 10). From the field and

perspective of philosophy, this contribution argues for a multiplicity of methods and an emphasis on judgement rather than neutral objective premises of certainty in researching practice work and learning. It proposes that the messy research problems found within professional fields of practice warrant consideration within that context and needing to be grounded within explanations that can accommodate such indeterminacy and multiplicity. In making this case, he adopts critical realism as his foundation and premises this choice on its applicability to addressing issues that are relevant to practitioners, including its transdisciplinary reach. In their chapter – *A phenomenological perspective on researching work and learning* (Chap. 11) – Gloria Dall’Alba and Jörgen Sandberg similarly seek to account for the complexity of relations between work and learning. They hold that conventional approaches tend to separate individuals who are learning and the work to be learnt. Rather than accepting this separateness, they hold that the subject and the object are richly intertwined and, as a consequence, methods and procedures are required that can accommodate both perspectives and their interactions. In doing so, they elaborate a life world perspective on researching work and learning, which emphasises interdependence and relational perspectives as informing both work and learning.

From a distinct perspective, in his chapter – *The neuronal base of perceptual learning and skill acquisition* (Chap. 12) – Mark Greenlee examines the relationship between the organism and the environment. This chapter proposes that as interactions between persons and their environments progress across life histories, that a greater understanding of how the neural system mediates what is experienced and how responses arise is now warranted. Adopting views and conceptions from neuroscience, these are utilised to elaborate both perceptual learning and the process of skill acquisition. A review of concepts and contributions from this science provides a platform through which a case is made about understanding the immediate and longer term consequences of interactions with the environment as mediated through neural processes. These consequences include changes that arise in nervous system as a result of encountering particular kinds and configurations of stimulus. In conclusion, considerations are given, to the qualities of particular learning environments.

In another specific approach, Eva Kyndt and Patrick Onghena in their chapter – *Hierarchical linear models for research on professional learning: Relevance and implications* (Chap. 13) – propose that it is important for quantitative analysis to be applied to the field of professional learning because much of the conceptions, theorisations and literature emphasises qualitative method. In essence, the chapter provides an overview of these models, their applicability to the field and key premises through which they utility can be understood. They seek to make explicit the ways that hierarchical linear modelling can lead to significant contributions to the field of professional learning. The authors then exercise and exemplified this claim through engaging with the body of literature about employees’ intentionality as directed towards their learning. In doing so, they rehearse and extend many of the key premises associated with quantitative method and its broad applicability to this field. Catherine Hasse, conversely, in her chapter – *The anthropological paradigm of practice-based learning* (Chap. 14) – makes the case for anthropological research to

be used more fully and comprehensively in enquiries associated with work and learning. Again, this chapter sets out much of the method adopted within this paradigm and introduces foundational studies and more recent contributions in elaborating its utility. In doing so, she offers the reader an account of the origins of anthropological method and its development over time. She includes examples from broadly related fields of the development of culturally important knowledge and practices and then makes the links to the application of these foundations to understanding professionals' learning and work. In doing so, she also engages with current debates within and contributions from anthropology that have direct relevance to professional learning.

Although by no means exhaustive, these contributions represent some of the methods and paradigms that can be used in the field of professional work and its learning. As such, key and contrasting methods are included, illustrated and discussed in this part.

Chapter 8

Understanding Learning for the Professions: How Theories of Learning Explain Coping with Rapid Change

Erno Lehtinen, Kai Hakkarainen, and Tuire Palonen

Abstract Working life is increasingly in turbulence. Whole traditional professional fields disappear as new ones emerge. Within traditional professions technological and organisational development often means rapid changes in knowledge, skills, and working attitudes required from workers. All of this results in a challenge to develop vocational and professional education, and models of workplace learning that respond to these changes. The central questions are how new generations should be prepared for a future, at least partly unknown, working lives and how old workers should be supported in the necessary updating of their knowledge and skills during their work careers are added challenges. The aim of this chapter is to analyse how adequate the contemporary theories of learning are for dealing with these challenges.

Keywords Change • Learning theories • Soft skills • Transfer • Expertise • Knowledge acquisition • Participation • Sociocultural learning • Conceptual change • Knowledge transformation • Activity theory • Deliberate practice • Cognitive theory

8.1 Introduction

Working life is increasingly in turbulence. Whole traditional professional fields disappear as new ones emerge. vocational and professional education, and models of workplace learning that respond to these changes. The central questions are how new generations should be prepared for a future, at least partly unknown, working lives and how old workers should be supported in the necessary updating of their knowledge and skills during their work careers are added challenges. The aim of this chapter is to analyse how adequate the contemporary theories of learning are for dealing with these challenges.

Certainly, a great deal of the changes requiring gradual or more radical reconsidering of professional practices and competences, takes place within existing professions. New technologies, increasingly complex production methods, marketing and distribution networks, internationalization and globalization change not only influence the work of those professionals in higher positions within work hierarchies, but have an influence throughout the work organizations (Harkin 2004). Moreover, Globalization, changes in communication technologies, and unexpected consequences of previous and contemporary technologies result in deep reaching changes in society and modify our daily lives. Increasing market competition and companies' attempts to profit from rapidly changing products and reduced production costs also lead to pressures towards innovation and the restructuring of organizations. Many researchers have analysed conditions and processes that cause such radical changes in working life and which result in the emergence of new professional fields (e.g., Talwar and Hancock 2010; Redecker et al. 2010; Davies et al. 2011). Studies such as these have identified several 'change drivers' that require co-ordinated, often global solutions, e.g., in the fields of environment, finance and security.

Indeed, various threats and possibilities, demographic change, economic turbulence, political change, norms, and legislation have resulted in the creation of totally new jobs, or hybridized existing jobs in complex ways. Hybrids, such as personal debt advisors, game addiction therapists or energy efficiency experts can all be institutionalized as a subfield of existing disciplines, or a permanent cross-disciplinary program, or they can remain informal (Klein 2010). Talwar and Hancock (2010) analysed how new jobs arise as a consequence of opportunities and implications for science and technology, which lead them to present quite exotic examples of future professions (e.g., body part maker, nano-medic, farmer of genetically engineered crops and livestock, social 'networking' analyst). In general, these new jobs seem to emerge at the edge of and in between various professional domains (Palonen et al., 2014). Multi-scientific and multi-disciplinary domains such as sustainability science have arisen to address the impacts of climate change and redress other sustainability challenges. These are sometimes attempts to bridge the natural and social sciences in responding to these complex challenges (Jerneck et al. 2011). Some of the changes to existing professions and the creation of new professional fields augment and build on previous fields of expertise and only require gradual enrichment of previous knowledge and accepted competences. However, in many cases new emerging professions or deeply changed work requirements in existing professions cannot be dealt with using monotonic learning – based on existing knowledge, skills and practices – but require non-monotonic learning – creating a radically new knowledge base and professional practice (Ohlsson 2011).

The orthodox way to consider education, vocational training and expertise development assumes that there is a known societal context, working life or professional practice for which learning in educational programmes should prepare students. Analogously, learning in workplaces is deeply embedded in the existing structures and practices of workplaces or relatively well known intentional plans and arrangements to change or develop some of the practices in those workplaces. The very nature of general education and institutionally-based vocational education is to transmit established knowledge and culturally-formed practices to new generations (Pring 2004). Historically, the dominating model of vocational training is based on apprenticeship in workplaces, and this continues to be the practice in many countries. However, vocational training in special institutions dominates training for occupations on higher levels of the occupational hierarchy (Powell and Solga 2008). Also, with vocational and professional learning taking place in educational institutions, there are also often practical training experiences provided in work environments and which are now considered as fundamental elements of initial occupational preparation. The role of these workplace experiences is to provide students with experiences that familiarize them with authentic work practices and experiences of working life. All this is aimed at transmitting existing knowledge, skills and practices to new generations of workers. These orthodox conceptions of schooling and training might work relatively well in preparing newcomers to professions where changes are slow and incremental and the occupational requirements have remained relatively stable. That is, without deep reaching qualitative changes.

In these circumstances, the content of the curriculum is based on a consensus among societally recognized domain experts about the competences needed in particular fields (Billett 2003). In the best cases, the content of vocational and professional education programs, particularly when connected with well-organized practice in workplaces, provide novice workers with sound bases for their professional careers in the assumption that no radical changes in the nature of the work are likely to occur. However, outside of such circumstances, the limited capabilities of educational institutions and traditional teaching methods to adequately prepare new generations for the challenges and potentiality of a rapidly changing working life in the future are widely recognized. A frequently enacted response to this challenge is to provide students with what are referred to as transferable ‘soft skills’ – the kinds of capacities associated with communicativity and adaptability (Fallows and Steven 2000). Globalisation, information and communication technologies and new forms of organisations as well as rapid change of professions and work practices have changed the way work competences are defined. It has particularly resulted in a strong emphasis on soft skills as the key issues which explain employability and productivity in contemporary and future work. Large international projects have focused in defining the future competences and particularly the soft or generic skills needed in the future (Markes 2006).

Although soft skills may be useful in a variety of work situations and occupational practices, they are not a sufficient solution for helping new generations or older workers to cope with the more radical qualitative changes in work. For instance, an ability to apply disciplinary knowledge (e.g. mathematics) and work specific

skills in meaningful ways is held to be fundamental for successful work processes (Stasz and Brewer 1999). The requirements for coping with rapid and unexpected changes is not what kinds of soft skills workers have, but how they are able to restructure their basic disciplinary knowledge and work-specific skills in adaptive ways to respond to these changes. Based on his analysis of the nature of changes in a turbulent world, Ohlsson (2011) concluded that coping with radical changes requires non-monotonous learning which is not constrained by the experience that are similar to what has traditionally been described as learning. Instead, he defines this approach called “Deep Learning” as follows:

In the course of shifting the basis for action from innate structures to acquired knowledge and skills, human beings evolved cognitive processes and mechanisms that enable them to suppress their experience and over-ride its imperative for action. (Ohlsson 2011, p. 21)

The key premise in this definition is that in the history of humankind there have always been groups or individuals who have been able to surpass the immediate experience in their acting and thinking, resulting in novel ways of interpreting the world and these stand as powerful tools for overcoming the constraints of human’s biologically-determined limitations. With the term monotonic learning Ohlsson (2011) refers to additive cognitive growth of knowledge, which is consistent with what is known before. In an analogous way, two decades ago Hatano and his collaborators (Hatano and Inagaki 1986) introduced the term Adaptive Expertise, which approaches the same questions as Ohlsson’s definition of Deep Learning from a somewhat different perspective. Adaptive Expertise is an integrating concept that consists of cognitive, motivational, and personality-related aspects of orientation to approaching novel tasks and challenges. Problem-solvers generally demonstrate adaptive expertise when they are able to efficiently solve previously encountered tasks and generate new procedures for new tasks (See also the flexibility concept of Feltovich et al. 1997). Here it is proposed that, respectively, Ohlsson and Hatano conceptions of Deep Learning and Adaptive Expertise are needed for coping with radical changes taking place in working life. However, it is far from easy to describe what Deep Learning or Adaptive Expertise means in concrete terms and applicable terms. Thus, it is important to analyse if contemporary theories of learning can adequately describe the processes through which individuals and collectives secure or fail to learn the knowledge needed in radically changing circumstances.

8.2 A Systemic Approach to Theories of Learning

Since the nineteenth century there have been serious attempts to study learning by using scientific methods. This long tradition has resulted in a large number of theories, some of which have become widely accepted in the research and educational communities. However, it is clear that there is no one theory, which explains learning (Lehtinen 2012). The most obvious reason for this is that situation is that there is no consensus on a theory of learning because learning is not a specific phenomenon but

a kind of metaphoric concept. Moreover, it is a term used in everyday language and scientific literature to refer to very different processes from simple behavioural change in animals to learning abstract mathematics in the university, or learning as organisational change in enterprises (Lehtinen 2012; Säljö 2009). It has been common for the theoretical developments in learning research that when new approaches have been developed there have been intensive, critical and often unfruitful discussions between the advocates of the “old” and the “new” theories. During the last few years, there have been several attempts to analyse the diverse and complex field of theories and approaches of learning research from a meta-theoretical point of view (Lehtinen 2012). In her widely cited article, Sfard (1998) argued that certain kinds of metaphors underline the development of all theoretical thinking and proposed that it is possible to organize the field of learning research by classifying the dominating approaches into two loose categories, characterized as acquisition and participation metaphors of learning. Acquisition and participation metaphors are ontologically different ways to define what we mean with learning.

Sfard’s metaphor idea was later elaborated and extended further by Paavola et al. (2004), who proposed a third metaphor that they called the knowledge creation metaphor. None of these models construes the different metaphors as mutually exclusive. Indeed, learning is a complex phenomenon and different theoretical approaches are needed in analysing it in different situations (Lehtinen 2012). A very different approach was used by Alexander et al. (2009) who proposed a model that they called a topographical framework of approaches and theories of learning. They identified a set of principles that are common for most of the known theoretical approaches to learning (Alexander et al. 2009, p. 178). When commenting on the article of Alexander et al. (2009), Säljö (2009) highlighted that the model of Alexander et al. did not take into account the differences in the units of analysis of different approaches and the ontological and epistemological suppositions related to the use of these units in research.

Here, our aim is not to choose a theoretical camp or propose any “unified” theory. Instead, we propose a complex system view for dealing with the different theoretical approaches. The main theoretical approaches are typically attempts to answer different questions and they focus on different units of analyses (Lehtinen 2012; Säljö 2009). According to idea of complex systems, these approaches represent different systemic levels, which are mutually dependent, but not reducible to each other (Lehtinen 2012; Ohlsson 2011). In human learning, there are several system levels which all have their own characteristic properties that extend from primary concerns on neural processes through to cultural activity systems. As parts of a complex system, the properties of one level are interacting with properties of the other levels.

The complex system approach indicates that it is important to study the characteristic properties of different systemic levels and the interactions between them (Ohlsson 2011). A further assumption here is that cultural or situated activities and mental cognitive processes are two distinct, but interrelated levels of the learning system and both are particularly relevant when our aim is to understand how individuals or larger social communities are able to cope with rapid change. This coping

requires developing new knowledge and skills that go beyond previous experience and monotonic enrichment of prior knowledge and practices. In this chapter, the principal focus is on individual level cognitive processes. But, before reviewing the cognitive literature, we will briefly discuss how socio-cultural theories are dealing with the challenges of a turbulent world.

8.3 Do Theories of Learning Give Tools for Preparing People for a Turbulent World?

In his recent book “Deep Learning” Stellan Ohlsson (2011) argues that the seventeenth century scientific revolution in the natural sciences led to successful findings about the regular and predictive nature of many physical phenomena. In line with these findings, highlighting the regularity of physical world through a clockwork system became a general metaphor for science and it has dominated scientific thinking for centuries. Recently, alternative theoretical traditions have developed in natural sciences, which deal with chaos, complex systems and emerging processes. The focus is in phenomena and processes that do not follow clockwork type regularities (Ohlsson 2011). However, most of the existing approaches or theories of learning describe learning, which follows a clockwork-like model where learning is described as acquiring representations of known regularities and causal relations. This type of learning can also be characterized as monotonic additive change acquiring of knowledge or practices. However, in a turbulent world, it is becoming more and more important to ask how theories of learning help us understand flexible and adaptive forms of learning. In particular, it assists understand how non-monotonic learning that creates new knowledge and skills thereby enabling people to cope with emerging and surprising phenomena in their environment (Ohlsson 2011). In what follows, we review how sociocultural theories and theories describing individual level cognitive and constructive processes deal with the challenge of rapid and radical change.

8.3.1 Sociocultural Theories and the Challenge of Change

Most dominant ways of conceptualizing learning in sociocultural and situated theories emphasize a conservative rather than a radically changing or creative nature of learning. The Vygotskian (1978) idea of the zone of proximal development describes learning as a process in which new knowledge or skills first appear on the social level in interactions with a more knowledgeable collaborator (e.g. parent, teacher or experienced professional) and are afterwards internalized by the individual. In the seminal contemporary descriptions of situated learning theories, such as legitimate peripheral participation within a community of practice, the conservative

nature of learning is even more obvious (Lave and Wenger 1991). The relevant knowledge and skills already exist in the communities and newcomers become competent members of the community through the process of a gradually deepening participation.

However, more general level sociocultural approaches include a strong idea of qualitative change in the course of history. One of the approaches is Donald's (2000) theoretical description of how culture literally *reformats and re-programs the human cognitive architecture*. As a consequence of extensive cultural re-shaping, cultural resources became internalized as a part of human cognitive architecture and drastically affect the available cognitive resources on many levels. Because human cognitive capacities are not only biologically given, but also culturally-mediated, biologically equivalent brains adapt by sustained cultivation of expertise to prehistoric hunter-gatherer culture, the concurrent knowledge-intensive society, and to whatever will emerge in the future. Expertise in this way can be seen as a cultural-historically evolving interface between humans and the cultural environment of their activity. It represents a set of culturally programmed capacities that allow human beings utilize their cultural-historically accumulated knowledge and know-how and to go beyond biological limitations of intellectual achievement. There are a few more concrete theories that aim at describing how the creation of new knowledge could take place in social-cultural context.

8.3.1.1 From Tacit to Explicit Cycle as Innovation Creation Process

Within the sociocultural tradition there are many attempts to describe processes that not only mediate existing knowledge and practices, but also create new practices and innovations. Nonaka's model of knowledge transformation and innovation has been largely cited as a model of how new conceptual knowledge and practices emerge in an organisational context. According to Nonaka and Takeuchi (1995), western ways of thinking have been too concentrated on explicit knowledge. Explicit knowledge means all that knowledge which is easy to articulate and express formally and in clear terms. But in innovation, tacit knowledge is much more important. Tacit knowledge means personal and subjective knowledge that is embedded in individual experience and action; it involves personal intuition, ideas, and values. Due to its very nature, tacit knowledge is difficult to communicate to others. It especially addresses the dynamics of knowledge creation. In their model, knowledge creation is based on the interaction between tacit knowledge and explicit knowledge. Nonaka and Takeuchi (1995) also proposed that such creation involves passing through several "ontological" levels, i.e. individual, group, organizational, and inter-organizational levels, in order to be effective for all people and for whole organizations. The basic question in innovation is how this personal know-how and experience can be transformed so as to be useful for the whole group, and, conversely, how explicit knowledge in the group can be transformed into personal know-how and experience.

Nonaka and Takeuchi's solution is based on four "modes" of knowledge conversion. Knowledge can be transformed: (a) from tacit knowledge to tacit knowledge (a phase which is called socialization); (b) from tacit to explicit knowledge (externalization); (c) from explicit to explicit knowledge (combination); and (d) from explicit to tacit knowledge (internalization). These are four phases of the "knowledge creation" spiral, which commence when tacit knowledge and experiences are socially-shared at the group level. The idea is that the conversion involved in the knowledge spiral is a social process *between* people rather than one that takes place *within* people. In these processes analogies and metaphors are used to articulate ideas for innovation (Hakkarainen et al. 2004b).

8.3.1.2 Activity Theory and Expansive Learning

Engeström (1999) shares the same aim of describing the collective process of innovation creations with Nonaka and Takeuchi's (1995) but he criticizes their theory for not taking into account the key aspects of the innovative learning process. He has studied innovative learning cycles in work teams using cultural-historical activity theory and the theory of expansive learning as a framework for his analysis (see Engeström 1987). His main critique of Nonaka and Takeuchi's (1995) model is that it does not take into account those phases of knowledge creation where problems are formulated and analysed in the first place. According to Engeström, innovative learning starts by criticizing, questioning, and analysing existing practices. A particular aspect of Engeström's theory is in its focus on dialectical tensions, contradictions, and conflicts within communal activities; these are usually ignored (and considered nuisances) by other approaches focusing on immediate empirical generalizations. As an alternative to Nonaka and Takeuchi's model, Engeström (1999, pp. 383–384) has provided his own model of an expansive learning cycle. It starts by (1) individual subjects *questioning* and criticizing some accepted practices, which is followed by (2) *analysis* of the situation, i.e. analysis of those (historical) causes that have led to the situation in question, followed by (3), *modelling* of a new solution to the problems, and (4) *examining* the new model by experimenting and seeing how it works, and what potentialities as well as limitations it has. Next is (5) *implementing* the new model in practical action and applications, and (6) *reflecting* on and evaluating the process. Finally there is (7), *consolidating* a new form of practice. Different phases do not necessarily take place in a fixed sequence but Engeström emphasizes the flexible nature of the process in contrast to the mechanical order of the Nonaka and Takeuchi model.

However, despite their claims, both models have been successfully used in describing processes of change and innovation creation in organizations. The examples of the new innovations, boundary crossing processes and organizational changes described in the case studies of Nonaka's and Engeström's research groups are, however, closer to the monotonic extensions of existing knowledge than to non-monotonic creation of radically different ways to understand the world (Ohlsson 2011).

8.3.1.3 Knowledge-Creating Metaphor of Learning

A more ambitious attempt to theoretically describe how building fundamentally new knowledge occurs in collaborative processes has been presented by Hakkarainen and his collaborators (Hakkarainen et al. 2004a, Paavola and Hakkarainen 2005). Hakkarainen and his colleagues have proposed that professional learning in an advanced knowledge society can neither be reduced to the assimilation of already existing information (as assumed by the knowledge acquisition metaphor) nor growing up within prevailing community practices (as is often assumed by the participation metaphor). They propose a third, knowledge-creating metaphor of learning (Paavola et al. 2004) according to which learning may be seen as a process of deliberately creating new knowledge or transforming social practices in an interaction between individuals and communities. This process is driven by a central characteristic of adaptive experts' activity. That is the systematic working at the edge of competence, pursuing novelty and innovation. Their approach examines learning (a) in terms of building and extending shared knowledge artefacts, such as ideas, theories, or products, (b) creating collectively shared knowledge practices (making pursuit of innovation and novelty a social practice), and (c) interaction between personal and collaborative knowledge-creating efforts (transactive development of expertise).

Knowledge creation, in this way, may be seen as a collaborative process of working with a shared object and growing through the process. To solve complex and partially unforeseen problems at the edge of their competence, knowledge workers have to create, extend, and build shared knowledge artefacts (Bereiter 2002), such as texts, graphs and models, that crystallize their evolving knowledge and understanding. Pursuit of such artefacts is critical in knowledge creation because they can be endlessly re-interpreted and their evolving network used as a starting point of articulating and iteratively improving novel epistemic artefacts (Bereiter 2002; Paavola and Hakkarainen 2005; Skagestad 1993). As claimed by Knorr-Cetina (2001), creative knowledge work focuses on incomplete epistemic objects, objects that are open-ended and constantly generating novel questions and becoming more and more complex when pursued. Knorr-Cetina (1999) also pointed out that epistemic objects involve "pointers" (e.g. hints, guidelines, directions) regarding how further activities should be focused. These objects imply what is missing from the picture, and, thereby, guide further inquiries. Consequently, the epistemic objects created provide intuitive support, suggesting which way to look. Epistemic artefacts generated by knowledge communities' participants also appear to function as boundary objects (Star 1989) that assist multiple communities in carrying out coordinated inquiries, cross-fertilizing their knowledge, and hybridizing expertise across two or more domains of knowledge (Howells 1999). Knowledge-creating processes involve deliberate efforts in spanning boundaries of prevailing knowledge by creating novel and often far-reaching networking linkages to experts, communities, and networks representing heterogeneous knowledge and competence. The participants appear to co-evolve with the growing network of epistemic artifacts created in the course of their activity.

Hakkarainen and his colleagues (2011) argue, further, that professional creativity needed for encountering novel and unanticipated challenges does not only

lie within the human mind but is embedded in shared knowledge practices cultivated by such knowledge communities. They use the term “knowledge” in the broadest sense, to include what is explicit or stated in official discourse (e.g., approved texts), to what is implicit, informing one’s habits (perhaps pre-reflectively) of expert working; and further still to that which underlies the competencies of experts, for example, so called “procedural knowledge.” They argue that concurrent expert communities rely on “weakly determined, unstable, explorative, and problem-laden practices that are once in a while innovative” (Knorr-Cetina 2001). Knowledge practices, while sometimes just supporting routine learning (transmission), at their creative edge diverge from other routine social practices in that they take place in specific purposefully dynamic and fluid settings designed for the furtherance of innovation and knowledge (Knorr-Cetina 1999, 2001). Rather than merely relying on mundane habits or repeated routines (that may also be needed), such practices are aimed at solving emergent problems and constantly pursuing novelty and innovation. Professional experts have to increasingly meet novel challenges and engage in systematic creative reinvention of their shared practices so as to elicit novelty and innovation (Knorr-Cetina 1999, 2001). It is held that in the case of communities that follow such practices, innovation and the pursuit of novelty are themselves transformed to shared social practices through the cultivation of corresponding personal and collective competencies and patterns of shared activity (Knorr-Cetina 1999, 2001; Simon 2002). Whenever such innovative practices are encountered, we are dealing with *innovative knowledge communities* and their networks (Hakkarainen et al. 2004a).

Hence, the subject of knowledge creation is a collective rather than an individual. While individual experts often have a critical role in the pursuit of novelty and innovation, it takes place on a fertile ground provided by collaborative activity (Paavola et al. 2004). In parallel with social communities, adaptive experts may appropriate innovative knowledge practices to the extent that the pursuit of transformations relevant for knowledge-creation becomes their second nature, i.e., an integral aspect of their activity. There appears to be a dynamic and fluid reciprocally effective interaction between personal and collective practices that drives the development of collective activity. The development of expertise is a long-standing process involving profound personal transformations. Such a process cannot be understood by examining mere personal drives for developing expertise or stable features of the social and cultural environments but rather the dynamic “transactional” interaction between these two poles of development (Sameroff and Mackenzie 2003).

A sustained pursuit of deliberate practice enhances and augments the participants’ cognitive capabilities for adapting to the environment of their activity and allows them to address problems at higher and more complex levels. By systematically building their personal learning networks that reach beyond the boundaries of their immediate community, participants are transforming the ecology of their development. In order to orient towards constantly working at the edge of competence, experts have to develop dynamically evolving and gradually tightening criteria of assessing and evaluating their performance. Bereiter and Scardamalia (1993) distinguished between first- and second-order environments. First-order environments are

static in nature, and adaptation in these environments is oriented toward meeting a fixed set of conditions. In second-order environments, on the contrary, the conditions to which an agent must adapt change dynamically as a function of the other actors' (individuals or organizations) progress in the environment. High-tech companies or scientific research communities represent such second-order environments with progressively changing requirements. Exceptional competencies emerge collaboratively in *second-order cultures* in which the environment of adaptation transforms and the acceptable level of performance is dynamically growing as a function of other communities' success. This framework is compatible with an idea that individual, community, and larger knowledge networks constitute different systemic levels that are reciprocally dependent on one another.

8.3.2 How Individual (Mental) Level Theories Are Able to Explain Radical Change?

Following the approach that views theories of learning as conceptual tools for dealing with phenomena (i.e. units of analysis) on different levels of a complex system, we now focus on theories describing individual level cognitive processes. This approach reveals that individual cognitive processes are not independent of culturally and socially shared knowledge and practices. Worthwhile creative insights do not emerge accidentally or randomly. Creativity, intuition, and innovation are not based on spontaneous, unique, and in accessible subjective processes (Ohlsson 2011; Simon 1977). Even if new ideas may arise as sudden insights, these ideas are often held to be preceded by relatively long periods of collective work dealing with the problems under investigation (Csikszentmihalyi and Sawyer 1995; Gruber 1981, 1995).

A fundamental feature of generally accepted models of human cognitive and constructive processes is that situations and new information are interpreted within the frames of already existing mental representations. A consequence of that interpretation is the conservative nature of cognitive processes. How is qualitatively new knowledge possible if perception and thinking is based on already existing knowledge? Based on formal logic some philosophers (Gödel 1962; Fodor 1976) have concluded that a symbol system or a system of axioms can only generate sub-systems, which are not more powerful than the original system. When applied to learning and knowledge construction this means that there is a learning paradox, which questions the possibility of constructing fundamentally new knowledge (Ohlsson 2011).

However, it is clear that people are somehow able to break out of the initial frameworks and create radically new ways of thinking and acting (Ohlsson 2011). Many approaches in the cognitive tradition have focused on explaining change in knowledge and skills. The question of how the human mind is capable of going beyond its existing skills and experiences is not new. This type of learning and problem solving was clearly the aim for the psychological tradition, which was labelled gestalt psychology (Wertheimer 1959). Innovative studies about problem solving and insight carried out by the gestalt psychologists in the first half of

twentieth century are still topical, but this tradition failed to present a solid theory because it didn't have an established "language" for describing mental processes (Langley and Jones 1988; Ohlsson 2011; Simonton 2000). Piaget's accommodation concept and particularly the idea reflective abstraction and the characteristics of formal operation level thinking are attempts at describing how the human mind develops new forms of thinking, which make a higher level interpretation of world possible (Piaget 1976, 1978). However, the aim of Piaget's theoretical work was to explain general (epistemological) transitions between forms of thinking in the course of human development, from infancy to adolescence, and it is questionable how well these theoretical models can be used to describe the nature of learning concrete tasks.

8.3.2.1 Reconsidering the Concept of Transfer: From Immediate Transfer Towards Preparation for Future Learning

The issue of transfer is normally discussed in the context of education. However, it is even more important in the development of generalized knowledge and skills, including varying attempts to apply prior knowledge in different transitions from school to work, or from one working place to another. Firstly, it raises the question of the existence and role of abstract knowledge. Secondly, it highlights the role of people's own activity and agency in these transitions. Thirdly, it questions the immediate and correct application of previous knowledge as the main criterion for transfer.

According to De Corte (1999), the problem of transfer and general applicability of knowledge and skills has been on the agenda of research in educational psychology and learning research throughout the previous century, and the interest in the issue has increased during last 10–15 years. In their review article on transfer, Bransford and Schwartz (1999) emphasize the importance of transfer for the very idea of schooling. A belief in positive effects that extends beyond the exact conditions of initial learning underlie the very rationale of educational institutions and teaching activities. Educators are hopeful that students will show evidence of (positive) transfer in various situations. As far as vocational education and professional training is concerned the success depends on students' ability make use of their school learning in future work. However, the issue of transfer is very controversial and it has been the subject of many critical debates among researchers (see Anderson et al. 1996; De Corte 1999, 2003; Detterman 1993; Lave 1988; Ohlsson and Lehtinen 1997). The critical discussion is partly based on experimental empirical findings, often showing failures of transfer (e.g. Detterman 1993), and on theoretical analyses emphasizing the situated nature of activity and cognition, which call the whole meaning of transfer into question (e.g. Lave 1988).

In their frequently cited analysis of types of transfer, Salomon and Perkins (1989) distinguished between a 'low' and a 'high road' to transfer. The 'low road' transfer takes place when conditions in the transfer context are sufficiently similar to those in a prior context of learning. These can more or less automatically trigger responses similar to the learned processes in the initial situation. This type of transfer can be

explained in Thorndike's traditional terms of identical elements between initial and target situations or tasks. Singley and Anderson (1989) have reinterpreted Thorndike's behaviouristic view into cognitive language within the frames of their ACT* theory, and defined transfer in terms of identical cognitive productions. The traditional Thorndikean view and its modern cognitivist version highlight the objective similarity of the situations, and they pay less attention to the subjective interpretations of the learners. From the point of view of understanding learning radically new ways to understand situations the traditional transfer concept doesn't provide very much because it refers to a simple repetition of previously learned knowledge or at the most gradual monotonic change.

Institutional vocational education and formal professional training are based on the assumption that knowledge and skills learned in these situations are widely applicable to diverse situations. However, the dominant traditions of learning and expertise research have emphasized more restricted possibilities of transfer. Theories of development of expertise (e.g. Ericsson et al. 1993; Lave 1988; Lave and Wenger 1991) and laboratory experiments on transfer (e.g. Detterman and Sternberg 1993) all seem to concur that activity in a particular situation depends on knowledge and skills that are situation specific and highly particular (Billett 2001). The ability to perform a given task resides primarily in how much one knows about that particular task in a certain context, not in general principles or in any capacity for abstract thinking (Lenat and Feigenbaum 1991).

Many current ideas emphasize the use of concrete, episodic and socio-culturally embedded information without the involvement of general principles and abstract knowledge that have traditionally been connected to higher-order thinking. Lave's (1988) widely cited descriptions of the use of situated strategies instead of formal school mathematics in grocery shopping or preparing meals at home have been used as a proof that "abstract" school mathematics does not transfer to practical situations. However, the examples could also be explained differently. They all include several aspects of formal mathematical knowledge, which are used as a part of the situational strategies to solve the particular problems. From this point of view, the examples describe creative ways of transferring abstract mathematical knowledge to concrete situations and embed them in activities and tools available in these situations. Recent findings of the use of mathematical knowledge in different professions refer to this kind of interpretation. Formal mathematical concepts and procedures are very important in a range of professions, but these are applied very differently depending on the requirements of the particular tasks. Mathematical knowledge (i.e. that typically learned in general education) is used in relation to a particular work process or technological application. In boundary crossing communication between different professionals formal mathematical and scientific concept serve as a commonly shared basis, helping to avoid misunderstandings (Stasz and Brewer 1999).

Greeno and his collaborators (Greeno et al. 1993) have proposed an approach, which deals with the similarity of the situations from the point of view of the learner's activity in them. The activity in the learning situation occurs under certain affordances and constraints. Transfer is possible, if the new situation contains sufficiently similar constraints and affordances to the initial context, or if the learner interprets

them similarly. This view also highlights the similarity of the situations but not so much as an objective condition than as a set of features of the situation interpreted from the point of view of the learner's intentional activity. However, the critical question here is that what happens when no immediate similarity can be perceived.

There are theoretical approaches to transfer, which can be used to analyse situations in which there is no immediate similarity. The second road to transfer in the model of Salomon and Perkins (1989), namely the "high road" describes these kinds of situations. They argue that there is also a higher level of transfer, which depends on abstraction from the context of learning or application and a more or less conscious attempt to find general patterns and principles that go beyond the surface features of the situations. This type of transfer is not immediate but demands time for exploration and mental effort. It is not the similarity in any superficial feature of the initial and target problems or situations that characterize transfer but the thinking and knowledge which is transferred to new situation can be on a very high level of abstraction. Bransford and Schwartz (1999) argue very similarly that effective transfer requires a sufficient degree of original learning, which leads to relevant abstractions. For Bransford and Schwartz (1999), meaningful transfer is not only the immediate application of previously learned knowledge in new situations, but they broaden the conception of transfer by emphasizing that transfer should be conceptualized in terms of "preparation for future learning". Here, the focus shifts to the assessment of individuals' abilities to learn according to the future demands and opportunities arising in new situations. In addition, they point out that an important aspect of active transfer involves people's willingness to deal with novel and challenging tasks in social interaction situations and to understand others' ideas and perspectives. Bransford and Schwartz (1999) exemplify the preparation for future learning approach to transfer by describing teachers' transition from teacher education to work.

As an illustration of transfer as PFL, imagine elementary education majors who graduate and become classroom teachers for the first time. By the standard DA (Direct Application theory of transfer) definition of transfer, the test of transfer would be whether the beginning teachers, without coaching, can apply to the classroom the methods they learned in school. As noted above, this is an important concern yet it is only one part of the larger story. The larger story involves whether the novice teachers have been prepared to learn from their new experiences, including their abilities to structure their environments in ways that lead to successful learning (e.g., arrange for peer coaching). There is no preliminary education or training that can make these people experts; it can only place them on a trajectory towards expertise. (Bransford and Schwartz 1999, p. 68)

This conception is consistent with the suggestions of Lobato and Siebert (2002) who hold that transfer should be reconceived along individual and cognitive dimensions, while also examining how transfer is situated in group practices and socio-cultural aspects of the environment. To understand learning and transfer in natural and complex situations, it is important to examine how people construe situations as similar or different, regardless of whether or not the generalizations that people make across situations lead to "correct" or normative performance. Lobato's (2012) "actor-oriented transfer" perspective examines the processes by

which actors form personal relations of similarity across situations. The actor-oriented transfer perspective argues that the basis for transfer is the learner's construction of similarity rather than objectively given similar "elements" in the environment. This approach highlights the crucial question, which distinguishes the different theories of transfer: is transfer defined in terms of the qualities of the initial vs. the target situations and tasks, or is it mainly interpreted in terms of the immediate or long-term mental activities carried out by the learner in these situations?

The 'applying knowledge' metaphor of the orthodox transfer paradigm suggests that tasks across which transfer occurs remain unchanged during transfer, and that the "transfer" reproduces existing relations between fixed tasks (Beach 1999; Lehtinen and Hannula 2006). In contrast, in the actor-oriented transfer and preparation for future learning approach, the metaphor of *construction* replaces that of *application*. Relations of similarity are constructed or produced, not simply perceived or encoded. As a result, transfer situations are no longer viewed as static and unchanging but rather as dynamic sites for invention and reorganization (Lobato and Siebert 2002, p. 90).

How one recognizes the familiarity or similarity when entering new situations is important in these new approaches to transfer. If we shift our focus from very explicit experimental situations of typical transfer studies towards everyday situations or long-term learning of complex scientific or professional tasks, how people interpret the situations and recognize new phenomena with the help of their previously constructed mental concepts is far from trivial. In their article about the learning of abstract ideas, Ohlsson and Lehtinen (1997) claim that to recognize an object as an instance of abstraction, a person must already possess that abstraction. This is especially obvious in complex scientific theories like Darwinian evolution or Newtonian mechanics, as well as in many mathematical concepts. In the classical view, similarity is an epistemologically primitive category. The similarities between two particulars are the basis for creating a generalization. In contrast, Ohlsson and Lehtinen (1997) suggest that people experience particulars as similar to the extent that, and because, those particulars are recognized as instances of the same abstraction. Abstraction engenders similarity rather than vice versa.

These fresh approaches propose transfer as a preparation for future learning. They include learners' active role, interpretation and modification of the situations in a new way. This along with integrating abstract knowledge to affordances of the situation is a potentially relevant approach for explaining how people are capable of non-monotonic creation of new knowledge and practices in rapidly changing situations.

8.3.2.2 Deliberate Practice and Expertise Development

The development from novices to experts means remarkable quantitative and qualitative change in knowledge and skills. One way to explain this development is Ericsson's theory of deliberate practice.

Deliberate practice is practice, which intentionally aims at improving one's skills and competencies (Ericsson 2006; Ericsson et al. 1993). It is not enjoyable, but involves effortfully and selectively improving critical aspects of the performance. It is not a mechanical and repetitive process of making performance more and more fluid, as some studies appear to indicate (Dreyfus and Dreyfus 1986). Instead, it involves a great deal of thinking, problem solving, and reflection for analyzing, conceptualizing, and cultivating a developing performance. This includes directing and guiding future training efforts that are then fine-tuned to dynamically evolving levels of performance. It often takes place under the guidance and coaching of old masters who have already gone through a similar process and gained a great deal of experience (Gruber et al. 2008). In the musical domain, it appears critical for one to undertake solitary training in order to improve specific aspects of one's performance. Apparently, only "perfect practice" skilfully tailored to one's dynamically developing level of accomplishment makes one perfect (Ericsson 2006). Investigations indicate that human performance improves through extensive practice without any pre-given limitations. At the further stages of practice, individuals may have to invest more training in relation to each further step of improvement (Ericsson 2006). People do not become aware of the radical modifiability of their competencies because they deliberately give up training after achieving a satisfactory level of performance, which often takes place after a few dozens of hours of training.

Numerous studies carried out by Ericsson and his colleagues (Ericsson 2006; Ericsson and Lehmann 1996) indicate that the length and intensity of (masterful) deliberate practices alone explains exceptional performance and masterful accomplishments; we do not have to think (and there is no solid evidence) that even the highest performers and top masters were at the outset categorically different from other people (Ericsson 2006), i.e., were innately endowed with specific gifts or talents that would explain their excellence. The top performers have often started their practice earlier than those attaining a moderate level of performance and they have practiced much harder and more systematically (having several thousands of hours more of deliberate practice than their less accomplished colleagues, Ericsson and Lehmann 1996). All measures indicate that a superior expert engages in more intensive training rather than has any mysterious short-cuts to excellence based on their gifts. There are, furthermore, no reliable means of distinguishing those who will become elite performers during training; while many initially promising candidates fail (Starker and Ericsson 2003), some of those who do not initially show any promise may start excelling later on in training. Expert research problematizes the above mentioned cultural assumptions according to which creative achievements are based on fixed and innate gifts and talents that are trainable only to a limited extent (for criticism of such view, see Howe 1999).

It is difficult to evaluate the efficacy of the deliberate practice approach from the point of view of non-monotonic change. Definitions of deliberate practice clearly describe incremental learning which take place when people systematically practice on the limits of their existing skills and look for continuous improvement. The improvement is, at least in most of the published examples, based on detailed feedback given by coaches, tutors or colleagues and is to some extent dependant on

the knowledge these supporting people already have (Ericsson 2006). On the other hand, descriptions of deliberate practice include the idea of adaptive expertise by emphasizing the avoidance of automatization of an acceptable level of performance and the need to maintain the ability to control the execution of the skills, making intentional modifications and adjustments difficult (Ericsson 2006, pp. 684–685). In some cases, deliberate practice leads to exceptional performance and people are able to do something in a novel way, which goes beyond the constraints of prior knowledge and practices.

8.3.2.3 Theories of Conceptual Change

Ohlsson (2011) discusses the possibilities and processes of non-monotonic change in turbulent contexts, which he claims require radically new forms of knowledge and thinking. Interestingly, the same question has been asked in the science learning context, where students are basically learning very established and well known scientific knowledge. However, from students' view points, the learning of certain scientific concepts requires radical and non-monotonic restructuring of prior knowledge (Vosniadou 1994, 2008). The term "conceptual change" is used to characterize situations where learners' prior knowledge is incompatible with the requirements of the new tasks they are confronted with. During the last decades, research on conceptual change has produced a rich variety of models of the development of students' conceptual understanding and conceptual change (Chi 2008; Chi et al. 1994; Duit 1999; Ohlsson 2009; Vosniadou 1994, 1999). One of the important distinctions made by the researchers of conceptual change is the definition of learning as continuous growth or enrichment of knowledge, or as discontinuous change requiring radical restructuring of prior knowledge (Vosniadou 1994). The discontinuity of learning is defined similarly to the non-monotonic change by Ohlsson (2011) described earlier in this chapter and it occurs in a situation where prior knowledge is incompatible with the new tasks or information.

In learning certain scientific concepts, generally shared everyday beliefs or more trivial concepts learned during earlier school years are not enough to create an understanding of the requirements of the new tasks or knowledge, and in many cases prior knowledge is incompatible with the new tasks and may lead to systematic misconceptions. This means that misconceptions are not random products of insufficient learning, but have specific consequences of a particular prior knowledge. Intervention studies have indicated that when learning such scientific concepts in which systematic misconceptions frequently appear, students' prior knowledge is often resistant to teaching efforts (Limon 2001).

There are several theoretical explanations of conceptual change, which also lead to somewhat different recommendations about the instructional strategies for helping students overcome conceptual change problems. Most of the theories are directly related to the conservative nature of cognitive processes described earlier in this chapter. When new knowledge or a task is interpreted within the existing representations, the properties of prior knowledge constrain the possibilities to interpret the situation of tasks in novel ways, which are incompatible with prior knowledge.

Ontological shift theory developed by Chi focuses on the role of ontological knowledge in conceptual change (Chi 2008; Chi et al. 1994). According to this theory, a learner locates concepts to ontological categories, such as: object, matter, event, process, mental state, and so on. When learners try to learn to understand a previously unfamiliar phenomenon, they assign it some of their ontological categories typically on the basis of the most salient features of the new phenomena. As a consequence of this categorisation, the learned phenomenon is connected to the characteristics of that category. In learning scientific concepts, learners often interpret the phenomena within a wrong category for example electricity within the category of matter rather than within the category of processes (Chi et al. 1994). Changing the initial ontological category to one that is adequate to the advanced scientific interpretation of the concept has proved to be difficult and due to that learners have robust misconceptions. The theory of ontological category shift is a powerful tool for describing conceptual change problems in specific scientific concepts but it is difficult to see how widely applicable it is in the working life context.

Vosniadou (1994) has proposed an approach, which she calls framework theory. According to this view, people tend to develop relatively coherent explanatory mental models for phenomena they meet in their everyday environments. These subjective theoretical frameworks connect concrete experiences, and ontological and epistemological beliefs so that they form a sufficiently coherent model. New information is interpreted by individuals within this framework and if it conflicts with the framework it typically results only in peripheral changes in the mental models, but does not necessarily change the basic elements of the framework theory. Synthetic models described by Vosniadou (1994) are examples of situations in which conflicting information is assimilated within existing frameworks without changing it to meet the deeper requirements of the new information. When trying to understand astronomy, children today repeat the same difficulties that humankind has repeated in the course of our history. That is to understand the form of the earth and its location in the system of planets, they develop synthetic models (for example people living on a flat are inside the hollow sphere) in which the socially mediated information of earth as a sphere is connected to an initial mental model without changing the framework theory supporting the flat earth centred model. The framework theory approach and conceptual change research in general is considered to be a promising approach in studying professional learning but it has not yet been widely applied in empirical studies in working life context (Achtenhagen 1995; Tillema and Orland-Barak 2006; Sharpe 2004; Tynjälä et al. 1997).

Recent empirical research suggests that conceptual change is a very complex process that proceeds through the gradual replacement of prior beliefs and presumptions (e.g. Vosniadou 2008; Chi 2008). Researchers have agreed that these processes, which overcome serious conceptual change problems are influenced by motivational (e.g. Linnenbrink and Pintrich 2003) and metacognitive (Flavell 1979) processes. Intervention studies show that increasing a learner's meta-conceptual awareness could be an effective way to support conceptual change (e.g. Mason 2001). This means learning environments and materials, which help learners to become aware of how

they conceptualise the new phenomena and of the deeper differences between typical naïve concepts and the scientifically correct concept (Mikkilä-Erdmann 2001).

The conceptual change approach is an attractive possibility for analyzing learning, which results in radically new knowledge and skills. However, nearly all studies of this theoretical tradition have taken place in the formal science learning context. This means the presence of a more knowledgeable teacher or tutor who is able to analyse learners' misconceptions and guide them towards more advanced understanding of scientific concepts. However, this presence is not the case in turbulent working life situations in which radically new understanding should be developed. This raises the question of what triggers non-monotonic learning processes going beyond prior experience.

Early studies on conceptual change in science learning highlighted the importance of cognitive conflict as a key experience that triggers conceptual change processes (Posner et al. 1982). However, later experimental studies have shown that cognitive conflict doesn't lead to conceptual change processes in most of the cases even if there is a knowledgeable teacher organizing a planned conflict experience for learners (Limon 2001; Merenluoto and Lehtinen 2004). In a turbulent working life situation it becomes even more challenging and it is important to analyse how people recognize the cognitive conflict between their prior knowledge and new demands in a way that results in adequate conceptual change process.

Merenluoto and Lehtinen (2004) proposed a theoretical model of the dynamics of motivational, metacognitive and cognitive processes in experiencing cognitive conflict and conceptual change. The starting point in the model is a learning situation, where learners engage with tasks and materials that include phenomena calling for new conceptual understanding. The model is based on the assumption that the perception of the task (task situation) is influenced by students' cognitive, metacognitive, and motivational sensitivity to the task. Sensitivity in this model refers to the extent to which students are aware of, and interested in the novel cognitive aspects of the phenomenon. Cognitive and metacognitive sensitivity refers to the relation between a learners' prior knowledge and the cognitive demands of the task, and to the meta-conceptual awareness about their thinking about this relationship (e.g. Mason 2001). Motivational sensitivity describes the learners' tendency to look for novel and surprising features during learning activities (Merenluoto and Lehtinen 2004). Low sensitivity (cognitive, metacognitive or motivational) means that a person doesn't feel any need to develop new skills or acquire new knowledge, which would better enable them to manage new situations.

High sensitivity means that a person has sufficient prior knowledge to understand the cognitive demands of the task, which go beyond his or her current conceptual understanding, and is disposed to pay attention to the unknown features of the situation (Merenluoto and Lehtinen 2004). This is related to the expert vs. novice differences. In new problem situations, novices tend to pay attention to the superficial features of the tasks, whereas experts perceive the tasks in terms of underlying general principles (Chi et al. 1988). In turbulent professional changes new aspects of situations requiring conceptual change lie typically on the conceptual level and are not necessary observable on the surface level. The definition of sensitivity is similar to

the dynamic expertise model of Bereiter and Scardamalia (1993) where expertise is seen more as an orientation for seeking new challenges, than as a static state of established skills. A similar emphasis of sensitivity to new challenges is one of the key features the adaptive expertise model of Hatano and Inagaki (1986).

The experience of a cognitive conflict then leads to reduced certainty (e.g. Efklides et al. 1999; Merenluoto and Lehtinen 2004). This means that learners do not base their thinking merely on established knowledge, but are prepared to change their knowledge beliefs. Because in real professional situations the conceptual change process and construction of deeply new understanding takes time, learners need to tolerate cognitive ambiguity (Frenkel-Brunswik 1948) when reconsidering prior knowledge and beliefs (e.g. Stark et al. 2002). Thus, coping with a new complex conceptual system is possible only if learner have sufficient metacognitive skills and motivational orientation to grasp novel and conflicting features of the situation (sensitivity). These skills are, however, not sufficient as they also need to be motivated to tolerate ambiguity, and to trust that the experienced conflicts are solvable.

8.4 Conclusions

In the course of its development, humankind has been able to cope with catastrophic changes in their environment and has managed to develop more advanced knowledge, skills, and understanding of the world. All of this has made it possible for us to overcome the constraints of physical environments and some biological properties. This has required learning, which goes beyond our previous experience and prior knowledge and enables a non-monotonic creation of completely new ways of understanding the world. The ability to cope with rapid changes and pro-actively create new innovative ideas has become increasingly important in the turbulent working life of today. In this chapter our aim was to review some of the theoretical approaches within learning research, which try to describe this type of learning.

When dealing with the challenges of changing situations the major problem with traditional theories of learning is that these are practically all focused on the mediation of existing knowledge, skills and practices to new generations. Behaviourist and association theories describe how people learn simple factual knowledge or desired behaviour as a consequence of a direct influence of their environment, cognitive theories describe how prior knowledge constrains the interpretation of new situations and explains learning as a gradual enrichment of existing representations, and socio-cultural and situated theories base learning on gradually deepening participation in existing cultural activities. These theories provide a rich basis for organising education and learning opportunities within workplaces for learning established knowledge and practices. However, these mainstream theories fail to offer a solid basis for understanding how people should be educated to cope with rapid change and for a future working life which does not yet exist.

However, within cognitive and socio-cultural traditions there have been attempts to create approaches, which are aimed at describing how the expansion of

knowledge, innovation, and radical change in the way in which people conceptualize phenomena would be possible. The examples of socio-cultural theories described in this chapter have been developed and applied in a professional context and are thus better known among the professional learning and development research community. Some of the individual level cognitive approaches described in this chapter have mainly been used among researchers studying children's and adolescent's learning and applied in a school context. However, the findings of conceptual change research and the new idea of transfer as an active process and as preparation for future learning would be helpful for addressing the challenges of professional and vocational training in rapidly changing situations.

In this chapter, we applied ideas of complex systems in organising different theoretical approaches to different interdependent but irreducible units of analysis. Promising theories describing radical and non-monotonic change have been developed within the sociocultural and individual cognition levels, but well elaborated models to describe the role of mutual interaction between the levels are still rare. For developing learning environments for professional and vocational learning that assist address rapid change needs well elaborated and empirically tested theories. These will need to deal with non-monotonic change on both, individual and socio-cultural levels, and also a advanced conceptual understanding how these levels interact in different situations in workplaces and schools. To develop more powerful theoretical approaches to deal with rapid and deep going change we should consider the ways in which different theories describing individual learning could be integrated and how these individual level processes could be framed within the sociocultural context.

We propose that Ericsson's theory of deliberate practice is a promising starting point for analysing possibilities of professional learning on the individual level when confronted with radically new challenges. Although most examples of deliberate practice describe expertise development in established fields of expertise with the help of knowledgeable coaching, deliberate practice seems to also have an important role in processes in which fundamentally new ideas and applications are developed (Ericsson 1999; Weisberg 2006). Deliberate practice provides individuals with techniques and skills needed in the process where new ideas and applications are developed (Weisberg 2006).

However, deliberate practice theory does not offer conceptual tools for analysing the nature of the cognitive processes needed in the non-monotonic learning processes. Based on the previous analyses of different theoretical approaches we propose that integration of the findings of conceptual change research and deliberate practice would be a promising approach for analysing professional learning which results in radically new knowledge and work practices. On the one hand, deliberate practice strengthens established processes and interpretation and thus, in principle, increases the probability of applying established interpretations and processes in changing situations in which they are not any longer adequate. On the other hand, deliberate practice may help people see more deeply the discrepancy between their prior knowledge and the requirements of the changed situations. This makes it possible for them to develop meta-conceptual awareness, which is the key aspect of successful

conceptual change. Furthermore, the change of interpretations of the new professional situations on a merely conceptual level is not enough. A new level of deliberate practice is needed within the changed conceptual framework, which results in new innovations and work processes (c.f. Weisberg 2006). Furthermore, the ideas, reviewed earlier in this chapter, such as the alternative transfer theories describing transfer as actor oriented preparation for future learning may give valuable approaches for analysing the formation of deliberate practice within the changed conceptual frameworks.

Weisberg's (2006) detailed analyses of the processes related to historically important innovations not only show the importance of deliberate practice but also the collective nature of innovations. The persons working on the problems are embedded in knowledge cultures and facilitated by existing cultural artefacts. The collaborative knowledge creation approach (Hakkarainen et al. 2004a; Paavola and Hakkarainen 2005) provides us with the conceptual tools for analysing how different aspects of individual level deliberate practice and conceptual change are supported by the collective processes typical for innovative knowledge creating communities.

It is, however, beyond the possibilities of this chapter to present an elaborated theoretical model of the relationships of learning processes at different levels within the complex system of individual and collaborative learning confronted with radically new challenges in working life. Nevertheless, we believe that in future research on professional and work place learning it is important to make use of a larger variety of theoretical ideas and empirical findings of learning research which focus on individual and collective learning processes. There are valuable theoretical approaches in different fields of learning research, which have not been widely used within the professional learning research community.

Chapter 9

Understanding Learning for Work: Contributions from Discourse and Interaction Analysis

Laurent Filliettaz

Abstract In recent years, interaction and discourse analytic methods have been applied extensively in various areas of educational research and have become an important theoretical perspective for those concerned with the study of learning in social settings. Following this innovative perspective, this chapter advances two main arguments. First, it stresses the idea that adopting a discursive and interactional approach on professional practice can contribute to the body of concepts and methods applied for understanding practice-based learning. And second, it considers that there exists a strong epistemological continuity between social theories of learning on the one hand, and research methods belonging to the field of discourse and interaction analysis on the second hand. From there, the aim of the chapter is to identify and specify an interdisciplinary field intersecting linguistics methods and professional education research. It is also to show what these methods consist of, how they may be enacted and applied and what are their potentialities and practical implications for researching the field of professional and practice-based learning.

Keywords Discourse • Interaction • Language • Knowledge • Identity • Context • Multimodality

In recent years, interaction and discourse analytic methods have been applied extensively in various areas of educational research and have become an important theoretical perspective for those concerned with the study of learning in social settings. Initially conceived as descriptive tools elaborated by linguists for describing the complex organisation of language use in context, these methods have progressively been seen as powerful resources to gain a fine-grained understanding

e-mail: Laurent.Filliettaz@unige.ch

of teaching and learning processes in a wide range of formal and informal educational contexts. By studying discourse and interaction within classrooms and other educational settings, researchers have provided new insights into the dynamic relationships among language use, social practice, and learning. More specifically, they have provided understandings of the ways in which learning opportunities are constructed across time, groups, social institutions and joint actions.

Following this innovative perspective, this chapter advances two main arguments. First, it stresses the idea that adopting a discursive and interactional approach on professional practice can contribute to the body of concepts and methods applied for understanding practice-based learning. And second, it considers that there exists a strong epistemological continuity between social theories of learning on the one hand, and research methods belonging to the field of discourse and interaction analysis on the second hand. From there, the aim of the chapter is to identify and specify an interdisciplinary field intersecting linguistics methods and professional education research. It is also to show what these methods consist of, how they may be enacted and applied and what are their potentialities and practical implications for researching the field of professional and practice-based learning.

To address these issues, the chapter is divided in five main sections. The first section retraces the origins of a so-called workplace discourse research field. It reflects on the growing importance of discourse and interaction within contemporary workplaces and emphasises the role of language in social theories of learning, as they have been extensively disseminated within vocational and professional education research. These bring empirical as well as theoretical arguments for an interdisciplinary examination of discourse-mediated practices through which workers encounter learning experiences at work. The second section is designed to provide the reader with a synthetic understanding of discourse and interaction analysis. Key concepts and principles underlying this multidisciplinary field are exposed and the main requirements underlying methodological aspects are briefly summarised. The third section illustrates how the study of discourse and interaction may contribute to the understanding of professional and practice-based learning. It identifies a range of research topics that have been investigated from an interactional and discursive perspective and reports on recent research conducted internationally on these topics. Section 9.4 provides further illustration of how discourse analytic methods may be enacted to inform practice-based learning research. Referring to empirical data recently collected in the context of the Swiss vocational education and training system, the chapter observes how guidance is interactionally accomplished in discourse and how apprentices and supervisors use a variety of semiotic resources to shape learning opportunities in work production activities. To conclude, the fifth section discusses the potentialities and challenges associated with a discursive methodology and stresses its practical applications and implications for vocational and professional education.

9.1 The Emergence of Workplace Discourse Research

In the past two decades, a growing number of scholars with an expertise in various areas of linguistics have become interested in analysing and interpreting empirical data collected in professional settings. Depending on their theoretical backgrounds and origins, research topics conducted in this area have endorsed multiple labels, including for instance *institutional talk* (Drew and Heritage 1992), *professional discourse* (Candlin 2002), *workplace studies* (Heath, Knoblauch and Luff 2000), *organisational discourse* (Boden 1994), *language in the workplace* (Boutet 2008; Holmes and Stubbe 2003), *business discourse* (Bargiela-Chiappini 2009) or *workplace discourse* (Koester 2010). This body of research does not constitute a coherent and well-integrated research field, but it assumes that a fine-grained analysis of how workers make use of language, both in its oral and written forms, may contribute to better understand professional practice and the conditions in which it unfolds. Reciprocally to this “professional turn” in applied linguistics, it is also noteworthy that researchers in adult and vocational education often stress the role of language in professional learning and development and therefore refer to concepts related to linguistic theories.

Elaborating on the idea that there is a growing interest for an interdisciplinary research domain intersecting linguistics and professional education research, this section investigates why it is relevant and productive to care about discourse and interaction when investigating professional and practice-based learning. In the following paragraphs, empirical as well as theoretical arguments are brought for a multidisciplinary cross-examination of learning for work. We stress the importance of discourse and interaction processes in workplace practices and argue for epistemological continuities between social theories of learning and the study of language in action.

9.1.1 *The Linguistic Demands of the Contemporary Workplace*

There are strong empirical reasons why researchers concerned with the study of learning in and for professional practice should be concerned about the role and place of discourse and interaction in the workplace. As numerous sociolinguists have noted (Boutet 2008; Heller 2003), the historical evolution of work itself has established increased demands regarding language use and communication skills. In their everyday professional practice, workers are expected to share information, to solve problems, to cooperate with colleagues, to plan future actions or report on past experiences. This is particularly true in the context of what is often referred to as the “new work order” (Gee et al. 1996), an economy that is strongly dominated by the service sector, by information and communication technologies, by a dematerialization of production and by globalized management strategies. In many respects, the contemporary workplace sees language use not only as a peripheral

ingredient but as a central component through which professional practice occurs. In a sense, this has always been true for professional sectors such as education, health, law or social work. But these linguistic demands are also becoming increasingly significant in other domains from which they were historically perceived as absent or peripheral, such as the industrial sector for instance. It is now commonly expected from all workers that they should be able to cooperate with colleagues, have sufficient literacy and numeracy skills, adapt to norms and procedure that may take written or oral forms, and be capable of reflexive thinking. In other terms, discourse and interaction processes have become progressively perceived as productive resources and not anymore as a mere distraction.

In recognising the configuring role of discourse and interaction in contemporary workplaces, sociolinguists have also highlighted the multiple functions endorsed by linguistic resources in workplace contexts. These functions include practical, social as well as cognitive dimensions of professional practice (Lacoste 2001). First, language use at work has often been reported as serving practical functions. It is by engaging in discourse and interaction that workers “get things done”, that they plan and anticipate future actions, perform them, and provide accounts and evaluations about past events. Second, linguistic resources are also used by workers as resources for accomplishing the social dimensions of professional practices. They are means through which workers position themselves in groups, endorse specific identities, produce or reproduce cultural communities or establish power relations. And finally, linguistic resources as they are used in workplace discourse and interaction also serve cognitive processes related to memory, problem solving and learning. It is by engaging in discourse and interaction that workers share and negotiate a joint understanding of the world, that they take decisions, reflect on their experiences and that they may learn from more experienced workers.

Acknowledging the centrality and multifunctional nature of language use in professional practice has significant implications for vocational and professional education. These implications include reinforced expectations in terms of training and a renewed understanding of the skills and competences workers must share for facing the demands of the contemporary workplace. It is indeed of primary importance to prepare and adapt the workforce to the multilingual, globalized and discourse-mediated professional practices dominating the “new work order”. And it is also important to provide workers with resources that may assist them in facing these specific demands. At a more theoretical level, these evolutions also shed new light on the ways language and communication skills may be perceived in vocational and professional education. In the contemporary context referred to, these skills are not to be seen as “soft” or related to a general cultural background; rather, they have to be considered as key instruments for professional practice and as integral components of professional competences. Finally, it should also be noted that the “linguistic turn” mentioned here leads to a reconceptualisation of the relations linking language and education. Language, in such a perspective, is not only a matter of teaching and learning or a cultural tool that has to be acquired; it is also a means through which workers experience learning at work and therefore an important condition for learning through practice. This is what the next section proposes to develop.

9.1.2 *The Linguistic Aspects of Learning Processes*

Social theories of learning have recurrently underlined the collective and distributed nature of learning processes and the configuring role of “the others” and language in the ways individuals access and interiorise knowledge and develop skills. The Vygotskian concept of the zone of proximal development (ZPD) defined as “the distance between the actual development level as determined by independent problem solving and the level of potential development as determined through problem solving under adult *guidance* or in collaboration with more able peers” (Vygotsky 1978, p. 85) is often regarded as a central reference point for approaches that see learning processes as involving a plurality of individuals. From the Vygotskian perspective, it is assumed that psychological development does not consist of a process of individual and biological maturation but involves close interactions with the cultural environment and with more experienced individuals. Guidance and verbal interaction, in this framework, appear as important conditions for expanding the zone of proximal development and for developing problem-solving skills. Vygotsky also argued that the acquisition and use of language transforms children’s thinking. He proposed to see language as a “cultural tool” having a profound effect on both collective and individual thinking. One of the distinctive strengths of his theoretical model is that it “explains not only how individuals learn from interaction with others, but also how collective understanding is created from interactions amongst individuals” (Mercer and Howe 2012, p. 13).

Closely aligned to Vygotsky’s theory of psychological development, Bruner’s concept of “scaffolding” has often been used in sociocultural psychology to refer to discourse processes through which individuals are guided in their learning. Initially developed in the context of dyadic interactions between parents and young children (Bruner 1983; Wood et al. 1976), the concept of scaffolding is defined as a discourse mediated teaching and learning process, wherein the adult helps the child progress from assisted performance to unassisted once. Based on this seminal work, numerous scholars have attempted to transpose the concept of scaffolding into the context of school interactions (Panselinas and Komis 2009; Rojas-Drummond and Mercer 2003) in order to investigate the educative value of various sorts of dialogues (i.e. teacher-led dialogues; peer group discussions). From this standpoint, questioning practices initiated by teachers have been seen as powerful communicative means by which students are guided to elaborate their own thinking.

By transferring the concepts of guidance, scaffolding and the zone of proximal development beyond the limits of the classroom, contemporary approaches to professional learning have promoted new ways of understanding the relations between learning and work. In this respect, convincing alternatives to the distinction between formal and informal education have been advanced (Evans et al. 2006; Guile and Young 1998). In Lave and Wenger’s anthropological approach to apprenticeship for instance (Lave and Wenger 1991; Wenger 1998), participation in communities of practice is seen as an important means by which newcomers gain access to knowledge and develop practical skills in specific production contexts. Learning is not exclusively about the acquisition of expertise and practical intelligence, but also comprises a process of

identity transformation. That is, under specific conditions, including participation to communicative events, newcomers are progressively recognised as members of communities of practice as they move from peripheral to full participation.

Another particularly interesting contribution to this field is Billett's model of "relational dependencies" between social and personal ingredients to learning in the workplace (Billett 2001a, b). In line with sociocultural approaches, Billett sees learning in and through practice as related to "participatory practices" by which workers gain access to specific actions in workplace contexts. But, as pointed by Billett (2001a), "it is inadequate to believe that learning simply by just doing it will suffice" (p. 7). Both social and personal factors may either support or on the contrary hinder learning opportunities. Social factors are designated as "affordances". Affordances include for instance the sort of guidance provided to novice workers, the type of expertise available or not and more globally the range of resources workplace contexts are able to provide to learners. Personal factors are referred to as "engagement". Engagement is related to the specific ways individual workers elect to make use of the resources afforded to them in the workplace. These individual factors include for instance personal values, prior experiences and personal epistemologies. Affordances and engagement are seen as key determinants of learning in the workplace and as shaped by a relation of interdependence. Interestingly, Billett's model of "relational dependencies" between social and personal components acknowledges the contributions of language, discourse and other semiotic means to learning in professional practice. When describing efficient strategies by which close guidance may be afforded to workers, Billett (2001a, p. 144ss) proposes to see *questioning dialogues*, the production of *models* and *analogies* as processes through which workers elaborate, substantiate and extend their thinking. He thereby recognises the existence and potentialities of "scaffolding" strategies beyond the limits of the classroom and applies them to the understanding of professional learning.

From this brief inquiry into sociocultural theories of learning, it results that substantial connections exist between the "linguistic turn" taken by researchers in professional education and the ways sociolinguists approach workplace practices. In both fields, language use is seen as a major mediating tool by which individuals engage in social practices and encounter local, cultural and psychological transformations. Based on what can be seen as a strong epistemological continuity between sociolinguistic theory and sociocultural psychology, a growing number of scholars have applied discourse and interaction analytic methods for gaining a better understanding of how individuals learn in and from professional practice. This is what the next sections will illustrate and discuss.

9.2 Principles, Concepts and Methods of Interaction and Discourse Analysis

What is exactly discourse and interaction analysis and what underlying theoretical principles is it based on? There are of course many different ways to answer these questions but a common way to refer to discourse and interaction analysis is to

define it as the study of language use in relation to specific institutional and cultural contexts and with regard to its cognitive and social implications (Wodak and Meyer 2001). Discourse and interaction analysis does not constitute a unified research field but should be seen as a multidisciplinary approach made of a plurality of paradigms. The selected methodologies draw upon concepts and analytic categories from various fields of linguistics, such as interactional sociolinguistics (Gumperz 1982), conversation analysis (Sacks et al. 1978; Schegloff 2007) and critical discourse analysis (Van Dijk 1997; Wodak 1997). These fields have explored multiple avenues of linguistics and are often seen as offering competing or contradictory approaches for analysing discourse and interaction. Nevertheless, these frameworks also share common assumptions about language and social life. In particular, they view language not only as way of transferring information from speakers to recipients, but as a historical and culturally shaped medium through which individuals take actions, achieve cooperation, align identities, participate in social events and share a joint understanding of the world in which they evolve. In observing the con-creted actions among members and describing how these members communicate and interact, discourse analysts examine what members produce together, what they hold each other accountable for, and how they make sense of actions of others. In doing so, they identify patterns of practice that make visible what members need to know, produce, and interpret to participate in socially appropriate ways.

Beyond the internal boundaries that delimit distinct trends and affiliations in discourse analysis, a number of concepts and methodological requirements can be seen as shared principles across interaction and discourse analysts. In this section, these principles are made visible and a range of assumptions are selected that may be helpful to understand how discourse and interaction relates to professional and practice-based learning.

9.2.1 Key Concepts in Interaction and Discourse Analysis

In what follows, four key concepts are presented and commented, that have been broadly applied in various trends in discourse and interaction analysis: *contextual indexicality*; *situated identities*; *sequential organisation* and *multimodal meaning making*. It might be arbitrary to focus exclusively on these four categories, but these concepts shape diverse properties of discourses and relate to complementary theoretical perspectives adopted in the field. They can be seen as good candidates for introducing the field of discourse and interaction analysis.

The first concept closely related to a discourse analytic perspective is that of *contextual indexicality*. This concept relates to the idea that language use is seen as being cosubstantially linked to the contexts in which it is produced. It is indeed widely accepted amongst discourse analysts that discourses entertain multiple and complex relations with the social and material conditions in which they take place. On the one hand, discourses are often seen as being shaped by contexts in the sense that historic, cultural and material arrangements exert a form of influence on the

ways discourses are produced. But on the other hand, discourses are also shaping these contexts in the sense that participants may use linguistic resources to make visible how they interpret specific contextual arrangements (Duranti and Goodwin 1992). Within interactional sociolinguistics, Erving Goffman's framing theory has often been used as an important contribution to such a dynamic and constructivist conception of context in discourse analysis. This theory stresses the idea that the meaning of ordinary perceptions and human behaviour is highly premised in light of natural and social "frames" (Goffman 1974). These "frames" shape the ways individuals interpret social reality and adapt their own conducts to such interpretations. Developing William James' and Gregory Bateson's ideas, Goffman considers that these framing processes are never fixed, but are vulnerable to change. People may misunderstand the meaning of contextual arrangements; they may also be abused or influenced to produce false interpretations; finally, they may also revise the meaning they attribute to the reality they experience in social life. From such a *dynamic* perspective, "contexts" can be seen as the result of a process of "contextualisation" through which participants jointly negotiate how to interpret the conditions in which social action takes place. Such a renewed perspective on context and contextualisation deeply transforms the way the relations between contexts and language in social interaction is being looked at. As put by Gumperz (1982) amongst others, language use in interaction is not only shaped by the social conditions in which it takes place, it is also "context renewing" in the sense that participants may use it as "cues" to make inferences about what the context "is" and how to initiate changes to its local configuration.

Closely related to the principle of contextual indexicality, the notion of *situated identity* has often been used by discourse analysts to understand how participants to social interaction position themselves according to each other and with regard to broader cultural and institutional arrangements. Following Goffman again, these processes of positioning are not perceived as determined by preexisting social roles, but endorsed by participants in discourse and interaction itself (Goffman 1961). It is by "doing being" a person of a certain kind that participants endorse particular identities in social action and that they place co-participants in a reciprocal position. To capture this dynamic conception of relational work in interaction, the concept of *situated identity* has sometimes been used to stress how social relations are deeply shaped by local arrangements. For Zimmerman (1998), "situated identities come into play within the precincts of particular types of situations" (p. 90). These situations are effectively brought into being by participants engaging in activities and respecting specific agendas. It is by endorsing specific roles in discourse that participants display an orientation to these situated identities and that they make visible how they align or not the social values attached to them. In that sense, situated identities are very much a product of discourse and interaction rather than a personal attribute belonging to individuals.

To understand how these contextual arrangements and situated identities are dynamically produced in discourse and interaction, the concept of *sequential organisation* has often been used to capture the local temporal processes through which interaction unfolds. The notion of sequential organisation has been primarily investigated by conversation analysts and ethnomethodologists, who see it as a

central principle underlying situated interaction (Sacks 1992; Schegloff 2007; Ten Have 2007). By using the concept of sequential organisation, conversation analysts understand that social actions jointly accomplished by a plurality of participants do not unfold in an arbitrary way but reflect a specific social order. To align to this social order and to make it visible, participants engage in fine-grained coordination processes in which they take turns, use adequate places for leaving the floor to coparticipants and orient to the successive steps by which action is accomplished. From there, conversation analysts consider the sequential organisation of talk-in-interaction as the dynamic process through which participants make their actions publically accountable and shape interpretations about what they perceive as relevant in the context. The machinery of turn-taking in interaction becomes a resource for interpreting how participants orient to each other and accomplish a joint understanding of their actions.

The sequential organisation of interaction and its contribution to the understanding of contexts and the endorsement of situated identity does not exclusively rely on linguistic units; on the contrary, it also involves a wide range of other semiotic systems participants may use as resources for coordinating their participation. To refer to this multitude of semiotic resources combined in discourse and interaction, the concept of *multimodality* has recently emerged as a solid reference point within discourse theories. Multimodal discourse and interaction analysts originate from a variety of subdomains of linguistics such conversation analysis (Goodwin 2000), mediated discourse analysis (Levine and Scollon 2004; Norris 2004) or social semiotics (Kress and Van Leeuwen 1996). These various disciplines have developed distinct approaches to discourse and interaction, but they also share a tendency to break away from a logocentric view on language and communication. The concept of multimodality relates to the plurality of semiotic modes combined in human behaviour (gestures, gazes, body movements, spatial displays, images, objects, voices, texts, etc.) and to the local arrangements through which they are used as tools for accomplishing social actions. For multimodal discourse and interaction analysts, participants are constantly engaged in complex meaning-making processes in which they have to produce a joint understanding of their actions. It is by using and combining a plurality of modes that they produce and interpret meaning in context and that they elect to orient to specific resources (or not). Considering that these choices are not arbitrary but also, to some extent, shaped by the specific potentialities of these resources themselves and the conditions in which they are used, participants also express forms of agencies through the specific ways they make use of semiotic tools in interaction. Here is another instance of the close connections that exist between semiotic forms and their psycho-social implications.

9.2.2 Methodological Implications

The concepts presented above and the theoretical principles they are aligned with have significant implications at methodological level. Discourse and interaction analysts do not all use the same research methods, but the methodologies they enact follow, at least to some extent, convergent lines that can be specified as follows.

One first way to specify the methodological requirements underlying a discursive perspective relates to the role and nature of data used for research. Empirical data is central for discourse and interaction analysis in the sense they constitute the primary material on which the analysis is based. Data consist in written, oral and multimodal behaviour through which individuals accomplish social practices in specific contexts. Discourse and interaction analysts usually do not artificially provoke the data they are putting under scrutiny. They collect these data in the natural conditions in which they occur and conduct field work to gain access to such data. From there, close connections often exist between discourse analysis and the ethnographic perspective (Gee and Green 1998). Data collection should not be seen as a capturing process from which the observer is radically absent. On the contrary, it is the outcome of a joint elaboration and the result of a complex relational process in which the researcher has progressively acquired an understanding of the observed practices and made his presence understandable and acceptable to the observed participants.

A second way to specify methodological requirements associated with discourse and interaction analysis is to comment on the sorts of technologies used for collecting data. For capturing the indexical, dynamic and multimodal nature of situated interactions, discourse and interaction analysts have progressively come to use video recordings for research purposes (Erickson 2004a; Heath et al. 2010). Video recordings of naturally occurring talk-in-interaction capture the fine-grained details of how interaction unfolds, its relations with specific material and practical arrangements, and the complex range of semiotic resources used and combined by participants. The filming of discourse and interaction itself is not perceived as an objective process that gives direct access to all aspects of social practices. On the contrary, discourse and interaction analysts consider that recordings are very much shaped by the researchers' choices and by the kind of relation researchers established with the individuals they observe. From there, audio-video recordings of naturally occurring talk-in-interaction also express subjective and intersubjective dimensions.

Discourse and interaction analysts usually never work directly on audio-video recordings but produce mediated forms of data consisting in transcripts. Transcripts give a written and synthetic form of verbal and non-verbal behaviour as they unfold on audio-video recordings. They do not capture all aspects of what is possible to perceive on these recordings but make relevant details available to the analysis by using explicit transcription conventions. Apart from conversation analysis, which has developed a well-established and explicit conventional system (Jefferson 2004), there does not exist a unique and unified convention regarding the way to produce transcripts. These norms and practices are largely dependent on the purposes of the analysis itself and have to be regarded as theoretically oriented (Ochs 1979). However, beyond these theoretical variations, discourse and interaction analysts usually align to the principles underlying their conception of language use in context. Most of the transcripts aim at capturing the dynamic and sequential nature talk-in-interaction and have progressively integrated a growing range of information related to multimodal aspects of interaction (Norris 2004).

It is based on these transcripts and the audio-video recordings they refer to that discourse and interaction analysts produce interpretations about the social practices they study. The analytic approach underlying this perspective is highly qualitative but based not only on the contents expressed in the data. Details regarding the unfolding process of interaction are seen as meaningful cues for understanding how these contents have been understood by participants themselves. From there, analytic interpretations are based both on a general ethnographic understanding of the contexts in which data has been collected and on the qualitative properties of these data and their dynamic unfolding.

9.3 Discourse and Interaction Analysis as a Tool for Understanding Professional and Practice-Based Learning

By changing the focus from the description of the linguistic system to the organisation of social action, interactional and multimodal approaches to discourse have progressively been seen as research methods beyond the limits of linguistics. In many areas of educational research, discourse analytical methods have been applied as a way to explore multiple facets of educational practices (Rex et al. 2006). In the field of teaching and learning in schools for instance, concepts and tools borrowed from conversation analysis and interactional sociolinguistics have been extensively applied to describe and understand the specific patterns of classroom interaction and the conditions under which students access knowledge in the context of the classroom (Gee and Green 1998; Macbeth 2003; Mehan 1979; Mercer and Howe 2012). Applied linguists have also adopted a multimodal perspective for understanding how teachers and students make use of multiple semiotic modes to engage complex meaning-making processes in class (Kress et al. 2001).

Recently, discourse analytic tools have also been applied in vocational and professional education research so as to account for educational practices that take place outside the specific school context. In the following paragraphs, we highlight a range of research topics that have been investigated with a methodological focus on discourse and interaction and stress how these research topics illuminate our understanding of professional and practice-based learning. To do so, we will report not only on our own work but also on a more general body of research conducted in European countries and beyond.

9.3.1 Knowledge Transmission and Acquisition

One first research area for which discourse analytic methods may be fruitfully used relates to the understanding of the complex sorts of knowledge underlying professional practice and the specific ways these knowledge are made accessible to

workers in practice. Workplace learning theories usually consider that professional learning relates to multiple sorts of knowledge, including *conceptual*, *procedural* and *dispositional* components (Billett 2001a, p. 50ss). But little is known about the ways these various components of professional learning are transmitted and acquired, and how discourse and interaction helps workers to make these knowledge visible and accessible.

In an extensive research program conducted in our team at the University of Geneva,¹ we precisely addressed these sorts of issues and aimed at understanding how apprentices enrolled in practice-based apprenticeship programs in Switzerland gain access to vocational knowledge in the different institutional contexts in which they are trained. Based on audio-video recordings of naturally occurring interactions between apprentices and various sorts of trainers, the research program was designed so as to access and describe typical discourse practices by which professional knowledge are shared between experts and novices. Various strategies for providing instruction in the workplace were identified, most of them being finely tuned to the unfolding of productive work task (Filliettaz 2009a). From the data analysis, we also observed that both vocational teachers and workplace supervisors abundantly use analogies when referring to vocational knowledge and skills (Filliettaz et al. 2010b). We described the main forms and functions and such analogical discourse and showed how it serves both cognitive and social purposes in instruction. We also described how specific contents are systematically reformulated and resemiotised when teachers and trainers give explanations to apprentices (Filliettaz et al. 2010a). And finally, we observed how workplace supervisors handle questioning dialogues in the workplace: how they respond to questions asked by apprentices and how they address questions to apprentices (Filliettaz 2011a). Our observations in this area show that answers are surprisingly neither the sole nor the dominant form of responses following questions in the workplace.

Beyond these linguistic aspects of knowledge transmission and acquisition, this same research program also allowed to investigate the role and impact of the material environment on teaching and learning processes. Building on a variety of empirical contexts including car mechanics and the building industry, we described how teachers and trainers handle technical objects and make use of the material environment in order make perceptual components of professional knowledge accessible to apprentices (Filliettaz 2007). These descriptions provide evidence to the idea that space and materiality should not be seen as a mere static setting in front of which instruction unfolds, but as a key resource shaped and designed by teachers and trainers in their everyday situated practice.

In a completely different empirical field, that of medical doctors' training in the UK, Roberts et al. (2000) also used discourse analytic methods to reveal implicit and often hidden aspects of professional knowledge. Observing that medical

¹This research program was sponsored by the Swiss National Science Foundation (SNF) under references PP001-106603 and PP00P1-124650. It has benefited from the valuable contributions of Ass. Prof. Ingrid de Saint-Georges, Dr. Barbara Duc and Dr. Stefano Losa.

doctors trained abroad and candidates from ethnic minorities were relatively more likely to fail their final examination, they questioned if the conditions in which oral examination was conducted provided equal opportunities for all candidates or if these could lead to discriminatory outcomes. By recording and analysing gate-keeping interviews in undergraduate and postgraduate medical examinations, Roberts et al. highlighted the large amount of tacit cultural knowledge candidates were expected to acquire and mobilise to participate effectively in the oral examination procedure itself. These analysis suggest that candidates from ethnic minorities may experience particular hidden difficulties with oral examinations and that examination boards should educate their examiners about these difficulties and their implications.

9.3.2 Guidance and Participation at Work and in Vocational Education

A second research area that has attracted considerable attention amongst linguists and professional educationists is that of guidance and participation at work and in vocational education. In recent years, a number of scholars have used principles of discourse and interaction analysis to understand how novice workers are assisted in their participation and the learning outcomes potentially associated with such guidance. This body of research has aimed at describing how workplace supervisors or trainers shape the ways learners engage in professional practice and how they may contribute, effectively or not, to professional learning.

In the research program on apprenticeship training in Switzerland referred to earlier, these issues have been explicitly investigated. A detailed analysis of the data resulted in stressing contrasted forms of guidance provided by trainers and supervisors in workplace environments (Filliettaz 2010a; Filliettaz et al. 2009). Two main models of training were identified in the companies observed. According to the first model, referred to as “assisted participation”, apprentices were progressively introduced to various facets of productivity. They generally did not work on their own but assisted experienced workers in their tasks. These workers took in charge most of the work procedure, but afforded local opportunities for apprentices to gain access to practice, under close guidance provided by an expert. According to the second model instead, apprentices were immediately put to work and were ascribed full production work tasks very early. In this second training model, the kind of guidance provided to apprentices appeared to be more distant and less oriented by training concerns than by productivity. In close relation with this later observation, another research result consisted in underlining the collective nature of guidance in the workplace (Filliettaz 2011b). Our data showed that although apprentices were usually placed under the responsibility of specific work supervisors, they interacted with a plurality of colleagues, experts, workmates, peers, etc. when they engaged in productive tasks in the workplace. Our analysis of these data revealed that the pedagogical qualities of these distributed forms of guidance varied quite substantially

across contexts. In some cases, they took the form of complementarities and continuities across evolving steps of work tasks. In other circumstances, they consisted of misalignments or controversies between competing workers.

In the Francophone field of professional didactics, a number of researchers have also become interested in the role of “tutoring”, “guidance” or “supervision” in workplace learning and have highlighted the mediating role of discourse and interaction in the ways apprentices develop skills and competences in the workplace (Kunégel 2005, 2011; Mayen 2002). In his PHD dissertation devoted to apprenticeship in the field of car-mechanics in France, Kunégel for instance describes a dynamic model capturing the relational configurations between apprentices and the supervisors at various stages of the apprenticeship pathway. Kunégel proposes to distinguish six successive steps, including a phase of “familiarisation”, a phase of “instruction” and a phase of “attribution of work production tasks”. The main interest of this model is to show that there seems to be a strong alignment between the level of competences apprentices are expected to display and the sorts of verbal and non-verbal interaction existing between apprentices and their supervisors. The other interesting contribution of this model is that it proposes to see these interactional configurations as evolving in time and not as given or static realities. From that standpoint, language and communication between apprentices and their supervisors function as central mediating tools for understanding the relations between practice and learning.

In a different context, that of air traffic control, Koskela and Palukka (2011), made similar observations. Applying the tools of conversation analysis and ethnomethodology, they explored the ways in which trainers and trainees act and interact in training situations and aimed at identifying methods of guidance and supervision in this particular context. By collecting and analysing video recordings and ethnographic material gathered at a vocational institute for aviation and in two aerodrome control tower units, Kostela and Palukka identified different instructional strategies by which trainers guided and controlled the trainee’s actions. They showed that, as trainees progressed from simulator training to the on-the-job training phase, interaction evolved from being trainer-driven to trainer-guided. These results suggest that instructions and information deliveries are finely tuned to the trainees’ performance and the local practices of particular work position endorsed at various steps of the training program.

Within the similar framework of ethnomethodology and conversation analysis, Mondada (2006) also explored patterns of interaction between trainers and trainees in work-related contexts. Her study focused on professional training in the field of surgery and aimed at identifying specific aspects of the competences trainees must acquire and display to participate adequately to complex training practices. The data used for this study consisted in audio-video recorded surgical operations available through online video conference to a group of advanced trainees. In the course of these operations, the audience had the possibility to ask questions to the chief surgeon carrying out the surgery. The analysis of these data consisted in describing the local environments in which questions were asked and the ways in which participants dealt with these questions in the complex framing context of work and training

practices. Results showed that trainees had to identify adequate positions for asking questions and that trainers' evaluations helped them in learning how and when to ask questions in such practice-based training practices. At a theoretical level, this study also highlighted specific discursive and interactional aspects related to the acquisition of professional competences. By critically discussing the concept of competence within an interactionist perspective, Mondada showed ways in which conversation analysis can inspire an approach to cognition and acquisition based on the concept of *interactional competence*, defined as relevant forms of participation emerging from social interaction.

9.3.3 *Integration of Theory and Practice*

Another topic that has been extensively investigated in vocational and professional education in reference to a discourse analytic methodology relates to the integration of theory and practice in learning through work. Numerous scholars have indeed addressed the issue of the so-called "theory-practice gap" and have aimed at understanding how school-based teaching and learning experiences may best prepare for, elaborate on or complete the provision of practice-based training. Here again, concepts and tools borrowed from discourse and interaction analysis have been used to stress the continuities or the gaps that may exist between the various institutional or epistemic ingredients that are combined in vocational or professional training programs.

In our own research, data analysis consisted in describing and illustrating continuities and boundaries between training practices as they take place in the various sites involved in the Swiss "dual" training system. Significant contrasts were observed with regard to the ways apprentices gained access to vocational knowledge in vocational schools and on the job. In vocational schools and training centres, tasks were generally designed to support learning and teachers or trainers referred explicitly to knowledge (de Saint-Georges and Filliettaz 2008; Filliettaz et al. 2010a). In the workplace instead, vocational knowledge was certainly not absent from production work tasks, but often remained implicit or unnoticed by apprentices (Filliettaz 2010b, c). Consequently, it was not so much the kinds of knowledge available in the various training sites of the dual system that characterised the learning experience of apprentices (conceptual vs. procedural knowledge). Rather it was also the means by which these various forms of knowledge were made available to apprentices (de Saint-Georges and Duc 2009). Special attention was also paid to the rhythmic conditions in which action unfolded in the various observed training sites (de Saint-Georges and Duc 2007; Filliettaz and de Saint-Georges 2006). In the workplace contexts, it was observed that time pressure was very quickly brought to the attention of apprentices and strongly shaped the learning opportunities associated with workplace environments. However, various sorts of responses to this time pressure were detected (Filliettaz 2009b). In some companies, workplace supervisors explicitly softened these temporal constraints for

themselves and for apprentices and allowed extra time for providing instruction. In some other companies, time pressure resulted in a lack of time for assisting the apprentice.

Also noteworthy is Akkerman and Bakker's study about vocational training practices in the Netherlands (Akkerman and Bakker 2012). Deploying the theoretical notion of boundary crossing, the authors conducted field work and ethnographic observation in a Dutch senior secondary vocational laboratory education program and investigated the actions and interactions taking place between school and work during apprenticeships. The study aimed at taking into account both cognitive and identity-related aspects of learning. It consisted in analyzing how apprentices' experiences at work were discussed and reflected upon with students and teachers at school. The findings revealed that what students were expected to learn in work-related practices was largely rendered invisible by the technology-mediated, scripted and socially distributed nature of their work. From there, release days seemed to provide initial ways to explicate and reflect with teachers on what was going on at work. They functioned as useful contributions to vocational learning and provided a good illustration of how school and work institutions can mutually feed each other in facilitating apprentices' learning. Here again, a fine-grained analysis of talk-in-interaction collected in training sessions during release days was used as a means to understand the sorts of learning experiences made by apprentices across various training institutions and practices.

In a rather different empirical context, the research conducted over the past 15 years at the Victoria University of Wellington in the so-called Language in the Workplace Project (LWP) also contributed in a significant way to use sociolinguistic methods for integrating theoretical and practical aspects of professional education. Since 1996, Janet Holmes and her team began an innovative study of spoken communication in New Zealand workplaces aiming at identifying the characteristics of effective communication between workers, diagnosing possible causes of miscommunication and exploring possible applications of the findings for New Zealand workplaces. Data collection began in government organisations and was progressively expanded to factories, small corporate workplaces, medical settings and IT companies. Volunteers in each organisation audio-taped everyday work-related meetings or discussions, telephone calls or social conversations. Detailed and systematic analysis of these data resulted in highlighting the complex sociopragmatic skills displayed by workers when collaborating with colleagues (Vine 2004), doing relational work (Holmes and Stubbe 2003) or exerting leadership at work (Holmes et al. 2011b). Recently, the data and findings gathered in this particular research area were also used as teaching material for migrant workers and as support for the provision of a curriculum addressed to workers with specific linguistic and sociocultural needs (Holmes et al. 2011a, b). In an academic context, learners with a migrant background learnt to identify the sociopragmatic demands of the workplace by observing and analysing empirical data collected in workplace contexts. Later on, they also used workplace experiences to make use of what they learnt and to reflect on these sociopragmatic skills.

Such integrated teaching and learning methods were progressively applied extensively in New Zealand programs for skilled migrants. They showed promising results for integrating theoretical and practical aspects of second-language acquisition in professional contexts.

9.4 Learning Through Practice as an Interactional Accomplishment

Beyond the general description of the sorts of research topics that have been recently investigated with a discursive lens, it is also important to understand how analytic tools borrowed from discourse and interaction analysis can be effectively enacted to address subjects of increased attention in vocational and professional education. In this section, these contributions are illustrated by narrowing down the scope on the topic of learning through practice and by investigating the role of contextual variation in the ways workers experience learning in professional practice. These learning experiences and contextual variations are seen as accomplished in and through interactions between co-workers and the social and material environment in which they engage.

Numerous scholars in the field of workplace learning have stressed the idea that workplaces are not equal in the resources they provide to learners and that their qualitative properties may differ in substantial ways (Tynjälä 2008). For example, Fuller and Unwin (2003) have presented a continuum of restrictive vs. expansive organisations with regard to how these support workplace learning. *Restrictive* environments are characterized by the fact that they afford limited opportunities for apprentices to be recognised as legitimate learners and learning from their work. On the contrary, *expansive* work environments are supportive to learners, afford rich learning tasks and generate opportunities for apprentices to be recognised as legitimate learners and workers. This distinction, which should be seen as a continuum, argues for the configuring role of contextual variation in learning for and from practice.

From that standpoint, it becomes increasingly important to understand how contextual arrangements in the workplace may influence learning opportunities and enhance consistent pathways through practice-based training programs. It becomes also necessary to understand the role played by skilled professionals in helping novice workers to learn in and from practice and to assist these professionals to reflect on the resources they need to use to adapt the workplace into a training site. Moreover, addressing these challenges from a research perspective raises a number of theoretical and methodological issues: how do contextual and individual factors interact in the possibility for workers to learn in and from practice? How can learning opportunities in the workplace be defined, observed and understood? How can one account for contextual variation across workplace environments and identify contextual arrangements that support learning opportunities?

To illustrate the benefits of a discursive and interactional perspective for understanding contextual variation and its impact on learning in and from practice, we now turn to empirical material collected in the context of the above mentioned research program dedicated to apprenticeship training in Switzerland. In the following sections, two contrasting case studies are provided, documenting how first-year apprentices engage in work-production tasks in two different companies located in the Geneva area. The two training sites belong to the trade of car mechanics and involve first-year apprentices at the very beginning of their apprenticeship. The first case refers to the mechanics workshop of a large public facility. It involves Michael, a first-year apprentice in mechanics and Larry, his official supervisor and manager of the repair workshop. The second case refers to a small-sized private car repair shop, hiring Samuel as an apprentice. Samuel is supervised by Jeff, a skilled mechanics who has no official tutoring functions towards apprentices.

The participants belonging to these two work and training sites have been observed regularly on a voluntary basis during several weeks in spring 2006. With their consent, observations were video recorded by the researchers. These recordings took place after a period of preparation during which participants got used to the presence of the researcher and a relation of mutual confidence was established between partners. By observing and analysing brief excerpts of audio-video recorded data documenting naturally occurring interactions between these apprentices and their trainer, the following range of questions will be addressed, related to the general theoretical frame mentioned above: What sorts of learning opportunities are being afforded to apprentices in these two distinct workplaces and how do apprentices engage with these opportunities? How do workplace supervisors and apprentices reconcile production constraints with training and learning purposes? In what sense can these work and training environments be regarded as expansive or restrictive forms of participation? And what are the contributions of discourse and interaction to the ways participants shape and transform the local contexts in which they engage?

9.4.1 Transforming a Maintenance Procedure into a Teaching Sequence

The first case relates to a car repair shop belonging to a large public facility (Company A). Michael (MIC), a novice apprentice, works in close collaboration with Larry (LAR), an experienced mechanic who acts as a supervisor and trainer within the workplace. Both the apprentice and his supervisor are conducting a maintenance procedure on a truck. At the beginning of the excerpt transcribed next, they initiate a new task included in the maintenance procedure: the cleaning and fine-tuning of the valves located at the top of the six cylinders composing the engine. Michael and Larry are standing next to each other, in front of the open hood of the lorry, when Larry initiates the following sequence of interaction.

9.4.1.1 Interaction in Company A²

1. LAR: I'm trying to find a way to turn the engine so that we can access the cylinders\ . there should be a gear door below I'll go and get a gurney\
2. MIC: yeah\
3. LAR: what you can do meantime you look where the inlet and exhaust valves are located
4. MIC: I've already found them\
5. LAR: really/. and/
6. MIC: ((points to the valves on the engine)) exhaust/ inlet/ inlet/ exhaust/ exhaust/ inlet\
7. LAR: OK that's correct\ . firing order of a six-cylinder engine/
8. MIC: I haven't learnt that yet\
9. LAR: 1-5-3-6-2-4\
10. MIC: 1-5-3-6 I'll write it down\
11. LAR: here take a sheet of paper ((gives a piece of paper to MIC))
12. MIC: you write 1-5-3-6-2-4\
13. MIC: ((writes the sequence of numbers on the paper)) **【#1】**
14. LAR: OK now that you have the firing order you find out which cylinder is connected to each valve\
15. MIC: OK\
16. LAR: and meantime I'll go and get a gurney\
17. MIC: ((MIC observes the engine and writes down the solution on a sheet of paper)) **【#2】**
18. LAR: ((comes back with a gurney))
19. MIC: so/
20. MIC: I think each cylinder with its opposite\ . the first with the sixths/ the second with the fifth/ and the third with the fourth\
21. LAR: well done/ . so let's have a look\
[...]

#1: Michael writes the firing order of the engine on a sheet of paper

#2: During Larry's absence, Michael observes the cylinders and valves composing the engine

²The original recorded data are in French, and the transcript provided here is a translation. Transcription conventions are given in the [Appendix](#) at the end of the chapter.

According to Kunégel's dynamic model of tutoring (Kunégel 2005), a specific type of guidance or training model—that of *assisted participation*—can be recognised in the excerpt just presented. Michael, the apprentice, is not working on his own or in isolation from other workers; rather, he is closely supervised by Larry, who spontaneously provides guidance and takes responsibility for conducting the maintenance procedure. At the beginning of Excerpt 1, both Michael and Larry face a specific practical problem related to the “productive” dimension of their work. To turn the cylinders in order to place them in an adequate position, they must access a gear door located below the engine. This requires the mechanics to lie on the back below the lorry and to use a sort of gurney to work in a comfortable position. Since the gurney is stored in the basement of the workshop, the supervisor proposes to leave the apprentice alone for a moment while he looks for the gurney.

Interestingly, the trainer does not see this practical problem as a mere production episode, but presents various learning opportunities to the apprentice before leaving him alone. First, Larry provides a verbal account of the problem and explains why he needs a gurney for cleaning the valves of the engine (1). Second, he makes three successive attempts to place the apprentice in an active position for when he will remain alone. The first attempt consists of asking the apprentice to find out where the inlet and exhaust valves are located (“What you can do meantime you look where the inlet and exhaust valves are located”, 3). The second attempt consists of checking whether or not the apprentice remembers the firing order of a six-cylinder engine (“firing order of a six-cylinder engine?”, 7). And, the third attempt consists of the supervisor asking Michael to figure out which cylinder is connected to each valve (“OK now you have the firing order you find out which cylinder is connected to each valve”, 14). From the apprentice's perspective, it is also notable that Michael is closely aligned to the verbal exchanges initiated by Larry. He anticipates the trainer's instructions (“I've already found them”, 4), takes note of his explanations (10, 13), and provides correct answers to his questions (6, 20).

In doing so, both Larry and Michael considerably change the local contextual arrangements underlying the interaction. They progressively transform a production procedure of maintenance into a setting in which technical knowledge emerges as a central ingredient. The trainer is not only working with the apprentice at this stage; he is teaching the apprentice how an engine operates and how its main components interact. This contextual shift from “production” to “construction”, to quote the terminology introduced by professional didactics (Pastré et al. 2006), requires the use of a wide range of multimodal resources, including talk, body orientations, gaze, gestures and material objects. Noteworthy is the fact that this contextual shift involves a specific use of the material environment, a use in which technology does not only produce specific physical results but also supports an indexical reference to knowledge. It is by observing the engine and pointing to its various components (cylinders, valves, etc.) that both the trainer and his apprentice produce a joint conceptualisation of how an engine operates (6). As shown in the excerpt, this process of contextual shift requires a fine-grained alignment between both participants, namely, the supervisor being willing to train and the apprentice being willing to engage in learning opportunities.

9.4.2 Maintaining Production as a Dominant Action Frame

In other companies, such expansive learning opportunities tend to be scarce or they may be based on different interactional configurations. To illustrate this, a second example will be used, observed in a privately owned car repair shop in the Geneva area (Company B). Samuel (SAM), a first-year apprentice, is busy conducting a maintenance procedure on a small-sized passenger car, when, whilst going through the procedure step by step, he does not remember if he should change the spark plugs or not. To clarify this issue, he moves away from the car and addresses Jeff (JEF), an experienced mechanic working in another area of the workshop.

9.4.2.1 Interaction in Company B

- 1. SAM: ((moves towards JEF))
- 2. JEF/ eh: the spark plugs on the Sonata\ ..
- 3. JEF: yes and so what/
- 4. SAM: should I change them/ . there are three of them\ . no/ I don't know about the Sonata\
- 5. JEF: ((looks at SAM silently)) **[#1]**
- 6. SAM: these are platinum spark plugs then/
- 7. JEF: ((looks at SAM silently)) **[#1]**
- 8. SAM: yep I guess these must be platinum ones\
- 9. JEF: ((looks at SAM silently)) **[#1]**
- 10. go and check in the Hyundai documentation\ ((points towards an office located next to the workshop))
- 11. SAM: OK\ . ((moves towards the office and reads the documentation)) **[#2]**
- 12. ((comes back to JEF))
- 13. right I don't need to change them\
- [...]
- 14. JEF: you should know these things\ I told you to do a 30000km maintenance and not a 90000km one\ at 30000km one doesn't need to change the spark plugs but you keep forgetting these things all the time\
- 15. SAM: sorry I didn't remember\

#1: Jef looks at Samuel silently instead of responding to his question

#2: Samuel reads the documentation to find the answer to his question

First, it can be noted that a rather different participation configuration applies to this second example. Samuel, the novice apprentice working in this garage, is fully responsible for accomplishing work production tasks on his own and he is immediately experiencing strong expectations regarding autonomy. His supervisor, Jeff, is not exclusively dedicated to training tasks but is also engaged with various specific and distinct repair and maintenance activities. This has significant implications in terms of learning and access to knowledge. These resources are not spontaneously provided to Samuel, but have to be requested by the apprentice. When facing practical problems in the maintenance procedure, Samuel has to initiate and negotiate changes in the overall participation configuration underlying the workplace context. He has to interrupt his supervisor and request assistance and information (1, 2).

Interestingly, in this particular case, Jeff does not engage immediately or easily in this request for assistance, but displays various forms of resistance to answering Samuel's question. First, he does not seem to pay attention to Samuel's question, but goes on working without interruption (3). Then, he does not provide verbal answers, but keeps on looking at the apprentice with anger (5, 7, 9). He finally refers to the documentation and asks the apprentice to find the answer himself ("go and check in the Hyundai documentation", 10). After the apprentice comes back with the answer, Jeff blames Samuel for his lack of autonomy and for forgetting important information repeatedly (14). These particular responses to Samuel's request for assistance have a clear impact on the ways in which the apprentice engages in interaction at this stage. First, Samuel has to rephrase his initial question addressed to Jeff ("should I change them? There are three of them. No? I don't know about the Sonata", 4). He is then implicitly prompted by his supervisor's insistent and disapproving gaze to come up with an answer, and has to make guesses about how to deal with spark plugs in the existing context (4, 6, 8). He also has to find out the answer on his own by referring to some documentation (11). Later, when coming back from the office, he accounts for the solution to his problem ("right I don't need to change them", 13), and responds to the trainer's blaming him by producing an action of symbolic repair in the form of an apology ("sorry I didn't remember", 15).

In sum, it appears that the local context remains strongly shaped by production constraints in this second example, and that, in contrast with the first case, work activities are not being reframed as explicit learning opportunities. The trainer seems to retain knowledge and expresses resistance to interrupt his work for the sake of providing assistance to the apprentice. Elements of technical knowledge are certainly not absent from this sequence of interaction, but these elements of knowledge are not developed into a local teaching and learning opportunity. They do not reshape the ways in which the participants engage in the local context, at least not to the same extent that could be observed in the previously described case. This results in a form of misalignment between the apprentice's need for immediate guidance and the sort of resources his supervisor is willing to provide. In the end, a climate of potential conflict and relational tension emerges between Samuel and Jeff, which illustrates a typical form of restrictive learning environment (Fuller and Unwin 2003) in which the apprentice is recognised as part of the workforce and not foremost as a legitimate learner.

From what was observed in the two case studies, it appears that apprentices experience rather diverse learning environments depending on the company in which they are trained. These environments differ in terms of access to knowledge, the willingness of supervisors to provide adequate guidance, and with regard to participation formats through which apprentices are expected to engage in production work tasks. These environments also have an impact on the learning opportunities that workplaces are able—or not able—to create for learning workers. In some training companies, apprentices are closely assisted in their work, and learning opportunities may arise in the form of explicit teaching practices. In some other companies, apprentices are expected to be productive and autonomous very quickly, and training practices are perceived as interruptions conflicting with production constraints.

It also appears that contextual variation is not only visible *across* workplaces, but also *within* each training site. Variation takes the form of a dynamic process shaping social encounters. Ordinary workplaces may evolve into virtual teaching arenas or, to the contrary, may remain highly determined by production constraints. Workplace supervisors and apprentices play an active role in the ways that these contextual shifts can be operated locally. It is by engaging in interaction and by using a complex range of multimodal resources that they produce or reproduce the conditions in which they work and learn. They may express an openness to forms of “contextual fluidity” and flexibility or may resist operating local transformations of these contextual arrangements.

9.5 Challenges and Potentialities of Discourse and Interaction Analysis

In this chapter, arguments have been brought in favour of an epistemological compatibility between sociocultural theories of learning and approaches to discourse and interaction developed within the broad field of sociolinguistics. In line with Gee and Green (1998), it has been considered that “the approach to learning that is most compatible with an ethnographically grounded perspective on discourse analysis is one that defines learning as changing patterns of participation in specific social practices within communities of practice” (p. 147). Through a brief literature review and a case study based on empirical data, concepts such as *contextual indexicality*, *situated identities*, *sequential organisation* and *multimodality* have been seen as candidates for approaching learning as participation in specific contexts and communities of practice. It has also been illustrated how a fine-grained analysis of discourse and interaction may contribute to an advanced understanding of both cognitive and identity-related aspects of professional and practice-based learning. To conclude, additional considerations are brought to this epistemological continuity and the challenges associated with the discursive methodology for research are discussed as well as its potentialities for practice.

9.5.1 *Challenges for Research*

When adopting a discursive or interactional perspective in their investigations, researchers in professional and practice-based education face numerous challenges that deserve close attention. These challenges include both ethical and methodological aspects, which are specified below.

First, it should be highlighted that increasing ethical demands are closely associated with discourse and interaction analysis. The methodological perspective being grounded on situated empirical data and these data being intrinsically related with social practices, it is important to recognise the potentially damaging and exploitative effects data collection could have on the observed participants. Discourse and interaction analysis is not and has never been a neutral enquiry into human behaviour and institutions. It contributes to the visibility of social practices and may have an impact on the positions endorsed by participants within institutions. This stresses important requirements related to access to data, permission to make use of these data and ethical clearance for research. But more interestingly, it also progressively transforms the conditions in which researchers and observed participants interact and position themselves with regard to each other (Sarangi and Candlin 2003). As noted by many discourse analysts, researchers tend not only to apply their expertise and categories to the social practices they scrutinise, but also to negotiate complex forms of collaborations with practitioners they observe. In other terms, research methods have progressively moved away from a research “on” social practices towards empowering forms of research conducted “for” and “with” practitioners themselves. As put by Cameron et al. (1994) “we understand *empowering research* as research *on, for* and *with*. One of the things we take that additional “with“ it imply is the use of interactive or dialogic research methods, as opposed to the distancing or objectifying strategies positivists are constrained to use. It is the centrality of interaction “with“ the researched that enables research to be empowering in our sense” (p. 22).

Beyond these ethical considerations, the type of research illustrated in this chapter maps important methodological challenges for the development of discourse analysis as an applied resource for research on professional and practice-based learning. First, the type of analytical approach presented here stresses the relevance of a *multimodal perspective* that does not see talk as the sole or the main medium through which social interaction unfolds. As illustrated by our empirical analysis, the apprentices’ learning experiences in the workplace do not rely on language exclusively but also on a wide range of other semiotic resources. It is by positioning themselves in material environments, by establishing visual contact with partners, by pointing specific locations and artefacts, etc. that participants enact interactional participatory practices and negotiate learning opportunities in work production contexts. Secondly, the methodology underlying discourse and interaction analysis stresses the potentialities associated with a *contrastive perspective*. Highlighting contrasts from one context to another and from one interactional configuration to another may illuminate, as in Michael’s and Samuel’s case, mechanisms of

contextual variation and differentiation in learning through practice. They may also contribute to “scale up” local findings resulting from microscopic qualitative analysis and link them with macroscopic realities observable at broader social levels (Erickson 2004b). Finally, the type of research presented in this chapter also brings interesting arguments to the development of methods that aim at “opening up the scope of discourse analysis” (Scollon and Wong Scollon 2003) by integrating a dynamic and *longitudinal perspective*. Through a detailed multimodal analysis of sequences of interaction collected in various contexts and at different steps of training programs, discourse and interaction analysis reveals the interactional micro-mechanisms through which knowledge is acquired and identities tend to sediment and become more and more fixed in time. Such a longitudinal perspective is often regarded of primary importance to understand how apprentices’ journey from the periphery of a learning community to its centre is reflected in the interactional processes. In our own research, we also take this longitudinal perspective as a very promising method for investigating “situated trajectory of learning” and understanding both successful and problematic ways of experiencing transitions from school-based teaching towards practice-based learning (Duc 2012; de Saint-Georges and Filliettaz 2008; de Saint-Georges and Duc 2009).

9.5.2 Potentialities for (Transforming) Practice

What are then the potentialities associated with discourse and interaction analysis for change and what may be its impact on educational practices? Mercer and Howe (2012) seem to make rather pessimistic claims regarding school education and observe that “sociocultural concepts and research findings seem, so far, to have had relatively little impact on educational policy and practice” (p. 17). Is this also true for vocational and professional education and training? In our view, significant practical implications derive from discourse and interaction analysis, as long as it is not narrowly conceived as an abstract methodology but serves to address broader social and educational concerns.

One first area in which discourse and interaction analysis could benefit our understanding of practice-based learning relates to the status and place of language and discourse in vocational and professional training curriculum. Interestingly, when exchanging with vocational trainers, teachers, managers or policy makers, “language” is often regarded as a limited or even narrow issue, related almost exclusively to specific contents of teaching and learning and associated mainly with the classroom context. For most apprenticeship programs available in Switzerland at upper secondary level, the curriculum indeed includes first and second language teaching courses. However, language use is rarely regarded as being involved in other areas of the curriculum and as exerting a more global influence on the conditions under which apprentices encounter learning experiences in and across the various contexts in which they are trained. To most practitioners in the field, the social visibility of language seems to be limited to the classroom context and

remains external to the workplace. A discursive and interactional methodology, on the contrary, advances a new perspective for approaching the role of language and discourse in vocational education, a perspective that sees these ingredients not as peripheral components of the training curriculum, but rather as central mediating tools for vocational learning. According to this perspective, apprentices are not only exposed to vocational knowledge in the range of contexts in which training takes place. They also encounter specific discourse practices and face numerous and often implicit or invisible expectations regarding the ways these discourses may be enacted and conducted. It is by engaging with these discourse practices that apprentices gain access to knowledge, develop practical skills and may endorse legitimate social positions within the multiple communities they belong to during their training. These language and communication skills are neither transparent nor self-evident. Like other components of vocational training, they have to be seen and most importantly learnt. Obviously, some apprentices are very successful in identifying and acquiring the specific discursive demands underlying the range of practices included their training program. Some others are not and may encounter rather challenging experiences in their journey to a professional qualification.

This later point provides a direct transition towards a second possible practical implication for discourse and interaction analysis in vocational and professional education. One area in which the type of research presented here may have significant outcomes is indeed the understanding of problematic transitions from school to work. In the context of Switzerland, but in other countries as well (Filliettaz 2010b), increasing attention has been paid in recent years to the high level of non-completion, dropout and change in apprenticeship pathways. Depending on the occupations and the geographical areas, between 20 and 40 % of apprentices who enter the dual VET system do not complete their apprenticeship within the stated terms of their contracts (Stalder and Nägele 2011). Of these: 9 % change occupation, 11 % have to repeat a year, 7 % change the training company, and 7 % drop out from the apprenticeship system without having any immediate alternative pathway. Recent studies have investigated the causes leading to young people dropping out or making changes in apprenticeship programs (Lamamra and Masdonati 2009). These studies depict a nuanced portrait of the dual VET system and show that transitions from school to work are to some extent far from smooth and unproblematic. They conclude that poor working conditions, low support by trainers and workplace relations emerge as the main causes leading to dropout. Elaborating on these findings, the strength of a discourse analytic methodology applied to vocational education practices lies in its capacity to reflect not so much on the “causes”, “reasons” and “factors” that may lead to incomplete training pathways or delayed transitions to employment, but to understand the *processes* by which these causes and factors are being enacted in practice, how attrition is constructed in action, and how apprentices, trainers and workers are experiencing relational and practical issues when engaging into work.

Beyond data description and analysis, what then are the contributions researchers could propose in order to promote changes in the realities they investigate? One particularly promising avenue currently being explored by our team at the University of Geneva is to use the empirical material available in the context of training

programs addressed to vocational trainers. As shown by the studies presented in this paper, vocational trainers in the workplace play an active role in shaping local contextual arrangements that are able to support robust learning opportunities in production conditions. In consonance with Billett's findings (Billett 2001a), the research results presented here show an urgent need to increase the level of pedagogical qualification and awareness of trainers in the field of vocational education in order to enhance the overall quality of the guidance provided in workplaces. In the training sessions we have proposed recently in various institutional contexts (Filliettaz 2012), vocational trainers of different sorts develop analytical skills in the field of discourse and interaction analysis and apply their analytical skills to empirical material collected during our research program. By combining conceptual input about social theories of vocational learning with empirical data analysis, they progressively learn to identify expansive and restrictive interaction configurations and discuss in groups about their views. Being sensitive to "contextual indexicality", "sequential organisation" and "multimodality" does not solve the complex issue of attrition in apprenticeship programs. However, from our own experience as researchers and as adult educators, it can render the sorts of difficulties faced by learners when joining the workplace visible, and it can also help trainers and experienced workers to become more reflexive about their role when it comes to assist novices in learning for and from practice.

As illustrated here, discourse and interaction analysis may appear remarkably remote from generalisable strategies and recommendations. This could be seen as a weakness and as a form of limited impact on the provision of education. But as mentioned by Gee and Green (1998), "we can also point out that it is highly improbable that answers to many of the questions facing those concerned about learning in social contexts require generalizable strategies or recommendations" (p. 160). In other words, the main outcomes of discourse-oriented methodologies for understanding learning for work seem to lie elsewhere. They rely on their capacity to illuminate questions that require local and highly situated answers.

Chapter 10

Research Paradigms of Practice, Work and Learning

Paul Gibbs

Abstract This chapter considers how a number of the main research paradigms are warranted when investigating professional practice. By first setting out an understanding of research, the chapter moves on to consider the shift from the neutrality of epistemological authority of certainty to the ontology of judgement, made in the uncertain flux of practice, and offers reasons to believe that certain actions are more trustworthy in explanation than others. Three main methodological discourses are discussed in the context of practice, and a fourth is proposed: a trans- or post-disciplinary approach to the messy research problems of practice. This approach is grounded in critical realism and seeks to deal with issues of normative social practice in ways that matter to those who are involved: practitioners.

Keywords Positivism • Pragmatism • Critical realism • Epistemology • Ontology • Professional practice

10.1 Introduction: Researching Professional Practice

Research into practice should carry a warning—all is not what it might seem. Experimentalists beware! Unpacking the notion of research on practice demands recognition that research itself is a practice and, like any other social activity, has an associated discourse (Higgs et al. 2010: xi). Indeed, one might argue that the discourse is revealed in a number of languages, each opening a space for justification, persuasion, and argument on why they provide a specific and insightful glimpse at the truth that is sought through the inquiry. These discourses are to advance practice, improve its quality, and discover new ways for agentic justification of

professional intentional practice. The way that we structure and understand the phenomenon of professional practice to reveal, interpret and make sufficiently robust arguments concerned with practice reflects our belief as to what may best secure consensus for collective action and trust in a professional.

The building of such a consensus is contingent upon many influences. These range from the socio-political context of the research problem, the intellectual spaces it occupies, through to the goals inscribed in its purposeful intent. This is a messy task where a swathe of heterogeneous factors can deceive, illuminate, and contradict, and where interpretation and revelation through any form of methodology can further cloud the essential issue. This is not, however, reason to forgo researching practice in a systematic and robust way. Nor is it an argument for a relativism that bears no relation to the realism of a practical problem. Instead, it is an opening statement that illustrates the procedural limitations to researching practice, what can be legitimately relied upon and what can be claimed as truth through the many different research discourses.

The approach favoured here is a blend of a disciplinary-embodied approach with a range of methodologies selected for their fitness for purpose. To achieve it requires an understanding of the epistemological as well as the ontological issues that underpin the main approaches to research. Recognising that all approaches contain a both elements to them, the idea of a neutral reality, which can be revealed knowledge through methodologies independent of our own interpretation (as supposed by classical positivism), or that the world exists only as an ideal construction in our minds (strong constructivism) are both discussed alongside a third, the more promising approach of pragmatism. These three approaches are, however, each discounted in favour of a transdisciplinary approach to investigating practice.

This fourth approach to investigating our understanding assumes that our social work is an open system where change occurs in ways that are difficult to assign a causal attribution. It assumes that the world is fluid and open to possibilities; that neither the individual creates social context, nor that the context creates the individual. Rather, it assumes that the social is a prerequisite for the kind of professional practice that creates the person one will become. This is knowable in a predetermined way, but as a context within which one is able to operate. We are thus agentic within social, cultural, and political environments that shape our material-economic positioning within any given locale. Following Kemmis and Smith (2008), the situational 'extra-individual' features of practice create this environment in which the architecture of practice (i.e. its traditions, rituals, and practices) both limits the focus for individual and collective interpretations of their practical agency, and in so doing opens new possibilities. The surgeon cannot disregard her professional accountabilities, but in the novel experience of each operation often calls forth her creativity in ways unique to that specific surgeon. We may call this her 'mastery', for it is more than mere expert delivery of practice. It is the integration of skills, judgement and interpretation in a situation of uncertainty and fluidity where each action changes the context of the next. Mastery of professional practice transcends mere skill, and its investigation requires an epistemological stance that recognises the reality of the circumstances from a number of perspectives. Positivism assumes neutrality; constructivism, some

privileged personal knowledge; pragmatism, a transient confidence in the reliability of an action; and critical realistic transdisciplinarity assumes a theoretical approach to guide the messiness of real, live, solution of problems.

This chapter develops this argument by first contextualising the issue of investigating profession practice in the uncertainty of the world of work. The three main approaches to practice research are then discussed, examples of their use are offered, and their limitations identified. The chapter closes with a discussion of how critical realism can give transdisciplinarity a philosophical underpinning and offer a way forward. This approach is not methodologically separate from the three previous approaches. Indeed, it advocates their technologies, but within a richer context than a problematical mono reality. In doing so, it raises concern at the growing acceptance of mixed-method approaches as an epistemic device to resolve issues of validity, since what is at issue is the limitation of the forms of knowledge that they reveal, not the method itself.

10.2 The Context—The Work World

The points we need to address when considering the nature of professions or occupations are complex, often transdisciplinary, and usually messy. Our world is uncertain, and many of ways in which people learn need to be revisited when in the real world of work. This is clearly illustrated in the need for practical experience in all the professions. Getting professional practice right and understanding how this can be achieved is central to a sense of self-development and learning to become a professional. This has been conceptualised by Johnsson and Hager (2008) as ‘an embodied constructed experience with others in context’ (2008: 526), for it provides a point of departure in our understanding of being within a specific context: the workplace. As Kovacs (1986) comments, ‘work is an essential part of human life as recognized by all serious reflection on the value of human activity’ (1986: 195). As Shershow (2005) pointedly reflects, we see ourselves as ‘*working to live and as living to work*: understanding labour at once as inescapable obligation... and as the definitive essence of our humanity’ (2005: 13, emphasis in original). This phrase complements Arendt’s (1985) more dramatic distinction, where we ‘eat in order to labor and must labor in order to eat’ (1985: 143). Importantly, Dall’alba concludes that understanding of professional practice is central to how we both perform and develop that practice (2004: 679).

Specifically, professional practice within the professions, as well as in other workplaces, has an ontological intelligibility. This matters to the stance a professional takes on being a professional and being amongst others. Such practices are not conceptual but practical and, among other legitimising characteristics such as a shared knowledge base and moral code of conduct, call forth a way of being that treats clients not as objects for use through calculative expedient thinking, but as real and genuine entities in their own right. As Malinski and Bournes (2002) reveal in their review of the practice methodology used as a guide to practice within nursing,

a greater respect for clients' (patients') world view and self-determination of treatment leads to greater satisfaction with the provision. Dall'Alba (2004), amongst others (Webster-Wright 2010, or Edwards 2010), challenges the focus on detailed knowledge and skills as a base for professional practice and its understanding through performance, asking whether this is essential to the ontological development of a professional practitioner. This is particularly relevant to professional practice (Hager 2011) and sets it apart from everyday activities such as shopping or catching a train. It is more than activity; it has an associated moral good as well as a corpus of knowledge and expertise that needs to be attested to before, and often during, professional membership. This seems to be the intention of MacIntyre's famous, specific, and often contested definition of practice as:

a coherent and complex form of socially established cooperative human activity through which goods internal to that form of activity are realised in the course of trying to achieve those standards of excellence which are appropriate to, and partially definitive of, that form of activity, with the result that human powers to achieve excellence, and human conceptions of the end and good involved, are systematically extended. (1985: 187)

By new candidates' learning of physical and discursive practices, the profession's experiential practice creates a capacity for them to understand the collective ethos that a qualified participant commits to join. It is this notion of commitment, aligned with future intention to act as a member of a collective, that is demanded in order first to gain admittance and then to sustain membership of a group, association, profession or community of practice. It can be argued that, in joining such a community, individuals alter their assessment of their prudential values, not necessarily to forgo them but to reevaluate them by giving priority to the profession's principles.

To summarise, our world view is formed by the practices that we decide to disclose to ourselves and by those we disclose to others. Schatzki (1996) suggests that practice is 'a temporally unfolding and spatially dispersed nexus of doings and sayings' (1996: 89). This meaning differs from merely doing, which the 'Western philosophical tradition has opposed to theory: theory versus practice, contemplation and reflection versus doing' (1996: 90). Moreover, its potency is directly related to one's belief in oneself in the specific community of practice of which one is existentially part. It is how we understand the lived experience of the practices we adopt to gain recognition as community members. The role of learning in our community is a negotiation, by means of projecting an understanding of the workplace, to find a familiar and satisfying niche (Billett 2010). To reveal higher levels of knowledge, technique, and skill in practice does not need a university classroom or academic discipline, but a way of acknowledging higher levels of skill in practice. How and why we might do this is our next concern.

10.3 Ways of Understanding Professional Practice

There have been a number of contemporary methodological approaches to understanding the practice of research, each of which makes a contribution (e.g. Kemmis and McTaggart's five different notions of practice research (2005); Macpherson et al.'s

territory of professional practice (2006); and Green's edited collection on researching and understanding professionals (2009)). However, this chapter is guided by historically dominant discourses of research that continue to dominate current research practice: quantitative (loosely interpreted as positivistic), qualitative (loosely interpreted as interpretative), and pragmatic (again general conceived as mixed methods). Still more basic than these classifications is the inevitable connection between the type and the form of research questions that we ask and our philosophical frames of reference. The term 'discourse' recognises that language, themes, dominant messages, and interpretations frame our ways of knowing, knowledge making, and acting in the world. In developing each of the following discourses: positivism, phenomenology, pragmatism, and the complex ideas of critical realism with transdisciplinarity research, their ontological position (that is, from a sense of subjective personal agency) as well as the epistemological (what can be taken to count as truth) will be considered. For example, a positivistic position assumes a realist ontology (one where a reality exists external to oneself and the task is to find what is this external reality and its universal principles). An interruptive approach assumes reality is what we perceive, not what actually exist beyond our perception, and a relative ontology assumes an external intransitive reality is sought, but the way in which it is understood is personal. In the following section, each of these views is discussed in the light of how they might reveal issues relating to professional practice.

10.3.1 Positivism: A Realist Discourse of Rule-Bound Professional Practice

Descartes (2006) devised three pillars of methodology by which to discover an infallible basis for a claim for truth; his methods are as much about empiricism as they are about *a priori* reasoning. These pillars are to:

- Never accept anything as true that is not incontrovertibly known to be so;
 - To divide all difficulties under examination into as many parts as possible; and
 - Undertake complete enumeration and such general surveys as to leave nothing out.
- (Based on Descartes 2006: 17)

This dependence on the deductive reasoning, completeness, and reductionism launches us into the logical positivist position on the tenets of validity and truth. Positivism is not a mono-theoretical approach but comprises diverse threads and related approaches such as empiricism, scientism, determinism, and reductionism. It asserts that the world is ordered and that this order is controlled through and by universal laws (such as the law of gravity). This approach applies to both physical and social science (Comte 1988), with the intent to identify these laws and how they apply and can be verified. The threads all follow a similar direction, leading to understanding the natural world through perceiving what can be taken to be existence, which was the core of the views of thinkers such as Descartes, Kant, Bacon, and Hume. The logical positivists argue that verification can only be through experience or through reasoning. The most celebrated engagement with the social sciences is, perhaps, Hempel's discussion in 'Logical Positivism and the Social Science' (2001).

In this essay, Hempel (2001) contended that ‘there is no fundamental difference in subject matter between the natural sciences and the psychological and sociological disciplines’ (2001: 255), a view echoed by fellow logical positivist, Carnap, who claimed that ‘all laws of nature, including those that hold for organisms, human beings, and human societies, are logical consequences of the physical laws’ (cited in Hempel 2001: 267). Here there seems to be a problem, for professionals do not make decisions in their professional world without engaging with it, in a parody of cold, detached intelligence. We simply do not determine our action is such a logical, detached way.

Perhaps more than any other, Popper (2002) is responsible for sustained criticism of the logical positivist discourse of knowledge. His criticism is based on a notion of demarcation between the natural sciences, which are resolved through inductive logic and verification, and metaphysical speculation. This led to an assertion by the logical positivists of the Vienna Circle that only those questions susceptible to empirical confirmation or refutation are scientifically meaningful. Questions relating to the unseen—emotions, values, ethics; those motivational but hidden aspects of our lives—are inferences and, whilst acknowledged as able to affect behaviour, were thus not susceptible to scientific enquiry. Indeed, the positivists argued that induction, the most common form of inference, could never lead to successful verification. This is because, Popper suggested, ‘there is no such thing as induction’ (2002: 19), because one can never be certain of inference. Rather, one should look for correction. This led to his notion that the purpose of science is the falsification of theories. He argues that what characterises the empirical method is its manner of exposure to falsification: the system has to be tested in every conceivable way (ibid.: 20). Rather like Peirce (1998), Popper (2002) felt that induction was associated with conjecture at best, and at worst with guessing. This leaves empiricism not without merit, but without any status based on deductive reason. The best induction can contribute is collaborative agreement regarding existing hypotheses or, more substantively, refutation of a hypothesis. Popper’s logical positivism shares with positivism an assumption that a single reality exists that is external to the observer, but it is much more nuanced in its truth claims: truth is not absolute, but probabilistic and provisional. For instance, in professional practice much which is learnt in the classroom fails in the world of application. This is the reason for experience of practice and exposure to the messiness of nursing, courtroom dramas, and dealing with audit clients. Moreover, different interpretations of anything other than the most atomistic involve a range of observers whose ontological positions may be influenced by the theories that inform their observations.

Such concern about the neutrality of observation, upon which the forms of logical positivism rest, begs a number of questions related to how this neutrality can function in the real world of data collection to support a case for collaboration or refutation. This is at the core of the legitimacy of evidence-based practice that is so much at the forefront of policy on professional bodies. These are important questions for evidence-based practice (Hammersley 2005; Biesta 2007; Boaz et al. 2008; Kvernbekk 2009). When identified as grounds for formulating practice, ‘evidence’ is commonly assumed to be assured; that is, the evidence was created or based on

an empirical approach rather than on judgement, expertise, and experience. Such a position leads to a question of how reliable, as distinct from how valid, are positivistic approaches to investigating practice.

The hegemonic cultures and discourses of positivism remain dominant, if a little camouflaged (Kincheloe and Tobin 2009). Giroux (1997) argues that these objectivist forms of research and knowledge work have produced a 'culture of positivism' that accounts for the range of reductionistic and dominant ideology-based epistemological practices that continue in contemporary research. When researching professional practice, cultures of positivism convert the complex, messy, axiological, instinctual, emotional, and embodied nature of professional agency into procedural, behaviouristic, and skill-based discourses. Positivism's function, then, engenders control over matters of judgement and propagates grounds for the craft of the profession to be measured in technological ways.

Examples of such research practices are:

- Wastell et al.'s (2011) experimental approach to probing practice cultures, and for examining different patterns of professional sense making in social work practice.
- Stes et al.'s (2010) study using a quasi-experimental design of the impact of an instructional development programme for beginning university teachers on their teaching approach.
- Hoe and Hoare's (2012) critical appraisal of evidence-based practice in nursing professional development.

Zins and Murphy's (2007) report on the results of an exploratory national survey of school psychologists' involvement in peer support groups, undertaken to identify the potential contribution to improving professional practice.

In summary, positivism assumes a view of reality and of our place in it that seeks determination, neutrality, and control. This is best found in the closed system of an experimental environment, with control variables and an unchanging context, so that verification can be checked by repetitions. The real world is not like that. Although we can adopt methodological techniques from this tradition for use in the social science where appropriate, they clearly need caution. It may be well and good to know how many hours teachers take to prepare their classroom practice on average but, without knowing their reasons for doing this—their educational philosophy, their pedagogical approach, and their reason for teaching—it offers very little besides description and grounds for speculation. The next discussion is more open to interpretation.

10.3.2 Phenomenological Discourses, Perceiving the Essential in the Commonality of Practice

Positivist, measurement-oriented, and rule-governed discourse is, according to Avis, a form 'unsuitable for investigations of the emergent and constructional aspects of intentional human social behaviour' (2003: 996). This standpoint assumes

a distinctive understanding of the existential, emotive, embodied, non-theoretical, and situational nature of. Moreover, in van Manen's opening to his 1997 paper, 'From Meaning to Method', there is a strong and unambiguous connection with phenomenological research into profession:

the reason professionals remain intrigued with human science inquiry is that it is a science of plausible insight, speaking not only to our intellectual competence but also to our practical intuitive capabilities. Good phenomenological texts have the effect of making us suddenly see sometimes, in a manner that enriches our understanding of everyday life experiences. (1997: 345)

Furthermore, from the perspective of Husserl (1983) (generally recognised as the originator of phenomenology), this method of inquiry aims to exemplify the essence of an experience in a wide range of forms, either indirectly, as others might perceive it, or directly to uncover the intent behind the experience. Intent is what we intend, or perceive, as a purpose. It is an order relationship when we perceive things: a knife for cutting; a code of conduct for reference to acceptable professional conduct; an exciting read for a train journey.

From Husserl (1983) and Schutz (1967) via Heidegger (1962) to Arendt (1985), Derrida (2004), and Ricoeur (1981), the phenomenological approach is about thinking of experiences. It is an unconcealing of that which our ways of being have hidden in the unconsidered practices of our everyday, lived experience. Husserl's (1970) extended discussion of the world in which we perceive ourselves—our lifeworld—argues that the concept of scientific procedure has its roots in the lifeworld, amongst other things, and 'sets itself the task of transposing knowledge which is imperfect and pre-scientific in respect of scope and the constancy into perfect knowledge' (1970: 110–111). It is a world marked by the culture of Enlightenment and one where subcultures ought to be avoided (Luft 2011: 356). This Husserlian idea of the lifeworld (basically the world as we experience it as a coherent context for our agency) is common currency in social thought, thanks mainly to Schutz (1967). Pettit has developed Schutz's role analysis of the lifeworld, arguing that it presents six linked problems for the study of how people understand one another: 'the problems of the interpretability, explicability and justifiability of belief on the one hand, behaviour on the other' (2011: 260). This approach relies heavily on a theory of individualism where, as Pettit states, 'epistemological individualism leads naturally to an ethical individualism—specifically, to an existential exaltation of individual creativity' (2011: 266).

In a professional context, Sandberg and Dall'Alba (2009) describe the lifeworld's main features in terms of organisation. These constitute the key unfolding aspects of a lifeworld perspective, namely an 'entwinement with world, ways of being, lived body, being with others, and equipment' (2009: 1355). Their work is not cast in Husserlian terms, but inspired by Heidegger and Merleau-Ponty who, together, provide the phenomenological framework for an investigation of the phenomena of professional practice within a lifeworld perspective, 'where human beings are seen as constantly engaged in performing a range of activities that belong to their practice worlds. These activities are guided and directed by a sense of purposefulness

and agency' (2009: 1359). And, through Husserl and Schutz, inevitably we are led to a form of individualism that hampers our understanding of our functionality in a web of familiar practices.

The lifeworld differs from Heidegger's (1962) work-world of practice, where the world is determined by how its objects are recognised by our using them for specific purposes (see Gibbs 2008). Heidegger argues that the meaning of our actions is understood in terms of 'the background practices on the basis of which all activities and objects are intelligible or make sense' (Dreyfus 1992: 223). Research is thus an understanding, and we understand our world without noticing background practices. It is only when we conspicuously concentrate upon these practices, as when we apply a methodology to reveal them, that they are shown in terms that our understanding experiences as being-in-the-world in a certain way. The work-world of practice has a familiarity defined by its function. For example, the accountant world is one of financial accounts, business plans, and tax returns—not usually of Latin translations or stand-up comics. For the lawyer, it is of criminals, innocence, and juries. In this world, the lawyer does not see people as humanity but as actors in his world of law. This familiarity becomes the 'presupposed basis of any thoughts [which] are taken for granted and go unnoticed, and because in order to arouse them and bring them into view we have to suspend for a moment our recognition of them' (Merleau-Ponty 1962: xiii).

A phenomenological analysis of practice does not examine the specific elements of an experience, but the qualities of that experience and how they affect being, as a form of hermeneutical interpretation. The logic of this practical awareness is distinct from and, not reducible to, formal logic. It is practical. This practical logic is a 'logic that is intelligible. Coherent but only up to a certain point (beyond which it would no longer be "practical"), and oriented towards practical ends, that is, the actualization of wishes, or desire (of life or of death), etc.' (Bourdieu 1998: 132). It understands only immediacy of action and 'excludes attention to itself' (ibid.: 92). This applies to modes of knowledge that cannot be translated into conceptual and theoretical representations, but are 'corporeal, relational, temporal, situational and actionable knowledge' (van Manen 2007: 22). The insight of practical logic together with the temporality and tempo of practice is perhaps the major contribution to the phenomenology of practice that Bourdieu's habitus (our lifestyles, cultures and expectations) can offer us (1977, 1998). For Bourdieu, 'practice is inseparable from temporality, not only because it is played out in time but because it plays strategically with time and especially with tempo' (1977: 81).

To summarise, our world view is formed by the practices that we decide to disclose to ourselves, and those we disclose to others. These are often hidden from us by their everydayness; we just do them. To research these practices we must identify them and make them conspicuous through a praxis of searching and re-searching. In many professional fields such as pedagogy, law, nursing, and accounting, the dominance of technological and calculative thought is so strong that the presupposition of instrumental structures that grounds professional practice effectively hides the ontology of being such a professional. Through questioning and interpretation, through hermeneutics and narratives, the experience of being a professional

can be revealed. Those insights gleaned from how a professional sees her practice are, of course, personal. Because each professional has similar training in their profession, by using a phenomenological approach we can infer certain similarities but, at its core, it is about experience of the world that is personal; a world that is real only in the mind of the professional. The approach is often contrasted in this way with the external reality of the positivistic approach described in the previous section, but there is a blend possible and this is provided by a pragmatic perspective, discussed next.

Examples of phenomenological research practices are:

- Lee's (2009) investigation into professional doctorates and the transformation from an autonomous scholar into an enterprising self through reflection and reflectivity.
- Webster-Wright's (2010) phenomenological study of professional learning as a self-directed activity and intentionality.
- Johnsson and Hager's (2008) examination of the nature of learning, discovered by recent graduates participating in a symphony orchestra-initiated development programme designed to nurture them through the transition to becoming professional orchestral musicians.
- Hoskyns (2011) introduces the particular value of focus groups for music therapy research, highlighting their suitability for exploring 'real-life' practice issues.
- Paloniemi and Collin's (2012) data for their study is derived from a collective ethnographic research project focusing on surgical workplace learning and professional identity. The paper illustrates the manifestations of discursive power through three selected episodes.
- Fenwick (2012) presents interview-based research into the participation of older professionals and participation in learning and their understanding, through stories and practices, of knowledge, and themselves as knowledge workers.

10.3.3 Pragmatism: A Discourse on What It Is Feasible to Believe

Pragmatic philosophy argues that judgement about truth and morality is not a matter of mental processes or facts of consciousness, but is grounded in intersubjective practices and symbolic systems. In other words, we agree what warrants our trust and take it as trustworthy until there is evidence enough to suggest a better alternative. As such, it has roots in positivism but rejects notions of reductionism in favour of experience; of agency in the real world. For Peirce, the establishing truth is a foundational, normative, and rational discipline (1998). James sees truth as what is good in the way of belief (1968), while Dewey takes it to be what we are justified in believing, in the sense of a social phenomenon (2006). The neo-pragmatist, Rorty, argues that truth derives its legitimacy from a given social group (1982).

Early pragmatism tends to be portrayed as an American movement vitalised by Peirce (1998), James (1968), Mead (2002), and Dewey (2006). Their contributions

are to many of the social sciences. Mead's legacy lies in social psychology and social theory, Dewey's influence was on educational theory, James' on psychology, and Peirce's in contemporary Critical Theory. Often unmentioned in this gathering is the significant contribution from the Oxford philosopher, Schiller, whose essay on humanism was published in the same year as James' own 'What Pragmatism Means' (2007) and much admired by him. Indeed, the early 1900s were landmark years for pragmatism for, in the same year, Peirce's (1998) attempt to clarify its hazy meaning appeared as 'What Pragmatism Is' (1998). Historically, pragmatism is a strangely compelling mix of scepticism, especially of logic and empiricism, with no recourse to metaphysical precondition. Meaning is what we take it be or, as Rorty suggests, it is verifiable belief.

Dewey, especially, contested the notion of experience either as an accumulation of knowledge or as a dialectic transactional examination. In this sense it is not 'trial by error', but informed experimentation where the environment blurs subject and object. This notion of experience led Dewey to develop an understanding of inquiry activated by a rupture of the status quo. A rupture is first felt emotionally and developed through a process of hypothetic base inquiry. The results of inquiry are not radical changes in the state of one's understanding but an evolution, a change where premises are questioned and circumstances tested. This process is undertaken with the concepts, theories, and the experiences we have at hand. It is facilitated by theory and concepts, as they offer alternative ways by which others, be they teachers or craft masters—professionals—can help to provide new ways for learners to understand what they are experiencing. Learning thus is not solely about action, but about a reflection on concepts, theories, and experience. Experience thus provides a platform for building a view of the future, not an epistemology based on what has happened but on what might happen, with education a way of communicating what one has learnt. Rorty, it can be seen, calls this 'pedagogy' (1999) and, for Dewey, it is a process of anticipatory imagination. Moreover, such a view holds that what is known is provisional, fallible and correctable. Schiller offers the example of the abstraction of arithmetic when he argues that 'two and two make four, is always incomplete. We need to know to what "twos" and "fours" the dictum is applied. It would not be true of drops of water, nor of pleasures and pains. The range of application of the abstract truth, therefore, is quite limited' (Schiller 2009).

Dewey's approach gives the inquirer the role of an active agent of knowledge creation, testing it against the context in which it was rationally and socially constructed or adopted. His argument with propositional knowledge has its roots in the work of Aristotle (1995) and the more recent philosophies of Kant (2007), Merleau-Ponty (1962), Heidegger (1962), Bourdieu (1977), and contemporary approaches to learning and knowledge by post-structuralist thinkers such as Derrida (2004), Lyotard (1984), Foucault (1980), and Winch (2010). Often quoted as a significant but not an unchallenged contribution is Ryle's development to epistemology, in that we 'know' in two modes: both 'know how' and 'know what'. Moreover, Polanyi's (1966) insight is his acknowledgement of tacit as well as explicit knowledge as a legitimate notion, mediating what is done in practice. This pragmatic position has much in common with that of the early phenomenologists and the focus on

reflection is taken up in Schön's (1984) seminal text, *The Reflective Practitioner: How Professionals Think in Action*. It has become important in practice-based professional learning, where the field of study is the professional's own practice. Rather than formal external knowledge transfer, it comprises reflection-on and reflection-in-action.

Pragmatic philosophy has been selectively drawn upon by two major and competing lines of theoretical development to support their contemporary claims for practice. In Habermas' view, it has given up on the rational and emancipatory core of modernity and has been directed against the neo-pragmatism represented by Quine's (1953) and Rorty's postmodern scepticism, a competing strand. On the opposing side, Rorty argues for a non-foundational pragmatism that, unlike classical pragmatism, does not view science as the first and final site for reason and social progress. Going against widespread claims for foundational reason such as Habermas' universal pragmatics, Rorty is sceptical of the attempt to find the single, reliable method for reaching the truth about the nature of things. Although Quine's pragmatic epistemology acknowledges verification based on reductionism and the dogmas of analytical and synthetic truths, it also acknowledges that in 'abandoning them is... a blurring of the supposed boundary between speculative metaphysics and the natural science. Another effect is a shift towards pragmatism' (1953: 20). This does not provide a secure foundation for empirical epistemology.

Rorty discusses this as a concern for commensurability. Taken to be against epistemology and in favour of conversation, his approach is outlined in *Philosophy and the Mirror of Nature* where he states 'the rules which constrain inquiry, are common to all discourse, or at least to every discourse on a given topic. Thus epistemology proceeds on the assumption that all contributions to a given discourse are commensurable. Hermeneutics is largely a struggle against this assumption' (2009: 315–316). This represents a rebuttal of scientific method: 'if the core of pragmatism' is to 'attempt to replace the notion of true belief as representation of the "nature of things" and instead to think of them as successful rules of action, then it becomes to recommend an experimental, fallibility attitude, but not to isolate a "method" that will embody this attitude' (2009: 65–66).

Our truth claims, then, are a matter of whether our beliefs 'provide reliable guides to getting what we want' (Rorty 1999: 33). As Baert (2004) points out, researchers following Rorty are asked to commit themselves to a theoretical framework supposed to 'guide' or 'inform' the research. Being 'guided' or 'informed', unfortunately, often implies a blinkered way of seeing things, reading the social context in order to reinforce the very presuppositions that fuel the research. Rorty's neo-pragmatism steers the approach away from its original conception of inductive truth through empiricism. He breaks with the constraints of a hegemonic notion of epistemology that is intrinsically linked to the validity of the natural sciences and liberates the understanding of inquiry through a conversation of liberation and plurality. Yet, as Bhaskar (1989) points out, Rorty's view is susceptible to a Kantian critique: the tension between empirical selves and moral agents conflates a discourse of reality that ought, by rights, to separate an ontological and an epistemological notion of scientific truth.

In summary, pragmatism is a rationale for knowing and acting within the lived experience of the profession. It provides answers to problems and cautions about universals and generalities. It provides evidence for rational belief and offers an exploration of professional behaviour that is deep and meaningful, and structured around meaning-making that makes calls upon methodologies of creativity. To understand a professional's practice, arguments of reality can be side-lined, along with notions of epistemology, and data collection becomes a process of using appropriate methods to resolve specific questions. The truth revealed can be checked by using different methods to illuminate the subject of the research in alternative ways. This permits triangulation of knowledge and creates confidence in the findings of the research.

Such approaches are classified in the research literature as mixed or pragmatic methodology (see Creswell 2008 for a clear application to practice). They have become very popular in social sciences and, as the examples below show, in the study of professional practice. However, they may be criticised for confusing the nature of the object being investigated to benefit the outcome. In so doing a deep understanding is lost and future developments hampered. By introducing a meta-theory to support a transdisciplinary approach, the next section confronts this issue.

Examples of mixed methods research practices are:

- Bifano's (1989) study into understanding the leadership practice of the elementary school principal, suggesting a mode of leadership behaviour that may lead to increased professional effectiveness.
- Eraut's (2007) longitudinal study of early career professional learning, focusing on the first 3 years of employment of newly qualified nurses, graduate engineers seeking chartered status and trainee chartered accountants. It uses observation and aggregation of data, and is triangulated with interviews. This furthers the study (2011) on mid-career professionals, when Eraut revealed that informal learning was perceived by the professionals as work, not learning, using the same methodology.
- Caitlin and Sutton's (2009) investigation of the emotionality of teaching, especially when teachers must change their practice. Past research on emotions and change in the general population has been predominately quantitative, whilst that of teachers' emotions has been mostly qualitative. To draw on both these approaches, the study used a mixed methods approach.
- Sims' (2011) findings from a mixed methods study with practitioners qualifying on joint training programmes in learning disability nursing/social work, exploring the impact of such programmes on professional identity. The study reported in this article comprised a postal survey to graduates from five programmes, followed by in-depth, semi-structured interviews.
- Kolehmainen et al.'s (2010) review of the literature on individual community professionals' caseload management (behaviours related to assessment, treatment, and discharging of clients). This was to identify the main themes and concepts, and to synthesise the findings to inform practice, policy, and research. Qualitative and descriptive quantitative methods were used for data analysis and synthesis.

10.3.4 Transdisciplinarity Discourse: A Critical Realist Investigation of Professional Practice

The final approach discussed in this chapter is critical realism, which is contextualised within boundary-spanning definitions of transdisciplinary research that attempt to resolve value-laden issues requiring judgment of practical alternatives that affect others. However, given the ambiguity and ambition of transdisciplinarity, it is not surprising that a variety of interpretations abound. Finding an all-embracing definition shows Deleuzian multiplicity in its difficulty (see Pohl and Hadorn 2007; Lawrence 2010; Nicolescu 2010; and Klein 2010, as the most quoted authorities). Nevertheless, rather than focusing on the delineation of the approached offered, an analysis of these contributions points to consensus over which problems benefit from a transdisciplinary perspective. These tend towards the:

- Complex and heterogeneous
- Specific, local and uncertainty
- Epistemologically seeking satisfying explanations that enable and warrant, and improve our ability to seize opportunities
- Involving practical action for the good of, and through, others.

The study of professional practice, and of the practice of professionals, is often complex and takes place in open systems of social engagement rather than the closed systems of experimentation. Transdisciplinary knowledge is found in the liberation of reason from formality and in the multi-realities (see below) of the presenting problem. To seek such insights often requires collaboration, contextualisation, and reflection leading to reasoning that is a collective, ethical, problem-based ‘explanatory’ engagement. None of the three previous approaches offers an adequate meta-theoretical approach that allows a complex and layered praxis of practice to be usefully described, yet critical realism provides such a footing to discuss transdisciplinary research. The advantage over the previous meta-theories is that, whereas the empiricism of the logical positivist presupposes a regularity or law-like quality to practice, and the hermeneutics approach of the phenomenologist is constrained by existence outside the life-world, the critical realist includes both. Moreover, structuring reality rather than assuming the mono-reality of the pragmatists builds a more fluid conceptualisation of practice research, which allows for a re-conceptualisation of the research problem in a layered way.

There will be no attempt to repeat much of underlying philosophical grounding of critical realism, which owes much to Bhaskar and which is adequately summarised by Easton (2010). It is sufficient to state that Critical Realism offers an ontology that can conceptualise reality, support theorising, and guide empirical work to find adequate explanations. Easton suggests that ‘(C)ritical realists accept that there are differences between the empirical, the actual and the real, and that data are collected from people as well as from, and about, material things. As a result they accept that any explanations are necessarily fundamentally interpretivist in character’ (2010: 124). Pivotal to this approach is Bhaskar’s (1979) stratified ontology: layers of the

empirical, the actual, and the real. Each offers interpretation in a structured abductive approach and it is this that makes the approach offered here different, in that it implies that imagination and mystery explain transdisciplinary problems and, with them, the context to act.

According to Danermark, the five features of a critical realist study are (1) a stratified ontology, (2) an intransitive dimension of reality, (3) causation in terms of generative mechanisms, (4) the importance of contextualisation, and (5) the empirical reality. The stratification of reality we have previously mentioned as real, actual, and empirical. It helps us to accept both a reality outside of ourselves and a personally constructed engagement. Each reality is nested in the next and means that entities in external world exist without our perception of them. (They are intransitive, whilst those that exist only when we are concerned with them are termed transitive.) This applies to both social structures and entities within them. The power that they have to shape our world is within their generative mechanism. They are things that are not seen but structure our practice within the world, such as the market mechanism or climate change. Contextualisation is layered and integrative and it includes the case of professional practice mechanisms such as the psychological, socio-economic, cultural, and normative (personal identity, the economic and social power of the profession, its standing in society, and the values it is expected to uphold).

The final element, the empirical reality, is developed in six stages (Danermark et al. 2002: 109–111). The model begins with two process of disruption, from which flows an analytical resolution. Stages 3 and 4 begin to introduce the notion, with an abduction phase followed by retroduction (see below). Danermark et al. (2002) accept some blurring of these stages in actual research practice and it is this imaginative approach to re-description and interpretation prior to theory development, abstraction, and contextualisation that is relevant here. Danermark et al. (2002: 80) differentiate abduction and retroduction as follows:

- Abduction is to ‘interpret and recontextualise individual phenomena within a conceptual framework or a set of ideas. To be able to understand something in a new way by observing and interpreting this something in a new conceptual framework’.
- Retroduction is ‘from a description and analysis of concrete phenomena to reconstruct the basic conditions for these phenomena to be what they are’ (ibid.).

Bhaskar and Danermark (2006) developed this approach when investigating the practice of professionals in the field of disability. They claim that such an approach indicates more clearly ‘than the other positions the appropriate direction and context of explanatory research—from the manifest phenomena to the mechanisms that produce them, in their complex co-determination’ (2006: 280). According to Bhaskar, this will necessitate:

epistemological transdisciplinarity, involving the exploitation of pre-existing cognitive resources drawn from a wide variety of antecedent cognitive fields in models, analogies, etc. Such transdisciplinarity in creative interdisciplinary work has seemed to some writers to involve breaking with the very notion of a discipline, to the extent that there has been talk of postdisciplinarity. (2010: 5)

The central claim here is that there is a difference between retroduction and abduction, which makes this approach distinct.

For example, a critical realist investigation into the professional development of lawyers would require a layered approach to the reasons for personal development as an identified professional. The sub-cultural aspects of the development are the hegemony of the professional structure of the profession and the importance of professional development as a societal sign of confidence (or reconceptualised in any other societal engagement) in the profession, and engagement with the legal system as a whole and the role this plays in entrusting its democratic values to a select group of people. Having described the research problem as such, then one would need to reconceptualise what professional development might mean in this layered context and consider ways in which its multi-layered purpose might be investigated. At that stage, one would consider how the differing reality layers could be disclosed and what techniques would best be able to offer understanding of the causal powers that derive the form and content of professional development programmes: accreditation, assessment, exclusion, and cost.

Clearly, not all problems concerning professional practice lend themselves to this approach to research. It is an approach that is best suited to the rubric of case study methodology and good examples are provided in two collected works of transdisciplinary case studies, edited by Hadorn et al. (2008) and Brown et al. (2010). The insights for transdisciplinary action are based on readiness to see within a problem a reality that may be concealed by a disciplinary lens. This moment of vision is the origin of the abductive process of creatively and imaginatively considered ways of understanding the presented problem or changing its definition. This insight is identified within the abductive case study and triggers the processes of retroduction by presenting it as reasoned through phronetic abduction. The wise decision is the responsibility of the investigative team and the need to move ‘towards the “exemplary knowledge” of abduction and phronesis’ (Thomas 2010: 578). As Thomas concludes, we are ‘left with a view of case study’s validation coming no longer through reference to a body of theory or generalized knowledge. Its validation comes through the connections and insights it offers between another’s experience and one’s own’ (ibid.: 579). Thomas justifies case study as a process of empathy, of understanding the other person’s perceptual horizon, and advocates an ‘anatomy of narrative’ approach. Helpful though this method may be, it seems its insights to some extent bracket off the case study from the world in which it exists. This positioning statement has resonance with what is advocated in Flyvbjerg’s (1998, 2001), Flyvbjerg et al. (2012) phronetic method and the ‘thick’ analysis of the details of a phenomenon from which more general insights can be gained (see also Thuesen’s 2011 discussion of phronesis and the handling of elite interviews as a way of dealing with power and reluctance in interviewees). Transdisciplinary case studies do not seek theoretical validation, but a means to a satisfactory understanding of deep and complex problems and then their solution. Critical realism offers both a meta-theory and a form of investigation.

Examples of such research practices are:

- Easton’s (2010) description of the critical realist approach of Sayer and development of its general application to case research. An example of its use in practice

is presented using the case study of the development of the buyer–seller relationship after the installation of a new MIS system.

- Blom and Morén’s (2010) presentation of a conceptual framework and a theoretical model, helping us explain the way results in social work practice arise from the content of interventions and its contextual contingencies.
- Pohl’s (2011) querying what is progress in transdisciplinary research, where several disciplines and further societal actors may be involved.
- Kavanagh’s (2013) outline of a phronetic paradigm for organisational inquiry, concluding by briefly examining the implications of such a paradigm for research and learning.

10.4 Concluding Comments

This chapter engages with ways of understanding the practice of professionals as it emerges and can be understood. It takes a route from positivist realism ontology through the critical world experienced by the phenomenologists, to the warranted beliefs of the pragmatists, and rests with the insight of the critical realists. It ends with conversations concerned with transdisciplinarity and the replacement of epistemology with phronesis as the goal of understanding the practice of professionals. Along the way, appropriate uses of methodologies are identified and examples of these approaches abound. These have been mentioned in concluding paragraphs at the end of each section. It is now the time to try to pull together our concluding thoughts.

In moving to examine a variety of contrasting approaches to researching practice, a major limitation soon rears its head. It is apparent from examination of the contrasting paradigms to examine practice that the truth of any claim for knowledge that may emerge from particular forms of research is entirely dependent upon the paradigm used. And, from the perspective of the agency involved in research, it has been argued that one needs to be reflexive in examining the culture, and often the hegemonic forms of culture, of such agency to gain some understanding of the research, its approach to the collection, archiving, and analysis of data, synthesis of evidence, and the form of knowledge claims that are disseminated about practice. But what has complicated the matter still further is the multiplicity of understandings that actors involved in the process—researchers, practitioners, and other related agencies—have about the very nature of researching practice itself; both the materiality of its unfolding at the workplace and the multiplicity of discourses mediate such practice. Nor does the move towards transdisciplinary forms of inquiry about practice appear to provide ready-made solutions to the many concerns identified earlier in the chapter about researching practice.

There is a need to emphasise, however, two strong themes from this review of some of the paradigms involved in practice-based research in the workplace. These are the virtue of phronesis or practical wisdom concerned with researching practice, and the intentional structure of such research. It has been argued that the precise

locus for the exploration and examination of these two themes is that of the collective action of researching. From the very limited studies of such collective forms of action, it is clear that we are now standing on the frontier of what is done in researching practice.

In seeking to attain new horizons for researching professional practice, this chapter has argued that there is considerable merit in examining further the implications of research approaches to professionals and their practices. In particular, the chapter has provided a review of the most popular research approaches used to investigate professional practice and suggests that there is considerable value in researching practice that involves the interplay of critical realism and transdisciplinarity as forms of inquiry. Both these, it has been argued, pose the challenge of transcending, transgressing, and transforming extant forms of practice-based inquiry and the outcomes of such research. Perhaps future research is warranted on the discourse of practice in the open systems of praxis. In this way, it is suggested, the very practice of research becomes laminated, to use Bhaskar's term. The assumption of one reality, so vital to the other research approaches discussed in this chapter, is forsaken for a more complex and rich conceptualisation of a three-level reality. Conceiving the possibility of understanding afresh what is practical practice and the wisdom of those who have professional mastery becomes a more holistic enterprise. Such an approach does not reject out of hand the tools for data collection developed by varieties of positivism, nor does the notion of pragmatic triangulation. Rather it structures, reconceptualises and combines knowledges to offer a coherent picture of what practice is, how it works, and what are the constitutive parts of its emergent power.

Chapter 11

A Phenomenological Perspective on Researching Work and Learning

Gloria Dall’Alba and Jörgen Sandberg

Abstract Conventional research approaches typically conceptualise learning within and for work in terms of two separate entities: subject and object. More specifically, the individual subject who is learning is considered to be independent of the work to be learned. In contrast, practice-based approaches commonly emphasise the relation, rather than separateness, of subject and work. In this chapter, we engage with phenomenology in extending previous accounts of learning within and for work by bringing to the fore the manner in which practice is constituted through the *entwinement* of life with world.

We elaborate a lifeworld perspective on researching work-related learning, which challenges the ontological assumption of a subject-object constellation in significant ways. This challenge is pertinent whether subject and object are seen as independent of each other (as in conventional approaches) or as becoming related during performance of work (in several practice-based approaches). We explore how entwinement with world makes learning possible, while pointing to ways in which a lifeworld perspective affords novel resources for informing and enhancing research on learning within and for work.

Keywords Lifeworld • Phenomenology • Entwinement • Work-related learning

11.1 Re-examining Research on Work-Related Learning

A central question for all research on work-related learning (and human learning, in general) is how to define learning. Our understanding of what learning is informs what to investigate, how to design our research, what empirical material to collect, and how to analyse and theorise learning within and for work. In other words, researching work-related learning presupposes assumptions that enable us to conceptualise learning *as* something in the first place. Conventional research approaches typically conceptualise learning within and for work in terms of two separate entities: subject and object. More specifically, the individual subject who is learning is considered to be independent of the work to be learned.

While this dualist ontology has been questioned in various ways over the years (see, for example, Dewey 1938; Packer and Goicoechea 2000; Prawat 1998; Semin and Gergen 1990; van Manen 1977), a growing number of practice-based approaches has intensified this critique during the past two decades (Billett 2001; Engeström et al. 1999; Gherardi 2006; Lave and Wenger 1991). The main criticism has been that work-related learning cannot be meaningfully understood when subject and work are regarded as two independent entities. This is because key aspects of work-related learning only manifest themselves in the practitioners' engagement with their work, that is, in their actual work performance (Billett 2010; Nicolini et al. 2003). Therefore, practice-based approaches commonly emphasise the *relation* rather than separateness of subject and work. Through this reconceptualisation, practice-based approaches have advanced our understanding of work-related learning in important ways. In particular, practice-based approaches have contributed new and more precise accounts of how work-related learning occurs in practice and how this learning can be appropriately evaluated (Billett 2010).

However, in reviewing contemporary practice theories in social sciences, Andreas Reckwitz (2002) concluded that these theories are fragmented and in need of more systematic elaboration in order to provide a powerful alternative to prevalent social theories. Perhaps contributing to this fragmentation, common practice approaches draw on a combination of philosophical and theoretical traditions, such as phenomenology, Marxism, pragmatism, Lev Vygotsky's social constructivism, and Ludwig Wittgenstein's later philosophy. A majority of these approaches, however, are inspired by the notion of the "lifeworld" in phenomenology, as the practice turn is tied to an interest in the "everyday" and, in particular, to people's "doings" in their everyday world (Reckwitz 2002). Although many practice-based approaches have been inspired by the notion of the lifeworld and have used related concepts, they have not necessarily adopted this perspective consistently throughout the research (Sandberg and Dall'Alba 2009).

In this chapter, we engage with phenomenology and propose a lifeworld perspective on learning within and for work. We outline the origin of the concept of the lifeworld and sketch some of its later developments, as a means of contextualising and elaborating a lifeworld perspective for researching work-related learning. A lifeworld perspective challenges the ontological assumption of a subject-object constellation in significant ways. This challenge is pertinent whether the subject and object are

seen as separated (as in conventional approaches) or as becoming related during the performance of work (in several practice-based approaches).

From a lifeworld perspective, learning is made possible and circumscribed by a way of existing that is more basic than the subject-object constellation, namely, what Martin Heidegger (1962/1927) called being-in-the-world. This notion stipulates that subject and world are not primarily separated, but that we are *always already entwined with others and things* in the context of specific practice worlds, such as teaching, occupational therapy and plumbing. In other words, it is our inevitable entwinement with specific practice worlds that makes learning possible. In this chapter, we argue that a lifeworld perspective enables us to extend previous accounts of learning within and for work by bringing to the fore the manner in which socio-material practice is constituted through the entwinement of life with world.

The chapter is structured as follows. We begin by describing the main features of the dualist assumption stipulating that work-related learning is defined by two independent entities, the learning subject and the work to be learned, which underlies conventional approaches. Second, we show how practice-based approaches have questioned this dualist assumption by emphasising the relation between subject and work, rather than their separateness. Against this background, we propose a lifeworld perspective on learning within and for work. Finally, we discuss some features of the proposed lifeworld perspective, which can advance research on work and learning. In particular, we endeavour to demonstrate that a consistent elaboration and utilisation of the notion of the lifeworld enables a more comprehensive and closer examination of learning within and for work than we see in much of the work-related research to date.

11.2 Dualist Ontology: Subject and World as Independent Entities

The dualist assumption of an independent subject and work, which underlies conventional approaches to work-related learning (for example, see Berliner 1994; Boshuizen and Schmidt 1992; Collier 2004; Ericsson and Smith 1991), derives from a more general ontological assumption that “world” is comprised of independent entities with specific properties. The entity assumption forms the foundation for the conventional Greek-Western philosophical tradition in which “world” is seen as a totality of things that are externally related to each other (Inwagen 2001; Inwood 2000; King 2001). As Magda King expressed it, “when Greek-Western philosophy speaks of to be, it thinks of the is of a thing” (2001, p. 12). Saying that a thing *is* typically means that “things” such as trees, factories, teachers, managers, biotechnology really exist among other things, that they have a real presence in one sense or another, and that in combination they make up reality. Hence, the human world and all its inherent practices, such as architecture, political science and building construction, are seen as comprising a totality of things that are externally related to each other.

When the world is regarded as comprised of externally related entities, the dualist assumption follows that an individual subject is externally related to an independent world. There are subjects, on the one hand, and the remaining things in the world, on the other. As soon as we are born, we discover a world consisting of a myriad of things, both material and immaterial. In order to find our way in the world we, as subjects, constantly learn about these various things. As Sandra Bartky expressed it, “the subject, originally worldless and isolated from the object, somehow leaps out of its domain and is able, through its own intellectual activity, to appropriate, certify or otherwise ‘master’ the object” (1979, p. 217). In other words, from a dualist ontology, it is assumed that learning happens when an individual subject attempts to learn about independent things in the world. Work-related learning is assumed to occur, then, when an aspiring or experienced practitioner acquires specific knowledge and skills to be applied at work, with this application often taking place at a subsequent time. Within this conceptualisation, there is the practitioner, knowledge and skills to be acquired, and the work, each of which is distinct from the others. Hence, the dualist assumption underlying conventional approaches to work and learning leads to research that investigates the various procedures and activities an individual subject uses while learning (decontextualised) knowledge and skills to be subsequently applied at work.

11.3 Subject-Object Dualism Questioned by Practice Approaches

The “practice turn” in the social sciences (see, for example, Schatzki et al. 2001) has given rise to a broad variety of practice-based approaches to work and learning. These practice-based approaches examine the everyday doings of people and things in organisations, while also emphasising the broader social practices of which these doings form a part. Although drawing from a range of different philosophical traditions (for example, actor network theory, activity theory, Marxism, phenomenology, Wittgenstein’s later philosophy), a common theme in practice-based studies is the everyday world of practitioners; specifically, the way practitioners perform their work (Reckwitz 2002; Sandberg and Dall’Alba 2009). The strong focus on the performance of work has meant that many practice-based approaches have questioned the dualist ontology within conventional approaches to work and learning in important ways. In particular, advocates of practice-based approaches argue that by treating person and work as separate entities, conventional approaches overlook central aspects of what characterises the kind of learning and knowing involved in practitioners’ actual performance of their work (Lave 1993; Lave and Wenger 1991; Dall’Alba and Sandberg 2006; Sandberg and Pinnington 2009).

In contrast to conventional approaches, many practice-based approaches emphasise the *relation*, rather than the separateness, of subject and work as a means of researching and more fully understanding work-related learning. This is because when practice becomes the locus, learning and knowing are regarded as indistinguishable

parts of the performance of practice (Blackler 1995; Engeström 1993; Gherardi 2006; Lave 1993; Wenger 1998; Whittington and Vaara 2012). In other words, learning and knowing are not considered to be located within individuals, nor are they seen in terms of intellectual activity that drives behaviour. Instead, learning and knowing are seen to be performed within social practice. For example, as Davide Nicolini and colleagues argued:

knowledge and learning cannot be conceived as mental processes residing in members' heads; rather, they must be viewed as forms of social expertise, that is, as knowledge in action situated in the historical, social, and cultural contexts in which it arises and embodied in a variety of forms and media. (2003, p. 3)

Similarly, Jean Lave stressed that, “knowledge and learning ... cannot be pinned down to the heads or bodies of individuals or to assigned tasks or to external tools or to the environment, but lie instead in the relations among them” (1993, p. 9). Accordingly, rather than focusing on a subject acquiring decontextualised knowledge and skills for subsequent application, research on learning to engage in practice commonly conceptualises this process as movement from the periphery towards full participation in practice (for example, Atwell 2009; Billett 1999; Lave and Wenger 1991; Morell 2004). Knowing and learning are seen to occur as an integral part of practice. Given the focus on performing practice, this research is often located in workplace contexts where the relations are more readily apparent, rather than in formal education.

However, although practice-based approaches stress the relation between subject and object, several of these approaches are still captured by the very ontological subject-object constellation they criticise. While rejecting the dualist separation of subject and object, they typically conceptualise learning and knowing in terms of subject and objects that become related through human activities or during practice. For example, Richard Whittington (2006, pp. 618–623; Whittington and Vaara 2012) conceptualises the practice of strategy in organisations as consisting of three discrete entities (praxis, practices and practitioners) that come together through practice activities, even while emphasising the interrelatedness of practitioners and strategy practice. He proposed “a framework that can link together different subsets of the three core elements, according to the particular task in hand,” although he acknowledged “their ultimate membership of an integrated whole” (Whittington 2006, p. 620). Similarly, in a review of the situated learning theory generated by practice-based approaches, including activity theory (for example, Engeström 1993), the sociocultural approach (for example, Wertsch 1991) and the distributed cognition approach (for example, Hutchins 1995), Stephen Fox observed that this learning theory:

[in] its very *theoretical* attempt to transcend the division between abstract mind and concrete practices, replicates the dualism when it seeks to mediate the two (as in activity theory) and/or favours the abstract “mental” side of the dualism as all Hegelian attempts at transcending division through higher order *theorisations* must. (2006, p. 429)

In other words, while practice-based approaches regard subject and object as interrelated, several of these approaches continue to treat them as separate entities

that become related through practice. As a consequence, these practice-based approaches still operate within the subject-object constellation, albeit in a more sophisticated manner than conventional approaches to work and learning.

11.4 From Subject and Object to Entwinement with World

We now turn attention to engaging with phenomenology in proposing a life-world perspective on work and learning that challenges, in significant ways, the subject-object constellation underlying both conventional and some practice-based approaches. The notion of the lifeworld within phenomenology stipulates that subject and object are not primarily separated or become related through practice, but that we are *always already entwined with our world*. Interestingly, although many advocates of practice-based approaches have been inspired by the notion of the lifeworld from phenomenology (see, for example, Chia and Holt 2006; Schatzki 2002; Wenger 1998), they have not fully adopted this notion throughout their research on work and learning.

Several phenomenological thinkers, such as Edmund Husserl, Martin Heidegger, Maurice Merleau-Ponty, Jean-Paul Sartre, Hannah Arendt, Hans-Georg Gadamer and Alfred Schutz, have heavily questioned the ontological subject-object constellation prevalent in the social sciences. As Dermot Moran pointed out:

Indeed, the whole point of phenomenology is that we cannot split off the subjective domain from the domain of the world as scientific naturalism has done. Subjectivity must be understood as inextricably involved in the process of constituting objectivity ... there is only objectivity-for-subjectivity. (2000a, p. 15)

In other words, we cannot step outside our world to observe it as though we were impartial bystanders. We are implicated in our observations, as well as in our encounters with others and things. As Amedeo Giorgi formulated it, “objectivity is not possible without a subject, and subjectivity is not possible without an object” (1992, p. 7). Making an effort to be impartial presupposes entwinement. It is this prior, inevitable entwinement that necessitates the effort involved in distancing ourselves as we seek to achieve impartiality. Acknowledging the centrality of reconceptualising our relationship with world for phenomenology, Moran goes on to argue that “phenomenology’s conception of objectivity-for-subjectivity is arguably its major contribution to contemporary philosophy” (p. 15).

Phenomenologists use the concept of the “lifeworld” for capturing and highlighting how subject and world are inextricably related. This concept has its origins in the phenomenological movement (Spiegelberg 1982) and is common to the distinct branches of phenomenology that developed during the past century. While the concept of the lifeworld is attributed to Edmund Husserl, the founder of modern phenomenology, it has been expanded and elaborated by several other phenomenologists, such as Heidegger, Sartre, Merleau-Ponty, Gadamer and Schutz. Since each of these thinkers pursued a specific knowledge interest, there are not only commonalities in their conceptualisations of the lifeworld, but also some

differences and tensions. We outline the origins of this concept and sketch some of the later developments as a means of contextualising our own lifeworld perspective on work-related learning. As we draw primarily on Heidegger and Merleau-Ponty's concepts of the lifeworld in this chapter, we mainly focus here on their accounts, after briefly outlining the origins of the concept.

11.4.1 Husserl: Intentional Character of Consciousness as Entwinement with World

In a lifelong attempt to establish a secure foundation for scientific knowledge, Husserl provides a substantive critique of the assumption that subject and object are separate and independent of each other. In one of his later endeavours (Husserl 1970a/1936), he used the concept of the lifeworld to describe the everyday world with which we are unavoidably entwined through our lived experience. According to Husserl, the lifeworld is simultaneously my world and a world shared with others and things. He argued that the lifeworld provides the point of departure for all our actions and activities, as well as for our learning and knowledge; it is through our lived experience of the world that we can engage with that world and come to know. The lifeworld is, then, pre-reflective and pre-scientific.

Husserl's contention that person and world are inextricably related through lived experience was a response to what he understood as a crisis in the natural sciences at the time. This crisis centred around an assumption that we are independent of our world and can, therefore, adopt an objective stance towards it. According to Husserl, such an assumption overlooks the role of consciousness in the constitution of knowledge about the world. In particular, he argued that a pre-occupation with gaining objective knowledge independent of the subject within science was leading to neglect of, and lack of awareness about, how we can achieve meaning and, thereby, knowledge about the reality in which we live. According to Husserl, we achieve knowledge of the world through lived experience. For example, when we conduct research—whether within natural or social sciences—we are able to investigate aspects of our world through the access that our lived experience provides.

A central outcome of Husserl's phenomenological investigations of how knowledge is possible through lived experience is his theory of intentionality. This theory challenges a conventional view in which consciousness is regarded as something inside the mind (and somehow leaps out, as Bartky expressed it). For Husserl, the notion of intentionality stipulates that consciousness is not closed but *open* and always directed toward something other than itself. He argued that an individual's various modes of consciousness, such as perceiving, judging or imagining, are always related to something, which is not consciousness itself, but is intentionally constituted in an act of consciousness (Husserl 1970b/1900–1901). What is intentionally constituted, however, is not the object in itself, but the object *as* something, that is, the meaning of the object. For example, when looking at the things on my desk, I do not experience them as things, as such, but as something with a particular

meaning, such as a book and a laptop. The meaning, such as “book” or “laptop,” therefore, is inseparable from both the object and the subject who experiences it. Hence, for Husserl, we are inextricably entwined with world through the intentional character of consciousness: it constitutes the meaning of reality, that is, the meaning that appears to us in our lived experience and, thereby, our knowledge about the reality in which we live.

More specifically, for Husserl, the meaning of reality constituted through acts of consciousness (such as, perceiving, judging and imagining) is presupposed in all scientific and pre-scientific dealings with the world. It is in this sense that the lifeworld is both pre-reflective and pre-scientific. This is because without the initial meaning that entities have for us, it would be possible neither to make our way in the world nor to investigate the world scientifically, thereby developing knowledge about the reality in which we live. According to Husserl, therefore, phenomenology’s prime task is to analyse how the (initial) meaning of entities, “presupposed in all scientific, and pre-scientific dealings with entities, gets constituted through ‘acts’ of consciousness and their ‘syntheses’” (Crowell 2005 p. 54).

11.4.2 Heidegger: Being-in-the-World as Our Entwinement with World

In contrast to Husserl’s epistemological investigations, Heidegger’s primary knowledge interest was ontological: he explored what it means for something to be. Through his phenomenological inquiry into being, Heidegger’s (1962/1927) existential ontology both elaborated and challenged Husserl’s notion of the lifeworld in substantial ways. More specifically, while he accepted Husserl’s insight that we are entwined with world through the intentional character of consciousness, Heidegger wanted to “radicalize the philosophical interrogation of intentionality by raising more fundamental questions, neglected in conventional philosophy, of ‘the question of being’ and, specifically, the question of the being of the intentional” (Moran 2000b, p. 42).

According to Heidegger, there is a more basic form of relating to world that precedes the intentional character of consciousness, namely, our *being-in-the-world*. Here, Heidegger does not refer to a conventional “container” view of world, such as a totality of entities. Instead, he regards “world” as a meaningful whole in which we always already live, including specific practice worlds, such as the “world of business”, the “world of sport,” and the “world of the arts.” Moreover, world has an existential meaning for Heidegger (1962/1927, p. 62) in the sense that we, as humans, grow up in, embody and enact various ways of being-in-the-world, such as greeting, talking and sharing meals. We also later enact and embody work-related practices, such as teaching, nursing, managing and so on. Therefore, according to Heidegger, we are *always already entwined with others and things* in specific practice worlds. He attempted to capture this inevitable entwinement by using the hyphenated term, being-in-the-world, as a means of seeking to overcome the limitations of language in expressing this more radical conceptualisation.

For Heidegger, our entwinement with others and things in specific practice worlds forms a meaningful whole or “totality of significance” (1962/1927, p. 93). Our entwinement, then, makes it possible for something to be at all, by providing *intelligibility* to who we are, what we do, and the things we use in our activities and projects. For example, our entwinement with others and things in the practice of teaching enables us to act and to understand ourselves as teachers. In doing so, we may write on a whiteboard and engage in dialogue with students as specific teaching activities, as well as using pens, whiteboards and laptops as specific equipment for carrying out our teaching activities. Similarly, Jörgen Sandberg and Ashly Pinnington (2009) show how the practice of corporate law forms a relational whole of significance, namely, assisting clients with legal risks in various business transactions, so they can achieve what they set out to accomplish. This relational whole of significance enables the lawyers to understand themselves as corporate lawyers, performing corporate law activities in which they take instructions from clients about particular business transactions and conduct associated legal analyses, for which they use legal documents, computers, buildings and clothes as tools.

Hence, Heidegger’s existential ontology proposes that our most basic entwinement with world is not via the intentional character of consciousness, but takes the form of *being-in-the-world* (1962/1927, pp. 49–58). Distinguishing between subject and object derives from this primary mode of existence. Differently expressed:

the subject-object relation becomes possible only insofar as we acknowledge the ontological priority of being-in-the-world. This is because it is our engagement in—entwinement with—particular sociomaterial practices that enables us to understand ourselves as particular subjects and objects as particular things in the first place. (Sandberg and Tsoukas 2011, p. 345)

Even though we may distinguish subject from object for some analytical purposes, then, this distinction itself is derived from our entwinement with world. In other words, the distinction is derived from our being-in-the-world. As Blattner (2006, pp. 12–13) so eloquently captured it:

Heidegger offers an alternative description of experience. He argues that our fundamental experience of the world is one of *familiarity*. We do not normally experience ourselves as subjects standing over against an object, but rather as at home in a world we already understand. We act in a world in which we are immersed. We are not just absorbed in the world, but our sense of identity, of who we are, cannot be disentangled from the world around us. We are what matters to us in our living; we are implicated in the world.

In other words, Heidegger replaces Husserl’s notion of intentionality with being-in-the-world as our primary entwinement with world.

11.4.3 Merleau-Ponty: The Lived Body as Our Entwinement with World

Like Heidegger, Merleau-Ponty considered our being-in-the-world to be our primary entwinement with world. Similar to Heidegger, he, too, explored the ontological character of the lifeworld, taking inspiration from Heidegger’s concept of

being-in-the-world. In contrast to Heidegger, however, Merleau-Ponty's particular focus was the way in which bodily perception mediates our being in the world. In other words, Merleau-Ponty demonstrated how our being in the world is achieved through the perceiving body. He criticised both Husserl and Heidegger for not having explicitly taken into account the role the *lived body* plays in our entwinement with world. For Merleau-Ponty, the lived body is not merely a physical body, as it is typically portrayed, but more importantly, an incarnate subjectivity. On the one hand, Merleau-Ponty argued that we are entwined with world through our lived body rather than via the intentional character of consciousness, as claimed by Husserl. On the other hand, while he agreed with Heidegger that our being-in-the-world forms our primary entwinement with world, Merleau-Ponty claimed that our entwinement with world occurs through our lived body.

Hence, according to Merleau-Ponty, we are always entwined with world through our lived body; our entwinement with world originates from our lived body. As he described it: "I am conscious of my body via the world ... [and] I am conscious of the world through the medium of my body" (1962/1945, p. 82). In his phenomenological investigation of the lived body, he shows how "my body is the fabric into which all objects are woven, and it is, at least in relation to the perceived world, the general instrument of my comprehension" (p. 235). When a medical practitioner uses a stethoscope to listen to a patient's heart rhythm or examines an X-ray of the heart, for example, the stethoscope or X-ray becomes an extension of the body, expanding the capacity for hearing or seeing.

Moreover, for Merleau-Ponty, the notion of the lived body suggests that the primacy of our entwinement with world is non-representational: "to move one's body is to aim at things through it; it is to allow oneself to respond to their call, which is made upon it independently of any representation" (p. 139). As Hubert Dreyfus expressed it, our entwinement with world through our lived body means that we experience ourselves "as an *open responsiveness* to what solicits our activity" (2002, p. 35, italics added). Our ways of being-in-the-world settle in the lived body, then, as ways of thinking, feeling, acting and being that function spontaneously.

Through their particular phenomenological investigations, Husserl, Heidegger and Merleau-Ponty significantly challenge the assumption of a subject-object constellation within conventional approaches to work-related learning—where subject and object are seen as independent of each other—as well as in many practice-based approaches—where subject and object are considered to become related in work performance. Their investigations suggest that we are never separated from our world, but always already entwined with world. Husserl shows that we are inevitably intertwined with our world through the intentional character of consciousness. Heidegger demonstrates that we are entwined with world in a more basic way, namely, through our being-in-the-world. Merleau-Ponty makes Heidegger's insight more complete by highlighting that we are inescapably entwined with world through our lived body in that we always embody specific ways of being-in-the-world, such as teaching and engineering. Taken together, these phenomenological investigations suggest it is not the subject-object constellation

that defines and makes work-related learning possible, but our entwinement with world. How, then, can work-related learning be researched and understood in terms of our entwinement with world?

11.5 Learning and Work from a Lifeworld Perspective

Against the background of the origins and concept of the lifeworld, in the remainder of the chapter we discuss ways in which a lifeworld perspective can advance research on learning within and for work. We begin this discussion by turning attention to what learning entails from a lifeworld perspective, drawing upon the theoretical concepts introduced above. In doing so, we continue to critique the prevalent subject-object notion as a means of clarifying a lifeworld perspective on learning.

11.5.1 Learning Within a Meaningful Whole of Significance

From a lifeworld perspective, learning is made possible by entwinement with our world. Of particular significance for learning is the manner in which our entwinement with others and things in particular practice worlds forms a meaningful whole of significance. Learning takes place on the basis of, and through, this shared meaning totality. For instance, learning to use a stethoscope when examining patients makes sense because tools and procedures such as these are relevant to the practice of medicine and its role within the health system. The various people and things that make up the practice of medicine, such as medical practitioners, patients, stethoscopes and pharmaceutical drugs, take on meaning due to the health system of which they form a part. Conversely, there would be no health system without the practitioners, patients, tools and treatments of which it is comprised.

Learning to be a practitioner only makes sense, then, within such a significance whole. Our activities, concerns and projects are afforded shared purpose and direction in relation to a significance totality, such as the health system. This shared meaning is manifest in ways of being practitioners, both by individuals and collectives. For example, the practice of medicine and its role in the broader health system provides both openings and constraints in terms of what is possible and appropriate in the treatment of patients, for individual medical practitioners and the profession, more generally. It is important to note, however, that a specific practice world is typically not comprised of a singular, unvarying practice (Sandberg and Dall'Alba 2009). Instead, practice worlds incorporate diverse and sometimes competing ways of practising, as we discuss below.

What, how and why we learn, then, takes its meaning from the totality of significance within which we are entwined with others and things. As noted above, this entwinement challenges a conceptualisation of learning that assumes an individual subject learning about an independent object. Subject and object only have meaning

and relevance in relation to meaningful significance wholes; they are never entirely independent or separable. In other words, from a lifeworld perspective, what makes learning possible is not an individual learning about an independent object. Instead, learning is made possible and takes place within a specific practice world and a meaningful whole of significance. Moreover, the totality of significance guides and shapes our learning. It provides learning with meaning and purpose, such as what matters to us in our learning, what is relevant to learn and appropriate ways of doing things in the particular practice.

Within Heidegger's notion of the lifeworld, we are continually engaged with a range of such concerns, activities and projects, many of which are shared with others. Rather than being subjects independent of our environment, we are oriented towards what we are learning within a meaningful whole of significance. As Heidegger expressed it, we are oriented towards what we are "not yet" (1962/1927, pp. 185–186). In other words, our learning matters to us; is of consequence for us in some way. If this were not the case, it is unlikely that learning would be worth the risk involved, especially, perhaps, the risk of failure to learn. As we are oriented to learning what matters to us, the possibility of complete disinterest and impartiality is removed. Through this commitment to learn, we invest something of ourselves (Blake et al. 2000, p. 26), which precludes separateness.

Not only does our entwinement with a practice world guide what we learn, but also our shared commitment and interest in learning something entails entwinement with others in a significance whole, whether or not we meet these others face to face. For instance, we are intertwined with the author(s) (and readers) of a website or book we read on a topic of interest, as well as with colleagues, fellow students or friends who discuss with us what we have read. In other words, when we learn we are part of a wider learning community. This is an additional sense in which we are not independent individuals seeking to acquire knowledge that is separate from our lives and ourselves. Rather, it is the various concerns, activities and projects that are integral to living our lives which make us willing to learn (Barnacle 2005; Barnett 2007), while also providing direction and purpose for our learning. At times, the commitment to learn that we share with others endures for an extended time, such as throughout the period required to enrol in, and complete, a programme of study necessary to entering a particular profession or occupation. Sometimes this commitment to learning can persist throughout working life, although the people with whom we share this commitment may shift over time.

11.5.2 Learning as Enacted and Embodied

While entwinement with our world makes learning possible, Merleau-Ponty (1962/1945) provides insights into the manner in which the lived body is the means by which we are inevitably entwined with, and gain access to, our world. What we learn is not simply acquired or accumulated, but is incorporated into the body and

enacted as we perform our work or go about in the world. This embodiment and enactment of our learning is evident in the way a medical practitioner examines a patient through carefully listening, feeling and looking, while diagnosing an ailment. Similarly, melodiously playing a musical instrument, creating an intriguing narrative, fashioning an elegant garment and constructing a well-crafted building are all demonstration of the enactment and embodiment of what we have learned. They are also enactment of how we learn. On a more everyday level, our fluent use of language in communication and the manner in which we navigate within local landscapes also exhibit enactment and embodiment of learning in various forms.

In embodying and enacting what we learn, we are not constrained within the boundaries of our material body. Rather, as Merleau-Ponty has pointed out, our body extends into, and incorporates, things in our world:

To get used to a hat, a car or a stick [for example, a blind person's cane] is to be transplanted into them, or conversely, to incorporate them into the bulk of our own body. Habit expresses our power of dilating our being-in-the-world, or changing our existence by appropriating fresh instruments. (p. 143)

This body extension illustrates how the body “is the fabric into which all objects are woven” (p. 235). This capacity to extend the body through incorporating tools and technologies has made possible the recent developments in telemedicine in which patients' ailments are diagnosed, even when the patients and medical specialists may never meet (see, for example, Gherardi 2010). In these technology-mediated medical examinations and consultations, the various parties involved and the technologies used are intertwined in a manner that collapses or overcomes some of the obstructions due to distance. As in the case of telemedicine, new ways of extending the body and of enacting practice can lead to new forms of sociomaterial practice. Our embodiment of practice, then, is a further demonstration of entwinement that undermines the notion of subject and object as independent of each other. In underlining this point, Merleau-Ponty turned on its head the subject-object notion by noting that “I apprehend my body as a subject-object, as capable of ‘seeing’ and ‘suffering’” (1962/1945, p. 95). Person and world are, then, unavoidably entwined in the performance of work or everyday activities.

11.5.3 Learning as Transformative

The performance of work or everyday activities is given shared purpose and direction through our ways of being in the world, as noted above. Through our ways of being electricians, historians, speech pathologists and so on, we come to understand ourselves as practitioners, practice as consisting of particular activities, and things as equipment used in carrying out our activities. Similar to the aspects identified above, ways of being provide an additional sense in which subject and world are entwined, as we illustrate below. Again, there is no subject independent of a world about which we seek to learn.

Our ways of being give meaning, then, to what we do and who we are, both personally and as members of shared practice. In other words, ways of being can be seen as personal-social (Dall'Alba 2005; Sandberg and Pinnington 2009). Max van Manen (1999) illustrated this personal-social character of practice in his phenomenological study of teachers in schools. He explained that the shared practice of teaching is manifest differently by teachers in response to the interactions and situations in which they find themselves:

Teaching techniques employed by different teachers may look behaviorally the same on the outside but individual teachers always have acquired and developed these practices in a personal manner—sometimes in entirely different biographical and situational settings. Thus, particular practices get embodied in the context of personal life histories and backgrounds, and these practices become habituated in uniquely different situational and relational spheres. (p. 74)

While we can simply fall into line with the ways in which others research, teach or manage, we can also exercise agency in contributing to enacting and developing practice in new ways. We are not simply limited to what has occurred in the past in enacting practice. Importantly, we can allow our “open responsiveness to what solicits our activity” (Dreyfus 2002, p. 35) to guide us in learning and performing practice. Heidegger illustrates this responsiveness through the example of a cabinetmaker's apprentice who is learning the craft:

His learning is not mere practice, to gain facility in the use of tools. Nor does he merely gather knowledge about the customary forms of the things he is to build. If he is to become a true cabinetmaker, he makes himself answer and respond above all to the different kinds of wood and to the shapes slumbering within wood—to wood as it enters into man's dwelling with all the hidden riches of its nature. In fact, this relatedness to wood is what maintains the whole craft. Without that relatedness, the craft will never be anything but empty busywork. (1968, pp. 14–15)

In this quote, Heidegger points out that simply acquiring knowledge or skills through repetition can lead to “empty busywork.” This form of repetition contrasts with learning how to be a cabinetmaker, which includes responding to the various kinds of wood. In the latter instance, increasing experience can progressively contribute to learning ways of being that settle in the body as they become familiar. This does not merely involve repetition in the sense of repeating the same actions, but each new situation, each new piece of wood, brings novel challenges that must be responded to if learning is to progress beyond empty busywork. Moreover, as we noted above, learning ways of being entails embodying and enacting practice, which includes entwinement with others and things.

As entwinement with our world makes learning possible, obviating separateness, it implies that we not only learn knowledge and skills but, more importantly, our relation to our world changes in the process. As Heidegger pointed out, fields of knowledge, such as economics, carpentry or social work, are not only forms of knowing, but also ways of being human (1962/1927, p. 408; see also pp. 88–90). This means that learning incorporates not only an epistemological dimension (or *what we know* and *can do*) but also an ontological dimension (or *how we are learning to be*) (for elaboration, see Dall'Alba 2005, 2009; Dall'Alba and

Barnacle 2007; Thomson 2001; Vu and Dall’Alba 2011). These two dimensions of learning are not additive in character, but are inevitably integrated as we learn. This conceptualisation of learning follows from Heidegger’s existential ontology, which we outlined above. A lifeworld perspective highlights the integration of epistemological with ontological dimensions for learning to engage in practice. Our learning unavoidably extends beyond what we know and can do, to who we are.

11.6 Researching Work and Learning from a Lifeworld Perspective

The conceptualisation of work-related learning that we elaborated above provides a springboard for describing how a lifeworld perspective can inform and enhance research on learning within and for work. We propose that this research can be advanced through a shift in focus from either a subject and object that are independent of each other (as in conventional approaches) or that become related during work performance (in several practice-based approaches) to the inevitable *entwinement* of people and things in specific practice worlds.

While there are many aspects of a lifeworld perspective with relevance for work-related learning (see, for example, Gibbs 2011; Dall’Alba 2009; Sandberg and Dall’Alba 2009; van Manen 1999), in the remainder of this chapter we select some key features that enable us to expand upon the theoretical concepts we elaborate above. These features include attending to the multiplicity of practice and associated development trajectories within the historical, social, cultural, material contexts in which they occur, as well as taking account of the ontological dimension of learning to engage in work. Each of these features derives from our *entwinement* with world. Below we use empirical material from longitudinal research on students learning to be medical practitioners (see Dall’Alba 2009) in illustrating these selected features of researching work and learning from a lifeworld perspective.

11.6.1 *Multiplicity of Practice*

While practice approaches commonly regard specific practice as a singular, relational whole (Dall’Alba and Sandberg 2006), such as the practice of medicine, accounting or neurobiology, a lifeworld perspective draws attention to the multiplicity of practice across and within settings. Due to *entwinement* with our world, any particular sociomaterial practice is enacted in a range of ways. This is clearly evident when we investigate the enactment of practice over time. For instance, while blood-letting was one of the few treatments available within early twentieth century medicine, it has been replaced by the highly technologised, institutionalised practice of medicine we encounter today. These contrasting ways of practising medicine within

distinct time periods have required substantially different ways of being medical practitioners.

As well as becoming modified over time, the enactment of practice at any specific point in time varies across social, material contexts (Billett 2001; Dall'Alba 2009; Mol 2002; Sandberg and Pinnington 2009; Schutz 1945). For instance, the treatment of a health ailment can be approached in markedly different ways from one hospital department to another, even when there is agreement about the source of the ailment (see, for example, Mol 2002). Additional variation in practice across settings can be seen from one country to the next. For example, changes to laws regulating in vitro fertilisation in Italy necessitated modifications to practice that have distinguished in vitro fertilisation practice in Italy from that in other countries (Gherardi and Perrotta 2011). Moreover, the medical treatments widely available to patients in Italy differ from those provided in Mozambique due to dissimilar resources, with implications for how medical practice is enacted. Not only does practice change over time with new developments, then, but also the social contexts and material conditions for practice influence how it is performed. This multiplicity in the enactment of practice demonstrates entwinement with world that is highly relevant for research on work and learning.

Even within one and the same setting, practice is understood and enacted in a variety of ways, albeit within the constraints of what is possible and considered appropriate. For example, a Swedish student named Gunnar¹ who was learning to be a medical practitioner described the task of a medical doctor, as follows:

My task, yeah, when the patient comes in, to identify the problem or let the patient talk about it and then, yeah, the medical, you make a diagnosis or, in any case, define the problem. And then you start an investigation or address the problem through treatment or send the patient home, if you make that judgement. And you can give calming advice and can really motivate why, or at least always be able to explain in a language that suits the patient. Which I think, in actual fact, can be very difficult. It varies so much, how you should tell different people. (second semester of fifth year, pp. 41–42)

For Gunnar, medical practice was conceptualised in terms of the work of the medical practitioner in defining, diagnosing, investigating and/or treating the problem presented by the patient, unless the practitioner makes a judgement that treatment is not needed and sends the patient home. In other words, medical practice is framed in terms of a range of procedures and solutions that the health care system has to offer, as well as informing the patient about the medical practitioner's decision in an appropriate manner. Gunnar's way of being a medical practitioner ascribes an active role to himself, while the patient is constructed primarily as a source of information about a problem that may or may not be defined as medical in nature. This is part of the decision to be made by the medical practitioner.

While Gunnar's conceptualisation of medical practice was not unusual within the cohort, some of the students within the same medical programme were quite

¹Names of research participants have been changed for reasons of anonymity and quotes from medical students have been translated from Swedish.

critical of this way of being medical practitioners. For example, Max described what medical practice involves, as follows:

In a professional way, deal with the problems patients think they have. That's the core in all of it. And, in any case, don't only deal with the problems that you, as a doctor, think the patient has.

Interviewer: Yeah, and do you think there's a difference between them?

Yes, yes.

Interviewer: The patient's problem and

Yes, definitely. You see that a lot. And I think it's very easy to start to do that, too, that you think in terms of diagnoses. And if it isn't any of them, then it isn't anything. While a patient who comes in, of course, always has a cause behind why they come. But you can still take care of it in a professional way, even if it means sending them to someone else or if it means having a good conversation and explaining what it, what you've come up with. And, but it's actually the professional disposition it's about.

Interviewer: Is it difficult to work out what the patient's [problem] is, when you yourself have this, all the medical with you, do you think?

Yes, it can actually be a reason. You think, you can just try to locate what the patient says on some diagnostic map. Well, clearly it might be, but I don't think it's so impossible to actually listen when they're talking about what it is. (p. 43)

Interviewer: And you think it's possible, it's possible to work it out, what the patient really wants, you mean?

Mm, yes, I think so. (pp. 42–43)

Similar to some of the other medical students, Max argued that affording the health care system priority over the health of patients often led to negative consequences for addressing patients' health problems:

There are many patients who never really get taken care of well, and they go to someone else and get sent around some more. And they never get the help they maybe could have got right from the start.

Interviewer: Yeah, and what do you think that depends on? That they don't get the help at the start?

Yeah, that probably depends on being so directed to, to what you yourself, what healthcare has defined as diseases. And not, not to dealing with all the problems that come. (Max, first semester of fifth year, pp. 44–45)

Max went on to comment in an ironic tone that it was possible to respond to the question of what medical practice involves in an entirely different manner from what he had been arguing:

But you can respond more cynically to it. That you, that it's about sending patients onwards [pauses, then laughs]. And it ends up being some kind of circulation, so that the whole thing [the health system] itself survives. (p. 45)

Within the same medical programme and student cohort, medical practice was enacted in markedly different ways, even at the end of the programme (see Dall'Alba 2009). Similar variations are also evident in the practice of experienced professionals within and beyond medicine (see, for example, Billett 2001; Mol 2002; Sandberg and Pinnington 2009; Stålsby Lundborg et al. 1999). This multiplicity challenges the duality of a single subject performing independent work, as well as the notion of practice as a singular, relational whole. Instead, practice is enacted and embodied in varying ways due to the entwinement of diverse practitioners with shared practice worlds at particular points in time that each has its own material conditions.

The multiplicity of practice also calls into question a prevailing view of development from novice to expert along a single development trajectory (Dall'Alba and Sandberg 2006). Although we acknowledge the potential value of regarding novices as located on the periphery of practice worlds and then progressing toward more fully enacting and embodying practice, our research challenges the assumption that this movement is unidirectional along a common development path. Such a model of learning fails to adequately account for development in diverse, and even unexpected, directions (Engeström and Miettinen 1999). In a phenomenological study of workplace learning by allied health professionals, Ann Webster-Wright (2010) argued that professional development programmes often fail to take account of such complexity and, consequently, do not adequately meet the learning needs of professionals.

The multiplicity of practice has particular relevance for research on work and learning in several ways. Variation in the way in which practice is enacted within and across settings can present challenges for aspiring practitioners who are learning to engage in practice and for practitioners who move from one workplace to another. If a procedure or activity is carried out in a specific way by one practitioner or in a particular setting, but done differently elsewhere, how is a newcomer to deal with this? And what do these differences mean for the researcher investigating the practice in question? When enactments of the 'same' practice vary, taken-for-granted assumptions by practitioners and researchers about what characterises the practice may be called into question.

In addition to presenting challenges, this multiplicity of practice opens possibilities for enacting practice in varied ways. Experiencing this multiplicity, in itself, can extend awareness about possible ways to be, as well as demonstrating how some of these ways of being practitioners are embodied and enacted. The multiplicity of practice can provide a source of both positive and negative exemplars that assist in identifying how to act and also in discerning the way one does not want to be as a practitioner. As one medical student, Kristina, expressed it in relation to contact with patients:

All patient contact is particular, in its own way. It isn't an ordinary meeting between people, and that. But it's a bit particular. And that, that's the same whatever you do, whatever type of doctor you are, that it must be. Yeah, it's a particular contact and this contact maybe you haven't been able to practise so much under supervision [during the medical programme]. But this, you've stood and watched and listened to how people do it and hoped that I want to have a sense of what I'm doing when I meet patients, so I can do what that doctor did, because I think it's good. Or that was clumsy, I don't want to become like that. (first semester of fifth year, p. 21)

Encountering a range of ways of being practitioners, therefore, can enable aspiring and experienced practitioners to engage in practice in ways that are consistent with their own understanding of practice and their preferred ways of being practitioners. In other words, the varied ways of being practitioners that we encounter contribute to guiding and shaping our learning about how to engage in practice, as well as how to be practitioners. Moreover, this multiplicity of ways of being offers opportunities for enhancing practice, both as an individual and collectively, through exposure to other ways of being practitioners.

The multiplicity of practice carries an inherent risk, however. It is possible to learn to carry out the various procedures and activities comprising a practice with limited or inappropriate understanding of what the practice entails. The realisation of this risk is evident when those seeking a service fail to be provided with the service they seek and also when negligence claims are successfully brought against practitioners. In both promoting learning and conducting research, recognising the multiplicity of practice does not imply acceptance of any form of enacting practice as appropriate. Instead, key questions concern what constitutes ethical, skilful and accountable performance of the practice in question.

11.6.2 An Ontological Dimension of Learning

In addition to overlooking the multiplicity of practice, practice-based approaches commonly adopt an epistemological focus in exploring learning and participation in practice, which emphasises the knowledge or activities that are learned or used in preparing for, or engaging in, practice. In adopting a focus on knowledge or activities, these practice approaches overlook or downplay the ontological dimension central to work and learning or, in other words, attention to who learner-practitioners are becoming, both individually and collectively. Where an ontological dimension is taken up, it is frequently treated as occurring “in addition” to learning the necessary knowledge or activities. Often it is unclear how personal (or identity) transformation is integral to learning to perform the practice in question.

Not only do aspiring medical practitioners learn about symptoms, diseases, procedures and activities that are integral to the practice of medicine, they also *learn to be* medical practitioners. In adopting a focus on knowledge or activities, attention is diverted from how practitioners are learning to be. Moreover, in research on doctoral candidates learning to be researchers, Robyn Barnacle (2005) pointed out that the emphasis in the current policy context on research that meets labour and commodity requirements within a knowledge economy is not conducive to taking into account this ontological dimension. She argued that a limited conceptualisation of doctoral becoming in line with this policy emphasis “misses the real import of the learning experience: that it is transformative” (p. 187). The process of becoming that occurs while learning to engage in work is not incidental, but is necessary to enacting and embodying practice. In this way, learning to engage in practice transforms practitioners’ relation to their world or, in other words, their being-in-the-world. This means that entwinement with world is never static, but the process of becoming practitioners continues throughout working life.

While ways of being are enacted and embodied in the performance of practice, they are not only an individual matter but entail learning to perform social practice. As noted above, learning how to engage in practice and how to be practitioners is guided and shaped by the ways of being practitioners that we encounter as this learning occurs. More particularly, we take over others’ ways of being through socialisation, education and work. This is especially the case when we are learning

unfamiliar practice or aspects of practice we have not yet accomplished. As Kristina noted above, taking over others' ways of being is not necessarily immediate or uncritical, but many of the students gave considerable thought to the kind of medical practitioner they aspired to be.

Kristina's experiences within a clinical course in psychiatry during her fifth year in the medical programme serve to illustrate the way in which we take over others' ways of being as we continually learn to engage in practice. In this course, Kristina was gradually introduced to ways in which medical practitioners worked with patients who had mental health problems. After an introductory week of lectures that provided an initial orientation to psychiatry, Kristina observed experienced practitioners during their interactions with patients. Immediately prior to these observations, it was standard practice that the medical practitioner asked the patient if the student could observe. Kristina began her observations in the outpatients clinic where she began to get a sense of how to hold a conversation with those who have mental health problems:

In outpatients, for example, I mostly sat and watched. But I was able to sit in the whole time.... I went with a fantastic doctor there, who introduced me in such a smart way that I was not once turned down.... I think I got a lot out of it, even if I wasn't so active. Just sat and listened and was there, so just how you hold a conversation like that, when people have problems. (p. 16)

After a period of observing, Kristina was given some opportunities to initiate conversations with patients about their mental health, while under supervision from experienced psychiatrists:

It was this general psychiatric ward. And I had two patients there who I followed a bit more closely, that I had conversations with. With a supervisor, that is, not by myself, but I was the one who talked and that. And we had gone through it beforehand, what should be taken up. And then, in most cases it was the patients themselves who had requested the conversation. And then we'd asked if it was OK that I led the conversation, with a supervisor present. So that's how it was. (p. 16)

Prior to each of the patient conversations, Kristina was given an opportunity to draw upon the experience of a psychiatrist in discussing what was appropriate to take up with the patient. These discussions alerted her to ways of dealing with the potentially sensitive and challenging nature of talking with patients who have mental health problems, with which she had previously little experience. Kristina then used these discussions with the psychiatrists to guide her conversations with patients:

It started with, that I asked what is was that made the patient want to have this conversation. And then you get a response, depending on what it can be and sometimes then, then it was easy to follow a kind of thread. While with other patients, maybe it was difficult to find something to take hold of. Then I had to kind of try to, well, direct it by asking a bit about how the days had been maybe or things like that. And then we went through what it, what had, what we had planned. It was discussed from the point of view of where the bar was likely to be, you could say. How much you could discuss this. Like, just now with this patient, you could say. And so try to—it has a sophisticated name—"build an alliance," to earn the patient's trust and all that. I had, naturally, worked on building that up a lot beforehand and so. Because it's quite difficult to hold a sensible conversation. You don't know where you, well, as I said, I have a lot of respect for these people, although it can be,

can look very confused.... But I think it turned out to be quite a good conversation. And then afterwards we [student and psychiatrist] went through it in a way that was helpful, since there was time set aside for students and discussion afterwards and that. It was really good. But it happened several times that I got really good follow up. (pp. 17–18)

So, after observing the practice of experienced psychiatrists and discussing this practice with them, Kristina made some attempts to talk with patients under supervision. In other words, she attempted to take over and enact some of the practice she had observed and discussed in order to gain a preliminary understanding of what is involved in being psychiatrists. As Kristina acknowledged, some of the conversations with patients were difficult, so the supervising psychiatrist showed her a way forward when this was needed, allowing her an opportunity to deepen her understanding of the practice of psychiatry:

Before one of the conversations [with a patient] my supervisor said that we, “I’ll take over it if becomes difficult” and that.... Yeah, he was able to sharpen the questions a bit maybe in a way that I had missed, so he did that, I know, on some occasion. I continued to talk, but he shot in small details, more detailed, focused questions that made it easier for the patient to respond to them.... I understood, like, since I heard the question, well, where he wanted to get to. So I thought it worked well and I learned a lot. (p. 21)

Kristina appreciated the value of benefitting from the more extensive expertise of the experienced practitioners during the medical programme, both in having access to how they performed the practice and in receiving advice about her own unfolding practice of medicine:

I think this degree programme is so fantastic, just in these situations where you have, where you stand there with a patient and examine them in your fumbling way and, like, your inexperienced way, and then you have a supervisor right next to you. Then the supervisor can be a real luxury, in a way. And I feel that, it’s quite something to be able to do such a programme. Because you are very close to, to experience and that. And most of the ones I’ve met have been really generous with it. And they’ve wanted to share what they can. And I think it’s good to be able to see how, how ordinary people do it. Because you have to deal with people, and that. You can’t just read how to do it. You have to do it and then do it again and then maybe you don’t make mistakes so many times, if someone gives you advice while you’re doing it (pp. 6–7).

Taking over others’ ways of being is an additional sense in which ways of being are personal-social: we take over others’ ways of being in social practice, embodying and making them our own. In this way, the character of our entwinement with world shifts, unfolding over time. For complex forms of practice, this typically takes an extended period of time. As Kristina notes above, it is not something that can be learned only from reading how to do it. Embodying and enacting practice also requires developing some sense of what the practice involves, as Max pointed out: “You have to, like, find your feet a bit ... and it’s very much getting a feel for it. If you are new somewhere, then maybe you don’t have that feel for what it all should actually lead to” (first semester of fifth year, p. 12).

In the students’ accounts of how they were learning to engage in the practice of medicine, they interwove descriptions of what they learned about symptoms, diseases and treatments with how they were learning to be medical practitioners.

In other words, their accounts included both epistemological and ontological dimensions of learning to engage in practice. Similar to some of the other medical students, Kristina pointed to the distinction between epistemological and ontological dimensions—without using this terminology—and she noted the importance of both dimensions for medical practice:

You know, [when interacting with patients] I have myself to start from, in fact. And it’s, I’ve been so fortunate in my life to be quite healthy, and that. So I don’t have so much experience of being a patient. But I, I would appreciate being respected as a person, whatever was involved. And I’d want a sensible explanation at my level, about what [ailment] it is that I’ve got. And, of course, I’d want to know what kind of help there was available. But, and that’s what I have to start from, in fact. And that’s what I’d like to be [as a doctor], the person who can do that. And we do this degree and gain knowledge about things and that’s what I want to communicate [to patients], then, in a sensible way.

Interviewer: And do you think you get what you need during the medical programme to become the kind of doctor you want to be?

Well, yes and no. I think that actually what you get during the medical programme is a heap of theory. And mechanisms and aetiologies about conditions you can suffer and diseases here and there. And diagnoses and things. And then different treatment strategies and that. And that’s a part, which is some kind of core, I would think. Or which is some kind of part of the whole. But you aren’t trained so much in the rest, more than when you have those conversations before and after you’ve met a patient. The rest is a, the rest is being a good doctor. That, that ability to converse and that ability to meet a person with respect, in fact. And that’s another journey. (pp. 27–28).

In order to capture fully what learning to engage in practice involves, then, it is important that research on work and learning pays attention to this integration of epistemological with ontological dimensions as part of learning. A lifeworld perspective highlights the integration of epistemological with ontological dimensions for learning to engage in practice. As noted above, our learning extends beyond what we know and can do, to who we are.

11.7 Concluding Remarks

In this chapter, we have proposed and elaborated a lifeworld perspective on learning within and for work. We have developed a critique of a conventional separation of subject and object as a means of explicating a central tenet of the notion of the lifeworld, namely, that we are always already entwined with others and things as we engage in various practice worlds. We have explored how a lifeworld perspective calls into question the assumption of a subject-object duality in substantial ways. This challenge is pertinent whether the subject and object are regarded as independent of each other (as in conventional approaches) or as becoming related during the performance of work (in several practice-based approaches).

Utilising our critique of the subject-object constellation, we have discussed various aspects of a lifeworld perspective. We have explored how our entwinement with world makes learning possible, while pointing to ways in which such a perspective affords novel resources for bringing features of practice under critical scrutiny.

Some of the features that we have sought to illustrate include the multiplicity of practice, which contrasts with a prevalent conceptualisation of practice as a single, relational whole. Across time, cultures, and social and material settings, the enactment of practice varies in line with our entwinement with world. We have pointed out that the multiplicity of practice allows us to call into question a pervasive view of learning within and for work as occurring along a single, unidirectional development trajectory.

Drawing upon Merleau-Ponty's notion of the lived body, we have described how the body provides the means of access to our world, thereby comprising a vehicle for learning and engaging in practice. This bodily entwinement with world is evident through the ways in which our bodies extend into, and incorporate, things in our world, such as tools we use in carrying out our work. This body extension also enables connections with others, such as through technology-mediated communication. The concept of the lived body dispels a prevailing conundrum in which subjects leap into a world from which they are separated. In explaining how the body is the vehicle of access to the world, this concept enables closer analysis of the embodiment and enactment of sociomaterial practice.

As we noted above, the lived body can be regarded as personal-social. This is evident when we take over others' ways of being practitioners and make them our own. The performance of work is attributed shared purpose and direction through these ways of being. Our ways of being give meaning to what we do and who we are, both personally and as members of shared practice. These ways of being highlight an integration of epistemological with ontological dimensions of learning within and for work. Not only do we learn knowledge or activities within practice, but also our relation to our world is transformed in the process. We have illustrated how this ontological dimension is not simply an additional component, but is integrated with an epistemological dimension of learning to engage in practice. This account extends research on personal transformation or identity change in work-related learning in that it demonstrates the integration of these dimensions.

In conclusion, we have explored how social, historical, cultural and material features of practice are interwoven within a lifeworld perspective, undermining the notion of a subject independent from an object. We argue that consistent adoption of such a lifeworld perspective can advance research on work and learning in new and significant ways.

Chapter 12

The Neuronal Base of Perceptual Learning and Skill Acquisition

Mark W. Greenlee

Abstract Procedural and perceptual learning are important processes involved in skill acquisition and the formation of expertise. This chapter provides an overview of recent research on the neuroscientific investigation of these different learning forms underlying the acquisition of skills. We focus on low-level processes in perception and motor control and how these low-level processes are improved by learning. Other forms of neural plasticity like adaptation, habituation, sensitization, conditioning and extinction are differentiated from procedural and perceptual learning. A brief introduction to the neuroanatomical basis of visual function is given. We next review the research on the cognitive neuroscience of these forms of learning with a focus on studies that use functional magnetic resonance imaging (fMRI). Recent results on dopaminergic and cholinergic processes underlying learning are discussed in the context of a top-down attention-gated model of perceptual learning. Finally an overview is given of research on skill acquisition and the implications of this research on the design of learning environments.

Keywords Perceptual learning • Procedural learning • Skill acquisition • Functional magnetic resonance imaging (fMRI) • Implicit memory • Brain function • Visual system

Sensory systems represent an essential interface between the organism and its environment. Throughout life the organism continuously interacts with stimuli, objects and environments and this interaction has a long-lasting effect on its central nervous system. Humans learn to respond optimally to stimuli as they

M.W. Greenlee (✉)

e-mail: mark.greenlee@psychologie.uni-regensburg.de

occur in everyday scenarios. The neuroscience of learning and memory attempts to explain how the nervous system adapts to new environments and learns through repeated practice. Two forms of learning have been the focus of neuroscientific investigation: procedural learning and perceptual learning. *Procedural learning* is defined as a training-induced change in performance for a given task, in which repeating a complex activity leads to an automatic (and often unconscious) production of highly adaptive behaviour or skill. *Perceptual learning*, on the other hand, is

the specific and relatively permanent modification of perception and behaviour following sensory experience. It encompasses parts of the learning process that are independent from conscious forms of learning and involve structural and/or functional changes in primary sensory cortices (Fahle and Poggio 2002).

These two forms of learning are involved in skill acquisition and they underlie at least partly the formation of professional expertise.

This chapter will introduce concepts in neuroscience required to understand the possible changes that occur in biological nervous systems when an organism is repeatedly exposed to a particular stimulus configuration. The focus in this chapter will be on low-level processes in perception and motor control and how these low-level processes are improved by learning. More complex cognitive skills that build on these low-level processes will be discussed in the final section of this chapter.

To introduce the reader to concepts used in neuroscience (see glossary below), processes like adaptation, habituation, sensitization, conditioning and extinction will be defined and differentiated from procedural and perceptual learning. Each of these processes exhibits specific time constants that describe the change in neural activity over time, being either short- or long-term. These low-level forms of learning are discriminated from other forms of learning and memory that require conscious encoding, consolidation and recall. Next, a review is given of the most relevant work on the topics of perceptual and procedural learning. Some recent insights into the role of dopaminergic and cholinergic processes will be given. The chapter will conclude by providing a description of the state of the art in the neuroscientific study of skill acquisition. A discussion of the possible ramifications of this research on the design of learning environments will be given.

12.1 Introduction

The mammalian brain exhibits a great capacity to adapt itself to the environment in which the host organism lives. This chapter will focus on the changes that take place in the developing and the adult brain as the organism interacts with its environment. Perceptual learning has been investigated for all sensory systems (Fahle and Poggio 2002). Here, a review of the literature is given on perceptual learning and it is compared to procedural learning and general skill acquisition. Finally, conclusions will

be drawn from this work and a statement will be made about how neuroscientific research can help us better understand skill acquisition and the formation of expertise with a focus on visual function and visually guided sensorimotor skills. The limitations to the neuroscientific approach will also be discussed.

Expertise reflects the explicit and implicit forms of domain-specific knowledge and skills acquired over an expert's lifetime. Such complex learning processes are currently only indirectly accessible to neuroscientific analysis (e.g. Schlegel et al. 2012). However, sub-processes like expert perception, perceptual learning, skill acquisition, as well as the acquisition of high-level cognitive skills such as problem-solving, insight, formations of concepts, categories and strategies can be studied in human participants while they interact in simulated scenarios during brain imaging. This chapter will review findings from research on different aspects of the acquisition of human expertise with a focus on implicit learning. To introduce the reader to the neuroscientific approach to the study of implicit memory, definitions are given of different forms of learning and forms of neural plasticity as they can be studied in humans and other mammals in the neuroscience laboratory.

12.1.1 Definitions

To start a few useful definitions will be given that can help to guide the reader into the topic of the neuroscientific approach to understand forms of implicit memory like procedural and perceptual learning.

Procedural learning is the ability to acquire a set of skills required to perform a particular task, such as the various perceptual and motor skills requisite for sports expertise in e.g. competent alpine skiing. Procedural learning also implies the optimization of skill execution, as measured by motor latencies, reaction times and kinematics. Procedural memory is an implicit form of long-term memory that reflects the ability of the organism to store knowledge about “how to do” something. In most cases, procedural learning and procedural memory are non-verbal forms of learning and memory. This form of knowledge cannot easily be expressed in words, but rather is illustrated in the act of performing the skilled task activity. Procedural memory should thus be differentiated from explicit forms of long-term memory like autobiographical and semantic memory. The former type of memory provides us with knowledge about how to do things – like the skills associated with using a smart phone or riding a bicycle – whereas the latter form of memory provides us with knowledge of ourselves, about the present-day world and about history. Although robust over time, skill memory can be interfered with if a second skill is learned immediately after the first (Robertson 2004).

Perceptual learning is related to the long-lasting improvement in our ability to perceive external and internal stimuli based on repeated exposure to these stimuli. Eleanor Gibson (1963) defined perceptual learning as

“any relatively permanent and consistent change in the perception of a stimulus array following practice or experience with this array ...”. Perceptual learning “... improves discrimination between stimuli that could not be discriminated before the learning; observers may learn to perceive something new that they could not perceive before.” (cited in Fahle and Poggio 2002, p. ix)

Although a large majority of perceptual research has been conducted with visual stimuli, it is not restricted to this modality. Perceptual learning takes place after practice or experience with any type of stimuli affecting any of our senses, including auditory (Fitzgerald and Wright 2011), somatosensory (Carey et al. 2011), vibrotactile (Tang et al. 2009), olfactory (Moreno et al. 2009) and taste (Hughson and Boakes 2009).

Other related concepts in neuroscience are adaptation, habituation, sensitization, conditioning and extinction. To appreciate the difference between these concepts and those of procedural and perceptual learning, a brief definition of each is provided below.

Adaptation is related to a change in sensitivity to stimulus intensity following prior exposure to a particular stimulus. These effects usually have been found at or near the absolute detection threshold (Blakemore and Campbell 1969), but can also be shown for supra-threshold stimulus intensity levels – such as for contrast discrimination (Greenlee and Heitger 1988). Although usually associated with low-level visual features like light level, colour, contrast, spatial frequency, orientation, etc., adaptation has also been shown to affect high-level visual perception required for identity recognition, ethnic classification and gender categorization (Webster et al. 2004).

Habituation is related to the absence of an orienting reflex after a stimulus has been presented many times without negative or positive consequences for the organism (Groves and Thompson 1970; Castellucci et al. 1978).

Sensitization is the reverse of adaptation: here repeated stimulation leads to a higher likelihood that the organism or individual receptor will respond to the stimulus (Groves and Thompson 1970; Carew et al. 1979).

Conditioning (Classical or Pavlovian) is a form of associative learning, where a neutral, conditioned stimulus (CS), e.g. a medium-intensity tone, is presented together with an unconditioned stimulus (UCS), e.g. an electric foot shock. The organism learns to exhibit a conditioned response (CR) in an anticipatory fashion to the presentation of the CS even in the absence of the UCS. The Russian physiologist, Ivan Pavlov, discovered this form of conditioning while studying the salivary response to food in the dog (Pavlov 1927).

Operant conditioning (also referred to as reinforcement learning) is a form of associative learning, where a response is reinforced with a reward. In operant conditioning behaviour is modified by its consequences. Rewards or reinforcement increase the likelihood that the behaviour will be exhibited again, punishment decreases the likelihood that the behaviour will be shown again.

Extinction is related to the dissociation between the prior learned association between in the CS and the UCS in classical conditioning. The organism ceases to respond to the CS when it is repeatedly presented in the absence of the UCS (Carew et al. 1981). In operant conditioning, the organism no longer exhibits the conditioned behaviour when the reward is no longer given.

As can be seen from these definitions, there are many forms of learning and neural plasticity. A detailed comparison between procedural and perceptual learning suggests that there are some similarities but also a number of differences between these different types of learning. Both forms of learning lead to an improvement in performance. For procedural learning the emphasis is placed on motor learning, speed and precision of response execution and long-term skill acquisition, whereas for perceptual learning the focus is on sensory discrimination performance and the specificity of this learned perceptual skill. In this chapter the experimental evidence is reviewed for these two different types of learning. To set the stage, a short introduction is given to the most important of sensory systems – vision – that allows us to detect and discriminate objects at a distance without having to come into immediate contact with them. The neural basis of visual processing is described and examples of neural plasticity in the visual system associated with the training-induced improvement in visual processing are given. The results of studies are described that examine the neural basis of procedural and perceptual learning by means of micro-stimulation, electrophysiological or brain-imaging techniques. Briefly a description is given of a model put forth by Roelfsema and colleagues (2010), the attention-gated reinforcement learning (AGREL) model, according to which a reward-based neuromodulatory signal enhances responses in all active synapses during perceptual learning. In the final section of this chapter, recent findings are reviewed on video game playing, expertise in board games, expertise in music or sport and associated brain processing, as well as other forms of professional expertise. Finally, the chapter concludes by describing potential avenues of future research and application of these results in learning environments.

12.2 Primate Visual System: Hard-Wired or Plastic?

It would be beyond the focus of this chapter to provide a complete description of the neural basis of primate vision. Several text- and handbooks exist that summarize our knowledge about primate vision (Werner and Chalupa 2013). In the context of perceptual learning it is important to understand how visual information is first encoded in the retina and how this information is projected from the left and right eyes to form binocular representations of the two visual hemifields (Fig. 12.1). The axons of the retinal ganglion cells bifurcate in the optic chiasma, where fibers emanating from the nasal hemi-retina cross to the contralateral

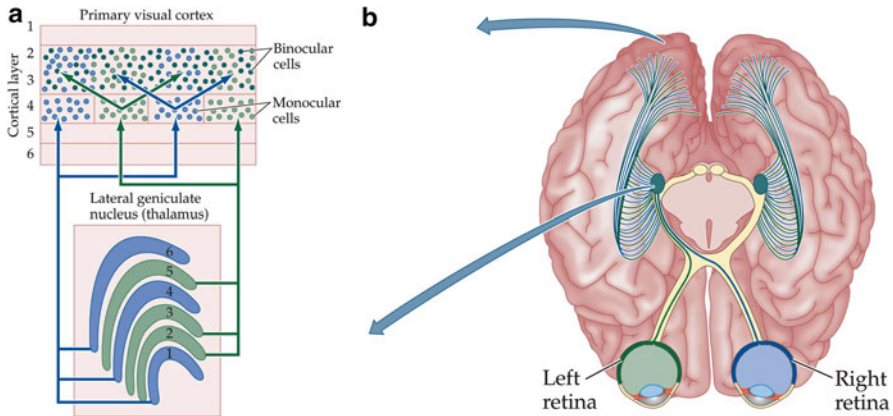

Fig. 12.1 Wiring diagram of the human visual system (a) with projections schematically illustrated from the left and right eyes to the LGN and the primary visual cortex (b) (From Purves et al. (2008). With permission)

hemisphere while those stemming for the temporal hemi-retina remain ipsilateral. Ganglion cell fibers from the contralateral eye project into layer 1, 4 and 6 of the lateral geniculate nucleus (LGN) of the thalamus, where those from the ipsilateral eye project into layers 2, 3 and 5 of this nucleus. The ventral two layers 1 and 2 are populated by cells with large cell bodies and are thus referred to as the magnocellular layers of the LGN, where the dorsal layers 3 to 6 are populated by cells with small somata and are thus called the parvocellular layers. Anatomical studies suggest that the magnocellular layers of the LGN receive input for the large parasol cells in the retinal ganglion cells and these neurons, in turn, get their input primarily from the rod photoreceptors. The parvocellular layers receive their input from retinal midget ganglion cells which process information from the cone photoreceptors, primarily from the long- and middle-wavelength sensitive cones (Lee et al. 2010). The intermediate zones that lie between the six layers of the LGN are referred to as the koniocellular layers. These LGN neurons receive input from the shortwave sensitive receptors.

The LGN neurons project via the optic radiation into the primary visual cortex, specifically into lamina IV of the visual cortex. Projections from the left and right eye form an orderly structure referred to as the ocular dominance columns, which were explored by Wiesel and Hubel (1963) in young kittens and depicted anatomically by LeVay et al. (1980) in monkeys. The existence of ocular dominance in human visual cortex has been verified using high-resolution functional magnetic resonance imaging (fMRI; Cheng et al. 2001).

The pattern of ocular dominance columns is illustrated in monkeys with normal binocular visual experience in Fig. 12.2a. This pattern of staining is achieved by

Fig. 12.2 Illustration of silver staining pattern in the primary visual cortex related to the ocular dominance columns in macaque monkey. The pattern of ocular dominance columns in normal binocular development (**a**) is compared to that found in monocularly deprived animals (**b**) (From LeVay et al. (1980). With permission)

treating one of the eyes with a silver stain that is transported anterograde along the optic tract from the one eye into the recipient parts of the primary visual cortex. The striped appearance of the cortex reflects the pattern of projections from the one eye into the cortex. Layer IV of the primary visual cortex is populated by cells that respond primarily to input from the one or the other eye. Early visual deprivation induced by closing the eyelid over one eye leads to an abnormal pattern of ocular dominance columns (Fig. 12.2b). The deprived eye has a much weaker representation in layer IV of primary visual cortex, as can be seen in the reduced stripes associated with that eye. The consequence of such early monocular deprivation is a loss of visual acuity in the deprived eye (referred to as amblyopia) and a complete loss of binocular disparity perception.

Normal adult vision is characterized by a distribution of cells that vary in their responses to stimulation from the left or right eyes (Fig. 12.3a). Based on a 7-point scale, some cells in the superficial layers of the visual cortex show a preference for the contra (1) – or ipsilateral (7) eye, whereas the large majority of cells can be driven by input from either eye (2–6 along the abscissa in Fig. 12.3a). This distribution of preference for input from the one or the other eye is significantly altered by early deprivation (Fig. 12.3b), shown here schematically for the kitten (Wiesel and Hubel 1963; Löwel et al. 1998). These changes in the pattern of ocular dominance columns demonstrate the striking nature of visual experience in shaping the connectivity between neurons in the visual cortex. Early monocular deprivation can lead to amblyopia, which is a loss of acuity and high-resolution form vision in the deprived (squinting) eye. Extensive research points to a sensitive period in the development of the visual system

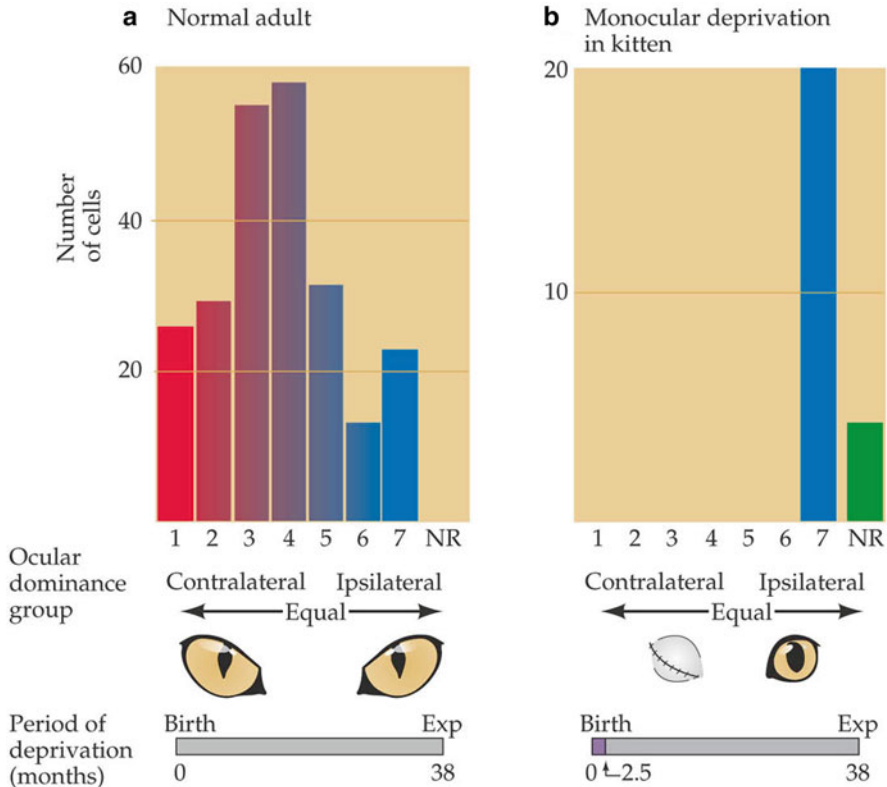

Fig. 12.3 Distribution of ocular dominance in cat visual cortex ($n=233$ cells) is shown schematically. The normal adult cat exhibits a near normal distribution of preference for input from the contralateral to ipsilateral eye (a). Cells in a monocularly deprived cat (induced by placement of a translucent contact lens over the right eye at birth) that respond only to input from the untreated left eye (b). The period of deprivation was restricted to the first 2.5 months of life. Taken from Purves et al. (2004) after Hubel and Wiesel (1962) and Wiesel and Hubel (1963) panels a and b, respectively. NR: cells that did not respond to stimulation of either eye of a 2-month old kitten (From Purves et al. (2008). With permission)

where balanced stimulation from both eyes leads to the normal development of ocular dominance columns and binocular vision. Some evidence suggests that training on perceptual tasks can have some beneficial effects on acuity in the amblyopic eye (Levi and Li 2009). In summary, there seems to be a critical period, where absence of appropriate stimulation leads to irreparable impairment in sensory function and perception. After the critical period, vision can still be altered by experience, but these changes are less pronounced than those observed prior to the end of the critical period.

12.3 Perceptual Learning of Visual Function

Performance on visual discrimination tasks can improve with practice (Fahle and Poggio 2002). Training a specific visual discrimination ability exhibits selective improvements on, for example, hyperacuity tasks, i.e. the ability to discriminate whether two vertically aligned bars are offset to the left or right. However, this learning-induced improvement in performance does not transfer to similar tasks with different orientations (Poggio et al. 1992), suggesting that the improvement in performance can be very specific for the trained stimulus feature. Perceptual learning effects can also be retinotopically specific: learning a task in one visual quadrant leads to performance increases in that quadrant but to little transfer to other quadrants (Karni and Sagi 1993). Monocular training with one eye does not transfer to post-training testing when the participants use the untrained eye (Karni and Sagi 1991), suggesting that perceptual learning and neural plasticity alter sensitivity of neurons in early stages of visual processing (see, however, Mollon and Danilova 1996). Thus, it seems that the benefits from practice are limited to the neurons involved in the original training. There is an extensive literature on various aspects of perceptual learning and neural models (involving synaptic reweighting and over-fitting) that, owing to space limitations, cannot be reviewed in this chapter. The interested reader is referred to the edited volume by Fahle and Poggio (2002), as well as other, more exhaustive, reviews (Fine and Jacobs 2002; Fahle 2005; Sagi 2011).

12.3.1 *Effects of Reward, Dopaminergic Innervation and Feedback on Perceptual Learning*

As is known from operant conditioning and reinforcement learning (Sutton and Barto 1998), rewards reinforce the association between a stimulus and a response to that stimulus and thus increase the likelihood that the response will be made again. Feedback or knowledge of result is a form of cognitive reinforcement, where the participant is given information (either trial by trial or block-wise) regarding whether the participant's response was correct or incorrect (Gopher et al. 1994; Herzog and Fahle 1997). Can rewards lead to an improvement in perceptual learning? Evidence for a possible link between reward and neural plasticity in auditory cortex suggests that temporally synchronized reward signals evoked by microstimulation in dopaminergic neurons in the ventral tegmentum area can indeed lead to a sensitization of neurons in auditory cortex (Bao et al. 2001). Coupled stimulation led to a larger response in auditory cortex for the stimulus frequency band associated with microstimulation (Fig. 12.4). These findings support the role of dopaminergic projections to sensory cortex in shaping the sensitivity of sensory neurons to repeated stimulation. Dopaminergic neurons in the substantia nigra of monkeys, which received large or small rewards for correct responses in coherent motion tasks of varying difficulty, exhibit a positive relationship between firing rate and the predicted reward (Nomoto et al. 2010). In the fMRI study of Daniel and Pollmann (2010) participants learned to

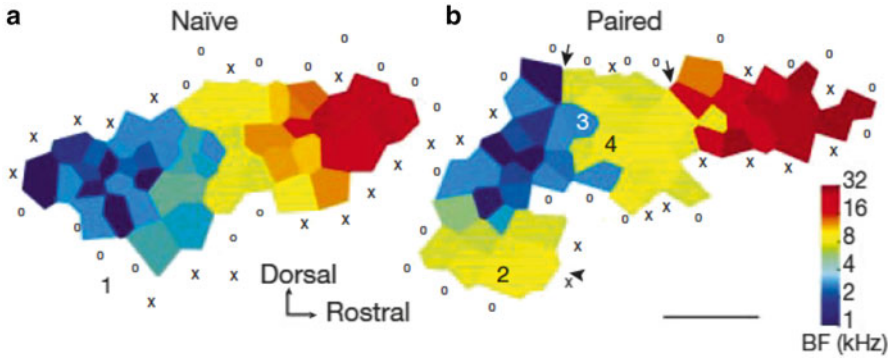

Fig. 12.4 Tonotopic distribution of cells in primary auditory cortex in the rat is depicted. Following stimulation with a 9 kHz tone paired with microstimulation in the VTA, the region preferring the 9 kHz band significantly increases from the naïve (a) to the treated rats (b). Note also an additional region of activation (in yellow) representing cells that become responsive to the trained frequency (After Bao et al. (2001). With permission)

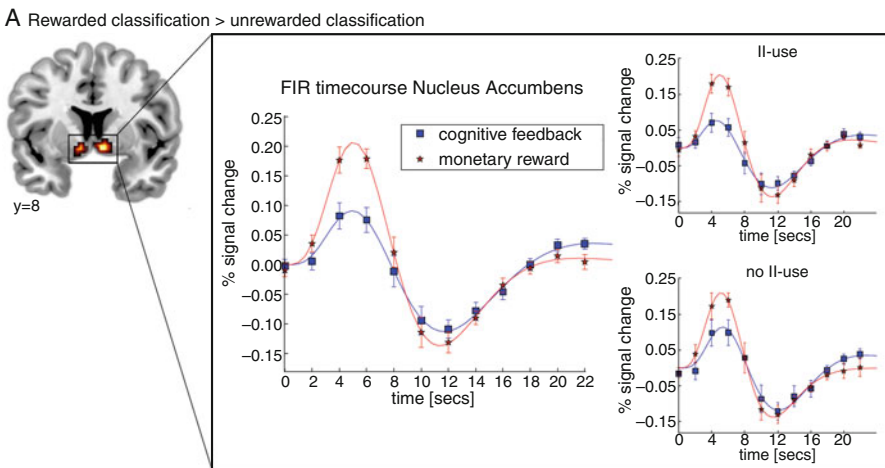

Fig. 12.5 Activation time course of the nucleus accumbens on correct trials where participants received monetary rewards (20 Euro cents) for each correct response (red curves) compared to trials where the correct response was merely signalled via a green-coloured disk (blue curves). Participants who optimally integrated information about the stimulus categories (II-use) show more pronounced difference in haemodynamic responses in the monetary reward and cognitive feedback conditions (upper right) compared to participants who did not make optimal use of this information (lower right) (After Daniel and Pollmann (2010). With permission) (Color figure online)

classify by trial and error visual stimuli (Landolt C and dual bars) that varied in line thickness and orientation. Correct performance was either fed back visually or rewarded monetarily. The nucleus accumbens, a dopaminergic structure in the mid-brain, and the caudate nucleus were significantly more active on trials with monetary rewards (Fig. 12.5). The anterior cingulum responded in a differential manner to

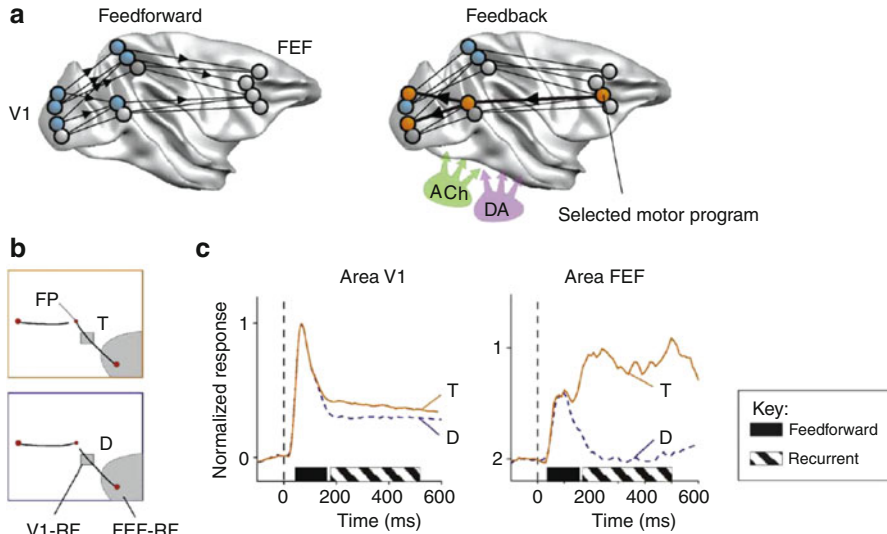

positive and negative feedback. Direct reward has a larger effect on brain activation than does cognitive feedback (i.e. knowledge of result). Trial-by-trial feedback led to more activation in the caudate nuclei in participants performing a phonological recognition task (Tricomi et al. 2006). In a recent fMRI study, Amiez et al. (2013) gave participants varying levels of juice reward while they learned by trial and error to classify abstract images. Their results point to the mid-cingulate/paracingulate cortex as an important cortical area that evaluates feedback and its associated rewards. A model for how reward signals can enhance learning of task-relevant and task-irrelevant aspects of task performance has been proposed by Seitz and Watanabe (2005).

Using multivariate pattern analysis and machine-learning classification algorithms, Kahnt et al. (2011) showed that perceptual learning in an orientation discrimination task was associated with an increase orientation-specific information in the anterior cingulum. The anterior cingulum could contain the information required to make optimal decisions based on the incoming sensory information.

12.3.2 Role of Gated Attention on Perceptual Learning

Roelfsema and colleagues (2010) have recently put forth a theory of attention-gated reinforcement learning (AGREL), according to which a reward-based neuromodulatory signal enhances responses in all active synapses and a selective attention mechanism that selectively tunes the sensitivity of synapses responsible for the behavioural response (see Fig. 12.6). According to this model, during perceptual learning changes in synaptic strength only occur in those synapses that receive the top-down attention-based signals. Visual stimulation leads to activation in prefrontal cortex via feed-forward connections. The neurons that dominate send feedback signals back to visual cortex leading to response enhancement. Reinforcement learning strengthens the synaptic weights that represent the critical feature or combination of features underlying the perceptual task, thereby leading to an improvement in performance.

Can perceptual learning take place in the absence of attention? This question was addressed by Watanabe et al. (2001), who used a rapid serial presentation task (RSVP) to resolve this issue. In this task a total of 10 letters were presented sequentially on a 1° grey disk, each letter for 33 ms. Two light-grey letters were presented serially among eight dark-grey letters and the participants were asked to type in the two grey letters at the end of each trial. In the background, task-irrelevant random dots moved in random directions (Fig. 12.7a). Unbeknown to the participants, 5 % of the dots moved in a coherent direction and this direction was coupled to the onset of the light-grey target letters. Despite the fact that the coherent motion direction was “invisible” to the participants, after repeated exposure to these dynamic displays, their performance at post-test improved for the motion direction coupled to the onset of the target letters. This finding suggests that perceptual learning can take place in the absence of feature-specific attention, in this case, in the absence of attention to the coherent dot motion, which was sub-threshold and thus invisible to the

TRENDS in Cognitive Sciences

Fig. 12.6 Activation of neurons in primary visual cortex of macaque monkeys that are trained to respond to a saccadic target in a curve-tracing task is depicted. A hypothetical network of activated (*blue circles*) neurons in V1 that project to prefrontal area FEF (frontal eye fields) in the target-distractor discrimination task (**a**). Positions of receptive fields of V1 and FEF neurons are depicted in grey (**b**). FP=fixation point, T=target, D=distractor. Normalized responses in V1 and FEF neurons are presented as a function of time during the feed-forward (*black horizontal bar*) and recurrent, feedback (*striped bar*) phases of the response (**c**). Approximately 200 ms poststimulus onset, the response curves begin to differ for the neurons that respond either to the target of the distractor on different trials (locations shown with respect to fixation point). The monkey discriminates which of two possible saccade targets are connected by a line to the central fixation point. Activations in FEF are suppressed to the distractor but are enhanced to the target during the presaccadic phase. Dopaminergic and cholinergic signals from the substantia nigra and ventral tegmentum area reinforce synaptic connections that lead to a successful response (*orange circles* in (**a**) (*right side*)) (After Roelfsema et al. (2010). With permission) (Color figure online)

participants. Tsushima et al. (2006, 2008) varied the strength of the task-irrelevant motion stimulus and discovered that only motion coherence levels near the detection threshold led to significant direction-specific learning. According to the model of Roelfsema et al. (2010) this form of perceptual learning only takes place for near threshold stimuli (Fig. 12.7). Motion stimuli with a high level of direction coherence lead to inhibition from prefrontal cortex to neurons that are stimulated with the motion direction paired to the target presentation in the RSVP task. These studies strongly suggest that near-threshold stimuli can be learned without conscious awareness of the presence of these stimulus cues (*in casu* coherent motion directions). Important is the close timing between task-relevant and task-irrelevant cues to allow directed attention to gate reward signals (Seitz and Watanabe 2003).

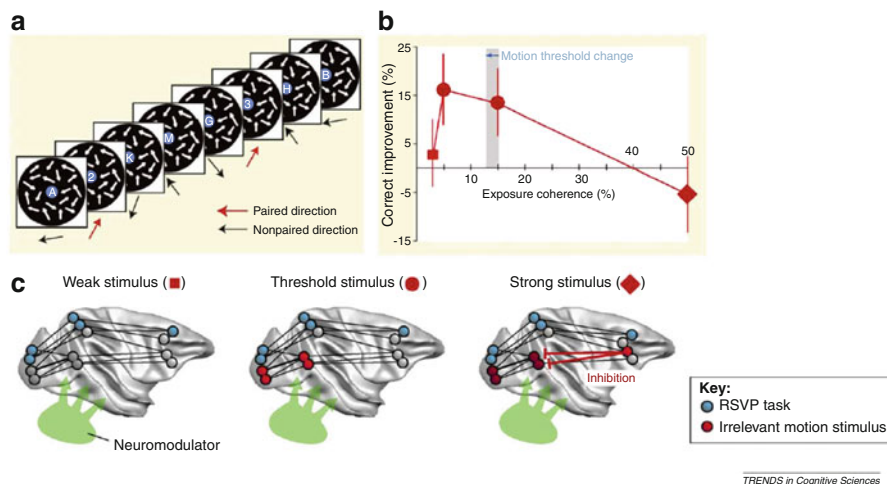

Fig. 12.7 Modified RSVP digit detection task as used by Tsushima et al. (2006). (a) Schematic illustration of the RSVP task (digit identification) embedded in the task irrelevant random-dot motion stimuli (white arrows on black annulus signify dot motion). In this paradigm the task-irrelevant dot motion was varied in coherency level from subthreshold (red square in b) to near threshold (red circles in b) to suprathreshold (red diamond in b) levels. Post-training improvement in performance during motion-detection is plotted as a function of the task-irrelevant motion coherence level during original training. (c) The results suggest that inhibitory feedback signals (red circles in c) are triggered by the suprathreshold coherent motion direction, leading to a relative decline in performance (After Roelfsema et al. (2010). With permission) (Color figure online)

12.3.3 Enduring Changes in Occipital Cortex After a Week of Training

Recently Frank et al. (2014) found long-lasting changes in visual cortex after extensive training on a visual search task for a feature-conjunction. Over a period of 8 days participants were trained to find a red-green target disk amongst an array of green-red distractor disks. All training sessions were carried out with fMRI-scanning to relate behavioural learning effects to changes in neural activation. Participants showed improved task-performance over the course of training (Fig. 12.8a). This improvement was correlated with increasing activity in visual cortex (Fig. 12.8b). Even after 9 months without any further training behavioural performance was still high and was underpinned by increased activation of visual cortex. Interestingly it was found that the difference in activation for target vs. distractor stimuli also increased with learning suggesting a higher neuronal signal-to-noise ratio as a potential mechanism for target vs. distractor feature-conjunction learning.

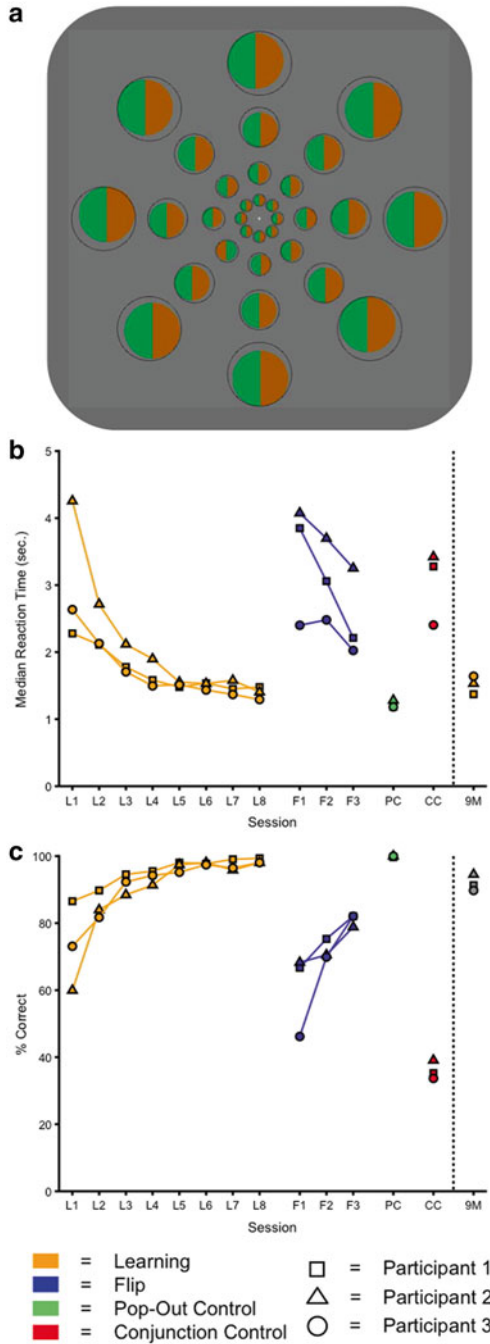

Fig. 12.8 *Left panel:* Example of the visual search task used by Frank et al. (2014). Participants had 4 s to find the red-green disk among the green-red distractors (in this example, the red-green

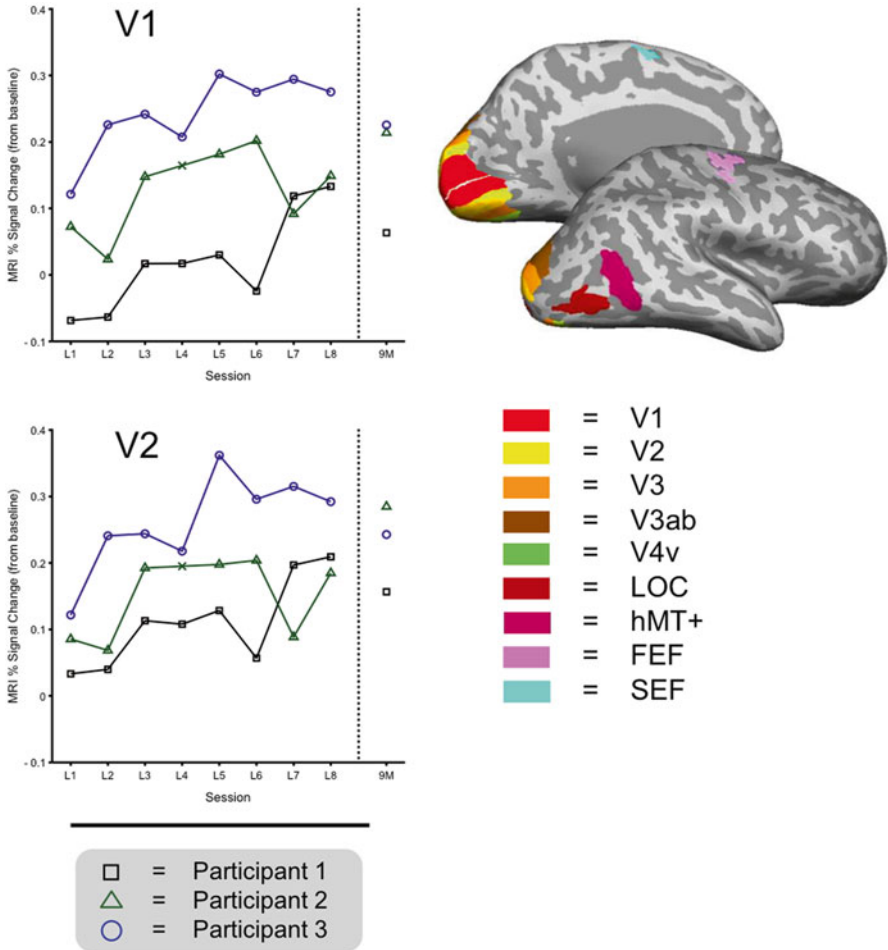

Fig. 12.8 (continued) target is in the second innermost ring). **(b)** Reaction times for the three participants during 8 days of training (*orange symbols*) decrease with learning. The specificity of learning was examined by flipping the target features with those of the distractors and vice versa (target is now *green-red* and the distractors are *red-green*; see *blue symbols* in **b**). Reaction times increase abruptly and learning must start again. The *green symbols* show the results for an easy pop-out search task that requires no training, while the *red symbols* present the results for a difficult conjunction search task that was not trained on. The *rightmost orange symbols* present the results of a follow up measurement 9 months after training ceased. **(c)** As for panel **b**, except now for performance values (percentage correct). *Left panel*: MRI-signal (percentage signal change) in primary (V1) and secondary (V2) visual cortex for the three participants as a function of the learning days (L1–L8), as well as at follow up 9 months after training ceased (Color figure online)

12.3.4 Role of Cholinergic Processes and the Effects of Sleep on Perceptual Learning

As described above, perceptual learning is a form of non-declarative learning that involves experience-dependent plasticity in sensory cortices. The cholinergic system is known to modulate declarative learning in explicit memory tasks. Reduced levels of the acetylcholine facilitate declarative memory consolidation (Hasselmo 2006). Microstimulation of the cholinergic nucleus basalis paired with auditory stimulation leads to a reorganization of the tonotopic map in primary auditory cortex in rats (Kilgard and Merzenich 1998) and guinea pig (Bakin and Weinberger 1996). Such reorganization could represent the neural substrate of perceptual learning. Rokem and Silver (2010) found that the cholinesterase inhibitor donepezil enhanced perceptual learning in humans.

The role of the cholinergic system in memory consolidation in perceptual learning was recently explored by Beer et al. (2013). These authors compared performance of two groups: one group chewed nicotine-containing tobacco for 1 h directly after training on a visual texture discrimination task (Karni and Sagi 1991), while the other group chewed a similar tasting placebo substance. On the following day, both groups showed improved performance and reduced reaction times, but the learning effects were more pronounced in the group that consumed nicotine. By enhancing the efficacy of nicotinic acetylcholine receptors implicit memory consolidation was facilitated. Beer et al. (2013) conclude that the cholinergic system promotes memory consolidation in perceptual learning.

The effects of sleep have been documented for both implicit and explicit forms of memory. Perceptual learning and implicit memory consolidation can be facilitated by sleep (e. g., Aeschbach et al. 2008; Karni et al. 1994; Mednick et al. 2003; Yotsumoto et al. 2009). Memory consolidation in perceptual learning is also promoted by rapid-eye-movement (REM) sleep (Karni et al. 1994). Hasselmo (2006) proposed that a reduction in acetylcholine levels during slow-wave sleep (SWS) suppresses afferent signals and enables excitatory cortical feedback thereby promoting memory consolidation. Declarative memory consolidation during sleep is blocked by the cholinesterase inhibitor physostigmin (Gais and Born 2004). In summary, this suggests that higher levels of acetylcholine are beneficial for perceptual learning but disadvantageous for declarative memory consolidation.

12.4 Procedural Learning

As noted in the introduction, procedural learning is related to a training-induced improvement in motor tasks. What are the neural correlates of these training-induced improvements in performance? Karni et al. (1995) asked their subjects to perform two different finger-tapping sequences in the MR scanner. Only one of these sequences was trained. The trained sequence led to a larger BOLD response

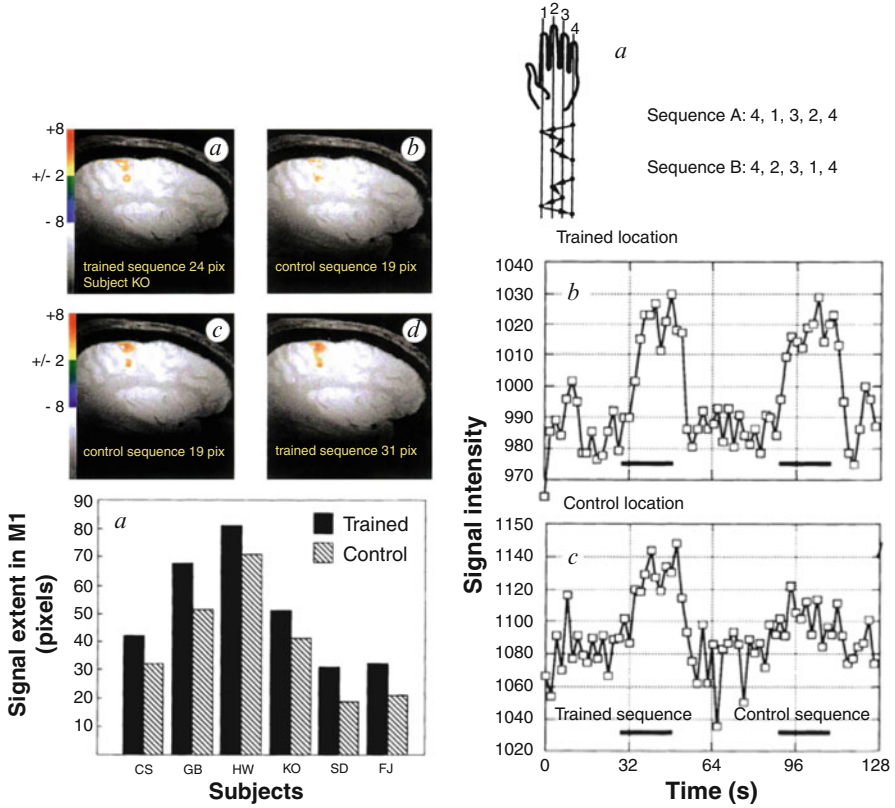

Fig. 12.9 Summary of the results from Karni et al. (1995). Brain activity was recorded using fMRI in individual participants who were trained to perform a speeded finger-tapping sequence (*upper right*). Following training, more voxels in primary motor cortex (M1) were activated during the trained compared to an untrained sequence (*upper left*). Signal extent in M1 of six participants is shown for the trained (*black bars*) and untrained (*striped bars*) tapping sequences (*lower left*). Time course of the haemodynamic response in individual voxels of M1 for trained and untrained sequences at trained and control locations (*lower right panel*). Whereas the activation at the trained location is comparable for both trained and control sequences, the response to the trained sequence is relevantly more robust at the control location, reflective of a neural recruitment process after learning (After Karni et al. (1995). With permission)

recruiting more grey matter (Fig. 12.9) compared to the control sequence that was not trained. A comparison of the time course of single voxels in the trained and control activation sites in primary motor cortex suggested a recruitment of neurons that respond to the trained tapping sequence. These early fMRI results suggest that procedural learning induced by weeks of motor training leads to changes in the fMRI response pattern in motor cortex. Repetitive transcranial magnetic stimulation (rTMS) over contralateral motor cortex applied after participants practiced finger movements eliminated all benefits of prior motor practice without impairing the ability to learn the task with further practice (Muelbacher et al. 2002). These latter

results suggest that primary motor cortex is essential in implicit memory consolidation for learned skilled movements.

Poldrack et al. (1998) and Kassubek et al. (2001) trained participants to read mirror script. Before and after training, fMRI was recorded while participants silently read normal and mirror-script words. The findings of both studies point to larger activations in visual and parietal cortex for words presented in mirror compared to normal script (Fig. 12.10). After training the overall activation for mirror script was

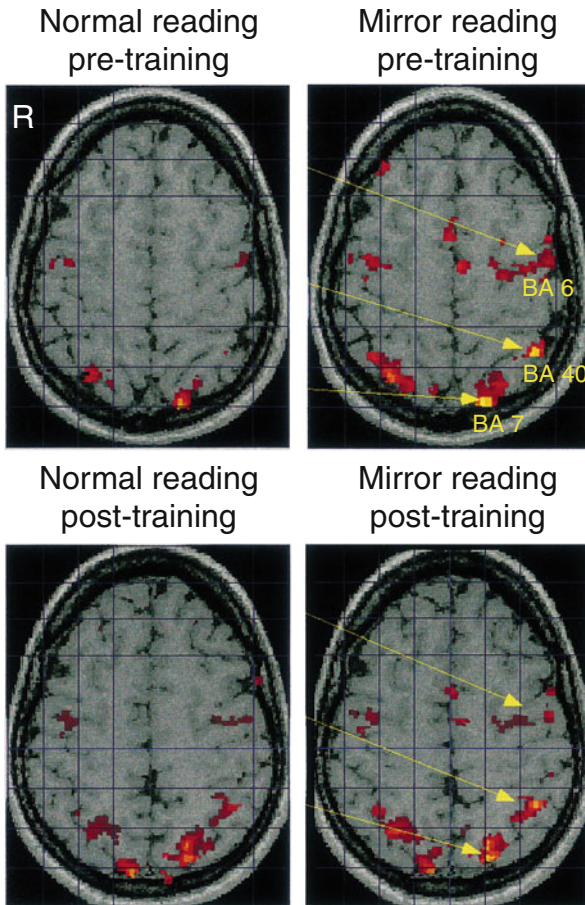

Fig. 12.10 Summary of the results from Kassubek et al. (2001). Brain activity was recorded using fMRI in individual participants who were trained to perform a mirror-script reading task (*left panel*). The brain activity was compared in each individual before and after a 1-day training period for the trained mirror script and for normal script reading. Following training, less activity was found for areas activated during mirror script reading (*black bars, right panel*). Mean results are presented for six regions of interest (BA6 representing the frontal eye field, BA7 and BA40 representing posterior parietal cortex, BA17–BA19 representing visual cortex for the left and right hemispheres (After Kassubek et al. (2001). With permission)

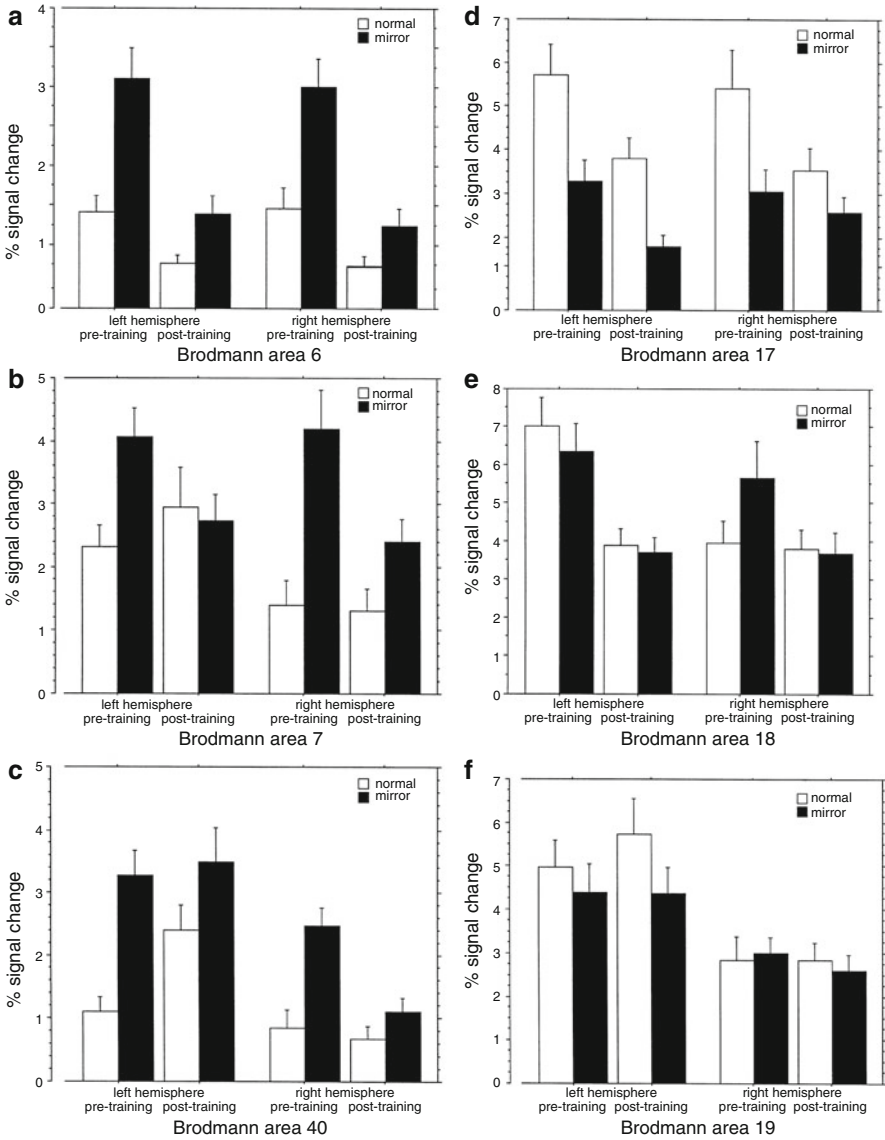

Fig. 12.10 (continued)

reduced and was in most cases no longer significantly different than that recorded during normal script reading. Kassubek et al. (2001) suggest that these results support the idea that procedural learning leads to automatic processing of the learned material and thus to lower responses in the activated brain regions. Similarly, Poldrack et al. (1998) reported mirror-reading skill acquisition to be related to decreases in activations in parietal and occipital cortex. In a review Poldrack (2002)

surveyed the results of several studies that assessed brain activation changes after visual skill learning. He concludes that perceptual skill learning is associated with an increased activity in the ventral visual stream including inferior temporal gyrus and fusiform gyrus, increased activity in the caudate nucleus and reduced activation in the dorsal stream including occipito-parietal regions.

Morse code is way to transmit individual letters of text via a combination of on-off dashes and dots, either as a series of tones (auditory) or flashes (visual). The interpretation of Morse code is an interesting skill that can be learned over a period of a few weeks. Schmidt-Wilcke et al. (2010) performed a combined longitudinal functional and morphometric magnetic resonance imaging (MRI) study on healthy volunteers who learned to decipher auditory Morse code. They investigated 16 healthy subjects using functional MR imaging and voxel-based morphometry (VBM) before and after the participants had learned to acoustically decipher Morse code. The same set of Morse-code signals was presented to the participants pre- and post-training. The authors found a post-training increase in task-specific neural activity in brain regions known to be critically involved in language perception and memory, such as the inferior parietal cortex bilaterally and the medial parietal cortex during Morse code deciphering. Furthermore they found an increase in grey matter density in the left occipito-temporal region, extending into the fusiform gyrus after learning. Anatomically neighbouring sites of functional and structural neuroplasticity were revealed in the left occipitotemporal/inferior temporal cortex, but these regions only marginally overlapped. These findings are interesting because they show that procedural learning is accompanied not only by activation increases in the underlying neural structures but also by anatomical changes in grey matter density (Fig. 12.11).

In a highly cited study, Draganski et al. (2004) trained volunteers to juggle three balls. Before and after training, as well as 3 months after the end of training, these authors determined the morphometric changes in grey matter of the brain. They found increases in grey matter in the region in extrastriate visual cortex known to underlie our ability to perceive visual motion (Fig. 12.12). The grey matter increases were less pronounced but still evident 3 months after the end of training. These results point to the ability of the adult brain to modify itself in response to prolonged sensorimotor training.

These experiments point to the changes that take place in the human brain as a consequence of acquiring a new motor skill such as juggling (Draganski et al. 2004; Draganski and May 2008), deciphering Morse code (Schmidt-Wilke et al. 2010) or reading mirror-script (Poldrack et al 1998; Kassubek et al. 2001). The efficiency with which the brain processes task-related information improves with training. This improvement is associated with a change in the brain functional response and anatomical structures underlying these responses. A very recent study suggests that anatomical changes in white matter diffusivity can take place after only 2 h of spatial training (Sagi et al. 2012). The interested reader is referred to the review by Ungerleider et al. (2002).

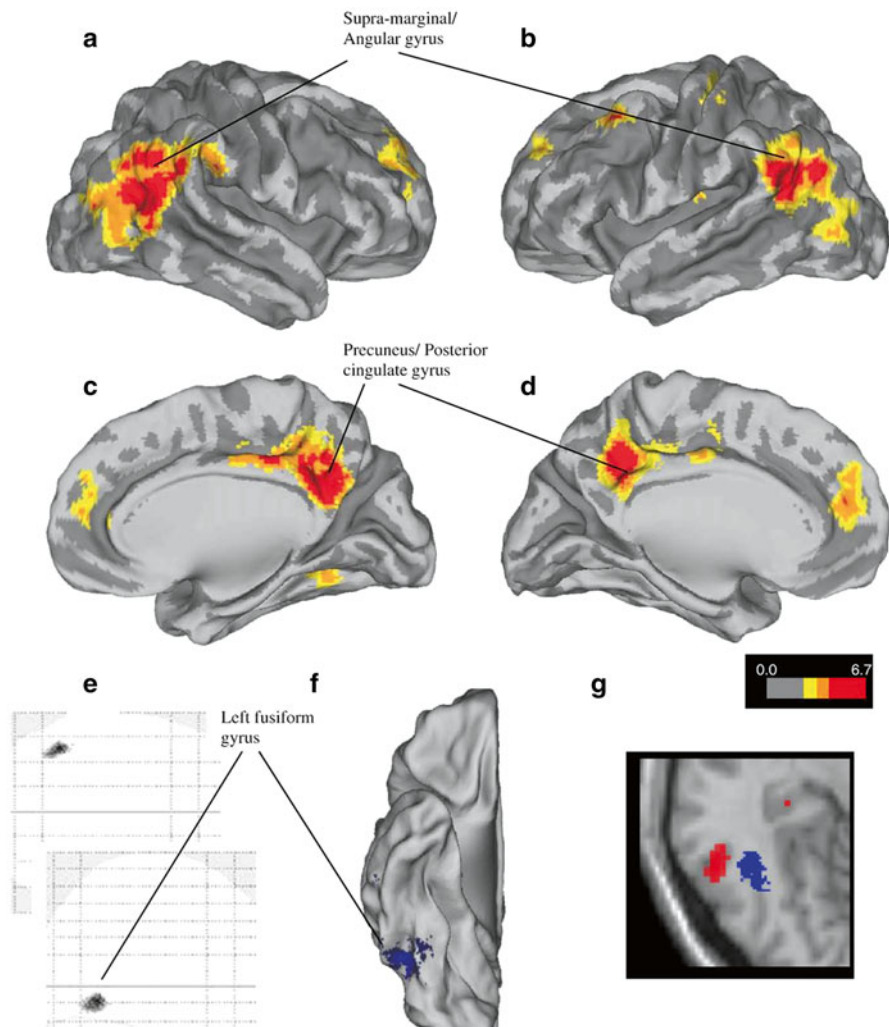

Fig. 12.11 Summary of the results from Schmidt-Wilcke et al. (2010) is presented. Brain activity was recorded using fMRI in 16 participants who were trained to decipher acoustically presented Morse code. Their results are compared to 16 control subjects who did not train to decipher Morse code. The brain activity was compared between these groups after training. Following training, more activity was found for the supramarginal and angular gyri (a, b) as well as in midline structures in the precuneus and posterior cingulate cortex (c, d). Results of voxel-based morphometry (VBM) in the trained participants compared to controls (e, f). Blue clusters denote the voxels that showed significantly more density in grey matter in the training group. The location of a cluster in occipito-temporal cortex activated during fMRI is located near the grey matter increase (g) (After Schmidt-Wilcke et al. (2010). With permission) (Color figure online)

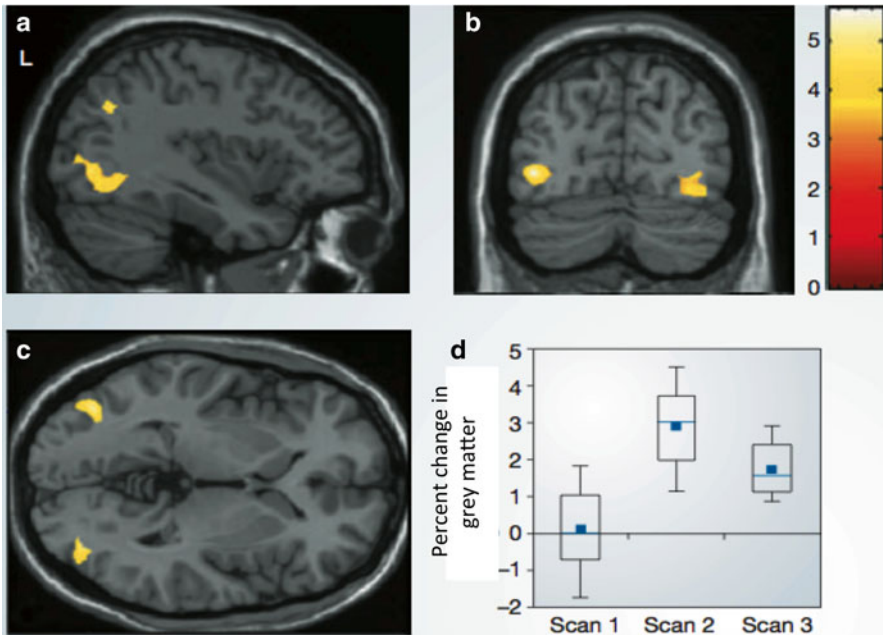

Fig. 12.12 Study of Draganski et al. (2004). Results for VBM analysis of grey matter density are shown for participants who learned to juggle three balls. Training-induced structural changes were found as bilateral clusters in extrastriate visual cortex at a neural location important for visual motion processing (panels a–c). Participants’ brains were scanned on three occasions and percentage change in grey matter is presented for the regions of interest shown in (a)–(c) prior to training (Scan 1), after training (Scan 2) and 3 months after cessation of training (Scan 3) (d) (After Draganski et al. (2004). With permission)

12.4.1 Video Game Playing, Dopaminergic Transmission and Training Strategies

Habitual video-game playing has been associated with enhanced contrast sensitivity (Li et al. 2009) and increased visual attention capacities (Green and Bavelier 2003, 2012). Task switching costs are reduced in video-game players compared to non-players on a variant of a flanker task (Cain et al 2012), suggesting enhanced executive functioning in gamers. Higher grey matter values in the ventral striatum and a negative correlation between deliberation time in gambling tasks and striatal grey matter have been reported (Kühn et al. 2011). Evidence from ^{11}C -raclopride positron emission tomography points to an enhanced dopaminergic transmission during video-game playing and a significant correlation between ^{11}C -raclopride binding potential and task performance (Koepp et al. 1998). A replication study (Egerton et al. 2009), while revealing similar trends, points to possible confounding effects of regional cerebral blood flow and head movements, suggesting caution while interpreting these results. A 15-week training program with the Japanese board game shogi led to

significant increases in the fMRI-signal in the head of the caudate nucleus (Wan et al. 2012). In summary, video-game playing has some positive effects on visual processing. Dopaminergic signalling in the ventral striatum and the caudate nucleus might be important causal factors promoting visual and cognitive functioning.

Training strategies can also impact on learning with video games. Comparing two different training strategies (i.e., variable-priority versus full emphasis), Lee et al. (2012) reported significant differences in superior frontal gyrus and precuneus between the groups. The participants who trained according to the variable-priority approach (placing an emphasis on part skill acquisition) outperformed the full-emphasis (emphasizing the entire skill sequence) and control groups. Interestingly, the variable-priority group showed significantly lower activations in the studied regions of interest, suggesting more efficient usage of neural capacity.

12.5 Professional Expertise and Brain Function

Cognitive neuroscientific research has mostly been concerned with the acquisition of fairly simple types of motor performance like finger tapping or perceptual tasks that can be conducted in the fMRI scanner. Brain changes associated with more complex aspect of professional training have so far focused on detecting structural and/or functional differences in the brains of professional musicians with or without perfect pitch perception (Schlaug et al. 1995; Zatorre et al. 1998; Jäncke et al. 2012), golfers (Jäncke et al. 2009), expert versus novice badminton players (Wright et al. 2011), archers (Kim et al. 2008) and pilots (Pérès et al. 2000). These studies have revealed both differences in grey and white matter in voxel-based morphometry, as well as functional activation differences in fMRI in brain regions underlying domain-specific skill acquisition. One obvious shortcoming of these approaches is that the causality of these brain differences cannot be determined, since the participants are by definition not randomly assigned to the experimental and control groups. Longitudinal studies where the participants are randomly assigned to a treatment or control group and then followed over a longer period during skill acquisition appears to be the more promising approach (see Schmidt-Wilcke et al. 2010, discussed above). First studies using this approach are appearing and point to significant changes in structure and function in the brains of participants who learn a new foreign language over a 9-month period (Schlegel et al. 2012), or who practice meditation techniques (Allen et al. 2012), or motor sequences (Steele et al. 2012).

12.6 Learning by Doing Versus Learning by Viewing

Although the studies reviewed above indicate different brain regions involved in perceptual and procedural learning, some common aspects are shared by these different types of learning. Whereas in procedural learning the emphasis is on

“learning by doing”, where a motor sequence or skilled action is practiced over and over, in perceptual learning the mere act of perceiving the critical stimulus feature in the presentation time given leads to an improvement in performance. Could skilled motor actions benefit by the mere “viewing” of the enacted motor sequence? To address this issue Nyberg et al. (2006) trained two groups of eight participants each to perform specific finger-tapping sequences. Before and after 1 week of training both groups were scanned to determine fMRI-activations during finger tapping of the learned sequence or of another (unlearned) tapping sequence, both performed with the left hand. One group physically enacted the tapping sequence repeatedly during training, whereas the other group mentally rehearsed the tapping sequences without actually enacting the sequence. Interestingly, physical and mental practice led to fairly similar patterns of activations and changes in activation in the motor/premotor cortex and cerebellum (see their Fig. 1), where activation was reduced following training. Direct comparison of the two forms of training revealed small clusters that were more activated in the supplementary motor area (SMA) after motor training and in the extrastriate visual cortex after mental training. The findings indicate that mental rehearsal alone leads to training-induced changes in brain activations.

Similar findings have been reported for activations in premotor and parietal cortex for more complex motor sequence learning required for dance, with a significant negative correlation between training gain and MRI-signal change in premotor cortex (Cross et al. 2009). The training effect on making complex finger-hand positioning while playing musical chords on a guitar was investigated by Higuchi et al. (2012) in participants who physically practiced the movements or just imagined executing the prior observed movements. Practice led to significant reductions in activation in parietal and premotor cortex, with a large overlap in the effects of physical and observational practice (see their Fig. 3).

In summary the studies reviewed above indicate that “learning by doing” and “learning by viewing” (i.e., either by real observational viewing or by mental imagining) induce robust changes in behaviour and brain activation in fronto-parietal motor networks involved in action-planning. Although physical practice shows an “enactment” advantage, mere mental or observational practice affects behaviour and brain activations in a similar way.

12.7 Critical Appraisal of the Neuroscientific Approach to Skill Learning

The advent of in-vivo structural and functional brain imaging using magnetic resonance imaging has allowed for new avenues of neuroscientific research in healthy participants, who are instructed to perform tasks while their brains are repeatedly imaged. The advantages of functional MRI over other forms of brain imaging are obvious, since it is non-invasive, requiring no radioactive tracer substances to be injected into the blood stream of the participants (as is required for positron emission

tomography). With high-field magnetic strengths of 3 T and higher, the human brain can now be studied with millimetre resolution and high precision. Reliance on the blood-oxygen level dependent signal (BOLD) has the disadvantage that the haemodynamic response lags some few seconds in time behind the actual neural activations that the researchers are interested in. However, more sophisticated experimental designs with virtual time resolutions of 1 s or less have led to more information about the dynamics of brain activations and functional or effective connectivity. Despite these obvious advantages, the reader should be careful when evaluating the results of functional brain imaging studies for the following reasons. First, the participant is highly restricted and instructed not to move his or her head at any time. Although motion correction algorithms are used to correct for residual head displacements that take place during the scan session, the fact that the head is restricted limits the types of experiments that are possible in the fMRI scanner. Second, the participant lies in the supine position while viewing visual stimuli via a restricted mirror or eyepiece and/or listening to sounds via headphones. Thus, the ability to study sensorimotor learning is often limited to stimuli that can be delivered via projection systems and headphones or to movements that can be made with the distal extremities, such as finger tapping. Postural movements of the trunk would not be feasible, since this would lead to head movements and image artefacts. Third, the participant is aware that his/her brain is being scanned and that everything experienced in the scanner is part of the cognitive or sensorimotor experiment. Immersive stimulation is difficult to obtain, restricting the realistic nature of the challenges that a participant can experience during brain imaging. Despite these limitations functional MRI has become one of the most prominent methods in modern cognitive neuroscience, leading to a huge number of studies each year that report on a brain activations for each selected experimental paradigm. With such a wide variety of studies, selective reporting can lead to biased interpretation of the evidence for or against a certain theory. First attempts to perform meta-analyses using activation likelihood estimation (ALE) for cortical activations during motor actions observation and imitation (Caspers et al. 2010; Molenburghs et al. 2012) and for cerebellar activations during visuomotor adaptation and memory tasks (Bernard and Seidler 2013) have been reported. Such meta-analytic methods will help integrate the vast literature that is accumulating with fMRI methods. For perceptual and procedural learning the current evidence suggests that learning alters the human brain structurally and functionally.

12.8 Conclusions and Implications for Learning Environments

This chapter has introduced the reader to some of the concepts used in neuroscientific research to study changes that take place in the brain during perceptual and procedural learning. These two types of implicit learning share several features. Foremost, they reflect the capacity of the adult brain to modify itself to challenges placed on it by demanding tasks. Prolonged practice can lead to striking

improvements in our ability to perceive aspects of stimuli that had gone previously unnoticed. With extensive training, trainees can learn to discriminate between tiny differences between stimuli that are very similar or have been flashed on the screen for a very brief moment. The experimental results of several laboratories are discussed as well as a model presented by Roelfsema et al. (2010) that combines the effects of dopaminergic and cholinergic rewards systems in the midbrain with sensory and decision processes through attention-gated feedback signals. Such dynamic signalling might also be involved in procedural learning, where the emphasis is placed on the motor or sensorimotor performance that increases after training. Here not only is the brain more activated following training, but morphometric analysis of the cortical grey matter suggests that the synaptic connectivity is enriched after training. Such training-dependent alterations in brain structure and function in adults indicate that the mature brain remains plastic and can benefit on the long-term from repeated practice.

These neuroscientific results have a number of potential implications for the design of learning environments. They suggest that the adult brain remains plastic and can be modified by training. To increase transfer to other tasks or stimulus configurations, these training protocols should take into account under which circumstances transfer can be expected to take place and under which training protocols learning will not transfer. These insights open up novel inroads in the area of neuro-rehabilitation by demonstrating that disorders such as amblyopia might be accessible to perceptual training protocols.

Further implications exist for training programmes used to improve professional efficiency in all sorts of industry. The results reported above suggest that feedback and reward are important during the learning process. Feedback and rewards can enhance training-induced improvements in performance. Dopaminergic and cholinergic innervation from reward centres like the nucleus accumbens or the nucleus basalis of Meynert increase dopamine and acetylcholine at the synaptic level, leading to an increase in neural transmission and increased learning.

Acknowledgements The author would like to thank Sebastian M. Frank (Dartmouth College) for his critical and helpful comments. The author also acknowledges funding support from the Federal Ministry for Education and Research (BMBF, Project “Brain Plasticity and Perceptual Learning”) and the German Research Council (DFG, FOR 1075, Project GR988/22-2).

Glossary

¹¹C-raclopride positron emission tomography A brain imaging technique involving the radioactive isotope ¹¹C combined with raclopride to label dopaminergic brain regions.

Anterior cingulum Cortical area in medial prefrontal cortex thought to process various aspects of attention and executive control.

- Caudate nucleus** A component of the subcortical basal ganglia involved in motor control, learning, memory and other forms of cognition.
- Cholinesterase inhibitor** Or acetylcholinesterase inhibitor is a chemical substance that inhibits acetylcholinesterase enzyme from breaking down acetylcholine thereby increasing cholinergic transmission.
- Extrastriate visual cortex** Secondary visual cortex beyond the striate (stripped) cortex representing area 17 (containing primary visual cortex).
- fMRI** Functional magnetic resonance imaging, a non-invasive, in-vivo brain imaging technique.
- Fusiform gyrus** Part of the ventral visual cortex involved in object and face recognition.
- LGN** Lateral geniculate nucleus of the thalamus involved in visual processing with magno-, parvo- and koniocellular layers.
- Laminae I–VI** Six layers of the neocortex, where lamina I borders the pia mater and lamina VI the white matter.
- Mid-cingulate/paracingulate cortex** Parts of the cingular cortex in the medial neocortex.
- Nucleus accumbens** A dopaminergic structure in the midbrain thought to be involved in reward processing.
- Nucleus basalis** Nucleus basalis of Meynert: a group of neurons in the substantia innominate in the basal forebrain involved in cholinergic innervation of the cortex.
- Occipito-temporal cortex** Part of the ventral visual pathway at the junction between the occipital and temporal lobes.
- OC** Optic chiasma, a location in the brain where the optic nerves partially bifurcate.
- Physostigmin** A cholinesterase inhibitor that acts by interfering with the metabolism of acetylcholine.
- REM** Rapid-eye-movement sleep, a form of paradoxical sleep in which the person executes rapid eye movements during dream-like states.
- RSVP** Rapid serial presentation task, a visual task involving the presentation of a rapid sequence of images containing two or more targets that require a motor response from the participant.
- SN** Substantia nigra, a brain structure in the midbrain involved in motor control and reward processing.
- SWS** Slow-wave sleep, stage 3 to 4 of (deep) sleep that is associated of low frequency EEG delta waves.
- VBM** Voxel-based morphometry, a data analysis technique that determines statistical differences in grey and white matter voxel intensities. Used to measure cortical grey and white matter thickness.
- Ventral striatum** Part of the basal ganglia involving the nucleus accumbens, the olfactory tubercle, as well as the caudate nucleus and putamen.
- VTA** Ventral tegmentum area, a dopaminergic structure in the midbrain involved in dopaminergic innervation and control of attention.

Chapter 13

Hierarchical Linear Models for Research on Professional Learning: Relevance and Implications

Eva Kyndt and Patrick Onghena

Abstract The goal of this book chapter is twofold. Because research on professional learning using Hierarchical Linear Modelling (HLM) is scarce, the first goal of this book chapter is to familiarise the readers with HLM. The opportunities, assumptions, and limitations of these techniques will be discussed and illustrated with an authentic dataset. Secondly, this chapter will focus on the relevance and implications of HLM for research in the field of professional learning and training: Why and when should this method be adopted within research on professional learning? Which conditions should be fulfilled? What are the advantages of this technique in general and which advantages are specifically relevant for the proposed field of research?

This chapter will provide a basic introduction into HLM. HLM, also known as multilevel modelling, is a statistical technique that takes the nested structure of the data into account. First, HLM will be introduced from a conceptual point of view and discussed why and when it could be applied. Subsequently, the different steps in HLM analysis will be presented and illustrated with an authentic dataset of a study investigating employees' learning intentions. The following section will focus on prior research in the field of professional learning that applied HLM. Finally, the main conclusions and future research perspectives will be provided.

Keywords Hierarchical linear modelling • Multilevel analysis • Professional learning

13.1 Introduction

The research field on professional learning has been growing considerably over the last decade (Billett 2008). While the field on professional learning has a long and rich tradition of applying qualitative research methods, nowadays more and more quantitative methods are being adopted to investigate the complex reality of professional learning. However the valid and relevant application of quantitative methods in this field is not self-evident: Employees with their own personal characteristics are embedded in different organisations that in turn have their own policies and characteristics. In addition, these organisations have to operate within a continuously changing society due to rapid technological changes and global competitiveness (Kyndt et al. 2009). With any method a researcher uses, it is important to keep in mind that the data collection and analysis needs to be in accordance with the complex reality that is under investigation (Goldstein 2003). Therefore, it is our opinion that the field of professional learning would benefit from applying more advanced statistical techniques that are appropriate for analysing this complex reality.

The current chapter will focus on Hierarchical Linear Modelling (HLM), which is also known as multilevel modelling. The goal of this chapter is twofold. Because research on professional learning using HLM is scarce, the first goal of this chapter is to familiarise the readers with HLM. The opportunities, assumptions, and limitations of these techniques will be discussed. Secondly, this chapter will focus on the relevance and implications of HLM for research in the field of professional learning and training: Why and when should these methods be adopted in the research on professional learning? Which conditions should be fulfilled? What are the advantages of these techniques in general and which advantages are specifically relevant for the proposed field of research? The general aim of this book chapter is to provide a basic introduction to HLM without using mathematical formulas, without making it overly complex while at the same time staying true to the complexity of the presented analysis.

In the first section of this chapter, HLM will be introduced from a conceptual point of view and discussed why and when it could be applied. Subsequently, the different steps in HLM analysis will be presented and illustrated with an authentic dataset of a study investigating employees' learning intentions. The third section will focus on prior research in the field of professional learning that applied HLM. Finally, the main conclusions of this chapter will be summarized.

13.2 Hierarchical Linear Modelling (HLM): Why and When?

In order to present HLM from a conceptual perspective, the “why and when HLM should be used” will be discussed. We will explain that when the data are nested HLM should be used. In general two types of nested data can be distinguished; individuals can be nested within different contexts, that is employees within

organisations, or multiple measurement moments can be nested within individuals in longitudinal research (Raudenbush and Bryk 2002). Subsequently, the different types of relationships and models that can be investigated will be discussed, followed by which conditions should be fulfilled to be able to execute the analysis.

There are two main arguments for using HLM instead of regular regression analysis. The first argument pertains to the fact that the collected data need to be analysed in such a way that it takes the structure of the data into account. In other words, if the individuals from whom the data is collected are employed within different organisations – thus are nested in different organisations – then the analysis needs to take this nested structure into account. The second argument for using HLM refers to the theoretical grounding of the empirical research study. If theory and therefore hypotheses include variables at different levels then an analysis appropriate to handle these different levels is needed. For example, if theory describes that firm policy (equal for all employees of the same organisation) influences the individual job satisfaction of employees, an analysis that is able to investigate the relationship of firm policy at the organisational level with job satisfaction at the individual level is needed.

Both arguments can be related to the fact that '*ecological fallacy*' should be avoided. Ecological fallacy refers to the fact that relations are assumed to hold for individuals, whereas in reality they are observed in groups (Luke 2004). For example, research could identify that males and females differ in the number of trainings in which they participated, while in fact it is possible the differences are situated at the level of the organisation (e.g., industry, type of profession) but that some organisations have more or less female/male employees. Empirical research has indicated that occupational segregation could explain gender differences (Oosterbeek 1996; Simpson and Stroh 2002). In addition, disregarding the nested structure will lead to a higher likelihood of Type I errors. In other words, statistical relations are found that might not really exist. To ensure the reliability and validity of the findings, it is important that techniques are used that are appropriate for identifying the unique impact of specific factors at various levels (Snijders and Bosker 1999; Van den Noortgate et al. 2005).

Data collected in cross-sectional research may be nested, such as in the examples above, with individuals nested in organisations, but a specific type of nesting always occurs when performing longitudinal research. In longitudinal research, repeated measurements are nested within individuals. These models are also known as growth curve models, because researchers applying this technique are often interested in the growth trajectory of individuals (Anumendem et al. 2013; De Fraine et al. 2007; Prinzie et al. 2005). For example, research on transfer of training is concerned with the retention period of what has been learned, therefore they often use multiple measurement moments (e.g., Gegenfurtner 2013). Analysing growth curve models informs the researcher on the pattern or growth trajectory of the individuals.

The combination of both types of nesting is of course also possible; collecting longitudinal data with multiple measurement moments from individuals that are nested within different organisations. In this case an additional level is introduced in the model, resulting in a three-level model. Building further on the example of

Fig. 13.1 Level-1 relationship

transfer of training; it could be that the collected longitudinal data stem from employees coming from different organisations. Another three-level model within the context of professional learning is for example an investigation of individuals nested within organisations that are in turn branches of larger (international) companies. These examples show that HLM offers a broad range of possibilities; this chapter will however limit itself to models with two levels, for more information of HLM including three or more levels we can refer the reader to the work of Goldstein (2003) or Raudenbush and Bryk (2002). In the second part of this chapter HLM analysis will be illustrated with a cross-sectional dataset involving two levels, for a good example of HLM analysis involving longitudinal data, the reader is referred to Van den Noortgate and Onghena (2006).

13.2.1 *Types of Relationships*

HLM analysis including two levels can involve different types of relationships. Even when no level-2 predictors are included in the model, because no characteristics of the organisation were collected, HLM is appropriate for nested data. Level-2 predictors are predictors that are identical for all the individuals within each organisation. Level-2 predictors can be (objectively) measured organisational characteristics, concern information retrieved from the human resource department of the company such as training budget or an aggregate of individual perceptions. However when aggregating individual perceptions, individual variation is lost therefore one can consider including these individual perceptions as a level-1 predictor. Figure 13.1 presents a type of relationship that includes one outcome variable and one predictor at the first level in a schematic way (Pustjens et al. 2004). The squares in the figure represent manifest variables, the arrows represent the relation between the variables and the dotted line separates the two levels in the model. The main difference between an HLM analysis of this type of relationship and regression analysis is that initial overall differences in the outcome variable between organisations are taken into account; this is not the case when using regression analysis. The article of Kyndt et al. (2013) is a published example of a research study within the field of professional learning investigating this type of relationship with HLM. They investigated the relationship between different predictors at the individual level (e.g., self-directedness, perceived support, etc.) and the learning intention of low-qualified employees while taking initial differences in learning intentions of employees belonging to different organisations into account (Kyndt et al. 2013).

When level-2 predictors have been measured, it can be investigated whether these organisational characteristics explain the variation observed at the individual level. For example, it could be investigated whether the company budget for training

Fig. 13.2 Cross-level relationship

Fig. 13.3 Cross-level relationship including level-1 predictor

Fig. 13.4 Cross-level interaction

explains individual differences in participation in training. This type of relationship is called a cross-level relationship. This can be investigated apart or together with predictors at the first level. For example, company budget could be one of the predictors of training participation next to an individual’s self-efficacy (e.g., Maurer et al. 2003). Figures 13.2 and 13.3 represent these relationships (Pustjens et al. 2004).

Finally, HLM allows us to investigate whether an interaction between characteristics at the level of the organisation and characteristics at the level of the individual explain the variation in the outcome variable at the individual level. For example, the interaction between the industry in which the organisation is active and the employee’s level of education could predict the career development of employees. This relationship is known as a cross-level interaction effect and is represented in Fig. 13.4 (Pustjens et al. 2004). All figures in this section represent the relationship between manifest variables, however HLM can also be applied to latent variables (see e.g., D’Haenens et al. 2012; Muthén 1994). It is however important to point out that the outcome variables in HLM analysis need to be located at the lowest level that is included in the model. HLM analysis does not allow the prediction of a level-2 outcome based on level-1 predictors. For example, HLM cannot be used to predict the profits of an organisation based on the variation in individuals’ level of education.

13.2.2 Different Types of Models

Before the different types of models that can be investigated with HLM are explained, the notion of fixed and random coefficients (intercept and regression coefficients determining the slope) needs to be introduced. Fixed coefficients are

Fig. 13.5 Fixed intercept and slope

coefficients of which it is assumed that they hold for all cases in the data. When a coefficient is said to be random, it means that its value can vary. However, random is in itself a confusing term because it gives the impression that the coefficients can take on any value, while this is in fact not the case (Field et al. 2012). An assumption regarding these random coefficients is that they are normally distributed around the average population coefficient.

Regression analysis operates from the assumption that all parameters are fixed, that the score on the outcome variable for each individual can be predicted based on the same values of the intercept and regression coefficients. Figure 13.5 presents a traditional regression line of a model with fixed intercept and fixed slope.

Within HLM analysis the intercept, the slope or both can vary between organisations normally distributed around respectively the average intercept and slope that holds for the population. HLM is able to assess the amount of variation at each level (Raudenbush and Bryk 2002).

13.2.2.1 Random Intercept Model

Within a random intercept model the group effect is conceived as random – normally distributed around the intercept of the population – rather than fixed (Raudenbush and Bryk 2002). This type of model assumes homogeneity of the regression slopes across the different groups or organisations included in the study, in other words it assumes that the nature and strength of the relationship between the dependent and independent variables is equal across the different organisations. This model does however allow that initial differences in the overall level of the outcome variable between organisations are taken into account. Figure 13.6 presents the regression lines of the different organisations when a random intercept model is chosen.

Fig. 13.6 Random intercept and fixed slope

Fig. 13.7 Fixed intercept and random slope

13.2.2.2 Random Slope Model

The random slope model represents the heterogeneity of the regression slopes. With this model it is possible to investigate whether the relationship between the outcome and predictor variables differs in nature and strength across organisations. In addition, this variance can possibly be explained by means of predictors situated at the level of the organisation. This model does however assume that the intercept does not vary across organisations. Figure 13.7 illustrates this model. In reality, this model is rarely used because it is to be expected that variability in the nature of the relationship (slopes) would normally create variability in the overall level of the outcome variable (intercepts).

Fig. 13.8 Random intercept and slope

13.2.2.3 Random Intercept and Slope Model

Within this model both the intercepts and the slopes can vary across organisations. Both the initial differences in the overall level of the outcome variable and differences in the nature and strength of the relationship across organisations are being considered. Figure 13.8 represents this model.

13.2.3 Which Conditions Should Be Fulfilled?

13.2.3.1 Assumptions

Because HLM is an extension of regression analysis all assumptions of regression analysis apply to HLM. There is however one exception, in some cases the violation of independence can be resolved if this independence is caused by a level-2 variable, that is a variable at the level of the organisation. However, not all absence of independence can be explained by variables on the organisational level.

In addition, two supplementary assumptions are made that pertain to the random coefficients. In a random intercept model, it is assumed that the intercepts across the different organisations follow a normal distribution. In a random slopes model, this assumption also applies to the regression coefficients (Field 2009).

13.2.3.2 Sample Size

The complexity of HLM makes it difficult to formulate rules of thumb concerning the required sample size that can be applied to all datasets (Cools et al. 2008). However, some general guidelines can be offered together with the advice to execute

power analysis with the help of statistical software packages. In general, introducing another level in the analysis means that more parameters need to be estimated, and the more parameters that need to be estimated the larger the sample needs to be. It has been suggested that the number of groups are more important than the number of individuals in that group (de Leeuw and Kreft 1998). When interested in cross-level interactions the general guideline is that more than 20 groups/contexts (i.e., organisations) are needed and that each group size should not be “too small” (Field 2009). A more general but debateable rule of thumb is the 30/30 rule, meaning that at least 30 groups with 30 individuals are needed. However, as mentioned before the more complex the model, the larger the sample size needs to be and vice versa. For example, a simple HLM analysis (e.g., level-1 relationships with a random intercept) can be run with a dataset that is comparable to what would be needed to run a regression analysis.

The sample size of the collected data will also be important for the choice of the estimation method of the parameters, these estimation methods are discussed within the following section ‘analysing and interpreting the data’.

13.3 Analysing and Interpreting the Data

Within this section the goal is to offer some guidelines for making decisions about the data and the steps that could be followed within the analyses, as well as the interpretation of the results. However, bear in mind that how the model is build and the decisions taken within this process need be theory driven. The procedure can differ depending on the subject and data at hand.

13.3.1 *Illustration: Concept and Sample*

Throughout this section the use of HLM will be illustrated with a dataset that was compiled to investigate the learning intentions of employees. The theory of reasoned action of Fishbein and Ajzen (1975) serves as the theoretical framework for defining a learning intention. Within this theory an individual’s intention plays a central role in the decision making process of the individual (Baert et al. 2006). A learning intention can be defined as a readiness or even plan to undertake a concrete action in order to neutralise the experienced discrepancy, and to reach a desired situation by means of training and education (Kyndt et al. 2011). Within this investigation the role of self-efficacy, employability, self-directedness in career processes, time management, pay satisfaction, and perceived organisational support was investigated. These variables can all be situated at the level of the individual. The sector of the organisation (public versus private) was included as a level-2 predictor. A more complete theoretical background on learning intention and its predictors included in the dataset can be found in Kyndt et al. (Accepted).

Table 13.1 Educational level participants

Educational level	Frequency	Percentage	Cumulative percentage
No degree	48	3.9	3.9
Elementary school	28	2.3	6.2
Lower secondary education	124	10.2	16.4
Special needs education	28	2.3	18.7
Vocational secondary education	144	11.8	30.5
Higher secondary education	440	36.2	66.7
Professional bachelor	194	15.9	82.6
Master	193	15.9	98.5
Other	18	1.5	100
Missing	26		

The sample consisted of 1,243 employees (55 % female). The majority of these participants (82.3 %) were employed within 21 different organisations; the remaining 29.3 % of the participants did not provide the name of their organisation. Almost half of the participants (48.42 %) was employed within the public sector, the other 51.58 % was active in the private sector. The majority of the employees had a fulltime tenured position (61.8 %), 13.28 % had a part-time tenured contract, 10.66 % were temporarily employed and the remaining 14.26 % indicated having an ‘other’ type of contract (e.g., independent, constitutional appointment, etc.). On average, employees were 41.88 years old ($SD=11.91$) and had 13.54 years of seniority ($SD=12.85$). Table 13.1 contains the information regarding the educational level of the participants.

For this illustration the analyses were performed with the *lmne* package of R. R is free software for statistical computing that can be downloaded from www.R-project.org (R Development Core Team 2012). The R code of this example can be found in Appendix. HLM analysis can also be performed with SPSS, SAS MIXED procedure, HLM 7.0 or MLwiN. Each package has its advantages and disadvantages, see Tabachnick and Fidell (2001) or Twisk (2006) for a comparison of software for HLM analysis.

For this illustration, we chose to present the outputs as given by R so that the readers would recognise these outputs when undertaken the analysis themselves. These outputs present more information than discussed in this introductory chapter therefore we have marked the values on which the interpretations are based. We will explain step by step how the final model was built. When performing the analysis in R, the first steps that need to be undertaken are setting a working directory, loading the data, and installing the necessary packages. All information regarding the structure of that data, reliability of the scales, descriptive statistics and correlations can be found in Kyndt et al. (Accepted). For the clarity of the illustration the demographic characteristics of the participants will not be included in the multilevel model. Therefore results in terms of the research topic should be interpreted with caution. Readers interested in this research topic are referred to the article (Kyndt et al. Accepted).

The following steps in the analysis process will be explained and illustrated:

- Choosing an estimation method
- Assessing model fit and comparing different models

- Checking the need for HLM
- Centring the data
- Random intercept model with fixed predictors
- Random intercept and slope model
- Calculating effect sizes
- Reporting the results

13.3.2 Choosing an Estimation Method

A first step in the analysis involves choosing an estimation method for the parameters. In general two different estimation methods are used: Full Information Maximum Likelihood (FIML) and Restricted Maximum Likelihood (REML).

Both methods have their advantages and disadvantages, as already mentioned the sample size is one of the things that plays a role when deciding which estimation method to use. When the sample size is rather small, for example when only the minimum requirements discussed in the section ‘sample size’ are met, REML is more suited because FIML can lead to a negative bias in the estimates, especially when the number of parameters increases (i.e., additional predictors and random slopes). However, FIML has a large advantage when building the model. Later on it will be explained how different multilevel models can be compared in terms of how well they fit the data. When using FIML, it is possible to compare the fit of both the regression coefficients and variance estimates, whereas REML only allows comparing variance estimates (Peugh 2010). In other words, when comparing multilevel models REML only allows a researcher to conclude which model explains the most variance in the data. When comparing multilevel models estimated using FIML, it is also possible to draw conclusions about the comparison of regression coefficients, for example it can be determined whether a random intercept shows a better fit than a fixed intercept. For a more in depth discussion of these methods, the reader is referred to the work of Peugh (2010), Goldstein (2003) and Raudenbush and Bryk (2002).

Because the sample size in our illustration is sufficiently large ($n = 1,243$) and the interest lies in comparing the coefficients of different HML models, the FIML estimation method will be used for this example.

13.3.3 Assessing Model Fit and Comparing Different Models

Comparing different models is an essential part of HLM analysis, based on the comparisons of these models the (final) model is built up in search of the best model possible given the data. The overall fit of a multilevel model is tested by means of the Chi-square likelihood ratio test. To calculate this Chi-square likelihood ratio test, the $-2\log$ -likelihood statistic can be used. When comparing different nested models, that is models that built further on each other like in our example, a smaller

$-2\log$ -likelihood is better; however this value cannot be interpreted as such because there are no cut-off values that indicate a good or bad fit. It can only be concluded that in comparison with another model, a certain model has a better or worse fit with the data (Field et al. 2012). A significant Chi-square statistic indicates that the model with the lowest $-2\log$ -likelihood has a significantly better fit than the model to which it has been compared. Typically a new model that includes all the parameters of the old model complemented with new parameters is compared to the old model. Each new parameter that is included in the model will lead to a decrease in the $-2\log$ likelihood, however the goal is to reach an as good as possible model fit with an as simple as possible model. Therefore the statistical significance of this difference is tested.

13.3.4 Checking the Need for HLM

Two different dominant views are present within the literature on HLM concerning the fact whether or not one should check if there is a need for HLM. On the one hand there is the view that this should not be checked, because HLM should always be applied when the data are nested (e.g., Goldstein 2003; Raudenbush and Bryk 2002). On the other hand, researchers have argued that nested datasets do not automatically require HLM (Peugh 2010). In the latter view, if there is no variation in response variables across organisations (level-2 units), there is no need for HLM and regression analysis can be used to analyse the data. In favour of the first view it can be said that it is not wrong to use HLM for nested datasets even if the variation across organisations is limited or non-existing. The results of HLM will resemble those of the regression analysis, but will from a conceptual point of view reflect the model in a more appropriate way.

However, from a pragmatic point of view, it can be argued that it is easier for researchers and readers with a limited amount of statistical knowledge to conduct and interpret regression analysis in comparison with HLM. Therefore also the second view has its merits. These researchers check the need for HLM by calculating the intraclass correlation (ICC) and the design effect statistics (Peugh 2010) based on the variance components of a random intercept model that does not include predictors (null model). The ICC reflects the proportion of variance of the dependent variable that can be explained by the mean scores of that same dependent variable across the organisations. A large ICC indicates that a large proportion of the variation in the dependent variable occurs at the level of the organisation and that the assumption of independence of regression analysis is violated. When the ICC is large, this means that differences are occurring at the level of the organisation rather than at the level of the individual. For example, when investigating the difference in participation in work-related learning amongst employees, a large ICC would indicate that differences in participation could be attributed to the differences at the organisational level (e.g., training budget) rather than differences at the individual level (e.g., age).

Calculating the ICC

Step 1: Calculate the null model.

Step 2: ICC = variance intercept / (variance intercept + variance residual)

The design effect is calculated based on the ICC score and the average number of employees within the organisation. Note that this average number of employees pertains to the average number of participants in the dataset that are nested in each organisation and not the size of the firm in terms of number of employees, which is often used as a predictor when investigating participation in work-related learning for example (Kyndt and Baert 2013). This design effect quantifies the effect of the violation of independence on standard error estimates; it quantifies the negative bias that results from nested data (Peugh 2010). According to Peugh (2010) a non-zero ICC combined with a design effect higher than 2, indicates the need for HLM (Muthén 1994; Peugh 2010).

Calculating the design effect

$$\text{Design effect} = 1 + (n_c - 1) \times \text{ICC}$$

n_c = average number of participants per organisation

Next, we will illustrate this approach with the data from our example. Output 13.1a shows the results of the random intercept null model predicting learning intention, subsequently it was calculated that the ICC equals .17 and design effect equals 9.03 (Output 13.1b). These values indicate the need for HLM because the ICC is larger than zero and the design effect is larger than 2 (Peugh 2010).

Random Intercept Model

Calculation Design effect:
Design effect = 1 + (nc - 1) x ICC
Design effect = 1 + (48.24-1) x .17
Design effect = 9.0308

```

Output 13.1b Calculation of ICC and design effect

Alternatively when using FIML, the need for HLM can also be checked by calculating a null model with a fixed intercept (using maximum likelihood estimation) and a null model including a random intercept and subsequently test with the Chi-square likelihood ratio test which model fits the data best. However, only the fit of two models that are identical with the exception that in the first model the intercept is fixed and in the second model the intercept is random, can be compared. If the Chi-square likelihood ratio test is significant and the random intercept model has the smallest $-2\log$ -likelihood value, a HLM analysis should be applied to the data.

It is important to notice that for this comparison the same number of subjects should be included in both analyses. When a complete dataset is available this will not be a problem. However, when confronted with missing values a listwise deletion of missing values is the easiest way to achieve this equality. Output 13.2 shows the results of both models and their comparison. The Chi-square likelihood ratio test is significant and the $-2\log$ likelihood of the random intercept model is smaller than the $-2\log$ likelihood of the model with a fixed intercept. These results confirm the need for HLM. In other words, a sufficiently large proportion of the variance of employees' learning intentions can be situated at the level of the organisation. For the purpose of this book chapter both methods were illustrated, of course it is sufficient to execute one of these methods.

13.3.5 Centring the Data

In HLM analysis it is often useful to centre the predictor variables, in fact very few situations are suitable for not centring these variables (Peugh 2010). Centring involves rescaling the predictor variable by subtracting a mean score of the predictor from each individual score. This is done so that a value of zero can be interpreted meaningfully as the central tendency of the distribution (Field 2009; Peugh 2010). This is recommended for predictor variables within professional learning because a

```

Output 13.2 Fixed intercept and random intercept model

score of zero usually has no intrinsic substantive meaning or because a score of zero is not within the range of scores for which interesting conclusions can be derived (e.g., Likert scales from 1 to 5). For example, if one would be interested in the relationship between an individual’s IQ and his monthly wage, centring would be recommended because an IQ of zero and wage of zero do not occur, therefore interpreting an intercept of zero is meaningless within the relation between IQ and monthly wage. In addition, centring can partly resolve multicollinearity between predictor variables and centred multilevel models are more stable (Field 2009).

Two forms of centring are common for HLM analysis: grand mean centring and group mean centring. *Grand mean centring* involves subtracting the sample mean

(the mean score of all individuals included in the sample) from the predictor score of each individual. With *group mean centring* the mean of the individuals in the group (or organisation) is subtracted from the predictor score of each individual in that group. In this case, the mean is calculated for each organisation separately and then subtracted from the predictor score belonging to the employee of that organisation. Grand mean centring does not change the model, meaning that is comparable across groups. Because group mean centring involves subtracting a (possibly) different mean for each group it is logical that the models cannot be compared as such across the different organisations. Therefore Peugh (2010) advises to use group mean centring when only level-1 predictors are included in the analysis, because when only investigating level-1 relationships it is only necessary to merely control for the nested structure of the data and group mean centring is appropriate. When interested in differences between organisations, it is necessary to be able to compare the model across the different organisations. Therefore when level-2 predictors (i.e., organisational characteristics) are included in the analysis Peugh (2010) recommends grand mean centring. Enders and Tofghi (2007) make four recommendations that are partially in line with Peugh's (2010) recommendations. Their recommendations start from the research questions of the empirical study at hand. They advice group mean centring if the primary interest focuses on the association between level-1 predictors (a). For example, group mean centring is appropriate when investigating the relation between an employee's motivation and his approach to learning at work. In this case one can say that it is merely controlled for the fact that individuals are nested within organisations. When the primary interest is on the level-2 predictors while controlling for level-1 predictors, Enders and Tofghi (2007) advice grand mean centring (b). A possible research question could for example focus on the relationship between the industries and employees' participation in formal learning activities. In their view, and in contrast to Peugh (2010) both types of centring are possible when looking at the differential influence of a variable at level-1 and level-2 (c). In other words, when investigating the relationship between both individual and organisational characteristics on individual outcomes, such as the influence of learning attitude and sector on employees' job satisfaction. Finally, group mean centring is preferable for examining cross-level interactions (Enders and Tofghi 2007), such as the interaction between employees' educational level and a firm's training policy (d).

The choice between group mean and grand mean centring only applies to level-1 predictors. Group mean centring cannot be applied to level-2 predictors because it is an inherent characteristic of these predictors to be equal for all individuals within the same organisation (Enders and Tofghi 2007). For level-2 predictors, a researcher can choose between the raw score or grand mean centring (Enders and Tofghi 2007). Because only predictors are centred, there is no need to centre the data before the need for HLM is determined because the need for HLM is determined based on the model that only includes the intercept.

The study that is used as an illustration in this chapter includes both level-1 and level-2 predictors, in line with the guidelines of Peugh (2010) the predictors self-efficacy, time management, perceived organisational support, self-directedness in

career processes, pay satisfaction and employability will be centred by means of the grand mean centring method. The sample mean of each variable is subtracted from the score of each subject.

13.3.6 Random Intercept Model with Fixed Predictors

HLM analyses involve several steps in which a model is built up. When the need for HLM is established, the analyses are continued starting from the empty random intercept model. In a first step fixed predictor variables are added to the null model. Like in ordinary least-squares regression analysis this can be done stepwise or full subsets of predictors can be used. The analysis can either be started by adding the variables that are hypothesized to make the most important contribution to the model, followed by the second most important variable, etc. Each time it should be tested if this results into a better model than before. In this example, the predictor self-directedness in career processes was added to the model. Output 13.3 presents these results. The model including self-directedness shows a better fit than the model containing no predictors. In addition self-directedness is a significant predictor of an employees' learning intention when initial organisational differences in terms of the intercept are taken into account.

Output 13.4 Random intercept model including all level-1 predictors (fixed effects)

Besides this stepwise forward method, a full subset method can be chosen. In this example all our predictors were inserted at the same time into the model. Output 13.4 shows the results of the model containing all level-1 predictor variables included in this research study. Self-directedness in career processes, time management, pay satisfaction, employability, perceived organisational support, and self-efficacy are simultaneously included in the model to predict an employees’ learning intention. The results show that directedness, time management, employability and perceived organisational support are significant positive predictors of an employees’ learning intention. Self-efficacy and pay satisfaction are not significant.

Now it can be decided to continue with this ‘full’ model that comprises all the level-1 predictor variables or to remove the non-significant predictors. In this case, it can be tested whether a model only containing the significant predictors still yields a better fit in comparison with the previous model that showed an improved model fit. For our example this means that self-efficacy and pay satisfaction will be removed from the model. Output 13.5 shows that the model without these

```

Output 13.5 Removing non-significant predictors

non-significant predictors still has an improved model fit in comparison with the model only containing self-directedness. Because Model 5 contains fewer predictors than Model 4, the $-2\log$ likelihood is slightly higher. However Model 5 is a simpler model than Model 4 and shows a fit that is not significantly better or worse than the model including the non-significant predictors. Especially, when the dataset is limited and additional parameters need to be included, we would give the advice to remove non-significant predictors in order to avoid an over-parameterisation of the model, which may lead to convergence problems.

13.3.7 Random Intercept and Slope Model

When it has been determined that the intercept is random, researchers usually built further on this model because the variability in the slopes would normally create variability in the overall level of the outcome variable (intercepts).

When it is expected that the relationship between the predictor variable and the outcome variable may vary between different organisations, a random slopes model can be tested. To determine whether the variance in the slope is significant, two models including the same parameters for which the only difference is that the parameters are fixed instead or random can be compared. After testing the random intercept and regression coefficients, level-2 variables that could explain the variation in the slopes and intercept can be introduced.

It is important that it makes sense from a conceptual point of view that the predictor variable of which the slope is set to random can actually vary between organisations. In other words it should be possible to hypothesize from the theoretical background that the relationship between a predictor variable and outcome variable can potentially vary between different organisations. In this example, it is hypothesized that the relationship between perceived organisational support and an employees' learning intention could vary across organisations. Output 13.6 indeed shows that including a random slope for the organisational support improves the model fit. Within this

Output 13.6 Random intercept and random slope model

random intercept and random slope model, perceived organisational support is a significant random predictor for an employee’s learning intention. Self-directedness, employability and time management remain significant fixed predictors of an employee’s learning intention. The relationship of these three latter variables to an employee’s learning intention is assumed to be equal within every organisation, whereas the relationship between organisational support and learning intention varies between organisations. Based on this model however, the variance between organisations based on organisational characteristics or level-2 predictors cannot be explained. It can only be concluded that this relationship varies.

After testing if a random slope model yields a better fit, level-2 predictors can be added to the model. In our example, the only level-2 predictor that was included was the sector (public versus private) of the organisations. First sector is added as a fixed predictor. Output 13.7 demonstrates that including sector in the model resulted into a better fit. The public sector was given the code ‘0’, while the private sector was

coded '1'. The results show that employees in the public sector have higher learning intentions than those in the private sector.

Subsequently, a cross-level interaction effect between sector and organisational support is added to explore whether sector is able to explain the variation in the slope of organisational support. Output 13.8 shows that this cross-level interaction does not improve the model fit. Because the random slopes model including sector as a level-2 predictor (Model 7) was the last model that increased the model fit, this model is considered as the final model on which the conclusions are based.

13.3.8 Calculating Effect Sizes

The calculation of effect sizes in HLM analysis is a debated topic and currently no consensus exists with regard to which effect sizes are the most appropriate. In addition, it can be noticed that these effect sizes are actually very rarely reported in published articles. Probably due to the lack of consensus and the difficulty in calculating these effect sizes. However, within the framework of this chapter, it is important to provide the reader with a basic knowledge of effect sizes in HLM.

Below the basic effect sizes that are generally accepted will be presented (Raudenbush and Bryk 2002). Overall two types of effect sizes are distinguished: effect sizes that represent the variance in the outcome variable that is explained by all predictors, and the effect sizes that represent the effect of a specific variable on the outcome variable. When interested in the variance that is explained by all predictor variables, the predicted score for each individual in the dataset can be calculated. In most software programs the option to save these predicted values can be chosen when calculating the final model. Subsequently, the correlation coefficient between the predicted and observed scores of the outcome variable needs to be calculated and squared. This squared correlation coefficient is known as the pseudo- R^2 (Peugh 2010; Raudenbush and Bryk 2002).

Calculating the effect size of each variable separately is more complicated in comparison with the pseudo- R^2 . This effect size is called the proportional reduction in variance (i.e., reduction in residual variance). However, to calculate this effect size for each variable separately, each variable would have to be added separately to the model because this effect size simply informs the researcher about how large the proportion of residual variance reduction is in comparison with the prior model that did not include the predictor for which the effect size is being determined (Peugh 2010; Roberts and Monaco 2006). The proportional reduction in variance (PRV) can be calculated as follows:

$$PRV = \left(var_{\text{prior model}} - var_{\text{model with predictor}} \right) / var_{\text{prior model}} \cdot$$

var = residual variance model

However, some caution is needed when interpreting this effect size because the results can be counterintuitive. For example, this *PRV* can be larger than the overall pseudo- R^2 , however these two effect sizes are not comparable and should not be interpreted in relation to each other (Peugh 2010). In addition, it is possible to obtain negative values for *PRV* when for instance level-2 predictors are included in the model (Roberts and Monaco 2006). Roberts and Monaco (2006) present of an overview of adjustments to the calculation of this effect size proposed in order to solve this problem.

Besides calculating the above-described effect sizes there are other ways to determine which variables contribute the most or the least to the model. By standardizing the variables included in the research, standardized coefficients are

calculated that can be compared. In addition the ICC discussed above, can be interpreted as an effect size of the random effects (Roberts and Monaco 2006). Readers who wish to know more about the effect sizes in HLM are referred to Hedges (2007, 2011).

13.3.9 Reporting the Results

Multilevel models can take on many different forms, making it difficult to offer one template that can be applied to all types. As was illustrated throughout this chapter, performing HLM analyses includes multiple steps in which a model is built up. It is advisable to report on all of these stages (Field 2009) as well as the software used to calculate the model. In addition, it is important to report the estimation method and the type of centring that were adopted.

For each model the F -statistics or t -statistics, degrees of freedom, and p -values should be reported. In addition, the variance components (random effects) and $-2\log$ likelihood should be presented. The output in R presents the standard deviations of the random coefficients, these need to be squared in order to obtain the variance components. For the model comparison statements need to be underpinned by reporting the Chi-square statistic, degrees of freedom, and p -value. This information can be presented in a table (see for example Table 13.2).

For our example, the results could be presented as follows:

The final multilevel model calculated to test our hypotheses was built up in several steps. Table 13.2 presents the results of the multilevel analyses and model comparisons. The first step involved testing a model without predictors that included a fixed intercept (Model 1). Secondly, a model without predictors including a random intercept was calculated (Model 2) and compared to Model 1 using the chi-square likelihood ratio test. Model 2 showed a better fit than Model 1. The analysis was continued by adding self-directedness as a fixed predictor (Model 3). Subsequently, all other predictor variables were added to the model (Model 4). Because self-efficacy ($t = -.52$, $df = 986$, $p = .60$) and pay satisfaction ($t = -.21$, $df = 986$, $p = .84$) were non-significant predictors, the variables were removed from the model (Model 5). After adding all level-1 fixed effects, a random slope model was tested, more specifically a random slope for organisational support was added (Model 6). In a next step the level-2 variable sector was included (Model 7). Finally, a cross-level interaction effect between organisational support and sector was added (Model 8). This did not improve the model fit. Therefore Model 7 was chosen as the final model.

The results of the final model (pseudo- $R^2 = 42.80\%$) show that self-directedness, time management, and employability are significant positive fixed predictors of an employee's learning intention when initial overall differences in learning intention between organisations are taken into account. In addition, results show that employees in the public sector have a higher learning intention than employees in the private sector. Self-directedness is the strongest fixed predictor of all the

hypothesized predictors. Pay satisfaction and self-efficacy were non-significant predictors of an employees' learning attention. Finally, the perceived support of the organisation is a significant positive random predictor of an employee's learning intention. The cross-level interaction between organisational support and sector could however not explain this variation across organisations.

13.4 Applications of HLM in Research on Professional Learning

Throughout this chapter examples from the research field on professional learning have been offered when clarifying the conceptual explanation of HLM. In fact, as already mentioned, all research studies that collected nested data should be analysed with a HLM approach. Within this section, the research topics within the field of professional learning that have been addressed with HLM analysis by prior research will be presented.

When searching for empirical studies within the field of professional learning, a first thing that comes to the fore is that the majority of this type of studies focused on the professional development of teachers who are nested in schools. This can probably be explained by the fact that the related field of research on school effectiveness has a rich tradition of using HLM (e.g., Cools et al. 2008; Opdenakker et al. 2002). Several research studies in the field of teacher development have investigated the effect of professional learning communities (e.g., Chi-Kin Lee et al. 2011; Lakshmanan et al. 2011), the role of teachability culture on collegial trust among teachers (Van Maele and Van Houtte 2011) and the role of teacher learning opportunities for reflective practice (Camburn 2010).

Over the last decade the interest in team learning has grown substantively (see Chap. 36 by Dochy, Gijbels, Raes, and Kyndt). Up till now the majority of the studies that have investigated this topic by aggregating individual scores to the team level (e.g., Raes et al. 2012; Van den Bossche et al. 2006), however recent research demonstrates the relevance of adopting HLM analysis when investigating team learning (Liu and Fu 2011) or advises the use of HLM for future research (Akgün et al. 2007). When considering the adoption of HLM for research on team learning it is important to keep in mind that the outcome variable should be situated at the lowest level of interest.

Other research in the field of professional learning adopting HLM appears to be scarce and scattered. For example, Martin (2009) investigated the role of learning for the motivation and engagement in the workplace using HLM and Yeo and Neal (2004) explored the role of learning orientation for performance in skills acquisition. Xiao (2002) focused on the role of education in salary growth. Other studies have formulated the advice that research on learning climate (Haurer and Westerberg 2012) and transfer of learning (van den Eertwegh et al. 2013) would benefit from adopting HLM.

In sum, research within the field of professional learning adopting HLM, especially research situated outside of the traditional school context is scarce. In addition, it can be noticed that the studies that did adopt HLM are very recent.

13.5 Discussion

Within this final section, the advantages and disadvantages of HLM for research on professional learning will be discussed. The main advantage of HLM is the fact that it is the most appropriate method of analysis for nested data. If the nested structure of the data is ignored, it is more likely that statistical relations are observed in the sample that are in fact not true (Type-1 error), in addition it might be that it is concluded that a relationships holds for individuals when they are actually true for groups (ecological fallacy). HLM allows us to identify and explain the variance at different levels of the data, in other words, it is able to identify the variance at the individual and organisational level. Moreover, predictors at the level of the organisation can be included in the analyses simultaneously with predictors at the level of the individual. Something that can be very important in the research on the professional learning of employees, because an employee's learning is the result of the interplay between the organisation and the individual (Tynjälä 2008).

However, HLM also has disadvantages and limitations. First, fairly large samples are needed, especially when multiple predictors at various levels are included. With small samples, the researcher is often confronted with convergence problems. If the software (e.g., SPSS) presents results after reporting that it was unable to reach convergence, these results should not and in fact cannot be interpreted, therefore other software package (e.g., R) do not report results because it was actually not possible to calculate results. Secondly, HLM is a fairly complex analysis (due to the many possibilities) in comparison with regression analysis, for example it requires the researcher to make decisions throughout the entire process of analysis. Finally, as discussed, it is very difficult to calculate and interpret the effect sizes when conducting HLM, in addition no consensus exists and the existing body of literature rarely reports effect sizes.

This chapter has attempted to introduce the reader with HLM without using mathematical formulas. On the one hand, the aim was to inform the reader on when this method of analysis could be appropriate. On the other hand, the goal was to introduce the reader with how a two-level analysis on cross-sectional data can be executed by integrating a theoretical explanation and illustration of the analysis performed on an authentic dataset and topic within the field of professional learning. It is believed that in a field where employees are nested within organisations and trainees are nested within trainings or trainings institutions, applying HLM can have an added value. With this chapter we hope to make a contribution to the introduction and application of HLM in the field of professional learning.

Chapter 14

The Anthropological Paradigm of Practice-Based Learning

Catherine Hasse

Abstract The anthropological approach to studying culture has implied observations of and participation in other people's practices however strange and exotic they may seem. These practice-based experiences are the backbone of the anthropological profession. Anthropology has for a long time been more or less consciously entangled with defining these experiences as learning experiences and subsequently defining culture as the result of learning processes. It is, however, primarily in relation to the general focus on practice that the anthropological paradigm of practice-based learning takes shape.

The article introduces the early anthropological interests in the concept of learning as tied to teaching and culture transmission in 'exotic' cultures and discuss how 'learning' from the 1970s and onwards gradually began to establish itself as a major subfield in anthropology including cross-cultural studies of schooling 'home and abroad'. The studies of practice and the studies of learning, however, for a long time went their separate ways. Since Margaret Mead learning theory in anthropology has been intertwined with concepts like enculturation or socialisation (Schwartz 1980, ix) but often without a clear cut definition relating learning to practice. Some anthropologists have called for an explicit exploration of the concept of learning in relation to ethnographic practices and knowledge making as well as a lens for studying cultural transmission (e.g. Hansen 1982; Wolcott 1982). Others have made an implicit use of the concept of learning as an explanatory term pointing to the anthropologists' journey from novice to a more experienced knower of exotic cultures (e.g. Stoller 1987; Briggs 1970). The field where anthropological learning theory has been most systematically developed is in relation to the anthropology of education, but here little has been done in terms of developing concepts of practice-based learning (see e.g. Anderson-Levitt 2012). Finally some anthropologists

studied people's everyday life 'at home' and found new ways of understanding culture using a cognitive rather than a practice-based learning perspective. Over time the anthropological engagements with teaching and learning have turned towards an explicit interest in learning in connection with practical activity and agency (Pelissier 1991) and most recently the concept of practice-based learning has been considered a key concept for the practice of anthropology itself (Lave 2011; Jordan 2014). This expansion has been developed in close collaboration with primarily Vygotsky- or Piaget-inspired cultural psychologists on the one hand and researchers of work-place learning on the other. More or less simultaneously a new interest in workplace practices began to appear in anthropological research but it was rarely connected to an interest in learning and cognition. These work-oriented anthropologists developed a practice-based framework of understanding workplace activities, but often without an explicit interest in connecting learning to practice. With the seminal fieldwork and subsequent publications by anthropologists like Jean Lave, Brigitte Jordan, Dorothy Holland and Ed Hutchins the interest in combining learning and practice spurred a new paradigm for studying practice-based learning through participant observation. The final section take a closer look at this last development combining theoretical issues with the future perspectives of theories on practice-based learning in the field.

Keywords Anthropology • Practice-based learning • Ethnography • Fieldwork • Participant observation • Cognitive anthropology • Cultural learning • Materials and materiality • Cultural transmission

The anthropological approach to studying culture has implied observations of and participation in other people's practices however strange and exotic they may seem. No matter how distant from their own background, anthropologists have always built their analysis on learning about everyday life by observation and sometimes participation in practical activities. An analytical understanding of these practice-based activities is the backbone of the anthropological profession. This implies studying not only what people do but also learning about the cultural meanings emerging from and through human-material engagements. It moreover implies learning about the material constraints, resources and structural conditions offered by local cultures. It is primarily in relation to the general focus on practical activity and agency that an anthropological interest in practice-based learning takes shape (Pelissier 1991). Even so there is no single definition of 'practice-based learning' in an anthropological perspective accepted by all anthropologists. In Tim Ingold's discussions of learning, practice-based learning is defined as learning through doing and understanding in practice (Ingold 2011a). Apprenticeship-studies like Jean Lave's analysis of the gradual process of becoming a tailor in Liberia (e.g. 1977) have inspired researchers from many disciplines to study learning and work practices through ethnographic methods. Studies of work-based practices in Western societies have been inspired by these detailed ethnographic studies and anthropological analysis of the variable relations between humans, cultures and practice based work.

Today the anthropological approach has become paradigmatic in parts of the social sciences of organization and work, where Tayloristic and quantifiable studies on the one hand and psychological tests on the other have been replaced with the ethnographic micro-perspectives (Bauer and Gruber 2007). The connection between situated and practice-based learning and culture as resources and structural arrangements offer valuable insights into what Stephen Billett has called the “didactics of practices in work settings” (2011, 136). Today the concept of practice-based learning is acknowledged as a key concept for anthropology (Lave 2011; Jordan 2014) but anthropological studies of practice-based learning at work is as yet an emerging field. This chapter is divided into five sections that explore the development of concepts of practice-based learning in anthropology. (1) The first part looks at how practice and learning are connected in the detailed anthropological monographic descriptions of how e.g. children learn to grow up as members of a particular culture. Children’s learning has been studied in relation to teaching and schooling cross-culturally. The main contribution to the development of notions of practice-based learning are, however, found in the detailed descriptions of children learning outside of formal schooling systems. This kind of studies has, in combination with cultural-psychological studies, challenged Western conceptions of school-based learning (e.g. Rogoff and Lave 1984). (2) The next section take a closer look at how anthropology has contributed to general learning theory and in particular learning theory with practice-based elements. These theories are both very general and abstract systemic or cognitive approaches to learning. They are dispersed and only to some extent connected with theories of practice-based learning in work. (3) The particular connection between work and practice-based learning is discussed in the next section which deals with the ethnographic studies of adult practice-based learning in relation to work. Also these studies cover a wide range of approaches. Again we find a particular interest in taking turns with the cognitive sciences. (4) The next section deals with methods and methodology. Anthropological studies of practice-based activities of work rest on two premises: ethnographic method and the holistic anthropological analytical approach. Ethnography is usually referring to the fieldwork method used by anthropologists, which implies presence and sometimes participation in cultural activities. Anthropological analysis implies a holistic approach. In anthropology ‘holism’ refer to a theoretical and methodological approach that tries to avoid a particular view on what is being studied and remains open for new and unexpected connections (see Otto and Bubandt 2010 for a thorough discussion). The distinction between ‘ethnography’ (as a data collection method employed by many different disciplines) and anthropology, which combines the ethnographic study of particular people in particular places with a theorising about the human species has been widely discussed (e.g. in Ingold 2011a and Astuti and Bloch 2012).

This section discusses how ethnographers themselves learn when they observe and sometimes even participate in cultural activities. (5) The last section discuss the influence of anthropology on studies of practice-based learning and what kind of future for workplace studies of practice-based learning this paradigmatic turn may imply.

14.1 Cross-Cultural Learning Theory

The anthropological paradigm of practice-based learning grew out of a joint cultural-psychological and anthropological effort in the 1970s to question that learning is isomorphic with institutionalized teaching and written curriculum. This critical approach is a direct extension of classical anthropological monographs. In meticulously elaborated field-reports and monographs anthropologists have reported about how children learned to become skilled cultural members without formal lessons and how young people through apprenticeships learned to master the handicrafts of importance to the local culture. In these descriptions we are for instance introduced to the practical activities of how children learn the craft of the Kpelle blacksmith in West Africa through play (Lancy 1980) and how Skolt Lapps learn circumpolar reindeer herding (Ingold 1976). It has for long been acknowledged in anthropology that even when anthropologists present their data in monographic form, cross-cultural perspectives (involving their own background as well as other anthropological monographs) always are more or less explicitly part of the study.

14.1.1 *Learning as Cultural Transmission*

Since Margaret Mead learning theory has been intertwined with concepts like enculturation or socialisation (Schwartz 1980, ix) often without a clear cut definition linking practice, learning and culture in concepts like enculturation or socialisation. In classical anthropological monographs learning is generally used synonymously with concepts like ‘socialisation’ or ‘enculturation’ or as an explanation of cultural transmission.

Many of these studies focus on how children learn the local skills of importance in particular cultural settings without the schooling dominant in Western culture (Lancy et al. 2010). As noted by Cathrine Pelissier Margaret Mead was the first anthropologist to offer a study of teaching and learning in her monograph *Coming of Age in Samoa* (Pelissier 1991, 82). She initiated a new field of interest with her study of how adolescent Samoans developed in different ways than young Americans, thus raising questions of the influence culture had on what had before been considered self-evident and biologically formed ways of reaching adulthood (Mead 1928). In this book Mead took up a criticism of the American system of schooling, which was later followed up by many other anthropologists (e.g. Lave 1988; McDermott 1974). Contrary to Samoan children, who learned in a free and easy way about their society, the American schooling system did not prepare American children to the many choices in a culture full of commercials and impressions. The study of the Samoan socialization process became a cornerstone of the American culture and personality school, which underlines how culture and learning shape personalities, behavior and thinking.

In a later study Mead affirmed: “We are forced to conclude that human nature is almost unbelievably malleable, responding accurately and contrastingly to contrasting

cultural conditions.” (Margaret Mead 1935/1963: 289). Together with her husband, Gregory Bateson, she later explored the way Balinese children were formed as ‘cultural characters’ by subtle means (Bateson and Mead 1942). Without explicit references to practice-based learning their study of child-rearing added to a wide range of studies of how children are socialized through observation, imitation and learning from reactions. Many of these studies had a more or less explicit cross-cultural perspective on child-rearing and most often learning was seen as a process of cultural “transmission” (Kimball 1972). In most monographs, we find sections describing how this ‘transmission’ takes place through processes which come close to descriptions of practice-based learning and involves no formal learning or schooling. Children learn by doing, observing, imitating or by being praised and reacted to by grown-ups. This is how Hopi-girls learn to grind corn, Torres Strait children learn to become reef foragers and Mbuti-boys learn to kill animals (Lancy and Grove 2011). The learning is tied to local gender roles as well as different patterns of transitions from toddler to adult. Cultural learning is in most of these monographic descriptions highly structured and tied to local distributions of work tasks tied to status systems, gender and age. Most of the monographs do, however, not take the relation between practice and learning as an explicit focal point of the studies. Learning is used in an explanatory fashion to explain general processes of socialization and cultural transmission.

14.1.2 Cross-Cultural Teaching and Learning

Studies of schooling have developed an explicit interest in exploring the concept of teaching and practice-based learning, often with an underlying criticism of Western school systems. Learning theory tying practice and learning has been connected with studies of children learning e.g. mathematics at the marketplace outside of school (e.g. Lave 1977; Cole et al. 1971; Verran 2001). Many anthropologists collaborated with cultural psychologists and educationalists in order to expose the Western bias on formal schooling as the only road to learning. Anthropological studies of cultural narratives and languages have also drawn upon learning theories (e.g. Goodwin 1993; Harkness 1973; Ochs and Schieffelin 1984). Many of these studies were concerned with the “us/them” dichotomy, which had been established in much general cross-cultural research. These studies often took turns with the different kinds of experiments, testing Western style schooling and learning up against indigenous cultures (following long historical traditions in cross-cultural psychology e.g. the British A.C. Haddon-expedition to Torres Strait, New Guinea, in 1898) (Cole 1996, 42).

The early interests in cultural transmission and (lack of) schooling in different societies in time developed into a strong subfield: “the anthropology of education”. The scope of this field sits, as noted by Brad Levinson and Mica Pollock, “at the crossroads of anthropology as a discipline, schooling as a professional field, and education as a perennial human endeavour” (Levinson and Pollock 2011, 1). The

history and ramifications of the subfield ranges over George and Louise Spindler's cross-cultural fieldwork and their effort to carry what was learned in "exotic places" back into studies of American education (Spindler and Spindler 1982) to studies underlining the civilizing effect of schooling institutions, discussions of cultural transmission, teaching, transfer theory and formal versus informal learning (Lave 2011).

From the 1970s a new interest in studying education and schooling at home in e.g. USA or UK emerged – often driven by very critical approaches to cross-cultural studies commending the Western approach to schooling. Some of these anthropological studies at home challenged notions of the practice of schooling and explicitly included a perspective on practice-based learning *within* schools – often in relation how *not* to succeed in Western schooling and on how Western school culture created "disability" learning (e.g. McDermott 1993; McDermott and Varenne 1995). This kind of anthropology of education does not include formal or informal learning at work-places in general but is limited to studies of schooling. Although many, especially Western, anthropologists have studied schooling abroad (e.g. Levinson et al. 1996), Kathryn Anderson-Levitt has also noted that anthropologists studying education "are more likely to study schooling or learning "at home" rather than "abroad," even in countries where other anthropological studies are conducted away from home" (Anderson-Levitt 2012, 16). Another particular detail is that neither learning nor practice is in general focal points in these studies of Western education. In the comprehensive overview of the anthropology of education, *A Companion to the Anthropology of Education*, we find only one reference to the concept of learning in the register and none for the concept of practice (Levinson and Pollock 2011, 568, 570). Instead we find an interest in education in relation to the structural cultural conditions of educational systems (often national or ethnic), gender, age, politics and language. Even though much has been done in studying the "educated person" (Levinson et al. 1996) the focus in the anthropology of education is still, as Harry Wolcott noted, more on schools as institutions, focused largely on teachers and teaching rather than learners and learning (Wolcott 1982, 86).

14.2 Contributions to General Learning Theory

The anthropological paradigm of practice-based learning has many forerunners in anthropology circling around concepts of practice and learning but only a few anthropologists have studied and developed general theories of learning processes in their own right. The interest in learning theory comprising also adult learning is not new in anthropology, but the issue has always been a niche. In the following section, a selection of anthropological contributions to general learning and practice theory will be discussed.

Harry Wolcott went further than most when he called for more general studies of anthropological learning theories, which could be seen as forerunners of

anthropological studies of practice-based learning such as “learning by osmosis,” “concomitant learning,” “incidental” and “unintended” as well as “latent learning,” “intentional learning” as well as recognizing the importance of Bateson’s “deutero-learning” for anthropological analysis (Wolcott 1982). The main focus on learning in anthropological studies was however limited to discussions of learning as transmission and acquisition of culture in a broad and general perspective rather than on how culture could be tied to everyday practices. Furthermore, the traditional anthropology on learning as transmission focused on specific areas of learning: knowledge, child development, schooling, and cultural continuity but not practice as such (e.g. Kimball 1972; Whiting 1941).

Many, both cultural psychologists and anthropologists interested in learning have been inspired to develop notions of practice through the work of Pierre Bourdieu. He is sometimes referred to as an anthropologist sometimes as a sociologist and not least his early fieldwork among the Kabyle people in the Atlas Mountains has been extremely important for the development of anthropological theories of practice-based learning. Not because he has defined learning – but practice. The logic of practice is not that of a logician – it is a process evolving between habitus and structure (Bourdieu 1990). The anthropologists Dorothy Holland and Jean Lave have discussed his work thoroughly and criticised his lack of learning theory in dealing with the notions of habitus and structures (e.g. Lave 1997). Bourdieu’s theories of practice have, however, been tremendously influential in the development of anthropological theories of practice-based learning and it may be regretted that Bourdieu did not himself develop his work in relation to anthropological theories of learning.

Only a handful of anthropologists concerned themselves with a more general interest in learning theory (Wolcott 1982). One of those was Mead’s husband, Gregory Bateson, who turned out to be one of the most influential of the anthropologists contributing to general learning theory. He developed a special interest in the concept of learning and formulated what is today a widely recognized systemic theory of learning (in the early days named “deutero-learning” and later “learning-to-learn”) (Bateson 1972). Bateson’s learning theory is systemic and cybernetic focusing on change and pattern recognition in a rather abstract manner. Though this contribution was seminal as a contribution to general learning theory, Bateson explicitly denounced the possibility to study learning as everyday practices. He argued that anthropologists, through their specific methods of simultaneously participating in and observing other peoples cultural lives only would be able to formulate new questions (e.g. about learning), which then would have to be tested and answered in laboratories by psychologists (Bateson 1972, 115). Even so the systemic approach to learning he developed has gained renown far beyond anthropology (and is probably even more appreciated in other disciplines like psychology, biology and cybernetics). Bateson’s theory of learning is not about practice, nor is it about culture, but about context. Or rather culture is context and context is not running on “transmission” or “transfer”. Context is classifying the information exchanged and every transaction that takes place between people is in itself a context of learning (Bateson 1972, 246).

14.2.1 *Cultural Models Theory*

Another important contribution to general learning theory, that come closer to practice-based learning, is found in cognitive anthropology. In cognitive anthropology there is an explicit attempt to connect culture, learning, and cognition with studies of everyday activities (Bloch 2012) – and further link these concepts with other relevant psychic processes such as motivation and emotions – in a coherent framework. Cognitive anthropology has been especially interested in the processes creating cultures (e.g. Shweder and LeVine 1984; Shore 1996). Major general contributions to anthropological theory often develop when a small group of people meet and develop their thoughts at a certain physical place. In this case the group of cognitive anthropologists were all more or less connected with the University of California, San Diego in the 1990s (and later dispersed to other universities). Here they developed a specific theory of cultural learning inspired by the cultural anthropology of Margaret Mead, Ruth Benedict, Gregory Bateson and Edward Sapir. Following their work researchers like Roy D’Andrade, Claudia Strauss, Naomi Quinn and Dorothy Holland continued to ask questions about the relations between culture, practice and learning. Together they, with other anthropologists such as Theodore Schwartz, Geoffrey M. White and Cathrine Lutz, developed the anthropological theory of cultural models in works like *Cultural Models in Language and Thought* (Holland and Quinn 1987), *Human Motives and Cultural Models* (D’Andrade and Strauss 1992), and *A Cognitive Theory of Cultural Meaning* (Strauss and Quinn 1997).

Roy D’Andrade has presented an introduction to the field in *The Development of Cognitive Anthropology* (1995). Schematized models not only have potential for directing our acts, but does so in culturally rather stabilizing ways (D’Andrade 1992, 29). Cognitive anthropologists adds three important aspects to the general cognitive theory as well as the actor-network notion of ‘scripts’ and ‘inscriptions’ by refining notion of ‘schemas’ or more complex patterns of schemas named ‘cultural models’. (1) The models for action are cultural in so far we find diversity between cognitive basic schemas found in different ethnic groups and national cultures, but also diversity between groups of scientists, butchers, nurses or other groups, where people learn to form cultural models through their everyday activities. Cultural models are thus tied to ‘doings’ rather than biology, ethnicity or nationality. (2) Basic schemas for how to act are organized in cultural models of ‘self-evident’ connections of knowledge which are learned through every day activities, (3) As learning differs with differences in everyday practice we cannot assume the organisations of cultural knowledge to be equally motivating for all members of an ethnic group or a national culture. Homogeneity must be determined through empirical research.

Once internalised, cultural models ‘fill out’ knowledge about what we perceive with what we expect to perceive. A much used example could be the way young college students expect to be treated on a first date. Knowledge about the course of a dating event is highly cultural. In the American high schools young people have

internalised many expectations which will not be shared by Masai youngsters in Kenya. They do not share the ‘figured world’ (Holland et al. 1998) of how to date.

Cultural models are directive in so far these mental models influences our goals and our feelings about for example using artefacts and organize personal memories around prototypical events, which we might contrast to our own experiences. In this capacity cultural models are “learned internalized patterns of thought-feeling that mediate both the interpretation of on-going experience and the reconstruction of memories” (Strauss 1992a, 3). In this view culture is an ongoing learning process rather than ‘content’ as e.g. material culture. Within this wide framework the more specific theoretical approach of cultural models offers an analytical tool to capture both end-products (cultural models which affects emotions and motivations to act) and processes (learning the connections through which cultural models are formed). What they name ‘cultural models’ are intertwined and organised connections of knowledge about how to act and understand acts formed in activities and “doings”, while models on their part give directive force to certain motivations to act, without making persons ‘cultural dopes’ (Holland and Quinn 1987; Strauss 1992b).

Even so in empirical studies the theories of cultural organizations of knowledge has mainly been applied on our ability to understand and agree with linguistic statements as in proverbs, commercial slogans or abstract general concepts and thus underscore ‘representation’ just like in Cultural Studies. Though this framework also explore the relation between materiality and practice – explicitly developed into an even broader theory of ‘figured worlds’ (Holland et al. 1998) – the emphasis has been on *cognition* more than *practice*. So far cultural model methodology has primarily concentrated on discourse analysis and interviews designed to elicit informants underlying self-evident cognitive schemas (Garro 2007) as well as the more encompassing cultural models or figured worlds. Research has primarily been related to studies of abstract concepts like cultural models of ‘marriage’ and ‘romance’ and “the American Dream”, or on maxims, proverbs, morality tales, and other verbal expressions. (e.g. Strauss and Quinn 1997). The theoretical framework has only in a few studies been connected with empirical studies of how people form the basic cultural models connections in ‘doings’ with material artefacts in cultural practice (e.g. Holland and Cole 1995).

14.3 Work and Practice-Based Learning

Anthropology has a long tradition for studying organisations and institutions but this has rarely been connected with practice-based learning (see e.g. Wright 1994). In the late 1980s another subfield of the discipline of anthropology evolved which proved decisive for developing a concept of practice-based learning – studies of and at workplaces all around the globe. The focus is not just on work, or learning or cultural structures and resources, but on the relations between all of these elements. This work has been inspired by the anthropological interest in apprenticeship-studies that followed the critique of Western systems of schooling. In these studies

there was a focus on practical activity as the way to learn a particular handicraft. For some reason many of these studies emerged in West African anthropologies. Some, like Michael Cole and Jean Lave, conducted formal experiments in order to show how apprenticeship training, along with school training, provided the problem-solving skills needed to solve arithmetic problems (e.g. Cole et al. 1971; Lave 1977). Others like David Lancy studied the skills acquisition in everyday life. Lancy made a study of how the blacksmith craft was learned in a small Kpelle village, Gbarngasuakwelle. He argued that patterns of learning and play come together when Kpelle children learn to acquire the skills possessed by Kpelle adults (1980). Being a skilled worker in this context involves more than we normally would expect from the education of a blacksmith in a Western culture. Learning begins with children playing with sticks and stones and later involves learning about the traditions and customs encapsulated in stories and songs. To become a Kpelle blacksmith the apprentice goes through two kinds of processes. One involves a specified learning process with a local master teaching his pupil about forging. The other, but equally necessary learning process, is much more complex and involves learning through play and other means to combine craftsman skills with the art of being a medicine man and a 'big-man' also tied to the activity of a blacksmith in the Kpelle society. This detailed anthropological analysis is typical of the ethnographic holistic 'wholeness' approach that try not to compartmentalize the world into previously formed Western categorisations. And, as also noted by Lancy, contrary to the cognitive studies conducted by cultural psychologists (e.g. Cole et al. 1971) and other anthropologists like Jean Lave (1977) this study did not study how West African apprentices or children acquired cognitive skills, but how they acquired the practical skills valued in Kpelle society (Lancy 1980, 266).

14.3.1 Learning at Work

From these kinds of anthropological studies of marketplace- and apprenticeship learning a specific approach to studies of work emerged as in for instance the study of the (transformed) practices of Mayan weavers (Greenfield 2004) or the craftsmen building Minarets in Yemen (Marchand 2001).

Many of these studies of practice-based learning in relation to work have been inspired by a group of anthropologists based in Palo Alto, California, not far from San Diego. In their work, studies of West African apprentices met with studies of Americans trying to operate copying machines. Contrary to former anthropological studies of organisations, which often centered around the concept of 'organisational culture' and had a close collaboration with managements studies (Jiménez 2007) the technology-oriented studies at Palo Alto took an interest in both everyday learning, as well as design and practice. The most important contributions emerged from the local institutions: the Work Practice and Technology group at Xerox-PARC

and the Institute for Research on Learning, IRL. Some of these anthropologists had formerly been working with cultural psychologists, but now they moved to a new kind of collaboration with computer scientists, engineers and technology consultants. Anthropologists like Lucy Suchman, Julian Orr, Jeanette Blomberg, and Brigitte Jordan were invited in to study work-practice in order to improve the functioning of the technology (see e.g. Suchman et al. 1999; Jordan 2014). The ethnographic work of Julian Orr on technicians working on copying machines (Orr 1996) has for instance been accentuated as a contribution to workplace research on organizational learning, because his approach point to the connection between “work practices” and organizational learning (Yanow 2006). Many have also been inspired by Lucy Suchman’s eloquent analysis of plans in relation to the everyday situated actions (Suchman 2007). These, and other anthropological approaches have been an acknowledged source of inspiration for organisational scholars (e.g. Czarniawska 2012).

14.3.2 Situated Learning and Practice

One of the main figures in this paradigm of practice-based learning is the anthropologist Jean Lave. Initially she worked within the paradigm of cognitive anthropology and cross-cultural studies of education. Here she met and teamed up with educational cognitive psychologists working in West-Africa as Michael Cole, who just like she did, conducted small experiments with informants to find out about the difference between formal and informal learning. In a testimony over her lifelong development as an anthropologist she explains how her work among the Vai and Gola tailors of Happy Corner, Monrovia, in Liberia gradually moved her away from perceiving learning as either formal (in schools) or informal (as apprentices learned from their masters). Instead she asks “what if learning is all there is?” (Lave 2011, xx) and gradually came to acknowledge that learning is ubiquitous. In other words she dissolved the dichotomy between informal and formal learning. Learning takes place all the time and everywhere and affects not only knowledge, language and individual identities but whole communities of learners.

In her early studies of learning mathematics in everyday life in Orange County, California, Lave (1988) argues against a notion of cognition as an abstract knowledge people can possess (a knowledge poured into a container). Mathematical insight is rather a knowing in a practice, learned within that practice. Far from being detached ‘encyclopedic’ knowledge, situated knowledge arises with the needs of a particular practice. This approach may explain why people may be excellent at calculating numbers when engaged in counting calories in commodities at a supermarket whereas the same kind of calculations poses problems when they are confronted at a school setting, which present the insights of mathematics as purely abstracted knowledge. In the empirical study Lave and her colleagues for instance follow a class of Weight Watch participants in kitchens and

supermarkets. It turns out they use even quite advanced mathematics with ease as long as it is connected with their Weight Watch program. The conclusion drawn by Lave is that rather than talking about knowledge as abstracted from everyday experiences, “knowledge takes on the character of the process of knowing” (1988, 175). In 1987 Jean Lave visited the learning-center at the Xerox-financed IRL and here she teamed up with the computer scientists Etienne Wenger. Together they wrote the most influential books in the anthropological paradigm of practice-based learning: *Situated Learning: Legitimate Peripheral Participation* (1991). In this book a theory of learning as practice-based ‘legitimate peripheral participation’ in communities of practice was introduced. The book built partly on Lave’s earlier work of apprenticeship learning in West Africa (e.g. Lave 1977) but also involved a number of studies in which people learned ‘ubiquitously’ without formal schooling as they engaged themselves in various everyday practices. Learning is not confined to specific ‘learning settings’ or formal learning situations, it is argued. Ubiquitous learning is often unrecognized and involves changes in knowledge and actions as we learn in ongoing activities. These changes are central to what is meant by ‘learning’ (Lave 1993, 5). This approach makes it possible to move learning outside of the classroom and into the practice-based learning that take place in everyday life including workplaces. People may learn through direct guidance of their more experienced colleagues or more skilled peers but often learning comes about without any explicit instruction – simply through observations and doings in the course of an evolving identity and membership in a community engaged in a particular local practice.

The notion of learning in everyday apprenticeship-like situations on the shop-floor, which could be studied through ethnographic methods of participant observation, became immensely popular in work place studies of practice-based learning. In the uptakes learning became an issue in relation to occupational practice and it is discussed as a practice-based learning which makes no distinction ‘between engaging in practice and learning’ (Billett 2010, 2). Communities of practice are not just sites for learning particular skills, but places where identities, knowledge, activities, languages and artefacts are formed through situated learning processes (Lave and Wenger 1991, 52–54). The particular anthropological interest in practice-based learning is influenced by the cultural learning tied to everyday practices (Greenfield 2007). Often these anthropological endeavours are not distinguishable from how cultural psychologists, like e.g. Patricia Greenfield and Barbara Rogoff, have dealt with culture and apprenticeship in relation to learning.

In the paradigm of practice-based learning one of the important contribution is the ethnographic approach shared by anthropologists and cultural psychologists alike that help keep the physical, culturally constructed setting in mind and the material objects that help constitute social space and thus focus on the evolving learning of everyday life, that may be “the blind spot” of many other types of organizational studies (Yanow 2006, 1751). Another contribution is the integration of learning, practice and cultural diversity – an area which may still be developed further in organisational studies.

14.3.3 *Distributed Cognition*

At the same university in San Diego where Roy D'Andrade developed his theory of cultural models and Holland and Lave visited Michael Cole's Laboratory for Comparative Human Cognition, another anthropologist began to study what comes close to studies of practice-based learning at work. For this anthropologist, Ed Hutchins, the main interest was to understand human cognition in social, cultural and material contexts and this implied studying learning in relation to *Cognition in the Wild* (Hutchins 1995). Like so many other American anthropologists, Ed Hutchins takes turns with the general dominating cognitive science, which, he claims, "leads to a serious overattribution of knowledge to individual actors" and thus overlook that "when context is ignored, it is impossible to see the contribution of structure in the environment, in artifacts, and in other people to the organization of mental processes" (Hutchins 1993, 63).

The 'wild' refers to studies of everyday life outside of laboratories and this comes close to a practice-based learning approach. Hutchins' studies focus on the distributed cognition in practical activities (as navigating ships) thus emphasizing an integrative approach to learning in cultural (human and material) communities. On board huge ships the captain's cognition differs from the deck clerks but it is through the distributed cognition between them and their tools that the ship is sailing. Learning is not tied to individual minds but to reconfigured arrangements of knowledge distributed among people engaged in different tasks as well as the artefacts in use.

Hutchins empirical work often concerns the working of complex systems of human-technology relations, which e.g. enables huge ships to sail (Hutchins 1995) and aeroplanes to fly. Parting from traditional understandings of cognition as information processing the practice-based approach taken by Hutchins led to an identification of cognition as distributed (Hutchins 1995). In one such case Hutchins recounts a detailed description of a large ship, USS Palau, which, while it was sailing into a harbour in San Diego, ran into a problem with some of the navigational equipment and a breakdown of electrical power. In the ensuing work-situations the navigation team answers to this situation. Hutchins notes, that one normally expects that work situations on big ships are organised in accordance with plans, which may ensure that even in times of a crisis the organisational structures support reflected and efficient answers to a crisis. Instead the crew and their equipment answer by an intricate system of adaptations spread across human and material artefacts to avoid a collision with a sailboat and a buyer. The collisions are avoided. Not because of separate individuals reflections, but rather through the reactions of a systemic whole (Hutchins 1991).

In work settings the boundaries between group and individual is dissolved in this approach and the distributed cognition furthermore involves both material artefacts and representations. In distributed cognitive systems no one person (nor any one technological artefact) has the full overview of a situation. In order to get USS Palau safely into harbour, no one – not even the captain or the technical instruments – have the full overview of the situation and what plans to be executed.

In distributed cognitive systems each individual and each machine contribute with dispersed and differentiated understandings of the situation. It is when they come together and adapt to each other that a solution emerges to solve the crisis. In the cognitive system described by Hutchins the distributed cognition may be analysed based on several levels of learning. The individual captain or helmsman learn in relation to each other or in relation to their instruments, or including their relation to all others and all the relevant instruments. The knowledge possessed by humans and machines is variant and collaborates with different kinds of knowledges and resources. Thus access to each others responses and resources is of huge importance for the possibility for the whole system to respond to a crisis. In the reported case USS Palau was successfully shored at its berth – but the success would not be attributed to any individual, nor to a group of persons or materiality, but to the whole interacting system of distributed cognition.

Hutchins makes a special case of how practice-based learning is tied to this system of varied cognitions working together. Learning happens in culturally informed doings (Hutchins 1995). Once learned cultural relations to artefacts and other people become a self-evident horizon for our range of actions. Artefacts and humans are in this respect simultaneously extensions of the individual knowledgeable body engaged in an activity (as e.g. avoiding that a large ship collide with a buyer) and one node in an extended distributed system of human and non-human cognition about how to act in unison.

14.3.4 Material Artefacts and Bodily Practices

Another anthropologist, who has expressed admiration for Hutchins concept of distributed cognition, is the anthropologist Bruno Latour, who goes even father in attributing agency to material artefacts. Although he does not operate with an explicit notion of practice-based learning some have remedied this and developed theories of how practice-based learning and materiality may be connected with Latour's actor-network-theory and theory of socio-material assemblages (Latour 2005) – most notably Estrid Sørensen (2009) and Tara Fenwick and Richard Edwards (Fenwick and Edwards 2010). Like Bourdieu before him Latour only sporadically contribute to theories of practice-based learning. Most notably this perspective is unfolded in an essay of body and learning to e.g. become a taster of perfume in France (getting the 'nose' (*un nez*) which selects good perfume from bad). Latour claims that being sensually affected is related to learning. This is: "especially salient when we compare what happens to a pupil learning to become a 'nose' with what happens to her teacher devising his odour kit through a long enquiry among 2000 untutored 'noses', and with what happens to the chemists when they try to build instruments and apparatus to register chemical differences in the various disciplines surrounding the industrial branch of perfume manufacturing. Each of these different actors can be defined *as bodies learning to*

be affected by hitherto unregistrable differences through the mediation of an artificially created set-up." (Latour 2004, 209, italics by the author). Affection is learned in ways which gradually make us more sensitive to differences in for instance the tastes of wine and perfume scents.

The sensuous approach to learning is even more evident in the works of Tim Ingold. There are many likenesses between them though Ingold explicitly distance himself from the work of Latour (in one occasion he, with a witty pun describes this difference as the one between an ANT (pun referring to Latour's 'actor-network-theory') and a SPIDER (referring to his own 'meshwork' theory)) (Ingold 2011a). Though Ingold shares Latour's interest in materiality his approach is much more connected to how humans dwell in the worlds through which we physically move (Ingold 2000). Inspired by phenomenological theories Ingold unfold how practice-based learning is tied to these emergences and intricate webs of materials (rather than materiality), bodily engagements and movements in environments. Drawing on an extensive knowledge of anthropological monographic descriptions of how people all around the world learn to engage with the animals they herd, the plants they harvest, the baskets they weave and the lines they create, Ingold argues that sensory perception and practical activity inform each other (Ingold 2011a, 31).

Dwelling does not imply that humans snuggle up in cosy caves of dwelling free of struggles for space and power games. What is fundamental to the dwelling perspective is "the thesis that the production of life involves the unfolding of a field of relations that crosscuts the boundary between human and non-human" (Ingold 2005, 503). Furthermore, this unfolding is not following explicit rules nor is it depending on reflections. Often rather the opposite is the case.

Ingold for instance describe a seminar with anthropologist and craftsperson Stephanie Bunn. Bunn is an expert on weaving and basket making. At the seminar the participants are asked to make a particularly decorative knot, named a 'Turk's head'. Ingold notes: "Trying to do this from step-by-step diagrams proved virtually impossible" (Ingold 2011b, 7). The participants can see the pattern of the completed knot in the printed material but they do not understand how the knot is made. "The path to understanding lay in the ability to grasp the knot, intuitively and by way of our bodies, as a composition of rhythmic movement. Only then could we find a way forward. The diagrams, in turn, only made sense when we looked back on what we had already done. Thus the argument from design explains too little because it does not account for the intuitive, inventive component of skilled practice." (Ingold 2011b, 7).

Our engagements with places (and we could add 'workplaces') are like knots, Ingold argues. The threads from which they are tied, "are lines of wayfaring" (Ingold 2011a, 149). These lines constitute a 'meshwork' Ingold argues – borrowing a phrase from Henri Lefebvre. In meshwork we learn intuitively to tie the knots of everyday activities. Following Bunn (as Ingold does):

We may see the pattern in our mind's eye, but we do it, we know it, we embrace it through the movement of our bodies (Bunn 1999, 26).

14.4 Method and Methodologies

The method of fieldwork is a cornerstone in the anthropological paradigm of practice-based learning. Ideally we could argue, that all of the above perspectives of practice-based learning, also formed a cornerstone in the ethnographic methodology so important for anthropological theorizing. This is however not the case. The anthropological understanding of fieldwork has only slowly been connected with theories of practice-based learning.

The importance of fieldwork in itself constituted a paradigm-shift in anthropology, in the Kuhnian sense, from Malinowski and onwards, which in anthropology emerged out of a showdown with both ‘armchair’ ethnography and an anthropology of comparison, replacing them with the anthropologists armed with suitcases prepared for long stays aiming at understanding the natives point of view (Sanday 1979, 527).

This implies first of all a positioned and legitimate presence, which makes observations possible. The legitimate presence refers to the acknowledged position of an ethnographer in other people’s practiced everyday life. Positioned refer to the physical presence of the ethnographer in places which not only allow observation of other peoples practices but also include a social designation of what makes activities meaningful. Sometimes the legitimate position even allows the ethnographer to engage in the observed activities (see e.g. Hasse 2002, 2008). The legitimate presence of the ethnographer also implies the possibility to move around in order to get many different impressions of what kind of cultural structures and resources are implied in learning for instance at work. This holistic approach makes it possible to follow unexpected connections, which were not beforehand envisioned by the researcher. David Lancy not only studied the blacksmith as his forge, where grown-ups and children met to watch and gossip but also followed the children out in the field, where they played ‘blacksmith’ with sticks and stones. This gave unexpected insights into how being a blacksmith and childhood learning was connected. The anthropologists might even herself be allowed to participate in limited activities, but it is not a necessity to make a comprehensive analysis of how others learn in practice. The apprentices in Lave’s study at Happy Corner can be observed to become more and more skillful as they move through the different stages tied to the sowing of a jacket. And in their talk words and worlds of identities are changing. Likewise the practice of anthropology is itself moving as anthropologists learn from their ‘doings’ in the field and at the writing desk. Thus the discipline of anthropology is in many ways depending on the anthropologist being a kind of learning apprentice (Lave 2011). Culture is in this perspective most often learned without being taught. Just like children in many cultures around the world learn to grow up as cultural beings without any formal teaching (Lancy et al. 2010) anthropologists may learn about other people’s cultures through ‘ubiquitous’ learning. What is analysed as ‘culture’ could be seen as the result of the anthropologist/ethnographers practice-based learning processes. The concept of culture is today acknowledged as a category of thought rather than a bounded and tangible entity as it was in

the days when monographs discussed learning as cultural transmission. This has shifted the conception of the anthropological object. Holism found in anthropological analysis must be reinvented. Today anthropologists generally acknowledge that “[t]he whole studied or made manifest by anthropology is not a reifiable entity, but a space that embraces the process of knowledge production itself” (Hastrup and Hervik 1994, 2). This opens up for a new understanding of practice-based learning, which also includes the practice of ethnographic work as a kind of practice-based learning. The anthropologist as a learner is discussed in Lave’s book on the anthropologist as an apprentice in critical ethnographic practice (2011). If there is no ‘formal’ or ‘informal’ learning to be studied but only context-embedded situated activities (ibid., 145), where does that leave the researcher studying other people’s practice-based activities? Jean Lave opens up this discussion, but she does not close it with answers. Lave describes herself as an apprentice in critical ethnography – learning from her informants and her colleagues as well. What is then the difference in learning as a Vai apprentice engaged in cutting and sowing and learning as the observing anthropologists engaged in noting and writing? Why do groups of anthropologists emerging from San Diego or Palo Alto develop similar theories on learning, cognition and practice? Lave has elsewhere underlined that “[r]elational concepts of the social world should not be explored in isolation from conceptions of persons acting and interacting and their activities,” (Lave 1993, 5). These findings could be explored further from the perspective of the ethnographers’ practice-based learning.

14.5 The Next Anthropological Paradigm

This may also call for a new distinction between ‘anthropology’ and ‘ethnography’ – which is often explained as the distinction between the overarching anthropological theorizing and the ethnographic description (Ingold 2011, 231). The anthropological concept of practice-based learning has itself emerged in a continuous learning process drawing on all of the ethnographic studies of work, of apprenticeship, of schooling ‘home and abroad’, and children’s everyday learning as well as general learning theory. More work on practice-based learning is needed in anthropology just as we still need to explore the relations between the work of ethnographers and how their empirical studies and anthropological analysis may be connected to a concept of practice-based learning.

The anthropological contribution to the general field of workplace learning and practice-based learning at work has been twofold. Anthropologists have inspired fieldwork in local settings, where it is possible for a researcher to move among people doing and working in practice. Anthropological theory stemming from this kind of close-up ‘micro-studies’ have inspired theorizing about how people learn and learn to know in doings with each other and material artefacts. These influences are apparent in much work on practice-based learning, notably Billett (2004), Strati (2007), Gherardi et al. (2007), Gherardi (2000), Nicolini et al. (2003), Yanow

(2006), Orlikowski (2007), Czarniawska (2012) as well as cultural psychologists (e.g. Cole 1996; Sørensen 2009).

Not least Jean Lave's contributions and her underscoring of a focus of situated 'knowing' rather than the Cartesian abstracted 'knowledge' (1988, 175) has influenced the field of studies of practice-based learning at work.

Paradoxically this development has evolved together with an increasingly critical approach to how anthropology understands and develops its own methodology. One of the sharpest critics is professor emeritus from London School of Economics, Maurice Bloch, who claim that anthropology is "anecdotally at the ethnographic level, but at the theoretical level not systematically tested and simply left to float in never never land. This incoherent fragmentation, in any and every direction, so long as it will find favour with funding bodies and seems relevant to the concerns of the moment, makes the existence of anthropology departments as working units difficult to justify" (Bloch 2005, 2).

Though learning with material artefacts often plays a major role in many these studies, and everyday practice-based learning is often set up against the formal learning of schools, the main focus is not on material practices but on cognition and situated learning as a cultural and historical development. In the most practice-based areas of this line of research, cultural psychologists (like Michael Cole) often joined forces with the anthropologists (e.g. like Jean Lave or Dorothy Holland) using e.g. cultural historical Vygotsky-inspired theory as a bridge-builder (e.g. Holland and Cole 1995). Together these psychologists and anthropologists (as well as contributors from other disciplines) formed the field of cultural psychology (Jahoda 1982). In time this cross-field of cultural psychology/cognitive anthropology developed an anthropological interest in studying cognition in practice (e.g. D'Andrade 1995; Hutchins 1993; Strauss and Quinn 1994; Garro 2007). There are many scattered and important contributions to the development of the more coherent framework called for by Bloch. The theory of situated learning is so far the most connected and comprehensive, covering a major group of anthropologists who were working more or less together in California during the 1980s and 1990s, knowing and learning from each other in intricate and complex ways (Jean Lave, Julian Orr, Lucy Suchman, Ed Hutchins, Dorothy Holland to mention a few). Interestingly this group of American anthropologists have often taken a showdown with the cognitive sciences as a basis for developing their own theories. Equally interestingly the group of European anthropologists working on theories connected to practice-based learning appear even more scattered. Even though e.g. Ingold refers to e.g. Latour and Bateson (who is to be considered both 'American' and 'British' in this context) no coherent framework has been developed. What the European anthropologists share (if anything) seems to be a much more keen interest in practice-based learning in relation to materiality than in relation to cognition. Though there are notable exceptions (like Ed Hutchins and Lucy Suchman focussing on materiality and Maurice Bloch on cognition) no attempts have been made so far to seriously connect the theories of cultural models, discourse and practice-based learning with theories of material artefacts to combine these into a coherent theory of patterns of self-evident meaning

in activity. This might be the next important step in the development of the anthropological paradigm of practice-based learning.

How should we study practice based learning within the paradigm of anthropology? Following recent discussions within the field we might stand before a new paradigmatic shift. Not because fieldwork and participant observation is abandoned, but because we have to find new ways of explaining, what it is that ethnographers do.

Since 1970s it has been a dictum that the ethnographer *writes* (Geertz 1973, 19). This is how anthropology is made. This has called for a problematisation of the dichotomy in fieldwork between ‘participation’ and ‘observation’. As noted by Ingold, most anthropologists believe the ethnographer in the field *turns away* in order to write observations down – but this view on ethnography is much too limited. The real problem with ethnography “lies not in the alleged contradiction between participation and observation, which is a chimera, but in the disconnection of the art of description from observational practice”. (Ingold, 2011a, 224). Doing ethnography could be perceived as a learning practice in itself. In the ‘anthropology’ called for by Ingold the ethnographer is moving in the field, observing and describing by following the materials people work with, copying the gestures they make and drawing the lines in handwriting and drawing, which present their world to us – not as a coherent whole but as lines drawn.

Ethnographers do not claim to capture the world (which could be a workplace) they study in its totality. They are engaged in this world and as such carry it “*forward*, in real time, in concert with the movements of the worlding world, in an ever-unfolding relation between observant eyes, gesturing hands and their descriptive trace” (ibid., 225).

This is indeed a beautiful vision, which has a lot to offer to the field of workplace studies and practice-based learning. Ingold’s studies are intimate studies of learning how e.g. to tie the knot of the Turk’s head. When we span the whole landscape of the anthropological paradigm of practice-based learning some questions remain, however. What is implied in the theories of cultural models is that culture may be *found* (Quinn 2005). There are ‘default values’ to be filled out by the ethnographer, when people engage in knot-work. They are there in other peoples cultural models about self-evident doings. The visiting ethnographer is not a usual newcomer, but a learner who has to learn how to better understand what is so self-evident for the people visited. In this sense the knot-work is a puzzle. It is maybe only recognized as a puzzle by the ethnographer, but other newcomers may wonder as well why people do as they do in such self-evident ways. Something which cannot be seen with the naked eye is at stake. Something which may be learned when the ethnographer engages herself in a situated practice to learn. Engaged in this learning process we learn from actions and reactions from humans and non-humans. We use our senses as well as the material resources available to us and gradually learn to make connections and form our own new self-evident cultural models of what to expect in a workplace setting which become more and more familiar to us. This certainly might be done by doing what the other participants do. When we talk workplace studies this might be difficult, however. Not any new coming anthropologist is trusted with using a pair of scissors in order to cut up expensive cloth, nor

hammering iron without the appropriate skills. In some situations the ethnographers may be enrolled as an apprentice among other apprentices (Hasse 2008), but most often ethnographers will have to make do with observation and talking. It is a process of movement as well as of halts in which ethnography only gradually become with and not of the people studied. When we learn about their lives and work with materials, sensualities and social quibbles and victories we also learn about our own lives. In this sense anthropology is inherently comparative. Talk, materiality and sensuous movement together with an acknowledgement of just how difficult it is to practice ethnography may be the combined approach needed in a new anthropological paradigm of practice-based learning, which includes studies of work as well as a methodology for doing fieldwork.

Part III

Educational Institutions and Systems

This part comprises contributions identifying the purposes and processes (i.e. curriculum and pedagogy) used by educational institutions to initially prepare professional practitioners and then maintain their competence across working lives. So, included here are selected accounts of the way educational systems have been organised and enacted to secure professional learning outcomes and what kinds of conceptions of curriculum and curriculum practices are utilised in securing effective professional capacities through educational institutions and systems. In his chapter – *Professional education between school and practice settings: The German dual system as an example* (Chap. 15) – , Peter Sloane provides analysis of the German dual system as a means of securing co-operation between and support for learning across school and practice settings and in doing so identifies key lessons for professional education. Emphasising the three elements of the didactic, organisational and governance factors, he elaborates an explanatory scheme comprising both vertical and horizontal dimensions of cooperation. He holds that, given the incommensurable environments that comprise these two settings, and their distinct rationales, that issues associated with reconciling organisation and governance imperatives, and are central concern for didactical issues within these reconciliations is central to how this functioning cooperation is an active and sustained. It is these factors and principles informing this cooperation which he holds have specific implications for professional education. Focusing on the same set of educational practices, in their paper – *The dual system of vocational education and training in Germany: What can be learnt about education for (other) professions* (Chap. 16) – Bärbel Fürstenau, Matthias Pilz and Philipp Gonon offer an account of how this education system has transformed over time in response to changes to stakeholders' needs and circumstances of its enactment. Changing concerns about the cost to enterprises of this system of education, and how its utility for those enterprises can be sustained are discussed, as is the ongoing concerns about the parity of standing between not only general and vocational education, but across different kinds of occupations. In this way, the central concern of this system about the integration of work and learning is set amongst sets of concerns which are both highly situated, but also embrace

broader societal concerns about educational worth. Madeleine Abrandt Dahlgren, Tone Dyrdal Solbrekke, Berit Karseth, and Sofia Nyström also address issues associated with relations between the provision of education and the practice of the occupation. In their chapter – *From university to professional practice: Students as journeymen between cultures of education and work* (Chap. 17) – they identify some consequences of the different ways that professional education is organised and enacted in terms of professional identity formation and professional responsibilities. A key focus for this chapter is the ways educational system provides a pathway for students as they transition from being students to practitioners, through a process of negotiating two distinct cultures: education and work. These transitions are held to be set within and enmeshed within these two distinct sets of cultural practices. In this way, this chapter explores the different level the relations between those participating in educational systems and what those systems afford.

This theme of providing and integrating experiences across educational and practice settings is also the explicit focus of Stephen Billett and Sarojni Choy's chapter – *Integrating professional learning experiences across university and practice settings* (Chap. 18). Given the concerns about the integration of the two sets of experiences in contemporary tertiary and higher education this contributions seeks to identify what are the premises for providing experiences in both settings and seeking to integrate and reconcile them to make more effective the provision of professional education. Drawing upon conceptions from socio-cultural perspectives and curriculum theory, this chapter seeks to offer curriculum and pedagogies premises for ordering and enacting experiences that will intentionally promote the reconciliation of experiences students have in both settings as directed towards a more effective utilisation of those experiences and rich learning outcomes. Effective transitions from professional education are also the focus of Päivi Tynjälä and Jennifer Newton's chapter entitled – *Transitions to working life: Securing professional competence* (Chap. 19). Quite specifically, they identify a series of challenges that graduates report confronting in the early stages of their careers and which positions these transitions as being able to negotiate (successfully) these challenges. Focusing on the challenges associated with being able to secure employment, the adequacy of their knowledge and skills, their efficiency and ability to manage stressful work lives and the formation of professional identity set within working contexts that can be characterised by high attrition rates and transforming occupational practices, this chapter elaborates all of these within a consideration of professional competence. These challenges are illustrated by drawing upon experiences of student nurses' transitions into working within health care settings which illustrate these challenges and the means by which they stand to be negotiated a process which constitutes these transitions.

One of the key goals for individual and workplace professional practice is for greater interprofessional working. This then has become a key focus for education and in particular an emphasis on interprofessional education. In that chapter, Elizabeth Molloy, Louise Greenstock, Patrick Fiddes, Catriona Fraser and Peter Brooks elaborate the issues associated with – *Interprofessional education in the health workplace*

(Chap. 20). Using medical students' experiences of interprofessional working within clinical settings, this chapter identifies the ways in which practice factors and the standing and agency of medical students although key factors in interprofessional working and learning, often inhibited the potential of these experiences and potential for effective and long-term interprofessional working. Faced with new challenges as student and novice doctors, goals for interprofessional education were soon displaced by others associated with professional concerns and development as they exercise what they might describe as necessary resistance. In all, the evidence suggests that easy optimism about the efficacy of interprofessional education leading to more effective cross disciplinary and occupational working through such means may well be misplaced.

Staying within health care, Tim Dornan and Pim W. Teunissen chapter entitled – *Medical education* (Chap. 21) – again examines experiences in practice settings as a means of educating the next generation of doctors, including their motivations as well as the limitations of an overly technically focused medical education curriculum. The authors note that the conceptual bases for understanding medical education processes are now expanding and maturing. They use these bases to understand the identity development of new doctors and offer models (i.e. Professionals learning within practice and the boundaries of practice) about the pathways and transitions towards these nascent doctors formation of a stable occupational identity. Aligning a view about educational systems with the needs of those participating in them is central to the chapter entitled – *A phenomenographic way of seeing and developing professional learning* (Chap. 22) – by Ming Fai Pang. As this title implies, he adopts an orientation focused on the way in which professional learning is experienced by workers and students and how they come to know and respond to particular situations and settings. While focusing upon the experiencing and sense making of the learners, from this account and orientation, comes the suggestion about the ways in which particular sets of experiences might be engage with and have particular consequences for students as learners. That is, the ordering of experiences and their consequences for these learners. Curriculum and instructional considerations and consequences are elaborated in this chapter with a particular focus on the development of teachers' professional capacities.

Finally, in this part on education systems, Monika Nerland and Karen Jensen refer explicitly to the knowledge cultures that exist within particular kinds of social practice and professionals learning in education and work settings. Their chapter, entitled – *Changing cultures of knowledge and professional learning* (Chap. 23) – focuses on particular kinds of epistemic objects and practices (including educational systems) and how these contribute to professional learning. The central concern here is developing 'epistemic fluency' – how learners can come to know and engage epistemologically to initially learn professional practice and then to further develop it through engagement in practice. In all, the analysis here is offered of the way in which knowledge cultures afford opportunities for learning in particular ways and how a broad understanding of these cultures can assist the provision of and engagement experiences associated with professional learning.

Chapter 15

Professional Education Between School and Practice Settings: The German Dual System as an Example

Peter F.E. Sloane

Abstract This chapter uses the case of the dual system in Germany to derive general and exemplary conclusions for co-operation between school and practice settings in professional education. It can be shown that co-operation between two learning settings as unequal as enterprises and schools does not come by default. It needs to be organized taking into account didactical, organisational and governance dimensions. The dual system is used to illustrate how these dimensions impact vertical and horizontal co-operation on four distinguishable action levels: macro-, exo-, meso- and micro-level. Characterising schools and enterprises as incommensurable living environments is then used to shape the requirements for didactical designs, which leverage the fact that learners in the dual system cross the borders between these settings regularly. Here it is pointed out that each setting is constituted by distinct rationalities and both have a theoretical and practical dimension. If co-operation is still to be fostered, school and enterprise actors need to find a 'higher standard', which can be used to design sequences of instructions in the alternating settings. Therefore the learners perspective is to be considered. Finally a ladder-model of co-operation in vocational education and training is employed to systematise best practices for co-operation between school and practice settings.

15.1 Introduction

Professional Education takes place at different settings. In this chapter vocational education and training (VET) in Germany is taken as an example to elaborate the potential and problems that occur when different settings are to be linked, because learners cross the borders between these settings. These considerations are of particular relevance when learning at schools and enterprises is at stake.

15.1.1 Starting Points: Learning in Different Environments

With an open-minded view of the world, what would we see if we looked at different learning arrangements in schools and enterprises? Let us imagine that vocational education is fostered in schools and enterprises. Teachers would instruct students and trainers would work together with employees. There would be a typical classroom, on the one hand, and a working environment on the other. Maybe we would recognise differences in the ways students and teachers interact, compared with trainers and employees. And possibly we would have the impression that enterprises are real-life settings and schools are preparing students for this real life.

However, at the latest at this point we have to acknowledge the assumptions we have made: Depicting an enterprise as a real-life setting where learning goes on is such a theoretical assumption, as well as the idea that schools and enterprises do something called vocational education. And, of course, we can try out different lenses to point out specific characteristics, but also similarities, of these two learning environments.

In an initial step we can define four layers to describe these two learning environments:

- 1st We can look at the *micro-level* of schools and enterprises. This means that we can compare the teaching and learning arrangement (class-room-setting) of schools with the working arrangement (job-setting) of enterprises. This leads to questions according to the learning approaches and the instructional designs in these different environments. At this level we see vocational education as a *learning approach* and an *instructional design*.
- 2nd We can analyse the different organisational structures of schools and enterprises looking for regulations, incentive systems, objectives, and so on, which, to a certain extent, regulate the possibilities to learn. This is called the *meso-level*. This is the *organisational setting* of vocational education.
- 3rd Schools and enterprises are not situated in neutral zones. They are always part of social life and are embedded in a network of regulations. In the school sector these are school authorities, normally a national administration system. The regulations for enterprises differ between countries. We have market-driven systems where enterprises primarily have to cope with the market and can

decide freely what they want to do with regard to learning. They mostly follow a market rationale. But there are also countries such as Germany, Switzerland, Austria and the Scandinavian countries where there are certain regulations for teaching and learning in enterprises. Therefore, we have to separate an *exo-level* which frames the learning and teaching activities in schools and enterprises. Vocational education is seen as an *institutional system*.

4th Finally, we can state that the administration (macro-level) is the result of political decisions in each country. This *macro-level* refers to the governance approach and is the institutional background of education. Vocational education follows a *governance approach*.

The differentiation of vocational education into these four layers: micro-level, meso-level, exo-level, macro-level was introduced by Uri Bronfenbrenner (cf. 1979). It makes it possible to separate different acting levels and show the interdependencies between the levels. There is some kind of *vertical co-ordination* between the layers.

Nevertheless, we are looking at two different settings. On the one hand, there are schools with their school organisation, embedded in an institutional system based on national agreements about what has to be taught, and by whom in school. On the other hand, there are enterprises that also carry out vocational education, based on the already mentioned market rationale and with the aim of achieving economic advantages through this work. Furthermore, there are differences in the institutional background, the organisational settings and, finally, of course in the different instructional approaches. This would be an interesting task in itself. However, it becomes more sophisticated when we take another perspective and look at students and workers who move between schools and enterprises. In other words, we do not look at the structure of both school and enterprise and work out differences and similarities. Instead in this chapter, we look at individual careers and ask what kind of changes happen if someone learns in schools as well as in enterprises.

These changes between the two so-called *learning places* can happen in different ways:

- It can be a biographical experience: a student enters work after finishing schooling, and continues learning in the enterprise.
- It can be part of a programme in vocational education and training. Here, there are three possible approaches (cf. Greinert 2004, 20 ff.):
 - It is a school-driven programme with phases of practical experience. This would be typical for vocational colleges in, for example, France or Finland. In the following this is defined as the *school-based approach*.
 - It is an enterprise-driven programme with seminars and workshops organised for the trainees. This is typical for big enterprises. In the UK this kind of programme is run by Rolls Royce. It is called the *enterprise-based approach*.
 - It could be a co-operative programme from enterprises and schools. This is the German *dual approach*, called the dual system (cf. also Raggatt 1988 and Deissinger and Hellwig 2005, 312 f.).

Action Layer	Acting Context (Field)	Learning Places	
		School	Enterprise
Macro-Level	Policy	Governance	
Exo-Level	Administration	National authorities	Market/Chamber ¹
Meso-Level	Organisation	School	Enterprise
Micro-Level	Working/Learning	Classroom	Working place
<i>Horizontal Co-Operation</i>			

Fig. 15.1 Vocational Education (VET) as an ecological system

If we look at the object ‘vocational education and training’ from the perspective of the learner who moves through different learning arrangements than we can ask the following questions on professional education:¹

- 1st Can school-based and work-based learning be linked together? This is a matter of co-operation between teachers at schools and trainers at enterprises. The concrete co-operation depends on the specific circumstances of each learning place and the co-operation needs. These depend on the sort of programme. There are different needs according to whether it is school- based, enterprise-based or has a dual approach.
- 2nd As the learning is embedded in different learning places can there be pathways between these different places? Can these pathways be built up? In other words: How is the co-operation between school and enterprise as specific social organisations organised?
- 3rd As schools and enterprises follow different regulations (institutions) it is necessary to compare the institutional background of the learning places and look for connections between these requirements. If the movement between school and enterprise is institutionalised in a dual programme it is mandatory to develop new regulations. In social systems where dual approaches are already established these regulations already exist.

Considering this necessary horizontal co-operation the BRONFENBRENNER model has to be further developed to become a bilateral co-operation approach. Therefore the four different layers – micro-, meso-, exo- and macro-level – are not only linked to a corresponding field of action – such as working/learning, organisation, administration and policy – but are also distinguished for both learning places. Here the learning places ‘school’ and ‘enterprise’ are further explored, by specifying each layer separately. In addition to that vertical and horizontal dimensions of co-operation need to be considered (see Fig. 15.1). How this complex framework will be developed throughout this chapter is described in the following Section.

¹As is shown later on, VET in enterprises can also have a specific administration. It is, for example, part of the German governance approach to regulate VET in enterprises. The chambers have the function of public authorities in regulating the education work going on in enterprises.

15.1.2 Vertical and Horizontal Co-operation in Vocational Education and Training

To develop a framework for co-operation on different levels, I will discuss the vertical and horizontal co-operation, which occurs when a systematic connection between schools and enterprises is established. This will be discussed on the basis of the German dual system, which is taken as a case study to illustrate the complex nexus of highly specific individual aspects. Such single objects are: the instructional approach in enterprises, the syllabus types in the school and in the enterprise sector, the incentives in school and in enterprises, the organisation of work in enterprises, the school organisation, the profession of teachers and trainers and so on. Research has been undertaken in each of these aspects and of course into many objects not mentioned here. The point of view in this paper is the question of how these single aspects work together in the complex world of vocational education.

The German dual system is the broadest approach. It covers the school approach and the enterprise approach to a certain extent. Thus, these sub-approaches can be illustrated in the case of the dual system as special applications.

In this contribution, the German dual system will be examined as a case for a co-operative training programme where schools and enterprises work together in joint programmes on vocational education and training. Therefore, the background of the so-called dual system will be summarised and the kind of co-operation established in this system will be detailed (Sect. 15.2). After that the theoretical approaches towards co-operation will be discussed (Sect. 15.3).

15.2 The Case: The German Dual System

In Germany, initial vocational training is organised into three different pillars: (1) the so-called dual system, in which enterprises and schools run a co-operative programme, (2) school-based VET, which is of relevance to the health sector, music and education and (3) the so-called transition system, which consists of various disjointed educational provisions aimed at providing pathways into one of the first two pillars of VET or into the labour market. Despite its shrinking quantitative scope, the dual system still receives the most attention and can be seen as the centrepiece of VET in Germany. Even though it is not the exclusive vocational track, it represents what makes VET in Germany special. One of the particular features is the corporative structure, on which the dual system is based. The basic concepts of this structure are the focus of the following Sect. (15.2.1). In addition to that complementary dimensions of co-operation within this structure are discussed later on (Sect. 15.2.2).

15.2.1 *The Basic Structure of the Dual System*

At first sight, (see Sect. 15.1) the two learning places of school and enterprise are working together, educating young people. This necessarily establishes co-operation, but only in an organisational meaning of building an agenda for the learners to inform them when they are at school and when they are at work. Behind this agenda lies an institutional framework. Schools have to implement a syllabus which, in Germany, is formally established by a Regulation of the Government of a Federal State, for example, Lower Saxony. This is based on the cultural autonomy of the German *Länder* (the federal states) which is based on German Constitutional Law. The result could be 16 different syllabi. The comparability of these state regulations is therefore organised by a supra-regional organisation: the so-called standing conference of the *Ministries for Culture*. There are also regulations regarding the part of the programme which is run by an enterprise. These *training regulations* (*Ausbildungsordnung*) are a centralised Regulation of the federal Government and not of a regional government of one of the *Länder*. Trade unions and employers' organisations together work out the aims, content and organisational framework of the enterprise part of the training programme and develop training *regulations*. This is then legalised by decree of the Federal Government. In summary it can be noted that behind the joint VET-programme of enterprises and schools lies a sophisticated regulation system which, in Germany, depends on regional syllabi for schools and a federal syllabus for enterprises. The programme is a hybrid of compulsory education (the school part) and a private contract (the enterprise part).

As a consequence of this, different stakeholders influence the organisational and curricular framework of the programmes. They are located in an area of tension characterised by educational and economic aims. Thus vocational education claims to foster a twofold development of skills and personality.

Generally speaking, three underlying, independent concepts constitute the field (cf. Kutscha 2000, 5 ff.): (1) the concept of duality, (2) the concept of corporatism and (3) the concept of vocational education (*Beruf*).

These concepts are now discussed in more detail in the following Subsections.

15.2.1.1 **The Concept of Duality**

An apprenticeship in Germany runs on average for between 3 and 3½ years. It consists of two basic parts: (1) Training on-the-job in enterprises and (2) school-based learning in vocational colleges. Trainees spend about 3 or 4 days a week on in-company training and up to 2 days a week at vocational colleges.

Learning processes in training companies focus on learning at the workplace or instruction in company training departments with an emphasis on the practical elements of the training occupation. The vocational college provides general and vocational education for students in one specific vocational field. These students usually have their on-the-job training in different companies within the commuter belt of the school.

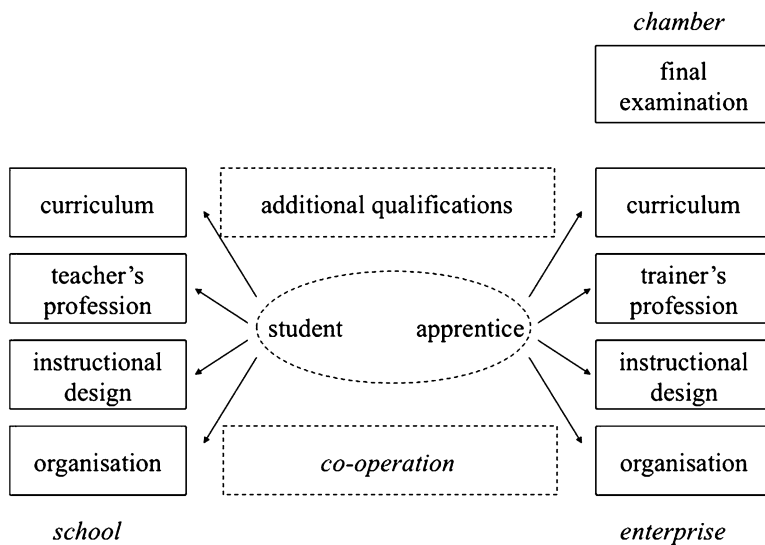

Fig. 15.2 The structure of the dual system

Whereas federal law regulates the former, the latter falls, as already mentioned, under the legislation of the regional Government. Harmonisation processes are in place to integrate both parts of the training and to ensure the comparability of the provision in the 16 *Länder*. The term 'dual' refers primarily to the division of training into two separate learning places, each regulated by its own distinct legislators.

However, the principle of duality goes beyond the division of training into two training venues. The duality of the structure is also reflected in systematic features such as the role and status of training personnel, the funding regime and the supervision of training processes (cf. Ertl 2002; Sloane et al. 2004). That means the attribute of duality goes beyond merely the location of learning. Even teaching and learning processes are shaped by duality, what will be discussed in more detail later (see Sect. 15.2.1.4 and Fig. 15.2).

15.2.1.2 The Concept of Corporatism

The term corporatism describes an institutionalised form of collaboration between governmental bodies, employers' associations, trade unions and other collective actors. This form of policy making is of particular importance to labour-related decisions including collective bargaining and vocational training in Germany (cf. Voelzkow 2009, 461). The negative connotation of this is legalised lobbying. The reverse interpretation is corporatism as a form of participation leading to broad consensus among social groups and greater social stability (cf. Sloane et al. 2004, 218). The dual system is a typical example of this type of governance and therefore, in terms of its regulative structure, may be best described as a state-controlled

market model or Rhineland capitalism (cf. Greinert 2004, Sect. 15.2). Characteristic of this form of capitalism is a state that sets the guidelines for the co-operation of employers and trade unions. Within these guidelines social actors make their own choices. This model is regarded as an efficient way of limiting the risks of ‘market failure’, on the one hand, and ‘state failure’, on the other (cf. Kutscha 1995, 10).

Another important feature in this model is the delegation of regulatory competence for the training system from the government to corporatist bodies. The most important of these bodies are the local, self-governing Chambers of Industry and Commerce, the Crafts Chambers, the Chambers of Agriculture and the Associations of Professions. They have the status of ‘competent bodies’ (*Zuständige Stellen*) and play a crucial role in the organisation, administration and examination of vocational training. More precisely, these bodies act as intermediate organisations between the state and companies and put training laws and regulations into practice. The Chambers have the status of public autonomous agencies that oversee the legal and regulatory norms of vocational education and training within their sphere of responsibility according to the legal guidelines set by the state.

Following the ‘principle of voluntariness’, no employer is obliged to take on trainees. Legally the trainee contract affiliates to private law. However, all firms have to register with a Chamber and those wishing to provide training must be approved by the Chamber as a training company. The approval depends on the equipment and resources of the company, and the qualifications and experience of the trainers working for the company. Furthermore, the local Chamber supervises the organisation and assessment of intermediate and final examinations and acts as an awarding body for vocational qualifications.

Trainees in Germany have a training contract with an enterprise and they have to attend the vocational school, unless they are older than 18 when signing the training contract. In that case they are allowed not to attend school. However, this hardly ever happens, because the shared responsibility of schools and enterprises for vocational education in the dual system is a deeply institutionalised pattern of thought and action that does not require tighter legislation. Having a contract does not mean that the two partners, i.e. the trainee and the enterprise, are allowed to develop their own training programmes. The structure of the training programme is regulated by regional (*Länder*) and federal (*Bund*) laws.

A further example reflecting the principle of corporatism in the training sector is the composition of regulating and executive bodies of the dual system. For instance, supervising and examining bodies are set up by the Chambers and consist of equal numbers of employers’ representatives, employees’ representatives and vocational college teachers. The most important of these bodies at the executive level of the training system are the vocational training committee and the board of examiners.

15.2.1.3 The Concept of Vocational Education (*Berufskonzept*)

The German term *Beruf* can be regarded as broadly untranslatable. Given its original formative context, ‘*Beruf*’ carries the meaning of ‘calling’. After its application

to the world of work in the age of industrialisation, a change of meaning took place. Nowadays neither 'vocation', nor 'profession' is congruent with the German term, but the former is used here because the latter is too closely bound to academic occupations. The idea of vocational education is the already mentioned twofold idea of developing skills and being educated. From this point of view, vocational education and training aims to develop competences and competencies.

Competency refers here to specific capabilities (skills, attitudes) which are useful for the challenges of the workplace. Competence has a generic and holistic meaning referring to a person's capacity, and has a more educational perspective (cf. Eraut 1994, 179). Therefore, vocational education and training in the German tradition is a concept of 'education in and through work'. The individual personality is indeed influenced by working. The concept of vocational education identifies the individual's capability to work and act competently in a vocational environment as the overarching aim of vocational education and training.

Education as part of the learner's personal development has been a constant feature of vocational education in Germany. Further, this concept reflects the need to prepare young people not only for a small number of specific tasks at one company, but to provide a qualification applicable to many employment contexts and responsive to the changing economic and social environments of a whole occupational field. Facilitating a student's personal development is, in most countries, a function of the higher education system. In Germany, this kind of development is also seen as an integral part of vocational education.

15.2.1.4 Didactic View on the Dual Training Approach

The dual system is not only seen as an economic vehicle providing a pathway from school into qualified employment, but also as a didactic approach carried by several social actors. Therefore it is quite useful to describe vocational education and training from a didactic point of view.

In the case of vocational education and training, the German concept of didactics integrates different aspects into one holistic approach²: (1) the organisation (regime) of education, (2) the instructional design, (3) the intentions and the curriculum (syllabus, basic assumptions, main tasks and so on.) of teaching and learning, (4) teachers resp. trainers and (5) learners as subjects of the learning process. Learners in the dual system hold multiple roles: students at a vocational school and apprentice at an enterprise. It is important to note that these aspects are interdependent elements. By further conceptualising them, innovation processes within the dual system can be explained. Furthermore the duality mode of the system becomes visible again. Each of the didactical aspects can be worked out school-based and enterprise-based. In addition to these basic elements also (6) additional qualifications and

²*Didactic* is not an approach just referring to vocational education and training. It is a general mindset for learning and teaching perspectives in various socio-economic living environments as well as the aims of these processes and mechanisms to regulate instructions.

(7) final examinations are discussed in more detail. All of these didactical aspects respective institutional elements also reflect the core topic of this chapter: the need for vertical and horizontal co-operation on different levels. Figure 15.2 offers an illustration of all these elements.

In the following all these illustrated elements are specified:

(1) *Organisation*

Vocational colleges and enterprises are educational *organisations* within an institutionalised field. In economic theory, *institutions* were defined as humanly devised formal and informal rules that shape human interaction (cf. e.g. North 1990, 3–5). The terms ‘institutions’ and ‘organisations’ can therefore not be equalised. Organisations are social entities that establish boundaries to determine members and non-members, whereas institutions may be the cause of an organisation, define the relationships of the organisation with other social actors and establish a basic set of rules for the interaction within the organisation that is shaped by the organisational/corporate culture. Thereby institutions determine the way in which work challenges enter teaching and training contexts. As we have seen, the principle of corporatism is at the heart of the institutional framework of the German training system and provides the social partners with a high degree of influence. Schools and training institutions interpret the guidelines set out by the authorities and social partners and decide on the ways in which they react to the changing challenges from the world of work. As will be shown below, educational organisations can be part of variable living environments, which are, among other things, established by distinct causes. Schools are established for educational purposes and enterprises for maximising profit. However, within the German VET system, beyond maximising profit, enterprises also fulfill an educational purpose.

(2) *Instructional designs*

Instructions are not only techniques and methods teachers and trainers use to enhance the trainees’ learning processes. Instead, the *instructional design* is a complete learning and teaching approach referring to learning theories and cognitive strategies of learners, on one hand, and the intervention strategies of teachers and trainers on the other. These approaches are worked out in rather sophisticated programmes such as case studies, projects, research-based learning and problem-based learning.

Education of those, who do this work and research on this type of VET is performed by university units for Business Education. Further research is done by public and private funded research institutes. Whereby two different styles of research can be distinguished: a psychology-based empirical program, which focus on testing instructions in a stable context and on verifying competence levels (cf. e.g. Achtenhagen and John 1992) on the one hand and a design-based research program, which focus on the development of prototypes for specific contexts together with field actors on the other hand (Euler and Sloane 1998). Considering the context of applying didactical theory is of importance also, because quantitative empirical test designs show that the variance of instructions in different settings, which were all

designed based on a generic didactical concept may be larger, than the mean variance of instructions in a number of test settings based on alternative didactical concepts (cf. Euler 2011, 529). This can be explained by the “quality” with which didactical instructions are developed and used (cf. Nickolaus 2010, 57). Based on that, Achtenhagen and John (1992) argue that there is consensus among experts that complex learning-teaching-arrangements are a concept that attempts to respond to wider social and economic megatrends within the field of vocational education and training.

(3) *Curricula*

Curricula set the standard for the knowledge and skills regarded as relevant by the institutional actors and enterprises and schools have their own forms of them. Curricula include documents such as training plans and lesson plans. There are different ways to formulate the challenges of the world of work in curricula: they might be outcome-oriented (describing the tasks trainees should be able to perform) or input-oriented (describing the way in which the training processes should be conducted). In Germany, curricula were traditionally expressed in terms of inputs such as teachers’ and trainers’ qualifications, class contact hours and training contents (Koch and Reuling 1998). However, the last one and a half decades have seen a sweeping shift towards outcome-oriented curricula. In this shift ‘learning areas’³ for the schooling part were introduced and a large number of enterprise-related curricula were rewritten. For the years 1996–2012 that applies to more than 300 curricula for enterprise-based VET (*training regulations*) and more than 250 curricula for school-based VET (cf. KMK 2013). Usually the processes for the development of enterprise- and school-based curricula referring to the same qualification are synchronized. Nevertheless, the curricula of schools and enterprises remain in distinct legislative regimes, which influences the transfer processes between the world of work and the school-based training contexts. Furthermore during the shift to learning outcome also new curricular formats were introduced such as educational standards (cf. Ertl 2006) and qualifications frameworks (cf. Sloane 2008).

Returning to the case of the dual system, a situation with only loosely-coupled curricula, it can be argued from a more theoretical perspective, that increased opportunities for learners to integrate their developing academic and work knowledge have to be provided, as they develop their learning/work identities through repeated episodes of ‘boundary crossing’ between school and work (Griffiths and Guile 2001). The type of curricular options available to link these worlds will be discussed later on in this paper (Sects. 15.3.3, 15.3.4, and 15.3.5).

(4) *The teachers’ and trainers’ profession*

Pedagogic staff in schools and enterprises are characterised by distinct recruiting and education processes. While teachers receive their education at universities and develop a pedagogical self-image, trainers are promoted within the company after

³For more on curricula based on *learning areas*, see Sect. 15.3.4.

professional experience. Their pedagogical qualifications are often quite limited, even though a relatively weak legal minimum standard is in place (*German Trainer Qualifications Act*, AEVO). To this end, teachers and trainers translate the contents and aims set out in their respective curricula into teaching and learning situations on a day-to-day basis. In addition, they are sometimes part of the institutional framework, since they assume roles in school administration and curricula commissions. The way in which they fulfil these functions depends on their qualifications and their interpretations of their professional role. The degree to which teachers have contact with the world of work varies; some of them might consider this contact as less important than pedagogical skills and knowledge.

(5) *The Learners: students and apprentices*

Learners in the dual system are integrated into two different learning places. As has been said before they are working up to 4 days a week at their respective enterprise and up to 2 days a week they go to school. The roles and expectations in these two roles differ a lot. At their enterprises the learners are also expected to contribute to the value adding process. Especially small handicraft enterprises depend on the work of apprentices, who receive compensation in form of collectively negotiated wages below the level of skilled workers or employees. When theories, values or practices taught at school and enterprises are not consistent with one another, learners have to decide to which concepts they align their actions. More often than not the enterprise side proves to have the greater power of persuasion. However the theoretical knowledge that is offered at school is usual considered crucial to pass the exam for the enterprise-part of the qualification. This exam is owned by enterprise representatives, but includes so called practical and theoretical parts (for more on theory and practice see Sect. 15.3.1).

(6) *Additional Qualifications*

Additional Qualifications are supplementary programmes to the institutionalized and closed vocational profiles, for example courses in entrepreneurship, intercultural communication, foreign languages and so on. These are offered by schools and enterprise organisations (cf. Braukmann and Sloane 1997). They are outside the formal regulations and are seen as a possibility to individualise the apprenticeship programme and offer further flexibility. They are often established on the basis of Chamber provision. In a study of about 6,000 apprentices 65 % say it is important or very important for them to gain additional qualifications (Gei and Stertz 2010, 3). This reflects the need for individualizing the standardised profiles of the dual system.

(7) *Final examinations*

The regulation of the *final examinations* for the dual system is completely controlled by the enterprises. *De jure* the schools have their own examinations, which are *de facto* of minor relevance. The most significant final examination should reflect the instructional design, on the one hand, and the curriculum on the other. In this case it would be possible to evaluate how well the training programmes

work. However, in fact there is a huge distinction between the work in the enterprises and vocational colleges and the examination bodies (chambers, collectively representing enterprises). This predetermines the pedagogical work in the training programmes. The final examination has the quality of a *'hidden curriculum'* because the teachers often have to organise their work referring to the examination structure of the enterprises in the dual system and not referring to the basic syllabus of the schools. Ongoing research on this type of examinations shows that the intended competence profiles may not be validated by the exercises currently used. For example it can be shown that domain-specific and cross-domain knowledge is not tested separately, thereby allowing apprentices with prior experience advantages in the test design that go beyond their actual (latent) knowledge (cf. Winther 2011). Regardless of these challenges, the final examinations for a vocational profile within the dual system proves to be of great quantitative importance. About 750,000 apprentices pass their vocational exams each year compared to just about 360,000 graduates of higher education institutions (cf. Destatis 2012, 82).

Having considered these seven elements of the dual system, which also specify fundamental differences between the learning settings, it is now necessary to consider in the next section how co-operation between enterprises and schools may still get in place.

15.2.2 The Co-operation Between Enterprises and Schools

The co-operation between the distinct learning places 'enterprise' and 'school' might be considered to be the centerpiece of the dual system. However, as shown earlier, separate forms of legislation, curricula for job-based-learning and colleges as well as a disparate institutional logic emphasise the separation of both settings, rather than the dual sides of a shared learning process or objective. To show how the co-operation between both learning places can be organised, the current state shall be discussed.

Co-operation between enterprises and schools within the dual system addresses, on the one hand, the didactical quality of learning and teaching and, on the other hand, institutional questions. Institutional questions are relevant when it comes to the organisational infrastructure and co-determination in political decision-making.

Institutional order and didactical-organisational implementation are two sides of the same coin that represents co-operation:

- the didactical dimension of the dual system: the combination of generalised (systematic) learning arrangements in schools and case-based learning in enterprises. The didactical perspective considers the matching of both forms of learning and/or teaching;
- the institutional dimension of the dual system: this includes the political organisation of the participation network of governmental bodies, trade unions and employers' representatives regulating the dual system. This neo-corporatistic

governance system applies explicitly to the enterprises, but *de facto* also impacts on the schools. This institutional order leads to a further distinct German feature: the funding of apprenticeships predominantly by enterprises (totalling about 25 billion € per year, BIBB 2009, 229). However a further study reveals that average training costs per apprentice per year of 15,288.00 € are reduced by an average income per apprentice of 11,692.00 € to net costs of only 3,596.00 € (cf. BIBB 2009, 233). However the high stake of enterprises in the funding of the whole system is unchallenged.

When the importance of VET in Germany for the integration of a large share of a cohort into the labour market and for the economy is in question, both sides of the coin have to be considered. Even though the didactic dimension serves as the focal point of the discussion in this chapter, the institutional side remains complementary. This bilateral composition is already visible in the contractual form. Trainees are, through their trainee contract, which is a type of employment contract, part of the enterprise and thereby part of the economic system. Then again this economic system constitutes a complex learning environment for them, which the trainees unlock through an individual learning process. Furthermore, trainees have a second role as students in a vocational school, which is a part of the schooling or educational system.

Alternating roles, learning places and institutionalised systems raise the issue of relating educational and economic systems. School and enterprises are seen as sub-systems of these parent systems with distinct rationalities (cf. Stratenwerth 1959, 812; Pätzold 1997, 126 f.). In order to harmonise school-based and enterprise-based learning, a reference to a “higher standard” (cf. Euler 1999a, 6, translation by the current author; Euler 1999b, 249) must be established. A point of reference for such a higher standard can be the didactical design of transfer options, which are characteristic of a system in which two learning places are involved.

With regard to co-operation two different forms of alignment between schools and enterprises are possible:

- 1st The School precedes Enterprise
- 2nd The School follows the Enterprise

(1) School precedes Enterprise

This is, for the most part, the standard case in the dual system. In recent decades schools have had some kind of hidden leadership in organising the instructional design of the dual programmes. This becomes clearer when the training contracts are taken into consideration. In 2009 approximately 560,000 contracts for a training programme were concluded by 493,000 enterprises.⁴ These simple figures already show that enterprises participating in the programme have, on average, only one apprenticeship per year. The school part of these apprenticeships is organised by 8,800 schools.⁵ In the standard case in a school class for, for example, industrial

⁴Figures from: BIBB 2009, 111, 172.

⁵Figures from: DESTATIS 2012, 86.

clerks, 30 students study in one class and work in between 25 and 30 different enterprises.

This makes the schools and the teachers the hidden organisers of the programme. On a day-to-day basis teachers have to organise the co-operation with the enterprises.

This is often managed at an instructional level. Approaches are:

- Teachers present theories and concepts and give the students advice regarding how to experience them in the enterprise. This can, in some cases, cause problems if the enterprises perceive this as interference in their work. This is the process from knowing to doing.
- Teachers ask students, for example, to summarise this and develop some of the theoretical backgrounds of these examples. This approach, from doing to knowing, can also have certain difficulties as it is necessary that the students access practical experience in their enterprise work (for illustrations see Sect. 15.3.3 ff.).

These two examples already show that the co-operation can be regulated by two instruments: it can be established in the curricula of enterprises and schools to organise a convergence of practical experience and school-based learning. It can also be managed by some kind of collusion between trainers and teachers. In both cases we have to keep the figures in mind: 560,000 contracts: 30 students, 30 enterprises and one class with one or two teachers respectively. The discussion of this aspect of co-operation will be continued later (see Sect. 15.3.4).

2. School follows enterprise

This approach is typical of some in-house classes in large enterprises. In Germany firms such as Siemens have the possibility to make arrangements with single vocational schools. In these – in this case so-called – Siemens classes they can then have, of course, special arrangements with the school. This makes it possible to have problems and cases in the enterprise as a starting point for instructional arrangements. The learning starts in the enterprise and students are sent by their trainers in the enterprise to the school with the task to find relevant knowledge to solve the problem. Teachers at school are then in a position to offer theories and concepts for real-life problems. This is an ideal approach to de-contextualising practical problems, providing theoretical background and forcing students to contextualise this knowledge in the enterprise surrounding. In Sect. 15.3.3 this will be analysed more deeply.

This approach needs far more than reconciliation at the level of the curriculum or some kind of exchange of information between teachers and trainers. In this particular case trainers and teachers have to develop a joint approach. This is of course a far deeper co-operation (see Sect. 15.3.2 for various levels of co-operation).

In the light of the above assessment the following preliminary conclusion can be drawn: From a naïve perspective on vocational education the daily work on training and teaching in schools and enterprises can be seen as two different learning surroundings. The interesting question then is whether there are any systematic pathways between these learning places which the students or the apprentices, respectively, can take in order to develop useful competences.

This discussion leads to institutional, organisational and curricular backgrounds of vocational education. The above discussion shows these backgrounds for the German case. A rather complex system of rules and levels of co-operation has been illustrated. At the end, two rather naïve approaches, and deliberately so, have been stated: A pathway from school to enterprise and one from enterprise to school. In summary the normal case according to the real conditions of the majority of apprenticeships is an organisation of the co-operation between school and enterprises by the schools.

In the following section this naïve position will be theorised again through applying some exemplary research results to different aspects of this co-operation between schools and enterprises.

15.3 Theoretical Approaches Towards Co-operation in Vocational Education and Training (VET)

In this section the following theoretical issues associated with understanding and evaluating co-operation will be discussed:

- 1st Co-operation versus incommensurability of learning places
- 2nd The Ladder-Model of co-operation in VET
- 3rd ‘Running into practice’ – sophisticated approaches towards co-operation in VET
- 4th The ‘*Lernfeldkonzept*’ – realistic approaches towards co-operation in VET
- 5th Integrated apprenticeship – a visionary approach towards VET

Regarding the purpose of this chapter it is useful to note, that these conclusions from practices within the dual system in Germany, provide vantage points and pathways for the development of professional education.

15.3.1 Co-operation Versus Incommensurability⁶

Despite the vast potential for such distinctive didactical considerations, the logic of co-operation in the dual system is determined by the institutional order. This leads to routinised practices at the political and administrative level, where curricula are developed, whereas at the didactical level (i.e. learning places at schools and enterprises), co-operation remains random and casual. Therefore it falls to the trainees to connect the dots of fragmentary, inconsistent and unrelated experiences in enterprises and schools (cf. Euler 1999a, 13). Consequently, the didactical model of the dual system has to be challenged. The idea of a joint curriculum (*Gleichlauf-Curriculum*, cf.

⁶This subsection is based on the experiences in the research-programme WisLok which was founded by the Federal Minister for Research and Science (cf. HELP 2001; Dilger et al. 2001).

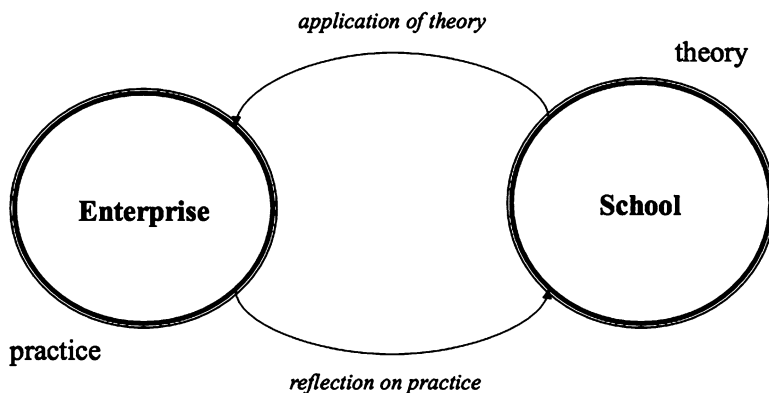

Fig. 15.3 Synchronization of theory and practice within the dual system – the traditional idea of joint curricula

Lipsmeier 1987, 57), which parallelises theory, provided by the school, and practice, provided by the enterprise, is considered obsolete (cf. Euler 1999a, 7; Kremer and Sloane 2001, 11 ff.; see Fig. 15.3).

Rather, theory and practice cannot be allocated to just one learning place, but must likewise be integrated in learning settings at both the enterprise and the school (cf. Kaiser 1994). This premise leads to schools creating space for practical experience (simulations, tutorials, junior firms, cases) and to enterprises providing theory (classrooms, e-learning tools). In fact, this not only happens at a conceptual level, but is also cognitive and tangible. Hence, the inherited theory-practice-model of the dual system is not viable any longer (cf. Kremer and Sloane 2001, 12; Tuomi-Gröhn and Engeström 2003).

Following this argumentation, designing transfer processes is not about allocating theory to schools and practice to enterprises and drawing on this ‘good’ matching of theory and practice. Instead the suggestion is made to see schools and enterprises as two incommensurable living environments, of which the matching has to be organised. Even though both living environments are constituted by distinct rationalities and institutional backgrounds, they each share a theory and a practice dimension (see Fig. 15.4). Linking theoretical knowledge and everyday experiences (cf. Pätzold 1997, 128) becomes a challenge within schools as well as within enterprises. In both living environments, the learners are confronted with distinct instructions, which demand actions consisting of both a theoretical and a practical perspective (cf. the findings at the symposium on ‘dual system caught between tradition and innovation’ in Twardy 1991). Thus, co-operation in professional education is not the matching of enterprise as the practical learning place and school as the theoretical learning place, but the matching of two distinct living environments, each deploying a practical and theoretical dimension. Both living environments provide distinct learning options. Therefore the suggestion is made to see co-operation as a combination of instructions in dual living environments which have to be organised taking into account the didactic and institutional dimensions.

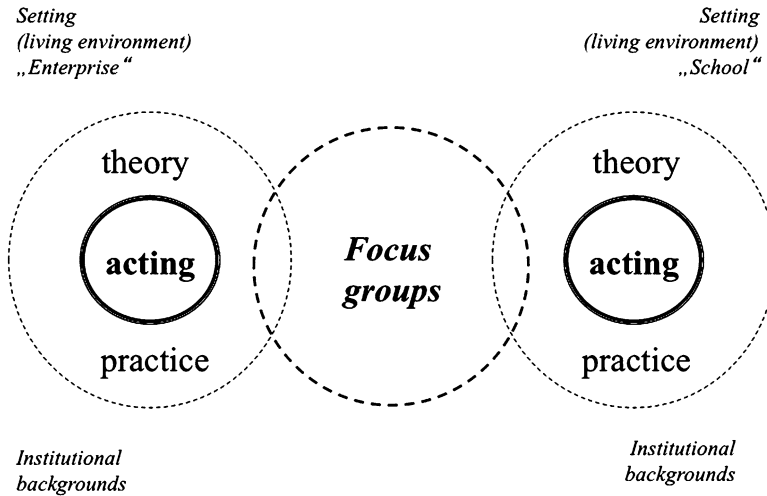

Fig. 15.4 The dual system as a matching process of distinct living environments

Furthermore, it is worth noting that the school carries out the lion's share of the organisational tasks within this co-operation. This specific form of task assignment is not formally codified anywhere and is in conflict with the formal statement of emancipated learning places. However, allocating the burden of managing two incommensurable living environments to the school is the result of routinised practices that have been going on for decades.

Even in a context where co-operation is needed, enterprises and schools sustain their own logic and institutionalised identities. Given this type of situation it is best to speak of co-operation in the dual system as loosely-coupled (cf. Weick 1976) entities.

15.3.2 *The Ladder-Model of Co-operation in VET*

In the discussion on co-operation the intensity of collaboration has been differentiated. Euler (1999a, 7) and Buschfeld and Euler (1993, 26ff) differentiate the intensity of co-operation according to mutual information, mutual matching and collaboration. Given that there is a basic demand for mutual information processes between the school and the enterprise, and given that co-operation is analysed in the context of the concept of learning areas (see Sect. 15.3.4), five levels can be distinguished: beyond merely informing one another, co-ordination, temporary co-operation, long-term co-operation and team-based partnership can be discerned (see Fig. 15.5). The continuum ranges from a relatively loose and unconnected co-existence to a didactic-based rehearsed collaboration. Scaling these different levels tends to be very difficult for the actors involved. Design-based research projects

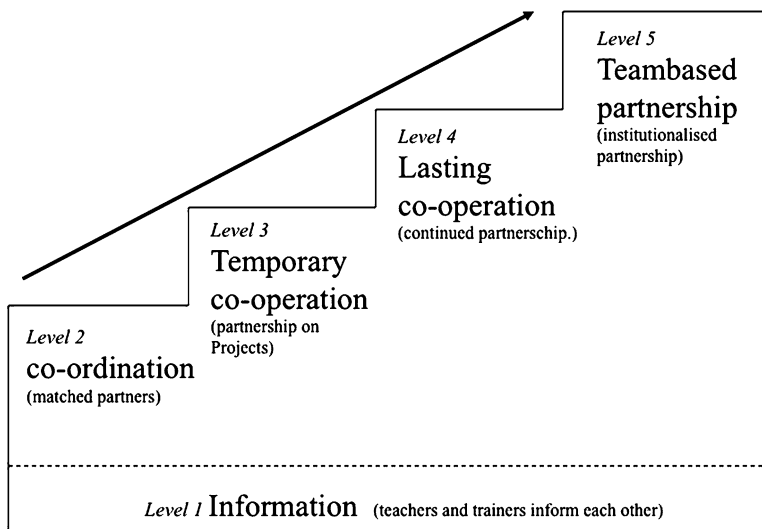

Fig. 15.5 Intensity of co-operation

show that a moderating voice is needed at least to introduce these processes and to have ownership of some procedures (cf. Diesner et al. 2004).

The examples in Sect. 15.2 on the two sequences (1) from school to enterprise and (2) from enterprise to school can be put into these classifications. The ‘normal’ school-to-enterprise co-operation is one on level 2. Based on level 1 (information) co-ordination between schools and enterprises is necessary. The enterprise-driven approach is at least at level 3. It is a partnership project.

15.3.3 ‘Running into Practice’ – Sophisticated Approaches Towards Co-operation in VET⁷

As mentioned in Sect. 15.2, learning between the two learning places is often organised as a ‘shift’ from the school to the enterprise: At school, the subject knowledge and heuristic strategies are developed. It is then up to the students to apply this knowledge to practical problems. As there is no real matching between enterprise work and school learning (see Sect. 15.3.1), this often leads to declarative knowledge and non-contextualised knowledge.

Thus, it is to some extent a deductive approach with the following problems:

- 1st The students already have to have some kind of sensitivity towards practical problems. If they do not have this ability they simply do not know why they are

⁷This chapter is based on results from the project, FäLou’ which was funded by the German Research foundation (cf. Sloane 2004).

learning specific subjects in school. Teachers often do not achieve this properly and may believe that theories are self-explanatory. Teachers have to understand that this knowledge has to be situated in a working context.

2nd The knowledge students gain at school cannot automatically be used by the students in their working context to understand the working context. In contrast, in the enterprise a ‘working language’ is often used which differs with regard to concepts and rules to the theoretical knowledge offered at school. This is not only a matter of vocabulary. There is quite a difference between practical (vocational) knowledge and theoretical knowledge.⁸

3rd Nevertheless, there is a gap between the tacit knowledge of the students and the knowledge students gain at school. In daily life they decide on the basis of tacit knowledge.

In the research and development-project ‘FäLou’ a ‘context change’ was organised. This change refers to a student’s movement between the school and the enterprise. The central idea is that the contexts in enterprise and school fit together, and thus the students have to solve tasks in both learning places which match each other. The ‘scenery change’ is a joint learning arrangement of participating enterprises and a school. A focus group established by trainers of participating enterprises, teachers of the school and a research group developed this arrangement. This group-based work is an example of a co-operation at level 3 or 4 according to Fig. 15.5. It took nearly 2 years for the group to find a common basis for their work. During this time it was necessary to establish joint ideas on education, learning and so on.

After this establishing phase the focus group developed an arrangement for *cost structure analyses*. This concept is used to find out if the increasing prices of suppliers are justified. Normally, this analysis can be proved with a benchmark of prices of different suppliers simply by comparing competing offers. Now, the cost structure analysis is used for the case where there are no other comparable suppliers on the market. Then statistical approaches have to be applied to analyse the general development of costs in particular market segments. This is a practical task where theoretical knowledge can be applied.

In this arrangement the students have to manage three tasks. First, they have to assess a particular offer made to the enterprise. To do this they have to learn different statistical approaches and then apply these techniques to a report on cost development. This was done in school. Secondly, they had to write a refusal of the offer which was again part of the enterprise work. In this refusal they were supposed to mention some reasonable grounds. Thus the supplier understood the argument and had the possibility to upgrade respectively to correct their offer because the enterprise wanted to continue the business relationship with them. Finally, the students summarised the experience at school.

⁸This is of course also a matter of the different curricula as schools in Germany traditionally have research or science based syllabi during training profiles that are driven by practical problems. See also Sect. 15.3.4.

It can be seen that this is a sequence enterprise-school-enterprise-school with different foci: Starting with orientation in the enterprise where the problem is worked out, the students go to school to gain knowledge to deal with the problem. Then the students have certain experiences in applying the knowledge in a working environment. These have to be generalised. Figure 15.6 illustrates the design of the arrangement:

The effects of this arrangement were documented by comparing the pre-knowledge and post-knowledge structures of the trainees (cf. Sloane 2004, 148f). For the specific argumentation here these effects are not the main point of interest. Here, it is important to point out the working process of developing this type of joint arrangements between schools and enterprises. It has to be seen that this is a long on-going process of co-operation which leads, according to the ladder-model, to co-operation at level 4. The actors establish a continuous programme of developing tasks together.

However, a final point must be made: This kind of co-operation only works and stays stable when somebody organises it. There is a high degree of instability, especially at the enterprises. The actors change, the enterprises re-organise, change their priorities and so on. The schools are relatively stable, but have to deal with the changing modes of the enterprise's actors.

Nevertheless, this can be used as a sophisticated approach which could be possible in a good working co-operation. Coming back to real-life settings in daily work in vocational schools it has to be asked how and to what extent this example can be transferred. A realistic view is necessary.

15.3.4 *The 'Lernfeldkonzept' – Realistic Approaches Towards Co-operation in VET*⁹

Arguably the most important step of reform in the current crisis has been the so-called '*Lernfeldkonzept*'. The term *Lernfelder* can be roughly translated as 'areas of learning' or '*learning area*', which form the basic unit of newly developed curricula for the school part of the dual system. The concept was introduced formally by a decision of the Conference of Education Ministers (*Kultusministerkonferenz*) in 1998 and revised in 2012 (cf. Dilger and Sloane 2013). It applies the notions of didactic innovations, such as activity-oriented and comprehensive learning, to the context of vocational colleges.

The main idea of this concept is the reconstruction and/or simulation of vocational processes at vocational colleges. Tasks and activities the trainees are typically confronted with in training companies ('working area') are the basis for the

⁹This chapter is based on a number of research projects (NELE, segel-bs, mosel) completed for the Federal Minister of Research and Science and the Ministries of Culture in Bavaria, Hessen and North-Rhine Westfalia between 1999 and 2009. The outline of this chapter was first published by Hubert Ertl and the current author (Ertl and Sloane 2004; see further Sloane 2004).

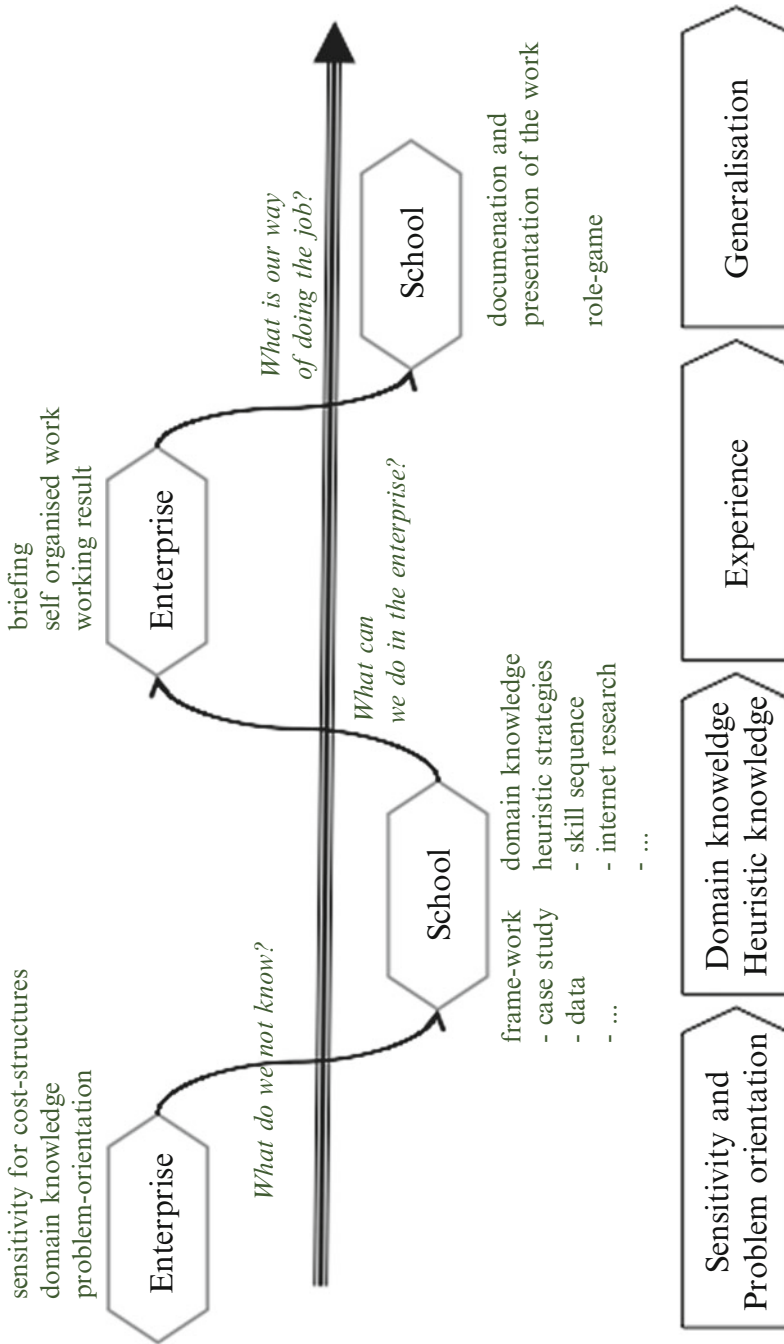

Fig. 15.6 The movement between learning places as a context change

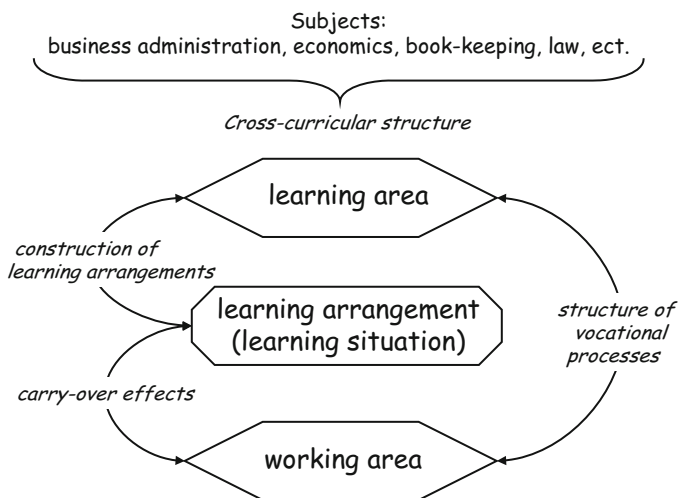

Fig. 15.7 Connection between areas of learning and work contexts

construction of ‘learning arrangements’ (learning situations at vocational colleges) that constitute an area of learning (Sloane 2001). Learning areas also draw on the knowledge that is represented in conventional school subjects. However, the traditional subjects are transformed into a cross-curricular structure in which comprehensive tasks have to be completed and real-life problems have to be solved by the trainees. Put in a nutshell, learning areas represent pedagogically adapted and enriched vocational processes derived from actual work contexts (Kremer and Sloane 2000, 73). The connection between learning and working areas and the way in which learning arrangements are constructed is illustrated in Fig. 15.7.

There are a number of conditions for the successful implementation of the concept of learning areas. These conditions and the resulting changes in the set-up of college-based training provisions have an impact on the three transfer elements conceptualised earlier. The changes outlined in the following illustrate the interdependence of the transfer elements.

First and foremost, the ‘*Lernfeldkonzept*’ is a *curricular* reform. Whereas curricula for vocational colleges used to be strongly prescriptive in terms of content, aims and time allocated to content and aims, curricula developed on the basis of the concept of areas of learning are formulated in an open way. The processes of curriculum construction are transferred from the state level to the level of individual colleges. This means that actors at the political level, who assumed the responsibility of developing the prescriptive curricula in the past, now only set broad guidelines for the teaching at vocational colleges. On the basis of these guidelines workable aims and operational contents for teaching are developed at the level of the individual colleges.

This means that the work and the role of *teachers* at vocational colleges have changed. The translation of curricula into instructional designs has become part of

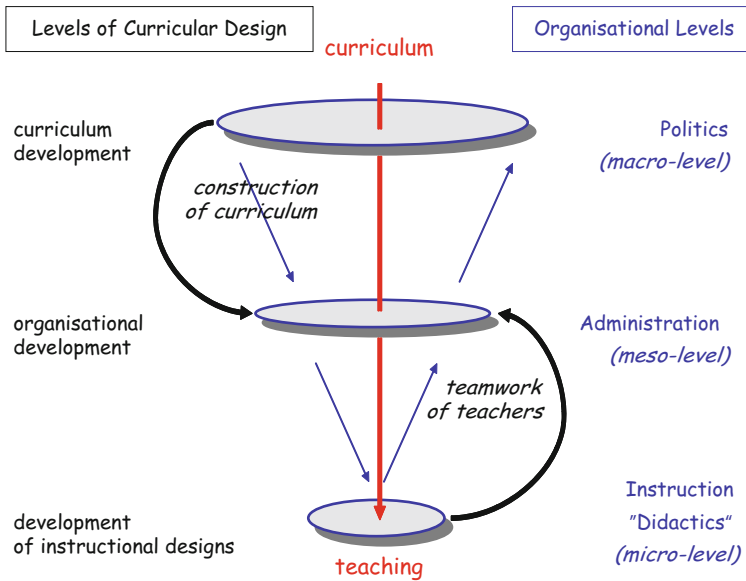

Fig. 15.8 Curricular and organisational changes in the 'Lernfeldkonzept'

the work of teachers. This task can only be fulfilled through close the co-operation of the teaching staff, which has consequences for the *organisation* of vocational colleges. For instance, teachers have to co-operate as a team in order to develop schedules and lesson plans on the basis of the curricular guidelines.

In summary, the responsibilities of the teachers increase and the tasks they are asked to fulfil become more complex. These are typical indicators of a changing notion of *professionalism* of teachers and of job enrichment. Also, the organisation of colleges has to change to initiate and support the teamwork of teachers. This change is part of a wider reshuffling of responsibilities in the institutional set-up of vocational training. The changes are illustrated in the following figure (Fig. 15.8).

In order to be able to plan teaching and learning processes on the basis of vague curricular guidelines, teachers have to take real-life work contexts into account. As hinted at in the previous section, learning areas represent pedagogically adapted and enriched vocational processes derived from actual work contexts. This means that teachers have to co-operate with training companies while planning their lessons. The long-standing organisational and pedagogical challenge of co-operation between the two main venues of training in the dual system has become more pressing than ever (cf. research documented in Euler, 1999a, b). Keeping in touch with developments in the economy and establishing contact with training companies becomes a central task for vocational colleges and teachers.

15.3.5 Integrated Apprenticeship – A Visionary Approach in VET

As enterprises and vocational schools in Germany are embedded in different institutional settings, co-operation is an organisational reaction to arrange pathways between these two learning places. Dual system indeed does not mean that there is one system with two sides, but rather it correctly implies two systems which have to co-operate.

There have been many discussions in Germany about whether it is possible to establish more access between enterprises and schools by introducing requirements. However, in the end the gap between the two learning places is too wide. As mentioned in Sect. 15.3.2, enterprises and schools are part of two distinctive, even incommensurable life settings.

Nevertheless, at least one of the more visionary approaches should be mentioned. It is an integrated approach towards VET which is found in the area of social and medical services. Medical and social institutes run this kind of concept. Here schools and enterprises are often in one system. In other words: there is no institutional gap.

Similar experiences can be found in new vocational programmes, and joint programmes of enterprises and universities of applied sciences should be mentioned in particular. In all these cases there is an integrated curriculum for the enterprise part as well as the school part of the programme. Thus, an ideal co-operation can be established which strictly follows the idea of an institutionalised partnership programme according to level 5 of the co-operation ladder (see Fig. 15.5).

Figure 15.9 illustrates the main ideas of such a sophisticated approach. It generalises the concept in so far as it adopts the principal aspects of the dual system. In this approach the regulations of the school and the enterprise are linked together on the basis of generalised action fields. This is adopted from the '*Lernfeldkonzept*'. If the regulations for the enterprises (training regulations) and for the schools (framework syllabus) were both based on a uniform framework of action fields this could lead to more coherence between the two learning places. Action fields are typical qualifications, but they could also be defined as competences. The school-based learning tasks and the enterprise-based working tasks could be co-ordinated.

This would then possibly lead to a sequence of learning phases in the school and in the enterprise (like in Fig. 15.6). Nevertheless, a co-operation between teachers and trainers would be necessary. Teachers and trainers would still have to generate tasks resp. instructions, which foster the learners to apply knowledge to diverse situations, let them be work processes or learning situations. Both, work processes and learning situations, can be designed by shared didactical principles. If these learning units are to sequenced beyond the border of an enterprise or a school, then teacher and trainers need to have common ground for their didactical decisions. Generalized action fields that serve as a basis for training regulations (enterprises) and framework syllabus (schools) could be used to come to common understanding about didactical co-operation (Fig. 15.9).

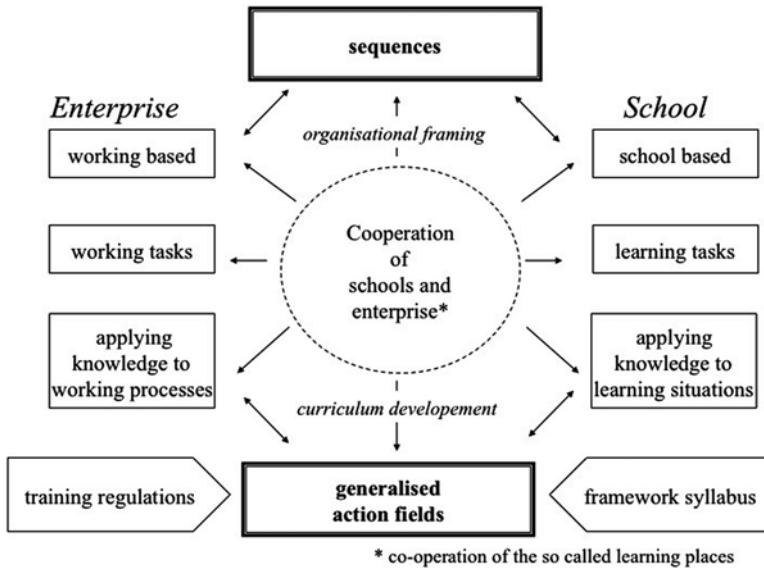

Fig. 15.9 The integrated approach towards VET

15.4 Final Remarks: Behind the Curtain

Finally it is important to examine the discussion of vocational education and training and the emphases made with regard to the dual system. In Germany there is an on-going discussion about the success of this system and a strong belief that this approach should be transferred to other countries. Every once in a while excited statements are made in the media that another country wants to adopt the system. Sometime later the excitement calms down and the country is not further mentioned until a new aspirant is located. In the end the dual system is and remains a German approach and it does not seem to be transferable.

This has something to do with the different layers, which were discussed in this chapter and has to be reflected in the ambivalence of naïve examples, on the one hand, and the also discussed complex framework, which constitutes the dual system, on the other. This framework brings three aspects together: didactics, governance and organisation.

When practitioners or politicians look at the dual system they refer to the organisation between enterprises and schools. They often do not understand that it works on the basis of a German governance approach. That vocational education is, for example, an educational and not an economic model seems to elude them. Something similar, by the way, happens if German politicians reflect on the system. They always point out that the enterprises do sterling work in offering apprenticeships.

That is, of course, a basic decision. By doing this they offer to take on costs for education which in other countries are paid for by the government. However, it

should be mentioned that in a 3-year programme apprentices bring in more profit than they cost after 2 years. The enterprises break even at that point at the latest.

Enterprises and schools co-ordinated to some extent, even if the enterprises and schools are in some particular way incommensurable to each other. That has something to do with the role of vocational colleges, or schools, respectively. In the German perception the enterprises guarantee the success. However, all the experiences mentioned in this contribution show that most of the work is done by the schools. Good co-operation and success in final examinations is always the result of schoolwork.

Therefore it seems useful to think more about the functions of schools in co-operative systems where enterprises and schools work together. This is a matter of how schools apply their work to practical life. Teachers in vocational schools have some kind of external reference because they have to find some pathways into practice. The correct reason for the success of dual apprenticeship, therefore, is not the simple fact of participation of schools and enterprises, but the sophisticated possibilities of linking school work to the practical problems of daily life in enterprises.

To realise these opportunities a specific type of teacher is required who is able to organise co-operation using a didactic approach. Finally, the dual system may seem to be spectacular, but behind the curtain there are hard-working and well-educated teachers doing their work.

Chapter 16

The Dual System of Vocational Education and Training in Germany – What Can Be Learnt About Education for (Other) Professions

Bärbel Fürstenau, Matthias Pilz, and Philipp Gonon

Abstract The dual system of vocational education and training (VET) in Germany is a specific training system that aims at systematically combining the advantages of training in a company and education in a vocational school. Germany's dual system is expected to strongly support a successful transition of young people from school to work and to guarantee a skilled workforce as a prerequisite for a successful economy. In addition it plays a role in educating young people. The central goal of VET in the dual system is to help students attain and develop competence in action so that they can meet current and future professional challenges and participate in defining their vocational lives. Because of on-going changes in society, economy and at the workplaces, the dual system has been under pressure of adaptation in order to further maintain its effectiveness and efficacy. Consequently, especially since the 1980s, many adjustment processes have taken place on different levels of the system, namely the institutions involved, the syllabi for the different venues, and the teaching-learning processes. The article will explain the dual system as well as highlight and comment on the different endeavours for its modernisation. It focuses on parity of esteem between general and vocational education and between different forms of vocational education. Furthermore it takes into account cost and benefit of in-company training, modularisation of training occupations, and the relationship between learning and working. As a result, it will give some advice on what can be learnt about education for professions.

Keywords Vocational education and training • Dual system • Education for professions

16.1 Outline

Dual systems of vocational education and training (VET) are specific training systems that aim at systematically combining the advantages of training in a company and education in a vocational school. Dual systems in this form do exist to a considerable extent in Germany, Austria, Luxemburg, Switzerland, Denmark, and parts of the Netherlands. German-speaking regions of France and Italy also (often) fit into this framework. This article focuses on the dual system of VET in Germany (hereafter only referred to as “dual system”).

Germany’s dual system is expected to strongly support a successful transition of young people from school to work and to guarantee a skilled workforce as a prerequisite for a successful economy. In addition it plays a role in educating young people. Consequently, the central goal of VET in the dual system is to help students attain and develop competence in action so that they can meet current and future professional challenges and participate in defining their vocational lives.

In order to meet this challenge and in order to further maintain its effectiveness and efficacy, especially since the 1980s, many adjustment measures have been implemented. Reasons for the adjustment measures can be seen – besides others – in the demographic development, shift from industrial to service economy, or changes of workplaces and demands for the workforce. The demographic development has led to a drop in the demand for training places and thus to problems of recruiting a skilled workforce. The shift from industrial to service economy has required an increase in apprenticeships in the service sector and more service orientation of apprenticeships in other sectors of the economy. Workplaces have become more complex and require more intellectual skills such as systems thinking, and they require continuous learning. The measures taken refer to different levels of the dual system, namely the institutions involved (companies in the private sector, vocational schools, employers and employees, the Federal Government, the German states etc.), the syllabi for the learning venues (schools and workplaces), and the working and/or learning processes at the different venues. The levels cannot be strictly separated. Accordingly, if a decision is taken on one level, the other levels are usually affected too.

This article will explain the dual system as well as highlight and comment on the different endeavours for its modernisation. As a result, we will point out what can be learnt about education for professions. The concept of profession here is understood in a broad sense, including professional practice and approaches to learning in and for professions as well as all kinds of initial and further professional education, whether it takes place in school settings or at the workplace or at both venues. Thus, we pick out aspects from education in the dual system which might be regarded in professional education in general. We explicitly do not aim at discussing a transfer of the dual *system* to other *systems* of professional education in detail but only comment briefly on it. Through our approach, we aim at contributing to solutions for the problem of effectively developing professional (occupational) capacities that are important for fulfilling both personal and societal needs.

The article starts with a description of the historical development of the dual system and its current structure in Germany. After that, an overview of current challenges and reform approaches will be taken into account. Consequently, we select relevant topics to be looked at in more detail. The selected topics address the different levels of the dual system and are – in our opinion – relevant both from a national and an international perspective. On the level of institutions, we discuss the parity of esteem between general and vocational education on the one hand and between apprenticeship in the dual system and full-time school-based vocational education on the other hand. Furthermore, on that level, costs and benefits of vocational education will be discussed. On the level of syllabi we examine/consider initiatives that have been taken to more closely relate teaching/educational goals and contents to practice and workplace reality as well as to regional or branch-specific needs. For that purpose, new apprenticeships have been developed and existing ones have been re-structured according to modules. On the level of teaching-learning processes we focus on measures aiming at preparing apprentices to effectively cope with modern work structures and organisations that have been implemented. For that purpose, the relationship between learning and working is reconsidered and combinations of learning and working, both at the workplace and in school, will be addressed. Though it would be possible and worthwhile to argue solely from a national perspective, we also will discuss the topics from an international perspective, which allows us to consider the German approaches from other angles and integrate it in a broader context. As a summary, we will conclude what can be learned about education for other professions by taking into account the different levels and by regarding an international perspective.

16.2 Historical Development of the Dual System of Vocational Education and Training

The roots of the dual system can be traced back to the medieval ages, or even beyond, to the ancient Roman and Greek world (e.g. Münk 2010, p. 401). Based on early forms of apprenticeship, the dual system unfolds in three major phases:

Early forms of apprenticeship had been embedded in the craft system for both craftsmen and merchants. The apprentice worked together with his (or her) master craftsmen in his/her shop or travelled together with the master merchant to trade merchandise. Apprenticeship usually followed the so-called *Imitatio Majorum* principle, which refers to the sequence of observation, imitation, autonomous accomplishment, and customisation (Kell 1995, p. 371). It aimed at providing the apprentice with abilities and skills matching the conventions and the accepted behaviour in the profession and the respective craft system (Bruchhäuser and Horlebein 2010, p. 408). Due to technological and cultural developments in industry and society, general knowledge, e.g. qualifications of reading, writing and accounting, became more and more important, and thus schooling became necessary in order to prepare apprentices for job requirements (Pahl 2012, pp. 25ff; Reinisch and Götzl 2013, p. 20).

The founding phase of the dual system in Germany can be dated back to the late nineteenth and early twentieth centuries (Greinert 1995). The craft system decomposed because of the advent of a more liberal trade law, as fixed in the Trade Regulations of the Northern German Confederation. However, the empire politics aimed at protecting craft by law in order to prevent middle-class, respectively small firms and traders from becoming proletariat (Greinert 1995, p. 21). Amendments for protecting retail trade, dated 1897, enabled the recovery of corporate structures and the apprenticeship model comparable to that of the former craft system. Furthermore, education of apprentices required a master's certificate. Besides traditional apprenticeships, schools for further education with a specific focus on vocational subjects (in German: Fortbildungsschule) were established. In 1900 the German Pedagogue Georg Kerschensteiner had recommended gearing the Fortbildungsschule towards vocational education and, in so doing, to legitimise it by claiming that vocational education and professional work contributes to general human education. Through vocational education, non-academic youth should also be integrated into the national state (Gonon 2009). Between the end of the nineteenth century and the beginning of the twentieth century, the number of such vocationally oriented schools increased. To sum up, the formation of the Fortbildungsschule is result of the promotion of small- and medium-sized craft enterprises on the one hand and youth education in times of crisis at the turn of the twentieth century on the other (Harney 2006, p. 233).

The *consolidation phase* between 1920 and 1970 was influenced by the attempt of German industry to establish an own apprenticeship model under exclusive control of companies. This was motivated by qualification needs of industry (engine building and electrical industry) that grew comparatively fast and used modern production methods. Consequently, workforce in industry had to learn to cope with new technology. For that, instruction at specific learning venues (e.g. apprenticeship workshops or factory schools), standardised courses, curricula, and test requirements were necessary (Herkner 2013, p. 16; Pahl 2012). However, industry could not implement its own apprenticeship model but instead implemented a new qualification type for skilled workers/technicians that compares with the level of assistant in craft (Benner 1997, p. 56). Since the 1930s, the Fortbildungsschule has been renamed Vocational School (in German: Berufsschule). In 1938, (empire-wide) 3 years of compulsory VET was enacted and, in the beginning of the 1940s, the weekly hours of schooling were fixed while curricula and both school authorities and financing were harmonised. In the 1950s, the craft was successful in enforcing comprehensive regulations for VET established by the Handicrafts Regulations Act (in German: Handwerksordnung). However, a VET law was not enacted until 1969, the so-called Berufsbildungsgesetz (Wahle 2007, p. 195).

The *further development phase* since the 1970s is characterised by rationalisation of the dual system and by enhanced state influence. The Berufsbildungsgesetz regulates the responsibilities of Federal Government, the German States, the representatives of employers, the trade unions and, to some extent, the teachers for vocational education. Furthermore, a reporting system aimed at making the developments on the apprenticeship market transparent was established in form of the vocational

education report, which is published yearly. In addition, since 1972 inter-company vocational training centers were established to compensate apprenticeship shortcomings, especially for small firms. Almost every apprenticeship now also had a structure that separates 1 year of basic vocational qualification from 2 years of specific vocational education (Greinert 1995, p. 32).

16.3 The Dual System of Vocational Education and Training – Basic Features

Worldwide, different systems of VET exist. In order to differentiate between these systems, the role of the state can be taken into account. In market economy systems (e.g. USA, Japan, Great Britain) the state is not involved in vocational education. In school systems (e.g. France) the state plans, organises, and controls vocational education. In state-controlled market economy systems (e.g. the dual systems in Germany, Austria, and Switzerland), the state defines regulations for vocational education, but the private sector is responsible for the supply of training places. All other systems can be interpreted as variation of these three basic types.

Students can enter the dual system after finishing 10 years of compulsory schooling on the secondary level I at a grammar school, a comprehensive school, an intermediate school, or a secondary general school. Entering the dual system means entering the secondary II level. As an alternative to the dual system, students can choose to complement senior classes in grammar school, to attend a specialised grammar school, to attend a full-time vocational school, or to remain in the transition system to receive preparation for an apprenticeship in the dual system. After finishing one of these alternative tracks, it is also possible to apply for an apprenticeship training place. Currently, about two-thirds of students leaving school start their professional career by beginning an apprenticeship in the dual system (BMBF 2013, p. 9). Overall, the dual system can be regarded as bridge from school to work-life.

Apprenticeship in the dual system is only possible for state-recognised training occupations (Greinert 1995, p. 35), of which currently approximately 350 exist, ranging from baker, boat-builder, hairdresser, optician, and precision mechanic to sales associate or clerk. Successful completion of an apprenticeship programme entitles the trainee to practise an occupation as a qualified skilled worker in either the training occupation (Hippach-Schneider et al. 2007, p. 25) or an occupation which requires the knowledge and skills of the training occupation. Training occupations and occupations/professions in the labour market in general do not necessarily correspond. In contrast, compared to the number of training occupations, multiple occupations/professions exist. Occupations can be grouped according to areas, main groups, groups, sub-groups, and genres. Currently, 10 areas, 37 main groups, 144 groups, 700 sub-groups, and 1,286 genres exist. Areas are, for example, agriculture, forestry, and gardening or raw materials production, production and manufacturing, or commercial service, trade, sales, hotel and tourism. Main groups

in the latter area are purchasing, sales, and trade occupations or sales, tourism, hotel- and restaurant occupations. Groups in the purchasing, sales, and trade occupations are purchasing and sales or trade. Sub-groups within purchasing and sales are occupations in purchasing or clerks in trade. Genres within purchasing and sales are occupations are, for example, specialised trade clerks and unspecialised trade clerks (Bundesagentur für Arbeit 2012). Consequently, an apprentice who completed a training occupation as a clerk can apply for numerous occupations and work as a clerk or as specialised or unspecialised trade clerk, or even as a secretary.

The dual system is not the only possibility for complementing an apprenticeship. Full-time vocational education in schools is offered as well, but it is not as established and appreciated as vocational education in the dual system. Furthermore, the dual system has to be strongly distinguished from the general education system. It has its own vocational education legislation as fixed in the *Berufsbildungsgesetz* (Greinert 1995, p. 10).

The name dual system refers to the fact that two learning venues in two institutions, namely vocational schools and workplaces in companies, cooperate in order to qualify apprentices for a profession (Greinert 1995, pp. 10–16). Depending on the state-recognised training occupation, the course of the apprenticeship takes 2–3.5 years. The apprentices spend approximately three fourths of this time in the companies, one fourth in vocational schools. The different learning venues are embedded in different systems formed by a different history, i. e. the vocational training system on the one hand and the school system on the other. Both systems aim at cooperating in qualifying the apprentices (Harney 2006, p. 232). From a legal point of view, the young people are both student and employee. The most important features of the dual system can be described as follows.

16.3.1 Companies/Workplaces

Training places are offered by companies in the private sector (industry, craft, and agriculture), institutions of the public sector, offices or institutes of the liberal professions and, to a limited amount, by private households (Greinert 1995, p. 35; Hippach-Schneider and Hensen 2012, p. 16). A provider of training places, e.g. a company, has to be approved by the respective chamber or guild. In the dual system, “the state delegates regulatory competence for training system to corporatist bodies. [...] They have the status of ‘competent bodies’ (*zuständige Stellen*) and play a crucial role in the organisation, administration and examination of vocational training” (Ertl and Sloane 2004, p. 3). Chambers and guilds as corporatist bodies regulate apprenticeships by supervising final exams, by registering training contracts, by establishing inter-company vocational training centers, by allocating training warranties to companies, by reforming apprenticeships, and by controlling the training quality (Harney 2006, p. 232; Rebmann et al. 2011, p. 13). The in-company training follows mandatory training regulations legal for the respective state-recognised training occupation and valid for all companies independent of

branch or size. The development and remittal of the training regulations is the responsibility of the federal government and should guarantee comparable standards for in-company training nationwide. However, representatives of trade unions as well as of employers' and employees' head organisations are involved in the development of training regulations. Every training regulation comprises denomination, length (duration) of the apprenticeship, occupational profile, framework plan, and examination requirements (Rebmann et al. 2011, p. 13).

Trainers only complete a basic course on pedagogical eligibility (AEVO 2009), or sometimes even none. Usually trainers work as full-time employees and not as full-time trainers. Thus, they often suffer from heavy work pressure and, consequently, time limits for taking care of trainees. Big companies usually are more likely to offer systematic training compared to small and medium size companies.

The companies finance the apprenticeships by paying training remunerations to the trainee on a monthly basis (Greinert 1995, p. 16). The individual company decides autonomously whether and what training is provided and how many apprentices they take (Hippach-Schneider et al. 2007, p. 59).

It should be mentioned that sometimes companies are not able to offer full apprenticeships. They either do not have enough trainers or sufficient technical resources. In that case, parts of the apprenticeship can be relocated from the individual company to an inter-company vocational training center. Alternatively several companies can form an apprenticeship network, thereby jointly taking care of an apprentice (Hippach-Schneider and Hensen 2012, p. 17).

16.3.2 Vocational Schools/Classes

Vocational schools have the task of complementing in-company training by imparting both general knowledge and job-specific knowledge to the students. The students (=apprentices) attend the vocational school 8–16 h a week. Education in schools complies with a framework curriculum that is developed for every state-recognised training occupation (Hippach-Schneider and Hensen 2012, p. 16) by the Standing Conference of the Ministers of Education and Cultural Affairs of the Länder in the Federal Republic of Germany (in German: Kultusministerkonferenz), or rather its subcommittee, and is valid nationwide. As is true for the in-company training regulations, the framework curriculum aims at guaranteeing a uniform national standard for education in vocational schools. Because education in schools is the responsibility of the individual states (and not of the federal government), each of the German states can modify the framework curriculum according to specific needs but must adhere to central aims and contents. Furthermore, each state issues school laws which regulate kinds of schools (e.g. vocational schools, commercial high schools), educational plans, and lesson plans. In addition, each state issues regulations concerning tests, giving marks, promotion to the next class, and exams (Rebmann et al. 2011, pp. 9–10).

Teachers for vocational schools take 5 years of university education and graduate with a master's degree or a state examination. After that they have to complete a 1–2 year (depending on the regulation of the respective German State) internship in a vocational school. Only after completing these requirements are they fully certified to teach.

The respective German state, or specifically the local authorities' public funds, covers the costs for in-school education (Greinert 1995, p. 16). The German states "bear the costs of internal school affairs (e.g. supervision of schools, laying down of curricula, teacher training, teachers' pay), and the local authorities are responsible for financing external school affairs (e.g. construction, maintenance and renovation of school buildings, ongoing management, procurement of teaching and learning resources)" (Hippach-Schneider et al. 2007, p. 59).

16.3.3 Coordination of Schools and Companies

The coordination of in-company training and school-based learning is strictly regulated by a procedure to develop and harmonise training regulations and school curricula in order to jointly accomplish a central aim. As defined in every framework curriculum, the central aim of education in vocational schools is to support students in developing competence in action, which means possessing the willingness and ability to act deliberately and be socially and individually responsible in the workplace as well as societal and private situations. Competence in action develops in three dimensions, namely in professional competence, individual competence, and social competence (KMK 2011, p. 15; Dilger and Sloane 2012, p. 32). The same aim is true for in-company training. The coordination on the local level between individual schools and companies is not regulated and often either happens by chance or is instigated for specific reasons, e.g. misbehavior of the apprentice in matters such as daily attendance.

16.4 Current Challenges and Reform Approaches of the Dual System of Vocational Education and Training

The most important asset of the dual system is seen in the fact that it comes with a low rate of youth unemployment compared to other European countries. In Germany, the rate was about 9 % in 2011 (Esser 2011, p. 3; Hippach-Schneider and Hensen 2012, p. 10) and has remained low even during the latest economic crisis. Countries that implemented school-based vocational training or have no VET system are typically confronted with high rates of youth unemployment (Busemeyer 2012, pp. 6, 9). The dual system effectively enables the transition from apprenticeship to employment because vocational and occupational systems are closely linked (Bosch 2010, p. 37).

By offering apprenticeships, companies can easily support young workers in their commitment to professional development and thus recruit from a skilled workforce (Busemeyer 2012, p. 16).

In order to guarantee a skilled workforce, the dual system is under constant pressure to change or adapt in response to economic, societal, and educational developments. Those developments comprise, for example demographic change, the shift to the service sector, the development of a European work and education market, or new forms of work organisation (BMBF 2012). They lead to challenges in multiple areas: the availability and suitability of training places, the integration of low-skilled youth in VET, the establishing of a European framework for education and training, the training of a highly-qualified future workforce.

16.4.1 Availability and Suitability of Training Places

Taking the big picture of the apprenticeship market into account, the demand for apprenticeship training places exceeded the supply until 2007. In 2008 the global financial crisis negatively influenced economic growth and led to a drop in training places. Since 2011, the amount of training places has again increased (Bosch 2010, p. 37; Deutscher Bundestag 2010, p. 1; Hippach-Schneider and Hensen 2012, pp. 9, 18). Due to demographic change, companies lack skilled personnel. The age group of young people between 17 and 25 is expected to diminish about one-fifth (BMBF 2012, p. 5). Consequently, companies face the increasing problem of recruiting suitable apprentices (BMBF 2012, pp. 4, 7, 24; Autorengruppe Bildungsberichterstattung 2012, pp. 101, 107). The percentage of vacant apprenticeship training positions increased about 30 % (Esser 2011, p. 3). More than one-third of companies could not fill one or more apprenticeship training positions. Dependent on branch, size of the company, and the region, the imbalance of supply and demand on the apprenticeship market varies. Concerning the branch, problems mainly occur in the largest sector of the economy, the service sector (BMBF 2012, p. 5; Hippach-Schneider and Hensen 2012, p. 29), e.g. the hotel and catering industry, or the health care and welfare sector. In addition, a qualified workforce is missing in science and technical fields. In contrast, banks and insurance companies are less likely to run into problems. Concerning the size, small enterprises have more problems filling positions than large firms. And concerning the region, big cities in the western part of Germany with a balanced labour market and high dynamics are more likely to have a balanced apprenticeship market than big cities, also in the western part of Germany, which already have a high rate of unemployment and regions in the eastern part of the country (Krone 2010, p. 27f.; BMBF 2012, p. 33). Resulting from demographic changes, companies cannot afford to be as selective as before when hiring apprentices. Thus, the group of apprentices for one state-recognised training occupation in one company, and also across companies, sometimes may be very heterogeneous. That, in turn, may cause problems for both the trainers and the apprentices.

In order to support companies in recruiting a skilled workforce, some measures of deregulation were taken to make more training places available. For example, the regulations for in-company trainers' pedagogical eligibility were suspended for a couple of years in order to allow companies to offer apprenticeships without having officially-recognised trainers. In the field of skilled craftsmen, the requirement limiting the ownership of a personal business to only those certified as master craftsmen was suspended. State-recognised training occupations, which were less theoretically/more practically oriented and only last 2 years, were defined. However, all these measures had only limited success and have been partially abolished in the meantime (Busemeyer 2012, pp. 6, 20). Nevertheless, the supply-demand relationship on the apprenticeship market has improved since 2008, meaning that the supply of training places slightly exceeds the demand (BMBF 2012, p. 13).

Another approach to increase the supply of training places was to offer more full-time, school-based apprenticeships, that is to say vocational training in the education system. According to an amendment of the *Berufsbildungsgesetz* in 2005, the graduates of school-based apprenticeships should be allowed to take an exam established by the respective chamber or guild and thus become a fully-acknowledged, skilled worker without having been an apprentice in the dual system. However, a time limit was put on this regulation. It terminated in 2011 and did not lead to the establishment of a school-based vocational system (Deutscher Bundestag 2010, p. 8; Busemeyer 2012, pp. 7, 21).

From a financial perspective, the possibility of apportionment of costs was discussed to relieve companies who offer training places and motivate them to further invest in training. Furthermore, the federal government considered increasing investment in education (Busemeyer 2012, p. 5). The cost of training in the apprenticeship system for the companies was 23.8 billion Euros (15,288 Euros per year and apprentice) in 2007. This sum, reduced by productivity profits and other income for the companies, results in 5.6 billion Euros net costs or 3,568 Euros per year and apprentice (BMBF 2013, pp. 282–283). The states covered the cost for the vocational schools with 3.2 billion Euros (BMBF 2013, p. 280).

In order to match apprenticeship programs with labour market needs while subsequently guaranteeing a skilled workforce, a total of about 51 state-recognised training occupations have been newly defined and 147 existing state-recognised training occupations have been modified since 2000 (BMBF 2012, p. 64; Hippach-Schneider and Hensen 2012, p. 29). In the course of this modification, some apprenticeships have been modularised. Consequently, by structuring apprenticeships according to both mandatory and optional modules, apprentices can complete basic training and then specialise. Another approach was to restructure school curricula according to so-called learning areas instead of subjects (such as business, economics, bookkeeping, etc.) (Euler and Sloane 1997). The concept of the learning area was formally introduced by the Kultusministerkonferenz in 1996 (KMK 1996). Learning areas represent typical workplace situations or problems and thus are expected to better prepare students for the world of work than conventional curricula. Conventional subject-oriented curricula presumably caused difficulty integrating knowledge from different areas and applying it in real-life situations (Ertl and

Sloane 2004, p. 8; KMK 2011, p. 11). So far, no empirical evidence that learning areas are superior to traditional subject-oriented curricula – concerning the development of competences of apprentices – exists. However, the learning area approach is much more in line with learning theories such as problem-based learning, situated learning, and job requirements (see Sect. 16.5.4).

16.4.2 Integration of Low-Skilled Youth in Vocational Education and Training

Despite the lack of skilled personnel and anew rise in the supply of apprenticeship training places in the last 2 or 3 years, many young people remain in the so-called transition system; that is to say, after finishing (compulsory) school, young people are not able to get a training place because they are poorly qualified. They usually move to the transition system, i.e. 1 or 2 year education promotion measures or pre-apprenticeship training in order to gain access to VET (Busemeyer 2012, p. 16). The problem of integrating poorly qualified persons in the job market is still not successfully solved, though the number of people in the transition system has decreased slightly (Bosch 2010, p. 37; BMBF 2012, p. 4).

In order to reduce participation in the transition system, several measures have been taken (Euler and Sloane 1997; Siecke and Heisler 2011). For example girls' days and boys' days, which aim at letting boys and girls experience a company for a day, have been implemented as a measure of professional orientation. Substantive professional orientation contributes to thoughtful decisions about an apprenticeship and a professional career. In addition, under-qualified young people can participate in special training to help them acquire the basic qualifications necessary to start an apprenticeship. Again, the implementation of exclusively school-based vocational training attuned to the under-qualified could help integrate young people into an apprenticeship and the job market (Busemeyer 2012, p. 8). Furthermore, young people can be assisted by seniors in the initial phase of their apprenticeship or in situations of conflicts. Both of the latter measures can help avoid the termination of apprenticeships (BMBF 2012, p. 43).

16.4.3 European Framework for Education and Training

The German VET system should be attractive and competitive from a European perspective. VET should be outcome-oriented and oriented towards the labour market. In addition, competences, whether they are acquired in Germany or in another European country, and whether they are acquired in the VET or in the academic system, should be comparable in order to foster mobility of young people and to recruit a skilled workforce from other countries (BMBF 2012, p. 8). For that purpose, the European Qualification Framework (EQF) and corresponding National

Qualification Frameworks (NQF) were developed. The aim is to rank and compare competences independent of where and how they were acquired. The EQF is strictly outcome oriented and can be used to assess equal value of different educational backgrounds or different grades based on academic or vocational education (Esser 2011, p. 4; BMBF 2012, p. 7). This might facilitate the exchange between academic and vocational education and thus the permeability within the education system. In order to assess competences gained in foreign countries or in order to accredit informally gained competences, assessment techniques are still to be developed (Esser 2011, p. 8). Closely connected with EQF, the European Credit System for Vocational Education and Training (ECVET) and the European Quality Assurance Reference Framework (EQARF) for VET were developed. The ECVET aims at acknowledging credits gained during a temporary employment abroad or in different learning situations. The EQARF supports its member states in implementing quality control systems (Deutscher Bundestag 2010, p. 12). Some more initiatives of the European Union are in preparation (BMBF 2012, p. 8). The introduction of the new instruments is still on the way; therefore empirical evidence for this political perspective is still unavailable.

16.4.4 Highly Qualified Future Workforce

The increasing and more manifold use of information and communication technologies led to systemic rationalisation, and consequently new forms of work organisation. Systemic rationalisation is associated with forms of ‘lean production’ and ‘lean management’, more team-work and working on projects. Routine tasks have been automatised, and employees are more frequently in charge of controlling processes. Furthermore, workplaces have been virtualised and now come along with flexible working hours and new requirements for work-life-balance. The developments led to more complex tasks and thus to new challenges of coping with workplace requirements such as understanding complex interrelationships, working independently, and using soft skills (Achtenhagen 1997, p. 611; Bosch 2010, p. 45; Esser 2011, p. 3). To sum up, workplaces require a highly qualified workforce. This has to be regarded in the course of adapting both previously existing and newly developing state-recognised training occupations, e.g. by integrating academic contents in vocational training programs. An example for this is the training occupation of a mechatronics fitter, which was invented in 2006 and requires academic skills such as planning and controlling work processes, checking and evaluating work results, or programming mechatronic systems (Ordinance on Vocational Education and Training in the Occupation of Mechatronics Fitter 2011, § 3). In the field of commerce and administration, for example, the regulations of the training occupation “agent in marketing communication” includes many competences that are also part of academic programs (Ordinance on Vocational Education and Training in the Occupation of Agent in Marketing Communication 2006, § 3). It is assumed that the tendency for higher qualification will continue over the next few years

(BMBF 2012, p. 5; Krone 2010, p. 30). Consequently, this might not only lead to more sophisticated apprenticeships, but also to more competition between vocational education and academic education as well as to problems for lower skilled young people to either have access to those training occupations or to keep up with other apprentices. Presumably, the demand for academic education, but also for education in the dual system, will increase (Dehnbostel 1997, p. 167; BMBF 2012, p. 5; Autorengruppe Bildungsberichterstattung 2012, p. 101).

In order to prepare apprentices to cope with complex workplace requirements, more authentic and complex tasks and problems are assigned to them. The aim is to get them actively involved in learning, thus avoiding the accumulation of inert knowledge and better guarantee application of knowledge and skills from school to the workplace. Case studies, simulations, or simulation games often replace traditional forms of teacher-centred instruction (Achtenhagen 1997). As a consequence, the boundary between learning and working has become more and more fuzzy. The same is true for the division of labour between the institutions. Theory is no longer the exclusive responsibility of the school and practice of the workplace. Instead, both institutions have to combine learning and working with theory and practice (see Sect. 16.5.4).

16.5 Selected Reform Approaches in Detail

16.5.1 *Parity of Esteem Between General and Vocational Education and Between Different Vocational Education Programmes*

16.5.1.1 Parity of Esteem Between General and Vocational Education

Parity of esteem is an important component in the education debate both internationally and in Germany. For many decades, a range of groups involved in educational policy in Germany have been calling for parity of esteem between general and vocational education, bringing many arguments to support their case (BMBF 1997, p. 9). Their focus is on initial training. However, they also acknowledge parity of esteem as a sound basis for further education in the process of lifelong learning and as a measure to boost individuals' career prospects (Weiß 2000, pp. 69–71).

While those involved in educational policy fundamentally accept vocational education on its own terms, the reality of the labour market is that vocational education courses are still not seen as being as attractive as general academic courses. The current thrust of Germany's long-established entitlement of qualifications (Kell 1982, 1987) privileges academic qualifications in terms of both social and occupational status. When measured in terms of income, prospects for advancement, and field of activity, academic qualifications outperform vocational education qualifications (Adler et al. 1993, pp. 3–4; Berger 1998, p. 46).

Over recent years, a number of initiatives have therefore been launched in Germany to achieve parity of esteem. First, since the beginning of the new century, the concept of vocational education itself was given a boost by modernising occupational profiles (Dybowski 2000). The idea was to work towards an independent system that is as attractive to the labour market as academic education (Adler et al. 1993, pp. 8–10). The educational policy rationale behind this approach was the argument that, though the content and ways of learning for vocational education courses are not of the same nature as comparable academic courses, they equip students with wide-ranging practical skills and may therefore be seen as being of equal value (Kell 1987, pp. 154–155).

Second, other initiatives focused on establishing formal links between the two strands. We shall give brief details of just a few examples of educational practice in Germany (for a full account, see Pilz 2003). The examples can be subsumed under what is known as the permeability principle on the one hand and dual qualifications on the other. The permeability principle means that a qualification formally entitles its holder to gain access to a higher level of the general education system. The qualification may be purely vocational in its emphasis or may add general educational competences to vocational competences (combined form). Contrastingly, dual qualifications equip their holders with both a vocational education and a general education grade at the same time. Dual qualifications can be ‘integrative’ or ‘additive’.

The purely vocational forms of the permeability principle imply that vocational education is as capable as general education of equipping students with competences that enable them to complete tertiary academic courses. However, rather than the first form of parity mentioned above, this form allows – admittedly seamless – access to academic courses. It does not aim at presuming equal value for vocational and academic education, which would declare academic education after completing a vocational education degree obsolete. The best known example of this process is the opportunity open to master craftsmen to move into tertiary education without holding the *Abitur*, i.e. Germany’s school-leaving certificate that entitles holders to take university courses. Over recent years, more and more skilled workers have been taking advantage of this opportunity (Loebe and Severing 2011, p. 81). The combined forms of the permeability principle are offered by full-time vocational schools known as subject-specific grammar school (in German: *Fachgymnasium*), subject-specific secondary school (in German: *Fachoberschule*), or vocationally-oriented secondary school (in German: *Berufsoberschule*). Other countries may lack a direct equivalent of these institutions, which are all forms of vocational senior school. These institutions, whose operation varies from one German state to another, are very attractive in Germany. In the school year 2010/2011, a total of 12,296 students completed the *Berufsoberschule* and gained the qualifications to move on to higher education. In the same year, 42,135 students completed the *Fachgymnasium* and 57,793 the *Fachoberschule* (Statistisches Bundesamt 2013). To contrast, in the same year 476,580 apprentices successfully finished their training in the dual system (BMBF 2013, p. 197).

An example for the integrative dual qualifications would be that students who completed the dual system can also be awarded an intermediate school-leaving

certificate when they match certain minimum requirements (a mark of at least 3.0 – an “average” pass in Germany’s six-grade assessment system – and basic English language skills) (Ministerium für Schule und Weiterbildung des Landes Nordrhein-Westfalen 2008, pp. 42–43). Additive dual qualifications, in contrast, cover a greater scope of curricular content and, therefore, more teaching and learning units and contact hours than integrative dual qualifications. The extent to which vocational and general academic curricula are combined varies: there may be only marginal additions of vocational content to comprehensive academic content or vice versa; or the two curricula are fully completed by students. Successful students are awarded two qualifications, a vocational and an academic one. Providers of dual qualifications (Deissinger 2000) include vocational academies (17 % of all courses), the Baden-Württemberg Cooperative State University (21 %), universities of applied sciences (59 %), and universities (3 %) (BIBB 2011, p. 23). The providers differ in that they either offer university courses with a full apprenticeship or include practical training placements within a company during a more traditional course of study. In 2010, 50,764 students were taking such dual courses; by the following year, this figure had risen by 20.5 %, to 61,195 (BIBB 2012, p. 250).

The examples given point to ways in which parity of esteem may be boosted. Introducing a national qualifications framework in Germany (see Sect. 16.4) may also help to boost both parity and transparency. However, it will take some time before the impact in terms of changes becomes evident because it has not been fully put into practice yet.

16.5.1.2 Parity of Esteem Between Apprenticeship in the Dual System and Full-Time School-Based Vocational Education

Besides its dual system, Germany has a comprehensive system of full-time, school-based vocational education. Unlike the dual system, which operates uniformly across Germany, full-time vocational schools are governed by the federal states. This kind of decentralisation along with the burgeoning number of private educational schools means that this sector of the VET system is becoming increasingly opaque and complex in structural terms, with more marked regional disparities than ever (Baethge et al. 2007). Nevertheless, more than one million students attend full-time school-based vocational education, accounting for around 40 % of all students within vocational schools (Statistisches Bundesamt 2012).

In general terms, two types of full-time vocational schools can be distinguished. The first includes schools who aim at supporting students in acquiring those general educational qualifications, which are for prerequisite for access to higher education. The second includes schools whose main aim is to award vocational qualifications. These may be sub-divided into those offering partial qualifications (whose role is to equip trainees with the basics of a specific training occupation) and those offering independent qualifications, which offer a full course of vocational training accredited under German federal legislation (*Berufsbildungsgesetz/Handwerksordnung*) or a course leading to what is known in Germany as an “assistant occupation”, governed by federal state legislation.

We shall focus here on the second type and compare it with the dual system in terms of successful transition to the labour market. While trainees completing their training within the dual system have a good record of success in moving directly from training to employment (Granato and Ulrich 2001), only just over half of all trainees leaving vocational schools move straight into employment. Just under half are still not in employment a full year after completing their vocational education. Of these, more than one-third take a follow-up apprenticeship, 25 % embark on a course of academic study, and 40 % take further training within a vocational full-time school (Feller 2000; see also Müller 2003). However, access to employment is dependent on the demand of the labour market and on whether a comparable apprenticeship is available in the dual system. For example, students receiving full-time education for the health professions move directly into employment (Müller 2003) whereas, in the commercial sector, students completing a school-based apprenticeship are directly competing with apprentices in the dual system and thus are less likely to become employed (Feller 2004). In general, students completing full-time vocational schools are more likely to opt for further training than those completing an apprenticeship in the dual system. Just fewer than 15 % of all trainees from eastern Germany and a little more than 10 % from western Germany opt for further vocational training within 3 years of completing their initial training. Most of them opt for an apprenticeship within the dual system (BIBB 2012).

To sum up, it is impossible to argue that the dual and full-time school-based training models are of equal status. School-based training often lacks structured links with companies, depriving their students of what Feller (2004) terms “socialisation in the company environment” (authors’ translation). Potential employers, in turn, often lack insight into trainees’ competences. Given the current demographic trends, the significance of full-time vocational schools is under consideration. To strengthen the full-time, school-based vocational education by focussing on those occupational areas in which the dual system is not well established would be a plausible way forward.

16.5.2 Cost/Benefit Analysis of In-Company Training

If it is to be ensured that companies remain involved in training in the long term, even without state subsidies, then the costs and benefits of VET will be key arguments. In this regard, businesses’ decisions to offer apprenticeships do not need to be seen exclusively from a monetary perspective but in light of their motivation to invest in securing skilled workforce or enhancing their reputation instead.

Starting from a monetary perspective, according to Beicht et al. (2004), it is possible to further differentiate costs and benefits of training as follows: Gross costs include apprentices’ labour costs (their remuneration plus social security contributions), a proportion of their trainers’ labour costs, capital (such as apprenticeship workshops) and material expenditures, and other costs, such as examination fees. The benefits derive from the gain represented by the productive work of apprentices,

the savings of costs for external recruitment in case apprentices stay in a company once they completed their training, the savings of costs for not recruiting candidates whose skills are inadequate because they were not trained within the company, and the social kudos the company accrues from its involvement in vocational training.

The most recent research shows that the annual net cost of in-company training is € 3,596 per apprentice and per company (BIBB 2012, p. 262); this total is made up of a gross figure of € 15,288 (in which the main elements are € 9,490 for the apprentice's labour costs and € 3,292 for the trainer's labour costs), offset by the benefits, quantified at € 11,692. Compared with a previous cost/benefit analysis, the net cost of apprentices to German companies has actually fallen by 40 %, mainly as a result of apprentices being deployed more productively. The figures vary widely from company to company, and Wenzelmann et al. (2009, p. 3) even note that "across Germany, around one third of all trainees actually generate net benefit for their companies during their training, while 10 % of trainees cost their companies more than € 15,000 net on an annual basis" (authors' translation). Wenzelmann et al. (2009) offer three explanations for this very broad range. Firstly, they argue, salaries vary between eastern and western Germany; secondly, net costs per trainee are higher in large companies than in smaller ones, for example because paid trainers are often only employed in larger companies. It is, therefore, surprising that larger companies are more likely than smaller companies to be satisfied with the cost/benefit outcome of in-company training: 77 % of companies with more than 500 employees are "very satisfied" or "satisfied". Companies' subjective assessments confirm that providing vocational education within the company also pays off in economic and business terms, with 60 % of the companies being either "very satisfied" or "satisfied" with the cost/benefit outcome and just 11 % being "dissatisfied" (Wenzelmann et al. 2009). Thirdly, net training costs differ between individual sectors. For example, while the public sector, manufacturing, and commerce all have relatively high net training costs, these costs are much lower in agriculture and in hotels and catering. Moreover, the cost of training apprentices whose training is conducted partly in apprenticeship workshops is relatively high. According to Wenzelmann et al. (2009, p. 4) "the gross costs average € 20,063 whereas the benefit yields only € 6,890" (authors' translation). Wenzelmann et al. (2009, p. 10) conclude that companies generally benefit from training young people though apprenticeship and subsequent recruitment of apprentices by the company "[...] do not guarantee a positive cost/benefit outcome" (authors' translation). The companies surveyed reported being able to offset even more of the upfront costs in case their workers went on to gain additional skills and qualifications through in-service training, developing the specialist skills the companies needed.

Concerning non-monetary aspects, demographic trends in Germany and the corresponding shortage of skilled labour provide one possible motivation for companies to invest in training. It is possible to argue that companies are forced to resort to apprenticeships in order to ensure their own future supplies of skilled labour. Troltsch (2008) investigated the extent to which companies' willingness to become involved in training was directed to their own future needs for skilled labour. His findings show that companies that had internally recruited skilled workers with

intermediate skills levels in the past were more likely to offer training places so that they could continue to meet their own skilled labour needs. His survey also shows that the amount of apprenticeship training places within a company was not diminished by that company's past or planned recruitment of graduates from universities or universities of applied sciences. Ebbinghaus (2009) came to similar conclusions on the basis of a research project into quality assurance in vocational training. His findings show that providing training was one of the most important tools used by companies to meet their requirements for skilled labour, particularly when the company's needs were high (Ebbinghaus 2009, p. 28). These survey findings show that investment in VET can be lucrative for German business, particularly since providing such education also helps them to meet their own future needs for skilled labour. Company surveys also show that companies value the "high-quality product" (Kremer 2006; authors' translation) generated by the dual system of vocational training, using its quality and adaptability in particular to meet their own needs for skilled workers.

16.5.3 Definition and Modularisation of Training Occupations

Vocational training needs to evolve continually in order to keep pace with the changes in company environments arising from, for example, changes in working structures, challenges for the workforce, or shift to the service sector. The dual system's adaptability to the needs of companies is particularly evident in relation to state-recognised training occupations, which are constantly being updated or newly developed (see Sect. 16.4). As stated above, since 2000 more than 50 state-recognised training occupations have been newly defined (out of approximately 350 existing ones), and 60,000 young people embarked on training in these occupations in 2010 alone (BMBF 2012, p. 64; BIBB 2012, p. 130).

In addition to newly defined occupations, existing ones have been modified. Though from an international perspective, Germany's training system is often regarded as static and stable, closer scrutiny shows that there are moves towards innovation, flexibility by modularisation. However these moves are not achieved easily. For example, the modularisation of initial vocational training has been under discussion in Germany since the 1990s, but its generalised introduction has been hampered by the concerns expressed by both employers and unions (Pütz 1997). As a result, some forms of modularisation have been imposed in very specific sectors of the VET system, for example pilot schemes for continuing training of the 'older young unemployed' (Davids 1998) or preparatory modules that can, where appropriate, be acknowledged in an apprenticeship taken later (Brötz 2004). Training modules instigated as part of the *Jobstarter-connect* pilot scheme run in 14 selected training occupations are relatively new. The aim was to offer young people who had applied for, but not so far obtained, a training place an opportunity to transfer into a traditional apprenticeship and, hence, to gain access to the labour market. Curricula in the framework of the Jobstarter scheme have typically been sub-divided into

seven or eight modules. These modules are not individually tested and accredited; rather the intermediate and final assessments associated with traditional apprenticeships are preserved. Instead, the aim is to ensure that training offered in different locations can be linked more effectively by means of acknowledging the documented discrete elements and the training modules already successfully completed (Frank and Grunwald 2008; Frank and Hensge 2007). The pilot scheme is still in the development phase.

Modules are already built into standard apprenticeships in the form of optional extra training provisions (Berger et al. 2000). In addition, flexible elements have been integrated into standard statutory training frameworks by means of specialisms and electives. The most interesting development is the introduction of elective skills modules. In 1998, Germany introduced curricula of state-recognised training occupations in which compulsory components can be complemented by a certain number of elective modules. These modules can take 6–18 months. Twenty-five training occupations are currently structured this way, including laboratory, retail, and printing occupations (BIBB 2012, p. 91).

Experience with these forms of modularisation show that the moderate and tailored form of modularisation can improve flexibility, even in traditional and rather rigid VET systems, without destroying the advantages of what is known as *Beruflichkeit* – the holistic view of an occupation and of a skilled workers in Germany. For example, even smaller and highly specialised companies can offer the state-regulated, more generally-oriented apprenticeships because the elective components can meet the companies' specific needs (Pilz 2012).

16.5.4 Relationship Between Learning and Working

16.5.4.1 Renaissance of Work-Based Learning and Learning-Based Work

In response to fast technological development, changed management conceptions and work organisation (e.g. business process reengineering, systemic rationalisation), globalisation, the knowledge economy, and the ageing workforce, the relationship between working and learning has been reconsidered. The developments mentioned led to more complex and continually changing demands in the workplace, which in turn require continuous learning and thus integration of working and learning, throughout an employees' working life (Baethge and Oberbeck 1986; Buttler 1992; Achtenhagen et al. 1995; Engeström et al. 1995; Bergmann and Pietrzyk 2000; Schirmer 2000; Minssen 2006; Dehnbostel 2007). Scope and extent of learning across working lives are expected to increase proportionally. Occasionally it might even be necessary to learn entirely new occupations in order to attain a vocation and secure employability (Billett 2011, pp. 131–132).

In general, learning and working cannot easily be separated. Learning and working are similar in that both are conscious and goal-oriented actions. They differ in that learning aims at changing the individual, e.g. his/her knowledge or cognitive structure,

whereas working aims at changing the environment. The products of working are socially useful and serve as a means to satisfy material and intellectual needs and to secure existence. Learning and working can overlap or occur simultaneously (Kell 1989, p. 16; Bader 1992, p. 233; Pätzold 2011, p. 17). In the early forms of apprenticeship, as practiced in the crafts in the medieval, learning and working were not distinguished (Van Woerkom and Poell 2010, p. 1; Billett 2011, p. 131; see Sect. 16.2). On the contrary learning and working habitually took place in a conjoint process at the workplace (Dehnbostel 2007, p. 14). The strong interconnection of learning and working was necessary for the development of occupations and society or, as Billett (2011, p. 31) put it: “Key means by which humanity has sustained thus far and secured its achievements has been through learning in the circumstances of work”. Vocational schools or institutions focussing on learning are a comparatively recent phenomenon (Billett 2011, p. 131). They regularly come into play when the potential of workplaces to provide sufficient learning is limited and more formal and organised forms of learning are needed. This was true for the founding phase of vocational schools in the early twentieth century (see Sect. 16.2).

“From the second half of the 1980s the learning potential of the workplace has been rediscovered” (Van Woerkom and Poell 2010, p. 1). The potential of workplaces as learning venues (not only as the venue where what was learned elsewhere is applied) is seen in that workplaces are authentic environments that provide opportunities for combining formal and informal learning, individual and team work, and exchange of ideas between experts and novices. In addition, workplaces are assumed to better guarantee transfer of knowledge and skills to working situations than learning in school contexts (Severing 1997, p. 310; Billett 2011, p. 132). These and other features of authenticity cannot be reproduced easily. Sometimes they are neither known nor can they be anticipated (Severing 1997, p. 310; Dehnbostel 2007, p. 16; Van Woerkom and Poell 2010, p. 2). Thus, schools in many cases might not be able to provide effective preparation for the workplace due to teaching-learning processes that focus on declarative knowledge and not on imparting students with the procedural knowledge they need to accomplish everyday tasks in the workplace (Billett 2011, p. 133). Furthermore, dislocating learning from workplaces to schools can cause rote learning and thus serious motivational problems. Apprentices might be unable to make sense of what they learn due to the fact that they do not know when and how to apply the knowledge.

Though workplaces account for high learning potentials, they have serious learning restrictions to be taken into account. For example, routine tasks to be carried out only have very limited learning potential. Furthermore, if tasks are (partly) processed by computers, underlying principles or theories cannot be observed or physically perceived (Achtenhagen et al. 1995). Consequently, additional training is necessary. Another argument is that if working and learning are situated in only one specific workplace situation, transfer might be hurt unless systematisation and abstraction is added through training. Last but not least, tasks characterised by high physical and mental stress or by devastating consequences in the case of erroneous accomplishment are not even assigned to apprentices. Consequently, those tasks cannot be exploited for learning (Severing 1997, pp. 307–317).

16.5.4.2 Forms of Combining Work-Based Learning and Learning-Based Work

Against this background, the question arises as to how schools and workplaces can contribute to the re-integration of working and learning during an apprenticeship in the dual system and how the traditional division of labour between the learning venues can be (re-)defined. For that purpose over the last three or four decades several forms of combining learning and working have been established at the different venues. Dehnbostel (2007) suggests categorising the different forms as follows:

1. Learning takes place directly at the workplace (learning while working) like in traditional forms of apprenticeship or in communities of practice.
2. Learning is strongly connected to working, however dislocated from the shop floor to a separate place in the company (work-connected learning). Typical forms of work-connected learning are so-called learning islands or learning factories, which were established in the 1990s in the automotive industry. The idea was that apprentices learn to complete tasks for different sectors of production in groups (e.g. mounting, tool design, construction) guided by a trainer or an experienced employee. The apprentices can spend up to 6 weeks in one of those decentralised venues. Examples for more modern forms of work-connected learning are internships or quality circles (Debener and Siehlmann 1992, pp. 279–278; Achtenhagen 1997; Dehnbostel 2007).
3. Learning takes place in a specific institution, e.g. a vocational school, but is oriented towards working (work-oriented learning). Work-oriented learning is usually implemented by different forms of complex learning environments, that is to say management games, case studies, role plays, practice firms, or projects to be accomplished (Achtenhagen 1997; Dehnbostel 2007). The idea is to put apprentices into authentic situations in which they have to solve complex everyday-life problems. Working on the problems should enable them to understand complex interrelationships and apply knowledge in new situations and to new tasks. In contrast to workplace situations, complex learning environments are characterised by an instructional design that focuses on enabling learning.

Both schools and workplaces contribute to combining learning and working at the respective venue. However, joint projects between schools and companies can rarely be found. Some approaches aiming at combining working and learning across the venues in the course of model experiments or individual research studies have been undertaken (WOKI 1991; Buschfeld et al. 1995; Krafczyk and Walzik 2001; Kremer et al. 2001; Fürstenau 2003). However, in most cases cooperation between schools and workplaces is limited to mutually informing one another about expectations, experiences, and problems in daily routine of apprenticeship or in agreeing upon measures which are then taken as self-dependent at the individual venue regarding the respective institutional framework (Buschfeld and Euler 1994, p. 10). Consequently, it is left to the apprentices to integrate the experiences made at the different venues. This might be a problem in dual systems.

16.5.4.3 Research on Work-Based Learning and Learning-Based Work

To identify whether the learning potential of workplaces is exploited in the course of apprenticeships, some studies were conducted (Getsch 1990; Keck 1992, 1999; Noß and Achtenhagen 2000; Rausch 2009). The studies reveal that the learning potential depends on both the apprentice and the situation. On the part of the apprentices, their attitude towards learning, their learning premises, and their behaviour play a decisive role (Noß and Achtenhagen 2000, p. 238; Rausch 2009, p. 18; for the general discussion on workplace learning Billett 2010, p. 13). On part of the situation, mainly the tasks and the trainers have to be taken into account. Apprentices are often only given routine tasks, e.g. copying, filing, searching, or they become acquainted with only parts of complex business processes and are not allowed to take on responsibility (Keck 1992, pp. 293–294). Tasks assigned are inadequate, that is to say they do not meet the apprentices' premises, are not interesting, and not new. Criteria identified by research on work design or designing tasks as crucial for learning and motivation, such as autonomous, manifold, and complete actions, and feedback (Hackman and Oldham 1976; Hacker 1986; Volpert 1989; Bergmann and Pietrzyk 2000, p. 42) are not achieved. Thus, learning potential is only limited (Noß and Achtenhagen 2000, p. 238; Keck 1999, p. 170). In addition, immediate, elaborate feedback, assistance, and support of the trainers, which positively influences learning at the workplace, are not regularly given (Bahl et al. 2009, p. 2; Rausch 2009, p. 20). Reasons can be seen in that the trainers decide which tasks they assign to the apprentices and whether and how they give feedback, or whether they are available for assistance. The assignments, in turn, depend on how the trainers perceive and assess the motivation and the competence of the apprentice (Keck 1999, p. 179). The ability and readiness to assist the apprentices, however, depends on the daily pressure of work, interest in training, supervising competence, and trainers' occupational biography (Keck 1992, pp. 293–294; Keck 1999, p. 179; Rausch 2009, pp. 19–20). However, taken as a whole, research on the learning potential of workplaces in the course of apprenticeships is deficient (Beck 2005, p. 549).

Concerning the evaluation of work-based learning in schools, many studies have been carried out in order to assess complex learning environments, e.g. management games or case studies, which should enhance problem-based and self-regulated learning. Results show that complex learning environments contribute positively to the competence development of apprentices. Tests on retention, development of structured knowledge, problem solving, transfer, or argumentation skills prove the efficacy of those environments. However, in many studies, groups instructed traditionally and complex-learning-environment groups did not differ significantly. In addition, data show that students have difficulty understanding complex systems, applying knowledge to new situations, or working together in groups. Overall, complex learning environments do not hurt learning but are not generally superior to traditional instruction. It seems that their potential is often not fully exploited (for an overview see Fürstenau et al. 1999; Beck and Krumm 2001). In this respect it is of main interest to prepare teachers for instruction based on complex learning environments. This is necessary because teachers face challenges when using those

environments. In addition to deep knowledge of the contents, structure, and functioning of the respective environment, they have to leave their role as knowledge provider and act as moderator, coach, advisor etc. (Rebmann 2001, p. 23).

16.6 Dual System(s) of Vocational Education and Training Seen from an International Perspective

From an international viewpoint the societal, economic, and educational challenges are not very different from Germany's. Transnational organisations forecast the skills need in Europe with a specific focus on a highly-qualified workforce, which becomes more and more important. The growing service sector especially needs skilled workers (Cedefop 2012). Though sceptical voices warn not to overestimate the benefit of skills development for economic growth (Nilsson 2010), work- and vocationally-oriented education is regarded a key issue for solving the problems of economic growth and social inclusion (ILO 2010). That is why VET systems are important but have to be modernised (Cedefop 2009).

There is a growing literature which aims at suggesting reforms in a variety of countries because the satisfaction with existing VET systems is low. Publications, like Alison Wolfs' "Review of Vocational Education", recommend beside other elements more apprenticeships, in this case for England (Wolf 2011). And, on a world scale, the quest for a robust education for young people who do not attain either academic or specific higher education has focused on VET and on apprenticeships specifically (Rauner et al. 2009). Publications such as "The State of Apprenticeship" (Steedman 2010) and "Apprenticeship Systems and Issues" (Steedman 2012), a paper in the name of the ILO for the G20 Task Force on Employment, are in line with the endeavours towards enlarging dual apprenticeship models on a world scale, as Britain is attempting, which foster viable ways of introducing such reforms (Dolphin and Lanning 2011). These papers fit with other claims that depict developments in Ireland and other places, where policy makers decided to "rediscover" apprenticeships (Nyhan 2010; Rauner and Smith 2010). Apprenticeships, in this understanding, cover a range of criteria, e.g. a legislative framework, a clearly defined duration, emphasis on workplace attendance, nevertheless orientation towards a programme of learning, formal assessment leading to a recognised certification, and wages for the youngsters. If one of these criteria is missing, it is more a traineeship, an internship, an informal apprenticeship, or just work-place learning (Steedman 2010, p. 3).

The dual system or, more precisely, elements of duality play a prominent role in these reform approaches. Like in Germany, apprenticeship models that combine workplace learning and school attendance are recommended. A longstanding tradition in adding a complementary scheme of "apprentissages" can be observed in France (Ott 2013). The US, Canada, and Australia are debating how to establish or to strengthen apprenticeships as well. And countries like England, France, Italy, Spain, and Sweden try to introduce apprenticeship or more dual system-like

schemes in order to open new pathways, especially for low-achieving students (Gonon 2004; Rustico 2013). Most countries do not aim at replacing one system with another but to offer more opportunities of training for more youngsters.

From an international viewpoint the most important benefit of the dual systems such as the ones in Germany or its neighbour countries (Switzerland, Austria, and Denmark) is seen in the fact that the youth unemployment share is much lower than in other European states. The explanation for this favourable situation seems to be quite evident: due to a smooth transition from school to work but also due to the engagement of employers, the integration into the economy is much easier to achieve than in school-based systems (Steedman 2012, p. 1). In addition, another signum of countries with dual systems is seen in the fact that higher completion rates at the secondary II level are achieved. This shows that VET in a dual system is a valid alternative to traditional schooling and an incentive for youngsters not to abandon education too early. In considering dual systems, it is of great interest for other countries how Germany is able to involve firms in the training system and why and how firms are willing to train young people. The existing literature sees one core element in the coordination of relevant stakeholders (Busemeyer and Trampusch 2012; Gonon and Maurer 2012). Besides the private engagement of firms and also public investment, the role of players in the field is decisive. This leads to the fact that political culture is important in order to coordinate efforts towards providing a system.

Although the dual system is seen mainly in the light of its advantages, the following challenges are considered as well. A lack of a highly qualified workforce is an issue which gains more and more importance, even in countries that have implemented a dual system themselves. It is the demographic change including lower birth-rates of the home-grown population specifically which leads to a demand for mainly highly qualified but also a lower qualified workforce, which is often covered by recruiting specialists or specific categories of workers from abroad.

Furthermore, researchers claim the equity aspect. There is a gender bias related to professions as in other nations. Besides this, the social division remains a topic of controversy. It is much more likely that a youngster from a poor educational background and of working class has more difficulty entering an apprenticeship or accessing an appropriate school. The growing transition system leads to a prolongation of the status of an applicant without a guarantee of continuation (Mayer 2010; Hupka-Brunner et al. 2012a, b; Siecke 2012).

Dual systems are criticised or questioned when the debate is about tertiary education. The tertiary education completion ratio is comparatively lower than in mainly school-based education nations. In a knowledge society, the tertiary level of education is seen as a decisive advantage in mastering future challenges. Like Germany, Switzerland and Austria are also faulted for failing to provide a sufficient number of university graduates. Moreover, there is a debate as to whether the dual system in these countries is suited to the knowledge economy and whether it should be reformed. New schemes of easing the access to higher education and establishing new programs in the field of higher vocational education have been realised. Full-time vocational education and training school systems keep some advantages

and are also easier to handle for certain employers: they have no costs for education. However, they have problems of recruiting skilled workforce.

As a result, we can talk about a paradox: international policy extols the dual system as a remedy for youth unemployment and getting the firms willing to train. Nevertheless, there are certain constraints caused by the shortage of a highly qualified workforce and a decreasing tendency to integrate weak learners.

16.7 Conclusions – What Can Be Learnt About Education for Other Professions?

16.7.1 Conclusions Concerning Selected Reform Approaches

As already indicated in the beginning of this contribution, the question of learning from the dual system has to be seen on different levels. The basic assumption is that the dual system as a nationally rooted model is in an on-going reform process on all levels and that it is dynamic, flexible towards the education system, the needs of the economy, the workplace, and adaptable to new challenges. However, the process of modernisation is gradual and evolutionary in nature and does not represent the ‘big bang’ approach found elsewhere. The reasons for the approach are to be found largely in the corporatist structure of the players involved and in the balance of power between them (Thelen and Busemeyer 2012).

On the level of institutions, the relationship between academic education and VET illustrates that equalising the value of vocational and academic education or awarding general (academic) qualifications within the VET-system would be two possibilities to reach parity of esteem between the two systems. However, vocational training with a strongly practice-based component will stand the test of ‘academic drift’ only when the quality of vocational training is maintained at a high level and when transition possibilities from VET to academic education are either created or preserved. It is self-evident in this context that the different players have to negotiate and to agree on how to cover the emerging costs.

Concerning the relationship of full-time, school-based VET and VET in the dual system, regulatory activities of the federal government have to be critically assessed. Where competing structures are maintained, of which one offers fewer labour market prospects than the other, the inferior form of VET degenerates into the ‘second choice’ provision, which is disfavoured by potential students. Given the current demographic trends, the significance of full-time vocational schools is to be considered. Occupational areas in which the dual system is not well established could be an important opportunity to establish full-time school-based VET.

With regard to financing, in Germany, the state is not required to subsidise companies that become involved in training, a measure that has met with only modest success in many other countries. Thus, transfer of this specific feature of the dual system might be difficult, and forms of financing have to be negotiated.

On the level of the curricula, increasing differentiation and flexibility has to be discussed. This phenomenon is relevant not only to VET; the entire German tertiary education sector will eventually be affected, once the Bologna process reforms take full effect. The English-speaking countries in particular have many years' experience with modular curricula in both the academic and the vocational context. However, this is still a comparatively new area for Germany, and success will depend on learning and making use of the experiences both of other countries and of other parts of the national system. Thus, the design of the curriculum, the definition and the interlinking of discrete modules, along with the relationship between core modules and electives, are general problems. They are exacerbated when two coordinated learning venues are involved, as is the case within Germany's dual system.

On the level of processes of learning and instruction, it seems worthwhile to consider forms of relating working and learning both at the workplaces and at the schools and, if possible, in cooperation with both venues. Furthermore, on the side of the workplaces, it seems necessary to assign not only routine but also complex tasks to the apprentices as well as tasks that suit the apprentices' premises. In addition, adequate guidance and support of trainers seems to be crucial. For that purpose, trainers should communicate with each other. Furthermore, they have to be trained as trainers and need to be partly relieved from daily work pressure. Last but not least, the management should appreciate training efforts in companies. On the side of the schools, suitable learning environments have to be developed and integrated into instructional processes. In addition, teachers have to be prepared for taking over different roles and for systematically relating abstract and situated knowledge in the process of teaching conceptual knowledge.

16.7.2 Conclusions Concerning the Transfer of the Dual System to Other Contexts

Despite the great approval and recognition of dual systems, previous experience shows that an unreflective and non-tailored export of entire training systems is hardly possible. The list of failures of such transfer attempts in the last decades is quite long (Gonon 2012; Stockmann 2013). A variety of factors may hinder transfer – among them the following:

A country's tradition of VET and the way in which a culture develops historically is a major determining factor in how it designs its VET structures and processes. A VET system, thus, is a result of cultural preferences and conventions. Therefore, any change or more radical shift requires a very long timescale. Often, a pathway-bound development of VET systems can only be challenged in phases of juncture, triggered by a deep political or economic crisis. But even then, the common will for change and the resources for fundamental innovations are missing. The results of introducing dual VET patterns are often isolated projects, which are hardly sustainable (Schippers 2009; Maurer et al. 2011).

Another decisive factor is the disposition and aptitude of employers to train and the cooperation of “stakeholders”. In dual systems, employers, although competitors, have to work together to construct a mutual agreement and also to find compromises with other fractions of industry, commerce, and the trade unions. Furthermore, players collaborate not only with the state, the regional authorities, the chambers and associations but also with the parents and youngsters. All participants are crucial for a well-functioning system. Only if they work together and find compromises is such a system possible. Again, this is dependent on a cultural tradition and historically grounded socialisation. Political scientists define this as a strategic alliance of relevant actors, which is often the case in coordinated market economies (Streeck 2009). A broad acceptance of the VET system is one of its greatest strengths because the problem of ‘poaching’ that is evident in many countries can be avoided only when large numbers of employers are convinced of the benefits of training (Pilz 2009).

Another important factor is the interplay between schools and enterprises. A lot of transfer attempts simply implanted schools in another place, hoping that the enterprises there would be eager to collaborate. Or, as frequently occurs nowadays, employers are encouraged through incentives to offer training places without securing real access to suitable schooling (Wentzel 2011).

A further aspect, as well a result of a longstanding political culture, is the kind of legislation dealing with the contract of apprentices, the mandatory schooling, and many other regulations clarifying the interplay between the players involved.

This more or less widely acknowledged, decisive factor of culture and pathway-dependent history encourages comparative researchers to shift away from policy borrowing and head to policy learning. This focus is less ambitious and ubiquitous and discerns between global rhetoric and local practices (Steiner-Khamsi 2012). The focus is to establish reforms that are informed by successful models on a lower scale and level. Unlike a copy-paste procedure, the dual system and its functioning works as an inspiration for developing one’s own pathway.

To sum up, what has been learned in one country cannot easily be transferred to other countries. In the educational sector, policy borrowings are limited by different cultural frameworks (Phillips 2005). The necessary involvement of diverse stakeholders in the vocational sector as well as the interaction between the educational system and the employment system make a direct comparison between countries even more difficult. Nevertheless, German experiences on the individual levels can be exploited for learning about education for the professions in general.

Our very last remark accentuates the unique structure and capacity of the research the German speaking countries (Austria, Germany, and Switzerland) make into VET. In addition to researchers within private institutions, approximately 60 university chairs for VET and their groups are currently researching this area while teaching business and economics education. They cover the full range of topics on the levels set out above. In addition, there is also relevant research capacity within related disciplines, including sociology, political science, and psychology. Moreover, the centrally funded Federal Institutes for VET are also engaged in research, development, administration, and data gathering in this area. Their expertise represents a major contribution to modernisation initiatives and provides critical assessment of the trends towards modernisation.

Chapter 17

From University to Professional Practice: Students as Journeymen Between Cultures of Education and Work

Madeleine Abrandt Dahlgren, Tone Dyrdal Solbrekke,
Berit Karseth, and Sofia Nyström

Abstract The overarching research problem addressed in this chapter is the relationship between professional/higher education and professional work. The chapter will discuss the relevance of university education for professional practice with a particular focus on professional identity formation and formation of professional responsibility. We discuss how different professional programs and their traditions and cultures shape different curricular structures that have an impact on students professional identity formation and transition to work. We will also discuss experiences with and learning of professional responsibility in the web of commitments within educational settings and how new multiple expectations emerge and lead to new learning experiences when entering work life. The argument of the chapter is based on the rationale and findings from an extensive international research program, conducted between 2001 and 2008.

17.1 Introduction

The overarching research problem addressed in this chapter concerns the relationship between higher education and professional work. This issue is of high relevance globally as well as from a European perspective. Against the backdrop of the common European labour market and the idea of mobility of the workforce, this also raises the question of how the higher education systems in different European countries prepare individuals for working life. During the twentieth century, there has been an increasing pressure on universities to incorporate a variety of professional programmes into higher education. As a result, the relationship between higher education and work life has become more complex and diffuse and thereby open for debate. There is growing awareness that not only the content of educational programmes, but also their design and forms of delivery may contribute to students' learning. The policies of the European Union emphasise the importance of employability and mobility of professionals. However, institutions and higher education systems are constrained by national legislation around higher education, and the policies are translated and materialised in local contexts of programs, curricula and through individuals. This means that there is not a one-to-one relationship between policies and what is implanted and enacted in national higher education systems.

Previous research has predominantly focused on graduate employability and career paths. Professional identity formation and the formation of professional responsibility in the web of commitments within and between educational settings and work contexts are less frequently studied (Solbrekke 2007). In this chapter, we address the formation of students' professional identities and professional responsibilities in their transition to work. We also discuss how different programs and their traditions and cultures embedded in curricular structures have an impact on students' trajectories from higher education to work life. The argument of the chapter is based on the rationale and findings from an extensive international research program covering three generations, conducted in the period 2001–2008. The research program takes its starting point within a comparative context of four universities in four European countries, Sweden, Norway, Poland and Germany, represented by the universities in Linköping, Oslo, Gdansk and Duisburg-Essen. The project was financially supported by a grant from the Fifth Framework of the European Commission of the European Union and was entitled 'Students as Journeymen between cultures of Higher Education and Work' (Dahlgren et al. 2007). The Journeymen metaphor has since then been applied to denote a broader international research program, including various projects that focus on a similar research object (Reid et al. 2011).

A Journeyman was historically a concept denoting an apprentice, learning a specific trade or craft as they travelled across Europe in the late medieval times. They arrived, unannounced and stayed with masters of the trade, trusting in their hospitality, to learn the skills and techniques of the master. The ideal was also to learn from different masters, and the journeymen wandered from town to town to get experience from different workshops. The travelling itself was an important

part of their training. In the industrial era, the journeyman became an apprentice that was employed and was bound to a master for several years. Eventually, they received a tradesman's certificate that allowed them to practice all aspects of the trade, without the supervision of a master. Today, the definition of a journeyman still denotes a stage of transition between a trainee and a master (Boucher 2006). It has even been argued that universities are the last guild – while the union and corporation aspects have almost disappeared, universities are still regulating standards of behaviour, levels of education and research (Huisman 2012). Huisman argues that universities in a sense function similarly to the old guilds, with their network of knowledge and learning that is still viable in the modern information age. “MSc and PhD students perhaps more than ever travel across the globe to study under certain masters, all within the university framework”, he argues (p. 4).

The findings from our studies show that the journey from higher education to working life is by no means a straight or well-defined path. Following students as journeymen has provided access to formal, informal, and non-formal aspects of their learning from different masters, in different educational and pedagogical settings as well as in work life settings. The research object, i.e. the relationship between higher education and work was conceptualised as a transition, framed within the metaphor of a journey. The Journeymen metaphor as a concept contains an aspect of historicity through the emphasis on the role of the subject. Another aspect of Journeymen is the mobility between and across different socio-cultural and material contexts. Journeymen can also be viewed biographically; the experiences are part of the formation of identities and responsibilities.

The chapter is structured in six sections. In Sect. 17.2, we give an overview of research on the transition between higher education and work-life. In the third section we elaborate on the metaphor of Journeymen and how this is used to structure the chapter. Section 17.4 provides a theorization of aspects of identity formation and professional responsibilities in relation to pedagogical and institutional conditions. In the fifth section, the theorizations are exemplified through empirical evidence. Finally, the sixth and concluding section discusses the contribution of the chapter to the understanding of professional identity and responsibility formation.

17.2 Research on the Transition Between Higher Education and Work

The relationship between higher education and work has during the recent decades been debated, not least in relation to the harmonisation of the educational systems within Europe and beyond through the Bologna process. Furthermore, the current climate of wider labour market uncertainty has also given the topic an intensified focus (Tomlinson 2007). Different perspectives on the expected usefulness of higher education have been put forward in this debate. Lindberg (2012, p. 9), who argues that these perspectives can be summarized in a number of ways, claims that higher education should be useful: (1) to the graduate in return for an investment in time

and money. The gain should be in the form of a job with substantially better conditions than the graduate would have had if he had not undertaken a higher education programme; (2) to the labour market in educating a competent workforce possessing skills and knowledge needed in the workplace; (3) to national economic prosperity by facilitating innovation and research, giving corporations a competitive edge over other countries and regions.

In line with these perspectives and especially 2 and 3 above, recent European policy documents strongly argue for the need for employers to engage in the design of curricula to ensure their relevance for the labour market and to encourage a more systematic dialogue between higher education institutions and employers (Bologna Beyond 2010 2009, p. 10). On the other hand, it has been pointed out that HE institutions “prefer a loose connection between education and work, stating that preparation for more complicated professional tasks is possible to obtain in other ways” (Dahlgren et al. 2007, p. 307). In that context the pressure concerning the labour market appears futile. However, we may argue that competitive pressure is stronger in most countries today. In his review, Tomlinson refers to research that confirms the importance of extra-curricular activities in the light of concerns about the declining value of formal education.

The question of graduate employment is a central topic within the research on the transition from education to work. A comparative study worth mentioning is the CHEERS study (Careers after Higher Education – A European Research study), which included more than 30,000 graduates (academic year 1994/1995) in 12 countries (see Teichler 2007a, b). The findings show that while the transition is somewhat precarious for a minority of graduates, most graduates enjoy a rather smooth and successful transition. However, the timing of the job search differed significantly by country (Allen and van der Velden 2007). According to the findings, graduates in countries such as Spain, Italy and France failed to find work within 6 months after graduation (ibid. and Stavik and Arnesen 2007). Furthermore, the findings from the CHEERS study indicate that success in finding work after graduation is more strongly related to countries than to field of study. For instance, while Norwegian, Finnish and Dutch graduates perceive education as a field of high specificity and preparation for high level occupations, graduates from Spain and Germany perceive education as a field of study characterized by low specificity and also as preparation for low level occupations (Murdoch and Paul 2007). The CHEER study also included questions concerning graduates’ values and orientation (Teichler 2007b).

In order to take national differences into account, Tomlinson (2007, p. 417), with reference to Hall and Soskice (2001), follows the *varieties of capitalism* approach and argues that countries with more coordinated occupational labour markets such as those in continental Europe tend to have stronger regulations on access to particular occupations due to a tighter coupling between individuals’ levels of education and their allocation to specific jobs. On the other a hand, in countries characterised by more flexible liberal economics and intensive competition such as the UK, the US and Australia there is a greater potential for displacement between the level of education and occupational position.

According to Leuze (2011), previous studies reveal similarities and differences in labour market outcome, where explanations refer to the field of study and countries, whereas differences by type of institution and type of degree are studied less often. In her study, she analyses the institutional stratification of German and British higher education. The findings indicate that the institutional set-up is important and the author concludes that a vertically differentiated higher education system is more likely to generate hierarchical differences in employment outcomes among graduates. As shown by Noeke et al. (2012), analysing the transition from higher education to work in five central and east European countries (post-socialist) the organization of higher education appears to be a central dimension of stratification. Not surprisingly, university master's degree holders enter the labour market significantly faster than graduates from vocational colleges and university bachelor programmes.

The concept of coherence between content and learning experiences from the classroom to professional practice is another central research topic on the transition from education to work. With respect to professional education the research points to a common criticism of the inadequacy of the theoretical content as a basis for professional practice (Smeby and Heggen 2012). The discrepancies have been characterized as knowledge gaps between knowledge acquired in professional education and knowledge demands of professional practice (Smeby 2012). However, to measure the level of transitional coherence is problematic as the research seems to indicate that the respondents report a higher level of coherence after several years in the field rather than after a few years after graduation (Smeby and Heggen 2012).

Finally, individual differences are important to take into consideration. Despite following the same programme, research shows that some students on the point of transiting to employment are significantly more oriented towards the labour market than others (Tomlinson 2007). These differences in orientation imply that graduates' emerging labour market identities are linked to other forms of identity such as social background, gender and ethnicity (Tomlinson 2007).

As argued above, there is a great pressure on higher education institutions to deliver an employable and flexible workforce. In addition to moving higher education institutions in new directions, this additionally challenges the ideas of what a professional should be and what we may expect from current professions and their members (Sugrue and Solbrette 2011). However, what remains commonly recognized is that professions and their members are assigned public responsibilities and granted a specific status and levels of autonomy to deploy expertise in the interest of both individuals and societal interests (Freidson 2001; McKee and Eraut 2012). Consequently, becoming professional implies more than acquiring substantial knowledge and skills to solve problems at work (Jensen et al. 2012). It also involves learning about and becoming engaged in the broader public, moral and social purpose of the profession. While, as reported above, a significant amount of research has dealt with different issues with respect to the relevance to work life of the educational outcome of graduates, there are few studies which critically investigate the formation of professional identities and the sense of responsibility in the transition from higher education to the work context, a theme that is of great interest and relevance in the changing world of education and work. We will be drawing on

findings from an extensive research program on the relationship between higher education and work life. Through the combination of longitudinal and cross-sectional data, a combination of different methods of analysis, and the development of a common analytic framework as described in the following sections, the Journeymen research program contributes to the knowledge of professional learning and professional identity formation. In the following section, we will outline our theoretical perspectives and how these become integrated through the Journeymen metaphor.

17.3 The Journeymen Metaphor as an Analytical Framework

The research object, i.e. the relationship between higher education and work as regards the development of professional identity and responsibility, was conceptualised as a transition, framed within the metaphor of a journey. Using metaphors as a rhetorical tool for interpretation is a common strategy in qualitative research. Often metaphors are considered to be powerful in conveying an immediate understanding of meaning (Janesick 1994). Metaphors can be used to construct a narrative contract with the reader, described by Atkinson (1990) as *hypotoposis*, a technique to capture the reader by means of lively and image-like descriptions. Additionally, a metaphor can be used not only as a tool to ensure immediate understanding of whole entities, but also as a means of giving a structured and analytical description of the dynamic functions or dimensions encompassed in the metaphor. Lakoff and Johnson (1980) have described the use of metaphors as a structured way of analysing an unknown domain (the target domain) with the help of concepts from a known domain (the source domain).

The authors argue that a metaphor is not just a figurative expression we choose after having experienced or thought about a situation; in fact, the way we label a situation is indicative of our understanding of the situation, linked to our previous experiences and knowledge. In that sense, metaphors make visible the experience and world-view of the researcher. It could be argued that the use of metaphors is counter-productive to generating new knowledge, and that the main contribution is only to confirm the prevailing prejudices of the researcher. Dexter and LaMagdeleine (2002) argue, however that the deliberate use of metaphors in the analysis of qualitative data communicates the emerging understanding and interpretation of data in a way that makes the researchers more aware of their subjectivity and personal pre-assumptions which otherwise may colour the interpretations, unknowingly to the researchers. Using a metaphor as an analytical concept means that we deconstruct the meaning of the metaphor with which we associate a certain phenomenon or social practice, so that the inherent functions and relations of the metaphor become visible.

The immediate understanding of the Journeymen metaphor as a concept is that of individuals travelling. When we deconstruct the metaphor further, we can discern

a function of historicity through the emphasis of the role of the subject travelling over time. Another function of the Journeymen metaphor is the mobility between and across different socio-cultural and material contexts. Journeymen can also be seen as comprising a biographical function; the experiences are part of the formation of professional identities and responsibilities of the individual.

A third discernible function of the metaphor is that of change through the obtained experiences of the journey. If we consider the relationships between the functions of the metaphor in the context of education and work, the change can be seen as the outcome of a mutual interplay between institutions and conditions of higher education and the students and teachers that populate them. The dimension of mobility in the Journeymen metaphor in this study hence implies more than a shift from one context to another; we are implying a trajectory of movement and change. The implications for our chosen focus of learning for professional work and the transition to work life in this sense are not only about how education impacts on people, but also how people impact on education. The Journeymen metaphor hence allows us to trace the subjective individual trajectories as well as the collective, socio-cultural aspects of the transitions from higher education to work with a particular focus on identity formation and professional responsibilities.

Another assumption with using the Journeymen metaphor was that basically the same journey, or in this context, educational initiatives, might bring different results in different national, institutional and disciplinary contexts. For that reason, the different course structures encountered by students were also included as a topic for analysis, and comparisons are made between different institutions and programs.

Following the metaphor of a journey, data was gathered at different points in students' travelling from education to work. Semi-structured interviews with freshmen students in their first year of studies and senior students in the last year of their Psychology and Political science studies were conducted, focusing on how they experienced their university education and how they pictured their prospective professional work. To supplement the interview data, curriculum documents concerning the different programs were also used. The project also included a longitudinal part, that put these same questions to senior students and later to professional novices, after 12–18 months and after 3 years of professional practice. The aim was to enquire into how they conceived themselves as professionals, and how they viewed their university education in retrospect, particularly in relation to their professional work. In parallel to psychology and political science, the Journeymen project also comprised related studies on the same research problem in other disciplines and professional programmes such as mechanical engineering, computer engineering, law, and teacher education. The findings from these studies are also used to inform the theorisations in this chapter.

We have chosen to focus on professional identity formation and responsibilities in the transition from higher education to work life. There are several reasons for this choice. As argued above, there is a great pressure on higher education institutions to deliver an employable and flexible workforce. In addition to moving higher education institutions in new directions, this also challenges the ideas of what a professional should be and what we may expect from current professions and their

members. Some express fears that the recent years' political engagement in the economic and functional purpose of higher education commodifies 'knowledge' and narrows 'professional competence' to 'technical skills'. It is claimed that this trend challenges the moral and social purposes of both higher education and professional work (Kalleberg 2011; McArthur 2011). Research within a variety of professional fields seems to support such concerns. Evidence indicates that neither pre-service professional education nor work place learning offer sufficient opportunities to learn about and practice complex moral and societal responsibilities (McKee and Eraut 2012; Nyström 2009b; Shulman 2009; Sugrue and Solbrekke 2011). It is argued that the moral and social dimension of professionalism is threatened by a tendency toward more individual 'self-realisation' (Bebeau and Monson 2012) or a 'utilitarian ethos'; an inclination to think of professional education primarily as a means of obtaining credentials that will be valuable for each individual on the labour market (Brint 1994). New forms of 'managerial' or high stakes accountability dominating the logic and current practices of New Public Management seem to have weakened moral responsibility (Cranston 2013; Green 2011; Solbrekke and Englund 2011) and expectations of what professionals 'should be', how they should perform, and what public responsibility they are expected to take on, are shifting (McKee and Eraut 2012; Sugrue and Solbrekke 2011).

Taking such a scenario seriously requires an investigation and discussion of what is expected of professionals today and how learning experiences from higher education and the transition to work life influence the formation of professional identities and notions of professional responsibility. Empirical evidence collected from the Journeymen research program provides examples of individuals' journeys through different cultural contexts. As will be elaborated below, these examples demonstrate how notions of professional identities and responsibilities are continuously (re)-negotiated. However, it is impossible to identify all the multiple forces and sources that influence professional formation within the confines of this chapter.

17.4 Professional Identity and Responsibility Formation – An Intertwined Process

Our assumption is that professional identity and conceptions of professional responsibility are the result of the interplay between individuals and collectives. The idea of active participation, negotiation as well as reflection, strongly suggests that internalisation of societal norms is a result of a dynamic process whereby the individual gradually comes to identify with the (possibly negotiated) enterprise of a community of practice (Wenger 1998, p. 295). The moral philosopher Larry May articulates it like this: "The idea of professional integrity or professional responsibility is intimately connected with the way a group of people comes to regard itself, and the way that society comes to regard that group" (May 1996, p. 109). Such a group-oriented perspective integrates personal, professional and wider societal norms – thus notions of professional responsibility are seen as part of the collective

and individual professional identities that are constructed and influenced by dominant social attitudes and norms and the respective profession's position and status in society (Solbrekke 2007).

While all workers are expected to be responsible, the groups we define as *professionals* are assigned public responsibilities and granted a specific status and levels of autonomy to deploy expertise in the interest of both individuals and societal interests (Freidson 2001). This ideal of 'collectivity-orientation' stems from the classical notion of professionalism (Durkheim 1957/2001; Parsons 1951, 1968), and implies the commitment to a body of knowledge and skills, both for the profession's own sake *and* for use in the service of individual clients and society. These purposes of professionalism have been reconceptualised as the moral and political obligations of professionals, and have been characterised as "social trustee professionalism" (Brint 1994), "civic professionalism" (Sullivan 2005), and "critical professionalism" (Barnett 2011). Such ideals may appear clear on an abstract level, but how they should be understood and lived out in practice is more complex and vague.

When Durkheim developed his ideas at the beginning of the twentieth century it was possible to speak of professionals as a more coherent group with distinctive social and moral values. In the twenty-first century, professionals are more varied and have more diversified and specialized expertise and roles (Brint 1994; Evetts 2006). Such circumstances lead to a variation of understandings regarding what a professional should be or do. However, current work conditions also imply constraints on professionals' lives and work that inevitably influence professional and personal decisions. No professional agent is free from multiple commitments and embedded responsibilities for not only clients' and societal needs, but also for science and the standards of one's profession and for professional colleagues, and they have to account to employers (Solbrekke 2007). Moreover, in the flow of rapidly expanding information technology and distribution of knowledge, boundaries between expert and novice have become less distinct, and lay people are encouraged to subject individual professional's actions to private as well as public 'scrutiny' (Castells 2000). The interests and desires of 'customers', clients, and patients increasingly influence what is considered 'best practice'. Contemporary realities of pluralism and relativism render moral positions contested and contestable, and to carry out work that is both excellent in quality and socially responsible is challenging (Gardner 2008).

While focusing on the professional, it is also necessary to be cognisant of the private sphere, with its domestic and family commitments, which may conflict with other professional responsibilities (May 1996; Nyström et al. 2008). Collectively, these multiple expectations of professionals result in a rather complex and 'messy' concept of professional responsibility, where dilemmas and conflicts are embedded in the inescapable tensions between responsibilities to clients, professional domain/discipline, society, employer, colleagues, family and/or friends, and one's own professional self and personal integrity (Sugrue and Solbrekke 2011, p. 22). As a society and individuals we expect professionals to be able to blend analytical and practical habits of mind, make decisions grounded in professional discretion that resemble what Aristotle called *phronesis*; situated judgements that result from reflective reasoning and deliberation (Sullivan 2005).

How, then, are students prepared to take on such demanding responsibilities? While it is readily recognised that much professional formation and learning is informal, incidental and dependent on previous learning and socialisation (Fishman et al. 2004), studies have proved the importance of the learning trajectories – the journeys individuals construct through formal professional education – and into work life (Hodkinson et al. 2004; Nyström 2009a, b; Solbrekke 2008; Solbrekke and Sugrue 2012). Abrandt Dahlgren et al. (2006) showed that students' ways of experiencing aspects of knowledge in their professional programmes, and their understandings of the knowledge relevant for professional work could be described in two contrasting conceptions. In the first conception, students viewed the knowledge learned as *ritual*, meaning that they could not see why or how the content they were learning in the program was connected to any professional work. In this category, the exchange value of knowledge was emphasised, certain things that just had to be learned, and got through in order to pass. The connection to a specific context or professional field of work was lacking.

In the second conception, the knowledge students were achieving in their study programme was seen as *rational* in relation to coming professional work. This means that the utility value of knowledge was emphasised, and connection to a specific field of knowledge or professional field of work was clear. This category also had two subcategories: students talking about substantive knowledge that is content specific and contextually situated, and also talking about generic skills that are transferable between different contexts. In an Australian research project, the Professional Entity project, focusing on similar topics, Reid and Petocz showed in a series of studies across a number of professional and classical liberal arts programs (e.g. music, law, design, mathematics, statistics) that students have varied conceptions of their coming professional work (c.f. Reid and Petocz 2003; Reid et al. 2008). These include an *extrinsic technical* conception of professional work as a group of technical components that can be utilised when the work situation requires it and an *extrinsic meaning* conception of professional work as focusing on developing the meaning ascribed to the objects handled by the professionals. The most developed conception of professional work is the *intrinsic meaning* conception, where professional work is seen as essentially related to a person's own personal and professional being.

Reid et al. (2011), also demonstrated that a rational substantive or generic conception of knowledge for the profession and an extrinsic meaning or intrinsic meaning conception of learning for professional work was strongly related to engagement with learning and formation of a professional identity. In a similar sense, a ritual understanding of knowledge for the profession combined with an extrinsic technical conception of learning for professional work was strongly related to a weak engagement in learning and a weak formation of professional identity. Abrandt Dahlgren et al. (2008) also emphasise that the different communities of higher education are of decisive importance for how the graduates become prepared for and identify with their future work, and what they perceive to be their responsibility as professionals. At stake therefore is the question of what identities and conceptions of professional responsibilities students develop through their journeys in higher education, and how these conceptions resonate with the identities they construe. To what extent do

these conceptions and identities correspond with what they encounter at work? What strategies do novice workers develop to cope with new commitments at work?

These questions will be discussed below from the perspective that learning is a complex formation process, and what it means to become and perform as a competent professional is socially and culturally contingent and may vary across contexts and time (McKee and Eraut 2012). We concur with socio-cultural stances that correspond with May's group-oriented perspective, advocating that identity and conceptions of professional responsibility evolve through engagement and negotiations of meaning in communities of practice (Billett and Pavlova 2005; Billett and Somerville 2004; Nyström et al. 2008) in the nexus of multi-membership in education, work and private (Giddens 1991; Lave and Wenger 1991; Shotter 1984; Wenger 1998; Wertsch 1991). Consistent with this reasoning, both a sense of self and conceptions of professional responsibility are understood to be a result of the dynamic consequences of the reciprocal interaction of personal and cultural factors in both their potentiating and constraining influences (Billett and Pavlova 2005).

The theoretical perspective we have applied to the realm of higher education means that students are seen as individuals as well as members of different disciplinary and professional cultures and degree courses. These degree courses may have a clear or less clear connection to a professional work life area, and may also have different educational arrangements. Patterns of relationships between higher education and work are here traced through the accounts of how students understand their education and coming professional work as they enter and as they leave their university education, how they see the coming work, and what they see as the relationship between study and work. In this regard, we draw on findings from a variety of programmes in psychology, political science, law, mechanical engineering and ICT engineering when discussing the impact of different institutional and pedagogical conditions in relation to the development of professional identities and responsibilities in the transition from higher education to work and over the first 3 years of professional work.

17.5 Tracing the Journeys from University to Professional Practice

Students' experiences of studying at university shape and change their life (Brennan and Teichler 2008) and also form their identities (Kaufman and Feldman 2004; Nyström 2009a). In this section, we follow similar lines of reasoning in theorizing on students' journeys from university and into work life over the first 3 years in professional practice. We will provide examples to demonstrate the complexity and diversity of how professional identities and professional responsibilities are formed and (re)negotiated through the experiences of education and work.

However, as journeymen through higher education, students encounter academic traditions and cultures, influenced by institutional and pedagogical conditions, which frame their educational journeys in different ways. Thus, before the discussion

on individual learning trajectories, we compare and discuss the variation in institutional and pedagogical conditions across contexts. By this we indicate how different educational designs might frame students learning trajectories.

17.5.1 Institutional and Pedagogical Conditions

The conclusions drawn from the comparative study involving four European countries, demonstrate that although the four universities deal with the same programme, they have a different emphasis depending on their learning organisation, and follow different pedagogies and conceptions of learning (Dahlgren et al. 2007). When contrasting the programmes in psychology and political science across the four universities these differences become clearly visible. The psychology programme offered at the University of Linköping (Sweden) applies methods of problem-based learning with a strong focus on confrontation with practical problems in the learning process. However, the psychology programme at the University of Gdansk (Polen) is mainly based on working with literature and theoretical reflections. The latter orientation also goes for the programme offered at the University of Duisburg- Essen (Germany). The psychology programme at the University of Oslo (Norway) is more in line with the Linköping programme by offering clinical studies, but does not follow a problem-based learning approach and builds on a linear relation between theory and practice (Karseth and Solbrekke 2006). The comparison of political science programmes shows that the students in all four institutions display a weak professional identity at the end of their studies. The content of the programmes is academic in its orientation and does not offer any strong professional profile. Taken together, the programmes, with the exception of the psychology programme at Linköping, provide students with a discipline-based identity.

Despite differences in institutional and pedagogical conditions, there are some features discernible across the four universities that refer to other distinctions. These are the differences between non-professional and professional programmes. In cases where notions of a professional role are developed, this seems to be accomplished during the later, sometimes more applied, elements of the programme. The institutional conditions seem to support the value of classical academic generic skills such as analytical and critical thinking identity (Dahlgren et al. 2007). A major aim of the Bologna process is to ensure the employability of the graduates, and the higher education institutions have been confronted with increasing international and national pressures to embrace changes to accomplish this. Nevertheless, higher education institutions do not always follow international and national precedents. The different institutions and departments have their own agendas too, and academic knowledge is still at the core when defining and legitimating educational programmes within the universities (Karseth and Solbrekke 2006).

Furthermore, how students and novices perceive the value of their education is highly dependent on the labour market. At the time the study was conducted the socio-political conditions and employment rates differed significantly between

the four countries. Furthermore, the perceptions of the students and graduates also reflect what we have labelled the “institutional pacts” between higher education and professional corporations or other stakeholders in the social environment of the university (Dahlgren et al. 2007; Karseth and Solbrekke 2006; Solbrekke and Karseth 2006). For instance, political science at the University of Oslo was established in order to educate professionals in public administration. An important aspect of this perspective was to establish a research-based theoretical education that aimed at educating reflective bureaucrats. We may argue that there still exists a “pact” between the educational institution and important stakeholders in the bureaucratic sphere. According to this pact, the educational institution is responsible for the theoretical formal knowledge base, and the work place is responsible for training the novices for concrete professional work (Solbrekke and Karseth 2006, p. 113).

So far, we have discussed the differences in institutional and pedagogical conditions that become discernible if we compare programmes between a sample of different universities. A reasonable assumption is that there is also a variation in pedagogical conditions between programmes within the same university. In the following, we will illustrate how that kind of variation can be described, using the data from Linköping as our focus for comparison between programmes.

When comparing programmes in psychology, political science and mechanical engineering, the trajectory from higher education to work life in terms of identity and knowledge formation can be described as a process of *continuity*, *discontinuity* or *transformation* (Abrandt Dahlgren et al. 2006), and these differences to a certain extent are linked to the structural and pedagogical conditions of the programme in question.

The psychology programme in Linköping was shown to have the most obvious professional focus and a high degree of continuity during the transition from being a student to being a professional novice. The socialisation and transition to work was immediate; when the novices showed evidence of professional skills in practice, this led to, in Wenger’s words (1998) a full legitimate participation in the professional community. The emphasis on contextualisation to the diverse field of psychology throughout the programme may be a feature of the educational design that contributes to the feeling of preparedness for work, as it is a strong feature of problem-based learning (Abrandt Dahlgren et al. 2005). In PBL programmes, the positive impact on graduates’ perceptions of communication, and generally on the feeling of preparedness for professional work, has previously been shown in the field of medical education (Jones et al. 2002; Antepohl et al. 2003; Willis et al. 2002).

The students in the Linköping political science program as well as in the mechanical engineering programme experienced the transition from higher education to work as a process involving some kind of *transformation or discontinuity*. In the case of the political science students, the transformation meant re-contextualising their general knowledge and generic skills to specific areas of work (Johansson et al. 2008). The mechanical engineering students experienced their journey into work life as a discontinuity. At the end of their studies they saw themselves in their future professional identity as being experts and belonging to an elite. As novice workers, their view of their professional identity changed since they saw themselves

as exchangeable, moveable project workers. The character of the working tasks as delimited parts of larger projects could be seen as the novices reaching what in Wenger's (1998) terminology could be described as peripheral legitimate participation in the professional community. There were also indications of engineering novices experiencing the professional programme in a more ritual sense, to achieve a formal legitimacy by passing the programme. Passing the program in that sense was seen as a marker of being able to learn fast and work hard, and thus functioned as a door opener to the labour market.

17.5.2 Journeymen Through University: Developing Academic Identities and Idealistic Understandings of Professional Responsibility

During the years spent in higher education, students' develop a strong identification with academic values, scientific knowledge and certain professions. Their perception of their future professional work will influence how they experience learning (Reid et al. 2008). The development of a professional identity is therefore intertwined with the perception of future responsibilities, and as our data illustrate, students have great expectations about what they will learn and become through their university studies. A freshman psychology student stresses that she, through her journey in higher education, will develop expert knowledge which implies membership of a particular professional group that has power. Power is seen as attached to expert knowledge and the specific trust accorded to professional groups by society: *"All experts have that sort of responsibility, because the moment you say you are an expert, you get a lot of trust. I think psychologists will be trusted a lot, although people really don't have any clue why. We have knowledge that very few people in society have, and consequently it becomes very easy to abuse the role. I think we have a great responsibility"* (Solbrekke and Karseth 2006, p. 108).

A law student emphasises an idealistic sense of professional responsibility and how he expects this to be an outcome of higher education. He expects to learn the moral purpose of higher education and the duty to use knowledge for the "good in society". Values like honesty and justice are highlighted: *"You should not look for the loopholes for the rich ones and defend the guilty ones. I guess a lot of people do that, but I will say that you have a moral responsibility not to exploit the system that you are privileged to have an insight into for the benefit of those who can pay"* (Solbrekke and Karseth 2006, p. 111). Similar views are expressed by the freshman political scientists as they see themselves as watchdogs for democracy (Johansson et al. 2008).

In general, the freshmen students start to develop a professional identity with the aspiration to dedicate their competence to the needs of others, as this statement from a student by the end of the studies illustrates: *"... It essentially means that you should apply your competence in the best interests of others, and that you must never act against moral, ethical and societal interests..."* (Solbrekke 2008, p. 492).

Typically, they are convinced that their professional trustworthiness depends on their ability to live up to the expectations of being ‘specialised experts’: “*As psychologists we enjoy much confidence from society related to solving a good deal of problems that other professional groups, so to speak, are not meant to cope with.*” (Solbrekke 2008, p. 491)

By the end of their studies, the notion of becoming an academically trained person has been reinforced in the students. They articulate a strong sense of academic identity, and value the knowledge they have learned and developed through their studies. No doubt, the years at university have given them new perspectives and understandings of themselves. They stress their advancement as human beings and also a change in the way they look upon life, since they have a new language and ability to be critical of the surrounding world. Adam, a political scientist, says: “*I have gained another understanding about knowledge itself, which has made me look upon life in a different way. It sounds pretentious but when I look at society, now I start to analyse*” (Nyström et al. 2008, p. 223).

Typically, the students see themselves as academically trained ‘experts’ that society needs. But having developed a scientifically based competence, they are also obliged to make their knowledge available in pursuit of a more humane society. A law student argues that there is a link between academic knowledge and societal responsibility: “*...because one is a well-educated individual with comprehensive training in how a system works and has to work for society to function.*” (Solbrekke and Sugrue 2012, p. 202).

Despite variations in learning outcomes contingent on different cultures and epistemic traditions in higher education (Dahlgren et al. 2007; Abrandt Dahlgren et al. 2006), a shared ‘formation outcome’ is that these journeymen have strengthened the sense of belonging to professional groups, with a strong reliance on scientific or academic knowledge as the ‘hallmark’ of their professional identity. While they all underline personal engagement and empathy as important ‘qualifications’, the need to be scientifically and analytically trustworthy seems to dominate their horizon. What happens, then, to their professional identity and conceptions of responsibility when moving from the theory-oriented training in communities of higher education to communities of work – when responsibility has to be lived out in practice?

17.5.3 Journeymen After a Year at Work: Re-negotiating Identities and Understandings of Professional Responsibility

Students’ transition from higher education will vary according to previous learning trajectories (McKee and Eraut 2012). What they all have in common though, is the fact that they start their journey into work life as newcomers who aim to move from a peripheral position in a community of practice to a more central position (Wenger 1998). The community of practice to which one belongs as a student is different and distinct from a community of practice where early career experience is acquired and

professional identity (re-)negotiated. It is through the negotiations between personal and socially derived imperatives that identity formation progresses throughout working lives, and what is seen as professionally responsible behaviour may change. This 'transition' represents a period where a new 'settlement' is sought, an identity dissonance that is re-settled, and re-negotiated. However, the force of the influence from the culture of their new work contexts will depend on the newcomers' position and motivation to engage in the practices and enterprise of the new community, and the extent to which they are willing to renegotiate their own conception of professional responsibility (Nyström 2009a; Solbrekke 2008).

A novice assistant attorney demonstrates how idealistic attitudes are renegotiated after a year at work. While she struggles to maintain what she sees as her morally and professionally defensible standards, simultaneously she begins to (re)negotiate her (pre)conception of professional responsibility as a consequence of participation in work practice. New commitments and contesting interests force her to wonder whether her values as a senior student were too idealistic: "*...I think that maybe my moral code was too high, I mean in a way unrealistic... I have to face the fact that the world is not such an ideal place and that you can't expect it to be one either.*" (Solbrekke 2008, p. 493). Commitments change in character when shifting the identity from student to professional.

As newcomers in a work context, by renegotiating what is seen as responsible behaviour, they also change notions of what is important to do as professionals – thus also renegotiating identities to 'fit' with the culture, repertoire and enterprise of their new communities of work practice. Henrik, a psychologist, can exemplify the negotiation between the spheres concerning what is 'correct' professional behaviour. He says: *... if you are at a party and there is a client there then you cannot behave in any way you like. I think it is hard... I haven't solved it yet, where the line is, but I don't think you can behave in any way you like* (Nyström 2009b, p. 10).

At this stage professional training implies developing an advanced and increasing ability to understand and handle the tasks of practice while also being able to behave in accordance with what is socially expected (Nyström et al. 2008; Shotter 1984). For some, as we have described previously, the transition can be experienced as smooth continuation of what has been experienced in the professional educational programme, such as in the case of many of the psychology students. They may experience affirmation of self-esteem and a sense of professional identity and responsibility based on their knowledge, but they may also experience that values and norms as a newcomer may be challenged or even contested in their new context of work. Hence the transition becomes more of a discontinuation or transformation of the learning outcomes of their professional programmes.

As novice workers, they have shifted from being prospective professionals with no responsibility, to being novice professionals with a heavy work load and responsibility for others. A clinical psychologist demonstrates a feeling of inadequacy when starting work in a place where she had successfully practiced as a student, and had thus been recruited: "*The responsibility was rather overwhelming: Now you are a psychologist and you are expected to know this, that and the other and be able to do various things, and it was rather difficult*" (Solbrekke 2008, p. 493).

The statement from this novice psychologist indicates that even well-educated students may experience severe changes in self-esteem when shifting from the communities of students to communities of workers. What she experiences is what theory suggests: that emerging professional identities are not stable when the character of commitments change. The shift from the role as a student, with limited responsibilities at work, to becoming fully responsible for all consequences of actions within a complex work situation, is more demanding than anticipated, even when tasks are stimulating and inspiring. What this statement additionally indicates is that professional identity formation is to some extent sequential: from a limited individual focus as a student to more relational and integrated ways of reasoning about one's profession as early career professionals (Nyström et al. 2008).

While focusing on the professional identity it is also important to take into account the personal and the private sphere, since commitments from these spheres can conflict with one's professional role (Nyström et al. 2008; Nyström 2009a; Solbrekke and Sugrue 2012). Collectively, these multiple expectations of professionals may result in dilemmas and conflicts as a consequence of the inescapable tensions between responsibilities to: clients, professional domain/discipline, society, employer, colleagues, family and/or friends, and one's own professional self and personal integrity (Barnett 2011; Nyström 2009b). Although all these dimensions of professional responsibility are not equally pressing for everyone, or at all stages in a professional's life and career (Fishman et al. 2004), our studies illustrate further how novice workers must handle a demanding life situation of living in a 'web of commitments'. Nyström's (2009b) study shows that this "web of commitments" yields different forms of professional identity formation over time, and that the relationships between the professional, the personal and the private spheres change. Our data indicate how novice workers are willing to 'postpone' their first choice career, and even avoid excessively demanding responsibilities when other commitments are pressing, such as this lawyer who chose to work in public administration with regulated work days for a period, although he hopes to become an attorney in the future. He says: *I have a daughter who is 8½ years old and I want to spend a lot of time with her... I have friends who have started to work as assistant attorneys and they work their heads off. ...I work regular hours from eight to four and then I go home* (Solbrekke 2008, p. 496). Such priorities do not necessarily mean ignorance of professional responsibilities. Rather, they suggest that it is necessary to understand professional responsibility in light of all the relationships that exist for a person, "...based on reasonable expectations of individual behaviour" (May 1996, p. 120).

It appears that the shift from the context of education to contexts of work, where novice workers encounter the realities of 'multiple responsibilities' and conflicts of interest in daily situations at work, causes them to renegotiate their (pre)conceptions of professional responsibility. It becomes apparent that the surroundings and culture of the local context significantly challenge the professional identities and conceptions they have developed through their journey in higher education. This makes it necessary to reach 'negotiated compromises' (Nyström et al. 2008), and compromising on one's moral stances or principles does not necessarily mean

that a professional acts irresponsibly (May 1996, p. 120). Rather, compromises are probably necessary in the context of plurality, insecurity and the need for flexibility, because making legitimate compromises implies the responsibility of taking into consideration the multiple conflicts of interest a professional is obliged to handle.

17.5.4 Journeymen After 3 Years at Work – Shifting Identities

After 3 years of work, the early career professionals are now full members of a professional community (Wenger 1998) and have developed an ability to handle the new ‘web of commitment’. They have now developed a strong sense of who they are as professional individuals, albeit in different ways and through different relationships between work identity and identity for activities (Billett and Pavlova 2005). When reflecting on their professional identity it is important to emphasise the role gender plays in how the female and male early career professionals construe themselves as professionals. Kristina, a psychologist, stresses “...*I think that I have to show that I’m skilled. I have a weak voice, I am quite small, and that is not something that we associate with competence, so first I have to show them that I know what I am doing.*” (Nyström 2010, p. 12). Studies of gender and professionalism point to inequalities in the extent to which females and males are viewed as competent and skilled (Kirpal 2004; O’Neil and Bilimoria 2005; Ranson 2003). It has also been suggested that these inequalities could lead to females and males occupying different occupational positions and responsibilities (Collinson and Hearn 1996; Mainero and Sullivan 2006; Teichler 2007a, b). Nyström (2010) found that female and male early career professionals acquire different kinds of legitimacy, which could, in turn, be derived from the gendered processes that exist in contemporary organizations. Another example of how ‘the web of commitment’ changes after 3 years in working life is the relationship between the different spheres of life, professional practice, and how the subjects constructed their gender identity (Nyström 2009a, 2010). After 3 years of professional work the early career professionals start to have other aspirations which influence their professional identity and also their thoughts about what is valuable in life. Niklas, a political scientist, argues “*I do not want to do it any more [referring to an international career]. The situation has changed as well as what kind of dreams and wishes I have./.../I’m getting married next summer...*” (Nyström 2009a, b, p. 13).

When the graduates reflect on the journey, and consider their professional trajectories from the last year in higher education to 3 years of professional work, the graduates’ visions and experiences reveal a shift from taking in new knowledge and making it their own, to a need to change direction and for some, do something different. One example is a psychologist who has worked professionally for 3 years, and when he thinks about the future he has ‘...*a hard time picturing myself here in five years. It is very hard.*’ (Nyström et al. 2008, p. 225). Another example of an early career professional in psychology envisioned himself starting on a professional

development course to become a psychotherapist in order to work with teenagers with eating disorders. This scenario depended on him continuing to work as a psychologist but *'then, sometimes, I just think I don't give a damn about all this. .. this thought is more diffuse but if I decide to get away from this, I think that I would like to work in design or interior design.'* (Nyström et al. 2008, p. 225). The graduates express a complex, dynamic and ever changing process of professional development that stands in contrast to the traditional vision of a more linear professional development (Baruch 2004).

Experiences of the journey toward becoming a professional and developing a professional identity over the first 3 years of professional work depend on educational background (Nyström 2009a, b). Nyström shows (ibid.) that the psychologists' professional trajectory was somewhat predefined by the discipline. They knew what profession they would enter and they were familiar with the professional practice, i.e. there was continuity between education and work (Abrandt Dahlgren et al. 2006). Nevertheless, after 3 years of work it seems that they were not fully prepared for their professional tasks and what the work as a psychologist would actually mean for them as individuals, e.g. the responsibility for their clients' mental health, or the stressful work environment. The political scientists, on the other hand, entered a program that did not prepare them for a specific professional role, which made their encounter stressful with the result that they had to transform and re-contextualise their knowledge (Abrandt Dahlgren et al. 2006; Nyström 2009a). On the other hand, after 3 years of employment they redefined their professional identity based on their new work practice and work tasks.

17.6 Conclusion

When drawing together the conclusions from our broad and varied studies in the realm of professional learning and the transition from higher education to work life, it is clear that professional learning can mean different things across nations, educational programmes and individuals. Our studies demonstrate that the interplay between national policy agendas, and disciplinary and professional traditions and practices has a profound impact on students' journeys from higher education to work life. Previous research on the transition from higher education to work life has provided important knowledge about the numbers of students who graduate and the patterns of certain career paths after graduation, but less research has focused on how the transition between education and work is played out through the trajectories of the students. The Journeymen project has, through its qualitative design of combining prospective and retrospective views on both education and work, provided a unique contribution to the knowledge of individual sense-making and understanding of socio-cultural conditions in the process of establishing professional identities and responsibilities for professional work. The ways students see the knowledge and learning that is needed for their future professional work

impacts on the way they identify with their profession and engage in their studies and learning.

From a disciplinary viewpoint, appropriate pedagogical approaches can allow the discipline profile to move from emphasizing ritual knowledge, to emphasizing rational substantive and rational generic knowledge. This can be achieved for instance, by specifying a curriculum that has numerous opportunities for addressing the rationale for including specific topics (particularly early in a course), for making explicit links to the profession, and for including the broadest and most transferable skills and knowledge.

We have also demonstrated that there is a link between institutional and pedagogical conditions and the patterns of transition from education to work. Dependent on different institutional and pedagogical conditions, the transition can be characterized as a process of continuity, discontinuity or transformation, in which the established professional identities and responsibilities are confirmed or re-negotiated. The studies reveal how formation of professional identity and understanding of responsibility as personal learning trajectories take form in on-going (re)negotiation(s) of identities and responsibility. When entering higher education and joining an educational programme, students not only become aware of a specific body of knowledge and skills, they are also initiated into the moral order of a profession by being exposed to communities of practice with particular sets of traditions, values and boundaries. Our findings indicate that students tend to learn and maintain a sort of 'idealistic' understanding of what they will do as professionals. However, what the studies also demonstrate is how the realities of contemporary professional lives thrust novice workers into situations that challenge the more idealistic professional responsibility. Assuming that professionally responsible behaviour is contingent on the professional's integrity and a profound understanding of the moral implications of his or her profession, it is appropriate to ask to what extent the 'academic capital' and ethical guidelines students develop and learn about in higher education are sufficient to cope with the shifting and complex commitments that work life represents.

There is a critical limit to how far personal stances, professional values and commitments may be (re)negotiated before they 'tip' towards 'illegitimate' compromises. Thus, without a moral awareness of the normative professional mandate there is a risk that what remains is 'compromised' compromises – and not results of *legitimate negotiations*. In order to avoid capitulation to a 'slide-rule' approach, both higher education and workplaces need to create learning spaces where the dilemmas of professional responsibility can be revisited on a regular basis. Particularly in a time of rapid change and powerful market forces, prospective professionals should be trained – in education as well as in on-going professional learning – to evaluate continuously and negotiate the core values of their professions and the implications of the unwritten contract with society. Professional learning implies deliberation, not to create harmony and consistency but as a way of representing pluralistic attitudes and conflicts of interests typical of modern work life. It is timely to point to the responsibility of higher education to offer space for discussions of legitimate negotiations and compromises and of what distinguishes such deliberations from illegitimate negotiations.

Chapter 18

Integrating Professional Learning Experiences Across University and Practice Settings

Stephen Billett and Sarojni Choy

Abstract This chapter identifies and discusses the educational benefits of providing and integrating experiences in practice settings within tertiary education programs. It does so by adopting a broad curriculum perspective and focussing on developing the capacities required for effective professional practice. These capacities are now of growing importance as, in many countries with advanced industrial economies, higher education provisions are directed towards specific occupational outcomes. The provision and integration of practice-based experiences are seen as a way of securing that goal. Indeed, there are now growing expectations that higher education institutions will provide these experiences in preparing students who will be ready to proceed smoothly into their selected occupations upon graduation. A concern here is to identify an alignment between student experiences in educational institutions and those in practice-settings. This chapter explores ways in which these alignments can be considered and secured.

Keywords Integration of learning experiences • Higher education • Practice-based experiences • Work integrated learning • Professional education • Preparing students for work experiences

18.1 Evolving Demands of Learning for the Professions in Higher Education

This chapter identifies and discusses ways to maximise the educational benefits of providing and integrating experiences in practice settings within tertiary education programs. It does so through adopting a broad curriculum perspective and focussing on developing the capacities required for effective professional practice. The goal of effective professional preparation is now of growing importance as, in many countries with advanced industrial economies, higher education provisions are directed towards specific occupational outcomes. Moreover, the provision and integration of practice-based experiences are seen as a way of securing that goal (Cooper et al. 2010). Indeed, there are now growing expectations that higher education institutions will provide these experiences in preparing students who will be ready to proceed smoothly into their selected occupations upon graduation. Rightly or wrongly, such outcomes are now commonly anticipated by students, industry and professional bodies, governments and organisations that employ graduates (Organisation for Economic Co-operation and Development 2010). Whilst such demands are problematic, contestable and described by some pejoratively as comprising higher vocational education, they represent a line of continuity that has long shaped higher education. That is, there has always been a strong alignment between higher education provisions and occupational outcomes (Roodhouse 2007), albeit either through their direct focus on the major professions or through so called liberal arts degrees that afforded somewhat explicit but no less successful pathways to well-paid occupations in the public service, clergy etc. However, in many countries this alignment is shaped by direct associations with specific occupations and with unprecedented quantum of students within mass higher education systems.

Together, these occupational specific requirements, the quantum of students and broadly based expectations about being ‘job-ready’ on graduation are making new demands upon higher education institutions, their curriculum provisions and teachers. They also comprise tough educational processes and goals for those who administer and teach in higher education institutions. In response to the specific occupational focus, a broadly adopted strategy is the provision and integration of experiences in the kinds of settings where the occupation for which students are being prepared is practiced. Although, there have been long-standing arrangements in some university courses for students to have practice-based experiences (e.g. for medicine, teaching and nursing), the scope, extent and expectations of and for these experiences are now growing to include all programs with an occupational specific outcome (Cooper et al. 2010). These experiences are no longer seen to be those where students merely practise and hone what they have learnt in university-based provisions. Instead, they are becoming a key element of higher education experiences and providing distinct kinds of contributions to students’ learning (Tynjälä et al. 2006).

As noted, this chapter discusses the provision and integration of work experiences for higher education students from a perspective that is broadly from curriculum

practice. That is the intended, enacted and experienced dimensions of curriculum and how these assist explicating and advising about the process of securing an integration of students' experiences in practice settings. As a consequence, in attempting to realise the popular, but tough educational goal of securing smooth transitions to practice upon graduation, it discusses how practice-based experiences might be effectively engaged with and integrated into higher education provisions. That is, their ability to generate in students the kinds of capacities required for initially engaging with some effect in their selected occupation where they secure employment and also to become effective learner-practitioners across their professional lives. So, there are goals associated with securing occupational, situational and life-long learning competence. Therefore, these competences comprise: (i) the canonical capacities required to practice the occupation, (ii) the requirements for that occupation to be applied effectively in the circumstance where graduates come to practice and (iii) those required by practitioners to be proactive, intentional and self-directed learners across their working lives.

So, beyond the specific requirements of occupational and situational preparation, is how to prepare students as active learners, rather than being reliant upon teaching by others. This third line of development captures much of what might be expected as an outcome of higher education. This consideration is also important because much of the effectiveness in the experiencing and integration of activities and interactions in practice settings is necessarily premised on how students elect to engage with them, including the intensity and direction of their engagement. These emphases direct educational intentions to how students are to be prepared and made ready to engage relatively independently in the activities and interactions that are afforded to them in practice settings. This includes them appraising and reconciling what they have experienced in relation to the intended outcome of their higher education programs. Consequently, it is both necessary and appropriate to focus upon students as active learners and how their learning might be promoted in both the practice and university settings. Considerations for curriculum, therefore, are not only about something that is intended by the educational institution and enacted both within the institution and practice settings (i.e. the intended and enacted curriculum), but also something experienced by students (i.e. the experienced curriculum). Therefore, in considering pedagogic practices, it is necessary to go beyond didactic instruction (i.e. teacher-led) and select approaches and models (Tynjälä et al. 2003) to focus upon learners' activities and how to include and utilise learning experiences occurring beyond and outside of teacherly engagements (Billett 2011). For instance, support within the practice setting and how students engage with pedagogically rich work activities become part of the considerations for enriching higher education students' learning experiences.

So, beyond contributions of the intended and enacted curriculum and pedagogic practices, are students' central roles in learning for their selected occupations and, subsequently, their ongoing development across working lives. This conception of experienced curriculum emphasises students' personal epistemologies, and how these are needed to be exercised intentionally and actively (i.e. agentially) and leading them to become effective and autonomous graduate practitioners in their

selected occupations. So, these epistemologies will do much to secure their capacities and direct their efforts to be effective learners across their lengthening working lives. Within the discussions here, the phrase learning refers to the change that arises through the continual process of experiencing through engaging in activities and interactions. When applied to individuals, the phrase development here refers to as the accumulated outcomes of the process of experiencing, titled ontogenetic development (Scribner 1985).

In advancing these premises, considerations for the integration of experiences are discussed here in making the case about how learning for specific occupational outcomes might best be developed initially and advanced further over time. One challenge here is that many existing educational accounts may not inform about or even encourage the use of experiences in practice settings, let alone how they might be effectively integrated into the higher education provision (Cooper et al. 2010). Hence, how concepts such as curriculum and pedagogy are understood need to be freshly defined and positioned as being part of, but in some ways distinct, from accounts provided through much of the education literature.

It follows, that the chapter continues from this introduction with considerations of the demands now being placed upon higher education provisions and the goals that need to be secured for effective occupational practice, including canonical occupational, situational and personal competencies. Having identified and outlined the educational goals that are planned to be achieved in programs seeking to develop the capacities required to move directly into occupational practice, the following sections in turn identify and discuss the kinds of curriculum and pedagogic practices that might be appropriate for such educational purposes. The chapter concludes with a set of suggestions about how the utilisation and integration of both sets of experiences needs to be advanced, appraised and utilised in distinct ways depending upon the particular discipline or occupation.

18.2 Mandate for Provision and Integration of Work-Based Experiences

As noted, governments and industries in countries with advanced industrial economies are demanding that university students are able to engage actively and productively in work activities upon graduation (Department of Innovation Universities and Skills 2008; Universities Australia 2008; Organisation for Economic Co-operation and Development (OECD) 2010). Also, these graduates need to be prepared in ways that make them able to effectively negotiate and manage their initial and ongoing participation in work and working life (Tynjälä et al. 2006), which ultimately extends to them being able to sustain their employability across lengthening working lives. This requirement for continuous learning across working life is salient because of the: (i) changing demands for occupations, (ii) ongoing transformation

of the needs of occupational practice, (iii) dynamic requirements of work practices, and (iv) need for developmental opportunities to move within and across occupations (Billett and Choy 2011). Learning to respond to these kinds of changes is now almost obligatory as few workers and even fewer occupations are immune from such changes. In many ways, these changes set out the mandate for the provision of and integration of practice-based experiences in higher education programs.

Certainly, there is a growing consensus amongst government, employers, professional and industry groups, students and many educators (OECD 2009, 2010), that learning experiences in educational settings alone will be insufficient for developing the kinds of capacities required for active and productive occupational practice (Griffiths and Guile 2003). Hence, there is growing interest in and use of work-based experiences as part of higher education provisions to: (i) augment what will and can be learnt in educational institutions, and (ii) find ways of effectively integrating experiences from practice settings to promote the kinds of learning required for effective professional practice (Cooper et al. 2010). Employee development in and through work is now increasingly seen by both public and private sector organisations as being central to their continuity and development (OECD 2010). Seemingly, these kinds of imperatives are serving to transform how workplaces are now viewed increasingly as valuable and legitimate learning environments. A growing interest in work-integrated learning has garnered attention and generated interest in gaining further understandings about how to conceptualise and work to effectively integrate these experiences for educational purposes (Tuomi-Grohn and Engestrom 2003). Regardless of these interests and demands, integration of practice-based experiences into the university curriculum serves only as a preliminary approach to preparing graduates as novice workers. Following this, they will need to become lifelong learners to respond to constant changes in work and occupational requirements. It may well be that engaging in work-based experiences may assist the development of this lifelong learning capacity. However, there are no guarantees that such integrations will secure either of these goals, as they are shaped by factors beyond the educational project.

As noted, there is nothing particularly new here. Practice based learning experiences have long been used in preparation for and the process of becoming a practitioner in the major professions (Tynjälä 2008). The internships in medicine, article clerkships within law, probationary periods in accountancy and teaching have served as preparatory and assessment for those seeking to enter those professions. However, now a far wider range of occupations are expecting and requiring that university graduates will have engaged in work experiences albeit for professional recognitions or licensing (e.g. engineering or midwifery) and be 'work-ready' upon graduation. Approaches to the provision of these experiences includes those referred to as co-operative education, work experience, placements, practicum, internships, field work, workplace projects, workplace research, work-based learning, sandwich years and cadetships, community-based learning and service-learning (Cooper et al. 2010). Common across these experiences are the periods of time spent in circumstances

where the occupational practices students are preparing for are being enacted. Yet, these approaches differ in terms of focus of activities (e.g. orientation to the world of work, specific occupational preparation), duration (e.g. short, long, day release), sequencing (e.g. before, in the middle or end of an educational program), and the degree of deliberate attempts to link these experiences into educational programs. Through these diverse arrangements, distinct educational goals, such as developing strategic, domain-specific and situational capacities, are aimed to be achieved, with personal qualities of being active, critical and reflexive sometimes being an intended learning outcome. Although many of these goals represent employers' and industries' aspirations for and expectations of graduates from higher education, they also reflect those anticipated by students who invest time and resources through participating in higher education, and whose expectations about outcomes are often quite personally strategic (Billett 2011). Their purposes include developing the procedural competence for selected occupations that will lead them to be effective when employed. In a growing number of countries, higher education students are experiencing increased costs or accruing debts associated with their studies. So, being employable upon graduation also has direct financial implications. Hence, for these reasons and those outlined above, the importance of students' personal epistemologies – i.e. those shaped by learners' beliefs, agency – mediate how they engage in learning related activities (Billett 2009b). This multitude of expectancies and requirements means that university programs are needing now to extend their provisions beyond existing institutionally provided experiences (e.g. tutorials and lectures in classrooms) to utilise and accommodate practice-based experiences in these students' programs (Cooper et al. 2010). Central here is integrating experiences and learning through university-based experiences into practice setting and vice-versa.

The case made here from a curriculum perspective is for this integration to be realised through the sequencing and organisation of learning experiences (i.e. vocational curriculum) as assisted by pedagogical practices – how these experiences can be enriched to assist and support opportunities available in both settings. Importantly, this integration needs to extend beyond those intended for immediate academic and work performance purposes to accommodate a critical and transformative perspective (i.e. not merely reproduction of routine work tasks) that may assist lifelong learning goals. Moreover, and as proposed, the efficacy of a curriculum for productive and purposeful educative experiences relies on the nature of engagement by students and their learning as the focus of the activity; duration; how it is arranged; who supports the learning at the worksite; and partnerships between the universities and workplaces. Given all of these imperatives, it makes sense to find ways of appraising and appreciating the educational worth of integrating work experiences in university curricula. However, it would be wrong to transitions to practice can be simply fulfilled through processes of integrating students' experiences alone, as factors outside the scope and influence of educational institutions. Nevertheless, the case proposed here is on the educational worth of integrating work experiences.

18.3 Educational Worth of Integrating Work Experiences

The belief that knowledge being produced and learnt in universities can then be applied directly to work activities and in workplaces is no longer sustainable as a principle for organising higher education provisions to be generative of occupational capacities. The broad situated cognition movement has emphasised the importance of setting, context and applicability, not the privileging of educational experiences and settings. Hager (2004) proposes that occupational practice is a lot messier than what can be presented outside of it. Work tasks and situations do not necessarily present clearly defined problems that can be addressed with the application of unitary conceptual explanations or ready-made solutions. This circumstance is largely because the goods/services requirements for and social practices in workplaces require and structure knowledge in distinct ways that often cannot be known about until they are engaged in and with. The diverse settings, in and across workplaces, offer a multiplicity of social and physical circumstances with disparate contingencies and bases for occupational performance (Billett 2001b). Moreover, while learning as reproduction of existing concepts and procedures is important for developing many occupational capacities (e.g. routine tasks, conforming to workplace standards), this approach may be inadequate for bringing about continuous improvement or novel or unfamiliar tasks.

Rooted within various analyses of changes in work and work practices and the requirements for active learning, there lies much promise in work-integrated learning as a means of achieving key goals of professional education. That is, beyond developing canonical occupational capacities (i.e. those required and expected of practitioners) that may be accessible through tertiary educational institutions these experiences offer the potential to extend knowledge and understandings for application in practice. This is also important given that the scope and dynamic qualities of canonical knowledge differs across occupations, hence presenting distinct challenges for professional education. For instance, future activities of surgeons may be subject to less change than information technologists who need to accommodate rapid developments in their occupational field.

However, Ellstrom (2001) cautions against easy and optimistic views about the efficacy of work integrated learning by questioning the concept of learning for 'integration' where some aspects may be defined and others indeterminate, expecting individuals "to use their own competence and to define and evaluate the task, methods, and results" (p. 423). He refers to two types of learning occurring in workplaces: adaptive and developmental, maintaining that these are not exclusive, but complementary. Creative learning is held to be the 'highest' level of learning, yet he notes that both reproductive and creative learning have places in work integrated learning. Aside from debates about conceptions of work integrated learning, Hager and Hodkinson (2009) also raise issues about what counts as transferable learning arising through such integrations. They hold that much of the learning curriculum is designed for learning as a product (acquisition of discrete items of knowledge or skills, Hager 2004, p. 3) instead of learning as a product and process that better

prepares learners for lifelong learning. However, such views may underestimate the active nature of learning through practice and that it is premised on procedural development alone, and a diluted appreciation of the experienced curriculum. Indeed, it is likely only to be those kinds of experiences that comprise lengthy periods in practice settings (e.g. apprenticeships, internships) where significant specific procedural development occurs.

Despite these considerations, much literature mirrors a widespread agreement that workplaces are rich, potent and authentic that affords a range of opportunities to learn. A body of empirical studies (e.g. by Eraut et al. 1998; Collin 2002; Fuller and Unwin 2004) attest to the potential of workplace experiences as productive learning, albeit with their particular attributes and any inherent limitations. Nevertheless, opportunities available to learners are not necessarily organised in educationally optimal ways for experiential or self-directed learning because the key imperatives for workplaces are on the services they provide and/or goods they produce (Tynjälä 2008). However, like any other social practice there is often also a realisation about the importance of continuity and change and the need for employees' learning and development in workplace settings. Yet, considered and informed ways of approaching and supporting interventions in work settings are necessary if tertiary students are to maximise their learning from work integrated learning. That is, more than just providing experiences in work settings they need to be augmented in some ways.

Learning experiences of all kinds can be made more effective through specific and targeted pedagogical interventions (Tynjälä et al. 2003) and those in workplaces are no exception. Many researchers concur that considerations of workplace learning extends beyond "simply individual, taught, self-directed learning, but that learning also includes formal, non-formal, informal and tacit aspects, experiential and incidental learning, reflective learning, legitimate peripheral participation, and learning "activity" (Sawchuk 2010, p. 369). These conceptions accentuate the multi-faceted phenomena of learning through work settings and grant variability to the broadly accepted concept of 'situated learning'; and that it leads to diverse sets of outcomes. However, the concept of situated learning is a salient consideration in understanding the educational worth of integrating learning in the university with that from work experiences. The contributions and influences of the socio-cultural environments in workplaces to knowledge construction suggest that a range of intentional and unintentional integration likely arise variably (Guile and Young 2003). Nonetheless, it may be appropriately designed and utilised curriculum and pedagogies that offer the best prospect of securing potentially rich, active and contextualised learning for students and workers alike, because these can be directed towards achieving outcomes beyond those realised through mere participation. It follows that approaches to integration require understanding the relations and contributions of personal and social interactions for learning, culturally developed occupational knowledge, and learning through practice.

Against a backdrop of these considerations there is emphasis on aligning the intentions of a university curriculum with the occupational and workplace cultures and discourses for the purposes of developing: (i) effective occupational practice,

(ii) occupational identity and (iii) capacities to be effective practitioner learners across professional life. According to Dewey (1933/1989), action (not theory) is the starting point for individuals' learning as they engage and interact with the contributions and suggestions of work environments and in doing so construct meanings, perform tasks, make assertions, solve problems and cooperate with others –all within the rules, values, attitudes and expectations of workplaces. Based on these premises, Svensson et al. (2004) conceptualise the integration of learning in universities and the workplace as the “intellectualisation of work associated with modern, integrated production systems” (p. 479) which demand increasing levels of theoretical knowledge and intellectual skills. However, effective occupation outcomes eventuate from a curriculum enacted in ways that invites individuals to construct what is valued for and by work. It includes them being able to negotiate what is referred to as the threshold transgression continuum between the workplace and the university (Davis et al. 2009), each supporting different forms of learning.

University based conceptions of curriculum as integration risk a tendency to be shaped by regulatory imperatives for structuring activities to integrate theory and practice for assessment, accreditation and compliance requirements (Guile and Young 2003). They are sometimes requested to learn and apply so called generic skills (e.g. communication, time management, professionalism and independence) in diverse situations and also take responsibility for their own learning. In these ways, students are being directed towards developing skills, behaviour and self-awareness associated with conceptions of work and self-development, often specified by government agencies and professional associations. Yet, these imperatives may be overstated. Instead, students need to learn to apply theoretical concepts in practice within different physical and social contexts where they were initially learnt. Experiences in the workplace form the main source of practical and tacit everyday knowledge and skills needed for professional competence. Paloniemi (2006) proposes work experiences are worthy because they contribute to three key areas of competence, namely:

- (i) practical skills and knowledge required in specific occupations and job-tasks.
- (ii) knowledge related to the work community and organisation.
- (iii) knowledge that helps one to assess one's work and ways of working and acting (pp. 443–444).

She holds that not all experiences necessarily contribute to specific occupational competence and differentiates those learning experiences in the social and physical context of work that contribute more to occupational development other than experiences in work tasks alone. Work tasks that are routine for individuals mainly contribute to individuals' development through reinforcing and honing what is known. Novel activities for individuals that were “not automated, involved conflict, and when followed by debriefing” (Paloniemi 2006, p. 446) are held to be more powerful in generating new learning. So, in quite different ways, these distinct kinds of activities lead to particular kinds of occupational development. However, it needs to be noted here that what constitutes novel or routine activities and learning is person dependant. What for one individual is a routine activity for another is quite novel. This is likely to be the case for students engaging in work integrated learning given

the increasingly diverse experiences they have before selecting their university courses (Newton et al. 2009). Nevertheless, unless the workplace community recognises, values and shares experience-based and tacit competence, individual learning may not be optimised. Therefore, considered and organised experiences for learners in workplace settings help maximise professional learning. However, workplaces, like educational institutions are not always benign and personal, and professional contestation and other organisational factors can shape the distribution of and bases for engaging in learning experiences in circumstances of practice (Bernhardt 1999).

Learning in practice settings also contributes to the development of students' occupational identity. It does this through assisting to achieve three purposes. First, it can develop capacities required for individuals to realise a preferred occupation which they assent to become their vocation (Dewey 1916). Second, it can provide experiences through which to develop the capacities to maintain competence and to remain employable (Field 2000), and, thirdly, it serves to engage individuals in a process through which they advance their occupational competence and attachment to it, or learn that it does not meet their needs and goals (Hodges 1998) and progress to a new one. Given that development of occupational identity is on-going, individuals need to know about workplaces as sites for learning because increasingly they have a responsibility for maintaining their occupational currency throughout working life and sustain identities that are congruent with what they know and reflect their sense of selves. Through these processes, the ongoing appropriation of domain-specific occupational conceptual, procedural and dispositional knowledge may arise. However, these processes are founded in a duality between the suggestion of the social world and individuals' engagement. Hence, beyond what workplaces afford learners, the process of appropriation and directing human intentionality to achieve both the initial and ongoing learning is premised in learners' agency, enactment and intentions. It is learners who select what, when and how to learn and construct meanings. Hence, those organising intentional learning experiences (i.e. curriculum developers and teachers) should mindfully include activities that develop and engage learners' personal epistemologies (as proposed by scholars such as Brookfield 1997; Marsick 1988; Simon et al. 1991). This is because, ultimately, it is the interactions amongst curriculum, pedagogy, and personal epistemologies that lead to learning that is effective for particular social and physical circumstances. This meaningfulness is mediated by those who engage with and learn through and from them. Such interactions can be generative of capacities that are personally purposive and socially aligned to occupational practices – making it worthy for individuals as well as work.

The case made here is that the interface of university curriculum with the workplace can pose challenges for university programs, teachers and students as well as workplaces in organising rich learning opportunities. Not only the curriculum, but pedagogies that complement learning at the two sites also need careful consideration and selection to effectively secure the contributions of authentic (practice) settings and experiences. At the outset, an understanding of the educational worth of providing and integrating experiences for effective occupational practice offers some direction towards this goal. For instance, nine learning outcomes of work

integrated learning are proposed by (Eraut 2004) as justification for their efficacy. These comprise: (i) learning about task performance; (ii) gaining awareness and understanding; (iii) experiencing personal development; (iv) engaging in team work; (v) participating through role performance; (vi) acquiring academic knowledge and skills; (vii) learning about distinct ways of decision making; (viii) problem solving; and (ix) making judgements. More recently, Coll et al. (2008) have extended this listing to include learning that provides opportunities for students to prepare for the 'real world', realise personal achievements, and network (i.e. interact) at work. Whereas Eraut's outcomes focus at the task performance level, Billett's (2011) list includes emphases on: (i) learning about the occupation, (ii) about variation of the occupation, (iii) extending knowledge, (iv) gaining orientation, (v) building capacities, (vi) developing occupational specific forms of knowledge, and (vii) meeting requirements for licensing. Together, or on their own, these kinds of frames point to the potential scope of learning in and through work activities and interactions.

The prospects that work integrated learning experiences will translate to a smooth transition for graduates into professional practice are widely anticipated. However, Eraut (2004) alludes to a range of traditional, cultural and structural legacies that shape the local nuances of the workplace and these take time to identify and understand. It is through opportunities to engage in work based experiences that these kinds of nuances can be experienced and understood. Given that learning of this kind comprises an inter-psychological process (i.e. between individuals and social sources of knowledge) this engagement with the social world through both close personal interactions as Vygotsky (1978) and others (e.g. Rogoff 1995) propose, and more distally through observing, listening and imitation (i.e. mimesis) seems essentials. These understandings have expanded the repertoire of pedagogical approaches to facilitating learning in the workplace. However, these embellishments draw on discipline based teaching and learning. Lee and Roth (2006) claim that many ethnographic studies have either been too context specific or too broad, and are too descriptive to advance broader advice about such matters. Furthermore, the findings of such studies are often interpreted from the perspective of the researchers themselves (the analysts' paradox).

So, knowing more about the what, how and who is useful to understand the pedagogical strengths and affordances (invitational opportunities) in the workplace that provide platforms to organise and enact a curriculum that offers purposeful experiences for students. The provisions that reproduce occupational capacities should not progress at the expense of developing "the kinds of critical capacities" that contemporary workers require (p. 828). This is consistent with accounts on process of meaning-making through experience as the initial catalyst for intentional learning (Merriam et al. 2007). All of these concerns suggest a greater focus on the development of students as lifelong learners who are critical and adaptive in their practice and can actively engage in the constant remaking of social and cultural practices shaping changes in the knowledge required for particular work practices. These are the types of outcomes that likely will appeal to workers, enterprises and governments and prompt their engagement.

This wide ranging rationale for the educational worth of work-integrated learning experiences endorses the need for curriculum and pedagogic practices that can utilise and augment the provision of work-based experiences and establish bases for supporting graduates' ongoing learning across working life as necessitated by constantly transforming occupational and work requirements. In sum, to realise the educational worth of providing and integrating experiences in both workplaces and university settings, necessitates careful alignment amongst pedagogic, curriculum and personal initiatives so they are generative of the combinations of capacities that enable learners (i.e. students and those working) to become active agents, participants, contributors and co-constructors of knowledge in work environments. It is, therefore, important to constructively align the curriculum and design of appropriate pedagogies within the context in which learners utilise their knowledge and skills (Lynch et al. 2006) because work experiences are becoming an integral and primary element of the higher education curriculum.

18.4 Alignment of Curriculum and Pedagogic Practices for Work Integrated Learning

The case presented above favouring the efficacy of learning in practice settings includes a consistent conclusion that curriculum and pedagogic practices for work integrated learning are required, because just have work-based experiences alone will be insufficient. Instead, students need to engage in goal-directed activities and interactions in ways mediated by workplace experiences and then be integrated or reconciled with other experiences they bring to their university studies. Through these processes arises the prospect that the abstracted knowledge gained from university experiences and the situationally embedded experiences can be reconciled and mediated by learners to develop personal domains of knowledge that are adaptable, and form habits of adaptiveness of the kind that are likely to be successful in accommodating these changes (Vosniadou et al. 2002). Indeed, it is these imperatives that shape consideration of how the intended, enacted and experienced curriculum might be ordered through higher education provisions.

However, before discussing these considerations, some definitional matters need to be addressed. Curriculum is seen as the provision, organisation and sequencing of experiences albeit in educational or practice settings. This definition derives directly from the origin of the term, which refers to the pathway to progress along or the course to follow. That is, a set of experiences intended to secure kinds of intended learning. As noted, there is the intended curriculum, what is supposed to occur and what learning is held to be acquired. The enacted curriculum is what actually happens when it is implemented, as shaped by the range of situational factors, including the teachers, capacities, interests, etc. Pedagogies are held to be means of enriching or augmenting these learning experiences. This enrichment can arise through teacherly acts in educational institutions or practice settings (e.g. explanations, guidance, modelling) or through engagement in activities that

are particularly rich learning experiences or engagement with artefacts and objects that are generative of rich learning. These underpin the experienced curriculum – what learners experiences.

18.4.1 Curriculum for Integration

The intended curriculum arrangements supporting the provision and integration of practice-based experiences needs to take into account the kinds of capacities that need to be learnt and also the means of securing those capacities. Indeed, the origins of the word ‘curriculum’ refer to the course to follow or track to progress along, which incites consideration of the journey (i.e. process) as it does outcomes (i.e. the destination). So, there is a need to consider processes of learning as well as intended learning outcomes. For instance, the provision of experiences for students undertaking the same course may need to be of different kinds. The pathway of experiences for students who are new to the occupation would need to be different to those who are familiar with it. For example, although experienced enrolled nurses engage in the same nurse education program as school leavers, the readiness and familiarity with the work of nursing and hospital wards across these two cohorts may be quite distinct. The enrolled nurses are already familiar with and have been immersed in the health care work and settings, and as nursing assistants. Hence, their work integrating learning experiences would be more helpfully focussed on augmenting and extending what they already know. However, for the school leavers, these experiences are likely required to develop initial understandings of nursing work and orientations to the kinds of physical and social settings in which it occurs (Newton et al. 2011). So, for these cohorts of learners, an appropriate intended curriculum needs to focus on developing further the foundations of the occupations upon which their occupational practices are premised. Yet, even here there are likely to be variations as enrolled nurses have diverse sets of experiences and direct entry students sometimes have a range of related experiences (Newton et al. 2009).

Therefore, although much consideration is given to the intended learning outcomes the intended curriculum needs to highlight and make accessible the kinds of capacities or knowledge that need to be learnt, including that which is hard to learn through practice (e.g. resulting from new discoveries and understandings), and knowledge that is complex, yet in different ways for different kinds of students. However, having clear intended outcomes or goals for the learning is important for guiding selection and integration of experiences. Based on cognitive accounts of what constitutes expertise, it is proposed that the capacities for effective occupational performance are premised on three types of knowledge to organise the kinds of experiences to secure appropriate kinds of outcomes. These are:

- (i) domain-specific conceptual or declarative knowledge (e.g. Concepts, facts, propositions and the links between these) (Anderson 1982; Glaser 1984). These can easily be learnt from books, texts, different forms of media and artefacts.

- (ii) domain-specific procedural knowledge (Anderson 1982; Shuell 1990; Sun et al. 2001). Its acquisition involves active participation in a range of activities and rehearsal until the task can be completed without conscious thought.
- (iii) dispositional knowledge (e.g. interests, beliefs). Individual's interests and beliefs moderate and shape the type, intensity and degree of involvement in experiences presented in the workplace (Billett 2001a).

Each of these forms of knowledge is richly interconnected and interdependent with each other and their effectiveness arises through episodes of practice that offer opportunities for their deployment and development through work activities. Each type of knowledge captures aspects of situational pertinence and is appropriated and remade by and for particular practice settings. Raelin (2008) explains this in terms of distributed systems of appropriation, where knowledge is developed and mediated within social, cultural, political, and ethical frameworks. Hence, workplaces provide physical and social contexts for learners to transform and construct canonical occupational as well as more situational capacities including socially pertinent conceptions, procedures and dispositions. Within the diverse and 'fluid' contexts of practice settings, the challenge for those who organise curriculum is to arrange experiences, including their form and duration through which learners can access and develop these three types of knowledge and in ways that permit them to meet performance requirements of their occupations and learn something of the situational variations in that practice, not just for now, but also the future.

Acquisition of knowledge that is demanding to be learnt or difficult to access may require particular educational or pedagogical interventions to make it explicit for comprehension, application and reconstruction of new knowledge. As referred to later, particular pedagogic strategies and provisions that can assist these learners are required to secure this kind of knowledge. Hence, combinations of appropriate curriculum and pedagogic practices might be used to provide access to and connect particular forms of these three kinds of knowledge that may not be otherwise learnt within the boundaries of everyday experience in the university or practice setting. For instance, opportunities to be involved in work tasks that generate instances for learning and demand the conciliation and consideration of a range of knowledge types. Whether referring to patient care, completing a project based activity in the workplace, taking a task across a range of work areas or planning a semester's teaching exemplify activities of this kind. Hence, opportunities to access these kinds of experiences and their sequencing become part of the organisation of the curriculum.

Regardless of the knowledge to be learnt, engagement in work experiences offer perhaps the single greatest source of accessing work-related knowledge, and therefore is central for curriculum endeavours associated with work integrated learning. Billett's (2001a) investigations found that learning through everyday work activities and interactions in a range of occupations arose in reasonably consistent ways, and these offer useful bases for the organisation of a work integrated learning curriculum. He explains that the efficacy of learning through everyday work experiences arises from four key affordances (invitational qualities for individuals to construct

work-related knowledge). These are noteworthy: (i) engaging in authentic work tasks (both routine and non-routine); (ii) access to indirect guidance (e.g. observation and learning); (iii) access to direct guidance (i.e. by more experienced workers); and (iv) provision of opportunities to practice (i.e. to rehearse, refine and secure development of the kind where tasks can be completed without resort to conscious thinking and that allowing causal associations to be developed). Experiences in practice settings are helpful for developing a range of procedural, dispositional and conceptual capacities yet particular intentional learning experiences are required to make that knowledge visible and accessible. Such experiences can also expedite specific links to individuals' practice and their readiness to act in effective ways. Nonetheless, a purposeful curriculum for work integrated learning relies on the learners' agency and the intentions of those who have the skills, knowledge and time to advance learning (e.g. more experienced workers, supervisors, clinical preceptors). For instance, others in the workplace, such as colleagues, supervisors and mentors, through experience or intuition (or both) may identify opportunities where they could act or intervene to assist, guide or comment on activities for those less experienced.

There is also a growing understanding that different kinds of experiences and, indeed, settings are generative of particular forms of knowledge, suggesting that curriculum and pedagogic consideration need to be informed by clear statements of educational intentions. For instance, certain pedagogic strategies might be required for making knowledge that is inaccessible or hard to learn accessible (e.g. explanations, analogies, diagrams). The particular kinds of heuristics might be used to assist practitioners remember something. For instance, medical doctors are advised to remember particular conditions by the patient who first encountered them (e.g. remember Mr Smith) or a celebrity who had that condition (Sinclair 1997). The point here is that these pedagogic practices need to be introduced at certain times (e.g. before or during practicums, or clinical experiences). Hence, useful integration relies on the selection of workplace pedagogies, best suited to achieve relevant outcomes and their inclusion at specific points on the curriculum.

Furthermore, the provision of experiences needs also to take into account the limitations of learning through practice and developing contingencies. Limitations such as: (i) developing bad habits and dangerous practices (e.g. inappropriate short cuts); (ii) no opportunities to practice or learn from mistakes; (iii) absence of support and guidance; (iv) performing tasks without fully understanding the purpose; and (v) performing tasks that did not contribute to the development of vocational identity have been identified in studies of work related learning (Billett 2001a). These limitations can be minimised through appropriate pedagogical approaches to optimise the strengths of learning from experiences in practice settings. Therefore, important curriculum decisions need to be made to organise experiences to accommodate these contributions and limitations. This qualification that authentic experiences may need explicit structuring and sequencing emphasises that it is not sufficient just to provide work-based provisions. Instead, just like any other element of students' learning experiences a curriculum for work integrated learning requires careful structuring and enactment.

In sum, curriculum considerations for providing and integrating work based experiences needs to go beyond the mere provisions of such experiences. Instead, the intended curriculum needs to planfully consider the kinds, duration and sequencing of experiences in practice setting and how those experiences need to be augmented by specific pedagogic practices. As foreshadowed in the considerations above, specific pedagogic strategies that support and augment a work integrated learning curriculum are required. These strategies emphasise the important role to be played by more informed partners, co-workers, clinical supervisors etc. in these educational provisions. They can permit individuals to draw upon their experiences and expertise in practice settings and augment the activities and interactions that comprise those set out for the learners.

18.4.2 Pedagogies for Integration

As argued earlier, workplaces are potentially rich in their contributions to support occupationally aligned learning. But to optimise that potential, particularly in the integration of experiences may require engaging with the pedagogic opportunities of workplaces. This becomes important because while workplaces are widely recognised as powerful sites for professional and vocational learning, where individuals construct and negotiate their work identities, and learn about their self and agency at work (Etelapelto 2008), learning at work is not necessarily perceived as learning, nor are workplaces always positioned to optimise the learning potential (Eraut 2008). Yet, the source of competence for work principally resides in the workplace (Collin and Tynjala 2003), as per the theories of expertise (Etelapelto 1998). Paloniemi (2006) similarly maintains that “experience gained in authentic work practices is a prerequisite for competence construction and for the development of expertise” (p. 440). Other findings by Tikkanen and Kujala (2000) and Paloniemi (2004) propose the role of work experiences as a way of developing competence, especially for those competences that cannot be developed in educational institutions, other than personal characteristics and more formal training.

Importantly, selective use of the pedagogical tools available in the workplace can augment and extend learning in particular ways, and this needs to form an important consideration for the enacted curriculum. These pedagogies have wide-ranging significance for work integrated learning because the socio-cultural experiences in practice settings shape interpretations, meaning schemes and knowledge formation. Such experiences may be difficult to replicate in other or substitute environments (Symes and McIntyre 2000). While curriculum designers may suggest appropriate pedagogical strategies in the workplace, it is the learners themselves who need to decide what is most appropriate and navigate through the environment to secure opportunities. Hence it becomes necessary for students to become aware of the efficacies of workplace pedagogies in contributing to learning in different ways, and how they can engage with them, not just for academics studies but also lifelong learning. A set of seven dimensions proposed by Billett (2002), that students might

use comprise: (i) daily work practices; (ii) coaching; (iii) other workers (co-workers, supervisors, guides, technical experts); (iv) questioning; (v) observing and listening to others; (vi) modelling; and (vii) workplace document and procedures as means through which workplace learning experiences can be enhanced. Of these, modelling and coaching, supplemented with questioning, explanations and the use of diagrams are useful guided learning strategies for developing procedural and conceptual capacities, respectively. Each of the seven elements and ways they contribute to learning is briefly discussed below.

- (i) *Daily work practices* allow learners to apply their knowledge and skills, and practise the same tasks until those tasks can be done without recourse – from a conscious to unconscious phase. Practising daily work activities also gives an opportunity to learn from mistakes and enhances the ability to solve problems and increase confidence. Students need to understand the requirements of job tasks and also know the types of knowledge and skills required to perform the tasks effectively. Careful planning, actively accessing opportunities and then reflecting on their performance will allow them to optimise learning through daily practices and continue to refine performance.
- (ii) *Coaching* shows the correct method of performing tasks. The workplace coach/guide is seen to have expertise to provide support, correct mistakes and listen to learners' issues or concerns. Coaching approaches instil confidence and also present challenges. However, students' agency in seeking clarification through questioning for instance is important to gain greater benefits from coaching.
- (iii) *Other workers (co-workers, supervisors, guides, technical experts)* share their knowledge base, and exchange knowledge and experiences, enabling individuals to learn about different ideas and perspectives. Co-workers provide technical and moral support. As individuals openly share their experiences and receive confirmations of correct procedures and approaches, they augment their levels of confidence. To experience the benefits of learning from co-workers students need to actively seek space with colleagues within and across the socio-cultural groups. It is they who have to initiate frequent conversations and interactions, and engage in active listening/observations.
- (iv) *Questioning* is a strategy that provides quick answers to learn about the way things are done, and how problems are generally solved in the workplace. Questioning also clarifies things for better understanding, but hinges on appropriate questioning techniques and general etiquette.
- (v) *Observing and listening* assists in learning how to perform a task or solve problems using the correct and accepted procedures. Individuals learn new ways of solving problems, acquire new information and access experienced workers' knowledge. Active observation and listening offers opportunities to gain a systems level understanding of the workplace. Particular nuances, discourses, codes of behaviour, and cultural practices of specific workplaces are acquired through careful observation and listening. These strategies also contribute to the development of tacit knowledge.

- (vi) *Modelling* is when tasks are performed by experts and learners observe and build mental models of the task and gain an understanding of the requirements for performance. Through this strategy models of practice that demonstrate the correct way of solving problems are learnt.
- (vii) *Workplace document procedures* provide the prescribed ways and standards for practice and may also help learners understand how their roles and tasks relate to the overall business of the organisation. This strategy relies on self-directed learning by the students who may not necessarily have the opportunity or time to read the procedures during work.

Beyond this listing of workplace pedagogic practices are those associated with storytelling (Jordan 1989), half-worked tasks (Makovichy 2010), and heuristics, such as mnemonics and devices such as associating a particular medical condition with the name of the first patient it was encountered (Sinclair 1997) and also what (Bailey et al. 2004) refer to as identifying teachable moments arising from workplace activities.

While some of these pedagogic practices are consonant with university-based activities, their efficacy in the workplace may vary. For instance, everyday activities, observing and listening, and other workers form significant sources of learning through practice, but the richness of learning may be determined by a range of socio-cultural and other factors. Then, having access to particular kinds of workplace experiences that provide teachable moments is also crucial. An example here is doctors and nurses' handovers in hospital wards, teachers planning a semester of work, or tasks associated with diagnosing a problem and developing a solution. Yet, in structured educational experiences there is the use of learning circles and focus group activities or co-op seminars (Grubb and Badway 1998) that provide opportunities for students to share their experiences and engage in critical reflection about them.

In sum, intentional pedagogic events and activities such as those mentioned here need to be structured, organised and enacted in ways that are directed towards appropriate and intended learning outcomes. Doing this can augment learning provided through practice-based experiences and promote the development of capacities that will not arise through discovery alone. Nonetheless, the learning activities need to focus on learning rather than on teaching and also offer genuine spaces for learning in workplaces where productive outcomes take precedence over learning.

18.4.3 Learner Agency

The provision of practice-based experiences and pedagogies to augment learning experiences in both settings forms the foundation of universities' work integrated provisions. Yet, the enactment of both the curriculum and the kinds of pedagogic strategies referred to above will not be effective without the readiness, directed engagement and agency of students. Their interest in and capacity to independently integrate learning experiences afforded by the educational institution and the

practice settings form the foundation for successful integration. As the key agents in the integration of learning in university and workplace settings, students need the appropriate skills, attitudes and willingness to engage in ways that can optimise the benefits of work related experiences. This engagement extends to their interests in and abilities to reconcile experiences in both of these settings, thereby integrate their respective contributions to learning and development. Four elements appear critical here. First, the interest in and capability to gain new procedural, conceptual and dispositional capacities through work experiences. Second, taking an active role in and responsibility for their learning whilst contributing to workplace tasks because work and learning co-occur. However, there is a cost to learning and development when individuals prioritise work in favour of studies. Combining work and studies is challenging, yet critical according to Svensson et al. (2004). Third, is the need to recognise that different work sites offer particular developmental and transformative opportunities, making it necessary to plan and engage students in diverse work experiences to gain maximum benefits, even through processes of sharing those experiences. Finally, students need to appreciate the significant role of being introspective about the outcomes of their work and learning experiences, hence the need to be pro-active in improving learning. Teachers can promote agency by increasing opportunities for individual and collective reflection, extending the notion of reflective learning and self-directed learning (Raelin 2000, 2007). Essentially, more specific student preparation is required for work integrated learning to be optimal.

Hence, beyond a consideration of curriculum and pedagogic practices are the personal epistemological practices of students and the need for these to be exercised agentially when engaging in and learning from and across the range of experiences that comprise their higher education. Together, these three sets of considerations come into play when educational efforts to promote effective work integrated learning are enacted. There is one other important reason why learners need to be active and agentic, and self-directed in their learning related activities in workplace settings. Workplaces are contested spaces, essentially a domain for existing workers who feel more entitled to access learning opportunities (Billett and Pavlova 2005). Hence, mere peripheral participation by students will limit the scope of learning. While learning opportunities are present and available in most workplace settings, access to these may be influenced by a range of workplace factors such as cliques, affiliations, gender, race, language or employment standing and status (Bernhardt 1999; Darrah 1996; Hull 1997). Hence, provisions in the workplace may be contested and students need to know how to negotiate and manage on-site affordances.

18.5 Preparing for Work Integrated Learning

The preparation for effective work integrated learning extends to developing students' capacities to be active and effective in their engagement in both educational and workplace settings. Learning about diverse instances of practice, synthesising what

is common and distinct about each place and experience will expose new possibilities and potential for application/adaptation in current as well as future circumstances. But this will only arise if they engage effortfully in such activities and the knowledge gained may extend the repertoire of students' experiences in work integrated learning and give better understanding of expected practices when they venture outside practice settings to gain other preparatory experiences. It will further develop their agency to become intentionally active learners in preparation for future employment in different practice settings across their working lives.

So, curriculum and a range of appropriate pedagogic practices (planned and unplanned) for work integrated learning offer the prospect for learners to enrich and extend their existing knowledge, access and learn knowledge that would be otherwise inaccessible to them in practice settings alone, and certify what is learnt. Notwithstanding these potential, Merriam and Clark (1993a, b) hold that unless the experiences are valued by learners, this potential will never be fully realised. Therefore, pedagogical practices need to be appropriately enacted to augment past and current experiences to extend students' learning as directed towards their university courses and being prepared for effective occupational practice including securing any required professional certification. Tennant and McMullen (2008) similarly assert the importance of this, acknowledging that contemporary graduates need to be multi-skilled and adaptable to – “quickly and willingly apply existing knowledge and skills to new situations, and ... be prepared and capable of engaging in new learning as circumstances warrant” (p. 522). They need to increasingly rely on their learning skills to continually update knowledge and skills, primarily through experiences in practice settings to utilise work itself as the curriculum. Furthermore, they need the skills to access and actively engage with the affordances in the workplace. These contentions suggest that enactment of any integrated curriculum needs to focus on the learners as the constructors of knowledge, because it is they who learn and those who teach should remind themselves that educational provisions are nothing more or less than an invitation to change (Billett 2011). This point was posed by Tennant and McMullen (2008) who asserted that learning in the workplace necessitates dispositions to adapt and respond to changes in circumstances, and that such dispositions are premised on the “ability to reflexively engage with workplace problems and issues which involves critically reflecting on oneself as a learner and worker” (p. 259). Competent and proficient workers are expected to perform routine tasks without having to consciously think about their actions. This emphasises the importance of learning in ways and through means that can integrate conceptual, procedural and dispositional knowledge to achieve particular goals in given situations. The connection between these dimensions of knowledge extends beyond the *techné* (technical capacity) to carry out a task requiring learners' skills to critically review situations and draw on past and current knowledge and experiences to respond appropriately. Brookfield (1997), Marsick (1988), Simon, Dippo and Schenke (1991) and Giddens (1991), among others, have long proposed this type of orientation, maintaining that such a goal is not impossible because learning is an on-going process.

Ellstrom (2001) suggests there are five key factors that influence integration of learning and work and form important considerations for planning and preparing for such outcomes. These are: (i) the learning potential of the task; (ii) opportunities for feedback, evaluation, and reflection on the outcomes of work actions; (iii) the formalisation of work processes; (iv) employee participation in handling problems and developing work processes; and (v) learning resources (p. 425). Eraut's (2008) typology that includes work processes with learning as a by-product; learning activities located within work or learning processes; and learning processes at or near the workplace (p. 149) makes students aware of the wide range of learning modes will also influence the quality of learning.

Notwithstanding the theoretical and practical efficacies of a well conceptualised and designed work integrated curriculum with a range of appropriate pedagogies, as discussed, learners need to be adequately prepared for the integration of university and workplace learning. This is because university students are well schooled in academic tasks (Tennant and McMullen 2008) and use work integrated learning opportunities to extend what is learnt in the university and make judgements about the efficacy and relevance of the educational provision before applying these in meaningful ways to suit different workplace contexts. Worker-learners undertaking university studies, on the other hand, may be more familiar with work practices and seek experiences in educational programs to enrich and extend their occupational or workplace knowledge. Many of these learners, such as the enrolled nurses mentioned earlier, may have weaker educational foundations to learn wholly new forms of knowledge. The integration of their practice based experiences into the university curriculum enables them to do this. Overall, proactivity and agency is equally important for both groups of students to support rich learning as well as professional practice. Regardless of the two groups, it becomes necessary to prepare students as agentic learners who can perform well in practice settings.

18.6 Developing Capacities for Integrating Experiences

As argued above, there is a need to develop students' capacities to effectively integrate or reconcile their experiences and learning from work settings. Although strategies for learning in universities may improve the ability to assimilate learning in the workplace (Svensson et al. 2004), learning episodes may need to be organised to promote students' skills for engaging effectively in practice experiences and maximising their learning from those experiences, including how they reconcile such experiences in terms of the knowledge they need to learn for their selected occupational practice. Tennant (2000) and Major (2005) contend that academic learning skills, while appropriate to the requirements of writing assignments, are less applicable to learning in the workplace where students' roles in the process and management of learning becomes more salient. Tennant (2000) goes on to suggest supplementary skills that complement traditional academic learning and are

essential for effective transition to work. These are: analysing work experiences; learning from others; functioning with incomplete information; contemplating multiple courses of action to decide on the most appropriate action at a given moment; learning about organizational cultures and sub-cultures; expanding learning opportunities by using a range of resources and activities; and understanding various competing interests in the profession.

While these skills are highly desirable, they cannot be guaranteed to arise through mere participation. Instead, the preparation of graduates for work integrated learning experiences may warrant particular kinds of interventions before, during and after the learning episode. Drawing on the findings of twenty projects associated with the provision and integration of practice based experiences, Billett (2009a) suggests a series of curriculum and pedagogic activities before, during and after learning in the workplace as a starting point for effective integration of experiences in university and practice settings. These are summarised below.

18.6.1 Before Practice-Based Experiences

These days it is common for students to have experienced some learning in workplaces in preparation for and when engaged in part-time employment, mainly to manage fee debt. However, this does not necessarily mean they are fully aware of the educational worth of workplace experiences. Three questions posed by Eraut (2004) form the premise for student briefing before practice based experiences. There are: (i) What are students expected to learning for practice based experiences? (ii) How is learning expected to take place? and (iii) What factors will influence learning? For more purposeful learning to meet academic requirements and lifelong learning, it is helpful to orientate students to the requirements for effective engagement at the worksite, establish bases for experiences, and develop capacities for work performance. Clarifying purposes and expectations of work performance will better inform them about roles and responsibilities of the different agents and ways they can operate as agentic learners. Furthermore, an appreciation of the socio-cultural settings and their significance to learning and work in practice settings will help students understand the cultural traditions and structural legacies that shape and may even disfigure practice. Billett's (2006) research concluded that different forms of social practices influence how knowledge is appropriated and structured. Appropriation is also effected by industry or worksite specific jargons that students need to learn. Additionally, because learning involves others, forming and maintaining quality relationships for learning is also time consuming. They need to become aware of competing and varied interests of workers and managements, contested resources and opportunities and as 'outsiders' learn ways to navigate through challenges to access and secure learning. Appropriate personal attributes such as communication skills, expected behaviours, attitudes or dispositions towards work will be highly valuable too. On the whole, preparing students before practice needs to concentrate on how learning occurs in the workplace and their roles in enhancing learning (Tennant and McMullen 2008).

18.6.2 During Practice-Based Experiences

Students need to be mindful that the daily goals of workplaces focus more on productivity and services than on learning, and that workers and supervisors are often preoccupied with their daily duties and targets. However, when opportunities arise it is necessary for students to seek and access direct guidance by more experienced workers and actively engage in pedagogically rich work activities and interactions. Sometimes newcomers to the workplace can also offer rich understandings about the contexts (Eraut 2008) because they have recent experiences in exploring and making sense of the socio-cultural nuances. Learning requires sequencing and combining activities from the prescribed learning curriculum and practice-based curriculum by effectively interacting with peers, and actively and purposefully engaging in learning in the workplace. In terms of assessing how to approach a particular work-learning situation, Ellstrom (2001) advises learners to ascertain how well the tasks, methods or results are prescribed and to what level of detail. These, he explains, influences the type of learning – reproductive, productive or creative.

18.6.3 After Practice-Based Experiences

The personal benefits of work integrated learning have been widely reported as contributing to ‘greater self-awareness, self-confidence, self-belief, and improved task, project, and time management skills (Coll et al. 2008, p. 114). Practice based experiences also reaffirm the value of theoretical knowledge and how academic studies lead to career preparation. These and other benefits need to be shared and critically analysed to explicitly link what is learnt in the two sites as well connect any new knowledge to what students have experienced. The active and selective qualities of learning that is valued by individuals can be emphasised to then generate critical perspectives on learning and work. However, Goldman (2008, p. 105) cautions that these tasks take time and ‘is hard work’.

The development of critical and reflective thinking skills before, during and after each learning episode is also advocated by others. Lakes (1994) argues that critical and reflective thinking skills are important for appraising changes in work requirements, technologies and practices to ascertain their worth and applicability. Knights and Willmott (2000) also contend that these skills are necessary because critical insights arise through experiences other than in educational settings. Essentially, critical and reflective thinking skills need to be embedded in interventions before, during and after the learning episodes in practice settings.

It is proposed here that appropriate interventions before, during and after learning episodes in practice settings can minimise surprises and facilitate enjoyable and productive experiences. Smooth transitions to effective professional practice are expected to be enacted by graduates who are informed, prepared and have capacities for professional practice, including critical insights and personal agency (Billett 2009a, b). This preparation includes preparing students to be proactive learners, capable of exercising critical, but productive agentic learning. However, there are

other intervening factors that influence these outcomes. Learners' past knowledge and experiences, what is valued as worthy knowledge at the time, what is afforded by the learning environment, and access to relevant discourses will all shape how they engage in activities and interact in educational or practice settings. Regardless of all these, it is the quality of experiences and how the learner engages in them that determine the degree of success. Hence, curriculum decisions need to consider combinations of affordances and engagement that can generate robust and critical occupational knowledge.

Finally, learner agency underpins the quality of engagement. The skills for life-long learning to integrate learning from different sources serve well the necessities to engage in learning in the workplace either as a new graduate or as a worker-learner engaged in continuing education and training. Nevertheless, personal epistemologies and their place within the curriculum and supporting pedagogies also play a critical role in their engagement, and, hence, learning. In sum, the success of integrating university and workplace learning relies on how well the students are informed and prepared, as well as their personal epistemologies and agency. Three approaches to make pedagogy, curriculum and personal epistemologies are proposed by Billett (2009a, b) as potentially helpful. These are:

- (a) identify and acknowledge the pedagogic potential of practice experiences, and consider how these can be engaged and integrated within higher education curricula to maximise students' learning experiences;
- (b) include within curriculum considerations about how best to prepare for, position, sequence and identify the most appropriate duration of practice experiences, and consider support for learning from those practice experiences; and
- (c) identify what kinds of experiences might best develop, sustain and utilise students' personal epistemologies, including their critical engagement and reflection (p. 840).

These propositions highlight the importance of universities' roles in developing students as proactive learners, capable of exercising critical, but productive, agentic learning and development.

18.7 Advancing Integration of Learning Experiences Across University and Practice Settings

In conclusion, the integration of learning experiences between the two sites and students effective reconciliation of those experiences are not without challenges. They rely heavily on the partnership between universities and setting where students engage in practice-based experiences (i.e. workplaces). These partnerships necessitate negotiations to balance the interests of the universities in facilitating and maintaining learning experiences required for course curriculum, and productivity and workforce development imperatives of workplaces where students can engage in experiencing their occupation in action. Necessarily, both partners need to be involved, by degree, in the designing, delivery, assessment and review of learning, and be committed to student learning, although it will likely always be the case that

education institutions will carry by far the greatest portion of this burden, and quite rightly. To expect otherwise is to court failure. Indeed, there is much that universities can do in terms of their provision of experiences and finding ways of elaborating those experiences. As has been proposed above, many of the goals for higher education that are related to effectively preparing graduates to move smoothly into practice are associated with the provision of practice-based experiences. Much is being undertaken to now provide such experiences. But, the provision of such experiences is the commencement point, not an endpoint. Instead, as argued here there is a need to organise, sequence and structure those experiences to generate the kinds of knowledge that need to be learnt. Yet, to do this requires the identification, selection and enactment of pedagogic practices that can augment that learning. As noted particular kinds of augmentation are required and these can be located in the strategies used by teachers and others before, during and after practice-based experiences as well as particular kinds of work experiences that are inherently pedagogically rich. Then, there is the need to assist students become active and intentional learners as they will need to learn independently or interdependently in the workplace, and thereby develop capacities that will assist them across their working lives. It is this collection of practices that are educationally sound, adroit and relevant for contemporary higher education that have been introduced and discussed across this chapter.

Chapter 19

Transitions to Working Life: Securing Professional Competence

Päivi Tynjälä and Jennifer M. Newton

Abstract This chapter examines the transition from education to work as a critical phase of professional career and the development of professional competence. Literature on transition to working life has brought up several challenges that many graduates meet in early stages of their career such as threat of unemployment, inadequate knowledge and skills, decreased self-efficacy and increased stress, instability of professional identity, early attrition and changing occupation, newcomers' role and position in a work community, and the importance of workplace learning. This chapter examines each of these challenges from the professional competence point of view. Special attention is paid to the role of social partnerships in meeting the challenges.

Keywords School-to-work transitions • Professional competence • Partnerships • Challenges of newly graduated • Youth unemployment

19.1 Introduction

This chapter examines the transition from education to work as a critical phase of professional career and the development of professional competence. Literature on transition to working life has identified several challenges that many graduates meet in the early stages of their career such as: threat of unemployment, inadequate knowledge

and skills, decreased self-efficacy and increased stress, instability of professional identity, newcomers' role and position in a work community, early attrition and changing occupation. The importance of workplace learning in supporting graduates as they transit to the workplace is influential in assisting graduates deal with these challenges. This chapter examines each of these challenges from the professional competence point of view drawing upon examples from several research projects undertaken by the authors to accentuate how these challenges might be addressed. In particular special attention is paid to the role of social partnerships in meeting the challenges.

Most of the studies pertaining to school-to-work transition have focused on the employment of newly qualified people (e.g. Teichler 2007; Betti et al. 2005). Comparisons between transition practices across countries have revealed substantial differences in how they provide workplaces for youth. However, qualitative analyses on circumstances beyond the cold figures are rarer. One exception is Guile's (2009) conceptual analysis in which he argues that the transition from education to work should be thoroughly rethought. According to him the transition should be understood as the development of vocational practice rather than acquisition of qualifications. This follows that the conceptions of vocational practice need rethinking as well and seeing vocational practice as "evolutionary, laterally-branching and envisioning". In other words, vocational practice in this view involves creating new practices and objects as well as modifying and developing existing practices; and workplace pedagogies are central to these processes. This kind of conceptualizing of vocational practice entails the idea of vocational development as a continuum starting from education and continuing throughout one's working life, involving both vertical and horizontal transitions and transformations. It also entails the idea that transitions are not only individual phases of development, but also junctions that link individual and institutional processes (see Volanen 2012).

The conceptualization of transitions to working life as the development of vocational practice and as junctions of individual and institutional processes, in turn, suggests a paradigm change in how the transitions are enacted. Two different approaches can be discerned in this respect: *an individualistic approach* that relies on developing individual attributes that help in transition (e.g. training career adaptability, Koen et al. 2012; or "newcomer socialization", Saks and Gruman 2011) and *an institutional approach* which is based on building social partnerships between education and work (e.g. Billett and Seddon 2004; Deitmer and Heinemann 2009). In this chapter, our main focus is on the latter. In some vocational education and training systems partnerships between education and work have a long history. A well-known example is German dual VET system where industry and education sector jointly take care of apprenticeship training. In many other countries, VET partnerships have been developed only recently and are organized in a less structured way. For example, in Finland students' workplace learning is organized within the framework of national and local agreements between the education and industry partners. In recent years, there has been increasing interest in social partnerships across higher education institutions internationally to ensure that university graduates have the ability to make smooth transitions to into professional practice (Billett and Henderson 2011).

In the following sections, we examine the transition to working life from the professional competence point of view. We discuss the challenges of the threat of unemployment, inadequate knowledge and skills, decreased self-efficacy, instability of professional identity, newcomers' role and position in a work community, and the importance of workplace learning (cf. Tynjälä and Heikkinen 2011). The specific role of social partnerships in relation to each of the challenges is discussed drawing upon, where relevant, empirical evidence from several research projects in the field of healthcare to provide insights into how the above challenges can be addressed. We argue that the role of social partnerships is central to understanding and responding to transitions issues. In particular, the presence of pedagogical arrangements with strongly aligned education and practice experiences seems essential.

19.2 Challenges in School-to-Work Transitions

19.2.1 *Threat of Unemployment*

A study by Betti et al. (2005) describes school-to-work transition in EU countries by analyzing the employment situation of individuals as a function of the time elapsed since the person's most recent exit from education or training in relation to the current employment situation. Their findings show big differences between the countries in overall employment situation and for the newly graduated in particular. The countries where the overall employment situation is poor (Spain, Italy, Greece) the disadvantage of the newly qualified group tends to be accentuated. During 2012, media reports indicated the unemployment rate of Spain being above 25 % and more than half of young people being out of work. In general, the probability of unemployment seems to decrease as the level of education increases (e.g. OECD 2000; Woolbers 2000; see also Teichler 2007). However, in recent years the unemployment also among highly educated has been increasing in many countries (e.g. Moreau and Leathwood 2006; Livanos 2010). Therefore, the threat of not getting a job after schooling may be true not only for low-skilled workers, but also for highly educated (Vuorinen-Lampila and Stenström 2012). Indeed, recently in Australia there has been considerable concern raised from nursing's professional and union organisations that newly degree qualified nurses have been unable to secure employment in a graduate program with a health care organisation (White 2013). This has significant employment implications for these new nurses as many non-graduate nursing positions advertised require a registered nurse who has a minimum of 12 months experience. Thus gaining a university qualification may, into today's competing workforce not necessarily guarantee a successful transition from school to work and it would appear that this might be influenced by unemployment rates. Betti et al.'s study (2005) showed that there are differences amongst countries in how the unemployment rate varies across education levels. For instance, Austria and Finland were characterized with high index of the overall employment situation of "juniors" (i.e. persons with the exit-from-school-to-observation interval of up to 5 years), and the employment situation was quite equitable for persons with

different levels of education/training. By contrast, in the UK and Ireland, also characterized by good overall employment situation of juniors, there were marked differences based on levels of education/training, meaning that the employment situation for poorly educated was much worse than for the better educated.

As noted above, here we discuss the challenges of school-to-work transition from the partnership point of view. From this perspective, the employment situation becomes a very interesting case and the following question arises: Are there differences in employment rates between the countries with or without dual system in vocational and professional education and training? In other words, is the employment situation of young people better in the countries where vocational students are employed in apprentice-type agreements during their education and training? This consideration is founded on the kinds of preparatory programs that include significant components of workplace. According to Betti et al.'s (2005) study there was no clear-cut relationship between the type of vocational school system and the employment outcome. In European Union statistics (European Union 2012), the lowest level of youth unemployment rates were found in the Netherlands, Germany and Austria of which the latter two have dual VET-system. (The lowest youth unemployment rate in Europe is in Switzerland, but it was not included in the statistics because it is not the EU member state.) In OECD statistics from 2011 (OECD 2012), the lowest unemployment rates among young people were in Switzerland, Netherlands, Japan, Austria and Germany. Thus, among the top performing five EU member states, the dominating vocational training type is based on the dual system in three countries, and on a school-based system in two countries. The reason for the inconclusive findings may lie in the fact that there may be functional social partnerships also in these countries with the school-based VET-system. For example, in the Netherlands, there is a widespread use of work-based learning. Outside of the EU, within Australia for example, the VET system is informed by industry and is client-focused to deliver flexible, relevant and responsive education and training. Similarly in Finland, a work-based learning system was introduced as part of school-based vocational education and training at the beginning of the Millennium, with positive effects on vocational school graduates' employment (Tynjälä et al. 2006a). Although the phenomenon in question is complex in nature with complicated interrelationships between educational and labour market systems as well as societal conditions, the findings of their review suggest that close collaboration between vocational schools and workplaces is conducive to effective post-school transitions that lead to employment. The mechanisms behind this probably lie in the fact that partnerships provide students and employers with an interface to meet each other and thus make smooth transitions possible.

19.2.2 Inadequate Knowledge and Skills

When young people are facing the challenge of finding a job, they also often have a feeling that their education has failed to prepare them with adequate skills and knowledge for the working life (e.g. Crebert et al. 2004; Murtonen et al. 2008; Stenström 2006; Teichler 2007). For example, in a Finnish study university

graduates after 2–10 years of work experience were asked where they had learnt the skills they required in their job. Of the respondents (n=955) 66 % thought that they had learnt the most important skills at work and only 14 % mentioned university as the learning site of these skills (Tynjälä et al. 2006b). Research on newly qualified health professionals also clearly demonstrates graduates' concerns about a sense of lack of preparedness for the demands of their professional role. In a study by Newton and McKenna (2007) examining newly qualified nurses' experiences of their first few months in practice, participants reported lacking appropriate knowledge and skills. Thus, when they began their graduate program they did not feel prepared. Olivia, a new graduate nurse, illustrates this point well,

Now I understand that I was not very prepared, I knew that I could probably get through the day. I could get patients showered and meds [medications to patients] given but if anything had gone wrong I don't think that I was prepared for any little hitch in my day.

This sense of unpreparedness, generates a lack of confidence in the graduate's competence in managing the reality of everyday practice as Cathy, another graduate, stated:

Clinically I don't think that I felt ready...when you're out there doing it with very sick patients...very hard to um ... be prepared for that.

Research on doctors' transition from student to newly qualified doctor and transitions from generalist to specialist clinical practice highlights the complex kinds of learning that occurs in the reality of everyday practice as the novice acquires the competence to manage difficult and complex situations (Zukas and Kilminster 2012). To an extent, these feelings of inadequate competence in early phases of a career can be seen as a natural phase of professional development. Studies of expertise have consistently shown that the development from a novice to an expert takes about 10 years (Feltovich et al. 2006). Keeping this in mind, it is not reasonable to expect that newly qualified employees would have high level expertise right in the beginning of their career. Rather, the slow development of expertise combined with the rapid change in society and the world of work suggest pursuit of the kind of professional development models that are based on the idea of continuum from initial professional training towards lifelong continuous professional development. From the education point of view, a worthwhile question related to skill development is what kind of educational practices are associated with expected learning outcomes. As the relationship between learning outcomes and their predictors is highly complicated there are only a few studies that have tackled this question. In a survey of more than 1,200 Dutch graduates by Vaatstra and Vries (2007) it was reported that graduates from highly activating learning environments (such as problem-based learning and project learning) attributed more generic and reflective competences to themselves than graduates from conventional learning environments. The findings also showed that learning ability, analytic competences, working independently and working in a team positively contributed to the development of competences in the later careers of graduates. As regards vocational education and training, Virtanen et al. (2014) examined factors predicting vocational students' learning outcomes during their workplace learning periods. The largest explanatory factor was the active membership. The more students reported that they were able to

function as active members of their workplace (i.e. having the possibility to influence the way things were done at the workplace, with regular workers asking their opinion and advice and possibly learning from them) the higher they evaluated their skills learning and professional identity development. The second biggest factor explaining students' learning outcomes was the integration of experiences between school learning and workplace learning. This is an element of educational practices and it describes, at a very concrete level, the connection between the students' two different learning environments, the school and the workplace. The closer the students held the integration between school and workplace learning to be, the better were their (self-assessed) learning outcomes. The integration factors included variables describing features of integrative pedagogy (e.g. Tynjälä 2008; Tynjälä and Gijbels 2012) such as discussing workplace learning situations at school, learning tasks from school to work, and applying knowledge learnt at school at work. The integration factors also contained variables referring to connective model of work experience described by Guile and Griffiths (2001).

Critical then to ensuring students perceiving they possess the necessary competences to function in their impending professional role is the pedagogical approaches utilized to foster the integration between the two learning environments, of school and the workplace. As a component of a larger project exploring preparation for practice for healthcare professional students, Newton (2011) examined how to enhance this integration between university studies and the clinical workplace with a group of final year undergraduate nursing students through a facilitated reflective learning group. Six students over a period of 7 months met monthly and were encouraged to identify their own action points at the end of each learning group that would then be revisited the next time they met. The intent behind this was to encourage the students to develop a sense of personal empowerment and foster reflexivity and agency. Fenwick (2013, p. 364) argues that education needs to "attune professionals to the multiple and complex nature of transitions – the shape of their personal transitional experience(s) in terms of the assemblages or practice, regulations, work arrangement, knowledge cultures in which their experience is unfolding". Certainly, this was the educational process that the students in Newton's (2011) study experienced. The reflective learning group allowed for consideration of multiple perspectives of practice issues that students would not have necessarily undertaken without this guidance as they prepared for their transition to their professional role. The learning group provided a space in which the students were able to explore and challenge their previously held values and assumptions about professional practice, organizational cultures and demands, and expectations. This space enabled the students to consider how to work more independently and to recognize that they were not expected to 'know everything'. This is illustrated through Donna, a third-year nursing student, who shared the following insight:

Realizing that I do know stuff, which I didn't think I did, I just think it's a confidence thing and having the support from the University is really important ... because I've had this wonderful start to this year, I'd be much more able to cope next time I think...

Through the sharing and drawing out experiences, the students perceived a reduction in fearfulness of being regarded as not having adequate knowledge if they asked others for advice. The reflective learning group provided a pedagogical process

to develop the students' capacity to be better prepared for facing problems and simultaneously working out how to resolve problems or issues at the time. The students gained an awareness of how to create learning opportunities when working in clinical practice alongside a registered nurse, acknowledging how to indicate where their level of competence was at, as illustrated in the following quote:

I think it's okay to, tell the preceptor [a registered nurse] this is where I think I'm at and, and this is the level that I think I can perform to and then you know, that might be above what that preceptor thinks that I'm at, but they don't know me, so, but, if you tell them then, then they don't expect too little or too much.

During the 7 months, as the students engaged in both university studies and clinical workplace practice, the students gained confidence that enabled their skills and theoretical knowledge to be refined into understandings about actual nursing practices as they learned how nurses might behave in the workplace- enabling integration of these views into a personalised model of professional practice. The students' evaluation of participation in the reflective learning group highlighted that participation had given them 'a voice' and that they felt more prepared and empowered for the transition to professional practice.

The studies above suggest that for the development of skills needed at work it is important to design learning environments where students actively engage in problem solving and integrate theoretical and practical knowledge. Thus, educational practices such as problem-based learning, project studies, integration of work-based and school-based learning, and other types of work-related learning and activated instruction are arguably conducive to development of working life skills, and hence as Newton's study evidenced may decrease feelings of inadequate knowledge and skills. Especially important here is to arrange students' possibilities to participate in authentic work communities and environments. As Filstad and McManus (2011, pp. 763, 777) state, "what is the most important for newcomers is how they become knowledgeable as they recognize that it is not their educational knowledge, but working out how to engage and participate in the social practices, that counts" ... Newcomers "find that their 'theoretical knowledge' is not the most important" but that access to social-cultural knowledge, that is, norms, values, rules and regulations – organizational culture – is vital. Indeed research on graduate nurses' transition to the workplace (Newton and McKenna 2007; Newton et al. 2009) highlights this impact quite clearly, as the novice nurse finds learning to 'fit in' to the workplace a critical element of their transition to clinical practice. Thus, the role of partnerships between education and work seem to be significant not only from the employment point of view but also from the competences point of view.

19.2.3 Decreased Self-Efficacy and Stress

Transitions from one phase of life to another are always considered involving the source of possible stress (Salmela-Aro 2012). The causes of stress of newcomers seem to be quite similar to what is typically found in older workers, such as social stressors, cooperation problems and quantitative overload (e.g. Grebner et al. 2004).

In particular, in professional fields involving high personal input, quickly changing situations, and socially and psychologically challenging relationships, the early career experiences may be psychologically and socially overwhelming. For example, in the field of nursing Duchscher (2009) has described *transition shock* as the experience of moving from the known role of a student to a less familiar role of professionally practicing nurse. Typical of this experience is a contrast between the relationships, roles, responsibilities, knowledge, and performance expectations required within the academic environment to those required in professional practice setting. The transition shock involves emotional, physical, socio-cultural, socio-developmental, and intellectual aspects. Emotionally, it manifests itself as extreme sensitivities, seeking validation and reassurance, fears of failure and incompetence, and so on. Physically, it may cause exhaustion, sleeplessness, poor nutrition and lack of exercise, for example. Socio-developmental aspects include role uncertainty, inadequate guidance and intergenerational dynamics (Newton et al. 2009); and intellectual aspects are related, among other things, to incongruences between theory and practice, lack of knowledge on transition, limited practical knowledge, and professional role-relations immaturity. In a current study being undertaken by Newton and colleagues on workplace learning in nursing in Australia, these aspects of incongruences are illustrated by a new graduate, Pink who was 6 months into her first year as a qualified nurse, reported:

I feel quite daunted and really questioning yourself and what you've learnt... you realize you rely on your senior staff a lot more than you thought you would and really there is still so much to learn.... Since becoming a graduate I see things I'm not sure about and I have to go back to the theory to look it up....I'm still observing other people learning how to do things and seeing what they're doing and I might try that next time....I'm sort of still learning my way around things and so my autonomy is not there yet ... It feels so surreal having to supervise a student; it's such a strange feeling... Sometimes I feel I shouldn't have to supervise a student, some days it's like the student and I have to sort of navigate it together.

Similarly to nursing, the early phase of teachers' career is often characterized by lowered professional self-confidence and self-efficacy as well as stress and burnout symptoms. For example, in their study Woolfolk Hoy and Burke Spero (2005) observed significant increases in self-efficacy during student teaching but significant declines during the first year of professional teaching. In a study among university teachers by Postareff et al. (2007, 2008), it was found that teaching-related self-efficacy among teachers who had taken few pedagogical courses was lower than among teachers who did not have pedagogical training at all. Those who had acquired more pedagogical training reported highest self-efficacy scores. Fives and her colleagues (2007) found that stress symptoms (which they called "burnout") increased and self-efficacy decreased during the first teaching practice period among student teachers, but in the long run significant increases in self-efficacy and decreases in stress symptoms were found. On the basis of these findings, it can be assumed that in the first phases of pedagogical training and teaching career teachers become aware of their personal weaknesses or learning needs, leading to decrease in self-confidence and self-efficacy. Along with the increase of experience over the years, self-efficacy expectations increase as well.

The findings described above suggest that in the early phases of professional career, in any field requiring high level expertise, there is a clear need for support systems. In the fields such as teaching and medicine there is a long tradition of mentoring being used as a support system for newcomers. Fives et al. (2007) found that student teachers experiencing high levels of guidance reported higher levels of self-efficacy for instructional practices than did those who reported less guidance. Similarly, studies on the relationship between mentoring and stress at the workplace suggest that close interaction between the younger colleague and the mentor has a potential of decreasing stress and increasing self-confidence (Thomas and Lankau 2009; see also Aspfors et al. 2012).

As to mentoring and related support systems, the role for partnerships can provide an avenue for reducing the stressors of decreased self-efficacy and increased stress as students' transitions to their professional role and workplace. For example, in Finland there is a nationwide network for organizing mentor training, peer-group mentoring, and other forms of teacher induction support (<http://www.osaavaverme.fi/eng>). The network is coordinated by the Finnish Institute of Educational Research by the University of Jyväskylä, and the members include all teacher education units in Finland. Furthermore, among other stakeholders, national teachers' organization, Trade Union of Education in Finland, and national employers' organization, representing the biggest employer group of teachers, Local Government Employers, are active participants of the network. Within these collaborative partnerships it has been possible to develop and disseminate a new form of mentoring called peer-group mentoring. While traditional one-to-one mentoring has mainly focused on unidirectional transmission of knowledge from an experienced colleague to a younger one, peer-group mentoring is based on knowledge sharing in a group. The mentor is still usually a more experienced colleague, but the interaction and relationship between the mentor and group participants is dialogical and reciprocal (Heikkinen et al. 2012). Without the national network involving teacher education departments, national labor market partners and other stakeholders, it would not have been possible to disseminate nationwide this new form of support system for newly qualified teachers. Thus, this network is a good example of the power of partnerships.

Another successful example of a partnership model, that in this case utilized preceptorship, is one implemented between a university and a healthcare organization to enhance the transition of novice nurses to the workplace and reduce the *transition shock* described earlier in this section. The preceptorship model has been widely adopted in the United Kingdom, Australia and North America and is designed to increase collaboration between tertiary institutions and healthcare settings (Ockerby et al. 2009). In this model, a preceptor who is a qualified nurse is assigned to work alongside a student nurse for the duration of the student's clinical placement. Research undertaken to examine this preceptorship model, between one tertiary healthcare facility in Melbourne, Australia in partnership with a school of nursing and midwifery from a major university; found that this partnership fostered the development of the students' competence through the continuity of returning to the same healthcare facility (Newton et al. 2011).

In this particular project, second and third year undergraduate nursing students, 20 of whom were in their second year of study and 8 were in their third year, were followed for a period of 2 years. During this time, the student informants were interviewed on five occasions. The students' age ranged from 18 to 55 years with a mean age of 29.5 years. The participants' fifth interview, by which time they were either engaged in or had recently completed their graduate year (i.e. the first year as a registered nurse); and included questions about the contributions of clinical placement experiences and the support provided by preceptors to participants' perceived work-readiness is drawn upon, to illustrate the outcomes of this partnership. The fifth interview also included a quantitative component comprising of four key questions, using a 5 point Likert scale ranging from 'not at all' to 'extremely' that sought participants' responses regarding: the effectiveness of the preceptorship model, the extent to which the participants felt 'work ready' at the end of the program, the extent to which their clinical experiences facilitated work readiness, and the effectiveness of preceptorship for work readiness. Ninety per cent of the students indicated a very positive response to this preceptorship model rating the program as 'very' or 'extremely' effective. More than half of the students reported 'very' or 'extremely' work ready at the completion of their degree and a similar proportion indicated that their clinical experiences prepared them 'very' or 'extremely' well to become a nurse. The nurses reported that their transition to work was enhanced through having familiarity of the organisation, as Amy, a newly graduated nurse noted:

I'm already familiar with the hospital, I don't need to learn about the paperwork, I don't need to learn about how the shift runs and, like what time the shifts start and finish, when the breaks are, um, how to do certain procedures, whether you need one nurse for a procedure or you need two.

Having this familiarisation with the actual organisational structure, reduced the nurses' stress and generated a degree of confidence amongst this group of new graduates and created a sense of continuity for them in their transition from student to new graduate worker. The nurses articulated that they did not feel, "so much like a fish out of water". This type of partnership model also fostered the important element of social participation which contributed to the new graduates' overall sense of work-readiness. The graduates recounted a sense of belongingness to the workplace when they were greeted by healthcare workers they had met or worked with during a clinical placement as a student. These 'familiar faces' within the workplace who acknowledged the participants generated an awareness of belongingness and being a part of a healthcare organisation. This point is illustrated by Marissa, a new graduate undertaking her first work placement at the healthcare facility where she had participated in the preceptorship model as a student nurse: "*It also is wonderful to be able to walk into the hospital every day and you walk in every day and people greet you. You have this sense of belonging*". This type of partnership model appears to enhance the social practice knowledge that individuals require to effectively engage in practice and further learning (Eraut 2004).

Research on graduate nurses' transitions (Andersson and Edberg 2010; Newton and McKenna 2007) found that the most influencing factors for new graduates to

gain confidence in their skills was the support provided in the workplace through their relationships with colleagues. Clearly such a partnership model, as this preceptorship model, enables the transition from student to worker a smoother passage, reducing the stress and enhancing the graduates' self-efficacy. Indeed, Korte and Lin (2013) found that for newcomers entering a work organisation that their levels of confidence was facilitated by the quality relationships and good mentoring offered to them. All of this points to the salience of partnerships in providing supportive educational experiences.

19.2.4 Instability of Occupational Identity, Early Attrition, and Changing Occupation

Occupational identity in the early phase of one's career is often weak, and young people may change their vocational field while actually studying a vocation. Dropping out from education is usually seen as a risk factor for remaining without any qualifications, unemployment and marginalization. However, it can also be seen as an opportunity for improving future prospects by opening possibilities for education in some other field that young people may experience more attractive. For example, Schmid and Stalder (2012) followed 1,300 Swiss young people who had experienced an early apprenticeship contract termination and found out that about three quarters of these continued their education within 3 years of the contract termination, and that the majority of them already resumed their education in the first month. Furthermore, these occupation changers were happier with their new education than with the previous one.

The issue of early attrition in health care, particularly among nursing, remains obstinately resistant despite significant efforts of government and employers. In exploring the premises of becoming a nurse Billett et al. (2010) found that diverse pathways were taken by individuals in pursuing nursing as an occupation. Billett et al. (2010) presented illustrative data of 9 student nurses from a subset of 28 student nurses who had participated in a longitudinal, multi-method investigation on workplace learning in nursing, in Australia. Individuals' pathways into nursing were either from direct school or from their experiences in which they had observed and came to appreciate nursing work. The informants shared that they had either undertaken care-related activities as part of their secondary schooling; volunteer community work in an aged care home having been previously expelled from school; as an option to secure employment and salary; commenced a higher status health related degree (physiotherapy) and changed to nursing; to caring for elderly parents. In a small follow-up study in 2010, Newton interviewed nursing students from the United Kingdom (UK) and America to ascertain if these types of occupational pathways into nursing were reflected elsewhere. Similar stories emerged with the students in these countries sharing accounts of always wanting to be a nurse to entering the occupation through association with a caring experience or incidence,

as Ruth from the UK, a third year student at the time of the interview, illustrates this with a change in occupation as well:

Entering nursing was a complete surprise for me. I went into nursing at 26 years of age having studied art for four and half years. It wasn't till I got pregnant and I just loved interacting with nurses and thought what a lovely job it is... you're with people at the most vulnerable times; it's such a privilege position to be in and to be part of it...

Prior to her change in occupation, Ruth had worked as a resident artist in schools and the community. Another student, Francis from America indicated that nursing was not always something that she had initially intended to do. She had spent her first three and half years after leaving school working as a customer representative in a hospital and then worked as nanny for two years. The prospect of the diversity of fields of nursing that a nurse can pursue a career in, led her to thinking about going to university.

The early phase of an individual's working career seems to be critical for attrition or retention. Early attrition has been widely examined in teachers' profession although research shows that attrition rates in teaching are not higher than in other professions that require comparable levels of education. For example, in a study by Harris and Adams (2007) turnover rate was about 15 % in social work, 8 % in accounting, 8 % in teaching, and 6 % in nursing. However, there are differences between the years of experience in attrition rates. According to the report by OECD (2005), younger teachers are more likely to leave the teachers' job than more experienced teachers. As the main reason for leaving, the report mentions poor working conditions. These may be related to workload, lack of support, student behavior and relationships with parents. Findings by Hong (2010) also showed that pre-service teachers tended to have naïve and idealistic perceptions of teaching. This finding suggests the need for more practice and real-life work experience during teacher education and training may be needed. This might also apply to other practice based professional field as well.

The issue of vocational school dropouts and occupation changes raises the question of the functioning of career guidance provision. Experts in the field of career guidance have argued for expansion of the guidance paradigm because the everyday field of guidance has changed (Sultana 2004; OECD 2004). One example of this paradigm change is seeing guidance as part of a wider horizontally and vertically networked support system of the society. For instance, Nykänen et al. (2012) have introduced a model in which schools, social, health, and public employment services jointly design, implement and evaluate regional guidance services. In this way, the networked partnerships may provide tailored and timely support for individuals in every life situation. It is worthy to note that the importance of preparation for practice in choosing an occupation was first brought to our attention by Dewey (1916). He proposed that the two purposes of vocational education was supporting individuals' capacities and interests; and preparing individuals for the occupation to which they are drawn too. Given our rapidly changing world, and from the examples offered from the studies on nursing students, it would seem that it is not only young people, but also more experienced people who may need

support while looking for their future field of study and work. Consequently, requirements for supportive arrangements may be far more widespread than just for ‘newcomers’.

19.2.5 Newcomers’ Role and Position in a Work Community, and the Importance of Workplace Learning

Hakkarainen et al. (2004, p. 145) have pointed out that typical of many communities of practice in contemporary workplaces is asymmetric distribution of knowledge and competence: Old-timers’ knowledge is mostly valued and transmitted to newcomers who, again, are supposed to adjust to existing working culture and practices. In one of the first author’s in-service training sessions a young teacher described this situation as follows: “New teachers with their new ideas will be suppressed in less than a year”. Many studies on novice teachers’ work challenges have confirmed these experiences. For example, in a study by Shoval et al. (2010) among novice physical education teachers it was found that very often new teachers suffer from a gap between their initiatives and the environments’ lack of appreciation. Similarly, Saka et al. (2009) have reported a case study illustrating a situation where a reform-minded novice teacher moves away from his goals of reform and compromises his earlier willingness to significantly contribute to the school context (see also, Maynard 2001). Naturally, these kinds of experiences of ignoring newly qualified professionals’ skills and knowledge are not restricted to teachers’ profession only but are common among new employees in any field.

Some newcomers’ support systems explicitly address the need of enhancing beginners’ engagement. For example, the study by Saks and Gruman (2011) represents a traditional approach where newcomers’ induction into a workplace is conceptualized as a *socialization* process. The purpose of this process is to get newcomers adjust to their new workplace and learn the behaviors, attitudes, and skills necessary to fulfill their duties and act as an active member of the organization. In their study, Saks and Gruman (ibid.) found that institutionalized socialization tactics involving structured, formalized and fixed forms of support was positively related to newcomers’ perceived person-job and person-organization fit as well as emotions and self-efficacy. Furthermore, they were indirectly related to newcomer engagement. Similar findings have also been recently reported by Simosi (2012) and Korte and Lin (2013) who found that perceived organizational support, supervisory support and colleague support influences transfer of training and commitment towards organization.

An alternative to the concept of socialization of newcomers into existing practices is presented by Wang and Odell (2007) who have analyzed models on the background of one of the most popular way of supporting new workers, mentoring. They make a distinction between three approaches to mentoring: (1) *humanistic perspective* emphasizing the development of newcomer’s self-esteem and confidence,

(2) *situated apprentice perspective* focusing on newcomers' adjustment to the prevailing culture of practice (and, thus, representing the above mentioned socialization view), and (3) *critical constructivist perspective* supporting critical outlook towards existing practices and structures, and developing reform-oriented mindset and collaborative knowledge transformation cultures. The last mentioned perspective could be seen as part of an organizational culture that Hakkarainen and his colleagues (2004) call "innovative knowledge communities". Typical of these communities is intentional pursuit of creating new knowledge and practices, open communication, networking, and knowledge sharing. The distribution of knowledge is symmetric and heterogeneous, meaning that not only old-timers' but also newcomers' knowledge is valued and utilized, and their fresh insights are heard and taken seriously in developing practices. Rubin (2009) refers to the concept of collaborative leadership as a form of leading the communal learning processes aiming at these kinds of practices. When this idea is applied into guidance provision discussed earlier, guidance personnel takes multi-professional responsibility for students' learning and education with actions promoting the practices, strategies and structures that support students' transition from one educational level to another or to working life (Jäppinen 2012).

Common to the ideas of innovative knowledge communities, professional learning communities, and collaborative leadership is that individuals' agency is supported in social communities. As Billett (2004) has described learning at work is mediated by both the contributions of workplaces and individual's agency. This same pattern was found to apply to studies of students' transitions from school (Billett et al. 2012). How individuals participate and interact in their workplace is central to their learning. But this is not enough. As the newcomers' experiences of suppressing their ideas described above show it is not only in the individuals' hands in how they learn and proceed in their job and career. The quality of learning depends also on the workplace affordances. Thus, in Billett's (2004) terms, learning at the workplace is reciprocally constructed in co-participatory practices where individuals elect how to engage in and learn from what workplaces afford them. These set of factors also played across accounts of school students to post-school life and extended to whether and how they elected to remain in educational programs or withdraw from them. Returning to the Australian study on the preceptorship model in nursing (see Sect. 19.2.3) the development of this co-participatory practice is illustrated through this longitudinal investigation of nursing students' transition to practice from student to qualified nurse and how the role of the registered nurse, who was the preceptor, influenced the novice's engagement in learning. The value of this partnership model as a developmental model for supporting competences resides in the close guidance provided by the more experienced practitioner to the novice. This is an important element of learning for health professional students as they adapt the teachings from the academic setting and make situational adjustments to the clinical environment under the guidance of their preceptor (i.e. a registered nurse). Preceptors' interest in engaging with novices and actively seeking out learning opportunities is also fundamental to the productive engagement of the

novice (Newton et al. 2011). Whilst preceptors might provide diverse learning experiences in the workplace, students, in this particular study, recognised and valued that engagement in learning opportunities is a reciprocal process. For example Stef, a 3rd-year student, pointed out that not only did one need preceptors who were: *'interested in and willing to help you learn'* but that it was also important for her to engage with the opportunities provided: *'I think it's a two way street.'*

The preceptors also acknowledged that in undertaking this role it was an avenue for enhancing their own clinical knowledge as they learnt alongside their students. For example Rose, a preceptor, reported: *'sometimes when they [students] ask something or they query something, I have to go and look it up too which I don't mind doing because that also shows up what you know and don't know.'* This willingness to engage in a preceptoring partnership is an essential component of learning in the workplace as Ben, a 2nd-year nursing student, commented: *'preceptoring is everything...a good preceptor can make or break a clinical placement.'* Zilembo and Monterosso (2008) suggest that effective preceptors are those who exhibit characteristics that include being competent, organised, supportive, motivating, and approachable with strong interpersonal skills. Thus engagement in learning through preceptorship is premised on a reciprocal process. This process, however, is augmented for novice nurses if their preceptors relate to them as individuals and realize the novice's personal knowledge and skill level. Participants in this study by Newton et al. (2011) identified the importance of preceptors being familiar with a range of learning styles, and recognising novices as unique individuals. As Jayne, during her second year as undergraduate student nurse, pointed out that it is important that preceptors acknowledge: *'each student as an individual in deciding what they can and can't do, recognising a person as someone unique.'* Whilst understanding the variations in individual novices' learning needs might generate more work in supporting and guiding them, Polly, an experienced preceptor, explained that, being a preceptor is: *'about allowing somebody to, to find their own way but guide them safely.'* An example of the guidance experience sought by students was described by Clare, during her third year as an undergraduate student, when learning two new skills:

When you are doing things like taking blood or doing an ECG, what I find helpful is a good preceptor, when I do the skill for the first time that I can be shown it and then I do it and that someone [the preceptor] is with me. That makes a big difference.

In her current research on workplace learning whilst undertaking fieldwork on a medical ward at a regional hospital in Victoria, Australia, Newton observed what she considered exemplary guidance by a preceptor, Sumi, to her second year undergraduate nursing student. A description of the event is below:

[At the nurse's work station] The patient is due for a daily injection. Sumi gives the student an explanation about the generic name of the injection drug and where to locate the drug order on the patient's medication chart. She questions her student on where she'll give the injection, seeking information from the student about what she has been taught at the university about giving this particular type of injection. Sumi provides detailed instructions including the underlying pathology on where to locate the injection making sure the student

is aware of the need to alternate injection sites, avoiding anywhere that might be pressured by clothing elastic. [Sumi and the student move to patient's bedside] Sumi guides the student as the student gives the injection, offering a calming voice "nice and steady" she says to her student. Sumi then directs the student to sign the patient's medication chart with her and make sure the patient is left in a comfortable position to have her breakfast. Sumi then checks that her student is okay, 'how did that feel?' She reassures her student that she did a great job.

This guidance by more experienced co-workers certainly can assist in developing the kinds of knowledge and skills required for expert performance. However, as identified above it needs to be recognised as a reciprocal process of participation by both the guide and the learner (Billett and Newton 2010). Students in the preceptorship model study did not always experience a facilitative guided learning environment. An experience shared by Eddie, when she was a second year undergraduate nursing student, she recounted an occasion when: "I walked into the handover room (i.e. a room where nurses at the end of a shift pass on information to the on-coming shift of nurses) and sat down and not a word was said to me. It was very hard, coming into an established team and they'll all know each other and have their way of doing things..." This situation was particularly challenging for Eddie, for despite having prior experience as an enrolled nurse and being a mature-age student, she felt quite intimidated by the nursing staff during her clinical placements.

The invitational qualities of the workplace are pivotal in enhancing the translation of learning from school to work. Experienced practitioners, Newton et al. (2011, p. 48) contend "need to be aware of providing appropriate and challenging learning opportunities and be flexible in allowing novices to experience different procedures and to practice skills themselves". Studies on workplace learning have shown that there are big differences between the workplaces in how and what kind of learning opportunities they offer for their employees' learning and professional development (Tynjälä 2008, 2013) and this variance can be seen in the examples offered from the studies presented in this chapter in nursing. Fuller and Unwin (2004) have made a distinction between what they call *expansive and restrictive approaches to workforce development*, the former representing an environment where people have plenty of opportunities to participate in diverse activities and communities of practice, while the latter describes workplaces that offer limited opportunities for learning. Certainly, the experience Eddie recounted above was one of a restrictive environment yet had the potential to be a rich pedagogical opportunity. The nursing shift handover can provide a learning moment for all the practitioners who are at different levels of competence, offering insights into nursing practices (Billett and Newton 2010). An expansive workplace arranges time for reflection and opportunities for boundary crossing, uses managers as facilitators, values innovation and offers people chances to learn new jobs and skills, while restrictive workplaces tend to rely on old practices and do not seek innovation. However, beyond what Fuller and Unwin (2004) propose about the different qualities of workplace settings, it is also necessary to include how individuals elect to engage in those environments. As Billett (2004) has shown even the most expansive of workplaces can be rendered restrictive if individuals elect not to engage in them and the most restrictive can be

render rich learning environments if learners act agentially. All of this emphasizes the importance of considering not only the two environments, but also the relations and interdependencies between them.

19.3 Conclusions

In this chapter, we have examined transition from education to working life as a critical phase in the development of professional competence. We have identified several challenges that newly qualified people meet when entering the world of work. The examination revealed that school-to-work transition is not only a young person's individual movement from one place to another but a part of individual, social and institutional process where individuals' learning needs and environments' requirements and circumstances meet each other. Transitions are influenced by individuals' cultural knowledge and expectations of others, their positioning within the organization and the opportunities afforded to them (Fenwick 2013), and also how learners elect to engage in these environments. Therefore, because transitions are practices that involve individuals making decisions about how they engage and for what purposes it is important to consider not just social practices of the settings, but also how individuals engage in them.

Transitions in human life cycle are phases when susceptibility to stress may increase. Finishing schooling brings about concern over employment and adjustment to a new working environment. Individuals may experience decreased self-efficacy and feel their skills and knowledge inadequate. Sometimes young people's expectations of the occupation or job have been unrealistic, or their identity development has been in such turbulence that they may find themselves as in a totally wrong line of work.

These kinds of challenges of newly qualified workers and professionals may give a quite dark picture of the transitions from school to work. However, there is another side as well. There are several ways to smooth over the problems and setbacks in the transitional phase, and here the role of social partnerships is crucial. Our analysis cautiously suggested that in countries where vocational education and training is based on apprenticeship training or includes a considerable amount of workplace learning the threat of unemployment after qualifications is smaller than in countries with a strictly school-based education. Partnerships may also be used in organizing induction support systems such as mentoring as was the case in the Finnish education system or through preceptorship as illustrated in nursing. Furthermore, lifelong guidance systems have been recently developed based on multi-professional networking between schools, social, health and public employment services in order to provide tailored and timely support in transition in any phase of a life cycle. Altogether, it seems that different forms of partnerships may play an important role in paving the way to smooth transitions and securing continuous professional competence development. At the same time these partnerships not only help individuals but they also may serve the development of vocational practice. However, the challenge in

determining if partnerships assist in enabling a ‘successful’ transition are difficult to determine due to the complex interplay of the myriad of educational, sociocultural and material relations that need to be considered.

Chapter 20

Interprofessional Education in the Health Workplace

Elizabeth Katherine Molloy, Louise Greenstock, Patrick Fiddes,
Catriona Fraser, and Peter Brooks

Abstract Interprofessional education has served as a long-standing topic of interest in the health professions education community, mainly because of its reported capacity to develop the learner's disposition for team-based practice. This chapter synthesises the findings from the health professional literature and focuses specifically on the impact of interprofessional education on students within clinical placements. The review sets the scene for the reporting of an empirical study conducted by the authors, examining medical students' experiences of an interprofessional education placement. Medical students who rotated through the targeted interprofessional placement were interviewed via focus groups to elicit their experiences of the initiative. Their perspectives on how the context and the activities within the placement influenced their ability to learn 'with, from and about' other professionals were captured and analysed. Only a small percentage of participants reported that the workplace environment adequately supported opportunities for engagement with other professionals. The medical students, while able to voice the advantages of interprofessional practice "once they become" a practitioner, saw the agenda as

relatively low on their priority list as busy students, subject to regular assessments of their ‘doctoring’ competencies. The results challenge the cheerfully optimistic literature on interprofessional education. It may be useful to acknowledge the resistance learners have in learning about other professions or disciplines when they have a fixed target of professional membership in sight. Undergraduate students seem to make judgements about what is important to learn, and who are the most legitimate models to learn from, very early in their curriculum. Students look to summative assessment as a key device to help differentiate the core from the peripheral within their program of study.

Keywords Interprofessional education • Interprofessional practice • Workplace learning • Health professions • Curriculum design

20.1 Introduction

20.1.1 *Overview of the Literature*

Interprofessionalism has increasingly emerged as an educational philosophy over the last 60 years. Outcomes of interprofessional education in the health context have typically focused on the student, and largely at the level of whether students’ enjoyed or reported value in educational initiatives designed to promote interprofessional learning (Barr 2005; Reeves et al. 2008; Reeves 2010). Many of these studies report that educational initiatives, particularly in the pre-clinical context, fail to engage learners. Even for those initiatives perceived as useful, there are few longitudinal studies tracking the impact of these activities on learners’ practices once they hit the authentic workplace (Davidson et al. 2009). The latest literature argues for the importance of positioning the patient at the centre of health professional education, and valuing the patient’s capacity as a teacher. This subtle re-orientation may better enhance health professional teamwork to achieve the best patient outcomes. This section will highlight how interprofessional education emerged, how it is being enacted in health professional education, at both pre-clinical and clinical (workplace-based) interfaces, and what we know about its impact on learners, patients and workplaces.

20.1.2 *The Emergence of Interprofessional Education*

Abdel-Halim (2006) refers to Arabic documents from over 1,000 years ago that promote the positive impact of teamwork on patient care. The earliest known reference to interprofessional learning in health occurred at the annual session of the American Dental Association held in Cleveland in 1953 where the House of Delegates discussed a paper, Sugar and Teeth. In that session, reference was made to a joint meeting of two medical and dental societies being held 15 years earlier, to

discuss interprofessional problems and the application of the newer knowledge of nutrition in practice (Hartford 1953). A further reference to interprofessional learning occurred in a paper published in a Pharmacy Journal (Illinois 1969), following which the Interprofessional Commission of Ohio, established at Ohio State University in 1973, offered interprofessional courses for graduate students and professionals in education, counseling, law, medicine, nursing, psychology, social work, and theology.

The further history of the development of interprofessional education is comprehensively discussed in *Motives & Movements* (Barr 2005) where he examines the development of cooperative care within nursing and social work during the 1970s, the rapid growth in medical specialization that led to an ultimately unhelpful separation of medical specialties from a shared engagement with other health professions. Barr (2005) also highlighted the emergence of collaborative care models in general practice, aged care, and psychiatry that acted as a stimulus to develop better shared care models for all patients. Much of the drive to develop better care models followed adverse publicity over a number of cases of poor medical care outcomes that informed Government policy decisions and directives to achieve better quality of care. These changes have contributed to improved accountability and shared care developments over the past two decades, with the key objectives of improving patient care, reducing the dependence on hospitals for much of the provision of care for the increasingly complex patients suffering multiple health issues and the increasing numbers of the elderly. These shared care developments, although well-meaning, have been somewhat fragmented and relatively unproductive (Bywood et al. 2011; Barr 2005).

This observed fragmentation of patient care has led to an exponential growth in the development of interprofessional education within the health professions, designed to promote effective teamwork and communication. This growth has been the subject of much government and university support in many countries with the development of specific societies to promote interprofessional education, such as the Centre for the Advancement of Interprofessional Education (CAIPE), founded in 1987, dedicated to the promotion and development of interprofessional education in the UK and overseas. It has a close association with the *Journal of Interprofessional Care* that commenced publication in 1992.

Parsell (1998) proposed that students need to know about the roles of other professional groups, need to be able to work with other professionals in the context of a team where each member has a clearly defined role, and need to be able to substitute for roles traditionally played by other professionals when circumstances suggest that this would be more effective. It has also been proposed that interprofessional education may afford flexibility in career routes, where individuals can move across discipline boundaries (Finch 2000). CAIPE (2002) subsequently defined interprofessional education as ‘occasions when two or more professions learn with, from and about each other to improve collaboration and quality of care’. The definition attends to three components; firstly, different health professions collaborating in the learning process, secondly, learning which embraces learning with, from and about one another, and thirdly, an outcome intended to improve patient care (CAIPE 2002).

Interprofessional education is underpinned by principles of adult learning and typically leans on interactive, collaborative and group-based learning approaches. There is also a strong flavor of learning about and appreciating the values of each other's professionalism.

Interprofessional approaches to health care are not only seen to improve patient outcomes, but have been linked to increased job satisfaction for health professionals (Barr 2005; Reeves et al. 2008). Although there are no data to demonstrate the next link, it would be a logical assumption that increased job satisfaction might have an impact on recruitment and retention of health professionals. In a health care climate characterized by an aging population and increased incidence of chronic disease, there is an associated marked workforce shortage. With this imperative to strengthen workforce numbers, there is a large amount of investment into searching for mechanisms to improve recruitment, retention and efficient work practices of health professionals.

20.1.3 Underpinning Educational Principles in Interprofessional Education

The role of and place for interprofessional education in health has been the focus of many texts and reports over the past decade (Hammick et al. 2007; Delany and Molloy 2009; Reeves 2010). These authors have explored the theoretical basis, the enactment, and the outcomes of over 25 years of interprofessional education endeavour. The results of interprofessional education initiatives were appropriately summarised in Allison's (2007) title, 'Up a river! Interprofessional education and the Canadian healthcare professional of the future', where she posited that while the benefits of an interprofessional approach to patient care were becoming well known, the establishment of interprofessional education in health care programs remained largely in the developmental phase (Allison 2007). She advised that if health professionals do not learn to work together, interprofessional education would continue to go in circles.

Cooper (2010), in appraising the work of Hammick et al. (2009a, b), noted that 'learning how to work interprofessionally is an evolving process grounded in experience, making fieldwork central to interprofessional learning' (p. 435). She pointed to the fact that much of the interprofessional learning research has been predicated on the learner's outcomes (being focused on assessment of interprofessional learning pedagogic practice) rather than taking into consideration improved care that is central to the patient's outcomes. At the core of this educational philosophy lies the re-emergence of the patient; the study of patient experiences as the axis of learning and an understanding of patient values, expressed in the view 'Nothing about me, without me' (Nelson 1998). Stewart (2001) and Slote (2007) also support a model of care based on listening to patient voices rather than as a virtue reflecting on our self. These researchers state that the design and implementation of patient care plans should be the priority, rather than persisting with interprofessional education projects that are centred on the student and their learning outcomes.

CAIPE's interprofessional learning definition embodies the well recognised 'learning with, from and about others', as well as the goal of these activities- improved patient outcomes. Hammick et al. (2009a) has suggested that we reverse the 'with, from and about' to, 'about, from and with' so as to emphasise the transitional change in learning moving from an interdisciplinary process to an interprofessional process. The so-called 'higher' goal of an interprofessional process positions collaboration or learning together as a joint process to achieve improved patient outcomes. Learning about and from does not necessarily translate the learning process into a joint learning enterprise of equality and interprofessionalism.

20.1.4 The Goals of Interprofessional Education

The ultimate goal of interprofessional education is to enable health professionals to undertake their roles as a part of a team in the effective care of patients (D'Eon 2004). Interprofessional education is underpinned by two assumptions (Davidson et al. 2009): first, that interprofessional education initiatives will lead to better interprofessional practice and second, that interprofessional practice will lead to better health outcomes for patients, clients and communities. The key to achieving this goal of better patient care relates to better understandings of the relationships between different professional groups as values and beliefs, collaboration and teamwork as knowledge and skills, roles and responsibilities as what people actually do, and the benefits to patients, professional practice and personal growth being what actually happens (Parsell 1999). Through these understandings, the prejudices existing between professions and the lack of awareness of the functions of each other may be changed, contributing to better teamwork and patient care. Each of these characteristics needs to be taken into consideration in designing an interprofessional education program. A further goal is to involve the patient, the family, the community of health professionals and the hospital or the providing institution in the process of effective participation and the communication of decision-making by each care-team member to the patient and family.

20.1.5 The Many Shapes of Interprofessional Education

Despite an international surge in discourse around the potential advantages of interprofessional education, there is still a lack of clarity about what constitutes effective interprofessional education. Davidson et al. (2009) presented a helpful conceptual framework where they positioned interprofessional learning activities in a table, ranging from low relevance to high relevance, based on mode of learning (passive to active), and degree of contextualization (ranging from away from the workplace setting, to experiential learning within the applied setting). The activities and the scope for interprofessional education are summarized below in Table 20.1.

Table 20.1 Activities used to promote interprofessional education (Adapted from Davidson et al. 2009, p. 75)

Learning activity	Evaluation of relevance to interprofessional education
Lectures	Typically limited scope for interprofessional interaction and collaboration. May be used to achieve content relating to interprofessional education objectives- including orientation to purpose of interprofessional education and interprofessional practice, models of teamwork and communication etc. Learner engagement often constrained due to class size and environment.
Practical or lab-based sessions	Rich in experiential learning opportunities (including technical and communication skill acquisition). Typically uni-professional but can be structured to accommodate different professions working together to develop targeted skills.
Tutorials	Vary in terms of experiential learning opportunities. Smaller student numbers cater for interactive learning and feedback opportunities on team work and communication skills (either peer driven or teacher driven). Problem-based learning can be an effective learning format as it is patient-centred by nature and students can see the relevance.
Online learning	Both individual and group-based learning. Scope for learning and assessment of competencies related to interprofessional education and practice. Student engagement may depend on the degree of authenticity of the virtual environment.
Simulation	Increasingly used as an educational modality due to its potential to replicate clinical environments and to generate opportunities for team-based care.
e-Clinics	Provide opportunities for students to observe either recorded or real-time patient-practitioner interactions or team-based communication. The lack of direct involvement of the learner lowers the stakes of the learning activity and allows learners to focus and reflect on the communication and teamwork skills exhibited. Needs a skilled facilitator or well designed prompts to engage the student and shift it from a passive ‘watching’ experience.
Experiential workplace learning	High relevance and authenticity. Can range from observational in nature (i.e. shadowing a practitioner) to practice under supervision (depending on the knowledge/experience levels of the learner). High potential for both informal and structured interprofessional learning and practice.

This chapter focuses on the potential for interprofessional education in the authentic workplace environment, as summarized in the last cell in Table 20.1. Within the clinical workplace environment there is large potential for structured interprofessional education where students ‘share’ patients and observe practitioners from a range of disciplines working together for the patient’s benefit. For example, medical, nursing and physiotherapy students may attend the one patient, complete a joint assessment of the patient (history taking and physical examination), engage in a collaborative process of clinical reasoning or problem solving

Table 20.2 Barr's (2005) modification of Kirkpatrick's Learning Outcomes

Outcome level	Impact of intervention
Level 1	Reaction-Learners views on the learning experience
Level 2a	Modification of attitude/perceptions
Level 2b	Modification of knowledge/skills
Level 3	Behavioural change
Level 4a	Change in organisational practice
Level 4b	Benefits to patients/clients

where they come to a consensus about the key problems and devise a prioritized management plan. This shared patient model is gaining momentum in health professional education (Anderson et al. 2006; Kent et al. 2012) and has received positive evaluations from students, staff and patients. Other forums such as team meetings and ward rounds also offer rich opportunities for students to engage in interprofessional learning and practice. Students may also observe the practices of other professionals either informally (for example, a nurse inserting a cannula while the medical student is taking a history of a patient) or in a more structured format, where a medical student may shadow a nurse or an occupational therapist for an afternoon on placement.

20.1.6 Evaluations of Interprofessional Education

While interprofessional education may improve learners' short-term knowledge and attitudes, there has been little evidence of persistent improvement or behavioral change in learners and insufficient evidence to guide the rapid changes in educational models or clinical practice that are developing (Piterman et al. 2010). Piterman recommended the need for prospective controlled trials with objective measurements of short and long-term learner behavior, processes of care and patient-based outcomes.

Many reviews of interprofessional education have been undertaken and have been evaluated using the modified Kirkpatrick Framework (Kirkpatrick 1994), published by Barr (2005). This classification system is useful in that the outcomes of the study are classified in terms of the impact of the intervention, ranging from the learners' views on the effectiveness of the intervention (level 1), to an impact on patients or clients (level 4b) (Table 20.2).

Using such a typology or classification system allows educational researchers and teachers to make meaningful comparisons between studies of interprofessional education. As Davidson et al. (2009) report "one of the challenges in reviewing examples of interprofessional clinical education is the range of evaluation approaches and outcome measures used in the field" (p. 78).

Barr (2005) review of 107 interprofessional education studies found that the majority of studies of interprofessional education in health have limited evidence of significant or sustained outcomes above level 2b. Of the more recent reviews, Hammick's et al. 2007 systematic review of 21 interprofessional education studies examined the effectiveness and contribution of interprofessional education to collaborative practice and better care. The review concluded that interprofessional education was generally well received by learners and that learners reported acquisition of knowledge and skills necessary for collaborative working. However, the review concluded that interprofessional education interventions were less successful in positively influencing attitudes towards others in the team. There was limited evidence to support the proposition that learning together would help practitioners and agencies work better together. The review concluded that staff development has a key influence on the effectiveness of interprofessional education and where such education reflects the authenticity of practice it is more effective (Hammick et al. 2007).

Davidson et al.'s (2008) systematic review specifically examined studies looking at interprofessional education in a fieldwork setting. The authors reviewed 25 studies of interprofessional education in pre-registration programs and found that there was a diverse range of interprofessional education experience durations (2.5 h to 9 weeks, with the most common intervention being 2 weeks). The team size varied markedly also- ranging from two to ten individuals. The review illustrates the wide diversity in how interprofessional education is enacted. And of course this intervention heterogeneity makes it very difficult to compare studies. The most common configuration of the interprofessional team was medicine and nursing students.

Margalit's 2009 study was undertaken by the Institute of Medicine, Nebraska, where they developed an integrated interprofessional education program in health profession curricula to improve health care quality. The program was developed, implemented, and evaluated as a campus wide program, shifting from traditional educational silos to greater collaboration and involving 155 nursing, medicine, public health, allied health, dentistry and pharmacy students and 30 faculty. The evaluation showed an increased understanding of health care quality and interprofessional teamwork principles, and reported positive attitudes toward shared learning (Margalit 2009). A further Cochrane study by Zwarenstein (2009) reviewed randomised controlled trials of practice-based interventions in interprofessional care compared to no intervention or to an alternate intervention. The effect of the interventions on patient satisfaction, the effectiveness and/or efficiency of the health care provided and the degree of interprofessional care achieved were examined. Five studies, four of them published since 2000, met the inclusion criteria. The review suggested that practice-based interprofessional learning can improve healthcare processes and outcomes, but given the small number of studies, the sample sizes and their heterogeneity and problems in measuring learning outcomes, drawing any conclusions about the key elements of interprofessional learning and practice is difficult (Zwarenstein 2009).

20.1.7 The Move to Patient-Centred Education

In Australia there has been a rapid growth in interprofessional education initiatives, particularly involving rural clinical placement programs, new interprofessional clinical educator positions, interprofessional practice professional development, workforce programs and the use of simulation centers. However, these activities occur in pockets across Australia, without co-ordination or communication between the committed educators and professionals driving these programs. There has also been a lack of direction by governments (Thistlethwaite 2007). This collective of individual activities contrasts to the central government approaches which have been in place in the UK, Canada and Sweden for some time (Davidson et al. 2008).

The widespread growth of undergraduate student interprofessional education and the expansion of the activities being undertaken do reveal improvements in understandings of the roles of health professionals, and the importance of teamwork and shared learning. Contemporary literature identifies only a few studies showing evidence of benefits to patient outcomes. More recent patient-centred projects have shown a progression from learner-centred educational objectives that by their nature are limited to level 2 outcomes (Barr 2011), to outcomes arising from direct student-patient dialogue grounded in the patient's experience and discussed in realistic clinical situations such as student clinics, giving benefit to the patient and improving patient outcomes-levels 4 (Anderson et al. 2012; Kent and Keating 2013).

Hudson et al. (2010) argues that the next phase of interprofessional education should embrace the richness of the patient experience, which is so readily and willingly available to students. This can be achieved through further adapting the intent and design of workplace-based learning experiences where students are orientated explicitly to interprofessional practice competencies and are guided towards opportunities to develop these skills. The opportunities or invitations that are most likely to impact on learners are those that are based directly around the patient. As Sir William Osler advised 'In what may be called the natural method of teaching, the student begins with the patient, continues with the patient and ends his study with the patient, using books and lectures as tools, as means to an end. For the junior student ... it is a safe rule to have no teaching without a patient for the text, and the best teaching is that taught by the patient himself' (Osler 1903, p. 331).

The next section in this chapter will present a pilot study that sought to better understand the interprofessional learning opportunities available to medical students placed in a sub-acute clinical environment. This case study serves to highlight the interprofessional experiences of students in the workplace-based setting, and in doing so, sheds further light on how we might better design interprofessional education programs to legitimately capture students' attention and build their capacity to work effectively with others.

20.2 A Case Study: Medical Students' Experience of a Clinical Placement Program Designed to Develop Interprofessional Learning and Practice

The research team undertook a study to examine the impact of an interprofessional education clinical placement on medical students' knowledge of the roles, responsibilities and functions of nursing and allied health staff, and their perceptions of their own development of skills in interprofessional communication and teamwork.

20.2.1 Methods in Brief

The study examined the experiences of a group of medical students in their first clinical year of the program, completing a clinical placement at a palliative and rehabilitative care facility. The clinical placement took place in a sub-acute hospital comprising two rehabilitation wards and a palliative care ward, each with clinical directors, resident staff, specialist nursing and allied health staff. The placement was designed for 3 weeks, and involved three to four students at a time, rotating as singles or pairs within the three wards. Prior to the placement the students were informed by the Clinical Education Director that one of the objectives of the placement was for medical students to work with and learn from other health professionals, in addition to the supervising doctors. It is important to note that no formal interprofessional education activities were mandated, and that no assessment tasks were linked to the interprofessional competencies. Rather, the clinicians carried out 'normal practice' with the knowledge that medical students had opportunities to learn about, and work with other professionals while on the placement.

Participants were recruited from the student cohort undertaking this clinical placement rotation in the academic year 2011 (n=15). Students were invited to participate in the study via email, and interested participants took part in one of three focus groups after their placement. Students were assured that their attendance was not compulsory, and would not impact their course assessment in any way. The focus group questions are represented in Box 20.1 below.

The audiotaped raw data was transcribed and anonymised after each focus group.

The data were interrogated using Thematic Analysis, starting with coding of the data where sections of data were labelled with a node (Miles and Huberman 1994). Coding was undertaken by three independent researchers (LG, EM, CF) and was facilitated by QSR NVivo2 data management software. The list of nodes was then consolidated through grouping nodes of similar meaning. This resulted in a shorter list of nodes that emerged as the themes in the data set. The themes and illustrative quotes that support these findings are presented in this next Section.

Box 20.1

- Please provide a brief summary of the placement – what was the clinical focus?
- Have you completed any other placements this year?
- Would anyone in the group like to comment on the possible benefits and outcomes of their learning in this placement?
- Could you please describe the interactions you had with non-medics?
- Could members of the group please explain whether they feel their perceptions of the roles and responsibilities of the health professionals have altered?
- Could members of the group comment on what they think is the best time to learn with, from and about other health professionals?
- Could members of the group comment on whether shared/interprofessional learning (if you feel you experienced any) assisted the development of communication skills and/or patient care?
- Would anyone in the group like to comment on whether they feel that shared learning helps medical student learning or not?
- Could members of the group please comment on whether they feel that the period of learning at the placement in question has had any influence on the development of the way you might practice as a doctor?
- Do you feel that you modelled your supervisors at all?

20.2.2 Key Findings

The three key findings that emerged from the study were that medical students reported that:

1. Interprofessionalism sits on the margins of medical practice
2. The placement, although intended to promote the development of interprofessionalism, lacked the design qualities needed to achieve these competencies
3. Discipline-based role models are key to orientating learners to what is important in practice

20.2.3 Theme 1: Interprofessionalism Sits on the Margins of Medical Practice**20.2.3.1 It's Important but Not Very Important**

It was encouraging to note that almost all of the participants in the study acknowledged that there is a role for interprofessionalism in health care practice and most were

able to articulate the benefits of interprofessional practice in terms of improving the quality of patient care:

I spent most of my time on the rehab so I saw a lot of mainly physiotherapists. They play quite an important role because they do most assessments of the patients' physical illness, whereas the doctors didn't really have the opportunity to do that. – FG1

So I guess in the doctors' case is the treatment on how the patient is doing and what the physiotherapists feed back to the doctors. They basically work in hand in hand to figure out what's best for the patient. – FG1

The above quotation typified the responses from many of the participants- that practitioners from multiple professions work together to optimise outcomes for patients.

However, despite acknowledging the importance of understanding the different roles of different professionals, and the importance of teamwork to enhance patient outcomes, the bulk of students' statements reflected that interprofessional education and practice in the workplace were seen as peripheral to 'core medicine.' The quotes below illustrate this positioning of interprofessional education and practice at the margins of medical practice.

It [the placement] has got to be relevant to the medical things – FG3

I think there's less appeal [an interprofessional placement], especially at the early stages where we're just trying to acquire all that medical knowledge – FG1

It was more incidental that you learned something from physiotherapists... definitely more interested in looking out from the medical point of view – FG2

It's definitely valuable but I don't know at this point whether it's a major priority. – FG2

As students we're limited in time and we're always running around. So we don't get into that depth, so I think if you just want to know what's happening with a patient, we just look at the medical issues. – FG2

We [also] have so much other stuff that's more important at this moment – like studying for exams – FG3

Some participants were more overtly suspicious of the value of interprofessional education within the curriculum, and the role of interprofessionalism in the workplace. Their responses betrayed their bias that interprofessional practice is restricted to referral of patients to different services offered by others:

I don't know what the actual aim of the whole inter-professional aspect to the course is. I know they keep talking about it's well and good but when you go in and sit in the dregs of rehabilitation, it's great to get sort of your head around it. You do a little rehabilitation, you do some exercise movements and things like that. But at the end of the day I'm never going to be confident to be able to do those rehabilitation procedures with a patient for example. At the end of the day that, really, all I should be able to say is, yeah, we're going to send you off to this person who is a specialist in their own field – FG2

20.2.3.2 Why Invest in Structured Learning When the Skills Are Intuitive?

Even the students that were able to articulate the need for an understanding of what other practitioners do in order to refer patients correctly seemed to believe that this knowledge would come to them in time, without purposeful effort or structured learning. A similar sentiment is reported in literature describing student and practitioner attitudes to 'non technical skill' development- encompassing communication, teamwork, leadership and reasoning (Nestel et al. 2011). In short, this parallel

literature presents the tendency for practitioners to think that non-technical skills are not ‘technical’ by nature, and are therefore skills that people either possess or do not possess- impacted minimally by structured learning experiences.

It’s important for us to know about the different allied health services because we’ll probably have to send our own patients there ... I suppose I’m leaving that to time rather than any structured learning – FG2

I can see a lot of people trying to avoid it or miss it [interprofessional education] because they’d be like ‘oh well, what am I possibly going to get out of it?’ – FG2

20.2.3.3 Challenging Early Expectations About What ‘Doctoring’ Means

Many students alluded to the hierarchy in health care practice, with doctors positioned as the leaders, and other health professionals supporting the role of the doctor. Some participants were legitimately surprised when practitioners other than doctors took the lead in clinical scenarios or meetings.

So I saw a MET Call. A lady collapsed at the Rehab Facility, and when we had come there was already a doctor, nurses and physiotherapists around, because it was in the physiotherapy department. You’d expect the doctors to be calling all the shots but I think the nurse there was quite experienced and she obviously had her training as well. So she was asking all the questions and the doctor was obviously asking questions as well but not so much as the primary person in that situation. So I think that nurse played quite an important role in that, to ensure that – she asked a lot of questions, that the patient was okay and that, so obviously she had the doctor there for support but that was an example where the role of the nurse was the leader – you wouldn’t expect that. You’d expect the doctors to be – FG1

I mean I guess just seeing how there can be team work and interplay between different health professionals and allied health and that it’s not strictly doctor’s role’s a doctor’s role and a nurse’s role is a nurse’s role and doctor tells nurse what to do – FG1

The atmosphere was very casual and everyone gets a turn to talk, which is a lot different to what I’ve seen in an acute hospital, because usually it’s a consultant talking the whole time and other people are just furiously writing down notes – FG1

Of note are the students’ reports that they would expect that the doctor would take the leadership role in any team-based interaction. These three students had only experienced 3 weeks of clinical practice so it is fair to assume that these expectations about the role of different professions are already set before the students reach the clinical interface. These stereotypes may well be established or reinforced within the pre-clinical curriculum (Davidson et al. 2009), or even before enrolment, through the influences of popular media and popular narratives. The attitudes expressed in this data set prompt us to question how early to start interprofessional education initiatives within the curriculum. Indeed there is plenty of heated dialogue in interprofessional education circles about when to introduce interprofessional education activities within a professional program (Davidson et al. 2008; Barr 2005). Advocates for the early introduction of interprofessional education argue that these competencies are framed as part of being a competent practitioner, regardless of the individual profession. Advocates for a later introduction argue that there is merit in learners understanding and relating to their own professional standards and culture, before they are able to decipher differences and similarities between professional groups.

For one third of the sample in our research, this particular placement represented their first ‘hands-on’ exposure to the roles of other practitioners in health care. Their responses suggested that they had already established a frame for the hierarchy and roles of practitioners in the workplace. The responses prompted the focus group facilitator to probe further about their pre-clinical curriculum and the potential impact of formal or informal learning about interprofessionalism:

- Interviewer: Had you, in your own opinion in your academic course, had you had formal lectures or people come in to talk about those roles [of practitioners outside medicine]?
- Respondent 1: Not really.
- Respondent 2: No, not really, I agree with you.... We know that they’re there and we were told when we came here to the placement that it was going to be different and that was probably the place we were going to, I guess, appreciate the role of allied health in the health care. – FG2
- Interviewer: What about – I’m just thinking in terms of your academic curriculum, the first year when you’ve got case based learning or problem based learning. Was there much sort of inter-professional practice fed into the actual cases? Did you learn about what social workers did in the case or was it medico-centric?
- Respondent 3: Everyone was different – every group was different. It depended on your tutor.
- Respondent 2: Yeah, you make your own objectives. You read the case and you make your own objectives. So if your tutor or your group didn’t value that sort of stuff you wouldn’t make objectives that related to that. Everyone has slightly different learning.
- Respondent 4: But even then, there wasn’t ever written into a case that he goes to see an OT now, or he goes to see a physio now. So it was never really prompted for us to learn. One of my friends was applying for [medicine at another University] and apparently for their first two years they do some classes together, like med students do it with physios and all that. Maybe that would be a good opportunity to [unclear], like a joint class with a doctor and a physio leading it. – FG2

The students acknowledged that the emphasis on interprofessional education in the pre clinical curriculum was dependent on how much they chose to invest in it- that is, whether they saw it as a priority in their case based learning sessions. Notably, the students reported that it was their tutor’s inclination that helped them to navigate and prioritise learning objectives within formal teaching activities. The data is a reminder that the ‘experienced curriculum’ can be indeed very different to the ‘intended curriculum’ (Billett 2006; Molloy and Keating 2011), and that factors including teacher interest, motivation and skill, and student individual interest and motivation can intersect to produce very different learning experiences within the one cohort.

20.2.4 Theme 2: Placement Design Properties

20.2.4.1 Lack of Formal Invitations

Students reported that they were aware of the overarching goal of the placement to learn about and practice with other professionals. Many reported that they did not successfully achieve this objective, namely because of the lack of structure of the placement, and formal activities that aligned to the interprofessional education objective.

- Interviewer: Can you comment on the interactions that you had with people that weren't doctors?
- Respondent 1: Mine was minimal.
- Interviewer: Minimal?
- Respondent 2: Minimal.
- Interviewer: No Allied health or other practitioners?
- Respondent 3: There was more on palliative. They all did ward rounds together with the allied health and the – what was that guy? There was a – he wasn't a social worker – palliative care?
- Respondent 2: He's in the pastoral care group.
- Respondent 3: Pastoral care.
- Respondent 3: I don't know. Anyway, the pastoral care worker was – he took us aside and told us his aspects and I talked to him a little bit. I think I might have had more experience with the allied health there because I used to be a dietician and I knew the dietician there and so I used to sit in the allied health tea room instead of the doctors' tea room. But I think if I hadn't had that I wouldn't have had much experience with the allied health. FG3

The students alluded to a lack of legitimate invitations for learning:

They said we were welcome to join the physios I don't know where that offer went missing or whether it was just a failure on our part to initiate it – FG2

In this response above, the student entertained that the lack of engagement with other professionals may have been a function of their lack of initiative in seeking out the experiences. There is ample literature in health professions education describing the challenge of workplace-based learning for students, particularly as they enter the environment for the first time (Molloy and Keating 2011; Delany and Molloy 2009). Not only do students experience a steep learning curve in skill and knowledge acquisition, they also need to read and engage in a new practice environment, often bound by unique culture and rules. Students also report that negotiating the relationship with their supervisor is another significant stressor in their early learning experiences (Molloy 2009). It takes a proactive and highly confident student to approach their own designated supervisor for learning experiences and feedback on their own performance. Approaching another practitioner outside their profession, who may not be receptive to the teaching encounter, may represent a significant challenge to students. This study did not examine the opinions or expectations of health professionals within the clinical environment. The student data alluding to this lack of structured facilitation suggests that it might be important to better understand the readiness and skill levels of practitioners in relation to interprofessional education and practice.

One student indicated that this difficulty in accessing other professionals might be overcome with formal and mandated opportunities to shadow other practitioners. For example, an opportunity to spend a half day with an allied health practitioner and another half day with a nurse, and to log this experience as part of satisfying the expectations of the placement:

- Respondent 1: I think if we spent one day with each different kind of allied health person, like one day with the social worker, one day with the physio, one day with the OT...
- Interviewer: Like shadowing?
- Respondent 1: Yeah, we'd find out a lot more about their profession than we think we know. – FG2

20.2.4.2 Informal Invitations

In contrast to the students who reported little contact with others outside medicine, some students experienced rich unstructured episodes of learning that were initiated by allied health staff. In the example below, the student conveys their productive experience of ward rounds where the physio, positioned at the back of the group with the medical students, took on an informal teaching role, ‘interpreting’ the events occurring between the patient and the consultant in the ward round.

Just during rotations I found that the older physios who had their own students to teach, they’re far more available to explain what’s going on because the doctors are really involved with the patient. We’re usually standing at the back and that’s also where a lot of the allied healthcare workers stand. So quite a few times the physio used to explain to me what was going on. – FG2

I had that same sort of experience as well with a physio on ward rounds explain things to me – FG2

20.2.4.3 Clinical Context Affording Interprofessional Learning Opportunities

Many participants thought that the greatest strength of the placement in encouraging interprofessional learning, was the nature of the clinical environment itself. The palliative care ward was recognized as a distinctly different way of practicing medicine, where there was focus on the person and their agency, compared to a typical acute ward, where the focus was on fixing pathology. The patient-centred nature of the care was seen to promote more opportunities for practitioners to work together for the patient.

I guess it’s a different approach to medicine, as much as the doctors there is a strong nursing support and pastoral care and a lot of other services that work together. That was a great place to be exposed to it – FG1

Yeah, so it was really good to see the – I don’t know the aspect of more looking at the human being. Even though the disease is never going to be stopped, they helped a whole person instead of just one condition – FG2

20.2.4.4 Geography Playing a Part in Generating Silos

Although the clinical context itself was seen as a facilitator of interprofessional practice, the physical setting of the placement, including the student common rooms, was viewed as a constraint to student-to-student interprofessional interactions. When asked if medical students interacted with students from outside medicine, one participant stated:

No, not really. Even in the common room downstairs the physio students go into a different room and the med students hang in a different room and that started to break down because we all watched basketball together. But that’s about the only time we really talked to them – FG2

20.2.4.5 Assessment Creates the Learners We Deserve

Students repeatedly raised the concept that assessment was a strong pointer to what is most important in their learning. This sentiment that assessment drives learning is expressed in the literature on assessment in both higher education and workplace based learning (Ramsden 1992; Boud 2000; Boud and Molloy 2012). Boud's (2000) paper on sustainable assessment argues that teachers' design and implementation of assessment tasks strongly influences the type of learner that is generated. Reeves et al. (2002) and Davidson et al. (2008) have also written about the importance of assessment in driving students to develop interprofessional knowledge and skills.

At the end of the week you would be like, well, how is this going to help me progress? – FG3

I would probably look at it [interprofessional education] and say, how is this going to help me? You know, looking very short-sighted, how is this going to help me pass my exams? When you're that smashed for time you really want to get down to the nitty gritty – FG3

We had a huge focus [on interprofessional education] in ours [problem based learning tutorials]. It depended on your tutor and our tutor was pretty forceful about what does a social worker do, what does an OT do? It had to be an objective. But whoever got that objective wasn't happy with it. At the time it was not assessed on our exams so no-one wanted to learn about it – FG2

The students alluded to the crowded nature of their curriculum, and the need to prioritise what needs to be learned. They (sensibly) saw summative assessment as a way to help them navigate the educators' priorities. The lack of formal assessment tasks relating to teamwork and knowledge of other professionals' roles served to devalue interprofessionalism within the program. Boud (2000) describes the multiple functions of assessment in learning. As well as its stated aims in evaluating specified learning outcomes, assessment acts to both overtly and covertly communicate what is valued by a profession.

20.2.5 *Theme 3: Discipline-Based Role Models Are Key to Orientating Learners to What Is Important in Practice*

20.2.5.1 Like Likes Like

Almost all the participants reported that they looked to mentors within their own profession as good models for practice, including interprofessional practice. Intuitively, it makes sense that learners, in seeking to reach membership within a profession look to 'one of their own' as models for practice and as credible sources to provide them with feedback on their own performance in relation to intended standards (Molloy et al. 2013).

Every time you see a doctor do something good or do something bad, you think oh I want to do that, or I don't want to do that – FG2

But yeah, you just had to model yourself against the medical rather than the other allied health, I think. But I think you probably could learn from allied health in the way they approach things as well, but I just haven't been exposed to enough allied health to comment on that – FG1

We weren't sort of going in and going let's watch physio and let's try to be physios this week – FG3

The students tend to want to just attach themselves to the doctors and the consultants and learn from them rather than trying to ask a social worker whether they could follow them for the morning – FG3

Rather than educational designers being optimistic about the degree to which students engage in innovations that target interprofessional competencies, it may be important to acknowledge the resistance that learners have in looking outside their profession for clinical role models. In our own case study, the most persuasive players are the doctors themselves- in the way they demonstrate productive teamwork, in the way they talk to other professionals and in the way they talk to students about the role and value of other professionals.

20.2.5.2 Unhelpful Modeling

Students reported picking up on stereotypes and antagonism between the professions during their encounters with practitioners outside medicine. In asking to learn from a nurse, one medical student reported that the nurse agreed to help on the condition that he would not turn into a doctor 'all pushy and stuff' when entering the workforce.

- Interviewer: So how did that go? How did you invite yourself to follow the nurses?
 Respondent 1: 'I'm really crap at this, you're obviously better, can you show us how to do it?' We just kind of said 'we're students, we're not very good, can you show us?' The nurses are always like 'oh yeah'. Every time you get to a nurse they're always like 'alright I'll show you this, but remember this when you're a doctor and don't be all pushy and stuff'. Every nurse I ever talked to. They just like to say 'in the future don't be a jerk.'
 Interviewer: I'm seeing some heads nodding. Did other people experience that?
 Respondent 2: Yeah, I've heard that quite a few times. Because I guess we're in a position now where we don't know much and we're happy to learn from anybody. So when we do the nurses always like to throw that in. But yeah, I guess they want us to be pleasant to work with.

Ironically, although this nurse may have been attempting to dissolve professional boundaries, they may have further perpetuated professional divisions through referring to stereotypes.

20.3 Pulling the Threads Together: Facilitators of Interprofessional Education

Although there is a compelling rationale for training health professionals to work together, there are few published guidelines on how to enact interprofessional workplace based learning. In most countries, uni-professional clinical education is the staple, and there tends to be a peppering of interprofessional objectives within

Table 20.3 Curricular components to consider when implementing interprofessional education in programs

Curricular component	Examples
1. Learners orientated to the purposes of interprofessional education and practice	Explicit learning outcomes relating to developing interprofessional practice, clear expectations that students will learn with other students and practitioners from professions ‘outside their own’ and providing early examples of effective team-based patient care.
2. Profession-based role models endorse the importance of interprofessional practice through narrative and action	Role models talk the talk and walk the walk of IPP. For example, a doctor teaching into the academic curriculum at University will ‘tell stories’ about the positive impact of IPP on patient outcomes. In the workplace setting, a doctor will communicate with other professionals effectively when caring for a patient, and frame other professionals in a positive light when debriefing with medical students about a case.
3. Practitioners from ‘other’ professions teach students at knowledge and skill level	Students are taught by capable others, outside their native profession. For example nurses teach into medical PBL tutorials, physiotherapy academics give anatomy lectures to medical students, an occupational therapist provides a tutorial on hand rehabilitation post tendon trauma in the workplace setting.
4. Learners participate in activities promoting interprofessional education	Activities to build student engagement and foster interprofessional education including patient cases –what would the paramedic do at arrival on the scene? How would the nurse assess the patient on arrival to the emergency department? etc. Clinical placements- following or tracking patients and involved in all aspects of their care. Team meetings also feature invitations for interprofessional education.
5. Learner disposition for working with others developed through formative and summative assessment in the workplace	Identification of IPP-based behaviours on the workplace assessment instrument (for example an item on “Works effectively with other professions and healthcare teams.” This explicit item serves to orientate learners to the fact that interprofessional competencies are a core outcome in workplace learning experiences. It also ensures that students receive feedback on how to improve aspects of their interprofessional practice.
6. Incremental challenge of interprofessional tasks that are consumer centred	Development of tasks that progressively challenge learners to work together for the consumer/patient. Without progression in complexity of required knowledge, skills and attitudes, learners are unlikely to engage with these competencies over time.

these experiences to encourage learners to observe and respect the practices of ‘others’ outside their profession.

The case study presented in this chapter illustrates the difficulty in establishing an effective interprofessional education program, embedded within the workplace. Although the case study focuses on the health workplace, the emergent themes may have application to the broader field of interprofessional education. Table 20.3 within this section highlights key curricular features that may encourage students to learn

with, from and about others. Again although these recommendations stem from the study of interprofessional education in the health workplace, it is anticipated that these program features may add value in the broader context of interprofessional education.

In the case study, despite medical students articulating the interprofessional learning aims of the placement (developed by curriculum designers), their reported experience deviated considerably from these aims. Medical students reported lack of legitimate invitations to work alongside ‘other’ professionals or health professional students, intimidation in asking to be exposed to experiences or knowledge provided by professionals outside medicine (stepping on toes), and conveyed their biases about the perceived importance of interprofessional learning and practice- along the lines of yes, it is important, but not as important as learning the technical skills needed to be a doctor.

These attitudes were expressed by some students at the very start of their clinical placements. This illustrates the potency of the university-based curriculum in shaping attitudes about what professional practice is about, and what is important to know in order to get there. In other words, even though this chapter has focused on initiatives in workplace based (clinical) education to promote interprofessional learning, the success of such initiatives may be influenced by how learners are socialised within their academic curriculum. A study by Reeves et al. (2002) also supports the importance of the pre-clinical curriculum in orientating learners to the importance of interprofessional practice and learning. The data suggest that to further the cause of interprofessional education, we may need to better focus on how activities are sequenced throughout the entire curriculum, rather than focusing on the implementation and evaluation of discrete, once-off pilot interventions.

Many of the focus group participants acknowledged that interprofessional practice is important long-term, but reported that development of these skills was not a key priority for medical students. Their focus was on ‘medical knowledge’ and technical skill acquisition. This privileging of technical skill development over ‘non technical skill development’ is reflected in a number of studies examining health professional students’ preparation for practice (Molloy and Keating 2011; Chumley et al. 2005; Prince et al. 2005; Small et al. 2008). As one participant noted:

It’s [interprofessional education] definitely valuable but I don’t know at this point whether it’s a major priority. I know that in our final year, our fifth year, our pre-intern year, we don’t have as many tutorials and it’s more about what you want to do and learning about that. Maybe it would be more suitable at that sort of session because you should have, I guess, an understanding of the medical side of things – FG1

The students’ positioning of interprofessional education and practice outside core ‘doctoring’ was a feature in the data set. The sentiment expressed in the quote above is that, yes, interprofessional education is valuable, but it is an added set of skills to acquire once you have the nuts and bolts of medicine under your belt. Interestingly, communication and teamwork, key capacities needed for interprofessional practice, also feature under the umbrella of ‘non-technical skill’ (NTS) development in medical education. There has been a recent shift in the literature on NTS development in the health professions, with a call that even the term ‘non-technical’ skill is unhelpful in the plight to orientate learners to the pivotal role

of these skills in health professional practice. Nestel et al. (2011) proposed that the term NTS is unproductive and unrepresentative in that it oversimplifies the importance of these skills in professional practice. As an alternative to NTS, they advocate using the term ‘human factors’ to represent the collection of skills needed to work effectively with others. The authors posit that the ‘non technical’ implication may lead learners to think that the associated capacities are not specialised and can not be learned as they are linked to personality (you’ve either got it or you don’t mentality). The danger of this ‘non-technical’ sentiment is that learners may not invest time or energy into developing these capacities, particularly given the packed nature of their curriculum.

One of the barriers to achieving interprofessional learning is the view that learning or practising interprofessionally may hinder professional identity formation (Hall 2005). As reported by Davidson et al. (2009) “there is a great deal of investment by various professions in socialising new inductees into their chosen profession” (p. 84). The participants in our case study also expressed this belief that you have to learn what it means to be a doctor first, before you can take on knowledge about the roles of others in the health system. This is a ‘staggered’ approach of learning, where students focus on ‘what you are’ first, and then use this understanding to delineate self from ‘others’. The danger of this approach is that it positions interprofessional learning and practice away from a core competency – something that you learn once you become an occupational therapist, or once you have become a nurse. We argue that a more productive framework is to position interprofessional practice as part of being a doctor/physio/nurse. To achieve this ‘core competency status’, it is very likely that interprofessional learning and practice needs to be introduced as early as Day 1 in the curriculum, along side knowledge and skills in hand hygiene, anatomy, suturing and communication.

The need to position interprofessionalism as a core set of competencies is also argued convincingly by Davidson et al. (2009). If learners do not see the value in engaging in the learning activities designed to promote these skills, there is very little value in setting up such opportunities within the workplace setting. This peripheral positioning of interprofessional education within a health professional curriculum is not a phenomenon unique to interprofessional learning. Molloy and Keating’s (2011) study, examining how physiotherapy students prepare for workplace learning, also highlighted that students, very early within their academic program, make decisions about what is needed to be learned in order to progress and to work as a practitioner. This physiotherapy study did not specifically examine students’ regard for interprofessional education, but rather how they viewed reflective practice.

When focussing on students’ lack of prioritisation of certain aspects of the curriculum, a number of comparisons can be made between the literature on developing reflective practice and interprofessional practice in students. As reported by Molloy and Keating (2011) “One of the constraints to students’ engagement in this learning agenda is their quick judgement of ‘peripheral’ content – viewed as removed from core business” (p. 79). As discussed in this chapter, thoughtful and deliberate curriculum design, can help navigate students to what it means to be a good practitioner, and what they need to prioritise in their training.

It is also likely that role modelling by staff (both in orientating students to the value of interprofessional education and practice) and the type of teacher (nurses teaching anatomy in the medical curriculum, physios teaching orthopaedic assessment skills) will enhance the message that working with others, and learning with, from and about others are core skills for any practitioner. Medical students repeatedly raised that it was natural for them to look up their medical colleagues and teachers as role models. This suggests that perhaps if we want to orientate learners to productive interprofessional behaviours, it might be best achieved through the efforts of teachers within their own profession.

So what are the curriculum features needed to develop effective interprofessional education in a pre-registration program? The medical students in our 2012 study helped to distil these components through their discussion about what worked and what did not work in their interprofessional education placement. Interestingly, even though our study examined interprofessional education in the workplace learning environment, the data pointed to the importance of setting up interprofessional objectives, activities and assessment throughout the entire curriculum—both pre-clinical and clinical. Table 20.3 above summarises the key components that may be considered at both university and workplace/fieldwork interfaces in order to develop practitioners with dispositions to work effectively with others.

As argued by Davidson et al. (2009) “there is no universal blueprint for how to ‘do’ interprofessional clinical education” (p. 84). What is apparent is that there are plenty of discreet educational interventions that are being trialed, perhaps with a lack of deliberate consideration for how these initiatives sit within the wider curriculum. The case study presented in this chapter highlights the lack of genuine student engagement in the interprofessional education placement. While students did not explicitly frame their disenchantment as a product of poor curricular design (they are, after all, not necessarily charged with the language of ‘constructive alignment’ and ‘vertical and horizontal integration’), their experiences pointed to a lack of preparation for how to engage in the interprofessional education placement objectives. Very early in their program, they had made decisions that interprofessional practice, including team work and communication, were skills peripheral to the core business of ‘doctoring’. The lack of assessment of interprofessional competencies in the academic context, and again the lack of summative assessment of these skills in the workplace setting, served to reinforce to students that they should invest their learning energies elsewhere. The six curricular features presented in Table 20.3 may help educators to reflect on ways of designing the curriculum to better develop students with capacities to work and learn with others in practice.

20.4 Summary and Where to Next

In drawing on the literature, and on our own study of an initiative designed to promote interprofessional learning and practice in medical students, it is clear that most people consider interprofessional practice as important for effective patient care.

What our own study brought to light was that acquiring these skills was not seen as an immediate priority for students, compared to the ‘hard’ knowledge and skills of medicine. A placement experience designed to promote development of these inter-professional capacities needs to be better designed than the somewhat ‘hopeful’ placement that was available for students in the study. Students reported that the lack of structured activities, the lack of legitimate teaching invitations from other practitioners in the workplace and the lack of summative assessment all contributed to their limited interprofessional experience.

Within the placement, there was no formal assessment that linked to the inter-professional education, or interprofessional practice experience, nor were their learning objectives of observation and interaction with other non-medical health professional students and practitioners promoted or mandated. For these reasons, it was only the confident or proactive medical students who actively sought experiences and informal teaching outside their medical supervisor. For example, one student reported following a “blood nurse” on placement to hone his skills in taking blood, but this was an exception within the participating cohort. Many of the findings related to professional identity formation and the strong impulse to work with and be supervised by doctors because that was who students were aiming to become.

The students alluded to the importance of role models within their own profession. The impact of this intra-professional modelling, both the narratives and the demonstrated behaviours, needs to be examined further. We encourage research designs that seek to answer the following questions about interprofessional education:

- To what extent do educators model interprofessionalism in the academic workplace?
- What can other health professionals teach medical students about interprofessionalism-in both the university and clinical setting?
- How do doctors model interprofessional practice within the workplace?
- Are ‘other professionals’ prepared to teach medical students in the clinical setting when they are already over-burdened with clinical and teaching responsibilities?
- How can educators better design a clinical placement model with the aim of promoting (and assessing) interprofessional learning and practice? And what is the impact on short and long term learning outcomes?

What is becoming increasingly clear from the mounting reports on inter-professional education initiatives in health, is that learners and practitioners are more likely to see the value of interprofessional communication and teamwork if they understand, and see for themselves, the positive influence of these practices on patient outcomes (Kent and Keating 2013). Studies that focus on patients’ experience of effective interprofessional practice, as well as impact on health outcomes and workplace efficiencies, are likely to provide a persuasive rationale as to why these skills are worth developing. Engaging learners in the ‘why’ of interprofessional practice early in their curriculum is just as important as the exposure to tasks and activities designed to promote these behaviours. The results from our study suggest that when it comes to a persuasive rationale for interprofessionalism, it may need to come from the practitioner native to the student’s profession. As one student stated, ‘I want to learn to be doctor, so it is only natural that I will watch what they do’.

Chapter 21

Medical Education

Tim Dornan and Pim W. Teunissen

*I swear by Apollo Physician and Asclepios and Hygeia and Panacea and all the gods and goddesses ... that I will ... hold him who has taught me this art as equal to my parents and to live my life in partnership with him ... and ... to give a share of precepts and oral instruction and all the other learning to my sons and to the sons of him who has instructed me and to pupils who have signed the covenant and have taken an oath according to the medical law, but to no one else.
Hippocratic Oath*

(Lyons and Petrucelli 1987, p. 214)

Abstract Educating the next generation of doctors is closely linked with caring for patients. Everyone learns to be a doctor in and through practice, and it is a basic professional duty of every doctor to help others learn to be doctors. This chapter defines what attributes of medicine shape its contribution to the wider scholarship of practice-based learning. It identifies tensions: Is medical practice applied science, or is it a practice that is informed by science? Is it just biomedical science that is relevant or do behavioural and social sciences contribute? Can art, music, literature, language study or other fields of study usefully contribute to making doctors? We describe admission to medicine, preparation for practice, practice-based learning, and continued learning in practice in ways that might give useful insights to other walks of life. The conceptual

landscape of medical practice-based learning is broadening from one dominated by psychology to one that derives valuable insights from sociocultural theory. Both conceptual orientations have much to say about what many now regard as the central feature of medical education: Identity development. It is not a smooth incremental process so much as one in which transitions along a trajectory of identity development alternate with periods of identity consolidation. We offer two models developed through our own research that conceptualise medical practice-based learning in its basic and post-basic stages. Medicine's contribution, we conclude, is to show how the expertise of seasoned professionals can be made accessible to novices in a scholarly way under the conditions of twenty-first-century society.

Keywords Workplace learning • Practice-based learning • Clerkship • Residency • Transition • Identity

21.1 Medicine and Medical Education: The Context

According to Cheetham and Chivers (2005, p. 13), a profession is “an occupation **based upon specialised study, training or experience**, the purpose of which is to supply skilled service or advice to others (...) in return for a fee or a salary” (our emphasis). So, education underpins professional practice. The Hippocratic Oath, cited above, shows that doctors have been under an obligation to share learning for over two millennia. The UK General Medical Council (GMC) re-emphasised that obligation in the present age in the following quotation from “Good Medical Practice”. (General Medical Council 2006, pp. 15–19): “Teaching, training, appraising and assessing doctors and students are important for the care of patients now and in the future. You should be prepared to contribute to these activities”. The guidance elaborates the educational duty of doctors as to “develop the skills, attitudes, and practices of a competent teacher”, properly supervise younger colleagues, accurately assess the competence of other doctors, and report it honestly in, for example, references supporting job applications.

This chapter sets out to answer the question “what attributes of medicine shape its contribution to the wider scholarship of practice-based learning?” In doing so, it will argue that medicine is an archetypal profession because it has embraced education as an integral part of practice and has, latterly, made professional education itself a professional practice.

21.1.1 *Historical Perspective*

A tension that has taxed medical education throughout its history is the one between medicine as an academic discipline and medicine as a practice. Jolly (1998, pp. 173–4) noted that Universities like Oxford and Cambridge had no requirement or facility for a clinical component to medical education in the sixteenth century. Practice was the menial work of barbers. Over the ensuing centuries, academic and practical

components gradually came together until a landmark report on the state of medical education in the United States and Canada authored by Abraham Flexner in the early twentieth century formalized their relationship (Dornan 2005). Awareness was growing that medicine was not serving society as well as it could. At the same time, the germ theory of disease was providing medical scientists and doctors with more effective weapons and moving medicine from a purely empirical basis to scientifically founded practice. Andrew Carnegie's charitable foundation tasked Flexner, an educationalist whose brother was a leading biomedical scientist, to report on how medical education could be improved. With the publication in 1910 of Flexner's report, "Medical education in the United States and Canada", medical education and practice were indelibly stamped with features that characterize them to this day. Flexner (1910, p. 20) attributed the poor quality of the physicians being produced by medical schools at the turn of the twentieth century to a progressive shift from preceptorship learning to didactic teaching of a set of doctrines. Patients had lost their crucial place in learning medicine. Flexner's aim was for a medical student to rely "no longer altogether on the senses with which nature endowed him, but those senses made infinitely more acute, more accurate, and more helpful by the processes and the instruments which the last half-century's progress has placed at his disposal." Those processes and instruments were provided by biomedical science. Medical schools should be research-active university departments with full-time staff. Entry requirements should be high. After preclinical grounding in scientific disciplines, clinical education was to take place through participation in apprenticeship hospital attachments, supported by bedside teaching. It was possible for theory and practice to be closely linked at that time because the same scholar physicians taught science in laboratories and practice in the hospital wards of leading institutions in early twentieth century America.

Flexner's curriculum design set what became an international gold standard for the relationship between theory and practice that is apparent to this day in theory-to-practice curricula and a dominant discourse of "medicine as applied science". Departures from the Flexnerian model have mostly been in the development of graduate education, which did not exist in any formal way in his day.

21.1.2 Medical Education

Having noted some similarities and differences between historical and contemporary educational systems, we end this section with a factual description of the practices of medical education and medicine as they exist today.

21.1.2.1 Before Admission

Different countries have different policies about admitting direct from secondary school, requiring foundation degrees, or having mixed entries. In North America, for example, medicine is an exclusively graduate study whilst Britain has undergraduate

and graduate entry streams, and mainland Europe requires bachelor studies of Medicine at the undergraduate level before qualifying as a “doctor” after completing a masters degree. Whatever the system, it is customary to call education up to the level of qualifying as a doctor “undergraduate medical education”.

If bioscience underpins medicine, it follows logically that understanding the chemical processes that underpin bioscience is prerequisite. Foundation knowledge in chemistry, then, is a requirement for entry to medicine in at least some countries. The sciences of “whole people” like psychology and sociology are seen as less important than sciences of those people’s body parts. Humanities are given even less credit, but recognition is slowly dawning that they too can contribute to the education of humane practitioners.

21.1.2.2 Admission

Medicine is so popular that medical schools can take their pick from people entering higher education. How to pick is less easy. Good academic performance is necessary, but opinions vary about whether it is sufficient and whether other attributes can and should be assessed. North America and Australia led the way in developing aptitude tests – the Medical College Admission test, and Graduate Medical School Admission Test respectively – which provide (inter)national standard measures of reasoning to supplement measures of competence brought forward from secondary or earlier tertiary education. The quest for measures that go beyond cognitive competence to professional and personal attributes has been particularly vigorous, given that it is important for doctors to be able to relate to patients and uphold rigorous ethical standards. These have included personality tests, measures of emotional intelligence and, of particular importance, interviews. The quest for reliability has moved interviewing procedures towards ones that draw conclusions from multiple small samples of performance in a circus of interview stations – so-called “Multiple Mini Interviews” (Siu and Reiter 2009). Many countries have introduced procedures to increase the diversity of medical school applicants and help less privileged people consider themselves as candidates for what might otherwise seem an unattainable career goal.

21.1.2.3 Curriculum Design

Undergraduate Medical Education

Undergraduate medical curricula last between 3 and 7 years. As laid down by the Flexner report, they have traditionally had a so-called “H-shaped” curriculum design. They begin with scientific study and little if any exposure to practice. After a more or less abrupt transition approximately midway through curricula (which

represents the cross-bar of the H), students move from lecture theatres and laboratories to wards, outpatient departments, and primary care physicians' offices as contexts in which to learn from and to practice. There is an emphasis at this stage on developing skills as well as knowledge. Meanwhile, students are exposed to practitioners espousing and (ideally, at least) modelling the ethical and moral basis of practice. Medical students function as clinical apprentices and transfer what they have learned in earlier years to the contexts in which they have to put their learning into practice. After tests of their knowledge and skills, they are awarded a final medical degree and a license to practice. Throughout undergraduate medical education, universities are responsible for the assessment and evaluation of education, though health provider organisations collaborate in providing opportunities for practice-based learning.

In recent decades many medical schools have adopted “Z-shaped” curricula, which have a less abrupt transition from theoretical to practical medical education. In accordance with constructivist didactic principles, learners are given opportunities to put abstract principles into practice in what would have been the “preclinical” phase of a Flexnerian curriculum. Integrated courses of theoretical education are coupled with relevant practical experiences in laboratories or clinical workplaces. Practical aspects of education progressively increase relative to theoretical components.

Postgraduate Medical Education

A period of graduate education as a “resident” is now mandatory in all medical subspecialties worldwide. The duration of residency varies, as does the extent to which universities or academic bodies affiliated to health care services oversee the process. In the UK, for example, some universities provide masters and doctoral education for residents but postgraduate medical education is, otherwise, provided, assessed, and evaluated by “Deaneries”, which report to a central regulatory body. In the USA and many other countries, by contrast, graduate education is provided by the same universities that provide undergraduate education. In both systems, residency lasts 3–8 years. Residents progress to the status of independent practitioners on the basis of time served, observed performance in practice, and formal assessments. Increasingly, such assessments are administered in workplaces, using multiple samples of performance of authentic tasks as measures of proficiency. There may also be formal tests of skills and knowledge outside workplaces. Up to this point, doctors are not allowed to practice independently or privately, and are not allowed to supervise other doctors. Once certified fit for independent practice, it is normal for doctors to become supervisors of medical students and doctors in training. Graduate education does not end with specialist certification. Participation in programmes of continuing professional development (also called continuing medical education) is now required of all specialists. Moreover, licensure may be time-limited and subject to periodic re-assessment of proficiency.

21.1.2.4 Lifelong Learning and Transitions

Whilst medical education is often described as a lifelong continuum, the career trajectory from medical student to postgraduate trainee and onwards to independently practising medical specialist is, in reality, divided into distinct stages. According to Petersdorf, the components of medical education are like children's building blocks, "piled one atop of another to make a tower that from a distance may look like a coherent whole, but a closer perspective reveals the discrete nature of the components and a fragmented overall structure" (Petersdorf 1994). The times when learners move from one phase to the next are distinct transitions. Learning can be repetitive and disjointed rather than incremental. For instance, learning about diabetes for a written exam in the first curriculum year requires different learning skills from learning about the treatment of diabetes when you are a clerk in a busy outpatient clinic. Education research shows that medical education does not prepare learners to move easily from one stage of their careers to the next one. And there still remains the problem of helping fully trained specialists learn from their ever-changing practices (Teunissen and Dornan 2008).

21.1.3 Medical Practice

Even the most technical aspects of medical practice must be based on a strong moral foundation, which emphasises the autonomy of patients and the ethical obligation of practitioners to support their autonomy. The UK GMC is unequivocal that the primary duty of a doctor is as follows:

Patients must be able to trust doctors with their lives and health. To justify that trust you must show respect for human life and you must make the care of your patient your first concern (Ref: GMC – Duties of a Doctor)

Licensure and the ability to earn a livelihood depend on adherence to a code of moral conduct, which is strictly enforced. A doctor's responsibility, it has been argued, is not to make altruistic personal sacrifice on the behalf of patients, rather to have a pro-social orientation, which includes taking care of oneself so as to be fit to take care of others (Burks and Kobus 2012). Sutton and colleagues (2011, p. 11) wrote that mutual trustworthiness provides an important foundation for doctor-patient relationships and explored how the principle of trustworthiness could be extended to the triadic relationship between patients, specialists, and doctors-in-training. They concluded that "the educational process itself should help learners examine the moral basis of medical practice" (Sutton et al. 2011, p. 15), emphasizing the close parallel between doctors' therapeutic relationships with patients and their educative relationships with medical students and doctors-in-training.

It is hard to generalize across medical subspecialties, whose tasks are as varied as performing microsurgery, looking after populations of people, and caring for people who are dying, but they have in common highly-developed underlying

knowledge-bases, a need to use knowledge within complex reasoning processes that lead to potentially high-stakes decisions, and an ability to function in one-to-one relationships and in team settings. Complex psychomotor skills are needed in an increasing number of specialties because technology is providing many novel “minimally invasive” diagnostic and therapeutic procedures. Dextrous procedures are no longer the preserve of surgeons.

21.1.4 Potential Significance to Other Walks of Professional Life

One answer to the question “what attributes of medicine shape its contribution to the wider scholarship of practice-based learning?” is that it is a profession that calls for the application of complex knowledge and skills within strongly social contexts of one-to-one and collaborative relationships. It is similar to other health professions in having a strong ethical imperative to work to the benefit of patients, but differs in being the health profession *par excellence* in which practitioners are expected to craft knowledge-rich solutions to unique and complex situations rather than work solely in conformity to norms of practice. Medical problems can be not just complex, but unpredictable in their behaviour and it is not at all uncommon for doctors to be faced by diseases or situations that have never before been described. Technological advance both shapes and is shaped by practice but practice is essentially located within human systems, as illustrated by the most technically proficient surgeons achieving suboptimal patient outcomes if they cannot behave in a reasonable way with the other people who work with them in operating theatres.

21.2 The Conceptual Landscape

21.2.1 From Positivism to Constructivism

This section aims to answer the question: “How is learning medicine conceptualised?” The philosophical background to the Flexner report was a positivist one. According to Guba and Lincoln (2000), positivism assumes external realities “exist” independently of the people who apprehend them. That fitted the era in which Flexner wrote his report, which was a time when biomedical sciences were showing themselves able to increase ‘real’ medical knowledge so dramatically. Flexner’s epistemology shifted the task of students away from being “parrot-like, to absorb” to a very different one (Flexner 1910, p. 21). As Ludmerer explained, “the aim of medical education had to be that of instilling proper techniques of acquiring and evaluating information, rather than merely inculcating facts through rote memorization” (Ludmerer 2011). Instead of a sole focus on lectures and textbooks, medical

education moved towards active participation in laboratories and clinical clerkships; “a generation before John Dewey, medical educators were espousing the ideas of what later came to be called ‘progressive education’” (Ludmerer 2011). Dewey conceptualised experience as the starting principle for learning and development. He believed that active engagement in practice helped learners gain applied rather than abstract knowledge (Yardley et al. 2012). A progressive shift towards an outlook on learning that “can be seen as a process whereby learners actively construct their understandings based on previous experience, knowledge, and their perceptions of the world” has remained a driving principle in medical education since then (Mann et al. 2011).

21.2.2 Theoretical Orientations

Theoretical orientations that have influenced medical education have been as varied as the backgrounds of those involved in medical education, but three strands have had major influences on the study and conduct of medical practice-based learning: Cognitive psychology, as exemplified by skills training and problem based learning; cultural-historical learning theory, with a particular emphasis on communities of practice theory; and vocational workplace learning theories.

21.2.2.1 Cognitive Psychology

Cognitive psychology has influenced many aspects of medical education. It focuses mainly on mental processes involved in learning and fits with a constructivist perspective in that it views learning as an active process. Areas in medical education that have both benefited from and contributed to the literature on cognitive psychology are expertise development, clinical reasoning, reflective learning, and self-directed learning. A good illustration of cognitive psychology’s influence is problem-based learning (PBL), which was first introduced at McMaster University, Canada, in 1969 and has been adopted around the globe since then.

According to Schmidt et al. (2011), the defining characteristics of PBL are:

1. Problems are used as triggers for learning;
2. Students collaborate in small groups for part of the curriculum;
3. Learning takes place under the guidance of tutors;
4. Curricula includes limited numbers of lectures;
5. Learning is student-initiated, and
6. Curricula offer ample time for self-study

The level of students’ prior knowledge strongly influences their learning. For them to build on their knowledge, it must be activated, which is done by presenting them with problems that ‘trigger’ their learning. One way of achieving that is to make problems interesting and motivating. For instance, a visit to a patient at home

may throw up several meaningful problems that present students with manageable challenges. Prior knowledge on the topic will help them create meaning as they interact in small groups to try to solve the problem together. As they do so, they form mental models of the problem, elaborate on them and, by using various resources, look for possible explanations and solutions. “Moreover, as the learners’ preconceptions are activated, they become more easily able to identify gaps in their prior knowledge, thus enabling better learning to take place” (Schmidt et al. 2011). PBL fits well with cognitive perspectives on knowledge development. It is hypothesised that, for their knowledge to be effective and available for use, individuals create elaborate networks (Schmidt and Rikers 2007). Elaboration is promoted by group discussions, teaching peers, reading, gaining additional experience with other facets of problems, or reflecting on it.

One of the challenges for PBL curricula is to help students develop transferable knowledge and skills. Although PBL was developed with the assumption that transfer occurred quite readily, it is now clear that both teachers and learners have to build in educational activities that promote transfer. In a similar vein, PBL was once thought to develop generalized problem-solving skills but research has shown that problem-solving skills are context specific. Mann, Dornan, and Teunissen explain that “looking for underlying concepts and principles can be strengthened by effective tutoring; for example, by encouraging students to compare the current case with others in their experience or think of other examples that reveal similar concepts” (Mann et al. 2011). Elaboration of knowledge based on clinical experience can also be facilitated by a good match between a clinical clerkship and the content of the PBL case, effective tutoring, and the self-directedness of the student (O’Neill et al. 2002). Cognitive psychology provides a theoretical orientation for much contemporary research in clinical reasoning, the acquisition of skills, and their transfer from training to practice context. As an example, McConnell and Eva took a cognitive perspective to examine how emotion affects the processing of information and its transfer between learning and practice situations (McConnell and Eva 2012).

21.2.2.2 Cultural-Historical Learning Theory

The origins of cultural-historical learning theory can be traced back to a group of Russian psychologists in the 1920s and 1930s, led by Lev S. Vygotsky (Engestrom and Miettinen 1999, pp. 1–16). In what is now referred to as first-generation cultural-historical activity theory (CHAT), but is also called socio-cultural theory, Vygotsky positioned activity as the “general explanatory category of psychology” (Roth and Lee 2007). Luria and Leont’ev further clarified the nature of this category in the second generation of CHAT. They proposed that all human activity is “motivated by the need to meet a goal, or object” (Roth and Lee 2007). According to Wertsch, del Rio & Alvarez, the goal of a “sociocultural approach is to explicate the relationships between human action, on the one hand, and the cultural, institutional, and historical situations in which this action occurs, on the other” (Wertsch et al. 1995, p. 11). Engeström developed an ‘activity triangle’, shown in Fig. 21.1, to investigate an

Fig. 21.1 Activity triangle

activity system (Engeström and Miettinen 1999, pp. 19–38). It shows how activity exists in an interrelationship between an individual or group (subject), the objectives they have, their roles and pertinent rules in a community, and the artefacts that mediate activity. Together, this complex interaction leads to outcomes at different levels and with potential consequences for further subsequent activities.

Socio-cultural learning theory makes it possible to consider the development and functioning of medical students and doctors without divorcing them from their specific social contexts and is thus a social constructivist theory (Mann et al. 2011). Therefore, it helps explore students' and doctors' practice-based learning. As medicine is an old profession that has become more complex with time, it seems self-evident that the cultural, institutional, and historical situations in which actions occur should be taken into account. De Feijter et al. (2011) exemplified the use of cultural-historical activity theory when they studied the activity system in which final year medical students learn about patient safety. Using CHAT to guide their analysis, they found that two main activities were important and each had a clear goal: learning to be a doctor; and providing safe patient care. Those two activities could, at times, create contradictions when the rules and division of labour of one activity adversely affect the other one. Contradictions in roles and rules could give rise to unsafe situations, which caused stress for students who had to manage the two activities simultaneously, whilst also stimulating reflective learning (De Feijter et al. 2011).

21.2.2.3 Communities of Practice

Another, related, perspective on practice based learning is Lave and Wenger's work on communities of practice (CoP) and legitimate peripheral participation (Lave and Wenger 1991; Wenger 1998). As in CHAT, learning is viewed as situated, which means that it "is an integral and inseparable aspect of social practice" (Wenger 1998).

But where CHAT provides a structured approach for understanding aspects of, or problems within, activity systems, Lave and Wenger's work focused specifically on the relation between novices and experts in CoPs, which they defined as a "set of relations among persons, activity, and world, over time" that result from collective learning in the "pursuit of a shared enterprise" (Lave and Wenger 1991; Wenger 1998). Newcomers' participation alongside more experienced community members stimulates an exchange of knowledge and a negotiation of meaning between members resulting in the ongoing reproduction of a CoP. Like activity theory, CoP is a social constructivist theory.

After studying a number of apprenticeship situations, from Vai and Gola tailors in West Africa to U.S. Navy quartermasters, Lave and Wenger proposed legitimate peripheral participation as a descriptor of how practices are made accessible to newcomers (Lave and Wenger 1991). Initially, they are introduced by, for instance, being allowed to observe tasks, participate in low-risk ones, or perform more skilled ones under close supervision. This peripheral participation provides an entrée into practice that has to be accompanied by enough legitimacy for newcomers to be fully engaged. If, for whatever reason, a CoP does not open up, then "inevitable stumblings and violations" become a "cause for dismissal, neglect, or exclusion" rather than opportunities to learn (Wenger 1998). Through their participation in a CoP, newcomers develop along personal trajectories towards the kind of full participation that is characteristic of experts. Research on learning in operating theatres and on trainees' participation in internships suggests that situated learning theories, and the specific focus of communities of practice and legitimate peripheral participation on the development of newcomers, can be valuable for understanding medical workplace learning (Lyon 2004; Sheehan et al. 2005). For instance, conceptualising learning in the operating theatre as a social process allowed Lyon to show that medical students find learning most valuable when they engage in the practice of surgery by "getting involved, standing scrubbed in at the table, rather than being removed from it as passive onlookers." To become 'full participants', "students use strategies to promote themselves to gain the surgeon's trust and to gain legitimacy by presenting themselves as deserving students, showing interest and intent, motivation, professional behaviour and respect" (Lyon 2004). A more recent example of how CoP has been able to inform medical education research is a study of patients' involvement in medical student teaching encounters (McLachlan et al. 2012). Patients, the study showed, were participants in the practice of patient care, but did not usually see themselves as anything more than learning objects in the practice of medical education. An ability to make those two practices overlap with one another, the study showed, is an attribute of effective workplace clinical teachers.

21.2.2.4 Workplace Learning Concepts

Originating in the study of vocational learning of, for instance, nurses, hairdressers, and metal workers, there is a line of social constructivist research that has conceptualised workplace learning in a way that is very significant to medical practice-based learning.

Eraut contributed by emphasising that much learning at work, even in an educational context, occurs outside formally organized and delivered curricula. He describes informal learning as taking place “in the spaces surrounding activities and events with a more formal educational purpose” (Eraut 2004). This situation is typical of many learning events in medicine where doctors and students engage in clinical activities, often without a distinct educational purpose in mind. Working with patients and discussing cases with colleagues informally helps them learn medical knowledge, social norms, traditions, and attitudes. In this way, informal learning is closely linked to tacit learning, which Reber describes as “the acquisition of knowledge, independent of conscious attempts to learn and in the absence of explicit knowledge about what was learned” (Reber 1993). “In general, four types of activity can be distinguished that have a high potential for learning: participation in group activities, working alongside others, tackling challenging tasks, and working with patients” (Eraut 2004). The very nature of implicit learning makes it difficult to recognize. Doctors don’t notice the resulting knowledge or regard it as part of a person’s general capability rather than something that has been learned. This is problematic because, although they might be aware that they are learning by doing, both learners and teachers find it difficult to maximize workplace learning (White and Anderson 1995).

From an educational viewpoint, the complexity of everyday medical practice, which is not geared to teaching, may appear to be unstructured, unintended, and opportunistic. However, as Billett explains in his work on practice-based learning, that is not the case. The participation of medical students and doctors in medical practice is structured by the goals of specific workplace. Obstetrics, for instance, is a very different milieu than dermatology. Billett argues that “workplaces will invite workers to engage and learn, insofar as that participation serves its goals and/or the interests of those within it, that is the continuity and/or development of the workplace or affiliates or individuals within it” (Billett 2006). In this respect, every workplace has a ‘workplace curriculum’, which affords learners opportunities to move along particular learning trajectories in the time they spend there (Billett 2004a). Opportunities for engagement and expectations depend on the workplace as well as the learner. Clearly, the learning trajectory will be different for a medical student than for a newly hired medical specialist. And individual learners play an active role in choosing what activities they participate in and how. But looking at medical practice from the viewpoint that it is structured, although usually not for education, and that learners are afforded different trajectories of learning, helps medical educators disentangle practice-based learning. Jha and colleagues, in recent research, related the concept of a ‘workplace curriculum’ to workplace based summative assessment procedures (Jha et al. 2012).

After reviewing the importance of identity formation in the trajectories of doctors’ learning, the next section relates these different concepts to different phases of the medical education trajectory in order to get a comprehensive overview of medical practice-based learning.

21.3 Identity Formation

This section introduces identity formation as a central concept in practice-based learning, and explains how doctors-to-be strive to resolve, or at least handle, various tensions as they form their professional identities. Whilst recognising that learning to be a doctor is, in reality, a discontinuum with “transitions” between successive stages, we will argue that discontinuity can open up positive learning opportunities as well as pose unhelpful challenges (Teunissen and Westerman 2011a).

Students typically encounter the theory-practice tension on the day they enter medical school. A doctor, senior in years and avuncular in manner, gives a pep talk, explaining that medicine is as much an art as a science. Almost in the same breath, students are told of the scientific education they must follow for 3 years or longer before they can come into contact with the art of medicine. Other tensions are in the curriculum content. An increasing number of disciplines jostle with one another for space in crowded curricula. Behavioural and social sciences, often regarded as ‘soft sciences’ and minority partners in curriculum development, are amongst those disciplines. Even though social sciences are given curriculum space, students may pick up biomedical scientists’ negative attitudes towards them and their place in medical curricula. And there are tensions between biomedical scientists, who may have been detailed to teach medical students because their research performance was poor, and doctors, who command higher salaries and status. The theory-to-practice curriculum design inherited from a century ago, remember, was predicated on laboratory scientists teaching the early curriculum years being the same people as the expert clinicians who teach at the bedside. No longer! Few teachers of medical sciences are medically qualified, let alone expert clinicians.

Whilst Flexner’s (1910) recommendations formalized undergraduate medical education, residency has come into existence and been formalized over the century since then. That has been made necessary, partly by the increasing complexity of medical practice, partly by it becoming unacceptable for doctors to learn by trial and error, and partly by the current climate of accountability. Here, again, there are tensions – between off-the-job and on-the-job education, and between workplace learning and workplace assessment. One easy way of showing education is being delivered is to provide (mandatory) off-the-job education, often in the form of large group teaching. Eraut has argued, however, that the most important learning of any practice takes place on-the-job (Eraut 2004). An important breakthrough was the demonstration by Norcini et al. (1995) that multiple low-stakes assessments of competence on-the-job could take the place of high-stakes off-the-job assessment. So, workplace-based assessment came to assume the prominence it now has in medical education. There is an inherent complication, however, in a supervisor being judge of a resident’s proficiency and the same supervisor being a professional colleague in patient care and a partner in what Wearne et al. (2012) have termed an ‘educational alliance’. The development of simulation techniques to train technical medical skills has gone some way towards resolving those two tensions. It makes good sense

to train and test technical skills (e.g. skills in operative surgery) *in vitro* before allowing learners to apply them *in vivo*. Simulation is taking an increasingly important place in medical practice-based learning, particularly in specialties that require complex psychomotor skills though the best balance between low-fidelity simulation, high-fidelity simulation, and real practice remains to be identified. High-fidelity simulation models do not currently outperform low-fidelity ones. Perhaps that is because different simulation models are not sequenced to best effect (Norman et al. 2012).

Important as technical proficiency is, the importance of “non-technical” skills, has come to be recognized, even in very technical specialties. Whereas surgeons who were deft technicians but lacked interpersonal skills were formerly tolerated or even celebrated, it is now clear that their lack of interpersonal skills has an adverse effect on patient outcomes. The human qualities of doctors – values, emotions, interpersonal skills, and adherence to the underpinning moral precepts of medicine – are important, whatever their specialty.

The net result of these various forces, operating on an educational field with such a rich culture and history, can be seen in a number of contemporary trends in medical practice-based education. Whilst the emphasis on science remains strong, there is a move towards what Kuper and d’Eon (2011) termed “curriculum transformation” and “rethinking the basis of medical knowledge”. There is recognition that affects – particularly emotions – are important components of medical expertise, alongside knowledge and skills (Helmich and Dornan 2012). Competency frameworks have been developed to emphasise that doctors must be professionals, communicators, and collaborators as well as medical experts (Frank and Danoff 2007) and curriculum outcome frameworks are being promoted to make doctors’ development of professionalism measurable (Cooke et al. 2010).

21.3.1 Discourses of Competence and Identity Development

Reviewing identity, identification, and medical education, Monrouxe (2010) wrote: “Medical education is as much about learning to talk and act like a doctor as it is about learning the content of the medical curriculum.” Individuals, she continued, have multiple identities and there may be dissonance between them, which gives rise to powerful, negative emotions. Identity dissonance has been proposed as the cause for a worrisome decline in empathy and idealism and increase in cynicism that has been observed as medical students move from the science to the practice phase of their education and progress towards qualification (Griffith and Wilson 2001; Testerman et al. 1996). The term “hidden curriculum” is used to describe the informal interactions between students and staff, which are observable in students’ accounts of their learning (Gaufberg et al. 2010) and have been blamed for creating identity dissonance and loss of idealism. The problem was laid bare by a Foucauldian analysis of medical students’ and teachers discourses of curriculum (MacLeod 2011). Medical students developed their identities as doctors within two competing discourses: a discourse of competence and a discourse of caring. The discourse of

competence tended to be privileged whilst the discourse of caring was marginalized. The discourse of competence was associated with biomedical and clinical issues while the discourse of caring was associated with social issues. MacLeod went on to describe how medical students constructed their identities by demonstrating themselves to be confident, capable, and suitable to be doctors in relation to the discourse of competence. In contrast to the privileged discourse of competence, students constructed caring identities by showing themselves to be benevolent and humble. MacLeod's discourse analysis (MacLeod 2011) brings this review of tensions in medical education to a close by showing how, for all the efforts made by curriculum designers to provide balanced and transparent education, social, historical, and institutional forces have a strong hold on professional learners' identity development and the influences they are subject to.

The next section introduces the topic of (dis)continuity in professional practice-based learning and examines individual transitions in detail.

21.3.2 Growth Towards Independent Practice and Transitions

In the course of their medical training, students change from being passive observers to bearing ultimate responsibility for patient care as a medical specialist. The first major transition occurs when non-clinical medical students start the clinical part of their training. At the periphery of practice, they get first-hand experience of what it means to be a patient and what it takes to be a doctor. There is a second transition when graduated students start taking (supervised) responsibility for the care of patients as specialist trainees ("junior doctors"). A third transition takes place when specialist trainees finish postgraduate training and tackle the demands of posts as medical specialists. A transition, which can last for months, results from individuals moving from one set of circumstances to another (Nicholson 1984).

New circumstances, such as starting at a new workplace, bring a variety of challenges. After physically coming to know your way around comes the more difficult task of learning the social and cultural norms of your new workplace, of identifying the expectations of others, marrying them with your own, and learning new knowledge and skills to be able to live up to new tasks. In the three major transitions mentioned above, medical students and doctors appear to cope in different ways. There is compelling evidence that a large proportion of (student) doctors experience transitions negatively. They experience levels of stress and negative emotions, which have an adverse effect on their performance (Bogg et al. 2001; Brown et al. 2009; Helmers et al. 1997).

Each major transition has its own challenges. Reviewing the literature, Teunissen and Westerman (2011b) showed that almost half of all students find the transition from preclinical to clinical education too abrupt. Their main stressor is understanding their workplace roles and responsibilities, which exemplifies the clash between the learning orientation of medical school and the performance orientation of practice-based learning (Teunissen and Westerman 2011b). Suddenly, they need to take full responsibility for their own learning in a way that was not taught or learned

in medical school. Most students feel uncertain if they have what it takes to ‘fit in’ because they lack clinical skills and find it hard to apply theoretical knowledge to clinical reasoning, although PBL curricula go some way towards mitigating those problems (Westerman et al. 2010).

The transition from clinical student to resident is no less intense. Research shows that about a quarter of junior doctors experience high levels of burn-out on the Maslach Burn-out Inventory (Bogg et al. 2001). As well as being very challenging, research shows that this transition is also a time for rapid personal development. Lempp and colleagues, for instance, found that junior doctors in this phase develop strategies to help them cope with everyday clinical practice and take on more professional responsibility in relationships with patients (Lempp et al. 2004). Medical schools have begun to respond to those difficulties by offering their students induction courses to learn specific skills or help them cope with the new demands of major transitions.

One might expect that reaching the goal you have been working towards for 10–15 years would result in a feeling of accomplishment but the third major transition – from specialist trainee to licensed medical specialist – is a time of mixed feelings as well. After many years of supervised practice, new medical specialists find themselves wanting in a variety of aspects. They lack teaching skills, are unfamiliar with being clinical supervisors, and lack competence in managerial and financial aspects of running a medical practice (Westerman et al. 2010).

Jarvis-Selinger et al. explored how learners develop their identities as they progress through medical curricula. Like Teunissen and Westerman (2011a), they described identity formation as taking place over a series of qualitatively distinct and discontinuous stages. Rather than learners progressively developing the identities of doctors, they develop (and then have to leave behind) the identities of university student, clerk, resident, and eventually specialist. Changes in identity are precipitated by emerging crises, which arise as a result of discrepancies between individual people’s understandings of themselves in their professional role, and the experiences and challenges their situation confronts them with (Jarvis-Selinger et al. 2012). Looking at transitions as inevitable life-events that coincide with different life-phases calls for a different approach from the present one. Instead of trying to eliminate transitions by making the differences between successive phases smaller, or introducing induction courses, medical education is beginning to look into ways of preparing future doctors for the sure struggles that lie ahead (Teunissen and Westerman 2011b). Optimally preparing individuals for a transition is a matter of helping them cope with changes, recognise learning opportunities and take responsibility for their own learning processes and outcomes (Hannon 2000; White 2007).

21.4 Models of Practice Based Learning in Medicine

Up to this point in the chapter, we have explored historical and other forces that explain why medical education is as we know it today. We have explained characteristics of the practice of medicine, the practice of medical education, and the

relationship between the two. We have done that so other professionals can examine similarities and differences between their own practices and ours, and perhaps derive useful insights. We now move firmly in the direction of educational practice, proffering approaches that are directly applicable. We describe how we have synthesised models of practice-based learning from the empirical research of ourselves and others in undergraduate and postgraduate medical education. There is, of course, a danger that doing so will simply embed weaknesses of current educational practice. The research on which our model-building has been founded, however, seeks not to idealise but to analyse practice. It seeks to make more explicit those parts of educational practice for which there is research evidence of benefit. Much of it comes from qualitative research, whose ability to illuminate causal mechanisms has made model-building possible.

The scholarship of medical education owes more to the social than the biomedical sciences so the research we draw on is well theorised. Its central assumption is the social-constructivist one that people construct knowledge by interacting with the world. Human activity in all its complexities is what gives meaning to things and situations. People learn from contextualised activity so their learning is historically, culturally, and socially laden. Accordingly, learning is a social process. As Kim explained “it does not take place only within an individual, nor is it a passive development of behaviours that are shaped by external forces. Meaningful learning occurs when individuals are engaged in social activities” (Kim 2001).

There is an important distinction between learners who are not yet licensed to be members of a clinical workforce – medical students, who have a peripheral relationship with practice – and learners who are members of a workforce – residents and trained specialists. Legally, undergraduate education has to be separable from patient care, because medical students are not allowed to take responsibility for patients other than under very close supervision. Residents and trained specialists do take responsibility for patient care (albeit under supervision in the case of residents) so there is a clear legal distinction between the learning of unlicensed students and licensed doctors. The distinction is not solely a legal one because there are important empirical and theoretical differences between the ways those different groups learn. Therefore, they are treated separately in the discussion that follows. For each category of learners we describe:

- What *conditions* influence learning?
- What learning *mechanisms* operate?
- How do those processes affect learning *trajectories*?

21.4.1 Professionals Learning Within Practice

21.4.1.1 What Conditions Influence Learning?

‘Learning by doing’ is the easiest way of describing how medical professionals learn in and from practice. But this often-used term does not explain how they learn by doing. This section explores the topic (Teunissen et al. 2007b; Watling et al.

2012). Watling et al. and Teunissen et al. both studied qualitatively how junior doctors and specialist trainees learn and concluded that the foundation of their learning was “the clinical work itself: learning occurs through the accumulation and processing of clinical experiences” (Teunissen et al. 2007b; Watling et al. 2012). There is a difference, however, between the degree of autonomy of residents and trained medical specialists in deciding how to shape their practice and, consequently, their learning. Whereas the training of residents is governed by the requirements of professional societies and/or governmental bodies, medical specialists are freer to organise their lifelong learning activities. There has been a shift in residency education over the last 15 years from no process requirements, or very general ones (e.g. only stating for how long and where training should take place), towards outcome-based curricula (Scheele et al. 2008). Working in supervised practice for a specified number of years is no longer regarded as sufficient evidence of specialist training. Wallenburg et al. have conducted a comparative historical-institutional analysis of postgraduate medical training reform in the United Kingdom and the Netherlands. Although there are political and institutional differences between the two countries, “medical professional bodies had to give up their monopoly in professional training and increasingly had to share power with other stakeholders” in both the United Kingdom and the Netherlands (Wallenburg et al. 2012). This greater transparency and accountability will likely also affect specialists’ continuing education in the future.

One of the results of the reform of practice-based learning for specialist trainees and a growing number of medical specialists, is the formalisation of learning activities and assessment. For instance, in specialist training, assessment programs have been introduced that make use of different tools, often based on structured observation and feedback clinical practice, to support and monitor trainees’ learning (Van der Vleuten et al. 2012). The information gathered in this way, is collected in a learning portfolio that is supposed to guide further educational activities, tailored to the needs of individual learners.

Shah and colleagues (2014) conducted detailed qualitative research into residents’ learning from clinical work. They found that learning almost always started from the care of some individual patient and rarely from formal educational activities like day-release courses. Organisational features of learning environments both afforded and, at times, constrained residents’ learning. Workload was a simple example. Respondents described how either insufficient or excessive workloads constrained their learning because it provided insufficient stimulus on the one hand, or overwhelmed them on the other. The relationship between affordances and learning outcomes was further complicated by attributes of trainees, best exemplified by the relationship between trainee seniority and the complexity of patients’ clinical problems. What might be an overwhelmingly complex case for a junior trainee to handle could be a very positive educational stimulus for a senior one. The attribute of trainers that most strongly influenced learning was, unsurprisingly, their capacity to engage in warm, supportive, and stimulating social relationships with learners.

21.4.1.2 What Learning Mechanisms Operate?

The practice-based learning of residents and specialists is mostly informal and implicit because only those activities that are directly relevant to healthcare tend to be made explicit. Learning results from social interaction within communities that have long and strong biomedical traditions of focusing on the value of evidence-based truths, knowledge, and tangible skills. A quote from a participant in a study on clinical supervisors' views on trainees' practice-based learning illustrates nicely that clinical supervisors don't think in terms of education but in terms of doing your job and assuming that learning will be a by-product of wanting to do it well (Teunissen et al. 2007a).

'So in the morning the residents come to the hospital and eh, when they're scheduled on the delivery ward, then eh... Well if they didn't do any deliveries then they watch someone else do one, but at some moment they're going to manage that delivery their selves [sic] and from that perspective they learn by doing as they go along. The realistic impression of things is that they are learning while working.'

A model that describes how people develop in such a complex system requires contributions from both cognitive and social practice-based learning theories. What ties together most medical education research in this area is that researchers have drawn on a variety of other research fields to explain the phenomena they observed. This has led to a patchwork conceptual framework at multiple levels, from the mental processes involved in memory, emotion, and action to the historical and sociopolitical influences on the state of healthcare provision and education. Medical education researchers have found concepts that could be applied to medical education at different places along this continuum. Academic fields ranging from cognitive to social psychology and situated cognition have contributed. Where the contextual and social conditions have been a researcher's focus, sociology and anthropology have provided frameworks, such as communities of practice, cultural-historical activity, or organizational socialization theory.

Topics that have emerged from this research are the importance of structure, effective feedback, participation, and relationships. Doctors, especially junior ones who have just made the transition to practice, find it hard to engage in self-directed learning. Specialists as well as residents need structure and guidance to help them learn from practice (Bravata et al. 2003; Teunissen and Dornan 2008). Feedback makes a particularly important contribution but it can be hard to get in practice. Feedback is performance related information that a person can use to identify areas in which their performance needs to improve. It can be explicit, obtained by observing the behaviours of others, or provided by measuring educationally relevant patient outcomes (Teunissen et al. 2009). According to Archer, "the health care professions have so far embraced feedback on their own terms. It is constrained by the classic medical hierarchical model, in which an expert supports a novice" (Archer 2010). There is room for medicine to find more effective ways of providing feedback.

Participation and relationships are two sides of the same coin. Practice-based learning requires participation in practice, which is a complex constellation of

professionals, rules, traditions, and histories. Whilst trainees and specialists engage with the different actors in workplaces in different ways, the requirements for effective learning are the same: legitimacy, feeling safe to contribute to common goals, and feeling safe to learn, which means being able to acknowledge failings. The relationships learners have with their supervisors and co-workers seem to have very important effects on feeling supported in their learning processes, in credibility judgments of other people's input, and in maintaining a safe healthcare system in general (Teunissen et al. 2007a, b; Watling et al. 2012).

Analysis of residents' narratives of their workplace learning by Shah and colleagues (2014) showed that the communicative practices of workgroups played a central role in learning. Verbal communication was with patients and their families, co-workers, expert advisers, and learners being taught by a resident. Informal discussion during practice – on ward rounds, or while co-reviewing a patient, for example – dominated but the many other discursive forms included questioning and being questioned, presenting cases for peer discussion, supervising and being supervised, receiving feedback and giving it, and teaching and being taught. Not all discourse was spoken. Some learning took place by modelling on behaviours demonstrated in embodied ways, as Bezemer et al. (2012) have also described, using social semiotics to analyse surgeons' learning. Contributing to and accessing written records, laboratory results, images, and resources of expert information were also important.

21.4.1.3 How Do Those Processes Affect Learning Trajectories?

Learning is guided by everyday activities that are dictated by the needs of healthcare and therefore difficult to regulate. Medical practitioners fear that participation in activities alone is not enough (Teunissen et al. 2007a). Their concern relates to what Billett describes as the “situational specificity of what is learnt, as well as the potentially too pragmatic focus” (Billett 2004b). Learning is opportunistic, determined by patients' presenting conditions. This adds to the value doctors attach to teaching theoretical knowledge. The opportunistic nature of learning leads to great diversity in the learning trajectories of different learners in the same phase of their medical careers. From the standpoint that expertise is always situated, contextual, and therefore unique, that is not problematic. However, doctors tend to move on from the place where they did their residency to a different workplace when they enter practice so drawbacks of the affordances of postgraduate training workplaces determining learning trajectories may come to light. Many do not feel competent in non-clinical tasks which have not been explicitly taught such as supervision, teaching, managerial, and financial skills (Stanley et al. 2005).

The learning trajectories of specialists, who develop their expertise within one or a limited range of contexts over many years, are even more diverse. Continuous professional development (CPD) is supposed to make sure they stay fit for practice. Traditionally, it has been organised as an educational activity; specifically, an 'update' model, according to which medical specialists get to learn about the latest

developments in their field of expertise, is still very alive today. That typically means “a large room full of physicians who have taken time off from their busy practices to listen to a series of speakers who lecture them about the most recent advances in their respective fields. The information presented may or may not be relevant to practice circumstances of members of the audience. And, even if it is, it may not be in a form that can be readily applied in practice” (Moore et al. 1994, pp. 4–31). That, however, is changing. In this domain as well, realisation has dawned that individual professional development goes hand in hand with the social and physical contexts that shape practice. As Cervero has said: “we need to find ways to better integrate continuing education, both in its content and educational design, into physicians’ ongoing individual and collective practice” (Cervero 2003).

There is a stark contrast between the dominant contemporary discourse of outcome based education, described above, and the learning trajectories described by respondents in studies of residents’ workplace learning (Teunissen et al. 2007b). Of course, residents celebrate achievements like successfully performing procedures and acquiring new knowledge, but they view their learning much more in terms of acquiring experience and becoming better able to engage in practice than in terms of reaching outcomes. Certainly, the type of outcomes that are supposed to guide learning in competency-based curricula do not seem to have the prominence that advocates of that approach might have expected (See, for example, Morcke et al. 2013).

21.4.2 Protoprofessionals Learning at the Boundary of Practice

This second example of medical workplace learning concerns the first major transition, when medical students get first-hand experience at the periphery of practice and learn to talk and act like doctors for the first time. The paragraphs that follow describe research that has contributed to the development of an “experience-based learning (ExBL)” model of medical students’ workplace learning.

21.4.2.1 What Conditions Influence Learning?

Using a design-based research methodology, Dornan et al. (2005) explored the extent to which medical students were able to behave self-directedly in clinical settings. They found learners were rarely fully autonomous or subservient. Learners depended upon support from their learning environments, which Dornan et al. (2005) categorised into three types: organisational; pedagogic; and affective support. In a later systematic literature review, they confirmed the value of those three categories and added a further categorisation (Dornan et al. 2014). Workplace learning was supported at curriculum level, placement level, and interactional level. Curriculum level support took the form of planning and resourcing experience as

part of the overall process of curriculum design. Placement level support took the form of organising the delivery of relevant experience. Support at the interactional level was both formal – helping students rehearse the duties of a doctor, for example – and informal, which meant doctors being approachable and willing to converse with students. Whilst it is generally taken for granted that being given a placement in a workplace ensures that a learner will have ready access to educationally valuable activities, that was not always the case. The subsequent research of Steven et al. (2014) discussed in the next section, elaborates that point. In parallel with those qualitative studies, a series of publications reported the development of a measure of the educational quality of clinical workplaces. The Manchester Clinical Placement Index has a theoretical orientation towards COP theory (Dornan et al. 2012). Its 11 items allow learners to rate organisational, pedagogic, and affective features of their learning environments, which contribute to a single summary quality measure. Evidence has accrued to support the validity of the scale across different types of clinical workplace.

21.4.2.2 What Learning Mechanisms Operate?

Consonant with the “participation metaphor of learning” (Sfard 1998), ExBL research has defined “supported participation” as the core condition for medical students’ workplace learning (Dornan et al. 2007). There are three levels of participation: Observing; rehearsing tasks performed by doctors; and contributing to patients’ care by performing those tasks “for real” (Dornan et al. 2014). Students learn best by participating at the highest level their current expertise and the complexity of a situation permit (Dornan et al. 2007). Whereas interactions between doctors and patients are conceived of as a dyadic relationship, medical students workplace learning takes place within triadic relationships (McLachlan et al. 2012). Exit interviews of patients and medical students after outpatient teaching encounters by Ashley and colleagues (2009) suggested that doctors moderated the interaction between students and patients within that triad for better or worse.

A wish to explore the place of patients within clinical communities of practice, and the effect of teaching encounters on patients’ identities, led to a further study (McLachlan et al. 2012). This confirmed the pivotal role of doctors in moderating students’ learning from patients, but made the surprising observations that patients more often than not represented “objects” for students’ learning, rather than subjects whose personhood was at the centre of students’ learning. More surprising still, patients not just accepted being objectified, but experienced that as a natural place for them to take in students’ learning. When, as in one particularly salient case observed in this research, patients wished to have more active roles, very sophisticated handling of consultation dynamics was required of doctors. From a communities of practice perspective, doctors’ role was to manage the boundaries of two concurrent practices – a practice of patient care and a practice of medical student education – to draw most effectively on the resources of the other two members of the triad, and to the greatest benefit of all parties. Given the scale of

the task, it is unsurprising that it not infrequently failed such that students did not gain educational benefit from patient care, or patients did not gain clinical benefit from medical student education. Steven et al. (2014) applied the concept that scholarly practitioners manage the boundaries of practice to achieve the greatest benefit of learners and patients to medical students' narratives. They found students' informal practice-based learning to be located within the discursive practices of clinical communities. They showed how the various stakeholders encountered by medical students in workplaces discursively positioned the boundaries of practice to support access, legitimacy, and the various levels of participation previously described. In another study, Singh et al. (2014) showed how more junior doctors were inclined to position the boundaries of practice to foster students' inclusion, whereas "old-timers" were more prone to exclude learners from the discourse of practice-based learning.

21.4.2.3 How Do Those Processes Affect Learning Trajectories?

Qualitative evaluation of medical students' workplace learning highlighted how much of their learning was affective (Dornan et al. 2007). By examining students' reports of what they had learned from contact with real patients, Bell et al. (2009) confirmed and extended that observation. They found that exposure to patients was an end in itself, not just an intermediate step in the attainment of measurable learning outcomes (Morcke et al. 2013). Put simply, experience of reality taught students about reality and they valued it. Given that reality is what they have to practice in the future, that did not seem an unimportant outcome. It is important to note, also, that students learned using touch and visual pattern recognition as well as through dialogue and physical examination. Affective outcomes included enhanced confidence, motivation, satisfaction, and a sense of belonging. Cognitive outcomes included perspective, context, a temporal dimensional and an appreciation of complexity. Real patient learning helped respondents link theory with their referable, visual, and auditory experiences. It also made acquisition of the theory and skills easier.

To summarise the impact of real patient exposure on medical students' learning trajectories, it was of intrinsic value and its downstream consequences were the acquisition of proficiency and the development of affects, which together constitute the emerging identity of a doctor.

21.5 Conclusions

Medicine is a profession, which applies a single underpinning ethical code to a wide diversity of practices. The ethical code has four main principles: autonomy, beneficence, non-maleficence, and justice. Doctors should work for the benefit of patients, not harm them, help them to be the people they want to be, and do so justly. The code

does not call for doctors to self-sacrifice but it demands that any benefit to them should result from benefit to patients. Education is embedded within the ethic of medicine. Doctors should promote the autonomy of trainees as well as patients. Every doctor learns to care for patients by practising alongside trained doctors. In due course, they must be prepared to practice education simultaneously with patient care. Sometimes that fails. Sometimes it is an uneasy compromise. But when it works well, it provides the most important underpinnings of trainees' future practice. So, practice-based learning is not something we can choose to include or exclude from medical practice. It is an expectation of every trainee and every trained doctor.

The diversity of medical practice ranges from specialties where doctors are connected with patients solely by performing technical services for or on them, to specialties where doctors are connected with patients solely through the medium of talk. Either way, the same ethical code applies. Importantly, medicine is not now seen as a solitary practice. Even – perhaps especially – doctors in technical specialties who have no direct social contact with patients work in teams. It is recognised that their technical skills are less valuable if they lack the non-technical skills that enable them to work with other people, whose status, level of education, and disciplinary background may differ from their own. So, medicine is an essentially social practice. Medical education is even more explicitly a social practice, nesting within medical practice physically, intellectually, practically, and ethically. That broadly answers the question posed at the start of the chapter: “What attributes of medicine shape its contribution to the wider scholarship of practice-based learning?”

Earlier sections described two dominant theoretical perspectives in medical education research: Psychology, particularly cognitive psychology, and social learning theory, particularly sociocultural theory. Social learning theories, sociocultural more than social cognitive theory, have become popular because of their ability to explain the social aspects of medical practice and education highlighted in earlier paragraphs. The medical education research community is increasingly conceptualising medical education as a process of identity development. Both conceptual orientations are able to explain how that occurs in social milieus and how identity development is interdependent with the emotional as well as practical nature of practice-based learning.

The question remains when and how practice-based educational approaches should best be used. The tendency in medical education is to introduce them early, in parallel with science education, so that each can inform the other. Instructional designs using simulation are in the ascendant but, even then, a key question is how skills learned in simulation can assuredly transfer into practice-based learning. Two tensions, which have important effects on practice-based learning, run through the discipline of medical education. The first is a tension between medicine as applied science versus medicine as scientifically informed practice. Most medical schools regard the “science” that is applied in medical practice as biomedical science. The notion of scientifically-informed practice, however, opens the way for behavioural and social sciences to take their place alongside biomedical sciences. The second tension is between medical practice as essentially standard, with exceptions, or

essentially non-standard, with some commonalities. Historically, doctors took the second position but their leaders, who are advocating “competency-based education”, are pulling them towards the first position. Doctors’ individualistic behaviour, it must be admitted has led to some spectacular professional failures. The move towards standardisation has been strengthened by those failures and the move to standardise medical competence is part of a politically-led, regulatory discourse of medical education. It cannot be predicted how that tension will be resolved over time, but efforts to ensure patient safety by standardising practice come at an inevitable cost. Some patients’ individual problems are best served by crafting individual solutions, and breaking rules rather than adhering to them.

We have shown how theoretical models of practice-based learning can be developed by closely observing and theorising about clinical and educational practice. The benefit of that approach is that it makes the wisdom of practice more widely available by finding its generalities, defining, and disseminating them. Used carelessly, that approach could institutionalise ineffective practice. We do not think that is likely because careful observational research, using qualitative methodologies, makes it possible to identify outcomes that are valued by learners and trace their origins within educational practice. The longer term benefits and harms of codifying medical practice-based learning are hard to predict. We conclude, nevertheless, that medicine’s contribution to the wider scholarship of practice-based learning is to show how the expertise of seasoned professionals can be made accessible to novices in a scholarly way under the prevalent conditions and pressures for reform of twenty-first-century society.

Chapter 22

A Phenomenographic Way of Seeing and Developing Professional Learning

Ming Fai Pang

Abstract The growing interest in professional education has brought questions about how and where professional learning can best be developed. This chapter proposes a basis for developing professional learning, which adopts the view of learning from phenomenography. It is argued that professional learning can be conceptualized as a qualitative change of the learner in his or her way of experiencing or seeing the phenomenon or situation, which can be defined in terms of the critical aspects of the phenomenon or situation which the learner simultaneously focuses upon and discerns. It is also argued that by providing the learner with the opportunity to experience certain patterns of variation and invariance in the learning condition, he or she will be empowered to discern and focus on the critical aspects, which in turn improve his or her professional capabilities to handle novel situations.

This chapter first discusses how three major theories of learning, i.e. cognitivism, constructivism and situated cognition, conceptualize professional learning. It is followed by an explication of the phenomenographic way of seeing professional learning, with the highlight of the underpinning theory of learning, the variation theory. To exemplify how we attempt to foster professional learning among the learners, an empirical study which helps student teachers to develop professionally by forming a more sophisticated way of experiencing good teaching is reported. The chapter concludes by discussing implications of this view of learning for instructional practice within professional education.

Keywords Phenomenography • Variation theory • Learning study • Professional learning • Student teachers

22.1 How Other Theories of Learning Conceptualize Professional Learning

Professional learning is regarded as a very complex, multi-faceted phenomenon. No researchers has yet been able to develop a single comprehensive theory of learning which can cover all aspects of professional learning and provide a complete explanation for how or why professional learning occurs. Often, different theories of learning have been developed to account for the different aspects of professional learning and each of the theories tried to tackle some central and fundamental questions about professional learning.

For instance, cognitive theorists conceived of professional learning as an individual's acquisition of information from a decontextualized body of knowledge, in which the learner forms a representation of the outside world in their heads, and certain mental operations are performed on this representation; thinking is thus a manipulation of the representation. This paradigm has a dualistic ontological stance, in that cognitive theorists view the world and the mind as separate entities. They believe that the learner develops the mental representation through drawing together sensory elements which are then placed in some kind of schema, with the result that the objective world "out there" is represented by various memory structures inside the mind. New experiences are interpreted in relation to existing schemas, and when there is a discrepancy between the new experience and existing schemas, the mind assimilates the input data with existing representations in order to resolve the conflict; and in this way, the schemas might be modified (Cooper 1993).

Professional learning is thus seen as a change in the learner's mind—in the mental representation of the external world and the mind becomes an information processing system whereby learners process information procedurally, starting from inputting sensory information into perceptual memory, then into working and long term memory, and lastly into response generation. Cognitivist theorists try to understand what people do in terms of what goes on in their heads, in other words, in terms of the internal representation as well as the procedures operating on the representation.

Where cognitivist theorists emphasized professional learning as an internal process, constructivists believed that professional knowledge does not come to us passively from the outside world, 'ready-made', nor innately, but is actively constructed within our minds. The constructivist paradigm also affords a dualistic ontological stance, in the sense that the learner and the world are regarded as separate entities. People do get information from the world, but this information is only sensory—in itself it does not carry meaning; it is the mind which combines these sensory impressions in order to construct meaning. Moreover, although people live in the same world, they construct meaning differently. This difference is not a function of what is out there, but rather of what is inside our heads. According to constructivist thinking, it is because we ourselves construct different images of the world in which we live.

At the heart of the constructivist view of learning (Ernest 1995; Phillips 1995; Steffe and Gale 1995; Tobin 1993; Treagust et al. 1996) is the belief that knowledge about

the external world is a human construct, and that learners actively construct their knowledge on the basis of knowledge already held. Romberg and Carpenter (1986) claimed that “the research shows that learning proceeds through construction, not absorption” (p. 868), or, in other words, that knowledge is not passively received but actively built up by the learner. Professional learning is thus seen as the building of mental structures. The “building blocks” of understanding are the results of previous acts of construction, in the sense that a previously built structure forms the basis for the ensuing constructions. Seen from this perspective, professional learning proceeds with construction, in the sense that learners actively construct their knowledge on the basis of knowledge already held.

Situated learning theorists, however, viewed professional learning as a social act, taking place in a social context. This school of thought used the metaphor: learning as participating in communities of authentic practice, and learning as “... an aspect of participation in socially situated practices” (Lave 1996, p. 150). In the process of “legitimate peripheral participation” (Lave and Wenger 1991), when the novice moves from the periphery of the community of practice to its centre, he or she becomes more active and engaged with the culture and thus assumes the role of expert. As Brown and Duguid (1996) put it, the newcomers “steal” the knowledge that they need by legitimately and peripherally participating in authentic social practice. Professional learning in this view is conceived of as belonging to and participating in that which embodies certain beliefs and practices. According to Lave and Wenger (1991), “A person’s intentions to learn are engaged and the meaning of learning is configured through the process of becoming a full participant in a sociocultural practice” (p. 83).

This notion of enculturation is central to the paradigm of situated cognition, in that professional learning is viewed as a cultural activity. Brown, Collins and Duguid (1989) argued that “... knowledge is situated, being in part a product of the activity, context, and culture in which it is developed and used” (p. 32). Lave (1988) contended that cognition is situated in the practical doings of “just plain folks” and knowledge is distributed not only amongst people but also across cultural artefacts. For instance, tailors’ apprentices learn not only how to make clothes but also certain ways of speaking and behaving as a tailor, in order to become a legitimate participant of a social group. This is in line with the Greeno et al. (1998) argument that learning is identity shaping. Individuals participate in different communities of practices and achieve their identity in each community through their personal trajectories of participation, i.e. changing participation of the learner in the community of practice (Wenger 1998). The prominent feature of situated cognition can be depicted as “shifting the focus from individual *in* environment to individual *and* environment...” (Bredo 1994, p. 29, italics as original).

Within this paradigm, the focus is on sociocultural forms of learning, and the unit of analysis is not the single individual but the social setting. Researchers such as Jean Lave (1988, 1991) and Lucy Suchman (1987, 1993) discussed the cultural construction of meaning and argued that learning should be studied as a social, collective phenomenon (Lave 1996). According to Lave and Wenger (1991), “Learning is a process that takes place in a participation framework, not in an individual mind.

This means, among other things, that it is mediated by the differences in perspectives among the co-participants. It is the community, or at least those participating in the learning context, who “learn” under this definition. Learning is, as it were, distributed among co-participants, not a one-person act” (pp. 15–16).

The most distinctive feature amongst these three theories of learning is that the first two theories of learning are grounded in a dualistic ontological position, in the sense that the world and the learners are treated as separate entities. A slight distinction between them is that the constructivist would argue that one can never reach the world out there because what one sees is one’s own construction, that is an image that one creates, so the two are completely separated. Knowledge is constructed in one’s mind. The cognitivist, however, would claim that we receive information from the objective external world through our sensory channels and then form mental representations of this information. Therefore, an objective reality does exist independent of the learner, and knowledge is found in the objective world. In contrast, situated cognition is opposed to the idea of understanding what goes on in people’s heads or their mental representations of the outside world. They see professional learning in terms of interactions with the world, which depends on the “whole connection”. Knowledge is socially negotiated and embedded in a particular context, in the sense that knowledge cannot be separated from the practices and occasions of which it is the outcome. To sum up, despite the substantive differences between cognitivism, constructivism and situated cognition, each theory of learning does deal with some very crucial questions about professional learning, which contributes to a better understanding of this pertinent phenomenon.

22.2 The Phenomenographic Way of Seeing Professional Learning

In contrast, phenomenography focuses on the understanding of people’s experiences of the world, which is distinguished from cognitivism and constructivism, for example, by its non-dualistic ontological stance. According to Marton and Booth (1997), “experiences do comprise an *internal relationship* between the subject and the world, and that is the fundamental characteristic: An experience is of its essence *nondualistic*” (p. 122, italics as original). According to Marton (1981), human experiences cannot be accounted for either by the elements of the situations or by the general cognitive functioning of the individual, as humans and the world are regarded as inseparable entities.

In phenomenography, professional learning is seen as a qualitative change in one’s way of experiencing or seeing. It is thus a process in which the learner reconstitutes the world which he or she has already constituted. It is different from cognitivism which regards professional learning as a change in one’s mental representations of the world out there; it is different from constructivism which conceives of professional learning as constructing an understanding of the world on the basis of knowledge which the learner already holds; it is also different from

situated cognition, which sees the social settings and cultural environments outside the individual as the fabric of knowledge. According to Marton and Booth (1997), learning takes place by a change in something in the world as experienced by a person. The new way of experiencing or seeing something is constituted in the relationship between the experiencer and the experienced, and the descriptions of people's experience is content-oriented and seen as concrete cases of human functioning (Marton 1981). Erickson (2000) suggested that phenomenography holds a more holistic position than other paradigms and thus the conceptual and empirical work which build on it should warrant careful attention on the part of the science education community.

Professional learning is conceptualized as a matter of seeing, or experiencing, something in a new way. The analogy is with the actual visual act of seeing a phenomenon in the real world, where one focuses on certain features of the object of one's vision at one particular time, and on other features at another time. In the same way, professional learning entails discerning, or experiencing certain aspects of the phenomenon or situation in one's awareness. According to Marton and Booth (1997), learning is a change in one's structure of awareness, i.e. those aspects of a phenomenon which are "figured" or highlighted simultaneously in a person's awareness at a particular time, or an increase in one's ability to see or experience something in a certain way. In other words, people can build up their competence in seeing, that is, understanding the world to deal with novel situations in the future (Bowden and Marton 1998).

Bowden and Marton (1998) posited that discernment "is a defining feature of learning in the sense of learning to experience something in a certain way" (p. 35). Professional learning is thus associated with a change in discernment, which entails a change in the aspect(s) of the phenomenon in the focal awareness of the learner: in other words, a change in the way of seeing the phenomenon. All the time people cast our focal awareness simultaneously upon certain aspects of a particular phenomenon, which are discerned in our structure of awareness. It is worth noting that being focally aware of these aspects does not mean that we are totally unaware of other aspects of the phenomenon in question. Rather, it means that these aspects become figural or foregrounded in a person's awareness, whilst other aspects remain in the background. This resembles the act of seeing when we may direct our attention to certain features of the object or person without paying much attention to other features.

In the same way, when we see something as something we cast our focal point over certain defining features of the object so that we can recognize it as such. We may not notice other features of the object, although they are still there, as they are at the periphery of our focus. For instance, when I am very thirsty and want to find a cup, I will try to look at the various objects in my sight with the defining features of a cup, but other features such as colour or shape may not be in my focal point at that moment.

Furthermore, even when we see the same object or phenomenon, the meaning may be different to the same person at different times. For instance, when the relationship between two good friends turns sour, each may focus on aspects of the

other that had previously carried different meanings. In the past, a smiling face may have been very sweet and sincere, but now the same smile becomes the masquerade of a cunning man. Wording that was once considered a joke now becomes a kind of harassment as one casts their focal attention upon different aspects of the same thing at a different time.

A way of seeing or experiencing something is thus conceived of as “the set of different aspects of the phenomenon as experienced that are simultaneously present in focal awareness” (Marton and Booth 1997, p. 101), and professional learning is seen as a qualitative change in one’s way of seeing or experiencing. This amounts to being able to discern certain aspects of the phenomenon that one could not previously discern or took for granted, and to keep them in focal awareness.

22.2.1 *Variation Theory of Learning*

In phenomenography, in order to develop professional learning, the question to be asked is “How is it possible to bring forth a change of the aspect(s) of the phenomenon or situation in the learner’s focal awareness and subsequently a change in their way of seeing or experiencing?”, or fundamentally, “What does it take for a learner to discern a particular aspect of the phenomenon or situation?”. According to the variation theory from phenomenography (e.g. Marton and Booth 1997; Marton and Pang 2006, 2013; Marton and Tsui 2004; Pang and Marton 2013), variation is the key for effective discernment, and the chief mechanism of learning.

According to Marton (1999), variation is the *sine qua non* of learning. In order to discern, one must experience variation. When a certain aspect of a phenomenon varies while other aspects remain invariant, the aspect which varies is discerned (Marton and Booth 1997). Discerning an aspect therefore implies that one has experienced a variation or difference between two entities or between two parts of the same entity. According to Marton and Pang (2006), “one cannot discern quality X without simultaneously experiencing a mutually exclusive quality ~X”. To put it another way, to discern an aspect, the learner need to experience its potential alternatives against the background of invariance in other aspects of the phenomenon.

For instance, suppose we were living in an entirely dark world, then we would be unable to notice and discern the darkness without ever experiencing light. Awareness of hotness presupposes awareness of coldness (or at least not hot), and awareness of a particular flavor, say sweet presupposes awareness of other flavors (or at least one other flavor). One cannot possibly understand what English is simply by listening to different people speak English if one has never come across another language, and one cannot possibly understand what loyalty is by inspecting different examples of the same degree of loyalty. A way of seeing or experiencing something does not originate from the experience of sameness, but rather from the experience of difference (cf Marton 2006).

According to the present line of reasoning, the learner is able to discern an aspect or part (or several aspects or parts) or derive a novel meaning of something by

Fig. 22.1 Contrast and discernment

contrast. What is focused upon is a component part of variation (e.g., “flavour,” “English,” “loyalty”), whereas the other features of the same entity (e.g., smallness or largeness, sharpness or dimness, formal expression or casual chat) are kept invariant. As an example, let us consider two different patterns of variation and invariance used to help someone to discern the meaning of “Chinese”, as shown in Fig. 22.1.

Learning to make a novel meaning one’s own amounts to discerning an aspect or part (or several aspects or parts) of something, through variation (difference) in the focal aspect (that to be discovered) and invariance in other aspects. We call this the variation theory (of learning).

For a particular feature to be discerned, it must be separated from that which it is a feature of. If everything is purple, then the color purple cannot be separated out. Hence, it cannot be discerned. To be able to separate out and discern “purpleness”, you must see something that is purple (a box, for instance) and the same thing (a box) in another color (say yellow). As seen from Fig. 22.1 (on the left), if you hear only one language, say Chinese, all of the time, then you cannot possibly separate “Chinese” from “Language,” or “Language” from “Chinese” for that matter. The two are glued together and become inseparable. To be able to “think apart” or “tell apart” the two and come up with two distinctive concepts (“Language” and “Chinese”) rather than one, you must encounter another language. As shown in Fig. 22.1 (on the right), by experiencing the difference between two languages—Chinese and English, for instance—you not only appropriate a rudimentary version of the concepts of “Language” and “Chinese” but, in this case, even the concept of “Korean.”

We thus acquire the meaning of something or discern an aspect of something by learning what it is not. Therefore, by listening to a language other than Chinese and noticing the difference between the two, we become able to separate “Chinese language” from “Language.” If, however, the Chinese that we have heard in our entire life is a particular dialect of Chinese, then Chinese and this dialect are for us identical, and we have a rather narrow understanding of what Chinese is. Through contrast, we have separated “Chinese” from “Language,” and learned that there are different languages of which Chinese is one. Now, we have to separate “Chinese” from our own particular dialect, and learn that there are different dialects of Chinese of which that is spoken in my hometown is just one. We can do so by encountering another dialect—or several other dialects—of Chinese. The pattern of variation and invariance is illustrated in Fig. 22.2. Now, “Chinese,” which was a focused feature (value) previously, becomes a focused aspect (dimension of variation) that is

Fig. 22.2 Chinese language and its dialects

Fig. 22.3 Patterns of variation and invariance

generalized across different dialects, all of which are Chinese. Here, it is not the meaning of “dialect” that is highlighted; rather, we are enriching the meaning of “Chinese” by separating it from any specific dialect and allowing for variation in dialects.

We call this pattern *generalization*, and the focused aspect (Chinese) is invariant. We are not attempting to locate the meaning of the focused feature. “Dialect” is an optional attribute of “Chinese”; regardless of the dialect, the language is Chinese.

According to this line of reasoning, learning amounts to the increased differentiation of experienced entities through the discernment and separation of features from other features and from that which they are features of. This view of learning is akin to going from an undivided whole to a differentiated and integrated whole, which resembles Werner’s (1957) orthogenetic law and Gibson and Gibson’s (1991) way of describing (perceptual) learning. The latter authors distinguish between two ways of seeing learning: as enrichment or as differentiation. The former way implies that what is perceived is interpreted using memory resources, and thus develops into a full-blown novel meaning: the learner must add to his or her originally meager perception. Our way of seeing something is always richer than that which we see. The latter way of seeing learning implies that the originally vague impression is differentiated—“the world gets more and more properties as the objects in it get more distinctive ...” (p. 34). What we see is always richer than our way of seeing it.

This second alternative means that in the course of learning, we learn to distinguish one thing from another, one feature from another, and one feature from one thing. Doing so involves experiencing both sameness and difference, which involves the simultaneous experience of those entities that are the same and those that are different. Once we have learned to tell them apart (through separation), we learn how to put them together (through fusion), that is, how to see them at the same time (simultaneously). The different patterns of variation and invariance through which this process takes place are shown in Fig. 22.3.

What does it take to discern a particular aspect or feature of a phenomenon or to separate one particular aspect from other aspects and from what it itself is a

feature of? A necessary condition for the former is that the learner experiences variation (or differences) in relevant aspects against a background of invariance in other aspects. Accordingly, learning is more likely to occur when there is variation to be experienced.

22.3 The Empirical Study

In phenomenography, we believe that how a person acts and performs in a professional context hinges largely upon how he or she sees the phenomenon or situation. Professional learning is thus characterized as a qualitative change in one's way of experiencing or seeing the professional phenomenon or situation encountered (e.g. Pang 2006). To illustrate how we attempt to bring about professional learning, an empirical study is reported here in which a group of student teachers were supported to develop professional learning through a "Learning study" (e.g. Pang 2010; Pang and Lo 2012; Pang and Marton 2005) premised on the variation theory. The primary aim of conducting the Learning study in the initial teacher education programme is to enable student teachers to learn professionally by developing a more considered and sophisticated way of seeing or experiencing teaching. It is done through experiencing variation in the critical aspects of good teaching in the subject area concerned. More specifically, student teachers will be given the opportunity to engage in the evaluation of the quality of the lessons taught by all the student teachers, in which the topic or concept to be dealt with by the teachers is kept invariant whereas other critical aspects of good teaching are varied in the course of reflection and deliberation, which are either introduced by the student teachers themselves or by the teacher trainer. With the use of this pattern of variation and invariance, student teachers will be able to discern and focus on the critical aspects of good teaching and demonstrate a progression in their way of experiencing or seeing good teaching. In the following section, the 'learning study' approach is firstly introduced, which is to be followed by an explication of the design and procedures of the empirical study as well as the findings.

22.3.1 The Learning Study

The Learning study approach is premised on design experiments (e.g., Cobb et al. 2003; Kelly 2004) and at the same time borrows the insights of both the 'lesson study' model from Japan (e.g., Lewis et al. 2006; Stigler and Hiebert 1999; Yoshida 1999) and the 'teaching research group' model from China (e.g. Ma 1999), in which teachers collaboratively plan, implement and evaluate lessons without explicit theoretical grounding.

In a Learning study, a group of (student) teachers works together to find ways of making it possible for pupils to appropriate a certain object of learning, i.e. what

pupils are expected to learn in the lesson(s). According to Pang and Marton (2003), an object of learning is a specific capability that the pupils are expected to develop during the lesson(s). The teachers first choose a specific object of learning which is ideally central to the curriculum and which causes consistent learning difficulties for their own pupils. Once the object of learning is decided, the group as a team does the planning of the lesson(s) together, drawing upon their own past experiences in handling this specific object of learning, relevant research and resources (which can be pure academic research, teachers' action research, case sharing or teaching and learning resources), the learning theory which they consider to be insightful (in this case the variation theory is used), and most important of all, the exploration of pupils' prior understandings and initial mastery of the object of learning through the conduct of pre-test and/or interview.

Based on the findings of the pre-test and/or interview together with the teachers' own disciplinary and pedagogical knowledge, the teachers attempt to find out the critical aspects of the chosen object of learning, which are considered to be critical to the pupils' appropriation of the object of learning. Thereafter the teachers draw upon the variation theory and use it as the guiding principle to design the instruction. The finalized design is usually expressed in the form of lesson plan(s) and learning resources.

One of the group members will then enact the lesson plan in his or her classroom while the other members observe. Usually, the lesson is video-recorded, and what the pupils have learned is probed by post-tests, which can be in the form of written tasks and/or interviews after the lesson(s). With the use of the variation theory as the analytic framework, the teachers analyze the lesson(s) in terms of whether it was possible for the pupils to appropriate the object of learning through the pattern of variation and invariance co-constituted by the teacher and the pupils. To evaluate the lesson(s), the teachers compare the post-lesson learning outcome with the pre-lesson one at an evaluation meeting. The gains and the absence of learning gains can be associated with what has been enacted in the classroom. The group may then come up with some suggestions for pedagogical improvement. Subsequently, another teacher in the group carries out the revised version of the lesson plan following the same procedure. The cycle is repeated until all group members have carried out the lesson(s) with all the participating classes, and the study is always concluded by documentation and dissemination to other teachers.

22.3.2 Design and Procedures of the Empirical Study

Ten pre-service student teachers and seven in-service student teachers who enrolled in the Postgraduate Diploma in Education programme majoring in economics education were invited to participate in the study. Before the introduction of the Learning study, all the student teachers were interviewed to obtain pre-entry data of their ways of experiencing of good teaching in economics. Furthermore, to prepare them for participating in the study, all student teachers attended three sessions of 4 h each which served to help student teachers learn about the rationale behind and the

ways to conduct a Learning study, with the use of examples of other Learning study done in the area of economics. They were then divided into five different Learning study groups and started their data collection to investigate the variation in pupils' understanding of *the same* economic concept or topic through observations, interviews and/or pre-tests. After getting the pupils' pre-lesson understandings, they held regular meetings with their group members during Self-Directed Learning sessions as well as outside the timetabled sessions to discuss about the teaching strategies and learning resources to respond to the variation in pupils' understandings and to help pupils master the object of learning, using the variation theory as the guiding principle for instructional design. An on-line platform was created, in which all student teachers were invited to put up their lesson plans and materials, and comment on the work of each other. Later on, each student teacher implemented the shared lesson plan of his or her Learning study group in his or her classroom during teaching practicum (for pre-service student teachers) or during normal teaching days in schools (for in-service student teachers). All the lessons were video-recorded for discussion and professional reflection in a debriefing session afterwards. By the end of the teacher education programme, student teachers were asked to document their learning experience in carrying out the Learning study in the form of a report.

To explicate, in order to enable student teachers to learn professionally by developing a more considered and sophisticated way of experiencing good teaching in economics, a debriefing session were held in which student teachers were invited to evaluate and comment on the video-recorded lessons of all the student teachers (including himself or herself). Each student teacher was asked to decide and justify whether the teaching of the lesson to be observed is in good quality. There is more or less a consensus among researchers and teacher trainers that classroom video is a valuable tool for fostering reflection of student teachers (e.g. Blomberg et al. 2014). This arrangement allowed the student teachers the opportunity to take different perspectives on their professional activity, which seemed to be useful. They were able to develop a feeling of "ownership" from these processes and were more intrinsically motivated to engage in professional reflection and learning.

Based on Pang's (2006) study, critical aspects of the ways of experiencing good teaching in economics such as student learning outcomes, teaching approaches and strategies, objectives of economics education and so on were identified. The teacher educator consciously created a pattern of variation and invariance in the debriefing session, through which students' focal attention was drawn to these critical aspects. In accordance with the variation theory, the teacher deliberately kept the economic concept or topic to be dealt with by the teacher in the lesson invariant, but opened up different alternatives and values in the dimensions of variation corresponding to these critical aspects.

To exemplify, in the course of deliberating and evaluating the lessons, the teacher educator posed reflective questions to student teachers about the various possibilities and alternatives in the critical aspect in question (i.e. student learning outcome), e.g. whether good teaching should help improve student learning outcome, and if so, what kind of student learning outcomes should be valued: grades in public examinations, understanding of the economic concepts or the capability of using the

economic concepts learned to deal with some issues related to pupils' daily life? Are these learning outcomes mutually exclusive with each other? By keeping the topic to be handled in the video-recorded lesson to be invariant, the focal awareness of the student teachers was directed to the critical aspects of good economics teaching, with the use of reflective questions and class discussions which brought up corresponding variation in the critical aspects. The variations could either be created by the student teachers themselves or brought up deliberately by the teacher educator. By experiencing variation in the corresponding critical aspects, student teachers were helped to discern the critical aspects of good teaching in economics and subsequently develop a more sophisticated way of experiencing.

Finally, in order to investigate whether this intervention has an impact on student teachers' professional learning in terms of their ways of experiencing good teaching, all student teachers were interviewed again after they had completed the Learning study. The outcomes were compared to the interview conducted with the students before the introduction of the Learning study.

22.3.3 Data Collection and Analysis

All the student teachers were interviewed twice to find out their ways of experiencing good teaching in economics. Semi-structured interview was conducted with each student teacher individually. The principal question was "What do you mean by good teaching in economics?". The other questions were derivations of it, such as "How do you characterize "good"?", "Do you think that good teaching in economics could possibly be different from other subject discipline and why?" and so on. For the purpose of clarification and for exploring more deeply the thoughts and ideas of the interviewee, spontaneous questions were asked from time to time. Each interview lasted for around 30–45 min and it was conducted in Cantonese.

The interview data collected were analyzed following the phenomenographic conventions (Akerlind 2005). The interview transcripts were first looked at holistically to get the global meaning, with some parts of the interview transcripts being labelled as significant quotes which were brought together to become a pool of meaning. Their similarities and differences were then highlighted and noted. The individual quotes were then labeled and put back to their original contexts to see if the labels matched the global meanings of the whole transcript of the individual interviewee, and at the same time they were compared and contrasted with the transcripts of other interviewees. This process went on and on until the critical differences between all the qualitatively different ways of experiencing the phenomenon were uncovered. Finally, a set of categories that displayed the variation in ways of experiencing good economics teaching were derived in accordance with logical inclusiveness and adequacy.

As our focus is on the professional learning of the student teachers in terms of their ways of experiencing good teaching in economics, if a student teacher expressed two different ways of experiencing in the course of the same interview, then the more complex and inclusive one was counted for that particular student teacher.

22.3.4 Results and Findings

The five qualitatively different ways of experiencing good economics teaching were identified from the data collected. They are presented and ordered here according to their increasing level of complexity.

Category A: Good economics teaching as managing to help pupils achieve good public examination results through the acquisition of examination techniques

As Hong Kong public examinations are high-stake, both teachers and pupils put top priority on how to obtain good grades in the examinations. Two of the in-service student teachers exhibited this way of experiencing before the conduct of the Learning study. They thought that good economics teaching means imparting examination techniques to pupils in an efficient manner through drilling past examination questions. In structural terms, they focused on the nominal outcome of teaching and learning economics—the grade in public examinations only, rather than on pupils' economics understanding and the way to achieve this is through mechanical mindless drillings.

I: So [...] what [features in a good economic teaching] do you think is the most important [...]?

S: If...for the most important, I think it must be the practice on past paper, since the practice on past paper is the most useful for [the preparation of] examination.

I: [...] Do you think the teaching of economics is for examination or...

S: If you are talking about secondary schools, inevitably it [the teaching of economics] is mainly for the [purpose of] examinations, unfortunately...

(In-service student teacher 01, entry interview)

Category B: Good economics teaching as managing to arouse pupil interest in learning economics through teachers' use of interesting examples and activities

Student teachers who expressed this way of experiencing thought that good economics teaching means arousing pupils' interest in learning economics. If the teacher is able to motivate his or her pupils to learn economics, he has made some good achievement. They focused on the teaching arrangements such as group work, games, jokes, etc, and the use of interesting examples which closely link to pupil life experience. This conception is more frequently found in student teachers who practice their teaching in schools which admit pupils of lower academic ability.

S: I think his teaching is quite good...Economics is a subject containing lots of information. Often, the class is dominated by teachers' lecturing and pupils are simply jotting notes. This teacher is quite good. He organizes group discussion for the pupils on some examples or cases which he had well chosen. The examples are relevant to the pupils' life experience, which can arouse their interest in learning this abstract topic. Some teachers may use examples which are beyond pupils' experience and maturity. But I like the examples used by this teacher.

(Pre-service Student Teacher 02 Exit Interview)

Category C: Good economics teaching as managing to help pupils understand economic concepts through teachers' well-chosen examples and clear presentation

Student teachers who exhibited this way of experiencing viewed good economics teaching as helping pupils develop good understanding of the economic concepts to be learned. They believed that the examples chosen by the teacher are very crucial for achieving this. If examples which relate to pupils' daily life experience and which can illustrate the critical attributes of the concepts, pupils would find it easier to grasp the economic concepts. Equally important is the clarity of teachers' presentation. If the teacher can present the concept in a clear and lucid manner, from simple to difficult, the pupils will be able to understand the concept and not get confused.

S: Good economics teaching...helps pupils develop clear conceptual understanding and does not make pupils feel confused. In other words, the teacher needs to present it very clearly. She needs to explain it systematically and tell how it distinguishes from another similar concept. Also, at the beginning the teacher should use some simple examples to help pupils grasp the concept before going to the difficult ones. ...Also, the examples should be related to real-life situation. Actually, the teacher in the video has done it. His examples are closely related to pupils' life experience. This would raise pupils' interest to learn economics.

(Pre-service Student Teacher 05, Exit Interview)

Category D: Good economics teaching as managing to help pupils apply the economic theories learned to real-life situation through teachers' use of well-chosen examples and cases

Student teachers who expressed this way of experiencing thought that good economics teaching needs to enable pupils to apply what they learned in economics to explain the real-life economic phenomena. They considered it as the most important goal of economics teaching. The way to achieve this is through teachers' use of real-life examples or authentic cases in their teaching. This would make the pupils realize that the economic concepts they learned can be applicable to the real world. The focus is on the applicability of the theory to reality.

S: I think good economics teaching should be that the teacher can clearly demonstrate to the pupils how the economic theory can be applied to real-life examples...The teacher should give more examples to demonstrate this. This will make the pupils better understand how to apply the theory to explain the phenomenon in the world...

(Pre-service Student Teacher 09, Entry Interview)

S: Am... good economics teaching would sort of, of course, teach the pupils like the theories, right? But I think it's important to tie the theories to the real world...to use real world examples so that they can put it into context, like for example, if we were going to talk about externalities whatever, like they know the definition, because we tell them or it's in the textbook, but in terms of examples, a lot of textbook use like pollution as a negative externality, but to put it into more like a real-life context, I usually tell them, like if they had a roommate and they are playing the music – music really loud, then they are causing like – sort of like a negative externality to them, so by using am... examples that they can relate to, I think it's easier for them to – to understand the theory.

Table 22.1 Comparison of the way of experiencing displayed by student teachers before and after the Learning study

Categories of ways of experiencing	Number of student teachers (before the Learning study)	Number of student teachers (after the Learning study)
A	2	0
B	8	1
C	1	5
D	4	5
E	2	6

Category E: Good economics teaching as managing to help pupils develop an economic way of thinking for problem solving through pupils' inquiry of real-life phenomena

Student teachers in this category saw good economics teaching as those can help pupils develop an economic way of thinking to make sense of the world around them from an economic perspective. In other words, if the teaching is really successful, the pupils will be able to develop an economics lens to see the world and use the economic concepts learned as an analytical tool to examine real-life phenomena. Structurally, the attention of these student teachers was focused on whether the teaching is able to facilitate the development in pupils of an economic way of thinking or seeing.

S: I think good economics teaching should help pupils solve problems and make decisions. Economics as a discipline studies and explains phenomena happening in the world. If the lesson starts off with an authentic problem and the teacher can then invite pupils to try to use the economic knowledge as well as the logical thinking skills to explain the real-life phenomenon and solve the problem. This would help the pupils develop an economic way of thinking to make sense of the world ...

(Pre-service student teacher 07, Exit Interview)

S: [Good economics teaching] needs to help pupils better understand the world they live... for example, when they do an inquiry of a certain social phenomenon or public issue, they manage to link it up with what they have learned in economics which helps them evaluate the incident in an economic way. Unlike many pupils who said, "After I study the concept of 'opportunity cost', I know 'opportunity cost' only and I know how to score full marks in the public examination", or under the topic 'Demand and Supply', some pupils just learn how to score marks, for example, which lines or signs in a diagram will deserve how many marks, however, they do not really understand the concepts at all. They merely learn the examination techniques. If one encounters a problem or an issue to be solved in the real world, no one will give you a question stem like in the examination question which indicates how many marks and what is required clearly...I think [the teacher] should help the pupils analyze real-life problem or phenomenon and how to handle the problem using economics...

(In-service Student Teacher 08, Exit interview)

As shown in Table 22.1, Categories A to E were identified in the entry interview before the Learning study whereas in the exit interview after the Learning study only Categories B to E were found.

Table 22.2 Distribution of category of way of experiencing among individual student teacher before and after the Learning study

Student teacher	Category before the learning study	Category after the learning study	Change
FT01	B	D	Great positive change
FT02	B	B	No change
FT03	C	E	Great positive change
FT04	B	C	Moderate positive change
FT05	B	C	Moderate positive change
FT06	D	D	No change
FT07	D	E	Moderate positive change
FT08	B	E	Great positive change
FT09	D	D	No change
FT10	E	E	No change
PT01	A	C	Great positive change
PT02	A	C	Great positive change
PT03	B	D	Great positive change
PT04	D	D	No change
PT05	B	E	Great positive change
PT06	B	C	Moderate positive change
PT07	E	E	No change

Based on Table 22.2, seven of the seventeen participants in the study were classified as having great positive changes in their ways of experiencing good economics teaching while another four demonstrated moderate positive changes. The other six teachers demonstrated no changes in their ways of experiencing after engaging in the Learning study. It seemed that many of the student teachers did benefit from this intervention.

In all, the use of the phenomenographic approach to improve the professional learning of student teachers seemed to be effective. In line with the phenomenographic view of learning which denotes a qualitative change in one's way of experiencing the phenomenon or situation, many of the student teachers involved in the study seemed to have developed professional learning as they have displayed a more complex way of experiencing good teaching in economics and demonstrated a progression in their ways of experiencing. All of the student teachers regarded highly the opportunity to comment on and provide feedback to the real lessons conducted by their peers, with the guidance of the teacher educator. The use of provoking reflective questions has helped them focus upon and discern the critical aspects of good teaching in economics which they have not discerned before.

22.4 Conclusion

Overall, the empirical study reported shows how we attempted to foster professional learning using the phenomenographic approach. To reiterate, professional learning is conceptualized as a qualitative change of the learner in his or her way of

experiencing or conception of the phenomenon or situation by phenomenographers. It can be defined in terms of what critical aspects of the phenomenon or situation which the learner simultaneously focuses upon and discerns. If two learners experiencing the same phenomenon or situation simultaneously focus on and discern the same set of critical aspects of it, then according to the variation theory, both of them will exhibit the same way of experiencing the same phenomenon or situation. However, if two learners experiencing the same phenomenon or situation simultaneously focus on and discern different critical aspects of it (which is often the case in the real world), then they will exhibit two different ways of experiencing the same phenomenon. Accordingly, they will act differently to the phenomenon or situation and possibly come up with different outcomes from their acts.

Professional learning is therefore associated with changing discernment of the learner with regard to the phenomenon or situation in question, which implies a change in the critical aspects of the phenomenon which the learner can discern. In other words, the learner, after learning has taken place, has developed the capability of discerning those critical aspects that he or she could not discern before, and/or he or she is capable of discerning the relationship among those critical aspects in a more complex and sophisticated manner than before.

In phenomenography, we posit that the qualitatively different ways of seeing, acquiring meaning, and being understood, can be captured in a set of categories of description that are logically related to one another. Phenomenographic research has shown that this set of qualitatively different ways of seeing can be rewritten in terms of critical aspects, some of which are discerned by certain learners but not by others. In the present theoretical framework, the critical aspects set of the specific entity discerned and focused upon defines how that entity is seen (Marton and Booth 1997), which in turn defines its meaning (or rather one of its meanings). Discerning critical aspects of novel situations enable people to see them in more powerful ways. Seeing novel situations in more powerful ways enable people to act in more powerful ways.

According to Phenomenography and variation theory, in order to improve professional learning for occupational practice, it is important for the teacher to help the learners develop the capabilities to handle novel situations which they may confront in their professions or occupations in powerful ways. It amounts to helping the learners develop a more considered and sophisticated 'way of seeing' novel situations, which enables them to discern those critical features and know what aspects of their knowledge and skills are relevant to the novel situations. The extent to which the learners are capable of handling novel situations in powerful ways depends on the extent to which they have developed the capability to discern the aspects of those situations critical for handling them in powerful ways, i.e. professional learning.

In order to help the learners learn to discern the critical aspects of novel situations, the teacher needs to find out what the situations may appear to the learners and create the necessary conditions of learning to improve professional learning for practice. By allowing the learners with the opportunity to experience certain patterns of variation and invariance in what is dealt with in the learning environment, the teachers can widen the space of learning and empower the learner to discern and focus on the critical aspects simultaneously, which helps develop professional learning.

Chapter 23

Changing Cultures of Knowledge and Professional Learning

Monika Nerland and Karen Jensen

Abstract This chapter examines the relationship between knowledge cultures and professionals' learning in education and work. An overarching question is: *What roles do knowledge cultures play as constitutive arenas for professional learning and development?* The chapter reviews theoretical and empirical contributions to this topic, focusing on how the relationship between knowledge cultures and learning has been addressed in research on higher education and in the context of professional work. Strengths and weaknesses from different research strands are discussed, and it is proposed that analytical resources from the Social Studies of Science may be helpful for capturing this relationship as dynamic and emergent in practice. Drawing especially on the perspectives of Karin Knorr Cetina, we present findings from two larger Norwegian research projects, where different ways of organizing knowledge and supporting practitioners' continuing learning are compared and discussed as differences in professional knowledge cultures. A premise for this discussion is that professional learning today should be understood in relation to wider ecologies of knowledge and practice, and that the continuing enrolment of practitioners in a profession-specific field of knowledge is a critical condition for participation.

Keywords Knowledge cultures • Epistemic objects • Epistemic practices • Fields of expertise • Professions

23.1 Changes in Conditions for Learning

The continuous learning of professionals is an increasingly important topic in educational policy, practice and research. Questions of the quality and effectiveness of educational programs when it comes to preparing students for the ‘world of work’, and to ways of engaging and supporting practitioners in further developing expertise in their given field, are critical in the era of the ‘knowledge society’. At the same time as these questions come to the forefront, the environments in which learning and expertise development take place are getting more complex. This is partly related to the dynamics of knowledge itself. As pointed out by social scientists, the way knowledge production is linked with the economy makes advancements in knowledge emerging from numerous sites within and beyond educational institutions and research communities (Bechmann et al. 2009). Furthermore, the ubiquitous presence of information technologies allows the products of these activities to spread rapidly across institutional and geographical boundaries. As noted by Collier and Ong (2005, p. 11), more abstract and symbolic modes of representation give rise to “global forms” of knowledge, forms that have a “capacity for decontextualization and recontextualization, abstractability and movement, across diverse social and cultural situations and spheres of life”. Such forms of knowledge circulate quickly in information networks, and on their way they provide new arenas for engagement as well as resources for community formation.

An important driver in the current dynamics of knowledge production and dissemination is also the co-evolution of new insights and new doubts. While scientific knowledge is believed to provide conclusive answers to societal problems, it is also generally marked with uncertainty and ambiguity. When new results are achieved, they often generate new questions and the need for further knowledge advancement (Knorr Cetina 2007). Fields of expertise are thus marked by stability and instability at the same time, in the sense that their histories and established collective knowledge regulate practices of knowledge production, while new advancements may question the “givens” and call for integrative actions in the expert community.

In the wake of this, the knowledge worlds in which professional learning is embedded are becoming more extensive and complex. Although not all professions may be influenced in the same way or to the same extent, it is generally expected that professionals, as well as their educational programs, keep up with the developments in their field of expertise. In educational contexts, students are presented with knowledge and ways of thinking that are linked with dynamic and geographically dispersed ecologies of knowledge. These wider worlds contribute to defining relevant knowledge and competencies. Moreover, as new technologies and advanced instruments are increasingly used in higher education and work, we cannot take for granted that practitioners’ engagement with knowledge is bounded to given sites. Technologies mediate participation across settings and may bring students in contact with distributed communities that relate to the domain or expert culture but exist external to the educational institution (Francis 2010; Ludvigsen et al. 2011). Educational programs

are, in this respect, more than formal instructional settings; they also provide access points to “disciplinary networks” of knowledge and practices through which people come to participate in multiple ways (Nespor 1994). Such networks could, for instance, include Web-based discussion forums, the activities of expert groups in professional organizations, and work practices of various kinds.

In a wider perspective, the relationship between education and work and the ways in which expertise is valued and comes into play in working life are also changing. One aspect of this is the increased presence of experts in society, which is related to the general rise in educational levels in the population and the development of new fields of expertise (Giddens 1991; Brint 1994). Equally important, however, are the cultural shifts that emerge in a society that places knowledge processes at its core. As noted by the sociologist Karin Knorr Cetina (2001, 2007), development towards a knowledge society brings with it a general focus on knowledge, not only in terms of products to be utilized to solve various kinds of societal challenges but also in terms of the very way of engaging with knowledge. In the words of Knorr Cetina (2001, p. 177), the emergence of the knowledge society thus “involves more than the presence of more experts, more technological gadgets, more specialist rather than participant interpretations. It involves the presence of knowledge processes themselves (...), it involves the presence of epistemic practice.”

She describes this development as a “spillover” of epistemic cultures into other spheres of social life and points to how people increasingly engage in observing and analysing phenomena, and validating and developing knowledge as part of their everyday life and work. This often involves modes of practice that historically have been associated with science communities. Moreover, it involves a shift in collective mentalities and ways of thinking about knowledge, in which transparency in knowledge production and processes—which traditionally has been a core value in science communities—now is extended to include, for example, user communities and requested across occupational sectors and in different types of work (Knorr Cetina 2007).

These developments bring an extended epistemic orientation to education and work, through which the notion of mastering epistemic practices comes forward as an ideal not only for students in academic programs but increasingly also in higher professional programs. For instance, graduates from programs in engineering, nursing, teaching, and accountancy will more often be expected to select, justify, and validate knowledge in the context of work and to engage themselves in opportunities for improvement (Jensen et al. 2012a, b; Nerland and Jensen 2012). Also, these competencies need to be prepared for in the students’ respective educational programs. As proposed by Goodyear and Zenios (2007), a significant task for higher education today is to develop students’ capacities for understanding and creating knowledge in different work settings by developing what they call “epistemic fluency”, which denotes the mastery of epistemic practices and knowing how they may be combined to solve problems and develop collective resources in professional work.

During the last few decades, the importance of involving students in epistemic practices and has been highlighted in higher-education policies and practices across national contexts, in terms of ideas about research-based teaching and

involving undergraduate students in research (Boyer Commission 1998; Elsen et al. 2009; Healey and Jenkins 2009; Brew 2010; Spronken-Smith 2010; Zimbardi and Myatt 2012 iFirst). This is also the case for professional programs and college education (Hu et al. 2008; UHR 2010). Moreover, the idea of considering disciplines and expert domains as not only comprising specialized knowledge but also distinctive knowledge processes seems to be gaining ground in several areas. In a recent report from the US National Research Council (2012) on what is termed Discipline-based educational research in science and engineering, it was stated that more attention should be given to involving students in the “set of investigative processes” that are distinctive for the given domain (Chapter 7, p. 141). Related ideas have been brought forward also in the professional contexts of teaching (Bulterman-Bos 2008; Grossman et al. 2009) and nursing (Elzinga 1990; Reed and Shearer 2011).

In the wake of this, the question of how professionals of today become acquainted with the principles for producing and validating knowledge in specific domains and develop as skilful practitioners capable of identifying, exploring, and utilizing knowledge in relevant ways emerges as a critical topic for research. However, the general emphasis on involving students in epistemic practices and research-like activities does not necessarily mean that these forms of engagement have been equally reflected in the research on professional learning. Moreover, as the processes and principles for developing knowledge and expertise are field-specific and likely to differ between areas of expertise, we need to understand how conditions for learning vary in and between the professions.

The overarching questions we raise in this chapter are: *What roles do wider knowledge cultures play as constitutive arenas for professional learning and development? And, How has this relationship been conceptualised and accounted for in research?* As a start, we address the second question, particularly focusing on research investigating learning in the contexts of education and work, respectively. Examining research in both these contexts and considering how they relate is interesting, as professional learning consists of a longer trajectory that inevitably spans these contexts (Lahn 2011). We show how there seems to be a discrepancy in theoretical constructs between research targeting learning in educational contexts and in professional work, as well as a call for new conceptualisations that better account for the complex and dynamic relationships of knowledge to learning. We then discuss in Sect. 23.3 how concepts and perspectives from Social Studies of Science may allow for an increased understanding of critical dimensions in practitioners’ learning in expert cultures today, and consider how the perspective is used in recent research of relevance for professional learning. In the fourth section, we delve further into this issue and draw on comparative analyses in the two Norwegian research projects ProLearn (2004–2008) and LiKE (2008–2011) to discuss how professional knowledge cultures generate different ways of organizing knowledge and supporting practitioners’ learning, which also seem to span the education-work divide. The chapter concludes by summarising main issues and suggesting some avenues for the future.

23.2 Research on Professional Learning in Education and Work: A Review of Prevalent Strands

23.2.1 *Learning in Higher Education: Socio-cognitive Perspectives*

One of the defining characteristics of a profession is their level of education (Freidson 2001). In today's society, the requirements to practice as a professional within most fields are at minimum a postsecondary education. This is also true for occupational groups such as teachers and engineers, and for the type of professionals that we have in mind in this chapter. Although the educational systems for professionals differ somewhat between countries, there is a general tendency that more programmes are offered by universities and colleges and expected to be research-based. As a consequence, many studies targeting student learning in higher education include students in profession-oriented programmes. Moreover, as these studies often categorise students after their type of programme or specialty, we find it useful to consider this research when discussing the relationship of knowledge cultures to professional learning. At the same time, research on student learning is widespread, as it may be addressed in several research contexts such as higher-education studies, cognitive science, and discipline-specific research. Hence, it is not our ambition to provide a comprehensive review of studies and their results, but rather to discuss some dominant perspectives and traditions in this research field. To do so, we build on some recent review studies in this field.

An overview is provided by Haggis (2009a, b), who reviewed studies published in three leading journals about higher-education research in the period 1970–2007. The selected journals were *Higher Education (HE)*, *Studies in Higher Education (SiHE)*, and *Teaching in Higher Education (THE)*. Haggis draws on Tight (2007) to argue that HE is considered as the leading non-North American international higher education journal, while SiHE is the leading UK-based one. THE represents a more recently established journal that was included to provide variety in the scope and profile of publications. The review was performed as a content analysis, starting with the ways in which learning was conceptualized in the article titles and then identifying what models and research approaches they draw upon. Haggis has also compared her analysis of publications in these journals with publications in two main North American journals (2009a) and with research published in the related areas of adult education and sociolinguistics (2009b). Moreover, the results are compared with key theoretical moves in psychology and sociology in the same period of time (Haggis 2009b).

Haggis' analysis shows that research on student learning in higher education has been dominated by phenomenographic approaches in the given period. This strand of learning research has been developed specifically within higher-education research and grew out of the work of Ference Marton and his colleagues in the

1970s and 1980s (Marton and Säljö 1976a, b; Marton et al. 1984). In this tradition, learning is investigated from the students' perspective, with an interest in revealing the variations in how students understand learning content and the approaches they take as learners (Marton and Booth 1997). Learning is in this research seen as a cognitive phenomenon that is often examined by way of questionnaires and interviews. This has led to important insights about how students differ in their learning approaches, which have been conceptualized as deep, surface, and strategic. Moreover, it has identified significant factors that call for teachers' attention, such as how course work can be designed to support in-depth engagement and critical reflection among students (Entwistle and Peterson 2005).

Socio-cognitive perspectives have also guided other powerful strands of research on student learning in higher education. In particular, this is reflected in research focusing on self-directed learning and, more recently, epistemic beliefs (e.g., Schommer-Aikins et al. 2003; Muis and Sinatra 2006; Bråten et al. 2009). This research has accounted more explicitly for knowledge and identified generic as well as domain-specific issues of critical importance for students' learning and conceptual understanding. For instance, it has shown that students who hold more complex beliefs about knowledge and knowing are more likely to handle complexity in information from multiple sources and to develop a comprehensive understanding of ill-structured phenomena. This research has also pointed to how differences between students may increase over time, as students who have sound conceptual knowledge and metacognitive skills are more likely to handle complex tasks and to benefit from instruction. Hence, it contributes to explaining important differences in students' achievement and how they develop over time.

Common for the research strands described above is that they tend to apply methodologies in which data from individual students and/or teachers are collected through surveys or interviews. While there are signs that the amount of studies based in phenomenography has decreased recently, the amount of survey studies seems to have increased (Tight 2013), which supports this impression. Hence, although we have learned important lessons about the different approaches students take as well as about how different types of conceptions and beliefs influence student achievement, less is known from this research about how students develop expertise in terms of learning to master specific knowledge practices. Moreover, collaborative knowledge practices and engagement across settings are among the issues that tend to fall out of scope.

Haggis (2009b) points to how research on student learning in higher education has employed a somewhat narrow scope of questions and methodologies, compared with other fields of social science and educational research. The turn towards socio-cultural and interactional perspectives that emerged in other fields during the 1980s and 1990s has not been taken up in higher-education research to the same extent. In addition, the development of network theories and approaches that have taken place in sociology during the last decades are not much reflected in research on student learning in higher education. This leads Haggis (2009b, p. 389) to conclude that research into learning in higher education has not accounted sufficiently for "the fleeting', 'the distributed', 'the multiple' and 'the complex'". For the specific

theme of this chapter, we would add that the above described research traditions often have treated knowledge as given and predefined course content to be learned, rather than as dynamic objects that are developed in practice through specific epistemic strategies.

23.2.2 *Disciplinary Cultures*

Within the field of higher education, there is a range of studies that focuses explicitly on knowledge cultures as constitutive for education. The conceptual framing of these studies has often taken the disciplines as a point of departure, and since the implications of disciplinary differences is a core issue, we find it relevant for the questions we raise in this chapter. Of major influence in this tradition are Biglan's (1973) distinctions between disciplines along the two continuums of hard—soft, and pure—applied. The work by Tony Becher (1989, revised version with Paul Trowler 2001) on “Academic tribes and territories: the culture of disciplines” took these ideas further in a broader analysis of disciplinary cultures in the university. Here, culture refers to shared ways of thinking and collective ways of behaving that has epistemological as well as social implications. Academic disciplines are seen to hold norms, values, traditions and belief systems that constitute certain logics of knowledge and knowledge production.

This perspective is first and foremost used to differentiate between disciplines and their social organization, for instance when it comes to whether their logics of knowledge production are oriented towards generalization or specialization, whether the methodological approaches strive towards pluralisation or unification, and whether the relations towards the outside world are marked by openness or closure (Becher and Trowler 2001). In later years, the perspective has also informed a range of research on teaching and curriculum development (e.g. Hativa and Marinovich 1995; Knight and Trowler 2000; Neumann et al. 2002; Mueller 2009). This research has contributed with specifying the knowledge-related and socially related aspects of teaching and learning, for instance along the categories of curriculum, assessment, teaching methodologies, and expectations to students. It has pointed to the importance of recognizing the distinctive features of knowledge domains and their social environments if we are to understand key aspects of teaching and learning. Moreover, some studies have raised an important critique towards the widespread idea in current educational policies that pedagogical approaches and the so-called generic skills are of universal nature. For instance, Jones (2009) showed that types of generic attributes, such as critical thinking, problem solving and communication, are understood and conceptualized quite differently in different disciplines. A core argument following from this study is that such skills emerge through disciplinary forms of engagement and that these specificities need to be accounted for when we use concepts like generic skills and competencies. Brint et al. (2008) analysed data from a survey carried out among students across the University of California system, and showed how students' experiences of academic engagement may be categorized in

two different disciplinary groupings that were conceptualized as the humanities/social sciences and the natural sciences/engineering respectively. As the study revealed considerable differences in norms and expectations to the students' engagement, the authors question the feasibility of promoting pedagogical principles that are believed to be valid across all knowledge domains.

When it comes to research approaches, studies that employ a disciplinary culture perspective largely rest on interviews and self-reported data from academics and students within the contexts of specific universities or educational programs. In this way, individuals' relations to and conceptions of their knowledge domain become a prime unit of analysis. The discipline is often treated as a context for learning, rather than as a dynamic assemblage of knowledge and practices with which the students engage. Hence, while important insights emerge from these studies on an aggregate level, and while it is generally acknowledged that engaging students in research and inquiry-oriented activities is among the most effective ways to develop their conceptual understanding and capabilities to 'think' like an expert in their given field (Healey and Jenkins 2009; Hu et al. 2008), few studies focus on the micro-processes of students' participation and engagement with knowledge during education.

There are, however, some noteworthy exceptions to this picture. One is the long-term ethnographic research program conducted by Janet Donald and her colleagues (Donald 2002), which provides a rich description of the ways in which students in 16 courses across 8 disciplines are introduced to core principles in their field of expertise and, through this, learn to think like experts. The analyses focus on core concepts around which the knowledge activities evolved, the knowledge structure of the course content, its validation principles, and methods of inquiry (e.g., hermeneutics, problem solving, critical reasoning, experiments, examining expertise through personal models or action schemes). The study reveals how "learning to think" implied quite different things and came with different expectations for students in the various disciplines. For instance, while systematic reasoning based on precedent cases was at the core of engagement with knowledge in law, and problem-solving through modelling and procedural exploration was significant in engineering, text-based criticism and creativity in a hermeneutic mode was important in the humanities. By focusing on issues such as validation principles and methods of inquiry, this study addressed core aspects of the epistemic practices that constitute a field of expertise. However, with respect to students learning more broadly, it can be noted that the study primarily focuses on course content and activities and their inherent demands. What it means to think like an expert in the different domains is highlighted, rather than the processes through which such capabilities are developed and commitment to the expert culture is generated.

An unconventional study of the relationship of knowledge to learning is presented by Nespor (1994), who investigates how students are mobilized as learners by the knowledge arrangements in two undergraduate programs of physics and management. Drawing on actor network theory in combination with other sociocultural perspectives, Nespor (1994, p. 131) defines learning as segments of "knowledge in motion" that "follow the shapes of more stable institutional or disciplinary networks". The analytical focus is on the socio-temporal networks of relationships

that produce and reproduce educational tools and practices such as lectures, presentation sheets, notebooks, and social arrangements in auditoriums and classrooms. The ways these elements are enacted and acted upon constitute trajectories that differ in their socio-spatial outreach and shape how students are mobilized and become enrolled in distinct ways. Hence, the discipline is seen as an emergent and networked apparatus more than as a stable context for learning. Although Nespor's focus is on two specific undergraduate programs, the analytical approach utilized in this study is sensitive to how the material tools and practices enacted in these programs are interlinked with wider networks of knowledge. The programs are conceptualized as regions in more complex networks, which simultaneously "concentrate student activity within bounded material organizations of space-time" and link students to "distant sites of disciplinary practice through representational organizations of space-time" (p. 133). This study contributes with new insights by turning the usual analytical focus "upside down" and tracing the networks of knowledge and practices rather than focusing on individuals' engagement. When it comes to disciplinary difference, however, it focuses on space and time relationships in the educational arrangements, but it pays less attention to the epistemic principles and strategies enacted in these spaces. Consequently, it does not attempt to reveal how students develop competencies and learn the epistemic principles of their expert culture by participating in the activities and trajectories offered.

23.2.3 Professional Learning: Socio-cultural Perspectives

In the wider context of research on professional learning, the sociocultural perspectives that emerged in learning theories in the 1990s gained a strong footing in studies of work- and practice-based learning. For research on professional practice, this 'sociocultural turn' was supported by the influential role of the book *Situated learning: legitimate peripheral participation*, which was published by Jean Lave and Etienne Wenger in (1991) and later followed up in e.g. Lave (1993) and Wenger (1998). In this perspective, learning is seen as a process of socialization within expert communities and conceptualized as a movement from being a 'legitimate peripheral participant' to becoming a full member of a professional community. Core concepts launched to analyse these processes were communities of practice, trajectories of participation, and learning to become a competent participant by way of access to, imitation of and identification with practice as enacted by more experienced practitioners. This perspective highlights the social organization of activities and learning as an integrated part of work, as well as the learners' changing capabilities of participation as they move towards more central tasks in the given practice. It has been utilized for studying learning in a range of professional and vocational occupations (see, for instance, Chaiklin and Lave 1993) and paved the way for researchers to reconceptualise and reclaim the value of apprenticeship models (e.g. Nielsen and Kvale 1997). Moreover, the perspective has generated research that underscores the active role of individuals in "remaking" collective practices (Billett et al. 2005;

Billett 2008). However, although this perspective highlights learning as participation in communities and the role artefacts play in this respect, it is primarily oriented towards the social aspects and does not account sufficiently for the epistemic aspects of work and learning, or for transformations in knowledge over time (Lahn and Jensen 2006). Another limitation is the emphasis placed on communities as single, localized and bounded fields of practice, which implies that practice is understood within these boundaries rather than as constituted of complex relations and movements across multiple sites (Jewson 2007).

Another influential strand of research on professional learning has emerged from Cultural Historical Activity Theory (Engeström 1987; Engeström et al. 1999). In this tradition, learning is conceptualized as expansive, embedded in object-oriented activity, and mediated by tools and objects in a given activity system. Development and change is here understood as driven by contradictions in and between activity systems. The concept of an activity system includes material and symbolic resources and the way these are negotiated and transformed as people engage with the object of activity, as well as the activity's dependencies on institutional characteristics like division of work. Moreover, the idea of activities as object-mediated refers to a double meaning of the object, referring to its instrumental character as well as its mediating function (Miettinen 1999; Lahn and Jensen 2006). Research within this line of theory typically takes the activity system as its unit of analysis, with an increasing interest in how new practices emerge at the interface of two or more activity systems, and how organizational change can be facilitated in researcher-practitioner collaborations around joint creation of artefacts and objects (e.g. Engeström 2001). Human action is seen as essentially mediated, and the role of artefacts and objects in facilitating change is a core issue. Recent developments in this theory also develop models to understand dialogue, multiple perspectives, and networks of interacting activity systems, hence taking into account several of the shortcomings pointed to in Haggis' (2009a, b) review of students learning in higher education. However, activity-theoretical studies of professional learning in educational contexts are sparse, as most studies that address the professions are carried out in work settings. And, as argued by Lahn and Jensen (2006) and Lahn (2011) in their accounts of models for professional learning, the activity-theoretical perspective has not accounted sufficiently for how epistemic shifts are generated from knowledge-dependent practices and cultures of contemporary working life. Although discussed by Miettinen and Virkkunen (2005) and Engeström and Blackler (2005) as emerging interests, even these more recent socio-cultural approaches to studying professional learning have tended to downplay the role of knowledge in the formation of expert communities.

23.2.4 *Summing Up*

The above review of research strands suggests that research on professional practice and learning show a more varied picture than the reviews on student learning in higher education, and that the former to a larger extent has developed ways of

accounting for learning that are sensitive to shifts in knowledge and the dynamic and multifaceted dimensions of knowledge work. These approaches are however hardly ever brought into studies of professional learning in educational contexts, and they are still somewhat restricted when it comes to ways of addressing wider networks and ecologies of knowledge. This is probably due to the fact that they often take artefact-mediated practices as their focus of analysis, rather than the knowledge culture in which these objects and practices are embedded. The research on disciplinary cultures, on the other hand, does focus on the knowledge cultures in play. However this research tends to treat knowledge as a more predefined content to be learned, and does not sufficiently account for the knowledge dynamics and practices through which students become enrolled and develop expertise. Moreover, it tends to focus on traditional academic disciplines rather than professional knowledge cultures. Hence, while all research strands provide significant contributions to our understanding of professional learning, important gaps emerge between them when it comes to understanding the relationship of knowledge cultures to learning. In the next section, we suggest that concepts and perspectives from Social Studies of Science may be useful in addressing this topic.

23.3 Capturing the Relationship of Knowledge Cultures to Professional Learning: Analytical Resources from Social Studies of Science

In recent years, researchers have turned to network theories and developments within *Social Studies of Science* to find concepts and perspectives that may supplement existing research and shed light on how newcomers become enrolled and participate in expert cultures today (see Hakkarainen et al. 2004 and Fenwick et al. 2011 for an overview of approaches in this respect). Of particular interest for our purpose is the work of sociologist Karin Knorr Cetina (1999, 2001) and her perspectives on epistemic cultures and object relations. Our reason for highlighting her work is twofold. First, she provides a perspective on expert knowledge that accounts for how knowledge is developed and shared in socio-historical contexts over time. Second, her conceptualisation of knowledge cultures provides analytical tools for differentiating between the professions and their distinct ways of handling knowledge. By using the term “epistemic cultures”, Knorr Cetina draws attention to the logics and arrangements through which knowledge comes into being and is circulated, approached, and collectively recognized within science and other expert communities. These logics and arrangements comprise tools, artefacts, and institutional arrangements, but also the specific strategies, visions, and procedures that constitute collective actions and form the “machinery of knowledge construction”, which, in a given area of expertise, “make up how we know what we know” (Knorr Cetina 1999, p. 1). Epistemic cultures hold, on the one hand, some common features that are shared across domains. For instance, the general expectations in today’s society about making processes of knowledge production transparent, and about

including user value as one criterion for recognising valuable knowledge, influence strategies for how knowledge is produced, validated and circulated across fields of expertise (Knorr Cetina 2002; Bechmann et al. 2009). On the other hand, logics and arrangements for knowledge production and circulation carry features that are distinctive for the knowledge domain in question and thus provide analytical means for distinguishing between different expert cultures.

While the concept originally was launched to study and conceptualize different cultures of knowledge production in the sciences (Knorr Cetina 1999), she has later extended her focus and used the same ideas to study other types of expert communities (Knorr Cetina and Bruegger 2000) and to conceptualize knowledge relations in professional settings (Knorr Cetina 2001, 2006). In one sense, her approach resembles the above described work on the cultures of disciplines (Biglan 1973; Becher and Trowler 2001) which has been influential in higher education research. However, by focusing more explicitly on the practices and webs of relations through which knowledge is produced and circulated, Knorr Cetina provides a dynamic framework that allows for investigating the very practices of inquiry in which experts—and students—engage. Moreover, the focus on knowledge processes and practices contributes to untying the concept from discipline-specific knowledge structures as well as from strong boundaries between contexts of production and contexts of use. As Knorr Cetina (1999, p. 2) argues, the concept of disciplines has been important to capture the differentiation of knowledge, but it has not sufficiently captured the strategies and policies of knowing that inform expert practice. Hence, her ambition is to “make visible the complex texture of knowledge as practiced in the deep social spaces of modern institutions”, and, to do so, it is necessary to “magnify the space of knowledge-in-action” (Knorr Cetina 1999, pp. 2–3).

A core concept to understand knowledge cultures and practices is epistemic objects. Expert communities are typically object-centred, in the sense that they are oriented toward exploring, developing, and mobilizing knowledge objects (Knorr Cetina 2001). Such objects are, however, not understood as separate, material things. Rather, they may be described as complex amalgams of material and symbolic resources that constitute knowledge around a problem and, through their inherent complexity, activate a set of opportunities when they are approached (Nerland and Jensen 2012). Moreover, following Knorr Cetina’s definition, epistemic objects are characterized by their unfolding and question-generating character. As she explains, “Since epistemic objects are always in the process of being materially defined, they continually acquire new properties and change the ones they have” (Knorr Cetina 2001, p. 181). In the context of professional work and learning, epistemic objects could be models for medical treatment, computer programs, legal texts, and complex representations of financial markets. They are created in epistemic cultures and further developed as people in different settings attend to them, explore their complexity, and materialize their potential in local activities.

For student and novice practitioners, engagement with epistemic objects may be regarded as an access point to their relevant expert culture and its collective ways of knowing (Jensen and Lahn 2005; Nerland and Jensen 2012). Moreover, they may stimulate learning by their ways of generating epistemic practices when they are approached. They typically carry structuring principles for practice, at the

same time as they may be approached in different ways in variegated settings. For instance, in some contexts they are subjected to validation efforts, testing, and types of evidence-making oriented toward closure and (preliminary) fixedness. In other contexts, they form an explorative site where questions and possibilities are opened up in an elaborative manner, which process may in turn envision new instantiations and possibilities. The dynamic interplay of these processes may involve students and novice practitioners in core epistemic practices in their expert domain.

From this perspective, the types and roles of epistemic objects in a professional environment will influence practitioners' opportunities for learning. The circulation of such objects is also constitutive for the ways local work is linked with wider knowledge circuits, and the types of intermediaries (Callon 1991) that are powerful in this respect. However, the role of epistemic objects is not limited to access to knowledge and participation in knowledge practices. As such objects typically incorporate suggestions for action and principles for how they might be used or explored, they also serve to construct and position the knower. In Knorr Cetina's words, they mediate the collective "epistementality", that is, a shared belief system that forms how knowledge is understood and envisioned in the given expert culture. Such epistementalities may, for instance, vary in their ways of emphasising control, complexity, and experience (Kastenhofer 2007).

In recent years, these analytical resources have been used to some extent to investigate knowledge practices and learning in different professions and types of expert work. Ewenstein and Whyte (2009), for instance, employed the concept of epistemic objects to reveal how visual representations in architectural design had an unfolding ontology that displayed incompleteness and were constantly in flux rather than fully formed. The interplay between these epistemic objects and technical, more frozen objects was important in the design process. Similar dynamics have been described in knowledge practices mediated by drawings in engineering (Bechky 2003) and clinical guidelines in nursing (Nerland and Jensen 2012). Mørk et al. (2008) investigated inter-professional knowledge production in a medical research and development organization and found differences between the epistemic assumptions and strategies of doctors, nurses, radiologists and engineers that generated obstacles for learning across the expert groups. Other researchers have focused on how practitioners from different areas of expertise collaborate in revealing and developing shared epistemic objects (Edwards 2010; Guile 2010). Knorr Cetina herself has, in collaboration with colleagues, investigated how objectual practices play out in the work of financial traders (Knorr Cetina and Bruegger 2000) and also explored how even financial information and economic transactions are mobilized and carried out by way of epistemic practices (Knorr Cetina and Preda 2001). Analyses of novice practitioners' relationships with knowledge have shown how the interplay between professionals and their knowledge objects generate opportunities for learning across space and time (Nerland and Jensen 2010) as well as a commitment to knowledge and a desire to engage in further explorations beyond what is known (Jensen 2007; Rudberg 2012).

In higher education, studies that draw on these analytical resources are scarce. However some examples do exist. Damsa et al. (2010) used the concept of shared epistemic agency to investigate how groups of university students collaboratively

created shared knowledge objects in the context of instructional design activities, and showed how this type of agency was constituted and differently articulated in different groups. Hence, the group dynamics and the collective epistemic strategies matter for the students' experience. Jensen and Lahn (2005) showed how nursing students engage with the concept of care as a knowledge object that incorporates ideas generated through science but at the same time presents itself as an open-ended object which allows for—and asks for—multiple interpretations and use. They describe how students first find the abstract, decontextualized world of theory challenging, but that the “back-and-forward looping between theoretical input and practical experience” (p. 313) offered in the educational program seems to involve the students in objectual dynamics and create ties to knowledge over time. Finally, Muukkonen et al. (2010) studied knowledge-creative practices around shared epistemic objects in student teams in the context of an undergraduate project management course. Here, students were distributed on teams that were geographically dispersed and presented with complex problems based on assignments from two customers in working life. The analysis showed how students, although somewhat distressed with the open-ended character of the problem during the process, benefitted from being involved in knowledge creation and inquiry-oriented processes over time. For these activities to be productive in students' learning, however, careful scaffolding of knowledge practices as well as team processes is needed.

To investigate further how students and novice professionals get access to and participate in epistemic practices, and through this become inducted in cultures of expertise, it is suggested that more research could benefit from drawing on the analytical resources described above. Interestingly, a similar concern has been raised from within the Social Studies of Science traditions, where researchers have pointed to a need for understanding not only how expert cultures operate but also how they come into being and are maintained through the on-going enrolment of new members (Meyer and Molyneux-Hodgson 2009). The Norwegian projects ProLearn (2004–2008) and LiKE (2008–2011) have drawn on these analytical resources and conducted comparative analyses of the relationship of knowledge cultures to learning in four professions. Although explorative in nature, interesting differences between the professions have been identified. In the next section we describe and discuss core findings from these studies.

23.4 Knowledge Cultures as ‘Educational Systems’

In the ProLearn project (*Professional Learning in a Changing Society*), we used the concepts of knowledge cultures, objectual practices and epistementalities as sources of inspiration to analyse how collective ways of organizing and engaging with knowledge in different professions constitute opportunities for learning (see Jensen et al., Eds 2012b, for a more extensive description of the project and its findings). The targeted groups were nurses, school teachers, auditors and computer engineers. The project followed novice practitioners in their transition from education to work,

as well as in two time periods in working life, by means of questionnaires, interviews, and learning logs.¹ We also conducted document analyses of curricula and core policy documents in the relevant professional associations, as well as targeted case studies of knowledge practices in working life. Together the analyses revealed interesting similarities between the knowledge cultures, but also considerable differences among the groups in terms of how they orient themselves towards knowledge and in the character of the wider knowledge worlds in which they engage. Moreover, the analyses indicated that professional cultures in which local practices are linked with extended networks and circuits of knowledge in a systematic and strategic way were more likely to foster an epistementality geared towards learning and continuous exploration among its members. In this respect, the character of the knowledge infrastructures and artefacts available for practitioners is important. To learn more about these dynamics, the LiKE project (*Learning Trajectories in Knowledge Economies*) was designed to conduct follow-up studies in the same professions that focused more in-depth on knowledge practices that evolved around epistemic objects and artefacts in professional work. This project comprised observation-based case studies in selected work settings, as well as follow-up interviews and questionnaires among the participants in the ProLearn project.

In what follows, we draw on these projects to discuss significant features of professional knowledge cultures as “educational systems” and how they serve to shape professionals’ practice-based learning. First, we describe and discuss similarities and differences in the respective professions’ knowledge relations and knowledge processes that create overall conditions for learning. Next, we look closer into what we see as a significant dynamism in professional learning, namely the practitioners’ relation to and engagement with epistemic objects. In the context of the latter, we also discuss how the work and learning of professionals today is embedded in wider “machineries of knowledge construction” that span organizational boundaries and present practitioners with new demands and responsibilities, but also new opportunities for epistemic engagement.

23.4.1 Professional Knowledge Cultures and Their Ways of Shaping Conditions for Learning

Across the four targeted groups, our analyses revealed that novice practitioners experience shifting knowledge demands in their work situations that call upon them to renew their competencies and ways of working. In the interviews, participants across the professions described how they experienced a knowledge domain that

¹ The project was carried out in the Department of Education, University of Oslo, in collaboration with the Center for Studies of the Professions at the Oslo and Akershus University College of Applied Sciences. The longitudinal survey “StudData – Database for Studies of Recruitment and Qualification in the Professions” was used as a basis for selection of participants for the qualitative studies.

was in development and that was influenced by external sites for knowledge advancement, be it scientific, technological or legislative impulses. Examples of developments that occurred during the research period are new procedures and approaches for solving professional tasks, such as risk auditing for the accountants and agile software development for the computer engineers (Mathisen and Nerland 2012). Nurses' work and learning demands were often related to new advancements in medicine (Christiansen 2010; Jensen et al. 2012a, b). Although the teachers described more stability in their core tasks and professional challenges, they were presented to new regulatory demands such as shifts in curriculum models that required an attitude towards continuous learning and development (Jensen et al. 2012a, b; Strand and Jensen 2012). Hence, professional practices are in all cases embedded in dynamic fields of knowledge, and practitioners in all professions seem to have embraced identities as knowledge seekers and lifelong learners (Jensen 2007).

An interesting finding across the professional groups concerns the role professional education plays in connecting students to their field of expertise and developing habits for knowledge seeking. Analyses of what kind of knowledge sources the students engage with during education and later in working life suggest that their habits from education seem to be continued in working life (Smeby 2012). For instance, nursing students approached scientific journals and research-based knowledge during education to find answers to their questions and continued to do so in working life. Teachers did not establish these habits during education, and were correspondingly less active in approaching research-based knowledge in their work. Moreover, students' experiences of insufficient competencies when graduating is not necessarily a sign of weaknesses in educational programs, but could in fact indicate that the students' have developed a commitment to their field of expertise as well as capabilities of identifying the 'black holes' in their knowledge base and the need for further learning (Smeby 2007). Becoming enrolled in cultures of expertise is in this respect not only about becoming a competent knower but also about developing capacities for critical engagement with knowledge and epistemic curiosity, which is important to handle complex knowledge challenges today (Jensen and Christiansen 2012; Nerland and Jensen 2007).

While practitioners in all groups seemed to develop a sense of commitment to their field of expertise during education, we found interesting differences in the professions' ways of organizing knowledge and opportunities for learning. To identify and conceptualise these differences, we developed further Knorr Cetina's (1999) notion of knowledge cultures as "machineries of knowledge construction". We understand such machineries to comprise logics and arrangements through which knowledge is developed, circulated, accumulated, and applied in professional settings. Of particular relevance for understanding professional knowledge cultures and their ways of influencing learning are the types of intermediaries through which knowledge circulates and become accessible; the temporal and spatial scale of knowledge practices and participation; and the collective belief systems and epistemic orientations that emerge through the former aspects (Nerland 2008, 2012a).

Starting with the computer engineers, their knowledge culture is marked by a ubiquitous presence of information structures and technological objects. Knowledge

is circulated in information networks in ways that invite the engineers to keep in touch with the latest technological advancements while performing everyday work. This is supported by standards and codified knowledge, such as programming languages, which makes it possible to share knowledge across organizational and national boundaries. Moreover, the engagement with technological objects invites engineers to explore and develop knowledge as part of their problem solving activities. Systems, programmes, and codes can always be improved to be more efficient, more widely applicable, or more complex in their functionalities. In the moment of resolving a technical problem by means of, e.g., applying distributed codes or “best practices”, new possibilities and untried functionalities appear. The implications for practice-based learning are, first, that such representations of knowledge allow for an externalisation of learning and knowledge engagement that makes opportunities visible and generate curiosity and further exploration. As one engineer expressed it; “In fact the most important thing is to realise the potential of the system you are working with. As you learn more about it, you also see many new opportunities” (Nerland 2008, p. 61). Second, the type of intermediaries in this knowledge culture serves to link practitioners with circuits of knowledge that reach far beyond their current workplace. One example is the web-based forums and discussion groups facilitated by the large technology providers, such as java.net, where practitioners are invited to share their experiences with technologies and solutions to problems and in this way also to contribute to further advancements in their expert culture. Although novice practitioners themselves may not be very active in posting messages in these forums (Lahn 2012), they come in touch with others’ work by following discussions. Characteristic for this knowledge culture is that the development of profession-specific knowledge pursues technological advancements, and that knowledge distribution goes beyond the boundaries of the profession. For the computer engineers, these arrangements imply an individualization of responsibilities for continuous learning in which each practitioner is called upon to stay updated and manage his/her own career in a deliberate manner, sometimes within contexts of conflicting demands where short-term requirements and long-term interests do not go well together (Nerland 2012b).

The knowledge culture of nursing is also characterized by a plenitude of material tools and support structures. However, in contrast to the computer engineers, nurses are provided with a range of knowledge tools and resources that have been specifically designed for the profession, including manuals, intranet, reference works and textbooks (Christiansen 2010; Lahn and Christiansen 2012; Klette and Smeby 2012). They also receive systematic supervision from colleagues and have access to a wide range of specialised expertise in their work contexts. Of particular interest in this regard is the role of the clinical nurse developer in larger hospitals, who is equipped with the task to bring science-based advancements into the practices at the ward (Jensen and Christiansen 2012; Christiansen et al. 2009). Hence, the types of intermediaries are manifold and the materiality of the knowledge culture is miscellaneous and rich. While relations to science-generated knowledge are emphasised in this culture, considerable efforts are devoted to organising collective ways of validating and translating such knowledge for use in professional practice.

Here, the development of procedural standards for nurses' work is important. Such procedures link local and universal expressions of knowledge, and provide opportunities for learning in their development and use (Nes and Moen 2010; Moen and Nes 2012; Nerland and Jensen 2012; Nerland and Karseth 2013). Hence, while nurses get access to larger knowledge worlds in their everyday work, the knowledge practices and settings in which they participate are more often locally organized and have a more profession-specific character. This interplay between the local and the global seems to spur explicit engagement with knowledge also beyond the frontline work with clients. Our analyses revealed that nurses often wanted to learn more about the medical problems they faced (Lahn 2012) and that they volunteered to participate in developing work procedures (Jensen and Christiansen 2012). There was a general concern among practitioners for ensuring that they are familiar with research-based advancements and current collective procedures for good practice, which seems to stimulate learning (Jensen 2007).

The knowledge culture of accountancy is first and foremost marked by a strong emphasis on legislation and formal standards for work. While national agencies play a key role in this respect, the profession is heavily influenced by international legislation. Audit standards are often initiated and developed by transnational professional bodies such as the International Accountancy Federation, and literally translated into Norwegian for use in the Norwegian fiscal sector (Nerland and Karseth 2013). Nevertheless, such formal regulations build on and are turned into collective knowledge in the profession. Important intermediaries in this culture are a profession-specific language and terminology, which makes the sharing and use of distributed knowledge sources possible. Textual resources are also important, such as documents and books describing current standards and how they should be used. Moreover, the profession has initiated and developed an advanced, web-based audit support system called Descartes, which aims at supporting practitioners in following the current standard for risk-based auditing. This system is used by approximately 75 % of the members of professional association for accountants in Norway. It incorporates current standards, procedures and guiding models for audit work, and at the same time forms a site in which audit work is performed and documented (Mathisen and Nerland 2012). Through their engagement with current standards and models of best practice for auditing in their given line of business, auditors become involved in networks of knowledge that extend way beyond their local workplace. The emphasis on standards and legislation in this expert culture implies that parts of the practitioners' learning is highly formalised. In our projects, the accountants are the only ones who face formal requirements to attend courses and participate in training as part of their duties, and the only ones whose competencies need to be recertified. At the same time, however, the temporal arrangements and distribution of tasks over the annual year make it possible to focus on learning and competence development in certain work periods (Mathisen 2012). Moreover, our analyses suggest that the shifts in standards and regulations call upon practitioners to explore their meaning and implications in ways that stimulate analytic and epistemic modes of engagement (Mathisen and Nerland 2012). Standards are not simply ready to be used in the audit of specific clients. Rather, they need to be

explored and specified in each work context. This seems to generate epistemic engagement to fill the gap between the universal and the specific, as well as an interest in exploring the meaning of the standard beyond what is needed in the given situation (*ibid.*). Among practitioners, this informal learning is regarded as just as important as formal training, and also as something that makes their work exciting. As one auditor expressed it; “So many people have a misconception of this profession, and it is remarkable how long-lived the myth of the ‘correcting read pen’ is. That’s not what it is about anymore. It is a fantastic and exciting profession”.

The knowledge culture of teachers is characterized by strong emphasis on experience-based knowledge and face-to-face models of knowledge sharing. A common narrative is that the individual teacher needs to build up a wide repertoire of first-hand experiences gained in a variety of teaching and learning situations (Nerland 2012a). Moreover, this has been regarded as a core model for developing the profession’s collective knowledge base, in the sense that individual teachers have been encouraged to share and bring their experiences ‘upwards’ in their profession in this way to develop collective, agreed-upon examples of good practice (Karseth and Nerland 2007). Practitioners in this field describe a limited use of profession-specific knowledge resources from outside the local community, with the exception of factual knowledge related to subject matters they are to teach. When the teachers refer to research within their own profession or to extended circuits of knowledge, this contact has more sporadic character (Klette and Carlsten 2012; Klette and Smeby 2012). This seems to be related to a general resistance towards standardised procedures and work approaches in this profession. Both the Teachers’ Union and teachers themselves have been concerned with protecting the individual teachers’ right to teach in his or her preferred way, as a means to secure a space for professional discretion (Karseth and Nerland 2007). As a consequence, learning in the workplace is related to informal interaction and knowledge sharing within the local school, in which the learning professional is implicitly asked to take personal responsibility for seeking out advice and ideas. The strength of this model is that engagement with knowledge takes place close to its application in practical teaching, and that it allows individual and organisational learning in the workplace to coalesce. The possible limitations include that it may be difficult to exceed the local boundaries and thus to reconceptualise current practice, and that the practitioners are not offered the sense of excitement that being in contact with wider circuits of knowledge development may provide. While the professional mandate of supporting students’ learning and development is wide-embracing and complex in character, and thus offers questions and concerns that may invite learning, the lack of systematized knowledge and procedures makes it difficult to find answers to problems and clear directions for learning (Klette and Carlsten 2012). In recent times, however, we have noticed signs that the knowledge culture of school teachers is about to change in terms of a stronger emphasis given to specialization, to formalisation of work approaches, and to profession-specific knowledge generated through research (Strand and Jensen 2012; Nerland and Karseth 2013). For instance, initiatives to develop shared principles for assessment across schools and communities generate templates and standards that need to be explored and developed locally, thus

encouraging epistemic practices (Hermansen and Nerland 2013). However the strong emphasis on differentiating knowledge and practice to meet the needs of the individual student, together with time pressures and extensive demands for “front stage performances” at work, makes it difficult for teachers to see their own learning as a project distinct from that of their students’ learning.

In sum, these differences point to how collective ways of developing, sharing and understanding knowledge in the respective professions generate different conditions for learning as well as ways of positioning the learner. While the cultures of nursing and accountancy highlight collective knowledge, standardized procedures and consistency in the performance of work, they also stimulate analytical and explorative engagement in the intersection between the general and the specific. The cultures of computer engineering and teaching both place more emphasis on differentiation and individual choices in processes of knowledge application. In nursing and accountancy learning is more formalised and collectively regulated, while the knowledge arrangements in teaching and computer engineering imply an individualisation of responsibilities for learning. What it means to engage in learning is, however, highly different within these groupings. For instance, the support structures for handling individualised responsibilities are highly different in computer engineering and teaching. While computer engineers are positioned as career managers whose prime task is to keep up with advancements in an international technological field of expertise, teachers are positioned as experiential learners whose engagement often evolves around the challenges and needs of their current students.

Practitioners are through these arrangements invited to participate in practices that have a different temporal and spatial scale. The analyses in the ProLearn and LiKE projects suggest that professional cultures in which local practices are linked with extended networks and circuits of knowledge in a systematic and strategic way seem better equipped to stimulate and support continuous learning among their practitioners. In this respect, the character of knowledge resources and infrastructures is important. In the next section, we discuss how practitioners’ learning and continuing enrolment in their expert culture depend on dynamic relationships with epistemic objects, conceptualized as objectual practice.

23.4.2 Objectual Practice: A Significant Dynamism in Professional Learning

The term objectual practice is used by Knorr Cetina (2001) as a way of accounting for how practitioners not only rely on routine-based actions but increasingly engage in creative-constructive actions of reinventing practice and exploring knowledge beyond what is known. Such processes are mediated by material and semiotic objects, which in our times often have a complex form and incorporate abstract as well as concrete modes of representation. In the ProLearn and LiKE projects we have developed this idea further to explore and conceptualize how knowledge practices and learning is stimulated in a dynamic interplay between subjects and

objects, with a special interest in how practitioners become involved in learning when exploring complex problems by approaching different knowledge resources and identifying unfulfilled opportunities or temporary solutions (Nerland and Jensen 2010, 2012). In what follows we illustrate these mechanisms by highlighting how different knowledge challenges involve professionals in objectual practices; how such object relations give rise to community formation; and how epistemic objects and practices are embedded in wider epistemic contexts.

One aspect of this dynamic is the ways engagement with epistemic objects may stimulate interchanging modes of experimental and confirmative practice. For instance, computer engineers often search for best practices and source codes on the Internet and use these to solve local problems in programming tasks. Such actions are oriented towards closure and lead to a preliminary solution (Lahn 2012). However, when applied as part of larger activities such resources need to be combined and adjusted in ways that also involve analysis and exploration. The collaborative work of identifying best practices and programming patterns to be applied in a software project was by our informants described as a process of negotiation and inquiry, in which the temperature could get high and the discussion quite lively. In such phases, practitioners need to explore and validate the resources at hand, as well as creating imaginary scenarios of what the different choices could imply. Moving back and forth between the confirmative and the explorative was a core driver in their learning, which was mediated and even spurred by the knowledge objects at hand (Nerland and Jensen 2010).

This example also points to another aspect of objectual practice, namely the capacity of complex knowledge objects to invite engagement along short and long timescales simultaneously. Knorr Cetina (2007, p. 373) describes practices that evolve around epistemic objects as geared towards the future, in the sense that they “continually open up new questions and determine new frameworks of knowing”. Such processes do not only call upon practitioners to make use of existing knowledge but also to engage with its possible development in the future. To use another example from computer engineering, programming tasks seemed to be resolved with a twofold attention towards the present and the future. When developing a computer program, the engineers were concerned that it should not only respond to the given specifications, but also be prepared for future changes and incorporate possibilities for adding new functionalities (Nerland and Jensen 2010). Similar dynamics came to the fore in hospital nurses’ work with developing clinical procedures by way of assessing, selecting and translating scientific evidence for local needs. Here, professionals discussed the possible implications of their epistemic choices for different types of practice (Nes and Moen 2010). At the same time, they kept in mind that such procedures are based on the best knowledge available at a certain moment of time, and need to be updated and aligned with new scientific evidence in the future (Nerland and Jensen 2012). In this way, prospective scenarios become both a basis for engagement with objects and incorporated in their materiality, thus contributing to shaping the realms of future practices.

A third aspect of objectual practice is the capacity of epistemic objects to invite and support community formation. By calling attention to unresolved problems and

questions for people to engage in, epistemic objects may bring professionals together and form a focal point to which humans and their visions, epistemic strategies and procedures become interlinked. In our material, we found examples of knowledge communities of temporary character, defined by a specific problem and its possible solutions, as well as communities formed around more enduring knowledge objects. For instance, in nursing, practitioners formed specialized communities devoted to the development of clinical procedures to be used in particular medical contexts, such as the care of patients with lung diseases or prenatal care (Jensen and Christiansen 2012; Nerland and Jensen 2012). These communities span organizational boundaries and involved nurses from different work organisations, librarians, and distributed resources such as databases of research articles. Another example is engineers who form around a certain technology (“I am a J2EE engineer”) and share knowledge of this specialty in web-based environments. Even in teaching, we found related mechanisms at play when a group of teachers formed to examine and further develop research-based guidelines for student assessment to be used across their school (Hermansen and Nerland 2013). Such mechanisms of community formation in object-centred environments are well described in the context of research groups and in technology-driven areas such as hacker communities and the open source movement (Knorr Cetina 1997). Our analyses suggest that community formation around epistemic objects also take place in other types of professional work, which may be interpreted as signs of the suggested “spillover” of epistemic cultures and practices to other areas of social life (Knorr Cetina 2001, 2006).

Finally, an important aspect of objectual practice is the capacity of epistemic objects to link practices across knowledge settings and communities. Epistemic objects are typically shared across sites and levels in expert cultures. They incorporate important features of the knowledge culture in which they are generated, and may at the same time be used for different purposes in local activities. As complex amalgams of material and symbolic resources that constitute knowledge around a problem (Nerland and Jensen 2012), they inform local practice at the same time as this practice is linked with extended knowledge worlds. The outreach of these connections depends on the character of the knowledge challenge in question. Some types of problems and their knowledge relations are, for instance, more nationally bounded, while others are formed by more global circuits of knowledge and have a transnational outreach. In our analyses, we noticed that practitioners whose knowledge cultures included rich material devices and information structures were more in contact with, as well as stimulated by, wider knowledge circuits. For instance, auditors’ practices were linked with national and international standards for risk auditing through the work support system Descartes (Mathisen 2012; Mathisen and Nerland 2012). In a similar vein, nurses came in contact with specialized international communities and their terminologies, knowledge sources and arenas for knowledge sharing through their work on approving and developing clinical procedures (Jensen and Christiansen 2012; Nerland and Jensen 2012). These practices contribute to making professionals’ knowledge engagement visible and provide opportunities for engagement in which knowledge itself forms the object of exploration.

In sum, we would argue that the dynamics of objectual practice place professionals in a position to not only ‘consume’ but also contribute to knowledge production in their professional communities (Knorr Cetina 2001; Meyer and Molyneux-Hodgson 2009). Moreover, through the circulation and engagement with epistemic objects in various contexts, different settings and levels in the expert culture become linked. In this regard, object relations are important not only for learning but also for the continuation and further development of the expert culture. The circulation of and engagement with objects across organisational boundaries creates new challenges as well as new opportunities for learning and epistemic engagement. Understanding these dynamics, we will argue, is important for understanding conditions for professional learning today.

23.5 Conclusion and Suggestions for the Future

This chapter has examined how knowledge cultures shape opportunities for learning in distinct ways, as well as how this relationship of knowledge cultures to learning has been accounted for in research targeting professional education and work. While research on learning in higher education has been dominated by methodologies that target the individual student or practitioner, and research on work-based professional learning has emphasised students’ initiation into single and historically given communities of practice, the situation today calls for more research that examines the processes by which practitioners become enrolled, and manage to stay enrolled, in dynamic and changing knowledge cultures. To address this dimension of professional learning, we introduced ideas and concepts from Social Studies of Science, and especially from the work of Karin Knorr Cetina. This perspective and its analytical resources draw attention to the significant role epistemic objects and infrastructures play in professional’s learning, not only as mediating tools to solve present working tasks but also as structures that link between the local and the global and connect practitioners with wider circuits of knowledge.

Being part of these circuits is increasingly important to stay enrolled in expert cultures whose collective knowledge shifts over time. Moreover, engagement with complex knowledge objects that are shared in the expert culture creates conditions for motivation and desire as well as opportunities to contribute to collective knowledge development. In this respect, we suggest that access to participate in variegated knowledge practices and engage with epistemic objects in professional setting is at least as important for professional learning as more formal educational requirements and activities. Such opportunities may keep the relations between local work settings and the professions’ wider machinery of knowledge construction dynamic, and support the development of practice over time. Hence, these dimensions should be taken into account in our ways of discussing ‘educational systems’ for professional and practice-based learning, as well as in efforts to support such learning.

The chapter has also pointed to a need for more research on these issues, in different professional and educational contexts. Inspired by the differences

identified in our projects, as well as by the studies of Knorr Cetina (1999, 2007) and Kastenhofer (2007), we suggest that further research on knowledge cultures and learning in the professions should focus on the temporal and spatial scale of their activities; the ways in which they de- and recontextualize knowledge; their ways of dealing with complexity and uncertainty; their ways of handling the unforeseen; and their degree of inter- and transdisciplinary reflexivity. For instance, what is the spatial outreach of the learning activities in a given programme or in a work context? To what extent is knowledge represented in universal and ‘global’ forms which travel across sites? To what extent is its validity and use more experience-oriented and generated from below in locally bounded communities? And, to what extent are ways of employing knowledge geared towards unification or towards differentiation?

To address these questions, attention should be focused towards knowledge settings and processes rather than towards individual practitioners and bounded activities. This may also contribute to our understanding of modern societies as such, because, as Knorr Cetina (1999, p. 8) states, “the study of knowledge settings becomes a goal in the attempts to understand not only science and expertise but also the type of society that runs on knowledge and expertise”. At the same time, epistemic cultures and practices cannot be studied at a single analytical site. The examinations undertaken in the ProLearn and LiKE projects bring attention to how professional knowledge cultures are dispersed across a variety of sites, in which people come to participate in multiple ways and the processes and products of different activities are interlinked in complex ‘machineries’ of knowledge construction. In this respect the emergence of new actors and knowledge-verifying organizations, such as professional bodies at transnational levels, clearinghouses, and standard-setting agencies, should be taken into account. These “macro-epistemic” agencies (Knorr Cetina 2007, p. 367) contribute to creating and circulating knowledge objects in their respective expert cultures, which practitioners in different settings may come to explore and develop. While they certainly serve to regulate practice-based learning in distinct ways, they may also provide new opportunities for engagement. Hence, there is a need for research that investigates knowledge cultures and processes across and between sites, and that also traces knowledge-related connections between sites and societal levels. In this regard, recent perspectives on socio-material practices may be helpful (see, for instance, Nespor 1994 and Fenwick et al. 2011).

Finally, given that the latter described research traditions to a small extent have gained footing in research on learning in educational contexts, we suggest that more research should be conducted that focuses on the interplay of knowledge cultures and learning in professional education. The proposed perspective on knowledge cultures spans the education-work divide, as it focuses on the expert culture and its knowledge arrangements rather than on organizational contexts. One interesting question to explore in this regard is how students get access to core epistemic practices and principles in their expert culture by engaging in objectual practices during education.
