Contents of Volume I

1 International Trends in Research: Redressing the North-South Balance in What Matters for Early Childhood Education Research 1
Marilyn Fleer and Bert van Oers

Part I Theoretical Perspectives
Marilyn Fleer and Bert van Oers

2 Governing Childhood 33
Iris Duhn

3 Cultural-Historical and Activity Theories Informing Early Childhood Education 47
Marilyn Fleer and Nikolai Veresov

4 'Humpty Dumpty': Teaching Strategy or Postcolonial Method – What Do We Know About Power, Voice and Identity Within Early Childhood Education in the Twenty-First Century? 77
Karen Martin

5 Engaging with the Conceptual Tools and Challenges of Poststructural Theories 91
Affrica Taylor

6 Early Years Education in the Anthropocene: An Ecophenomenology of Children's Experience 117
Phillip G. Payne

Part II Research Methodologies
Marilyn Fleer and Bert van Oers

7 (Co)-Researching with Children 165
Alma Fleet and Deborah Harcourt

8 Policy Analysis and Document Research 203
Chris Peers

9 A Cultural-Historical Methodology for Researching Early Childhood Education 225
Marilyn Fleer and Nikolai Veresov

10 Narrative Learning of Literacy 251
Pentti Hakkarainen and Marja-Leena Vuorinen

11 Mixed Methods in Early Childhood Education 269
Judith Schoonenboom

12 Current Approaches in Quantitative Research in Early Childhood Education 295
Linda J. Harrison and Cen Wang

Part III Contemporary Research and Evidence – Early Childhood Education Globally: *Western Europe and UK*
Bert van Oers and David Whitebread

13 Quality in Early Childhood Education: The Contribution of Developmental Psychology 319
David Whitebread

14 Neuroscience and Early Childhood Education 335
Lysandra Sinclaire-Harding, Laura Vuillier, and David Whitebread

15 School Readiness in Europe: Issues and Evidence 363
Sue Bingham and David Whitebread

16 Early Childhood Education with Disadvantaged Children: Actions for Success 393
Marta Soler-Gallart and Ainhoa Flecha

17 Professional Development in a Competent System: An Emergent Culture of Professionalization 409
Florence Pirard, Pascale Camus, and Jean-Marie Barbier

Part III Contemporary Research and Evidence – Early Childhood Education Globally: *Eastern Europe*
Elena Kravtsova, Nikolay Veraksa, and Nikolai Veresov

18 Contemporary Research in Early Childhood: Roots and Perspectives 429
Elena Kravtsova, Nikolay Veraksa, and Nikolai Veresov

19 Symbolic Means in the Educational Programs for Preschool Children in Russia 449
Nina Salmina and Aleksander Veraksa

20 Preschool Education in Ukraine 461
Roman Shyyan, Igor Shiyan, and Natalia Sofiy

21 Pedagogical Center "Experiment": The Peculiarities of Preschool Education in Holistic Developing Education (HDE) 475
Bronislav Zeltserman, Margarita Dubina, Margarita Dragile, Maria Pekarskaya, Irina Maluhina, and Inta Baltina

Part III Contemporary Research and Evidence – Early Childhood Education Globally: *Australasian and South Pacific*
Susan Grieshaber

22 Introduction: Early Childhood in the Australasian Region 507
Jane Bone

23 The Historical Emergence of Early Childhood Education Research in Australia 511
Joce Nuttall and Susan Grieshaber

24 Connections Between Early Childhood Policy and Research in Aotearoa New Zealand: 1970s–2010s 531
Anne Smith and Helen May

25 Towards Wawasan Brunei 2035: Early Childhood Education and Development in Brunei Darussalam 551
Hanapi Mohamad, Rosyati M. Yaakub, Emma Claire Pearson, and Jennifer Tan Poh Sim

26 Early Childhood Care and Education in Bangladesh: A Review of Policies, Practices and Research 569
Shukla Sikder and Laila Farhana Apnan Banu

Part III Contemporary Research and Evidence – Early Childhood Education Globally: *Asia*
Liang Li, Yuejuan Pan, and Xiaoying Wang

27 Early Childhood Education Reform: Crisis and Changes 591
Liang Li, Yuejuan Pan, and Xiaoying Wang

28 Early Childhood Education and Development in China 599
Yuejuan Pan, Xiaoying Wang, and Liang Li

29 History and Reform of Early Childhood Care and Education (ECCE) in Japan 623
Xiangying Liu and Chiafen Lin

30 Early Childhood Education and Development in Singapore 649
Sirene May-Yin Lim

31 Vietnam Early Childhood Education 663
Phan Thi Thu Hien

Part III Contemporary Research and Evidence – Early Childhood Education Globally: *Africa*
Joseph S. Agbenyega

32 Examining Early Childhood Education System in Ghana: How Can Bourdieuian Theorisation Support a Transformational Approach to Pedagogy? 673
Joseph S. Agbenyega

33 Rising from the "Ashes": Quality Early Childhood Education as a Panacea for National Development in Sierra Leone 691
Joseph S. Agbenyega, Eleni Athinodorou, and Hilary Monk

Part III Contemporary Research and Evidence – Early Childhood Education Globally: *Canada and the United States*
Artin Göncü and Carollee Howes

34 Early Educational Practices in Canada and the United States 709
Artin Göncü and Carollee Howes

35 Early Childhood Education and Care in Canada 721
Nina Howe, Kathleen Flanagan, and Michal Perlman

36 Early Childhood Teacher-Child Relationships in the United States: Theory, Practices, and Regulation 745
Sandra Soliday Hong and Promjawan Udommana

37 Parent Involvement in US Early Childhood Education: Benefits, Limitations, and Reconceptualizations 767
Angela Pons Clifford and Marisha L. Humphries

Part III Contemporary Research and Evidence – Early Childhood Education Globally: *Latin America*
Rebeca Mejía-Arauz and Gloria Quiñones

38 Early Childhood Education and Development in Latin America 789
Rebeca Mejía-Arauz and Gloria Quiñones

39 Educational Practices and Young Children's Socio-Moral Development: A Cultural Psychological Approach 795
Angela Uchoa Branco, Angela Rabelo Barreto, and Ália Barrios

40 Early Childhood Education in Colombia 815
Francisco José Rengifo-Herrera

41 Early Childhood Education in Chile 825
Rodrigo A. Cárcamo

42 Early Childhood Education in Guatemala 833
María Eugenia Rabbe

43 Early Childhood Education and Development in Mexico 843
Rebeca Mejía-Arauz and Gloria Quiñones

44 Early Childhood Education in Peru 857
Susana Frisancho and María Isabel La Rosa

Part III Contemporary Research and Evidence – Early Childhood Education Globally: *Nordic Region*
Stig Broström, Johanna Einarsdottir, and Ingrid Pramling Samuelsson

45 The Nordic Perspective on Early Childhood Education and Care 867
Stig Broström, Johanna Einarsdottir, and Ingrid Pramling Samuelsson

46 Outdoor Education in the Nordic Region 889
Ellen Beate Hansen Sandseter and Olav Bjarne Lysklett

47 Toddlers in Nordic Early Childhood Education and Care 907
Anne Greve and Ole Henrik Hansen

48 Values in Nordic Early Childhood Education: Democracy and the Child's Perspective 929
Anette Emilson and Eva Johansson

Contents of Volume II

49 New Directions in Early Childhood Education Practice: International Developments and Practice Gaps 955
Marilyn Fleer, Feiyan Chen, and Bert van Oers

Part IV Innovative and Longstanding Programs
Bert van Oers

50 Long-Standing and Innovative Programs in Early Childhood Education: An Introduction 969
Bert van Oers

51 Piramide 995
Irma G.M. Koerhuis (red), Menno Boontje, Herman van Boxtel, Dita Breebaart, and Marieke op den Kamp

52 The 'Golden Key' Program and Its Cultural-Historical Basis 1023
Gennady Kravtsov and Elena Kravtsova

53 The Program of Developmental (Narrative) Play Pedagogy 1041
Pentti Hakkarainen and Milda Bredikyte

54 The Key to Learning Curriculum 1059
Nikolay Veraksa and Galina Dolya

55 Te Whāriki: The New Zealand Early Childhood Curriculum 1075
Ken Blaiklock

56 *Tools of the Mind*: A Vygotskian Early Childhood Curriculum 1095
Elena Bodrova and Deborah J. Leong

57 Developmental Education for Young Children in the Netherlands: Basic Development 1113
Bea Pompert and Marjolein Dobber

Part V Curriculum and Assessment
Geerdina van der Aalsvoort

58 Introduction to the Theme of Early Childhood Curriculum and Assessment ... 1141
Geerdina van der Aalsvoort

59 Curriculum and Assessment in Brazilian Early Childhood Education ... 1147
Maria Malta Campos

60 Review and Reflection on the Curriculum Reform of Early Childhood Education in China ... 1173
Jiaxiong Zhu and Jie Zhang

61 Constructing Early Childhood Curriculum and Assessing Young Children in Israel's Mosaic of Cultures ... 1191
David Brody

62 Developments in Curriculum and Assessment in the Early Years in Australia ... 1211
Susan Grieshaber

63 Supporting the Application of Playful Learning and Playful Pedagogies in the Early Years Curriculum Through Observation, Interpretation, and Reflection ... 1227
Pat Broadhead

64 Making the Case for Playful Learning ... 1245
Hande Ilgaz, Brenna Hassinger-Das, Kathy Hirsh-Pasek, and Roberta Michnick Golinkoff

65 Children's Perspective to Curriculum Work: Meaningful Moments in Finnish Early Childhood Education ... 1265
Lasse Lipponen, Kristiina Kumpulainen, and Maiju Paananen

66 Assessing Young Children's Learning and Behavior in the Classroom: A Complexity Approach ... 1279
Henderien Steenbeek and Paul van Geert

67 Conclusions and Discussion ... 1301
Geerdina van der Aalsvoort

Part VI Pedagogies in Early Childhood Education
Ingrid Pramling Samuelsson and Niklas Pramling

68 Pedagogies in Early Childhood Education ... 1311
Niklas Pramling and Ingrid Pramling Samuelsson

69 F. A. W. Fröbel 1782–1852 1323
Jan-Erik Johansson

70 Educational Tenets of the Highscope Curriculum 1347
Ann S. Epstein and Lawrence J. Schweinhart

71 Developmentally Appropriate Practice in the Twenty-First Century 1379
Kay Sanders and Flora Farago

72 The Waldorf Kindergarten 1401
Sara Frödén and Moira von Wright

73 Developing the Ability of Children to Use and Construct Visual Models 1421
Nikolay Veraksa and Aleksander Veraksa

74 Montessori Education 1439
Christina Gustafsson

75 Pedagogy Has Children's Voice: The Educational Experience of the Reggio Emilia Municipal Infant-Toddler Centres and Preschools 1457
Claudia Giudici and Paola Cagliari

Part VII Child, Families and Communities
Charlotte Højholt

76 Introducing Reflections 1471
Charlotte Højholt

77 Sharing Early Care: Learning from Practitioners 1483
Agnes Andenæs and Hanne Haavind

78 Children, Families, and Communities in Brazil: A Cultural-Ecological Approach to Child-Rearing Values and Practices 1503
Jonathan R.H. Tudge, Gabriela D.F. Martins, Elisa A. Merçon-Vargas, Letícia L. Dellazzana-Zanon, Cesar A. Piccinini, and Lia B.L. Freitas

79 Children's Cultural Learning in Everyday Family Life Exemplified at the Dinner Setting 1525
Mariane Hedegaard

80 Domesticating Markets: Early Years Education and Middle-Class Parenting in India 1541
Henrike Donner

81 Creatively Enhancing Community Transformation Through Work with Children and Families 1563
Fernanda Coelho Liberali and Alzira Shimoura

82 Children Participating and Developing Agency in and Across Various Social Practices 1581
Charlotte Højholt and Dorte Kousholt

83 Towards a Posthuman Developmental Psychology of Child, Families and Communities 1599
Erica Burman

About the Authors

Volume I

Part I Theoretical Perspectives

Editors: Marilyn Fleer and Bert van Oers

Iris Duhn is a senior lecturer in the Faculty of Education, at Monash University, Australia. Her publications and research projects contribute a critical childhood studies' perspective to early childhood education.

Professor Marilyn Fleer holds the Foundation Chair of Early Childhood Education and Development at Monash University, Australia, and was the immediate past President of the International Society for Cultural Activity Research (ISCAR). Her research interests focus on early years learning and development, with special attention on pedagogy, play, culture, science, and technology. More recently she has investigated child development in the contexts of home and school. She is currently a series editor with Ferando Gozalez Rey, Elena Kravtova and Nikolai Veresov for the Springer Cultural-Historical Series (Springer) and Series Editor with Ingrid Pramling Samuelson for International Developments in Early Childhood Education (Springer), and Series Editor with Mariane Hedegaard for Cultural-Historical Transitions in Every Day Life (Bloomsbury).

Bert van Oers (PhD.) is special professor of cultural-historical theory of education at the Department of "Research and Theory in Education" at VU Amsterdam. He specialized in cultural-historical activity theory since the 1970s and is now working at a CHAT (cultural-historical activity theory)-based theory of play and playful learning. His major research interest focuses on the implementation of a play-based curriculum in primary school and the elaboration and evaluation of developmental education. He published about this (among others) in B. van Oers (ed.), Developmental Education for Young Children, Springer, 2012.

Karen L. Martin is an associate professor in the School of Education and Professional Studies at the Gold Coast campus of Griffith University. Her research interests are in the areas of early childhood education, Aboriginal early childhood education, and Aboriginal knowledge and research. A major publication is *Please Knock Before You Enter: Aboriginal Regulation of Outsiders and the Implications for Researchers* (2008). This is a dual award-winning and best-selling book based on Assoc. Prof. Martin's PhD. studies. She is well known in Australia and internationally for her approaches to reconceptualizing and actualizing early childhood education, especially Aboriginal Australian early childhood education.

Affrica Taylor is an associate professor in the geographies of childhood and education at the University of Canberra. Her background in indigenous Australian education and her doctoral studies in cultural geography have shaped her abiding interest in the relations between people, land, and other species in settler colonial societies. She is a founding member of the Common World Childhoods Research Collective (www.commonworlds.net) that explores children's relations with the more-than-human worlds. She discusses these relations in her recent books, *Reconfiguring the Natures of Childhood* and in the coedited collection (with Veronica Pacini-Ketchabaw) *Unsettling the Colonial Places and Spaces of Early Childhood Education.*

Phillip G. Payne is an associate professor in the Faculty of Education at Monash University, Australia. He specializes in environmental and experiential education theory and practice and interpretive approaches to qualitative inquiry. Phillip is currently working on a major project called 'ecopedagogy as/in scapes.' It is a material, realist and empirical development of his theoretical chapter in this handbook.

Part II Research Methodologies

Editors: Marilyn Fleer and Bert van Oers

Alma Fleet has reconceptualized her work/life balance. She supervises PhD. students at Macquarie University and is involved extensively in consultancies related to supporting educational change. She learns from her work with Aboriginal and Torres Strait Islander early childhood teachers and leads others in practitioner inquiry projects and exploring pedagogical documentation. She enjoys publishing with colleagues, in books, journals, and professional resources.

Deborah Harcourt is professor of early childhood at the Australian Catholic University. She is particularly attentive to a research focus that invites children into conversations on matters of interest and important to both children and adults, as part of socializing education and research communities to the UNCRC. She is also interested in the strong links between the co-construction of educational documentation between adults and children and ongoing professional learning.

Linda Harrison is professor of early childhood education at Charles Sturt University and an honorary fellow at the Murdoch Childrens Research Institute. She has a PhD. in developmental psychology (Macquarie University), plus qualifications in early childhood education, and the biological sciences. Her research is primarily quantitative in approach and has addressed a range of issues including children's experiences of childcare/early education; transitions; child socio-emotional, cognitive, and speech-language development; processes within services that underpin the provision of high-quality education and care; and new methodologies. Her work has been widely published, including in *Early Childhood Research Quarterly*, *Child Development*, and *Developmental Psychology*. Linda is associate editor for the *International Journal of Early Childhood* and coeditor of a special issue of the *Early Childhood Research Quarterly* on the Early Development Index (EDI).

Hilary Monk is a lecturer in the Faculty of Education at Monash University, Australia. Originally from New Zealand, she has extensive experience as an early childhood teacher and teacher educator. Dr Monk's research interests include the learning and development that occurs in intergenerational families, the development of culturally relevant research tools to be used when evaluating early childhood programs, child-centered/child-friendly methodologies and the use of visual data generation methods.

Chris Peers is senior lecturer in the Faculty of Education at Monash University in Melbourne, Australia. Chris' research looks at education policy and the formation of educational concepts in Western history.

Judith Schoonenboom holds the chair for empirical pedagogy at the University of Vienna. She specializes in mixed methods in educational research. Judith is an associate editor of the *Journal of Mixed Methods Research*. She has wide experience in designing and evaluating innovations in education, with a special interest in educational technology. Her research interests include mixed methods design and the foundations of mixed methods research.

Marja-Leena Vuorinen is a special teacher in Early Childhood Education in Sotkamo, Finland. Earlier she worked as a researcher in the University of Oulu, Finland, with PhD. Pentti Hakkarainen. Her interests are in narrative learning and teacher's narrative tools.

Cen Wang is a research fellow at the Research Institute for Professional Practice, Learning and Education (RIPPLE), Charles Sturt University. She obtained her PhD. in educational psychology at Ball State University, Indiana, and has expertise in advanced quantitative analysis, especially in analyzing longitudinal data using latent growth curve modeling and growth mixture modeling. Dr. Wang's research focuses on understanding the diverse ways that children learn and achieve academic success and identifying personal and contextual factors that influence students' learning and motivation. Her work has been presented at conferences in the USA, China, and Australia and published in high-impact factor journals such as *Learning and Instruction*, *Developmental Science*, *Early Childhood Research Quarterly*, *Personality and Individual Differences*, and *The Journal of Educational Research.*

Part III Contemporary Research and Evidence: Early Childhood Education Globally

Western Europe and UK
Editors: Bert van Oers and David Whitebread

Jean-Marie Barbier (PhD.) is professor emeritus at the Conservatoire National des Arts et Métiers in Paris, where he founded the center for research on adult education and professionalization (Centre de Recherche sur la Formation). He specialized in adult education and in the analysis of professional activities and positions his research work in the area of collaborative construction of activities and the formation of the subjects within activities. His most recent publications concentrate on the experience of activities and the tools for their analysis. He facilitates entrance activities of students into research, education, and professional activity. He also holds a UNESCO chair for adult education and professional practices ("Formation et pratiques professionnelles").

Sue Bingham (PhD.) is a qualified Montessori teacher and spent over 15 years as a teacher and early years advisor for UK local authorities and a national preschool learning organization. During this time, she engaged with a variety of settings, advising and coaching practitioners in developmental education practice. Subsequently, she became involved in teaching at postgraduate level on the early years and primary PGCE course and on various education- and psychology-related master courses at the Faculty of Education, University of Cambridge, while completing her research doctorate there into children's emotional and social development in the early years and how teachers can best support this within classroom settings. Recent work includes working with newly qualified teachers in a range of UK-independent and UK-maintained schools in articulating and evaluating "developmental education" specific to a variety of London school contexts.

Pascale Camus (PhD. student) has been working as advisor in education in a public administration in Wallonia-Brussels Federation (Belgium) where she is in charge of questions linked to inclusion of children with special needs (Office de la Naissance et de l'Enfance, ONE). She has worked as assistant at the Department of Education and Training at the University of Liège from 2010 to 2014. She is currently involved in a doctoral thesis on how very young children take part in the everyday life of a childcare service. Her publications are focused on the challenges of professionalization and quality in childhood education.

Ainhoa Flecha (PhD.) is professor in sociology at the Autonomous University of Barcelona. Her research focuses on community-based conceptions of education and learning, particularly on the learning communities and the impact of family involvement on students' educational performance with a particular focus on vulnerable groups and gender. This work has been published in the *European Journal of Education* (2012) and *Qualitative Inquiry* (2014), among others. She participated in the FP6 INCLUD-ED project, coordinating a team of researchers working on the analysis of family education and health literacy actions.

Florence Pirard (PhD.) has been professor at the Department of Education and Training, at the University of Liège (Wallonia-Brussels Federation, Belgium) since 2010, but has worked in the early childhood education field for 25 years first as a researcher and then as an advisor in education in a public administration (Office de la Naissance et de l'Enfance). Her publications are focused on the initial training and professional development of practitioners in the early childhood education and care. She specialized in the accompaniment of the implementation of curriculum.

Lysandra Sinclaire-Harding (PhD. student) is a teacher (ADHD specialist); doctoral researcher in psychology, neuroscience, and education at the University of Cambridge; and associate lecturer at Birkbeck, University of London. Her research and teaching practice is dedicated to young people displaying complex emotions and behaviors in class and who may be struggling to learn.

Marta Soler-Gallart (PhD.) is professor in sociology and director of the Centre of Research in Theories and Practices that Overcome Inequalities, CREA, at the University of Barcelona. Her areas of research include the study of language and literacy, dialogic reading, and communicative acts, on which she has published in coauthorship with John Searle (*Lenguaje y ciencias sociales*, Hipatia, 2004) after she graduated from Harvard. She is currently the main researcher of the Horizon 2020 project "SOLIDUS. Solidarity in European Societies: Empowerment, Social Justice and Citizenship" and has published about this in journals such as *Cambridge Journal of Education* (2013) and *Current Sociology* (2014).

Bert van Oers (PhD.) is special professor of cultural-historical theory of education at the Department of "Research and Theory in Education" at VU Amsterdam. He specialized in cultural-historical activity theory since the 1970s and is now working at a CHAT-based theory of play and playful learning. His major research interest focuses on the implementation of a play-based curriculum in primary school and the elaboration and evaluation of developmental education. He published about this (among others) in B. van Oers (ed.), *Developmental Education for Young Children*. Springer, 2012.

Laura Vuillier (PhD.) is currently working as a postdoctoral research associate in the Department of Psychology at the University of Cambridge. Laura received her PhD. at the University of Cambridge in the Departments of Psychology and Education. She also has a master of science in neuropsychology and a bachelor in bioengineering from the University of Toulouse, France. Laura's research interests include emotions, their regulation, and their interaction with cognition. Laura has experience in working with various clinical and nonclinical populations (children, ADHD, bipolar disorder) using electroencephalography. She is also interested in researching how to bridge the gap between neuroscience and education. She has published numerous peer-reviewed articles on these topics.

David Whitebread is acting director (external relations) of the Centre for Research on Play in Education, Development and Learning (PEDL), at the University of Cambridge, UK. He is a developmental cognitive psychologist and early years spe-

cialist. Before entering higher education, he taught in early years and primary schools for 12 years, mainly in Leicestershire, England. His research interests are concerned with young children's development of metacognitive and self-regulatory abilities and the implications for early years and primary education. Recent and current research projects have examined the roles of language, social interaction, and play in these important aspects of development. His publications include *Teaching and Learning in the Early Years* (4th Ed. 2015, Routledge) and *Developmental Psychology and Early Childhood Education* (2012, Sage).

Eastern Europe
Editor: Nikolai Veresov

Inta Baltina has been working for Pedagogical Centre "Experiment" since 1993. She works as a math and logic teacher with preschool children and with students in classes from 1 to 12. In 1983, she completed her speciality "Teacher of Math and Physics" in Daugavpils Pedagogical University (Latvia). In 1995, she received her MAT degree from the University of Latvia. She is the author of the program "Introduction of elements of Maths for pre-school children in developmental system of education."

Margarita Dragile began to study in Pedagogical Centre "Experiment" when she was 4. Since 2003, she has been working for the center as a teacher of aesthetic cycle. In 2010, she obtained her higher education in culturology sphere from Saint Petersburg University of the Humanities and Social Sciences (Russia). She completed the courses of organization and management and was educated within the framework of the program of improvement of professional skills in the system of developmental education (2008 and 2013, Riga, Latvia, Pedagogical Centre "Experiment"). She is the author of the program "Playing Gymnastic" for development of dance abilities, coordination of movements and musical taste for small children (2–5 years old), and comprehensive lessons for development of imagination for children of 5–8 years old. She is also the author of popular articles for parents about features of lessons at home. She is the curator of individual educational projects.

Margarita Dubina has been working for Pedagogical Centre "Experiment" since 1990. In 1971, she completed her speciality in "Analytical Chemist and Teacher of Chemistry" from Dnipropetrovsk National University (Ukraine). In 1994, she completed a 3-year course in Kharkov (Ukraine) with the specialism of "Developmental Teaching in Primary School" (D. Elkonin-V. Davidov system). In 1999, she got her MAT (master of arts in teaching) degree from the University of Latvia. She is the author of the course "Introduction of elements of the learning activity during the preparation of children for school." She is a teacher of the courses "Development of Creative Thinking" and "Developmental Games" for preschool children. In primary school, she teaches maths, and in secondary school – chemistry. She is the author of projects concerned with after school-hour activities, methodology, and articles about teaching and upbringing.

Elena Kravtsova is the head of L.S. Vygotsky Institute of Psychology of Russian State University for the Humanities. She has got an experience of work in system of the Russian Academy of Education (since 1972 till 2005). She received her first PhD. degree in Moscow in 1981 and started her academic career in the Institute of Preschool Education of the Russian Academy of Education. She has published 7 books and more than 80 articles in Russian, English, and Portuguese languages. Her sphere of interest are cultural-historical psychology of L.S. Vygotsky, periodization of mental and personal development, and problems of the relationship of learning and development. Elena Kravtsova is one of the authors of education program "Golden key," "Master," "Discovery" for the children of infants, preschool, primary school, and adolescence. In addition, she has developed special courses of training and retraining teachers and psychologists.

Irina Maluhina has been working for Pedagogical Centre "Experiment" since 1995 as a teacher of developmental computer games. She works with children of age 3–10. Her first education is engineering; then in 2006, she obtained her pedagogical education from the University of Latvia (Riga, Latvia). Her areas of interest are development in early years and using IT in studying process. She is coauthor of projects concerned with off-hour activity and curator of educational projects.

Maria Pekarskaya has been working for Pedagogical Centre "Experiment" since 2002. In 1999, she got her degree of master of psychology from Daugavpils Pedagogical University (Latvia), and in 2012 from the International Higher School of Psychology, Riga (Riga, Latvia), where she received her professional bachelor's degree of higher education program (level 5). In Pedagogical Centre "Experiment," she realizes the program of psychological support of preschool children and students. She is the author of the program "Development of Cognitive Activity and Communication" and conducts lessons by sand therapy.

Nina Salmina is a doctor of psychology (1988) and honored professor of the Faculty of Psychology, Lomonosov Moscow State University. Her areas of interest are development in early years, developmental programs for preschool children, and developmental games.

Igor Shiyan is a chairperson of the Laboratory of Child Development in Moscow City University (2009 till now). He graduated from Moscow State Teacher Training University (Department of Psychology and Education) in 1987 and obtained PhD. in psychology in 1995. He was teaching psychology in Moscow State Teacher Training University (1992–2004) and Moscow City University of Psychology and Education (2004–2009). During 2000–2011, he was invited as a visiting professor to the University of Central Arkansas (USA). He published 5 over 60 articles available in Russian, English, and Ukrainian languages. His areas of interest are early child development, cultural-historical theory, and cognitive psychology.

Roman Shyyan is head of Lviv Regional In-Service Teacher Training Institute (1992–2000, 2005 till now). He graduated from Ivan Franko State University of Lviv in 1982 (now National University of Lviv). He obtained his PhD. in biology in

1990. He was engaged as a consultant on several international projects on education policy, which were implemented countrywide under the Soros Foundation, UNDP, World Bank, European Commission, Ministry of Foreign Affairs of Poland, and Ministry of Education and Science of Ukraine projects (since 2002), and was listed with the International Step by Step Association (1997–2000). He is coauthor of several textbooks for educators on education policy, school self-evaluation, and lifelong learning. His areas of expertise are education policy analysis, project design and implementation, and professional development of educators.

Natalia Sofiy is a director of the Ukrainian Step by Step Foundation (USSF), which is a member of the International Step by Step Association (1998 until now). The mission of the USSF is to promote the changes in the system of education toward child-centered, inclusive education. She graduated from the National Pedagogical Dragomanov University in Kyiv (1987). She was an international consultant of Open Society Foundations in developing models of early childhood and inclusive education in such countries as Azerbaijan, Bangladesh, Bhutan, and Tajikistan. She worked as a team leader of the World Bank's project "Equal access to quality education" (2008–2010). She is coauthor of several manuals for educators on inclusive education, community schools, and leadership. Her areas of expertise are inclusive education, early childhood education, leadership, and professional development.

Aleksander Veraksa is a doctor of psychology (2014) and associate professor of the Faculty of Psychology, Lomonosov Moscow State University, and vice-president of Russian Psychological Society. He is a several-time winner of the President of Russia Grant for Talented Young Scientists as well as Lomonosov Moscow State University awards for research activity and has an experience of guiding 11 national research projects in developmental psychology. His areas of interest are preschool education, symbolic mediation in childhood, and cultural-historical approach.

Nikolay Veraksa is doctor of psychology, professor, and dean of the Faculty of Psychology of Education, Russian State University for the Humanities, professor of Moscow State Pedagogical University, and leading expert of Federal Institute of Education Development of Russia. He has a vast experience of teaching and research project organization in early years education (Cuba, Czech Republic, Mexico, Poland, Portugal, the UK, Ukraine, the USA, Russia, etc.). Under his supervision, more than 35 PhD. were defended. His areas of interest are child psychology, dialectical thinking, and methodology of psychology.

Nikolai Veresov is an associate professor of the Faculty of Education, Monash University, Australia. He has an experience as a day care center and kindergarten teacher (1987–1991) and secondary schoolteacher (1982–1987). He finished his first PhD. degree in Moscow in 1990 and started his academic career in Murmansk (Russia) as a senior lecturer (1991–1993) and head of the Department of Early Childhood (1993–1997). The second PhD. was obtained in the University of Oulu (Finland) in 1998. From 1999 to 2011, he had been affiliated to the Kajaani Teacher Training Department (Finland) as a senior researcher and the scientific director of the international projects. He published 5 books and over 60 articles available in 10

languages. His areas of interest are development in early years, cultural-historical theory, and genetic research methodology.

Bronislav Zelcerman is a founder and scientific supervisor of Pedagogical Centre "Experiment," Riga, Latvia. He developed a model of developmental education based on the ideas of D. Elkonin and V. Davidov known as developmental teaching. He also drew upon the methodology of G. Shchedrovitsky to create a system of activity thinking. He is the author of more than 90 works about problems in education, game forms in teaching, and principles of the different age student development. He teaches the subject "development of thinking and activity" and conducts individual educational projects in secondary school and qualification courses for teachers.

Australasian
Editor: Sue Grieshaber

Laila Farhana Apnan Banu is a development professional working in the field of education development. She has worked in different capacities at BRAC University, the Aga Khan Foundation's Early Childhood Development Support Project, and the Bangladesh Government's sector-wide program for primary education PEDP3, mostly focusing on expanding disadvantaged children's alternative educational opportunities. Apnan is currently working as education officer at UNICEF Bangladesh. Her portfolio involves early learning and preprimary education, primary education, teacher education, inclusive education, parenting education, nonformal/second chance education, mother tongue-based multilingual education, and education in emergencies. Her research interests include language and literacy education; early childhood care, development, and education; equity and disparity issues in education; and inclusive education.

Jane Bone is involved in research in the area of early childhood education in Australia (and formerly in New Zealand). Her expertise is in holistic and alternative approaches to pedagogy and learning, including research involving Steiner-, Montessori-, and Reggio Emilia-based preschools. Her main research area explores spirituality in early childhood settings and is internationally recognized. This research involves sensitive areas of research about values and beliefs.

Susan Grieshaber is professor of early years in the Faculty of Education at Monash University, Melbourne, Australia. Her research interests include early childhood curriculum, policy, pedagogy, and families; qualitative research methodologies; and women in the professoriate. She has published widely and is foundation coeditor of the internationally renowned journal *Contemporary Issues in Early Childhood*.

Helen May is emeritus professor of education at the University of Otago, New Zealand. Her research interests are in early childhood policy, history, and curriculum. She has been involved in advocacy work and advisory roles across a range of early childhood policy initiatives in both New Zealand and international settings.

She is the author of a number of books including *The Discovery of Early Childhood* (1997, 2013), *Politics in the Playground* (2001, 2009), *School Beginnings* (2006), *I am Five and I Go to School 1900–2010* (2011), and (with B. Kaur and L. Prochner) *Empire, Education, and Indigenous Childhoods* (2014).

Hanapi Mohamad works as lecturer in early childhood education at the Universiti Brunei Darussalam. His research explores on creativity in early childhood education, with a particular focus on how to promote creativity in the classroom.

Joce Nuttall is a research professor in the Learning Sciences Institute Australia at Australian Catholic University, where she is director of the Teacher Education, Quality and Professional Practice research program. Joce's research describes, implements, and theorizes effective formative interventions in professional learning in early childhood education, particularly in childcare.

Emma Pearson currently works as senior lecturer in early childhood education at the Universiti Brunei Darussalam. Her research explores social and cultural contexts of young children's learning and development, with a particular focus on how these can and should be incorporated in both policy and practice.

Shukla Sikder is a PhD. student in the Faculty of Education, Monash University, Australia. Her thesis is on infant-toddler development of scientific concepts through play activities as part of everyday family practices. Her research interests include play, family practices, infant-toddler age group, child development, and early childhood science using cultural-historical theory.

Anne Smith (1940–2016) was professor emeritus at the University of Otago and adjunct professor at Southern Cross University, New South Wales. Formerly director of the Children's Issues Centre, she was involved in teaching, research, policy development, and advocacy about children and childhood since the 1970s. In 2011, Anne was a member of the Ministry of Education Early Childhood Taskforce. She published *Children's Rights Towards Social Justice* in 1916. Her other books include *Children's Voices*, *Children as Citizens*, *Learning in the Making*, and *Global Pathways to Abolishing Physical Punishment.*

Jennifer Tan currently works as senior lecturer in languages and literacy education at the Universiti Brunei Darussalam. Her research explores out of school literacy practices and teacher education and professional development, with a particular focus on reflective practices.

Rosyati M. Yaakub is a research assistant at the Sultan Hassanal Bolkiah Institute of Education, Universiti Brunei Darussalam. She is a speech-language pathologist holding a M.Ed. in early childhood education and care.

Asia
Editors: Liang Li, Yuejuan Pan and Xiaoying Wang

Phan Thi Thu Hien is currently a lecturer at Ho Chi Minh City University of Education (Vietnam). Her teaching and research interests include early childhood education, early childhood teacher education, and cultural-historical theory.

Liang Li PhD. (2012), ME (EC), ME (TESOL International), Grad. Dip. ECE, B. Law, is a senior lecturer teaching undergraduate and postgraduate students and an early career researcher in the Faculty of Education at Monash University, Australia. Her research interests focus on play and pedagogy, child development, cultural world of babies and toddlers, family study, early childhood teacher education, and visual methodology. Liang publishes nationally and internationally (contact: liang.li@monash.edu).

Sirene Lim is currently a senior lecturer at the SIM University, developing a locally awarded full-time early childhood degree program while volunteering with a center catering to disadvantaged children and families. Prior to this, she has worked in the Ministry of Education and at the National Institute of Education teaching a range of preservice, in-service, and research students. She continues to contribute toward strengthening the local community of early childhood professionals in Singapore.

Chia-Fen Lin is deputy director of the Master Program of Youth and Child Welfare, School of Continuing Education, Chinese Culture University, Taiwan, ROC. Her recent book is *Theory and Practices of Service Marketing in Cultural and Educational Industries: Examples of Chinese Preschool Edu-care Institutions* (Psychology Press, 2011).

Xiangying Liu is professor in the Department of Childhood Education, Faculty of Education at Fukuyama City University in Japan. Her areas of teaching and research are comparison of early childhood education and care system in East Asia, language development and education of bilingual children, and early childhood teacher education. She also created and published many picture books for infants in Japan in addition to the study.

Yuejuan Pan is an associate professor in Beijing Normal University. Her research interests focus on early childhood education quality and evaluation, play and kindergarten curriculum, and early math education. Currently, she directs a project on assessment of school readiness in math and a project on meta-evaluation of kindergarten quality evaluation system. She was awarded Beijing Higher Education Young Elite in 2013 by the Beijing Municipal Commission of Education and BNU Young Elite in 2014 by Beijing Normal University.

Xiaoying Wang is a professor in preschool and school education in the Faculty of Education at Northeast Normal University. She is a doctoral tutor, deputy director of the training center for principals of kindergarten education, and training department director with the Ministry of Education. She is a committee member of the

Preschool Education Experts Guidance Committee of the Ministry of Education and committee member of the World Organization for Early Childhood Education (OMEP) in China. She is a deputy director of the Health Education Professional Committee of the Chinese Preschool Education Research Association. She serves as an editor of *Studies in Early Childhood Education*.

Africa and Middle East
Editor: Joseph Agbenyea

Joseph S. Agbenyega is senior lecturer in early childhood inclusive education at Monash University Faculty of Education. His research focuses on developmental disabilities, cultural diversity, and teacher professional learning.

Eleni Athinodorou has recently completed a PhD. examining the nature of early childhood and the constraints and possibilities for preschool education in postwar Sierra Leone. Eleni is currently a lecturer at the Orthodox Christian College in Sierra Leone, West Africa, where she lectures on a range of early childhood subjects. She has worked as a kindergarten teacher in Australia, Hong Kong, and China and managed a range of children's services including family day care and center-based care in Australia and early childhood principal in China. Eleni is the author of three children's books and has been a consulting writer for several resources for preservice teachers. She was also a reviewer of appeals for the National Childcare Accreditation Council (NCAC), Canberra, Australia.

North American
Editors: Artin Göncü and Carollee Howes

Angela Pons Clifford (PhD.) has been an early childhood educator and teacher researcher for 17 years in both urban and rural areas of the USA. She currently teaches in South Carolina where she also serves as a mentor to new and interning teachers and as a member of leadership teams at the school and district level. Dr. Pons Clifford received her bachelor of arts in early childhood education from the University of South Carolina Aiken and master of arts in instructional leadership and PhD. in educational psychology from the University of Illinois at Chicago. Her interests include parent involvement, inquiry-based instructional practices, and early childhood curriculum and instruction.

Kathleen Flanagan has more than 40 years' experience in child and family policy, with a concentration in early childhood education and care. Her involvement includes teaching experience in early childhood education in both Canada and the USA. She has led interministerial initiatives and government task forces at the provincial government level and intergovernmental initiatives and negotiations focused on early learning and childcare agreements. An educational and social policy consultant since 2005, her recent work has focused on strategic policy design, curriculum development, and policy and program reviews at the provincial, regional, national, and international levels. She co-led You Bet We Still Care! – Canada's

national research on human resource issues in the childcare sector. She was the architect of Prince Edward Island's new system of early years centers and is currently (2015) leading Manitoba's Child Care Commission. She has authored numerous reports and studies and regularly presents at provincial and national conferences. Kathleen is a PhD. candidate at the Ontario Institute for Studies in Education (OISE) at the University of Toronto, specializing in the early years.

Artin Göncü (PhD. 1983) is professor emeritus at the University of Illinois at Chicago where he served as the chair of the Department of Educational Psychology (2006–2009) and taught courses in child development, sociocultural approaches to human development, practicum in early childhood education, and play and its role in education. Dr. Göncü's research illustrates the role of cultural and social contexts in human development and education. His specific research projects focus on the development of imaginative play during childhood, parents' and teachers' roles in child development, professional development of early childhood teachers, as well as the role of play in adult education and development. Dr. Göncü served as an editor of *Mind, Culture, and Activity: An International Journal*. His editorial board memberships include *Child Development*, *Human Development*, *Early Childhood Research Quarterly*, *American Educational Research Journal*, *Early Education and Development*, *International Journal of Behavioral Development*, and *Bogazici University Journal of Education* and board memberships of the Jean Piaget Society and Center for Child Culture at Ankara University, Turkey. Dr. Göncü's publications include *Analyzing Children's Play Dialogues*, *Play and Development*, *Children in Play, Story and School*, and *Children's Engagement in the World*.

Sandra Soliday Hong is an investigator at the Frank Porter Graham Child Development Institute at the University of North Carolina, Chapel Hill. Her research examines the association between the quality of early care and education and the school readiness and social development of low-income children and dual language learners, with a focus on implications for quality rating and improvement systems.

Nina Howe is a professor of early childhood and elementary education at Concordia University, Montreal, and holds a Concordia University research chair in early childhood development and education. She is also a principal member of the Centre for Research in Human Development at Concordia University. She teaches in both B.A. programs (early childhood and elementary education and child studies) and at the graduate level (M.A. program in child study, PhD. in education) and has been an active supervisor of graduate students. Dr. Howe's areas of research interest include the socio-emotional development of preschool and school-aged children, sibling relationships (particularly pretense, conflict, teaching), children's play, and early childhood education (e.g., professional development for early childhood educators). She has published numerous articles, and her work has been continuously supported by a number of granting agencies for over 25 years (e.g., Social Science and Humanities Research Council of Canada).

Carollee Howes is a professor emerita and research professor in human development and psychological studies at the University of California at Los Angeles. She is also director of the Center for Improving Child Care Quality at the UCLA. Her research interests are in the area of very young children's development of interpersonal relationships, children's experiences in childcare and preschool, and interventions for caregivers and teachers of young children. Howes has published in numerous journals including *Child Development*, *Developmental Psychology*, *Zero to Three*, *Social Development*, and *Early Childhood Research Quarterly*. Her recent books include *A Matter of Trust: Connecting Teachers and Learners in the Early Childhood Classroom* and *Culture and Child Development in Early Childhood Education: Practices for Quality Education and Care* published by Teachers College Press and *The Promise of Pre-K*, *Foundations for Teaching Excellence: Connecting Early Childhood Quality Rating, Professional Development, and Competency Systems in States*, *Dual Language Learners in the Early Childhood Classroom*, and *Effective Professional Development in Early Childhood Education* all published by Brooks.

Marisha L. Humphries (PhD.) is an associate professor in the Department of Educational Psychology and a licensed clinical psychologist. She received her bachelor of science in psychology from Howard University and her master of arts and PhD. in clinical psychology from the University of Illinois at Chicago. Dr. Humphries' research seeks to develop an integrated approach to studying African-American children's normative and prosocial development and utilizing this basic research to create culturally and developmentally appropriate school-based behavior promotion programs. Her work examines African-American children's emotional and social competence and the ways in which schools can support children's development in this area. Due to her interest and experience in applied research, Dr. Humphries' work considers the contextual and cultural factors associated with children, families, and schools.

Michal Perlman has a PhD. in developmental psychology from the University of Waterloo. She is an associate professor of applied psychology and human development at the University of Toronto and is also cross appointed at the School of Public Policy and Governance. Dr. Perlman studies issues related to quality in early childhood education and care (ECEC) including how it should be defined and measured as well as the links between different aspects of ECEC program quality and child outcomes. She has worked with different levels of government in Canada and the USA to explore how ECEC quality measurement can be used for monitoring and quality improvement purposes. Dr. Perlman's interests focus on the quality of interactions between ECEC staff and children but also on how interaction patterns between different family members impact the development of young children.

Promjawan Udommana specializes in early childhood development and education in diverse cultures and is currently a school licensee of Melodies International Kindergarten, Bangkok, Thailand. She is also a director of Child connect: center for educational research and consultation. There, she publishes early childhood-related articles and organizes seminars for parents and teachers.

Latin America
Editors: Rebeca Mejía-Arauz and Gloria Quiñones

Alia Barrios is psychologist and doctor of psychology in human development processes and health and serves as professor of psychology at Higher Education Institute of Brasília, Brazil. Her areas of teaching are human development and education. Her researches are focused on moral development.

Angela Uchoa Branco works at the Institute of Psychology, University of Brasilia, Brazil. She carried out research projects, from a cultural semiotic constructivist approach, concerning early child education and development, as well as the role of communication and metacommunication processes in different aspects of human development. Her research team investigates the microgenesis and ontogenesis of human values, moral development, and social interactive patterns among children, adolescents, and adults, published in various international journals and volumes. In 2004, she edited with Dr. Jaan Valsiner the book *Communication and Metacommunication in Human Development* (Info Age Publishing) and, in 2012, the book *Cultural Psychology of Human Values* (Info Age Publishing).

Rodrigo A. Cárcamo is associate professor of developmental psychology in the School of Psychology at the University of Magallanes, Punta Arenas, Chile. He received his doctorate in the Center for Child and Family Studies at Leiden University, the Netherlands, where he is currently guest researcher. His research has focused on childcare, attachment relationships, and quality of the early childcare programs [rodrigo.carcamo@umag.cl].

Susana Frisancho is faculty professor at the Department of Psychology, Pontificia Universidad Católica del Perú. She obtained the PhD. in psychology from Fordham University, New York. Her areas of speciality are cognitive development and moral development, constructivism, moral education, and construction of knowledge. Her recent work and publications focus on moral identity and justice in persons with moral and social commitment, on moral reasoning of indigenous wise persons and leaders, as well as on students' beliefs about human rights.

Rebeca Mejia-Arauz is faculty professor and researcher in the Department of Psychology, Education, and Health at ITESO University, Guadalajara, Mexico. She obtained the doctoral degree in developmental psychology from the University of California, Santa Cruz, M.Sc. in social psychology from the London School of Economics, and a speciality in cognitive development from ITESO University. Her line of research focuses on sociocultural and cognitive development, specifically on processes of social interaction, participation, and communication for learning. Current projects involve children's literacy development in urban Mexico, children's out of school practices in urban and indigenous contexts, and cultural and intergenerational family transformations affecting children's participation in cultural activities and their education and development.

Maria Eugenia Rabbe is a psychologist with a specialization in preschool education and educational administration. She has been a university teacher and worked in preschool education for more than 20 years. Her special interest is going to investigate the relationship between process to learn and the cognitive development especially in preschool students.

Francisco José Rengifo-Herrera is a Colombian-born psychologist. Over the last decade, he did research and teaching in the area of developmental and educational psychology. He obtained his master's in cognitive psychology and learning at the Universidad Autónoma de Madrid, and in recent years, he has been working from a semiotic and cultural approach. Rengifo-Herrera received his doctorate in human development and health from the joint graduate program of the University of Brasilia, Brazil, in 2014. His work research seeks to understand the development of social values in Colombian and Brazilian children about violence, peace, collaboration, and competition. Francisco was professor at different Colombian's universities; until March of 2014, he worked with the University of Ibagué. From April of 2014, he is substitute teacher at the University of Brasilia (address: Rua 19 Norte, Lote 05, Apartamento 1505, Águas Claras, Distrito Federal, 71,915–000, Brasilia, Brazil [email: frengifo@unb.br]).

María Isabel La Rosa is faculty professor at the Department of Psychology, Pontificia Universidad Católica del Peru (PUCP). She obtained the master in developmental and educational psychology from the Universidad Autónoma de Barcelona (UAB). Her areas of speciality are educational psychology, construction of knowledge, learning and teaching strategies, teaching teachers, and mentoring. Her recent works focus on microteaching in higher and basic education.

Gloria Quiñones is a lecturer in the Faculty of Education, Monash University, Australia, and member of the Child and Community Development Faculty Research Group. Her research interest focuses on play, pedagogy, emotions, and visual methodologies. Gloria is coauthor with Avis Ridgway and Liang Li for the book *Early Childhood Pedagogical Play: A Cultural-Historical Interpretation Using Visual Methodology* (2015), Springer.

Nordic
Editor: Stig Broström, Johanna Einarsdottir, and Ingrid Pramling Samuelsson

Stig Broström is professor in early childhood education at Aarhus University, Department of Education, Denmark. His main areas of research are based on cultural-historical activity theory related to preschool, transition to school, the first years in school, curriculum theory, children's play, social competence, democracy, and friendship.

Feiyan Chen is an assistant professor of Early Childhood Education at California State University, Fresno, United States. She has been in the field of early childhood education and development across diverse cultural contexts for about 20 years. Her research interests focus on early years learning and development, with special atten-

tion on social-emotional development, cultural-historical studies, pedagogy, culture, and visual methodology.

Johanna Einarsdottir is a professor of early childhood education and the dean of School of Education, University of Iceland. She received her PhD. in early childhood education, from the University of Illinois in 2000. She has been involved in several international research projects as a researcher and a consultant in her areas of expertise and published together with international colleagues. Recently, she has been conducting research on children's views on their preschool education and transition and continuity in early childhood education. She is on the board of trustees of the European Early Childhood Research Association.

Anette Emilson has a PhD. in pedagogy and works as a researcher in the field of early childhood education at the Linnaeus University in Sweden. Her research interest is directed toward values education in preschool as well as the communication between teachers and children. She has also a background as a preschool teacher.

Anne Greve is associate professor in early childhood education at Oslo and Akershus University College of Applied Sciences, at the Faculty of Education and International Studies, Norway. Her main areas of research are based on education and care for the youngest children in preschool, peer relations and friendship, play, and teacher's professional identity.

Ole Henrik Hansen is associate professor in early childhood education, at Aarhus University, Department of Education, Denmark. His main areas of research are based on education and care for the youngest children in preschool, professional care and interactions between preschool teachers and children, the correlation between social and cultural stimulation, and the child's mental development.

Eva Johansson is professor of education, at the Department of Early Childhood Education, University of Stavanger, Norway. She is an experienced researcher in the field of early childhood education with an extensive research and publication profile in the area of values education, issues of democracy, and children's morality. She is leading a Nordic research project, Values education in Nordic preschools: Basis of education for tomorrow supported by NordForsk.

Olav B. Lysklett is an associate professor in physical activity and health at Queen Maud University College in Trondheim, Norway. His main area of teaching is physical education for preschool teachers. His main research subjects are children's physical activity in preschools and the characteristics of nature and outdoor preschools (sent by Johanna in 17/9/2014).

Ingrid Pramling Samuelsson is professor of early childhood education at the Department of Education, Communication and Learning at the University of Gothenburg, Sweden. Her main research field is young children's learning and curriculum questions of early years education. Her many research studies of children's learning and play in the preschool context have led to the development of a didactics approach, labeled developmental pedagogy. One of her most popular books is *The Playing-Learning Child* (originally in Swedish, but also translated to German),

which is based on the idea that children are playing-learning individuals and preschool didactics needs to integrate play and learning. Her latest research concerns children's possibilities to learn in relation to group size. She has been a UNESCO chair in early childhood education and sustainable development, was the former world president, and is now senior advisor of the OMEP (Organisation Mondiale pour l'Èducation Préscolaire).

Ellen Beate Hansen Sandseter is an professor (PhD.) in the Department of Physical Education at Queen Maud University College (DMMH) of Early Childhood Education in Trondheim, Norway. Her primary research focus is on children's physical play, outdoor play, and risky/thrilling play among children in early childhood education and care (ECEC) institutions. She has cooperated with early childhood researchers from both England and Australia to study cultural differences in provision of outdoor and risky play in ECEC settings. She has also been involved in a study of Norwegian children's experiences of participation and well-being in Norwegian ECEC institutions as well as a project mapping all child accidents and injuries in Norwegian ECEC institutions.

Volume II

Part IV Innovative and Long-Standing Programs

Editor: Bert van Oers

Ken Blaiklock (PhD.) is a senior lecturer in the Department of Education at the Unitec Institute of Technology in Auckland, New Zealand. He has worked extensively in teacher education at the early childhood and primary school levels. His research interests focus on language and literacy development, assessment, and the comparative study of different early childhood curricula. He has published on these topics in a range of academic journals.

Elena Bodrova (PhD.) is currently the director for Research and Development at Tools of the Mind and a research fellow at the National Institute for Early Education Research at Rutgers University. Her work on applying Lev Vygotsky's theory to education started in Russia where she worked in the Institute for Preschool Education. Dr. Bodrova is the author of multiple articles and book chapters on early literacy, assessment, play, and self-regulation. Dr. Bodrova holds PhD. in child development and educational psychology from Russian Academy of Pedagogical Sciences and M.A. in child development and educational psychology from Moscow State University, Russia.

Menno Boontje is managing director of Cito's Piramide Approach and CEO of Cito Deutschland GmbH in Solingen, Germany. He has 21 years of experience as the Netherlands-based, international marketing and sales manager for Nienhuis

Montessori, a worldwide leading manufacturer of premium quality Montessori materials. He was responsible for export and marketing management as well as new business and product/concept development. Mr. Boontje joined Cito International in 2008, and as unit manager, he coordinates the international dissemination and adaptation of Cito's Piramide Approach to Early Learning.

Milda Bredikyte (PhD.) is associate professor at the Department of Developmental and Educational Psychology at Lithuanian University of Educational Sciences, Vilnius. She teaches courses on child development and narrative learning in play and Vygotskian theory of cultural development in childhood. She is the senior researcher and coordinator of research activities in the Research Laboratory of Play (LUES). Her research interests include cultural development and the impact of play on child development. M. Bredikyte is the author of several articles and book chapters on children's play.

Dita Breebaart (M.Sc.) received her training as an educator/teacher at the University of Amsterdam. She is an acknowledged education specialist in the development and training of the Piramide Approach. She has been involved in the development of new materials for Piramide from the beginning. In addition to training teachers in the Piramide Approach, she provides Piramide training for trainers in the Netherlands and in Germany. She provides ongoing support and coaching for teachers and trainers. Dita Breebaart has a special interest in working with the Piramide projects.

Marjolein Dobber (PhD.) is assistant professor at the Department of Theory and Research in Education at VU Amsterdam, and she works as a teacher educator and researcher at "De Activiteit," the Dutch center for developmental education. Her main research interest is the theoretical and empirical advancement of developmental education, for example, by studying the role of the teacher in promoting inquiry-based learning.

Galina Dolya (PhD.) is the curriculum director of Key to Learning, which has developed an innovative Vygotskian approach to early years education. She is an acknowledged expert on the practical application of Vygotsky's theory of learning and development. She has worked at every level from early years to university and trained hundreds of teachers and trainers worldwide. Currently, she is a researcher at the Pedagogical Academy of Preschool Education, Moscow. She is based in the UK.

Pentti Hakkarainen (PhD.) is professor of developmental and educational psychology at Lithuanian University of Educational Sciences, Vilnius, and professor (emeritus) in educational sciences at the University of Oulu, Finland. He has studied cultural development and motivation in play and learning. He published in cooperation with Milda Bredikyte *Introduction to Developmental Play Pedagogy, 2014* (in Finnish).

Irma Koerhuis (M.Sc.) is project manager of the Piramide Approach in the Netherlands. She was trained as an elementary schoolteacher and went on to earn her master's degree in language and culture studies at Tilburg University.

Subsequently, she developed the Alfa approach to adult literacy and taught Dutch as a second language at all levels. Her interest in education reaches beyond applied linguistics; she is particularly interested in a holistic approach to teaching that integrates all developmental areas in a cohesive framework powered by play. Irma Koerhuis is currently involved as project manager of Piramide e-learning programs for the Dutch. Her Piramide mission is to empower teachers as intentional educators of young children.

Gennady Kravtsov (PhD.) is the head of psychology of personality department of L.S. Vygotsky Institute of Psychology. He is well-known specialist in methodology of cultural-historical psychology, particularly interested in the problems of personality, volitional behavior, and child psychology. G. Kravtsov is the head of research group, engaged in developing educational programs, based on the theory of L.S. Vygotsky, for children of preschool, primary school, and teen ages.

Elena Kravtsova (PhD.) is director and head of projective psychology department of L.S. Vygotsky Institute of Psychology. She is one of the authors of the "Golden Key," "Master," and "Opening" educational programs for children of different psychological ages. Her researches into the periodization of psychological and personal development, zone of proximal development, and developmental educational environment are direct outcomes of the cultural-historical approach traditions. Among her other research interests are the problems of psychologists' and cultural-historical psychology specialists' training.

Deborah J. Leong (PhD.) is professor emerita of psychology at Metropolitan State University of Denver. She taught for 36 years in the Psychology Department and in the Department of Education. Dr. Leong developed Tools of the Mind approach with Dr. Bodrova with whom she has written numerous books, articles, and educational videos on the Vygotskian approach to psychology and the development of play. Tools of the Mind was named an exemplary educational program by the International Bureau of Education at the UNESCO, United Nations in 2001. Dr. Leong has written several books on early childhood assessment with Drs. McAfee and Bodrova. She has her PhD. from Stanford University and her M.Ed. from Harvard University.

Marieke op den Kamp (M.Sc.) is an early childhood specialist at Cito. She authored numerous Piramide publications and instructional materials. She has extensive knowledge and experience with the Piramide Approach to early childhood education and its dynamic system theory foundations. In addition, she developed several evaluation instruments to assess young children's mathematical, language, and motor development. She taught in primary school and studied educational sciences at Utrecht University. Marieke op den Kamp has a special interest in the application of research results to guide and inspire professionals in early childhood education.

Herman van Boxtel (PhD.) is an associate professor in developmental psychology at the Department of Developmental Psychology at Utrecht University (UU). Dr. van Boxtel specializes in cognitive development, intelligence, giftedness, and test construction. His work with Cito focuses on evaluating the quality of psychological and educational tests and on research of educational programs. Dr. van Boxtel has contributed to the growing body of evidence-based research in support of the Piramide Approach to Early Learning, a renowned Dutch preschool educational method.

Bert van Oers (PhD.) is special professor of cultural-historical theory of education at the Department of Theory and Research in Education at VU Amsterdam. He specialized in cultural-historical activity theory since the 1970s and is now working at a CHAT-based theory of play and playful learning. His major research interest focuses on the implementation of a play-based curriculum in primary school and the elaboration and evaluation of developmental education. He published about this (among others) in B. van Oers (ed.), *Developmental Education for Young Children.* Springer, 2012.

Bea Pompert (M.Sc.) was trained as an educationalist/pedagogue at VU Amsterdam. She is an acknowledged specialist in developmental education, an educational concept based on the Vygotskian cultural-historical activity theory (CHAT). Currently, she is a teacher trainer at "De Activiteit," the Dutch center for developmental education. She published many books, articles, and book chapters on curriculum development and teacher training in developmental education schools. Her special interests are play and literacy, content-based literacy, and inquiry-based education.

Annette Sibley (PhD.) is president and CEO of Quality Assist, a US-based company. She has extensive experience in research and evaluation and professional development for early childhood teachers. Dr. Sibley is coauthor of the *Assessment Profile for Early Childhood Programs*, an evaluation tool for early childhood programs, and has established numerous in-depth professional development programs including the *Partners in Quality Mentor Course* and the *Challenging Teachers Institute.* Under Dr. Sibley's leadership, Quality Assist is the US-authorized Piramide professional development provider and has developed a series of Piramide e-learning courses. Quality Assist has established itself as a leader in e-learning innovations that amplify engagement and individualize learning for adults from diverse populations including teachers, administrators, and parents.

Nikolay Veraksa (PhD.) is doctor of psychology, professor, and dean of the Faculty of Psychology of Education, Russian State University for the Humanities, professor of Moscow State Pedagogical University, and leading expert of the Federal Institute of Education Development of Russia. He has a vast experience of teaching and research project organization in early years education (Cuba, Czech Republic, Mexico, Poland, Portugal, the UK, Ukraine, the USA, Russia, etc.).

Part V Curriculum and Assessment

Editor: Geerdina van der Aalsvoort

Pat Broadhead (PhD.) is the recently retired professor of playful learning at Leeds Metropolitan University. Her research into playful learning spanned a period of 25 years with numerous journal publications, articles, and several books. Much of the research was undertaken jointly with teachers and early years practitioners. Her most recent book was co-researched and coauthored with a teacher and is entitled *Understanding Young Children's Learning Through Play: Building Playful Pedagogies* (Broadhead, P., and Burt, A., 2012, Routledge). She has developed and refined an observational tool called "the Social Play Continuum." This is designed to reveal the levels of sociability and cooperation in young children's play and to make informed pedagogical decisions about how scaffolding and resource provision might increase those levels, especially in open-ended play environments, also known in her work as "the whatever you want it to be place."

David Brody (PhD.) is the academic dean and chair of the Early Childhood Department at the Efrata College of Education in Jerusalem, Israel. He has been a leading figure in Israeli early childhood education for the past 20 years. His research interests include supporting early childhood educators in dealing with emotionally laden topics, gender balance in early childhood education, professional development of teachers and teacher educators, and the community of learners as a format for professional development. His recent book, *Men Who Work with Young Children: An International Perspective* (2014, IOE Press), focuses on the issue of gender balance in early childhood settings.

Maria Malta Campos (PhD.) is a senior researcher at the Department of Educational Research, Carlos Chagas Foundation, São Paulo, Brazil; a professor of the graduate program in education at the Catholic University of São Paulo; and the president of the NGO Ação Educativa. Graduated in pedagogy at the Catholic University of São Paulo, she has a PhD. in sociology. She has published books, chapters of books, and academic articles on the education and care of small children, quality of education, and educational policies.

Roberta Michnick Golinkoff (PhD.) the Unidel H. Rodney Sharp professor at the University of Delaware, has won numerous awards including the Guggenheim Fellowship, the Urie Bronfenbrenner lifetime achievement award from the American Psychological Association, the James McKeen Cattell Fellow Award for lifetime achievement in applied psychological research from the Association for Psychological Science, and the Francis Alison Award, the highest honor at her university. Her research is supported by federal grants and has resulted in over 150 articles and 13 books. She is an expert on language development, playful learning, and children's early spatial knowledge. She is passionate about the dissemination of psychological science and cofounder of the Ultimate Block Party movement to celebrate the science behind play. She speaks all over the world.

Brenna Hassinger-Das (PhD.) is a postdoctoral researcher in the Department of Psychology at Temple University in Philadelphia, Pennsylvania. Her research focuses primarily on developing interventions to improve academic outcomes for high-risk students in the areas of language and mathematics.

Kathy Hirsh-Pasek is the Stanley and Debra Lefkowitz faculty fellow in the Department of Psychology at Temple University where she serves as director of the Infant Language Laboratory. She is the recipient of the American Psychological Association's Bronfenbrenner Award for Lifetime Contribution to Developmental Psychology in the Service of Science and Society, the American Psychological Association's Award for Distinguished Service to Psychological Science, the Association for Psychological Science James McKeen Cattell Award for a lifetime of outstanding contributions to applied psychological research, and the APA Distinguished Lecturer Award as well as the Temple University Great Teacher and the University Eberman Research Award. She was also a finalist for the 2013 Best Professor of the year for the American Academy of Education Arts and Sciences Bammy Awards. Kathy received her bachelor's degree from the University of Pittsburgh and her PhD. from the University of Pennsylvania. Her research has resulted in 12 books and over 200 publications. She is a fellow of the American Psychological Association and the American Psychological Society and served as the associate editor of *Child Development.* She also served as treasurer, is on the governing board, and is the president-elect of the International Society for Infant Studies. Her book, *Einstein Never Used Flash Cards: How Our Children Really Learn and Why They Need to Play More and Memorize Less* (Rodale Books), won the prestigious *Books for Better Life Award* as the best psychology book in 2003.

Hande Ilgaz (PhD.) is an assistant professor in the psychology department at Bilkent University (Ankara, Turkey). She received her PhD. in developmental psychology from Lehigh University (PA, USA). She has worked extensively in several federally funded intervention projects that feature play and language components. These interventions were aimed at improving the language abilities of children from low socioeconomic backgrounds through activities that involved play components such as story enactment and guided play. Her research interests focus on pretend play as a learning context and its relation to children's language (vocabulary, narrative) and socio-cognitive development. Her work regarding play and child development has appeared in *Cognitive Development*, *American Journal of Play*, as well as edited books and encyclopedias.

Kristiina Kumpulainen (PhD.) serves as a professor of education at the Department of Teacher Education, University of Helsinki, Finland. Her research focuses on the cultural, relational, and emotional nature of human learning and development. She has examined tool-mediated learning and communication in various settings, including early childhood centers, schools, museums, and teacher education settings. She has also addressed methodological questions in the analysis of social interaction in collaborative and creative learning practices. Her current research centers on learning across contexts, playful and technology-mediated cre-

ative learning, positive pedagogy, learner agency and identity, resilience, as well as visual participatory research.

Lasse Lipponen is a professor of education, with special reference to early childhood education, at the Department of Teacher Education, University of Helsinki. His research work is directed to playful learning and technology-mediated learning, understanding children's experiences and perceptions in their lifeworld with digital documentation, and teacher education.

Maiju Paananen is a PhD. candidate at the University of Helsinki. She is interested in transnational and local early childhood policies.

Henderien Steenbeek (PhD.) is associate professor at the Department of Developmental Psychology at Groningen University, the Netherlands. In addition, she works as a professor at the Teacher College at the University of Applied Studies in Groningen. In her work, she focuses on child-adult and child-child interaction in play-educational settings. Her research themes are children's learning processes in primary education (with a focus on children with special needs and excellent performing children) and the dynamics of children's play. Most of her studies are focused on the observation of interaction behaviors in naturalistic circumstances (http://www.rug.nl/staff/h.w.steenbeek/research).

Promjawan Udommana specializes in early childhood development and education in diverse cultures and is currently a school licensee of Melodies International Kindergarten, Bangkok, Thailand. She is also a director of Child connect: center for educational research and consultation. There, she publishes early childhood-related articles and organizes seminars for parents and teachers.

Geerdina van der Aalsvoort (PhD.) is a professor at the Teacher College of Saxion University of Applied Sciences, the Netherlands. In addition, she works as lecturer at Groningen University, the Netherlands (http://www.rug.nl/staff/G.m.van.der.aalsvoort/research). Her main research work is focused on early childhood education with regard to the topics of play, early numeracy, and science. She has edited several books with coauthors on the development of methodology that allow analysis of social interaction during teaching and learning. She serves at several editorial boards and has written numerous articles.

Paul van Geert (PhD.) is a professor of developmental psychology at the Groningen University in the Netherlands since 1985. He has had a pioneering role in the application of dynamic systems theory to a broad range of developmental areas, including early language development and second-language acquisition, cognitive development in the context of learning-teaching processes, and social development including social interaction and identity. His main aim is to better understand the general nature of developmental dynamics, i.e., nature of the mechanisms that drive and shape a developmental process in an individual, as the individual, given his or her biological properties and potentialities, interacts with his or her actively explored and transformed environment. He has been fellow at the Center for Advanced Study in the Behavioral Sciences and has held visiting professorships at

the Universities of Torino (Italy), Paris V and Reims (France), and Trondheim (Norway) and Harvard University (Mind-Brain-Education program). For his research and an overview of his artwork, see www.paulvangeert.nl.

Jie Zhang (PhD.) is a senior lecturer of the Department of Early Childhood Education at East China Normal University, where she received her doctoral degree. During her graduate training, she spent a year studying at Arizona State University, USA. Her research are focused on curriculum, assessment, teacher professional development, and cross-cultural study in the field of early childhood education, which are also her current areas of teaching in the university. Her publications in international journals and books include *Contemporary Trends and Developments in Early Childhood Education in China (coauthored with Jiaxiong Zhu, 2008)* and *Approaches to Promoting Creativity in Chinese, Japanese and US Preschools (coauthored with Joseph Tobin and Akiko Hayashi, 2011).*

Jiaxiong Zhu (PhD.) is a professor of the Department of Early Childhood Education at East China Normal University. As a famous scholar in China, he has been not only a board member of some international and Chinese research associations but also an editorial board member of several academic journals. Among his publications in international journals are *Contemporary Trends and Developments in Early Childhood Education in China (2008)* and *Early Childhood Teacher Education in China (2008).*

Part VI Pedagogies in Early Childhood Education

Editors: Ingrid Pramling Samuelsson and Niklas Pramling

Paola Cagliari Graduated in Pedagogy, she worked as teacher in the preschools from 1978 to 1985, later on as pedagogista and from 2010 she is the Director of the Istituzione Preschools and Infant-Toddler Centres of the Municipality of Reggio Emilia. She is one of the members of the Scientific Committee of the Foundation Reggio Children – Centro Loris Malaguzzi. She participated in research projects with Italian and international universities and research centers. She has contributed to professional development events and conferences as a keynote speaker, and she has published essays about the educational experience in Reggio Amelia and topics related to childhood in Italian and foreign magazines.

Ann S. Epstein is the senior director of curriculum development at HighScope Educational Research Foundation in Ypsilanti, Michigan, where she has worked since 1975. Her areas of expertise include curriculum development, professional development, research and program evaluation, and instrument development. Dr. Epstein has published numerous books and articles for professional and practitioner audiences, including *The Intentional Teacher*; *Essentials of Active Learning in Preschool*; *The HighScope Preschool Curriculum*; *Me, You, Us: Social-Emotional Learning in Preschool*; and *Numbers Plus Preschool Mathematics Curriculum*, and

is coauthor of *Tender Care and Early Learning: Supporting Infants and Toddlers in Child Care Settings*, *Supporting Young Artists*, and *Small-Group Times to Scaffold Early Learning*. Dr. Epstein is a key developer of COR Advantage, an observational assessment of children from infancy through kindergarten and the Program Quality Assessment for measuring teaching practices and program management. She has a PhD. in developmental psychology from the University of Michigan and a master of fine arts degree from Eastern Michigan University.

Flora Farago is a doctoral student in family and human development at Arizona State University. She was born in Budapest, Hungary, and moved to Texas in 1998, where she earned her B.A. and M.S. degrees in psychology at the University of Texas at Dallas. Her research interests center around issues of prejudice and stereotype development in children, antibias curricula, and inclusive education in early childhood. She is particularly interested in mixed methods research.

Sara Frödén is a senior lecturer in education at Örebro University, Sweden. She previously worked as a preschool teacher and she received her PhD. in 2012. Her thesis focuses on the material and spatial dimension in the Waldorf kindergarten's practice in relation to gender, age, and spirituality. Her current research is on multicultural and feminist pedagogies, both in early childhood education and in higher education, and also on children's rights in education. She is one of the members of the Scientific Committee of the Foundation Reggio Children – Centro Loris Malaguzzi. She participated in research projects with Italian and international universities and research centers. Key note speaker in professional development events and conferences, she published essays about the educational experience in Reggio and about topics related to childhood in Italian and foreign magazines.

Claudia Giudici Graduated in Psychology, she worked from 1995 to 2007 as pedagogista and in 2009 she has been appointed as Chairperson of the Istituzione Preschools and Infant-Toddler Centres of the Municipality of Reggio Emilia. From 2016 she is President of Reggio Children s.r.l. She has coordinated, participated and collaborated in research projects with Italian universities and Italian and international research centres. Key note speaker in study seminars, conferences and professional development courses, she is the author of articles and essays published in magazines and publications in Italy and abroad.

Christina Gustafsson is professor emerita of education at Uppsala University and research director of educational sciences at the University of Gävle. She started as a classroom researcher and spent a couple of decades to evaluation as a theoretical and practical matter. For many years, she has participated in various kinds of evaluations related to education, curriculum studies, and educational sciences. For the past 20 years, she has devoted herself to research regarding higher education issues, mainly in teacher training. A parallel interest has throughout the whole career been education built on children's/students' activity in general and Montessori education in particular.

Jan-Erik Johansson is professor emeritus in early childhood education at the Department of Early Childhood at the Oslo and Akershus University College of Applied Sciences in Oslo, Norway. His main areas of research are research in pre-school teacher education, studies of young children in early childhood education, and the history of early childhood education in Sweden and the Nordic countries.

Niklas Pramling is professor of education at the Department of Education, Communication and Learning, University of Gothenburg. He is a member of the LinCS (Linnaeus Centre for Research on Learning, Interaction and Mediated Communication in Contemporary Society), a national center of excellence funded by the Swedish Research Council. He leads a national research school for preschool teachers (FoRFa). His research interests include how preschool teachers and children communicate about various phenomena. In particular, he is interested in such communication in the context of aesthetic domains such as music and literary arts. Another interest he is currently pursuing is how children, with and without adults such as preschool teachers, engage with new technologies designed for making music and stories, respectively.

Ingrid Pramling Samuelsson is professor of early childhood education at the Department of Education, Communication and Learning at the University of Gothenburg, Sweden. Her main research field is young children's learning and curriculum questions of early years education. Her many research studies of children's learning and play in the preschool context have led to the development of a didactics approach, labeled developmental pedagogy. One of her most popular books is *The Playing-Learning Child* (originally in Swedish, but also translated to German), which is based on the idea that children are playing-learning individuals and pre-school didactics needs to integrate play and learning. Her latest research concerns children's possibilities to learn in relation to group size. She has been a UNESCO chair in early childhood education and sustainable development and was the former world president of the OMEP (Organisation Mondiale pour l'Èducation Préscolaire).

Kay Sanders is professor of child development at Whittier College. Dr. Sanders received her PhD. at the UCLA Graduate School of Education and Information Studies, specializing in human development and psychology. She teaches a selection of undergraduate courses for the child development major/minor at Whittier College. Before becoming a professor, Dr. Sanders was a teacher of young children and a program director of childcare programs located in poor, urban communities. This past work with young children who were recent immigrants and/or members of language, ethnic, and racial minority groups is the driving force behind her work as a researcher. Her research focuses on the social and emotional development of young children who are ethnic/racial minorities and community-based practices associated with childcare quality.

Lawrence Schweinhart is an early childhood program researcher and speaker throughout the world. He has conducted research at the HighScope Educational Research Foundation in Ypsilanti, Michigan, since 1975 and served as its president from 2003 to 2013. He has directed the HighScope Perry Preschool Study through

age 40, the Michigan School Readiness Program Evaluation, HighScope's Head Start Quality Research Center, and the development and validation of the Child Observation Record. Dr. Schweinhart received his PhD. in education from Indiana University in 1975. He and his wife have two children and five grandchildren.

Aleksander Veraksa completed his PhD. in psychology in 2008 from Lomonosov Moscow State University (MSU). Currently, he works as an assistant professor at the Faculty of Psychology of MSU and holds a position of a vice-president of Russian Psychological Society. His main interests focus on symbol usage in children in different activities: learning, play, sport, etc. He is doing research on youth sport concerning possibilities of symbolic mediation implementation in training process (Moscow, Russia, 125,009, Mokhovaya street, 11/9 (Faculty of Psychology, Lomonosov Moscow State University)).

Nikolay Veraksa (PhD.) holds a doctorate in psychology. He has been a professor since 1996. Currently, he is a dean of the Faculty of Psychology and Pedagogy of Russian State University for the Humanities, professor of Moscow State Pedagogical University, and a leading scientific researcher of the Federal Institute of Education Development. As a student, he was supervised by A. Leontiev, D. Elkonin, and P. Galperin and worked together with A. Zaporozhets, L. Venger, and N. Poddiakov. For more than 40 years, he is doing theoretical and empirical research in dialectical thinking of children and adults, creativity of children, and methodology of psychology. He has a rich experience of international cooperation with universities from different continents: Santiago de Cuba Pedagogical University, Autonomous University of San Luis Potosi, University of Central Arkansas, etc. He is a scientific advisor for the most popular preschool education program in Russia known as "From Birth to School". More than 30,000 preschools have been established. He is a coauthor with Galina Dolya-Higgins of the program called, "Key to Learning". This program has been introduced into England, Wales, Scotland, Poland, India, Singapore, etc. (Moscow, Russia, 117,588, Litovsky bulvar, 34–53).

Moira von Wright PhD., is Professor of Education, currently engaged at the Ersta Sköndal Bräcke University College in Stockholm. Her research examines intersubjectivity, the educational situation, and the conditions of participation, reconciliation, and individual formation. She is also involved in academic leadership and the development of higher education, e.g., as previous Vice Chancellor of Södertörn University.

Part VII Child, Families, and Communities

Editor: Charlotte Højholt

Agnes Andenæs is professor of psychology at the University of Oslo, Norway. She teaches courses in qualitative research methods. Her own research investigates the everyday life of different kinds of children have been a common feature. For

decades, she has collaborated with Hanne Haavind in elaborating more context-sensitive ways of understanding care and development. See also special issue of *Nordic Psychology* ("Everyday Life in Psychology," 2011) and "Chains of Care: Organising the Everyday Life of Young Children Attending Day Care."

Erica Burman is professor of education, at the Manchester Institute of Education, School of Environment, Education and Development, University of Manchester, UK; visiting professor at the University of the Witwatersrand, South Africa; visiting professor in the Instituto de Psicologia at the Universidade de São Paulo, Brazil; visiting professor in Cibersomosaguas, Facultad de Ciencias Politicas y Sociologia, Universidad Complutense de Madrid, Spain; and adjunct professor of Oslo and Akershus University College, Norway. She cofounded (in 1990 with Ian Parker) the Discourse Unit (www.discourseunit.com), a transinstitutional, transdisciplinary network researching the reproduction and transformation of language and subjectivity, which draws on Foucauldian (as well as feminist, Marxist, psychoanalytic, and postcolonial) ideas as a key resource. Erica works on critical developmental and educational psychology, feminist theory, childhood studies, and conceptualizing and challenging state and interpersonal violence in relation to minoritized women and children (see erica.burman@manchester.ac.uk and www.ericaburman.com). She is an activist researcher and methodologist who is currently engaged in a range of practical projects on welfare cuts, models of the posthuman, and, in particular, challenging modes of psychologization under neoliberalism. She is also a group analyst and registered member of the UK Council of Psychotherapists (UKCP).

Letícia Dellazzana-Zanon is a psychologist, having graduated in 2001 from the Pontifical Catholic University of Rio Grande do Sul (PUCRS). She received a master's degree (2008) and a doctoral degree in psychology (2014) from the Federal University of Rio Grande do Sul (UFRGS). She is currently a CAPES scholar at the Department of Psychology, San Franciso University, Brazil. Her research interests are family psychology; human and moral development, more specifically, siblings' relationships; and life projects.

Lia Beatriz de Lucca Freitas is an associate professor at the Institute of Psychology at the Federal University of Rio Grande do Sul in Brazil. She gained her PhD. in psychology from the University of São Paulo. Her main interests are in moral development, the construction of values, and the development of gratitude in children and adolescents. She has authored The Production of Ignorance at School and The Theory of Morality in Jean Piaget's Work: An Unfinished Project, both published in Portuguese. She was a visiting scholar at the University of North Carolina at Greensboro, USA, in 2004 and 2010 (email address: lblf@ufrgs.br).

Henrike Donner is a senior lecturer in anthropology at Oxford Brookes University. Her research interests include gender and kinship, urban politics, and activism. She is the author of *Domestic Goddesses: Maternity, Globalization and Middle-class Identity in Contemporary India* (2008) and editor of *Being Middle-class in India: A Way of Life* (2011) and *The Meaning of the Local: Politics of Place in Urban India* (with Geert De Neve, 2006).

Hanne Haavind is professor of psychology at the University of Oslo, Norway. Her research interests concern parenting and care arrangements for children as well as children's developmental trajectories and engagement in social transitions. The meanings that get attached to gender and to age are central to her understanding the interface of persons' activities and their social circumstances. Her collaboration with Agnes Andenæs on the study of children's everyday life covers a period of three decades. See also special issue of *Nordic Psychology*, Everyday Life in Psychology, 2011; Loving and Caring for Small Children: Contested Issues for Everyday Practices.

Mariane Hedegaard is professor in developmental psychology and head of the Centre for Person, Practice, Development and Culture at the University of Copenhagen. She has a senior research fellowship at the Department of Education, Oxford University. In 2010, she was awarded a doctorate honoris causa by the Pablo de Olavide, Seville. Her research interests include children's activities across different institutional practices. She has authored and coedited 25 books, 11 in English, including Daniels, H. and Hedegaard, M. (Eds.) (2011) *Vygotsky and Special Needs Education: Rethinking Support for Children and Schools*; Hedegaard, M., Edwards, A., and Fleer, M. (Eds.) (2012) *Motives in Children's Development: Cultural-Historical Approaches*; and Hedegaard, M. and Fleer, M. (2013) *Play, Learning, and Children's Development: Everyday Life in Families and Transition to School* (www.marianehedegaard.dk).

Charlotte Højholt is professor at the Department of Psychology and Educational Studies, Roskilde University. The focus of her research is children's everyday life across contexts as families, schools, kindergartens, institutions for children's leisure time, and special help arrangements – as well as the cooperation between parents, teachers, pedagogues, psychologists, and other professionals. She works with point of departure in theoretical concepts about social practice, participation, and subjectivity. The work is aimed at methodological development in relation to creating knowledge through cooperation between researchers and different groups of professionals and users and thereby contributing to – and anchoring knowledge in – the development of social practice. She has published books and articles in the areas of development, learning, professionalism, interdisciplinary work, and methodology, including the 2012 coedited volume: *Children, Childhood, and Everyday Life* (Information Age Publishing) and a number of articles together with Dorte Kousholt as, e.g., Participant Observation of Children's Communities – Exploring Subjective Aspects of Social Practice, *Qualitative Research in Psychology*, 11: 316–334, 2014.

Dorte Kousholt is associate professor at the Department of Education, Aarhus University. Her research interest is children's and families' everyday life, children's communities in different institutional contexts, and parenthood in relation to children's everyday life. She works with outset in theoretical concepts about social practice, participation, conflictual communities, and conduct of everyday life. Methodologically, she works with practice research – research arranged as collab-

orative research processes involving researcher, professionals, children, and parents. She has published on children's everyday life across contexts and children's communities, parental cooperation, family life, and collaborative methodology, including, e.g., Researching Family Through the Everyday Lives of Children Across Home and Day Care in Denmark, Ethos 39(1) 98–114, 2011, and a number of articles together with Charlotte Højholt as Participant Observation of Children's Communities – Exploring Subjective Aspects of Social Practice, *Qualitative Research in Psychology*, 11: 316–334, 2014 (email: mariane.hedegaard@psy.ku.dk).

Fernanda Coelho Liberali has a PhD. in applied linguistics from the postgraduate program of applied linguistics in the Pontifical Catholic University of São Paulo (PUC-SP), where she has worked as a professor and researcher since 2000. She holds a fellowship from Conselho Nacional de Desenvolvimento Científico e Tecnológico, a national funding agency. She was the Brazilian representative for the International Society for Cultural and Activity Research (2009–2011 and 2013–2014). From 2012 to 2014, she participated in the Global Perspectives on Learning and Development with Digital Video-Editing Media: A Qualitative Inquiry in Everyday Lives of Marginalized Young People, a project with four international universities, funded by the Marie Curie Actions – International Research Staff Exchange Scheme (IRSES). Together with Cecília Magalhães, she coordinates the Research Group Linguagem em Atividades no Contexto Escolar. Besides, she acts as a consultant for the Secretariat of Education of the city of São Paulo and for some private schools. Her main research interests are related to school management, teaching-learning processes, citizenship education, performance, multiliteracy, and multiculturality, with an emphasis on multimodal argumentation. She has published articles, chapters, and books in Portuguese, English, and German (http://lattes.cnpq.br/0046483605366023. liberali@uol.com.br).

Gabriela Dal Forno Martins is an assistant professor at the Federal University of Rio Grande do Sul and a collaborating researcher at the Center for Children and Families of the Federal University of Rio Grande do Sul, Brazil. She has professional and research experience in the areas of child development and education, especially on the following topics: parents' and educators' child-rearing practices and beliefs, children's socio-emotional development, psychological interventions in the context of early childhood education, the functionality of play in childhood, and evolutionary developmental psychology.

Elisa Avellar Merçon-Vargas is a doctoral student at the University of North Carolina at Greensboro, USA, currently studying the development of gratitude and materialistic values among children and adolescents from different countries. She also holds a M.S. in psychology from the Federal University of Espírito Santo, in Brazil. Her research interests are in the areas of child and adolescent development, immigration, human rights, and ethnic minority population.

Cesar A. Piccinini is an associate professor and the director of the Institute of Psychology at the Federal University of Rio Grande do Sul, Brazil. He gained his PhD. degree from the University of London (UK). His main research interest is in subjective and behavioral aspects of parent-child interactions in different developmental contexts, such as prematurity, postpartum depression, chronic disease, HIV/AIDS, and pregnancy in adolescence (email: piccinini@portoweb.com.br).

Alzira Shimoura holds a bachelor's degree in English-Portuguese translation (1987), a bachelor's degree in English language and literature (1989), a M.A. in applied linguistics and language studies, and a PhD. in applied linguistics and language studies from the Pontifical Catholic University of São Paulo (2005). Currently, she is an assistant professor at Fecap (School of Commerce Foundation Alvares Penteado) and a professor at the extramural courses of the Pontifical Catholic University of São Paulo. Her areas of interest are teacher training, mainly in the following areas: teacher and coordinator training, critical thinking, genre, teaching-learning, and didactic material production (http://lattes.cnpq.br/6063516845320629).

Jonathan Tudge is a professor of human development and family studies at the University of North Carolina at Greensboro, USA. He gained a B.A. (history) from Lancaster University and an MPhil (sociology) from Oxford and moved from the UK to the USA for his PhD. (developmental psychology) at Cornell. He is interested in cultural influences on children's development and is the author of *The Everyday Lives of Young Children: Culture, Class, and Child Rearing in Diverse Societies* (Cambridge, 2008). He is currently studying links between autonomy relatedness and the development of values, including gratitude and materialism, in different societies.

Chapter 1
International Trends in Research: Redressing the North-South Balance in What Matters for Early Childhood Education Research

Marilyn Fleer and Bert van Oers

Abstract Knowledge construction in early childhood education has tended to be dominated by perspectives on what matters for countries in the Northern hemisphere, with limited attention being directed to the research needs and activities of countries in the Southern hemisphere. This chapter seeks to redress this situation by reviewing the content of the first volume of the handbook with a north-south analytical framework in mind. The outcomes of this analysis are focused around: What are the research trends evident, what methods are primarily drawn upon, and what theories have framed the studies and the findings? This analysis draws upon cultural-historical theory, notably Hedegaard's model of societal, institutional and personal perspectives for the holistic study of what matters. In order to understand the research landscape being presented regionally and internationally, the societal and institutional practices of specific countries, along with the activity settings of early childhood education, also require examination. These conditions give context to the research needs of a community, and shape how answers to pressing problems are framed, and findings theorised. It is argued in this chapter that 'First World problems' have colonised the international early childhood vista and distorted research trajectories and narratives around what counts as valuable knowledge for the field. In contrast, the theoretical contradictions and political contexts of countries in the south have generated exciting problems that make visible important international developments currently blind to the north. Diversification and the relations between play and learning were central problems identified in the analysis. From an international perspective, the maturity of early childhood research rests on what is currently evolving in the majority world and not those of the well-resourced north. This chapter seeks to make a scholarly contribution by making visible an analysis of the activities of countries in the north and south with a view to theorising new perspec-

tives on what constitutes a more balanced view of international research in early childhood education.

Keywords Theories • Research • Global perspective • Regional advances • Play and learning • Diversity

1.1 Introduction

This handbook brings together material from renowned scholars and emerging researchers who have been instrumental in generating scholarly knowledge in the field of early childhood education and development across the globe. In particular, this handbook captures both the long-standing well-known contributions made by leading early childhood researchers, but also those who are currently paving new directions and giving new insights into what may be possible for the future. This latter group may not be as well known due to their geographical location (e.g. northern vs. southern continent) or their relatively recent emergence within the field of early childhood education. However, their works have made a significant contribution to this handbook. As such, the content of this handbook gives a broader north-south representation than is usually achieved, and as a result, the content of the handbook is much more representative of research within the global context of early childhood education. It was an important and deliberate quest of the international editors to give a greater voice to those regions of the world that have been traditionally under-represented and through this to balance the presentations of knowledge and knowledge construction of research in early childhood education.

To achieve the goals of this handbook, in this first volume are presented current and emerging theoretical perspectives that have shaped or are shaping research in early childhood education and development around the globe. Conceptualising the theories that guide early childhood education within regions, countries and even local systems has been and continues to be under critique and in the process of development as the field of early childhood education has itself become more knowledgeable and politically active (see Taylor, Chap. 5, this volume). Through the continued deepening of its theoretical base, the field of early childhood education has moved beyond a representation of a singular view of child development that has privileged some cultural groups (see Göncü and Howes – Chap. 34, this volume), colonised others (see Martin, Chap. 4, this volume) or made invisible key cultural practices in particular communities (see Taylor, Chap. 5, this volume). An analysis of trends in how theories have been used in early childhood education more broadly is presented in this chapter in order to answer the question of: What and how are theories being used to guide the ways researchers conceptualise children's development and the associated pedagogical practices and political imperatives which frame how and what kinds of studies are undertaken in early childhood education?

In order to better understand the methodologies and methods that researchers are drawing upon to design their research to solve pressing problems for the field of early childhood education and development, this first chapter also examines how

researchers have conceptualised their research activities. Specifically, this chapter examines methodological trends across the globe in order to answer the dialectical question: What are the dominant methodological approaches to research being used, and how are the associated study designs framed to answer the pressing problems posed by the field of early childhood education?

Finally, the contemporary research and evidence for the field of early childhood education is presented from regions around the world, giving a global perspective on what is being researched and what are the problems that the regions and overall field are grapping with and finally giving a snapshot of evidence across global contexts. An analysis of these emerging trends follows in the first part of this chapter in order to answer the question: What are the key problems that are being researched within the field of early childhood education?

Together, these questions frame this introductory chapter. The intent of this first chapter is to give insights into research at the global level for early childhood education and to identify trends, gaps and directions for the field across both northern and southern continents. This first chapter goes beyond simply introducing the content of Volume 1 of the handbook, but rather seeks to give new insights into scholarship through the critique of theories, methodologies and research activity of the field across both north and south countries.

In order to ensure a balance between the northern and southern hemispheres, the specific regions that are presented in this handbook cover Western Europe and the UK, Eastern Europe, the Australasian region and the South Pacific, Asia, Africa, North America, South America and the Nordic region. Missing from the handbook are the Middle East and a comprehensive account of the African region. Similarly, key countries from each of the regions are also missing. As such, the theoretical analysis that follows in this chapter should be considered with this major limitation in mind. It is anticipated that updated versions of this handbook will redress this situation and will ensure an even broader representation of scholars from communities currently not represented.

1.2 Analytical Framework

In order to better understand how researchers in early childhood education across the countries have reported their work and conceptualised their activities theoretically and methodologically, we drew upon Hedegaard's (2014) model of personal, institutional and societal conditions as an analytical tool. For our analysis, we interpreted these concepts to be relational. Hedegaard's (2014) concepts are framed as a relational and dynamic model (Table 1.1). For example, how a country or region predominantly researches its problems is directly related to the kinds of research questions being posed and the ways in which the study design is conceptualised and implemented.

At the societal level, we took this to mean what a country or region identified as its pressing research needs and or present research activities. We also included in this what theoretical tools were drawn upon to inform research and how researchers predominantly conducted their studies within their country or region. At the institutional

Table 1.1 Personal, institutional and societal perspectives (Hedegaard 2014: 192)

Structure	Process	Dynamic
Society	Societal tradition and value demands	Societal conditions
Institution	Practice demands for type of participation	Value-laden goals/objectives/motives
Activity setting	Social situation demands on both child and others	Situated motivation/engagement/interests
Person	Reciprocal demands for concrete ways of participation	Motive orientation/intention

level, we conceptualised this as the practices that are dominating the early childhood settings, what values and goals mattered and how activity settings were predominantly organised for regions. At the personal level, we took this concept to focus on the intentions and orientations of the researcher or practitioners within regions. What did they participate in and what demands were they experiencing within their countries, and what did this say collectively about early childhood education for the regions?

We used these concepts as categories in our document analysis (Peers, Chap. 8, this volume) to identify research patterns across countries (societal level) and to examine how early childhood practices were being documented and analysed (institutional level) and what specific theories and concepts researchers were drawing upon to inform their work (personal level). The outcomes of this analysis are presented under three research headings:

What are the key problems that are being researched within the field of early childhood education?

What are the dominant methodological approaches and methods for researching children's learning and development?

What theories are being used to guide research and conceptualise children's learning and development?

The outcomes of this analysis are discussed in turn, with a special focus on examining the demands and research needs in the context of societal values and institutional conditions within and across regions.

1.3 Current Trends in Research Need Methods and Theories Guiding Early Childhood Education Across Regions

This section begins by examining each of the regions, detailing key research needs, dominant approaches and the main theories used. In the section that follows, a general discussion of this analysis can be found, where new insights into the key problems being researched globally are discussed. We examine in turn the Western European and the UK regions, the Eastern European region, the Australasian region,

the Asian region, the North American region, the Latin American region and finally the Nordic region.

What is evident in the snapshot of research captured in the regions of Western Europe and the UK is that detailed evidence of a link between quality early childhood education and care and increased outcomes for children is evident for the region (e.g. Sylva et al. 2010). European and UK research has collectively shown the benefits of quality early childhood education for children's academic success in school, and this has contributed to policy attention now being directed to the most disadvantaged children, including the growing numbers of refugee children arriving in Western European countries and the UK (Whitebread, Chap. 13, this volume). As a result of this societal need, research attention has focused on better understanding the implications of the policy imperative to begin formal schooling earlier (Bingham and Whitebread, Chap. 15, this volume), resulting in a renaissance of research into play, with new directions centred on executive functioning and self-regulation.

The rise in schoolification of early childhood education (Bingham and Whitebread, Chap. 15, this volume) has meant that new kinds of research are needed and the revisiting of existing research that examines the pedagogical practices that yield the best outcomes for children, both immediately on entering school, but also long term (Soler and Flecha, Chap. 16, this volume). Attention is being directed back to long-standing evidence from neuroscience (Sinclaire-Harding et al. Chap. 14, this volume), as well as Western European and UK research into interventions that focus on cognitive interactions where more adult guidance and enhanced peer interaction are featured (Soler and Flecha), but in contexts that promote playful encounters and support children's emotional development (Whitebread). The research directions appear to be responsive to the policy changes for starting school earlier and the increasing need by governments to show academic outcomes for the increased investments made in early childhood education. As will be shown further below, this issue has also recently arisen in the Nordic region and has been a long-standing problem in the North American region.

What is also evident in the Western European and UK region is that there is growing attention on formulating new ways of supporting the professionalisation of the field, where increasingly greater demands are being made on staff to structure their pedagogical approaches towards a more formal delivery of curriculum (Pirard et al., Chap. 17, this volume). This lies in direct contrast with the Asian region where teachers are now expected to know how to introduce play-based programmes (Pan et al., Chap. 28, this volume). The focus of best practice for supporting professionals as they deal with new practices is centred on the 'competent system' (Pirard et al.). This approach refers to various levels of responsibility that collectively supports new curricula, new practices and the individuals within the system. Changing societal demands for greater outcomes in many northern continents have resulted in changes in institutional practices, such as starting school earlier, which have impact upon the activity settings experienced by young children in Western European and UK preschools. Formal learning at a younger age is a different personal experience to a play-based curriculum. These new demands upon children are creating new research needs for better understanding the relations between play and learning for the very young child in the Western European and UK regions (see Table 1.2).

Table 1.2 Research themes in early childhood education for Western Europe and the UK

Structure	Processes across regions	Dynamic conditions across regions	Research needs
Societies are prosperous – focus on improving the outcomes for disadvantaged children and their families	Need for greater outcomes for disadvantaged children; accountability	Increasing pressure to formalise play-based curriculum; increasing investment in professional development programs	Play research that focuses on learning outcomes; Research on valid and reliable outcome assessments
Institutional practices	Starting school earlier	Goal to increase learning outcomes	Research into pedagogical practices that support greatest learning outcomes
Activity setting	Different pedagogical practices being expected	Curriculum goals may not be suitable for younger children	Research into self-regulation and emotional development in the context of early schooling
Personal perspective	New demands on children and new demands upon staff	Learning how to participate in the new practices	Research into how to support the new professional practices of staff

This new need in the Western European and UK regions is in contrast with the Eastern European region as is shown in Table 1.3 below, where play has always been a key area of research. What is different is that the play research in the Eastern European region has centred on the development of play itself. It is argued that it is through studying play periodisation that insights into the practices which support children's development can be determined. This is not to say learning has not been featured in the context of researching play, but because play is key to the early childhood period, research attention has been on this leading activity (Veresov et al., Chap. 18, this volume). As such, the focus of play research in the Eastern European region has been primarily on development, where researchers have been interested to know more about how the leading activity of play becomes the leading activity for learning. This is a very different problem framing and theoretical conception than what is evident in the Western European and UK regions where schoolification is being contested. However, synergies are also evident through the second line of inquiry that has dominated the research landscape in Eastern Europe, where the study of cognition has centred on learning, perception, imitation and cognition. The outcomes of this research have had impact upon pedagogy and curriculum development across the Eastern European region, with some influence in the USA (Tools of the mind; see Vol 2) and the UK (Key to learning, Dolya 2010) but less is known about the impact of this curriculum activity in Eastern Europe as limited research

Table 1.3 Research themes in early childhood education for Eastern Europe

Structure	Processes across regions	Dynamic conditions across regions	Research needs
Society – preschool education is established in 1960 and supported by psychological research (former USSR). Pedagogical Centre 'Experiment' (Latvia)	The study of children's development	The need to support families, particularly disadvantaged and high-need families	The study of a child's development of his personality – motive development, role of family, social context of development, emotional development and the study of children's play
Institution	State-funded research centres	Research-led and theoretically informed curriculum development	The study of cognitive development – learning, perception, imitation and cognition, methods of assessment
Activity setting	Psychologists work together with educators	'From birth to school' (Salmina and Veraksa) and the 'Golden Key Schools' (Kravtsova; see Volume 2) in Russia and the Elkonin-Davydov preschool curriculum in Latvia (Zeltserman et al.); Developmental Education in the Netherlands	
Personal perspective	Reciprocal demands for concrete ways of participating	Ongoing participation in the practices of the established curriculum	

attention appears to be directed to early childhood practices from this perspective (Salmina and Veraksa, Chap. 19, this volume).

State-funded and state-administered research centres in the former USSR have concentrated their activities around these two lines of inquiry – the study of a child's personality and a study of cognitive development. These early research activities with problems focused on personality and cognition have provided the foundation of an early childhood education system that is informed by psychological research, with current early childhood educational programmes informed by this foundational work, such as 'From birth to school' (Salmina and Veraksa) and the 'Golden Key Schools' (Kravtsova, Vol 2) in Russia and the Elkonin-Davydov preschool

Table 1.4 Research themes in early childhood education for Australasian region

Structure	Processes across regions	Dynamic conditions across regions	Research needs
Societies are culturally diverse and research evidence is specific to a community	Need for greater evidence for child outcomes in diverse contexts	Goal to increase funding for research in early childhood education in regions/countries	Build research infrastructure with a focus on outcomes for children for specific countries, rather than using research evidence from culturally different countries and contexts
Institutional practices	Building research capacity and competence	Increasing need to build research capacity and to fund research activity locally across a range of research areas	Diversity of research problems across diverse settings and cultural communities, where new research practices need to be conceptualised
Activity setting	Diversity of research settings	Diversity of research activity	Need for different approaches to researching in culturally diverse contexts
Personal perspective	New demands on staff to conceptualise problems for diverse settings and to build research competence to address research needs	Learning how to generate and work with evidence across groups	Building research maturity

curriculum in Latvia (Zeltserman et al., Chap. 21, this volume). These programmes are discussed in more detail in Volume 2 of this handbook. What is interesting to note is that there is a theoretical alignment between the research problems, the research activities and the resultant curriculum development, where the nature of child-teacher interactions is specifically theorised using concepts from cultural-historical theory. In contrast, the Western European and UK regions have a diversity of views on play and curriculum. Only recently have views on development moved from a maturational view of development, as noted by Sinclaire-Harding et al. (Chap. 14, this volume) when reviewing the neuroscience literature for the early childhood period in opposition to a maturational view of development and who state that 'young children do not simply follow fixed developmental trajectories'. Whilst Eastern Europe has used cultural-historical theory and activity theory for quite some time, Western European and UK regions are still building this theoretical foundation to support research and in turn using these theories to support the design of new pedagogical practices for the field.

In line with the context of the current research and political imperatives of the Western European and the UK region, the Australasian region has also concentrated

upon increased outcomes for children (see Table 1.4). However, the reasons are different. Rather than researching disadvantaged groups, the Australasian region has concentrated upon researching for improved outcomes in the context of diversity.

Diversity is the key societal condition that is foregrounded in the region (Bone, Chap. 22, this volume) and a topic of research that has endured over time, but in different ways. The corresponding research needs of the region are variable due to the diversity of cultural groups both within countries, but also across countries. As such, the specific countries that are included under the regional heading of Australasia and Asia more broadly (see below) are so culturally different, that it is difficult to draw out themes. There is a diversity in population numbers – Bangladesh at 153 million and Brunei at 415 thousand; there is diversity in terms of cultures both born to the country and those who have immigrated to the country; there is also diversity in the history of research for the region. However, what is common is the development of research activity in each country and therefore across the region in terms of research capacity and competency for investigating early childhood education. For some countries, such as Australia and New Zealand, systematic development of research competency has taken place over the past 40 years to support the maturation of research in the field of early childhood education (Nuttall and Grieshaber, Chap. 23, this volume). Whilst in other countries, political considerations and resources have not allowed for systemic development of research capacity, but despite these challenges, impressive research centres have been established (Mohamad et al., Chap. 25; Sikder and Banu, Chap. 26, this volume). Research infrastructure has a bearing on the breadth and depth of research possibilities in any region.

Political imperatives, such as the unification of higher education into one sector in Australia, or the national research and development project tasked to produce Brunei-specific curriculum, were important for ensuring that research becomes part of the work of early childhood academics, giving access to research infrastructure and the necessary funds so that research activity can be directed to early childhood education research. Similarly, international attention on the importance of early childhood education for the later achievements of children and outcomes for a society generally have generated a research need for more localised research within the region, as we see in Bangladesh (Sikder and Banu), Brunei (Mohamad et al., Chap. 25, this volume), New Zealand (Smith and May, Chap. 24, this volume) and Australia (Nuttall and Gieshaber).

In line with the development of research capacity within the Australasian region has been a focus on research that has mirrored the institutional and societal changes, such as quality reform (Nuttall and Grieshaber), or the preparation of new curriculum (Mohamad et al.). Research has increasingly shaped the policy agenda in some countries (Smith and May), where investigations into the lives and experiences of children have shaped the policies and practices of childcare and the development of curriculum. For example, this can be seen in New Zealand with the establishment of Te Kohanga, preschools for Maori children, and later with government demands on the field for hard data (Smith and May) in order to make more informed decisions about funding distribution and quality provision for early childhood education. These conflictual contexts between those who work in the field of early childhood

education and those who are developing policy and directing funds have been hard-won battles, but when evidence is presented, structural and institutional change is much faster and more appropriately framed. In both the New Zealand and Australian contexts, the tables are now turned, and policy developers and researchers work together to make informed decisions primarily based on research evidence. In order contexts, battles continue, as noted by Mohamad et al. when describing funding and provision of early childhood services and research in Brunei as a Cinderella complex, where ‘policies and programs at this level are considered relatively unimportant in comparison to the more important business of formal, outcomes-oriented teaching and learning that takes place in later school life’. These battles in Brunei are only too familiar to neighbouring countries (Sikder and Banu), who have also had these very same agendas and political imperatives to contend with. However, recent government initiatives in Brunei show that funding is now finally being directed to early childhood education research, not only supporting localised research needs but building research capacity in Brunei.

In the context of Brunei, research has centred on preserving the identity of early childhood education and pushing against the pressure to adopt more formalised teaching and learning approaches, as is currently still of concern in Bangladesh (Sikder and Banu) and is also evident in the Western European and UK regions where schoolification was introduced as a term to describe these challenges. However, in the Australian and New Zealand context, social justice, disadvantage and inclusion have been key themes for research, alongside of play, leadership and policy, professionalism, transitions to school, literacy and emotion regulation, the latter reflecting the diversity mentioned earlier, rather than a clustering of any particular research. Smith and May have alluded to this as sporadic research initiated by individuals, and as Sikder and Banu note for Bangladesh, ‘Some discrete research studies are taken by academics, individuals, service providers; however, no systematic approach is taken to compile a research depository or undertaking applied research to see what works’. However, in other countries, government-funded research has consistently focused on longitudinal research into both short- and long-term outcomes for children attending quality early childhood settings (Smith and May), where there has been a need for localised evidence for supporting the value of investing in high-quality early childhood education. This is in line with international trends in research discussed for the Western European and UK regions and as is evident for Brunei in the Australasian region. However, what is particularly important for the research needs of the Australasian region is for more localised evidence of country-specific and system-specific programmes that support outcomes for children in diverse settings, rather than relying upon research from Western European and North American context to inform the Australasian region. As noted by Mohamad et al., ‘there is a need in Brunei to build contextually-appropriate, “high quality” early childhood education and care programmes’.

Interestingly, the Australasian region has drawn upon a broad range of theories to inform curriculum development, with greater attention being given to sociocultural or cultural-historical theory in New Zealand and a breadth of different theories being privileged in Australia. Bangladesh and Brunei are both still working towards the development of new curricula, but little discussion has emerged in the literature

on which theories will be or have been used for curriculum development. In terms of methodology, the Australasian region has featured children as researchers, mixed methods, visual methodologies, quantitative research, action research, longitudinal research, interviews, surveys and a significant amount of case study research. Research approaches in Bangladesh have tended to be located mostly in the quantitative domain, where surveys and interviews have featured.

In the handbook are two countries specifically represented for the Asian region. They are China and Singapore. The former is a huge continent, whilst the latter is an island that is significantly smaller, with correspondingly different populations and research needs. However, like the Australasian region, they have huge diversity in their populations, and this has also been a focus of research attention for both countries. In many ways, these two countries and the Australasian region of Australia, Bangladesh, Brunei and New Zealand could have been brought together as one in the handbook. Many other countries did not participate in the handbook for these two regions, and this limitation should be kept in mind when considering the studies reported in this section of the handbook and the overviews given. As such, the general features of China and Singapore will be discussed in turn and links made back to the Australasian region.

In China a centralised system of government has provided policy directions for early childhood education and care, but funding to realise the goals is the responsibility of local provinces. This contradiction has generated a great deal of disparity in the quality and provision of early childhood education across the country, despite their policy reform agenda. As such, equity and quality provision have emerged as important societal needs, with research concentrating on illuminating the life conditions of children in different institutions and the dominant beliefs, practices and resources available to teachers (Pan et al., Chap. 28, this volume). As with Brunei, the Cinderella effect has also been noted in China, where early childhood education has not always been valued, despite central reforms that recognise this period of education as important for children's overall development. This has also been noted in Singapore, where early childhood education is still primarily viewed as a child-minding industry suitable for women and requires little professional education.

Societal beliefs and family values surrounding improving one's social status and to advance Ming-Fen through the traditional practice of examinations are still strong in China. Teachers and parents continue to 'highlight knowledge teaching and skills training, and treat play as a barrier for efficient learning' (Pan et al.). Academically oriented practices for preschool children have also been noted in Singapore, where families expect academic achievement so that they might be more successful at school and thereby do better in the high-stakes examinations for all 12-year-olds at the end of primary school. The contradiction in China, as noted by Pan et al., is between cultural transmission and cultural creation, between Western and Eastern cultures and between traditional values and values for pursuing the transformation of modern society, from planned to a market-driven economy. Lim also notes similar contradictions in the Singaporean context where Confucian ideals are still professed, but where the government has focused on building human capital. Lim draws attention to this societal value, as professed by the government that investing in its people as the only natural resource of the country is critical for the success of the economy. Human capital development and a strong belief in education by its

Table 1.5 Research themes in early childhood education for Asian region

Structure	Processes across regions	Dynamic conditions across regions	Research needs
Societies – valuing and building early childhood system	Early childhood education reforms	Researching outcomes of reforms across diverse contexts (China) and increasing localised research on impact of different programmes (Singapore)	Better understanding the outcomes of policy reforms and increased infrastructure in terms of equity
Institutional practices	Building early childhood education competence	Increased resource needs and changing pedagogical practices for greater equity	Need for understanding different pedagogical approaches in diverse contexts
Activity setting	New pedagogical practices – play centres	Diversity of contexts	Investigating child-adult interactions in play-based settings
Personal perspective	New demands to be child centred	Dealing with contradictions between traditional beliefs and ideals expressed through the reforms	Investigating teacher beliefs and practices

citizens have ensured that despite early childhood education not being compulsory, 97 % of children attend 1 year of early years of education (Lim, Chap. 30, this volume). Like China, families in Singapore schedule children's after-school activities, usually through tuition centres, which are focused on learning and which Lim refers to as the 'shadow education system'. She argues that the costly tuition centres alongside of family beliefs for promoting rote learning continue to promote the divide between rich and poor children.

China has a longer tradition of undertaking research specifically focused on the needs of its provinces (as summarised in Table 1.5), rather than relying solely upon research evidence from outside of China. For instance, research in China has examined the development of numeracy and literacy through brain imaging techniques specifically in relation to the cultural context of learners, such as Chinese character awareness. Singapore has a very short history of research, much of which is individual and nearly all of which has been done through the National Institute of Education. The research has focused on teacher beliefs, teaching practices and transition to primary school. Whilst research into child development has been ongoing, very little early childhood education research has been evident in Singapore.

Innovations in methodological approaches, such as children being coresearchers, are also evident in both Singapore and China. For example, in China the experiences of children in play-based programmes in their kindergartens are studied from the children's perspective in order to gain greater insights into how curriculum reform is being implemented (Pan et al.). These methodological innovations mirror the research activities also found in the Western European and the UK regions, the Nordic region and the Australasian region, where children as coresearchers has gained momentum over time.

At the societal level concerns for child rights, the questioning of a passive learning pedagogy in the context of a collectivist orientation, where group goals are prioritised over individual goals, has pushed forward new policy imperatives which ask teachers in kindergartens to value individual characteristics of children and to listen to children's perspectives. Play and the opportunity for children to 'make their own plan and choice' have emerged in policy as a 'political breakthrough' for supporting the development of new institutional practices in the kindergarten (Pan et al.). These new practices have generated research activity that has examined teacher beliefs and practices associated with different concepts and pedagogical approaches that support these new ideals. Particular attention has been directed to child-teacher interactions for supporting a more child-centred approach rather than teacher-oriented programmes. Similarly, the layout and availability of play resources and play areas and time have been a subject of study in China. Research into how a play-based curriculum is being implemented in different parts of China, in the context of equity and equality of resourcing at the local level, has been an important topic of research. Teacher pay and conditions across China have also been studied so as to gain a more holistic picture of the reforms in the context of beliefs, practices, resourcing and management of early childhood education at the local level.

The growth of the private sector for delivering kindergarten education has also been the dominant practice in Singapore. However, in order to reduce the disparity between children from rich and poor communities, the government has increased the number of supported childcare places through increasing the number of childcare operators in Singapore. In addition, improving teacher practices and instituting curriculum reforms have been implemented through voluntary quality assurance processes.

In line with the Australasian region, both China and Singapore have also concentrated on research that explores diversity, not just in terms of the implementation of reforms and government guidelines, but also through the close study of the development of children from different families, such as children from migrant worker families or from economically disadvantaged families, in order to better understand their preparedness for schooling. In Singapore much of this work has been supported by theories which are informed primarily by the USA on development – developmentally appropriate practice and both the cognitive and maturational interpretations of Piaget's theory. China has grappled with the influence of theories from the former USSR and educational approaches imported from Europe, such as the work of Maria Montessori and Reggio Emilia, but in the context of Confucian values as mentioned previously.

In the African region, only two chapters can be found in the handbook and this focuses only on Ghana and Sierra Leone. Subsequent revisions of the handbook will hopefully address this serious omission, but the title of the African region is kept so as to signal the significance of this region and the future need to include chapters from all of the continents, including the Middle East. The analysis that follows will only reference Ghana and Sierra Leone, rather than make any claims about the African region (Table 1.6).

In line with the Asia and Australasian regions, Ghana and Sierra Leone too are faced with the Cinderella effect. Even though the government has legislated for free early childhood education, in order to signal the importance of this period of educa-

Table 1.6 Research themes in early childhood education for Ghana and Sierra Leone

Structure	Processes across region	Dynamic conditions across regions	Research needs
Societal values: equity gaps and overcoming intergenerational poverty	Legislation of free early childhood education in context of poor infrastructure	Provision and streamlining of high-quality early childhood education services in order to close the equity gap	Need for building research infrastructure and capacity
			Investigations into what is quality early childhood education for Ghana
Institutional practices	Majority of centres are managed by staff without formal early childhood education qualification	Increasing access to early childhood education – free meals for children attending preschool	How to increase school retention?
			How to increase knowledge of early childhood education?
Activity setting	Limited play spaces	Rote learning in context of ratio of 1:50	Ways to increase parental awareness of the benefits of children attending quality early childhood education services
Personal perspective	Moving from passive to active child-teacher engagement	Teacher knowledge of child-centred practices	

tion, few families send their children to preschool. According to Agbenyega (Chap. 32, this volume), parents do not value early childhood education, and resourcing constraints mean that what is experienced is often in contexts of poor physical building and resourcing conditions, large group sizes and a formalised teacher-centred pedagogy with a correspondingly passive role for the child.

Localised research into investigating what quality early childhood education might be like for Ghana and Sierra Leone has not yet been funded. Mostly, efforts are focused on improving practices, such as how to increase retention rates of children. Wider problems of teacher knowledge of early childhood education, implementation of new curriculum and improved pedagogical practices based on localised research are yet to be instituted and are currently beyond what governments can resource. Curriculum in Ghana and Sierra Leone has, like Singapore, been informed by maturational views on development, notably Piaget's writings, but also it has been strongly influenced by the USA through the perspective of developmentally appropriate practice. However, Agbenyega, one of the leading scholars undertaking research in Ghana, and Eleni Anthinodorou in Sierra Leone both use critical theory, notably the work of Pierre Bourdieu, in order to make visible the challenges the field of early childhood education currently faces in both countries.

In contrast to Ghana, the North American region has a long history of research activity (Göncü and Howes, Chap. 34, this volume), having exported the findings

from many longitudinal studies of children's development associated with particular education programmes to many other countries to inform practices there (see Agbenyega) and to build evidence for the importance of early childhood education (see Whitebread, Chap. 13, this volume). Whilst there are many methodological debates surrounding the evidence (e.g. Peers, Chap. 8, this volume), many countries have been inspired by these well-resourced studies, but as we have discussed previously, regions in the south have also sought to undertake their own country-specific research.

Interestingly, as Göncü and Howes argue, 'while wealthy and powerful players in the global sense, [Canada and United States] are not global models for early childhood education systems'. The problems faced, focus directly on introducing formal learning to very young children, fragmented services and underfunded and of dubious quality early childhood education are evident (Göncü and Howes). Consequently, the research needs in the USA and Canada appear to be aligned with the problems faced in European and UK regions, another rich player on the world stage.

Howe et al. note the importance of play as reflected in position statements in Canada, the relations between play and learning presented through the development of early childhood frameworks across the provinces of Canada, investment in expanding services and importantly integrating care and education; however, 'very limited empirically-based research examining the quality of ECEC programs' is evident (Howe et al., Chap. 35, this volume). Hong and Udommana (Chap. 35, this volume) also note similar imperatives in the USA with concerns for the development of a more cohesive system so that quality rating and improvement systems can be put in place. With increased numbers of children attending early childhood programmes, particularly from bilingual and culturally diverse families, research interest has centred on determining what is quality provision for early childhood education for diverse populations and what school readiness means in this context (Hong and Udommana).

What is evident in the North American region is that not only has there been an expansive amount of research, but this research activity is long-standing. With research maturity, a more nuanced approach to researching in early childhood education is possible. That is, significantly different kinds of research problems are expressed, such as re-examining attachment theory through research into attachment relationships for differing cultural communities or how schools make adjustments to practices so that other 'ways of doing' seen in homes that are different to schools are considered and practised (Göncü and Howes). For instance, Göncü and Howes argue that 'parent involvement has often been conceptualized from the perspective of middle class researchers. It has been often the case that low income parents whose ways of involvement were not captured in the work of middle class researchers were labeled as uninvolved'. Critiques of this research show that new models of parent involvement are urgently needed and that different ways of theorising this area are more likely to support the 'many ways of doing things'. This is urgently needed in both the USA (Clifford and Humphries) and Canada (Hong and Udommana).

At this point in time, researchers, curriculum developers and teachers have been strongly influenced by the long-standing concept of developmentally appropriate

practice for informing child development. However, there is also a growing number of researchers, such as those published in this handbook in the North American region, who have been informed by sociocultural theory or, as is discussed in the European regions, cultural-historical theory. Understanding the many ways of doing things, as discussed above, has drawn heavily from sociocultural theory. Much of the work being done in early childhood education research and curriculum practices is now being informed by the work of Bodrova and Leong, Göncü, Howes and many others, including those who have been involved at some point in research supported through the lab of Barbara Rogoff in California, where sociocultural theory frames research and where culturally diverse communities participate in research activity.

In terms of the research methodologies being primarily drawn upon, a strong quantitative approach has been adopted but methodologies are variously theorised. Research has taken place in a context which has seen a long-standing push for both random controlled trials and intervention research. This has meant that early childhood education, as apposed to research in developmental psychology, has tended to follow traditional psychological approaches for framing research where particular types of quantitative research have dominated. Important work has been carried out, looking more broadly at how knowledge can be generated, and has produced other ways of researching, as noted earlier in the work of Barbara Rogoff, Suzanne Gaskins and Artin Göncü. In these studies, the cultural traditions of communities are also captured in the research, such as the play research done by Susanne Gaskins who draws upon a more anthropological approach to undertaking research. Many of these scholars feature in the handbook, and as such, this should be kept in mind when reviewing the results of this analysis for the North American region (see Table 1.7).

Concern for a cognitively oriented curriculum that focuses on school readiness, rather than a more holistic view of children's development in North American region, is also an issue for Latin America. In this region, the overriding concerns have been the lack of services available to families, the quality of the early childhood education services and the overall living conditions of families. Cultural diversity has also been noted within and across countries in the region, and the political will to better support equity and access to early childhood education for all families has been a key issue. This is consistent with many regions, particularly the Australasian, Asian, and Western European regions (see Whitebread Chap. 13, this volume; Bingham and Whitebread Chap. 15, this volume), where working effectively with diversity is a central problem and an important research need.

In contrast to all the regions, Latin America generally is dealing with an additional complexity of violence and issues of security. As noted by Mejia-Arauz and Quinones (Chap. 38, this volume), 'in Colombia there is a clear preoccupation for children's development in the context of guerrilla warfare and forced displacement, other countries in Latin America that have severe security issues due to the narcotic conflict'. What appears to be central is the well-being of children and their families, and in this context, research into social and emotional well-being of children is important. Further, the expansion of pedagogy from a predominantly cognitive orientation to a more play-based context is seen as an important part of promoting better life conditions for children in Latin America. In contrast to the other regions,

Table 1.7 Research themes in early childhood education for North American region

Structure	Processes across regions	Dynamic conditions across regions	Research needs
Societies – expanding and integrating early childhood systems to support diverse populations	Monitoring and assessing effectiveness of changes over time	Researching outcomes of policy initiatives	Evidenced-based services: researching quality improvement for developmental outcomes and effectiveness of the integration of services
Institutional practices	Assessment practices for determining quality provision of early childhood education for broader populations	Identification of other ways of doing things	Investigating in diverse contexts what family involvement means, identifying new pedagogical practices to support diverse learners and determining what school readiness means
Activity setting	Family-home relations	Diversity of contexts	
Personal perspective	Adult-child interactions that support diversity	Demands of contesting an expected White middle-class orientation	Investigating child-adult interactions in diverse play-based settings

Mejia-Arauz and Quinones draw attention to the lack of research and discussion on play as a valuable pedagogical practice for early childhood education and the need for greater attention being directed to the birth to 3-year-olds. These are gaps identified by Mejia-Arauz and Quinones and are in need of research for the Latin American region (see Table 1.8).

Methodological approaches in the Latin American context have primarily followed a quantitative tradition; however, innovative work is being done by Mejia-Arauz following the approaches developed in the lab of Barbara Rogoff in California. Culturally informed approaches which draw upon video ethnography, but which closely examine results in relation to both case study approaches and more quantitative techniques, are on the rise. These latter techniques support the cultural questions being asked in relation to the nature of diverse learners and culturally diverse communities that make up the Latin American region. Many of the newer approaches to research have been informed by sociocultural theory. However, much of the cognitively focused curriculum in place is informed by developmentally appropriate practice, and the pedagogical approaches being adopted are still informed by behaviourism (Quinones Goytortua 2013).

In contrast to all the other regions, the Nordic region places early childhood education as not just the responsibility of the individual family, but as the responsibility of the state where the democratic principles of supporting an equal society are foregrounded. This means that access to heavily subsidised early childhood education

Table 1.8 Research themes in early childhood education for the Latin American region

Structure	Processes across regions	Dynamic conditions across regions	Research needs
Societies – violent and unsafe societal conditions	An overly cognitively oriented curriculum	Foregrounding the emotional well-being of children in early childhood settings	Research into the emotional well-being of children
Institutional practices	New pedagogical practices that focus on play and emotional well-being of culturally diverse groups of children	Identification of broader range of curriculum goals and practices to support the well-being of all children	Investigating new pedagogical practices that can support diverse learners in more playful learning environments
Activity setting	Need for safe playful learning environments	Active learning contexts that feel safe	
Personal perspective	Adult-child interactions that support emotional well-being of children	Demands of unsafe everyday life conditions and how to create learning environments to support security and well-being	Investigating how to support emotional well-being of children through the introduction of play-based programmes

services is available in the Nordic countries, and most children spend their lives from 2 to 5 years in some form of early childhood education programme, with fully paid maternity leave, for example, from 8 months in Demark to 16 months in Sweden. Across the Nordic region, the development of early childhood education has been supported through a vision of democracy that gave opportunities for women to work, but this value is also embedded in the curriculum for young children, through play-based programmes which promote children's autonomy and capacity to make choices and decisions for themselves about what they learn (Emilson and Johanson, Chap. 47, this volume). As noted by Broström et al. (Chap. 45, this volume), 'The democratic person is a political subject, with knowledge and skills, and a desire to make use of these through transformative practice. This is a person who has knowledge, skills and a will to realize transformation though action, summarized in the concept of "action competence"'.

On most measures and ranking systems for children's education and development, the Nordic countries have tended to be ranked high or even the highest among other countries. A long tradition of a play-based programme, which integrates the upbringing and education of young children, can be seen in the Nordic region, with curricula that reflect democratic values. However, in more recent times, curricula have also included more academic goals associated with discipline areas such as literacy, numeracy and science. This development has corresponded with the movement of ministerial responsibility for early childhood education from welfare or social services to education.

It is argued that in the Nordic region, research attention needs to be directed towards investigating the outcomes of the 'trend toward a more content- and goal-

Table 1.9 Research themes in early childhood education for the Nordic region

Structure	Processes across regions	Dynamic conditions across regions	Research needs
Societies – highly ranked early childhood education	Trends towards a knowledge-oriented curriculum in a democratic curriculum context	Goal-oriented curriculum focused on discipline content areas	Investigating the outcomes of an academically oriented curriculum
Institutional practices	Relations between academic learning goals and play-based curriculum pedagogy	Implementation of curriculum that includes democratic principles and goal-oriented knowledge construction	Investigating how teachers come to understand and work with a more cognitively oriented curriculum
Activity setting	Child-formulated programme as 'action competence' in context of increasingly goal-oriented curriculum	Goal-oriented curriculum practice and child interests in a democratic value base curriculum	
Personal perspective	Negotiation between teacher and child regarding the focus of education programme	New demands upon teachers to engage in goal-oriented curriculum	Investigating the relations between democratic child action competence and goal-oriented curriculum

driven' approach to curriculum and pedagogy, in the context of play-based programmes where children are positioned as being 'involved in decisions concerning their own everyday life'. Concerns for a narrowing conception of the curriculum as a knowledge-oriented approach is counterintuitive to a holistic perspective on children's learning and development, in which the 'discourse of communication and negotiation between teacher and child concerning the education and well-being of the child, are formulated' (Bronstrom et al.). This concern is mirrored by teachers' lack of understanding regarding cognitively oriented curriculum due to the fact that this has not been a part of teacher education programmes in the past (see Table 1.9).

Methodological approaches to research in the Nordic region primarily follow qualitative case study approaches, where focus children are followed and studied using a variety of techniques, such as video ethnography. Children as coresearchers are also common. Many study designs, as well as curriculum, are primarily informed by cultural-historical or sociocultural theory. The works of Bronfenbrenner and Deleuze are still used in some contexts, and a number of research clusters have formed which drawn upon post-structuralist theories. However, Piaget's work is no longer followed. The sociology of childhood is also prominent in some research communities in the Nordic region.

1.4 What Are the Key Problems That Are Being Researched Within the Field of Early Childhood Education?

As part of the analysis, we were interested to learn how researchers within the field of early childhood education have generally framed their research problems. After analysing the content of the handbook following Hedegaard's (2012) model within each region as discussed in the previous section, we then brought the outcomes across regions together to give a collective analysis of research activity for early childhood education at an international level. The overall outcomes are summarised in Table 1.10 at the regional level and discussed further below.

Local conditions that focus on research programmes (e.g. immigration, policy environment), including historically specific traditions (e.g. Confucian philosophy), give the backdrop for the research needs that arise in each region. When brought together at the international level, the key areas of research that appear to dominate early childhood education are centred on the problem of an academically oriented curriculum. This can be viewed as a narrowing of the curriculum, where play possibilities are being reduced (north condition). This is mainly a northern hemisphere problem. This problem can also be interpreted as the opening up of curriculum from a formal discipline-based approach to increasing the possibilities for play-based curriculum with an active pedagogy for supporting learning. This is a southern hemisphere problem. As such, the predominant topic of research in early childhood education can be conceptualised as an interest in studying the relations between play and learning.

In addition to the relations between play and learning, an analysis of the overall findings identified the need for greater research evidence for child outcomes in diverse contexts. This problem is framed in the northern continents as a problem associated with disadvantage and the need to 'close the gap between the poor and the rich'. In the southern contexts (plus the research in the USA), this is conceptualised as a research problem in terms of finding the multitude of ways learning and development can be enacted in early childhood education due to the diverse cultural groups; diverse communities, geographies and languages; etc. This latter framing represents diversity in its broadest sense, whilst the former conceptualisation of diversity seeks to focus mostly on closing the gap between the advantaged and the disadvantaged. Specific diversity problems that have emerged are:

Better understanding the outcomes of policy reforms and increased infrastructure in terms of equity and quality provision (Asia)

Building research infrastructure with a focus on outcomes for diverse children for specific countries, rather than using research evidence from culturally different countries and contexts (Australasia)

Research into the emotional well-being of children potentially through play-based programmes across diverse contexts (Latin America)

In line with these research questions is the growing need for research evidence that is focused on country-specific issues, rather than drawing primarily upon research from northern countries. Research evidence, whilst generically useful, can

Table 1.10 Prevalent research themes for early childhood education

Region	Processes across regions	Dynamic conditions across regions	Research focus
Western European and the UK regions	Need for greater outcomes for disadvantaged children; need for evidence-based innovations in curriculum and asessment methods	Increasing pressure to formalise play-based curriculum	The study of play and learning, self-regulation and the associated pedagogical practices for improved child outcomes
Eastern European region	The need to support families, particularly disadvantaged and high-need families	Better understanding of children's development	The study of the development of a child's personality and the study of cognitive development
Australasian region	Need for greater research evidence of child outcomes in diverse contexts	Goal to increase funding for research in early childhood education in regions/countries	Build research infrastructure with a focus on outcomes for children for specific countries, rather than using research evidence from culturally different countries and contexts. As such, a diversity of research needs
Asian region	Need for community valuing and building of the early childhood system	Researching outcomes of reforms across diverse contexts (China) and increasing localised research on impact of different programmes (Singapore)	Better understanding the outcomes of policy reforms and increased infrastructure in terms of equity and quality provision
Ghana	Need to close the equity gaps	Provision of high-quality early childhood education that positions the child as active	Investigations into what is quality early childhood education for Ghana
North American region	Expanding and integrating early childhood systems to support diverse populations	Monitoring and assessing effectiveness of changes over time	Researching quality improvement for developmental outcomes and effectiveness of the integration of services for diverse populations
Latin American region	Violent and unsafe societal conditions	An overly cognitively oriented curriculum and the need for supporting the emotional well-being of children in early childhood settings	Research into the emotional well-being of children potentially through play-based programmes across diverse contexts
Nordic region	Trends towards a knowledge-oriented curriculum in a democratic curriculum context	Goal-oriented curriculum focused on discipline content areas	Investigating the relations between democratic child action competence and goal-oriented curriculum

never address issues of diversity and country-specific needs where contexts are completely different to those in the northern hemisphere.

1.5 What Are the Dominant Methodological Approaches and Methods for Researching Children's Learning and Development?

In this first volume of the handbook are presented methodological discussions on a variety of approaches and methods for undertaking research within the field of early childhood education. These chapters do not speak directly to regions. However, this third section of the handbook identifies methods and specific practices associated with researching early childhood education, and it offers some important critiques generally for the field of early childhood education.

One of the key methodologies and methods for researching with young children that has dominated both the northern and southern hemispheres has been co-researching with children. This approach to research was identified in the Australasian region; in the Nordic region; in the Asian region, specifically China; and in the Western European and UK regions. Alma Fleet and Deborah Harcourt (Chap. 7, this volume) give details of the variety of ways that this methodology can be realised in practice for children aged birth to 5 years. It is not surprising that this approach has emerged in the early childhood education community. The concerns for how academically oriented curriculum is being experienced by children demand a method that consults directly with children. This is also in keeping with the Nordic region, where children are routinely consulted in relation to the early childhood education programmes experienced so that their interests are foregrounded. In this context, narrative research has also gained momentum. Narrative research speaks directly to co-researching methods, but it also affords its own place in research methodologies. Narrative knowledge brings together evidence in ways that is holistic and person centred. In this handbook is a chapter which features a narrative methodology, where an example of narrative method is presented. Hakkarainen and Vuorinen (Chap. 10, this volume) showcase through a narrative methodology how play and problem solving can be investigated. Once again, the research approach adopted focuses specifically on the schoolification agenda, where a need for showing the benefits of play as a pedagogical tool is urgently required. It is in this context that the relations between play and learning are better understood for informing policy development.

Policy analysis and document research can also contribute to informing governments about the nature of play and learning. Evidence of this type of research can be seen presented through curriculum; rules governing ratios; teacher salaries, which are responsible for the care and education of children in the early period of their lives; and importantly decisions about quality assurance and measurement of quality outcomes at a system-wide level. Governments make legislative decisions

about policies that drive how care and education is managed, administrated and experienced by children and staff. Yet policy analysis and document research is an emerging research methodology in early childhood education (Peers). As with the issue of research being funded and enacted in the majority of northern countries to address research needs there, policy work has also tended to be driven in the northern continents. Powerful policy documents, such as those produced through the OECD, have both focused on informing directions for the north and developing reports for the south. Nongovernment organisations have also contributed to supporting policy directions, such as the implementation of the Global Millennium Development Goals. Peers argues that 'early childhood development is routinely treated as a factor that will contribute to a nation's future competitiveness and productivity', and it is this promise that has guided a great deal of activity in the south, despite the evidence for these claims being generated in the north. What Peers notes in his review of the document research across both north and south continents is that 'Researchers in public sector policy, such as early childhood care and education, are virtually compelled to read and contribute to studies published under the auspices of the OECD in areas such as family policy, labour market reform and the development of new statistical and technical indicators for the purposes of benchmarking quality in service provision'. These types of reports have raised concerns across both the north and south, as governments seek to benchmark against each other and contribute to world rankings on indicators of quality. Without researchers in early childhood education being a part of the policy debates, through either contributing, subverting or paralleling policy analysis and document research, then there is the danger that published reports, as an historical artefact, will continue to be 'treated as if it truthfully reflects real events, and that interpretations of the document is not complex, and does not usually lead to multiple interpretations' (Peers).

Concerns have been expressed about how to measure quality in the Western European and UK regions (Whitebread) as well as the North American regions (Göncü and Howes). Questions have been asked about how best to effectively research quality. What kinds of research methods best examine quality within diverse communities, across regions and internationally in early childhood education? Peers has warned that educational research that is based on psychological science that conceptualises the child in terms of measurable attributes focuses on universals and does not speak directly to the diversity of human experience and differing contexts and conditions of children's development. The latter is taken up explicitly by sociocultural researchers in the North American region, who worry about universals and how they inform policy decisions.

Quantitative research, with its focus on deductive methods to test theories and hypotheses, has also been used across continents as the basis of some or most of its research activity to inform policy. Only some questions can be answered using quantitative design (Harrison and Wang, Chap. 12, this volume). In early childhood education research, it is becoming evident that current 'approaches in quantitative research tend to align with a post-positivism paradigm which retains the idea of objective truth, or the existence of one reality, but warrants that the discovery of such reality is limited to a certain realm of probability. Post-positivists accept that

the theoretical frames, background knowledge and values of the research influence what is observed or measured' (Harrison and Wang). Mostly early childhood education research that draws upon quantitative approaches uses methods that focus on examining specific interventions. These studies are used as justifications for particular frameworks, curriculum approaches and importantly, measures of quality (Peers). This is primarily how early childhood education has been supported in countries in the south, where evidence generated through longitudinal quantitatively informed research from the north, particularly from the North American region and the UK region, has given directions for explaining aspects of 'the natural world through observation or experimentation and the collection of empirical (or measurable) data' (Harrison and Wang). Examples include Effective Provision of Preschool Education (Sylva et al. 2010) in the UK and Head Start Impact Study (Puma et al. 2010) in the USA.

Quantitative effects are based on correlations which when repeatedly found indicate a relationship between the occurrence of one phenomenon with another. It is through the process of comparing the scores of a substantial number of individuals on two or more constructs that results are obtained. But quantitative research on its own hides the diversity within a population (Schoonenboom, Chap. 11, this volume). Countries with diversity are interested in this diversity, as noted in the Australasian and Asian regions as being an important research need. Schoonenboom argues that what is needed in these situations is a mixed methods approach, where one reality with objective knowledge is obtained through quantitative research techniques, and multiple realities are gained through qualitative research. Schoonenboom suggests that researchers interested in diversity should incorporate the different realities where 'transformative and dialectical approach requires that researchers design for diversity, that they set up their research so that different perspectives from different realities are included'. In this interpretation of mixed methods, the pressing research needs of particular countries, such as China, who have diverse communities, require sophisticated research approaches for addressing complex problems, and mixed methods approaches would appear to make an important contribution.

Another methodology that is becoming increasingly popular is Vygotsky's cultural-historical methodology because it not only speaks directly to diversity, but if offers another perspective on how to 'measure' development. In this approach to research, both interventions and documentation of everyday life are captured and analysed so that the process of development can be determined. However, the view of child development does not follow a maturational view, but as is noted in the chapter by Fleer and Veresov, focuses on the relations between the child and the social and material context. Peers has argued that researchers in 'paediatric medicine, including psychiatric, neurological and epidemiological research, have all played an increasingly significant role in producing evidence about human development and how it can be measured'. The medical model of child development, which follows a maturational view of the child, is not relevant in early childhood educational research. The emergence of a medical model, in the context of a very different conceptualisation of the child in education, has caused some concern in many regions, both north and south. A cultural-historical methodology is the antithesis of

the medical model of research and also that of traditional psychology. Many regions have noted the research tensions between a cultural-historical conception of development and a traditional maturational view of the developing child. These contrasting models of child development continue to be problematic when assumptions are not made visible in how development in research is conceptualised.

Models of research, which are aligned closely with the medical models of researching young children and their teachers, appear to have less to say about the pressing research problems identified in this handbook. In contrast, the emerging and explanatory power of narrative methods, co-researching with children, mixed methods, post-positivist quantitative research and policy analysis and document research which includes contexts, histories and conditions have all emerged as tools that are helpful for researching the relations between play and learning in diverse contexts as has been shown as key for both the continents of the south and the north. However, as discussed previously, the framing of these problems is different, and sensitive methods that are framed to capture a cultural-historical conception of development are more likely to produce results that speak directly to each country's research needs, and this is particularly important for countries in the south. As argued by Peers in the context of policy research, 'Researchers ought to be wary of the historico-political complexities surrounding policy documents as they are generated in developing economies because many of the cultural and economic assumptions that are relevant to policy development in early childhood in a developed economy may be awkwardly or clumsily reproduced as if there were no difference between a developed and a developing economy. At the same time, since university research maybe lacking in a developing economy, policy-makers will sometimes have no alternative but to draw on the wisdom of Western sources and research as if it were automatically relevant. This is also reinforced by the mistaken perception that human development is a universal phenomenon which does not vary on the basis of cultural or economic context'.

What was evident in the south was that the maturity of the field of early childhood education research is still emerging. Both the quantity of research needed to support country-specific needs and the capacity of researchers to undertake this work are still patchy. It was identified that research activity in the southern region has either been scattered and individually undertaken, or research has been systematically done as large-scale research supported by governments. In contexts of limited resourcing, funding large-scale studies oriented directly to country-specific problems supports more evidenced-based approaches to early childhood education for a particular country or region. A second dimension for developing research maturity is the building of researcher capacity in a region. In resource-rich contexts, or regions where the importance of early childhood education is well understood in the community, funds are directed to individuals or a limited number of systematic large-scale research projects. In other regions, having access to research funds is problematic. Without access to research funds, it is difficult for a region to build research capacity and to generate research evidence for problems specific to the needs of particular communities. In the northern countries, funding for early childhood education research has a much longer tradition, and both capacity and infra-

structure appear to be in place. However, in comparison to other areas of research, the early childhood education research community has had to work hard to establish its research base and has had to advocate hard for their work to be taken seriously by the government in order to effect policy change. As noted by Peers, 'Given the late emergence of specialist early childhood educators and of corresponding programs of academic research about the practice of teaching, the cultivation of learning, and the design of curriculum and pedagogy for early years practitioners, especially by comparison with the whole field of medicine, the tension between medicine and education could not be described as a fair contest. Medicine, paediatric science, neurology and epidemiology each offer paradigms of knowledge that far outweigh the views of childcare workers in the determination of "good" policy'. The methodological chapters in this handbook address this challenge by providing strong arguments about the methods that speak directly to early childhood education research.

1.6 What Theories Are Being Used to Guide Research and Conceptualise Children's Learning and Development?

Presented in the first section in this volume of the handbook are some of the key theories and their associated concepts that have informed early childhood education research across the globe. Missing is a focus on Piaget's maturational and cognitive theory, which has influenced the rise of developmentally appropriate practice (DAP) beyond the borders of the USA. This theoretical orientation has informed constructivism, which is also missing from the handbook. Although Piaget's theory, constructivism and DAP are foundational to the North American context, and have colonised many countries in the south, this theory appears to be receding in a context in which sociocultural or cultural-historical theory has emerged. However, this has not been the case for the Eastern European region where cultural-historical theory and activity theory have always been the dominant theoretical approach (but in the context of arguing against behaviourism).

In the Eastern European region, researchers have a long tradition of drawing upon the theoretical foundations of Vygotsky and Leontiev under the name of cultural-historical theory and activity theory, respectively. What is evident is that a growing number of studies locate their study designs within the theoretical tradition of sociocultural theory, cultural-historical theory and activity theory in both the north and south continents. However, as noted above, China and some of its neighbours still struggle with the former Soviet influence and as such have not been as interested in the global focus on these theories. The essence of these theories, and their respective concepts, as discussed by Fleer and Veresov, points to how concepts from Vygotsky's work have informed over 20 years of early childhood education research in the Australasian region, the Western European and UK regions, the Latin

American region, the Nordic region and the North American region. Mostly new thinking about child development and approaches to researching child development have emerged through this work in early childhood education. However, other theories or anti-theories have also been influential in the reconceptualist movement. For instance, Taylor argues that 'Poststructuralist theories were not originally formulated or presented as theories per se. Rather they grew out of a series of ongoing and generative philosophical conversations that have travelled widely within the humanities and social science over the last fifty years or so. They effectively function as "anti-theories" – as a cumulative set of questioning interventions that provoke us to rethink the universalist truth claims of western scientific knowledge systems. The most solid thing these "troubling" poststructuralist conversations offer is a set of new conceptual tools to help us think differently' (Taylor, Chap. 5, this volume).

Taylor states that 'postcolonialization explores the constitute relationship between colonialist discourses, power and the construction of childhood within North American early childhood education'. In reviewing the early childhood literature, she notes that scholars have interrogated the 'normative and universalist assumptions of western developmental discourses'. She finds that the leading scholars of poststructuralist theory and postcolonial theory have noted how dominant discourses 'disempower, marginalize or Other children from non-western cultures while claiming to represent the interests of all children' (Africa, Chap. 5, this volume). Othering has also been taken up by those working with postcolonial theory in early childhood education. This is particularly pertinent to the north-south discussions in this handbook.

Postcolonial theory has had an impact on policy and made significant contributions to discussions surrounding knowledge construction and the colonisation and subjectification of peoples in both north and south continents where indigenous peoples have been culturally displaced (Martin, Chap. 4, this volume). The term postcolonisation suggests that the process of colonisation has ceased. Yet colonisation as the process of creating colonies in other countries, often seen as widespread across countries, results in subjugation of the home nation, often hard to see, but nevertheless impacting on the everyday lives of those who are colonised. Many have argued that this process still continues and continues to be felt. Martin, for instance, gives the example of re-naming territories with the names of the colonisers, and a process of colonisation that not only as immediate impact on peoples' everyday lives, but continues to colonise communities through its silencing and often wiping out past histories and through its obvious reminder of the colonisation process by celebrating daily the colonisers. What is important about postcolonisation is that it references an understanding of how the power of the colonisers is perpetuated. Martin argues that in the context of early childhood education, colonisation is ever present. She states that 'It seems that although the efforts to resist and thwart the normalizing effect of Western, Euro-centric theories in curriculum and teaching have garnered some traction, the same cannot be said for understanding the normalising effect inherent within early childhood education…An initial postcolonial framing shows how the field has been conditioned, where certain relationships, certain identifies and certain voices remain dominant'. She gives the examples of com-

pensatory education for low SES communities, such as head start. This is a fitting example, given how pervasive the work of the North American continent has been in the south, as discussed previously, due primarily to the lack of localised research evidence, thus making it necessary to draw upon evidence from elsewhere.

Martin argues that colonisation through early childhood education has reached ‘global proportions where a Western template has been similarly applied at national and local levels’. Further she suggests that the scientific discourse that surrounds the pathologising of early childhood education draws upon medical models of child development. Cultural-historical theory from the Eastern European region has offered one alternative view on child development to the dominant maturational models, but this too could be viewed as a new form of colonisation. What poststructuralists and postcolonalists point to is the need for localised conceptions of child development, curriculum and pedagogy. Others have also sought to build new understandings of childhood, children and development, as seen through the movement known as Childhood Studies.

Duhn (Chap. 2, this volume) states that ‘Childhood studies itself is a relatively new academic field which has emerged alongside the sociology childhood’. ‘Contributions to childhood studies have come from across disciplines’. Duhn examines the shifts in conceptualisations of childhood, critiques the idea of the global child and introduces the concept of diverse childhoods. The latter is most fitting for the regions of the south as diversity is a key area of research need and also for those working from within a sociocultural paradigm in the South American region. Duhn says, ‘Rather than thinking of childhood as a category which is being re-organised in post-industrial contexts, childhood can be considered as a discourse which constitutes and is constituted by a new economic and political order’. Childhood Studies also supports a critical view of the dominant global discourses. For instance, Duhn has noted in her critique of how the child is conceptualised locally, nationally and globally that we are now faced with the challenge of the ‘ideal of childhood’; she argues that ‘the cultural response to western nations seems to be a clinging to the ideal rather than a williness to re-imagine what globalized childhood may mean’ (Duhn).

A related and emerging field is the study of how human activity has significantly disrupted the earth’s ecology. This is known as Anthropocene and this new concept also critiques existing practices and beliefs about humanity, specifically perspectives on childhood development and progress (Payne, Chap. 6, this volume). In the handbook, Payne calls into question many dimensions of early childhood pedagogy. What Payne draws attention to specifically is the new philosophy of children, where non-anthropocentric epistemologies in education are being considered. In speaking of theory-practice and research methodologies, he suggests that there are now ‘presupposed conceptual/theoretical binaries, presumed values-hierarchical thinking, and over privileging of pedagogical perspectives about child development, cognitive development and so on’ (Payne). He argues that research and theorisation of children’s experiences of the temporal-spatial dimensions of nature as part of everyday life (home, gardens, bush, open spaces, urban, neighbourhood) are missing. Part of the new thinking put forward by Payne is the designing for body-time-space in

the context of these environmental affordances. This theorisation pushes against 'Cartesian inspired disembodiment, disembedding, displacement and decontextualization of the subject from the human-non-human and animate-inanimate vital world privileged by the ecocentric reconceptualization and reposition of its various subject/object things' (Payne). In this zone Payne suggests that 'body-time-space relationalities' as embodied and '"felt" in movement, memorying and meaning-making' are found within what he calls the eco-/somaesthetic. According to Payne, play begins to capture this dimension because it is timeless and embodied and a felt phenomenon. The thinking put forward by Payne invites more consideration of humans as part nature, rather than as controllers and purveyors of environments for economic gain, in an increasingly fast-paced society. He labels the current conceptions of childhood as clockwork children.

Conceptions of clockwork children, childhood studies, postcolonisation and poststructuralist theories have become powerful tools for noticing and disrupting subjectification of the global early childhood discourses which have emerged in the north and are often applied uncritically in the south – as evidence; as informing curriculum; as conceptualising childhood, children and child development; and as guiding assessment and monitoring of what counts as quality early childhood education. It is interesting that the field of early childhood education has drawn upon so many theoretical tools to research and conceptualise practices. Further, the colonising of beliefs, practices and measurement tools in the north have swept the south, often being invited in by governments and the profession itself, initially as tools to persuade the government to invest in both resources to support practice, but also to support more localised research. The chapters of the handbook provide the much needed content for giving more space for perspectives from the south and through this greater understanding of how the whole global context of early childhood is currently drawing upon a broad range of theories to guide new thinking.

1.7 Conclusion

In the analysis of the content of the handbook, it was found that knowledge construction in early childhood education has tended to be dominated by perspectives on what matters for countries in the north, with limited attention being directed to the research needs and activities of countries in the south. What is evident is that perspectives from both outside of early childhood education and research taken from the northern continents have primarily shaped what the government pays attention to, which in turn shape policy and curriculum in particular ways – as Martin suggest – in ways that privilege certain forms of knowledge and colonise local practices and thinking.

This chapter sought to redress the north-south imbalance by ensuring that greater representation of works from the south was included in the handbook. Through reviewing the content of this first volume with a north-south perspective in mind, different contexts for pressing problems could be identified. The outcomes of this

analysis identified two major research trends. The first research problem focused on the relations between play and learning, and the second centred on the need for diversity rather than universalism in early childhood education. The methods that were primarily drawn upon focused on approaches which pushed against a traditional medical model so that diversity of children and early childhood practices could be featured. The theories that the early childhood education field has drawn upon focused primarily on moving beyond maturational theory of child development, where the universal child is foregrounded, to looking for other theories of child development that examine diversity and do not normalise the child against external and Western standards. Theories that supported critical thinking through asking questions about the dominant early childhood discourses helped early childhood researchers make visible the effects of colonisation and push against this effect. This was noted as being particularly relevant for those in the south.

What has been found is that 'First World problems' have colonised the international early childhood vista and distorted research trajectories and narratives around what counts as valuable knowledge for the field. The contributors of this handbook have examined theoretical contradictions and political contexts of their regions, particularly those in the south, where new research problems have been made visible and where a need for diversification was found. Further, the growing maturity of the early childhood education research community and the pressing problems faced within regions in the south give new insights into what can be deemed a more balanced international perspective of early childhood education. What is fascinating is how the problems of the north and the south have a common thread, but come from a completely different cloth.

This chapter contributes to scholarship by making visible an analysis of the activities of countries in the north and south where new perspectives on what constitutes a more balanced and diverse view of international research in early childhood education have emerged.

Chapter 2
Governing Childhood

Iris Duhn

Abstract The chapter provides an overview of ideas of childhood to explore how childhood as a domain is governed in cultural, social and educational discourse. The core assumption is that childhood is a modern invention: the child as potential, as knowable and describable and as essentially different to the adult has made childhood one of the projects of the modern state. Particularly in the twentieth century, childhood has been considered as a domain where future adults can be shaped. Childhood appeared as a cultural resource and provided a specific focus for reform, based on the understanding that childhood is essentially different to adulthood. There seems to be broad consensus that we now live in times of rapid change where traditional assumptions, beliefs and rationalities appear less coherent than in the past. The modern core beliefs in essential 'truth' as a possibility, and in progress as a given, are being contested. It is not surprising then that traditional ideas of childhood are currently 'under reconstruction'. The chapter traces some of the shifts to outline how childhood is governed in discourse.

Keywords Childhood • Governmentality • Malleability • Discourse • Modernity

2.1 Introductory Note to the Reader

This chapter makes reference to Foucault's concept of governmentality and is indebted to post-structural thought and discourse analysis. There are limitations to a focus on childhood as discourse and as currently emerging scholarship in early childhood highlights, language is only one aspect of being and becoming (Kocher et al. 2015; Lenz-Taguchi 2010). The emphasis on considering materiality, performativity and the complex entanglements of being human in an ultimately unknowable, lively world which is inhabited by multitudes of humans and more-than-humans is a vital contribution to early childhood scholarship and education at a time when human-induced change affects life on a planetary scale (Barad 2003; Heise 2008;

Panelli 2010). While the turn towards matter generates new perspectives and insights that pose urgent questions regarding humanness and the human place on a shared planet, this chapter reviews childhood as a modernist invention (Steedman 1995). It complements the newly emerging themes and provides a perspective of childhood as a governable domain.

2.2 Governmentality and the Domain of Childhood

Foucault's notion of governmentality (1994) is particularly useful in understanding how ideas of the child generate discourses and practices which govern childhood. Governing and knowledge production are intimately linked in the concept. It is through the human sciences, such as education, sociology, psychology and economics, that expert knowledge and practices with regard to the human subject emerge. Studies of governmentality emphasise that these sites of knowledge production play a vital role in generating bodies of knowledge that cohere into mentalities or 'truths' which then legitimise particular forms of governance (Rose 1999). Generally speaking governmentality refers to rationalities or ways of thinking about governing with a focus on 'the bodies of knowledge, belief and opinion in which we are immersed' (Dean 1999, p. 16). Governmentality as critique is concerned with how social and cultural products, listed by Dean as 'theories, ideas, philosophies and forms of knowledge' (Dean 1999, p. 16), legitimise practices to such a degree that other ways of thinking and doing become not only unacceptable but also unimaginable.

Why then think about the governing of the child and childhood? As argued by sociologists of childhood, who investigate childhood predominantly in western social, economic and cultural contexts (Buhler-Niederberger 2010; Cook 2005; Cunningham 2009; Curti 2009; Lee 2005; Prout 2005), childhood often serves as an indicator of broader social and cultural understandings, and thus it is important to pay attention to the specific configuration and governance of the domain. Historically, early childhood education is a modern invention and the idea of the unfolding, incomplete child who is socialised and enculturated, and thus made fully human through education, still dominates much of the discourse, policy and practice in early childhood education (Baker 2001; Brosterman 1997; May 2006). As argued by Cannella and Viruru (2004), '….the status of the child is used to signify and legitimise the regulation of behaviour of particular human beings…We [early childhood experts] are trained to think that children are egocentric, easily distractible, noisy and curious and that our job [as educators] is to be accepting of those characteristics while moving children forward' (p. 2). The writers pinpoint 'the child' in early childhood discourse as the subject of intense regulatory practices. These practices aim to educate and socialise the child from the child's state of becoming – and thus its incomplete and yet unformed state – towards adulthood as 'being' and thus complete and stable (Stables 2008).

2.3 Imagining Childhood

Methodologically, the chapter does not intend to define how childhood is governed nor find a solution to a particular educational problem. In a way this endeavour is inimical to the field of education with its traditional emphasis on intervention and reform (Baker and Heyning 2004). Instead the idea is to intensify understandings of the child by tracing its conceptual implication in the making of 'worlds' (Taylor and Blaise 2014). How do we think the child? What is the basis for knowing her? While largely assumed as known in educational discourse, the child as subject and childhood as a category or domain are rarely analysed. The child is often taken for granted in educational discourse. The child subject can be described, observed, assessed and educated – on what grounds? By tracing the child in discourse, the familiar concept of childhood becomes strange and less knowable and creates a space for critical engagement with ideas of childhood in early childhood education (Duhn 2011; Kjorholt 2002; Rossholt 2009).

Specifically, the chapter explores how contemporary changes in political rationalities and cultural imaginaries coalesce around childhood as a concept in early childhood education from a critical childhood studies lens. It does this by drawing on cultural studies, in particular cultural literary theory, on governmentality studies and on the sociology of childhood. Such a broad approach to the topic responds to the call for interdisciplinary perspectives in critical childhood studies and in the sociology of childhood (Cannella and Viruru 2003; Prout 2011). Childhood studies itself is a relatively new academic field which has emerged alongside the sociology of childhood (James et al. 1998; James and Prout 1997; Jenks 1996; Prout 2003). Contributions to childhood studies have come from across disciplines. For the past two decades, literary criticism and cultural studies (Kincaid 1998; Lesnik-Oberstein 1994; Warner 1994; Zornado 2001) as well as childhood education scholars (Cannella 1997; Dahlberg et al. 1999; Moss and Dahlberg, 2005; Tobin 1997) have generated new perspectives of the child and childhood to challenge childhood as a domain that has been essential to modernity (Prout 2003). These perspectives have analysed childhood as a function of language (Rose 1994; Wallace 1994, 1995) and, from a governmentality perspective, as a political domain in discourse and policy (Baker 1998; Bloch and Popkewitz 2000; Grieshaber 2000; Hultqvist 1998). Governmentality perspectives contribute a relatively new way of understanding power relations in education, and it is evident that early childhood education has much to gain from governmentality perspectives that engage critically with understandings of childhood as deeply embedded in power relations (Ashenden 2002; Bloch 2003; Duhn 2006; Hearst 1997; McGillivray 1997; Millei 2011; Popkewitz 2003; Popkewitz and Bloch 2001).

2.4 Imagining Modern Childhood: Childhood as Adulthood's Other

While childhood as a domain shares some characteristics with other social denominators of difference (i.e. ethnicity, gender, sexuality), childhood has one overriding aspect that is singular: childhood is essentially different from adulthood. Childhood has a particularly strong association with three of the cornerstones of the modern episteme: universality, origin and progress (Rose 1994). These cornerstones reinforce the essential difference of childhood as adulthood's other. Western discourses of childhood emphasise that every adult on this planet has had a childhood (regardless of whether it was ideal or less than ideal). Childhood is thus assumed to be a universal human experience. The second cornerstone is an origin which appears in discourse as the understanding that many problems in adulthood have their origin in childhood and can thus be traced back to their source. And thirdly, there is the idea of progress which finds its expression in the belief that childhood is a state of being that is left behind or 'grown out of' as biological maturity is reached. The child moves steadily towards the future where adulthood awaits as a goal of becoming.

Another way of making sense of how childhood is governed in discourse is to consider it as adulthood's conceptual 'other'. The child is essentially different to the adult, and this difference as otherness produces the child as the not-yet adult, the adult in the making. Conceptually, adulthood is the normative domain against which childhood is assessed (Popkewitz and Bloch 2001). Childhood, the domain of the child as the incomplete and unstable subject and thus in need of adult governance, strengthens and normalises adulthood as the domain of the self-governing adult subject. The child represents all that which either complements or opposes the idea of the adult: the child is innocent/the adult knows, the child is dependent/the adult is autonomous, the child creates fantasy/the adult lives in reality, and so forth.

2.5 Childhood as Origin

Childhood's essential nature depends on the story of origin and almost mystical beginnings. Childhood is the time and space where the future adult takes shape – a conceptual womb. Childhood thus is dangerous territory; this is where the foundations for normal/problematic adulthood are laid. Childhood is not only time and space; it is also essence: the normal adult has left the child behind or locked it safely inside ('the inner child'). As essence, childhood can be revisited in an effort to stabilise the adult self (Lesnik-Oberstein 1994; Rose 1994). The child serves as a touchstone for normality in times of personal crisis, caught in phrases such as 'finding the child within' to understand or heal or change the adult for the better. Childhood operates through separation and the idea of essence; childhood is an essential condition for the yet-to-unfold adult as well as for the adult whose 'unfolding' has been incomplete (Caselli 2010). The child and the adult are conceptually locked in

an asymmetrical relationship where one, the child, represents 'raw material', a malleable resource, for the other, the adult. In addition, childhood as a domain presumes that all children share the essential universal traits which define them as different to adults, regardless of location and culture (Stephens 1995).

2.6 Childhood as Potentiality

Adult longings and yearnings do not only coalesce around the child; they produce the expectation of the child's unfolding as normality. Childhood appears as a repository where the child's unfolding potential can be monitored, controlled and regulated. Castaneda (2002) suggests that the idea of the child carries potentiality as its overriding principle. She proposes that the condition of childhood finds its value in potentiality. The form that the child's potentiality takes is consistently framed as a normative one, in relation to which failure is always possible. Should a child either fail to possess or to realise its potential (as in the notion of 'stunted growth'), he or she remains a flawed child and an incomplete adult (p. 4).

Childhood is by definition risky territory and thus warrants high measures of intervention. Childhood is the domain of the child subject whose normality is measured against the expectation of unfolding potential. This is of particular relevance to education (Fendler 2001). However, the child's potentiality is shadowed by the risk of failure to fulfil expectations.

2.7 The Child as Cultural Resource

In her work on the function of the child in discourse, Castaneda (2002) argues that the child, categorised as unequal and essentially different to the adult, has to be analysed in relation to the ways in which childhood has been used as a resource for cultural projects. She suggests that this kind of analysis foregrounds the value of childhood for the maintenance and stabilisation of the concept of adulthood. This emphasis on potentiality links concept of childhood directly to the future and makes childhood essential to the idea of transformative change, particularly in education (Bloch et al. 2006). The child is that which has the potential to become anything. This implies that the child is also never complete in itself. The child is not only in the making, but is also malleable – and so can be made (Castaneda 2002, p. 3).

The substance or essence of the child in discourse is precisely the lack of 'its' form. That is why childhood is a domain where new and old discursive regimes overlap: it seems that the child's malleable 'nature' is becoming more pronounced in times of accelerated social change. Possibly due to its malleability, the child now makes its various and multi-faceted appearances across and within discourses outside of the traditionally binary categories of adulthood/childhood. An example is the softening of the adult/child boundaries, with current research focusing on the

performative nature of both adulthood and childhood and its complex interrelationship (Johansson 2011). According to Castaneda, however, regardless of the discourse, the child is continuously reinscribed as an entity in the making and as a cultural resource.

2.8 A Very Brief History

To gain a sense of the malleability of the child as entity in the making and as cultural resource, filmmaker and cultural critic Patricia Holland's (1996) seminal snapshot of some of the transformations in perceptions of childhood over the past 50 years is insightful. Holland, who has based her analysis on visual representations of the child, argues that particularly during the second half of the twentieth century, childhood has consistently been linked to the future of the nation. According to her, childhood represented a beacon of hope in the post-war period, while in the 1970s, childhood and children 'bore the vision of a child-centred, spontaneous renewal of society' (p. 156). From the 1990s onwards, the child still represented the future, however, the earlier hopes that were attached to childhood have taken a more pessimistic turn. Holland emphasises that:

> Children have become the focus of moral panics which suggest a future that seems bleak and unknowable. Hope for a better world now seems unrealistically utopian and a childish search for the sensation of the minute is placed above future plans. Paradoxically we no longer look forward to a maturing world but to a world of recurring childishness. (p. 156)

The childishness that Holland identifies as a characteristic of the future arises specifically in relation to consumerism which thrives on the idea of the child as rapacious and in need of instantaneous gratification of desires. Alongside well-established discourses of the innocent and docile child, new discourses of the child as consumer see childhood increasingly 'in danger' of being governed through commercialisation (Buckingham 2011; Kanner 2005), while others propose to consider 'the consumer child' in terms of normative participation in new economic and social configurations of 'the neoliberal self' (Ailwood 2008; Saltmarsh 2009).

2.9 Shifts in Perception of Childhood

Holland (1996) argues that as an effect of the discrepancy between 'old' and 'new' representations of children, childhood itself has moved into the focus of adult fantasies. Children, who through new technologies have access to a wide range of highly diverse knowledges and pleasures, can no longer be easily imagined as innocent or controllable. As cultural resource, children at times represent a society or even a world that appears as potentially out of control and dangerous which makes childhood the focus of moral panics:

Reports in the tabloid press – on the addictive qualities of computer games, on the tendency of children to imitate violent videos, and so on – have been couched in terms of pure hysteria, while those in the responsible press often reflect a mixture of panic, ignorance, and denial (Holland 1996, p. 156).

Socially and culturally, the idea of childhood as a safe territory, well protected and regulated by well-meaning adults, is in danger of being subverted by a multitude of new, less homogenous and global representations of childhood (Chin 2003; Pence and Hix-Small 2009; Rizzini and Bush 2002). Holland suggests that a general sense of uncertainty about the future has led to a gap between representations of children and the very idea of childhood.

Sociologist Nick Lee (2001) echoes some of Holland's sentiments by emphasising that before we entered 'the age of uncertainty', adults and children fell into distinctly different categories of being human. However, Lee suggests that rather than falling into general childishness as a result of blurred boundaries, this blurring could be an opening up of conceptual space for adults to 'becoming child'. Lee is concerned with the danger of romanticising and stereotyping the child in attempts to re-establish the adult/child binary. The romantic view of the child represents the child as an embodiment of all that which the adult has to leave behind in the process of growing up (O'Loughlin 2009). The adult, understood as complete, self-possessed, stable being, views the child as a source of imagination and creative becoming. The blurring of boundaries between the adult and the child, Lee argues, offers the opportunity of considering 'becoming child' as a turn towards imagination and creativity as human (not childish) capabilities and potential.

Holland and Lee highlight two very different aspects of current understandings of childhood. Holland detects a ruthless use of images of the child as consumer which puts the fantasy of childhood as a time of innocence at risk. She interprets the blurring of adult/child boundaries as an indication of a general push towards increased mindless consumerism, based on the idea of the child as in need of instant gratification and in search of endless pleasure. The child and the adult become the same in the pursuit of untethered consumerism. At the same time, the media produces discourses of 'the child' as risky and unpredictable, while adults' fantasies of childhood as a time of purity and innocence are reinvigorated as a representation of that which has been lost (Kincaid 1998; Louv 2008; Malone 2007). Lee (2001) gives the blurring of boundaries a positive spin by suggesting that we introduce multiplicity or 'becoming' into our understanding of the adult/child relationship. Through different lenses, Lee (2001, 2005) and Holland (1996) both argue that the child appears in cultural discourse to produce meanings about adulthood. The child itself remains strangely insubstantial – a field of possibilities that is constantly reshaped by power relations.

2.10 The Global Child: Old and New

This section examines how familiar discourses of childhood are reinvented, reshaped and realigned in a post-industrial/post-modern paradigm. I have deliberately excluded discourses which are traditionally strongly associated with modernist early childhood education, such as developmental psychology (Burman 2000). The reason for this is that developmental psychology is a discourse in itself, which produces a historically specific child whose development is predictable and measurable. Much work has already been done to analyse how the dominance of developmental psychology in early childhood education constructs the child as a subject of modernity (Burman 1994; Cannella 1997; Dahlberg et al. 1999; Fendler 2001; Peukert 1999; Walkerdine 1984). More recently, the focus has shifted to global trends which include the rapidly changing economic, social and cultural landscapes of post-industrial societies and newly emerging industrialised nations, such as China, India and Brazil, amongst others. These analyses emphasise the need for multiple perspectives of the child with an emphasis on diversity and the willingness to accept, and work with, complex issues arising within new post-structures, such as networks, mobility and relationality (Prout 2011). These kinds of analyses, however, are only just beginning to reshape understandings of childhood which may be an indication of the solidity of childhood as a modern invention.

2.11 Maintaining the Domain and Challenging the Domain

The persistence of cultural representation of the child as subject of the future or as future subject highlights childhood's deep attachment to modernity. 'The child of modernity has been closely associated with the idea of progress—childhood has been, and still is, intertwined with imagining the future' (Holland 1996). But whereas the modern ideal child has been inscribed as essentially different to and completely dependent on the adult, the child of global modernity emerges through representations of the autonomous and capable child (Pence and Hix-Small 2009). These new representations of the global child transgress the segregated space of modern childhood: the new child still leads the way into the future, forging a youthful path ahead; however, this representation of childhood presents the child as capable, confident and knowledgable. This can be extended to mean that as adults we are now subject to discourses that encourage our desire to be like that child, or to develop some of the modern/global child's characteristics and dispositions, such as a dynamic youthful disposition that is embedded in the new global post-structures of networks, mobility and relationality (Bratich 2009; Depeau 2001; Packer 2003).

2.12 Towards Diverse Childhoods

The emerging global child is not represented through one image or idea – the very nature of desire in consumer culture is to awaken new, different desires; the global child is an assemblage of old and new discourses. By outlining some of the shifts and tensions in contemporary childhood, I continue the argument that current ideas and practices around childhood/the child are constituted through discourses which contradict, reinforce and disrupt modern ideas of what makes childhood (De Block 2007). Some of disruptions of modern childhood coagulate around a new image of the child as far more capable than its modern predecessors. Despite this new emphasis on capability, the global child retains its function as a malleable entity and as subject-in-the-making (Castaneda 2002); however, the subject in question is global and neoliberal. Global and neoliberal shadings create a child who is different and yet similar to its previous incarnations as a modern subject-in-the-making.

Childhood as a constitutive discourse of modernity and of the liberal capitalist world order is deeply entangled in the reorganisation of political and economic structures through discourses of neoliberalism and globalisation. Rather than thinking of childhood as a category which is being reorganised in post-industrial contexts, childhood can be considered as a discourse which constitutes and is constituted by a new economic and political order (Ruddick 2003; Stephens 1995). From a governmentality perspective, the global neoliberal child is produced by, and produces, changing understandings of what it means to be a 'good subject' in global times. Ruddick (2003) suggests that childhood has largely been excluded from critical analyses of global shifts in political and economic rationalities. According to Ruddick, this is an indication of the positioning of childhood on the local level where childhood 'has often been relegated to the private and/or domestic sphere' (1991, p. 334). The private and/or domestic sphere seems far removed, and thus irrelevant, for analyses of macro change such as the restructuring of national economies on a global scale. Childhood remains largely a local or national issue, unless it is discussed as a global project as, for example, in international debates on child labour (Burman 2008). Childhood in global times is marked by, on the one hand, the prevailing ideal of childhood as a protected space where the child is dependent, economically unproductive and under the care and control of the family. On the other hand, the ideal of childhood is increasingly challenged by 'children who, riding waves of global tides, head households, fight in civil wars, and travel alone transnationally' (Chin 2003, p. 310). Faced with the challenges to the ideal of childhood, the cultural response in western nations seems to be a clinging to the ideal rather than a willingness to re-image what globalised childhood may mean.

The images of unchildlike children, or 'children out of bounds' (Chin 2003), that flood middle-class living rooms all over the world during prime-time television have the effect of raising parental anxieties with regard to their own offspring. The desire to protect and shelter middle-class children from the undesired effects of globalisation has fuelled the fear that childhood itself is at risk. The notion of paranoid parenting (Furedi 2001, 2002) captures the western middle-class phobia of

cotton-wooling or 'bubble-wrapping' children (Malone 2007). This means that children have less possibilities of sharing their experiences and understandings with each other, due to an increased emphasis on protecting their imagined innocence. Childhood, specifically middle-class childhood, is in danger of becoming a domain of ever more intense surveillance and parental investment (Ema and Fujigaki 2011; Vincent and Ball 2007; Wise 2004; Yeshua-Katz 2013). One of the many tensions created by the current transformation of childhood is the fact that many children have extensive knowledge of the world which they have to make sense in isolation rather than in conjunction with their peers (Dahlberg et al. 2007). This 'knowing' (but possibly confused) child may then become a challenge to the romantic ideal that, as another effect of globalisation, is making the rounds as the only acceptable version of childhood. The global child seems to be a construct that individualises while it creates totality, while romanticised images of childhood make idealised western childhood appear as a global phenomenon; fewer children, both 'at home' and in developing nations, befit the ideal (Bordonaro and Payne 2012; Sircar and Dutta 2011).

This chapter has argued that it is across discourses and domains that the child functions as an organising principle of adult worlds. Jo-Ann Wallace made the point 20 years ago that in the field of theory, 'the child' as a 'foundational product of the modern episteme, remains an unacknowledged and therefore unexamined organising principle' (Wallace 1995, p. 284). Although some ground has been covered in the past decades, childhood studies scholars continually emphasise that Wallace's argument still stands (Kehily 2009; Prout 2011; Thomas 2007). As long as the child's function remains uncontested and largely invisible, more complex perspectives on the child in theory cannot emerge. The intention throughout the chapter was to problematise the concept of the child by mapping how the child is, and has been, made intelligible in the modern episteme. I have followed diagnostic rather than interventionist desires.

Childhood as a domain has, it seems, suffered from a particular absence of a focus on specificity. Childhood, and being a child, controls and generalises those who are deemed to belong primarily to this domain. To be a child is assumed to be an identity that overrides all other possibilities of being. It is one of those instances when 'identity becomes a set of hard and fast rules that police comportment' (Probyn 1996, p. 23). It is also the one domain that is particularly temporary and spatial in western social realities – everyone has been a child, everyone has experienced the spaces of childhood (for instance, schools), and everyone has very firm beliefs about what ideal childhood should be like and who should experience it. This chapter has argued for critical engagement with the concepts to create spaces in education and beyond where more complex becoming across domains support fresh perspectives of childhood, adulthood and, ultimately, humanness.

Chapter 3
Cultural-Historical and Activity Theories Informing Early Childhood Education

Marilyn Fleer and Nikolai Veresov

Abstract There are many theories that have informed early childhood education, including cultural-historical and activity theories. In this chapter, we present a discussion of cultural-historical and activity theories, beginning with the foundational logic that has informed both these theories – dialectical logic. We focus our discussion specifically on play and learning because this is the period of development being addressed by this handbook. Beginning with the original conception of play, learning and development proposed by Vygotsky, this chapter moves forward to the contemporary context of early childhood education, where we specifically illustrate key concepts from cultural-historical and activity theories through the research and theoretical writing of leading early childhood scholars. Cultural-historical concepts have been extensively used in the contemporary literature, as foundational for the key themes of: *Play pedagogy; Pedagogical models that support the development of play; Play from the perspective of children;* and *Digital play.* Together, these point to how cultural-historical concepts have been used by scholars to inform their work, as well as setting out the challenges and future directions in early childhood education.

Keywords Early childhood • Play • Learning • Development • Cultural-historical theory • Activity theory

3.1 Introduction

L.S. Vygotsky left a huge legacy for the field of early childhood education by generating a theory of development that we have come to know as cultural-historical theory. Activity theory (AT) emerged in order to capture Leontiev's work (Miller 2011), and until recently this theory dominated thinking in the Soviet Union and

later Russia (Zinchenko 2007). Yet today, both theories can be found used in early childhood education in many different countries of the world. The aim of this chapter is to discuss those key concepts that have come from cultural-historical and activity theories and that have informed early childhood education research. To achieve this goal, this chapter discusses the foundational logic that underpins cultural-historical and activity theories, introduces the seminal works of Vygotsky, Leontiev and Elkonin on play, briefly explores the zone of proximal development and leading activity and examines how contemporary play researchers have drawn upon these concepts to inform their research and models of curriculum or pedagogy.

An increasing awareness of Vygotsky's work began to emerge in the Western world in the 1960s. Scholars published books in English on cultural-historical theory, although it was not always named in this way. The various translations of Vygotsky's original writing (e.g. *Journal of Russian and Eastern European Psychology*; The Collected Works of L.S. Vygotsky) also contributed to this interest in cultural-historical theory and activity theory. A number of journals were formed with the view to publishing papers related to theories and empirical work that drew upon Vygotsky's concepts, but also those of Leontiev (e.g. *Mind, Culture and Activity*; *Cultural-Historical Psychology*; *Outlines: Critical Practice Studies*). These journals published in English have brought well-known works written in Russian to many parts of the world. These journals sit alongside of a range of different journals in different countries that have reproduced and progressed the original work of Vygotsky and Leontiev. Further, regional and later international conferences dedicated to cultural-historical theory and activity theory were held (e.g. International Society for Cultural-Historical Activity Research). The latter bring together all the different continents of the world to share in discussions and present findings informed by cultural-historical and activity theory theories, all of which have been influential in early childhood education.

The keen interest in Vygotsky's work in the West saw a different trajectory for discussing and naming his work to that of the Soviet and later Russia. The journal papers, translation of articles and the Collected works, plus the conferences and congresses, were activities that saw a change in how the original ideas of Vygotsky and Leontiev were discussed and used. Miller (2011) remarks that the secondary commentary published in English is now named as '*Cultural-Historical Activity Theory*, or *CHAT* as it is more colloquially known, and *Sociocultural Theory*' (p. 19; Original emphasis). There exists difference, similarities and tensions in the various groups that subscribe to these emerging terms to name the original theories of Vygotsky or Leontiev. For instance, the field of early childhood education has drawn upon cultural-historical theory, activity theory or sociocultural theory to name how their study designs are framed. The latter has tended to dominate the field more than the former two in Western European and Northern American contexts. In the Nordic and Eastern European countries, we find the term cultural-historical has tended to dominate the early childhood literature (both psychology and early childhood education), but also references to activity theory and sociocultural theory exist.

What is prevalent in the broader education literature are AT, CHAT, sociocultural and cultural-historical theories. However, in this chapter we focus only on activity theory and cultural-historical theory because more early childhood scholars have drawn upon the concepts that come under these two theories. In our discussions of the contemporary literature, we have categorized papers that use the term sociocultural theory under the heading of cultural-historical theory, because the works reviewed tend to fall under this theorisation more than activity theory.

What is common to both cultural-historical theory and activity theory is the use of dialectical logic, which is a non-reductionist materialist (non-dualistic) conceptualization of human development (Fleer 2014c; Stetsenko and Arievitch 2010). We now turn to a brief overview of this key foundational logic in the next section so that a deeper philosophical understanding of cultural-historical and activity theories can be achieved.

3.2 Dialectical Logic: The Foundations of Cultural-Historical and Activity Theories

Cultural-historical theory is a developmental theory since it takes the *very process of mental development* as its subject matter. Development is not a simple change, growth or maturation (Vygotsky 1998, pp. 189); it is a complex dialectical process of sociocultural genesis of human mind. This section outlines several characteristics of a dialectical approach to development, which are general and foundational for cultural-historical studies of cultural development.

3.2.1 Development as the Process of Sociocultural Genesis of Human Mind: Overcoming Dualism

Dialectic as presented in works of Hegel is a general logic of studying any kind of complex processes of development in all its key and foundational aspects. However, psychological development, the development of human mind, has its own specific nature and characteristics; this should be taken into account when we apply a dialectical analysis to this particular domain of development.

In contrast to classical developmental psychological theories, non-classical cultural historical theory considers the social world not as factor influencing the process of development, but as a source of development of higher mental functions of a human being. As Vygotsky puts it:

> …development is not simply a function which can be determined entirely by X units of heredity and Y units of environment. It is an historical complex, which at any stage reflects its past content. In other words, the artificial separation of heredity and environment points us in a fallacious direction; it obscures the fact that development is an uninterrupted process

> which feeds upon itself; that it is not a puppet which can be controlled by jerking two strings. (Vygotsky 1993, p. 253)

Rethinking role of social environment is a key foundational distinguishing feature of cultural-historical theory

> The role of the social environment is the source for the appearance of all specific human properties of the personality gradually acquired by the child or the source of social development of the child… (Vygotsky 1998, p. 203)

The following example illustrates the developmental content of this position. This example, Vygotsky wrote, shows the essence of the process of cultural development expressed in a purely logical form (Vygotsky 1997, pp. 105). In the beginning, the pointing gesture of a child is merely an unsuccessful grasping movement aimed at an object. When the mother comes to the aid of the child and comprehends his movement as a pointing gesture, the situation essentially changes. The child's unsuccessful grasping movement gives rise to a reaction not from the object but from another person. The original meaning of this unsuccessful grasping movement is thus imparted by others. And only afterwards the child him/herself begins to treat this movement as a pointing gesture. Here, the function of the movement itself changes: from a movement directed towards an object, it becomes a movement directed towards another person, a means of communication; the grasping is transformed into a pointing. Thus, the pointing gesture first begins to indicate by movement which is understood by others and only later becomes a pointing gesture for the child him/herself.

In cultural-historical theory, the development of human mind is a 'path along which the social becomes the individual' (Vygotsky 1998, p. 198). Social environment therefore is not considered as a factor in development, but as a source of development (Vygotsky 1998, pp. 203).

Rethinking the status of 'the social' not only creates a pathway of 'distinguishing the natural and the cultural, the essential and the historical, the biological and the social in the mental development' (Vygotsky 1997, p. 2); it creates opportunities to overcome a dualism of two groups of factors (biological and social) existing in a traditional psychological theoretical framework, by introducing a dialectical approach to the study of mental development. In this, the cultural-historical approach overcomes a postulate of external factors and orients research on the internal essence and the origins of development.

3.2.2 Transformation and Qualitative Reorganisation: Overcoming Mechanistic Approach

Development is always a very complex and contradictory process, but, first of all, it is a dialectical process of qualitative change. The process of mental development,

> …is not confined to the scheme 'more-less', but is characterized primarily and specifically by the presence of qualitative neoformations that are subject to their own rhythm and

> require a special measure each time. It is not correct to assume that all development is exhausted by the growth of these basic, elementary functions which are the prerequisites for higher aspects of the personality. (Vygotsky 1998, p. 190)

Second, mental development is not a linear, homogenous process. Simultaneously, there are different levels of development of different psychological processes and functions in the child. At each age, there are functions that are already matured (developed) and there are functions that are in a process of maturation. So there is always a complex nexus of (1) functions that will develop but are currently in an embryonic state, (2) functions that have not yet developed but are in the process of development and (3) developed functions. Metaphorically, they could be defined in turn as 'buds', 'flowers' and 'fruits' of development (Vygotsky 1935, p. 41).

Continuing Vygotsky's metaphor, we could say that the results are 'fruits' of development. However, these 'fruits' are of a very special nature. The result of development is not just new functions that appeared as outcomes at the end. Results of development are not new higher mental functions only, they are 'qualitative neoformations' (Vygotsky 1998, p. 189).

'Neoformation' is a result of reorganisation of whole system of functions, a new type of construction of child's consciousness and mental functions (Vygotsky 1998, pp. 190). This new type of construction is the result of qualitative reorganisation of the whole system. Actually,

> Higher mental functions are not built up as a second story over elementary processes, but are new psychological systems that include a complex merging of elementary functions that will be included in the new system, and themselves begin to act according to new laws; each higher mental function is, thus, a unit[1] of a higher order determined basically by a unique combination of a series of more elementary functions in the new whole. (Vygotsky 1999, p. 43)

Thus, not a new function in itself, or a new higher mental function, but a qualitatively new structure of functions characterises the results of development.

This dialectical understanding orients research to focus on transformations as an important aspect of the process of development. However, not every transformation is of a dialectical nature, as a qualitative change of the whole system; there are transformations that happen within the system as reconfiguration of existing components, parts and elements. Following Hegel's dialectical approach, we could call them 'mechanical transformations'. Human mind is not a mechanical system by its nature, and developmental transformation is not a recombination of existing components. Developmental transformation is a qualitative change of the whole system where a new organ brings reorganisation to the whole system in such a way that the new (reorganised) system becomes a unity of a higher order and begins to act according to new laws. Distinguishing two types of transformations allows for the study of the process of social formation of human mind in two interrelated aspects: (1) as a quantitative change and (2) qualitative reorganisation.

[1] Unity (единство) in Russian original text (Vygotsky 1984, Vol 6, p. 58).

3.2.3 Dialectics of Contradictions: Development as Drama

General philosophical idea of dialectical contradictions as a moving force of development was reconsidered within cultural-historical theory in terms of development as a dramatic process, as a drama.

> …social relations, real relations of people, stand behind all the higher mental functions and their relations (Vygotsky 1997, p. 106). …every higher mental function was external because it was social before it became an internal strictly mental function; it was formerly a social relation between two people. (Vygotsky 1997, p. 105)

This foundational theoretical position was developed into a general genetic law of cultural development of higher mental functions:

> … every function in the cultural development of the child appears on the stage twice, in two planes, first, the social, then the psychological, first between the people as an intermental category, then within the child as a intramental[2] category … (Vygotsky 1997, p. 106)

'The basic principle of the functioning of higher functions (personality) is social, entailing interaction of functions, in place of interaction between people. They can be most fully developed in the form of drama' (Vygotsky 1929/1989, p. 59). The social, interpsychological form of higher mental functions is a dramatic interaction between people; it is an (interpsychological) drama of the personality as a participant in an (interpsychological) drama (Vygotsky 1929/1989, pp. 69).

The dramatic frame of the personality as the unique organisation and hierarchy of higher mental functions is the result of unique dramatic interpsychological collisions that have happened in the life of the human being and their overcoming by a human being, the intrapsychological result of the individual' s unique developmental trajectory. In overcoming social dramatic collisions (dramas of life) human being creates his/her unique personality.

The drama of the personality as a participant in the drama of life is the essential contradiction and the moving force for development. Thus, the intrapsychological consists of internalized dramatic social interactions: 'the dynamic of the personality is drama' (Vygotsky 1929, p. 67). Here an abstract dialectical idea of a contradiction as a moving force of development obtains its concrete psychological content in the concept of the drama of life as a moving force in the development of human personality (Veresov 2016).

A cultural-historical understanding of development as a process of sociocultural genesis of human mind is based on the general principles of Hegel's dialectics. Contradictions existing in various forms of dramatic social events on the interpsychological plane bring qualitative reorganisations to intrapsychological system of the child's higher mental functions. This is a foundational framework for studying development in a cultural-historical theoretical tradition. All concepts of cultural-historical theory, such as 'the social situation of development' and 'zone of proxi-

[2] In Russian original it is interpsychological (интерпсихическая) and intrapsychological (интрапсихическая) (Vygotsky 1983, p. 145)

mal development', reflect different aspects of complex and dynamic processes of development, and therefore, they represent a system of interrelated theoretical tools, which orients the research lens on the dialectics of development (Veresov 2014).

We now turn to a discussion of these interrelated concepts that fall under the lens of dialectics.

3.3 Conceptualising Play

There are three foundational studies on play and its role in the child's development – the articles of Vygotsky (1966, 2016)[3] and Leontiev (1959; 2009)[4] and the book of Elkonin (2005/1978). In this section, we will discuss some key dimensions of research on play that are generated by the theoretical framework developed in these two foundational papers. We begin with a brief analysis of Vygotsky's paper. This relatively small paper does not represent the advanced psychological theory of play that one might expect, but it does contain several key theoretical and methodological ideas which were accepted and developed in both the cultural-historical and activity theory traditions. Specifically, Vygotsky's writing on play represents some directions for a cultural-historical analysis of play. In his work, we find two interrelated analytical foci: (1) the socio-cultural nature and genesis of play itself and (2) its role in the mental development of the child.

The analysis of the socio-cultural nature and genesis of a child's play covers four main aspects that include (1) the view of play as a social and cultural phenomenon; (2) the imaginary situation, as the main distinguishing feature of play; (3) the contradictions in play through studying the genesis of play; and (4) the development of play itself. The role of play in the mental development of the child is discussed through the conceptual lenses of (a) play and zones of proximal development; (b) the discrepancy between the visual field and the field of meanings in play; and (c) the dialectical relationship between meaning and action, as the developmental characteristics of play. In this section, we will mostly discuss two of these – the socio-cultural and historical nature of play and play in relation to ZPD.

3.3.1 Socio-cultural and Historical Conception of Play

The socio-cultural and historical nature and genesis of children's play was the focus of the long-term research of Daniil Elkonin. According to Elkonin, the most important contribution to the theory of role play is that:

---

[3] We refer to a new translation of Vygotsky paper on play of 1966 published in the special issue of International research in Early Childhood journal.

[4] This article of Leontiev was published in Russian in 1959 (Leontiev 1959, pp. 270–286).

> …role play develops in the course of society's historical evolution as a result of changes in the child's place in the system of social relationships. It is thus social in origin as well as in nature. Its appearance is associated not with the operation of certain internal, innate, instinctive energy, but rather with well-defined social conditions of the child's life in society (Elkonin 2005/1978, p. 86).

This conclusion, supported by the huge amount of experimental data presented in the 'Psychology of play' (2005/1978), could be considered as a continuation of one of Vygotsky's key ideas, but this conclusion cannot be attributed only to role play, and it seems to have a relevance to all kinds of play.

Another of Elkonin's foundational contribution to the cultural-historical conception of play was through his broadening of Vygotsky's notion of play to include different types of play (such as manipulative play in early infancy) and in developing a conception of developmental order of play as a leading activity linked to particular orientation to reality in early childhood.

Play as a cultural and socio-historical phenomenon, the challenges and contradictions of play, and new types of play in contemporary sociocultural environments, remain central in the research of Smirnova and Gundareva (2004), Smirnova and Ryabkova (2010), Elkoninova and Bazhanova (2007), and Kravtsova (1999, 2004). Some of these research programs contain critical analyses of Elkonin's theory of play; Elkoninova and Bazhanova's (2007) research discovered a connection between an 'ideal form' of play and fairytales. These scholars have progressed the original small paper on play written by Vygotsky, through sharpening theoretical understandings and empirical work in this area.

3.3.2 Contemporary Work on Cultural Expressions of Play

Recent research that draws upon cultural-historical theory, not only within cultures but across cultures, expands the original work of Elkonin (2005/1978). For instance, Pellegrini (2011) in looking primarily at the northern hemisphere continents has argued that research into the development of play has a very short history and that mostly research on play has been embedded in other topics, such as theory of mind, and that a focus on studying play from a multi-disciplinary perspective is needed. Important to expanding this argument is going beyond a particular cultural view of play and considering how play develops within and across different cultures.

Play has been conceptualised as a cultural expression, even within the dominant play practices privileged in the north American context (see Goncu and Gaskins 2007). What is key here is that observed play practices and the derivative theories have tended to be based on only some cultural groups, and the subsequent models of play have become the universal view of how children play and how their play develops. Other ways of playing have been made invisible in this process (Goncu et al. 2007). What is argued is that *play is a cultural activity* (Goncu et al. 1999), a *cultural construction* (Goncu et al. 2007), and a *cultural interpretation of children's everyday lives* (Gaskins et al. 2007), lives that are different in different cultural

communities (Goncu et al. 2007), and where the enculturation process is specific to that community (van Oers 2010).

What has emerged in northern hemisphere continents is that early childhood settings are increasingly becoming more academic (Husa and Kinos 2005), there is more pressure on teachers for raising academic standards (Hedges and Cooper 2014) in contexts of a knowledge economy with new demands (van Oers 2009), and the narrowing view of what is play in the policy arena, where intellectual and imaginative dimensions of play are being considered in new ways. Some have pushed against the policy imperatives to narrow the view of play as being only associated with cognitive development (Husa and Kinos 2005) and have suggested that we need to move beyond the binary between play and learning and consider the socially valued developmental and educational goals of play as being mutually constitutive sociocultural practices (Wood and Hall 2011). What has emerged in the many continents of the northern hemisphere is a focus on the functional value of play, as a pedagogical tool to support children's learning, and a great deal of research has sought to examine this problem from a cultural-historical perspective. *New societal needs have created demands for different kinds of research, and this in turn has resulted in the need for a theorisation of play that can meet these new demands.*

In contrast, some countries in the southern hemisphere have focused on how agentic children are in play-based programmes where the societal values have supported academic learning (Pui-Wah et al. 2015) and where research into the degrees of freedom children have are needed (see van Oers 2010, 2013a). Researchers have found that in play-based programmes in Hong Kong, for example, children spend their time engaged in tightly packed teacher-directed activities and have little opportunity to play with each other in interest corners.

In contexts where cultural-diversity exists not only within the preschool population (e.g. Parmar et al. 2004), but also through new arrivals into a country where family values and goals for play based or academic programs may be different (Adams 2015), we see new kinds of conditions being created and the early development of a learning motive (Adams and Fleer 2016; Wong and Fleer 2012, 2013), and these studies speak differently to understanding the relations between play, learning and development. For instance, Wong and Fleer (2013) found that following Hong Kong immigrant families in Australia, the children developed a learning motive as a result of increased competence. For example, in the case of learning to play the guitar, it was found that with perseverance and practice, and the incremental building of competence, enjoyment of success helped to develop a learning motive for learning to play the guitar. Similarly, Adams and Fleer (2016) found that when Australian families moved to Malaysia, the children entered into formal 3-year-old schooling, and as the children developed competencies in literacy and numeracy, the family play practices changed at home, and a greater amount of academic learning began to appear with a changed motive form play to learning by the children. These findings are consistent with that presented by Parmar et al. (2004) who looked at the play beliefs of families of Asian-heritage (Korea, Pakistan, Nepal and India) and Euro-heritage (not given) background residing in communities in north America and found that the former saw little developmental value in play, whilst the later did.

The Asian-heritage families believed early academic training was important and spent a great deal of time on pre-academic activities with their children, whilst the European heritage families acted as play partners with their children (Parmar et al. 2008). The European heritage families engaged in pretend play with their children and the Asian-heritage participated in constructive play. These studies, as illustrations only, give insights into the complexity of the nature of play, learning and development across cultural communities, showing the need to *move beyond a universal view of play*.

3.3.3 Play and ZPD

An analysis of a series of publications on play shows that a process of the 'development of generative understanding' of Vygotsky's theory is taking place among researchers of play who belong to the cultural-historical tradition. In addition, new developments in the understanding of play in various sociocultural and educational settings are enriching the theoretical framework. Again, we will limit our overview of these developments to a few examples. However, we believe they reflect the main traits of the whole picture. For instance, Chaiklin (2003) notes in relation to ZPD:

> ... one must appreciate the theoretical perspective in which it appeared... That is, we need to understand what Vygotsky meant by 'development' in general, if we are going to understand what he meant by 'zone of proximal development' in particular. In this way, the reader can develop a generative understanding of the theoretical approach, which will be more valuable than a dictionary definition of the concept (Chaiklin 2003, p. 46).

It seems that this generalisation also applies to the conception of children's play. To paraphrase, if we are going to understand Vygotsky's approach to play and its role in child's mental development, we need to draw upon and understand a cultural-historical theory of development, where ZPD is a key concept to both development and for play.

Veresov (2004) introduces 'a hidden dimension' of ZPD in play where the level of potential development of a child cannot be reduced to the task the child can solve in cooperation with more competent peers as it always includes child's individual attitude (personal sense) to the task within the play situation. Lindqvist's (1995) conception of playworlds is another example of an original contribution to the cultural-historical conception of play. Ferholt (2007) explains this contribution as follows:

> Lindqvist's pedagogy is designed to investigate how aesthetic activities can influence children's play, and the nature of the connections between play and the aesthetic forms of drama and literature. She is trying to find a 'common denominator' of play and aesthetic forms, a denominator which she calls 'the aesthetics of play' (Lindqvist 1995). Lindqvist considers one of the most important conclusions of her investigation to be that the development of adult-child joint play is made possible through the creation of a common fiction, which she calls a 'playworld' (1995). The playworld is created through the activity of

bringing the actions and characters in literary texts to life through drama. It is the interactive space in which both children and adults are creatively engaged (Ferholt 2007, p. 17).

The conception of a playworld introduced by Lindquist is rooted in Vygotsky's conception of play and, at the same time, significantly enriches our understanding of play in a child's development (for more on this see Lindqvist 2001, 2003).

Another example of new developments in the cultural-historical conception of play is the study of M. Bredikyte (2011). Researching the zones of proximal development in children's play, she came to the conclusion that a critical feature of any play situation is how much space is left for the children's own initiative, improvisation, co-operation and creativity. In another paper (Hakkarainen and Bredikyte 2008), the authors claim:

Actually we are proposing that the full integrative definition of the ZPD should include one more step: from joint action (problem solving) to child-initiated social experimentation and developmental, qualitative, system level change… The internalization phase is not included in the basic definition of the ZPD as the distance between individual and joint problem solving. Another problem is that individual change is focused on instead of broader cultural units. In play context the necessity of joint experimentation is obvious and an extended concept of the ZPD is needed (p. 9).

Hakkarainen and Bredikyte (2008) agree that the zone of proximal development in play includes experimentation with human values and motives; they suggest an expanded definition of ZPD in play:

This definition proposes two distances: 1) between individual action and joint higher level potential, and 2) between joint higher level potential and qualitative change in personality (p. 10).

A recently published book on play (Schousboe and Winther-Lindqvist 2013) provides us with new theoretical and methodological findings in the cultural-historical approach to play and its development. Despite the ZPD being an influential concept, more often it is only used in ways that suit each researcher's own particular project. In the authors' words:

This key concept is surprisingly rarely discussed, and elementary questions like 'Is the playing child always ahead of its age, ahead of its own normal behaviour?' are often not asked. This seems remarkable if one supposes that all researchers, who have for longer periods observed children at play, have seen children that enjoy stepping into the role of a demanding, crying and extremely unruly baby (Schousboe and Winther-Lindqvist 2013, p. 3).

The chapter by Fleer (2013) introduces the dialectics of individual imagining and collective imagining. This new theoretical perspective develops Vygotsky's conception of play as both a cultural phenomenon and a human activity.

Traditional approaches to play which draw upon maturational or biological theories of development foreground the play activities of children over time, categorizing them into stages. However, these theories have not been able to show concretely and theoretically what occurs across a whole community of players in care and education settings. Play, when conceptualized as a dialectical relation between collective imagining and individual imagining, makes visible how both collective and individual action in play support the development of theoretical knowledge in early childhood group settings. This reading of

> play gives a different conceptualization, building upon earlier empirical and theoretical works which seek to understand play within group settings (Fleer 2013, p. 85).

In the study described by Fleer (2013), she not only introduces new dimensions in understanding of the relationship of two types of imagining, but shows new theoretical dimensions in understanding ZPD through the dialectics of collective and individual actions.

3.3.4 Play as a Leading Activity: Theoretical Advances and Contemporary Studies

Although Vygotsky's paper on play does not provide an explicit explanation of the meaning of 'leading activity', this was the first paper where the idea of play as a leading activity in early childhood appeared. Vygotsky wrote:

> Is play the leading form of activity, or is it simply the predominant activity, in a child of this age? It seems to me that from the point of view of development, play is not the predominant form of activity, but is, in a certain sense, the leading line of development in preschool years (Vygotsky 2016).

We could therefore assume that the concept of the leading activity originated in Vygotsky's paper on play. It was advanced and further developed by Leontyev in his foundational theoretical paper on play (Leontiev 1959, pp. 384–406; Leontyev 2009, pp. 331–354). In this paper, we find the following definition:

> What is a leading activity in general? We call 'leading activities' not just those activities occurring most often at a given stage of development of the child. The leading activity is an activity the development of which brings about major changes in the child's mind and within which mental processes occur that prepare the child's transition to a new and higher stage of his development (Leontyev 2009, p. 334).

Therefore,

> …with respect to play, as to any leading activity in general, our task is not only to explain this activity from the child's mental aptitudes already formed but also to understand, from the origin and development of play itself, the psychic connections that appear and are formed in the child during the period when this is the leading activity (Leontyev 2009, p. 334).

This general idea was further developed by Elkonin by introducing a conception of periodization of psychological development on the basis of a leading activity within the social situation of development (Elkonin 1971) where play is a leading activity in early childhood period[5].

Contemporary studies of play as a leading activity in early childhood and its role in child's mental development include an impressive variety of approaches and empirical research projects. For instance, Duncan and Tarulli undertook an analysis

[5] New translation of this paper was done Veresov in 2000 and is available at https://www.marxists.org/archive/elkonin/works/1971/stages.htm

of the concept of play as a leading activity, comparing the approaches of Vygotsky, Leont'ev and Bakhtin (Duncan and Tarulli 2003). Lubovsky (2009) notes the development of the concept of leading activity in the works of Vygotsky, Leontiev and their followers (Lubovsky 2009). Edwards looks at the relation of play and imagination in children through the lens of the concept of leading activity (Edwards 2011). Research by Kravtsov and Kravtsova (2010) develops Vygotsky's original idea of looking at play and its development as a historical and socio-cultural complex phenomenon. Fleer (2009) looks at a child's play in a wide cultural-historical theoretical perspective:

> Vygotsky's (1966) theory of the role of play in the mental development of children provides powerful new directions for re-thinking how we have conceptualized play. Considering play as the leading activity in the development of young children is different to thinking about play as the 'child's world' or the 'child's work'. A cultural–historical study foregrounds the motives, needs and interests of children alongside of the cultural contexts which privilege and value specific practices (Fleer 2009, p. 14).

Fleer's research provides new insights into understanding play as a leading activity in various cultural communities. This approach is important as it brings to our attention the cultural contexts and content of play and challenges Western perspectives. The thinking moves beyond a universal view of the construct of play. Culture and context are central to the understanding of how play is valued, expressed and used as a pedagogical approach in early childhood education internationally.

In research by van Oers (2013a, b), it is argued that the format of activity is a general characterisation of human activity based on three parameters: involvement, rules, and degrees of freedom. It is assumed that every human activity can be characterised by specifying the level of involvement of the actors, the type of rules that they are following and the degrees of freedom that are allowed them in making their own choices as to the actions to be performed, the goals to achieved, the tools, the rules, etc. From this activity point of view, play can be defined as an activity that is accomplished by highly involved actors, who follow some rules (either implicitly or explicitly) and who have some freedom with regard to the interpretation of the rules and to the choice of other constituents of an activity (like tools, goals, etc.) (van Oers 2013a, pp. 191). This theoretical work on play advances understandings about play as a leading activity and provides the conceptual tools to better understand the role of adults with respect to children's play, to explaining learning and the development of play in the course of human ontogeny (van Oers 2013b, pp. 195–196).

In this first part of the chapter, we have specifically examined concepts from cultural-historical and activity theories that are foundational for understanding play and development, as key for the field of early childhood education. We also examined the conception of play by seminal theorists, such as Vygotsky, Elkonin and Leontiev, and illustrated some key contemporary scholars who have drawn upon these foundations to progress research in play. We now turn to a deeper analysis and coverage of the literature, so that we may determine how researchers have used these concepts for examining the relations between play, learning and development

in early childhood education. We seek to not just present key concepts from cultural-historical and activity theories, but also to analyse and present how these concepts are being used in the field of early childhood education.

3.4 How Do Early Childhood Education Researchers Discuss the Relation Between Play, Learning and Development?

In this part of the chapter, we take a closer look at how researchers have drawn upon the seminal theories and used cultural-historical conception of play and development to solve the central problem facing many countries around the world: 'What is the relation between play and learning' (see Fleer and van Oers, this Volume)? We do this by looking at how researchers have contributed to better understanding how one leading activity changes into another. We examine the empirical insights that can together support an explanatory model for better understanding the relations between play, learning and development in early childhood education. Four key themes form the focus of what can be learned from the relevant literature. They are:

1. *Concepts underpinning pedagogical models that support the development of play*
2. *What concepts have been used to discuss play pedagogy?*
3. *Play and learning from the perspective of children*
4. *Digital play*

These themes have emerged in the empirical and theoretical literature associated with early childhood education that draws upon cultural-historical concepts. They are discussed in turn.

3.4.1 Concepts Underpinning Pedagogical Models that Support the Development of Play

The introductory chapter to this volume is on contrasting perspectives on the relations between play and learning, with a special focus smuggling concepts into play (northern hemisphere) or freeing up instruction to be more playful and motivating for children (southern hemisphere). The research primarily supports conceptualising new pedagogical practices but with a different play-learning orientation. Less attention has been focused on how specifically designed pedagogical models support the development of play itself, and through this develop the child (Hakkarainen 2006). Handbook presents a number of innovat programmes or pedagogical models that feature play, learning and development (see overview by Fleer, Chen and van Oers, Volume 2). In this chapter we concentrate our discussion on those models which draw upon cultural-historical theory or activity theory and which have specifically teased out the relations between play, learning and development.

In conceptualising the dialectical nature of play, Hakkarainen (2006) has argued that there are many contradictions in play, for instance, role-playing being an adult whilst being a child; having a high social position in play, whilst at the same time cooperating equally in play so that the play can proceed; role-playing freely, whilst at the same time role-play with certain rules of behaving; and doing immediately what you want whilst at the same time controlling your own behaviour. In following the logic of cultural-historical theory, these contradictions help to create the conditions for developing the play and through this the overall development of the child. This basic logic forms the foundations of many pedagogical models of play that are informed by cultural-historical or activity theories. When learning is included in the relations between play and development the 'goal is to make learning an integral part of the play structure itself, rather than something separate and compartmentalized' (Hakkarainen 2006, p. 208). The models that follow have sought to integrate learning by theorising pedagogy in ways that are sensitive to the child's motive for play whilst projecting forward into the child's zone of proximal development where learning is the leading motive.

Four key pedagogical models are presented as examples to illustrate pedagogical models that focus on the relations between play, learning and development from a cultural-historical or activity theory perspective. They are Playworlds (Lindqvist 1995, 2003; Hakkarainen and Brėdikytė, Volume 2), the Golden Key Schools (Kravtsov 2008; Kravtsov and Kravtsova, Volume 2), Developmental education (van Oers 2012; see also Pompert and Dobber, Volume 2), and Tools of the Mind (Bodrova and Leong 1998; see also Bodrova and Leong, Volume 2). Each of these is described in detail in Volume 2. In this section, we draw out the key theoretical dimensions only.

Playworlds was originally designed by Lindqvist (1995), with many others drawing upon this foundational pedagogical model in Finland (Hakkarainen et al. 2013; Rainio 2008, 2009), the USA (Ferholt 2009; Ferholt and Lecusay 2010; Nicolopoulou et al. 2010), Italy (Talamo et al. 2010) and Australia (Fleer 2016). The latter being in digital virtual contexts. Theatre pedagogy (Lobman 2003) is central to this model where the adult has a direct role in children's play. This is different to how the adult is conceptualised in the general play literature, where different theories are drawn upon (e.g. maturational theories, where stages of play are biologically determined, and adults get in the way of children's play or it is not play if adults are involved).

Lindqvist (1995) used Vygotsky's conception of play to create a playworld that was designed for children and teachers to jointly enter into, where the play was developed through going on journeys, and real world problems were encountered and had to be solved through both imagination and subject content knowledge. The teacher took an active role in the children's play, and both the journeying and the re-orientation of the teacher to be inside of the imaginary play took a long time. The Vygotskian conception of play (Vygotsky 2016) and his work on the psychology of art (Vygotsky 1971) were foundational for Lindqvist's (1995) model of playworlds. Key ideas were the importance of art (Vygotsky 1971), correspondence between the internal and external (Vygotsky 1971), imagination and reality (Vygotsky 2004) and the imaginary process (Vygotsky 2016). Those that have followed have elabo-

rated the pedagogical role of the adult (Hakkarainen and Bredikyte 2008), the significance of the story chosen to create dramatic tension (Hakkarainen 2010) and adult-child relations (Nicolopoulou et al. 2010), the Socratic dialogue in the playworlds (Ferholt and Lecusay 2010) and the jointly created narrative as a transitory activity system (Hakkarainen 2010; see also Hakkarainen and Bredikyte, Volume 2), and contemporary contexts of virtual worlds (Talamo et al. 2010).

Another pedagogical model that draws on cultural-historical theory is the Golden Key Schools in Russia (Kravtsov 2008; Kravtsov and Kravtsova, Volume 2). The foundations of the Golden Key School rests on the assumption that the model of education will transform children's personal meaning into cultural meaning, where a new sense is given to children's everyday life experiences. The Golden Key Schools are framed on the idea of the family, where multi-aged groups of children aged from three to 12 years are taught together. These groups are between 15 and 25 children. The pedagogical practices focus on the idea of an event, such as a lost letter arriving from a soldier, or a person dresses up as a fairytale character and who sets a challenge, such as 'Can you help me find my fairytale?' The children, their families and the teacher collectively solve the problem over time. In addition to the pedagogical practice of an event, the educational program is organised in the first four years into four components: Year 1: spatial orientation; Year 2: time and history; Year 3: different materials; and Year 4: reflection on actions (Kravtsov and Kravtsova 2011).

The foundational concepts of the Golden Key Schools are: Integrating intellect, affect and emotion and individuality, will and personality (Vygotsky 2005). The central concept that underpins the pedagogical model is the development of elementary and higher psychological functions, where the zone of proximal development is supported by Kravtsova's conception of pair pedagogy and subject positioning (discussed above).

The Dutch name for developmental education is Ontwikkelingsgericht Onderwijs, which translates as *development-oriented schooling* (van Oers 2012). The foundation of Developmental education is not maturational theory, but rather cultural-historical theory. Developmental education is for children aged three to twelve years and is described in detail in Volume 2. This pedagogical model was conceptualised and researched by van Oers over an extensive period in the Netherlands (van Oers and Duijkers 2013; Pompert and Dobber, Volume 2). Developmental education is a play-based curriculum and should not be confused with Davydov's (1988) model of Developmental Education. Developmental education does not design trajectories of subject matter learning for children, but rather is a process of collaborative restructuring of current activities and subject matter to build developmental trajectories. The key pedagogical approach is to collaboratively develop solutions to inquiries that are of interest to children (personal sense) in play-based settings and where the agency of the child is central for taking forward learning and development so that a new cultural sense develops (cultural meaning). The chapter on a cultural-historical methodology of this volume presents an example from van Oers (2008) in which children role-play a shoe shop and encounter a problem of retrieving shoes quickly to fit customers, but the system of storage causes difficulties, and it is not until the children

are introduced to the idea of putting symbols on the shoe boxes that the problem is solved. Discussions about what symbols (personal sense) can be understood by all the children (new cultural sense) generate a need for standardization of symbols, which is both personally and culturally meaningful to the children. This is needed so the play can continue. Careful pedagogical thought is directed to creating the educational conditions which support the development of the child and where child agency is central for developing culturally meaningful practices for the children.

The central concepts that underpin developmental education are the social situation of development, meaningful learning (cultural meaning and sense) and the zone of proximal development. Here Vygotsky's conception of play and the concept of leading activity theorise the pedagogical practices of the model put forward by van Oers (2012). Specifically, the relations between play and learning are characterised in developmental education through a play-based approach to school learning for children aged three to eight years. Role-play in developmental education is theorised by van Oers (van Oers 2010; van Oers and Duijkers 2013) following Leont'ev (1983) conception of play where the shared rules, the degrees of freedom open to children regarding how the activity is to be carried out, and the level of personal involvement is key. They suggest that 'as cultural activities essentially include the function of learning, we can also integrate learning and play, but considering the changes in the playing actions or in the content of the activity as demonstrations of learning' (van Oers and Duijkers 2013, p. 515). Further, van Oers (2012) argues that the child's perezhivanie as the emotional relationship that is established in a particular situation or cultural activity is evident in role-play, and the extent to which the child feels deeply involved, and will actively participate in a personally meaningful way, is key to developmental education. Accordingly, a play-based approach theorised in this way builds up a meaningful and functional social situation for cultural development, and the child takes on a role in the play-based program that she/he feels 'emotionally related to, a role which is supported by a personal imagination of what it means to act out this role' (p. 22).

The model of play and learning developed by Bodrova and Leong (1998) known as the *Tools of the Mind* draws upon cultural-historical theory to theorise play, alongside of conceptualising the pedagogy needed for supporting the development of mature forms of play in preschool settings in the USA. In contrast to maturational views of play dominant in the USA, Bodrova and Leong (1998) discuss the characteristics of play as a cultural phenomenon. Central to the *Tools of the Mind* is the use of play plans as a tool for pedagogically supporting the development of mature forms of play (see also Bodrova and Leong, Volume 2).

In line with Vygotsky's (2016) conception of play, Bodrova and Leong (1998) discuss the characteristic of mature forms of play as featuring children who enter into an imaginary situation where they give new meaning to actions and objects, including people. The imaginary sense given to the objects is different to what and how the physical objects appear to the children. Mature forms of play work with the idea of the imaginary object, or with words rather than objects, whilst less mature forms of play need realistic props in play, as placeholders for supporting the pretense enacted between and with other children. In mature forms of play, agreed rules

and roles are assigned and these stay stable throughout the play. The themes of the play expand, going beyond the obvious roles found in particular settings. For example, in police play, the police officers and the criminal case would be expanded to include the staff and their roles in the police station. In less mature forms of play, children will tend to follow a script, playing in the same way each time. Whilst in mature forms of play which afford the integration of various themes, children will negotiate their play and will plan how the play script should develop. Play maturity can also be seen through the use of children's language during play. Mature forms of play will include specialized play language, as has already been noted by many longstanding play researchers (e.g. metacommunicative language, Bateson 1971). It is observed that children change their intonation, register and even use particular words to signal they are pretending. They also use language to regulate the actions of others, so that the play narrative can continue in particular ways. In mature forms of play, children tend to spend longer discussing the roles of players and rules of play, than actually playing. Further, children stay focused on their play plans and will not be distracted by a routine change, a social diversion or an attractive toy. In contrast, less mature forms of play usually go with the flow of the event and may not return to the play that was previously started by the children, or there are short play themes that change regularly over the course of the play, rather than the development of one play theme.

Important for the development of play in the Tools of the Mind approach is Bodrova and Leong's (1998) conceptualisation of play plans which act as a tool for pedagogically supporting the development of mature forms of play. According to Bodrova and Leong (1998), a play plan is prepared by the child with the support of the teacher. The play plan documents what the child expects to do in their play. The teacher supports the children to describe the imaginary situation and to detail the roles that are to be adopted in the play. They argue that unlike oral plans that can be easily forgotten, documented play plans as a cultural tool for supporting children's play development can be re-examined and discussed during or after the play period. Further, the play plans allow children to document changes in their play themes or roles assigned, thus making more explicit, and therefore conscious to the child, their play. It is argued by Bodrova and Leong (1998) that this also develops children's self-regulation. Play plans also help players to carry their play themes over from one play period to another, thus helping the play themes to develop and become more complex. It has been found by Bodrova and Leong (1998) that when play plans are reviewed after a play period that 'the teacher can model how to reconstruct what happened or suggest new play elements that can be used to extend the play. As a result, children would spend more time in a mature play thus practicing self-regulation through its imaginary situation, roles, and rules' (p. 122). The play plans when combined with subject matter content, such as literacy development, increased outcomes in children's academic competencies have been reported (e.g. Diamond et al. 2007).

Taken together, these pedagogical models have both theorised pedagogy and researched these new models of practice, where the relations between play and

learning have centred on the development of the child. What is unique about these models is that cultural-historical theory has focused their attention on the development of children's play and schooling/pre-schooling (van Oers 2012) and through this careful attention has been given to child agency (van Oers 2008), degrees of freedom in play (van Oers 2013a) but where subject matter content is related to continuing children's play (van Oers 2008; van Oers and Duijkers 2013; Hakkarainen et al. 2013; Rainio 2008, 2009) and where play maturity is key for developing the child (Bodrova and Leong 1998; Kravtsov and Kravtsova 2011) through specially created cultural conditions named as Playworlds (Lindqvist 1995), Tools of the Mind (Bodrova and Leong 1998), Developmental Education (van Oers 2012) and Golden Key Schools (Kravtsov and Kravtsova 2011).

3.4.2 What Concepts Have Been Used to Discuss Play Pedagogy?

In addition to the pedagogical models described, there are researchers who have specifically investigated teacher-child interactions in play based programmes, and these researchers discuss their work in terms of *pedagogical play* (Ridgway et al. 2015), *purposeful play* or *learning through play* (Sim 2015), *play-based learning* (Sumsion et al. 2014), *playful pedagogies* (Goouch 2008), *educational play* (Wood 2014), *inquiry-play* (Hedges 2010), *developmental pedagogy* (Pramling Samuelsson and Pramling 2014) and the *playing-learning child* (Pramling Samuelsson and Carlsson 2008). What these terms point to is the current international need for better theorising the relations between play and learning, where the role of the teacher can be better understood in practice and conceptualised pedagogically.

The *play-pedagogy interface* (Wood 2014) has been quite well researched. For instance, Wood (2014) has examined the discourses of play and learning and proposed that there are three modes of play pedagogy: (1) child initiated; (2) adult guided; and (3) technicist/policy-driven forms of educational play. She argues that each of these modes is framed around particular pedagogical interaction between adults and children. Other research has revealed different pedagogical beliefs about play, such as a*trust-in-the play approach* (no role for the teacher), a *facilitate-play approach* (organising for play by the teacher) and *enhance-learning-outcomes play approach* (where the play goals are narrowly focused on discipline knowledge), and it is argued that there is a need for another way of conceptualising play and learning that is an integrated, responsive model of play intervention (see Trawick-Smith 2012). Integrating play and learning has been a key problem in Sweden where research has sought to examine how this is achieved in practice. It was found that three categories of interaction between children and teachers were observed, explorative interplay (shared imaginary play with the teacher pointing out some-

thing associated with a learning goal), narrative interplay (expansive play in which the teacher expanded the play through introducing learning goals) and formalistic interplay (teacher directed question-answer dialogue, no joint imaginary situation) which together showed that when teachers and children were jointly involved in the same imaginary play, a higher level of integrated play and learning was achieved (Pramling Samuelsson and Pramling 2014).

In the USA where concerns have been expressed about the dominant imperative to increase outcomes for preschool aged children, researchers have examined how teachers systematically integrate play into the learning curriculum for low SES communities, where, for instance, storytelling and story acting practices features, noticing that social competence and the social position of children previously deemed a trouble maker, had improved for programs which integrated play and learning more (Nicolopoulou et al. 2010).

Cultural-historical studies into teacher views and practices associated with their role in children's play have been investigated, showing that adults generally do not involve themselves in children's play in some cultural communities (McInnes et al. 2011). In Australia, for instance, researchers have grappled with how learning and play are enacted in practice, researching explicitly how educators bring together free play and play-based learning (Sumsion et al. 2014) in the context of intentional teaching. The latter has generated a need to reconceptualise the role of teachers in early childhood settings, as taking a more active role. This is in contrast to expectations in, for example, Singapore where 'Purposeful play in the local context requires the need for active involvement on the part of the teachers in an activity that all children like to do best, to play, in order to deliver the objective of education: to learn' (Sim 2015, p. 228). Like intentional teaching in Australia, purposeful play has been explicitly built into the curriculum guidelines. Wood (2010) in the UK has suggested there now is a need to reconceptualise the play-pedagogy relationship away from Government control and more in relation to pedagogical practices that support play complexity. The latter point is picked up by Ridgway et al. (2015) who introduce the idea of agentic imagination and conceptual reciprocity (subject matter content) as a way of dealing with both play and learning as new imperatives for research and practice in early childhood education. This is also picked up by Hedges (2010), but in the context of teacher professional knowledge, who has found that the concept of *play-inquiry* moves teacher professional knowledge from a developmental to a sociocultural theoretical conception of play, thus affording the need for more subject matter knowledge.

What is evident in all the early childhood literature on play that draws upon cultural-historical theory is the imperative in the continents of the north to introduce more concepts in playful ways and in the south the focus is on making learning more playful. Both imperatives focus on finding new ways of conceptualising pedagogy (Fleer and van Oers, this Volume).

3.4.3 Play and Learning from the Perspective of Children

What is unique about each of the pedagogical practices discussed in the previous section is whether they are sensitive to the perspective of children. This is not surprising because central to a cultural-historical theory of play is the child's motive for play as a leading activity in early childhood. There is a plethora of studies that seek to gain the child's perspective; however, these researchers draw upon theories other than cultural historical or activity theories. Yet following the child's intentions in play can also be observed in studies that draw upon cultural-historical theory (e.g. Hedegaard and Fleer 2013; Ridgway et al. 2015) or activity theory (e.g. van Oers 2010). For instance, in Australia, Theobald et al. (2015) investigated children's perspective of play and learning in everyday life and found that children believed them to be intertwined and not separate activities. This was also found in research in Sweden by Pramling Samuelsson and Carlsson (2008), Wallerstedt and Pramling (2012) and Pramling Samuelsson and Johansson (2009). Ridgway et al. (2015) also draw attention to the child's perspective in play and learning in Mexico and Australia by referencing the concepts of intersubjectivity and conceptual reciprocity as a way of capturing the relations between play and learning for the child.

These studies highlight the need for theorising pedagogy in new ways that take into account the change in relations between play and learning. These studies foreground how to create new cultural conditions for supporting children's development through not just play, as was the previous focus in the northern hemisphere, or through learning, as was the focus for the southern hemisphere, but through a new conception of the relation between play and learning. This is discussed further in the next section.

3.4.4 Digital Play

Since the original works of Vygotsky's were written and translated, communities and societies have continued to culturally develop. One of the cultural changes that is worthy of attention when considering early childhood education is the unique context of digital devices and virtual play environments that are accessible tools for play, learning and development of infants, toddlers, pre-schoolers and children in the early years of school. The emerging literature that draws upon cultural-historical theory for informing cultural-practices is still limited and mostly has focused on describing practices in the home or early childhood institutional settings. Research into how digital technologies act as a developmental tool for children is rare, but insights into how digital technologies could potentially change cultural practices for children are evident. For instance, Stephen and Plowman (2014) suggest that digital play has moved discussions to the new possibilities of the:

- Digitally enhanced tangibility of the lived environment of children (sensors, computer chips in devices)
- Play objects that are combining real and virtual worlds (touchable toys using tags for communicating on and off screen)
- Robotic toys with inbuilt and adaptable gesture and speech recognition, including displaying emotional responses
- Augmented reality games where interactive virtual figures are superimposed onto images of the environments in which children are living and playing; and
- Software tools for designing, drawing, and communicating in new ways (e.g. Skype, Vogs)

It is argued that how these new cultural tools change the play and learning of children in a fast changing technological context is yet to be researched. Some have sought to investigate how digital tools can and do integrate into play-based programmes (Edwards 2013; Moore 2014) and if existing software can afford imaginary play opportunities (Verenikina et al. 2010). Exciting research into digital playworlds (see Talamo et al. 2010) shows how theorised and researched models of play and learning open up new possibilities for children's development, alongside of research into how children digitally enhance their play through using digital placeholders and virtual pivots (Fleer 2014a). The latter is also shown through the cultural-historical research of Björk-Willén and Aronsson (2014) who show how children in play draw upon the digital speech patterns of virtual characters and how they also give a personal sense to the figures in virtual play, as if they are play partners. Together, these studies show new relations between play, learning and development that were not available in Vygotsky's time. These studies suggest that digital devices and software can act as a developmental tool and that digital play is a new cultural condition that needs to be better understood. However, the challenge will be advancing the research in a context in which the development in technologies usually outpace the research.

3.5 Contemporary Challenges: How Is the Relation Between Play, Learning and Development Discussed?

In examining the contemporary studies and theoretical papers in early childhood education that have drawn upon cultural-historical theory and activity theory, it is evident that how the motive for play develops into the motive for learning was key to the current research needs of the field. New societal needs have created demands for different kinds of research, and this in turn has resulted in the need for a theorisation of play that can meet these new demands.

What has emerged is a series of studies and theoretical pieces that seek to better theorise pedagogy, as a litmus test of a greater need for having available to early childhood educators a model of play and learning that together acts as a cultural tool for children's development. The terms used include pedagogical

play, purposeful play or learning through play, play-based learning, playful pedagogies, educational play, inquiry-play, developmental pedagogy and the playing-learning child.

The models of pedagogy that have resulted to address the societal need to bring play and learning together have as expected from within a cultural-historical framing conceptualised this relation directly to development. These educational models have not only drawn upon important concepts found in Vygotsky's and Leontiev's theories, but have theorised play and development in relation to learning. In so doing, they have theorised pedagogical practices which support children's play, learning and development in early childhood educational settings. The pedagogical models that act as a cultural tool for supporting development reviewed were Playworlds, Tools of the Mind, Developmental Education and Golden Key Schools. In these models, careful attention has been given to child agency, degrees of freedom in play, but where subject matter content is related to continuing children's play and where play maturity is key for developing the child through specially created cultural conditions. Interestingly, the digital playworld of Talamo et al. (2010) and that broadening of play to include digital placeholders and virtual pivots (Fleer 2014b) together point to how digital devices and software can also act as a developmental tools.

The key problem of the relations between play and learning has been addressed by contemporary researchers through drawing upon powerful concepts from cultural-historical and activity theories. Many have theorised the relation between play and learning, and many have pointed to the problem of how one leading activity changes into another leading activity as a way of capturing children's development. But what is the character of each leading activity and what might be the mechanism by which one leading activity is replaced by another, and finally what might be the interconnections between leading activities and the educational conditions created for the child's development (Kravtsova 2006)?

Vygotsky discussed development in terms of crises and cultural age periods, where preparation from one age period to the next was conceptualised as neoformations (Vygotsky 1998). As was discussed previously, Leontiev elaborated Vygotsky's idea of play as a leading activity, to introduce a series of leading activities, such as learning as a leading activity. Yet how one leading activity changes into another leading activity was not discussed in these works. Elkonin (1971) examined this relation as a stage model, where two different periods dominated, tool elaboration and motives, and through this he sought to integrate Vygotsky's theory of development with Leontiev's theory of activity (see Hakkarainen 2010). But research to explain development within stage theory was not evident to support this model.

Kravtsova (2006, 2010) has discussed the relations between play and learning in the context of self development in the Golden Key Schools, where education is the source for the development of the child and where the child gains a new self-awareness. During a crisis, new formations can be associated with the new self-awareness, where the child begins to regard her or his actions in new ways and where a new social relation with others emerges (Kravtsova 2006). Kravtsova (2010) in elaborating Vygotsky's experimental genetic method (see Fleer and

Veresov, this volume) introduces the projective method for modelling the conditions for supporting the development of inter and intrapsychological functioning in an education context (see Kravtsov and Kravtsova; Volume 2). Through the Golden Key Schools where programmes are future oriented and where communication in multi-age groups allows for what Kravtsova (2010) calls pair pedagogy (2 teachers) and subject positioning between them and the children (e.g. above, below, primordial we, equal), she creates the special future oriented communication (i.e. ZPD) that mirrors the developmental conditions, as defined by Vygotsky, in education contexts. The projective method captures the relations between learning and development, because it simulates the conditions for how 'new psychological formations as special features of consciousness and self-awareness during both lytic and critical ages' changes the child's activity. The changes occur in the child's communication and the new relations with adults, and this is promoted in the Golden Key schools through pair pedagogy (Kravtsova 2006, pp. 6). In this way, Kravtsova (2006, 2010) addresses the problem of the change in the child's activity from play to learning by drawing attention to the new leading psychological formations as the basis for continuous education.

Hakkarainen (2010) explains the relations between play, learning and development as a transitory activity system through narrative learning as a developmental intervention for transition. A transitory activity system draws attention to the relations between learning and development through play. In drawing upon Lindqvist (1995) pedagogical model of playworlds, Hakkarainen (2010) suggests that through children being invited into the imaginary situations and problem scenarios created through playworlds, they find they cannot solve problems by narratives alone (see also Hakkarainen and Bredikyte, Volume 2). The play stops if the children and their teacher do not draw upon a realistic solution, that is, through some learning activity. As such, Hakkarainen (2010) theorises that play or playworlds is the key transitory activity system that speaks directly to the change in relations between play and learning, which leads the child's overall development.

What each of these scholars' point to is the challenge of theorising and researching the unsolved problem of 'what really happens when the previous activity does not make sense any more and the new activity has to replace the old one?' (Hakkarainen 2010, p. 77), or put simply, how do these theoretical models help explain the relations between play, learning and development in education

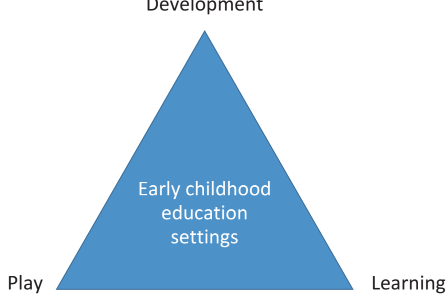

Fig. 3.1 The international problem of what is the relations between play, learning and development in early childhood education settings?

contexts? This theoretical problem is shown in Fig. 3.1 and highlighted in this chapter as a key challenge contextualised concretely for early childhood education settings.

3.6 Conclusion

The theoretical discussions in the first part of this chapter were the backbone for understanding the relations between play, learning and development introduced in the second part of this chapter. The concepts discussed were specific to play and development for early childhood education – the focus of this Handbook. Foundational and contemporary works were introduced in this chapter from the perspective of both cultural-historical and activity theories. More contemporary papers for the former were found, and as such, a more expansive discussion of cultural-historical view of play, learning and development featured.

What can be argued is that play as a cultural activity acts as a cultural interpretation of children's everyday lives and this will be expressed differently in and across the countries of the northern and southern hemispheres. The cultural-historical and activity theory models of pedagogy that have evolved in particular cultural communities to culturally develop children appear to move beyond a universal view of play because the theory of development that underpins them is always a dynamic relation between the social and the individual. The challenge is how to advance research and the development of theory, in a continually changing international context, where the imperative for greater academic outcomes in the north and for more creative and agentic children in the south are in constant motion.

Chapter 4
'Humpty Dumpty': Teaching Strategy or Postcolonial Method – What Do We Know About Power, Voice and Identity Within Early Childhood Education in the Twenty-First Century?

Karen Martin

Abstract Although some would consider postcolonialism redundant because colonialism is considered dead and a paradigm of previous centuries, its discourses and their impacts remain. By applying the well-known nursery rhyme 'Humpty Dumpty', this chapter revives three tenets of postcolonialism, namely, power, identity and voice to explore just how colonial discourses remain entrenched and reified in education and more specifically early childhood education. It asserts that unlike Humpty Dumpty, who could never be put together again, postcolonialism should never be put together, in its varied forms, towards challenging and changing discourses of power, identity and voice unless it is decolonised, thus understanding how early childhood education is as much a colonising tool, asserting power, subjugating identities and silencing voices through the implanting First World early childhood models in Third World contexts. As a discourse, decolonisation must be constructed, framed and led by those whose power, identity and voice are not merely given a place but effectively restored and centred in early childhood education in the twenty-first century.

Keywords Early childhood education • Imperialism • Colonialism • Postcolonialism • Decolonising • Identity • Power • Voice • Ambiguity

4.1 Background

Humpty Dumpty sat on a wall,
Humpty Dumpty had a great fall.

All the King's horses and all the King's men,
Couldn't put Humpty together again.

It seems rather fitting to discuss postcolonialism and early childhood education with a rhyme that is standard in the repertoires of early childhood educators, even in countries where English is not the dominant language. The verse, 'Humpty Dumpty', has colonised early childhood pedagogy and occupies a prominent position amongst the all-time favourite nursery rhymes used by early childhood educators across generations.

Whilst the verse needs no introduction to the field of early childhood education, the same cannot be said for postcolonial theory (Viruru 2005). What then has postcolonialism got to do with this very popular nursery rhyme? As you'll read, 'Humpty Dumpty' is far more than a ditty for entertaining young children or teaching particular language skills and knowledge. By using a postcolonial approach, it has value for framing an understanding of the widespread and orthodox nature of colonialism, its pervading effects and legacies for all, the emergence of postcolonialism and the implications for the field of early childhood education.

Each line introduces a section, signifying the topics and discussions that follow. The first section pertains to the topics of colonisation and imperialism. This is necessary in order to introduce and discuss the second topic of colonialism. The third section explores postcolonialism and in relation to the discipline of education. The fourth section applies a postcolonial framing to understand how power, identity and voice (tenets of postcolonialism) are understood by early childhood scholars and educators.

4.2 Humpty Dumpty Sat on a Wall: Imperialism, Colonisation and Power

Two central questions arise from this line: who was Humpty Dumpty and why did he sit on the wall? A general online search (as so often required these days) revealed two lines of thought (Vacca Foeda Media 2012). One is that Humpty Dumpty is not a person at all but a small canon, most effective when positioned on a wall. Another is Humpty Dumpty was an important individual of the time, perhaps even a member of the English Royal family. There seems to be some conjecture on the authenticity of either version, so his identity remains a mystery. In early childhood literature, Humpty Dumpty is often depicted as an egg. An egg, being an early phase of a life cycle, is a temporary state of being. It is a fragile container, an incubator, critical for successful transition from embryo to the next phase. So, for an egg, there is a high level of risk involved in sitting on a wall. For Humpty Dumpty, the consequences were dire and irreparable.

However, sitting on a wall does provide elevation and the ability to see areas well beyond it and, then, also areas within. But it is not a random act. Something, and/or someone, prompted Humpty Dumpty to do so, even at great risk to his safety and life. Therein, the wall, although often forgotten, is as important as Humpty Dumpty

to this discussion. Further consideration uncovers four important factors. The first factor is the wall has a dual purpose: to protect the people and the property within and to keep intruders out. The second factor is the wall marks the property of a particular individual or family. The third factor is the wall is an indicator of wealth. It requires a lot of money to build a wall and that is because there is a significant amount of property or an important type of wealth to be guarded. Therefore, the fourth factor is that property, wealth and social standing are signifiers of power.

This same situation of building walls, protecting property, amassing wealth, achieving power and enjoying the benefits of a particular social standing is not something of the past. Where once it was focused on the regions within Europe, by its very nature, it required the acquisition of resources from lands further away. This expansion is referred to as imperialism whereby an empire (e.g. Roman, British, Spanish, Ottoman, French, Greek, Mongolian, Russian, Chinese, Portuguese, Japanese) increased its territories and subsequently its resources to achieve power and ultimate rule (Armstrong 2014; Ballantine and Hammack 2009; Wadham et al. 2007; Young 2012).

According to Wadham, Pudsey and Boyd, colonisation is 'the process of creating colonies in a foreign land to bring that land under the control and subjugation of the home nation' (2007, p. 177). This was achieved through the invasion and occupation by a military force and, inevitably, the exertion of physical violence. It was a strategy used by a number of empires in many locations across the globe such as Africa, Asia, the Middle East, the Caribbean Islands, North America, Canada, the Pacific and South America (Armstrong 2014; Ballantine and Hammack 2009; Fox 2004; Hamadi 2014; Lazarus 1998; Wadham et al. 2007; Young 2012).

However, it wasn't just the land and its resources that were colonised. The people fared no better. Those who survived the military invasion and occupation were exploited (retained within the same territory to work as servants), displaced (pushed off their lands, thus creating a diaspora) or commodified (sent to territories far away as slaves to expedite colonisation there). All of this was driven by an ideology of a supposed superiority and belief in a divine right to rule. It was underpinned by a set of values presuming the racial superiority of 'whites' and, concurrently, the racial inferiority of 'non-whites' (Stam and Shotat 2012; Wadham et al. 2007; Young 2012).

Colonisation was widespread and all pervasive. Not one country, nor one population in the world, has escaped. We are all tangled, directly or indirectly, through the colonisation of lands and peoples that began in Europe and the Middle East as early as the thirteenth century (Armstrong 2014; Stam and Shotat 2012; Young 2012).

When Humpty Dumpty sat on the wall, this marked his ownership and his identity as a person of wealth and, therein, social status. When Humpty Dumpty sat on the wall, it was a strategy of both defence and attack. These are also components of colonisation that an empire claims a territory, marks it as its property, occupies it, controls it and defends it. The relationships between coloniser and colonised are forged in this way. The next section explores this further.

4.3 Humpty Dumpty Had a Great Fall: The What and Where of Colonialism

The search of literature re. 'Humpty Dumpty' also revealed this to be part of a much larger story (as per Baum 1901; Day 1921; Denslow 1903). In each version, Humpty Dumpty has been depicted as an egg, but he is one of a number of main characters and not the sole character. We learn more about Humpty Dumpty in these versions than in a verse of four lines.

What does this second line of the verse have to do with postcolonialism? At first, it would appear very little, especially if the focus remains on the character of Humpty Dumpty. However, here it is the item that was instrumental to the fall, namely, the wall, that is of more relevance as it represents, not colonisation, but that of colonialism. The difference is that colonisation (i.e. invasion and occupation) occurred in the earlier phases of colonialism and involved a particular set of strategies and actions to achieve it, most often the exertion of physical dominance and power. Slavery is a prime example here. An empire used people as a commodity to expand its territories, its influence and its wealth. This slavery benefitted the empire, making numerous individuals and companies in the tobacco, tea, sugar, timber, cotton, gold, diamond and other mining industries very wealthy.

This physical domination was used as a means to control 'the natives' as a subclass to 'whites' (Nieuwenhuys 2013; Yassie 2002). Colonisation endured beyond these physical forms, entrenched through colonial governance and administration, laws, education, language, religion, economy, politics and values and norms, in other words, all the structures and systems of a coloniser's society. Colonisation was transposed by the more sophisticated yet more harmful processes of colonialism. As Hickling-Hudson, Matthews and Woods point out:

> The exercise of colonial power is supported not only by economic and political force but also by the cultural power of a body of literature – scholarly works, political tracts, journalistic and creative texts, travel books, religious and philosophical studies. (2004, p. 5)

These forms of colonialism are harder to see, and so, they are insidious because they penetrate and impact on every part of the lives of those colonised, for example, in giving alien names to the people of a colonial territory (Stam and Shotat 2012) and being forced to speak the coloniser's language (e.g. English, Spanish, Portuguese). Through colonialism, the peoples became their property, and changing their identities ensured its effectiveness. Subsequently, their voices were of no interest or value to the colonisers, only if it facilitated their goals (e.g. people served as guides in the territory).

Where it was foreseeable that imperialism could not endure simply because there were a finite number of 'new worlds' and 'new lands' to invade, occupy and own, this was not the case regarding colonialism. The effects and consequences of World War II reverberated throughout the empires and their colonial territories (Armstrong 2014; Hamadi 2014; Hickling-Hudson et al. 2004; Nieuwenhuys 2013; Tiffin 2004; Wadham et al. 2007). Millions of people were impacted resulting in changes to previously omnipotent empires, constitutive of a 'great fall'.

One form of change appeared when independence was pursued internally through conflict, such as a revolution, to overthrow the colonial regime (e.g. Cuba, Zimbabwe). Another form of change occurred when the colonial powers relinquished the control of the territory, for example, ceding their role (but not necessary control and certainly not their influence and conditioning) and withdrawing (e.g. Hong Kong, India, the Carribbean). Another form of change occurred through the constitution of new states (Armstrong 2014; Wadham et al. 2007): one type being instigated by the former League of Nations, now the Assembly of United Nations (e.g. Israel), and another type was instigated by the colonial rulers (e.g. in the partition of India and Pakistan at the withdrawal of British colonial rule). Former relationships of power, changes to the identities and the assertion of voices of the formerly colonised could no longer be controlled in the usual ways (Lazarus 2011).

Many writers (Fox 2004; Hickling-Hudson et al. 2004; Stam and Shotat 2012; Tickly 2004; Young 2012) assert that colonialism has not fallen, even given the changes and challenges of post-World War II. They maintain that it persists in any relationships of power between the former colonisers and the formerly colonised. This is a very important aspect, because what has seemed like an historical analysis has been necessary to foreground discussions of postcolonialism. There may have been a fall in the omnipotence of imperialism and colonisation as per Humpty Dumpty, but the immense changes that tempered the forms and practices of colonialism serve as reminders that the wall (colonialism and its effects) remains. This brings the discussion to the third line of the verse regarding the emergence of postcolonialism.

4.4 All the King's Horses and All the King's Men: The Who and How of Postcolonialism

In the third line of the verse, there is a shift from the focus of the main character (Humpty Dumpty) and the main feature (the wall) to other characters: the King's cavalry. There is insufficient information to know with certainty why they are there, but it can be surmised their presence (and not merely an assemblage of local farmers and herdsmen) is significant.

The state of most of the world's peoples and its countries after World War II was an impetus for change within many areas, including academia. Scholars not just examined the war itself, or the regimes of colonialism and ideologies of imperialism, but the knowledge systems that engineered them. Scholars interrogated and challenged what had been set as truths that fuelled imperialism and led to two World Wars and numerous civil wars (Pudsey et al. 2007; Lazarus 2011; Tiffin 2004).

Here, scholars (of past and present) do not so much represent the 'King's men', but their work – and our work – requires a loyalty to certain ideas and values. However, the King's men have also attacked and defended (analysed, examined and challenged) former regimes of knowledge as these have been entrenched as truth (Stam and Shotat 2012). Some scholars conceptualise, dream and initiate change. Others fight to diminish the impacts of power, to renew identities and to open spaces

for voices of the previously silenced to be known. These power, identity and voice are some of many tenets of postcolonialism and are given focus in this chapter.

Initially, postcolonialism began as means to understand how power is perpetuated in the written word as:

> a critical approach to the legacy of colonisation on colonised countries using the literature of the colonising countries to show how the colonised people were represented and to justify colonisation. (Wadham et al. 2007, p. 200)

It is largely undisputed that the work of Edward Said, 1978, a Palestinian American, is seminal in postcolonialism (Cannella 2000; Hamadi 2014; Hickling-Hudson et al. 2004; Lazarus 2011; Martinez-San Miguel 2009; Stam and Shotat 2012; Young 2012). Said introduced particular concepts to explain how texts produced by colonisers about the colonised reproduce their own power, identity and voice. One major concept is that of 'Other' (Said 1978 cited in Hamadi 2014, p. 40). When the coloniser wrote about the 'Other', implicitly he/she wrote about himself/herself, often in binaries such as native-modern, savage-civilised, treacherous-brave, evil-good and progressive-ancient.

These writings produced a process of Othering (Cannella and Viruru 2002; Fox 2004; Hamadi 2014). It is through this Othering that the identities of the colonised are produced to justify the colonisation of their lands and the colonialism to extract its resources and gain wealth. (Stam and Shotat 2012).

Colonial texts are written for colonial readers, so the only voice is that of the coloniser. For the colonial reader, the experiences in the territories are fascinating, strange and even disgusting (yet compelling). The colonisers are heroic, romanticism builds and this is rarely questioned (Hamadi 2014).

This notion of 'voice' (Spivak 1990 as cited in Fox 2004, p. 92) is another tenet of postcolonialism. In the dominant literature of the colonialists, the voices of the colonised are rarely included. When this does emerge, it is often where the colonised speak and write to suit and serve a colonial narrative. This is a form of subjugation of identity which was forever impacted (Bhabha 1994 as cited in Matthews and Aberdeen 2004, p. 194).

This has been merely a very simplistic outline of key concepts that underpin a postcolonial approach. A deeper reading shows how scholars apply understandings of the 'postcolonial condition' (Tickly 2004, p. 110) as:

Manifestations of power, identity and voice through binary representations (Fox 2004; Hamadi 2014; Pudsey et al. 2007)

Constructions of knowledge and discourses (Hamadi 2014; Hickling-Hudson et al. 2004; Matthews and Aberdeen 2004)

The maintenance of power in relation to race (Hickling-Hudson et al. 2004; Matthews and Abderdeen 2004; Stam and Shotat 2012)

Anticolonial and decolonising approaches to address the subjugation of colonised peoples (Battiste 2002; Laenui 2002; Martin 2008; Moreton-Robinson 2004; Tuhiwai-Smith 1999; Youngblood-Henderson 2002), contributions from previously colonised and silenced peoples (Fox 2004; Stam and Shotat 2012) and further approaches pertain to:

Non-linear evolvement of postcolonial scholarship (Fox 2004; Lazarus 2011; Stam and Shotat 2012)
The nature and implications of the disruptions and disjunctures in the scholarship of postcolonialism (Fox 2004; Lazarus 2011; Stam and Shotat 2012)
Ambiguity as a feature of postcolonialism (Nieuwenhuys 2013)
The relevance of postcolonialism in the modern world (Lazarus 2011; Tickly 2004; Young 2012)
Relationship to the scholarship of poststructuralism, postmodernism (Lazarus 2011; Stam and Shotat 2012) and cultural studies (Wadham et al. 2007)
Identifying neocolonial ideologies such as capitalism, nationalism and globalisation and their implications (Hamadi 2014; Lazarus 1999, 2011; Tickly 2004; Young 2012)

Scholars in the discipline area of education employ postcolonial approaches with the understanding that schooling is an instrument of colonialism. This scholarship has a keen interest on how Western, Eurocentric regimes of knowledge are reproduced in education, schools, curriculum and teaching (Hickling-Hudson et al. 2004). There is an almost complete agreement this dominance began with the Industrial Revolution to keep children off the streets (Hickling-Hudson et al. 2004; Lazarus 2011). The purpose of schools has not changed significantly because the ideology that underpins this is impermeable. When instituted in a colonial territory, schools also had the task of civilising and training the young, keeping them out of mischief and out of sight of adults (Hickling-Hudson et al. 2004; Matthews and Aberdeen 2004).

Given that schooling is now spreading across the globe, postcolonialism provides scholars with a frame to identify and examine how power is reproduced, either overtly or covertly, in curriculum, texts and teaching resources (Cannella 2000; Cannella and Viruru 2002). The premise here is:

> we cannot assume that colonialism is over, only that colonial relationships continue to order and reorder the cultural and economic hierarchies of knowledge and disciplines. (Hickling-Hudson et al. 2004, p. 3)

The King's cavalry has achieved much, and yet there is much that remains to be done to understand how education remains a device of colonialism (and, therein, hegemony) and also how our roles, as educators, researchers and academics, serve this intentionally or not.

4.5 Couldn't Put Humpty Together Again: Postcolonialism in Early Childhood Education

This brings the discussion to the last line of the verse, the one where the outcome is inevitable but not satisfying. It leaves us in a state of ambiguity because even with the amount of professional skills and knowledge present at the time ('all the King's horses and all the King's men'), there is no way to help Humpty Dumpty.

By convention this section is supposed to bring the discussions and analysis made previously to a cohesive and succinct conclusion. In some ways it does, but in other ways, it doesn't, nor should it because of the very nature of postcolonialism. Thus, there is no set of instructions or strategies. There is, however, a postcolonial framing regarding power, identity and voice in relation to early childhood education.

The relationship between postcolonialism and early childhood education is far from new. It grew in prominence during the decade of the 1990s and then in the early 2000s when some foundational work was generated. Of this, it is the work of the reconceptualists in early childhood education that stands prominent. This began with challenges to the dominance of Western, Eurocentric theories of child development and early childhood programmes and curriculum and the call to 'explore differing cultural and theoretical world-views' (Soto and Swadener 2002, p. 39). An early analysis of this reconceptualist's scholarship identified six 'intersecting discourse spaces' (Soto and Swadener 2002, p. 39). These are scientific orientations (child development); qualitative/interpretative research; early multicultural and bilingual education; advocacy and social justice; critical reconceptualist, feminist and postcolonial theory and liberatory praxis (decolonising the field).

Based on this, attention is mostly at the micro level and contexts where issues pertaining to power, identity and voice between individuals and groups are analysed. There is ambiguity in that these analyses bear no relationship to wider societal, political, economic and especially historical contexts. It isn't surprising that Viruru (2005) argued postcolonialism has had 'minimal impact' (p.7) on early childhood education as an academic field and discipline area. She also argues it has had 'even less on the daily practices of early childhood educators' (Viruru 2005, p. 7).

It seems that although the efforts to resist and thwart the normalising effects of Western, Eurocentric theories in curriculum and teaching have garnered some traction, the same cannot be said for understanding the normalising effects inherent within early childhood education, such as philosophy, values and purposes. An initial postcolonial framing shows how the field has been conditioned, where certain relationships, certain identities and certain voices remain dominant because:

It is a Western, European construct that came into prominence after World War II.

One strand focused on the middle-class mothers and their children. Staff were young, middle-class white women for whom early childhood teaching occurred in a finishing school.

Another strand focused on the physical welfare (not well-being) of young children of impoverished families. It was staffed by nurses and infant carer under the direction of doctors.

Compensatory education was developed and introduced to low socio-economic families from the 1960s (e.g. Head Start in the United States). The philosophy then, as now, was based on the premise that parents were deficient, inadequate and incapable in their roles, and, so, the children needed 'topping up' in cognitive skills, social abilities and health information.

This form of mass provision of programmes and services is assimilatory; it is a colonising force just as much as compulsory schooling.
It is now of global proportions where a Western template has been similarly applied at national and regional levels.

What does this tell us? That we have been conditioned to do things in predictable ways, circumscribed by contexts and conventions from centuries ago beginning with the mass schooling of children and the effects of the Industrial Revolution (Ballantine and Hammack 2009). We have been conditioned, more recently, to do things in long-established and acceptable ways in the care and education of very young children. We have been conditioned to not look at this as an invention of social, political, economic, religious and social times but as simply being a good thing for young children. We have been conditioned to believe that we are good because we do this important work for young children – denying this has anything to do with fulfilling our own personal beliefs and goals, needs and ambitions. To put it another way, we, as early childhood educators, have been colonised and are therein products of this colonialism.

If 'liberatory praxis' (Soto and Swadener 2002, p. 51) is something early childhood scholars and other scholars seek to attain (Stam and Shotat 2012; Young 2012), then this cannot be limited to challenges to theories of child development and knowledge reproduction in curriculum and pedagogy. These are applied at localised level (of teachers and students and sometimes researchers and projects) where postcolonialism has proved of value. Likewise, Cannella and Viruru (2002) suggest a 'critical disposition' (p. 131) is needed by early childhood educators and provide these pertinent questions (pp. 131–132):

What are the underlying assumptions in a particular theory (or body of work, including scholarly works)?
How is the notion of theory a Euro-American, an elitist construct?
Whose interpretations are privileged?
Whose cultures and perspectives are valued?
Whose are denied?
Are there perspectives that would appear to involve rethinking and reconceptualisation whilst actually reinscribing old (or even new) forms of power and oppression?

Note here these questions are aimed at the micro level with regard to power (underlying assumptions, privileged, theory, valued, denied, reinscribing), voice (particular theory, perspectives, interpretations) and identity (Eurocentric, elitist). This may achieve some level of liberation of the individual at that level, but without also examining the macro levels where the very structures and systems where decisions regarding the field of early childhood education are made and then implemented, the liberation will also be micro in nature as it fights against much more powerful systems such as education institutions and governments.

Like the wall Humpty Dumpty sat on, these macrostructures will persist to maintain a dominant position and to preserve those beliefs and values and particular

forms of knowledge that were entrenched centuries ago through colonialism. For example, how is it that an early childhood centre looks much the same throughout the world in difference to the contexts where these are delivered? The replication of a dominant model, a template, is a colonising model. How should a liberatory praxis look, sound and feel at this level? To continue, how is it that models, such as Reggio Emilia, can be decontextualised and exported to other countries, particularly Third and Fourth World populations by First (and Second) World early childhood educators and academics? This is not to be taken as a criticism of the Reggio Emilia model, but rather to make the point that it (and similar models such as Montessori and Steiner education) has become a colonising form of early childhood education when identified by those with power, identity and voice as a solution for the Others. It is often labelled a 'sociocultural' model without understanding the nature of how it is so.

These are important questions because they sit at the nexus of power, identity and voice in early childhood education. They are important not because they pertain to early childhood education but because their answers expose those systems of power, identity, voice, authority and knowledge within this field.

Like the above, these questions shouldn't result in easy answers, but they should invoke ambiguity. This ambiguity is a symptom that our conditioning is being called to the fore. In this state, it is not to be taken as a personal affront, but part of a postcolonial framing where we can identify and uncover the layers of our conditioning to more effectively understand who we are as early childhood educators and scholars, how we do this work, why it is done in those particular ways, what else is possible (Cannella and Viruru 2002) and importantly what else is necessary. To reiterate, this must be done at the micro and macro levels simultaneously (as per Bronfenbrenner's ecological systems model).

Such questions remind us that knowledge is not neutral and, especially, that people are not neutral. Having been conditioned over time in particular ways for particular purposes, a postcolonial approach requires how we look beyond this conditioning to where the uncertainties and the ambiguities exist (Nieuwenhuys 2013; Stam and Shotat 2012). Ambiguity reminds us that not all things can be 'put together again' (as these are surely symptoms of certainty and then normality). Nor does it excuse us to just do nothing, do as we have always done, pretend it didn't happen, blame it on someone else, do anything to cover it up or, worse, get defensive and angry when dominance has been called into question to believe that the term 'culture' only applies to people who do not speak English as a first language and/or have coloured skin and particular facial features (Chamberlin 2002).

Ambiguity, within a postcolonial approach, is a necessary state of being because it sets to the side, the things that are taken for granted (affording power), the usual (affirming identity) and the comfortable (asserting voice). Nieuwenhuys (2013) maintains 'postcolonialism enjoins academics to abandon the high ground position from where they have usually sought to understand the world and to look up from a multiplicity of different, marginal positions' (p. 6).

Where Soto and Swadener referred to 'liberatory praxis' (2002), they also referred to 'decolonizing the field' (2002, p. 39), and yet this seems to only apply to

those labelled, 'Third World', 'Fourth World', marginalised, people of colour and Othered (i.e. anyone who is not white, not Western Euro, not middle class, who is not of the dominant group).

The decolonising work in early childhood, it seems, is the task of the Others as something 'they' do (Stam and Shotat 2012) and is of no real purpose or consequence beyond that (remembering this was a strategy in the colonial territories where native voices were only valuable if they contributed to opening up the frontier). This isn't ambiguous, but the responses from 'the early childhood field' seem to construct and position it as such when it is regarded as a choice/optional, a hobby, an obsession, annoying or unnecessary. Perhaps, this is one reason for the lack of change Viruru (2005) identified all those years ago.

Oddly, decolonisation could be the only discourse unexplored by the wider field of early childhood education (Cannella and Viruru 2002). Decolonising the field of early childhood (i.e. the King's men) would reveal how and where colonialism is reified in our work with young children and families, communities and neighbourhoods, regions and countries and colleagues and officials. Where the reconceptualisation has served to bring the early childhood field to this point, and critical reflection is part of the repertoires for many, it is argued here there is another layer that sits between these two discourses and that is a discourse of decolonisation.

What does this decolonisation look like? At the risk of not providing definitions (apart from stating it is not in relation to the independence experienced in some nations post-World War II), it looks like the questions posed previously by Cannella and Viruru (2002) because the questions themselves serve to frame both a critical analysis and the processes of decolonisation. They expose the extent to which the conditioning has been effected and to which one's conditioning influences decisions as an early childhood educator (e.g. in teaching, curriculum) and/or as an early childhood scholar (e.g. the types of research topics, subsequent questions, methodology and interpretation).

To decolonise is to invite ambiguity into the process and so purposefully experience changes to one's power, identity and voice. As these conditions change, the conditioning becomes more apparent and only then can it be fully understood that same conditioning cannot be 'put together again'. Without this decolonising work, the costs for those who are supposed to benefit are many, unchanged and compounded. Early childhood education remains a promise never fully realised. Decolonisation brings ambiguity to the dominant early childhood principles, because, without it, it is easy to justify taking early childhood education to a Third or Fourth World population without a heightened understanding of one's own conditioning (personal and professional). It is easy to erase the contexts and forms of imperialism, colonisation, colonialism and even neocolonialism experienced by those very same populations (Stam and Shotat 2012). Researchers tread the same precarious path in that their power, identity and voice can be elevated, centred and privileged. As select members of the King's cavalry, so to speak, they are entrenched in and conditioned by discourses and knowledge regimes within the structures and systems of: universities, research, ethics and funding. This is seductive but dangerous work if a decolonisation of the field is the cause for which they are fighting.

At the same time, decolonisation must continue within and amongst early childhood educators and professionals for whom colonialism shouldn't be put together again – people who are First Nations (not Other, Third World, marginalised, Fourth World for these imposed identities surely recentre the dominance of Western/Eastern/Euro colonialism). For these members of the King's cavalry, decolonisation is a means by which to understand the extent to which the impacts of colonialism are so entrenched and the extent to which their identities have been subjugated (often involving three or more generations) and their voices silenced (Hingley 2002). This work is to avoid the profound experience of the colonised replacing the coloniser. This decolonisation has an additional (not different) purpose for sovereignty through power/agency, identity and voice. Therein, models of early childhood programmes do not need to be imported or implanted, but the work of all divisions of the King's cavalry (in the field of early childhood) is not to put things together but to fully understand the historic, social, political, economic, cultural, religious and neocolonial conditioning of any given person, community, region, state and nation as this underpins the goals for liberatory praxis, reconceptualisation and decolonisation of early childhood education, knowledge and research.

4.6 Conclusion

Where to now? An ambiguous question that has an ambiguous reply – we won't know until we're in that space of not a 'postcolonial struggle' (Cannella 2000, p. 218) but where a decolonising framing has become as natural and regular for the field of early childhood education as breaking into the rhyme of Humpty Dumpty.

Chapter 5
Engaging with the Conceptual Tools and Challenges of Poststructural Theories

Affrica Taylor

Abstract This chapter outlines the challenges that various poststructural theories pose to the dominant discourses of early childhood education. It discusses where poststructural theory comes from, identifies the key poststructural philosophers, and discusses how their ideas first entered the field of early childhood education. It reviews how early childhood scholars have engaged with key poststructuralist ideas and concepts, such as: 'discourse, knowledge and power'; 'whiteness and othering'; 'subjectification'; 'sex/gender performativity'; 'desire and becoming'; and 'assemblages and rhizomes'. It concludes by reflecting upon the recent challenges that the 'material' and the 'animal' turns are now posing to poststructuralism.

5.1 Introduction

Scholars that engage with the conceptual tools of poststructural theories do so in order to critically interrogate modern western society's dominant discourses and the norms and truth claims that these discourses produce. Within early childhood education, this means calling into question the dominant discourses, norms and truths about childhood and learning that emerged from the behavioural sciences in the twentieth century.

Poststructural theories were not originally formulated or presented as theories per se. Rather, they grew out of a series of ongoing and generative philosophical conversations that have travelled widely within the humanities and social sciences

over the last 50 years or so. They effectively function as 'anti-theories' – as a cumulative set of questioning interventions that provoke us to rethink the universalist truth claims of western scientific knowledge systems. The most solid thing these 'troubling' poststructural conversations offer is a set of new conceptual tools to help us think differently. I will be unpacking some of the key conceptual tools in this chapter.

Poststructural theories do not appeal to everyone. They have many detractors. However, because of their viral nature, there are very few fields within the social sciences and humanities that remain unaffected by them. The field of early childhood education is no exception. Even though poststructuralist conversations first started to make inroads into early childhood education in the late 1980s (RECE 2014), a relatively small proportion of early childhood education scholars have engaged with them. They remain like a foreign language to many, as they have their roots in the esoteric world of (European) Continental philosophy, not in the empirical and structuralist traditions of the behavioural sciences that directly inform mainstream early childhood educational theory and practice.

The terminology of poststructural conversations and the ideas that they espouse are notoriously challenging. This is because they have cumulatively assembled a new vocabulary, or in some cases reappropriated existing words, for doing their interrogative work. This new vocabulary provides the conceptual 'tools of their trade'. It allows those that join poststructural conversations to critique the taken-for-granted meaning-making traditions of dominant western academic traditions. It is therefore not surprising that poststructural thought has gained traction in the peripheral, questioning spaces of early childhood education.

These are spaces that are more closely aligned with the critical traditions of social inquiry (sociology) than with human development theory (psychology), which make it their business to question the status quo by exposing the dynamics of power differentials. Armed with a new toolbox of analytical concepts, many poststructuralists within the field of early childhood education now refer to themselves as being a part of the 'reconceptualist' movement (Canella 2010; Bloch et al. 2014). They are reconceptualizing not only the established development theories in early childhood education but also their former critical frameworks for challenging these theories.

I begin this chapter by providing an overview of poststructuralism's viral conversations in order to situate their uptake within the interrogative spaces of early childhood education. I discuss where poststructuralist ideas came from and their important relationship to the traditions of structuralist thinking. Poststructuralist theory is intensely conceptual and reflexive. In the remainder of this chapter, I unpack the key concepts that facilitate poststructuralism's challenges to mainstream western thinking and extrapolate upon the ways that these conceptually based poststructuralist interventions have reshaped existing critical perspectives within the field of early childhood education. I conclude the paper by touching upon the reconfigurations, mutations and challenges that poststructuralism itself is currently experiencing.

In the spirit of poststructuralist thinking, I begin with the caveat that my overview of poststructuralist theory in early childhood education will be *partial*

(in the double sense of being incomplete as well as being reflective of my particular experiences), it will be *contingent* (conditional on the circumstances in which it was written and is read), and it will be *contestable* (as no one can have the definitive last word on the exact nature of poststructuralist traditions).

5.2 Where Did Poststructuralist Theory Come From?

The body of thinking that is now loosely clustered under the umbrella term of poststructuralist theory emerged from the traditions of Continental philosophy in the latter part of the twentieth century. It is primarily associated with celebrated paradigm-shifting European thinkers such as Jacque Derrida (1968), Michel Foucault (1972, 1977, 1980) and Gilles Deleuze (1991, 1994), although none of these scholars referred to themselves as poststructuralists. There are also many influential second-generation poststructuralist theorists, who have led extended engagements with the ideas of these philosophers within their own disciplinary locations. They include (but are not limited to) scholars such as Edward Said (1978) from postcolonial studies, Stuart Hall (1992) from cultural studies, Judith Butler (1990) and Donna Haraway (1991) from feminist philosophy and feminist queer theory, James Clifford (1988) from anthropology and Nikolas Rose (1999) from sociology and political theory. In the field of education, some of the notable scholars who first engaged with poststructuralist theory are Michael Apple (1982), Bronwyn Davies (1989), Stanley Aronowitz and Henry Giroux (1991), Patti Lather (1991), Henry Giroux and Peter McLaren (1989, 1993), Jennifer Gore (1993), Steven Ball (1990), Thomas Popkewitz and Marie Brennan (1998) and Elizabeth St. Pierre and Wanda Pillow (1999).[1]

Regardless of disciplinary location, all poststructural theorists partake in a critically reflexive mode of contemporary intellectual practice that deconstructs the form, function and effects of modern western epistemologies *from within*. More specifically, they critique the epistemologies of structuralism – a modern western academic disciplinary tradition. Contrary to popular belief, the 'post' prefix does not simply indicate a neat and complete temporal 'afterwards' of structuralism. Instead, the 'post' of poststructuralism signifies a mode of thinking that is born out of, makes a series of breaks with, but also remains in a questioning relationship with structuralist research and theory. An appreciation that the 'post' relationship is an inverse and constitutive one (not just an after-the-fact one) goes some way towards understanding that the mind-bending qualities of poststructuralist thinking are part and parcel of turning familiar (structuralist) ideas inside out. Because poststructuralism is born out of the structuralist project and premises, it also helps to have a basic understanding of what these are.

[1] For a detailed account of the emergence of poststructural theory and its influence upon the field of education, see Peters and Burbules (2004).

In the most general terms, structuralist theories systematically apply scientific methods in a quest to discover the foundational structuring laws, rules and patterns of social phenomena and human behaviour. Structuralist methods and modes of theorizing, therefore, are modelled upon those of the natural sciences. So are its fundamental premises. Structuralism is founded upon the premise that the social world (like the natural world) is structured by essential or innate rules or laws, which have universal applicability. Structuralist theorists have pursued this project and applied this premise in a diversity of disciplinary fields. For instance, Ferdinand de Saussure's (1916/1983) theory of structural linguistics details the innate and universal signification processes of all human languages. Karl Marx's (1867/2009) critical theory of political economy reveals how capitalism's economic infrastructure essentially determines all exploitative social power relations. Claude Levi-Strauss' (1958/1963) theory of structural anthropology identifies the innate kinship relations and rules that govern all human cultures. And most pertinent to the field of early childhood education, Jean Piaget's (1936) psychological theories of human cognition propose that there is a hard-wired universal structure to children's staged growth and development.

Poststructuralists challenge structuralism's 'grand theories' for their unacknowledged Eurocentric conceits and for their lofty presumptions to have discovered essential, innate and universal truths about social phenomena through objective (western) scientific inquiry. In lieu of claiming objectivity and universality – or to put it in more cynical terms, the 'god trick' of a transcendent view from nowhere that applies to everyone, everywhere – poststructuralists emphasize the 'partialities' and 'situatedness' of all knowledge production (Haraway 1988).

They not only resist the veracity of structuralism's essentialist and universalist claims, but they turn the spotlight back onto the premises of structuralism's theorizing traditions. These, they claim, reveal more about the imperialist tendencies of the modern western intellectual project, and more about the reproductive processes of the west's own theoretical/disciplinary cultural traditions, than they do about the universal and innate truths, laws, rules and relationships that they claim to have discovered. In other words, rather than engaging with the *substance* of structuralism's universalist truth claims, poststructuralists refocus upon the historical, political, social and cultural conditions and contexts in which these substantive truths are *constructed*. They set out to unveil or *deconstruct* them in order to better understand their social and political *effects*.

5.3 Where Did Poststructural Theory First Appear in Early Childhood Education?

In the cognate fields of psychology, education and early childhood studies, Jean Piaget's (1936) foundational and universalist truth claims about the innate developmental stages of childhood quickly became the front line for poststructuralist

critique. UK critical psychology scholar, Valerie Walkerdine (1988), was the first to use the tools of poststructuralism to contest the truth claims of developmental psychology from within.[2] European and Canadian early childhood scholars Gunilla Dahlberg, Peter Moss and Alan Pence contested the push towards predetermined standards of 'quality' in early childhood education and care and asked challenging questions about the kinds of knowledges that have become the benchmarks of 'quality' claims (1999). Drawing upon their own schooling in Continental philosophy, Swedish scholars, Kenneth Hultqvist and Gunilla Dahlberg (2001) offered a strong overarching critique of the scientific truth claims that dominated the field of early childhood education. Their bold assertion 'There is no natural or evolutionary child, only the historically produced discourses and power relations that constitute the child as an object and subject of knowledge, practice and political intervention' (p. 9) is an exemplar of pioneering poststructuralist critique in the field of early childhood studies.[3]

Marianne Bloch (1991) was one of the first to critique developmentalism's hold on the US field of early childhood education. Shortly afterwards, contributors to Shirley Kessler's and Beth Blue Swadener's 1992 edited collection, *Reconceptualizing the Early Childhood Curriculum: Beginning the Dialogue*, argued that the national guidelines for 'developmentally appropriate practices' (DAP), based upon Piaget's stages of cognitive development, promote Eurocentric cultural norms and values as universal ones and ignore the cultural, linguistic and socio-economic diversity of North American childhoods. As a follow-up, Gaile Cannella's 1997 book, *Deconstructing Early Childhood Education: Social Justice and Revolution*, utilized poststructuralism's deconstructive methods to expose the ways that the dominant discourses, or the monocultural 'grand narratives' that circulate in the field of early childhood education (particularly DAP), privilege dominant culture children, reconfirm the knowledge and power of dominant cultures and disempower and marginalize minority children and knowledges.

---

[2] As a feminist, as well as a critical psychologist, Walkerdine's interest subsequently turned to applying a poststructural lens to the construction of gender in childhood. Her groundbreaking book *Daddy's Girl: Young Girls and Popular Culture* (1997) was the first to combine a feminist poststructural psychoanalytic perspective (a feminist reworking of Freud and Lacan) with a poststructural textual analysis in order to deepen understanding of the complex ways in which western cultures of fantasy and desire produce young girls' subjectivities.

[3] Gunilla Dahlberg and Peter Moss have been major drivers of the European chapter of poststructuralist early childhood research and scholarship. In 2005, they launched the highly successful 'Contesting Early Childhood' Routledge series with their book *Ethics and Politics in Early Childhood Education.* This series, which they co-edit, has published 13 titles. Many of these are commissioned works, which Dahlberg and Moss have championed because they bring new strands of poststructural thinking into the field of early childhood education. This series also includes many works that showcase the practical application of poststructuralist Continental philosophical traditions within Reggio Emilia and Reggio Emilia-inspired early childhood settings. This uptake of poststructuralist ideas within European early childhood educational settings is reflective of their embeddedness within the milieu of Continental philosophical traditions.

As pioneers of social justice and equity in early childhood education, many of these scholars had shifted from structuralist, Marxist-inflected critiques of education's role in reproducing social inequities into poststructuralist critiques. Poststructural theories offered them a new working set of conceptual tools.[4]

5.4 Poststructuralism's Theoretical 'Toolbox'

All theories use specialized terms or key concepts as the 'tools of their trade'. It is these key concepts that allow them to put their theories to work. Poststructuralist theories are no different in this regard, although it often noted that the concepts that they use – whether newly invented or reappropriated – are often quite challenging and difficult to understand (Peters and Burbules 2004). In this section, I unpack a selection of conceptual tools from the poststructural theoretical 'toolbox' that are commonly used by early childhood education scholars. But first, I reflect on the purpose of using concepts as theoretical tools.

In a 1972 conversation between prominent (poststructuralist) French philosophers, Michel Foucault and Gilles Deleuze, about 'intellectuals and power', Deleuze declares: 'A theory is exactly like a box of tools… It must function. And not for itself'. He goes on to clarify that if a set of theoretical tools is not to become a set of self-serving instruments used to maintain the status quo and to firm up established inequitable power relations, it must open up and 'multiply' avenues for thought and action. Theoretical tools should not be used foreclose on alternative possibilities, as structuralism's 'totalizing' theories do. Deleuze infers that the point of assembling and using a theoretical toolbox is not to slavishly apply the conceptual tools in a mechanistic way, but to use them in an experimental way – to pose new kinds of questions and to provoke new ways of thinking (Nealon and Giroux 2012, p. 8). In another context, Foucault refers to all his writings as 'little toolboxes'. He encourages his readers to put his conceptual tools to work in a subversive way: '… to use this sentence or that idea as a screwdriver or spanner to short-circuit, discredit or smash systems of power' (cited in Mills 1997, p. 17).

So what kinds of new questions and subversive thinking might these key poststructuralist conceptual tools open up for the field of early childhood education? The remaining sections are organized around these conceptual tools. As well as unpacking some of poststructuralism's key concepts and exploring the destabilizing

[4] Unlike in Europe, where (poststructuralist) Continental philosophies were congruent with and thus easily integrated into the existing cultural practices of Reggio-inspired early childhood education, in the USA, poststructuralism was primarily engaged as an analytic for sharpening existing sociological critiques of education. Pioneering US early childhood social justice scholars such as Bloch, Swadener and Cannella put poststructuralism's powerful deconstructive tools to use to deepen understandings about the ways in which the racialized, classed and gendered divisions and inequities that characterize US history and multicultural society are embodied, enacted and reproduced within early childhood education settings.

questions and thinking they afford, I offer an overview of the ways they have been taken up and applied within the field of early childhood education.

5.5 Discourse, Knowledge and Power

Discourse is one of poststructuralism's most central, provocative and indispensable 'short-circuiting' tools. In fact it is so central and game-changing that the arrival of poststructural theory within the social sciences is sometimes referred to as the 'discursive turn'. But what does this mean? In everyday usage, discourse has a straightforward meaning. It generally refers to a form of communication – either spoken or written. It can be a speech, or a written text, or a conversation, or even a body of disciplinary knowledge – such as an educational theory of child development.

Heavily influenced by Foucault's complex and expanded understandings, poststructuralist theorists have reappropriated the concept of discourse. They are not simply referring to forms of communication but to 'practices that systematically form the objects of which they speak' (Foucault 1972: 49). This reframing of discourse is a radical conceptual move, because it refutes that there is a pre-existing set of truths (laws or rules) about the social world that are waiting to be discovered, and which discourses simply describe. The twist is that discourses, in the Foucauldian sense, are seen to shape the worlds that they presume to describe. They are powerful and productive practices, all the more so as they obscure and/or disavow their own generative functions. It is this shift from understanding discourses (including academic discourses) as a vehicle for describing the world that already exists to an understanding that discourses actively make and shape the world they name, which is referred to as the 'discursive turn'.

In early childhood education, poststructuralists reframe child development theories as powerful productive discourses of dominant western culture. To stress that developmental theories are the target of their poststructural interrogation, some early childhood poststructuralists explicitly call themselves postdevelopmentalists (Blaise 2010; Noland and Kilderry 2010). Instead of accepting developmentalism's foundational premises as universal truths, they reposition the theories as truth-producing discourses and focus upon their *practices* and *effects*. The practices include the reiterative telling, writing, discussions and learning about child development, which form the basis of most early childhood education and training programmes; the endorsement of developmentally appropriate practices in early year curriculum frameworks and guidelines; and, of course, the multifarious modes through which developmental perspectives are applied in early childhood education and care settings (see Bloch et al. 2004; Lee and Vagle 2012).

The effects of these discursive practices are twofold. Firstly, they figuratively position the 'developing child' as a central object of knowledge in textbooks, in education and training courses and in professional conversations. The objectified figure of the 'developing child', as represented in the textbook or in the curriculum framework, then functions as a norm. And like all norms, it has normative effects.

It becomes the benchmark for determining if children are 'normal' or need 'fixing' (Blaise 2010). This has particular implications for children who are not from the dominant culture, as I will soon discuss in more detail.

The second effect is that children come to know themselves in relation to the practising of developmentalism's norms and benchmarks. The ubiquitous application of developmental practices within early childhood education establishes the grounds of intelligibility whereby children themselves become the 'knowing subjects' of child development theory. They understand that 'normal' children should be able to do certain things at certain times and they measure themselves as developing (or not) according to the established norms. In simple terms, developmental discourses have the effect of (at least partially) shaping children's own identities (Bradbury 2013; Srinivasan 2014). This is a process I elaborate upon in the following section about subject formation.

It is not possible to appreciate the productive effects of discourses outside of the mutually constitutive operations of *knowledge* and *power* (Mills 1997). As education's core business is knowledge production, it is a prime field in which to study the relations between discourse, knowledge and power (Popkewitz and Brennan 1998; Ball 2013). As Foucault himself points out: 'Every education system is a political means of maintaining or modifying the appropriateness of discourses with the knowledge and power they bring with them' (Foucault 1972, p. 46). The curriculum, in particular, determines which kinds of discourses are deemed appropriate and reified as regulatory regimes of truth/knowledge/power and which are deemed inappropriate and thus excluded. It functions as a kind of gatekeeper of knowledge and truth.

Early childhood education scholars influenced by Foucault's insistence on the relationship between discourse, knowledge and power have framed the universalization of (white, middle-class) western knowledge about the 'normal development' of the individual child as a political act and have been quick to point out that it automatically excludes and/or devalues alternative non-western cultural knowledges about children and childhood (Bloch et al. 2006, 2014; Cannella 1997; Grieshaber and Cannella 2001; Robinson and Diaz-Jones 2006; MacNaughton 2005).

Australian Aboriginal early childhood scholar, Karen Martin, has a keen understanding of the powerful exclusionary effects of western developmental discourses. Picking up on the insights that poststructuralist critiques offer, Martin (2007) details the ways in which ancient indigenous relational understandings of childhood and learning are discounted when western individualist and developmental discourses are imposed on Aboriginal children. She claims this is entirely consistent with the ways in which colonialist discourses have historically rendered Aboriginal people's knowledges invisible. Martin argues that in early childhood education, the discounting of all but the dominant white developmental discourses of childhood and learning serves to perpetuate and regulate colonial power relations in the present.

Such exclusions are widespread. Childhood anthropologist Elizabeth Montgomery points out that within the multitude of cultures and related childhood discourses that exist across the world, very few are commensurate with the western

developmental model (Montgomery 2009). It is through systematically excluding non-western discourses of childhood (for instance, through discounting, devaluing or simply ignoring them), and concomitantly claiming the universal applicability of their own understandings, that western developmental theories continue to constitute and reiterate their dominance in the field of power, that is, early childhood education.

However, rather than concede that these discursive power relations are monolithic and immutable, it is also important to note, as Foucault (1980) stresses, that the relationship between discourses and power is anything but fixed and stable. He takes pains to point out that 'Discourses are not once and for all subservient to power or raised up against it, any more than silences are. We must make allowances for the complex and unstable process whereby discourse can be both an instrument and an effect of power, but also a hindrance, a stumbling block, a point of resistance and a starting point for an opposing strategy. Discourse transmits and produces power; it reinforces it, but also undermines it and exposes it, renders it fragile and makes it possible to thwart' (Foucault 1977, pp. 100–101). In other words, in the face of the dominant discourses that operate in any social context and at any given time, there is always the possibility for an emergent power play of resistant or oppositional discourses. This is another reason why poststructuralists regard the nexus of discourse, knowledge and power as both regulatory and productive.

Those who engage with poststructuralist theory, itself a resistant form of discourse, do so in order to deconstruct and thus destabilize powerful discourses and to expose their regulatory regimes of knowledge/power. In so doing, they enter into a power play, identifying the vulnerable, weak points of dominant discourses in order to thwart them and to foster resistant and oppositional discourses. This is precisely what Kerry Robinson and Cris Diaz-Jones (2006) do in their book *Diversity and Difference in Early Childhood Education*, which systematically explains and applies Foucault's analytical tools, not only to expose the knowledge/power dynamics that marginalize children from non-dominant social and cultural backgrounds but also to encourage and support other early childhood scholars and practitioners to do the same. Glenda MacNaughton's (2005) book, *Doing Foucault in Early Childhood Studies*, has an explicitly activist agenda. She writes in order to demonstrate how Foucauldian understandings about the nexus of discourse, knowledge and power can be applied to the practice of early childhood education. Drawing on the critically reflective pedagogical practices of a group of early childhood educators, she describes how poststructurally informed practitioners can identify and resist the (often unintended) exclusionary side effects of dominant approaches and ensure that their pedagogies are more inclusive.

5.6 Whiteness and Othering

Resistance to the dominance of white western discourses drives the second-generation poststructural fields of critical postcolonial theory and critical whiteness theory. Scholars engaging with these theories frequently use the key concept of

Othering to name and destabilize the strategies and effects of racialized discourses, knowledges and fields of power. A critique of the process of Othering originated from Edward Said's (1978) application of Foucault's philosophies to the history of western colonialism. In his seminal book, *Orientalism*, Said (1978) stresses that colonization was not only enacted through brute force but also by sustained discursive violence. He notes that colonialist discourses (including the discourses of academic disciplines such as history, geography, English literature and anthropology) have produced dominant western knowledges about colonized people as inferiorized Others. Thus Othering refers to the process whereby assumed-to-be superior (white) western subjects quickly became the knowing subjects about colonized (non-white) Others. This racialized discourse/knowledge/power relationship not only justified the acts of European colonization, but it has perpetuated the radically uneven west/east (or north/south) colonialist relations that persist in the present.

More recently, critical whiteness scholars have analysed the relationship between Othering and unnamed whiteness within multicultural postcolonial societies in which the dominant culture is white. Instead of naming ourselves/themselves as white, it is common for members of the dominant white cultural group to identify by nationality, as not belonging to any particular racialized identity group. The identification of racialized identities is reserved for non-white Others. When the field of power is white, the assumption is that majority white culture subjects/discourses/ knowledges are just 'normal', whereas minority non-white culture subjects/discourses/ knowledges are perpetually Other to the (unnamed) white norms.

Within early childhood education, there are a number of scholars who have used the critical concepts of Othering and whiteness to reposition child development theory as a part of the ongoing (white) western imperial project of bringing 'progress' and 'development' to the rest of the world (Taylor and Pacini-Ketchabaw 2015a). One of the first to do this was Radhika Viruru (2001), whose book *Early Childhood Education: Postcolonial Perspectives from India* interrogates the normative and universalist assumptions of western developmental discourses. Viruru exposes the ways that these dominant discourses disempower, marginalize or Other children from non-western cultures while claiming to represent the interests of all children. Published a few years later, her co-authored book *Childhood and Postcolonization* explores the constitutive relationship between colonialist discourses, power and the construction of childhood within North American early childhood education (Cannella and Viruru 2004).

In Australia, contributors to *'Race' and Early Childhood Education*, edited by Glenda MacNaughton and Karina Davis (2009), deploy the tools of critical whiteness theory[5] to deepen understandings of the ways in which white Australian

[5] Critical whiteness theory emerged in the late twentieth century in the USA, largely in response to the profound racialized divisions that African-American slavery has left upon US society. It focuses upon whiteness as a construct used to justify a belief in (white) racial superiority and the concomitant oppression of black and coloured peoples. It is also used to deconstruct the persistent assumptions and the ongoing legacies and effects of white privilege. It continues to be a central critical analytic tool for challenging ongoing white privilege and racialization in the US education system (see, for instance, Persky and Viruru 2015). Critical whiteness theory also has strong reso-

children maintain a hegemonic position in early childhood education despite Australia's prevailing multicultural and diversity discourses. They focus upon the ways in which Australian children's perceptions of whiteness are directly related to patterns of peer inclusion and exclusion (Davis et al. 2009) and also challenge white early childhood educators to critically reflect upon the ways in which they might be unintentionally 'Othering' non-white children (Davis 2009). More recently, Prasanna Srinivasan (2014) analyses the discourses that shape the identities of Australian children who do not belong to the dominant white culture. In her book *Early Childhood in Postcolonial Australia*, she details the specific ways in which non-white immigrant Australian children are Othered and assigned to marginalized national identities (see also MacNaughton et al. 2010; Taylor 2005; Robinson and Diaz-Jones 2006).

The tools of critical postcolonial and whiteness theories help early childhood scholars to drill down into the sedimented inequalities that have been laid down by the histories of colonialism and other forms of racial persecution, violence and forced diaspora, which still underpin culturally diverse early childhood contexts despite the surface rhetoric of inclusion and diversity (Grieshaber and Cannella 2001; Mutua and Swadener 2004; Pacini-Ketchabaw et al. 2011; Pacini-Ketchabaw 2012; Pacini-Ketchabaw and Viruru 2010; Ritchie and Skerrett 2013). In the recent edited collection *Unsettling the Colonial Places and Spaces of Early Childhood Education* (Pacini-Ketchabaw and Taylor 2015), contributors reflect upon the ubiquitous and often covert ways in which colonialist discourses lurk in early childhood educational contexts in contemporary settler colonial societies.[6] For instance, Emily Ashton (2015) considers how in Canada, even curricula that purport to be inclusive and to celebrate diversity can conceal unexamined white settler norms and inadvertently position those children who appear to embody diversity as 'Other'. Fikile Nxumalo (2015) considers how indigenous stories are routinely erased from children's encounters with 'natural' place in settler colonized societies. As a decolonizing strategy, she proposes early childhood educators deliberately learn how to 'refigure' indigenous presences when taking children for walks in colonized natural places. Another contributor, Jennie Ritchie (2015), who is a long-time exponent of counter-colonial early childhood education in Aotearoa, New Zealand, details how

nance amongst Australian early childhood scholars. This is because the longstanding 'White Australia Policy' (which denied Indigenous people rights as national citizens until 1967 and sought to restrict immigration to whites only) has fundamentally shaped the Australian national imaginary and is still played out in early childhood educational settings (see Taylor 2005).

[6] Settler colonial societies are the ones in which the colonial settlers and their descendants have claimed and maintained sovereignty and now outnumber the dispossessed indigenous peoples they originally colonized. Most settler colonial societies are also immigrant multicultural societies. However, it is the white settlers' languages, laws, systems of government, knowledge and faith systems that maintain a hegemonic hold on the conduct and identity of these culturally diverse nations. Poststructural scholars living in white settler colonial societies such as Canada, New Zealand, Australia and to a lesser extent the USA (because of the additional foundational legacies of slavery) have contributed new insights into the ways in which colonial legacies and dominant white settler discourses function to perpetuate specifically racialized forms of knowledge and power within their early childhood education contexts.

pervasive colonialist legacies continue to undermine the aspirations of Te Whāriki to function as a genuinely bicultural and bilingual Māori-Pakeha curriculum (see also Ritchie and Rau 2007; Ritchie and Skerrett 2013).

5.7 Subjectification

The concept of subjectification is central to poststructural theory. This is the process whereby 'human beings are made subjects' (Foucault 1982, p. 212). It is important to note that Foucault's productive concept of the 'made' human subject is a radical departure from the (Cartesian) notion of the individual subject as born with biologically determined, innate, fixed and essential characteristics (awaiting 'development'). This point of departure around understandings of the subject is very pertinent for the field of early childhood education, as the prevailing structuralist notion of the individual child as a pre-existing subject waiting to unfold is foundational to child development theories.

In discussing the relations between subjects and power, Foucault (1982) declares that his main project was to elucidate the modes of subjectification. He identifies three main modes. The first are the scientific discourses that produce knowledge about human subjects, as I have already discussed in relation to child development theory. The second are the 'dividing practices', which use binary logic to produce dominant and subordinated human subjects (p. 212). These are the modes that I have discussed above in relation to the Othering of non-white children. The third is the mode by which modern western subjects become self-regulating, or self-disciplining, without the need for coercive power. This was of particular interest to Foucault. He notes that it is the liberalist discourse of the individual as autonomous, free and agentic that plays a cameo role in producing the self-regulating western subject. This is not to say that we *are* free and self-determining individuals, but to recognize that we are compliant subjects because we *believe* ourselves to be free and autonomous. In line with these arguments, he proposes that liberal individualist discourses (such as the discourse of the individual as exercising free-will and self-determining agency) are prime modalities for governing the modern western subject (see also Rose 1999).

A number of early childhood education scholars have engaged with these ideas. For instance, the edited collection *Governing the Child in the New Millennium* by Hultqvist and Dahlberg (2001) features writings that variously trace the ways in which liberalism's dominant educational, policy, legal and cultural discourses of childhood have produced self-governing child subjectivities and bodies (see also Bloch et al. 2004). Drawing upon Nicolas Rose's (1999) Foucauldian-inspired work on liberal democratic governance, Zsuzsa Millei (2011) explores the tensions that exist within liberalist early childhood discourses around the contradictory notions of discipline, guidance, autonomy, choice and freedom. Along with Rebecca Rabi, she considers how children embody such tensions and how they become self-disciplining subjects as they navigate the discourses of 'choice' that proliferate,

paradoxically, around the discipline and punishment regimes of educational institutions (Millei and Rabi 2010).

5.8 Sex/Gender Performativity

Feminist poststructuralist theorists are particularly interested in the ways in which we become gendered and/or sexed subjects. They see the process of gendering as core to the development of our sense of selfhood, and they also see it as a process that is highly regulated by a proliferation of geohistorically specific gender/sex discourses. Judith Butler (1990) stresses that our gender subjectivities and identities are not only produced through the discourses we inhabit, but they are relational, and we actively take part in performing or doing them. This means that our gender identities are not simply outward manifestations of who we really are on the inside; they are something that we continually work on and *do* in our relations with others. We make ourselves into gendered subjects, for instance, by repeatedly performing ourselves as certain kinds of girls, boys, men and women according to the prevailing discourses. Moreover, our gender identities are 'doings' or 'performances' that we enact for others as much as for ourselves.

Such gender 'performances' or 'doings' begin in early childhood. Bronwyn Davies (1989) was one of the first feminist educators to engage with poststructuralist theory and to use it to throw new light on the complex ways in which children negotiate prevailing gender discourses – many of which are contradictory and operate in tension with each other. Her book, *Frogs, Snails and Feminist Tails: Preschool Children and Gender*, uses observations of children's play and their reactions to a gender-transgressive feminist retelling of a fairy tale to analyse the ways in which young children actively shape and reshape their own gender identities in response to the (sometimes contradictory) gender discourses that they are exposed to. Davies' work was one of the first in the early childhood field to sidestep the structuralist 'nature/nurture' debate about children's gender identification, which pivots around proportioning causality to either biology and/or socialization. Instead, she engaged with the tools of poststructuralist theory to analyse the powerful and productive effects of gender discourses in producing young gendered subjects.

Other feminist scholars followed suite. Glenda MacNaughton's (2000) book, *Rethinking Gender in Early Childhood Education*, explicitly revisits the poststructuralist gender analysis offered by Davies a decade earlier, similarly arguing that gender is not natural, but a complex set of discursively constructed power relations. With a focus upon the ways in which gender continues to be narrowly regulated in early childhood, despite gender equity policies, MacNaughton asserts that it is 'the regime of truth about the "developing child" … [that] hampers feminist interventions' (p. 6). This is because developmentalism's focus upon the 'natural' processes of childhood masks its complicity in perpetuating discursively constituted cultural norms, including deeply entrenched cultural gender stereotypes. MacNaughton's book offers early childhood educators practical ways of identifying how dominant

gender discourses infiltrate early childhood settings under the guise of 'natural' girl and boy behaviours and for intervening to ensure that these discourses do not regulate children's gender identities, behaviours and relationships in covertly limiting and negative ways.

In an extension of her Foucault-inspired ideas about the performativity of gender, Judith Butler (1990) insists that the conventional performance of normative gender binaries (of 'correctly doing' masculinity and femininity) relies upon the structuring logic of normative heterosexuality (which she also refers to as heteronormativity or hegemonic heterosexuality). In other words, gender binaries only make sense within the broader context of hegemonic heterosexuality. Her observations have strongly influenced the emergence of another branch of feminist poststructural thinking that is often referred to as 'queer theory'. Queer theory scholars seek to 'trouble' or destabilize the heteronormative assumptions that prop up gender binaries.

While many would insist that sexuality is neither relevant nor developmentally appropriate in early childhood, some poststructural early childhood scholars have used queer theory to further understandings about the gendering of young children within heteronormative early childhood contexts. One of the first to do this was Mindy Blaise (2005). Her book, *Playing It Straight*, explores how prevailing gender discourses in an infant classroom are framed by the norms of heterosexuality. Blaise argues that children are not only learning how to perform their gender in the early years of education, but they are simultaneously learning how to perform it via the dominant norms of heterosexuality, or via what Butler calls 'the heterosexual matrix' (Butler 1990). From her extended study, Blaise observes that children enact themselves not just as girls and boys but predominantly as *heterosexual* girls and boys.[7] In a similar vein, Emma Renold (2006) also draws upon queer theory to detail the means by which children regulate each others' gender performances through enforcing heterosexual norms in the school playground, and Carmel Richardson and I observe how normative notions of the heterosexual family both structure the architecture of 'home corner' in the early childhood centre and infuse the gendered play of girls and boys (Taylor and Richardson 2005).

Kerry Robinson (2005, 2013) is another early childhood scholar who engages with queer theory. Her work focuses upon exposing the contradictions inherent in adults' attitudes and beliefs about children's sexuality. She draws upon queer theory in order to extrapolate upon the ways in which heteronormative discourses reinforce discourses of childhood innocence while simultaneously (and paradoxically) disavowing the significance of (hetero)sexuality in young children's gender identity construction (see also Renold et al. 2014). All of these scholars engage with the

---

[7] Following her original longitudinal study of gender/sexuality performances in an infant's classroom, Blaise (2013a, 2014) has gone on to further extrapolate upon the reasons why it is important to acknowledge that children's engagement with prevailing heteronormative sexual discourses plays a formative role in the construction of gender. Against the grain of prevailing developmentalist beliefs that sexuality is only relevant in adolescence, she has consistently argued that efforts to achieve gender equity in the early years of education would be much more effective if they recognized the significance of young children's simultaneous negotiations of gender and sexuality discourses (see, for instance, Blaise and Taylor 2012).

critical tools offered by queer theory in order to encourage early childhood educators to deepen understandings of the complexities that underpin sex/gender stereotyping and to expose the buried assumptions that can stand in the way of dislodging these stereotypes and fully embracing gender/sexuality diversity (Blaise and Taylor 2012).

5.9 Desire and Becoming

While Foucault himself insisted that liberal governance can and does produce resistant and subversive subjectivities, as well as the more common compliant subjects, many scholars who apply his concepts tend to emphasize the ways in which dominant discourses regulate subjects and reproduce social norms and inequities. With an underlying interest in education for social justice, they focus upon the power relations that are part and parcel of the subjectification process. Most of the early childhood poststructural scholars whose work I have so far reviewed maintain such a focus. Those who seek more fluid, open and creative possibilities tend to engage with the conceptual tool box offered by Foucault's contemporary, Deleuze and his collaborator Guattari. In a departure from Foucault's focus upon power and subjectification, Deleuze (2006) emphasizes the primacy of desire over power. For Deleuze, desire is the central productive force that is constantly destabilizing forms of subjectivity and which drives becoming. This is the desire to become other. In Deleuze's (1991) cartographies of the subject, nothing stands still. Desire propels lateral movements or lines of flight across the surface of relations, constantly seeking new forms of otherness and seeking new becomings.

Needless to say, the mercurial Deleuzian concept of desire-driven and relational becoming is radically different from developmental psychology's structuralist notion of the child becoming sequentially more rational through a set of predetermined cognitive stages until she/he reaches the end point of adulthood. Deleuze's alternate conceptualization of becoming is very attractive to many poststructuralist early childhood education scholars as it affords open-ended, transformative, fluid and affective ways of approaching children's subjectivities and seems to mirror the desire-propelled modes through which children relate to and move through the world around them (Olsson 2009; Blaise 2013b; Renold and Mellor 2013; Sellers 2013; Lenz Taguchi 2014). Moreover, as Deleuze's concept of becoming is inherently relational, it offers a complete break with developmentalism's focus upon the individual child as a unified subject and as the primary unit of study. Viewed through a Deleuzian lens, children's becomings are continually emerging from relations with others within the milieus, places or communities in which they are located (Davies 2014; Somerville 2011; Pacini-Ketchabaw 2010). Becoming is not a solitary human process. It is only through their relations with others in the world around them (not all of them human) that children's subjectivities emerge through 'becoming worldly with' (Giugni 2011).

UK early childhood scholar, Liz Jones (2013), states that she consciously engages with Deleuze's concept of becoming as a way of resisting the tendency to foreclose on understandings about children subjectivities and to remain open to their unfolding desires and embodied relations. In reflecting upon what is happening during a children's dress-up princess play event, she takes heed of Deleuze's and Guattari's (1987) insistence that becoming is not about seeking correspondence in relation to others or about seeking to literally resemble or imitate others, but is a relation of experimentation and potential that can take us beyond the threshold of knowable identity. Australian arts educator, Linda Knight (2013), uses Deleuze's insistence that becoming has no beginning or end point, to refute more conventional interpretations of children's drawings as offering a window into children's stages of cognitive development. She rereads a series of children drawings in order to reveal how the children that create them are always in relation to others around them and 'always in the midst of being formed' (p. 261).

In her Deleuzian- and Reggio Emilia-inspired book *Listening to Children: Being and Becoming*, Bronwyn Davies (2014) speaks about the importance of staying open to the not yet known. Rather than searching for evidence that conforms to a predetermined developmentalist script, she suggests that the Deleuzian concept of becoming enables early childhood scholars to follow children's desires for real-world relations and to focus upon the kinds of emergent becomings that exceed predictability and full-known ability.

5.10 Assemblages and Rhizomes

There are many Deleuzian concepts that have helped scholars to think differently about the business as usual of early childhood education – far too many to cover here.[8] I have selected just two more to mention – the key concepts of assemblages and rhizomes. Both of these concepts extend and deepen understandings of children's becomings. According to Deleuze and Guattari (1987), human becomings take place within relational assemblages of heterogeneous elements, such as objects,

[8] There is a considerable body of educational scholarship that engages with the multitude of provocative concepts that make up Deleuze's and Guattari's 'toolbox' for thinking differently – including concepts such as affect, nomadic subjects, de-territorialization, schizoanalysis, bodies without organs, etc. (see, for instance, Carlin and Wallin 2014; Semestsky 2006; Semestsky and Masny 2013). Many leading Deleuzian educational scholars also engage with the second-generational works of feminist Deleuzian philosophers such as Rosi Braidotti (2011), Claire Colebrook (2002) and Elizabeth Grosz (2008). Excellent examples of the application of feminist Deleuzian work to education can be found in Rebecca Coleman's and Jessica Ringrose's 2013 edited collection *Deleuze and Research Methodologies* (which includes early childhood chapters by Emma Renold & David Mellor and Mindy Blaise) and in 'Thinking with Deleuze in Qualitative Research' a special issue of the *International Journal of Qualitative Education*, edited by Massei and McCoy 2010. The 2013 special issue of *Global Studies of Childhood* on 'Deleuze in the Early Years', edited by Liz Jones and Judith Duncan, includes works by leading early childhood scholars from a number of different countries, who engage with a wide range of Deleuzian concepts.

other living bodies, affects, practices and semiotics. Like Foucault's conceptualization of discourses, these assemblages always *do* something; they produce effects.

This collective and generative notion of an assemblage has been fruitful for many childhood scholars. It allows them to break away from an exclusive focus upon the child and to take account of the complexity of relational events that constitute children's lives and produce specific effects. Alan Prout (2005) was one of the first to theorize the ways in which children's lives are constituted through ever-shifting assemblages of heterogeneous cultural, social, biological and technological elements. For instance, in detailing how the assemblage of childhoods, classrooms, genetics, psychopharmaceuticals and information and communication technologies has produced the diagnosis of ADHD and, in turn, produced new child identities and medicated and altered many children's bodies, he illustrates how newly emerging childhood understandings and experiences are the direct effect of new and emerging socio-bio-technical assemblages.

Other scholars have also put the Deleuzian notion of assemblage to use in their applied studies in early childhood settings. In a microstudy of infants in an Australian family day-care home, Ben Bradley et al. (2012) describe the event of mealtime as an assemblage that includes not only the babies but also the bottles, highchairs, technologies, regulations, a carer, food, gravity, etc. An appreciation of these complexly assembled relations allowed them to tease apart some of the layered effects of connection, power and becoming. In their ethnographic study of a Welsh childcare centre, Emma Renold and David Mellor (2013) focus upon the affective and actively embodied aspects of nursery room assemblages. They describe infants' relations within the nursery environment as an assembled series of multisensory doings: 'a complex affective assemblage of other bodies and things' (p. 24). Liselotte Olsson (2009) concludes her extended Deleuzian study of young children's relational learning in a Swedish early childhood centre by characterizing learning itself as the effect of mutable 'assemblages of desire' (pp. 133–178). In reflecting on her collaborative research in New Zealand early childhood settings, Iris Duhn (2012) similarly concludes that it is assemblages of vibrant material, elements and forces that simultaneously shape early childhood places and pedagogies.

The assemblages that Deleuze and Guattari (1987) have in mind are never fixed. Their elements are always reconfiguring and transmuting. Deleuze and Guattari (1987) related concept of the rhizome helps to further elucidate how these surface movements and reconfiguring assemblages unfold. Taking the botanical form of rhizomes (plants that propagate through horizontal underground root systems) as their point of reference, they describe rhizomatic thinking as thinking that moves in horizontal lines across the surface, proliferating in multiple lateral directions, but which nevertheless always remains interconnected. They suggest that rhizomatic thinking offers us a way of thinking nonhierarchically about multiplicity and connectivity and propose it as an alternative to structuralist tree root (or top/down) modes of thought that are always searching for origins and causes. It is rhizomatic thinking that has helped early childhood scholar, Marg Sellers (2013), to reconceptualize the relationship between children and the Te Whariki curriculum in Aotearoa, New Zealand, and guided Jennifer Sumsion and Sue Grieshaber (2012) in mapping

lines of connection within the Australian Early Years Learning Framework. As an extension of rhizomatic thinking, it is rhizomatic analysis that has enabled MacNaughton et al. (2010) to offer multiple readings of children's racialized identity and its implication in power relations and to thereby think differently about children's subjectivities.

5.11 Recent Challenges to Poststructural Theory

The conceptual shifts in early childhood scholarship that have been largely enabled by the work of Deleuze and Guattari are echoed throughout the social sciences and humanities. Their notion of assemblages of interconnected human and non-human entities and forces, in particular, has encouraged poststructural scholars to broaden the hitherto exclusive focus upon human meaning-making practices and subject formation that characterize scholarship within the 'discursive turn'. Their insistence upon the mutually constitutive relations between all elements of the assemblage – human and non-human – has contributed towards further retheorizations of relational and distributed agency, taking it well beyond the framings of exceptional human rationality and clever human meaning-making practices. In general, their ways of thinking differently have helped to decentre the human in poststructural thinking. They have helped us to become more aware of the dangers of overdetermining the extent to which discourses (human meaning-making practices) shape our worlds and not paying enough attention to the ways in which the non-human (more-than-discursive) world also acts upon and shapes us.[9]

Across the social sciences and humanities, there is growing awareness of the ways in which the discursive turn has inadvertently reiterated the nature/culture divide, by separating humans and our activities off from the rest of the world (for a commentary specifically related to childhood studies, see Prout 2005; Lenz Taguchi 2010; Taylor 2013a, b). Both the 'material turn' and the 'animal turn' are now posing challenges to the anthropocentrisms of poststructural thinking. Within early childhood education, Hillevi Lenz Taguchi's (2010) engagement with feminist science scholars' re-theorizations of human/material relations, in particular with feminist science scholar, Karen Barad's (2007) work on the productive intra-actions of meaning and matter, has generated a new interest in the pedagogical intra-actions

[9] It is important to note, however, that Deleuze and Guattari are not the sole inspiration for scholarship that pushes beyond the human-centric limits of poststructuralist thinking. The boundary-blurring feminist science philosophies of Donna Haraway (1991, 2008), for instance, have long been extremely influential throughout the social sciences. In early childhood education, they have influenced scholars with an interest in children's relations with the more than human, for instance, a number of contributors to Taylor et al. (2012) special issue of *Global Childhood Studies*. The work of science studies scholar and actor network theorist Bruno Latour (1993, 2005) has also played a major role in displacing the human-centric notion of exclusive (and rational) human agency with a distributed notion of collective (human and non-human) agency. Latour's work has in turn inspired the influential work of leading childhood studies scholar, Alan Prout (2005).

between children and materials. The material turn has been of particular interest to those working in early childhood arts education (Clark 2012; MacRae 2012; Pacini-Ketchabaw et al. 2015) but has also prompted retheorizations of the material/discursive aspects of children's learning more generally, including their language learning (Davies 2014; Rautio and Winston 2015).

The animal turn has come to early childhood education predominantly via an engagement with the multispecies relational philosophies of Donna Haraway (2008). Unlike Deleuze's more abstracted relational philosophies, Haraway emphasizes that the entanglement of human lives with other species is most significantly felt on the ground and in the ordinary everyday lived relations that are triggered 'when species meet' (2008). This makes Haraway's ideas particularly applicable to empirical research that is concerned with everyday child/animal and child/plant relations, such as the situated 'common world' research[10] that traces children's relations with other species within their immediate environments (Pacini-Ketchabaw et al. 2014; Pacini-Ketchabaw and Taylor 2015; Taylor 2011, 2013a, b, 2014a, b; Taylor and Pacini-Ketchabaw 2015b; Taylor et al. 2013). The emergence of multispecies ethnographies that trace the mutually affecting relations between young children, plants and animals (Pacini-Ketchabaw et al. 2016) and hybrid studies that apply queer interventions at the nexus of material/animal/plant/child relations (Taylor and Blaise 2014) represent some of the recent initiatives within the field of early childhood education to challenge the anthropocentrisms of poststructuralism, by blurring the boundaries between nature and culture, decentring the child and actively engaging with notions of more-than-human agency.

5.12 Conclusion

In this chapter, I have set out to chart how the philosophical conversations that cumulatively challenged the premises, certainties and universalism of the twentieth-century structuralist theories, and thereby became known as poststructural theory, have travelled across disciplines in the social sciences and humanities and into the field of early childhood education. I have unpacked a number of the key critical concepts from the toolbox of poststructural theory and its cognate fields such as postcolonial theory, critical whiteness theory, queer theory and post-humanist theory and provided an overview of how these concepts have been engaged with and applied in early childhood scholarship and research. In each case, these tools have been used to uncover the blind spots of earlier conceptualizations and theorizations from within. The task has always been to question prevailing truths and norms about what it means to be human, including the norms and truths about childhood and learning.

[10] The possibilities for reconstructive research that 'reassembles' children along with other creatures and entities in their 'common worlds' are extrapolated in my book *Reconfiguring the Natures of Childhood* (Taylor 2013b). For more information about 'common world' early childhood researchers and projects, see the Common World Childhoods Research Collective (2015).

By ending with a very brief outline of the current challenges that the material turn and the animal turn pose to poststructuralist theory in early childhood education – namely, its propensity to inadvertently perpetuate the nature/culture divide through focusing upon the cultures of human meaning-making and agencies – I hope I have demonstrated that this philosophical 'conversation' is by no means over.

Chapter 6
Early Years Education in the Anthropocene: An Ecophenomenology of Children's Experience

Phillip G. Payne

Abstract The intersections of early years curriculum, pedagogy, policy and their research must now confront two seemingly intractable but mutually constitutive global problems within their materially 'grounded' geocultural-historical circumstances and conditions. The 'lives' of children embedded in the socioecological contexts of families, homes, meals, schools, playgrounds and neighbourhoods are 'fast' (dromosphere) 'heating up' (Anthropocene). Without alternatives, the accelerating and intensifying consequences are deeply disturbing. This chapter addresses a *vital* need in early childhood education and research. There is a compelling 'early intervention' warrant for critical problem identification, theory building, methodological innovation and empirically qualified insights into the increasingly vulnerable body~time~space *scapes* of childhood in the now complex, accelerated, climactic and abstracted/digitalized 'everyday' of their precariously 'lived experiences'. Empirically informed theoretical development of an *environmental* education and its *ecopedagogies* capable of *slowly* sustaining an intergenerational ethic is overdue. This chapter anticipates the formatively sensitive development of an experience-rich education (and research within it) that is ecopedagogically meaningful to children's immersion in various body~time~space scapes in, and with, a still vibrant nature that, in so doing, critically (en)*counters* the deeply problematic dromospherical advent of the Anthropocene.

Keywords Ecopheneomenology • Ecopedagogy • Childhood scapes • Ontology-epistemology-methodology • Body-time-space • Dromosphere • Anthropocene

6.1 Clockwork Children

'Children need wild, unlimited hours but this unenclosed time is in short supply for many, who are diarized…' (Griffiths 2013, p. 109) and, quoting from Jean-Jacques Rousseau's classic *Emile* (1762), '*Shall I venture to state…the most important, the most useful rule of all education? It is not to gain time, but to lose it*' (Italics mine). Griffiths (2013, p. 110) continues, 'A clockwork child loses a metaphysical freedom, the sense of autonomy and the inner sovereignty of the hours…'.

6.2 Time Dissonance

Alberto Melucci (1996) draws our attention to the problem of children's time introduced above by identifying three recurrent symbolic representations of the inexpressible dimensions of time created by historical cultures. These are:

○ The *circle*, as that which was cosmologically experienced in tribal societies as the existentially 'felt' of the cyclical renewal of all things, unfolding primordially as a repeatable atemporal event over different (re)cycles – breathing, sleeping, suns and moons, tides and seasonal variations all of which intrinsically 'matter' to those deeply embodied and lived rhythms of physiological, biological, social and ecological nature.

➔ The *arrow* is the progressively unilinear durations of monological, objective, external, quantified, measurable and predictable western, industrialized, techno-scientifically organized time 're'presented analogically by the calendar, clocks, hours and minutes of modernity's rationally expressed, mechanistic, disciplined and strictly timetabled social formations, cultural arrangements and teleological worldview.

• The *dot* of the digitally instantaneous of disconnected blips, chaotic bytes (or bites) and amnesic memories cybered into the globally always present of now and nano postmodern times-spaces.

6.3 Raising an Unhurried Child

Carl Honore (2004) sums up a fundamental problem confronting children's • post-modern lives when he asserts, 'Rescuing the next generation from the cult of speed means reinventing our whole philosophy of childhood' (p. 236).

These images, metaphors and their figurations are all 'now' presenced simultaneously in the embodied, lived present/moment – our flowing *interior* organic times ○; our *socially* constructed and mechanically regulated family, school, work and leisure times ➔; and our globally *exterior*ized mobile 'real times'. • Inner-social-global times and their chaotically intensified spaces, maybe splaces, are compressed

and concentrated in the everyday. Their intensifications compete for, and in, our accelerated selves. Overlaps, contradictions and fragmentation between O➔• abound in the now hyper-individualized performative and, increasingly, techno-teleological 'posthuman' condition (Braidotti 2013). The (c)rush on the instant of the turbocharged present/now sunders our nature-culture bodies and may well be an underlying source of a number of new pathologies, human, social, cultural, environmental and, even, now and in the future, anthropogenically ecological. We have a problem!

6.4 Dromosphere

Dromology is the study of speed and how the technologically driven acceleration of time now instrumentally objectified and commodified, as a competitive 'race' against anything and everything, changes the nature of 'things', including its beings, both animate and inanimate. Paul Virilio's (1977/2006, 2007/2010) studies of the science of speed investigated the manipulation and material control of 'speed' to win wars: His "dromosphere" describes the imploding world of that accelerating human 'race against time' and is embodied in the now 'naturalized' and normalized 'fast' of daily living in, not coincidentally, 'first' world nations. Time, and space, don't 'wait' the dromospherical race - as children no longer reimagine Aesop's tortoise 'winning' its patient "test of speed" with the lair of the hare. Nor do fast human bodies and their war against nature's rhythms in the omnipresent dromosphere. Bear/bare witness to the new natural and normal; the speed of the internet, the 'fast food' industry; the now 'on-line on-demands' for/of every'thing' on and in 'screen culture'; Google it; the selfie; Instagram. Speed dating; speed reading; web surfing; three minute theses; fast degrees. Fast schooling? Click on/off infotainment. Down/upload it. Fast children, faster childhood, parenting and teaching? A posthuman race, and war, against time and the spaces of nature as were once natural? Dromocracy as 'naturally' normalized? Or, self-catalyzed, destructive "accelerationism" – the implosion of global, neoliberal, techno-capitalism? (Noys 2014). Interpreting Paul Virilio (1977/2006, 2007/2010).

6.5 Vibrant Matter

Jane Bennett in *Vibrant Matter* (2010) provides a vital clue to the 'slow' contribution of ecophenomenology to the 'fast' problem of children's accelerated and intensified lives when she asserted, '…it can take shape again, for a version of this idea already found expression in childhood experiences of a world populated by animate things rather than passive objects…a latent belief in the spontaneity of nature' (p. vii).

This chapter addresses a vital need in early childhood education in the Anthropocene.[1] There is a compelling need for critical problem identification, theory building, methodological innovation and empirically qualified insights about the increasingly vulnerable body~time~space scapes of childhood in the now complex, accelerated, climactic and abstracted 'everyday' of their precariously 'lived experiences'. The insights and 'outcomes' of those critical inquiries will inform the development of an alternative 'early intervention' form of environmental education capable of slowly sustaining the next generations. The warrant for an empirically qualified theoretically informed and experience-rich education meaningful to children's experiences of body~time~space (non)relations in and with a still vibrant nature mirrors the warrant for educational interventions to (en)counter the deeply problematic dromospherical advent of the Anthropocene. Jussi Parikka's (2015) *Anthrobscene* throws the needed material light on the 'deep time' geophysical consequences for the environmental wasteland created by the mining of minerals and chemicals required by the abstracted media/communications technology industry and their toxic sedimentations in a new surface strata of the globe's geology and geography. Even 'education for sustainable development' through its unbridled celebration of a 'technics of experience' masquerading as 'learning' endorsed through the rapid pedagogical (sic) uptake of information and communications technologies (ICT) in environmental education, globally 'online' curriculum perpetuates this intellectually barren wasteland (Payne 2003a).

There is, therefore, very good reason to be critical of how and in what ways the ecologically paradoxical experiences of ➔~• body~time~space relations are structured instrumentally, technically, deterministically and economically by global, technocratic, performative and consumerist forces – all ingredients of the 'stealth revolution' of neoliberalism (e.g. Brown 2015). On the 'othered' side of this fast time phenomenon, the deep time of 'nature', even in its romance of the past/passed, might well be at its predictable 'death' (Merchant 1980) or 'end' (McKibben 1990) due to its intersections with catalytic culture (e.g. Soper 1995; Soule and Lease 1995; Weiss and Haber 1999). But, maybe, remnant and memoried versions of nature do 'live on' in human and 'non' or 'more-than-human' things, like our pulse, flesh, a tortoise, a rock, the moon and its dust, memories of significant experience at the beach when a kid, or climbing a tree, or eating a fresh apple fallen from the

[1] The Anthropocene denotes the geological epoch (following the 11,700 year long Holocene before the present) in which human activity is acknowledged as having a significant impact on the earth's ecosystems. The time of the onset of the Anthropocene is debated, some claiming it commenced with the advent of the Industrial Revolution in the eighteenth century; others post World War II as many nation states industrialized their economies. Anthropogenic global warming and its contribution to climate disruption is only one amongst numerous 'environmental' problems confronting the collective being of things, including desertification of lands, toxification of oceans, chemicalization of air, water, soil; loss of biodiversity and increase in species extinctions and endangerments (Christoff and Eckersley 2013). Common 'namings' for these 'outer' problems of nature include 'environmental crisis' but, phenomenologically/existentially, 'inner' and 'social' natures must be included in the notion of 'ecologically problematic human condition' as it less abstractly alerts us to the embodied experience of the human sources and accelerating/fast global consequences of the modern Anthropocene and its numerous derivatives.

branch above – all of which still 'matter' a great deal. And what about that 'inner' playful nature of children and childhood where times did not 'matter', following Griffiths, Rousseau, Honore and Bennett, to name just a few who help us sense the problems of childhood now confronting us if children are to be 'sustained'.

Either way, and in between somewhere/how, we need to grapple with an escalating intergenerational problem about how the relations of human and non-human natures are (re)configured by numerous accelerants in those hyperintensified, individualized and dissonant body~time~space transitions (Payne 2010a). And how early years education and research has a vital role to play. This contribution demands greater researcher reflexivity about the researched. It proposes a post-critical framing of an early interventionist ecophenomenological study of children's experience. This post-critical vantage point provides for the inquiry into, critique of, and development of a constructive educational response to the ecologically problematic human condition outlined in the above introduction.

Todays' children will assume responsibility for what appears to be an increasingly intractable 'socioecological' problem about the disconnection and 'divorce' of those embodied relations. A 'reconciliation' of inner, social and exterior natures is called for. The centrality of 'first' ○ nature in children's lives must be discovered, or recovered, so that it does not become a distant 'other' or 'more than' a receding memory, nostalgic romance, etc. but, rather, a vibrant actant reanimating children's vital ecobecoming. If so, now needed in various conceptions and constructions of early years education are keener and timely insights and generative evidences about the slower human experience of animate times and wild spaces of nature – human and non-human (Grusin 2015) as such environmental experiences of temporal and spatial processes and consequences are bodily enacted in and through toddlers~children's movement (e.g. Johnson 2008). The insights highlighted in this chapter are key conceptual ingredients of the theory building and methodological innovation efforts now called for if we are to (re)generate a meaning-rich, formatively and normatively aware intergenerational ethic for the 'sustainable' global future (Payne 2010a, b).

6.6 A Digress to Method

Figure 6.1 maps the basic thematic contours of the 'big' problem outlined above. It orients the reader to the 'wild' (e.g. Abram 2010; Griffiths 2006), 'alien' (e.g. Bogust 2012) and even 'uncanny' (Trigg 2012) concepts animating this chapter.[2]

[2] Beyond metaphor often used here, Paul James (2006) provides a detailed theoretical account of the ontologies of time, space and their embodiments in the different social formations of tribalism, traditionalism, modernism and postmodernism. Time~space representation commenced through human's capacities to create analogical means of understanding and proceeded interpretively and then explanatorily through genealogical, mythological, cosmological, empty, relative and virtual time~space understandings, while for the embodiments of these time~space 'layers', James replaces the latter three with metaphorical, biotechnological and cybertechnological bodies.

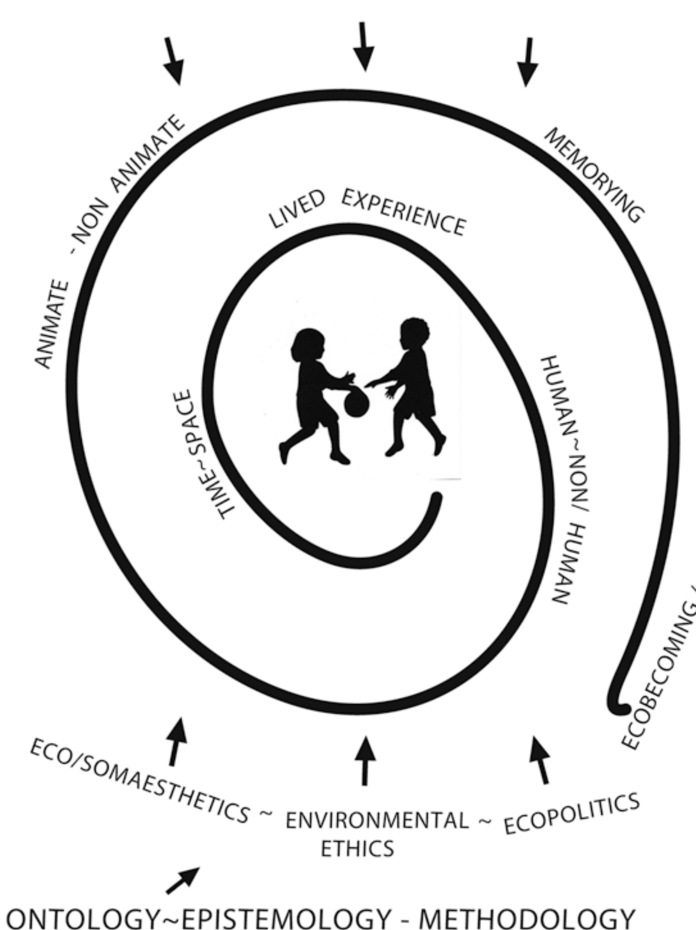

Fig. 6.1 A post-critical ecophenomenology (from 'a critical ecological ontology for inquiry', Payne – numerous)

Central to James theorization is that a contemporary onto-epistemic layer does not replace the preceding layer but gradually dominates it, causing it to recede, or fade. There is a cumulative effect of escalating the 'abstraction' of social and ecological relations but, clearly, for example, the current layer of postmodernity • is now a technologically chaotic and globally dissonant (re)shaper of the still dominant, modern ➔ body~time~space relations. James argues the crucially relevant point that we, as hyperindividualized and atomistic selves, are constituted increasingly as 'abstractions' beyond the preceding layers as, consequently, so are our 'extended' social and ecological relations, their 'loss' being a key concern of this chapter. For example, a great deal has been written about the death, rape, colonizing, end, new and beyond 'nature' giving rise to multiple natures. Simplistic mass slogans and uncritical educational efforts and interventions to '(re)connect' (children/adults) with nature must be seen in this heavily abstracted human, social and environmental condition – as 'ecologically problematic'.

My empirically qualified interests in theorizing children's experiences from the 'grounds up' of nature hones in the environmental design of pedagogies of the 'irreal' – the 'real' that is unreal and the 'unreal' that is real (Payne 2010c).[3]

This thematic mapping of a post-critical ecophenomenology for inquiry and critique is derived, here, from a broad survey of how 'classical' phenomenology has recently 'turned' to a 'post' phenomenological (e.g. Ihde 1993) vantage point. It, speculatively with some needed empirical qualification for the non-anthropocentric and ecocentric purposes here, incorporates elements of a nascent 'ecophenomenology' (Brown and Toadvine 2003) whose theoretical incorporation critically extends the contemporary critical discourse of environmental education, revisionary impulses in early years education and empirical insights into children's experiences of environmental learning. With the assistance of 'new' theory sprinkled through this assemblage of themes and concepts, this chapter arrives tentatively at a critical ecophenomenology for inquiry, critique and theoretical and methodological development sufficient to address the problem posed and questions raised in the introduction. This partially historicized 'post-critical environmental education' (e.g. Hart 2005) concludes with a summary of the key methodological challenges for critical inquiry in early years education. Figure 6.2 illustrates these. That is, there is a concerted effort in this chapter to link (a) the historical trajectories of education and critical environmental education within a post-eco-phenomenological hermeneutic of 'new' theory and (b) 'emergent' methodological deliberation consistent with (partially) addressing, from an ecocentric philosophical perspective, the otherwise intractable anthropocentric problem of the dromospherical Anthropocene and *Anthrobscene*.[4]

[3] Those 'remarkable' and 'edgy' embodied/experiential pedagogies I have used with children (and adults) over the past decades emphasize the movement/mobile experiences of exploration, rediscovery and reimagination in/of nature's things. Its pedagogical eco/somaesthetic and, subsequently, 'story-like' narrating of experiences affectively and physically felt in the outdoors is indicative of yet another of the 'turns' animating the post-critical-'magical realism.' Gabriel Garcia-Marquez is a well-known literary exponent. Robert Ingpen, artist, illustrator and conservationist as well as recipient of the Hans Christian Andersen Medal in 1987 for lasting contributions to children's literature, inspires my work in the imaginative pedagogies of the irreal (Payne 2010c). Arguably, magical realisms are an element of what Gratton (2013) refers to as a 'post-deconstructive realism' within the speculative realisms movement but might more satisfactorily linked with the literary imaginations and ecopoetics of environmental criticism (Buell 2005) and ecocriticism (Garrard 2004) as understood in children's culture (Dobrin and Kidd 2004) and storying of their emplacements (Cutter-Mackenzie et al. 2010).

[4] Methodological issues emerging from using different theories, including some mentioned here, to interpret data are well demonstrated in, for example, Jackson and Mazzei's (2012) 'reading' of how qualitative research is conducted and what it represents. Jackson and Mazzei's deployment of various theories to 'read' and represent the same data to foreground interpretive and representational differences highlights a fundamental problem grappled with in this post-critical chapter. The data set they use is limited to interview only. I emphasize the persistent anthropocentric problem of 'correlationism' in theory building and methodological development with anti-correlationism as a way of highlighting the gap between *being* and *thought,* or *experience* and its *representations.* 'Knowledge', as typically assumed, is, therefore, problematic, partial and always contingent, but necessary in education, requiring a far more expansive expression of meaning-making and aesthetics of self-social-ecological I explore here and temporarily conclude with as an 'end-in-view' for ethical early years environmental education.

Fig. 6.2 A cultural-global-ecological design of inquiry, critique and methodological reflexivity

Figure 6.1 highlights some of the relevant key ideas of the largely unknown philosophical orientation of interpretive or hermeneutic phenomenology. Amongst more established movements of contemporary western 'thought' such as positivism and deconstructionism, the interpretive approach to inquiry underpins the post-critical 'ends-in-view' of a slower environmental and early years education (and research) described above. Phenomenology, as an 'access' point to the 'lived' of 'experience', has its anthropocentric limitations, like any inscribed thought pattern, and, hence, requires supplementation with various other critical 'theorizations' whose non-anthropocentric and ecological dimensions are required for the twin imperatives of theory building, as reflexive inquiry undertaken by the researcher/reflective practitioner, and methodological development, as inquiry deliberation about how the 'researched' (human and non-human over time~space relationalities) are positioned in such research.

The dromospherical rush of the Anthrop/obscene really complicates for any researcher the question of what framing and naming concepts 'matter' most in reconceptualizing our current views of education. The dominant assumptions in education thought (in the Anglo-'west/north with which I am most familiar) now demand intense scrutiny for interpreting how its major dominate, if not hegemonic, concepts' act to reconstitute what this chapter finds deeply problematic at that intergenerational level of the lack of an (eco) aesthetics~ethics~politics of education. Indeed, in early years education, what are children being 'developed' for and upon what assumptions about their 'growth' and 'experience?' The rapidly accelerating transition from the relative stability of the Holocene to the 'Anthro'p/obscene is telling, in more ways than one, about how we currently live experience, via contemporary western thought and its practices. The presumed 'anthropocentrism' (and offshoot of patriarchal andromorphisms) of human-centred 'education' must be 'checked' for what those 'isms' convey to young 'learners' in their subjectifications, be they in families or in schooling, particularly through the 'medium' and shallow prism of the accelerated quest for children's technoliteracies. And, if need be upon deeper scrutiny, qualified severely for what those constructs do to 'development', such as the child's brain and its chemistry as a consequence of 'screen culture' for 'learning' (Greenfield 2011). In turn, what then are the consequences (theoretically and practically) for 'education' and efforts to develop personal, social, global and ecological 'sustainability' when the term sustainability is regarded critically as little more than an increasingly hollow slogan in education, including its consequential pedagogical deployment in shallow 'places' (e.g. Payne 2003b, 2006, 2014, 2015).

From a post-critical perspective, 'sustainable development', children's 'growth', 'maximizing potential', enabling or 'empowering' 'agency' and 'relations' or 'connections', 'screen culture' and so on suddenly take on an 'identity' quite different to that so often innocently presumed in education. What do those uncritically presumed educational concepts 'do' pedagogically (as distinct from 'ecologically') for children and in those fragile and vulnerable formative senses of self, brain, body and learning and the social, the environmental and their interrelated and emergent agencies?

Alternatively, wild ideas like non-anthropocentrism and ecocentrism are troubling 'worldview' concepts that serve to destabilize, at least, the hegemonic assumptions and framing conceptions made by researchers and reflective practitioners about the researched. Ecophenomenological inquiry of the type described here 'grounds' the transcendental loftiness of 'worldview' abstraction in the immanent actualities of the materially real and creative agencies of its things in the everyday. This post-critical destabilization of conventional wisdoms, practices, assumed inheritances and legacies undertaken in this chapter undoubtedly requires further conceptual/theoretical and methodological 'working up' in numerous 'applied' contexts such as early years education policy, or pedagogical development in schooling, or parenting in different socioeconomic or cultural-geographic circumstances and, closer to home for this readership, even, in play theory and the 'environmental design' of playgrounds, amongst its many things!

For those interested in the theoretical and methodological commensurabilities of a revitalized, animated early years education and its research, the critical ecophenomenological access point developed here will explain why and, partially justify, how it 'fits' a slow response in early years education to the heavy ecological footprints of the dromospherical Anthrop/obscene. The incorporation of a series of rewilding concepts into revitalized theory building and research development, with emergent methodological deliberation, underpin a particular dispositional approach to the framing of alternative orientations within the post-critical inquiry fashioned here. Simply, the big 'sting in the tail' here is phenomenology's historical 'rejection' of the scientism of empiricism achieved through the meteoric rise in modernity of the now dominant positivist-experimentalist movement of western thought. It is ingrained in much 'said' about children and 'practiced' for them, on their behalf. The sting is potentially a nasty one at the subjugated sense of self (e.g. Butler 2015) of the researcher/pedagogue where we often 'misrecognize ourselves', and our educational purposes, in how we 'post-intellectually' go about framing research and positioning the researched (Cooper 2002). Indeed, we do not need to look too far in, for example, education and development to see how much the fast, faster of automatically 'accelerated' but always made invisible body~time~space relations are not only fostered but celebrated and privileged in the various 'enclosures' of curriculum, schooling, testing, parenting and family functioning.

Researcher reflexivity? My framing and, following a Deweyan-inspired pragmatically reconstructive 'end-in-view' of mapping, contouring and navigating the subterrain and terrain of a critical ecological phenomenology is acutely aware of one of the main critiques of phenomenology's alleged 'naivete' and anthropocentric 'limits'. To be sure, that limit lies in interpreting and describing lived experience only in the moment in the absence of taking into account numerous other structural factors, historical forces and ecological misunderstandings or misgivings influencing and shaping our individual subjectivities, identities and, phenomenologically speaking, individual and collective senses of being and becoming. Post-critical ecophenomenology is one response to this limitation, while other theory turns mentioned all-too-briefly here are more than alert to the flaws of traditional phenomenologies.

The term 'critical' is crucial notwithstanding its variations of meanings (and practices). Rather than being viewed as a retreat from modern critical theory (e.g. Held 1980; Dallmayr 1991) as some have concluded, post-critical here extends and advances the political warrant 'of' and 'for' an environmental education, and the reflexivity required for the ecocentrism it demands, within making a clear research of the politics of ontology, epistemology and methodology (Fig. 6.2). Irrespective, the excavating of the 'openness' of such subterranic naivete (or alleged 'innocence' of childlike experiences) is not necessarily a major problem when aspects of the most contemporary stratospheric 'high' theory touched on throughout this chapter 'mirror' the animated, vital, imaginative, creative and speculative manner in which children 'be' before and sometimes 'playfully' during the 'hold' of other structural factors and 'grip' of historical forces. Those thwarts to metaphysical 'becoming' are neatly captured in Griffiths' reference to how 'enclosures' found in children's ter-

rain consume the spontaneity of animation Bennett seeks to recover. Nonetheless, the post-phenomenological incorporation of the 'critical' and the 'ecological' asks the researcher to bring to presence the grounded richness of children's deep and meaningful experience as well as their (dis)affections imposed by structural/historical and cultural problems such as 'class', ethnicity, physicality, ability, language, religion, species, land/water/air and mobility/fluidity/liquidity issues. Alleged childlike innocence/naivete and sociohistorical risk/vulnerability go enigmatically and precariously hand in hand. They require teasing out if early years education is to be reanimated and vibrant.

Fortunately, for those more conventional critical purposes, various intellectual and theoretical resources are available in environmental, cultural, feminist, animal, postcolonial and other theorizations of the 'postmodern condition', as a characterization of advanced techno-industrial, globalizing 'societies'. The trick here, however, is not to simply download such theory but, from the ecophenomenological grounds of young children's bodied experiences and lives in nature, and inquiry into it, inductively and adductively reinterpret the relevance of such critical theory. An example is Virilio's 'dromology'.

6.7 The (Sub)terrain

The 'ecocritical' version of environmental education has waxed and waned over the past 30 years – predictably so. Discursively, some only in environmental education and its research have remained 'true' to the field's formative identity established in the early 1980s where its primary purposes were not only to educate in/with, about and for the environment but serve as an overdue educational critique of any 'education' that reproduced or reconstituted various socioecological problems, issues and their various injustices (e.g. Huckle 2014; Robottom 1987, 2014; Payne 2015). Critical curriculum theory in environmental education, however, has fallen on 'hard times' (Payne 2006), like most reconstructive efforts in (environmental) education that are critical of the neoliberalization of education (e.g. Hursh et al. 2015) and its policies (e.g. Payne 2016), including funding, schooling as well as in its corporatization of 'post-intellectual' university research, publishing, teaching and 'cognitive capitalism' efforts (e.g. Cooper et al. 2002).

Unlike recent efforts in education to re-enthuse the more general, less critical, field of environmental education, such as Louv's (2005) 'children's nature deficit disorder', the alternative (eco)phenomenology of children's experience of time~space outlined in this chapter eclectically injects a substantial dose of critical theorizing about the dromospherically manuf(r)actured experiences of the postmodern time~space 'poverty' condition of children's lives in their 'un-places' (Trigg 2012) or 'non-places' (Auge 1995). These (dis)places of children's lives are devoid of ○ nature but replete with its derivative ➔• natures. The existential and partially ontological warrant for a 'counter' ecophenomenology of children's 'authentically' (sic) lived experiences in and of the 'lifeworld' (including remnant/memoried 'first

nature') calls ethically for a renewed ecopolitical vibrancy of things that affectively and aesthetically as well as ethically and politically enliven the 'matter' of children's lives according to how those researched 'subjects' are framed as curriculum, pedagogical and research problems and, more precisely, questions.

Troubling questions about the problematic status and 'quality' of children's time experiences in various spaces have not been posed, as the following review reveals. More assertively than what so far has been introduced, those sharper research sub-questions about the 'subjects' of inquiry/critique need to probe the socio-environmental 'design' of the meaningfulness (or not) of the experiences of children (and adults or the elderly) as they are 'felt' and practiced enigmatically, paradoxically and (non)ecologically in the 'everyday' (Ginsborg 2005) of various contexts, including the home (Blunt and Dowling 2006) or postmodern oikos (Payne 2009), the neighbourhood, the playground, the school, the classroom, outside and inside and here and there. To reiterate, at stake, in not posing research questions of a non-anthropocentric type is, probably, the loss of metaphysical freedom and inner sovereignty that Griffiths (perhaps Pestalozzi, Froebel, Steiner, etc.) alert us to. At risk, is ignoring children's 'agency' as beings or actancy as an ecobecoming within the unavoidability of nature's things; things that Bennett seeks to rematerialize politically as a gesture to the 'reinventing afresh' a philosophy of childhood which Honore (2004) insists upon in resisting the dromospherical cult, race and war of speed.

For the specific questions probed here and tactically recycled throughout this chapter, deafening silences and alliances in educational discourse persist about children's largely invisible or hidden vulnerabilities to the often abstract, paradoxical and contradictory experiences of 'micro/bodied' **O** time~space – as that layer of primordial experience is recalibrated within the 'meso/social' ➔ time~spaces of the structured, routinized and timetabled every day that schooling supports – as each of those two body~time~space layers are then confusingly accelerated, intensified, compressed and individualized by the technologies of 'macro/global' • time~space and its technics of experience in education (Payne 2003a, b). The 'scientism of children' discourse can't grasp (or comprehend) this crucial subterrain of needed inquiry and critique, as this subterrain is often 'affectively' pre-rational/discursive in its bodily felt somaesthetic sensitivity and 'eco/somaesthetic' complexity (Payne 2013). In this enigmatically layered manner of what it now paradoxically is in the postmodern to be a •➔ child, 'uneducated' or 'unlived' about **O** 'nature' and inexperienced in its slow times~spaces, the quest for a reconciliation of its 'inner', 'social' and 'outer' versions might be partially reclaimed in a richer meaning-making manner for early intervention environmental education and its research.

Terrain? This 'ecological' stage of 'development' envisioned here has, indeed, been promoted for some time. Critical progress on disclosing the duplicity of the increasingly fast cultures of children's lives is, ironically, far too slow! Brofenbrenner's (1979) formulation of a (social) 'ecology' only touches anthropocentrically and reductively upon aspects of the subterranic ends-in-view pursued non-anthropocentrically and ecocentrically in this chapter. Brofenbrenner's theoretical framing of 'development' (like Piaget and Vygotsky) has, indeed, undergone major 'recontextualization' efforts over the past 30 years. Like my critical and eco-

logical supplementation of phenomenology's naivete, these admirable efforts in mainstream theory of children (and education) incorporate broader social and cultural contexts and issues (e.g. Gershoff et al. 2014; Saracho 2014). But, they still exclude the environmentally 'ecological' issues relevant to the subterranic sources and global consequences of the Anthrop/obscene and dromosphere, and numerous other examples of the ecologically problematic human condition such as anthropogenic climate destabilization, toxification of lands, acidification of water, as these 'resource problems' and accompanying socio-cultural issues are experienced differently in various circumstances in different historical~geocultural~ecop olitical contexts as 'locations of knowledge' (e.g. Canaparo 2009).

Contouring the moving terrain? Despite its stealth absorption into the neoliberalization of education, the critical legacies of environmental education and its research provide, potentially, a timely response to these gaps in early years education about those existential dilemmas, risks and disjunctures now normalized and 'naturalized' in young children's lives. This curriculum field of education, like phenomenological philosophy, is relatively unknown in early years education. Promising developments are still available and are considered later. Environmental education and its research have a four-decade-long history (Stevenson et al. 2013) that, unfortunately, remains on the margins of mainstream education discourses, possibly because it serves as an untimely critique of much of it, as indicated earlier! This marginalization of environmental education reoccurs despite numerous studies of a 'socially critical' type in the 1980s and 1990s of younger children's active engagements in problem-solving of local environmental problems and social issues through interdisciplinary participatory action research type programs in primary/elementary and secondary schools. This highly active curriculum and pedagogical development in schooling was often facilitated externally by teacher education academics, or as a consequence of professional development and research development (e.g. Robottom 1987; Fien 1993; Robottom and Hart 1993; Reid et al. 2008; Payne 2015).

Children's 'relations' or 'connectedness' with nature and their agencies are receiving attention in innovative practices of environmental education and education for sustainability. For example, 'outdoor' schools without walls for very young children are being piloted in Canada (Blenkinsop and Piersol 2013); 'forest' kindergartens and schools are found in different European countries and 'bush' schools for toddlers now exist in Australia. All, it seems, provide rich outdoor experiences for children in, and of, or about nature but, perhaps, not ecocentrically with and for it. These environmental schools remain underresearched and, probably, undertheorized in that 'newer' critical dromospherical context of the Anthrop/obscene. Irrespective, claims, often anecdotal or rhetorical, are frequently made in these alternative outdoor and experiential/immersive educations about the children's learning 'outcomes' of greater engagement, wonder, creativity, thinking, interactions, wellbeing and understanding of academic knowledge. If validated by research (of the type recommended here, amongst other interpretive and qualitative possibilities), there are likely to be far-reaching implications for any 'new' ethic of caring, parenting, pedagogy, schooling and socializing. If so, greater attention might also be paid post-critically to how the environmental designs and ecopedagogies of play-

grounds, gardens, parks and related urban, city and rural amenities in which our children socioecologically might become over such time(s)~space(s).

More precisely for the body~time~space relationality questions highlighted here, the signs are promising as new theory emerges, as alluded to throughout this chapter. Anecdotally, empirically and theoretically, the promise of repairing culture-nature relations lies in the ecopedagogical creation of 'slow(er)' bodied time in various nature spaces and outdoor places, as that notion of a body~time~space relationality might 'replicate' the ○ ontological subterrain of epistemological conditions adequate to an alternative early environmental education for socioecological sustainability. In moving the subterrain of inquiry, the temporal scales of our memorying and becoming (Grosz 1999) of wild, alien, uncanny and irreal experiences of the vital environments of vibrant nature are worth speculating about for further inquiry into both the enablements and constraints of those body~space relations of children's dromospherical timescapes within the Anthrop/obscene. Numerous disjunctures exist in and between these assorted layers of temporal and spatial movement. This chapter, therefore, assertively problematizes for researcher reflexivity the researched subterrain of that temporal spatiality, or geographies of children's time.

6.8 Moving the Terrain and Its Contours

The dominant positivist-inspired psychological focus on developmental and operational perspectives of children's temporal (and spatial) cognition (e.g. McCormack 2014) barely acknowledges these ontologically 'bodied' existential concerns. The ecophenomenological, reconceptualist orientation to 'experience' is gaining traction in the discourse of environmental education research (Sauve 2005; Lotz-Sisitka et al. 2013; Payne 2013). Environmental philosophy (Thomson 2006) is now viewed as one of the key contemporary issues in phenomenology and existentialism (Dreyfus and Wrathall 2006). The 'lifeworld and lived experience' (Jay 2006) and 'temporality' (Brough and Blattner 2006) are identified as two of the central concepts of the main movements in phenomenology while 'affectivity' (Han-Pile 2006) and the 'body' (Hofffman 2006), as well as claims on authenticity, are included in the main movements of existentialism. Typically, however, phenomenology and existentialism are anthropocentric. Post-phenomenology (Ihde 1993) partially rectifies this limit and informs the 'post-critical' orientation pursued here that incorporates 'moves' and 'turns' if, indeed, the non-anthropocentric, inclusively non-human and ecocentric 'worldviews' are to be clarified within the discourses of education and early years education. Conceptual clarification of complex, ground-breaking ideas is only partially adequate if the 'praxis' commitments and interests of materialist approaches to critical theory are to be sustained.

The needed empirical basis underpinning and critically qualifying this ecophenomenological inquiry draws selectively, given the limitations of this chapter, on a series of small-scale research projects undertaken over the past three decades about the nexus of critical environmental education theory development, slow ecopeda-

gogy practices and ecocentric reinterpretations of emerging genres of interpretive inquiry and critique in educational research. These projects are part of a much larger research program titled a critical ecological ontology for educational inquiry, or 'named' simply as an education for being for the environment (e.g. Payne 1999a, 2005a, 2006). In addition, those studies of oftentimes 'insignificant' (Payne 1999b) childhood experiences in and of nature should also be viewed within the 'significant life experience' research literature so well established in environmental education, following Tanner's (1980) 'classic' study (see below), extending most recently to studies of the student experience of environmental learning (Rickinson et al. 2009). Aspects of the phenomenological approach and ecophenomenological orientation prioritized in this chapter can be found in closely related children's research (Hart 1979; Sobel 1993; Kahn and Kellert 2002; Chawla 2001; Barratt-Hacking and Barratt 2007).

This, therefore, politically 'untimely' (Grosz 2004; Payne 2013) interventionist chapter about a critical ecophenomenology of children's experience of nature's relations proceeds with an overview of phenomenology, as it has only sparingly informed the (western) ➔ modern and • postmodern discourses of education and its research over the past 50 years. Children's lived experiences of time~space have rarely been investigated, most of all from the critical perspective of dromology in the Anthrop/obscene. Those risk-intensive 'major events' are further elaborated in a post-critical (Hart 2005, 2013) manner by incorporating ideas found in recent major turns in theory in the post-humanities, social sciences and arts. One key is 'post'-phenomenology (Ihde 1993) because it deals emphatically with (human) experience from the grounds up. These theoretical turns coalesce around a 'non'-anthropocentric and 'constrained constructivist' (and non-subjectivist) interest in ontologies of objects within a renewed materialist concern about the status of agency (Coole and Frost 2010). Pertinent matters for critically reflexive inquiry, theory building and research development are raised in the final part of this chapter.

6.9 Contour Tracking and Navigation: Phenomenology and Education

Gaston Bachelard's *The Poetics of Space* (Bachelard 1958/1964) captured well the historical mood of twentieth century phenomenology in providing an alternative approach to and understanding of the human and non-human condition. His proposal to interpret how we (aesthetically) experience intimate places and poetically represent them implores us to 'forget' our 'learning' of the growing rationalism and authority of science while also breaking from the habits of conventional philosophical research. Central to Bachelard's thesis is the lyrical need for a reimagination of social spaces and nature's things. Bachelard's 'travel to the land of motionless childhood' exemplifies his immediate relevance here (see also Bukatman 2012). His emphasis on the intimacy of the house and its daydreaming as a 'frozen' memory

over time~space calls for extension into those more natural environments upon which houses and their oikos are also dwelled in or inhabited socioecologically in the postmodern (Payne 2009). Phenomenologists of perception like Maurice Merleau-Ponty (1945/2002, 1968, 2003) consistently broach the 'other' and 'facticity' of things 'already there' in themselves, often 'invisible' in nature, that are 'lived' perceptually in the 'world'. 'Things' and their intrinsic actancy and ecological creativity now occupy centre stage of the most contemporary high theory indirectly informing this chapter and, more particularly, how the important notion of (children's) agency and intra-agencies might be reworked in very different ways. Perception and reception occur. And, as already indicated and will become patently clear in regard to the theory building and research development purposes of this chapter, it was Martin Heidegger (1927/1962, p. 60) who declared 'Phenomenology is our way of access to what is to be the theme of ontology, and it is our way of giving it demonstrative precision. Only as phenomenology, is ontology possible'.

Hinted at only above, numerous criticisms of classical phenomenology persist, in particular its alleged anthropocentrism (human consciousness, perception) and allegedly 'naïve' claims on 'authenticity' and 'subjectivity' (e.g. Adorno 1964/1973; Sparrow 2014). Rapproachements have been sought in critical theory leading into 'critical ontology' (Fay 1987; Dallmayr 1991) and 'post-phenomenology' (Ihde 1993). Ihde's *Postphenomenology* is pragmatically attentive to the contemporary issues of 'technology and the lifeworld' (Ihde 1990) and has a strong underlying concern about the 'environment' and how the instrumental realism of technoscience creates new hermeneutic demands on the technics of experience and its embodied praxis. The (dis)connect with self/nature is evident in Ihde's post-phenomenological 'revealing'. The new wave of speculative realists have deepened the critique of the lingering anthropocentrism of phenomenology through their deconstruction of the assumed 'correlationism' of (human) being and thought, notwithstanding the broader post-phenomenological interest in things in (them)selves (e.g. Shaviro 2014).

In education, the development of critical curriculum theory via a 'critical ecological ontology' for inquiry (Payne 1995, 1997, 1999a, 2006) is consistent with this trend, including acknowledgement of the 'lifeworld textualism' correlationism problem (Payne 2005c), as is the rise of post-critical inquiry and research (Hart 2005, 2013). Ecophenomenology, as characterized here, therefore, is a 'manner' or 'style' of thinking reflexively that, more recently, post-critically searches for an ecocentric approach to interpretation, representation and methodological deliberation and development. The quest for non-anthropocentrism and ecocentrism, therefore, draws selectively and unevenly across critical, poststructural and phenomenological perspectives as they are being reshaped by the current wave of theoretical turns. A critical ecophenomenology in education pragmatically incorporates the interests of critical environmental education in enabling socioecological and environmental justices.

In historicizing this chapter to give phenomenology its due in education, the pragmatic linking of philosophical phenomenology, existentialism, hermeneutics and educational theory and curriculum/pedagogical practice has been sporadic over

the past five decades. The focus on children is limited. Before 'post'-phenomenology, Denton's (1974) collected essays is one concentrated foray. Kneller (1984) included phenomenology as one of eight 'movements of thought' in modern education. Husserl, Heidegger, Sartre, Buber, Freire and Merleau-Ponty are identified as classic figures. The latter is viewed as most relevant here in that Merleau-Ponty's philosophizing did account for children's 'lived bodies', their immersive prereflective perceptions and movements in different environments through which objects are manipulated and generalizations are conceptually made through discovery that, in turn over time, 'sediment' thinking, acting and perceiving a relative 'lifeworld'. Temporally, the adult's world is seen as an 'elaboration' of the world of the child. Yet, interestingly, conventional understandings dictate that adulthood is reified against childhood where, according to Kennedy (2006b), childhood appears as and in the 'shadow of the enlightened man'.

Hermeneutics is another of Kneller's (1984) movements of thought. Dilthey, Gadamer, Heidegger, Ricoeur and Kuhn are discussed. Hermeneutics is promoted as a method with variations. Interpreting children and their lives is not included, only assumed in Kneller's otherwise important mapping of the philosophical terrain of education. Importantly, Denton's (1974) essays include a chapter by Leroy Troutner. Troutner's (1974) interpretive phenomenology focused presciently on the question of time and education and, in particular, probed two interrelated questions of relevance here. The first deals with the how of a child's living of time (see also Burton 2011) and is posed normatively in terms of the 'primordiality' and 'authenticity' of the child's becoming, following Heidegger's extensive investigations of Dasein, the question of being. Troutner's second question examined how the child learns time and what kind of time is learned as a particular expression of the relative cultures from which the past, present and future of time are conceptualized, manufactured and lived in society. For example, I recall being instructed in my early years education of how to 'tell the time' on analogic clock/'watch' faces of ➔. No(thing) else sticks in my memory. I wonder how • digital time is now taught and learned (by parents, teachers) and what meanings of or about are ascribed by young children to the ever-pulsating blips of the moment. Following Troutner's concerns about the pedagogies of time, these constructed modes of fast temporality are cast normatively as 'inauthentic', leading, allegedly, to the increased atomization and fragmentation of life, resulting in the loss of significance and meaning. For Troutner, these troubling insights are a significant consequence of the existential phenomenological analysis of time.

Pinar and Reynolds' (1992) phenomenology is another edited contribution to education theory and includes a genealogical history of phenomenology and post-structuralism in curriculum studies. The North American contributions of Dwayne Huebner, Maxine Greene, Madeleine Grumet and other 'second-generation' scholars like David Jardine, an early visionary, persistent advocate and outstanding exponent of (eco)phenomenological hermeneutics in (environmental) education and ecopedagogy (e.g. Jardine 2000), are outlined. Children go missing, or inferred only, in Pinar and Reynolds' 12 chapters.

6.10 Grounded Contours: Ecophenomenology and Education

In some respects, the prefix ‘eco’ is unwarranted because the ontologies presupposed by many phenomenologists (try to) endorse a deeply grounded form of philosophical ‘monism’, contra dualisms privileged epistemologically and axiologically in much western anthropocentric/humanist thought. This attempted non-dualism opposes the ‘dualism’ often attributed to the Cartesian-inspired thinking about the authority and sovereignty of scientism and empiricism. Monism and dualism invoke starkly different conceptions of just about everything – be it matter, the self and subjectivity~objectivity, others, things in themselves, nature and the world. Epistemological implications also vary widely where, for example, despite the persistent anthropocentric bias in much phenomenology, the Cartesian mind and body are ‘separated’, as is reason and emotion and physicality, theory and practice and I and lifeworld. Consequentially, their pedagogical spatialities separate the materialities of indoor and outdoor ‘learning’. Increasingly, the *Anthrobscene* is unwittingly endorsed and uncritically valorized. Another offshoot of epistemological dualism within axiology is ‘values-hierarchical’ thinking. Put simply, one of the ‘enclosures’ identified by Griffiths as most valued in modernity is ‘learning from the neck up’ and constrained to the ‘indoor’ only of a very limited practice of body~time~space relationality.

Ontological monism may well be a generalized form of holism or indicator of non-anthropocentrism, even ecocentrism. Its ‘flat’ rather than hierarchical conception of things, including humans, is of post-critical educational interest. Most children ‘connect’ with animals; they like to play with things; they like to explore, discover and ‘pretend’. The beingness of many things enlivened in children’s experience is, potentially, a form of ecobecoming over the time~space of various environments. The slow flow of time in children’s irreal and ‘nomadic’-like playful experiences warrants attention in our theory development efforts about what, in the various environmental designs for an ecology of things, constitutes for children ‘meaning’ and its ‘making’ without pedagogical/epistemological intervention. If so, methodological deliberation about how that monistic ‘affect’ can be interpreted, described or represented as the ‘experience’ of an ecobecoming. Anthropocentric dualistic logics have privileged epistemology over against ontology with priority in education typically given to the former of that binary of learning, teaching, assessing and other dimensions of schooling, parenting and pedagogy. Shaviro (2014, p. 3), amongst speculating others about ‘thought’ and experience, concludes, ‘… epistemology must be deprivileged’. In education, Huebner’s (1967/1987) highlighting of the materialism of the environmental design of curriculum expresses similar concern about the pedagogical preoccupation in the philosophy and practices of education with formal ‘learning’ and its ‘outcomes’ (see also Payne 2014, 2015 for empirical ‘case’ studies of environmentally designed transpositions undertaken in outdoor experience).

The implications for conceptions and practices of early years education of ontological monism, characterized here (via the access point of ecophenomenology) as body~time~space relationalities with things in themselves are, bluntly, massive and might well please Honore's plea for a new philosophy of children. A case can be made for an 'authentic' demand for non-anthropocentric epistemologies in education theory/practice and research methodologies and deliberation 'different' to the presupposed conceptual/theoretical binaries, presumed values-hierarchical thinking and overprivileging of pedagogical perspectives about child development, cognitive development and so on. Incorporating, or memorying, the authentic 'otherness' of children's affectively meaningful lives must confront the Cartesian-inspired disembodiment, disembedding, displacement and decontextualization of the subject from the human-non-human and animate-inanimate vital world privileged by the ecocentric reconceptualization and repositionings of its various subject/objects/things.

The above microexamples of children's vital connections with animals and vibrant experimentation in discovering things aim to bring to the 'surface' the subterranic ontology~epistemology 'tension' and, more often than not, dualist anthropocentric-non-anthropocentric and human-non-human figurations of it. Any new contours of early years education thought will need to navigate meso- and macrolevel tensions, for example, the social and environmental design and development of schools, curriculum and pedagogy, the experience of being/coming 'educated', the rewilding of the underlying normatively driven epistemologically privileged categories of cognitive~affective~sensorimotor growth and, even, 'worldview' assumptions of culture-nature as they are remade in an early intervention environmental education in the dromospherical Anthrop/obscene. These micro-, meso-, macro- and global ontological~epistemological tensions are far too numerous to list here, the above sampling being indicative. Even assumed notions of language and literacy (and 'ecoliteracy' as now popularized) can be challenged for what they express and represent, and anthropocentically and 'politically/discursively' legitimize. As noted, language used about the rich depths of (children's) experience of, for example, 'imagination' cannot correspond or correlate well to that complex, dynamic and ever temporally spatially moving subjective 'reality' that initiates imagination and creativity in the very first (ontological) instance. At best, language is an approximation only of experience, and much experience is not accessible even to the experiencer and experience of things. If 'non-representation' and the critique of 'correlationism' are even partially considered, the meanings researchers 'give' to children's 'talk' and 'voice' warrant caution from an ecophenememenological and post-critical perspective given their present conceptual and methodological challenges to inquiry and critique.

We don't necessarily need to start anew in navigating 'new' contours of childscapes. Numerous intellectual resources are available and briefly outlined below. The most definitive accounts of ecophenomenology anticipate the transdisciplinary intersections of phenomenology, environmental philosophy including ethics and the philosophy of nature including its aesthetics (Brown and Toadvine 2003). For the reflexively normative purposes of this partially historicized account of high and grounded contours, the scholarly field of environmental ethics was formalized in

1979 with the publication of a journal bearing that name. And much of that environmentally ethical discourses clearly anticipated the anthropocentrism are now so heavily critiqued in the latest high theorizations of speculative realisms and new materialisms and qualified in post-phenomenologies. This ground-breaking subterrain of theory occurred at about the same time the field of environmental education was formalized following a series of international conferences organized by the United Nations during the 1970s (e.g. Palmer 1998). The formalization of environmental education, following earlier 'nature studies', 'conservation education' and elements of 'outdoor education' in the first half of the twentieth century, prioritized interdisciplinarity and experiential learning and education, well beyond the 'science education' of the time that was only just beginning to address environmental problems and issues. Environmental education and ecophenomenology neatly link in the ways I'm 'ethically' suggesting.

Ted Toadvine (2009) posed three questions central to the idea of ecophenenomenology that, taken together, deftly summarize the challenge this chapter presents to formulating the 'early intervention' experiential environmental education and its research development terrain, contours and childscapes navigated here. Toadvine's 'meta'phenomenology draws inspiration from Merleau-Ponty and asks us (as educators and researchers) to describe and understand: What is the nature of experience? What is the experience of nature? And, therefore, what is the 'pedagogical' relation between experience and nature? Toadvine's ecophenomenology insists on bringing to life the 'ontological, epistemological, aesthetic and theological' dimensions of experience (p. 6). But his pursuit of an environmental ethics is ontological rather than the dominant epistemological of the field of environmental ethics, the latter of which, however, is central to 'education' and the ontological~epistemological, pedagogical and methodological 'tensions' referred to so often throughout this chapter. As such, Toadvine's demands for a comprehensive understanding of the philosophy of nature provide a valuable and, potentially, useful set of interrelated criteria for framing curriculum inquiry and its design on/for environments (Huebner 1967/1987). Toadvine's questions might well guide the planning of research (and professional development) that revisits the centrality of deliberation about ontology and epistemology in methodological framing and development (Robottom and Hart 1993). Toadvine's triad of questions are also useful for developing adequate curriculum and appropriate ecopedagogy as they apply in different educative circumstances in schooling and their educational contexts within certain cultural~ecological formations and socio-political arrangements.

Furthermore, in not starting afresh in accessing and navigating relevant intellectual resources, the (eco/post)phenomenological influence on various other disciplinary approaches to inquiry cannot be underestimated in terms of their interdisciplinary potential to reshape educational practice, theory and research. 'Environmental perception and values' and the 'perspective of experience' occupied the human geographer Yi-Fu Tuan's account of *Topophilia* (Tuan 1974) and *Space and Place* (Tuan 1977). 'Eastern' and indigenous ontologies and epistemologies occupy much of Tuan's theorizing. Tuan's human geography, like the different critical geographies of Soja (1989), Harvey (1996) and Massey (Massey 2005), ecological anthropologies

of Tim Ingold (2000, 2011) and Philip Descola (2013) as well as Marc Auge's (1995) 'non-place', the ecological psychology of James Gibson's environmental 'affordances' (Gibson 1979), Andy Fisher's radicalization of ecopsychology (Fisher 2002), Jeffrey Maitland's (1995) therapeutic somatic ontology of the spacious body, Robert Levine's (1997) geo-psychology of time and Nigel Thrift's (2008) sociological non-representational 'spatialities of feeling' provide different 'disciplinary' vantage points that in different somatic and material ways illustrate the ontological and post-phenomenological centrality of movement, perception, affect/emotion and experience and historicity, temporality, spatiality and cultures of nature's environmental differences.

Like Troutner's phenomenology of children's time in education, Tuan's (1974, 1977) inclusion of children's lives and experiences in his phenomenological theory of place is important for the purposes here. Tuan pursued the question of how a young child experientially perceives and understands his or her environment. Movement of the body in places within the timing of such experiential space is 'core'. The child's 'biological imperatives' of growth impose increasing demands on 'learning' over time and space, as well as place, while responding to the inevitability of cultural influences whose 'specific emphases', according to Tuan, are ultimately 'transcended' by those imperatives. Tuan's 'experiential perspective' offers a synthesis of active sensation, perception, emotion, conception and thought. More recently, Dylan Trigg's phenomenologies of the 'uncanny' (Trigg 2012) and 'horror' (Trigg 2014) are heavily shaped by the temporal-spatial qualities and thingly characteristics of 'memory' where, clearly, memories of childhood places and things in them are crucial to how 'meaning' is generated, created, stored and memoried in and through the processes of experience. Somewhat akin to Toadvine's ontological~epistemological questions about the experience of nature, nature of experience and their pedagogically non-dualist/binary mutual constitutions, Trigg pursues the parallel ontological~epistemological questions of the place and things of memory, memory of place (and its things) and their mutual constitutions. Any 'pedagogy of place' in education will need to navigate these contours and questions but, also, critically climb the postmodern mountain of non-place, un-place and splaces ushered into and downloaded into the mobile/liquid/fluid lifeworld that dromology recommends (Nakagawa and Payne 2014).

In the above vein, phenomenologies of children's experience that foreground the ontological~epistemological tensions of body~time~space and nature considerations are scarce (e.g. Chawla 2002), more so in education discourse (Kennedy 2006b), most of all those that provide some evidential insight into schooling. Eva Simms (2008) is a rare exception (see also Rossholt 2012), noting various phenomenologists of children's lives only ever 'indirectly' address the question of dromospherical time highlighted critically here. They tend to emphasize places and spaces like gardens, kitchens, cellars, attics and their 'secrets', as well as the times of the bodied experience of them and things found there (e.g. van den Berg 1961; Langeveld 1967/1983a, b). Critical phenomenologies of the now dominant screen, for example, of fast culture await so as to put into comparative perspective the case for ecophenomenological inquiry (Payne 2003a).

Louise Chawla's (2002) 'spots of time' is particularly helpful in navigating the conceptual base for how theoretically inspired research development and empirical qualification might proceed. Chawla reviews how certain Romantic ideas that first defined the modern notion of childhood and nature, particularly the Wordsworth's, contributed to the interpretive approach to research now gaining momentum in educational research. Chawla interprets this trend through the work of the contemporary Swiss philosopher Jean Gerbser. He provides a means for describing different ways of knowing nature in childhood, as well as different ways of relating to childhood in adulthood. Chawla's spots of times includes and describes Gebser's 'the ever-present origin', 'the necessity of the archaic', 'magic union', 'mythic and mental experience', 'archaic identity', 'magic relations', 'magic and archaic consciousness at play' and 'mythic places'. Chawla concludes with a call for research into what she refers to as 'integral experience' where, in regard to time, the qualities of time experienced by children demand renewed attention, as do responses to the question of how we inhabit our bodies in the world if we are to develop some (re)connection with the natural world. Children's 'memories' are central to Chawla's proposed research program, noting her contributions to the significant life experience (SLE) literature in environmental education and its research. Early years education researchers might grapple equally with the ecopedagogical conceptualization, construction and enactment by educators of such experiences and memories of them.

Simms' (2008) *The Child in the World* does part of that work. Simms proposes a 'genetic phenomenology of lived time' that assertively extends but contrasts with Piaget's psychological emphasis on the logical formation of 'operational time' in children's cognitive development. Like others mentioned throughout this chapter, Simms highlights the 'lived time' of prereflective experience where she asserts time is experienced in a nonhomogeneous way but as dynamic within various flows of spatial presence all of which are indicators of changing movements and modalities of activity over the flow and duration of time. Lived time is a primitive for Simms, as well, in that, as we have already noted, that primordiality is layered by various social, cultural and now global constructions of accelerating time(s) whose enigmatic 'natures' culminate intensively and individually in what I have referred to earlier in this chapter as embodied forms of paradoxical and, even, contradictory body~time~space dissonances. Drawing on David Abram's (1996) ecological phenomenology, Simms also posits that the rise of language is the initial stage in the civilized social reconstruction of time and deconstruction of primordially lived organic time. Indeed, Abram is more critical than that asserted by Simms in that he persuasively argues that the emergence of the alphabet, particularly the invention and insertion of vowels, provided a key anthropocentric turn in the rational severing of the human species from its variously lived animations in nature and relations with more/other-than-human species and animate and inanimate things. Now children are abstracted even further into the languages of the net, the msn, screen culture of the *Anthrobscene*, reiterating its material role and increasingly fast contribution to the environmental and intellectual wastelands of the ecologically problematic condition. Simms also proposes that the combination of schooling and literacy is at odds with Piaget's genetically predetermined biological change as depicted in his

account of children's development. Simms phenomenological focus on the 'solidarity' of spatiotemporality and children's prereflective perceptual experience of lived time covers numerous concepts like the events and action sequences or frames and scripts of experience, co-temporality of doing with, the deep present, the ambience of children's becoming – all of which provide rich understandings, like Chawla's, for phenomenologically inspired pedagogical development, reformulation of research problems around, for example, the challenge of eco/somaesthetics~ethics~politics as a 'grounded/bodied' inductive and adductive basis of educational, social and cultural critique.

Simms' (2008) phenomenology, interestingly, is responsive to how children experience the future given the nonhomogeneous, non-operational notion of the dynamic flow of time~space solidarities. Again, the concepts deployed by Simms and Chawla are helpful on this matter ranging from the well-known and established constructs of 'play' that demand ecophenomenological reinterpretation such as its 'trauma' to notions of the 'lived and narrated past', things 'tamed and old' (and wild), 'family narratives' and the cultural past. Memory and anticipation of things are key dimensions of children's experiences of time, as indicated in, for example, Trigg's (2012) account of 'place memory'. Simms is critical of how contemporary schooling acts as a collective and cultural memory that very selectively and reductively focuses on the cultural artefacts of literacy acquisition and mathematical notation at the expense of children's natural desire to 'become'. Simms (2008, p. 158) finds it not surprising that children, in general, do not like school and that a paradox exists in education where the future-oriented and teleologically constructed child has to engage the past-oriented knowledge of the culture in which he, or she, and they reside. Griffiths (2013, p. ix) asks why so many children in Euro-American cultures are so unhappy.

Those 'clockwork children' and their cultures of screened enclosures are now a global one in the dromospherical Anthrop/obscene. The future consequences for children's ecological development are likely to be devastating at an intergenerational level and, consequently, for critiquing and revising education discourses within the international quest for an aesthetics, ethics and politics of and for sustainability. And as an aide, at this level of a global response to the ecologically problematic human condition, the United Nations Decade of Education for Sustainability (2006–2015) is drawing to a close. What is next, noting critics of this massive, well-funded, global effort to promote the practices of sustainability find this admirable effort has failed, for many reasons that can't be pursued here apart from one revealing fact? According to research completed by the Australian Education for Sustainability Alliance (2014), 80% of teachers in Australia are either unaware of education for sustainability (EfS) or do not understand what it is. Nine percent of teachers lack a knowledge of how to integrate Efs into their classroom, while 7% are integrating 'compliant' in their classroom and 2% are EfS 'engaged' in their classroom. These findings are damning about the past, present and future. And a compelling indicator of the need for an early intervention for early years environmental education.

From the more critical ecophenomenological perspective formulated here for children, additional concepts and empirically qualified insights and evidence relevant to

the rich possibilities for research, curriculum and pedagogical development and critique can be gleaned not only from Simms and Chawla, for example, but also a number of Payne's studies of children's experience in and of 'nature' and its environments, spaces and places. Payne's 'critical ecological ontology for inquiry' aims at the recursive nature of theory building about environmental education and the normatively reflexive development of research about an education 'for being for the environment and natures'. This empirically qualified research program stresses the critical dimensions of more ecocentric persuasion and praxis 'work'. It has addressed curriculum theory through posing nine interrelated questions (Payne 1995, 2006); movement as experiential ecopedagogy (Payne 2003b, 2005c; Brown and Payne 2009); its pedagogical and democratic inclusion of young children (Payne 2015); children's conceptions and valuings of nature's environments (Payne 1998a, b); children's imaginative experiences of environments (Payne 2010c); the importance of insignificant experiences (Payne 1999b); family studies and narratives (Payne 2005a) of intergenerational influences in the oikos (Payne 2009) of 'pale green' children (Payne 2010a); young adults' embodiments of the socioecological problematic (Payne 1997); technology as subjectification of identities (Payne 2003a); the mobility and fluidity of 'splace' experience (Payne 2009, 2013); slow ecopedagogy as justices (Payne 2014); as well as how research approaches like 'post-phenomenology' (Payne 2003b, 2005b), phenomenological deconstruction (Payne 2009, with Wattchow) and 'new' methodologies in the social sciences, humanities and arts are responding 'post-critically' (Payne 2005c) to a number of 'turns' in theory (Payne 2013).

Payne's conceptual-empirical insights-evidence into children's experience of the temporal-spatial experience of nature confirms much of that identified above or alluded to about the centrality of sensation and movement, perception and reception in meaning-generation and its creative and imaginative making. He highlights the aesthetic role of the 'sensorium',[5] often intuitively and spontaneously according to movings in various environmental affordances and their 'designs' for and of body~time~space in different scapes (home/oikos, school, neighbourhood, urban, gardens, beach/coast, bush and other 'open' spaces). Payne's studies reveal the degree and extent of how what counts as 'natural' and 'wild/wildness' vary in experience and are, often, dynamically pre-rational or pre-discursive but 'elemental' to interpretation, memory, valuing, understanding and conception and learning and 'knowing'. Indicated already, other layers of social and cultural constructions of experience always overlap, some only summarized here for 'practical' purposes of theory building and research inquiry into children's educative experience – be it formal, structured schooling or other pedagogical circumstances, such as parenting, or informal contexts, such as playing, holidays, weekend activities and so on.

[5] Stoller (1987) and others assert the sensory apparatus of human beings can't really be disaggregated into separate senses even if visuality is (claimed to be) dominant. Hence the conceptual use here of the eco/somaesthetic/affective dimension of experience, or 'synaesthesia', follows Abram's (1996, p. 123) reinterpretation of Merleau-Ponty's 'chiasma' of intertwining, overlapping or sensory fusion. Note also Abram's affirmation of our 'forgetting of the senses' or 'synamnesia', as part of the 'memory problem' of adults already mentioned.

Key 'practices' identified repeatedly by Payne in these studies include the role of active and 'passive' movements and moments in 'other' environments, the spontaneity of exploration and opportunity for discovery in/of nature and the importance of mystery, puzzlement, imagination, skepticism, speculation, hypothesizing and other 'creative' experiences of the 'suspension of belief' and 'promotion of disbelief' via pedagogies of the 'irreal' as embodied in various 'natures'. Methodologically, creative expression of experience via a range of representational forms such as illustration, 'drama' and music, including well-storied 'voice' – be it individual and/or collective narratives – is valued. Other practical/ecopedagogical empirically qualified constants emerging from these actions and practices for retheorizing and research include paying strong attention to the proximal 'environmental design' (Huebner 1967/1987; Payne 2014) of the 'curriculum design' that 'scaffolds' children's memoried ecological experiences in, of and for different versions of 'nature', lived proximally/geographically but within the inevitability of the hybridity/fluidity/liquidity of 'sp(l)ace' lived temporally in the accelerating dromsophere of children's 'lived' experience. One critical ecopolitical constant of these studies is the impact on educative experience of an environmental design where the 'openings' and exposures (and becomings) of various 'natures' – inner, social and external – are bodily enabled, revealed and expressed somatically through a low consumption, low commodity and low 'technics' design of experience. Other 'things' that matter in nature are revealed when an array of techno-things/gadgets 'at hand' and their 'tool designs' are minimized materially (Payne 2003a) and pedagogically (Payne 2014).

Based on these studies of environmental education practices as they often occur 'outdoors' in urban, seminatural and open, natural or wild environments, any 'strong' evidential conclusion of a normative type about the vital/vibrant and animated 'ecologies' of somaesthetics, ethics and politics, usually disaggregated like the reductively individualized senses, is not warranted at this stage. Further reflexive studies are required and, indeed, speculation in materialist, critical and, perhaps, magical/imaginary ways. Again, the pedagogical implications for environmental 'learning', be it in children's or others' socioecological development, call for playful risk taking and role experimentations in experiential approaches to environmental education (Payne 2014, 2015), its theory building and research development.

6.11 Back to the Mind Temporarily: Phenomenology and Environmental 'Learning'

The ecophenomenological reconceptualization for theory building, methodological innovation and research development outlined above discloses 'other' gaps and flaws in what research currently focuses on. For example, somaesthetic meanings (or somatic understandings) and their intercorporeal 'making' of spatialities of feeling and 'affect' are, basically, precognitive. This largely hidden 'pre' of

consciousness, conceptualization, rationalization, cognition, language, discursive and 'mind' (and 'knowing') is brought into much sharper relief when inquiry and critique is 'bodied' in the action or conative capacities and capabilities afforded in body~time~space relationalities as they are 'felt' in movement, memorizing and meaning-making within the eco/somaesthetic. Play theory touches upon some of those issues that have been foregrounded in contemporary high theory about affect and its non-representational status (e.g. Jay 2002; Ranciere 2004; Thrift 2008; Butler 2015).

High theory about affectivity, aesthetics, spatiality and environmental designs of meaning generation and the ecological sources of its making creates a real conundrum for conventional theories of learning in education and psychological discourses. For example, in mainstream environmental education research, empirical evidence is limited to formal 'environmental learning' which is only now emerging. That development can only be a minor part of the claims of an environmental education envisioned here for early years education. Learning, as we formally use that term, is, in itself, insufficient for the purposes here because it does not acknowledge the significance of the 'pre's' listed above or the material conditions in which they are lived socioecologically and historico-culturally. The significance of affectivity in ecological meaning generation and its making in different environments and their 'designs' as they are moved through (or played in) needs to be incorporated into theories of learning. To reiterate, 'indoor designs' of spatially and temporally limiting 'learning' dominate and are abstracted (or disembodied) further by the acceleration of cyber/digital screen technologies designed by invisible corporate and entrepreneurial interests. Put differently, the *Anthrobscene* (Parikka 2015) can be understood as an insidious form of what I will refer to as 'digital colonialism' and 'cognitive capitalism', dimensions of the neoliberal 'stealth' (Brown 2015) downloading or bombing of, in this instance, children's fast 'learning' and accelerated 'development'.

In practical pedagogical terms, the long-term absence of evidence in education research about the bodied, somatic, corporeal, affective value of ecologies of meaning generation (as well as intersubjective or social) dramatically hinders the progress of the Deweyan-inspired field of 'experiential education' (and even constructivist epistemologies) already well known in the discourse of education theory and philosophy as they are pedagogically deployed not only in environmental education but also in outdoor, physical, health, service and citizenship, human development and even adult educations. Each aims to bridge the persistent mind-body, cognition-affectivity, theory-practice and rhetoric-reality gaps so prominent in education. And to which early years education and its research are vulnerable.

As will be outlined below about recent developments in cognitive science, phenomenological philosophy, linguistic sciences and even 'official' cognitive/mind theories of learning and associated pedagogical strategies will find it difficult to avoid those often invisible 'pre' dimensions of the affectivity of environmental experience, as emphasized environmentally and ecologically throughout this chapter under the umbrella notion of eco/somaesthetics. For that purpose for early years education, building blocks are needed. The phenomenology of play is one amongst

numerous socio-cultural-historical and ecological possibilities in children's experience, and in childhood, proposed for researching, theory building and methodological innovation. But, to state the obvious, the 'ambiguity of play' (Sutton-Smith 1997) is already complicated before we assertively add in 'slower' considerations like the affective, intercorporeal and environmental dimensions of eco/somaesthetics of movement. This aesthetics of experience demanding research is, of course, complicated further by the 'fast' of its technologization or 'technics of experience' (e.g. Payne 2003a, b) via, for example, the enclosured clockwork diarizing of children candidly observed by Griffiths in the introductory problem identification.

Rickinson et al. (2009) developed some useful evidential insights into the importance of 'student experience' as an official form of 'environmental learning' in education. Their approach to the study of learning, as environmental, can be contrasted with conventional positivist understandings that emphasize causal relations and linear effects of largely measurable cognitive and behavioural perspectives during short-term educational interventions. However, this promising research is persistently anthropocentric in design and methodology. It steers to learn about and 'in' the environment, an inherently conservative view (and practice) of environmental education that has attracted considerable criticism in the past, notwithstanding the absence of critical consideration that research gives to the neoliberal-techno-postmodernization of education. Nonetheless, the authors recommend further research on learners' experiences, greater emphasis on emotions and values, better use and development of theory, broader consideration be given to life-long learning and stronger collaboration between researchers, practitioners and learners. In view of the ecophenomenological approach described here, Rickinson et al.'s findings and recommendations are relevant and partially useful but can be broadened significantly, noting their use of the term student 'experience' requires much greater clarification and qualification as it reoccurs spatially and temporally in different settings and contexts or environmental designs of education.

In moving the environmental contours of 'learning' beyond the cognitive mind and indoor enclosures, there are additional but seemingly disconnected developments about the relations of experience and learning that are of immediate relevance to future inquiry about children's experience and memorizing of it. The historicizing first is the 'significant life experience' and 'memory work' literature found in the discourse of environmental education. The second is found in the very recent hybridity of the fields of phenomenological philosophy, cognitive science, neuroscience and linguistics. On both counts, the importance of meaning generation and making in and through experience as formative of (environmental) learning must be stressed, given the importance already explained about key concepts in the phenomenological discourse, such as primordial, primitive, sensation, perception, reception, intuition, somaesthetics, feeling/affect and the various other often invisible or hidden 'pres' of conventional accounts of reason, rationality and the discursive and other epistemological privilegings such as the requirement for assessment of such rational understandings. Again, it is timely to remind ourselves of the problem of correlationism – the gap between being as experience and mind as knowing.

Studies of the possible formative contributions of significant life experiences to sometimes unofficial environmental learning and activism (broadly defined) have been undertaken for three decades commencing with Thomas Tanner's (1980) 'classic'. This research program now extends to international comparisons and contrasts of various factors influential in formative learning and development (see Tanner 1998; Palmer et al. 1999). The program and its methods have been debated (Scott 1999) and revisited (Chawla 2001) in ways that examine the strengths, weaknesses and recommendations for future research. In substantive terms, the somewhat contentious 'end' (for some) of environmental 'activism' is viewed as complex, while the majority of 'influences' interpreted as 'significant' such as time spent in natural areas, with frequent contact with habitat, and its alteration, roles of parents, teachers and even books are all traced to childhood and adolescent experiences. Memory, clearly, plays an important role in this research not only of 'house' and home as accentuated by Bachelard (or postmodern oikos, Payne 2009) but also, more broadly, 'other' socio-environmental and ecological conditions. To what extent a 'cause and effect' relation exists between particular episodes/events (and/or slowly accumulated) and significant experiences, and environmental activism exists is open to debate and further research. But, the empirical fact that significance has been attributed, and memoried, to those formative years of childhood is suggestive of what an early intervention environmental education might include in its curriculum design and ecopedagogical imagination. These studies examined the key influences on attitudes toward the environment and influences on practical concern 'for' the environment as well as interest 'in' the environment' for working in environmental education and commitment to environmental protection.

The investigative methods employed were fairly 'standard' for the time in which the studies of 'significance' were conducted. That time of research coincided with the transition in environmental education research from quantitative to qualitative approaches and the latter's propulsion of different, emergent genres of inquiry (Hart and Nolan 1999; Russell and Hart 2003). This emergence quested interpretively for 'commensurability' of research purposes, means and ends (e.g. Payne 2005b) within the 'post-critical' (Hart 2005). After much 'heat' had previously been cast critically on quantitative and 'applied' post-positivist research in the field focusing on a combination of behaviourism and cognitive development, searching questions about the development of the qualitative alternative were being posed about the field's substantive foci and need for renewed methodological innovation. At risk was an internal struggle to sustain the critical imperatives of environmental education, as introduced earlier, but here played out precisely within environmental education research and the need for greater commensurability. Lessons for early years education research are clear. Progress is being made in environmental education research (Stevenson et al. 2013) and more specifically (McKenzie et al. 2009; Lotz-Sisitka et al. 2013) that heighten interest in the question of agency and emergence of moral sensibilities and ethical as well as political 'growth'.

Second, exciting insights and needed evidence about environmental and ecological learning are now emerging in the 'harder' (human) sciences as phenomenological philosophy, particularly Merleau-Ponty's, is incorporated into 'interdisciplinary'

research programs in the cognitive, neuroscientific and linguistic sciences. There can be no doubt that this revolutionary development will profoundly influence the appraisal and redevelopment of current learning (and teaching) theory and practices in education. Already, this still anthropocentric but hybrid reconceptualization of interdisciplinary human science incorporates movement-oriented therapeutic treatments of a range of mental and intellectual 'health' problems. Characterizations of this revolution are contributing to major debates about the 'embodied mind' and/or 'mind embodied' or 'embodied meaning' and 'embodied cognition' in various environmentally 'embodied realisms' of society and culture (e.g. Lakoff and Johnson 1999; Dreyfus and Dreyfus 1999; Csordas 1999; Gallagher 2005; Petitot et al. 1999; Varela et al. 1991). However, to what extent this 'new' interdisciplinary science can deal with numerous 'contexts' and 'designs' of, for example, children, parenting and schooling remains an open question reiterating the critical orientation of this chapter to body~time~space relationalities and the eco/somaesthetics of experience. Even in these hard sciences, the negative effect of fast/instant 'screen culture' on the dromospherical 'plasticity' of children's brains and their development or growth cannot be simply wished away (e.g. Greenfield 2011), least of all in the slow environmental education envisaged here.

Similarly, and in cross/transdisciplinary hybridity, the philosophical notion of 'somaesthetics' (Sullivan 2001; Shusterman 2008; Johnson 2008) will help (re) shape 'play' and 'learning' theory and pedagogical research as well as provide additional affective insights into the significant and insignificant life experience and cognitive science literatures. Unavoidable now in educational theory and practice is the experiential, generative, affective and, inevitably, normative role in meaning-making that 'non'-representationally mirrors that 'body consciousness' of the otherwise preconceptual, pre-rational and pre-discursive or even cognitive unconscious. Enlisting Merleau-Ponty, again, James, Dewey, de Beauvoir and Alexander are historical key informants of the somaesthetic understandings of movement as 'body pedagogy' as a form of affectivity.

6.12 Ecophenomenology and Methodology

Many concepts emanating from an ecophenomenological orientation to interpretive inquiry in education are outlined above. A major limitation of this chapter is that a number of recent 'turns' in (high) theory have only been alluded to via the brief use of conceptual examples, metaphorical empiricism and figurational micronarrative. For example, high theory alerts us to questions about how human and non-human things exist ecologically as material actants within body~time~space relationalities. This type of less anthropocentric thought is weird, wild and irreal. It's a strange reframing notion of human-non-human natures, but not 'really' – until we remind ourselves that children love to play, discover, explore, imagine, mimic and memorize animate and inanimate things if given the 'unenclosed' chance of such spontaneously driven metaphysical freedom.

Researchers will no longer be able to hide from the anthropocentric problem of correlationalism in (non)-representing children's lived experience (by both researched and researcher, Payne 1998b/2014). This significant problem of (re)presenting what we think we know about children's 'reality' and 'experiences' of it stresses the rational limits of language, texts and discourses to adequately or accurately represent the complexity and ecology of human and social experience and its meanings, let alone 'speak for', or on behalf, of things of/in/as nature and its/their ecologies. Uncomfortable questions must, therefore, be raised alongside those of a conceptual type at this point about the importance of methodological innovation and experimentation in researching children and their experience. For example, what is children's voice (or thinking) and who/what is voicing it? Concern about this fundamental problem of representation is now well argued in critical perspectives of (high) theory (e.g. Shaviro 2014) but, for the purposes here of representing children's eco/somaesthetic experiences of time~space in varied material and symbolic contexts including the Anthrop/obscene, there is a compelling need for 'new' interpretive methodological demands and explanations (alongside new high theory) responsive to the empirical question of what can reasonably be represented in research. (Eco)phenomenological inquiry within post-critical framings of research rejects positivism and embraces evolving forms of creative interpretivism. Numerous mobilities and movements in/of experience as well as ecopoetic type sources and resources are possible, as identified throughout this chapter. At best, the enlivened 'representation' of corporeally rich and meaningful experience over time~space will only ever be partial and contingent; much of affective 'experience' and eco/somaesthetic 'nature', and our intercorporeal and intersubjective relations between beings and things, defy interpretive, quantitative and qualitative representation.

This practical, theoretical, methodological and empirical problem of what can adequately or appropriately be represented about children (or adults) as a claim on 'truth' and 'knowing it' inevitably flags major questions about credible 'communication' of deep social~cultural~ecological experience and subsequent claims on the 'multiple (un)realities' of human and non-human experiences. It highlights the value of the notion of yet another 'turn' in theory called the 'non-representation' (e.g. Thrift 2008) encapsulated in the correlational problem of 'accessing' the relationship between the affect of being and thinking (e.g. Sparrow 2014), the researcher and researched and the subject and object of inquiry, critique and evidence (or insight).

With these methodological (correlationism, anthropocentrism, representation and non-representation) limits now in fuller view, the problem of representation, voice and text is exacerbated by the ecophenomenological interest in bringing into 'being' and 'becoming' a somaesthetics~ethics~politics of body~time~space relationalities in and with or for nature(s). We do the best we empirically can to share and communicate our understandings of children's lives and experiences, reiterating the interpretive/hermeneutic rise of increasingly varied representational efforts in the humanities and social sciences that gather under the notion of ecopoiesis – a poetic bringing forth of things ecological. Pragmatically (and practically), in environmental education, worthy of consideration are David Jardine's (2000) textual representations of ecopedagogies and children's visual examples of eco/artography

reproduced in Cutter-Mackenzie et al. (2010). Elsewhere, for representational and methodological experimentation, my own narrative representations of body~time~space relationalities carefully and tactfully emphasize the affect of the sensorium and environmental perception and reception of animality 'in place'. The construction of that (con)text deliberately 'backgrounded' (critically) the debilitating consequences of anthropogenic climate destabilization while indicating the non-representational absences, and presences, as speculated about in experience, so as to 'open' up 'other' possibilities (Payne 2013).

These new theoretical turns demand methodological innovation and experimentation. The turns are extremely complex. Given the acceptance of the Anthropocene (e.g. Latour 2013; Morton 2012; Shaviro 2014)), specifically its material consequences, there is now great interest in thought that is non-anthropocentric and non-human and, therefore, creates a genuine puzzle for researchers of an empirical persuasion and need for evidence. All gather around the 'ontological turn' as an object of inquiry. These skeptics of the excesses of anthropocentric thought focus unevenly but critically upon the primacy of ontological sources of epistemology and its debates. Turns in theory abound, as do the enlivened concepts many of those authors play with – philosophical ecocentrism, new materialisms, speculative realism, post-phenomenology, things/matter/stuff theory, post and trans-human, corporeal~intercorporeal and animal, magical realisms, affect and non-representational theory. Many, particularly in the 'post-humanities', gravitate around the revitalized need in inquiry for a politicized 'aesthetics' of the human condition, mostly from a non-anthropocentric posture where the epistemologies of constructivism are to be emphasized far less in these 'new materialisms' and 'speculative realisms'. All invoke the parallel demand for new or different framings, symbols, languages, names, genres of inquiry and methodological innovation adequate to reconceptualizing the research problems and questions brought forth by various new concepts, metaphors, figurations and their transpositions (Braidotti 2006). They cannot be listed, described, contextualized and explained in detail.

As should now be apparent, the common denominator of these turns is the renewed interest in 'ontology', objects and things that exist materially and interact, as a type of agency, within the thing. Surely, this is a 'wild' proposition that will leave methodologists in education scratching their heads. The ontological turn is a departure from the conventional authority of epistemology which so much education discourse embraces in its constructivist stress in pedagogy, teaching and learning. While the politics of epistemology as methodology are well known in educational research, ontology and its politics (e.g. Johnson 2015) have largely escaped the scrutiny that 'being' a human, social and ecological being or thing and the associated becomings now demand. The inclusion in inquiry of the politics of ontology as 'messy' (Law 2004) as that politics might non-anthropocentrically and representationally be, and ecocentrically and non-representationally become, foregrounds a major substantive (e.g. conceptions of children and relations with nature) and methodological challenge (plausible revealing and limited representation) for educational, early childhood, environmental education researchers. The challenge is to accept, understand and make as clear as conceptually possible the

ontology~epistemology presuppositions we make in formulating inquiry and critique and framing of research. Declaring those propositions must also account for the generative and recursive nature of the preferred conceptual propositions. That is, having justified particular propositions in the framing and processes of inquiry; how do they 're-enter' the conduct of research and its consequences for the researched and other stakeholders?

In the post-critical wake of these new turns that, indeed, should build on earlier theory that straddles the ontology~epistemology tensions, it now behoves the researcher to make communicative sense to any audience of the 'relations' assumed or presumed in the triad of ontology~epistemology~methodology, according to the research problem and questions and their conceptions and contextualizations. As persistently as possible in this chapter, the more exacting derivative of that triad for empirical work is the empirically qualified retheorizing needed of body~time~space relations via, for example, the ecophenomenological vantage point so conspicuously promoted post-critically here. Of course, within each turn in theory, there are significant differences and serious debates and hence their politics of entanglements. Applied contexts are affected, like the conceptualization and construction, 'naming' and 'framing' of 'early childhood', 'development' and 'education' or 'inquiry' or 'research,' become major concerns in legitimizing and representing the triads of ontology~epistemology~methodology in the academic/intellectual world in which most readers of this performatively live and body~time~space relations in the post-phenomenological and socioecological everyday world. In the applied context of environmental education research, the notion of 'a critical ecological ontology' for inquiry which, in praxical terms of (eco)curriculum and (eco) pedagogy, highlights the practical triadic focus in education of the social ecology of 'eco'/somaesthetics~environmental ethics~ecopolitics'.

A second common problem highlighted by these new theoretical turns is, therefore, the desired coherence, or commensurability, in research of the 'best fit' of a problem's conceptions, contexts and theories and methodological invention, extension, deliberation development and representation, reiterating, again, the correspondence problem and non-representational concerns, particularly of affect and eco/somaesthetics of issues and experiences 'lived' (Fig. 6.2). These 'openings' for different other than literal/textual (and numerical) epistemologies of representing an underlying ontology have paved the way for different perspectives of, and approaches to, ecophenomenological inquiry and practice in, for example, ecopedagogies of artography, musicology and dramatology as they performatively emphasize the contribution of the sensorium in alternative meaning-making/somatic explorations of culture-nature relations and their embodiments. Not coincidentally, the field of aesthetics education and policy development is now moving 'beyond' art education into environmental and natural aesthetics (Smith 2004), while arts education promisingly includes, amongst many foci, child cultures, social and cultural issues and the body but, beyond a short interlude by David Abram, excludes ecological issues and environmental aesthetics (Bresler 2007).

Beyond the many sensitizing concepts for further 'reconceptualist' inquiry described by Simms, Chawla, Payne and others like Bachelard, there is a wide array

of affectively evocative insights into the lived experience of nature that once were named as 'nature writing'. That ecopoetic sensibility and genre is well known to North Americans, following Thoreau, Emerson, Muir, Leopold, Lopez, Berry and numerous others and, well before them, many European 'romantics' including Rousseau, the Wordsworths and Coleridge. More recently, in what has been dubbed the 'environmental humanities', marked by the rise of environmental criticism (Buell 2005) or ecocriticism (Garrard 2004) and ecopoetics, evocation is well illustrated in, for example, Griffiths (2004, 2006, 2013), more broadly in environmental discourse by David Abram (1996, 2013) and in education by David Jardine (2000). Children's aesthetics, subjectivities and wellbeing in education (Kennedy 2006a, b) and children's culture and ecocriticism (e.g. Dobrin and Kidd 2004) have only recently attracted interest in environmental education research (Cutter-Mackenzie et al. 2010). But it must be said of the environmental humanities and its influence in education that preferred methodologies exist within that movement that line-up mostly with versions of discourse and language/semiotic analyses. The persistence of the correlationism problem within the commensurability problem highlights, yet again, the politics of ontology~epistemological tensions.

At the more difficult methodological-empirical demand of phenomenological research, Max van Manen's (1990) researching lived experience for an action-sensitive pedagogy is, perhaps, the most significant contribution to hermeneutic phenomenology method and, potentially, the requirement for heightened sensitivity to children's realities and their lifeworlds. Hence, his pedagogical emphasis on 'tact', where the researcher's required tactfulness, incorporates reflection, thoughtfulness, seeing, showing, ineffability and competence as components of the creation of action-sensitive 'knowledge'. Central to van Manen's methodology of lived science, one of the very few authors to lay out in detail the relationship between philosophy (phenomenological, in this instance) and interpretive methodology of human science, are four 'existentials'.[6] Elsewhere in environmental education research, Kaufman et al.'s (2001) use of the 'memory work' methodology in revealing four women's 'experience' of nature deeply extends into their collective corporeality the notions of (in)significance and memory and, more emphatically, locates the researcher (as also the researched) in the ontological~epistemological (and methodological) locus and focus of inquiry outlined here. Marilyn Doerr (2004) uses a phenomenological environmental autobiography about teaching and learning ecology to highlight many of the subtleties of ecopedagogy.

Some caveats. The emphasis here on an ecophenomenology of children's experience of nature's body~time~space scapes necessitates four interrelated qualifications needed in research (and its representation) for the ecopedagogical vantage

---

[6] These existentials act as guides for reflection in the research (and pedagogical) process. They are lived space (spatiality), lived body (corporeality), lived time (temporality) and lived human relation (relationality or communality). These are well represented in this chapter. Van Manen is adamant that children 'probably' experience these existentials in a different modality than adults. Spatiality is 'felt'; corporeality understands we are 'always' bodily in the world; temporality is subjectively felt rather than objectively; and relationality is the lived relations we maintain with others in the 'interpersonal space that we share with them'.

point anticipated in an alternative early intervention environmental education. The four propositions aim to minimize the potential for van Manen's existentials to be interpreted solely or primarily and singularly or reductively in an andro/anthropocentric and intersubjective manner in pedagogy, curriculum, research and policy deliberation and development. The qualifications stress, first, an 'ecocentric' (non-anthropocentric) disposition in education and its research; second, the intercorporeality of (children's) bodies and their time/scapes in material relations with other bodies, things, matter and stuff, both animate and inanimate; third, the perceptual/sensory importance of the 'affect' of the sensorium and its environmental resources and ecological antecedents in the felt of both the researcher and the researched. Hence, for example, the rise of sensuous ethnography (Pink 2009) highlights movement and other 'mobility' methods like walking (in nature). Such experiences (or activities) are heuristic to methodologies that 'live', for example, children's experiences in ways that pedagogically enhance and extend current methods used with children in environmental education research (Barratt-Hacking et al. 2013; Blenkinsop and Piersol 2013). Fourth, despite the above recommendations, the correlationism problem of what can be represented and what remains 'non-representational' persists, notwithstanding how that problem might be reconfigured by the way in which research is conceptualized, contextualized and then represented and legitimized. Walking theory/philosophy (e.g. Gros 2014)) as environmental practice (Davidson 1980/2012) and methodologies (e.g. Moles 2008) will 'post flaneur' like grapple with these issues, as will experimentation and innovation in new 'play' and 'childhood' methodologies anticipated here.

In different ways that cannot be elaborated here (but see Payne 2013 that combines first person singular description and theoretical exegesis), this reconceptualizing and, subsequently, reframing of an ecophenomenological hermeneutic in theory and research methodology addresses a number of key ideas emerging in the range of 'turns' indicated above. Working with these theoretical issues, concepts and methodological and pedagogical issues in the various ecological contexts of children's lives in different time~space settings remains a formidable and exciting challenge.

Figure 6.2 provides another mapping of the global~local~body~space~time 'relationality' challenge for critical inquiry and methodological deliberation in a critical ecophenomenology.

6.13 Ends-in-View: Post-critical Ecophenomenologies of Childhood, Theoretical and Research Directions

This chapter critically emphasizes the fragilities, frictions, vulnerabilities and collisions between children's sensuously lived bodies in their affective being, moving, memorying and becoming as constituted in and by nature's environments and the constructed realities of social, cultural and global times and their natures, primordiality and postmodernity, slow and fast and ontology and epistemology.

In emphasizing the former of these broad couplings, various tensions and dissonances are highlighted and abound for a possible normative and ethical reconciliation of O➔• in the ecologies of internal, social and external natures. My aim is to ferment a wild contribution of education to a 'sustainable' intergenerational eco/somaesthetic~environmental ethic~ecopolitic. Inquiry~critique~theory and empirical research with methodological experimentation as reflexivity are needed.

6.14 The Nick of Time

The timeliness of this needed ecophenomenological disruption of our current postmodern amnesia and somnambulism is captured neatly in Elizabeth Grosz's (2004) *The Nick of Time*. Grosz declared, '…the precarious, accidental, contingent, expedient, striving, dynamic status of life in a messy, complicated, resistant, brute world of materiality, a world regulated by the exigencies, the forces, of space and time. We have forgotten the nature, the ontology, of the body, the conditions under which bodies are enculturated, psychologized, given identity, historical location, and agency. We have forgotten where we come from…' (p. 2).

6.15 The Aesthetics of Childhood

And following Grosz's (2004) rationale for memory work and Honore's (2004) plea for a new philosophy of childhood, Pauline von Bonsdorff (2009) extends both with her 'non-adultcentric' proposition of 'The aesthetics of childhood is not just about children, but about the human situation. We were all children once, and childhood is on the whole a permanent structure of individual lives, of culture and society' (p. 74).

6.16 Social Control

And following Griffith's (2013, p. ix) probing of the 'riddle' of an 'unnatural' childhood and denial of 'metaphysical freedom' via the 'enclosures' of schooling leads us directly to the always prescient John Dewey (1938) who, in *Experience and Education*, challenges the potential for a 'timely' intersecting of ecophenomenology and pedagogy in children's lives with his reconstructive 'growth', 'I have said that educational plans and projects, seeing education in terms of life-experience, are thereby committed to framing and adopting an intelligent theory or, if you please, philosophy of experience. Otherwise they are at the mercy of every intellectual breeze that happens to blow' (p.31).

A critical ecophenomenology of children's embodied becoming in time~space provides at least one radical (re)source for developing an intelligent theory of children's lived experience in education, and its research, and to the challenges now harshly presenced in experience for children's 'sustainable' development in, and against, the dromospherical Anthrop/obscene, amongst numerous issues children now confront.

Any strategic response to this global presence in early years education requires further conceptual clarification, theoretical development, methodological innovation, experimentation or extension and empirical elaboration in inventing an experiential environmental education whose slow ecopedagogical resistance to various intellectual and epistemologically privileging breezes is meaningful for children within a broader ethical formulation of children's survival. The need for researcher reflexivity in revealing what von Bonsdorff realizes is as compelling as what Honore demands. For these critical purposes, an array of sensitizing concepts appropriate to pedagogical, curriculum and research renewal have been outlined. Education and schooling can be part of the problem; an experiential (environmental) education for socioecological sustainability can be part of a solution. Time as we mostly live it problematically in ➔• is, indeed, a social construction par excellence, as is its enclosing of childhood and as is its education. Those dominant categories, amongst many such as the home, the family, can, therefore, be deconstructed, existentially, (eco)phenomenologically and textually/discursively (or poststructurally). The deconstruction is only a step in the Deweyan-like reconstructive problem and 'end-in-view' sensitive to the precariousness of 'childhood' with/in that increasingly problematic ecological and social condition filtered materially and symbolically through the thing of a cultural artefact called education.

At the same time in early childhood education studies, we might or must ask with what degree of confidence can we state empirically and/or theoretically, as well as methodologically, that we have sufficient grasp on how children (subjectively) experience time~space in the 'places' they 'inhabit' and 'voice'. Moreover, where does an 'early intervention' environmental education exist in the curriculum for (young) children? Rousseau, Froebel, Pestalozzi, Steiner, Malaguzzi and others were probably on to something important in their respective but much slower times, spaces and places. Now, in the cult of speed, there is an intergenerational urgency in the formative 'foundations' of early years education that requires revisiting for 'adulthood' as well, if there is some truth in von Bonsdorff's observation. Different vantage points for inquiry, critique, theory and research beyond the usual suspects are needed for a revitalized and reanimated renewal of education.

The theoretical and methodological developments of an ecophenomenology of and for childhood beckons. On the weight of the critical insights and sporadic evidence described above about phenomenology's effect on educational and methodological development, the proposition is emergent only at this stage of educational theory and practice about the pedagogically precarious state in which children are 'positioned' in and by conventional 'thought'. A critical ecophenomenology of childhood provides a 'disciplined' inter/transdisciplinary response and counter to those hegemonic epistemological and empirical breezes Dewey alerts us to. Shaviro

(2014) speaks the unspeakable for educators when he concluded, with others, that epistemology requires deprivileging and that ontologically the reality of an ecology of things cannot be subordinated consistently to the never-ending quest for refining ways of knowing or 'how we know' because that ecology of human and non-human beings is the animated actuality and vital source of what can or might be known, not the reverse. But Shaviro might equally be challenged by the 'practical' and pragmatic educator and researcher as to what things, their ecologies and 'environmental designs' might then be pedagogically privileged in the curriculum designs of early years non-anthropocentric education.

Like others speculatively advocating for a non-anthropocentric materialist 'worldview', Shaviro concludes that aesthetics must become the 'first philosophy'. This chapter, theoretically and empirically, pushes his 'aesthetics' more ecocentrically and assertively into the need in education and its research for an eco/somaesthetics~environmental ethics~ecopolitics of body~time~space relationalities as an applied or practically oriented reinterpretation of the underlying tension of ontology~epistemology~methodological deliberation.

In broad summary (Figs. 6.1 and 6.2), given the massive variety of particular local and global contexts in which children experience and live in numerous environments, the 'mapping' of the 'sub/terrain' and 'contours' of reflexive post-critical inquiries requiring navigation in that critical ecophenomenology for future theoretical and research, inclusive of body-time-space relationalities conflicted by O➔•, demand deliberation about, in summary of certain keys:

(i) The politics of the triad of ontology-epistemology-methodology. Translated, following Toadvine's and Trigg's respective questioning of experience and place 'natures' as a possible guide for inquiry, theorists as well as researchers and practitioners must reflexively clarify the assumptions and/or presuppositions they make about ontology and epistemology as that non-dualist ontology-epistemology framing of research is conceptualized, contextualized and represented. Limits, particularly those presented by the problems of correlationism and nonrepresentation, must be acknowledged and justified. For the purposes here, concepts, contexts and representations employed by the researcher with and about the researched will try to accommodate many paradoxes, all of which are inescapably 'political' and ethical. First and foremost, a key substantive one is children's (and their parents, teachers and researchers) increasingly disconnected sense of 'self' from 'nature', its environments and things, In an allegedly more connected fast techno/screen world. Methodologically, what do researcher/reflective practitioners assume substantively about the ontology-epistemology of a school, child care centre, classroom and playground as these mediums of meaning-making and modes of pedagogy inform 'development', identity formations, transitions and, problematically, emergent symbolic sense of *becoming* in the dromospherical Anthropocene?

(ii) The triad of a normatively predisposed eco/somaesthetics-environmental ethics-ecopolitics whose 'social ecology' overlays the deeper and richer

ontological-epistemological basis of an adequate theorizing of environmentally experiential education relevant to the undertheorized question of children's everyday 'agency' (Duhn 2014) and ecological actancy of the things they experience that matter (Bennett 2010). Moreover, that crucially important relationship of agency and education might also be reconceptualized in a broader post-critical and non-anthropocentric manner. Many 'childhood' agencies associated with the new political ecology of things and their wild and vital materiality affectively connect human and nonhuman forces and animate and inanimate things (Attfield 2000; Bennett 2010). For example, Karen Barad's (2007) notion of 'agential realism' highlights the 'intra-active' nature of things/matter and their 'entanglements' in performatively creating 'diffracted' social and ecological relations. Shaviro (2014), following Whitehead's process philosophy, accentuates the intrinsic *creativity* of all things within their interactions and relations of always becoming some*thing*. The normativities expressed by these agential relations are, inevitably, political and ethical, as well as being driven aesthetically by the unfortunate 'invisibility' in contemporary discourse of affectivity (Bennett 2010) and, for example, its spatialities in time (Thrift 2008). How these new 'post' understandings of the everyday practices of eco/somaestheticized agency and actancy of things, somethings and nothings are constructed, produced and reconstituted in, for example, theoretical and methodological approaches to the critical development of children's education is an exciting and formidable challenge. Given the precise focus of this chapter, time(-space) is a politically material thing and not another abstraction, for children as well as others. It is a fast object requiring critique as it is invisibly lived for better or worse (e.g. Birth 2012; Boscagli 2014) as part of the body-time-space condition lived relationally. Time is eco/somaesthetically-ethico-politically charged, as Grosz reminds our forgetting, in various environments and their material things/stuff, settings, locales, milieu and places. 'Slow' is, therefore, a practical and pragmatic but partial response to the 'dechildrening' of children.

(iii) 'Politics' (e.g. Johnson 2015), therefore, is the educational 'core' of deliberation about ontology-epistemology-methodology, as that triadic politic shapes, and is shaped by the 'applied' triad of eco/somaesthetics-ethics-politics in theory and research development in an experiential environmental education of and for children. Typically, in education, the epistemologies of pedagogy and 'learning' understandably preoccupy practitioner educators, while education researchers emphasize methodologies most suited to epistemological concerns about 'best practice' pedagogies and children's cognitive development. Ontological concerns about children's *being* and considerations about their *becoming* are all too often not included. Eco/somaesthetics, ethics and politics of children's lives are often relegated to the theoretically and empirically 'too hard' (or hot) basket. If so, the lives and 'learning' of children are vulnerable to ongoing misrepresentation (and questionable legitimization) and call into question the veracity, plausibility, value and efficacy of many well-meaning educational interventions and the research upon which they are based. But this

assumes a critical, intergenerational concern for sustainability of lives, things and planet. Again, the theorist, researcher and practitioner will need to carefully identify and examine the 'entry point' assumptions and presuppositions about ontology-epistemology they make axiologically about children and their positioning and (non)representation in theory, practice and research. Consideration must be given to the meanings of aesthetics, ethics and politics as they in turn are a key ontological-epistemological basis of meaning generation and making in people's lives. A post-critical ecophenomenology provides a distinctive 'access' point for ontologically focused inquiry and critique into the lived and affectively felt environmental *and* social designs of experience. The 'environmental design' of education practices entailed by the turn to a *non-anthropocentric* or *ecocentric* childlike conception of experience calls for a radical reappraisal of the alleged 'learning' conditions and structures over body-time-space in which children are positioned in curriculum and emplaced by pedagogy (e.g. Payne 2015). Ecophenomenology is an 'other' opening into these questions about what often remains invisible in theory building and research development, notwithstanding the critique that its fullest 'access' into those 'others' suffers from limits indicated much earlier in this chapter (e.g. Sparrow 2014).

(iv) The advent of new theory/turns and the exciting but always vexed question of how theory and theory of practice deductively invokes or inductively invites not only the (re)conceptualization and (re)framing of research, curriculum and pedagogical problems and questions but the interpretive, representational and, at times-spaces, (non-)correlational quest for commensurability with methodological experimentation, innovation, deliberation, debate and legitimation in educational research (e.g. Pink 2009 cf Jackson and Mazzei 2012, footnote 5). The turns in theory indicated above are different responses, overt or covert, to the omnipresent 'fragility of things' and heightened importance now of democratic 'role experimentation' (Connolly 2013) in a 'mode of existence' increasingly laid bare for repair in the Anthropocene (Latour 2013). Early years environmental education is one such experiment in rectifying that troubled mode.

6.17 A Deep Riddle: A Difficult Riddle

The not so final words of this needed returning to, and reclaiming of, an ecophenomenology of children's lives in the dromospherical Anthropocene go to some powerful imagery extracted from Jay Griffiths (2013, p. ix) *Kith: The Riddle of the Childscape.*

Nature is at the core of the riddle: I began looking for the nature of childhood…
Childhood has not only lost its country but the word for it too;
A country called childhood.

How has childhood become so unnatural?...
Born to burrow and nest in nature, children are now exiled from it.
They are enclosed indoors…unthinkable a generation ago.
Children's lives have been subject to intolerable enclosure for the profit of others.
Who owns the child, anyway?
It is in the very nature of the child to want to learn, yet society has historically contrived a school system that…too easily ignores the very education which children crave.

Acknowledgements In preparing this chapter, thanks are expressed to Jane Bennett, Louise Chawla, Iris Duhn, Kieran Egan, Marilyn Fleer, Ingrid Stefanovic and Max van Manen for helping me refine the focus of this chapter, for which I take full responsibility for the content. Chapter 7
(Co)-Researching with Children

Alma Fleet and Deborah Harcourt

Contributors: Anette Boye Koch, Sue Gascoyne, Jóhanna Einarsdóttir, Colette Gray, Penny Lawrence, Jane Merewether, Suallyn Mitchelmore, Jane Murray, Andi Salamon

Abstract This chapter offers a collaborative dialogue between academics and practitioners who have given consideration to the literature, the challenges and illustrations from practice in order to examine the notion of child voice in research. It illuminates the researcher-child relationship with an accent on hearing children's standpoints through the lens of interested and invested adults. These considerations are intended as further provocations to the growing research base that is attentive to foregrounding children's perspectives. While the chapter is not co-authored by children, it has been constructed so as to respect children's voices and to task the research community to further deliberate the complexity of issues involved when positioning research practice as 'researching with children'. Organised in several sections, the chapter explores ethical issues of assent and/or consent from children, examines issues in relation to children in a range of age cohorts and proposes a number of ways forward for this particular conversation using practice-based strategies such as pedagogical documentation and clarification of language use. These broad concepts are scrutinised through a conversation between examples of cooperation, collaboration and co-research, in an attempt to clarify the ongoing perplexity in this research terrain.

Keywords Co-researching with children • Children's voice • Ethical consent • Children's rights • Pedagogical documentation • Reconceptualising research

---

This chapter was invited through the vehicle of the Children's Perspectives Special Interest Group of the European Early Childhood Education Research Association; support from this group and its members is gratefully acknowledged. Acknowledgement is also given to all children, families, educators and researchers engaged in these important conversations.

7.1 Introduction (Alma Fleet, Suallyn Mitchelmore, Deborah Harcourt)

With a focus on listening to children's voices in research in order to better investigate their lived experience of early childhood, the past 20 years has seen a reconceptualisation of early childhood research (Einarsdóttir 2014). The consideration of researching with or co-researching alongside children is not only paradigmatic but at heart philosophical. It is a topic that draws heavily on human rights, particularly the United Nations Convention on the Rights of the Child (UNCRC) (1989), as well as from a perspective which expects all stakeholders in a research context to be involved in decision-making. In addition, when policy is shaped by notions of projected productivity, a political and economic discourse runs through this topic, with both parents and children being positioned as consumers of early childhood education (Einarsdóttir 2014). As Holt (2004) and Smith and Taylor (2000) note, there is a social viewpoint that hopes to empower the marginalised, as children 'have been the invisible and voiceless objects of concern, and not understood as competent, autonomous persons who have a point of view' (p. ix). Similarly, Pascal and Bertram noted that in policy and research contexts, 'children's continued lack of voice and power persists' (Pascal and Bertram 2009, p. 253). Nevertheless, Thomson (2007) asks, 'Is doing research with children different from doing research with adults?' (p. 207).

Consideration of this discourse, however, is not furthered by pursuing polarities. The debate on research *with* children rather than research *on* children has progressed in the literature from a justification of including children's perspectives to one that carefully considers how this can be undertaken with ethical and methodological rigour (Clark 2011; Harcourt and Einarsdóttir 2011). This chapter therefore offers a constructive engagement with a team of researchers to share literature, challenges and illustrations of practice to examine the evolving state of the construct in the sector. It will highlight 'connections and reciprocal relationships' (Einarsdóttir 2014, p. 320), emphasising hearing children's standpoints about matters that concern them and how the adults involved engage and respond to these ideas and opinions. These considerations build on growing interest in the importance of foregrounding children's perspectives, as is represented through reviews such as that reported by Powell (2011) for Childwatch International and Coleyshaw et al.'s (2010) contribution.

The inclusion of young children's voices within data collection and analysis is to give a rightful place to the richness that children's perspectives can contribute to our understandings of the world to:

> Surprise us, make us think, ask critical questions, appreciate the peculiarity of what we have taken for granted, illuminate implicit understandings and values, make us stutter, open us to new possibilities. (Moss and Petrie, 2002 in Carr et al. 2005 p. 130)

Research committed to working collaboratively with and alongside young children, honouring the rights of the child to have a voice and informed opinion in

matters that affect their lives, positions childhood education 'first and foremost as a place of ethical practice' (Dahlberg and Moss, in Lenz Taguchi 2010, p. xvii). Dahlberg and Moss (2005) reveal that a lens of 'ethical practice' is embedded with the belief that rather than positioning knowledge as objective or fixed, knowledge is responsive to new possibilities and the potentialities of diverse ways of understanding that welcome multiple perspectives. It is this disposition of the researcher, to value plurality and to be open to the potentiality of uncertainty and the unknown, which is the invisible suspension bridge that supports the possibility of 'thick data', full of the subjectivities of young children's perspectives and understandings.

7.1.1 Background Issues in Researching with Children (and Educators)

Researching with children is underpinned by the premise that adult-child relationships are reciprocal; children are not seen as incomplete adults but rather equal participants in the co-construction of data collection (and analysis and research findings). To omit children's perspectives from the research design would give an incomplete and incongruent picture. As Kjørholt et al. (2005) offer:

> Children are co-constructors of their childhoods and are active participants in the constructions of their identities in everyday lives and in establishing relationships with adults and other children. They are caring subjects who contribute emotionally to their own and others' quality of life (p. 184).

It is essential that decisions related to the role of young children in research are grounded in ethical guidelines that 'call on researchers to avoid undue intrusion, and using methods which are non-confrontational and participatory, and which encourage children to interpret their own data...' (Morrow and Richards 1996, p. 100). Similarly, decisions related to the place of the researcher within the research context should be evaluated based on their capacity to be inclusive of children's subjectivities and agency. For example, the adoption of the role of participant-observer, with an emphasis on participation and therefore the researcher's participation within the context of the children's play space, is underpinned by 'the children's trust and a willingness to engage with me and involve me in their social worlds' (Warming 2005, p. 58). When considering a collaborative research design with young children, particularly one that seeks to uphold a child's ethical right to participate in decisions and policy that affect their lives, nonintrusive, noninvasive and nonconfrontational methods should be evaluated and employed.

While they note (p. 200) that 'The idea that infants express themselves nonverbally through their bodies and behavior is unproblematic', Elwick et al. (2014a) claim that 'the participatory research agenda with infants' is contested:

> Knowing anything for certain about infants, including whether such things as 'infants' perspectives' exist, is profoundly difficult if not impossible. We conclude that awareness of the

> inherent uncertainties in studying infants reconstructs such research as a site for ethical rather than epistemological practice. (p. 198)

There is growing recognition of children's ethical right to participate in research (Alderson 2008; Eide and Winger 2005; Moss et al. 2005; Morrow and Richards 1996; Rhedding-Jones et al. 2008; Woodhead 2008; Smith 2011; Rinaldi 2005; Harcourt and Conroy 2011). Article 12 of the UNCRC (United Nations 1989) states that children's views are to be respected and that they have the right to be consulted; essentially this involves respecting children's competencies and recognising that young children's experiences of the world are unique and valid (Morrow and Richards 1996; Woodhead 2008; Alderson 2008; Smith 2011).

Ethical considerations for the inclusion of children in the research design are underpinned by the same premise as researching with adults – the asymmetry in power relations between the researcher and the participants (Bae 2005, 2010; Rhedding-Jones et al. 2008). It is therefore important that the methodology empowers and respects children taking part by ensuring that they are not simply passive objects on the receiving end of research processes imposed upon them. Bae (2005) cites this responsibility of addressing the inevitable inequality with the more powerful person in the relationship – the adult researcher – who needs to find ways to invite participants into dialogue about 'what is going on, and how to interpret what comes out' (p. 286). This is particularly pertinent when an objective of the research design is collaboration and cooperation.

Therefore, trust has a significant place in the ethical considerations of research with children; this is a process that is developed over time through the researcher being 'understanding, open and confirming when doing research in preschool contexts' (Bae 2005 p. 284). Listening with all the senses is the key to building trusting relationships (Moss et al. 2005; Rinaldi 2005). This means listening as mental attitude rather than as a skill – '*Listening* as sensitivity to the patterns that connect'; '*Listening* as welcoming and being open to difference'; '*Listening* as an active verb that involves interpretation, giving meaning to the message and value to those who offer it' (Rinaldi 2005, p. 20).

In a research design that strives for researcher-child collaboration, reflective analysis of the changing and diverse nature of mutual recognition throughout the phases of the project is essential (Bae 2005). Ensuring that research analysis is presented in a way that empowers children to contest and respond to representations is an important strategy towards ensuring that children do not feel 'not just textualised but also contextualised' or defamiliarised from their experiences and insights (Tobin and Davidson 1990, p. 278).

The chapter has not been designed with or co-written by children. It is an adult academic task which has been crafted to respect children's voices and to challenge the research community to consider complex issues involved in the notion of researching *with* children. To that end, the chapter is organised in several sections, including explorations of ethical issues of assent and/or consent from children who are the subjects of and/or participants in research with adults, consideration of issues in relation to children in broad age brackets (recognising blurred boundaries

between ages, stages and individual characteristics) and proposals for ways forward in the conversation, through the vehicles of pedagogical documentation and clarification of language use. Concepts are also investigated through examples of cooperation, collaboration and co-research, perhaps under the umbrella of respect for children and between adults and child research participants, in an attempt to clarify confusion and casual use of language in this terrain.

7.1.2 Researcher Reflection Valuing Children's Perspectives: (Jane Merewether)

Smith (2011) points out that the world abounds with research on children, but the body of research with children that has found ways to make children's voices visible is limited, although this has been changing over the last two decades. As has been stated above, a significant catalyst is the *United Nations Convention on the Rights of the Child* (United Nations 1989), which recognises children as active citizens with rights to participate in matters affecting them, including research. A second contributor to changing perspectives is the field of Childhood Studies (James and James 2008; Kehily 2009; Qvortrup et al. 2009), which focuses on children's rights, voices and participation. By conceptualising children as social actors and capable holders of opinions and ideas, Childhood Studies presents the possibility for researchers to work together with children as co-constructors of research data. A third major contributor to strengths-based views of young children is the educational project of the city of Reggio Emilia in Italy which, through its use of multiple forms of listening and documentation, has graphically made visible the capabilities of young children (Edwards et al. 2012b; Giudici et al. 2001; Rinaldi 2006). [Excerpt from: Merewether 2015]

7.2 Beginning the Research Conversation with Children: Informed Consent (Deborah Harcourt)

As we have seen in the chapter introduction, the international research community has been investigating ways in which young children can be positioned as active and authentic participants in research processes. Clark (2005a, b, 2010) has identified clearly the significance of engaging with children's ideas and opinions in order to further inform matters that affect children. However, in order to genuinely reflect the significance of children's role in research, we must give careful consideration to their informed consent as a crucial part of research design. The term *consent*, and not *assent*, has been used deliberately here, to indicate the intention to work in genuine partnership with children just as a researcher would with an adult. While

this may be considered semantic, there is currently no legal imperative to refer to the agreement to participate as *assent* when involving children.

Thoughtful deliberations must be given to trust, equity and security whenever a researcher is inviting a participant to share the lived experience of a particular phenomenon. Grover (2004) noted the importance of establishing trusting relationships in research with children, while Harcourt and Conroy (2005, 2011) continue to warn that the time to develop these relationships cannot be circumvented or foreshortened. Any participant in a research project needs time to reflect and clarify roles and responsibilities to ensure that there is shared understanding of what is involved. For children it becomes critical that they understand that what they are thinking and what they have to say make a worthy contribution to the project.

Harcourt and Conroy (2011) suggest that familiar surroundings such as homes and prior to school may provide the most conducive circumstances in which to initially invite children to engage in research. This notion is supported by the earlier work of Valentine (1999) and Edwards and Aldred (2000) who agree that thoughtful consideration needs to be given to contextual and relational milieus. Perhaps these everyday places where children live their childhoods may well prove the most optimal environments.

In addition, the manner in which children are invited to participate will be dependent on their evolving capacity to engage with the research topic and to make meaning of the research partnership that is being proposed. Positioning the research topic and roles within their everyday experiences assists the children to make connections with their own understandings of the world around them. In this way, intersubjectivity or shared meaning (Rogoff 1990) will assist both children and adult researchers to reach common ground thereby achieving an agreed foundation on which to investigate the focus topic.

The experience of the adult researcher in providing information to children could, at this point, prove vital. Those experienced in working with groups of children, such as teaching professionals, may have an advantage over those who only work with individual children. In our experience, children prefer to be informed in small groups, as they are able to help each other in establishing and negotiating shared meanings. For example, in two studies examining how children measure the quality of their early childhood education experiences, the children had to hypothesise what the word 'quality' meant. In one study (Harcourt 2012b), they decided it meant 'good' as the group consensus in that contextual environment offered the children reference points for a shared construction of that term. Yet in the second study (Harcourt and Mazzoni 2012), the children decided quality meant 'important' as that contextual and relational environment offered a different perspective in framing the notion of quality. Therefore, the ability of the adult researcher to support these group conversations, connections to the real world and subsequent constructions (and sometimes reconstructions!) of meaning is critical to attaining intersubjectivity.

By positioning children as active participants in the research process, the manner in which the invitation is proposed can mean the difference between genuine voluntary participation and the provision of an answer that the child suspects the adult is

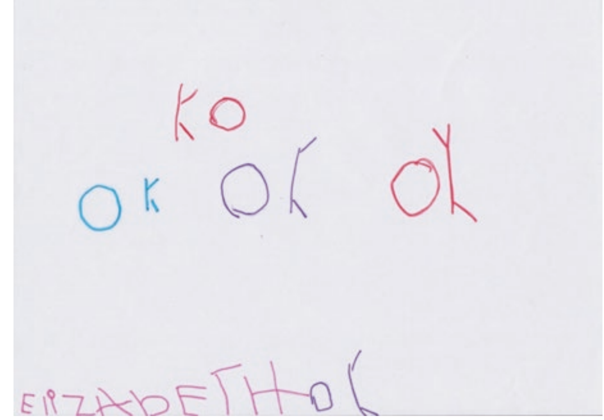

Fig. 7.1 Elizabeth: The OK paper tells you that it is ok for us to work together. If we don't do the ok, then it is not ok for you to talk to us

seeking. Providing the invitation to participate as a foregone conclusion (*e.g. I have come to get your agreement*) disempowers children's capacity to agree/disagree. It is critical that children are offered a full explanation of the project, which should be briefly revisited at each research-focussed meeting to not only support children's memories but also to assure that they can opt in and/or out at any point.

Supporting children in understanding the documentation of consent follows a similar process to that of informing, that is, assisting children to make connections with their known competences as communicators. In the case of very young children, this may well be their willingness to have their photograph taken using expressive cues. With children over three, written consent can be used. For example, in a study undertaken with children investigating rights (Harcourt 2012a), 3- and 4-year-old children used the written word 'OK' to document consent at the beginning of each research conversation. As can be seen in Fig. 7.1, children were given opportunity to revisit an affirmation of their agreement to participate in individual conversations, following the adult researcher's prompting of what had happened before and what was happening next.

This focus on informed consent with young children has been offered to help researchers give purposeful deliberation to the notion of research with children. In this way, there is a greater likelihood that shared understandings of the topic, roles and responsibilities will have clarity and bring legitimacy to an authentic and respectful research relationship between adults and children.

7.3 In What Sense Can Babies Be Research Collaborators? (Sue Gascoyne)

The argument about the nature of infants' participation in research (Dalli and Stephenson 2010; Farrell 2005; Sumsion and Goodfellow 2012; Thomson 2008) rests in part on adults recognising and being advocates of babies' capabilities

(Gascoyne 2012; Edwards et al. 2012a; Salamon 2015). Thomas (2001, cited in Waller and Davis 2014, p. 35) coined the term 'presumption of competence' recognising that if we believe in children's competence, rather than incompetence, they 'often turn out to be more capable and sophisticated than they are given credit for' (Waller and Davis 2014: p. 35). Alderson (2008) and Alderson et al. (2005) argue that despite an infant's 'essential vulnerable dependence' (Alderson and Hawthorne 2005, p. 33), even babies born prematurely are 'not only actors but agents who alter relationships, decisions and the working of social assumptions or constraints' (p. 47).

With inherently unequal power relations and limited language cues, researchers need an 'ethical radar' (Skånfors 2009, p. 1) or awareness of infants' physical expressions, to avoid missing otherwise potentially unnoticed signals. It is in this respect that *mind-mindedness* may have a role to play. Referring to an adult's 'ability accurately to "read" [an] infant's' intentions, thoughts and wishes (Meins et al. 2006, p. 182) can contribute to the ethical radar of researchers working with infants. Often referring to a parent's understanding of their own child's behaviour, mind-mindedness points to the benefits of familiarity when working with babies or even of researchers working with their own children in order to be sensitive to the child's cues.

The concept of 'process assent' is also relevant as this recognises the importance of researchers in ensuring that they are always mindful of children's responses within the research context so they may respond appropriately Dockett 2009). This is particularly helpful when considering infants, as adhering to the principle of process assent, gives children 'multiple opportunities to either confirm or withdraw their participation in the research' (Dalli and Stephenson in Loveridge 2010, p. 15). Dockett (2009) continues to remind the researcher of the importance of developing a relationship with the child prior to the research in order for a certain level of trust to develop.

Although infants' involvement in research was not the focus of Gascoyne's (2012) observations of babies playing with Treasure Baskets (collections of sensory-rich objects), babies' mastery in being able to express a desire for an activity to end appears to lend evidence to this 'presumption of competence'. Infants are primarily sensory beings, so the close observation of their sensory experiences seems to fit with gauging embodied responses in the research processes. Pink et al. (Pink et al. 2013) similarly recognise the value of sensorial information in their work on sensory ethnography, primarily with adults or families with older children. Gascoyne's observations of babies exploring and playing with objects revealed a range of strategies – physical actions, body language or vocalisation – for ceasing the session or expressing non-involvement. From turning their whole body away from the Treasure Basket to crying or crawling away from the resource/researcher, babies were able to express their withdrawal from participation. As these photographs demonstrate – if babies can convey delight, surprise and excitement or conversely dislike of objects through their facial expressions, body language and joint attention, then surely the same is also potentially true of an infant's relationship to the researcher/activity.

Photos: Gascoyne July 2006 – 6-month-old baby with parental consent

Even young babies not yet physically able to move away unaided have been able to clearly indicate their desire for the play or observation session to end, like this 5-month-old, who shifted his body to the side, triggering a response from the researcher and termination of the session.

Photo: Gascoyne June 2006 – same 5-month-old baby with parental consent

Although adult driven and therefore open to the same difficulties of interpretation that befalls all infant research, Leuven's (1994) involvement and well-being scales raise the question of the extent and quality of the youngest children's participation in research. While clearly not definitive, Laevers' (1994) strategies do provide a potential indicator of an infant's process assent; casting a spotlight on body language (as a potential indicator of well-being) and engagement can help develop and fine-tune practitioners' and researchers' 'ethical radar'. With high levels of

Table 7.1 An example of a phased approach

	Phase	Participants	Activity
1.	Phase one	Centre directors	Making contact and establishing professional relationships
	October through April (i.e. the end of the year prior to the study and the beginning of the new school year)	Teachers	
		Parents	Agreement to conduct research (centre directors)
		Children	Familiarisation (parents, teachers and physical environment)
		Researcher	Informed consent processes (parents)
			Familiarisation (children and programme delivery)
			Informed consent processes (children)
2.	Phase two	Whole group discussions with all children and researcher in one (sometimes two) half-day encounter each week in each centre	Establishing shared understandings about research
	April through July		What does quality mean?
			Experimenting with representational tools/symbolic languages
			Child-generated questions and answers
3.	Phase three	Self-selected children and the researcher in small group sessions half-day encounters each week in each centre	Recorded conversations and dialogues
	July through September		Child representations using cameras, drawings and written texts
			Concurrent data collection and analysis (with children)
4.	Phase four	Predominantly the conversational leaders (e.g. Renee, Beatrix, Celine and Alan) and the researcher in individual or paired interactions each week	Generation of texts and drawings
	September through December		Recorded conversations that were responding to emerging themes
			Analysis both with the children's involvement and without
			Reporting/dissemination mechanisms
			Concluding the study

Harcourt (2011)

engagement typically found by Gascoyne (2012) when infants engage in Treasure Basket play, departures from this are all the more obvious to spot on the researcher's ethical radar (Table 7.1).

Seeking parental consent as proxy for young children's participation is 'common practice' in research (Hedges 2001). Although no substitute for engaging the consent of the child, Winnicott (cited in Holmes 1996) suggested that the entity of a baby could not be separated from that of its main carer (or circle of adult support), such that both adult and infant provide perspectives of each other. This also foregrounds the importance of reporting findings back to parents and caregivers to inform their understanding of and relationship with their infant. With this in mind,

perhaps parental consent takes on greater significance in informing parents' and researcher's understanding of and relationship with the infant.

Researcher Reflection (Andi Salamon)
The idea that we can afford infants participatory opportunities in research by being open to engaging with them in 'real' and meaningful ways is a big one. There has been some debate about the nature of participation of infants in research, for example, Can we gain their perspectives? How? Do we really know? and so on. What seems to be the outcome people are coming to is the suggestion that gaining/ascertaining infant perspective is not the only option (Elwick et al. 2014b) for infants' participation in research. Creating conditions for (Palaiologou 2014) and developing relationships with infants, as a part of how the research unfolds (Degotardi 2011), open up possibilities for interactions that afford their participatory opportunities (Elwick et al. 2014a, b). Underlying new perspectives on participatory research with infants, however, is important to position infant participants in ethically symmetrical ways to adult participants (Christensen and Prout 2002; Salamon 2015). Doing so 'does not justify treating children as if they were the same as adults' (Christensen and Prout 2002, p. 479) but recognises the commonalities of infants as human research participants while acknowledging and honouring their differences. Working with an ethically symmetrical perspective can be achieved when researchers adopt a methodological attitude that recognises, respects and incorporates the agency of infants in research processes (Salamon 2015).

7.4 Younger Children's Engagement in Research (Jane Murray)

During two decades as an early years teacher, I witnessed the children I worked with investigating, questioning, developing systems to achieve goals, testing properties of materials and exploring; these seemed to be higher-order processes in which children engaged when directing their own activity. My experiences led me to believe that I observed young children researching naturally as part of their daily quotidian activity. However, I recognised that, while research in the academy is regarded as a universal right (Appadurai 2006), '…children are excluded…from the …rarefied world of the academy' (Redmond 2008, p. 17): a privileged space where foundational methodologies and deductive reasoning enjoy primacy (Hanna 2006; Hatch 2007; Thomas 2007) and where knowledge is produced (Warren and Boxall 2009) – a 'score-keeping world' (Lees 1999, p. 382) which sets itself apart from 'the people' (Bridges 1998).

Tensions also exist between views of children as evolving humans and experts in their own lives from birth (Langsted 1994, p. 29). Yet young children's abilities to develop 'a philosophy of what counts as knowledge and truth' (Strega 2005, p. 201) – epistemology – were established years ago in England (Isaacs 1944).

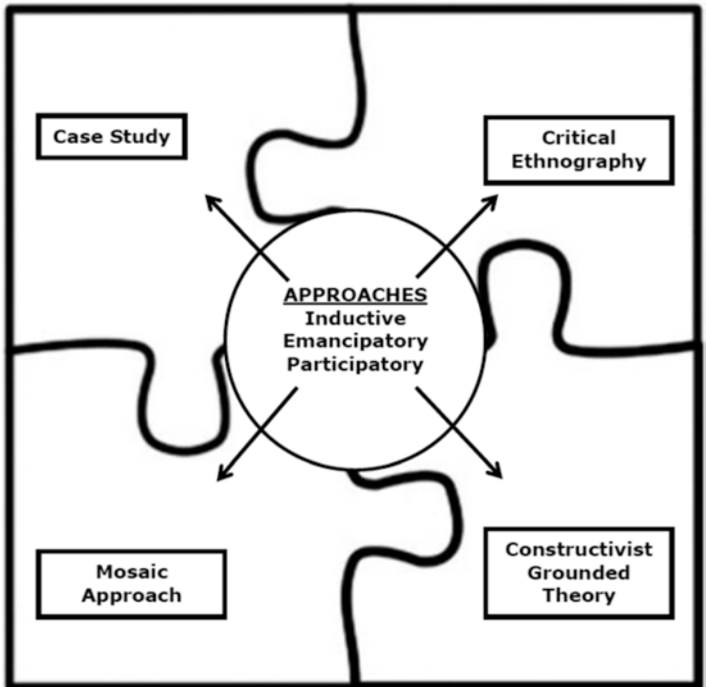

Fig. 7.2 Jigsaw methodology

Moreover, young children can be regarded as '…important human beings capable of understanding, communicating and influencing (their) own lives and those around (them)' (Harcourt et al. 2011, p. 7). It is appropriate, then, to challenge young children's exclusion from any aspect of society, particularly aspects which may affect their lives, as an issue of social justice (Truman et al. 2000). To address these contested spaces in regard to research, the Young Children as Researchers (YCAR) study (Murray 2012) aimed to conceptualise ways in which young children aged 4–8 years are researchers in everyday activities.

Beginning from a value orientation of social justice, three principled guiding approaches were adopted. YCAR was *emancipatory* to enable young children's own research to be evidenced, it was *participatory* to include young children as researchers, and it was *inductive* to maximise use of the children's contributions as the project developed. Following original intentions to work in an interpretive paradigm and adopt constructivist grounded theory (CGT) (Charmaz 2006), and in response to emerging data, those decisions developed as the project progressed, resulting in a pluralist qualitative approach (Frost 2009), comprising plural paradigms and a jigsaw methodology shaped by four single methodologies (Fig. 7.2).

The first phase of data collection and analysis was conducted with an adult group, reflecting young children's exclusion from the academy's world (Redmond 2008). To persuade the academy that young children aged 4–8 years can be researchers, the

Table 7.2 Phase 3 participants

	Annie and family A	Billy and family B	Gemma and family C	Harry and family D	Martin and family E
Setting (Phase 2)	Ash	Ash	Beech	Beech	Cherry
Gender	Girl	Boy	Girl	Boy	Boy
Age during Phase 3	8 years	8 years	5 years	5 years	5 years
Living with	Mother	Mother	Mother	Mother	Mother
	Father	Father	Father	Father	Father
		Sister (9 years)	Brother (8 years)	Brother (4 years)	Sister (4 years)

YCAR study set out to identify a definition on the academy's terms, before applying that definition to the quotidian behaviours of young children. Therefore, the YCAR's first phase comprised a survey, semi-structured interviews and a nominal grouping exercise (Delbecq and VandeVen 1971) with experienced professional researchers (n = 34) from the fields of education and early years, whose research profiles indicated their affiliation with the academy. A single definition of research remained elusive: instead this process elicited 39 research behaviours, forming a Research Behaviour Framework, from which the professional researchers identified their four most important research behaviours: exploration, finding a solution, conceptualisation and basing decisions on evidence.

In the study's second phase, data concerning 138 children's naturalistic behaviours were captured in their three English primary schools by myself, the children and their practitioners and analysed and interpreted by us as well as a focus group of professional researchers. This phase included 106 4- and 5-year-olds and their 13 practitioners and a class of 32 7- and 8-year-olds with their two practitioners. Subsequently, five of the Phase 2 children and their parents participated in Phase 3 (as in Table 7.2), capturing and analysing data at home.

For Phases 2 and 3, data emerged from multiple methods: interview conversations, live and video observations, photographs, field notes, focus groups, artefacts presented by the children, documents and analysis sheets. Guided by the jigsaw methodology's four components, a complex recursive, participatory approach was adopted for the analysis and interpretation of data. The incremental development of the research design was valuable in facilitating recognition of data. As a researcher, I matched appropriate methodologies to emerging data rather than the data being dictated from the outset by a single predetermined methodological rubric. In this way, the research design remained faithful to its value orientation and guiding approaches: its form matched its function. The findings focussed on the four most important research behaviours identified by academy members in Phase 1. Final analysis elicited 80 subfactors spread across nine key epistemological factors that were present in participating young children's quotidian activities at home and at school. These epistemological factors indicated young children's engagement as researchers, demonstrating behaviours such as application of prior experience, innovation, autonomy, material contexts, dispositions and cognitive and social domains.

Table 7.3 Martin's behaviour as causality

Hume's definition of causality (1739, iii, pxv)	Martin's behaviour
'The cause and effect must be contiguous in space and time'	Martin jumped and within seconds his hat fell off
'The cause must be prior to the effect'	Martin jumped (cause) and then his hat fell off (effect)
'There must be a constant union between the cause and effect'	Martin articulated his perception of the correlation: 'I'm seeing if my hat falls off! Watch this, dudes!'
	The 'union' occurs when his hat falls off as he jumps: the hat falling off seems to result from his jumping
	Furthermore, prior to the event when Martin says to his friends: 'I'm seeing if my hat falls off! Watch this, dudes!' he indicates that he had developed a causal theory in advance of testing it (Gopnik 2009)

The following vignette is a demonstration of how the epistemological factors were derived from the children's everyday activities.

One day during school playtime in Cherry Setting, Martin (5 years) stood in the middle of the playground, wearing a sunhat. Two more boys (5 years) joined him. Martin bent over and said to the boys: 'I'm seeing if my hat falls off! Watch this, dudes!' then he jumped up and down until his hat came off.

This is an example of a child's engagement with cause and effect as a subfactor of the cognitive domain, as revealed through the research behaviour of exploration. Similar encounters illuminated other aspects of the identified research behaviours.

While causality has been redefined significantly in the past century in the physical sciences (Born 1949), Hume's definition of causality (1739) continues to prevail in the social sciences. It can be argued that Martin's behaviour in the vignette aligns with Hume's definition, as in Table 7.3.

Moreover, Martin seemed to indicate some 'intellectual understanding of physical systems and living organisms' (Smeyers 2008, p. 64) and a capacity to explore, congruent with professional researchers operating within the academy (Stebbins 2001).

In the YCAR study, adoption of a value orientation to social justice alongside principled guiding approaches informed an emergent, pluralist methodological approach that led to the capture of research behaviours undertaken by participating young children. In turn, these data led to the claim that children's behaviours captured during the study were congruent with adult researchers' behaviours. Despite the adoption of an inductive approach for the majority of the study, this claim is based on deductive logic, the academy's preferred model of reasoning (Pring 2000): a conclusion is true if its premises are true (Johnson-Laird and Byrne 1991). The

Research Behaviour Framework (RBF) is populated with behaviours identified by academy members as research (major premise). Participating children engaged in behaviours included in the RBF (minor premise). Participating children behaved as researchers (conclusion). Research is recognised as a universal right (Appadurai 2006), and the YCAR study demonstrates that this can be as much the case for 4–8-year-old children as it is for older people.

7.5 Preschool Researchers

7.5.1 Researcher Reflection (Anette Boye Koch)

Engaging Children in Research Photo taken by a 5-year-old boy in order to illustrate how he experiences joy when playing with his peers

When 4–5-year-old children are encouraged to be research collaborators with the explanation: *I am writing a book about preschools, but I need some children to help me explain, what it is like to be a preschool child. Because it is only the children who really know* and are requested to help take some photographs to illustrate 'the book', they usually accept the task with excitement. The children receive the digital camera they are offered and immediately start searching their preschool setting to find suitable motifs.

Young children are very eager to participate and co-operate in research. They are excellent collaborators and accept the challenge to speak up right away. They are skilled in providing answers to adult questions but also in telling an adult researcher *what they think she wishes to hear*.

An implicit theme within the idea of children as co-researchers is respect for the researched group and for their own views and abilities (Alderson 2008). Research design should therefore endeavour to get child informers to tell their *own version* of

an issue and thus provide child perspectives that are as authentic as possible. It is a child's right to be heard in all childhood matters, and it is necessary to find out how this might most credibly happen in each situation.

7.5.2 Different Ways of Collaboration

Collaboration is a necessity when doing research with children in order to encourage child informers to tell their 'own truth'. Research implementation should strive to provide children with power to take decisions, e.g. set the agenda of an interview or in another way experience a shared ownership to the research process. They should be invited to participate as active agents out of their own free will and with the awareness that their contribution is of great value.

Alderson (2008) differentiates between various kinds of co-research depending on the stage of research where the children are invited to participate. The author identifies the middle stage of projects as the most common stage – the phase when data is collected and analysed. MacNaughton et al. (2007) offer four different degrees of co-research with reference to an adaptation of Arnstein's (1969) ladder of citizen participation. I distinguish between involving young children in research either as informers and co-producers of empiric data or more radically as informers AND consultants in other project phases (design, analysis, dissemination and reporting.).

Collaboration in Practice

I have often introduced the actual research task by asking young children to pair up and take photos of motifs they choose independently ('what makes you happy in preschool?' or 'take some pictures of places where you have some memories of being with your preschool teachers'). Thus, the children are in charge of the photo session, while I try to follow them on their tour around the preschool in order to audio record as much of their mutual dialogue as possible.

Afterwards, we do the actual interview while running a slideshow on a PC, one photo at a time. In this manner the children themselves decide the agenda of the interview, as I ask questions like 'why did you take that photo?' 'what were you doing there?' and 'how did it make you happy?' The children reply to my questions as best as they can, while I try to follow their lines of thought and ask further questions accordingly.

The term *child informed* explicitly articulates in what way the children have participated in the research process. When children collaborate in research by answering questions and contribute with narratives, artwork, photographs or maps,

they inform the production of empiric data. They collaborate in the production of knowledge on a theme from a *child informed* perspective.

7.5.3 Various Child Perspectives

It is crucial to bear in mind that there is not *one* but *various* child perspectives. Children differ due to their diverse life circumstances, preferences and competences. It is important to include not only children who are verbally strong and adept at relating to adults in a study, though they are often far easier to engage. When children participate in research, we should listen to and include the voices of all different *kinds* of children – not just those who are most evident.

There is much intuitive feeling in being able to relate to children and encourage them to talk and participate in research; not all researchers are able to do this effectively. You need to be simultaneously attentive, curious, interesting, authentic, enthusiastic, humble and grateful. When a researcher manages to open her mind and turn her attention towards what is going on in the world from a child-sensitive perspective, it is like a special pair of glasses that enables you to sense the world from another angle. Details and nuances that were earlier overseen are now suddenly clear.

How is it possible for an adult researcher to understand and grasp what children express? Children express themselves differently mainly because they are not adults – in research their contributions are always interpreted by an adult in some way – so in what way and with what words do it make sense to talk of a child perspective in research? Sommer et al. (2010) differ between *child perspectives*, when adult professionals study children from the outside-in trying to imagine what it is like to be a child in a certain context and *children's perspectives* expressed by the children's own words or productions from the inside-out and the expressions that adult researchers try to interpret. I suggest a vocabulary, where I differ between studies taking either a child-informed perspective on a theme in comparison to studies that try to depict a child-sensitive perspective on ECEC everyday life. Such specific terms explicitly formulate in what way (through choice of research method) the children have participated, such as answering questions and otherwise informing the production of empiric data (a child-informed perspective). Alternatively they might participate less directly if a researcher is doing participant observations with a subtle sensitivity directed towards child expressions, actions and body language (a child-sensitive perspective).

7.6 Participatory Research with Vulnerable and Marginalised Groups (Colette Gray)

As has been suggested earlier, the ratification of the UNCRC (United Nations 1989) by 194 member states signalled a new direction for policy and practice. At the same time, the UNCRC informed paradigm shifts in the new social studies for childhood and developmental research towards a rights-based perspective which views children as active participants rather than passive vessels (Butler 2009). According to Ennew and Swart-Kreger (2003), these approaches reject the presentation of vulnerable and marginalised groups as broken or dysfunctional. Also eschewing the theoretical positioning of children with disabilities against a gold standard of 'normal', which treats them as lesser, recent concerns have been expressed about privileging Minority World rather than Majority World childhoods (see Tisdall and Punch 2012).

7.6.1 The Voice of the Child

This new era heralded a veritable torrent of child-centred initiatives (Gray and Winter 2012) and elevated listening to children to a 'new orthodoxy' (McLeod 2008: 45). A range of substantive issues have however been explored with the aim of affecting change. For example, the voice of the child with a learning disability is informing the development of child protection policies in Northern Ireland (McKee 2014). Research into children's experiences of living with a thyroid condition influenced policy and practice in a London hospital (Davidson 2008). Thomas de Benitez (2011) sought to give voice to marginalised groups of children typically termed 'street children'. Her report for the Consortium for Street Children which has 60 member organisations working in 130 countries challenges the term 'street children' on the grounds that it suggests a homogeneous group when children have multiple identities. There are noticeable similarities between the argument presented by Thomas de Benitez on behalf of street children and those coalesced around the social model of disability, which drove forward anti-discrimination legislation. From a rights-based perspective, both focus on children's agency. Introducing a caveat, Tisdall (2011a, b) notes that the agency model can be inhibiting rather than liberating as it ignores the physical and situational limitations that make agency an aspiration rather than a reality. For example, Connors and Stalker (2007) found children with a disability tended to minimise their differences in order to present as more similar than different from other young people. They argue that this is the child's response to pressure from parents and the school who discourage them from discussing their disabilities and encourage them to 'pass [themselves] as normal'.

7.6.2 Agency: Fact or Fiction?

With regard to agency, de Benitez (2011) reports how street children frequently juggle three jobs seeking seasonal labour and work at cultural festivals and tourist centres. She cautions against romanticising this as autonomy or agency. Although children show considerable resilience in finding work, Thomas de Benitez describes this, at best, as 'thin agency' (p. 30). This and the previous example lend support to claims that the focus on children's agency ignores the negative, challenging and limiting context where agency is circumscribed or not possible (White and Choudhury 2010). Similarly, the promotion of the child's voice risks privileging this form of communication over others and discourages researchers from actively involving children who are unable or unwilling to verbally communicate their thoughts and experiences. Support for this contention comes from a report by the United Kingdom Children's Commissioner (2008) which notes that children and young people with disabilities are much less likely than those without disabilities to participate at any level, particularly those with complex requirements or with only non-verbal communication. In essence, participatory research which seeks to give voice to the child remains adult managed, manipulated and reported. It is also argued that participatory research is tokenistic and has no long-term impact on children's lives (Gray and Winter 2012).

In summary, the voice of vulnerable and marginalised groups remains under-represented in the literature. Thomas de Benitez (2011), for example, found a dearth of studies seeking to actively engage street children in the research process; similar claims are made by Tisdall (2011a, b) with regard to children with a disability. The provocation remains for researchers working within Childhood Studies to debate, challenge and redefine claims regarding agency, participatory research and giving voice to children. In troubling the established discourse that influences policy, practice and taken for granted assumptions about agency, alternate interpretations become accessible and may be redefined within the frame of participatory research discourse.

7.6.3 Researcher Reflection: Voices from Pen Green (Jonathan's Story) – An Extract from Whalley et al. (2012)

The Pen Green Tracer Study (2012) questioned the difference nursery education may have made to children who later, then aged 11–21, revisited their nursery. Walking-talking discussions in the setting with members of staff they had known elicited the children's memories and values. Emerging research strands were the children's sense of self, key worker attachment and parental involvement. This methodological approach afforded a phenomenological reading and multimodal interactions with experiences.

Jonathan, now aged 21, is a talented musician. He is blind. Molly, his mother, selected this Children's Centre rather than a more specialised structured setting. During the Tracer Study, he listened to archives of his interactions with staff. He remembered names and characteristics of a range of workers from 18 years previously, particularly Katey, his nursery key worker. In a layered approach, Jonathan revisited the nursery with Sally, a researcher his own age, and Cath, another member of staff. In their company he identified the value of the pots and pans that he used to make noises with in the Home Corner, hammered a nail into wood and sat on the little chairs. He also relived his interaction with the resources hand in hand with Sally, bouncing on the trampoline and throwing balls while immersed in the ball pool. The discussion prompted him to consider if there was anything that nursery could have done to help him with the transition to school, Jonathan replied:

> I can't think of anything … Because when I went to school I still had someone with me the whole time … The only thing that, obviously, no nursery can really change is that you sometimes get told off at school, but that's … that's nothing … as frightening as it is at the time, you know, it's part of growing up.
>
> Sally explored the question of whether nursery could have prepared him for this by limiting his freedom of choice. Jonathan disagreed, saying that, 'No ... I think school, I think that's the right place to learn that. I didn't get that at nursery, I didn't get told off at nursery which was good.'
>
> S: You think that's good, that you didn't get told not to do things? I suppose it's like a progression as you get older, maybe?
>
> J: I got told **not to do things**, but not **told off** … there's a difference.

When asked to pick a word to describe his nursery, Jonathan replied, 'Idyllic or … magical, 'cause let's face it, nursery is a time of magic, it's brilliant, in terms of ... that whole kind of, anything you want to do you can do, it's all there'.

7.7 Approaches with Potential for Researching Authentically with Young Children

Alma Fleet and Jane Merewether

Einersdóttir (2007) cautions that 'Researchers who conduct research with children have to be creative and use methods that fit the circumstances and the children they are working with each time' (p. 207). While quantitative research is able to provide information about the lives of young children, it is qualitative approaches that have provided the most promise for researching *with* young children. Such approaches allow researchers to work with children in naturalistic, everyday settings. Qualitative methodologies are amenable to hearing participants' voices – crucial if children are to be heard – and they allow for the possibility of children's control of the research, although this is not necessarily the case. Qualitative approaches to gathering data through conversations and non-verbal means of communication such as gesture, drawing, photography and other arts-based means provide the possibility to offer methods that are attractive to children. However, as Fraser et al. (2014, p. 82) note,

'using the term "child-friendly" to describe data production techniques may wittingly or unwittingly undermine the principle that young people must be considered competent experts in their own lives'. This underscores the fact that so-called child-friendly strategies are also common to research with older people and are not the exclusive domain of research with children. In addition, Cheeseman and Robertson (2006) express a cautionary note about the potential of some forms of observation (and recording about) children being seen as surveillance, with little opportunity for young children to avoid (or choose to engage in) participation. In addition, while they note that 'The idea that infants express themselves non-verbally through their bodies and behavior is unproblematic' (p. 200), Elwick et al. (2014a) claim that 'the participatory research agenda with infants' is contested:

> Knowing anything for certain about infants, including whether such things as 'infants' perspectives' exist, is profoundly difficult if not impossible. We conclude that awareness of the inherent uncertainties in studying infants reconstructs such research as a site for ethical rather than epistemological practice. (p. 198)

Acknowledging this caution, it is also clear that two sources of inspiration have been particularly influential in developing respectful ways to work with young children: participatory action research (PAR) and the educational project of Reggio Emilia. These will be discussed before expanding on the particularly influential 'Mosaic approach', which draws on both PAR and the project of Reggio Emilia.

7.8 PAR

Participatory action research is an umbrella term for research that has its roots in the work of Kurt Lewin (1946) and has at its heart a desire to conduct research 'with' people rather than 'on' them (Reason and Bradbury 2008). PAR was developed by social scientists as a means of empowering groups of people to effect change by placing the research into the hands of the groups involved (Lewin 1946; McTaggart 1991). Participation continues throughout the entire research process, thus democratising knowledge production. This democratisation of knowledge allows people to engage in collective problem-solving using a reflective spiral of planning-acting-observing-evaluating steps in order to improve their own practice (McTaggart 1991). It uses a range of qualitative strategies such as participant observations, interviews, document analysis, field notes and journals (McTaggart 1991). Veale's (2005) work with PAR in Rwanda, as amplified by 'creative methodologies', highlights also the potential of arts-informed approaches with children and young people in challenging circumstances.

7.8.1 Reggio Emilia

The world-renowned Reggio Emilia educational project for children aged from birth to six in which children and adults work together with an 'attitude of research' (Rinaldi 2006, p. 101) that is carefully recorded using pedagogical documentation (Dahlberg et al. 2007; Edwards et al. 2012b; Fleet et al. 2006, 2012; Giudici et al. 2001) provides many methodological possibilities for research. Central to the project is the notion that children 'possess a hundred languages, a hundred ways of thinking, of expressing themselves, of understanding, and of encountering others' (Infant-toddler Centres and Preschools Istituzione of the Municipality of Reggio Emilia 2010, p. 10). For researchers, this metaphor opens the door to a myriad of data production possibilities. No longer are researchers constrained to verbal means of expression; the Reggio Emilia project has shown how children can communicate in many different ways.

Another key principle of the educational project of Reggio Emilia is the 'pedagogy of listening' (Rinaldi 2006, pp. 65–68). This pedagogy listens with openness, sensitivity and curiosity, using all of the senses. It involves interpretation, and rather than producing answers, it generates more questions. A pedagogy of listening welcomes different points of view, which requires suspending judgement and being open to change (Merewether and Fleet 2014).

7.8.2 Mosaic

Taking inspiration from both PAR and the Reggio Emilia project, Clark and Moss (2001) developed the 'Mosaic approach', a multi-method, participatory research approach for researching children's perspectives which uses traditional research methods of observation and interviews, as well as a variety of participatory strategies including child-led photography, book making, tours and drawing. The findings from these activities are then brought together to create a 'picture' of children's perspectives. The Mosaic approach has provided a framework for an increasing number of researchers who have sought young children's perspectives by involving them in the research process (Cremin and Slatter 2004; Dockett and Perry 2005; Fleet and Britt 2011; Merewether and Fleet 2014; Smith et al. 2005; Stephenson 2009).

Government instrumentalities in some countries may be on the cusp of acknowledging the importance of researching with children in order to gain their input on matters that affect them, using aspects or adaptations of the Mosaic approach (Clark and Moss 2001, Clark 2005a, b). For example, in 2013, the South Australian Department for Education and Child Development involved 350 children between the ages of 3 and 8 years in consultations across the state to investigate what was important to them in their communities. 'The question was deliberately open-ended so as not to pre-empt children's interests in some aspects of their communities and

not others' (Harris and Manatakis 2013, p. 68). Findings gained through multimedia formats fed into the state's planning procedures, in recognition of Article 12 of the UNCRC (United Nations 1989).

Local areas can also respond to this challenge, as has been evidenced in New South Wales, Australia. The city of Canterbury council worked with the local university to garner the perspectives of children from across the area over a 12-month period in order to influence their decision-making (Canterbury City Council 2014). Dockett and Perry (2007) worked with the State Government to develop a position statement on transitions to school in consultations that included young children. Such initiatives deserve to be more prevalent.

7.8.3 Researcher Reflection: A Phased Approach to Researching with Children (Deborah Harcourt)

The international research community is developing a rich, substantial body of work around investigations with children. However, with very few exceptions (see Clark and Moss 2001; Clark 2010), little has been advanced on how to systematically approach this work from conceptualisation through to dissemination. This reflection seeks to present a reference point for researchers considering such an enterprise.

A phased approach is offered here which has been constructed and reconstructed in various projects to respond to specific research contexts, across three international settings. As the basis for developing this approach, I sought the provision of research space for the active participation of groups of children, aged 3–6 years, and was interested in contributing young children's standpoints through acknowledging children as experts in the lived experience of early childhood education. Such an approach would firstly support the development of relationships, implicitly and/or explicitly, as a phenomenon is being examined. Wiltz and Klien (2001) suggest using participant observation across a continuum, from passive outsider observation to a participant role. Erikson (1979) proposes that a continuum could lead eventually to full engagement. This approach has assisted me in establishing an accepted active researcher presence in prior-to-school settings used as research sites and helped to avoid unnecessary discomfort or disruption to the programmes involved. Serious consideration was given to allocating time to develop relationships with staff and children, which is an imperative to the success of the studies. I acknowledge that extended periods of time are often not available to researchers, but genuine attempts must be made to focus on building authentic research relationships within the constraints of each project.

Planning by phases of research enables the researcher to provide a structure to their work that carefully considers the complexities not only of researching with young children but also the factors that may impact each context. In this way, the researcher is able to have flexibility to respond to matters such as time, group sizes,

capacities of the children, preferred communication and representational tools and other (sometimes unexpected) factors. While the ethical and practical applications of this type of research can at times seem overwhelming, the potential that young children's standpoints offer to critical conversations being undertaken in a range of disciplines will contribute enormous richness to our current knowledge about children and childhood. Not only can we engage young children's active participation in research processes as part of their mandated rights, but we also stand to add unique perspectives, on a broad range of issues, to understandings about matters concerning young children.

7.9 Through the Eyes of a Documentary Film-Maker: The Frontier of Documentary, Education and Research (Penny Lawrence)

To my mind the key principles in researching with children are to consider the extent of the co-construction of meaning with them and how we may move beyond our own perspectives. In Reggio Emilia the practice of documentation is made in dialogue between children and children, children and adults and between adults. It is that essential process of co-construction that moves beyond the transmission of children's ideas into a dynamic growth of knowledge. It is participatory research as education.

In documentary-making, the extent of co-construction can start very young. Two-year-old Ned was the first ever child to light up a Teletubby's stomach (Wood and Davenport 1997). It was Ned who established the way of relating to the viewer when he cycled up to the camera. He addressed us through the theatrical fourth wall. It was Ned who initiated and co-constructed that relationship. Of course he was relating to me, the director, and to the cameraman, not to the subsequent millions of viewers. However, the viewers also experienced something of his purposefulness, his agency as he cycled towards them and throughout the film as he described and demonstrated how he fixed his and his dad's bicycles. This quality of relating is possible, and I would even argue it is an ethical necessity when researching with children. I have in mind what Reddy (2008) calls a second-person approach, through which the researcher acknowledges his/her relation to the child. The second-person approach stands between an immersed first person subjective approach attempting to see the child's perspective and, on the other hand, engaging in an invisible third-person approach seeking an impossible objectivity.

Documentary-making can be instrumental, seeking materials to illustrate a preconceived argument. As such, video would work in the mode of extraction; the knowledge and experiences of children would be mined for the purposes of the project. Social science research can work with video in several ways beyond extraction. Haw and Hadfield (2011) identify four other modalities: reflection, projection and provocation, participation and articulation. Each modality would involve

children more extensively higher up the level of participation (Hart 1992), although of course each modality would have its own levels of intensity. For example, video used for reflection as it is in Reggio Emilia is a tool for the mind (Forman 1999) allowing children to leave the cognitive load or narrative burden of describing what happened and to move into higher-order reflection, explaining and evaluating their learning experiences as they look back at them.

Documentary-making can also work in an inductive way, seeking to find out the unknown, although this has greater resource implications for the necessary time to record and process the material. In this, the process is akin to qualitative research. Vidich and Lyman (2000) show how methods in early ethnography grew out of the researchers' interests in understanding the 'Other'. When the child is framed as *other*, methods may draw deficit comparisons with adults. Not othering the child means engaging with his or her perspective. Nagel emphasises that perspective is vital to the knowing of the other, 'it is the essence of the internal world, and not merely a point of view on it' (1974, p. 5).

The framing I choose determines what and how much (wide or close up) can be seen or known of the child's experience and the potential meaning of power – relations between children, adult and viewer are determined in the high, eye-level or low camera angle (Jewitt and Oyama 2001, p. 135; Goffman 1974; Goldman 2007, p. 5). For Goldman, the camera creates a shareable presence in four ways, including 'perspectivity', which affords both the videographer's and other subjective points of viewing (2007, p. 5). The deliberate use of perspective can change the appearance of events considerably when viewed from the point of view of a child, *if* we can adopt that point of view.

There is a sense in which phenomenological facts are perfectly objective: one person can know or say of another what the quality of the other's experience is. They are subjective, however, in the sense that even this objective ascription of experience is possible only for someone sufficiently similar to the object of ascription to be able to adopt his point of view (Nagel 1974, p. 438).

An example of the potential for shifting perspective is the experience I had of recording a certain siege in Sudan for the UK TV series, *The Investigators*, (Lawrence and Nicholson 2000) presented entirely by children. I worked with the descendent of the Mahdi who attacked and defeated Gordon of Khartoum. The 10-year-old girl turned the event 180° around from my expectations to describe the British as the threat and her forbears looking after the city, land and people. We worked with a model set in the desert as she retold the story, and I filmed from her point of view looking into the city at the outsider Gordon within.

It is important to document also the role of the adult when there is vitality in their interactions with children's thinking. For example, elasticity of mind and responsiveness is embodied in Evelina Reverberi, a teacher at the Diana School of Reggio Emilia. She lit up when a child opened up ideas beyond those she had planned for, beyond the preconceived, crossing the boundaries of her thoughts, (*attraversare il confine* roughly meaning 'to cross the border' in Italian). This light set the climate, the relational context in which a child wanted to share ideas. For her, seeing from another's point of view was enlarging and enriching. She taught alongside Malaguzzi who, to express that going beyond the confines of individual thought, used the

imagery of 'the eye that jumped over the wall'. This was the original name for the '100 languages of children's exhibition of children's thinking in a pedagogy based upon relationships' (Malaguzzi 1993). The eye or the knowing does not stop at the frontier of one's own wall or enclosed self. It is how the ethics of relationship is lived out, 'giving particular attention to how to relate to the Other in a responsive way' (Dahlberg and Moss 2005, p. 76) but not necessarily presuming that the Other is the same. My knowing of the child as *other* is partial, fragmentary and momentary; when observing we also have to jump over our walls to see these things.

7.10 Providing Insight Through Pedagogical Documentation: Seeing Research as an Everyday Practice (Suallyn Mitchelmore)

As a method, pedagogical documentation is a concept for making children's ideas and learning visible through gathering and analysing examples of conversations, photographs, video film and artefacts such as clay pieces, constructions, drawings and paintings. It is a way of working that is provoked by the work of educators in Reggio Emilia, Italy, where it is described as 'educational documentation' and is described by Rinaldi as 'visible listening' (2006, p. 100). Pedagogical documentation can take many forms, for example, an A4 or A3 booklet or a panel on the wall. It shares the journey and the thinking of the children and adults around a particular investigation and includes photographs of children and educators engaging in work in process, transcripts of children's reflections and conversations as well as the thinking of educators.

Pedagogical documentation does not simply tell or retell a story; significantly it is bounded by a conceptual thread or narrative running through the investigation (Edwards et al. 2012b; Guidici et al. 2001). Dahlberg et al. (2007) reason that pedagogical documentation has two interrelated qualities, 'content' and 'process' (p. 147). The content refers to the material that is produced in pedagogical spaces, including notes, photographs and observations, and it is fundamental to the 'process' of pedagogical documentation. The process is central to pedagogical documentation and involves analysing and researching the thinking and meaning making that accompanies pedagogical work.

7.10.1 Concurrent Data Analysis and Data Collection

The processes of pedagogical documentation serve as both 'mirrors and windows', reflecting back on an experience while simultaneously provoking 'new horizons' (Barry 1996, p. 428). Further, Clark (2005c) argues that inclusion of research methods that engage in 'multiple listening recognises the need to make space for the "other"' (p. 38). The processes of pedagogical documentation inherently support the interplay of concurrent data collecting and data generating. The inclusive and reflective nature of pedagogical documentation makes visible the thinking of children,

acknowledging the 'listener as an active participant, co-constructing meanings in a reciprocal relationship' (Moss et al. 2005 p. 11). Indeed, the methodology of pedagogical documentation is in keeping with the nature of knowledge as a space of plurality and a transformation. Documentation is in itself a generating, active agent that sustains the mutuality and interdependence of being and becoming:

> In terms of action, you document what happens, and then you lay out the documentation on the table to re-visit, re-live or re-enact and unfold some of the multiplicities and differentiations of the event, but instead of thinking of such actions in terms of the progression from the present to the future, we think about it as an ongoing duration of the event. (Lenz-Taguchi 2010, p. 95)

Pedagogical documentation invites and honours the multiple voices of children as equal participants in thinking processes. It is a form of data collection and analysis that is accessible; it does not preclude children from contesting interpretations and the educator's/researcher's final analysis (Bae 2005; Tobin and Davidson 1990). Moreover, pedagogical documentation has the capacity to fulfil the role of a 'prompt' of 'stimulus material' by stimulating and engaging discussion (Speer 2002). The documented images, observations and reflections support a respondent-centred avenue for exploring the insights of children and spring-boarding future decision-making. Furthermore the context of the research site is a fundamental consideration when evaluating the potential of pedagogical documentation as a methodology to support collaborative research with young children. Researchers must ask themselves, 'Is this a way of working that children within this context are familiar with?' If young children recognise the processes of pedagogical documentation through previous experiences of co-researching alongside their peers and educators, it is more likely that they will bring to the research project an understanding that you are interested in their thinking, actions and responses.

Prosser and Burke (2008) state that 'Visual research is well placed to access, interpret, and give voice to children's worlds' (p. 407). Pedagogical documentation can also be seen as a communication avenue that supports joint analysis of data collection, inviting children to interpret their own data (Morrow and Richards 1996; O'Kane 2008). The inclusion of young children's experiences gives a rightful place to the richness that children's perspectives can contribute to understanding the nature of early childhood education and other issues that affect and impact upon young children's lives.

7.10.2 Pedagogical Documentation and Privacy

Given that data collection involves the recording and representation of data in the form of text, photography and video, consideration of issues related to risk, privacy and potential vulnerability of minors is essential. The research design must adhere to policies of the early childhood service in relation to publication of images of children, as well as protocols related to local regulations associated with images and privacy. Furthermore, if at any time a child is uncomfortable with being filmed or

photographed, then filming should stop. Protocols should be in place to manage situations where a child has displayed discomfort, such as the researcher reporting to the primary caregiver or service director who will follow up on the welfare of the child, ensuring that they understand their right to withdraw.

In this context, an advantage of pedagogical documentation is the transparency of data collection. As it is a reciprocal process, the purpose of which is to make thinking visible, pedagogical documentation has the capacity to overcome any suggestion of 'secrecy' that may be felt by children. The images and text that are collected are then placed back into the hands of the participants, to create a forum where further data is generated and collected data can be discussed and contested. Significantly, it is essential that the researcher's role as an observer, documenter and participant be explained to the child, so that they are aware that they are being observed. It is imperative that children are asked if they are happy to be photographed and furthermore that opportunities are made available for children to view video and photographic data. As data is collected, the researcher utilises opportunities to check and clarify with children that observations have been understood through sensitive and age-appropriate questioning and open discussions. Being transparent with children is essential to the integrity and validity of research; pedagogical documentation can be considered a conduit to meeting this objective.

7.11 Challenges for the Future

It is clear from the work reported here that, increasingly, researchers are viewing children as knowledgeable and competent members of society who are capable constructors of their own knowledge (Dahlberg et al. 2007; Rinaldi 2006). Merewether and Fleet (2014, p. 898) note that:

> Theoretical perspectives associated with socio-culturalism (Rogoff 2003; Vygotsky 1978) have made a major contribution to changing images of children. Sociocultural theory draws attention to the role of social context and social meaning in learning and suggests that children, from birth, construct their understandings in partnership with others, both adults and children.

These orientations set the groundwork for conceptualising the ways in which researching 'with' children might proceed.

This exploration also raises issues, such as, is there a continuum of 'researching with children' that includes respectful designs, collaboration and involvement in one or more aspects of the study (e.g. design, data tools, timing, analysis, interpretation)? Note, for example, the work of Shaw et al. (2011) which seems a useful model for exploring the continuum of ways in which children can be involved and therefore could potentially be effective in recognising and structuring differences in involvement and ownership as a reflection of children's age. As Gascoyne notes, the idea of 'process assent' was raised in relation to babies' involvement in research but is equally relevant to older children too. She reports (2014, personal communication):

> As the focus of much of my own early research involved my own infant son, I have been able to revisit his involvement in research by seeking his views and consent for the continued use of his photos in publications like this. In one such discussion, my son- now 8 years old- explained that he was happy for photos of himself to be used provided that his name was not included. This raises the issue of the permanency of children's contribution to research, particularly images and therapeutic process work, and the child's right to change their mind or withdraw assumed assent/consent.

Presenting the nuances and subjectivities of children as individuals who are capable of sharing experience and perspectives lessens the possibility of research findings that are 'reductionist, static, limited and objectifying approaches to analysing data and describing and categorising' (Bae 2005 p. 288). Pedagogical documentation invites children into dialogue that is respondent centred and non-hierarchical and reflects multiple voices and perspectives (Speer 2002).

Can respecting and 'honouring' children usefully be seen to have multiple interpretations? And should the sector be more conscious about how the terms are used, i.e. what does (co)-researching with children mean to different people? What aspects of a respectful framework could be said to be 'general' (i.e. not age/context/individual specific), and what aspects are dependent on age/stage/culture and so on? Is this knowable or should it remain negotiable and interpretive?

Methodologies Are Critical

> Respecting the rights of young children to be heard necessitates a preparedness to create a space to listen to their views in ways appropriate to them- through music, movement, dance, sport, storytelling, role play, drawing, painting, photography, hobbies, community and family activities, as well as through more conventional dialogue. This requires the provision of time, adults willing to listen, and environments in which children feel safe and comfortable. (Harrris and Manatakis 2013, p. 75)

It is clear that the environmental vision projects that seek children's perspectives for policy development and the pedagogical practices that engage children as collaborators in processes such as pedagogical documentation highlight the potentials of enabling the rhetoric to more closely align with goals of co-researching with children and foregrounding their perspectives in matters that concern them. Trusting relationships and respect for children's time and space are paramount.

7.12 Addendum: Key Threads

On March 31st, 2015, as the result of a collaboration between the Australian Human Rights Commission and Early Childhood Australia, the Australian National Children's Commissioner, Ms. Megan Mitchell, launched a seminal document

entitled Supporting young children's rights: Statement of intent (2015–2018). In the context of this chapter, the document is important for several reasons: firstly, that the position of National Children's Commissioner exists in Australia – which is a political testimonial to valuing children, and, secondly, that of the five key themes, four are directly relevant to the points made by the authors threaded throughout this chapter. The five key themes include:

- The right to be heard
- Freedom from violence, abuse and neglect
- The opportunity to thrive
- Engaged civic and citizenship
- Action and accountability

Many of the specific elements that have been referenced in this chapter resonate strongly with the principles evidenced here. For example, in terms of action and accountability, the document states that the child will 'be informed about opportunities to contribute to decisions, debates and research activities' and further, that each child will 'be encouraged to express my views and opinions and know that these views and opinions will be listened to and valued'. Consequently, professionals working with young children are asked to 'advocate for engaging children ethically in data collection processes with their ongoing informed consent' (2015, p. 16). These statements move the opening paragraph of this chapter from the arena of philosophy to that of clear obligation.

The principles also sit comfortably alongside a consideration of epistemology, as explored by several Finnish authors: Paavola et al. (2004, p. 572) state '…it is most important for students to engage in knowledge-creating inquiry and to develop a corresponding identity- that is, to consider themselves to be not only consumers but also creators of knowledge'. In addition, as is indicated in recent research by Kumpulainen et al. (2013), who worked with young school children, the concept of co-researching with children using many of the principles highlighted here is finding acceptance across diverse purposes. In this case, using photography by children regarding their positive experiences (in the context of a well-being study), the researchers found the greatest benefit was in the agency demonstrated through the children's discussion of their photographic data. This finding reinforces the value of the approaches summarised in this chapter. It signifies that by including and valuing children's contribution at key points in the research cycle, by giving time for the establishment of relationships and consideration of process and by adapting research methods and hierarchies give rise to a reconceptualisation of the context of research purposes.

So where have we come from and where are we headed in the conversation around researching with children? We have moved from tendency to objectify, to conceptions of collaboration – or at least of recognition of the importance of seeking voice and authentic perspectives from children as rightful owners of their own experiences. There is recognition that enabling children to participate in research about matters that concern them requires multilayered methodologies, including time to develop respectful relationships.

It is nevertheless clear that the bulk of legislation and ethical development, organisational policy frameworks and community development programs proceed with an absence of child voice or even impact statements that take a child's perspectives on decisions being made. At this particular moment in time, there is clear movement towards the valuing of children's engagement and perspectives on matters ranging from educational decision-making to town planning. It is equally clear, however, that this is a nascent field that requires strong advocacy from those who value children as partners in research.

Chapter 8
Policy Analysis and Document Research

Chris Peers

Abstract This chapter discusses policy analysis and the related field of document analysis for the interest of early childhood education researchers. Early childhood research is relatively young, by comparison to other tiers of the educational community. In addition, policy writing about early childhood (by government) and the study of such policy discourse (by researchers) will express potentially disjointed historical relationships, especially given the intersection of policy discourse with other disciplines such as economics and sociology. The chapter offers a background for those researchers in early childhood seeking to begin examining policy material.

The chapter additionally addresses document analysis because so much policy work is a matter of reading the text and interpreting the content. Of concern here is the risk of treating documents without sufficient heed for the historical or discursive conditions by which they were shaped. The chapter makes brief reference to significant document analysis practices so as to provide researchers with a repertoire of analytical approaches from which to select. Recognizing one's own ideological preconceptions and the perspective that a researcher herself might bring to the work of document analysis are all chief considerations in this chapter.

Keywords Policy • Document • Textuality

Early childhood education is a relatively emergent academic field in which questions of policy analysis and document research are as yet still marginal to the mainstream forms of study and scholarship. This chapter will examine some key examples of each to provide the reader with a sense of the direction that research in these areas has taken in the first few decades of the field's history as an academic discipline. In addition, it will broach relevant issues about the nature of policy analysis and document research in order to consider the complementarity of mainstream approaches to policy analysis and document research, as methods of study that early childhood researchers may undertake in the coming years.

The field of early childhood education is essentially focused on the quality of, and necessity for access to, services to families with respect to care and upbringing of young children and infants. As such the predominant sources of knowledge for the field have formed authorities and values that often lie elsewhere, in the realm of psychological research, neuroscience, epidemiology, and increasingly, economics. For example, for over 200 years, psychologists have written extensively on human development, and there now exist both orthodox and alternative approaches to developmental psychology that are highly relevant to early childhood study (e.g., Bruer 1999). By contrast the field of policy analysis has emerged from political science and economics, understandably given that the main aims of this kind of study relate to the shaping and impact of government perspectives on a given portfolio of funding and services. Policy is often concerned, in the broad view, with how taxation revenue is to be spent for the public good (e.g., Lowenstein 2011).

Document analysis is strongly related to policy analysis, but, in education generally and early childhood in particular, it can also comprise research in scientific literature about problems facing practitioners and families, issues raised within debate about developmental psychology, learning and care of infants, etc. Documents are often apprehended in their most banal function as paper records; the text that they comprise is often reduced epistemologically as a reproduction of someone's thoughts in writing. Accordingly, document analysis can be misapprehended as the "correct" reading and interpretation of a text or literary artifact. When we acknowledge that such a reduction is possible, a second form of apprehending the "document" arises, in which the epistemological grounds for document research shift dramatically from the conversion and implementation of valid data, on one hand, to a hermeneutic method, on the other hand, in which the use of words, the development of sentences, and the function of a text are each given a completely new significance for scholars. For example, in historical study, the way artifacts of the nineteenth-century early childhood practitioners might be read in the early decades of the twenty-first century is a topic of a study that is distinct from the content of the artifacts themselves (Hinitz 2013; Attridge et al. 1987). The content of such archival texts becomes a topic of debate because the text is no longer a scientific datum that has a single, generalized intention that remains more or less constant.

To provide early childhood education scholars with an overview of the skills and methods relevant to policy analysis and document research, this chapter will approach the theoretical parameters of both policy and text to outline the kinds of scholarship that is already pursued and that might be undertaken to reshape the way we understand the field of early childhood education itself.

8.1 Early Childhood Care and Education Policy

Historically, the adoption of public responsibility for education, i.e., schooling, precedes public responsibility for early childhood care and education in most Western countries by at least a century. In many cases governments are still developing

policies toward childcare as an area of public welfare. The issue here is to recognize the historical and economic causes that have led to the legitimacy of taking responsibility for young children out of the private sphere and placing it in public control, where the costs for undertaking that responsibility are shared among taxpayers. Yet this historical shift from private to public is not straightforward. Prior to the 1960s and 1970s, childcare was largely in the hands of private charities and catered almost exclusively to families of poor and disadvantaged people, especially single mothers and orphans (Rose 1999, 2010). This means that in those cases where childcare remains a charitable venture, it is not necessarily subject to government regulation and is therefore effectively regarded as a private enterprise, even if it is not a commercial enterprise. Public policy does not cater to such private enterprises, and, historically, governments only begin to explore forms of regulation once a decision has been made to include childcare within public expenditure.

The postwar period in the United States and in the United Kingdom saw an intensification of industrial growth that led to increased demands for labor and considerable volatility in wage and salary levels for male heads of household (Kopczuk et al. 2007). This shift in the labor market in two of the world's ten most dominant economies began to provide opportunities for women to enter the workforce in a manner that was new and which coincided with cultural shifts accompanying the so-called sexual revolution. The widespread availability of contraceptives and gradual changes to family law meant that middle-class women in many Western countries did not have to follow their mothers into domestic lives external to the labor market; these women gained access to private income, in isolation from men; and in turn this produced an incentive for some women to reconsider their traditional child-rearing responsibilities (Hakim 1996). The commercial provision of childcare as a substitute for traditional forms of parenting was a radical and controversial change in moral and social values that continues to reverberate in the twenty-first century (Brennan 1998).

The entry of women to the labor market in the Western economies is without question the single most important factor in the reform of government perspectives on childcare and family policy more broadly (Blau and Jusenius 1976; Penn 2007; Joshi et al. 1996). At the same time, both psychologists and economists had launched research initiatives from the late 1950s and early 1960s that addressed the impact of early childhood contexts, how those contexts could be designed in order to maximize a child's academic potential, and to properly shape the responsibilities of professional carers.

The emergence of this interest in the measurement and maximization of children's potential stems from several different historical factors that are relevant in understanding the development of a policy with respect to early childhood development and education as cognate disciplines. To address these factors very briefly, it might be helpful to begin with the consequences of the industrial revolution for young children. The citizen was increasingly conceptualized scientifically in terms of measurable attributes, mainly for the sake of increasing employability as a measure of moral civility. Different psychological systems were brought forward through the nineteenth century, including phrenology (as practiced, for example, by

Maria Montessori) to address the demands for employable citizens in the industrial age; intelligence testing is only the most well-known form of this kind of psychometric classification. As Deborah Tyler points out, in 1939, those responsible for training kindergarten teachers were beginning to consider the purpose of preschooling in terms of the risk of damage to a citizen between birth and 6 years, due to being in the custody and management of an unskilled woman.

Children, born perfect, were "damaged" between birth and school in such a way that their maximum capabilities and potential for happiness would never be realized…[hundreds of child development experts and scientists such as Piaget and Gesell] solidly implicated parents and, particularly mothers, in the production of the imperfect child. Mothers, through their mode of child-rearing, stood between their child and healthy development (Tyler 1993, 49).

There were economic, medical, and social repercussions of inscribing power in women to rear young children without appropriate forms of government regulation, based on scientific research. It is not difficult to see that educational research that is based on psychological science consequently provides a basis for public policy and the regulation of the childcare sector. In combination with increased interest in the determination of incentives for women to enter paid work, this new research agenda slowly began to affect family policies in general in Western nations.

8.2 What Does Early Childhood Care and Education Policy Research Look Like?

Policy should generally be conceptualized in relation with the historico-political structure or institution through which it is generated. For example, it is only possible to represent education policy at all once the Western nation-state began to take administrative control for schooling, for example, within the emergence of a bureaucratic authority in Napoleonic France at the beginning of the nineteenth century (Donzelot 1997).

With particular respect to early childhood education, the earliest regulatory policies (involving initial forms of government spending) took the form of childcare frameworks that purported to describe the broad conditions within which services for childcare could be regulated. Most of this government intervention begins after the Second World War, for example, the Head Start program in the United States (Vinovskis 1993; Hofferth and Phillips 1987; Clarke 2007). The latter offers a well-known example of early childhood intervention, constituting a primary mode of public spending in the childcare sector.

Policy writers are trying generally to take account of the multiple variables contributing to the provision of a childcare service, such as how quality can be measured, how the effects of family background can be accounted for, and what the outcomes of a service can be when correlated with other contributing factors. A good example of this is provided by an American research program called the Cost,

Quality, and Outcomes Study, initiated in 1993, and which sought to aggregate the various factors impacting on service provision and the measurement of outcomes. This kind of policy writing is significant because it directly informs government, provides the basis for reporting to authorities and related sources who are funding a service, and enables a political discourse to emerge based upon empirical data (cf. Peisner-Feinberg and Burchinal 1997). However, it is equally significant to discern between the reporting of research about the provision of services and the nature of policy as a document in itself.

Early childhood care and education policies will take the form of a range of different kinds of documents and texts that aim to serve various purposes: a curriculum framework will be a relatively broad set of policy documents that describe the sorts of objectives and outcomes that should guide the practices of professional carers and educators.

By comparison, a government policy on the establishment of early childhood services may take the form of legislation that is bare of requisite detail for how those services should be conducted. The law is nevertheless a policy of the government which enacts it and will be subject to political discourse and debate. Such laws are usually formulated after considerable research has been conducted into the existing nature and quality of services and the manner in which improvements and reforms may need to be implemented. Governments often refrain from detailing the rationale for such policy frameworks as they appear in legislation, because the law is meant to apply in a wide variety of contexts and is understood as a generalized assertion or statement of conditions under which government responsibilities are to be implemented. It may be the case that these laws are then added to, and detailed, in the form of regulations that are formed under the powers of the legislation.

Alternatively, legislation may appear in the form of a budget statement, which accounts for the level of funding allocated to a given portfolio or department of government, and therefore the policy details may be provided in the form of programs that have grants of money attached to them in the budget itself. Such programs may already be in place, or it may be that a department or bureau of government must establish the program in order to implement the policy. Policy may therefore appear in the form of descriptions of a program, tenders created to fulfill the requirements of a program, or commissions for a researcher to undertake a study of conditions within the community, for which a report on the study is formulated and which can consequently be reported to the government.

Policy should be understood to take a range of forms that each demonstrate the interests of a governing power (Kirp 2007). In this manner researchers ought to recognize a direct link between policy documents and the politics of the day. Policy research cannot ordinarily be conducted without any reference to the historical context in which a given policy was formulated. Consequently, researchers must search for the content of a policy within and between different kinds of documents: no single policy can be properly comprehended within or through the text as it is published on a single occasion for the sake of a given instance of government regulation, such as a budget statement in which funding for the childcare sector might be announced. For example, it would be necessary to compare the level of expenditure/

funding in 1 year with rates of funding over a broader chronological period, in order to disclose the kind of policy perspective being contributed to by one document under consideration. By this means the policy researcher can sketch the outline of a policy as a scale of implementation and reveal the conditions in which implementation was given effect.

The "look" and "feel" of early childhood care and education policy documents will vary from one context to the next; however, the most significant distinctions in the manner of their compilation and content seem to follow the level of economic development within a nation or geopolitical context. This is again due to the correlation that is possible between the manner in which early childhood is perceived historically, as a gauge of civic and economic progress, as described earlier by Tyler (1993) and the level of resources that are available in a given nation-state to be applied to a public policy sector.

For example, in some developing nations, considerable pressure has been applied by international agencies to force governments to develop appropriate policies for maternal and child health and related services for early years of development (Penn 2010; Tomaševski 2005a, b; Kirk 2007). This is so despite the fact that, in many cases, developing nations do not have adequate resources to implement services across the board: this means that the generation of policy in these contexts may be driven by a perception that aid revenue will be impacted if governments cannot demonstrate the effort to develop appropriate policies. Researchers ought to be wary of the historico-political complexities surrounding policy documents as they are generated in developing economies because many of the cultural and economic assumptions that are relevant to policy development in early childhood in a developed economy may be awkwardly or clumsily reproduced as if there were no difference between a developed and a developing economy (Therborn 2003). At the same time, since university research may be lacking in a developing economy, policymakers will sometimes have no alternative but to draw on the wisdom of Western sources and research as if it were automatically relevant. This is also reinforced by the mistaken perception that human development is a universal phenomenon which does not vary on the basis of cultural or economic context. Accordingly, the quality of such documents is sometimes marked by the inadequacy of resources and the qualifications and values of bureaucrats responsible for their production.

However, such problems are not always the case, and their frequency depends largely on the highly variable factors which may be impacting on bureaucratic resources, including the level of funding and the skill set of staff in a given case. For example, Benson reports the factors which support or detract from the introduction of early literacy projects in a series of developing economies, including Nigeria, Guatemala, Bolivia, Guinea-Bissau, and Niger. These factors include the cultural importance of mother tongue where language groups have been marginalized as a result of colonial government, as well as the imposition of literacy testing regimes that aim to measure literacy using Western criteria (Benson 2000). In such cases, early childhood policy is produced in a manner that incorporates many complex issues raised by the citizens whom the policy will affect and the apprehension of such policies by a policy analyst may depend on whether the researcher herself is

able to fully recognize the cultural and economic context in which the document was generated.

8.3 How Is Early Childhood Care and Education Policy Research Conducted?

It is increasingly the case that academic research that informs policy debate and discourse must be composed in a literary genre that borrows from economic and statistical paradigms of knowledge. This is the case in any academic discipline; however, given the intensifying scale of attention paid to the childcare sector by the government, researchers find themselves propelled by several key factors that I outline below:

1. The globalization of markets in early childhood services
2. The medicalization of early childhood services
3. The introduction of epidemiological models
4. Tension between professionalization of early childhood services and costs of provision

8.4 Globalization of Early Years Services

In a global marketplace, the connection between an economic policy and a variety of public policy sectors in Western nations has produced a genuine proliferation of concerns about early childhood health and education that were unknown prior to the end of the Second World War. The Global Millennium Development Goals are only a single example of the manner in which the priority of early childhood health and education has penetrated Western discourse and economic goal setting in the last two decades.

Early childhood policy analysts and document researchers nowadays regard such global issues as central to framing what early childhood policy must achieve in the coming decades on a global scale. For example, Rianne Mahon describes the Organization for Economic Cooperation and Development (OECD) as a “pioneer of soft forms of transnational governance” (Mahon 2009). By this she means that unlike other institutions in government and international banking, the influence of the OECD is in the generation of policy and debate that connects economic factors to social and political problems. The literature produced by the OECD is presently a critical form of data informing government policies in many nations, and the selection of areas for debate in itself is a key driver of its influence (OECD 2011). Researchers in public sector policy such as early childhood care and education are virtually compelled to read and contribute to studies published under the auspices of the OECD in areas such as family policy and labor market reform and “the development of new statistical and

technical indicators" for the purpose of benchmarking quality in-service provision. It is important to distinguish OECD reports as analysis of the ways in which nations and economies can be compared in a global sense and that it informs policy by weight of value placed upon the quality of the reporting.

Globalization should be seen in this context as a matter of recognizing economies as competing against one another for control and dominance of markets: the complex intersection of public policy with corporate policy is one of the most significant outcomes of the influence of international institutions like the OECD. For example, early childhood development is routinely treated as a factor that will contribute to a nation's future competitiveness and productivity, with some writers measuring the "positive externality" of an average individual American child (for rates of return or future average income) at $100,000 (Esping-Anderson 2008).

8.5 The Medicalization of Early Years Services

To understand the way in which economic or statistical paradigms of knowledge impact on policy debate within the early years sector, it is important to recognize that human development in itself is a psychological construct and that scientific research about children's physiological development has increasingly intersected with psychological debate about measurements of human development. Indeed, pediatric medicine, psychiatry, neurology, and epidemiology have all played an increasingly significant role in producing evidence about human development and how it can best be measured (McCain et al. 2007; Shonkoff and Phillips 2000).

While the professional views of early childhood educators and carers are themselves not insignificant, those views are themselves generated within the context of the authority which medicine as a knowledge discipline already holds, prior to the insertion of early childhood education within the academy. As Tyler described earlier, scientific evidence prevails over and shapes educational priorities in the field of early childhood. Given the late emergence of specialist early childhood educators and of corresponding programs of academic research about the practice of teaching, the cultivation of learning, and the design of curriculum and pedagogy for early years practitioners, especially by comparison with the whole field of medicine, the tension between medicine and education could not be described as a fair contest. Medicine, pediatric science, neurology, and epidemiology each offer paradigms of knowledge that far outweigh the views of childcare workers in the determination of a "good" policy. Nevertheless, a range of scholars from both sides of this debate have argued about the quality of medical evidence for the development of measurement criteria with respect to children's cognitive development, but the weight of value placed on medical data as compared with the qualitative paradigms that often dominate educational research is overwhelming (Bradbury 2012; Allmendinger and Liebfried 2003; Clarke 2007).

A primary example of the way in which this tension takes effect is in the implementation of major projects such as the Early Development Index in Canada and its offshoot, the Australian Early Development Index. Largely designed and implemented by psychiatrists and epidemiologists, this model approaches the task of measuring the risk that children in disadvantaged contexts will not be sufficiently ready to transition to school, and the data it generates is entirely demographic, rather than examining individual performance. The early childhood profession in both Canada and Australia has mostly welcomed the adoption of this model by the government, because of the perception that it signals a recognition of the importance that is now being placed on the early years. What the early years sector seems to miss in this case is the increased authority such models give to medicine (and statistics in general) at the cost of the legitimacy of early years professionals themselves, in the evaluation of the evidence that it yields and its impact on policy (cf. Vernon-Feaghans et al. 2012).

What are the consequences of missing the significance of the increasing authority of medical science and empirical science generally for the determination of policy in the field of early childhood? The relevance of empiricism as a theoretical construct as it affects educational policy has been registered by writers such as Carol Bacchi (2000); similarly, Gaby Weiner has asserted that the academic community (from which much policy analysis and scientific research are derived) could now be said to fall into two groups:

> There are those researchers and academics driven principally by government research policies aimed mainly at disciplining and controlling educational research, such as research assessment exercises, research council priority programs, and the like, who are also mostly in high-ranking research departments, which means that income is drawn proportionally more from research than from teaching.
>
> I think it is fair to say that this first group is comprised of academics using predominantly empirical research paradigms and who are mainly driven by scientific ideas rather than the more theoretical task of calling a prevalent paradigm into question.
>
> The second group is less likely to be involved in research rankings, being in departments which draw their funding more from teaching than from research. The first group is compelled largely to focus on priority policy areas and is likely to be empirically unadventurous and draw for its theorizing on established disciplines such as sociology and psychology. Those less dependent on research income are less constrained theoretically and empirically and are more likely to draw on cross-disciplinary frameworks, especially women's studies [but in early childhood, this could also include a range of other approaches such as post-structuralism]. Both groups are themselves positioned (although differently) within the performative and surveillance cultures that they are seeking to understand and evaluate, and both offer a [different] critique of the patriarchal status quo This whole section in brackets is a quote from Weiner (Weiner 2008, 290).

I think that early childhood researchers, being often less experienced than educational researchers in general, are doubly handicapped by that inexperience together with the constraints of the surveillance culture that Weiner is describing, which operates throughout the higher education sector internationally. What is important for the future of early childhood research is therefore to provide opportunities for

scholars to challenge the prevailing ethos in order to give more dramatic effect to the kind of contribution they are making to community debate about children and their education.

8.6 The Introduction of Epidemiological Models

While population studies generally provide important evidence about health, patterns of disease, factors contributing to the spread and management of, for example, smoking and cigarette consumption on workplace productivity, etc., their utilization is comparatively invalid when the unit of analysis is an individual. Problems that vary from one individual to the next pose a special theoretical difficulty that statistical methods will inevitably overlook, likewise for epidemiology in general. It is only valid to apply constant or universally valid markers of development to the study of an individual's learning process, where it is reasonable to deny variations between individuals. In the arena of policy production, it is often unreasonable to determine funding arrangements in the public sector on the basis of objections oriented to the experience of a single individual and which are not common across an entire population. Accordingly, a policy usually stems from population studies, statistical evidence, and epidemiological research.

However even within epidemiology itself, concerns have been raised as to the validity of approaching public sector policy in this manner (Frohlich et al. 2001). This concern is relatively invisible by comparison with the overwhelming tide of new research which assumes population conditions as more critical than conditions that are reported by individuals.

As Keating and Hertzman (two respected Canadian scholars) argue:

> The development of health and well-being is a population phenomenon rather than a purely individual affair.
>
> Particularly striking is the discovery of a strong association between the health of a population and the size of the social distance between members of the population…in societies that have sharp social and economic differences among individuals in the population, the overall level of health and well-being is lower than in societies where these differences are less pronounced. (1999, 3)

This sense of "sharp" differences comes across even more distinctly as a divided social and communal space, when they describe the "central paradox of economically prosperous modern societies:

> on the one hand, material abundance and the ability to generate wealth unimaginable even by our recent ancestors; on the other hand, grave concern about the deterioration of the quality of the human environment required for high levels of developmental health and about the consequences of this deterioration as seen in increasing developmental problems among children and youth. (Keating and Hertzman 1999, 15)

Others such as Fraser Mustard echo this warning, declaring that the quality of early childhood development has become a matter of tremendous importance for the establishment of "stable, prosperous, and equitable societies" and indeed "for the

survival of our species" (Mustard in Mustard et al. 2007, 11). Each of these examples poses instances of the resolution of broad, population-based issues. The attention that such reporting has enjoyed at the level of government over the past three decades cannot be underestimated, especially given the parallel intensification of research about family policy and the ways in which early years provisions are perceived as an index of economic viability (cf. Lowenstein 2011).

8.7 Tension Between Professionalization of Early Years Services and Costs of Provision

Since in some instances of the early childhood sector the predominance of women within the profession is absolute (in Australia to take only one example, 98% of the early childhood sector workforce is female), policymaking in the early years is significantly informed by economic research about the inclusion of women in the workforce (OECD 2007; Lewis and Giullari 2005). Both the demand for childcare places (which is intimately related to whether or not a mother is in paid employment) and the provision of qualified childcare staff to undertake the service of childcare (in jobs dominated almost exclusively by women) are factors that directly lead early childhood education policy studies back to the question of female workforce participation.

On one hand, this means that as more women join the workforce, gravitate upward in socioeconomic terms, i.e., income, they increasingly regard childcare not only as a necessity enabling them to earn a salary but as a mark of consumer choice and status (Conley 2010). On the other hand, this also means that policy must come to terms with the increasing cost of childcare services when the quality of intervention, education, care, and transition arrangements escalates in correlation with the commercialization of those products (Brennan 2007).

One of the most significant issues that policy writers attend to in the "mix" of factors here is the increasing medicalization of intervention services, which means that parents are increasingly effected by community concern about the quality and provision of care, as well as the ever-higher profile of children's illness, developmental progress, delay, and success. The sheer proliferation of measurement instruments and their dissemination and consumption within the community at a variety of levels contributes enormously to the complexity of early years services as a new market in Western economies. Kirp (2007) reports the volume of private fees paid for childcare in some wealthy communities as increasing at rates that compare with much more traditional commodities like mineral resources.

When combined with the pressure to distribute childcare services evenly across the population and to keep costs for individual parents low enough to balance workforce participation with the consumption of those services, the additional pressure to train childcare professionals to a high level and to then pay them in accordance with their qualifications often proves to be a bridge too far for policymakers and treasury officials.

8.8 Summary

Policy research in the area of early childhood care and education remains a smaller component of the overall volume of academic and scientific research conducted in the early years sector, precisely because most of the research that is done in the sector is understood as the development of scientific evidence. Following on from the point raised by Weiner, however, there is a systemic relationship between the priority given to certain forms and methods of research and the way these studies inform policy, meaning that the institutions within which research is sponsored drive the production of statistical evidence that can be used in policy production. By dint of this logic, less priority is given to policy analysis that merely comments on or criticizes the historical context of policy implementation.

Again, this also discloses the basis for the higher value placed on measurement of children's development, practices to augment that development, and criteria for improving the quality of services and to thereby ameliorate risks. While some professionals and practitioners in early childhood may apprehend the priority of these knowledges about human development as a "good" in themselves that aids and benefits young children, the broader picture is one of producing images of child development in order to meet a hidden agenda oriented to economic prosperity and the production of capital.

In the same manner that early childhood practitioners are themselves made instrumental to the production of human capital in this manner, it is likely that policy research in this sector will continue to be dominated by writers external to the early years profession itself, which focuses on the delivery of services rather than on their analysis and evaluation.

However some of the issues that will arise over the coming decades that will necessitate a broadening of the scope of research that early years researchers engage in themselves include the nature of an expanding and changing labor market. Research about policies in this area may additionally consider the increasing intersection of problems in the staffing of childcare services, the delivery of quality and the competing concerns raised by their commercialization, and the geographic distribution of services to different strata of a given community.

OECD research tends to indicate that at a global level the sector is becoming concerned with the broader issue of regulation of the family as a basis for social and economic cohesion. The impact of globalization in economic and educational research requires the reporting of social factors that characterize the gap between developed and developing economies. The field of early childhood education policy is concerned with the ways in which education for young children in different economic settings will determine subsequent social and economic performances. The management and implementation of Global Millennium Development Goals (MDGs) constitute a chief measure of the impact of globalization on early childhood education policy, because it represents a benchmark for delivery of infrastructure and services in developing economies. Each of these matters is likely to feature more prominently in policy debate in the future, enabling the field of policy research

to deepen and to offer more challenges to the way it informs and shapes government perspectives in the sector.

8.9 Document Research and Analysis

8.9.1 What Is a Document?

There are two broad perspectives about the way to best define a document which are addressed in this chapter:

1. In early childhood education, the notion of a "document" is ordinarily taken from an empirical perspective for the purpose of research. In other words, a document is usually apprehended as an idealized "thing." To say that a document is idealized means that a document does not comprise different forms and that its form is stable and unchanging. It also means that from an empirical perspective, a document is something that can always perform the same function. For example, a document can be accessed for the purpose of reading, i.e., it is a text, which may be produced in the form of a book, journal, magazine, a motion picture, or photograph; it could be a virtual file downloadable from the Internet or stored on a computer, a government file or publication, school, university, or other institutional policies; or for historical purposes, it may be an archival artifact such as a diary or an enrollment record. None of these descriptors are exclusive, and there are many other items that might constitute a document. In each case, the key characteristic of a document is its function as a text: the item is something that can be deciphered or read, often as a form of literature.
2. However, from a theoretical perspective, to take the document as an item that can be read in each and every case is always to idealize a document in terms of the assumption that documents exist in the broader cultural context of written language and a literate society. In other words, to apprehend the document as a historical artifact means that its idealization is itself a cultural practice, and, accordingly, it would be necessary to acknowledge that documents are historically mutable or unstable. This observation attends to the possibility of making an artifact function as a text.

Documents are records of a literate culture, and it is a significant theoretical risk to impute legibility to an artifact that may not originally function as a document but does so purely for the sake of research, e.g., a tool or instrument may provide documentary evidence or be necessary for the sake of substantiating a claim of evidence with respect to a research investigation. However, researchers should be wary of presuming that documents always carry certain characteristics of literate culture. The question of treating an artifact of an investigation as a document is a matter of placing the item within a category without first defining or considering the cultural context in which it was generated; if an artifact can safely be regarded as a text, it

may be necessary to consider its original context in relation to the broader issue of what a literary society is or how literary culture impacts on a given research discipline. These precautions are fundamental to the undertaking of document research, especially for those scholars seeking to acknowledge the ontological premises on which the notion of a document has been generated.

The critical basis for considering the ontological premises of a "document" is the risk that documents may be taken naively as a form of "information" (Buckland 1997). In such cases, the document as information loses much of its historical context and structure, and the content of a document is more easily made transcendent of the concrete form of the document itself. This may mean that documents are understood as generic sources of information and that as such, the "truth" value of the "information" is fixed by the way it is used to verify historical events or professional practices.

The problem that underlies these issues about the truth of a "document as information" stems from the question of how reality is understood and the presumption of an experience of reality is assumed. To read a document is taken naively as a form of sensate experience, one in which writing on a page or screen, for example, can be visible to a human eye and decipherable by a literate individual. In most cases, empiricism would lead a reader to assume that the writing means the same thing to any person who reads it, since the letters are codified and always "read" in the same fundamental manner.

However, when seen in the context of literary theory, a document as text (rather than as a document as information) is always subject to interpretation, and despite obtaining a certain function that usually corresponds to the writing being deciphered, texts also possess a different level at which they cannot be directly experienced. From this perspective, the text is largely imperceptible (Derrida 1981). The point here is that if a document is taken as information, its content is relatively transparent, and one possible consequent implication of seeing a document as information is that the author's intentions are conveyed by what is written on the document. However, if a document is understood hermeneutically, i.e., within the context of a literary genre or style, as having a historical setting and of possessing qualities that emanate from the cultural practice of a language, then the meaning of the words written on the document is not exhausted by any initial reading. Multiple interpretations of a text will in this case reveal many different ways of understanding the content and lead researchers in a very different direction that is derived from empirical assumptions. In the latter case, the experience of a document is not purely sensate but is also more or less related to the functions of the text as a sign structure (Spivak 1988).

8.9.2 What Is Document Research?

In accordance with these two perspectives, document research can comprise a range of different practices, depending on the theoretical framework and methods of analysis adopted in any given case. The most general examples of empirical research utilizing documents in early childhood education will take account of the fact that documentation of children's development by researchers and professionals in the childcare sector is a routine aspect of understanding and recording children's learning.

Early childhood education researchers will undertake historical research using documents in which the document as artifact is treated as if it truthfully reflects real events and that interpretation of the document is not complex and does not usually lead to multiple interpretations, at least to the extent that differences between one interpretation and another are insignificant for the sake of historical study (cf. Press and Wong 2013).

Similarly, early childhood researchers may undertake policy studies, in which reading of statistical data about, for example, patterns of government subsidization of childcare for a population of families, may consist of reading numerical tables and converting results of surveys and questionnaires into algebraic symbols, in order to simplify the information as a variable of the problems involved in distributing subsidies across a population. In these cases, numerical data is usually seen as empirically consistent with the experience of the population as a whole, such that any discrepancies between individual families' experience of subsidization are irrelevant to the purpose and function of the statistics themselves (Heckman 2000).

By comparison much of the educational research undertaken in early childhood concentrates on apprehending the experience of individual children and does not collapse automatically into statistical methodologies. A good example of this is video documentation, which is an increasingly strong practice that corresponds heavily with the kind of routine documentation undertaken by practitioners in childcare, as well as with parents documenting their children's learning (Fleer 2008). There is a compelling argument that the complicity between video documentation as it is undertaken by early childhood researchers and between parents and childcare professionals affords a knowledge production that was hitherto unavailable within and across the intersection of families and institutions in the sector.

At a more technical level, this example of document research discloses the complexity of what a document consists of by deepening the capacity for a document to record a "real-life" situation. Video is a combination of audio and visual recording, which is then frequently reduced by researchers to a written transcription of the recorded events and the dialogue they entail. The document is therefore split into three forms: audio, visual, and written transcript. This fragmentation is already significant in an empirical study, because it discloses different forms of data. However, the breakup of the document into different forms is even more significant when placed in the context of a semiotic analysis.

It may be helpful to the reader to acknowledge further that from an empirical perspective, this form of video documentation assumes (generally speaking) that there is no major discrepancy between what the average viewer of a video will see in playback of the recording and what actually happened in the events the video purports to record and document. Accordingly, the theoretical framework for video documentation aims more narrowly at the analysis of the events that a document has recorded and understanding what they might disclose about a recognized issue or theoretical problem.

In the case of a semiotic analysis however, the need to define language and the way it is assumed to function for the purpose of analyzing the document would be a broader site for situating the document as a product of different factors. These may include attending to how children or adults might be understood as producing speech and the difference between speech and writing. Although early childhood researchers may not necessarily treat language as a natural outcome of being "human," they may instead define language in relation to a human community, especially a language community. When research makes such assumptions, the data produced becomes a document of the way children enter a cultural setting and the significance of language or speech acquisition within that process. The document is in these cases a record of a cultural community in a given place and time. For some researchers, the video as document also addresses the difference between language as a cultural instrument and the ways in which different communities and cultures understand and use language (Gachago et al. 2014; Radford 2000).

8.9.3 The Document as an Artifact of "Discourse"

In order to more broadly address the document in early childhood educational research – for the sake of deepening an understanding of practice and methodologies that involve policy analysis and its utilization of document research, as well as the significance of document study in itself in general for early childhood – I propose to finally draw attention to the term "discourse," which is often used as if it were synonymous with any form of conversation or linguistic interaction among humans. The document is an artifact of discourse in these instances by dint of the assumption that there is a direct and obvious correspondence between human language and the records of any given instance of language use.

However the definition of discourse changes dramatically depending on the disciplinary context in which it is being used: in some cases the notion of discourse analysis is used without proper definition and in the absence of strong theoretical parameters that enable a scholar to substantiate the assertions and conclusions they are reaching in their study. There is a risk of naïve and clumsy approaches among early childhood scholars who adopt discourse analysis as a fashionable approach. This risk is especially important in early childhood study because, unlike other domains of educational research, the object of scrutiny is often a young child whose

capacity for speech is still in the process of being developed and, accordingly, the requirement to define how an analysis of discourse might apply is heightened.

In order to summarize the best way to address these risks, I draw the reader's attention briefly to the question of whether it is safe to regard the individual child from a psychological perspective, in which a general assumption is usually made that each child expresses its own individual will and expresses its own autonomous thoughts and in which decision-making is a skill that the child is always trying to acquire. Each of these attributes is a product of the psychological framework in which most common assumptions about human development are already enclosed. However there are two different, broad approaches to discourse analysis that take quite different perspectives on this issue. I summarize these two dominant uses of "discourse" below:

In the first instance, the discipline of linguistics provides a set of structures through which a given piece of text may be analyzed, for example, a speech recorded in parliament or an article from a newspaper or magazine, which purports to "document" and record the details of a historical event. But what are the theoretical premises of this analysis? In the most widespread example of discourse analysis, the production of meaning can always be traced back to the mind of an interpreter of language.

Contexts defined as participant definitions, that is, as mental constructs, are able to function as the interface between situational and societal structures and discourse structures, because they subjectively "represent" relevant aspects of situations and society and directly interfere in the mental processes of discourse production and comprehension. If contexts "control" discourse at all, this is only possible when we conceive them as cognitive structures of some kind. And only in this way are we able to define the crucial criterion of "relevance," that is, in terms of a selective focus on, and subjective interpretation of some social constraint as defined by the participants. This also explains why discourse may be influenced by alternative, fictitious, or misguided definitions of the social situation, as long as the speaker or writer "sees" it that way. Thus, it is not "objective" gender, class, ethnicity, or power that control the production or comprehension of text and talk but whether and how participants interpret, represent, and make use of such "external" constraints and especially how they do so in situated interaction (Van Dijk 2006, 163).

From this perspective, the meaning of discourse is defined with respect to a universal capacity of the human mind to understand, interpret, and engage in linguistic contexts, i.e., discourses. But criticism of this theory would focus on the risk that the human mind as such may not be a universal or generic thing and that to treat human discursive interaction from such a premise demands that the mind be fixed and idealized.

However, in the case of a young child who is not yet in full control of these decision-making faculties as they are projected universally by psychology and linguistics, the validity of tracing an utterance back to an individual mind is complicated by the question of whether that "mind" is operational.

Broad criticism of linguistics has already asserted that Van Dijk's approach transforms language into a passive, insubstantial, and malleable thing that has no

force or power over those who use it. Van Dijk's approach is contradicted as follows: humans do not precede the linguistic context into which they are inserted at birth and cannot choose the language they speak as a "mother tongue"; accordingly, language is not simply a tool more or less appropriated by the individual mind or speaker. Young children would not be learning to speak a language so much as they are participating in a cultural practice that is retrospectively interpreted as if the individual child were an autonomous unit or a force capable of wielding speech as a cultural tool, available to exert their own privileged position over nature. Further, the weight and force of language as an instrument for the dissemination of antecedent cultural and political values are reduced and dissimulated, if the individual mind is privileged in the manner proposed by Van Dijk.

By comparison, Allan Luke points to the historical function of these theoretical premises vis-a-vis the industrial purpose of schooling and literacy. He notes, for example, that the very concept of an individual subjectivity (such as the human mind as proposed by Van Dijk, above) satisfied the needs of a capitalist approach to industry and productivity that is now outdated.

Much early and midcentury educational research attempted to define the human subject in ways that individuated difference and thereby focused the attention of successive generations of researchers, curriculum developers, and teachers on a universal, degendered, cross-cultural, cross-linguistic self. This behaviorally skilled citizen/worker was indeed the ideal subject of industrial, Fordist capitalism. By this account, a great deal of psychological research can be viewed as the historical vehicle of a political will toward defining and classifying a generic individual, toward monoculturalism, and toward education for industrial purposes (Luke 1995, 6).

From this "critical discourse analysis" perspective, the individual subject interacts with discourse in a manner that accounts for a range of variables that "discourse analysis" fails to do: the chief among these is the recognition of the subject as an object shaped by different discourses such as gender, race, and class. Language is not simply manipulated by the subject in the process of producing meanings for the words they speak or read, but neither is the reverse true: discourse accounts for the individual user-of-language (the subject) as a site of contestation in which a range of cultural forces are played out. Accordingly, Luke describes critical analysis of discourse in line with the work of Michel Foucault:

> Foucault described the constructing character of discourse, that is, how both in broader social formations (i.e., epistemes) and in local sites and uses discourse actually defines, constructs, and positions human subjects. According to Foucault (1972, 49), discourses "systematically form the objects about which they speak," shaping grids and hierarchies for the institutional categorization and treatment of people. (Luke 1995, 8)

The implications of incorporating critical discourse methods within document analysis include a broadening of the theoretical premises on which educational research can be conducted and allow for a new range of practical outcomes flowing from this form of study. But this approach to "discourse," and by implication, to the document, is only one of those offered in the development of educational research.

If we were to apply these implications in early childhood research, we would begin to challenge and contest many of the psychological premises on which prevailing scientific knowledge of the human child is based. Early childhood education might not simply be an instrument for the delivery and management of safe and healthy human development but a field of study and practice in which families and their children are given opportunities to independently evaluate the aims and objectives of care and education. We might begin to properly reconceptualize education from a new angle, in which the capacity to speak was not automatically treated as a symptom of human nature.

8.10 Summary

While conceding that early childhood education is a relatively emergent academic field in which questions of policy analysis and document research are as yet still marginal to the mainstream forms of study and scholarship, I nevertheless consider the opportunity to be presenting itself in this emergent field to contest many of the mainstream ideologies which dominate educational policy. Due to the tendency to systematically drive early childhood research in accordance with the overwhelming economic priorities of employability and healthy development at a population level, it has been difficult for many within the profession to obtain sufficient distance from the practices in which they are immersed in their daily work and produce an objective image of their function within the system.

But taking a fresh approach to policy analysis and document research may offer at least one angle on how to redress this problem of objectivity and distance. This chapter has examined some key examples of the direction that research in these areas has taken in the first few decades of the field's history as an academic discipline. But historicity cannot be assumed to correspond to a single universal reality, and each childcare professional ought to be equipped with the analytical tools with which to recognize the globalizing effects of international debate about early childhood and family policy. Accordingly, I have highlighted the importance of respecting diversity between cultural settings by questioning the practice of imagining that the text enclosed within any given policy document or historical artifact can be regarded as universally perceptible. We should not be teaching preservice teachers to assume that a document always means more or less the same thing; we should be attending to the fact that the document is itself a point of contestation about discourse itself (Derrida 1976). Within the scope of this chapter, there is insufficient space to delve more effectively into the range of research frameworks emerging from document analysis in this mode, but given the enthusiasm of writers such as Rhedding-Jones (2012), Ailwood (2004), Heydon and Iannacci (2009), and Wood (2004), early childhood education appears to be embracing the new forms of policy and document research with very positive effects.

Chapter 9
A Cultural-Historical Methodology for Researching Early Childhood Education

Marilyn Fleer and Nikolai Veresov

Abstract There are many ways to frame research, and there is a plethora of ways that researchers have theorised and discussed their study designs. In this methodology chapter, we present an overview of researching in early childhood education from a cultural-historical perspective. We specifically discuss aspects of a cultural-historical methodology which are related to play and development in early childhood settings. In this chapter we examine three key points. First we discuss what new perspectives the cultural-historical methodology can bring to the field of early childhood education research. Second, we show what a cultural-historical methodology will allow researchers to do. Finally, we (1) theorise a set of cultural-historical principles drawn directly from Vygotsky's legacy but in the context of contemporary research practices in early childhood education; (2) conceptualise digital tools dialectically, as both a research tool for capturing observations of practices and as a cultural tool for the development of young children, where microgenetic changes are made visible and (3) discuss the doubleness of the researcher, as a participant in the research site and as a researcher collecting data. Through the lens of cultural-historical theory, we examine the contemporary challenges and conceptualisations of researching in early childhood education contexts.

Keywords Early childhood • Cultural-historical research methodology • Digital tools • Doubleness of a researcher

9.1 Introduction

Researching in early childhood education can take many forms, such as sociometrics (Gazelle et al. 2015), mixed methods (Harrison and Wang, Chap. 12, this volume), critical incident techniques (Rous 2015), grounded theory (Thornberg, et al.

2015), case studies (Hill and Millar 2015), action research (Smith 2015), microethnography (Sutterby 2015) or policy research (Peers, Chap. 8, this volume). But what distinguishes one approach from another is how the methods for a particular approach are related to theory. The methodology is key for conceptualising the research process (Saracho 2015). In this chapter, we specifically examine a cultural-historical methodology for researching the learning and development of young children in early childhood education contexts.

As is well known, cultural-historical theory was originally conceptualised by L.S. Vygotsky. In his time, Vygotsky was interested in going beyond the descriptive models and principles that he believed underpinned the empirical methods of investigation that dominated many fields of psychology and education. Focused on behaviours, these methodologies and their corresponding methods sought to describe the behaviours observed. These traditional descriptive approaches have been influential in early childhood research over the years (Saracho 2015), amassing a great deal of data about what young children do and think. The theoretical perspectives underpinning those approaches have been captured through the term developmental research methodologies, and those researchers who have sought to adopt different approaches to researching with a focus on understanding the developmental conditions have been termed postdevelopmental methodologies (Fleer 2014a). This chapter is concerned with the latter only.

Set out in the six volumes of his collected works are examples of methods and principles for researching young children in families and educational settings, where the focus is on understanding development as a sociocultural genesis of human mind. These principles are nestled within a system of theoretical constructs that speak directly to a new way of conceptualising research. Vygotsky (1997b) implicitly introduced through the collected works (Vygotsky 1987, 1993, 1997a, b, 1998, 1999), explanatory models and principles for researching children's development. Foundational to the models and principles is dialectical logic, which has been taken up elsewhere in the theory section of this volume. This chapter should be read in conjunction with the chapter on cultural-historical theory (Fleer and Veresov, this volume).

Researchers in early childhood education have been drawn to a cultural-historical methodology because it not only focuses on development, but it also examines the process of development (Veresov 2014). Here specifically, early childhood researchers have sought to understand the conditions for young children's development (Hedegaard 2008a). Hedegaard (2008b) has termed this a *dialectical–interactive approach* for examining the conditions in which children participate. Other contemporary researchers have framed this as an *intergenerational family dialogue* for capturing family practices that are passed on and imbued with intergenerational meaning (Monk 2014). Still others have sought to capture the *past–present dialectic* for capturing the inseparability of the past and the present cultural practices (Ridgway 2014). In addition, some have sought to create specific conditions for children's development, such as the *educational experiment* (Hedegaard and Fleer 2008), *developmental education* (van Oers 2008, 2012; van Oers and Duijkers

2013), *film-play* (Ferholt 2010), *playworlds* (Bredikyte 2010, 2011; Ferholt and Lecusay 2009; Lindqvist 1995; Rainio 2008) and *transitory activity system* (Hakkarainen 2010), so that specific pedagogical approaches that support children's learning and development can be studied.

There appears to be an international trend to using *digital documentation* for capturing and analysing the developmental conditions of children in everyday life (Adams and Fleer 2015; Fleer 2008; Hao, 2016; Li 2014; March and Fleer 2017) including infants and toddlers (e.g. Johansson and White 2011; Sikder and Fleer, in press), families over extended periods (Hedegaard and Fleer 2013) and across cultures (Chen and Fleer 2015; Quiñones 2014).

In summary, researchers using cultural-historical theory have drawn upon some or all of the principles that underpin a cultural-historical methodology (Fleer 2016), and many have primarily used digital tools as their main method for generating data so that the process of children's development can be better understood (Fleer and Ridgway 2014). However, explicit methodological writing on what might constitute the collective principles and models as a methodology for researching in early childhood settings does not yet exist (exceptions include Fleer 2016; Fleer and Ridgway 2014; Hedegaard and Fleer 2008; Veresov 2014). To address this general gap, this chapter brings together all the principles outlined in the collected works of Vygotsky with examples of data to illustrate these principles in action. This is done to theorise a cultural-historical methodology with the corresponding methods that speak directly to researching in early childhood settings so that the following claim made by Vygotsky is realised:

> Finding a method [and therefore conceptualising a methodology] is one of the most important tasks of the researcher (Vygotsky 1997b, p. 27).

9.2 On Theory and Method

Vygotsky's theory is not just a collection of concepts and principles. What makes cultural-historical theory unique is that every concept refers to a certain aspect of the complex process of development of the higher mental functions. The role, place and interrelationships of all the concepts within the theory become clear in terms of the origins and development of the higher mental functions. Therefore, cultural-historical theory provides a system of interconnected instruments for the theoretical analysis of the process of development in its wholeness and complexity. However, a theory, even a highly developed one, without the method is nothing but just words. Theory without methods is a knife without a handle.

Cultural-historical theory provides a system of concepts which act as theoretical tools for investigating the complex process of mental development and at the same time allows the tools to be used for the investigation of the process of development. Cultural-historical theory includes a "nonclassical" type of method, which Vygotsky originally called the experimental-genetic method.

> The method we use may be called an experimental-genetic method in the sense that it artificially elicits and creates a genetic process of mental development. Due to this, we are able experimentally, in the laboratory, to elicit a certain development… (1997b, p. 68).

First, the experimental-genetic method of analysis was designed to investigate the process of mental development, capturing its dynamics and complexity. Second, this method was based on understanding development as a complex process of qualitative change. This method provided a causal (genetic), not descriptive (phenomenological), analysis of the phenomenon under study. Finally, the method was designed to investigate the developmental conditions of the child. In psychological research, the developmental conditions are often created artificially in laboratories with special experimental settings; however, in educational research, investigators mainly look at developmental conditions existing in the real life of the children within various educational, family and other social and cultural contexts.

The experimental-genetic method was created in (and for) the experimental investigation of development in early childhood and therefore is strictly connected with this age period. The majority of Vygotsky's experiments were done with children. However, the fundamental task of experiments was neither to describe changes or differences in development related to age nor to detect specific psychological characteristics of different ages. The general approach was to reveal the general laws of mental development which lay behind the external manifestations of changes. Early childhood is the most appropriate period in which to investigate this, since at this time higher mental functions are in the process of development. Thus, studies in child development are able to produce results which are important for general psychology and education, since they bring to bear on the experiment grounds for reconsidering general psychological ideas and principles.

An experimental-genetic method involves several principles which together form a system of experimental tools for the study of development. What is essential is that the principles of the experimental-genetic method strictly and directly follow from concepts of cultural-historical theory for the study of the process of development both theoretically and experimentally.

9.3 Principles for Researching in Early Childhood Settings

Each principle of the experimental-genetic method directly follows from the appropriate theoretical concept, and therefore, theoretical instruments and experimental instruments together create a unity as the main components of this concrete research strategy. Both the theory and method create a unity, as originally captured through the term the genetic research approach. Unfortunately, Vygotsky's scientific legacy does not contain a description of these principles. For many years, they were not even clearly formulated in Vygotsky's school. However, they can be "unpacked" and derived from descriptions of various experimental studies presented in Vygotsky's writings (see Veresov 2010a, b, 2014 for an analysis and the formulated

principles of genetic research methodology). In this chapter we use the term cultural-historical method and methodology, rather than the original term used by Vygotsky of experimental-genetic method, as the latter could be misinterpreted in the contemporary context of early childhood education.

Table 9.1 An overview of the key principles used by contemporary cultural-historical researchers in early childhood education

Vygotsky's original methodological principles	Methodological elaboration by contemporary researchers studying young children from a cultural-historical perspective	Examples
Principle of "buds of development" Genesis	Educational experiment (Hedegaard 2008b), genetic research methodology (Veresov 2014), transcending linearity (Fleer 2014a), developmental education (van Oers 2012).	Studying infant–toddlers' development in everyday life (Sikder and Fleer, 2015a), developmental education (van Oers 2008, 2012; van Oers and Duijkers 2013).
The principle of interaction of ideal and present forms Dynamic relation between the child and their environment as a source of cultural development	Wholeness approach (Hedegaard 2008a), dialectical–interactive methods (Hedegaard 2008b), iterative analysis (Fleer 2014a; Li 2014).	The relations between ideal and real forms of small science during collaboration among parents and infants–toddlers (Sikder and Fleer, 2015b); the dialectic between ideal and real forms of "sharing": a cultural-historical study through story acting through imaginary play at home (Hao 2016), and developmental education as shown through the shoe shop example (van Oers 2008).
Principle of dramatic event Drama	Dramatic collision or category (Veresov 2014), capturing change in motion (Fleer 2014a), transitions (Adams 2015; Adams and Fleer 2015).	Study of children and teachers in playworlds (Bredikyte 2010, 2011; Ferholt and Lecusay 2009; Hakkarainen and Bredikyte, 2008; Hakkarainen, et al. 2013; Lindqvist 1995; Rainio 2008), transitory activity system (Hakkarainen 2010), fairy tales (Fleer et al. 2014), film-play (Ferholt 2010) and digital devices (Fleer 2014c).
Principle of developmental tools	Past–present dialectic (Ridgway 2014), intergenerational family dialogue (Monk 2014), keepers of local knowledge (Ridgway 2014). Belongings as a source of development (Adams and Fleer 2016).	Signs for supporting young children's development of emotion regulation (Chen and Fleer 2015), using special toys to develop play complexity (March and Fleer 2017), moving countries: belongings as central for realising the affective relation between international shifts and localised micromovements (Adams and Fleer 2015).

(continued)

Table 9.1 (continued)

Vygotsky's original methodological principles	Methodological elaboration by contemporary researchers studying young children from a cultural-historical perspective	Examples
Principle of sustainable results	Social position of the child changes (Bozhovich 2009) from being a good school child to a school failure (Fleer 2016), motive orientation changes from play to learning as new leading activity (Fleer 2014b).	Longitudinal study of children's learning, development and play (Hedegaard and Fleer 2013), Golden Key schools (Kravtsov and Kravtsova 2010).

Adapted from Fleer (2016) and Veresov (2014)

We draw upon the work of Veresov (2014) and Fleer (2016) to bring together in Table 9.1 a snapshot of these key principles but in the context of contemporary research practices in early childhood education. We have limited our presentation of examples to those who have directly used Vygotsky's original conceptions of development and who have sought to research from the insights gained from cultural-historical theory. This table is followed by a detailed discussion of each of the principles, where further comments are made in relation to contemporary research practices in early childhood education. These principles taken from Veresov (2014) are reproduced here specifically for discussing cultural-historical research methodology for early childhood education.

9.3.1 Principle of "Buds of Development"

The principle of "buds" follows from two important theoretical positions which reflect the character of mental development. First, the process of mental development

> …is not confined to the scheme "more-less," but is characterized primarily and specifically by the presence of qualitative neoformations that are subject to their own rhythm and require a special measure each time. It is not correct to assume that all development is exhausted by the growth of these basic, elementary functions which are the prerequisites for higher aspects of the personality (Vygotsky 1998, p. 190).

Second, mental development is not a linear, homogeneous process. Simultaneously, there are different levels of development of different psychological processes and functions in the child. In each period of development, there are functions which are already matured (developed) and there are functions that are in a

process of maturation. So there is always a complex nexus of (1) functions that have not yet developed, but which are in the process of development; (2) functions that will develop but are currently in an embryonic state and (3) developed functions. Metaphorically, they could be defined as "buds", "flowers" and "fruits" of development (Vygotsky 1935, p. 41).

This methodological principle orients a researcher to focusing on defining the empirical/experimental study as a general question from that of "What psychological process am I going to investigate in my experimental study?" to the specific question of "Which stage of development is the process/function in?" To put it simply, development in existing or specially created conditions becomes the basis of empirical/experimental study. The study should begin with revealing that the function under study is on its "bud" (embryonic) stage and is not yet developed. It does not make any sense to study existing developmental conditions or to organise specially created developmental conditions when the function is already developed. That is, the function under study is in the "fruit" state. On the other hand, it makes no sense to study the function which does not yet exist in child's mind. The principle of "buds of development" helps the researcher to avoid these extreme poles.

This methodological principle orients concrete research programmes to identify not the objects under study, but rather the process under study, the process of the development of higher mental functions in the child, especially by purposely trying to construct them. Examples of this methodological principle can be found in the work of Bert van Oers. In the famous study of children role-playing being in a shoe shop, van Oers (2008) created the research conditions that allowed him to study the process of development, where he was able to focus on the "buds of development" as they were in the process of developing. Through children role-playing setting up a shoe shop, the children in his study encountered a problem during the process of greeting their customers, fitting them with shoes, and finding relevant sizes and colours. The children did not have a system for storing different-sized shoes or colours in boxes. Rather, they had to open each box to find the correct colour and size of shoe for their customer. In the context of early childhood education, the young children's development of mathematical reasoning, problem solving and classification had not yet developed into the mature form. Van Oers (2008) created a research study that documented the mental character of the children during the process of role-playing and examined how their mental development changed as a result of the problem formulation and the process of finding and enacting solutions. The study made visible the complex nexus of functions that had not yet developed, but which were in the process of development. The study design by van Oers (2008) allowed him to ask questions about the children's existing development and to study closely how both the problem formulation and the use of symbols changed the children's practices and how this in turn supported (or not) the development of mathematical competencies, competencies which his study showed were initially in an embryonic state.

9.3.2 The Principle of Interaction of Ideal and Present Forms

This principle follows from the idea that in contrast to traditional psychology, which describes the development of the human mind as a process influenced by two main groups of factors (biological and social), cultural-historical theory defines social environment not just as a factor but as a source of development.

> The social environment is the source for the appearance of all specific human properties of the personality gradually acquired by the child or the source of social development of the child which is concluded in the process of actual interaction of «ideal» and present forms. (Vygotsky 1998, p. 203)

This quotation features two theoretical concepts related to development: the social environment and the interaction of ideal and present forms. We illustrate their developmental content through an example of the origins of the pointing gesture in the child. This example by Vygotsky shows the essence of the process of cultural development expressed in a purely logical form (Vygotsky 1997b, pp. 104–105). In the beginning, the pointing gesture of a child is merely an unsuccessful grasping movement aimed at an object. When the adult comes to the aid of the child and comprehends his or her movements as a pointing gesture, the situation essentially changes. The child's unsuccessful grasping movement gives rise to a reaction not from the object but from another person. The original meaning of this unsuccessful grasping movement is thus imparted by others. Only afterwards does the child himself or herself begins to treat this movement as a pointing gesture. Here, the function of the movement itself changes: from a movement directed towards an object to a movement directed towards another person; the grasping is transformed into a pointing. Thus, the pointing gesture first begins by movement that is understood by others and only later becomes a pointing gesture for the child himself or herself.

The grasping movement is a kind of primary form which, from the beginning, interacts with the "ideal" form (the adult's comprehension of the movement as a pointing gesture), and this creates the moving force for the grasping action to transform into a pointing gesture. In both examples, social interaction as a source of development exists as a process of interaction of the ideal and present forms. The development of any higher mental function in the child is impossible without the interaction of the ideal and present forms. The grasping movement never becomes the pointing gesture without an adult.

There is no development if there is no interaction between the ideal and present forms. This methodological principle orients the researcher to focus on the study of developmental conditions in two interconnected ways. First, it orients the researcher to the identification of what are the actual ideal and present forms within the research design, and second, it focuses the design on the identification and analysis of how these ideal and present forms interact in existing or specially created developmental conditions. In some cases, the creation of experimental ideal forms and organisation of an interaction of ideal and present forms is in itself the developmental condition.

In returning to the research of van Oers (2008), it is possible to notice that the teacher has introduced the ideal form by suggesting the use of symbols to mark each

of the shoe boxes. In this study, it is therefore possible to see how the present form of the children's development (as discussed in relation to Principle 1) interacts with the ideal form. Looking at shoe boxes in a real shoe shop gives the ideal form of the symbol and gives the idea of classifying and storing boxes for easy retrieval, thus solving the problem. As with the example of the pointing gesture, first the movements of the children in the role-play of interacting with their customers created a primary form of a problem, but it was through the teacher noticing and the teacher's comprehension of the children's inefficient actions that she was able to orient the children to the need for symbols. That is, the use of symbols changed the way the play took place. A further example can be found in the work of Hao (2016), who closely studied a mother and daughter at home role-playing. The child held three candies and wanted to give each of her two toys a real candy as part of her game. The child also wanted to keep more than one of the candies for herself, and the game distressed her, as she didn't know how to share the candies to continue with the game. The child was originally oriented to the objects – the toys and the candies. It was through the mother's comprehension of the situation, where she instructed her daughter on sharing out different tasting candies by cutting them, that the present form of the child's development was oriented to the mathematical concept of division (ideal form). The interactions between the present form and the ideal form (division) changed the child's actions and allowed her to continue her play. In both examples, it is therefore possible to study the present form of the children's development (as discussed in relation to Principle 1) during its interaction with the ideal form (mathematical symbols; mathematical concept of division). This principle included in the study design allows the researcher to study the conditions of a child's development.

9.3.3 Principle of Dramatic Event

The principle that follows comes from two interconnected theoretical positions. The first is expressed in the following requirement for a specifically designed experimental study:

> Processes must be analyzed, and through analysis, the true relation that lies at the base of these processes, behind the external form of their manifestation, must be disclosed. (Vygotsky 1997b, p. 70)

The keywords here are "the true relation". Yet, what does it mean to disclose the "true relation", and what kind of relation is this "true relation"? The general cultural-historical law of cultural development gives the answer. Here is the formulation of the general cultural-historical law:

> …every function in the cultural development of the child appears on the stage twice, in two planes, first, the social, then the psychological, first between the people as an intermental[1]

[1] In Russian original it is interpsychological (интерпсихическая) and intrapsychological

> category, then within the child as a intramental category…Genetically, social relations, real relations of people, stand behind all the higher mental functions and their relations. (Vygotsky 1997b, p. 106)

Three points are important here: First, higher mental functions do not appear IN social relations, but AS social relations; every higher mental function was external because it was social before it became an internal strictly mental function; it was formerly a social relation (Vygotsky 1997b, pp. 105). Second, even in being transformed from interpsychological to intrapsychological, "they remain quasisocial" (Vygotsky 1997b, p. 106). So, "intrapsychological" is social by its origin and construction. Third, there is one more aspect in the relations between "interpsychological" and "intrapsychological" functions which highlights a complex and dialectical character in the process of development:

> The basic principle of the functioning of higher functions (personality) is social, entailing interaction of functions, in place of interaction between people. They can be most fully developed in the form of drama (Vygotsky 1929b/ 1989, p. 59).

The social, interpsychological form is a dramatic interaction between people; interpsychological drama is conceptualised as the dramatic social relation, and it is through the drama that the true relations as mental processes become disclosed (see Fleer and Veresov, this volume, for further theoretical elaboration of this concept).

This principle orients the researcher to discover or to design social collisions, dramatic events in children's social environments, which are turning points for their individual developmental trajectories. This might be in a real-life situation related to periods of transition, such as when a child starts school, where a potential crisis emerges, or during specially created conditions, such as dramas in fairy tales (March and Fleer 2017), dramatic story narratives (Hakkarainen 2010), playworlds (Lindqvist 1995) and many others. Such socially engineered critical moments of "small dramas" where transitions from interpsychological to intrapsychological takes place provide very rich empirical data where these transitions are made visible and analysable. These dramatic moments or crises as discussed by Vygotsky can also be in relation to a change in motive orientation, as we might see when a child's activity and orientation changes from primarily wanting to play to wanting to learning where the child enters into new social relations with others.

We can see this principle of dramatic events through the research of Lindqvist (1995). She used drama pedagogy to introduce young children to imaginary situations created through the story telling and acting of story books, folk tales, etc., but where the story line held dramatic moments or collisions. Through the children together with their teachers, entering into the imaginary world, or playworld of specific books, children encountered problems they had to solve. These events were usually emotionally charged and were always dramatic. The research of Lindqvist (1995) and those that have followed (Bredikyte 2010, 2011; Ferholt and Lecusay 2009; Hakkarainen 2010; Lindqvist 1995; Rainio 2008) focused on how these dramatic events supported the development of play, and through playing out the prob-

(интрапсихическая) (Vygotsky 1983, p. 145).

lem situations, this changed the collectively united social relations between children and teachers in the dramatic events (interpsychological), and which acted as the source of children's development as they took on the characters and solved the problems themselves (intrapsychological). Through social relations, children are collectively oriented to the playworld (interpsychological), but as they enter into the imaginary situations and solve problems as part of these dramatic events, the intrapsychological development of the children becomes established over extended periods of time. The playworlds research takes place over a term or even a full year, and children continue to go on adventures, meeting more dramatic moments and problem scenarios that they must solve in play. By studying the dramatic events (Principle 3), the researcher is tuned into not just the present form of development, but also the maturing functions that are in the process of development (Principle 1).

9.3.4 Principle of Developmental Tools

This principle is strictly connected with the concept of sign mediation, which is rightfully considered as one of the core ideas in cultural-historical theory. Even more, for many experts, this concept is a kind of distinguishing feature of cultural-historical theory. In Vygotsky's writings, we could find various examples of sign mediations such as knots for memory, drawing straws in case of two equal stimuli and many others. He even listed a number of examples of systems of cultural signs: "language; various systems of counting; mnemonic techniques; algebraic symbol systems; works of art; writing; schemes, diagrams, maps and mechanical drawings; all sorts of conventional signs and so on" (Vygotsky 1981, p. 137).

However, signs and mediation were known and had been studied in psychology long before cultural-historical theory. Vygotsky's specific approach to signs and mediation was essentially new; cultural signs and mediation were analysed from the point of view of their role and place in the process of mental development. The cultural sign (or system of signs) is seen as a developmental tool.

The development of the human mind is not a biological but rather a cultural-social process. The transition from the biological to the social path of development is the central link in the process of development, a cardinal turning point in the history of the child's behaviour (Vygotsky 1999, p. 20). The psychological essence of the sociocultural path of development is that:

> … the basic and most general activity of man that differentiates man from animals in the first place, from the aspect of psychology, is signification, that is, creation and use of signs. Signification is the creation and use of signs, that is, artificial signals. (Vygotsky 1997b, p. 55)

Therefore, sign and sign mediation obtain an extraordinarily important role in mental development. Reorganisation and transition are two important aspects of the process of development that the concept of sign and the principle of sign mediation are related to.

Cultural signs and sign mediation are essential for the process of qualitative reorganisation of the psychological functions in a course of development:

> The sign as a tool reorganizes the whole structure of psychological functions. It forms a structural centre, which determines the composition of the functions and the relative importance of each separate process. The inclusion in any process of a sign remodels the whole structure of psychological operations. (Vygotsky 1929a, b, p. 421)

Every new structure of mental functioning is the result of its remodelling, the product of sign inclusion. Using Vygotsky's terminology, a new structure is a "fruit of development". However, Vygotsky's methodology is not focused on "fruits"; it is directed on the analysis of the process of development, that is, the transition "from buds to fruits". This leads to the second aspect of the process of development that the concept of sign is related to, that is, the aspect of transition.

Mental development as a process is a "transition from direct, innate, natural forms and methods of behaviour to mediated, artificial mental functions" (Vygotsky 1998, p. 168). The sign (or system of signs) originally exists as an external tool, and later it becomes a tool of internal mediating activity. What is important is that the sign (external tool of activity) should not be given by the experimenter to the child directly. The processes of active searching and finding a sign, as well as the reorganisation of the whole unit and the transition from direct connections to indirect (mediated) connections, were the focus of Vygotsky's experimental studies of the origins of mediating activity.

This principle orients researchers to study the process of child development in three interrelated ways, depending on the research question. First, it allows for the study of different cultural tools existing in different cultural and historical settings from the point of view of their developmental potential and efficiency. Second, it allows for the investigation of the existing or specially designed situations of transitions of a child from direct to mediated activities at different stages of development. Third, it provides for an opportunity to study key aspects of the reorganisation of the whole system of child's mental functions in everyday or specially designed situations, where the child begins to use or create cultural signs as external tools which become internal psychological tools.

The principle of developmental tools can be shown in the research of Chen, who followed children during emotionally charged moments in everyday life contexts in order to study how families support their children to self-regulate. Her study examined the signs used by families, such as, the time-out chair, for supporting young children's development of emotion regulation (Chen and Fleer 2015). She made video observations over 3 months in the home and community during moments of transition. The sign (or system of signs), such as the time-out chair, originally exists as an external tool to direct the child. The time-out chair is used in the process of transitioning from direct emotional expression to mediated action through sitting on the chair and being asked to relax. This is the system of signs, which together mediate the child's emotions and behaviour. With repeated mediated support by the parents, the child engages in a transition from direct, innate, natural forms of expression of emotions and methods of behaviour surrounding the emotional state, to a medi-

ated, artificial mental function of self-regulation. The video observations capture these moments and give the researcher the opportunity to analyse closely signs and potentially a system of signs, which together support (or not) self-regulation. In Chen's study, she examined the cultural signs being introduced by families. The cultural signs, such as the chair, act as a mediating tool for families to support their children to self-regulate.

9.3.5 Principle of Sustainable Results

This principle of cultural-historical method reflects the results of development. Continuing Vygotsky's metaphor, we could say that the results are "fruits" of development. However, these "fruits" are of very special nature. The result of development is not just new functions that appeared as outcomes at the end. Results of development are not new higher mental functions only, they are "qualitative neoformations" (Vygotsky 1998, p. 189). "Neoformation" is the result of the reorganisation of the whole system of functions, a new type of construction of the child's consciousness and mental functions (Vygotsky 1998, pp. 190). This new type of construction is the result of a qualitative reorganisation of the whole system. Actually,

> Higher mental functions are not built up as a second story over elementary processes, but are new psychological systems that include a complex merging of elementary functions that will be included in the new system, and themselves begin to act according to new laws. (Vygotsky 1999, p. 43)

Thus, not a new function, or even a new higher mental function, but rather a qualitatively new structure of functions characterises the result of development.

The principle of sustainable results in relation to the research of the process of development means that the results of the research must not simply be statistically valid changes but rather a new quality. Therefore, an experimenter has to have enough supplementary means to investigate what type of changes happened during the experimental study to make sure that the changes reflect the new system (new structure) that appeared.

This principle is evident in the research of Hedegaard and Fleer (2013), who investigated the development of children from four families over 12 months as they participated in everyday activities at home and at school. Through video observations of the Australian families engaged in everyday practices, the children were followed rising in the morning, meal times, walking to school, being at school, walking home, bedtime routines, homework and play activities over two school years. The societal values, institutional practices of the home and school, and the intentions of each child were analysed holistically. Small, everyday transitions were captured in the video observations, and these observations of the same activity setting (e.g. breakfast) over different periods allowed for an analysis of the social relations, participating activities and the child's social situation of development over

12 months. Following the children from each of the families over an extended time period gave the possibility of seeing if and how children's social relations changed, how their social position changed, such as from being a child in the family to being a school child on entering school (Bozhovich 2009). Possible changes across time, alongside of studying the microgenetic transitions experienced, gave the possibility to notice qualitatively new structure of functions which characterise development. This development becomes visible through the new social relations. Determining the reorganisation of the whole system of functions is possible in a study design that extends over a long period of time. Over time it is possible to see sustainable change, such as a change in motives from play to learning as might be observed in the context of free play settings, where the teacher organises environments for both play and learning. This change in motives can signal to the researcher the child's development.

Summary In this section we have examined the five principles drawn from Vygotsky's cultural-historical theory and illustrated these principles through examples taken from contemporary research. What is evident is that a study design when theorised may not specifically draw upon all five principles, but rather it may only use one. What is key is which principles open up the possibilities for designing a study that uniquely answers the research questions being posed. A research question about sustainable results, as we saw for studying children's development and play in everyday life over 12 months (Hedegaard and Fleer 2013), is very different to following a family during times of transition over 3 months (Chen and Fleer, 2015). Sustainable results can be determined through the former study design, but not easily through the latter. Researchers like Chen rightly draw upon only two principles: the principle of the ideal and real forms of emotion regulation (Principle 3), and the dramatic collisions or small moments where families support their children to self-regulate in everyday practices (Principle 3). Contemporary research also introduces other research needs and makes available new cultural tools that were not available in Vygotsky's time. In the section that follows, we focus specifically on the contemporary context of researching early childhood education to discuss new developments for a cultural-historical methodology.

9.4 Contemporary Challenges and Conceptualisations of a Cultural-Historical Methodology

In this section we move from an examination of the foundational principles of a cultural-historical methodology as conceptualised by Veresov (2014), and as derived from the originally methodology of Vygotsky, and introduce contemporary challenges and conceptualisations specific to early childhood education research. Research is not only about objects or processes under study, but it is also about conceptualising the research tools and the position of the researcher in the research process. This section addresses the challenges associated with new practices in research and the conceptualisations made possible through cultural-historical theory.

We specifically discuss in the first part of this section the digital research tools, where we introduce the idea of tools not just for collecting data, but also as cultural tools for children's development. What have emerged in recent times are an awareness and a new practice of using digital tools for early childhood education research. There are two key aspects associated with the practices of using digital devices as research tools:

1. From a cultural-historical perspective, digital tools can act as both a research tool and a cultural tool for children's development. This is because young children already use these tools in their everyday lives. This is a dialectics relation, because the digital devices act as both research tools to capture children's development, whilst at the same time they are cultural tools that develop the child. Other theoretical perspectives take the research tools and cultural tools as separate domains of practices in the research process. Cultural-historical theory allows for the dialectical conceptualisation of the digital technologies as both cultural tools and research tools. Not every research tool is a cultural tool, and not every cultural tool is a research tool, but digital tools can afford this double possibility, when conceptualised from a cultural-historical perspective. But this double possibility disappears when digital tools are only used for collecting data.
2. When conceptualising digital tools as cultural tools, it makes it possible to create and analyse developmental conditions, which afford microgenetic changes and which can be captured through the digital tools because they have been deliberately made visible.

These two aspects of using digital tools, when conceptualised holistically, show the dialectical nature of digital tools from a cultural-historical perspective. This idea is taken up next, in the context of the historical and contemporary research needs associated with early childhood education.

9.4.1 New Cultural Tools for Researching in Early Childhood Education

In line with the foundations of a cultural-historical methodology, we know that the contexts for researching in early childhood education have historically changed over time. In the example of play, we know from the theoretical work of Elkonin (2005), who examined anthropological studies and excavated artefacts from archaeological digs, that the phenomenon of children playing was culturally and not biologically constructed. This he argued was due to the changing societal conditions, where new technologies meant that children could no longer, for example, simply use digging sticks or their hands to dig soil and plant seedlings in order to contribute to economic sustainability of families. Rather, children needed to practice using tools (e.g. fire lighting), usually miniature objects (e.g. string and stick spinning tops), and later toys (spinning tops), so that they gained the necessary skills and competencies to manage the tools of particular cultural communities, so as to

continue to contribute to the family's survival. Both resources (e.g. toys) and time to practice/play with these objects were supported in the communities at that time, thus introducing the phenomenon of children's play in some societies.

This example from Elkonin (2005) illustrates how the technologies in society create new societal needs, such as the development of toys and the conception of play as an activity of childhood, which change the cultural practices of families. As such, particular communities and societies value particular play practices by giving resources and time to play. New needs in contemporary times also create new practices, which societies or communities need to research. This is introduced here to illustrate how new practices and societal needs create new research problems – as was shown in the introductory chapter to this volume (Fleer and van Oers, Volume 1), where countries in the south were worried about how to introduce play practices in formal learning institutions, and countries in the north were worried about preschools becoming too formal, leading to the research problem of "What is the relations between play and learning?"

New problems may also create the need for new research tools. However, new tools, such as readily available digital video cameras and digital data storage and processing, also create new possibilities for research that were not readily available in Vygotsky's time, opening up new ways of researching that also require theorisation. We need to examine this contemporary research context in order to illustrate the dialectical nature of digital tools from a cultural-historical perspective.

It can be argued that the introduction of new technologies in research, such as digital video tools, has created new research conditions for early childhood education (e.g. Johansson and White 2011). For example, mounting action-cameras onto the heads of infants, so as to closely follow the gaze of infants in order to determine what they pay attention, at the same time as following what adults do, so that a close study of interactions is now possible. White et al. (2007) argue that this kind of research is not about the breadth of coverage, as this is only glimpses of what infants pay attention to, but rather it is about gaining a depth of understanding about the nature of the collaborative enquiry in which meaning is ascribed by infants to what they engage with and for how long. The new cultural tools available to researchers have allowed for new kinds of research questions to be asked because tools now exist which enable early childhood education researchers, rather than laboratory-based researchers, to examine real-world contexts in which young children, including infants, engage. Intersubjectivity between children/infants and educators in the context of formal and informal settings can now be studied in new ways. This has also created a new theoretical need for researchers, as a cultural-historical methodology as discussed in the previous section does not say anything about these new cultural tools. As such, this has opened up new methodological discussions (Fleer and Ridgway 2014). This is conceptualised methodologically in Table 9.2 as a new cultural-historical principle for researching in early childhood settings. Key here is how digital technologies allow researchers to capture both the dynamic and dialectical relations that occur naturalistically in early childhood settings, but also how they can contribute to research because children also have available to them new cultural developmental tools. The latter has been shown explicitly in the context of research

Table 9.2 New conceptualisations of digital tools for researching in early childhood education

Cultural tools for capturing the dynamic and dialectical relations in early childhood settings	Digital video tools have created new research conditions for early childhood education (e.g. Johansson and White 2011; White et al. 2007).	Theorising these new methods from a cultural-historical perspective has emerged (Fleer and Ridgway 2014; Hedegaard and Fleer 2008; Johansson and White 2011).
Cultural tools for analysing the dynamic and dialectical relations in early childhood settings by following the intentions of the participating persons.	New cultural tools for capturing in situ moments of intersubjectivity in everyday practices of early childhood settings.	For example, Johansson and White (2011); White et al. (2007).
Cultural developmental tools that create new play conditions through dialectical virtual and concrete play contexts.	Digital pivots and virtual placeholders: digital tools support children in their play so that they can capture digitally their own play activity (Fleer 2014c).	Fleer (2014c)

that uses software programs and digital devices that support children in their play so that they can capture digitally their play activity (Fleer 2014a), and uses the digital medium to produce movies of play practices where they change the meaning of actions and objects virtually (virtual placeholders and digital pivots) (Fleer 2014c). This is also reflected in Table 9.2.

There have also been other methodological developments noted in the literature in relation to researching from a cultural-historical perspective in naturalistic contexts, such as family homes. As was discussed in the introduction to this section, research is not only about the object under study or research tools, but also about the position of the researcher. In the next section, the position of the researcher from a cultural-historical perspective is discussed. This was a dimension of research that was not explicitly detailed by Vygotsky. The key question is "What role does the researcher take in the research process?"

9.4.2 The Doubleness of the Researcher

In line with Vygotsky's discussion about the need to include in research how the research process is set up, and also the nature of the researcher–participant interaction, Hedegaard (2008c) has introduced the concept of the *doubleness of the researcher* in order to theorise a more holistic conception of research. This concept captures the idea that the researcher is always a participant in the research, not as a fly on the wall disengaged from the participants, or as someone who actively plays with the child, for example, as might be seen in more anthropological studies where the researcher becomes a member of the community, but rather, the researcher takes on a double

position. That is, the researcher is both a person in the research context, interacting with the child when needed, such as if the participant wishes to show the researcher something, and also explicitly the researcher with a particular role that is made clear to the participants. Hedegaard talks about the specific role and gives the example of the participants naming her as "their researcher" when she accompanied them into a school context when following the daily lives of children growing up in Denmark (Hedegaard and Fleer 2013). This concept has been elaborated by Quinones (2014), who has made visible in research the affective dimensions of the researcher and the research participant, acknowledging that an emotional relation can also emerge in the process of researching. The emotional nature of researching is an underexamined area, as this has, in traditional research, been explicitly blocked as interfering with the quality of the results. This affective dimension has also been foregrounded in the work of Ferholt (2010) when engaged in undertaking research in contexts where theatre and playworlds together create the conditions for not only the participants to be in the imaginary situation, but also the researcher, so that fuller sense of the data being generated could be understood. The affective dimensions of this process are captured digitally, and through this, emotionally charged moments can be examined as part of the research context. The doubleness of the researcher, including the emotional positioning of the researchers, is captured in Table 9.3 as a methodological principle of a cultural-historical conception of researching in early childhood settings.

This new conceptualisation of the double position of the researchers brings questions of the validity and reliably of the data. Traditionally, the researchers should be seen as an external observer of the research process, without interference of what is being researched. However, a cultural-historical conception of the role of the researcher shows that reliability and validity are strengthened when their role is conceptualised as part of the research. This is discussed in the next section.

9.4.3 Reliability and Validity When Undertaking Cultural-Historical Research

In considering reliability and validity for undertaking cultural-historical research, we draw upon Hedegaard's (2008c) conceptualisation (summarised in Table 9.4). It is through the process of including the child's perspective in research that more

Table 9.3 Doubleness of the researcher

Researcher and their actions must be visibly present in the research method	Doubleness of the researcher (Hedegaard 2008c); affective and tactile positioning of the researcher (Quinones 2014); synthetic-analytic method; film-play (Ferholt 2010); researcher as orchestrating the capturing of dynamic motion in action (Fleer 2014a); digital tools and human relations (Quiñones and Fleer 2011).	Methodological books: Fleer and Ridgway (2014); Hedegaard and Fleer (2008).

Table 9.4 Reliability and validity when undertaking cultural-historical research

Double subjectivity of the researched participants	Digital video tools have created new research conditions for early childhood education (e.g. Johansson and White 2011; White et al. 2007) in three distinct ways:
	(1) New cultural tools for capturing in situ moments of intersubjectivity in everyday practices of early childhood settings.
	(2) New cultural tools for analysing the intentions of the participating persons.
	(3) Cultural tools that create new play conditions through dialectical virtual and concrete play contexts – digital pivots and virtual placeholders (Fleer 2014a, b, c).
Double subjectivity of the researcher	Doubleness of the researcher and their actions must be visibly present in the research method (Hedegaard 2008c); affective and tactile positioning of the researcher (Quinones 2014); synthetic-analytic method; film-play (Ferholt 2010); researcher as orchestrating the capturing of dynamic motion in action (Fleer 2014a); digital tools and human relations (Quiñones and Fleer 2011).

valid data can be generated because it enables the researcher to analyse how children contribute to their own developmental conditions. By paying attention to the child's perspective in relation to the societal values and institutional practices, a more holistic view of the research is determined, once again increasing validity of the data. As noted by Hedegaard (2008c), "In this type of research the validity is connected to how well the researcher can explicate the historical tradition of the practice and the preconditions that are anchored in the values that integrate and specify different perspectives. The validation question for studying children's development is: How can we conceptualise children's participation in everyday activities as the basis for understanding and guiding practice? The answer depends upon how well the model being used can catch the different perspectives of the participants in everyday practices, and how they are contributing to the conditions for children's development" (p. 43). For instance, digital research tools have created the possibility to bring together the perspective of the participants, as was discussed in relation to the work of Johansson and White (2011), where the action-camera captures the infants and toddlers' perspectives, whilst the second camera captures the practices in the institution through the perspective of the teacher.

Confidence in the reliability of the data can also be strengthened through explicitly theorising the researcher's role in the research. By making clear what the researcher does, at all phases of the study, and their intentions and motives as a researcher, the data being generated can be considered in relation to what the researcher was doing at that moment. As discussed previously, and summarised in Table 9.4, a cultural-historical conception of the researcher means they must take a double role – both as someone in the research situation as a participant, whilst also someone who is a researcher with their own motives and intentions. Hedegaard (2008c) has recommended that reliable data happens when the researchers "find a balance in their interaction with participants, especially children, so that when they ask questions and react in a way that is relevant to the situation" and when this is

done, "meaningful insights are gained into what is being researched" (p. 44). However, research is a scientific activity, and the researcher's project will not be the same as the participants' project. As such, the double subjectivity of the researcher is always relevant in cultural-historically informed research, and theorising the position of the researcher increases the reliability of the data. As such, reliable data for cultural-historical research will always distinguish between the researchers' motives and practices and the participants' motives and practices.

The researcher can take several positions in the research. For example, during interviews, the researcher can not only ask questions, but also answer questions posed by the participants, so that a genuine dialogue is created and the participants feel informed and comfortable. In the example of fieldwork, where the researcher takes on a participant observation role, the researcher can also engage with the participants, such as talking to children, sharing photographs, giving tasks, etc. In all situations, the researcher who draws upon cultural-historical theory will always continue to document/observe, even when interacting informally, or transitioning into and out of the research site. For example, video recording equipment will be turned on before the researchers knock on the door and will only be turned off after they leave the research site and the participants are no longer present. Hedegaard (2008c) has summarised the core ideas for undertaking valid and reliable cultural-historical research as follows:

- *Theoretical preconcepts based on the research tradition within the subject area studied have to be formulated as relations*. That is, the methodology and the methods support the researcher with selecting a system of concepts that together give a relational understanding of the data being studied. For example, in the research of Hedegaard, she examines the relations between the personal perspectives, the institutional practices and the societal values through studying the demands that are made on institutions, which in turn make demands upon teachers, who place demands upon children. But children also have agency, and they place demands upon the teachers.
- *These conceptual relations should be visualised as models that depict these relations, so that change in one aspect can be seen in other aspects.* Studying the demands placed on children, whilst also studying the demands made upon teachers by children, is captured when the conceptual relations are visualised in a model of interaction. When using a model of conceptual relations, the generation of more reliable data is possible, because the tools selected (e.g. cameras on child and on the teacher) capture the different dimensions of the relations.
- *The institutional practices should be outlined as conditions for the social situation.* The study design produces more reliable data when the institutional conditions are captured, whether this is the family or the childcare centre, because rules and regulations allow certain activities to occur. For example, mealtime routines may be different between institutions, creating new demands upon the child that need to be understood when analysing the data. We see this when a toddler who is used to eating whilst walking is expected to sit still at mealtimes in a childcare centre.

- *The activities that create the changes have to be the object of study.* In a cultural-historical conceptualisation of the study design, reliable and valid data are possible when the tools of the research capture data that allow the researcher to analyse how the object of an activity settings changes. For instance, in studying how a family organises homework routines, the object of each child needs to be studied, because their orientation to the activity may be different, and it may change over time. We may see this when the family sets up a homework routine for the oldest child in a family, who has just commenced school. Younger siblings see this new activity as a valued "school practice" with social status. The introduction of the homework activity and how it changes family practices and what it affords for children's development is the focus of ensuring reliable and valid research. Homework practices across families can then be studied, and more confidence in the knowledge claims being made through the research is then possible.
- *The perspectives in the field of research should be outlined.* Here the participants in the social situation have to be specified so that interactions between them can be documented. The generation of reliable and valid data is supported when the researcher takes the perspective of all the participants in the study – including all the family members because they will each have a different social situation of development and will interpret the same situation differently. Their interactions are key to understanding how the social situation may or may not create possibilities for their development. Does the younger child seek to do the same as the other children and "pretend to do homework"? How the adults interact with the child also matters – as a school child with new responsibilities or as a child with no responsibilities, but also how the child takes up either position has a bearing on their development.
- At minimum, there will be two perspectives – a researched person's perspective and the researcher's perspective (p. 45).

Tables 9.2 and 9.3 add to the cultural-historical methodology previously discussed. They show the new challenges and reflect the changing societal context of researching in early childhood settings, where new research needs have demanded new ways of working. Similarly, the new digital methods or tools have opened up new possibilities for researching in contexts that are dynamic, and where the nature of the participants' development has not allowed researchers in the past to iteratively and in microgenetic form, to follow the intentions of participants in naturalistic settings. Theorising these new methods as part of a cultural-historical methodology is still in its infancy. Yet what has emerged to date is in line with the principles (Veresov 2014), holistic conception of research (Hedegaard, 2008a) and digital contexts (Fleer and Ridgway 2014), previously discussed.

9.5 Conclusion

What this chapter has sought to examine is a cultural-historical methodology for researching in early childhood education. We specifically discussed aspects of a cultural-historical methodology which are related to play and development in early childhood settings. We examined three key points. First, we discussed what new perspectives the cultural-historical methodology can bring to the field of early childhood education research. Second, we showed what a cultural-historical methodology will allow researchers to do. Finally, we showed how cultural-historical theory afforded the possibility to (1) theorise a set of cultural-historical principles for the context of contemporary research practices in early childhood education (Veresov 2014); (2) conceptualise digital tools dialectically, as both a research tool for capturing observations of practices and as a cultural tool for the development of young children, where microgenetic changes are made visible and (3) discuss the doubleness of the researcher (Hedegaard 2008b), as a participant in the research site and as researcher collecting data (Hedegaard and Fleer 2008).

In bringing together both Vygotsky's original theory for undertaking research (Table 9.1) and an analysis of the current research practices of early childhood edu-

PRINCIPLES	**Principles of development**
	Buds of development

	A cultural tool for the development of young children, where micro-genetic changes are made visible
	Doubleness of the researcher
RESEARCHER POSITION	**Researcher and their actions must be visibly present in the research method**
	Researcher as a participant in the research site and as researcher collecting data
	Reliability and validity
	Double subjectivity of the researched participants
	Double subjectivity of the researcher

Fig. 9.1 A cultural-historical methodology for researching in early childhood education

cation researchers (Tables 9.2 and 9.3), it has been possible to make visible a cultural-historical methodology that supports researching in early childhood education contexts. The principles and contemporary challenges of a cultural-historical methodology which foreground development are summarised first as a set of five principles (Veresov 2014), second, as new conceptualisation of digital tools as dialectical cultural developmental tools and research tools, and finally as paying attention to the doubleness of the researcher. These three dimensions of a cultural-historical methodology are shown in Fig. 9.1.

Figure 9.1 captures the foundations of the principles, the tools and the role of the researcher that has emerged as key for researching in the field of early childhood education, where real-world contexts of classrooms and play-based programme with very young children, infants and toddlers need to be better understood. Although early childhood education research has a short history when compared with psychology, a cultural-historical methodology with the elaborations discussed in this chapter appears to have provided a foundation for framing studies and researching contemporary problems that are important for early childhood education. However, as societal needs change, and new demands for research result, we anticipate that the emerging field of early childhood education research will continue to develop, with new methods, and therefore a more developed methodology will also evolve. A cultural-historical methodology speaks directly to the dynamic and dialectical nature of researching young children in informal and formal contexts.

Chapter 10
Narrative Learning of Literacy

Pentti Hakkarainen and Marja-Leena Vuorinen

Abstract This chapter summarizes experimental work carried out at two sites in Finland. In both sites, we study children's learning process in narrative environments. A frame story combines imaginative events and students or permanent teachers participate in roles to joint play with children. Our special focus is children's problem solving and narrative tasks. We proceed from general characteristics of learning tasks embedded in story line and connected with helping motive to concrete literacy learning goals and tasks. Joint tasks of all children create a specific motivational space, which might be juxtaposed with Vygotsky's "general genetic law of development."

Keywords Literacy • Narrative learning • Oral language • Reading writing

10.1 Cultural-Historical Background

Transition to written language was a dilemma to Vygotsky. Even 9-year-old schoolchildren are weak writers. He asked why a collapse is observed in children's mastery of language at the transition from oral to written form. Relatively young children master complicated oral language skills and abilities. They are also productive. But their first written texts are short and elementary. What is the explanation? Why the collapse happens in the production of language? He compared the situation with looking at an object through a window: "If you observe an object through a glass you do not see the glass. When a child talks he is totally occupied by the object or thought that he does not see the words (glass). The child does not comprehend how he talks" (Vygotsky 1996, 385).

El'konin (1999a) sought for an answer to the problem. His idea was to make the structure of oral language visible to children and thus make it easier to move to reading and writing. He concretized the relation between oral and graphic forms in reading:

> With a view of primary education, we define reading as a process of reconstructing the phonetic form of words on the basis of their graphic (letter) model. What it is important to point out in this definition is that the beginner operates with the phonetic aspect of language in reading and that, without a proper reconstruction of the phonetic form of words, it is impossible to understand what is being read (El'konin 1999b, 96).

According to El'konin, in literacy learning, there is only one correct path – from phonemes and their systems to letters. Phonemic analysis should help to familiarize the child with the sound system of language. If the child does not master the phonemic analysis, he is not able to learn how to read. The next step according to him was letters and whole words. He wrote:

> After the children have learned to do phonemic analysis and after they have gained an orientation in the phonemic structure of language, the next step is to acquaint them with the letters designating phonemes. The main tasks are: (1) to acquaint the children with letters in their capacity as signs of phonemes, taking care not to confuse the letters with phonemes; (2) to teach them to direct their attention anticipatorily to the vowel letters and vowel phonemes necessary for reconstructing the phonemic form of a word. (El'konin 1999b, 110)

Reading process is recreation of phonetic structure on the basis of graphic letters. An important factor in reading according to El'konin is location principle. In other words, the meaning of a phoneme depends on the place among other phonemes. From this follows that it is necessary to separate vowels and consonants, all vowels and their symbols, all vowels in words, and all possible consonant combinations with vowels.

Vygotsky compared giving to speech a written form as great change as learning oral language in early childhood. But writing and reading is not a mechanical or narrow cognitive skill. This was the starting point of Lobok (1997) who emphasized the use of children's own texts adding to them poetic expressions. In the beginning, the teacher wrote children's important ideas to the blackboard, but then he told that his hand is aching and asked that children continue on their own. This approach not correcting technical mistakes from the very beginning has led to angry protests among other teachers (Lobok 2012). Children produce text from personally significant events and have a personal motive to express something in writing (in the beginning with errors and with great efforts).

Play and narrative mode was introduced already in the 1920s in Soviet literacy teaching. Zuckerman and Shkoljarenko (1997) proposed to use narrative learning play with preschool children. The first basic model was aimed to be used by mothers at home with preschool age children. El'konin's ideas on modeling in graphic visual form the basic structure of oral language were kept in narrative approach. El'konin's model was transformed to narrative form with the following changes: (1) the model of oral sound world (forest of sounds) was introduced as a story and imaginary play, (2) all activity was imaginary and characters of play personified concepts to be adopted (literary heroes were invented), (3) analytic actions on words were actions of characters, and (4) relations between characters were relations between linguistic phenomena. In other words, a role relation was a linguistic relation.

Meta-level of narrative learning was composed of a story line and solving difficult problems together with the story characters. Children were invited to play with Winnie-the-Pooh and his friends in Zuckerman's story line. The same characters

participated in two adventures: Adventure I in the forest of sounds and Adventure II in the forest of words and sentences. Children were invited to follow the characters and help them to solve problems met during the adventure. Transition from the forest of sounds took place when all aspects of phonetic analysis were carried out.

10.2 Developmental Potential of Narrative Tasks and Assignments

In earlier publications (Hakkarainen 2002), we have argued that in narrative play world environments, children's relation to tasks is different compared to adult problems or school tasks. The basic difference in our analysis is that a narrative task "captures" the child inside the imaginary situation of the task. We think this difference explains variation in developmental potential of tasks. Imaginative, emotional, and appealing (inviting) elements are on purpose eliminated from "learning" tasks, but they are intertwined with factual content of narrative tasks.

Traditional school didactics heavily saturate the concept of task. Often tasks aim at learning "facts" from a textbook. School tasks are "objective," cognitive, and fact-laden. Imaginative and emotional elements are minimized or totally eliminated as "distracting." Tasks are still written in learning materials or teacher guidelines of each lesson and subject. Alternative approaches emphasizing active role of children are slowly taken into use. Task is understood, e.g., in El'konin-Davydov system as an element of learning activity defined "a goal set by the child in defined circumstances." In other words, a task is child's goal of learning. The child sets a learning goal for himself. Traditional didactics supposes that children automatically transform teacher's briefing and demands into personal goals and tasks.

A personal goal never consists of cognitive, "objective" facts, only, claims A. N. Leont'ev (1978). We think that personal goal setting and taking on tasks is a special challenge of narrative learning in kindergarten and elementary grade age. In line with cultural-historical approach, social life is the source of goals and tasks. We decided that helping others is such a social ideal, which is understandable for children. In play world projects (about 20 alltogether), we never heard somebody to refuse.

In his analysis on ideal forms, Vygotsky uses a well-known Aesop's fable about grasshopper and ant as an example of how a tale preserves cultural ideal in the form of cultural sense making to next generations. In Vygotsky's example, sense making is not only derivative from cultural meaning as Leont'ev argued with the concept of personal sense, but cultural sense exists, for example, in folk tales. Vygotsky sketched further how ideal and real forms are important in child development:

> The most remarkable attribute of child development is that it happens in circumstances of interaction with the environment where ideal, final form that should be reached at the end of development not only exists in the environment and affects the child, but really interacts, really influence on primary form, on first steps of child development. I. e. something, which should be realized at the end of development somehow influence on the first steps of development (Vygotsky 1996, 88).

In different societies, ideal end points are different and they have changed during history of each culture.

Children meet these formations, e.g., in folk tales and stories as ideal forms of behavior of the heroes (the hero altruistically wants to help people in need). The example presented in affective ideal form may be adopted in individual development and be transformed into real (natural) form of individual psyche and consciousness. Developing subject is engaged in permanent struggle between ideal and real forms of acting. He accepts some forms and rejects others. From real forms new ideal forms may be produced. Zinchenko (1996) uses a metaphor of Mandelshtam who writes that culture and its ideal forms are figuratively described as inviting force and a subject is free to accept invitation or reject it. Invitation is intertwined with the difference of potentials between ideal and real forms. If a subject accepts invitation, "act of development" may happen (El'konin 1994).

How is an ideal form transformed to a real one? Vygotsky claimed that an ideal form has concrete bearers, which may function as mediators in the development of real forms. He named three types of mediators: an adult (in joint activity with the child), sign, and word. Zinchenko (1996) added to this list symbol and myth from the analysis of Losev and sense from Shpet.

We have reported in our earlier publications how children behaved in solving realistic problems met in a narrative environment (Hakkarainen 2008). Children accepted a realistic task associated with imaginative environment and demanding solution in order to continue events of the story line. This demonstrates how they differentiate solutions in miraculous tales and in the real world. In tales solutions are achieved by magic without explaining what tools, methods, and processes are used. El'koninova (2001) has emphasized in her analysis how tales underline motivational strivings of heroes to help other people and act for the common good. She called these tales as "the school of willing."

Assignment of narrative problem is an important stage in play world projects. In our "Rumpelstiltskin," project assignment happened one morning in the classroom after several visits of the characters from the folk tale (teachers in role). King "Alfred" visited in person the classroom in February and now in April his messenger waited in the classroom children coming. A condensed log was written from the videotape:

> The messenger stood in front of the classroom; he wore a helmet and had a parchment roll in his hand. When all children took their seat and sat quiet he solemnly opened the ribbons and started to read: 'King "Derfla" wants to curse you for your tricks you did not send to him. We did not find our son in the faraway field.' Children understood quite soon that something strange has happened and the messenger turns the message backwards. They started to make a 'translation' and loudly shouting corrected the reading of the messenger: "King Alfred wants to thank us for advice we sent to him. They found their daughter playing in the near by forest." Alfred's assignment was at the end. Children 'translated' it and accepted eagerly: Rumpelstiltskin has put a spell on the kingdom of 'Surmundia'. People walk backwards, their jackets are turned (buttons in the back) and they talk opposites like the messenger. Can you children come to 'Surmundia' imperceptibly and help to restore my court. The spell has turned all the rooms of my court upside down and my servants are imprisoned in the basement of the court. Are you ready to free my servants and turn the rooms back to normal position by solving spell elimination task of each room?

In our play world projects, children emphasized the difference between tasks in play world environment and in classroom by crossing the boundary between them. In order to secretly enter and move in "Surmundia," children turned their jackets, walked backwards, and talked changing meanings and words opposite. After getting the tasks in imaginary play world, children returned back to their classroom repeating the boundary crossing rituals contrariwise (talking normally, turning their jackets, and walking normally). After solving the problems, children returned back to the imaginary world with their solutions and the story line and play events could continue. Adults participating in play events in roles plan how story line and problems are related to each other. This part of the story line with the spell and its results adults added to the play world plot. Their motive was to create a new narrative dimension to selected preschool and elementary grade learning tasks. A set of solved problems turned each room of the court back to normal position according to the invented story line.

Children were afraid to go to the dark basement where Rumpelstiltskin might still be lurking and cast a new spell on them. (School basement was the basement of the court.) So they decided to make protective shields against possible spells. The shield making is reported in an earlier article:

> The children worked in groups to prepare their shields, cutting a piece of cardboard and attaching a handle to it. The children then decided to add colors and a personal spell written inside the shield to give them extra protection against Rumpelstiltskin's spells. Several girls agreed that the heart is the strongest symbol against evil powers, so they made red and white heart-shaped shields. Some girls made two human figures representing good and wrote a spell admonishing 'Monster, monster go away.' The boys' favorite symbols were a red triangle and the Finnish flag. They believed that the color on the shield would send a very effective symbolic message against evil powers (Hakkarainen 2008, 298).

Shields in the above-reported situation are psychological tools in Vygotskian sense of the term. They are not eliminating any outside threat, but personal fear inside of children. The psychological tool was made stronger adding more symbolic elements to it like personal spell, color, form, and symbols of goodness.

Narrative content of problem situation brings a moral dimension of good and bad to tasks, which traditionally are pretty neutral and without any tension. Now children are not solving tasks including numbers and literal material, but they are saving the court of the king they met some time ago (teacher in role). The motive of solving preschool or elementary school tasks is to help and fight against the evil. Tasks are now in the position of means of attaining more attractive motives and goals. Here we can see enlargement of the problem unit including a personal challenge and cognitive task in the position of mean. Personal motivating challenge brings to the situation the contradiction of ideal and real form (Zinchenko 1996).

Cultural ideal of helping others in need collides with the fear of meeting "Rumpelstiltskin" in the dark basement, eliminating his possible spell, and freeing the servants. Shields and other psychological tools were needed in this situation because he was a powerful magician turning whole kingdoms upside down. Adults participating in the events reported that normally boasting boys were not in front of the rescue team ascending to the basement.

Learning tasks intertwined with a story are usually tasks of the whole class or group. In a group, there always are learners on different levels of learning abilities and the challenge to somehow differentiate children in problem solving. In imaginative story environment, we have found that differentiation of children is flexible. For example, a group of nine 6-year-old special need children in math adventure based on a board game joint participation in the adventure eliminated differences in abilities and skills. Solving different parts of tasks did not lead to comparisons of individual differences in solving process. The joint total solution was the main aspect (Hakkarainen et al. in print).

A joint assignment of tasks of a whole class creates an interesting collective zone of proximal development. If children are divided into subgroups, they are automatically interested what happens in other subgroups because a joint problem unites all children. Bredikyte (2011) observed how roles and role relations create mutual zones of proximal development.

We can now summarize basic characteristics of narrative assignment and tasks. Earlier we have made a difference between narrative tasks and adult rational cognitive task by stating that children are rather inside a narrative task and do not have a distanced relation to "objective" problems in the outside world (Hakkarainen 2002). In the description above, we see some specific characteristics of narrative tasks:

Adult role characters (animals in two first parts and researchers in the third part) are equal partners of children and support children's initiatives, interpretations, and dialogues. Children are their helpers.

Assignment combining story line and tasks into enlarged developmental challenge (personal challenge of helping).

There is a "super task" creating a personal need for change and learning motive (helping the king).

Psychological tools directed to changing self are found (shields and other symbolic characteristics).

Children are invited to imaginary worlds and events (the spell put on the kingdom of "Surmundia," king's invitation for help).

Contradiction between ideal and real forms of behavior is confronted in the story line (own fears vs. helping the king).

Cognitive tasks are transformed to means of helping others (turning the rooms of the court back to normal position by solving school tasks).

Personal learning tasks can be flexibly differentiated and several zones of proximal development are created (math learning of special need children).

10.3 Three-Stage Literacy Learning Experiment

El'konin's approach to literacy learning has expanded to several languages and countries. There is also a Finnish version starting from phonetic awareness (Poskiparta 1995). This program includes all essential elements of phonetic

analysis, but following traditional linear proceeding of didactics learning tasks minimally allow children's own initiatives. The process is constructed as teacher-managed information transmission.

Our experiment was compiled from the following stages: (1) phonetic analysis and modeling of Finnish language, (2) letters and words as tools of meaning making, and (3) language as a system and tool of communication. Stage 1 and 2 were based on Zuckerman's approach. The original story used in Zuckerman's program was translated and adapted for Finnish language ("Kaapro the Bear's Adventures in the Sound Forest" and "Kaapro the Bear's Adventures in the Forest of Words"). Stage 3 introduced system character of language and its communicative function. As an example, we used Aidarova's (1983) work in teaching language as a communication system. Zuckerman's task structure and stepwise proceeding were adopted directly, but the adventures of Winnie-the-Pooh and friends were replaced with Finnish animal story characters. Students acted as live role characters, and children were their helpers and assisted in problem solving. In the third stage, children's role was changed to researchers doing time trips to ancient worlds and investigating languages and communication (e.g., hieroglyphs in ancient Egypt). University students acted as role persons in destinations of time trips or they were coresearchers doing research with children.

Learning experiment was organized once or twice a week during semesters. Eight teacher students participated in it as a team during 2 years time in 2007–2009. They with a researcher and assistant were planning the adventure of animal role characters and narrative tasks during each meeting. During the first year (autumn semester 2007 and spring semester 2008), Kaapro – the bear – and his friends first had several adventures in the forest of sounds (autumn semester), and they continued to the forest of letters and words (spring semester). The third part of the learning experiment (autumn semester 2008 and spring semester 2009) was more freely created by students because Aidarova's book did not have narrative elements. The students created researcher characters (students in role) investigating ancient cultures and characters communicating with each other in ancient grounds to where children "arrived" with their time machine. In experimental classroom were 19 children (5 preschoolers and 14 first graders; 6–7 years). The same children continued the next study year.

Each adventure day started with a set of transitional rituals. The goal was to move from the school environment to play world. Students, a researcher, a classroom teacher, and children all participated in rituals. Usually rituals took place in school corridor outside the classroom. Each participant was dressed in an adventure shirt, and an imaginary time machine was abstracted to the name of the place where the adventure happens (e.g., "forest of sounds," "ancient Egypt 4,000 years ago," etc. were written using letter cubes). The destination of each time trip and the "time machine" song was sung. Destinations were staged in different environments – in the children's own classroom, nearby forest, gardener's house, in the handicraft classroom, etc. To make a difference during first year, an adventure in children's own classroom presupposed that children crawl inside through a tunnel, not by walking through the door. An adventure tunnel separated two worlds (real and imag-

inary) from each other. For example, in the imaginary forest of sounds, words from which the "sound guzzler" had eaten some sounds could be restored by repeating clearly and loudly three times the whole word with all sounds.

The learning experiment was organized in a combined classroom of 0 and first graders. In the next study year, the children in the experimental combined class were first and second graders. The classroom teacher participated in all adventures during 2 years, but university students were responsible for the activities in the classroom during adventure days. The teacher took part in adventures in some minor roles. In adventures all children used nicknames they invented. So we do not know what is the real name of each child. Children's researcher role was supported with a special assignment to make observations and write field notes and reports in any adventure situation during the second study year like real researchers are doing. A notebook and pen was a regular companion of children in any adventure. As a result each child of experimental classroom produced written texts several times more than students in the first and second grade not participating in the experiment. (A girl asked if she already has produced sufficiently text for a doctoral thesis at the end of second study year.)

Basic tension of the frame story during autumn 2007 was between the evil goblin eating sounds and "soundlings" (fairylike beings living in the forest of sounds) maintaining and fixing sounds. The adventure took place in the "sound forest" and children helped in fixing the sound structure of broken words by pronouncing them correctly. Restoring lost phonemes happened by repeating the word clearly and loudly together at least three times. Quite soon children started to "write" sound structures using different symbols for consonants and vowels. During spring children moved from the "Sound Forest" to the "Forest of Words" and started to use letters instead of sounds and phonetic symbols. Basic tension in the "Forest of Words" was between the evil "Guzzler of Alphabet" eating letters, books, and everything written and "Aunt Soundling" and her brother "Knight of Alphabet" who maintained correct writing and texts.

It was necessary to adapt the program to the special characteristics of Finnish language. In the Finnish language, nearly all sounds have their own letters. Usually children learn the names of the letters before the names of the sounds. This often leads to confusion. Phonemic analysis of Finnish has some special challenges. They are connected with the system of double vowels and consonants. For children it is difficult to decide where you should have one vowel or consonant and in which words you should have double vowels or consonants. The amount of vowels and consonants change the meaning of the word. For example, the word "TULI" (fire) has one U-vowel and one L-consonant. When you have two U-vowels, the word changes to "TUULI" (wind), and if you put two L-consonants, the word changes to "TULLI" (customs). If you put both two U-vowels and two L-consonants, the word changes to "TUULLI" which means nothing. If you put two I-vowels (TULII, TUULII, TULLII, TUULLII) or T-consonants (TTULI, TTUULI, TTULLI, TTUULLI), the words mean also nothing. If a child cannot do this kind of phonemic analysis, he will most probably have big troubles when starting to write.

10.4 Unifying Literacy Learning Objectives, Assignments, and Tasks

10.4.1 Adventure in the Forest of Sounds

Adventure in the forest of sounds started with a short trip to a nearby forest in the campus. Animal characters were introduced to children before the trip. In the forest, adventurers met a scared squirrel (teacher education student in role) in a tree. The other animal characters tried to persuade her to climb down, but she was too scared to dare down. Children understood from the conversation that the reason was disappearance of the first sound of her name ("Kurre"). The Guzzler eating sounds was the culprit. Children were asked to help by pronouncing clearly several times the correct word. So they restored the name of the squirrel and sound –k in all other words.

Sound structure of Finnish words was studied in weekly adventures. At the first stage, children helped to restore sounds Guzzler had eaten from words. The second stage introduced voiced difference between vowels and consonants and method of indicating it in "sound writing," i.e., writing words using different symbols for vowels and consonants (triangles for vowels and squares for consonants). Surrounding long double sounds with a line in "sound writing" marked peculiarity of the Finnish language of making different meanings with minimal structural changes.

The following excerpt describes a task, in which children focus on the first and last sound of each word. In the story line, the animal characters arrived to a heavy stream and they should cross the river. The adventure took place in the forest of sounds and accordingly a bridge can be constructed from sounds. Children were asked to help in the construction. Durable construction presupposed that the last sound of the previous word and the first sound of the next word are the same. If they are not the same, the bridge may collapse and travelers fall to the heavy stream.

Bridge building was trained with empty milk canisters made from cardboard each having a word written on side. Animal character (teacher education students in role) constructed "bridges" and children helped them to find an appropriate joint according to the rule (last sound and first sound of joined words are the same).

10.4.2 Adventure in the Forest of Words

We have picked up from the adventures in the forest of words the stage of transition from sounds and phonemes to letter symbols. Their close relation is indicated in the beginning of this stage in writing words using both symbols in the same word (letters and oral sound symbols). This stage demonstrated to children the problem of writing oral sounds because one vowel symbol can be any of seven vowels in the Finnish language and the same problem is with consonants. Now when the children

select correct letters replacing two sound symbols (consonant or vowel), a more exact word meaning is indicated with letters.

The introduction to meaning making took place in February 12 and 13, 2008. The first challenge was to make clear what kind of task is waiting for children by reading the message "Aunt Soundling" had left at each "flowerbed." The task of six subgroups was to work on "flowerbeds" of "Aunt Soundling" and find out how many words they could find in place of each word written with two sound symbols (separating only vowel and consonant from each other). Next day "Aunt Soundling" (student in role) was present and helped children to root out "weeds" from flowerbeds. The "weeds" were words having no meaning in the Finnish language or they were written wrong.

Children were divided into subgroups so that at least one child was able to read. But the ability to read or write did not mean the mastery of phonetic structure of the language! Two animal characters worked with two child groups. Each group got their own "flowerbeds," and for "seedlings of words," there were colorful pieces of paper. Children should write words on paper and glue it to the suitable "flowerbed." There was one "extra" "flowerbed" without phonetic symbol model, too. The idea of this "flowerbed" was that children could figure out new models, if necessary. Because children's collective role in adventure was helping animal characters, only children corrected each other's mistakes. Only "Aunt Soundling" was the fluent adult character in interpreting written texts.

10.4.3 Entering the Forest of Words

A week ago "Aunt Soundling" had introduced herself and her "letter children," i.e., the sounds and their letter symbols. This time the adventure started when children and adult characters crawled to the "Forest of Words" through the tunnel separating two worlds (a canvas tunnel fixed to the door frame). Inside they found a letter of "Aunt Soundling" on the screen written by mixing phonetic symbols and letters. "Aunt Soundling" asked animals and children to prepare "flowerbeds of words" following her instruction (Table 10.1):

> Hello Adventurers and Animals!
>
> I had to go on errands. Your task is to take care for my flowerbeds of words. In the margin of flowerbeds there are instructions for what kind of seedlings of words you can prepare and plant in each flowerbed. In the seedlings of words you can use both letters and phonetic symbols.
>
> Search for your own flowerbed of words.
>
> Aunt Soundling

"Aunt Soundling" had written with the phonetic symbols on each "flowerbed" the names of the children working on it. Only one "flowerbed" was without names, and the animal characters decided to put it aside. Children read instruction easily aloud, but they were unsure what they had to do next. Animal characters proposed that children once again read the instructions and repeated important words during children's reading.

Table 10.1 "Aunt Soundling's" message to children (written mixing letters and "sound writing")

Picture 10.1 The "flowerbeds" with phonetic "word seedlings"

Children wondered where the "flowerbeds" would exist. After they had read the letter, they noticed brown paper scrolls on the floor and concluded that those must be the "flowerbeds" because there were phonetic symbols written on every scroll. After each child has found his or her group, animal characters asked the children once again what they should do next.

Children divided into small groups after finding their names on the side of "flowerbeds." Confusion created the form of instruction: at the end of each row, phonetic model was written showing the order of vowels and consonants in words children should invent and write using letters ("word seedlings"). Each word should have as many letters as there was in the model sound symbols. An open option was to invent completely new phonetic models and write with letters words of the same length.

10.5 Initiatives and Solutions

Children wanted to fill all flowerbeds and glue colored pieces of paper with words the rows full. In the flowerbed task, children have an opportunity to independently increase the difficulty of the solutions and get feedback from other children. RS was striving to more challenging problems.

RS planted a seedling in flowerbed □Δ□Δ. But she is eager to find a word to □Δ□□□Δ, which seems to be difficult for her. SP comes up with the word "LAMPPU" that fits to the phonetic model. MB asks RS if she can find some other word like "LAMPPU." A little later RS suggests to MB the word "IKKUNA." Phonetic analysis reveals that the model begins with "voiceless" sound (a consonant). SP adds that double consonant is in a different place than in the model. After a while RS asks: Does "VERKKO" fit there?

The teacher education student in the role of Matti the Badger (MB) wrote in his field notes: "RS was very interested in the most difficult flowerbed rows and she asked me which word could suit to them. I suggested her as if 'by chance' suitable words and soon RS proposed suitable words by herself. SP corrected mistakes that other children had made. Sometimes children peeked words of other groups and added them into their own 'flowerbeds'."

RS writes the word "VERKKO" and is going to plant it. SP looks at her writing and says: You wrote "VERKO." RS: "VERKO"? She sits back on the floor and corrects the word. RS writes the word "KURKKU" without mistakes and adds it to the row of "seedlings." RS checks the words of the flowerbed row □Δ□Δ. She finds one mistake and reminds SP: "You placed 'ÄITI' in this row, but letter 'Ä' has a voice." SP strikes through the word quickly.

Children worked intensively in good dialogical cooperation. They checked phonetic models carefully and paid attention to places of two same consonants or vowels. (Double consonants and vowels were marked with o double line in the phonetic symbol.) At the same time, they have to detect words that do not suit to any flowerbed.

TT proposed the word "TÄHTI," but no phonetic model was appropriate. TT was asked to make a new phonetic model and add it to flowerbed models.

10.6 TT Mastered This Task Perfectly

10.6.1 Adventure of Language Researchers: Plural Form

The narrative learning environment of the second year was called "The Mystery of the Object: Language Researchers' Adventure." Learning activity was organized like an arcade game, in which children and teacher education students searched keys for a mysterious chest hiding "The object." "The object" was communication model of human language, but for children it was a treasure hidden in the chest. During

separate adventures, children found keys to locks with which the chest was closed. Plural form was one adventure lasting 3 weeks.

Introduction to plural form took place dramatically. Children found a piece of ice in front of the classroom door (the adventure happened in winter). After melting the ice, two written messages were found. One text said: "I have in my possession your precious key. The solution of the riddle on the other text must be left half an hour before noon in the middle of the classroom. Don't dare to lurk any place nearby! If I see spies you will never see your key again!" Children decided that the message is from the wizard who interfered often in their adventures with time machine. The riddle to be solved was constructed from words in plural form in which the ending –t was replaced with the letter –s and syllable –ma was added in the beginning and syllable –pu at the end.

The riddle was quite complicated and the first solution was incorrect. The wizard returned the solution back and asked to solve it correctly by the next adventure day. After hard work, the solution was found. This time children wanted to stay near the classroom in order to see the wizard. But teacher education students proposed a trip to historical Stonehenge with the time machine. Time trip preparations were made and travel through time started. But the travelers arrived to a completely different place (next house from the school) where there seemed to be workstations and two workers. Soon children understood that they are in a car factory of plural country where cars are made from plural and singular forms. Explanation for wrong destination was that professor Ehnqvist, the head of their time expedition, was involved deeply in thinking children's plural riddle. Because time machine fuel is composed of thoughts, plural country attracted the vessel to this destination.

The factory was making cars from two types of parts, words in singular and plural form. During the last 2 months, a growing amount of complaints came from customers that their car was wrong assembled. This means extra money and time repairing such mistakes. We need exact instructions at each workstation on how singular is transformed to plural in Finnish. Especially the plural person at quality control point should brush up his language skills. Children were asked if they could help him and update his language skills because he is responsible of correctness of all plural parts.

10.6.2 Working on Assembly Line

"The assembly line" consisted of four workstations. Each subgroup could join assembly work on their choice. "The plural person" was responsible for quality control and demanded change of defective parts (the plural form of a word was not correct) thrown to the wastebasket. "The plural person" was student-invented character. Two female students made a jumbo size jacket big enough for both to fit in. So the character had two heads like a Siamese twin, but two arms only. The plurality was thus visually embodied in the character controlling the quality of plural parts.

Children's experiments and dialogues revealed them rules of changes in plural construction, but also exceptions from rules.

Excerpt 1
Three girls are working with the plural person at quality control point.

T: Suomi [Finland]. We add letter –t to the end and it will be Suomit.
M: "Names" are put in this basket.
T: Hey, but this is with –t Suomit.
Plural: Is this 'Suomit' correct? It sounds somehow funny.
T: There is only one Suomi.
Plural: Is it special waste in that case?
T: To the problem waste.

Excerpt 2
Plural: 'Kevät' (spring).
T: 'Kevät'
Plural: Let's think 'kevät'?
T: There are not many of them either [singular form ends with letter –t].
T: Plural: Isn't there?
T: 'Kevät' is not many.
Plural: Well, the previous and the previous before and the next. These may be all the springs of my life. Isn't it 'keväät'?

In these excerpts children first meet a word, which does not have plural form. In the second case, the word ended with the letter t in singular form, and plural form is constructed by transforming previous short vowel to a long one. In all workstations, children invented and tested words if they fit to building blocks of a car or they are problem waste not suitable for car assembly.

10.7 Visit of CEO in the Classroom and Preparing Instruction Boards

The CEO (a female student in role) arrived to the classroom without any warning before. She introduced herself as manager of the car factory emphasizing personal responsibility for the results of the factory. She complained permanent errors of cars and told that four cars only came from assembly line in perfect quality last week when children were helping. She asked if children are plural experts and could help her in preparing instruction board for all workstations explaining how plural form can be formed from singular in the Finnish language.

The CEO told that her secretary "Aila" has worked in another auto factory and they used an instruction board reminding that the letter –t indicates plural form in the Finnish. She hung up the old instruction board in front of the class and asked if children could form plural from a set of words she has with her. Children were

divided into subgroups and each child got a word in singular form to be transformed to plural. The CEO read the instruction aloud:

> Change the word on the piece of paper to plural form with your pair.
> Discuss in the group what similarities are in plural forms of your group
> Make instruction board of your group for which each child writes one word.
> Write plural form of your word and mark with a pen the point which is different compared to singular form
> Find an appropriate heading for the instruction board.

The challenge of the task was hidden behind the simple rule that letter –t at the end of word indicates plural form in the Finnish. Different transformations happen in the word except the change of ending. There are four main cases and several exceptions in plural construction. In subgroups most children were able to infer the correct transformed plural form on the basis of their oral mastery of language. In subgroups problem solving was quite easy because the method of transformation was the same, but different between the groups. Each subgroup solved the task; instruction boards were explained to the whole class, but solutions were not compared between the groups.

Children made in subgroup's instruction boards covering all possible four cases of transforming singular to plural form in Finnish language. They realized that the word ending –t is not the only transformation, but a more complicated change happens in the word root. In some cases double vowel becomes shorter or another vowel replaces the root vowel. Children found all the main grammatical rules in subgroups, but individual mastery hardly covered them all.

In this task, children concretely worked with the main message of "the object's" model: when structural changes happen in the word, its meaning will change. Traditionally language teaching doesn't reveal the connection between grammatical rules and meaning making. Grammatical rules are learned by heart without opening the fact that grammar is the collection of principles of meaning making in any language.

Aidarova (1983) even gave an assignment for older children to invent a new language using this communication rule.

10.8 Discussion

El'konin-Davydov system of learning activity inspired our literacy teaching experiment. Some elements are more or less directly adopted from the original approach or its elaborated parts. The first year follows Zuckerman's and her colleagues' model, which is a narrative version of El'konin's ABC – book. The idea of enhancing beginning reading and writing by making the system of oral language visible originally came from Vygotsky. The second year was used in the experimental work to introduce elementary communication model of human language, which Aidarova used in her language teaching experiment at school (Aidarova 1983). The basic idea

is to teach children elementary generalization as a tool for analyzing language: change of word structure changes the meaning of word.

In our experimental work, the whole two-year period was narrative. The experiment started in a mixed age classroom of 19 children. Younger children were 6 years old and the older group consisted of first graders. The experimental activity was introduced to children as “language adventure.” Eight teacher education students voluntarily participated in the two-year experiment. Students planned in-role activities, created imaginative situation, carried out roles, and created characters (animal character during the first year and language researchers during the second year). Tasks and assignments were mainly copied from Zuckerman’s material during first autumn term, but after that they were planned as part of each adventure.

During the second year, “Language researcher” adventure had a general plot: the frame story was a treasure hunt of mysterious “Object.” Children and adult characters first hunted for keys, which would open the locks in the chains around the chest hiding “The object.” Children should have all nine keys and find the chest with “The object.” “Bad guys and spirits” were also hunting the treasure and sometimes stole keys of treasure chest were stolen from children.

One of the problems in El’konin-Davydov system of teaching learning activity is continuity and developmental impact of play. Davydov analyzed the importance of advanced play in learning activity, but focused on scientific concepts and theoretical generalizations as “tool-producing” factor in his experimental work. He wrote that developed imagination and symbolic function are central products of advanced social role-play. Advanced play makes its task and “pushes” the child to “realistic” learning (Davydov 1996). The present situation all over the world indicates that advanced play is disappearing and children’s imagination and symbolic function is not developing in play. Perhaps we should bring advanced play and other narrative activities to school education in order to systematically support child development.

Chapter 11
Mixed Methods in Early Childhood Education

Judith Schoonenboom

Abstract This chapter presents a view on mixed methods research for early childhood education. Much research in early childhood education investigates or prepares interventions in educational practice. Such research is complex and involves various stakeholders, most notably children. Ultimately, such inquiry informs a decision for educational practice, either an immediate decision for the research site at hand or a possible, more generally applicable, future decision. A decision of high quality is informed by various perspectives and particularly by the voices of those with least power, the children. This chapter describes techniques for interactively articulating stakeholder perspectives and subsequently integrating them. A special challenge is posed by the integration of conflicting evidence, which preferably exceeds simple juxtaposition by finding a solution to the conflict through abduction or further inquiry. Next, this view is elucidated using a complex real-life example, Clark and Moss's Mosaic study. It is shown how various kinds of evidence play a role in this real-life example, how conclusions drawn from these diverse pieces of evidence build upon each other, and how they inform the ultimate decision. Finally, several validity requirements are discussed, with the overarching requirement being that "the description should be good enough for the decision."

Judith Schoonenboom holds the chair for empirical pedagogy at the University of Vienna. She specializes in mixed methods in educational research. Judith is an associate editor of the *Journal of Mixed Methods Research*. She has wide experience in designing and evaluating innovations in education, with a special interest in educational technology. Her research interests include mixed methods design and the foundations of mixed methods research.

11.1 Introduction

A common call in the literature on early childhood education concerns the wish and the need to make the voices of children visible, to perform research also *with* children, instead of exclusively *on* children (Liebenberg and Ungar 2015). Such calls point out the limitations of results of early childhood education studies that are based solely on quantitative research (Jones and Sumner 2009; Nicotera 2008). Quantitative research often results in very abstract statements of effects, which are considered generally applicable (Shaffer and Serlin 2004; Yanchar and Williams 2006). In the early childhood education literature, however, it is pointed out that effects can work out differently in different contexts (Ungar et al. 2007) and that it is important to understand how the experience of the children is affected by the context (Grover 2004; Hill 2006) and to reveal the diversity (Ungar 2011) and complexity (Liebenberg and Ungar 2015) of the underlying processes. Obviously, there is a need to complement the outcomes from quantitative studies with understandings from qualitative analyses.

This goes along with a call for the use of mixed methods research (Jones and Sumner 2009; Nicotera 2008). Differently from what is suggested by its label, this involves not only combining qualitative and quantitative research methods but also combining quantitative and qualitative paradigms, theoretical lenses, methodological approaches, disciplines (Creswell and Plano Clark 2011; Greene 2015), researchers' mental models (Greene 2007), and perspectives of researchers and research participants (Jones and Sumner 2009; Liebenberg and Ungar 2015). Qualitative research has the ability to reveal diversity (Maxwell and Mittapalli 2010), to deal with complexity (Johnson 2015b), and to sketch participants' perceptions and experiences (Hesse-Biber 2012). On the basis of quantitative research, generalizable statements can be formulated (Morgan 2007), i.e., conclusions that are assumed to be valid outside the specific setting in which they were drawn (Hankivsky and Grace 2015) (but see Ercikan and Roth 2009). In the context of early childhood education, many mixed methods studies are performed (e.g., O'Farrelly and Hennessy 2014; Sumsion 2014; Walsh et al. 2012), including many studies that have not been labeled as such by their authors (e.g., Clark 2005; Hargreaves et al. 2014; Marjanovič-Umek et al. 2015; Michael-Luna 2013)).

In this chapter, I present an approach and a model for mixed methods research in early childhood education. I do so as an expert in mixed methods with some knowledge of early childhood education. This chapter fits into two mixed methods traditions: the transformative and the dialectical tradition. Research in the transformative tradition (Mertens 2007, 2009, 2010) aims to give participants with little power, in this case young children, a voice in improving their situation. Transformative research focuses on generating results that are useful to the various groups and individuals to whom it applies. It does so by involving the various stakeholders, by recognizing and incorporating differences among those groups and individuals, and by collecting data in ways that are seen as appropriate and nonoffensive by those involved (Mertens 2007).

The mixed methods dialectical tradition (Greene 2007; Johnson and Schoonenboom 2016; Johnson and Stefurak 2014), although closely related in elaboration, has a different perspective. It emphasizes the dialogue with the other, whether these are other researchers, various stakeholders in a study, or other ideas. Actively seeking for different perspectives, stemming from various sources, results in a better understanding of the multifaceted and complex nature of social phenomena, and in decisions in which various stakeholders have a more equal voice (Greene 2007). An example in early childhood education is the dialectical "iterative research process" of Liebenberg and Ungar (2015). The stages of this process are dialectical in that they each incorporate perspectives of both researchers and participants and they are dialogical in that they build on each other.

This chapter first presents an ontological/epistemological and methodological foundation for mixed methods research. Next, a model of the mixed methods research process is presented, in which the researcher can go back and forth between three iterative stages. It shows how research components build on each other and how conclusions from different sources of evidence can be integrated. This process is subject to a set of validity requirements for mixed methods research in early childhood education. This approach is demonstrated on the basis of an existing and well-documented example of research in early childhood education (Clark 2005; Clark and Moss 2005, 2011).

11.2 Foundations for Mixed Methods Research

In this section, two foundations are proposed for combining qualitative and quantitative research. The first is an ontology and epistemology for mixed methods research. The second, methodological, foundation shows why and when quantitative and qualitative research need each other to obtain valid conclusions.

In the mixed methods literature, the question whether quantitative and qualitative ontologies and epistemologies can be combined with each other within one study has been much and hotly debated (Denzin 2012; Hammersley 1996; Howe 1988; Lincoln 2010). It has been argued that quantitative research assumes the existence of one reality, about which one can obtain objective knowledge. Qualitative research is based on multiple realities and different kinds of knowledge and ways of gathering knowledge. As such, quantitative and qualitative research seem incompatible.

This so-called incompatibility thesis can only stand to the test if all mixed methods research in practice proved to be flawed, which obviously is not the case. The incompatibility thesis, however, also plays a role in justifying mixed methods research. In the mixed methods literature, a good mixed methods researcher has been defined as someone who is able to easily go back and forth between the one, objective world of quantitative research and the multiple subjective realities of qualitative research. In practice, however, researchers generally do not have the feeling that they change worlds while they are performing mixed methods research (Bryman 2007). In addition, although good examples of going back and forth between

qualitative and quantitative research have been described in the literature (Greene 2015; Hesse-Biber 2010, 2012; Maxwell et al. 2015), an accurate description of the accompanying change in ontology and epistemology is missing.

Some authors have solved this problem by assuming an objective reality, which can be known in various ways (Campbell 1988; Maxwell 2012), each of which yields only provisional knowledge (Popper 1963). This critical-realist perspective combines a quantitative ontology with a qualitative epistemology. However, the function of this objective reality remains unclear. As the objective reality cannot be known, it cannot guide inquiry, and it cannot be used to derive criteria for judging which way of knowing comes closest to the objective reality (Chakravartty 2014).

By definition, a critical-realist approach has no place for multiple, subjective realities. In the practice of qualitative research, however, the latter is a very common and useful starting point. It makes sense to say that participants in qualitative research to some extent live in different realities – with different concepts, habits, interests, values, etc. – rather than that they look differently at one objective reality.

The critical-realist approach assumes that there are multiple ways to know reality, both qualitative and quantitative. This legitimizes the conduct of both qualitative and quantitative research (Maxwell and Mittapalli 2010). From the critical-realist standpoint, however, no arguments can be derived concerning the different roles of qualitative and quantitative research.

11.2.1 An Ontology and Epistemology for Mixed Methods Research

The approach of this chapter assumes a qualitative ontology and epistemology. People live in different realities, which can be known and investigated in different ways. These different realities are dynamic and changeable. Moreover, the concepts we use to speak about these realities are not fixed, and they change along as these realities change. This variability, however, has its limits, because the concepts that we use in a specific, time-bound context cannot exist without an intersubjective consensus about what they mean.

This is not the end of the story. Concepts interact with each other in endlessly complex ways and systems. Therefore, through reflection and research, we can *discover* properties of these systems, which until then had been unknown. These properties are not valid eternally, and they may change when the realities or our concepts change. However, on the basis of the intersubjective consensus of what the concepts mean, these discovered system properties can be considered objectively valid for a certain time and context (Putnam 1987).

In research, analysis of the multiple realities does not always aim to arrive at objective statements. Description and understanding are important goals of conducting research, and qualitative research is well suited for these goals. When

researchers have an additional desire to come to objective statements, quantitative research can play a role alongside qualitative research.

11.2.2 Why Quantitative Research Needs Qualitative Research

In addition to an ontological/epistemological argument, there is also a methodological argument for combining qualitative and quantitative research. Underlying quantitative effects are many, often hidden, assumptions (Howe 1988; Huberman 1987). It is possible, and sometimes necessary, to examine the plausibility of these assumptions (White 2013). Qualitative research can play a role in this.

Quantitative effects are based on correlations. When a correlation is found repeatedly, it is robust and indicates a relationship between the occurrence of phenomenon A and phenomenon B. Quantitative research is therefore suitable for "localization" (Schoonenboom 2014), for determining exploratively and objectively that "something is going on." However, correlation does not imply causation. The correlation between the number of ice creams sold and the number of drownings is very robust. Yet, this is a spurious effect, without a causal relationship. There are many ways in which a researcher can discover the causal effects underlying robust correlations. Again, qualitative research can play a role.

Quantitative effects are obtained by comparing the scores of a substantial number of individuals on two or more constructs. They are generally intended, however, to refer to a mechanism that is active in individuals (Danziger 1985). A correlation exists, e.g., between anxiety of children and their school performance. The corresponding effect is assumed to operate at the individual level: a particular child's high level of anxiety leads to low school performance of that same child.

In practice, however, quantitative research fails to demonstrate this effect in individuals. Usually, counterexamples are found within a sample, such as children with a high level of anxiety and yet good school performance. The mechanism therefore does not operate in all individuals, and quantitative research hides the diversity within the population (Maxwell 1995; Maxwell and Mittapalli 2010; Yanchar and Williams 2006). There is a need for additional qualitative inquiry into the different realities of the individuals involved, to better understand where the diversity stems from (Sandelowski 1996), when and for whom the effect may or may not occur (Pawson and Tilley 1997), and how, through which pathways, anxiety leads to poor school performance (Weisner 2005).

This ontology of multiple realities can be connected to the transformative and dialectical framework outlined above. Researchers should incorporate the different realities of the various groups and individuals involved into their research. Based on a shared understanding of the concepts used, it is then possible to arrive at objective statements. Therefore, a transformative and dialectical approach requires that researchers *design* for diversity, that they set up their research so that different perspectives from different realities are included (Greene 2007; Johnson and Schoonenboom 2016). This is how mixed methods is interpreted in this chapter.

11.3 Three Stages of Mixed Methods Research: Articulation, Integration, and Decision

In a transformative/dialectical approach, mixed methods research consists of three stages. In Stage 1, different perspectives are involved and articulated, and in Stage 2, these perspectives are analyzed and integrated. Together these two stages aim to describe the multiple realities of the various stakeholders. On the basis of this description, an informed decision is taken in Stage 3.

Describing the realities involved (Stages 1 and 2) and taking an informed decision (Stage 3) are the two fundamental goals of research. In a particular inquiry, one or the other may be emphasized. Together, they are subject to the following general validity requirement: the description of the realities should be *good enough* for making a well-informed decision. Together, the three stages connect ontology/epistemology, methodology (Stages 1 and 2), and use (Stage 3) (Cartwright 2007).

A "good" description requires content-rich, qualitative data; numerically rich, quantitative data (Shaffer and Serlin 2004) are required for a "good" decision at the level of the group or population. Depending on the balance between the aims of description and decision, the emphasis can be either on rich qualitative or rich quantitative data. Mixed methods research, therefore, does not necessarily require "thick descriptions" (Geertz 1973), qualitative descriptions that are as rich as possible, but rather qualitative descriptions that are as rich as needed for taking a well-informed decision (Schoonenboom 2015).

11.3.1 Stage 1: Articulating Perspectives

Stage 1 in conducting mixed methods research involves the articulation of various perspectives, in research terms: data collection and its preparation. In a dialectical approach, different perspectives may be involved from various stakeholders, as is the case in action research (Heron and Reason 2008; Martin 2008). Different perspectives can also involve different theories of various researchers, or different judgements by various participants on the theory of the researchers (Pawson and Tilley 1997; Torrance 2012). The number and kind of aspects that can give rise to different perspectives is fundamentally unlimited (Johnson 2015b; Johnson and Schoonenboom 2016).

Perspectives are complex wholes. Not only do different groups and individuals look with different goals to different things, but they also do so from different positions, with different responsibilities and power. In a research study, these differences in goals, responsibilities, and positions can easily lead to tensions. It is important to recognize and articulate these tensions.

Even more important from a research perspective, different goals put different demands on the generalizability (Mayring 2007) of the research outcomes, on the applicability of the conclusions of the inquiry to other situations and periods than

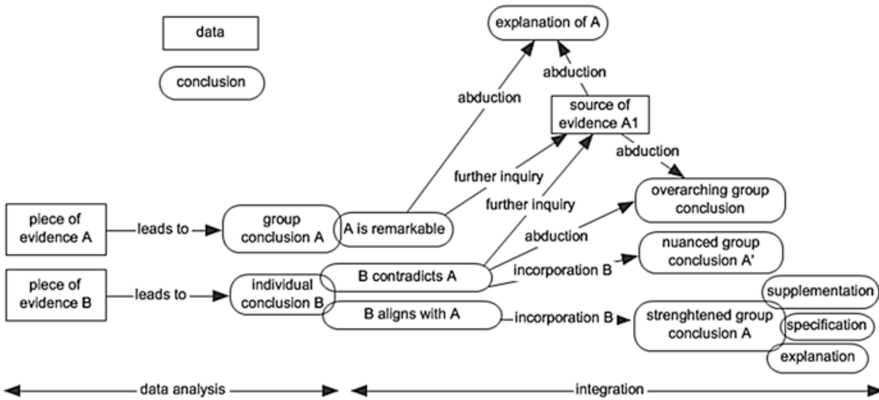

Fig. 11.1 Data analysis and integration in mixed methods research

the specific setting in which the inquiry was performed. In an intervention study in a school, e.g., teachers, management, and parents most likely will want the results to be useful for the school involved; they want to be able to generalize to future situations in their own school. Researchers usually want their results to be applicable to other similar schools or to other school types. In that case, goals of generalization differ among stakeholders.

Combining these various goals of generalization is a daunting task. Each evaluator, who has ever tried to write a scientific publication on the basis of a local evaluation, knows that this often fails, because research activities that are necessary for the scientific goal have not taken place in the evaluation (e.g., collecting certain personal details).

11.3.2 Stage 2: Integration

In Stage 2, the perspectives articulated in Stage 1 are brought together. Stage 2 consists of data analysis and integration (Fig. 11.1).

Data analysis involves the separate analysis of the perspectives obtained in Stage 1, which acquire the role of "evidence" in Stage 2. These individual results are then brought together in the phase of integration (Bazeley 2012; Bazeley and Kemp 2012; Fetters et al. 2013; O'Cathain et al. 2010). While data analysis is part of any empirical research, integration is specific to research in which data come from multiple qualitative sources or from multiple quantitative sources (multi-method), or from a combination of qualitative and quantitative sources (mixed methods). Without integration, multiple-source research leads to separate quantitative and qualitative outcomes and cannot properly be called multi-method or mixed methods research.

In a dialectical approach, integration is driven by the "both/and" principle (Johnson 2015a; Johnson and Schoonenboom 2016). The dialectical researcher

strives to give the various and different “voices” a place in the final conclusion. Integration is also dialogical: conclusions and voices build on each other. Finally, integration is hermeneutical: integration typically includes several cycles of incorporation, abduction, and further inquiry (Fig. 11.1). In a dialectical approach, data analysis and integration are not two separate, successive stages. Instead, the researcher goes back and forth between analysis and integration. In addition, the researcher can go back to Stage 1, and collect new data, if the findings give occasion to do so.

In a dialectical approach, the term *reflexivity* has a specific interpretation. A dialectical researcher is not only aware of how his or her own position affects research outcomes (Walker et al. 2013) but is also able to invite the other to contribute to the outcomes and thus to accept *changes* in the results originally planned or obtained by the researcher (Johnson and Schoonenboom 2016).

11.3.2.1 Ways of Integration: Incorporation

Integration, bringing together various outcomes, can be done in three different ways: by incorporation, abduction, and further inquiry (Fig. 11.1). Incorporation involves adding conclusion B to conclusion A. When B is in accordance with A, this leads to confirmation and strengthening of A, to what is called “triangulation” (Campbell and Fiske 1959; Greene et al. 1989). When B does not match A, this leads to disconfirmation and nuancing A (“A is valid, except in individual case B”). In the latter case, the final conclusion includes the diversity within the sample (Maxwell and Mittapalli 2010).

Triangulation has been considered an important goal of mixed methods research. However, this is an “after the fact” observation: examining additional evidence can always lead to either confirmation or disconfirmation. Therefore, the corresponding goal can better be formulated as “to investigate whether the various pieces of evidence lead to the same conclusion.”

On top of a “bare” confirmation, conclusion B can enter into dialogue with conclusion A and thus bring conclusion A further. B may, for example, supplement A, further specify A, or give an explanation for A. This is called “expansion” (Greene et al. 1989).

11.3.2.2 Ways of Integration: Abduction and Further Inquiry

Two other types of integration that further a conclusion are abduction and further inquiry. Abduction is a logical reasoning of the following form:

(P1) The surprising fact, C, is observed;
(P2) But if A were true, C would be a matter of course;
(C) Hence, there is reason to suspect that A is true (Peirce, *Lectures on Pragmatism*, cited in Hoffmann (1999, p. 278)).

Abduction plays an important role in mixed methods research (Erzberger and Prein 1997). In a dialectical approach, the inclusion of perspectives of both research-

ers and various stakeholders easily leads to conclusions that contradict each other or that are otherwise unexpected. This makes it necessary to find an explanation for these unexpected outcomes by using an existing or emerging theory. In that case, the overarching, abductive explanation forms the mechanism of integration. A fruitful strategy in the search for an explanation is to consider different levels. To understand, for example, teaching and learning in a particular class in a particular situation, simple measurement of a particular construct of interest is not enough. To interpret the results of such measurement in a sensible way, additional knowledge of the specific class, students, teacher, and school is needed, as is general knowledge of how schools operate. This is even more true when the results at the level of the simple measurements contradict expectations or common knowledge (Mathison 1988).

Conclusions can be elaborated by further inquiry (Fig. 11.1). The researcher will then search for additional evidence, which is subsequently integrated with the original conclusion. Further inquiry with the aim of explaining unexpected outcomes is called "initiation" (Greene et al. 1989). Initiation may involve the collection of new data or reanalysis of previously collected data (Creswell and Plano Clark 2011). Such an analysis may provide an explanation for the unexpected outcome A, or for the apparent contradiction between A and B, but may just as well lead to new contradictions.

11.3.3 Stage 3: The Informed Decision

Stage 3 comprises the informed decision, which may fall within or outside the actual study. In action research, the decision often falls within the study and may comprise, e.g., a follow-up of an intervention in the same setting at a larger scale. In a dialectical approach, mixed methods research is conducted to reach a decision that is better informed than a decision based solely on one of the research components (Johnson and Schoonenboom 2016; Torney-Purta 2009). That does not necessarily mean that the decision is taken democratically, but it does mean that several perspectives have been heard and listened to.

11.4 Guidelines for Mixed Methods Research in Early Childhood Education

11.4.1 An Example of Mixed Methods Research in Early Childhood Education: the Mosaic Approach

The remainder of this chapter is a demonstration of these foundations of mixed methods research on the basis of a well-known and well-described example in early childhood education, the Mosaic approach (Clark 2005; Clark and Moss 2005) (Box 11.1).

Box 11.1: A description of the Mosaic Study "Spaces to Play"
The review led to the outdoor environment being chosen as the focus for the second study, *Spaces to play* (see Clark and Moss 2005 for a full account of this research). This set out to make young children's perspectives the starting point for change to the physical environment. The study was a collaboration with Learning through Landscapes, a charity based in England that works to promote the use, development and maintenance of school playgrounds. This was part of a wider initiative by Learning through Landscapes to work with a local authority and 15 early years settings to develop accessible, replicable, 'low tech' and affordable solutions to developing their outdoor environment.

The study was based in a preschool for three- to four-year-olds. Twenty-eight children were involved, together with parents and practitioners. The preschool included a number of children with special physical or behavioural needs, including several with speech and language difficulties. It served a mixed locality including an area of social disadvantage.

The manager, practitioners and a group of parents wanted to take more advantage of the small outdoor space available to the preschool. This included a softplay surface, a small area of decking, a muddy bank and 'boggy' ground where there was an underground spring. The space was surrounded by a high-security fence, which separated the preschool from a park.

[...; one of the play objects is the playhouse JS] The playhouse was a small wooden shed given to the preschool by a local business. It had a door, which opened out onto decking, and two windows, which had clear views of the play surface, the decking and muddy ground. There was a plastic barbe[c]ue set, table and chair in the house. Four children or more could squeeze inside. [...]

There were two stages in the original study: first gathering material, then reflection and interpretation. The practical focus of: the *Spaces to play* study led to the articulation of a third stage to the Mosaic approach, in order to emphasise the decisionmaking element of the listening:

- Stage One: gathering children's and adults' perspectives;
- Stage Two: discussing (reviewing) the material;
- Stage Three: deciding on areas of continuity and change. [...]

Discussions centred around two main questions:

- Which places do children see as important in this outdoor space?
- How do the children use these places?
  […]

Starting with observation, the researcher worked with groups of children to find out their views and experiences of this existing play space in order to form the basis for any changes to the provision. Children took photographs of the space and made these into individual books. Others took the researcher on a tour of the site, recording the event with a camera and by making an audio-tape. Working in pairs or small groups, the children made maps of the outdoors using their photographs and drawings.

(continued)

Box 11.1: (continued)

The researcher interviewed children individually or in groups outside or on the move. Four practitioners and four parents were also interviewed for their perspectives on how the children used the outdoor space.

A new tool was added to the Mosaic approach for this study: the magic carpet. This was designed to open up new conversations with the children about their wider environment. What local spaces were the children aware of, what were their experiences of these places and what additional insights could these give to the current and future uses of their outdoor space? A slide show was made using images of the local town centre, local landmarks and the park (all taken from a child's height). The researcher added images of her local park as well as images taken during the study of the preschool's outdoor space. The home corner was converted into a darkened tent and children sat on a 'magic carpet' to watch the slides in groups. Christine Parker (2001) had tried this idea after her trip to Reggio Emilia as a way of talking to young children about different places.

11.4.2 Guidelines for Articulating Perspectives

11.4.2.1 Consider the Different Needs for Generalization of the Various Stakeholders, in Relation to Their Different Perspectives and Goals

In the Mosaic study, various groups are involved, each with different perspectives, goals, and needs for generalization. The goal of the manager, practitioners, and parents, as well as the interest of the children, is to improve the situation of this specific preschool. They want to be able to generalize the outcomes of the study to the future situation of their own preschool and to use the outcomes to take measures in their own preschool. Learning through Landscapes has a more far-reaching goal, namely, the development of good and affordable solutions for the outdoor environment of their preschools, of which the preschool in the Mosaic study is one. For Learning through Landscapes, it is therefore important that the research outcomes are generalizable to their other preschools.

The researchers have an entirely different goal, namely, involvement of children in a meaningful way in decisions that affect them at a very early stage (Clark and Moss 2005). The researchers aim to generalize their research method. Presumably, their need for generalization extends to preschool children in the UK and possibly beyond.

Differences in goals and perspectives easily lead to tensions and contradictions. For example, a game that is considered fun and exciting by the children may be too dangerous in the eyes of the practitioners or undesirable in the eyes of the parents. Dialectical researchers recognize and resolve these tensions, rather than deny them or automatically choose the perspective of the adult parties.

The different needs for generalization should be carefully combined and weighed. This places high demands on data collection and data analysis. For example, the answer to the questions what places in the outside environment are important to the children and how they use these places (Box 11.1) should be detailed enough to be applicable in this preschool's practice and at the same time abstract enough to be applicable in the other preschools. Consequently, researchers will have to identify the "active ingredients" in the use and appreciation of the playgrounds. Something similar applies to the active ingredients in the research method of involving children in decisions that affect them.

11.4.2.2 Use Adequate and Complementary Methods to Articulate the Perspectives

The transformative goal of the Mosaic study, the empowerment of children, can only be realized when methods are used that allow children to express their perspectives adequately. In the Mosaic study, children are given the opportunity to express their views with the help of visual means (Liebenberg and Ungar 2015): the camera. Their results are laid down in photo books, tours, and maps. The number of photographs provided information on the importance that children attached to the playhouse, its content, and how they used the playhouse.

The most detailed picture of how the children used their playgrounds was obtained by observation. Observation, however, has some limitations (Johnson and Christensen 2014). It is quite conceivable that existing cases of use accidentally do not happen to occur during the observations. The latter applies by definition to imaginable, and possibly desirable, forms of use, which have not occurred yet. In addition, some constructs do not lend themselves easily for observation, such as the importance that children attach to their playgrounds and how they appreciate them.

In the Mosaic study, information about these last two constructs was obtained by interviews. Adults and children alike are to some extent able to reflect on their experiences and to put these reflections into words (Gredler and Shields 2008; Howe 2004). Interviewing young children has some specific challenges, such as their limited ability to express themselves in language and to look back on their experiences and the impression that the adult researcher and other elements in the interview setting can make on the child (Cameron 2015).

Finally, the Mosaic researchers wanted to know how the way in which the children use their playgrounds in the preschool's outdoor environment stems from how they, as physically small people in development, look at the world. For this purpose, observation outside the preschool's outdoor environment is a conceivable but very labor-intensive method, with the risk that relevant ways of viewing the world happen not to occur during observation. Interviews are equally less suitable, because a look at the world can be verbalized only to a very limited extent. A way of looking can best be *elicited*, and this is done par excellence with the help of an experiment (Johnson and Christensen 2014), the Mosaic study's "magic carpet."

Box 11.2: Typographical adaptation of Clark (2005, p. 34)[1]
Places to expand: the house

Observing the children [1] revealed *the house to be a key resource for them*. The children **confirmed** this through their photographs [2], the tour [3] and their interviews [4]. Parents **also** mentioned [5] the house as an important space in the preschool. **However**, the interviews with practitioners [6] showed that *the house was a source of tension*. They felt *it was too small*. The review with children [7], practitioners [8] and Learning through Landscapes [9] **recognised these opposing views** and **raised some possible solutions**. The preschool has now *turfed a new area for children to use to build their own temporary structures*.

[1] Numbers in brackets indicate a method of data collection. Italic text contains conclusions. Text in bold shows how conclusions build on each other. Copyright 2005 by Policy Press. Adapted with permission.

11.4.3 Integration: How Conclusions Build on Each Other

According to the authors, the conclusions of the Mosaic study build on each other as shown in Box 11.2. Table 11.1 shows the chain of evidence of the Mosaic study, using the terminology of this chapter.

11.4.3.1 Use Conclusions to Focus the Inquiry and Formulate New Research Questions

In the Mosaic study, conclusions are not only used for incorporation, abduction, and further inquiry but also to focus the inquiry by altering, limiting, or expanding the research question. A common strategy is to focus the research question on what proves to be important to the participants (Hesse-Biber 2012; Mertens 2007, 2010; O’Cathain et al. 2013; Sandelowski 1996). Only after the playhouse had been identified as important to the children, it could become the focus of research questions 2–5 (Table 11.1). Traditionally, research subquestions are seen as substantive divisions of the research question. From a dialectical mixed methods perspective, it is often more convenient to see them as procedural divisions of the research question, as “intermediate” research questions (Schoonenboom 2014).

Using conclusions to formulate new research questions is often as important as using conclusions to answer existing research questions. In the Mosaic study, the conclusion that the playhouse was a source of tension was subsequently used to focus the inquiry on finding an explanation for this tension. This focus was deemed

Table 11.1 Chain of evidence in the Mosaic study

Question/ conclusion	Collection technique	Type	Level	Evidence	Integration process	Integration outcome
Question 1				**Which places do children see as important in the preschool's outdoor environment?**		
	Observations	Quan	Group	Children often used the playhouse	–	–
Conclusion 1a				**The playhouse is an important place for the children**		
	Photographs	Quan	Group	The playhouse was in 12 of the 60 photographs taken by the children	Incorporation	Confirmation
	Photographs	Quan	Group	The playhouse was included in the more often in the children's books than other objects	Incorporation	Confirmation
	Photographs	Qual	Group	Photographs included inside and outside shots	Incorporation	Confirmation + supplementation
	Photographs	Qual	Group	The playhouse was a place in which to hide, talk to friends, and watch what was happening outside	Incorporation	Confirmation + supplementation + explanation
	Tour		Group	Children took inside and outside photographs on their tours and included these on their maps	Incorporation	Confirmation
	Interviews	Qual	Group	The children provided detailed descriptions of the playhouse	Incorporation	Confirmation
	Interviews parents	Qual	Individual	One parent explained that her child also had a playhouse at home	Incorporation	Confirmation
Final conclusion 1				**The playhouse is an important place for the children**		
Question 2				**How do children appreciate the playhouse?**		
	Interviews children	Qual	Group	Some children call the playhouse their favorite place	–	–
Conclusion 2a				**Children appreciate the playhouse positively**		
	Interviews parents	Qual	Individual	One parent explains that her child enjoys playing in the playhouse	Incorporation	Confirmation
	Interviews practitioners	Qual	Group	Practitioners would like to give the playhouse to the children as a present	Incorporation	Confirmation

Conclusion 2b				**Children appreciate the playhouse positively**		
	Interviews children	Qual	Subgroup	Some children indicate that the playhouse is too noisy	Incorporation	Disconfirmation
	Interviews children	Qual	Individual	One single child does not appreciate the playhouse	Incorporation	Disconfirmation
	Interview practitioners	Qual	Group	The playhouse is a source of tension	Incorporation	Nuancing
Final conclusion 2				**The playhouse is appreciated, but it is also a source of tension**		
Question 3				**What causes the tension in the playhouse?**		
	Interview practitioners	Qual	Group	The playhouse is a source of tension, because it is too small	Further inquiry	Explanation
Final conclusion 3				**The playhouse is appreciated by the children, but it is also a source of tension, because it is too small**	Abduction	
Question 4				**How do the children use the playhouse?**		
	Photographs children	Qual	Group	Children took photographs of the inside and outside of the playhouse	–	–
Conclusion 4a				**The playhouse is used as an object to play with, as a space to play and as an observation post**		
	Interviews practitioners	Qual	Group	Children use the playhouse for various purposes	Incorporation	Specification
	Observation	Qual	Group	Children used the playhouse to hide, talk to friends, and watch what was happening outside	Incorporation	Specification
Final conclusion 4				**Children used the playhouse as a social place**		

(continued)

Table 11.1 (continued)

Question/ conclusion	Collection technique	Type	Level	Evidence	Integration process	Integration outcome
Question 5				**How does the way in which the children use the playhouse stem from how they look at the world?**		
	Experiment	Qual	Group	Children look at the world from children's height and like to keep an eye on what is happening outside	Incorporation	Specification
Final conclusion 5				**The way in which the children use the playhouse stems from how they look at the world**		
Decision				**The playhouse is a place to expand**		
Decision				**The children should have an area to use to build their own temporary structures**		

important by the researchers, but not necessarily by the participants. The children's general appreciation of the playhouse made it imperative to give the playhouse a prominent place in the redesign of the outdoor environment, and this in turn made it necessary to find a solution for the encountered negative tension. Hence, using conclusions to focus the inquiry is very important, and it is should therefore preferably be applied as a general strategy wherever possible, rather than being only invoked in the case of unexpected outcomes. This applies equally well to finding explanations, to finding out what is important to participants and to localization (Schoonenboom 2015), and to finding out "where the action is."

11.4.3.2 Do Not Ignore Individual Negative Evidence

The principle that quantitative effects are valid for all individuals involved leads to two guidelines for integration, "Do not ignore any individual" and "Do not ignore any negative evidence," combined, "Do not ignore individual negative evidence." In a dialectical approach, a conclusion B at individual level which contradicts a previous conclusion A at group level is not ignored but is used to nuance A, or to search for a new overarching conclusion, in which the contradiction is resolved (Fig. 11.1).

The Mosaic study makes good use of individual and negative evidence. There are some children who depreciate the playhouse and some others who do appreciate the playhouse but also see it as a source of tension. Thus, on the basis of some individuals' negative evidence, the researcher subsequently searched for an explanation for the tension in the playhouse, which was then found.

11.4.3.3 Quantitize Qualitative Data Where Applicable

The Mosaic study is to a large extent driven by a decision goal at the group level on the redesign of the preschool's outdoor environment. This goal requires rich quantitative data: the decision-makers have to know *at the group level* how children appreciate the various playgrounds in the preschool's outdoor environment. Knowing that, how, and why certain opinions and ways of using the playgrounds exist – typical outcomes of qualitative inquiry – is not enough. One also has to know *to what extent* these occur.

Quantitative outcomes can be obtained in different ways. Sometimes, the data collection technique is quantitative, and is then followed naturally by a quantitative technique of data analysis, as in a survey study. An example within the Mosaic study is counting the number of photographs showing the playhouse to determine the importance of the playhouse for the children. Sometimes, the data collection technique is qualitative, and the obtained qualitative data are then converted into quantitative data, which is called "quantitizing" (Collingridge 2013; Sandelowski et al. 2009). The importance of the playhouse for the children was additionally determined by counting how often the playhouse was mentioned in the interviews and how this related to the number of times other playing objects were mentioned.

Counting codes in interviews is not without risk. If the playhouse is not mentioned in a specific interview, this does not necessarily mean that it is not important for the interviewee. In addition, the interviewer might elaborate more on what the interviewee says about the playhouse in one interview than in another. This does not necessarily mean that the playhouse is less important to the interviewee of the latter interview.

11.4.4 The Informed Decision: Validity Requirements

For a well-informed decision, the description of the multiple realities involved should be good enough. "Good enough" has been described in the literature under the heading "validity." The methodological literature makes a sometimes more, sometimes less clear distinction between validity as an outcome, threats to validity, measures to increase validity or to address validity threats, and validity requirements or validity criteria (Bryman et al. 2008; Eisenhart and Howe 1992; Maxwell 1992, 2013; O'Cathain 2010; Onwuegbuzie and Johnson 2006; Spencer et al. 2003; Teddlie and Tashakkori 2009; Yin 2013). This section emphasizes measures to increase validity, because I believe that researchers benefit most from advice on what they can do. In the Mosaic study, the following measures have been taken to increase validity:

General

1. The study has been conducted in a real setting:

Articulating perspectives.

2. All stakeholders involved have been heard.
3. All stakeholders have been given the opportunity to make their voice heard through appropriate means.
4. A voice has been given to those with less power.
5. Multiple methods have been used with complementary capabilities and limitations.

Analysis and integration.

6. The information of all voices has been used.
7. The study focused on what was most important to the most relevant and at the same time least powerful stakeholder: the playhouse.
8. Individual information, especially individual negative information, has been used.
9. Additional information has been used not only to strengthen and nuance conclusions but also to come to new insights through further data analysis and abduction.

These validity measures reflect and extend the validity measures and criteria mentioned in the literature. Measure 1 leads to *ecological validity* (Hammersley 1996): The study's conclusions translate well to real-life situations.

Measures 6–9 reflect Yin's (2013) first of four "principles" of good case studies, namely, that the research should attend to all the evidence. This principle is reflected in Measure 6, the use of information of all voices, and in Measure 8, the use of individual and negative information.

Measure 8 extends Yin's (2013) third principle that the researcher should address the most significant aspect of the case study, by specifying that what is most relevant is determined by the least powerful stakeholder. Measures 4 and 7 refer to the voices of the least powerful stakeholders, to what I would like to call *transformative validity*.

Measure 9 leads to what I would like to call *dialogical validity*: Conclusions from different sources of evidence are used to further other conclusions. This validity criterion comes to the fore without label in Greene (2015) and Hesse-Biber (2012).

Measures 2–5 relate to generating the various pieces of evidence. Measures 2–5 remain undiscussed with Yin and other writers on validity (Eisenhart and Howe 1992; O'Cathain 2010; Spencer et al. 2003) or are only broadly described as the "involvement of users" (Bryman et al. 2008). Together, Measures 2–5 lead to *inside-outside legitimation* (Onwuegbuzie and Johnson 2006), an accurate representation by the researcher of both the insider's and the observer's view. In addition, Measures 2–4 also indicate which of the insiders the researcher should represent ("all" in Measure 2 and in particular those with less power in Measure 4) and how the researcher should represent them (through appropriate means in Measure 3).

Measure 3 leads to *analytic adequacy* (O'Cathain 2010; Teddlie and Tashakkori 2009): Data analysis techniques are appropriate for the research question and are applied properly.

Measure 5 leads to *weakness minimization* (Onwuegbuzie and Johnson 2006): The weakness of one approach is compensated by the strengths of the other, which I prefer to call "the incompleteness of one method is complemented by the other."

Together, these measures lead to *political validity*: The consumers of mixed methods research value the meta-inferences stemming from both the quantitative and qualitative components of a study (Onwuegbuzie and Johnson 2006).

One important validity criterion has not been considered in the description of the Mosaic study. That is Yin's (2013) second principle:

10. The analysis should address, if possible, all major rival interpretations.

The researcher should actively look for alternative explanations and then take steps to eliminate them as much as possible.

The following three validity measures apply to the relationship between the description and the decision:

11. The study is a sufficient preparation for the decision.
12. The decision fits the preparatory description well.

13. The quality of the preparatory description is high enough, but not necessarily higher than necessary for a good decision.

Taking Measures 1–9 automatically leads to the fulfillment of Measure 10. However, if the decision-maker ignores the preparatory description in his or her decision, then this decision is not a valid overall conclusion, hence the necessity of Measure 12. The description in Boxes 11.1 and 11.2 only globally indicates how in the Mosaic study the decision relates to the preparatory description.

Measure 13 corresponds to the "good enough" principle. "Good enough" means that it is not necessary to include "everything" in the study. As such, it is "good enough" to base the decision to expand the playhouse upon the quantitative outcome that a large majority of the children uses and appreciates the playhouse. Similarly, "good enough" means that matters are excluded that are less relevant to the decision, such as little-used play objects, or in-depth explanations for nonproblematic aspects of the playhouse. What is good enough depends partly on how decisive a piece of evidence is (Morse and Niehaus 2009). Counting the photographs of the playhouse requires a less stringent check on reliability and validity, because it is only one of the indicators of the playhouse's importance.

11.5 Discussion

11.5.1 Summary of the Mosaic Study as an Example of Mixed Methods Research

The Mosaic study describes from a transformative and dialectical perspective the multiple realities of the various stakeholders; the stakeholders were given the opportunity to contribute to this description through data collection instruments that fit their own capabilities. Next, the conclusions from the various data sources were brought together. In this process, the separate group and individual conclusions were maintained and used to conduct further inquiry and to come to overarching conclusions. From bringing together these multiple subjective realities, an objective picture emerged. Given our shared understanding of the playhouse and of the term "appreciate," it makes little sense to call the conclusion that the children appreciate the playhouse "intersubjective." Next, the description of the multiple realities has been used to take an informed decision, which at first sight appears to be "good enough."

In the Mosaic study, quantitative evidence has played a modest role and has always be accompanied by further exploration of its underlying assumptions. Concluding that the playhouse was important for the children on the basis of the number of photographs on which the playhouse occurred was done under the assumption that children take photographs and make these into books of objects that they find important – and not of arbitrary object, objects that are too big to ignore, or objects with an attractive shape. To test this assumption, qualitative interviews

were held with children, in which they could articulate the importance of the playhouse to themselves.

11.5.2 The Added Value of This Chapter

This chapter provides a foundation for acting in mixed methods research, in particular for the use of individual negative evidence. Because quantitative effects refer to principles that operate in individuals, they should in principle apply to all individuals involved. Contradictory conclusions, based upon individual negative cases, can therefore be used to nuance the main conclusion or to conduct further research. This chapter also provides a basis for the division of labor between qualitative and quantitative research. For the description of the multiple subjective realities, qualitative research is needed, while quantitative outcomes are needed for a description at group level.

This chapter is a further specification of Liebenberg and Ungar's (2015) iterative research process, because it makes clear how various conclusions build on each other, a process in which an important role is played by abduction and further inquiry. In this chapter, the example of the Mosaic study has been placed in two relevant mixed methods tradition: the transformative tradition of giving a voice to the least powerful and the dialectical tradition of designing for divergence. From the literature, those validity criteria have been selected that are most important to early childhood education, and these have been further elaborated.

Finally, this chapter offers a further elaboration of the three research stages in the Mosaic study (Box 11.1). The first two stages together are considered "the description of the multiple subjective realities involved," and a fundamental principle has been formulated that this description should be good enough to enable a well-informed decision in the third research stage. I hope this chapter has brought mixed methods research in early childhood education one small step further.

Acknowledgments Thanks to Bert van Oers for inviting me to write this chapter and for his patience and encouragement. Thanks to Bert and to the Research Group Higher Education at VU Amsterdam for their comments on earlier drafts of this chapter.

Chapter 12
Current Approaches in Quantitative Research in Early Childhood Education

Linda J. Harrison and Cen Wang

Abstract Research in early childhood education has witnessed an increasing demand for high-quality, large-scale quantitative studies. This chapter discusses the contributions of quantitative research to early childhood education, summarises its defining features and addresses the strengths and limitations of different techniques and approaches. It provides an overview of new directions and state-of-the-art approaches in quantitative research, outlined under four key topic areas: identifying and understanding naturalistic groups (i.e., chi-square analysis, analysis of variance, cluster analysis), identifying mechanisms (i.e., correlation, regression analysis, structural equation modelling), identifying causation (i.e. randomised controlled trial, regression discontinuity) and identifying trajectories and patterns of change in individual learning, development and wellbeing (i.e. latent growth curve modelling, growth mixture modelling). Each section explains the selected research methods and illustrates these with recent examples drawn from early childhood quantitative research conducted in Australia, Canada, Germany, the United States and Chile.

Keywords Postpositivist approaches in early childhood research • Statistical analysis in early childhood research • Testing causation in intervention studies • Trajectories of learning and development • Quantitative research in early childhood

12.1 Introduction

Research approaches in early childhood education can be broadly categorised as quantitative, qualitative and mixed method studies that combine qualitative and quantitative methods. Each of these methods has merit, and the researcher's first task is to determine which approach is best suited to their specific research topic and

questions (Mackenzie and Knipe 2006). Some questions can only be answered using a quantitative design, whereas others are best suited to mixed methods. The focus of this chapter is to discuss quantitative research methods as they are currently applied in early childhood education research and explain the logic of commonly used as well as new data analysis techniques. Examples of recent early childhood education research are drawn on to show how these techniques are applied in addressing specific research questions.

Quantitative research uses a deductive approach to test theories and hypotheses (Bryman 2012). Researchers using this approach seek to explain some aspect of the natural world through observation or experimentation and the collection of empirical (or measureable) data. As such, quantitative research has its roots in the positivist paradigm: it follows the scientific method, applying a series of steps to generate research questions, define a sample of participants, design a set of procedures for data collection that draw on well-substantiated measures, conduct data analysis in accordance with the sample and measures, interpret results and reach conclusions (Mertens 2010). Current approaches in quantitative research tend to align with a postpositivist paradigm which retains the idea of objective truth, or the existence of one reality, but warrants that the discovery of such reality is limited to a certain realm of probability. Postpositivism accepts that the theoretical frames, background, knowledge and values of the researcher influence what is observed or measured (Mertens 2010).

12.1.1 Why Is Quantitative Research Important for Early Childhood Education?

In early childhood education, quantitative research methods have been applied to questions about the effects of early education and care, or the impact of intervention programmes, on children's learning and development. Results of this type of research are often cited in the justification and design of early childhood policies; see, for example, Australia's National Early Childhood Development Strategy (Council of Australian Governments 2009) and the standards and curriculum frameworks adopted for the provision and regulation of early childhood education and care, such as the US Quality Rating and Improvements Systems (Office of Child Care 2014).

Increasingly, governments and nongovernment organisations are looking to large-scale, or population-based, studies for evidence to inform policy development. In New Zealand, for example, the Dunedin Multidisciplinary Health and Development Study has tracked the progress of 1,037 babies born over a 1-year period between 1972 and 1973 and provided invaluable information about their health, development and behaviour to inform national and international policy (Silva and Stanton 1996). Similarly, the Longitudinal Study of Australian Children (LSAC) with a sample of 10,000 children recruited in 2004 and followed every 2 years is producing a wealth of information on parenting, family relationships and children's health, development and wellbeing that is being drawn on to advance knowledge and facilitate policy reforms in early childhood education and care (Gray

and Sanson 2005). In the United Kingdom, the results of the Effective Provision of Preschool Education (Sylva et al. 2010) longitudinal study of 3,000 children have had a major influence on the focus of early childhood policy development, not just in that country but around the world.

Governments are not only supporting long-term studies through research funding bodies but are also collecting particular types of data at a national or state/provincial level. In Canada and Australia, for example, the Early Development Index has been used to collect teacher reports on five domains of children's development in the first year of school (Janus et al. 2016). National and international testing of school achievement outcomes is also playing an important role in government policy. Longitudinal datasets can be linked to the achievement test scores that governments collect; for example, the LSAC sample is linked to children's scores on the National Assessment Program – Literacy and Numeracy (NAPLAN) at Years 3, 5, 7 and 9 of primary school.

There is also an increasing interest in testing the effects of intervention programmes or curriculum approaches on children's learning and development outcomes. For example, in the United States, the effectiveness of Early Head Start (0–3 years) and Head Start (3–5 years) programmes for young children growing up in poverty has been examined in large-scale randomised controlled trials (RCT). The Head Start Impact Study of 5,000 children (Puma et al. 2010) and the Early Head Start Study of 3,000 children (Love et al. 2005), which tested immediate- and long-term benefits for children's social and emotional development, school readiness and academic achievement at school, provided evidence to enable communities to continue to receive ongoing government funding to support these programmes. In Australia, the New South Wales government recently announced the introduction of the Fostering Effective Early Learning Study which will apply a clustered, randomised controlled trial to evaluate the impact of a professional development intervention programme in the year children transition to school (NSW Education, 2015).

12.1.2 What Are the Defining Features of Quantitative Research Methods?

Quantitative research has been described as essentially "the study of relationships between variables" (Punch 2003, p.2). In quantitative research, variables are specific characteristics that are defined in numeric terms. At the simplest level, a variable indicates a code or category. This type of variable is referred to as a nominal (or categorical) variable. Examples of nominal variables are sex, language(s) spoken at home or type of childcare used at a specific age. Each of the codes in a nominal variable is distinct and independent of the other codes. In some cases, however, the codes can indicate a sequence, or ordered set of levels. These variables are referred to as ordinal. For example, level of qualification can be coded in increasing steps, such as certificate III, diploma, bachelor degree and master degree, to create a four-level ordinal variable. Most variables in quantitative research, however, are

measured more precisely, with each point indicating an equivalent or measureable increase in value. These are referred to as interval (or continuous) variables. Common examples of continuous variables are family income (in dollars), age (in years or months), education (in years), quantity of childcare (in hours per week) or scores on an achievement test. Continuous variables are also created from surveys or questionnaires that collect ratings, e.g. on a five-point scale from strongly agree to strongly disagree, for a series of related items that are designed to measure one construct. For example, the Student-Teacher Relationship Scale – short form (Pianta 2001) is a 15-item questionnaire completed by caregivers or teachers about their interactions with a study child. Two constructs are measured: closeness, which is measured by the average rating on the five-point scale for seven items, and conflict, measured by the average rating for eight items.

Quantitative data appear as variables represented in numeric form. In a variable-centred approach, the relationships between variables are tested through statistical analyses (Punch 2003). There are two major types of variable-centred analyses: parametric and non-parametric. Non-parametric tests are used for nominal or ordinal data and are limited in scope as the variables represent the number or percentage of the sample population in each category (e.g. 100 or 50 % boys in a sample of 200 children). Non-parametric tests are used to compare distributions across groups, for example, the proportion of boys and girls who attend preschool. A common non-parametric test is chi-square analysis. Parametric tests, on the other hand, are used when the variables are measured by continuous data which represent a range of scores across the sample population (e.g. families' average, minimum and maximum income). Parametric tests are used to examine the relationships among variables and provide insights into the relative magnitude or strength of the relationship, for example, assessing the predictive relationship between family income and children's scores on a test of vocabulary. Some common parametric tests are correlation analysis, regression analyses and structural equation modelling.

A feature of parametric analyses, and the variable-centred approach to statistical analysis in general, is the use of unidimensional variables to describe the functioning of each participant in relation to the overall sample; for example, a child's score on a vocabulary test will be higher or lower than the average score for the sample of children tested. The results of variable-centred analyses also report average findings for the sample being tested: for example, a correlation test of the association between family income and child vocabulary will generate a figure that is the average correlation for the sample being studied. Whilst variable-centred analyses can take account of individual or group differences, these are typically described in terms of precoded characteristics (variables) such as gender, cultural background or disability status. The focus on 'average' or generalised findings for a population has been seen as a limitation of variable-centred approaches in quantitative research.

An alternate approach is person-centred analysis, which focuses on relationships among individuals rather than relationships between variables. In these methods, the analysis takes account of the multidimensional nature of human functioning to explore the combinations of dimensions within individuals and provide a picture or profile of the individuals (Magnusson and Bergman 1988). The goal of the analysis is to "group individuals into categories, each one of which contains individuals who are similar to each other and different from individuals in other categories" (Muthén and Muthén 2000, p. 882). Some common person-centred analysis techniques include cluster analysis, latent class analysis and growth mixture modelling.

12.1.3 The Limitations and Challenges of Quantitative Research

As with any other type of research methodology, quantitative research has its limitations and challenges. These include the availability of a large enough sample to meet the requirements of statistical data analyses; the appropriateness of quantitative methods for collecting data with young children; the cultural appropriateness of some assessment tools; the reliability of some measures, such as self-report questionnaires, which can be affected by social desirability; measurement error; and the need for multiple sources of data to avoid bias in testing measured outcomes. Despite these limitations, quantitative research methods can help researchers examine key questions in early childhood education research.

The increased use of quantitative research designs and statistical analyses to address key research questions and inform policy poses new challenges for future early childhood researchers. Quantitative research is a complex and rapidly changing field. New approaches to data collection, and improvements to analytical tools and techniques, are moving the field forward at an astonishing pace. In this chapter, we discuss some of these new directions and state-of-the-art approaches, illustrating them with recent examples drawn from early childhood quantitative research conducted in Australia, Canada, Germany, the United States and Chile. The following sections are organised according to four topics: identifying and understanding naturalistic groups; identifying mechanisms – the processes and contexts that affect children's learning, development and wellbeing; identifying causation – the programmes and treatments that make a difference to children's learning, development and wellbeing; and identifying trajectories and patterns of change in individual learning, development and wellbeing. Each section explains the selected research methods and discusses strengths and limitations of these techniques and approaches.

12.2 Identifying and Understanding Naturalistic Groups (Categories)

An important first step in early childhood research is the identification and description of naturalistic groups and subgroups of children. Groups are described in terms of specific characteristics. From here, it is possible to identify factors that predict these characteristics, or to test the effects of these characteristics on children's performance or other aspects of their development. The identification of groups helps researchers to design more targeted interventions.

There are different ways that groups or subgroups of children can be identified. Existing differences such as gender and language (s) spoken at home are common ways for researchers to identify groups and compare their differential functioning in areas of interest. Identification methods can also include direct testing of children's ability, such as speech and language skills. Based on the outcome of these tests, children can then be grouped into identified categories, for example, as typically developing children and children with special needs.

Increasingly, person-centred statistical procedures are being applied to generate and identify groups of children based on a combination of dimensions. For example, researchers who are interested in different dimensions of behavioural problems may extract groups based on statistical analysis of data measuring children's emotional problems and conduct problems. These analyses may generate multiple groups: for example (1) children with elevated problems in both emotion and behaviour measures, (2) children with high emotional problems but low behaviour problems, (3) children with low emotional problems but high behaviour problems and (4) children with low problem scores on both emotion and behaviour measures. These groups are unlikely to be identified without the use of sophisticated statistical procedures. The researchers can then explore predictors of different group membership and the functioning of these groups.

In this section, three analytical tools that are commonly used to identify naturalistic subgroups and/or test differences between groups will be presented: chi-square analysis, which examines relationships between two categorical variables; analysis of variance (ANOVA), which compares two or more groups on unidimensional variables; and cluster analysis, which identifies groups by analysing relationships among multiple variables. Each of these is defined, illustrated using an example of recent research and discussed in relation to the strengths and limitations of the method.

12.2.1 Chi-Square Analysis

Chi-square analysis is a non-parametric test that is a very common analytical tool in social science. It can be used when researchers want to examine the association between two categorical variables that have two or more categories (i.e. two

nominal variables). Specifically, the chi-square test compares the distribution of people within and across groups and analyses statistically whether the observed frequency is similar to the expected frequency. Chi-square tests assume there is no known association between the two categorical variables. Significant differences between observed and expected frequency will result in significant chi-square (χ 2) statistics which suggests that there is an association between the two categorical variables.

Verdon et al. (2014) used chi-square analysis to investigate language maintenance and loss among multilingual children participating in the Longitudinal Study of Australian Children (LSAC) birth cohort ($n = 4252$). First, they identified categories of multilingual children who maintained or did not maintain speaking a language other than English from age 0–1 years (wave 1) to 2–3 years (wave 2) and 4–5 years (wave 3). Next, they tested the association between language maintenance and a number of personal and environmental factors, including gender, parental language use, presence of grandparent in the home, presence of an older sibling in the home, generations since migration, type of childcare and support of languages other than English in the learning environment. Each of these variables was also categorical; for example, two categories of children's language maintenance (maintained vs. not maintained) were tested against child gender (boys vs. girls), to generate a 2×2 table (four cells). Language maintenance was also tested against the type of childcare children received (three categories: centre based, family based, and no external childcare), in a 2×3 table (6 cells). The results of the chi-square tests showed significant results for five of the family factors. Children were more likely to have language maintenance when their parent spoke a language other than English, when there was the presence of a grandparent in the home, when the children were identified as first-/second-generation migrants, when children attended family-based day care as compared with centre-based day care and no childcare, and when languages other than English were supported in the learning environment.

However, there are a few limitations of chi-square test. To have confidence in the chi-square result, the expected frequency (number of participants) in each cell should not be lower than 5. This is a risk in small samples, particularly if the variables have many categories. Another limitation is that a significant χ 2 can only indicate an association between the two variables; it cannot analyse which combination of variables in the table contributes to the significant difference. Researchers usually make a judgement based on the size of the observed vs. the expected percentages to understand the details of this association, but this judgement can be misleading.

12.2.2 Analysis of Variance (ANOVA)

ANOVA is used to understand how different groups (identified by a nominal variable) are related to variables that are measured on a continuous scale, such as family income or children's vocabulary. As such, ANOVA is included within the broad

category of parametric tests. To conduct ANOVA, the independent variable should be a categorical variable with two or more categories, and the dependent variable should be continuous and normally distributed.

Using the Longitudinal Study of Indigenous Children (LSIC) child cohort data, McLeod et al. (2014) investigated Indigenous Australian children's speech and language competence at ages 5–7 years. The question of interest was whether children's expressive vocabulary varied in relation to children's level of geographical isolation. Isolation was coded using an ordinal variable with five levels: none, low, moderate, high and extreme. Children's expressive vocabulary was measured using the Renfrew Word Finding Vocabulary Test which produces scores ranging from 0 to 50. To answer their research question, McLeod et al. (2014) conducted one-way analysis of variance (ANOVA) to test if different levels of isolation (the independent variable) were related to children's expressive vocabulary scores (the dependent variable). Post hoc analysis was conducted to understand specifically which pair of categories in the independent variable was significantly different on the outcome measure (vocabulary). Children who were living in areas coded as moderately isolated had significantly lower scores on expressive vocabulary than those living in low or no isolation areas.

An extension of this research could test whether the significant differences observed among different levels of isolation were the same for boys and girls. To do this, researchers would conduct a two-way ANOVA which requires two independent categorical variables (i.e. level of isolation and gender) and test whether there is a significant interaction between levels of isolation and gender on the outcome: vocabulary.

Note that in the above one-way and two-way ANOVAs, there are different people in each of the categories. If, however, researchers were interested in testing children's expressive vocabulary each year for 3 years to see if there are increases over time, they would have scores for the same people over three time points or categories (time 1, time 2 and time 3). In this case, the researchers would conduct a one-way repeated measures ANOVA. A more complex scenario could test whether the increase in children's expressive language over 3 years was the same for children from different levels of isolation. In this case the researchers would conduct a mixed between-within subjects ANOVA, with the same children in the categories of time (within subjects) and different children in the categories for levels of isolation (between subjects).

ANOVA is a very versatile and useful procedure. Although there are assumptions that should be met when conducting ANOVA, ANOVA is quite robust to minor assumption violation. A detailed discussion of these assumptions and the corrections to implement when assumptions are violated is beyond the scope of the current chapter. Interested readers can consult Field (2005). Researchers can also consider its non-parametric counterpart, the Kruskal-Wallis test, when assumptions of ANOVA are violated. One limitation of ANOVA is that it can test only one dependent variable at a time. If the researchers have several dependent variables, running multiple ANOVAs may inflate Type I error rate which means that significant group differences may be found when there are, in fact, none. More importantly, if the

dependent variables are theoretically related to each other, ANOVA cannot take into account the correlations among the dependent variables which may lead to the failure to detect significant group differences. Therefore, if researchers have a series of dependent variables that are theoretically related to each other, multivariate analysis of variance (MANOVA) should be used to detect such effects.

12.2.3 Cluster Analysis

Cluster analysis is a person-centred data analytical technique that explores the relationships of variables among individuals and identifies homogenous subgroups in a heterogeneous sample (Jung and Wickrama 2008). The generated subgroup members have similar response patterns on the variables of interest. The concept of cluster analysis is informative and interesting for researchers as it can make interventions or strategic actions more targeted and effective for different groups of people.

An example of how cluster analysis has been used in early childhood research is seen in Ahnert et al.'s (2012) study of 105 children at the end of their first school year. They collected children's saliva samples at 8 am, 11 am, 2 pm and 6 pm on a Monday and a Friday of the same week to understand changes in cortisol, as a measure of children's levels of stress. Their research question was whether student-teacher relationship profiles were differentially related to children's capacity to downregulate their stress levels. Student-teacher relationships were measured using three subscales: closeness, dependency and conflict. These data were subjected to cluster analysis to generate different combinations of closeness, dependency and conflict. Four different profiles (i.e. clusters) were generated, identified as a conflict-loaded (CI) profile, which was characterised by higher conflict, lower closeness and higher dependency; a distant-independent (DI) profile characterised by lower conflict but also lower closeness and dependency; a proximal-dependent (PD) profile with lower conflict but higher dependency and closeness; and a proximal-balanced (PB) profile with low conflict, high closeness and low dependency. They conducted ANOVA to examine how different profiles were related to children's capacity to downregulate stress. Results showed that students experiencing proximal-balanced relationships with their teacher were better able to regulate (reduce) cortisol levels over the course of the day at school, than the rest of the students.

The above example suggested that there are four distinct groups of children with varying patterns of relationships with their teachers. To further progress this finding, the researchers could conduct additional analyses to understand what other characteristics might be related to each unique subgroup. Such results could lead to group-specific intervention strategies to support teachers to be aware of and guide their interactions with children towards a more adaptive relationship profile.

One limitation of cluster analysis is that it is not always straightforward to determine the number of clusters (subgroups). There are a number of statistical fit indices that facilitate the identification of optimal number of clusters. However, there are no "golden rules", and, more often than not, different indices may suggest a different

number of clusters. Researchers should consult these indices, but the key criteria to consider are the theoretical basis for identifying different clusters and the meaningfulness of the profiles.

12.3 Identifying Mechanisms – The Processes and Contexts That Affect Children's Learning, Development and Wellbeing

As a tool for studying relationships between variables (Punch 2003), quantitative research is uniquely placed to examine the processes and contexts that influence children's lives. In quantitative terminology, dependent variables [DV] (also known as outcome variables) are influenced by independent variables [IV] (sometimes referred to as predictor variables). For example, closeness in the student-teacher relationship (DV) may be influenced by the quality of the classroom environment [IV]. Other factors that are known to affect the DV also need to be included in the analysis of process; these are referred to as control variables. For example, closeness is known to be higher for girls, so child gender would be included as a control variable in an analysis testing the effect of the IV on the DV. Identifying the ways that variables are related can shed light on how to make a difference in children's life.

In this section, three analytical tools that are commonly used to identify the processes and contexts that affect children's learning, development and wellbeing will be presented: correlation, which is the basic tool for testing relationships between variables; regression, which is used to explain, or predict, scores on an outcome variable from one or more other variables; and structural equation modelling, which is used to create and analyse latent variables.

12.3.1 Correlation

Correlation is the basic statistical technique that explores linear relationships between variables. Because correlation tests the relationship between two variables, it is also referred to as bivariate correlation. Correlation analysis compares scores on one variable with scores on another to test the strength and direction of the relationship between the two variables. The direction can be positive (i.e. a correlation between 0 and 1.0), negative (a correlation between 0 and −1.0) or null (a correlation of 0). The strength of the correlation is described as weak (±0.1), moderate (±0.3) and strong (±0.5). When the two variables being tested are continuous or interval variables, then Pearson *r* should be used as the statistical test. If the two variables are ordinal, then Spearman's *rho* should be used.

Correlation analysis serves as a useful first step for data screening and exploration to inform more complex data analysis. As such, it is rarely used as the sole basis for a published paper, but a correlation table would be expected in the initial descriptive

presentation of the results. The exception to this rule would be a report that is designed to test the structure and reliability of a questionnaire or rating scale. A correlation matrix would be generated to test the strength and direction of the relationship between the set of items on the scale. Strong correlations (> .05) would support the computation of an overall score for the construct that the scale is designed to measure.

12.3.2 Regression Analysis

Based on correlations, regression analyses allow further exploration of the relationships among a predefined set of variables. The aim is to explain, or predict, an outcome from one or more variables. In regression, the outcome variables can be either continuous (i.e. simple and multiple regression analyses) or categorical (i.e. logistic regression analyses), but the same conceptual understanding applies to both. Regression analyses are strongly theory based in that theories should support the selection of one variable or multiple variables as predictors of the outcome variable.

Using data from the Longitudinal Study of Australian Children (LSAC) birth cohort, Williams et al. (2015) used regression analysis to examine the extent to which exposure to early home music activities when children were 2–3 years old was associated with children's outcomes 2 years later at 4–5 years old, in a sample of 2,376 children. Seven separate outcomes were tested: children's vocabulary, numeracy, school readiness, attentional regulation, emotional regulation, prosocial skills and behaviour problems. The authors controlled for the effects of socio-demographic variables, such as Indigenous status, language background (English vs. non-English) and maternal history of depression and also took account of the effects of early shared book reading activities. Using multiple regression analyses, they showed that early home music activities had a small but significant positive relationship with three of the outcomes: numeracy skills, attentional regulation and prosocial skills.

There are many advantages to conducting regression analyses. Regression analyses can include multiple predictors (in the form of continuous as well as categorical variables) which allow researchers to statistically control for the influence of a range of other variables and examine if the predictor of interest can explain the outcomes over and beyond the statistical controls. Williams et al. (2015), for example, examined if early home music activities contributed to child outcomes after controlling for important demographic information. Researchers can also compare the relative importance of different predictors on the outcome variables. Williams et al. (2015) examined the relative predictive value of early home music activities and early shared book reading on children's developmental outcomes. One of the attractions of regression analysis is being able to test what variables (circumstances and prior experiences) predict an outcome. This is informative for identifying risks and supports. The results of well-designed regression analyses can provide strong evidence for the design of intervention programmes.

Cautions, however, need to be taken into account. It is important to ensure that a thorough preliminary stage of data screening is conducted before running regres-

sion analyses. Regression analysis is very sensitive to the presence of outliers (participants whose scores are very high or very low in comparison to the population sample being studied). Exceedingly high correlations between predictor variables (≥0.9) can also lead to erroneous results. Regression also requires a relatively large sample especially when there are many predictors. A limitation of regression analyses is that there can only be one outcome variable tested at a time. If there are multiple outcome variables, this can potentially inflate Type I error. A solution is to use multivariate regression which can include multiple outcomes. Another limitation is that as a variable-centred analysis, regression analysis does not account for the combinations of dimensions within individuals in a sample (Magnusson and Bergman 1988). Rather, it provides a picture of the unidimensional "functioning of a statistically defined 'average' child" (Magnusson and Bergman 1988, p. 49). Finally, it is important to note that regression analyses can test prediction, but not causation.

12.3.3 Structural Equation Modelling

Structural equation modelling (SEM) is an increasingly popular statistical technique in education and psychology. It aims to test the fit of multiple hypothesised models for explaining mechanism, based on a sound theoretical and conceptual rationale, and select the model that best represents the data. SEM is different from regression in two important ways.

First, regression can analyse observed (coded or measured) variables, whereas SEM can analyse both observed and latent variables. A latent variable is a hypothesised construct that is indirectly measured through multiple observed indicators (Kline 2011). A classic example of a latent variable is intelligence, which is a construct that cannot be directly observed or measured. Instead, researchers use a number of tests that capture different aspects of intelligence, such as reasoning, processing speed, memory and knowledge, to indirectly capture the construct of intelligence. The difference between observed and latent variables lies in their approaches to measurement errors. Observed variables assume that all variables are measured without error, which is impossible in social science research. In contrast, latent variables are able to account for the random and systematic measurement errors in the indicator variables (Kline 2011). As such, SEM using latent variables is more likely to produce trustworthy results with strong statistical power.

Second, SEM is a multivariate statistical technique that can be used to test comprehensive models with multiple variables. The complex relations among all variables can be estimated simultaneously rather than running separate regression models. One example of complex relations is a mediation model, which is a common application of SEM in social science.

An example of a mediation model is reported by Feng, Shaw and Moilanen (2011) who investigated the relations among children's shyness, emotional regulation strategies and internalising problems in a longitudinal study of 257 boys from low-income families. They measured children's shyness at ages 1.5–2 years, emo-

tion regulation strategies at age 3.5 years and internalising problems through both mother and teacher report at age 6–7 years. They hypothesised that children's shyness (a latent variable assessed by indicators of unusual fear, cautiousness and withdrawn behaviour) would be related to children's internalising problems at school age. They expected that this relationship would be mediated by children's emotion regulation strategies. They hypothesised that, in stressful situations, children who used adaptive emotion regulation strategies, such as active distraction, would be less likely to develop internalising problems, whereas children who use maladaptive strategies, such as passive waiting, standing and requesting to be held, would be more likely to develop internalising problems. A path analysis model was used to simultaneously estimate the paths from shyness to emotion regulation strategies, from emotion regulation strategies to internalising problems and from shyness to internalising problems. The results confirmed the authors' hypothesis. Specifically, the active distraction regulation strategy mediated the relations between early shyness and maternal report of internalising symptoms, and the passive/dependent regulation strategy mediated the relations between shyness and teacher report of internalising symptoms.

SEM is a powerful analytical tool; however, it has specific requirements for researchers to be able to use it appropriately. First, SEM requires a large sample size. Although there are no strict guidelines, a sample larger than 200 is usually necessary to ensure statistical power and the validity of the results (see Kline 2011 for a review on the issue of sample size). The sample size requirement increases as the complexity of the model and analysis increases. Second, SEM requires researchers to have a strong theoretical rationale for the model(s) that are proposed and tested and a solid knowledge of the relevant literature. This is because SEM aims to find the best model that represents the data. In social science, there can be multiple theoretically supported models. Therefore, the researchers need to compare the validity of the preferred model and multiple alternative models. Third, mediation modelling within SEM is inherently an analysis of causation. Therefore, it is critical to have a clear theoretical rationale of causal processes and to have longitudinal data. For a more elaborated discussion, please refer to Cole and Maxwell (2003).

12.4 Identifying Causation – The Programmes and Treatments That Make a Difference to Children's Learning, Development and Wellbeing

Researchers, educators and policy makers are increasingly interested in establishing causation. For example, a state education department responsible for early childhood education might want to know whether a particular curriculum will make a difference to children's learning, or reduce behaviour problems, before committing government funds to the large-scale purchase of the curriculum. Similarly, providers of teacher education programmes or governments may want to find out whether

a professional development programme will enhance teachers' efficacy and teaching quality, before rolling out the programme to a large number of teachers. To be able to establish causation, careful attention is required to the design of the research method, ensuring that potential threats to validity are addressed.

Before designing a causal study, it is critical that researchers clearly define the research questions, the "cause" to be tested, the outcome(s) that will be affected and how these will be measured and the population for the study. This is necessary to be clear about what causal effect, and to what population, the results can be generalised. The ideal design for addressing causal questions is an experiment, which deliberately manipulates the levels of "cause" by an independent agent outside the participants in the research (Murnane and Willett 2010). This approach is common in scientific and even medical research, but experiments are rarely possible in the social sciences. Causal studies in early childhood lean towards randomised controlled trials, often with a wait-list design, and quasi-experimental designs.

12.4.1 Randomised Controlled Trial

The most robust experimental design is a randomised controlled trial (RCT) in which participants are randomly selected from the population of interest and then randomly assigned into a treatment and a control group. Randomisation in selection and assignment ensures that the two groups are similar in all aspects except for their group assignment. Therefore, any observed differences between the two groups can be attributed to the presence or absence of the "treatment", which makes it possible to claim that the treatment causes the outcome. Having a control group is important in addressing the potential threats to the validity of experiments, such as history, maturation and experimental mortality (see Mertens 2010 for a detailed account of threats to validity). The more rigorous the RCT study design, the simpler the statistical analysis. For studies where a true randomised controlled trial is conducted, a simple comparison of the results for the two groups, such as an independent t-test, can be used to answer the question of causation.

However, in educational research, it is unlikely that researchers would randomly select and assign individuals to treatment and control groups. More often, randomisation occurs at the level of the school or classroom so that all the individuals in a class (or school) are assigned to treatment and control groups. This approach is referred to as a clustered randomisation design. For both randomised controlled trials and clustered randomised controlled trials, it is important to ensure the sample size is sufficient to achieve reasonable power to detect the treatment effect, if it indeed exists. However, when conducting clustered randomised trials, the statistical power is determined by the number of intact groups such as classrooms rather than the number of individuals per classroom. Statistical analysis strategy for clustered RCTs also requires multilevel analyses such as hierarchical linear modelling to account for the higher level effect (i.e. individuals are nested among classrooms, which are nested among schools) and accurately reflect the effect of the treatment.

Yoshikawa et al. (2015) conducted a clustered RCT to examine the impact of a 2-year teacher professional development programme (Un Buen Comienzo [UBC]) in publicly funded prekindergarten and kindergarten in Chile. The outcomes of interest were classroom quality and child language and behavioural outcomes. Six municipalities with a total of 64 schools participated in the study. Among them, 32 schools with a total of 51 classrooms, 66 teachers and 1,033 children were randomly assigned to the full UBC condition, and the other 32 schools with a total of 39 classrooms, 53 teachers and 843 children were assigned to the comparison condition. Using multilevel linear regression analysis to account for the nested nature of the data, the research showed that the UBC programme produced moderate to large effects for classroom quality outcomes, namely, emotional support, instructional support and classroom organisation. However, the UBC programme did not produce significant effects for child outcomes, namely, vocabulary, letter-word identification, early writing, self-regulation and problem behaviours.

12.4.2 Quasi-experimental Designs: Regression Discontinuity

Understandably, in real life research, randomisation experiments can be impossible to conduct due to practicality and/or ethical issues. Quasi-experimental designs can also test causality where participants are not randomly assigned to the groups. Regression discontinuity (RD) pretest-posttest designs are one type of quasi-experimental research that offer an alternative to randomisation experiments when carefully and rigorously administered. RD design uses a non-random quantitative cut-off value such as a test score to group people. For instance, students who are below the cut-off on a pretest score will be given a remedial programme, whereas those who are above the cut-off pretest score will not receive the treatment. Then the post-programme test scores will be measured for the two groups of students. The rationale for RD design is that without the remedial programme, students' posttest scores should be a linear continuous function of their pretest scores. If the remedial programme is effective, then there would be a jump or discontinuity of the linear line at the cut-off score.

Weiland and Yoshikawa (2013) conducted a study using a quasi-experimental regression discontinuity design to examine the impact of a prekindergarten programme that implemented established language and literacy and math curricula, with teacher coaching support. The outcomes that were used to test the effectiveness of the programme were children's ability level in mathematics, language, literacy, executive function and emotional development. The sample was approximately 2000 students enrolled in Boston Public Schools, identified as either treatment or control by the non-random cut-off variable of the child's birthday. Children who had turned 4 on September 1 were eligible for the pre-K programme, whereas those who were not 4 on September 1 could not attend pre-K and thus did not receive the treatment. Regression models were fitted for samples that fell within the 365 days of the cut-off to produce unbiased estimates of the average causal effects of the pro-

gramme. The researchers applied highly complex analytical techniques to test the effects of pre-K on children allocated to the treatment group and, within this, subgroups of children from low-income and Hispanic backgrounds. Results showed that the prekindergarten programme produced moderate to large effect on children's language, literacy and mathematics skills and small effects on children's executive functioning and emotional skills, with the highest effects being noted for Hispanic and low-income subgroups.

Regression discontinuity (RD) designs have been applied as an alternative to RCT in some education studies. The requirement for a relevant and precise "cut-off" is the main challenge, but when found in "real-world interventions", these studies can generate strong practical evidence of the effectiveness of education policy (Meredith and Perkoski 2015). Often relying on existing data, RD designs can be very cost-effective in comparison to experimental RCT designs. They are also not subject to the ethical concerns that RCT studies raise when participants are allocated to the nontreatment (control) group. To address this, many RCT studies use a staggered or wait-list delivery design, so that all participants can be assured that they will receive the treatment and therefore the benefits of participating.

12.5 Identifying Trajectories and Patterns of Change in Individual Learning, Development and Wellbeing

In social science, it is informative and sometimes necessary when designing intervention programmes to understand the developmental trajectories of children's learning and wellbeing. This area of research is concerned with individual change over time, the mechanisms that affect change and the methodological features of longitudinal studies of change. In early childhood, we tend to think of growth in terms of increasing levels of ability (such as reading), but statistical models can be equally applied to outcomes that decrease over time (Singer and Willett 2003). For example, research has shown that children's intrinsic motivation tends to decrease as they move from primary to secondary schools. Along with understanding the nature of this decrease in intrinsic motivation, it is informative to explore factors that predict the beginning level of intrinsic motivation and the decreasing developmental trajectory and how the developmental trajectory is linked to other longitudinal outcomes such as academic achievement. Studies of changes in motivation can provide useful information for the design of effective intervention programmes that support the development of protective factors, such as positive relationships at school, and discourage risk factors.

In recent years, a number of specialist statistical techniques for modelling change over time have been developed. Singer and Willett (2003) outline three methodological features that these techniques share: multiple waves of data collection, outcomes that change systematically over time and a sensible metric for measuring time. The third feature, time, introduces a new challenge to researchers who must

consider when data collection should start (at what age or what point in an intervention trajectory) and how frequently data collection should occur after the start. There are no hard and fast rules, but the metric chosen needs to reflect "the cadence you expect to be the most useful for your outcome" (Singer and Willett p. 11). In this fourth and final section, we present two approaches to collecting and analysing longitudinal data. First, we look at a recent example of researchers who use data linkage techniques to create longitudinal datasets from administrative data held by government. Next, we present two approaches to analysing growth trajectories in students: latent growth curve modelling and growth mixture modelling, using data collected in traditional longitudinal studies.

12.5.1 Longitudinal Data Linkage

The design and implementation of traditional longitudinal research, as exemplified by the LSAC study (illustrated earlier in Verdon et al. 2014; Williams et al. 2015) and other international studies, is a lengthy and costly undertaking. Questions about the cost-benefits of early childhood education and care programmes, for example, require many waves of data, often into adulthood, to be thoroughly answered. Finding alternate sources of data, and even alternate ways of identifying a study sample, has therefore become a recent focus in early childhood research. Through the establishment of strong partnerships between researchers and government organisations, and the increased attention on the part of governments to the early childhood years, data linkage has arisen as a new and exciting research opportunity. A further benefit, and opportunity, comes from the fact that government data are collected from populations, not samples. These large, inclusive datasets make it possible to study populations as well as "population sub-groups within the larger population to generate comparative studies that provide compelling insights into implications for educational practice, and possible points and mechanisms for intervention" (Janus et al. 2016, p. 3).

Brownell et al. (2016) linked birth and prebirth data available from the Manitoba Centre for Health Policy with Early Development Instrument (EDI) ratings provided by teachers when children were ages 4–5 years for a sample of just under 9,000 children. They used structural equation modelling (SEM) to model the interrelationships among EDI cognitive and language outcomes and early child and family factors, including maternal prenatal health behaviours, child health at birth, family risk factors and neighbourhood socioeconomic status. Results indicated that family risk factors were the key driver of academic school readiness and that family risk, in turn, was strongly influenced by neighbourhood socioeconomic status. The implications drawn from this study are, firstly, that trajectories of development start early, and, secondly, that interventions and policies that support communities and the families that live in them may have a greater impact on early childhood development than interventions that focus on individual children.

12.5.2 Latent Growth Curve Modelling

Latent growth curve modelling (LGCM), which is a member of the SEM family of quantitative analysis techniques, is a powerful tool to analyse growth trajectories among children. It is also more advantageous compared to other repeated measures statistics such as repeated measures ANOVA in that LGCM can model measurement errors. LGCM can also statistically test whether the developmental trajectory is linear (showing a steady increase or decrease over time) or nonlinear. A variety of curvilinear (nonlinear) trajectories can be identified, such as rapidly increasing then levelling off, increasing then decreasing or decreasing and then increasing. The accuracy of these trajectory graphs improves with the number of data collection points.

LGCM can be applied to research questions that include a continuous variable that is repeatedly measured at three or more times. It is strongly recommended that the measurement tool is the same at each time to ensure that the changes reflect true change rather than being an artefact of the changing system of measurement. However, in some cases different measures need to be used to ensure age appropriateness. In these situations, the measures should have the same units/scaling and indeed capture the same construct the researchers intended to measure (Kline 2011).

Wetter and El-Sheikh (2012) conducted latent growth curve modelling to examine the trajectories of 251 US children's internalising symptoms such as anxiety and depressive symptoms. They further investigated the role that maternal internalising symptoms, respiratory sinus arrhythmia (RSA) and child gender play in the developmental trajectory of internalising symptoms. Specifically, children's internalising symptoms were measured at three time points (8, 9 and 10 years of age), with results showing that internalising symptoms decreased from 8 to 10 years. Lower maternal internalising symptoms predicted steeper decline of children's internalising problems, and higher RSA served as a protective factor. Children with higher RSA and lower maternal internalising symptoms showed the lowest internalising symptoms at age 10. However, this was only true for girls but not boys.

Note that the researchers used the same measure of internalising symptoms at all three time points. They have also accounted for measurement errors by modelling a latent variable of internalising symptoms with two indicators. A limitation of LGCM is that it produces the average developmental trajectory for the population sample, based on the assumption that all participants come from the same population, which is not necessarily true in all situations.

12.5.3 Growth Mixture Modelling

Growth mixture modelling (GMM) is an extension of LGCM which aims to identify trajectories that differ from the average developmental trajectories. It also requires at least three time points of data collection and a large sample size. Being able to

identify different developmental trajectories is immensely helpful because researchers can then explore the personal and environment characteristics of the most concerning groups of children and from this information design and implement interventions that can effectively target these risk factors.

GMM was used by Spilt et al. (2012) in a study of 657 US students with below-average literacy skills in Grade 1, the majority of whom were from families with low socioeconomic status. They focused on examining how conflict in student-teacher relationships changed from Grade 1 to Grade 5 and the implications of different relationship trajectories for academic achievement. The analyses generated four developmental trajectories of teacher-student conflict for boys and three for girls. These were a low-stable trajectory which was identified as the most adaptive trajectory, a low-increasing trajectory with low initial levels of conflict that increased over the course of primary school and a high-decreasing trajectory with high initial conflict that decreased over the course of primary school. They also identified a small group of boys who had consistently high teacher-child conflict throughout primary school. The results showed that for both girls and boys, the low-stable and high-declining groups did not differ in their academic achievement, and children in both these groups achieved better outcomes than children in the low-increasing group. The worst academic performance was noted for the group of boys who had high stable teacher-child conflict. The results also showed that children's externalising behaviours, IQ, ethnicity and socioeconomic status were related to their differential developmental trajectories.

12.5.4 Challenges and Limitations of Longitudinal Research

A key challenge in analysing longitudinal data, whether in traditional recruited samples or in linked datasets, is attrition or missingness. Participants either drop out of a study, drop out temporarily and then come back, or do not provide some of the data that are being linked. Researchers need to understand who is missing and determine if criteria for "missing at random (MAR)" or "missing completely at random (MCAR)" are met (Singer and Willett 2003). MAR and MCAR retain the original sample, but a sample can become imbalanced if, for example, vulnerable families are found to be more likely to have dropped out. There are a number of ways that researchers can deal with missing data. Imputation techniques can be used to replace missing data where MAR or MCAR can be argued (Kline 2011). In other cases, the researcher sets out a detailed flow chart or written explanation of the included and excluded sample. It is then incumbent on the researcher to test for important differences between the groups who were included in the analyses and those who were excluded. This information is then used when drawing overall conclusions.

12.6 Discussion

The aim of this chapter was to provide readers with an overview of current directions and approaches in the use of quantitative research methods in early childhood education. Four broad themes were presented (identifying groups, identifying mechanisms, identifying causation and identifying trajectories), along with particular statistical techniques that are applied in each of these areas of research, illustrated by specific studies drawn from international literature. The studies chosen as exemplars have met rigorous peer-review processes and are all worthy of further reading. The authors range from novice researchers, reporting PhD studies to established researchers recognised as leaders in the field. In addition to the statistical methods each of the authors applies, these papers also illustrate the wide variety in sample size (from 100 to 9,000 children) and composition (from birth to age 10 years, specific and normative samples) and measures (test scores, teacher and parent ratings and administrative health records) that are typical of quantitative research studies. We hope that the brief summaries of these published papers will inspire readers to follow up with a deeper reading of specific research studies or specific analytical techniques. We also hope that when researchers read about or undertake quantitative research, they will consider each study they read or conduct in relation to the four overarching themes (identifying groups, mechanisms, causation and trajectories) and the extent to which researchers attend to the principles, statistical techniques and limitations of each.

Contemporary Research and Evidence – Early Childhood Education Globally: *Western Europe and UK*

Bert van Oers and David Whitebread

Chapter 13
Quality in Early Childhood Education: The Contribution of Developmental Psychology

David Whitebread

Abstract Historically, there has been a strong contribution of Western European thought to high quality in early childhood education (ECE). Nevertheless, the powerfully child-centred approach running through the contributions of Steiner, Montessori, Isaacs and many others has in recent years been increasingly challenged. This chapter introduces the issues addressed in the Western European section, which reflect the current state of flux arising from the rapidly changing political, professional and research scenarios in which ECE provision is evolving within this region. Chapters address the impact of neuroscience research, the debate concerning school readiness and the 'schoolification' of ECE, the responses to the increases in migrant and other disadvantaged children and the current trends towards the professionalisation of the ECE workforce. In the second half of this chapter, culturally varying approaches to the issue of quality in ECE across Western Europe are reviewed, and the potential contribution of developmental psychology is outlined. The evidence of the individual and mutually supportive contributions of play, oral language and self-regulation to positive outcomes for young children is outlined, alongside the findings of studies concerned with pedagogies which support these key aspects of development. As much of this research has been conducted with school-aged children, the chapter concludes with a plea for more research focused on how these early developing abilities can be nurtured during the very early years of children's lives.

Keywords Issues in early childhood education • Process and structural quality in ECE • Measurement of quality in ECE • Developmental psychology • Play • Oral language • Self-regulation

13.1 Introduction: The Historical Contribution of Western European Thought to High-Quality Early Childhood Education

The philosophical, psychological and practical consideration of what is required to ensure high quality in early childhood education (ECE) has a long and distinguished history within the UK and Western Europe. The influence of the nineteenth- and early twentieth-century European thinkers and educationalists, including such as the Austrian Rudolf Steiner (see Volume 2, section on 'Pedagogies in Early Childhood'), the Italian Maria Montessori (see Volume 2, section on 'Pedagogies in Early Childhood') and the British Susan Isaacs, to name only a few of many, is present today, across the world, as ECE provision expands and high quality is sought. In some aspects these approaches appear to have quite different emphases. Steiner, as a spiritualist and philosopher, emphasised the importance of education supporting the development of the whole child, both emotionally and intellectually, and the role of the arts and pretence play with simple, natural play materials to nurture children's imaginations. By contrast, Montessori, as a trained medical doctor, emphasised a more scientific approach and developed specific materials with which children should play to learn life skills and develop their reasoning abilities. Her approach, however, like Steiner's, was essentially based on a model of children's development, which she believed was most optimally supported by allowing children to make choices and to construct their own understandings through activity with her materials, rather than direct instruction. Both Steiner and Montessori developed models of stages of development, although their first stages ended at age 7 for Steiner and age 6 for Montessori. Nevertheless, they both emphasised the role of early education in supporting children's natural development, rather than in providing instruction. Isaacs (1930), coming from the different traditions of psychoanalytic theory, nevertheless shared some of the same beliefs as Steiner and Montessori. Her principal contribution, however, was to emphasise the importance of nurturing the child's ability for independent thinking. Like Steiner and Montessori, nevertheless, she also believed that this was best nurtured through play, which she described as the child's work. She also recognised the importance of social interaction, both with other children and with adults. Like Steiner, she emphasised the importance of the child's emotional life and the role of pretence play in supporting this. She also believed that early education should support children's natural development and that schooling before the age of 7 would be damaging.

These early approaches, developed within early modern Western European philosophical, scientific and psychological traditions, have been, and continue to be, enormously influential. There are today literally thousands of Steiner, Waldorf and Montessori kindergartens and schools across Europe and the wider world, and their influence, together with that of Isaacs, on the 'constructivist' and play-based approach to children's learning within ECE, later supported within developmental psychology by the works of Piaget (himself significantly influenced by Montessori, in particular) and many others, has been profound.

13.2 The Current Crisis in Western European ECE

And yet, within countries across Western Europe, over the last few decades, some of the fundamental principles which these early and influential figures espoused have come under increasing pressure. The powerfully child-centred approach fundamental to all these long-standing approaches, and to the traditions of the British Infant School, the Danish First School and kindergartens across Western Europe, has been increasingly challenged.

This challenge has come principally from governments and from their acolytes working in the policy arena. The key drivers here appear to have been, perversely, the recognition of the significance of ECE for individual development, and consequently for the growth of the economy, and the publication of international league tables, based on narrow measures of academic achievement. This has led to the rapid expansion of early childhood services across Western Europe, but also the increasing involvement of central governments in its funding and its curricula. Accompanied, particularly in the UK, by an increasingly draconian accountability agenda and the introduction of a baseline assessment for 4-year-olds on their entry to school, and a phonics test at the age of 6, this has fostered, perversely, a push towards the earlier introduction of direct instruction of literacy and formal mathematics and a belief that 'earlier is better'. While, within the international ECE community, there is a strong drive to develop evidence-based, high-quality practice, at the policy level, across Western Europe, these current policy trends are in danger of undermining the very qualities of ECE environments which make them so powerfully effective.

13.3 Issues Addressed in the Western European Section

Against this backdrop of expansion and tension within early childhood education across Western Europe, the four subsequent chapters in this section address significant current trends and concerns. Having briefly introduced the issues addressed in these chapters, however, in this chapter, I wish to address the historical and current approaches adopted within Western Europe to the development of quality in ECE and the potential contribution of modern developmental psychology to achieving high quality of provision. This latter owes its origins to the works of the pioneers discussed above. Stimulated originally by the works of the Swiss Jean Piaget, and latterly by those of the Russian Lev Vygotsky, modern developmental psychology, over the last few decades, has provided an impressive and important body of evidence regarding young children's development and learning upon which any attempt to provide high-quality ECE must be based.

The immediately following chapter, entitled 'Neuroscience and Early Childhood Education' and authored by Sinclair-Harding, Vuillier and Whitebread, addresses a body of work, and its interpretations, which has directly contributed to the recent

recognition of the importance, individually and at the level of society, of ECE. As with much current commentaries on this area, the chapter recognises the potential contribution of neuroscience and the considerable interest and enthusiasm which it has generated amongst the policy and practice communities. However, it also addresses the potential dangers of over-interpreting early findings from what is a very young science exploring the astonishing complexity of the human brain. Examples of such 'neuromyths' are discussed. At the same time, there is already clear evidence of the impact of emotional warmth and responsiveness in early interactions and of the impact of play on brain growth. The authors further report strong indicative evidence that too early instruction in formal literacy can result in dysfunctional neural changes, further disadvantaging children who are not 'ready' for such formal instruction. The main contribution of neuroscience within ECE at the present time, however, the authors suggest, is likely to be in the early diagnosis of atypical developments, including problems with skills related to literacy and numeracy, social and emotional problems related to stress and specific conditions such as autism and ADHD.

The following chapter, authored by Bingham and Whitebread and entitled 'School Readiness in Europe: Issues and Evidence', addresses directly the tensions created in ECE in across Western Europe by the 'earlier is better' approach favoured by many politicians and policymakers. The chapter first reviews the current trend for children to commence formal schooling at younger ages than before, either officially or in practice, arising from the perceived international competitive pressures. This is followed by a section which examines the evidence on school starting age, showing that there is no evidence supporting an earlier start to schooling or the 'schoolification' of ECE. However, there is a significant body of evidence that reducing the period of time children spend in play-based, high-quality ECE provision of the kind advocated by the early pioneers discussed earlier, and supported by subsequent developmental psychology research, is potentially damaging, particularly for children from disadvantaged backgrounds. The authors conclude by presenting evidence of the beneficial effects of early interventions with parents which can crucially enhance young children's 'readiness' to learn through the more formal instructional approaches of schooling. The advantages of delaying the start of school until at least 6 or 7 years of age are also highlighted.

The third chapter in this section, authored by Soler and Flecha and entitled 'Early Childhood Education with Disadvantaged Children: Actions for Success', reports on a particular intervention, of the type advocated in the previous chapter, with disadvantaged children and their parents. In this particular case, the disadvantaged group addressed consisted of Moroccan families who had arrived as immigrants into Spain. This is greatly apposite, given the considerable numbers of minority ethnic groups within across Western Europe, a situation which can only increase further. As I write this chapter, the refugee crisis in Western Europe is headline news, with thousands of families fleeing from the civil wars, persecutions and terrorist unrest across much of the Middle East and Northern Africa. The young children in these families are clearly highly vulnerable and in need of high-quality support if they are to start out successfully on their school careers. The chapter

begins by reviewing the international evidence of the positive impact of early childhood education and care (ECEC) interventions with such disadvantaged children and goes on to examine the particular efficacy of the interactive group methodology, involving a dialogic approach to early learning, with adults from the community, including parents, working with small groups of children on collaborative tasks. In the particular case of the Moroccan children, Dialogic Literary Gatherings, in which parents and children together were supported to read and discuss classic literary texts, were shown to have highly significant outcomes for the parents and children's literacy and their attitudes to themselves as learners and readers.

Finally, in this section, the chapter authored by Pirard, Camus and Barbier, entitled 'Professional Development in a Competent System: An Emergent Culture of Professionalization', addresses a further currently highlighted development within ECEC across Western Europe. It is widely acknowledged that high-quality ECEC relies crucially upon a well-qualified and professional workforce. However, what is understood by professionalism and the professionalisation of ECEC vary across different European countries. The chapter reviews the various aspects of professionalism which need to be considered, which include working with children, with parents and within teams of co-professionals. The issue of the type of role adopted within each of these spheres is further discussed, with the authors arguing that the 'democratic professional' is preferable to the 'technical expert' model. The second half of the chapter reports a case study of the development of a professionalised ECEC service within a rural setting in the province of Luxembourg, situated in the Wallonia-Brussels Federation of Belgium. Within this the concept of professional ECEC practitioners as 'accompaniers', who work collaboratively with children, parents and fellow, multidisciplinary professionals to establish and carry out joint projects, is developed.

13.4 Western European Approaches to High-Quality ECE

Underpinning all the subsequent chapters in this section, however, is a concern to work towards and support high-quality ECE both within Western Europe and worldwide. In the remainder of this chapter, I want to set out the evidence we have concerning the development of high-quality ECE in Western Europe and to outline the potential contribution of modern developmental psychology to its further development. The most comprehensive evidence we have on this appears in the OECD's Starting Strong (OECD 2012) and Education at a Glance reports (OECD 2014). These reports cover the 34 most economically developed countries across the world, of which 24 are European and 19 in Western Europe (including Scandinavia).

From the data presented in these reports, it is clear that, simply in relation to provision and access to ECE, Western Europe is the strongest region in the world. In a majority of OECD countries, education now begins for most children well before they are 5 years old. More than three-quarters of 4-year-olds (84 %) are enrolled in ECE and primary education across OECD countries, but amongst these

countries that are part of the European Union, this figure rises to 89 %. In Belgium, Denmark, France, Germany, Iceland, Italy, Norway, Spain, Sweden and the UK, more than 90 % of 3-year-olds are now enrolled in ECE.

As a number of studies have demonstrated, however, provision of ECE alone is not sufficient. Indeed, as Minervino (2014) has recently reported, the evidence is quite clear that attendance at low-quality ECE actually has detrimental effects for children from disadvantaged backgrounds, medium-quality ECE has no effect and only high-quality provision is associated with improved 'school readiness', academic success and a range of positive emotional and social outcomes. While the general overall assessments on which these conclusions are based have been demonstrated to be fairly robust, however, the identification and measurement of the key elements that ensure high quality in ECE have proved to be difficult. As Slot et al. (2015) note, in a recent review of this literature, this arises from the complex relationships between the factors associated with high-quality ECE which have been identified. These factors are generally categorised as process characteristics (i.e. those describing the child's direct experience of the physical environment, activities, materials and social interactions in the ECE setting) and structural characteristics (i.e. those describing organisational features of the ECE setting such as adult-child ratios, group size, level of teacher qualifications and so on). While the evidence clearly indicates that process characteristics are most directly responsible for the individual and societal benefits of high-quality ECE (Vandell et al. 2010), governments and members of the policy community are generally concerned with structural characteristics, which are amenable to legislation and which are assumed to facilitate process characteristics. However, as Slot et al. (2015) demonstrate, 'the evidence for strong and consistent relationships between structural and process quality is far from conclusive' (p.64).

A recent study of ECEC in five Western European countries for the European Commission illustrates the complexities of the relations between structural and process characteristics within different cultural contexts (Slot et al. 2015). Secondary data analysis techniques with existing longitudinal data sets from England, Germany, Portugal, the Netherlands and Finland revealed quite different interactions between structural and process variables and various cultural variables, across these different countries. For example, in England their analyses revealed an interaction between teacher qualification level and type of provision. Poorly qualified staff provided a higher level of process quality in educationally orientated settings than they did in care-orientated ones. In Germany, they revealed an interaction between teachers' years of service and the proportion of children from immigrant families. More experienced teachers provided a higher level of process quality than less experienced teachers in classes with high immigrant numbers. In Portugal, there was an interaction between public and private sector settings and teacher-child ratios. Staff working in the public sector provided higher levels of process quality in settings with less favourable teacher-child ratios. In the Netherlands, they found several interaction effects, including one between opportunities for professional development and teacher-child ratios. A higher level of such opportunities was associated with a higher level of process quality in classes with less favourable teacher-child ratios.

Finally, in Finland an interaction was found between the location of the setting (in a day-care centre or a school) and group size. Teachers in day-care centres provided higher process quality with small class groups, whereas teachers in school settings provided higher process quality with large class groups.

Given these complex relations between the various structural and process elements that might be seen to make up high-quality ECE provision, it is easy to see why it has been difficult to establish reliable and consistent quality indicators and why the academic community has found it difficult to make clear recommendations to policymakers and governments as to how to achieve high quality. Slot et al. (2015) found some relatively consistent relations between structural and process elements across the five countries studied, principal amongst them being the level of qualifications of teaching staff and the opportunities for in-service professional development. However, it is clear that these factors do not directly affect the cognitive and emotional development of the children, but merely make it more likely that whatever experiences support these developments will be provided.

In addition, it needs to be recognised that the process quality variables examined in this literature are themselves fairly ill-defined. The process quality measures available to Slot et al. (2015) in their five-country study consisted of the Early Childhood Environment Rating Scale-Revised (ECERS-R) and its extension (ECERS-E) and the Classroom Assessment Scoring System (CLASS). These observational measures, together with the Infant-Toddler Environment Rating Scale-Revised Edition (ITERS-R), are the dominant measure of process quality used in the research in this area. However, with the exception of CLASS, these mix structural and process elements typically include measures of the quality of the physical setting, the curriculum, caregiver-child interactions, health, safety, time scheduling, indoor and outdoor play spaces, teacher qualifications, play materials, setting administration and the meeting of staff needs. Revealingly, psychometric analyses of ECERS-R (Perlman et al. 2004) and ITERS-R (Bisceglia et al. 2009) have shown that these both measure just one global quality factor rather than distinguishing between the individual aspects around which they are structured.

13.5 The Potential Contribution of Developmental Psychology

Clearly, if we are to establish the essential qualities of high-quality ECE, we need to be able to distinguish which aspects of early development are most crucial in providing young children with the bases for strong intellectual and emotional development, and we need to be more precise about which ECE practices provide significant support in this regard. Modern developmental psychology, very much inspired by the early European pioneers discussed earlier, but with the advantage of increasingly sophisticated empirical methods of investigation, is well equipped to support this endeavour. In this final part of the chapter, I want to set out what is currently

established in relation to early child development and how this can help us to give much more precise advice, at the level of policy and practice, in order to ensure high-quality ECE.

In their study of ECE quality in the Netherlands, Slot et al. (2015) point out that they have extended the measurement of process quality by including observations of teacher-child interactions and teacher reported developmental and educational activities. In order to achieve this, they used the CLASS observation instrument, which includes measures of emotional support, classroom organisation and instructional support, and combined this with a self-report questionnaire completed by the teachers, which covered their practices related to emotional support, play and self-regulation (which they considered to be indicators of emotional process quality) and pretence play, language activities, literacy activities and math activities (which they considered to be indicators of educational process quality).

The results of this study were able to show that, very much in line with the previous research in other European countries, process quality was moderate to high in relation to emotional support. Evidence was gathered of teachers frequently comforting children and showing them verbal and physical affection. However, educational or cognitive support, again in line with earlier studies in other European countries, was only low to moderate. Teachers much less frequently guided or participated in pretence play or in academically focused activities. High levels of process quality were also shown to be related to teacher professional development and the use of a comprehensive educational programme, such as High/Scope (see Volume 2, section on 'Pedagogies in Early Childhood') or Tools of the Mind (Volume 2, section on 'Innovative and longstanding programs').

This study has clearly considerably improved the conceptualization of what is understood by high-quality ECE and, in particular, has demonstrated the value of focusing on process quality. However, I want to argue that a more systematic examination of the findings of modern developmental psychology can help us to further specify the essential elements in high process quality by identifying the key aspects of development in young children that predict long-term, high levels of cognitive and emotional outcomes. As I have elaborated elsewhere in much greater detail than can be included in the present chapter (Whitebread 2012), the key drivers of children's emotional and cognitive development can be conceptualised most clearly under the general heading of 'self-regulation'. The psychological journey from babyhood to adolescence can fundamentally be characterised as one of increasing awareness and control by children of their own mental processes (often referred to as 'metacognitive' abilities), of developing independence from adult support and of the gradual transition from reliance on other regulation to self-regulation. This includes children's emotions, their social competencies and their motivations, perceptions, memories, reasoning, decision-making, cognitive strategies and conceptual understandings across all the domains of knowledge and ability. A widely recognised definition of the processes of self-regulation was provided over 20 years ago by Schunk and Zimmerman, two prominent researchers and theorists in this area:

> The process whereby students activate and sustain cognitions, behaviours, and affects, which are systematically oriented toward attainment of their goals. (Schunk and Zimmerman 1994, p. 309)

From an educational perspective, a very considerable body of research, conducted over the last few decades, has established two very significant features of children's developing self-regulatory abilities. First, a range of studies have shown that early self-regulation predicts long-term academic outcomes and emotional well-being more powerfully than any other aspect of children's development, including, for example, IQ (Veenman and Spaans 2005) and early reading achievement (McClelland et al. 2013). Second, it has been clearly established that self-regulatory abilities are significantly influenced by children's early experiences and that, as a consequence, they can easily be encouraged within educational settings (Dignath et al. 2008). Importantly, practices which support children's self-regulation have been shown to be those that make the processes of learning 'explicit' or 'visible' (Whitebread et al. 2015), that engage them in achievable regulatory challenges and that support and nurture their natural playfulness and curiosity (Whitebread et al. 2015).

Within this general framework, there are particular considerations relating to different emotional, social and cognitive aspects of development, and there are specific abilities and processes which significantly contribute to the early achievement of self-regulation. In relation to each of these various aspects of development and contributory processes, research in this area has established clearly defined educational practices which provide essential support.

In relation to emotional development, research has focused upon the crucial significance of early secure attachments, on the fundamental links between emotions and cognition, on the role of emotion regulation in developing resilience and on the emotional and cognitive components of motivation. Within the self-regulation intervention literature, the growing recognition of the importance of emotion regulation has led to a marked shift away from the direct teaching of metacognitive skills and strategies to a clearer emphasis on classroom 'ethos' and the emotional environment (Boekaerts and Corno 2005). It is notable, for example, that in highly successful interventions supporting self-regulation in the primary classroom, there is a strong emphasis on practices which promote a positive emotional climate and which support children's sense of autonomy, competence and relatedness (key motivational needs identified within the now widely accepted framework of self-determination theory developed by Deci and Ryan 2008), for example, giving children opportunities for decision-making, setting their own challenges, assessing their own work, encouraging positive feelings towards challenging tasks, emphasising personal progress rather than social comparisons and responding to and training children's helpless beliefs (Perry 1998). Underpinning all this, however, an emotional climate which is warm, responsive and non-judgmental, in which emotional issues are openly discussed and addressed, is fundamental to supporting children to develop emotional well-being, resilience and positive attitudes to themselves as learners, which are crucial to enabling children to derive the most positive benefit from their

educational experiences. Cefai (2008) has produced a very useful review of approaches to promoting children's resilience in the classroom.

As regards social development, research has focused on the early social competencies of young children, the skills of friendship and on social understandings, or children's developing 'theory of mind', and on the impact of early social environments on children's developing social regulation. This research has dealt with relations with peers and with parents and other significant adults. Howe (2010) has produced an authoritative review of children's social interactions and learning in classroom peer groups and has drawn from this review important implications for classroom practice. The first of these is that children's social experiences in classrooms, particularly in relation to their experiences of friendships, have a very powerful effect on a range of academic and emotional outcomes. The review thus endorses the importance of teachers' support of friendship skills at the individual level particularly, for example, with children who are overly aggressive and have difficulties making friends as a consequence or with children who are shy or anxious.

The research on adult-child interactions has mostly focused on parental behaviour and has identified two dimensions of this behaviour which appear to account for the most significant outcomes for the children, namely, 'responsiveness' and 'demandingness'. Combining these two basic dimensions of parenting led to the description of four characteristic styles, as developed in an integrative review by Maccoby and Martin (1983). Of these four styles, 'authoritative' parenting, which is high in parental responsiveness and in the demands and expectations made by the parents on the child, has been consistently shown, in a considerable body of research, to lead to positive outcomes for the child. Authoritative parents are the most emotionally warm and affectionate towards their children. In addition, however, they also set clear and consistent standards for their child's behaviour and convey high expectations of their performance. At the same time, they demonstrate clear respect for the child's developing need for autonomy and independence and support the child's adherence to the standards and rules established through discussion and negotiation, explaining their reasoning rather than simply asserting their authority. This style has been shown to support children's developing self-efficacy (i.e. feelings of competence) and self-regulation and, hence, their success as learners. Authoritative parenting has also been found to be associated with a range of positive outcomes in relation to children's social competence. As children they most easily make relations with other children and adults and are generally the most popular amongst their peers. Although much of this work has been undertaken with parents, a very clear message for ECE teachers is the crucial significance of structures and procedures within classrooms. The poor outcomes for social competencies and friendships arising in classrooms where individual performance is emphasised, and children are grouped by ability, have been contrasted with the positive social outcomes in classrooms where cooperation is emphasised, and working on tasks collaboratively in mixed ability groups is a more common feature (McGrath and Noble 2010).

Much of the research on cognitive aspects of development has focused on metacognitive processes related to children's memory abilities and their development of increasingly sophisticated cognitive strategies in relation to mathematics, literacy and other areas of learning. Early research in the area of metamemory and children's knowledge of learning strategies suggested that metacognitive abilities did not begin to emerge until around the age of 8 years. However, observational studies showed evidence of much earlier metacognitive abilities in children as young as 3 years of age (Whitebread et al. 2005, 2009), and subsequent research has suggested that interactions between parents and children in the first few months of life impact on children's early metacognitive and self-regulatory abilities (Whitebread and Basilio 2012; Brinck and Liljenfors 2013).

This area of research has also been focused on the specific abilities and processes which significantly contribute to the early achievement of self-regulation. Amongst these, the two areas of research with clear implications for developing high-quality ECE have been those relating to oral language and play. The crucial role of oral language in early childhood development is, of course, well established. This relationship is presaged very clearly in Vygotsky's model of development, in which social interaction and language are seen as central drivers in children's learning. As Vygotsky expressed it:

> Children solve practical tasks with the help of their speech, as well as with their eyes and hands. The unity of perception, speech and action … constitutes the central subject matter for any analysis of the origins of uniquely human forms of behaviour. (Vygotsky 1978, p. 26)

There is certainly a growing body of evidence to support this view in relation to the development of early metacognition and self-regulation. A number of studies, for example, have directly linked early language development with later emerging aspects of self-regulation. An American study of 120 toddlers in New England showed strong relationships between vocabulary size at 14, 24 and 36 months and a range of observed self-regulatory behaviours, for example, the ability to maintain attention on tasks and to adapt to changes in tasks and procedures (Vallotton and Ayoub 2011).

Three key implications emerge from the research on oral language and self-regulation in relation to educational concerns. First, those episodes of joint attention between adults and children are crucially important in children's development of their language abilities. Research has shown that there are considerable variations in the sensitivity and style of communication of adults when interacting with young children and that these variations are clearly related to individual differences in children's learning, particularly in relation to language development. As Schaffer (2004) reviews, adults who follow children's interests, rather than attempt to shift the conversation to their own agenda, are far more effective in fostering children's language development. This has very significant implications for the style of dialogue which is likely to be most productive within ECE classrooms. As long ago as the 1980s, Tizard and Hughes (1984), in a classic study of 4-year-old girls attending pre-school in the mornings and spending time with their mothers at home in the

afternoons, presented evidence of these young children engaging in intellectual search through conversations with their mothers. The kinds of meaningful dialogues they shared with their mothers, unfortunately, were sadly lacking in their pre-school experience. More recently, the EPPE study in the UK, a large longitudinal study of factors leading to effective ECE provision, identified episodes of ‘sustained shared thinking’ between adults and children as characteristic of high-quality pre-school settings which significantly impacted upon a range of emotional and cognitive gains, even overriding the effects of social disadvantage (Sylva et al. 2004).

Second, a series of studies within educational contexts have explored the impact of ‘metacognitive talk’ between teachers and children. For example, Ornstein et al. (2010) demonstrated that the amount of contingent metacognitive talk naturally produced by first-grade math teachers was a strong predictor of academic outcomes. Children taught by teachers who regularly made suggestions of memory strategies they could use and asked metacognitive questions aimed at eliciting strategy knowledge, such as ‘how could you help yourself to remember this?’, showed significantly improved strategy use at the end of the first grade, and, notably, this improvement was still present 3 years later, at the end of the fourth grade. The importance of metacognitive talk in supporting children’s developing ability as effective learners is explained by research showing a disjunction in the developmental trajectories of monitoring and strategic control, the two complimentary processes which comprise metacognitive ability. The development of monitoring skills in children (e.g. their ability to be aware of how well they are doing on a task) appears to be predominantly a maturational process, mostly dependent upon age and largely unaffected by developing ability. However, conversely, their strategic control abilities (e.g. their ability to select an appropriate strategy or way of going about undertaking a task) appear to be directly related to cognitive ability (Bryce and Whitebread 2012). Specifically, it appears that, even when they are taught an effective approach to a specific task and have shown they are able to produce an improved performance using it, the link between their use of the strategy and their successful performance needs to be made very explicitly clear to young children and particularly to those less able young children who would otherwise not make this connection for themselves (Fabricius and Hagen 1984). Numerous studies have confirmed the importance of this type of metacognitive talk in making the processes of learning explicit or ‘visible’ to young children (Hattie 2009; Whitebread et al. 2015).

Third, the link between oral language and self-regulation has been exemplified in research concerning the use of collaborative groupwork between peers within educational contexts. A range of recent and current classroom-based research has begun to identify in more detail the specific elements of a successful ‘dialogic’ pedagogy appropriate for children in ECE (Mercer and Littleton 2007). These elements include children constructing their own agreed ‘rules for talk’ which are required for productive dialogue, including supporting their views or opinions with reasons and attempting to agree on the solution to the problem under discussion. Following these general guidelines, Littleton et al. (2005) showed that young children could make significant strides in their ability to argue their case and provide explanations for their views and that there were measurable gains in both the quality of their

language and their non-verbal reasoning skills. Additionally, a recent study with Year 1 children (i.e. 5–6-year-olds) in the UK showed that this type of activity significantly enhanced the children's metacognitive abilities (Whitebread et al. 2015).

The second area of research investigating the specific abilities and processes which significantly contribute to the early achievement of self-regulation is concerned with children's play. This is a less developed area than that related to oral language, but one which is enjoying something of a renaissance currently arising from a range of highly promising recent findings. To begin with, within the motivational literature, the central significance of activities and experiences which support children's sense of autonomy has been indicated in a wide range of studies, both in classrooms and in the parental home. Overcontrolling interactions between parents and children have consistently been related to poor self-regulatory development (Stevenson and Crnic 2012), while parental support for their children's autonomy has emerged in a number of studies as a key predictor of self-regulation and academic achievement (Pomerantz and Eaton 2001). On a similar theme, in a recent study, the amount of less structured time experienced by young children in their home life was also shown to significantly predict their early metacognitive development (Barker et al. 2014).

Within educational settings, a number of strands of research related to all kinds of physical, constructional and social play have indicated that these provide opportunities for children to directly develop their skills of intellectual and emotional 'self-regulation'. For example, pretence play involves children in increasingly sophisticated processes of symbolic representation, involving oral language skills, which, as we discussed above, themselves support the development of self-regulatory abilities (Berk et al. 2006). A growing number of empirical educational studies have found that early play experiences enhance young children's academic achievement by supporting the early development of self-regulation (Ponitz et al. 2009). Children who attend pre-schools based predominantly upon models emphasising play rather than academic outcomes have been found to achieve higher scores on measures of self-regulation (Hyson et al. 2006). In a recent study investigating a playful intervention designed to support young children's narrative skills, the evidence supported the hypotheses that high-quality groupwork, involving significant episodes of 'exploratory talk', would support the children's development of metacognition, creativity and narrative skills and that playfulness within the group, particularly involving pretence play, would enhance the effectiveness of the intervention in these respects. It was also clearly evidenced that low-ability children made the strongest gains within these playful groupwork activities (Whitebread et al. 2015).

13.6 Conclusion

This chapter has reviewed a range of approaches to quality in ECE, ranging from the pioneering educationalists of Western Europe in the late nineteenth and early twentieth centuries to the modern attempts to define and measure the essential structural

and process characteristics of high quality. I have argued, however, that modern developmental psychology can advance our endeavours in this area, providing well-evidenced indications of the key early developments which predict children's long-term outcomes, both educationally and in relation to emotional well-being. As part of this, I have offered self-regulation as a compelling framework within which to move towards a coherent view of the essential nature of high-quality ECE.

There are studies within the self-regulation literature which have examined the qualities of classroom environments that support high levels of children's self-regulation. Perry (1998), for example, observed second and third grade classrooms during literacy activities. She found that classrooms supporting high levels of self-regulation were characterised by challenging and open-ended writing activities by opportunities for children to control the level of challenge and opportunities for them to engage in self-assessment. The teachers also provided support for the children's autonomy through strategy instruction and encouragement of a mastery-oriented approach to learning, fostering positive feelings towards challenge and emphasising personal progress and mistakes as opportunities for learning. However, these studies have overwhelmingly been set in classes with children over the age of 7 years, rather than in ECE settings. What is clearly required, if we are to significantly enhance the quality of children's experience within ECE settings in ways which support their development as powerful learners and equip them to be emotionally resilient and socially adept, is an expansion of studies within ECE settings which examine practices with young children that effectively and reliably support their attainment of the full gamut of metacognitive and self-regulatory abilities. Hopefully, this chapter has set out a framework which can guide this important research effort over the coming years.

Chapter 14
Neuroscience and Early Childhood Education

Lysandra Sinclaire-Harding, Laura Vuillier, and David Whitebread

Abstract Research in neurobiology and cognitive psychology has travelled a great distance in its journey to shed light on child development. The remarkable tools of brain imaging; powerful methods for measuring cognition, emotion and learning; and discoveries for genetics have opened vast opportunities for this emerging field. Governments around the world are investing enormous sums of money in understanding differences, disorders and diseases of the brain, and there is huge potential for science to inform us about child development. What enables a child to acquire the skills to read, write and calculate? Why do some children struggle to engage in learning opportunities and require additional support to adapt their behaviour to the social learning environment of the classroom? This chapter provides evidence from neuroscience and cognitive psychology related to how early experience lays a foundation for the range of student behaviours and capabilities educators witness each day in class. Research theory relevant to teaching practice is discussed in respect of the development of particular functions and processes required for early childhood, including literacy and number acquisition, regulating and sustaining attention and managing emotions and behaviour. Early years practitioners are challenged to consider the design of learning environments that optimise effective learning and encourage healthy development.

For any teacher, standing in front of a class of young people and preparing to respond to their persistent needs and questions is a daunting task. Early years teachers have a special responsibility, not just as educators but also as providers of responsive childcare. During their early years of schooling, parents and policymakers expect children to be taught number, letter and sound recognition. In addition to these fundamental skills, early years practitioners are also expected to teach children to fasten their own coat, await their turn and match each foot to the correct shoe.

Whilst teacher knowledge, experience and confidence are gained over years of practice, the needs of children are constantly evolving in response to transformations in the social and economic environment within which they are growing up. Family structure, gender roles, parental working hours, technical innovations and increasing cultural diversity (Shonkoff 2003) are all factors that influence the development of our children. Keeping apace with such changes and the impact they have on the care and learning needs of young people presents both challenge and opportunity for practitioners.

Research from neurobiological and behavioural scientists reveals new perspectives for educators on the impact of these social variables on child development and has led to growing excitement about the potential for how an understanding of developing brain architecture and functionality might impact upon pedagogical practices (Pickering and Howard-Jones 2007). Whilst new findings from the laboratory have clear potential, their usefulness to teachers is not immediately obvious and, for benefits to materialise, requires educators that are both curious to engage and cautious in their interpretations.

In support of this ambition, this chapter will summarise the key neuroscientific contributions to psychological explanations for how biology and experience combine to shape the foundations for learning. To begin, an introduction to the neurobiological prerequisites for healthy development will be presented, together with explanations for how loving, secure and responsive human relationships joined with enriched, playful environments support the development of the curious, thriving child.

In recognition of the concerns and priorities of early years practitioners, some of the known biological factors associated with difficulties in literacy and number acquisition will be considered alongside problems of a social and emotional nature often observed in the early years classroom, including those that occur as a result of significant life stress or unstable family relationships. Throughout this chapter, some of the misconceptions of neuroscientific interpretations for education will also be exposed.

A child's first few years are powerful indicators of how they will fare in later life. In acknowledgement and support of early child development, this chapter concludes with some suggestions for how practitioners can provide the kinds of relationships and secure, playful environments which form positive foundations for future achievement.

14.1 History and Methods of Neuroscientific Research

Since the optic nerve was first described in 500 B.C., a large volume of data on the brain has accumulated. Having emerged from neuroscience and psychology, the discipline of cognitive neuroscience is concerned with the relationship between the brain, the mind and the behaviour. The first anatomical proof of the localisation of brain function came in the 1860s from a French physician named Paul Broca. He studied the brains of patients who had lost the ability to speak after injury (lesion) to the posterior inferior frontal gyrus (Broca 1861). This region, named after Broca, is now well established as fundamental for the production of speech and language. Neuropsychology, with the analysis of brain lesions, has proven to be a great tool for understanding the relationship between the brain and behaviour. However, brain lesions are not always specific and analysing damaged brains has a limited use for understanding healthy brains. New tools and methods of noninvasive neuro-imagery techniques have proved invaluable in increasing our knowledge about the brain. There are two main techniques used in neuroscience research related to early child development and education: electroencephalography (EEG) and functional magnetic resonance imaging (fMRI).

The first recording of brain activity took place in 1929 when Hans Berger reported that by placing an EEG electrode on the scalp, one could measure the electrical activity of the human brain (Berger 1929). When matching specific events to this constant brain activity, event-related potentials (ERPs) can be measured. ERPs are employed in research interested in language, memory, response inhibition and emotion. For example, infants might be asked to listen to a series of distinct sounds whilst EEG signals from specific areas of the brain are carefully monitored. fMRI, although less precise time wise, is extremely precise in terms of location. This technique uses magnetism and radio-frequency waves to produce images of the brain. The haemoglobin in the blood flow has a different resonance when it is oxygenated to when it is not. With sufficient analysis, it is possible to visualise the parts of the brain that are working hardest to achieve a certain goal (e.g. recognise a written word) as the active region demands oxygenated blood.

14.2 Neurobiological Prerequisites for Healthy Development

The human brain begins life from just one single cell of the embryo. Contained inside this cell is a copy of the genes we inherit from each of our parents. Genes provide the instructions for creating proteins that in turn induce the cell to perform its function. At conception, these instructions are simply to divide and replicate, until the original generation of cells gives birth to others that differentiate, forming new and specialised cells. Once formed, they quickly migrate to their designated cortical region where they will form connections with other neurons.

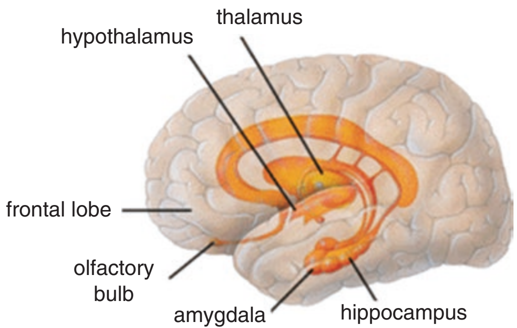

Fig. 14.1 *'The Emotional Nervous System'* (Boeree 2011)

The early signs of brain activity appear within the first few weeks in utero. The initial collection of neural cells roll up into a tube that will form the spinal cord (Stiles 2008). Cells at the head of this tube will continue to divide and expand into the fore-, mid- and hindbrain, each of which in turn gives rise to key neural structures with specific functions. Among many others, these structures include the thalamus responsible for translating sensory information to the brain, the hypothalamus for regulating thirst and appetite, the olfactory structures for smell, the hippocampus for memory, the basal ganglia for controlling movement and the amygdala for attaching emotional significance to experience (see Fig. 14.1).

Once a neuronal cell has acquired its identity, genetic signals guide it to a new destination (Gurdon 1999). Ongoing research seeks to better understand the molecular mechanisms that determine the process by which cells born deep inside the brain travel out to build the multiple layers of the cerebral cortex. Once their destination is reached, these cells grow and branch allowing new connections and networks to form. This process continues for several years, although some parts reach maturity sooner than others. For example, the connections between cells in the frontal cortex continue to grow and mature well into adulthood forming the most complex part of the brain that allows us to develop higher functions such as reasoning, perspective taking and abstract thinking.

14.3 Stimulating Environments and Neuroplasticity

Before and after the infant is born, stimulating environmental experiences trigger the growth of neuronal fibre connections (axons, synapses and dendrites). Initially, a far greater number of connections are grown, many more than will be retained into adulthood. This proliferation, occurring between 4 and 12 months (Goswami 2004), creates immense potential for the developing brain. Infants begin life with a nervous system wired for infinite possibilities but such a surplus is inefficient. The young brain consumes 50% more energy than the adult brain (Klingberg 2013), and this demand cannot be sustained into adulthood. As a child grows up and responds to the demands of his or her particular world, competition occurs between nerve cells that

will determine which neurons and neuron connections will survive. One aspect of this occurs as synapses compete for potential binding sites on receiving neurons. As connections engage, a chemical signal is stored, and if stimulated regularly, this will stabilise over time (Corrigall and Wilkinson 2003). These useful connections contribute to functional networks that remain and grow stronger whilst those that are unused, perish and disappear (Courchesne et al. 1994).

At around 8 months old, the infant brain begins to protect itself through a process called myelination. Likened to the plastic insulating layer that protects electrical cabling, many layers of the myelin membrane form around the developing axons. Not only does the myelin protect the brain cells, it also supports their communication by accelerating transmission signals. The frontal cortex is the last area to be myelinated, occurring well into childhood and coinciding with the development of advanced coordinated skills such as walking, talking and abstract thinking.

Some aspects of human development, such as eye colour and skin colour, are genetically predetermined and occur independently of any external influences or learning experiences. Other aspects, including the visual and auditory systems, are described as experience expectant. The infant's gradual introduction to the complex sights and sounds of early experience acts as a catalyst without which eye coordination, colour differentiation and discrimination between sounds would not naturally occur as neural pathways would remain disorganised (Greenough and Black 1992). The developing brain 'expects' and relies on these typical experiences for growth. For example, visual impairments may arise in infants that experience prolonged visual deprivation from congenital cataracts (Goswami 2004). Similarly, children affected by middle ear infections during the first 3 years of life are likely to find it difficult to discriminate between the distinct units of sound that are important for later speech and language acquisition (Roberts et al. 2004).

Experience-dependent aspects are those that develop in response to the specific features or demands of the environment. This type of brain development can be fostered throughout life and is unique to each child and the environment in which they are raised. For example, a young child that learns to master a stringed instrument will develop specific neural connections as a consequence (Pantev et al. 2003). Studies that investigate how experience modifies brain structure and function have found such modifications following experience as diverse as juggling (Draganski et al. 2004), music training (Elbert et al. 1996), video game playing (Green and Bavelier 2008) and a career in taxi driving (Maguire et al. 2000).

14.4 Language Acquisition

The way in which children acquire language reflects this early adaptation to the needs of everyday experience, and in early childhood, the acquisition of speech and language is the focus of intense study using neuroscience technologies. The world's languages contain around 600 consonants and 200 vowels (Ladefoged 2004), yet each language generally uses only 40 distinct units of sound or phonemes.

Early behavioural studies demonstrate that newborns have the ability to detect differences between phonetic contrasts used in all the world's languages (Eimas et al. 1971; Streeter 1976). This capacity is fine-tuned as the young child is exposed to distinct units of speech and, over time, develops into a language-specific phonetic capacity (Kuhl and Riveral-Gaxiola 2008).

One series of studies in America investigated the impact of exposure to a second language using behavioural (Kuhl et al. 2003) and brain measures (Kuhl and Rivera-Gaxiola 2008). Researchers invited native speakers of Mandarin to talk and read to 9-month-old infants of English-speaking parents. After 12 sessions listening to the Mandarin speakers, the infants' sensitivity to a range of Mandarin phonetic units was tested. The children who had spent time with the Mandarin speakers were able to recognise the Mandarin-specific phonetic units compared to a control group who had listened only to English (Kuhl et al. 2003). These studies went on to show that without continued exposure, the acquired sensitivity to Mandarin speech sounds declined over time (Kuhl 2004), perhaps reflecting the initial proliferation of specific connections in brain regions that provide the foundations for foreign language acquisition and the subsequent decline from the lack of use.

Research that explains the process by which infants acquire language has resulted in speculation about whether there are critical or sensitive periods for language development. A common misconception has arisen from such discussions, suggesting that a 'critical period' exists for learning foreign languages and that, once this biological window is missed, the opportunity to learn is lost. However, it is now known that the mature adult brain is able to generate new neurons (Eriksson et al. 1998) and that brain development continues on into maturity. A number of studies have shown that native-speaking levels can be achieved with sufficient motivation at any age (see Marinova-todd et al. 2000 for a review). So whilst there does appear to be a sensitive period for which young children possess some advantages in the early learning of a second language, it cannot be said that if exposure does not occur before a certain age, then a second language may never be learnt perfectly.

14.5 Self-Regulation and Play

The research into sensitive periods for the development of speech and language has led to questions as to whether there are similar windows for developing other processes such as attention, memory and self-regulation. Early years teachers recognise the huge variability in 'school readiness' that young children exhibit in relation to acquiring new knowledge and skills. Traditionally, the priority for teachers is to develop competency in reading, writing and arithmetic, but, increasingly, teachers and researchers realise the importance of developing self-regulation for school readiness. Difficult to fully define within the scope of this chapter (but see Kopp 1982), these complicated processes that allow children to adaptively and effectively respond to their environment are termed 'self-regulation' (Bandura 1991). Self-regulation allows students to understand and regulate their own thoughts, behaviours and

feelings and organise this knowledge towards taking greater responsibility for their independent learning. Researchers and teachers are discovering how capable preschoolers are at learning such skills.

In the early years, a child that stops playing when asked and begins cleaning up, seeks support when needed or shares a toy with a classmate is one that is learning to self-regulate, i.e. to evaluate cues from self and others, to adapt their behaviour in response to the demands of the situation and to initiate or cease a behaviour even if he or she does not want to do so (Maxwell et al. 2009). Proficient self-regulators can control their impulses and attention; they can plan, set goals, organise, monitor and self-evaluate at various points during their learning. These students are found to have the most success in school and life (Meltzer 2011). When obstacles are encountered such as a set of confusing instructions, distraction from peers or suboptimal learning conditions, competent self-regulators proactively seek out information and advice, find supportive friends and places that will help them engage, sustain attention and utilise appropriate learning strategies (Zimmerman 1990).

Early signs of self-regulation can be seen in the first weeks of life. Newborns are able to reduce levels of stimulation by turning away from the source, closing their eyes and eventually engaging in self-soothing activities such as thumb sucking (Kopp 1982, 1989). An important aspect of nurturing relationships is that the infant's caregiver provides a stimulating environment that changes in response to the infant's moods and interests. Whilst infants are developing their capacity to regulate their own arousal and impulses in response to this stimulation, they require help to co-regulate emotional reactivity and behavioural response from a sensitive parent or caregiver. As they develop, most children begin to self-regulate without prompts or assistance, learn how to manage incoming information, choose what to attend to and select appropriate responses (as well as control unhelpful impulses), whilst maintaining a level of arousal that allows them to actively participate in learning and to cope with challenging events (Sroufe 1996). Early years teachers play a vital role in helping children to develop these foundational skills of self-regulation that makes future learning possible.

There is growing evidence for how self-regulation can be taught in the classroom from researchers and practitioners exploring the developmental benefits of play (Diamond et al. 2007). In the 1940s, researchers began to consider the impact of growing up in playful and stimulating environments compared to deprived or disadvantaged conditions. Due to the difficulties of such research with humans, most knowledge has accumulated from studies with animals. Mark Rosenzweig at the University of California designed a paradigm in which groups of rats or mice were raised in large cages containing numerous toys such as tunnels, steps, exercise wheels and objects for the animals to explore (Rosenzweig et al. 1962). The physical activity of the enriched, playful environment was found to have a positive impact on learning and memory (Markham and Greenough 2004).

Researchers distinguish between different types of play: physical play, intellectual play and social/emotional play (Moyles 1989). Neuroscience demonstrates that playful experience stimulates growth of neurons and synaptic activity in the brain. The relationship between play and brain size has been compared in different animal

species (e.g. Iwaniuk et al. 2001), and animals with larger brains are more likely to engage in play than smaller-brained animals because more complex behaviour requires more neural tissue (Jerison 1973). Comparative studies have shown that particular parts of the brain are enlarged in response to specific types of play. For example, the amygdala and hypothalamus increased in anatomical volume with social play but not with object play (Pellis and Pellis 2009).

In humans, researchers have shown that children growing up in deprived, understimulated environments suffer from cognitive delays or deficits (e.g. Beckett et al. 2007), but as yet, no single factor has been identified to explain the full effect of an enriched play environment (Klingberg 2013). This may in part be due to the inherently spontaneous and unpredictable nature of play, which hinders the controlled definition and measurements necessary for scientific research (Whitebread 2012). Yet the empirical evidence from cognitive psychology for the benefits of childhood play is accumulating (see Bingham & Whitebread, this volume), and so in spite of the challenges, neuroscientists continue to seek explanations for how human brain mechanisms are modified as a consequence of childhood play (e.g. Pellis et al. 2010).

At least as far as laboratory animals have shown, neuroscience demonstrates that in different structures of the brain, enriched environments stimulate the growth of neurons and synaptic activity. These include the auditory cortex (Greenough et al. 1973), hippocampus (Fiala et al. 1978), amygdala (Nikolaev et al. 2002) and basal ganglia (Comery et al. 1995). Such effects have often been used to justify educational toys, cognitive training or early schooling for very young children. Many scholars refute the validity of these interpretations. DeLoache et al. (2010) conducted a study looking at children's increase in vocabulary from watching a DVD specifically designed for this purpose. In fact, they found that children's vocabulary increased when the parents, instead of the baby media, were teaching them the same words. Such misconceptions seem to have come from animal studies demonstrating that a complete absence of stimulation impairs the development of brain structures and that enriched environments stimulate the growth of neurons and synapse activity (Comery et al. 1995; Fiala et al. 1978; Greenough et al. 1973). However, caution is necessary. These studies do not justify the intense (over) use of educational toys and cognitive training in humans. Furthermore, overstimulation (stress) can also have a detrimental impact on development (Shonkoff 2011), and as yet, we have no idea what a recommended daily dose of stimulation might be.

What is clear are the beneficial effects of a stimulating, playful environment for young children's development as self-regulated learners. In the early years, children learn self-regulation best when they – rather than adults – set, negotiate and follow the rules (Sylva et al. 1976). Children who attend preschools that emphasise informal play-based learning, rather than academic achievement, are found to achieve higher scores on measures of self-regulation (Hyson et al. 2006). Pretend or dramatic play and games with rules are found to be particularly effective activities for developing self-regulation in the early years (Bodrova and Leong 2008).

For many children, school is the first and only place in which they learn to regulate themselves, and thus activities that provide opportunities to rehearse self-regulation in the early years are fundamentally important. As the child matures,

these necessary self-regulatory skills act as foundational precursors from which develops the child's capacity to learn via formal instruction, concentrated reading, writing and problem-solving activities.

14.6 Social Relationships and Emotional Development

As has been discussed, the process of brain development is constantly modified by the external environment. Undoubtedly, the most significant aspects of the environment to influence the infant's development are their relationship experiences. Secure infant-parent attachments are strongly associated with the development of social and emotional competence. Sensitive parenting provides stimulation that is gradual, nurturing, predictable, repetitive and attuned to the child's developmental stage (Perry and Pollard 1998). Nurturing that includes sensitive handling, responsive eye gaze, talking, singing, playing and reading to the child provides the security and cognitive challenges to exercise young minds and is the active ingredient to healthy brain growth. Many of these occur quite naturally, for instance, during 'parentese,' the musical sing-song talk that facilitates early sound discrimination and language development and is characteristic of parents talking to a young infant.

Caregivers do many things to stimulate development. Since young infants have not yet developed the capacity to regulate their own arousal and impulses, they require help from a sensitive caregiver to co-regulate their own emotional reactivity and behavioural response to distress, to help deal with frustration, to direct and focus attention and to restore a calm emotional state, free of anxiety (Glaser 2000). In this way, the secure infant-caregiver relationship acts as a protector from the stresses of infancy and prepares young children for the social and emotional challenges of early childhood and formal learning. Where young children feel secure and nurtured and protected from harm, we find a curious child eager to explore and embrace learning challenges.

The young mind is astonishingly active, creating new knowledge and learning experiences every day. Relationships are not just important within the immediate family; they include other relationship attachments that young children develop and depend upon during their early childhood such as with their peers and adults at school. A child's social and emotional development in early childhood is directly linked to their later ability to adapt to new social settings such as school, to form emotionally healthy relationships and to sustain attention and motivation for new learning opportunities. An infant learns to respond to emotional stimuli in part by the model demonstrated by his or her caregiver, and healthy interactions with significant adults provide the learning opportunity for appropriate social and emotional responding. Caregiving routines that provide support and structure for activities to make them manageable for a child, that stimulate playful curiosity and that sensitively respond to and manage a child's emotions, provide the optimal environment for promoting early cognitive, socio-emotional and neurobiological growth without the need for special educational toys, Mozart CDs or flashcards (Thompson 2001).

14.7 Biological Development: When Things Go Wrong

Whilst the early years have considerable opportunity for rapid growth and development, they are also the periods of greatest vulnerability where brain development can go wrong. For instance, if the neural tube of the developing embryo fails to close at the tail end, a child will be born with spinal complications such as spina bifida (Northrup and Volcik 2000). Problems with myelination of brain cells can lead to motor disorders such as multiple sclerosis (Kutzelnigg et al. 2005). The infant brain needs protection from hazardous drugs, viruses like rubella, environmental toxins, a lack of essential nutrients and sustained exposure to stress (Thompson 2001). A mother's use of alcohol during pregnancy can result in abnormal patterns of neurons found in children born with foetal alcohol syndrome (Garrett 2011), and chronic maternal stress during pregnancy and in infancy can also threaten healthy brain development due to the toxic effect of stress hormones (Talge et al. 2007).

Significant maternal stress during particularly sensitive periods of prenatal brain development is found to adversely impact learning and development. For example, in January 1998, Quebec was hit by successive storms over 7 consecutive days, described as the greatest natural disaster in Canada's history (Kerry et al. 1999). Several hundred thousand people were made homeless, among which were many pregnant mothers. The children whose mothers were in their first trimester of pregnancy when the storms hit went on to have delays in language acquisition, whereas the speech of toddlers whose mothers were further on in their pregnancy was unaffected (Laplante et al. 2004). Protecting the developing brain by keeping parental stress manageable during the first 4 to 5 months of pregnancy appears to be particularly important during this sensitive period.

Where developmental anomalies are present, the demands of the school environment may reveal a child's difficulties, and the early years educator may be the first to witness initial signs of learning or behavioural problems in the classroom. Such difficulties in language acquisition and number processing or from maladaptive behavioural, emotional and social disorders are of great concern to parents and teachers of early years children and are of enormous interest to the neuroscience research community.

14.8 Literacy Problems

Learning to read places advanced demands on the brain. The ability to process written words begins with the visual system that can recognise the lines and curves of letters and words. Regardless of whether the reading language is Arabic, Urdu or English, neuroimaging studies find that the same small area of the visual cortex (ventral occipito-temporal region) is active in response to letter strings (Dehaene 2009). As the child is taught to recognise letters and words, to link them with speech

sounds and to remember their meanings, a specialised circuit of connections is being organised within their brain. As reading skill advances, activity in this circuit increases, reflecting a functional change that allows for the production of spoken language through the visual system (Dehaene 2009). Some children in their early years struggle disproportionately with learning to read and write. Such problems may lead to a diagnosis of developmental dyslexia.

Dyslexia is of genetic origin, since it most often occurs in families. Some have suggested hormonal factors play a role, such as foetal testosterone levels during pregnancy. This interpretation is perhaps due to the large prominence of males with dyslexia, but empirical evidence is lacking (Tønnessen 1997). Several candidate genes have been isolated and implicated, and although the precise function of these genes is not fully understood (Klingberg 2013), it is believed they play a key role in influencing how the cortex is formed during development (Scerri and Schulte-Körne 2010).

Dyslexia is related to the unusual migration of neurons. Perhaps, the most significant contribution in recent decades to the neurobiology of dyslexia comes from studies of the brains of deceased men (Galaburda and Kemper 1979; Galaburda et al. 1985) and women (Humphreys et al. 1990) with developmental dyslexia. Compared to non-dyslexic brains (Kaufmann and Galaburda 1989), these studies found several congregations of displaced neuronal cells in abnormal locations. It is possible that during the migration phase of development, these neuronal cells lost their way, suggesting that particular migrating neurons fail to arrive at their correct cortical destination.

Dyslexia is often characterised by poor motor skills, balance and postural control (McPhillips and Jordan-Black 2007). Such observations have led to investigations between literacy achievement and deficits in motor coordination. Neuroimaging studies have shown unusual patterns of activation in a number of brain regions in adults with dyslexia, including the cerebellum (Sun et al. 2010). The cerebellum is one of the earliest regions of the brain to develop, beginning in the fifth week of gestation and continuing after the infant is born (Garel et al. 2011). This protracted growth means the cerebellum is vulnerable to a broad spectrum of developmental events, and abnormal cerebellar activation patterns of babies born prematurely or exposed to alcohol in utero have been associated with later difficulties with reading and writing (Stoodley and Stein 2013).

Many problems associated with dyslexia have been traced to the integration of primary reflexes, a system of coordinated movements that originates in the cerebellum (Welsh and Harvey 1992). For example, the asymmetrical tonic neck reflex (ATNR) is elicited by the rotation of the head to one side, resulting in the extension of the arm and leg on the same side whilst the opposite limbs flex. This reflex is thought to assist in the birth process and considered a precursor to coordination. Primary reflexes, such as grasping and sucking, are observed in the first few months of life and are essential to support the infant until they develop proficient motor control. As the growing infant establishes expertise with eye movements, rolling, sitting, balance, walking and running, these primary reflexes are inhibited and usually disappear (Blythe 2011). Neural connections are formed and strengthened

and muscles grow, providing increased control and range of movement. Children who retain these primary reflexes may have weak gross or fine motor skills. They may appear clumsy and have difficulties with balance and coordination. If the ATNR remains active in a school-aged child, it may interfere with balance, left-right coordination and control of the hand (Blythe 2011). Since writing is a motor task that depends on the coordination of the hands and eyes as well as the postural system, it is suggested that these motor-related skills affect reading and writing.

Several theories for dyslexia exist (for review, see Habib 2000), and neuroimaging methodologies allow researchers to distinguish between these different theories such as whether dyslexia has a visual or linguistic basis (Goswami 2004) as well as testing the impact of training interventions. For most, dyslexia reflects an impaired ability to process phonemes, and neuroimaging studies show less activation in the occipito-temporal area (Shaywitz et al. 2002). Neuroscience research has revealed the biological circuits that are enhanced as a child learns to read. This research shows that the regular teaching of how letters map onto speech sounds leads to rapid establishment of the brain's visual and phonological circuits (De Schotten et al. 2014) and provides useful support for how remedial interventions (see Singleton 2009) can optimise the reading process for children who struggle. Shaywitz and colleagues (2002) went on to show that children who undertake phonological training not only improve their reading, they also show increased activity in the posterior temporal lobe. Such findings support classroom training programmes designed to improve phoneme perception and letter coding and allow children with dyslexia to adapt and compensate for their difficulties.

In relation to identifying specific contributions that cognitive neuroscience can offer to education, dyslexia is one of the most promising and established areas of research application. Neuropsychological research has begun to show how children with difficulties can be identified in order that they can receive early intervention and, furthermore, that such intervention actually shapes the areas of the brain that are affected (Gabrieli 2009).

14.9 Number Problems

The ability to handle and process number varies across every classroom, but those children in the early years that particularly struggle with the acquisition of arithmetic skills in spite of adequate home environment, educational opportunity and normal learning ability across other school subjects may be later assessed and diagnosed with developmental dyscalculia. Although many are sceptical that children who have trouble with mathematics should be diagnosed with a disorder, there can be no doubt that some will experience great numerical difficulties, and research is underway, concerned with better understanding the relationship between mathematical skill and the brain.

Dyscalculia is highly heritable (Shalev et al. 2001), and this genetic effect appears to exist both for normal variation in mathematical ability and for those with

particular difficulties or at risk for dyscalculia (Ansari and Karmiloff-Smith 2002). Aside from the normal variation in mathematical skills, there are several medical conditions that are associated with increased risk of dyscalculia. These include epilepsy, Turner's syndrome, fragile X syndrome and extremely premature birth (Klingberg 2013). One fMRI study looked at the brains of a group of teenagers, all of whom were born prematurely and were later diagnosed with dyscalculia. These young people had thinner layers of grey matter in the intraparietal cortex (Isaacs et al. 2001) when compared to the control group. Children that are born prematurely with low birth weight seem to be at the greatest risk of facing difficulties with number processing.

One brain region that often emerges in studies of dyscalculia is the intraparietal sulcus (Rubinsten and Henik 2009). Studies of brain activity during visuospatial working memory tasks (Rotzer et al. 2009) and number magnitude processing (Price et al. 2007) find that children with dyscalculia have specific regions in the right intraparietal cortex, as well as two areas of the frontal lobe and occipital lobe that are less active compared to children without dyscalculia.

Developmental dyscalculia appears to have a similar prevalence to dyslexia, but in comparison, the neurological bases are only just beginning to be investigated. Researchers have identified three main aims for this area of research (Wilson and Dehaene 2007). The first is a neurocognitive description of dyscalculia that will allow for better identification, remediation and even prevention of dyscalculia. Based on this description, the second aim is to develop tests for accurate measurement of numerical ability. Finally, the third aim is to develop and test new interventions that will target children's core deficits.

14.10 Social and Emotional Problems

This chapter has emphasised the central role of the environment in shaping infant development. As has been discussed, secure family relationships that provide stimulation, interaction and nurture will promote adaptation and growth in neural structures that respond to the needs and demands of everyday experience. Where the conditions are less than optimal, perhaps in situations of insecure maternal attachments, chronic stress or malnourishment, the development of the child may suffer, and an absence of positive adult relationships is found to increase the risk for maladaptive behavioural and emotional problems in school settings (McCrory et al. 2010).

Ongoing research is beginning to reveal the genetic contributions that can either protect individuals or increase the risk of developing emotion or behavioural disorders such as anxiety, attention deficits or conduct disorders. Genes that are present at birth only have an effect if they are expressed, and current research efforts explore how the social environment can trigger the expression and thus effects of genes in a biological embodiment of experiences. In one such example, children with low activity of the monoamine oxidase A (MAOA) gene and who experience maltreatment

and adversity more often develop antisocial behaviours such as conduct disorder, whereas those found to have the high-activity MAOA variant seem to be protected (Caspi et al. 2002). Six-year-olds with the short version of the dopamine transporter (DAT1) gene are more impulsive and have less attention control than those with the long version of DAT1 (Rueda et al. 2005). In the classroom, such children would benefit from additional support and training to regulate their impulses and attention.

One such school-based therapeutic approach was developed in the 1970s by Marjorie Boxall, an educational psychologist in inner city London. Nurture groups (Bennathan and Boxall 2000) were set up to support the large numbers of children entering school with alarming emotional problems and disruptive behaviour and who are unable to meet the demands of kindergarten or infant school. It was Boxall's view that the problems children face in regulating their behaviour, forming relationships and responding appropriately to their peers, arose from impoverished early nurturing (Cooper and Whitebread 2007). In a secure space within the educational setting, children are encouraged to develop trusting and caring relationships with adults. From this foundation, children are able to learn prosocial skills with peers and engage in the challenges of formal curricular tasks. Studies have shown the effectiveness of nurture groups not only in improving emotional well-being but also in areas of academic achievement (Reynolds et al. 2009).

For children whose biological systems are still maturing, the greatest problems arise from the combined and cumulative effects of genetic vulnerability and negative environmental factors. These will be considered in the following section with examples from two disorders increasingly identified in early years classrooms: autistic spectrum disorder and attention deficit hyperactivity disorder.

14.11 Autistic Spectrum Disorders

Autistic spectrum disorders are characterised by impairments in social interaction, imaginative ability and repetitive, restrictive patterns of behaviour (Williams et al. 2001). The number of children diagnosed with ASD is on the rise (Baron-Cohen et al. 2009), and the disorder has been the focus of intense research over the last decade. Since the education and policymakers of many countries call for the inclusion of ASD children in classrooms with typical peers (e.g. National Research Council 2001; National Institute for Health and Clinical Excellence 2011), it is likely that most early years teachers will have the experience of supporting a child with ASD at some point in their career.

Early in their development, children begin to understand that the beliefs and intentions of others may be different from their own, and they begin to show empathy towards others who are experiencing sadness or pain. Empathy is a social skill that is fundamental to interpersonal sensitivity and successful human relationships (Gordon 2009). Baron-Cohen et al. (1985) demonstrated that children with autism had particular difficulties in understanding the beliefs of others and suggested that

they lacked a 'theory of mind' (ToM). This claim has been supported by a wealth of studies and has led some to argue that autism is caused by ToM deficits (e.g. Happe and Frith 1996; Leslie 1991 & Baron-Cohen 2000). However, others describe such explanations as unsatisfactory for a number of reasons. Firstly, ToM does not become robust in children until the age of 3 or 4. Secondly, the primary deficit is more accurately characterised as broadly socio-affective and by a lack of empathic and emotional engagement with others (Hobson 1993). Finally, ToM deficits do not well accommodate explanations for the repetitive behaviour, obsessive desire for sameness, delayed and deviant language development and difficulties perceiving or planning high levels of organisation (Williams et al. 2001).

Genetic studies have identified a number of different genes involved in ASD (Rutter 2005), and research suggests environmental triggers may collude with genetic vulnerability to increase the risk of ASD (e.g. Geschwind and Levitt 2007; Muhle et al. 2004). Some of the most well-reported findings have derived from Michael Rutter's studies of orphans who suffered extreme neglect in Romanian institutions and were then later adopted into UK families. Autistic-like behaviours were found in 9.2% of the adoptees, compared with 0% in the domestic control group of adopted children (Rutter et al. 2007). These studies followed the children from age 4 to their teenage years and found that distinctive social deficits faded away with time spent with their adoptive families.

Closely related to studies of autism, neuroscience research is interested in how learning is acquired through imitation. Research finds that repeated observations of actions (either passive or active) increase brain activity (Chong et al. 2008). It is believed that learning through imitation is made possible by a group of specific brain cells called mirror neurons (Rizzolatti and Craighero 2004). The mirror neuron system is a set of brain regions that are active both when we perform a specific action (such as clenching a fist) and when we observe this same action performed by another (Iacoboni et al. 2005). It has been suggested that through the mirror neuron system, children develop empathy, i.e. the ability to understand the actions and intentions of others (Blakemore et al. 2004; although see Dinstein et al. 2008 and Lingnau et al. 2009 for an alternative perspective).

Neuroimaging studies reveal a specific network in the typically developing human brain, near the right temporo-parietal junction, that is specifically active when people are thinking about other people's thoughts (Saxe and Wexler 2005). Children with autistic spectrum disorders are found to have anatomical differences in several areas of the brain, and research has identified their impact on learning (see Branson 2013 for review). One of the most consistent findings is that children with ASD have excess neuronal growth in infancy. This early overgrowth is followed by slowed or arrested growth in adolescence (e.g. Carper and Courchesne 2005). Furthermore, there is evidence that ASD is associated with under-connectivity within brain regions that would typically work together to accomplish tasks such as language processing, social interaction and goal-directed planning and monitoring. Many questions remain regarding autistic spectrum disorder, which early childhood teachers will appreciate in relation to the apparent variability of behaviours between children diagnosed with ASD in their classrooms.

14.12 Inattention, Impulsivity and Hyperactivity

All young children are naturally active, impulsive and easily excitable. Even excessive behaviour of this nature is most often due to immaturity and eventually outgrown. For some children, however, attention span is so short, activity levels so high and impulse control so limited that learning and social development are severely impaired (Barkley 2013). In the UK, inattention and hyperactivity are now the most common problem for children in the early years classroom (Brown and Schoon 2010). All young children have to learn sustained attention, concentration and regulation in order to control their emotional and behavioural impulses. A child with good impulse control can refrain from hitting another child during a conflict, pay attention to the teacher's instructions and wait his or her turn when playing a game.

Attention deficit hyperactivity disorder (ADHD) is a developmental disability characterised by deficits in sustaining attention and resisting distractions, behavioural impulsivity, lack of self-control and problems in regulating activity (hyperactivity or restlessness). Children with attentional deficits have greater difficulty in focusing, following tasks through to completion and sustaining effort and motivation. They are easily sidetracked, forgetful and disorganised, fail to plan ahead and have inconsistent school performance, mood swings, a quick temper and difficulties with social relationships (Barkley 2013).

Precise causes have not yet been identified but there is little question that ADHD is highly heritable. A number of genes have been identified, and it is likely that more will be as research continues. For example, the dopamine receptor (DRD4) gene is found in 50 to 60% of the ADHD population (Polanczyk et al. 2007). Stimulant drugs (such as methylphenidate), which act directly on dopamine receptors, are found to effectively reduce ADHD symptoms (Swanson et al. 2000) and have lead to the theory that dopamine has a key role in the manifestation of the disorder (Levy 1991). Where heredity does not seem to be a factor, other contributors have been identified, such as foetal exposure to alcohol and nicotine, or complications during pregnancy, difficult labour or premature birth. Research does not support popularly held views that ADHD arises from excessive sugar intake, food additives, excessive viewing of television or poor parenting (Sciutto et al. 2000; Barkley 2013) although such factors can contribute unhelpfully. It seems that a combination of early environmental factors, together with certain genetic susceptibility, is required for the full ADHD to emerge.

Neuroscience research is working towards a more complete understanding of the neurobiological and chemical processes involved in the development and regulation of attention. Since many questions remain about these mechanisms in normal, healthy development, it is difficult to know all that can go wrong. However, whilst the exact brain mechanisms that underpin attentional deficits have yet to be fully explained, neuroimaging and genetic studies have revealed some anomalies. A number of imaging studies have demonstrated that in children with ADHD, the size of specific anatomical structures (prefrontal cortex, basal ganglia and cerebellum) is found to be significantly smaller than in typical children (Castellanos et al. 2002).

These structures are found to be especially rich in dopamine receptors which have led to the hypothesis that the underlying problem for children with ADHD is related to dysregulation of the dopamine signalling system (Swanson et al. 2000).

With much uncertainty about the disorder, many questions exist regarding the most effective treatment for ADHD. Interventions are conceived around finding a means for the child to accommodate, cope with and compensate for their developmental difficulties and may include medications that can provide relief from symptoms (Barkley 2002). The main psychosocial treatments with proven efficacy for the management of ADHD include (1) parent training in child behaviour management (Barkley 1997), (2) teacher training in classroom management (DuPaul and Eckert 1997) and (3) combined pharmacological and behavioural treatments (Carlson et al. 1992). Few studies on psychosocial interventions for ADHD have conducted follow-up re-evaluations on the maintenance of treatment gains over time and across different school and home settings. In time, replication and follow-up studies will provide more conclusive recommendation for non-medication interventions.

Due to the difficulties with defining the causes of ADHD and the increasing certainty that causes are both biological and social, many questions arise over the prevalence of diagnosis and the ethics of treating children with stimulant drugs. At the time of writing, ADHD is one of the most heavily invested areas of research in childhood mental health. Over the next decade, it is likely that this research will increase our understanding of both the causes and nature of the disorder. Findings from this investment may even suggest new variants or subtypes of ADHD. For example, clinicians have begun to describe a different type of attention disorder named sluggish cognitive tempo (SCT). Those affected are described as daydreamers, acting as if they are in a mental 'fog,' staring frequently, seemingly sleepy and not attending to events around them and with slow processing speed and reaction times (Palmer and Finger 2001). Although they share similar attentional deficits, these children are not impulsive or hyperactive like those with ADHD, but actually lethargic and slow-moving compared to their peers. Unlike children with ADHD, they are likely to be quiet whilst working, yet not fully processing the task and its instructions (Barkley 2013).

Much of the discussion here in relation to inattention and impulsivity involves under control, i.e. impulsive children. However, at the other extreme is the child who may be overcontrolled, inhibited and anxious. Studies have shown that self-control is not always positive. For example, shy 2-year-olds rated as having high self-control are found to be more socially withdrawn and less socially competent (Fox et al. 2008). These children may be less visible in the classroom than the hyperactive, impulsive child as they are highly skilled at controlling their activity, nevertheless, they may suffer disruptions to attention processes, due to the potential for bias or preoccupation towards negative emotions or upsetting events (for a discussion on this topic, see Mathews et al. 1997). Current diagnostic criteria for ADHD do not yet fully accommodate such overlapping but distinct symptoms of attention deficit, and it is hoped that ongoing research will provide much needed understanding and support for those affected.

One intriguing area of promise for training attention and self-regulation arises from a programme developed by Helen Neville at the University of Oregon, from which promising preliminary findings have recently been published. Her research rests on the theory that early environmental enrichment in the form of intervention can protect and enhance the potentially vulnerable neurocognitive systems in children with or at risk for developmental deficits. Neville found that children from low socioeconomic status families were less likely to be able to sustain attention due to their difficulties with suppressing or ignoring distractions (Stevens et al. 2009). Children and parents of families whose children were enrolled in Head Start (a federally funded programme for preschoolers living below the poverty line) received attention-training exercises each week for 8 weeks (Neville et al. 2013). The activities target aspects of self-regulation, including vigilance, selective attention and task switching. For example, one selective attention exercise requires the child to focus their attention (e.g. colouring within the lines of detailed figures) whilst simultaneously suppressing distractions (e.g. ignoring other children balancing balloons in the air around them). Over 8 weeks, the activities became increasingly more challenging and similar to classroom situations. Positive changes were observed in the neural regions activated during selective attention tasks as well as in measures of cognition, language and behaviour and even positive changes in the parents themselves (Neville et al. 2013). Long-term benefits have still to be ascertained but are likely to emphasise the fundamental requirement to involve the parents in the child's training as a key component to enriching the environment of the child at risk of developmental deficits.

14.13 What Future for Neuroscience and Education?

Educational and neuroscience research shares the same purpose: to understand how the brain perceives, learns and adapts. Unsurprisingly, governments around the world are investing enormous sums of money in understanding the brain, its disorders and diseases. Out of concern for improving standards of achievement in schools, collaborative research between neuroscience and education is underway, and much has already been written about the applicability of neuroscience to the classroom. This chapter has identified some of the areas where cognitive neuroscience is influencing views on child development and learning.

The brain is fascinating and teachers are right to be excited about advances in neuroscience. For better or worse, teaching has long been dominated by political opinion and preferences that demand teachers to regularly implement new policy or curricula changes that they may have had little part in evaluating prior to implementation. Research among teachers has established a high level of enthusiasm for the role of neuroscience in education (Pickering and Howard-Jones 2007). This enthusiasm may result in the expeditious adoption of new teaching methods without thorough investigation of applicability in classrooms. In one illustrative example, many schools in the UK rapidly adopted Brain Gym®, a commercial package that

prescribes a series of simple body movements. These claim to enhance learning by accessing areas of the student's brain previously inaccessible or unavailable (Cohen and Goldsmith 2000). Suggestions that children can prepare the visual system for reading and writing by pressing 'brain buttons' located under the ribs are misleading, and scientists warn against overliteral or misinterpretation of scientific theory (Goswami 2006).

The role of the scientist is to test ideas and develop theory. For application of theory into effective, evidence-based intervention, educators are required to become critical consumers of cognitive neuroscience research (Ansari and Coch 2006). These educators in their capacity as professional practitioners are able to interrogate scientific research, interpret its relevance and application for their individual context and develop pragmatic strategies to promote learning according to the unique contextual environment in which they teach.

Perhaps one of the most significant contributions neuroscience is likely to have for education is in the early identification of learning difficulties. Schools provide the possibility for intervention via the creation of secure classroom environments in which children with difficulties can be identified and targeted (e.g. Wyman et al. 2010). This chapter has attempted to provide scientific explanations and understanding for teacher's observations of how individual children arrive in school in various states of readiness for the acquisition of new skills and knowledge. Some are easy to engage and motivate, are delightfully curious about a learning challenge and seem to effortlessly absorb facts and manage social conflict. Others in the extreme are oppositional, hard to motivate and for whom perseverance is fragile and conduct easily disrupted.

Parents may be unwilling or unable to provide much background detail for class teachers that might explain potential causes of learning difficulties or worrying behaviour. Without understanding the possible causes of such problems, or what they might suggest for potential outcomes in later life, classroom interventions to initiate positive change are often discovered through trial and error. In the future, we hope neuroscience will support educators in the early detection of adverse environmental inputs on young children's classroom behaviour and their potential effects on the development of self-regulated, socially competent individuals.

14.14 Implications for Early Years Education

This chapter has set out to emphasise the influence of the environment on developmental outcomes. At the molecular, genetic and neural levels, science has begun to show how and why young children do not simply follow fixed developmental trajectories. Neuroscience reveals how inputs from both genes and environment contribute progressively to development. Except in extreme cases of biological disorder, few genetic predispositions are static and without influence.

In the autumn of 2009, a team of researchers in the USA recruited 18 children all of whom were about to begin their first year of school. Collectively, these 5-year-olds

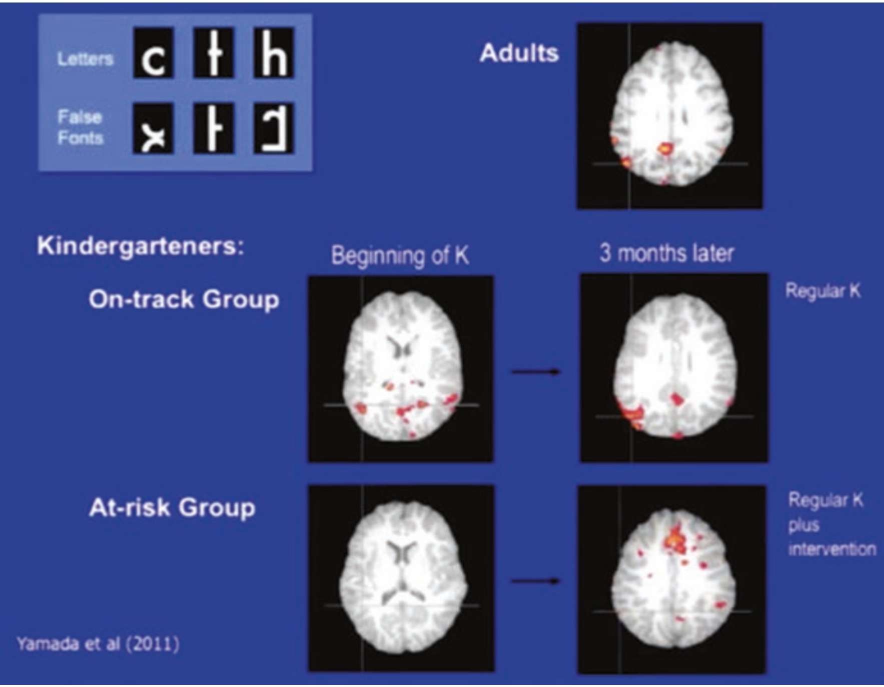

Fig. 14.2 Neural activations of on-track and at-risk children in kindergarten during literacy development (from Yamada et al. 2011)

represented a diverse range of preliteracy ability such as might typically be found in any early years classroom. The researchers wanted to compare the neural network in beginning readers to that of the mature, fluent adult (Turkeltaub et al. 2003). Whilst in the fMRI scanner, children were asked to press a button each time a letter was repeated twice in a row (Yamada et al. 2011). The children then began a regular half-day kindergarten curriculum, which included early literacy instruction.

After one semester of schooling, the children were invited back to the scanner to repeat the test. When asked to identify letter formations, just like adults, the on-track, typically developing children demonstrated activation in a region of the left angular gyrus. After just 3 months, these children's neural activations began to more closely resemble that of the mature literate adult. In other words, the instruction they were receiving from their school teachers had a direct impact on the specialisation of the neural networks required to support literacy.

By contrast, the individuals identified as less mature, less proficient and 'at risk' of reading difficulties were instead seen to recruit compensatory neural tissue in frontal regions, even after they had received supplementary reading intervention (see Fig. 14.2). On entry to kindergarten, these children were also seen to have more limited attention and self-regulatory skills (Yamada et al. 2011). Such prefrontal activation patterns during letter recognition tasks are explained by the necessary

additional neural workload involved for these children in recruiting effortful attention, motivation and cognitive resources for reading.

Children whose prenatal development proceeds without complication and who are raised into secure, loving and responsive families are most likely to be ready for school and able to respond positively to the early learning environment described in this study. However, not all children are physically and emotionally ready for school at the time they arrive in the early years classroom. The role and responsibility of the early years educator in a young child's life cannot therefore be overemphasised, not only to provide varied and stimulating opportunities to accelerate learning but also to mitigate the impact of adverse early experiences in order to prevent impairment (Shonkoff and Levitt 2010). In much the same way that we know that obstructions to hearing or vision need to be removed whilst neural networks are developing, how can we reduce the emotional and behavioural barriers that undermine the acquisition of early literacy or numeracy skills? Whilst an adverse environment may result in problem behaviours, the opposite is true of a warm, secure and supportive environment. Neuroscience provides every reason for teachers to believe that in the early years classroom, in which a child receives daily contact with warm and supportive adults and peers, the opportunity is for vulnerable children to draw upon these resources whilst the brains of these young people are still flexible and open to learning. Social and cognitive stimuli can be processed adaptively, and unhelpful behaviours can be extinguished through sensitive encouragement and contingent support.

Chapter 15
School Readiness in Europe: Issues and Evidence

Sue Bingham and David Whitebread

Abstract The issue of 'school readiness' has become a topic of considerable debate and controversy within Western Europe over the last few years. This is interpreted in widely different ways and includes debates on what capabilities a young child needs in order to successfully commence their schooling; what type of institutional and pedagogical provision constitutes 'schooling', as opposed to pre-school, kindergarten or nursery; and what is the appropriate age at which children should be expected to make the transition from home and pre-school into their primary school?

Keywords 'School readiness' • Teaching-learning methodologies • Primary education • 'Schoolifying' • Early childhood education

15.1 Introduction

This chapter examines the influence of schools upon children as their 'schooling' commences within a range of countries in Western Europe. In the main, no child is considered to require 'schooling' until they are at least 6 (and in some cases 7) years of age, and all member countries offer some form of early publicly financed programmes for children before the start of compulsory schooling. However, the diversity of children's home environments and early learning experiences, the age at which children may access early childhood education and care (ECEC) programmes, the length of time they attend and the nature of the provision are subject to significant cross national differences. Such diversity naturally has a huge impact upon the

development of the child, shaping their transition to 'school', a period during which children are required to respond to significant pedagogical changes, to changes in identity, roles and relationships as they become a 'pupil', with new or different expectations placed on them to learn the social rules and values associated with being in a formal 'institution'. Within this chapter we examine the ways in which the transition to school is handled in a range of key countries within Western Europe, with a particular focus on the consequences for children who are relatively disadvantaged due to their socio-economic home environments and others who are relatively young upon entry into school.

The chapter includes as follows:

An examination of the main characteristics of the structural and organisational frameworks set by the various statutory and advisory bodies in Western European countries in relation to education and care provision for children in the pre-primary phase and up until the age of 7 years.

An investigation of the objectives, curricula and teaching-learning methodologies of the different approaches employed within ECEC and the first years of primary education across these countries. We examine the objectives of the 'socio-constructivist' pedagogical systems, as well as the 'pre-primary' systems in other countries where governments intervene directly into the early years phase, with the aim of raising primary school test results. We investigate the reasons for other early educational interventions in some countries for children as young as 2.5 years considered to be 'at risk' and assess their long-term outcomes.

A brief overview of the psychological evidence of recent decades, illustrating that as the long-term consequences for children's development as learners are increasingly understood within these scientific domains, the importance of the ways in which children learn – and therefore the ways in which they need to be taught – come to the foreground. We go on to argue that the 'schoolifying' of the early childhood years is not supported by the research evidence and that it is very likely to be damaging, particularly for the most deprived and youngest children.

Hence, in the final section, we conclude that the real issue is not the age at which children 'start school' but how smoothly the transition is handled in terms of children's socio-emotional needs and – more importantly – that there exist high degrees of consistency in teaching methodologies employed 'across the divide' between pre-school and primary school – until at least the age of 7 years.

15.2 School Starting Age

Summarising the findings reported in 'Tackling Social and Cultural Inequalities through Early Childhood Education and Care (ECEC) in Europe' (Eurydice 2009), the author states that:

> ECEC programmes for 3–6 year olds exist in all European countries and at this level, the mission to educate is clear and overrides the child-minding function related to parental employment. The aim everywhere is to stimulate cognitive, social and cultural development

> and to prepare children for early learning activities in reading, writing and maths …altogether these trends are rather encouraging….. In the majority of European countries, educational provision for 4–5 year olds is increasingly becoming the first rung on the educational ladder. (p. 131)

This summarises well the highly significant changes in educational provision for young children across Europe and raises very clearly the vexed question of school starting age. Over the last one or two decades, in many countries across Western Europe and, indeed, across the world, governments have made a huge investment in early childhood pre-school provision, at least from the age of 3 years and often younger. In some countries there has been a long-standing tradition of early years provision, often building on the seminal work and theories of Froebel, Montessori and Steiner, and consequently founded on very particular views about the needs of the young child [for a more extended description of these views, see the Pedagogies-section, this volume]. This has always been in tension, however, with the more didactic and instructional approaches of traditional primary schooling, which has focused on the teaching of the basic skills of literacy and numeracy. With the recent expansion of pre-school provision, and the massively increased involvement of governments in this, applying models of economic efficiency involving 'targets' and 'standards', these tensions have become dramatically more marked. As Eurydice indicates, one outcome of these new developments has been the effective lowering of the age at which children begin formal schooling. In some cases this has been marked by an actual lowering of the legal school entry age, and in others has been a 'de facto' lowering, while the official age of school entry has remained unchanged.

The rationale that lies behind the 'starting age' of schooling is an important consideration. It is reasonable to suggest that any policy decision in this area should be based on what is beneficial for the child, but there have certainly been indications in some countries that other political agendas, such as encouraging young mothers to return to the workforce, have been part of the thinking. Nevertheless, there can be no doubt that the wide range of initiatives that have been implemented across Europe in recent decades attest, at least in part, to a political will to promote the participation in 'educare' programmes of children between 3 and 6 years of age, and in some cases younger, especially from families at risk. This demonstrates, at least to some extent, an awareness among policymakers of the importance of education in countering social inequality and poor educational outcomes. As we shall see, however, whether the policies that have been implemented are likely to have this desired effect is very much open to question.

As initial background to this debate, Table 15.1 provides an overview of compulsory school starting ages in Europe. The most common starting age is 6 years; however, it should be noted that this is often the latest age at which children must start school, and in some European countries, most children enter school below the compulsory school age. Further, in many of the countries with a later school starting age, there is a structured pre-primary school provision available for a period before the compulsory school starting age (usually one or 2 years). For example, Finland provides early years education and care for every child under compulsory school age.

Table 15.1 Compulsory school starting ages in selected countries

Age	Country
Four	Northern Ireland
Five	Cyprus, England, Malta, Netherlands, Scotland, Wales
Six	Austria, Belgium, Croatia, Czech Republic, Denmark, France, Germany, Greece, Hungary, Iceland, Republic of Ireland, Italy, Liechtenstein, Luxembourg, Norway, Portugal, Romania, Slovakia, Slovenia, Spain, Switzerland, Turkey
Seven	Bulgaria, Estonia, Finland, Latvia, Lithuania, Poland, Serbia, Sweden

Source: European Commission (Eurydice 2013)

The table shows that over half of the European countries listed have 6 as the official school starting age. The latest school starting age is 7 (including two in Scandinavian countries). Three UK countries (England, Wales and Scotland), as well as Malta and the Netherlands, start school at 5. Northern Ireland, with a starting age of 4, has the earliest compulsory school starting age in Europe.

The compulsory school starting age, however, only reflects part of the picture. Primary education programmes (defined as being for 6-year-olds onwards; UNESCO 2007) are designed to give a basic education in reading, writing and mathematics along with a basic understanding of other subjects. Pre-primary education is intended to meet the educational and development needs of children of at least 3 years of age (UNESCO 2007). As illustrated below, in a number of countries, pre-primary education is compulsory, and in others, pre-school systems exist which the majority of children attend. Several countries allow individual children to enter school before compulsory school age or to delay entry, in accordance with parents' wishes, teachers' views and/or the results of pre-school assessments. So, in several cases, the 'compulsory school age' represents the maximum age by which children start school – in reality, the majority of children are in school before reaching the compulsory age.

Furthermore, there is evidence of a clear trend across Western Europe towards requiring children to start schooling at an increasingly early age. Increasingly structured ECEC programmes for 3- to 6-year-olds now exist in all Western European countries, and attendance in these programmes is becoming either compulsory or, at least, very much expected. Indeed, in real terms, over the period 2000–2009, on average in Europe, the participation rate of 3-year-old, 4-year-old and 5-year-old children in pre-primary or primary education increased, reaching around 77%, 90% and 94%, respectively, in 2009 (Eurydice 2012).

A number of countries lowered their school starting ages over the period 2000–2009 – for example, Denmark and Romania reduced their school starting ages from 7 to 6 years, and others have made pre-school attendance compulsory; in Bulgaria, Greece, Cyprus, Latvia, Luxembourg, Hungary and Poland, for example, compulsory education was extended to pre-primary level and children (aged 4, 5 or 6 years) now take part in pre-primary education programmes designed, primarily, to introduce very young children to a school-type environment. In Poland the age of starting primary education has been gradually lowered from 7 to 6 years between 2009 and 2014 in order to increase participation in pre-primary education, which had

been offered to children between the ages of 3 and 6 years but had declined in terms of actual take-up over the previous decades; in 2002, just 52% of 3- to 6-year-olds attended a pre-primary setting. The government also made the kindergarten year, the year prior to starting primary school, compulsory for 5-year-olds from 2011.

Northern Ireland, England, Scotland, Wales, Cyprus and Malta have the lowest compulsory school starting ages in Europe, compulsory education starts at the age of 4 or 5 years and children are usually integrated directly into primary education programmes. The compulsory school starting age in Northern Ireland was lowered from 5 to 4 years almost 25 years ago because it was thought beneficial for the children to spend 12 full years in education. In England and Wales, children reach compulsory school age at the start of the school term following their fifth birthday, but most enter primary school before this point, usually in the September following their fourth birthday, thereby spending a full year in the reception class. In Scotland compulsory education starts at age 5, although many children start at 4 because schools have a single intake at the beginning of the school year. In Cyprus, pre-primary education is compulsory for 5- to 6-year-olds for 1 year, and children who reach 5 years and 8 months before the beginning of September must go to school. In Luxembourg, although primary school does not start until age 6, pre-primary education is compulsory from age 4. In the Netherlands, although early education is not compulsory until age 5, almost all children start school at 4. In the Republic of Ireland, although schooling is not compulsory until age 6, approximately 40% of 4-year-olds and almost all 5-year-olds are in publicly funded provision in the infant classes of primary schools.

While this drive across Western Europe to lower the school starting age might to some extent be influenced by the increasing acknowledgement of the impact of high-quality early education, there is clear evidence of a number of significant economic drivers. On the one hand, governments largely view the public funding of early years provision as an investment to strengthen the country's economic competitiveness, and, at the same time, particularly during a period of relative economic austerity, the parents of young children need to be in employment, if at all possible.

Almost certainly as a result of these economic drivers, in approximately half of the countries in Europe, education-oriented pre-primary public institutions are free of charge (Eurydice 2012). This universality evidently eases access to pre-primary education for children from poorer socio-economic backgrounds, as well as the adjustment of fees for non-compulsory pre-primary education that takes into account family income and other criteria (Eurydice 2012). In addition to broader policies designed to tackle social exclusion, in all countries where fees are payable for non-compulsory pre-primary education provision, some form of means testing occurs by which parental contributions are adjusted. This fundamental issue of finance may be one of the reasons for the trend for children to start pre-school or school before the statutory age. In some countries daycare and other early years services represent a significant expense, while pre-school or school is free. It is clear that some parents simply cannot afford to delay pre-school or school entry beyond the minimum allowable age.

15.3 Earlier Is Better?

It has become clear in recent years, then, that, for whatever reason, be it economic considerations or ill-founded misunderstandings about early childhood learning, policymakers in certain European countries have specifically held to the perspective that 'earlier is better' in terms of pre-primary educational models. These policymakers tend to support a school starting age of 4 or 5 years and tend towards a 'formal' approach in the recommended teaching methodologies, believing that:

> An early start provides an opportunity for children from disadvantaged backgrounds to make up the deficit in their academic skills;
> Early school starting age is thought to be popular among parents
> Children can get a 'head start' in learning;
> Young children are able to acquire the more cognitive skills inherent in the formal curriculum

> Thus, in Denmark, following the 2000 and 2003 PISA results showing a reduction in achievement levels (Artelt et al. 2003), government concerns arose surrounding the 'effectiveness' of the child-oriented pre-schools. A perception arose that the freedom being afforded to these young children was compromising their learning and development in some way. In the law of 1964, no guidelines had existed for the pedagogical content of the work of the 'pedagogue' and only some general aims and educational principles were described (Broström 2006; Peeters 2008). But in 2004, a curriculum was introduced for young children (Broström 2006); even though the curriculum is very open and still reflects the Nordic 'social pedagogical model', the majority of Danish pedagogues and researchers viewed the Curriculum Act as a step towards more bureaucratic state regulation and the 'schoolification' of early years learning. (Ellegaard and Stanek 2004)

Perhaps it seems counter-intuitive to policymakers and commentators who propose specific curricula and an earlier start to formal instruction that delaying the formal teaching of literacy, numeracy, etc. will enhance children's development as learners. Nevertheless, there is no serious evidence to support the 'earlier is better' position and a very significant body of evidence to support the alternative view that a later start at school might be advantageous in the long run.

On the initial narrow point about the impact of any particular school starting age, a range of different studies have been carried out which have either found no consistent outcome of children starting formal schooling at particular ages or have suggested that an earlier start might have some disadvantages.

Thus, research carried out on behalf of the UK's National Foundation for Educational Research (NFER) into school starting age in Europe did not find evidence for an optimum age for children starting school (Sharp 2002). A further study in the USA by the NICHD supports this, finding that age of entry effects were small in size and negligible as major determinants of children's school achievement.

In the specific area of literacy, studies by Suggate and colleagues (Suggate 2009a) in New Zealand have demonstrated that the early introduction of formal learning approaches to literacy does not improve children's reading development in the long run and may be damaging. Their study was made possible as children in New Zealand's regular state system start formal schooling at age 5, while those

attending the many Steiner schools do not start formal instruction in reading until they are 7. They found that by the age of 11, there was no difference in reading ability level between these two groups. Further, their study revealed some evidence that children who started formal instruction in reading earlier developed less positive attitudes to reading and, by the age of 11, showed poorer text comprehension than those children who had started later.

Finally, in Suggate's (2009b) more recent international study, data from the reading portion of the 2006 Programme for International Student Assessment (PISA) study were re-analysed. The relative reading achievement, as a function of school entry age, of 15-year-old students across 55 countries was investigated, controlling for social and economic differences. Results suggested no significant association between reading achievement and school entry age. In other words, an earlier beginning in formal reading instruction did not appear to result in higher reading achievement by the age of 15.

At the same time, a number of studies have directly addressed the length of time children spend in pre-school, play-based educational settings, arising from the age at which they start formal schooling. For example, in a longitudinal study of 3000 children funded by the Department of Education in the UK, Sylva et al. (2004) showed that high-quality, play-based pre-school education made a significant difference to academic learning and well-being through the primary school years, and an extended period (i.e. 3 years) of such provision was particularly beneficial for children from disadvantaged households.

This range of evidence appears to confirm the view that the specific age of starting school might not, in itself, be significant but that what is key is the style of pedagogy to which children are exposed at particular ages. Whether in school or pre-school, the evidence suggests that a too early introduction of formal instruction, and the consequent curtailing of play-based learning, can be damaging.

15.4 The 'Schoolification' of Early Childhood Education

Thus, although the intentions of policymakers are no doubt honourable, there is increasing evidence that in certain countries around Europe, specific groups of children are being disadvantaged by the teaching approaches taken in educational settings at early points in a child's life. Starting formal schooling involves children responding to changes in identity, roles and relationships as they become a 'pupil', with new or different expectations placed on them (Griebel and Niesel 2000) and learning the social rules and values associated with being in an 'organisation' or an 'institution'. Transitions between pre-primary systems into primary school pose difficulties for young children when they encounter contrasting or widely differing expectations, approaches and values in the new environment. An increasing number of commentators suggest that children aged 4 and 5 may not be ready for the more 'formal' teaching methodologies they encounter in some European primary schools

and that being compelled to participate in such approaches at an early age may cause stress and even long-term harm among young children (Sykes et al. 2009).

Four elements in the move towards earlier 'schooling' lead to various kinds of inappropriate formality and unhelpfully challenging difficulties for young children. These relate to the vexed question of adult-child ratios, to the introduction of set and highly structured curricula, to the 'accountability' agenda which leads to national testing regimes and a consequent narrowing of the curriculum and to the need for children to make early and abrupt transitions between very different institutional regimes.

First, as regards adult-child ratios, limits are set across the vast majority of European countries, and these are, of course, larger in primary school than in pre-school. In the general European context, primary class size limits have been set at between 25 and 33 children. The highest upper class size limits are found in the UK (Scotland) for primary education, with a maximum number of 33 pupils. In England and Wales, a maximum class size of 30 applies to pupils aged 5–7 years or 4–8 years in Northern Ireland.

The vast majority of European countries also have regulations establishing the maximum number of children per qualified adult in pre-primary education institutions. In about two thirds of the countries that have such regulations, the upper limit for a group is generally set between 20 and 25 children per adult. The remaining countries envisage groups of less than 15 children, with the smallest group size (seven) found in Finland and Croatia (for 3-yearolds). In several countries (Czech Republic, Estonia, Italy, Poland, Portugal, Slovenia and Slovakia) the maximum number of children per adult is reduced where one or more children have special needs. In Ireland, where pre-primary education stops before the age of 5, at which age children are generally enrolled in infant classes within mainstream primary schools, for children up to 4 years of age, the maximum number of children per adult is set at eight (in full-time pre-primary education), and where children attend part-time, the maximum number of children per adult is ten.

A consequence of an earlier start to school, therefore, is often that children have less access to an adult at an earlier age than might be developmentally appropriate. To begin with, of course, the structural limitations such as the size of class and the number of available adults have direct physical repercussions upon the feasibility of teaching and learning methodologies to be implemented in pre-primary settings. To maintain order and an environment conducive to safe learning, adults often require children to be less physically active and spend more time sitting still rather than developing their oral and social skills naturally through free play methodologies. Several commentators in the UK (e.g. Sharp et al. 2009) have highlighted the negative implications for a 4-year-old of being placed in a primary classroom where the access to an adult is restricted due to the size of the class and number of other young children competing for attention. In pre-school settings, the adult-child ratios are arguably more conducive to the socio-emotional needs of a 4 year old who is still adjusting to spending extended periods of time with unfamiliar children, forming relationships with unfamiliar adults, finding their place in a new hierarchy and assimilating and adhering to new rules.

Second, as regards the introduction of set and highly structured curricula, it is clear that part of the major policy change that has taken place in early childhood in Europe over the past 20 years has been a general acceptance of some 'structuring and orientation of children's learning' (OECD 2006, p. 146) and 'most OECD countries now use a curriculum in early childhood services'.

Countries with an integrated early childhood education system for the whole age range from birth to age 6 tend to develop pedagogical frameworks or curricula (e.g. Denmark 2004, Finland 1995/2003, Sweden 1998). While pedagogical frameworks generally identify the key goals of early childhood services at national and regional level, they vary in length and scope and in the values and attitudes towards children that are considered of significance in shaping early childhood education. For example, the Danish interpretation of curriculum is closely connected to the concept of the 'competent child' characterised by a focus on relational pedagogy in which interaction is more important than content (Broström 2005, 2006). Within this framework, teaching, based on the philosophy of Pestalozzi and the kindergarten model of Froebel, is not seen as a specific activity: it is rather conceived of as a by-product (Jensen and Langsted 2004). 'Pedagogues' make no distinction between care, upbringing and teaching (Broström 2006; Peeters 2008) in this holistic pedagogical approach. The Swedish curriculum emphasises democratic values: "All preschool activity should be carried out in accordance with fundamental democratic values". Policymakers in Norway set out in their policy documents a strong moral purpose for education, based on core Christian and humanistic values such as equality, compassion and solidarity. Teaching is explicitly defined as a caring profession, care being understood as creating an enabling environment for all children (Shakespeare 2000).

However, most European countries have chosen to introduce more formal curricula guidance for the stage closer to primary school, i.e. for children from the age of 3. Curriculum guidance such as that in N. Ireland puts an emphasis on learning areas and outcomes that are seen as important or, as in the case of France and increasingly England, even set standards for literacy and numeracy (OECD 2006, p. 134). As a consequence, children in primary school spend less time on tasks of their own choosing, instead being required to follow teacher-directed curricula that are more subject-related and place more emphasis on the formal skills of number, reading and writing. The danger here is that these formal skills require representational abilities that have not often sufficiently matured in children at the age of 4–5 years, with damaging consequences for the children's early formal learning experiences.

Third, as a consequence of the 'accountability' agenda which inevitably follows from governmental intervention in early childhood services, there has been a rapid increase in national testing regimes and a consequent narrowing of the curriculum [for more information about the accountability agenda, see also section on Curriculum and Assessment in this volume]. Such national testing systems, ostensibly positioned as instruments for assessing pupils during or at the end of compulsory education, have been increasingly used across Europe to monitor the performance of schools and education systems. From the 1990s onwards, the policy

frameworks underlying the national testing of pupils in Europe have increasingly focused on the systematic use of pupil assessment in schools to monitor the education system as a whole (Eurydice 2009, p. 9). Among the commonly reported aims are the comparison of performance across schools, the provision of input into measures for school accountability and performance evaluation of the entire system. Used thus, the results of tests serve as indicators of the quality of schools (and, less commonly, the performance of individual teachers) and of the overall effectiveness of education policies and practices, including whether or not improvements have occurred at a particular school or at system level.

Overall, the dominant model of academic testing in the majority of European countries is to administer national tests in two or three specific school years across the whole of compulsory education. The number of school years at which national tests are organised varies considerably across countries in Europe, however. For example, Denmark and Malta have developed national tests for almost every year of compulsory education. England and France are also regarded as countries in which national testing is widely practised, with seven and six national tests, respectively.

The most widespread practice is to carry out nationally standardised tests for the first time in school year 4 (as in Bulgaria, Spain, Lithuania, Hungary, Malta, Austria, Portugal, Romania and Iceland), or in a later year corresponding to the end of primary education (as in Belgium, France, the Netherlands, Poland and Slovenia). A small number of countries hold tests in the very first year of primary education, usually aiming to identify children's individual learning needs. For example, in England, the Early Years Foundation Stage Profile (EYFSP) is a statutory assessment for children in the final year of the Foundation Stage, based on teachers' classroom observations when the children are aged 4, but which the government is currently proposing to replace with a more formal 'baseline assessment' at the start of the reception year. A 'phonics screening test' is also mandatory at the end of Year 1 (when the children are aged 6). Belgium (French Community), Denmark, Italy, England and Norway hold standardised testing in the second year of school (when the children are aged 6–8). The stated aims for such testing have been variously cited as introducing standards and objectives which are serving to raise the expectation levels of schools and teachers regarding pupil performance; serving to allow for a 'value-added' assessment of individual schools; serving as instruments of social equality, in the sense that most pupils who receive additional support on the basis of their test results predominantly come from poor backgrounds; and, lastly, serving to identify the most gifted pupils.

One of the limitations of many national tests is that they assess pupil attainment with respect to just a small proportion of the curriculum. National testing is often concerned with just the two core subjects of the language of instruction and mathematics, supplemented in some countries by science or a humanities subject or foreign language. A real concern, therefore, is how to curb some potentially undesirable effects of testing, such as the tendency to adapt or restrict teaching to those aspects of the curriculum that are tested, or to place excessive emphasis on test-taking skills. Such effects may be especially marked not only where high stakes for pupils or students are involved but also for teachers and schools. There are very real concerns

being voiced by educationalists at the contradictions evident within policymakers' stances towards an appropriate educational approach for children aged 4 or 5 and some prescribed curricula. In England, for example, on the one hand, early years classes are places where play methodologies are often overtly emphasised by policymakers in curriculum guidance (e.g. DfE 2012a). On the other hand, however, learning outcomes of an academic nature are defined by the same policymakers, and their achievement advocated and determined through standard-based assessment. In other words, the curriculum recognises the 'informality of the learning experience' in the pre-school classes yet calls for learning outcomes that can only arise from the formal teaching of basic literacy and numeracy skills (e.g. DfE 2012b). The requirement for formal learning outcomes to be achieved is rigidly enforced via a draconian inspection system carried out by the Office for Standards in Education (Ofsted). This precise situation can also be found in the Netherlands, where there is no mandatory national testing until grade 8 but where in practice, under pressure from the school inspection system, most schools test children annually from grade 3 (at the age of 6) (van Oers 2013). Such approaches diminish the importance of the teacher's judgement of their pupils because of the great importance that the public attaches to the results of the national tests. As a consequence of these various pressures, it is often reported anecdotally that early years teachers are pressured by parents, school headteachers and the teachers of classes above them to introduce formal learning, even when it goes against their own judgement of how best to work with young children (Angus 2011). Opponents of national tests believe that they can demotivate pupils and increase their anxiety levels, that they are not in the interests of parents and pupils and that they lead to the teaching effort being focused on 'drilling' pupils to pass the tests.

Fourth, as regards the problem of early transitions, it is clear that the educational philosophy, teaching style and structure of learning in a primary school may vary considerably from any pre-school experience. In some countries the imposition of 'school' and curriculum into the lives of young children can be seen as marking an artificial boundary which demands that development has reached specific 'standards'. Not being 'ready' to make the transition to school at a particular time can and does have detrimental effects on future learning and self-esteem (Margetts 2003). Children are at risk of not adjusting easily to school when there is a disparity between the personal and cultural skills, attitudes and knowledge they bring to school and the expectations of the school itself (Fabian 2002). An unsuccessful transition can cause anxiety and stress leading to anti-social behaviour, fatigue and distraction, all of which potentially compromise the child's capacity to learn (Featherstone 2004).

> Adjustment is influenced by the level of comfort, familiarity and predictability the child experiences. Ensuring that each transition is smooth is important for children's emotional well-being and to their continuing cognitive engagement; settling well in their first year at school 'sets them up for later' (Laurent 2000). Transition practices are widely used to support school entrance, and across Europe there seems to be theoretical and practical consensus on the importance of these activities (e.g. Clark and Zygmunt-Fillwalk 2008; Einarsdottir et al. 2008). Activities that support learning across the transition aim to develop a child's

understanding about the ways of learning in school, helping them to anticipate change and difference between philosophical learning 'boundaries' (e.g. from play to 'formal' learning) in order to embrace change confidently and to enjoy what the new setting offers. Such methods include mentoring by children already at the new setting to demonstrate ways of learning, using play-based activities that start in one setting and are completed in the next (Fabian and Dunlop 2005) and using social stories that provide an insight into the next place of learning (Briody and McGarry 2005). In a Danish case study, Broström (2003) outlined the importance of child-ready schools whereby schools work closely with the 'feeder' preschools to develop curriculum continuity to meet the child's needs. Through meetings between pre-school and school staff in which the pre-school provide photographs, drawings, favourite stories and so on, teachers gain an insight into the interests of individual children and can plan transition activities accordingly. There is also recognition that children's dispositions towards school are generally associated with making friends. Margetts (2002) found that children who started at school with a friend in the same class had 'higher levels of social skills and academic competence and less problem behaviours than other children' (p. 112). This highlights the need for teachers to prioritise opportunities and processes for friend-making, thereby engendering children's emotional well-being and confidence in approaching new challenges.

Furthermore, there has been a recent growth in research drawing attention to the need for practitioners and teachers to take account of the psychological aspects of transition from the perspectives of parents and families, in strong recognition within the educational community and in policy statements that family engagement with schools facilitates educational success. Work from Scotland (Dunlop 2005), Germany (Griebel and Niesel 2000, 2002) and Denmark (Broström 2003), for example, focuses on the parental experience as parents anticipate, and then experience, their child's transition from the stage prior to school into school settings, part of which involves a change of identity within each family. Co-construction of the transition, readiness to be a schoolchild and becoming parents of a schoolchild require effective communication and participation by parents and teacher, enabling families to make sense of school with its often 'institutionalised' ways, bewildering new vocabulary and unfamiliar culture (Fabian 2002).

In some European countries, where the systems of education across the preprimary to primary divide have been thought through and 'joined up', and teaching and learning methodologies are applied appropriately and consistently, the question of a starting age at school almost becomes an irrelevance. However, in those countries where the approaches to early years teaching and learning are not 'joined up', and perhaps a more traditional or 'formal' teaching approach is imposed upon young children, there is evidence that this abrupt transition experience can be highly damaging. It is also clear that for some specific groups of children, such an early and abrupt transition leads to them being particularly disadvantaged. We return to this issue in the final section of the chapter.

Accompanying the lack of evidence of any clear advantage for children's development as learners of an earlier start to formal schooling, and concerns regarding the negative educational consequences discussed above, there is a wealth of evidence of the consequential dangers of this approach from developmental psychology. This evidence essentially addresses two key developmental processes, which

relate to the negative emotional and motivational consequences of requiring young children to learn in ways for which they are not yet equipped, and the positive benefits of learning through play.

A range of studies have pointed to the generally disturbing consequences of early and inappropriate formal instruction. In the USA, the longitudinal results of the High/Scope Perry Pre-School project (Schweinhart et al. 2005), for example, revealed disturbing long-term effects of early direct instruction upon individuals' social and psychological frames of mind. Although direct instruction methods of teaching seemed to bring some children initial advantages in terms of their early reading and numeracy competencies, the High/Scope children who had been in 'child-initiated' learning environments showed significantly more positive results over the long term. By the age of 23 years, children who had attended pre-schools where direct instruction prevailed were eight times more likely to need treatment for psychological or emotional disturbances and three times more likely to be arrested for committing a crime than those who went to play-based pre-schools. As Schweinhart et al. conclude, it seems that social problems arise when policy and curriculum directives fail to recognise that early education should be about the whole child; direct instruction does not cause social problems, but it seems that depriving children of the opportunity to develop socially is the unintended side effect.

Several researchers (e.g. Blaustein 2005) have highlighted the risks to developmental growth which occur through implementing early childhood programmes based on a directed academic curriculum, often replacing essential hands-on learning activities with skill-based performance and rote-learning tasks. It is argued (Blaustein 2005, p. 3) that in emphasising rote-learning tasks within an early years classroom, a child is conditioned to concentrate on a very specific skill and use 'lower' parts of the brain such as the limbic system, and the insufficiently developed cerebral cortex, to learn that skill. During this type of activity, it is argued, the child is forced to use parts of the brain that are immature, and although the child may be able to practise and acquire the skill, experts believe that the normal growth and development of the brain may be distorted by such practice (Healy 2004, p. 64) since the child will continue to use the lower part of the brain trained to perform the task even when the frontal cortex becomes more developed and suited to the task. Other research (e.g. Polizzi et al. 2007) suggests that the less mature central nervous system of younger children has a particular effect in terms of self-regulation of attention, emotion and other functions. This has implications for their ability to adapt to school life, for example, remaining seated for extended periods. There is also evidence to suggest that 4-year-old children are likely to be much less mature than 5-year-olds in terms of fine motor control, which is manifested in poorer writing ability (Sykes et al. 2009).

Other researchers highlight suggestions that an early introduction to a formal curriculum may have a negative impact on children's self-esteem and motivation to learn (e.g. Sharp 2002), and a report by Sykes et al. (2009) cites developmental psychology studies indicating that children as young as 4 or 5 may not be ready for

formal education particularly with regard to their 'social and emotional readiness'. Many children aged 4 years may not be ready or 'skilled' to face many aspects of starting school, including:

Being separated from carers each day for long periods of time and having to get to know 'strangers'
Being placed in unfamiliar surroundings with different equipment and resources
Having to develop new strategies and learn new skills within new routines
Finding out who can be trusted and liked and how to behave in a different 'hierarchy'

Within early years provision that is not attuned to the 'natural', informal and experiential ways in which young children learn, it is often the case that teachers believe that it is their role to make sure that children do things correctly, to convey to the children that they should do as they are told and to use controls in an attempt to make sure that they do. Such controlling contexts, often arising when teaching methodologies do not match the young children's learning capabilities, tend to pressure children to think, act or feel in particular ways. The teacher may resort to coercive strategies such as the promise of rewards or threat of sanctions and overtly controlling language (e.g. the use of 'you have to' and 'you must'). Such strategies place children under pressure to engage in the learning by inducing externally controlled regulation. However, children may also easily place themselves under stress to engage in a particular activity through a social pressure induced by the teacher in the child.

The second strand of evidence in relation to the dangers of the 'earlier is better' model concerns the loss, through an earlier start to formal schooling, of important play-based learning experiences. There are several strands of evidence which all point towards the importance of play in young children's emotional well-being and intellectual development and the value of an extended period of playful learning before the start of formal schooling. These arise from anthropological, psychological, neuroscientific and educational studies.

As regards the development of emotional well-being, Gray (2011) has documented the decline in free play opportunities for children in recent decades and the associated worrying increase in stress and mental health problems among children in the USA, including increases in anxiety, depression, suicide, feelings of helplessness and narcissism. He contends that:

> Play functions as the major means by which children (1) develop intrinsic interests and competencies; (2) learn how to make decisions, solve problems, exert self-control, and follow rules; (3) learn to regulate their emotions; (4) make friends and learn to get along with others as equals; and (5) experience joy. Through all of these effects, play promotes mental health. (p. 443)

Other work has identified specific links between lack of playfulness and identified behavioural problems or disabilities. In a series of neuroscientific studies, for example, Panksepp (2007) has demonstrated that ADHD is associated with frontal lobe deficits and can be ameliorated by access to social (particularly

rough-and-tumble) play. He argues that the increasing incidence of ADHD may be a consequence of 'the diminishing availability of opportunities for pre-school children to engage in natural self-generated social play (2007, p. 57).

In a classic paper entitled the 'Nature and uses of immaturity', Jerome Bruner (1972) argued that the relative immaturity of the human brain at birth, and the long period of biological and psychological immaturity that comprises human childhood, was an adaptation which evolved in early human social groups that enabled humans to become powerful learners and problem-solvers, through the mechanism of play. His evolutionary analysis of the importance of play in human development has subsequently been supported by extensive anthropological studies of hunter-gatherer societies (Gray 2009) and other work in evolutionary psychology (Smith 2006). Neuroscientific studies have supported this view of play as a central mechanism in learning. Pellis and Pellis (2009), for example, have reviewed many studies showing that playful activity leads to synaptic growth, particularly in the frontal cortex – the part of the brain responsible for all the uniquely human higher mental functions. A range of experimental psychology studies have consistently demonstrated the superior learning and motivation arising from playful as opposed to instructional approaches to learning in children (Sylva et al. 1976; Pellegrini and Gustafson 2005; Whitebread and Jameson 2010).

Within educational research, a longitudinal study by Marcon (2002) demonstrated that, by the end of their sixth year in school, children whose pre-school model had been academically directed achieved significantly lower marks in comparison to children who had attended child-initiated, play-based pre-school programmes. Marcon (2002) comments that 'their long-term progress may be slowed by overly academic pre-school experiences that introduce formalized learning experiences too early for most children's developmental status' (p. 12). Moreover, she comments 'Children with academically-directed pre-school experiences may have missed out on the more integrative experiences of peers in other pre-school models' (p. 13).

Individual differences in playfulness are associated with measures of cognitive development (Tamis-LeMonda and Bornstein 1989) and of emotional well-being (Berk et al. 2006), and work in developmental psychology is beginning to identify the two crucial processes which underpin this relationship. First, pretence play involves children in increasingly sophisticated processes of symbolic representation, which are fundamental to language, literacy, numeracy, artistic expression, visual media and the many other ways in which humans represent meaning. In symbolic play, each of these semiotic systems are themselves also the object of playful activity. Christie and Roskos (2006), for example, have reviewed evidence that a playful approach to language learning, as opposed to formal instruction, offers the most powerful support for the early development of phonological and literacy skills. The positive outcomes for vocabulary growth of a play-based curriculum, as opposed to a more teacher-led instructional programme, in grades 1–4 of Dutch primary schools, have also been recorded by van Oers and Duijkers (2013).

Second, through all kinds of physical, constructional and social play, children develop their skills of intellectual and emotional 'self-regulation', i.e. they learn to be aware of and control their own physical, mental and behavioural activity (Whitebread et al. 2005, 2007; Whitebread 2010). In a series of comprehensive studies of educational factors impacting on learning, these abilities have been shown to be significantly stronger predictors of academic achievement and emotional well-being than any other developing abilities, including general intelligence (Veenman and Spaans 2005), and educational interventions supporting children's self-regulation have clearly emerged as the most effective in supporting children's learning (Wang et al. 1990; Hattie 2009). In a major longitudinal study in the USA, McClelland et al. (2013) showed that a key element of self-regulation, attention span or persistence, in 4-year-olds significantly predicted maths and reading achievement at age 21 and the odds of completing college by age 25. The majority of this relationship was direct and was not significantly mediated by maths or reading skills at age 7. This is a clearly significant indication that an early emphasis on the teaching of literacy and numeracy is likely to be far less effective than a focus on supporting children to become self-regulating learners during their early childhood education.

A growing number of empirical educational studies suggest that early play experiences enhance young children's self-regulation and that self-regulation is related to academic achievement (Ponitz et al. 2009). Children who attend pre-schools based predominantly upon models emphasising play rather than academic outcomes have been found to achieve higher scores on measures of self-regulation (Hyson et al. 2007). A number of randomised controlled trials have shown that the Tools of the Mind play-based curriculum developed in the USA by Bodrova and Leong (2001), when effectively implemented, results in individual children's executive functions being enhanced and overall classroom quality being improved as a result of this enhanced self-regulation by the participating children (Barnett et al. 2008) [for more information about 'Tools of the Mind', see chapter on this programme in the section on Innovative and Longstanding Programmes, this volume].

15.5 Specific Groups of Children Disadvantaged by the 'Earlier Is Better' Educational Approach

A particular and arguably tragic consequence of the 'earlier is better' approach to early childhood education is that the consequent practices and arrangements we have discussed significantly disadvantage particular groups of children. And the irony is that these are often precisely the groups whose needs are cited as justification for the earlier introduction of formal instruction.

15.6 Disadvantage Due to Birth Date

There is significant evidence internationally to indicate that the youngest children in their year group at school tend to perform at a lower level than their older classmates, particularly in reading, writing and mathematics (e.g. Sharp et al. 2009). The research suggests that this 'birthdate effect' is most pronounced during pre-school and primary school and that the effect gradually and continually decreases throughout post-primary school. Nonetheless, it is thought to remain significant at later testing levels in secondary school and possibly during higher education. In a major review by Sykes et al. (2009), it is suggested that summer-born children may be an unacknowledged cohort facing disadvantage upon entry into school, in that they are both young (possibly just having had their fourth birthday in some countries) and the youngest in their class when they start school. They may be disadvantaged by being young because they may not have reached the level of cognitive competence required to tackle a curriculum designed for older children and, moreover, they may also experience other types of social and emotional difficulties when beginning education in an increasingly formal environment employing traditional teaching methodologies.

Research by the Institute of Fiscal Studies (Crawford et al. 2007) into attainment in English primary schools at Key Stage 1 (i.e. at the end of Primary Year 2) found that only 53% of the youngest in the year group (August-born girls) reached the expected level, compared to 80% of the oldest in the year group (September-born girls). At Key Stage 2 (i.e. at the end of Primary Year 6), the gap in attainment had narrowed, but remained significant, with 63% of August-born girls reaching the expected level compared to 76% of their counterparts born in September. It has been suggested that the age-related disadvantages of young-for-year children can lead to lower self-esteem, which may in turn have further impacts on behaviour and achievement (Sharp et al. 2009). For example, younger children may compare themselves with older classmates, leading to feelings of inadequacy, whereas older, more mature pupils may receive more positive feedback and assume a 'leadership position'.

The evidence also suggests that a disproportionately high percentage of relatively young children in the school year are referred for special educational needs, and many of them appear to be misdiagnosed. Concerns about 'teacher expectancy effects' have been raised (Sykes et al. 2009), where children are possibly being unfairly viewed as 'falling behind' and insufficient allowances for their level of attainment being made. These concerns have been expressed, in particular relating to summer-born children in England who do not achieve the writing goals by Year 1 and, on average, perform at a lower level than older children in their year group. As revealed in the English EYFS Profile scores for 2009, for example (DfE 2010), writing goals or 'standards' were generally more challenging than other goals, especially for boys, with 62% able to hold a pencil and use it to write letters by the end of the EYFS, compared to 79% of girls. A key hypothesis for this effect relates to the relative age of children, with the gap between the youngest and oldest pupils in

a class being almost a year in many cases. There is evidence to suggest that 'birth date' effects may be the result of lower levels of maturity in the physical, cognitive, social and emotional domains in the summer-born children, relative to those who are as much as a year older at the start of school (Sykes et al. 2009).

A particularly informative study in this area is that of Bedard and Dhuey (2006), who made comparisons across the educational systems of up to 19 OECD countries on performances on the TIMSS study (Trends in International Mathematics and Science Study), finding robust relative age effects for maths and science in the majority of the countries examined, except in the cases of children in Finland and Denmark, where no significant relative age effects were found at eighth grade (children aged 13). One possible explanation for this absence, Bedard and Dhuey suggest, is that children do not begin compulsory education until age 7 in Finland, and 6 in Denmark, where the early primary classes do not focus on a formal curriculum but employ play as a teaching methodology.

The evidence from developmental psychological research reviewed above would certainly support this hypothesis, as it also suggests that children's abilities to learn through direct instructional approaches, typical of formal schooling, are not clearly secured until around the age of 7 years. During the 3- to 7-year-old period, the rapid development of children's executive functioning (working memory, inhibitory control and control of their attention) (Garon et al. 2008) and 'Theory of Mind' (Klein 1998) support their crucially significant transition from being dependent on the guidance of adults, or 'other-regulated', to achieving independent cognitive control, or 'self-regulation'. In a number of recent publications, as we have reviewed, Whitebread (2012, 2013, 2014) has provided comprehensive reviews of research indicating the fundamental significance of early self-regulation for long-term educational achievement and emotional well-being and the role of informal adult-child interactions and playful learning experiences in supporting its early development. This evidence clearly supports the view that children are best supported to become confident and powerful learners by the provision of informal, play-based educational experiences up to the age of 7. At that point, they are then equipped, irrespective of the month of their birth, to be able to benefit from formal schooling.

15.7 Children from Economically and Socially Disadvantaged Backgrounds

Healthy child development may be supported by a variety of factors during the early years, or, conversely, the desired outcomes for a child may be compromised whether temporarily or on a more long-lasting basis. Such factors include, for example, the nature of early relationships with parents and other caregivers, the extent of cognitive stimulation and the access to adequate nutrition, health care and other resources such as a safe home and a safe and well-resourced neighbourhood environment (Shonkoff and Phillips 2000). The empirical evidence from a wide range of studies

indicates that children brought up in conditions of economic and social disadvantage do relatively poorly in relation to their physical, behavioural and cognitive development and do significantly less well in school than their more affluent peers. While poverty of itself does not cause children to have difficulties in their schooling conditions of unemployment, ill health, homelessness and illiteracy all reveal negative effects upon the well-being of families and the experiences of individual children.

This situation, and the response of governments and state education systems to it, is made increasingly critical given the currently rising levels of poverty in many European countries. A recent report by the United Nations Children's Fund (Handa and Natali 2014) revealed that 2.6 million children have sunk below the poverty line in the world's most affluent countries since the financial crisis first broke in 2008, bringing the total number of children in the developed world living in poverty to an estimated 76.5 million. Some of the most extreme increases have occurred in Europe. In Ireland, Croatia, Latvia, Greece and Iceland, for example, the numbers of children living in poverty rose since 2008 by over 50%.

As regards physical development, studies have shown that children born to economically disadvantaged mothers are more likely to be born early and have low birth weight (Bradshaw 2002; Duncan and Brooks-Gunn 2000; Treasury 2004), to experience a higher rate of accidents and accidental death (Bradshaw 2001, 2002; London Child Poverty Commission 2008), and are at greater risk of physical abuse or neglect from family members (Huston 2001). They are also less likely to be breastfed (Prince et al. 2006; Nelson 2000). The association identified between poverty and postnatal depression may, in turn, affect a new mother's relationship with her child and her ability to manage the demands of her new role as a mother (Mayhew and Bradshaw 2005) which, in turn, can impact on the quality of attachment between mother and child. A large number of studies connect growing up in a low-income household to poor mental health (Bradshaw 2001; DCSF 2007; Fabian Society 2005; Treasury 2008). One such study by Meltzer et al. (2000) highlights that children living in low-income households are nearly three times as likely to suffer mental health problems than their more affluent peers.

Children from low-income households are more likely to experience problems with nutrition, being more likely to follow an inadequate, 'unhealthy' (high sugar, high sodium) diet (Bamfield 2007; Bradshaw 2002; Gill and Sharma 2004; Nelson 2000). This can have a negative influence on the mental well-being of children (Gill and Sharma 2004) and over the longer term can lead to childhood obesity (Bradshaw 2002). Indeed the relationship between poverty and childhood obesity is well established; children living in disadvantaged neighbourhoods being significantly more likely to be obese than peers living in more affluent areas. Poverty is also associated with anaemia and diabetes (Duncan and Brooks-Gunn 2000) and neurodevelopmental problems (Singer 2003). Poor dental health is also more prevalent among children in low-income groups (Bradshaw 2002; Hirsch 2006). The 2003 Survey of Children's Dental Health showed that 'children in deprived schools have about 50% more tooth decay than children in non-deprived schools' (Hirsch 2006, p. 14).

Being born into certain geographical areas where high percentages of the population have income below the poverty line limits healthy development for many children. Such neighbourhoods offer limited opportunities in terms of resources important for early child development, including health facilities, parks and playgrounds (Leventhal and Brooks-Gunn 2000). Children living in disadvantaged communities are more likely to be exposed to environmental dangers, such as crime, violence and drug misuse which have been shown to have a negative effect upon child development (Aber et al. 1997). The dearth of safe places for children to play outdoors in turn promotes inactivity and contributes to problems of physical unfitness and obesity, as well as reducing the opportunity to build peer relationships. Overcrowding and living in a noisy environment have been associated with poor sleep patterns and homelessness, frequent moves and inadequate housing also contribute to poor mental health (Treasury 2004). Part of the reason accidents are higher among children from low-income families is that they are more likely to live in poor housing and have fewer safe places to play (Treasury 2004, 2008). However, accidents are not the only negative outcome associated with deprived housing and overcrowding. Inadequate housing is also connected to a multitude of childhood health problems including reduced resistance to respiratory infection, asthma (Bamfield 2007), hypothermia (HM Treasury 2004, 2008), developmental delay, skin conditions, immune system problems, depression and stress (Dowling et al. 2003; Spencer 2000). Children living in poverty are more likely to be absent from school due to illness, to be hospitalised, to suffer long-term illness and to spend more days ill in bed (Dowling et al. 2003).

Extensive research evidence has linked economic disadvantage to parental stress and inadequate responsiveness in parent-child interactions. In general, living on a low income can impair appropriate family functioning and can affect the quality of parent-child relationships (Russell et al. 2008), and the associations between poverty, mental health and stress, as well as the impact of these problems on parenting, have been the focus of many studies (e.g. see Duncan and Brooks-Gunn 2000; Russell et al. 2008).

Economic disadvantage is linked to a range of poor cognitive outcomes in young children, including adequate language acquisition. Research focussing upon family background has consistently shown it to be the most influential predictor of later academic success (Ansalone 2001). Differences in educational outcomes by income and background are apparent from a young age; these inequalities start early and increase (Treasury 2008). Analyses such as those of the 1970 cohort study, for example, and other longitudinal studies, reveal the negative picture that poorer children systematically achieve lower cognitive and behavioural outcomes at both age 3 and age 5 (Waldfogel and Washbrook 2008; Hobcraft and Kiernan 2010).

Early oral language development has been a strong focus of research in this area, particularly as it has been shown to be a strong predictor of cognitive development and school achievement. A number of studies have directly linked early language development with later emerging aspects of self-regulation. An American study of 120 toddlers in New England by Vallotton and Ayoub (2011), for example, showed strong relationships between vocabulary size at 14, 24 and 36 months and a range of

observed self-regulatory behaviours (e.g. the ability to maintain attention on tasks; the ability to adapt to changes in tasks and procedures) which, as we have reviewed above, are known to be strong predictors of academic achievement.

Bercow (2008, p. 13) produced a report on speech and language development in the UK and found that up to 50% of children from some socio-economically disadvantaged populations within the UK had less developed speech, language and communication skills than their peers on entry to mainstream education. One clear explanation of this is provided by Wolf (2008), who showed that by the age of 5 a middle class child in England had heard 32 million words more than a child from a deprived background. The potential negative impact of this difference upon later academic achievement is clear, given the widely accepted link between language abilities in the early years and later literacy development; Snow and Paez (2004) conclude that:

> Literacy development and school success are most effectively promoted during the preschool period by the development of oral language skills. (p. 14)

Policymakers' alarm about the growing achievement gap between children of low-income and higher-income families is understandable. However, the policymakers' assumption, to compensate those children who are not being given opportunities to learn at home through direct and sequential teaching in schools, although apparently logical, is, as we have argued, most likely to be counter-productive, further disadvantaging children from low-income families.

By contrast, the evidence from a range of intervention studies suggests that a much more productive approach is to support families living in poverty in ways which enable them to provide enhanced early experiences for the children within them. Recent evidence from the UK and internationally has shown that it is not poverty or its associated factors per se that adversely affect children's early development – indeed, it has become clear that it is not who parents 'are' but what they do to support their child that makes the difference to their development. There is now a clear consensus among professionals and academics that specific factors in the home environment – positive parenting, home learning environment and parents' attitude towards education – are highly significant (e.g. Gregg and Goodman 2010). Moreover, the evidence shows that what children of higher-income families actually receive at home is authentic, relational, spontaneous, conversational and play-based interaction (Pungello et al. 2009; Tudge et al. 2000), none of which is crucially dependent on family income.

Recent international research has also shown that early intervention contributes significantly to putting children from low-income families on the route to development and achievement in life through support for the whole family. Evidence from programmes such as the Family Nurse Partnership (Barnes et al. 2010), Parent-Child Interaction Therapy (Zisser and Eyberg 2010) and Community Mothers (McGuire-Schwartz 2007) has revealed that if appropriately related to health, employment and social services, early childhood services can effectively enhance parenting skills, community building and maternal employment and thereby decrease family poverty (Lynch 2004; Brooks-Gunn 2003).

Detailed analyses from the UK 'Effective Provision of Pre-School Education' (EPPE) study (Sylva et al. 2004) confirm that parental involvement in activities, such as reading to children, visiting places of interest, drawing and painting together, singing songs and nursery rhymes together, playing with letters and numbers and so on, influence young children's social and behavioural achievements over the pre-school period and are significant in accounting for differences in their social and behavioural development at the start of primary school. Duncan and Brooks-Gunn (2000) also showed that educational development and attainment are mediated by the home environment and the level of parental interest in their child's education, the latter factor proving to be a powerful influence on children's later educational success (Blanden 2006). Factors such as levels of parental interest in the current and future direction of a child's education have been seen to increase the child's chances of moving out of poverty as an adult by 25 percentage points (Blanden 2006). Evaluations of family literacy projects in the UK endorse this finding – revealing that children make greater progress when their parents participate in learning activities (e.g. Sabates 2008).

Research findings such as those of the 'Impact of the Home Learning Environment' (Melhuish 2010) suggest that policies which encourage these kinds of active parenting strategies for all SES groups can help to promote children's cognitive development and educational achievement. The evaluation of the Early Head Start programme, which provided combinations of home visits and centre-based interventions for the families of 0- to 3-year-olds, found that the intervention increased both the quantity and the quality of parental interactions with children, as well as children's social and cognitive development (Love et al. 2005). The extensive review by Barnes and Freude-Lagevardi (2003) concluded that to be optimal, interventions should include both parent and child together and the focus should be on improving interactions. These conclusions – which parenting behaviours are learnable and that enhanced skills can bring about improved developmental outcomes – have been echoed in the findings of Nutbrown et al. (2005) in relation to literacy during the pre-school period. There is, then, a considerable body of research on effective early interventions, and this provides clear guidelines of positive approaches to increasing the educational and life chances of children from disadvantaged backgrounds.

15.8 Conclusions

This chapter has examined the influence of schools upon children as their 'schooling' commences within a range of countries in Western Europe. This entailed an examination of the main characteristics of the structural and organisational frameworks set by the various statutory and advisory bodies in key Western European countries in relation to early childhood education and care provision for children in the pre-primary phase and up until the age of 7 years. A diverse range of national social and educational policies were briefly examined.

It is clear that the diversity of European children's home environments and early experiences, the age at which children may access early childhood education and care (ECEC) programmes, the length of time they attend and the nature of the provision are subject to significant cross national differences. Such diversity has a huge impact upon the development of the child, shaping their transition to 'school', a period during which children are required to respond to changes in identity, roles and relationships as they become a 'pupil', with new or different expectations placed on them (Griebel and Niesel 2000) and learning the social rules and values associated with being in an 'institution'.

Some of the ways in which transition to school is handled in countries within Western Europe have been compared, including the particular consequences for specific cohorts of children who are relatively disadvantaged due to their age or their family circumstances. We also saw that some governments in Western Europe have prescribed direct educational interventions into the early years phase of schooling, often with the aim of raising primary school test results. In some countries the age of entry to schooling has either been lowered by legislation or has effectively been lowered through various cultural, policy and economic pressures on schools and on families. In these countries, an 'earlier the better' model to starting school has been implemented, based on the belief that an earlier start to formal instruction and an emphasis upon cognitive processes will enhance children's development as learners. Hence in some countries, schools' curriculum and testing systems are focussed on a prescribed and narrow range of cognitive skills.

We have also reviewed the now very considerable body of evidence which suggests that this current direction of travel of school starting age policies across Europe, and internationally, is misguided and likely to be counter-productive. By contrast, the provision of extended informal, play-based educational and care provision for young children, up to the age of 7 years, has been shown to be a much more effective approach to enhancing the educational and life chances of all children, irrespective of their month of birth or the socio-economic status of their families. Approaches which also manage the transition of young children from their home environments to school by working sensitively with parents, and engaging parents actively in their young children's entry into the world of education, have also been shown to be the most effective in narrowing the gap of academic and life opportunities between the children of affluent parents and those born into conditions of poverty.

Many governments aspire to provide evidence-based approaches to educational provision, rightly believing that this will enhance the basic skills, creativity, problem-solving abilities and social and emotional competencies of their citizens. Given the known, crucial and powerful impact of early educational experiences on children's development as learners and on their emotional and social development, and thus their potential contributions to their communities and countries, the evidence presented in this chapter comprises a body of research to which national governments across Europe and the world would do well to attend.

Chapter 16
Early Childhood Education with Disadvantaged Children: Actions for Success

Marta Soler-Gallart and Ainhoa Flecha

Abstract Early childhood education has become central to achieve the objectives planned for Europe in 2020. Pre-primary education is considered to be a crucial factor to break the closed circle of intergenerational transmission of poverty and, to this respect, the investment with highest returns. In this chapter we present the concept of successful educational action (SEA) and its particular application to the case of early childhood education and care in diverse European countries and among vulnerable populations. Drawing from studies funded under the Framework Programme for Research of the European Commission, we analyze some of the SEAs such as dialogic literary gatherings, interactive groups, or family education. These SEAs have provided evidence of being effective on improving outcomes in cognitive, social, and emotional development of children; in this chapter we will focus on children from ethnic minorities and immigrant background and how SEAs in ECEC contribute to prevent their future disadvantage.

Keywords Educational exclusion • Disadvantage children • Successful educational actions

16.1 Taking the Challenge to Reverse Educational Exclusion

When the 25-year results on Head Start began coming in, they showed that it had made an astonishing difference, even if it hadn't produced a mass miracle. Kids who had been through the program were, by comparison to "controls," more likely to stay longer and do better in school, to get and to hold jobs longer, to stay out of jail,

to commit fewer crimes, and the rest. Only a "starting" subculture counteracts the subsequent social alienation of poor, black, and Hispanic kids and their families. Even under the least favorable conditions – psychologically, fiscally, and educationally – we still succeed in giving some children a sense of their own possibilities. We do it by getting them (and sometimes their parents) to collaborate in an enabling community. Perhaps successful school cultures should be considered as "countercultures" that serve to raise the consciousness and metacognition of their participants as well as enhancing their self-esteem (Bruner 1996, 74–78).

Jerome Bruner, considered to be the major architect of the Head Start program in the United States in the 1960s, has always studied and argued that children, from a very young age, are able to learn complex ideas and skills as long as instruction is organized appropriately, opposing Piagetian, constructivist approaches. His theory of scaffolding or providing the instructional formats to facilitate learning is close to Vygotsky's dual perspective of learning, in which social interaction is prior to the development of higher-order processes. These research perspectives and theories have made possible the development of high-quality early childhood education and care (hereinafter ECEC), in which early learning interactions are crucial for children's learning process throughout their lives. Particularly, children at risk of social exclusion need further efforts in the creation of stimulating educational environments, rich in learning interactions, from the very first years of their lives. High-quality ECEC, based on these premises, has therefore been an influence on future educational developments which guarantee equal opportunities of successful learning and subsequent social inclusion for all children.

In a context of crisis and deep concern about increasing social inequalities, the European Commission's recommendations on ECEC stress the need to provide effective early educational responses, as a way for lessening the risk of early school leaving and increasing the equity of educational outcomes. As reflected in the communication on early childhood education and care, providing all our children with the best start for the world of tomorrow (European Commission 2011a), the future benefits of effective early education are specially prominent for disadvantaged children and families, including those from migrant, minority, and low-income backgrounds. It is important to notice that the share of early school leavers among people with a migrant background was 29 %, reaching 32 % among people from less developed countries (Eurostat/Labour Force Survey 2011). One of the most alarming situations in this regard is experienced by Roma children, who have suffered different discriminations in schools and the subsequent social and educational inequalities (Gómez and Vargas 2003). As shown by a recent survey developed by the European Union Agency for Fundamental Rights (2012), in nine of the 11 EU Member States surveyed, there is a considerable gap between Roma and non-Roma children's attendance at preschool and kindergarten, as well as strong differences in later school performance.

High-quality ECEC is crucial in addressing these pressing challenges and particularly to "break the cycle of low achievement and disengagement that often leads to school drop-out and so to the transmission of poverty from one generation to the next" (European Commission 2011a, p. 15). It is stressed that universal access to

quality ECEC may be far more beneficial than educational initiatives exclusively targeted to disadvantaged children. The Council of the European Union also concludes that ECEC has a high impact in preventing this cycle of disadvantage by promoting enhanced cognitive, linguistic, social, and emotional development for all the children (Council of the European Union 2011). Alongside, the European flagship initiative platform against poverty and social exclusion highlights the role of pre-primary education, which is considered "the most crucial factor for breaking the vicious circle of intergenerational transmission of poverty, and it is the investment with the highest returns" (European Commission 2010: 8). Research on effective education suggests that the early childhood period gives the best opportunity for investment in human capital, particularly for the most disadvantaged families, leading to higher economic returns: social efficiency is enhanced, and inequality is reduced (Cunha et al. 2005; Heckman 2011). Therefore education, including ECEC, becomes essential for social inclusion in particular and economic improvements and growth in broader terms.

International research in the field supports the benefits of effective ECEC programs for disadvantaged children and families (Sordé 2010; Cullen et al. 2009; Stein et al. 2013). Evidence collected regarding the outcomes of different consolidated ECEC programs in the United States confirms this statement. For instance, the Harlem Children's Zone is oriented to improve the situation of marginalized families through early educational intervention. This project started in 1970 and mainly serves African-American families in Harlem, New York, who are at high risk of social exclusion and face difficulties associated with drug dealing and consumption. Their specific program addressing early childhood is called Baby College, and its main objective is to provide support to families with children aged 0–3 years in order to guarantee a happy and healthy start for their children. Families involved in this program receive different free services like breakfast, lunch, and child care which includes brain development programs and parent-child bonding. Similarly, the US federal program Early Head Start mentioned above gives attention to disadvantaged pregnant mothers and children up to age 3. A recent evaluation shows that participation in the program had a positive impact on different potential outcomes, such as child cognitive skills, child aggressive behavior, maternal supportiveness, and home language and learning environment (Vogel et al. 2013). For instance, regarding children's cognitive skills in ages 2 and 3, the evaluation evidences higher scores in the Bayley mental developmental index (BMDI), which assesses relevant abilities such as sensory acuities, memory learning and problem solving, verbal communication, mental mapping, complex language, and mathematical concept formation. Children attending the program reached good results, especially in vocabulary.

Evidences in relation to the middle- and long-term benefits of ECEC are consistent with the results of different international assessment studies. For instance, in OECD's PISA 2009, 15-year-old children from OECD countries who attended some years of pre-primary education scored 54 points higher in reading assessment than children who did not attend preschool (OECD 2010). Furthermore, PIRLS 2011 (Mullins et al. 2012) and PIRLS 2006 (Mullis et al. 2007) show that children

who have acquired early literacy skills during childhood achieve better reading outcomes at fourth grade.

The benefits of ECEC depend on the implementation of ECEC actions and programs which are contributing to children's cognitive, social, and emotional development, especially with those groups at risk of poverty or social exclusion. In this regard, recent scientific findings stress the importance that these programs and actions respond to quality standards which are positively related to child outcomes (Sylva et al. 2011). Drawing from the NICHD Study of Early Child Care in the United States and other similar large-scale studies in the United Kingdom and Ireland, Belsky (2009) points out that the quality of care (in terms of caregiver attentiveness, warmth, and stimulation) has a strong impact on children's development, especially on their cognitive-linguistic development. Sylva et al. (2011) discuss the relevance of stimulation, interactions, and environment in relation to ECEC quality. These three elements are interrelated and, when having specific qualities such as effective adult guidance of children's participation in cultural activities (Radziszewska and Rogoff 1991), may have a decisive influence on the children's cognitive and linguistic development (Vygotsky 1978; Bruner 1983; Fram et al. 2012) as well as on emotional development (Whitebread 2012). For example, dialogues which promote the inquiry of knowledge about diversity of problems and facts can enrich the learning environment of children, increasing stimulation opportunities and maximizing the developmental power of interactions among children and adults (Mercer 2000; Wells 2007). Additionally, research has also highlighted early family and community involvement in educational activities, which has a critical impact on children's developmental outcomes, especially among the most disadvantaged groups (Díez et al. 2011).

European ECEC interventions need to consider these elements in order to implement measures that will achieve successful outcomes among children, leading them to achieve a cognitive, social, and emotional development in the early years and a solid basis for further more effective learning. In this chapter we present "successful educational actions" (hereinafter, SEAs) (6th FP INCLUD-ED project, 2006–2011), identified and recognized by the international scientific community in the field of early childhood education, and how they have been implemented with children from vulnerable groups.

16.2 Successful Educational Actions in ECEC

Scientific research has already studied actions that are successful in improving children's development in different aspects: cognitive and instrumental as well as social and emotional. The INCLUD-ED project is the only research in the social sciences and humanities selected by the European Commission among the ten success stories in the Framework Program for Research for its added value. Its research results have been included in communications and resolutions by the European Commission, the

Council of Europe, and the European Parliament.[1] INCLUD-ED analyzed SEAs that led to better academic performance and improved living together at different levels of education (including pre-primary, primary, and secondary education) with a particular focus on five socially vulnerable groups: women, youth, migrants, cultural groups such as Roma, and people with disabilities. Thus, these five people groups were selected by the project as being considered in at-risk situation for facing socioeconomic disadvantages and, therefore, vulnerable to fall in poverty or social exclusion. SEAs were identified after a study of successful schools in Europe, schools that, while serving at-risk children, achieved very good outcomes in terms of high academic performance in comparison to schools with similar characteristics. Consequently, SEAs are not best practices, but rather practices that obtain the best results in all the contexts in which they are implemented. Therefore, the concept of "successful educational action" involves evidence of improvements and transferability to diverse contexts. Although SEAs have been identified at all levels of education, for the purpose of this chapter, however, we will focus on the findings which relate only to preschool and early childhood education.

INCLUD-ED conducted case studies of schools in four European countries (Finland, Spain, Cyprus, and Latvia) which responded to three important criteria: (a) they had demonstrated a contribution to educational improvements in relation to their context, (b) they served families and children from low socioeconomic status and minority background, and (c) they had strong community involvement. As a result of these analyses, three SEAs were identified: interactive groups, dialogic literary gatherings, and family education. This chapter mainly reports data from the Spanish case studies, in which the authors were involved. Children, family and community members, teachers, administrative staff, and policy makers from four different schools also participated in this research, which was carried out by using a communicative methodological approach (Gómez et al. 2011).

16.3 The Power of Interactions for Learning and Development: Interactive Groups

Interactions are key in cognitive and noncognitive development. According to Vygotsky (1978), human learning and development are results of our social nature. Consistently, he considers the "level of potential development as determined through problem solving under adult guidance, or in collaboration with more capable peers" (p. 86). Along these lines, the more interactions – and more diverse – children have with peers and adults, the more learning opportunities emerge. There is a wide body of literature with evidences about the effects of peer cooperation (Johnson and

[1] For instance, INCLUD-ED results have been considered in several European official documents on tackling early school leaving (Official Journal of the European Union 2010; European Commission 2011b; European Parliament 2009, 2011).

Johnson 1981; Stainback and Stainback 1996; Slavin 1991) and family interaction (Goodall and Vorhaus 2011).

This dialogic conception of learning is the basis of the "interactive groups" approach (Valls and Kyriakides 2013). Interactive groups involve organizing the classroom into small heterogeneous groups with more adult guidance. In one class there can be four groups and four adult volunteers, one in each group, who are usually family and community members, in addition to the class teacher. In each group there is a different activity (curricular tasks, such as pre-reading and writing, mathematics, logic, etc.) which lasts between 15 and 20 min. The children rotate in their groups, in order to fulfill all the activities, using language and dialogue to help each other to solve the required activities. The role of the adult volunteers is to guide, encourage, and monitor these dialogues. This dynamics multiplies interactions between peers, and between them and the volunteers, and therefore increases learning opportunities (Elboj and Niemelä 2010).

The analysis of the implementation of interactive groups in pre-primary schools shows that, at this education level, special emphasis is placed on language acquisition and emerging literacy. Teachers perceived improvements in the learning process within the interactive groups, as shown in the following quote:

> If they're doing language, for instance, learning how some letters sound …there are games with different levels of difficulty, and since some of them are more advanced than others, it's good for them all, because they can help each other (…) Then if I'm there helping someone and another one comes along, I say "Toni, come and see if we're doing this right", so they help each other.

Interactions among diverse children are a main component for instrumental learning in interactive groups (De Mello 2012). Teachers observe that peer interactions strengthen learning in a different way, and they associate these interactions with increased motivation and enthusiasm for learning:

> Sometimes I think it's better than when I just explain something to them, they get it differently (…) and they get more enthusiastic about reading.(…)

The interaction with volunteers makes a notable difference, which is crucial for the interactive groups' dynamics. Each volunteer takes care of a reduced group of children and promotes supportive interaction among them, ensuring that everyone participates in the activity and helps other classmates. In addition, this organization of learning increases the work completed in the same amount of time, as well as the quality of learning, and the children' enthusiasm:

> Three volunteers came along, and in one hour, we did so much! They had to do three different activities (…) it was done in such a calm and peaceful way, and the children finished the whole thing… everything went well, since there were three people (…) I remember that day as being amazing, (…)a great pleasure, (…) I think the children really enjoyed it, which is very positive, right? (…).Without any doubt, a lot more work can be done, work which is of higher, not less quality!

Community members' involvement is perceived by the teacher as being particularly beneficial for children of minority backgrounds, who relate to volunteers with different religions, cultures, or social backgrounds, increasing their motivation for

learning. The teacher in this quote highlights the fact that the participation of immigrant family members makes learning of "high, not less quality," emphasizing with her words and tone the stereotype about immigrant families of poor neighborhoods in the field of education. In fact, children feel a close connection with adults who are part of their everyday life and share their same culture and language, which supports a close connection between school and family life (Sordé 2010). Thus, adult participation also enhances the knowledge of other cultures and the consolidation of a positive coexistence.

The positive results of interactive groups on children's cognitive and social development are also related to the emphasis of interactive groups on the instrumental dimension of learning, that is, on the abilities that children will be required to use for future success at school. This implies intensive work on the emerging literacy and mathematics, among other competences. As shown in the following quote, teachers confirm clear advancements through interactive groups' work:

> It makes me so happy to see the children learning, to be honest, and I compliment their learning a lot I tell them they are the cleverest children in the world (…) and if someone comes to our classroom they would say to that person "we are the cleverest in the world" (…) And I can clearly see the results this year …in the area of language, in mathematics, in everything! it is a delightful class! and I am convinced they have future.

These efforts addressed to accelerate instrumental learning are contributing to improve all children's outcomes, including those from disadvantaged backgrounds. Rather than lowering down learning expectations and standards (due to the many difficulties they face in other contexts), learning interactions are multiplied in the school context, thus accelerating learning instead of compensating deficits. In one of the case studies analyzed, where most of the families were Roma, the progress in reading skills in the preschool years radically changed. While many children finished sixth grade (11–12 years old) and could barely read, after some years implementing interactive groups since the first year of preschool (3-year-olds), they all were able to read at 5 (Díez et al. 2013). The father of Fatima, a 3-year-old Moroccan girl from another school analyzed in our research, emphasizes the progress of his daughter in language learning:

> Thank God, yes, yes she has! It's not just because she's my daughter, but to tell you the truth her level is quite…she's very smart, she's involved in everything and I can see that she's doing well every day (…) She speaks Spanish better than I do.

INCLUD-ED has analyzed how interactive groups in childhood education not only accelerate the cognitive development but also the social and emotional development at the same time. Children learn to help each other as a usual attitude in their daily lives at ages in which individualism is common. Drawing from a sociocultural perspective, Cooper and Whitebread (2007) argue that in order to progress from egocentrism, from normal young children's behavior to a level of social competence, it is vital to promote the interactions of mutual help from early childhood education, on the basis of the social and psychological foundations of learning. In interactive groups children learn through mutual help, within a learning environment that promotes solidarity among children. Importantly, this solidarity supports

all children's improvements, not only those who have more learning of behavioral difficulties. Through interactions, all children are exposed to questions and are often asked to explain better or justify their words, thus strengthening meaning making. When a group of children from one of our case studies were asked what they liked about the interactive groups, they answered "that we become better friends." Through increased solidarity through the learning process, these friendships strengthen children's emotional development.

16.4 Dialogic Reading Development Through Literary Gatherings

Different authors have argued that high-quality early childhood education can prepare children from early ages for the development of literacy competences, especially the children from underprivileged contexts (Bruner 1983; Whitebread 2012). Emerging literacy approaches have been useful to recognize the development of literacy skills from children's natural interactions with the print sources available in the written world around them, without purposeful instruction. But the dialogic gatherings go beyond these approaches by introducing complex book reading through dialogue with adult guidance. The books read in these gatherings are from the universal classical literature such as *Odyssey The Adventures of Odysseus*, or the struggles of the *Pied Piper of Hamelin*, or the tales from *One Thousand and One Nights*, or Phileas Fogg's difficulties in going *Around the World in Eighty Days*. Therefore, children from vulnerable groups are brought in contact with high culture and its socially recognized literature, which usually has been withdrawn from them and their families belonging to low socioeconomic backgrounds. In her book *Other People's Children*, Lisa Delpit (1995) argued that unstructured teaching strategies such as open classrooms or those focused on process rather than product have put minority children from low socioeconomic background at greater disadvantage. Children from nonacademic families tend to have less school-based vocabulary and emergent literacy skills. For this reason, she argued for teachers to decode middle-class culture for poor kids and to close the achievement gap through skills building. According to this analysis, the dialogic gatherings provide learning opportunities for children to access classic universal culture, including literature, music, and art, especially in disadvantaged contexts when this type of cultural resources do not exist within the families and are often not promoted by schools (Serrano et al. 2010). The dialogic gatherings are a successful educational action which consists in reading little by little a classic work of literature and opening up, periodically, a dialogue from there. All children must reference a page (or passage) from the book in order to speak and share with others his or her thoughts. This dialogue is egalitarian (Flecha 2000) as what matters are the arguments each of them share. Interpretation is thus dialogic and collective rather than individually constructed. Dialogic literary gatherings can be also applied with children's parents and other adult relatives. In

this case, men and women without a higher education background, who had never read a book before, start reading, discussing, and enjoying books by writers such as Dostoevsky, García Lorca, Cervantes, or Joyce. They not only become readers and improve their own literacy skills but also transform their home interactions in the way described in the next section.

The implementation of dialogic literary gatherings in ECEC has shown successful results in terms of language and literacy development as well as building common bonds and shared values. One of the schools analyzed and implemented the gathering at preschool level. Once a week a group of learners meet in the library, and the teacher reads one chapter of Odyssey (an adapted version). After that, helped by a puppet, she tells through argumentation one part of the book she liked and why. The children then follow this model and share their ideas by raising their hands in order to speak and listening to each other. The different parts of the story are reread in the process. Children become strongly engaged in the story and the whole dialogic reading process. At the age of 5, when they were able to read, they read Jules Verne's book by themselves, weekly, in little bits, choosing paragraphs to share with their classmates and writing on their notebooks a few words and ideas to be shared. Because they had participated in these gatherings since they were 3, as soon as they could read, they rapidly got engaged in the dialogic reading process. Additionally, those who could not read well got support from the teacher, family, or volunteers, thus increasing their motivation and interactions to accelerate the reading process.

In only few years, some relevant results were reached. First, children's vocabulary increased and enriched. Children not only learned new words but they also used the language more appropriately. Second, kids were more interested in reading. Third, children learned about referents of recognized high culture, such as who Ulysses and Penelope were, what Ithaca means, how powerful Zeus is, why Mr. Fogg arrived 1 day earlier to London, etc. These referents from the universal literature will help them in their future learning developments. A teacher explained:

> Because each week I read a story, the children want to know what will happen in the next story, and as they also learn words that they didn't know before… for instance they did not know what "mayor" meant, now they know who the mayor is, that he rules in the city; they learn a lot…

The gatherings have also helped to develop sociability strategies, awareness about the other, and mutual respect, especially through taking turns to speak. A learner explains this in his own words:

> We must raise hands, when we finish the story we line up, listen to other boys and girls, and listen to friends, when they talk, and also when the teacher talks. We have to be quiet and listen

Emergence of solidarity values have been also identified, for instance, when a child spontaneously decided to help his friend in reading the paragraph, by pointing the text with his finger. In the same group, a girl who does not actively participate in the gatherings started to talk when the topic of mourning appeared and was discussed. Her uncle died a short time before and decided to raise her hand and share her feelings about him with peers and teacher. The group listened and supported her

feelings. Through these dialogues a new meaning about school and learning emerges, more closely connected to their lives.

Similar to dialogic literary gatherings, some schools bring these children closer to classical music or art. They listen to Beethoven's symphonies or watch Mozart's The Magic Flute and then talk about images and feelings through dialogue, thus proving that they are highly motivated to engage with classic works and are able to make very complex and creative interpretations.

16.5 Family Education and the Transformation of Interactions in Children's Environments

Family education, especially programs focused on family literacy, have been highlighted as important to transform the learning context of children, especially those from disadvantaged backgrounds (Paratore et al. 1999; Ponzetti and Dullin 1997; Tett 2001). Children do not only learn in child care centers or in schools; they also learn at home, in the street, and in diverse informal environments. Hence, children's development increases when there is continuity between what is developed in the center and at home in terms of socialization, daily routines, and learning. A teacher was explaining this relationship:

> It is beneficial to the children to see that their family is somehow so close to them in this way, I mean, so close to their school… and the way in which they [mothers] are involved in school and they also come here to learn, and they also learn at home. I mean, I see that it is very good, because it establishes more links between the family and pupils and us.

Different sets of statistical data have shown a correlation between parents' educational level and their children's school performance and attainment. The INCLUD-ED research however demonstrates that particular successful actions in family education contribute to transform present cultural capital and counter this tendency. Many ECEC initiatives have included family education and literacy actions that have already had a great effect on young children. In fact, according to Eurydice (2009), the most effective ECEC intervention programs provide both intensive early education and strong involvement in family training. Family-related ECEC actions can therefore contribute to break the aforementioned vicious circle of poverty.

There is a wide body of research about cultural activities in which parents participate and make a difference in the interactions they have with their children at home both in supporting school learning activities (i.e., homework) and also in transforming home interactions (i.e., reading the newspaper or listening to classical music, going to museums, or watching less TV). These studies have found that the effects from these interactions occur from very early age, as they are related to the presence of books and other print sources, home literacy practices, increase of cultural inputs, and among other relevant interactions (Hidalgo et al. 2002; Rogoff et al. 2001).

INCLUD-ED also found strong relationships between family education programs and children's improvements in successful schools in deprived areas. This research project found different types of family participation in schools, but not all the types were related to the improvement of children's outcomes (Díez et al. 2011). Among all the different types – informative, consultative, decisive, and educative – participation in learning activities had the strongest impact. Family education is most successful when it is designed in response to demand from families rather than a top-down program based on professional's beliefs. For instance, language classes for families were introduced in schools in response to demand from migrant families who identified the need to be more proficient in the language of the host country to understand what their children were taught in school and thus be able to help them to continue their learning at home more effectively. In the same way, IT courses and English as a foreign language were strongly demanded with the goal of helping their children in the near future, but also to improve their own education and possibilities in society as adults. In one of the schools studied, in a deprived area, teachers had organized a series of talks about health, habits, and emotional education. Few parents attended and participation dropped rapidly. After talking to families they started an IT course, with a volunteer from the neighborhood, and family participation increased. Time flexibility was also an important feature in family education: while some mothers needed their children to be taken care of while they were in the courses, others asked for evening classes so they would be able to attend after work.

One of the most successful actions in family education is the dialogic literary gathering that, as we mentioned above, can also be conducted with adults. In one of the schools studied, with a high percentage of Moroccan immigrant families and children, the mother of one of these families started to participate in these dialogic gatherings. She was low literate and could not speak Spanish and did not dare to leave her home because she could not communicate. With the support of another mother from the school, she decided to go to literacy classes and soon started in the gathering. They were reading Lorca's *Blood Wedding*, and she made strong efforts to read the agreed pages (with help of relatives and her older daughter). In this family, the mother was reading Lorca, the father Kafka's *The Metamorphosis*, and the children Homer's *The Odyssey*. Home interactions were clearly transformed, through new literacy practices and new conversations and new educational expectations, which influenced the child developmental environment. The dialogic literary gatherings dismantle reproductionist analyses, which assume that educational level and cultural interests and taste are strongly connected, according to the theory of habitus (Bourdieu 1984). Pierre Bourdieu argued that people with low educational level cannot appreciate classic universal culture and did not consider the possible transformation of cultural capital. The participation of mothers and fathers from cultural minority groups and low socioeconomic background, however, breaks down the closed circle of cultural inequality, tearing down elitist walls.

Family education programs have been demonstrated to contribute to different benefits. First, new opportunities are created in which children and their relatives can share learning spaces both at school and at home. These spaces transform home

discourses and promote later learning interactions within families closer to those in schools. This contributes not only to improve children's cognitive development but also their motivation while enriching family relations. Besides, providing that there are more women attending these family education programs, their active participation also influences the transformation of gender roles at home, which in turn influences children's imitation models and emotional development from an early age. The Moroccan mother mentioned above, who was reading *Blood Wedding* at the school and at home, was now perceived as both a mother and an intellectual by her daughters, and home conversations were also transformed in this way.

Second, besides transforming the relationship between family members, the relationship between families and the school is also transformed. New bonds are created between the school and the home context, transforming the overall learning context of the children. Children are aware of that connection and the shared purpose of both the school and their family toward improving their learning and their future achievements.

Third, and in relation to an increased perception of greater connection between the family and the school, research identifies improved attitudes and behavior developing among the children. This is what a teacher explained regarding a migrant child whose mother attended family literacy classes:

> In the case of Joshua, whose mother came to literacy classes the first year and the second year, and I think his sister did as well, and I can tell this really motivated him… seeing his mother coming one day a week… and actually the fact that she was also learning, and that she was starting to read letters, and that she was so happy… well he started to behave better, to like the school more. It made a whole difference, I think…

Fourth, participation in family education increases their participation in other activities in the school, as a result of being more familiarized with the school context and the diverse activities taking place there. INCLUD-ED found that family participation in children's learning activities – such as volunteering in the interactive groups – also contributes to improving children's cognitive and social development. Teachers explain how family education leads to further involvement in the school:

> Well it gets them closer and to understand how things work at school. This means that more parents start to collaborate then… once they see how it works, because they are already here through the course, parents become more involved, because sometimes people do not collaborate because they are unaware of how things work and they just don't dare or don't know.

Finally, both teachers and family members asserted that parents' expectations of their children's academic possibilities increased as a result of participating in family education activities. A Moroccan father of a 2-year-old girl explained:

> She will talk, and I'm sure she'll learn to speak great Spanish… I'm convinced she won't have any problems in her group, quite the opposite! There are children and babies who are at home and all day speaking Arabic, and later they speak very good Spanish. She'll be great and we'll help her, if we can.

Teachers, based on their experience, see the evolution of these expectations as a result of parental involvement in family education activities:

> Since we have the family education classes, we see that parents open up their expectations for their children a little bit, perhaps they used to say that well, maybe secondary school was as far as their children could go and now they talk about university.

16.6 Conclusions

The case studies conducted in INCLUD-ED on early childhood education have demonstrated that when SEAs are implemented, children's cognitive, social, and emotional development improves. Through interactive groups or dialogic literary gatherings, all children, but especially the ones belonging to low socioeconomic families, immigrants, and minority groups, accelerate their learning processes from very early years, achieving a solid ground for successful future learning and achievements. Through family education, learning interactions are transformed within the family, thus enriching the context in which children are raised, as well as the expectations toward them and their educational futures. Therefore, in the schools studied, potential inequalities among children's school performance were diminished from the early years in which children at risk are particularly supported through the transformation of the learning culture. This way the SEAs contribute to prevent school failure, early school leaving, and transmission of poverty from one generation to the other.

INCLUD-ED studied schools in low socioeconomic environments that served children from vulnerable groups which were successful in preventing early school leaving and promoting social inclusion. Success was measured by the standard evaluations already existing at national or regional level in each European country (at primary school level). In this way, the research was able to identify the educational actions that when implemented led to successful outcomes in different cultural and historical contexts across the European region. The commonalities across the different schools analyzed pointed to the implementation of educational actions that both multiplied and enriched learning interactions from a very early age, thus transforming these children's developmental context. The qualitative evidences presented in this chapter show how both teachers and parents perceived the SEAs as crucial for their children's cognitive and emotional development and a key for building and strengthening their potential capacities.

The SEAs and their impact on children's development were analyzed from a sociocultural perspective, focusing on the effects of social interaction on children's capacities. Previous research and theories of learning have emphasized the relevance of the introduction of scaffolding strategies, early stimulation, adult participative guidance, or interactions with high culture, among others, to set the basis and accelerate the learning process (Bruner 1983; Radziszewska and Rogoff 1991; Vygotsky 1978; Flecha 2000). Following this perspective, in the SEAs presented in this chapter, instrumental learning is a priority. So, far from reducing the level of

cognitive demand, in contexts of socioeconomic disadvantage, they emphasize the instrumental dimension and the inclusion of high culture, to help them acquire the skills that are necessary to succeed at later educational stages.

Interactive groups multiply cognitive interactions at the classroom level, by involving more adult guidance and enhancing peer interactions. They also impact on emotional development through the promotion of mutual help and dialogic-based child autonomy. Dialogic literary gatherings open up a window of high culture through introducing children to classic literature while building up literacy skills through dialogic interactions. Family education transforms the context of learning interactions and improves continuity between educational school and home discourses and practices. With these SEAs children can learn and develop successfully by sharing learning spaces and experiences with their peers and diverse adults (teachers and also family and community members). They accelerate children's development of cognitive skills, especially language and literacy (use of letters and rare words, motivation for reading and writing, oral expression), produce gains in autonomy (increased independence through dialogue), and enhance social skills (respect toward their peers, listening to them, and integrate solidarity as a key value). Finally, they escape any assumption about early childhood education that reduces educational expectations of children from vulnerable groups and lowers the challenges of their curriculum (Sektan et al. 2010). The future educational success and later social inclusion of these children depend widely on providing them and their families with SEAs from the very beginning of their educational experiences.

Chapter 17
Professional Development in a Competent System: An Emergent Culture of Professionalization

Florence Pirard, Pascale Camus, and Jean-Marie Barbier

Abstract Workforce quality and professionalization in the field of early childhood education are widely considered to be a powerful lever in improving the quality of childcare services. This emphasis demonstrates the necessity of increasing the level of practitioner qualification across the sector and to revise both professional profiles and training curriculum in response to the complex demands of professional activity. Nowadays workspace is recognized as a potential learning space where individual, institutional, inter-institutional and political actions interact. This approach to professionalization is grounded in a theoretical and systemic view that recognizes different levels of responsibility in the development of professional and quality services. This paper presents different educational cultures observed today in the variety of training and professional actions in the Western World. It shows that changes in early childhood education could be understood as a signifier of the emergence of a new culture of professionalization where actions, actors, and environment undergo change simultaneously.

Keywords Professionalization • Competent system • Action cultures • Accompaniment • Quality

17.1 Introduction

Improving the quality of childcare services remains a challenge in many European countries. Recent special issues (Johansson 2010; Rayna and Laevers 2011; Oberhuemer et al. 2012) show the extent of this challenge (especially in childcare services for children under three) in most countries where the structure of service supply is divided.

Among many different factors, workforce quality in early childhood education and care plays a major role, as underlined by the existence of current thematic working groups within the Organisation for Economic Cooperation and Development (OECD) and Eurydice Network institutions and by the increase of professional and scientific publications on this topic. However, the qualifications and professional training opportunities available often fail to reach agreed professional standards, and work conditions still need to be improved in most Western countries (OECD 2001, 2006, 2012; EACEA 2009; Penn 2009; Bennett 2010).

A review of relevant literature related to developments in Western Europe reveals the results of some innovations and reforms made to training systems, such as the "educateurs jeunes enfants" in France, early years professional in the UK, pedagogue or social pedagogue in Sweden or Denmark, pedagogista in Italy (Peeters 2008; Rayna 2010; Urban et al. 2011) and the pedagogical coach in Flanders (Peeters and Vandenbroeck 2010), and some new directions in curriculum for children under 3 years and its effects on teaching, training and accompaniment (Rayna et al. 2009; Pirard 2011). The challenge here consists not only in improving the standard of qualifications (European Commission Childcare Network 1996; Children in Europe 2008; UNICEF 2008; Leseman 2009) but also in creating a more holistic approach that takes into account the social, economic and psycho-educational dimensions of childcare services (Vandenbroeck et al. 2009b).

More widely, the research literature underlines the importance of professionalization in the sector. Unlike professionalism, a "slippery concept that alters over time and in different contexts" (Osgood 2011, 109), professionalization is a scientific concept that can cover and integrate different dimensions including individual professional development, professionalization of activity and professionalization within organizations (Wittorski 2008). For the purposes of this chapter, professionalization is defined as the "intention of an on-going transformation of competences, in relation to an on-going transformation of activities" (Barbier 2011, 106).

According to the theoretical perspective recently developed by the "International Network Observatory about professionalization in relational professions and human interaction"1, professionalization sets up new questions by referring to "professions that relate to the other, where organizational and institutional prescriptions are always subordinated to the complexity of the work" (Maubant and Piot 2011, 8). Professionalization requires a broad, multilevel and contextualized perspective that has been chosen by the European CoRe study (Urban et al. 2012). In a 15-country survey involving 7 case studies, this research proposes systemic approaches to professionalization. In the study, the concept of a "competent system" refers to

"reciprocal relationships between individuals, teams, institutions and wider political context" that contribute to develop a quality process in a country. "The professionalization process needs to be considered as a social practice and as a result of complex interactions between social evolution (…), policy measures (…) and new scientific insights (…) interacting in turn with researchers or pedagogic counsellors, staff members and users (parents as well as children)" (Peeters and Vandenbroek 2011, 72). Competent systems in the early childhood sector are linked to initial training, continuing professional development and all other forms of professional development of early years educators, their staff managers or leaders and their coordinators (in countries where this function exists).

International reports and research interpret the concept of professionalization variously and highlight the risks incurred by the standardization of training systems (Cameron and Moss 2007; Peeters 2008; Bennett 2010; Oberhuemer et al. 2010; Urban et al. 2012). Urban and Dalli (2008, 132) define professionalization "as a discourse as much as a phenomenon: as something that is constantly under reconstruction". These approaches to professionalization are considered to be plural, evolutionary and contextualized despite common major changes in educational modes of thought.

Grounded in adult training research theory, the concept of "action cultures" (Barbier 2005, 2009) developed in the French literature could be defined as constructed meanings sustained and shared by actors. This concept allows to apprehend some observable regularities in considering educational approaches and their evolution over time. The most recent of action cultures is called "professionalization culture". It is characterized by specific ways of considering educational work, the various actors involved and their connection with the environment and considered as distinct from those observed in the more traditional teaching or training worlds. This new action culture will be the central issue of this chapter, approached through the analysis of activity in ECEC field and the conditions of their transformation. The concept could also be useful on the international research ground as it connects theoretical questions on professionalization that have emerged in ECEC field to adult training research theory.

17.2 Professionalization of Childcare Activity

Professional activity in childcare services for children under three is now widely viewed as a complex field grounded on values, pluridisciplinary knowledge and evolutionary knowledge. All this must be interpreted in the context of a sector with a predominantly female workforce, where women have traditionally been viewed as "naturally" gifted to do the job, limiting the development of any real emphasis on training and competencies for many years (Miller and Cable 2008; Roberts-Holmes and Brownhill 2011; Bosse-Platière et al. 2011).

Various new trends can be observed in literature regarding current professional development practice and theory in the early childhood field (Urban and Dalli 2008; Lazzari 2011; Urban et al. 2012; Van Laere et al. 2012). These new

trends at times question, or even contradict, some existing professional guidelines and practice. Professional activity has until now been viewed as predefined and certain (i.e. the attitude that professionals know the right and best thing to do), but major changes in society have reinforced the complexity of a body of work that is partly uncertain and invisible. "Indeed, studies that shed light on on-going activities from the standpoint of the actors and that look at competences and resources of the professionals in action are scarce. As this work is seldom unfolded to make understandable what it includes, it keeps on being considered as relational and feminine in nature and therefore bound to relational competencies" (Ulmann 2013, 194).

The complexity of activity and the tensions inherent within this are present in different spheres of early childhood education: work with children, work with families and teamwork are all approached differently in terms of initial training requirements in Europe (Urban et al. 2012) and involve on-going debate in the field.

Working with children is the central dimension in formal competence profiles in Europe (Urban et al. 2012), even if there is no consensus on what is meant by "working with children". This lack of mutually defined terminology can lead to considerable variations in the field and potentially create tensions. For example, practitioners developing a profile of "a rich child" (Rinaldi 2006) while acting as that child's advocate could recognize that the care of babies requires particular competencies, accompanied by an appropriate social environment. At the same time, such practitioners could overprotect the same child because of his/her perceived psychological immaturity. These tensions are particularly vivid in inclusive experiences of children with special needs, increasingly promoted across several European countries. Professionals who take care of these children in what they consider the most adequate way could try to tackle deficiencies through a compensatory approach; others could adopt another perspective by considering the characteristics of the child as an expression of diversity within the group.

Working with parents and communities appears to be a less central dimension in formal competence profiles despite research theory emphasizing its importance. Tackling this issue can also involve questioning existing modes of practice (Urban et al. 2012). In examining differentiation between professional and parental positions (Bosse-Platière et al. 2011), there is an argument to be made that, for some, this distinction can cause a hierarchical relationship to develop (Vandenbroeck 2009; Brougère 2010), in turn, potentially altering the view of parental competencies in a European context characterized by policies on parenting support (Vandenbroeck and Humblet 2007; Sellenet 2007; Crepaldi et al. 2013). Indeed, new approaches foster the standing of individual or collective collaboration and explicitly involve parents in childcare services (Sharmahd 2009; Musatti and Rayna 2011; Kammenou and Agnostopoulos 2011; Lazzari 2012). In such a vision of coeducation, parents and professionals share their educational expectancies and goals. Nonetheless, practitioners have to deal with contradictions in childcare ser-

vices without imposing their own ideas and professional knowledge (Vandenbroeck et al. 2009a). Relationships between practitioners and parents can be viewed as a tool for professionalization (Peeters and Vandenbroek 2011), interpretable in several ways.

Team working is often overlooked in formal competence profiles, even if activity in the field requires the development of this competence (Urban et al. 2012). The recent introduction of a social and educational project elaborated by early childhood professional teams is evidence of this trend in European countries. This project was realized on the basis of both daily professional observations and knowledge of a variety of disciplines and also on the sharing of perspectives with other professionals, children, families and communities on physical, psychological, cognitive, emotional and social development areas in their childcare services. In some countries, professionals have to develop a coherent work team following official guidelines (curriculum, "charte", "réferentiel", etc.). Often viewed as a shared process of professionalization, the elaboration and use of such projects could also be subjected to standardization (Pirard 2011, 2013). In some cases, educational practice formalized in a childcare service project could be viewed as the application of predefined knowledge, of a specific model (e.g. Loczy, Montessori, Steiner, etc.) or of other official guidelines without a contextualized approach. In other cases, an educational project could be used to normalize parents rather than to listen and respond to their hopes and expectations regarding the daily life of their children in childcare services (Camus et al. 2012).

All these changes produce a picture of a "critically reflective emotional professional" (Osgood 2011) and childcare activity embedded in several relationships that involve developing relationships with children, their families, colleagues and the wider community (Dalhberg and Moss 2005; Peeters 2008; Urban 2008). However, the professional position also traditionally holds an expectation to maintain professional distance. As concluded by Dalli (2008, 173), "the structural components of a professionalised sector were beginning to bed down but raised questions about the criteria of 'autonomy' and 'optimal distance' between teacher and child in a sector where staff are expected to work collaboratively with parents, the community and other professionals (…)".

Consequently, professionalization of the sector appears to be a multidimensional process where tensions could exist between quality, equity and diversity goals (Rayna 2010): taking care of and educating children (children with specific needs included) in a holistic perspective, both involving and supporting parents in daily life with their children and working collaboratively in the context of both an interdisciplinary team and wider networks. Professionalization requires that practitioners develop practice linked to knowledge and values but also to "make meaning" about these tensions (Dalhberg and Moss 2005).

In response to this complexity in the sphere of childcare activity, new profiles should be defined with a more open approach where the "democratic professional" model increasingly prevails over that of the "technical expert". "It envisages a

worker who is a co-constructor of knowledge, a critical thinker, and a reflective and democratic practitioner, rather than one who is viewed primarily as a technician trained to apply pre-determined processes in a way that conforms to established norms (…)" (Cameron and Moss 2007, 143). These new profiles should concern not only early years educators but also their managers (Miller and Cable 2011) and coordinators (Baudelot and Rayna 2000; Baudelot et al. 2002; Musatti and Mayer 2003). These actors could be considered reflective practitioners (Schön 1983) who document, analyse, evaluate and regulate their practice together, without referring to predefined outcomes (Rinaldi 2006; EADAP 2011; Picchio et al. 2012). They can also co-construct a contextualized meaning of general guidance in the countries where a curriculum or official guidelines have been published (Pirard 2011). These practitioners are co-constructers of new strategic knowledge (Van Der Maren 1996), as well as other educational practice, "in situ", while taking into account the varying perspectives of other professionals, children, families and communities (Oberhuemer 2005; Pirard 2011).

17.3 Accompaniment in a Competent System

At a point in time when the complexity of childcare activity is widely recognized, new functions of "accompaniment" have emerged (Pirard and Barbier 2012). For the purposes of this chapter, it is necessary to outline a clear definition of the term "accompaniment" ("accompagnement" in French), a concept often referred to in French literature (Paul 2005; Pirard 2007; Beauvais 2008; Pirard and Barbier 2012). "Accompaniment" can be associated either with "coaching", "mentoring" or "counselling" functions on both an individual and collective level. Accompaniment considers the process in which the activity of one person (the accompanier, "accompagnateur" in French) is combined with the activity of the other (the accompanied practitioner(s)) in order to simultaneously develop the professional competencies of both practitioners, while also transforming their daily educational practice. Accompaniment is a continuous, interactive and open process that can produce unforeseen outcomes. The accompanier is seen as a resource person and the accompanied practitioner as an actor working in the same activity domain but generally without the same specialization as a teacher and trainer.

Current literature gives some examples citing the development of accompaniment functions in European childcare services. In some regions (i.e. Emilia-Romagna) and cities of Italy (i.e. Pistoïa, San Miniato), pedagogical coordinators combine professional accompaniment, administration and coordination functions "in improving children's educational experiences in early childhood services [that] has been acknowledged by regional legislation since 1979" (Lazzari 2012, 561). Lazzari shows that high levels of professionalization are embedded in coherent public policies, themselves, built on consultations with key stakeholders (particularly at a local level), thanks to the work of pedagogical coordinators, among others. In

Ghent (a city of the Flemish community of Belgium) pedagogical counsellors seek to initiate, sustain and guide "a mutual dialogue between the centres and encourage professionals' on-going reflection on their approach and beliefs [… They have] to assist the early childhood workers in "discovering what is possible" (Dalli 2008, 17) (Peeters and Vandenbroek 2011, 70). In other countries, new functions were created as advisors in education in the Wallonia-Brussels Federation in 2002; these practitioners aim to sustain professional development and socio-educational practice improvement (Pirard and Barbier 2012).

Accompaniment functions can be seen as a key factor in the professionalization of childcare activity when considered in the context of a "competent system" (Urban et al. 2012) that seeks to go beyond dominant discourses on lifelong learning, with their focus on individual professional development (Vandenbroeck et al. 2013). The competent system refers to the interactions between various levels of responsibility: individual (initial training, continuing professional development), institutional (time for teamwork and in-service training, accompaniment), inter-institutional (peer groups, training for staff managers or practitioners of new childcare services, professional networks, close collaborations between childcare services and research agencies) and finally political (curriculum, public funds and regulation governing continuing professional development and work conditions). In their daily practice, accompaniers carry out a major role in a competent system, along with other actors who share competencies at different levels inscribed in an adequate public policy.

17.4 Professionalization: A Culture of Education

Changes in childcare activity and the development of accompaniment have given rise to new challenges for research. These challenges provide some practical and theoretical prompts, useful in understanding the diversity of educational approaches. As suggested by Oberhuemer et al. (2010), this diversity can refer to "cultural scripts" (Rosenthal 2003) that permeate images of workers in childcare education and training. The three action cultures of education (culture of teaching, culture of training and culture of professionalization, see below) identified by Barbier (2005, 2009) as successively appearing in the world of Western education over the last few decades can be viewed as an "intelligibility" device helpful in understanding different approaches to professionalization in the field of early childhood education when viewed from a systemic perspective. They underline diverse representations of educational approaches, of practitioners, and of their relationships with the wider environment.

In the wider field of education and adult training, the action cultures of education and training correspond to the "culture de l'enseignement" ("culture of teaching"), the "culture de la formation ("culture of training") and the "culture de la professionalization" ("culture of professionalization").

In the teaching culture ("culture de l'enseignement"), knowledge is a central reference for educational work, based on the hypothesis that the learner's identity can be transformed through the appropriation of predefined knowledge. Education can be seen as producing a hierarchy between the person who holds, and is able to transmit, knowledge ("the teacher") and the ones needing to gain new knowledge ("the students"). The relationship between theory and practice is conceptualized as a process of application, and new knowledge or new subjects are seen as the primary drivers of change. Teaching culture – the most traditional cultural framework in the field of education and training – views educational action as a communication process, achieved through courses, didactical activities, educational programmes, e-learning, thematic seminars, etc.

In contrast, training culture ("culture de la formation"), developed in parallel to teaching culture (and sometimes in opposition to it), holds ability and skill as the central reference for educational work, based on the hypothesis of identity transformation through a new skills transfer process. Education can, in this way, be seen as specialized, producing a hierarchy between the person organizing specific learning situations and conceptualizing the "decontextualization-recontextualization" process ("the trainer") and those who have to acquire new skills and abilities ("the learners"), in order to apply them to other contexts and situations (e.g. for work). In this model, new practice is seen as the primary driver of change. Training culture views educational action as a space and a time to transform abilities and skills (the educational space and time), which can then be transferred to other contexts (both labour and social space/time). This culture can be found predominantly in training programmes focused on technical goals but also in general skills training promoting empathy, listening skills, etc.

In the 1990s, the dialectical relationship between these two educational cultures contributed to the emergence of a third culture: the culture of professionalization ("culture de la professionnalisation") which views the notion of competence as the central theme for educational work, based on the hypothesis that action and actors can be jointly and simultaneously transformed. Education is thus seen as developing competencies in context, in an evolutionary process of activity. This model emphasizes the importance of the person who "accompanies" the professional development of practitioners and the transformation of practice and the environment. The primary driver of change is a new management practice combining a number of previously disjoined actions. Professionalization culture involves viewing and organizing the wider context of service and product production as a context where individual and collective competencies are also developed. This culture is present in activities such as action research, mentoring and "accompaniment".

Existing research illustrates the way in which these three action cultures coexist in early childhood education and in care training action systems (Pirard 2007; Pirard and Barbier 2012), although many initiatives grounded in the culture of professionalization have developed more recently.

17.5 "Culture of Professionalization" in Early Childhood Education

As shown by the CORE research (Urban et al. 2012), competencies have become a central theme for early childhood educational work. Indeed, they can be viewed as a conceptual construct assigned to a person (an early years educator, a staff manager, a coordinator, etc.) or to a group (collective, team, network, etc.).

People who accompany professional and service quality development are, for the most part, neither trainers, teachers nor specialists (Pirard and Barbier 2012); rather they tend to be workers able to sustain a process of co-constructing and regulating daily practice on the basis of shared observation, discussion and argumentation. These practitioners increasingly refer to analysis of practice using various tools of professionalization such as writing (Cros et al. 2009) and videoscoping (EADAP 2011). Through their work, accompaniers are expected to develop actions aiming to jointly transform competencies (both their own and those of other practitioners) and daily educational practice, as well as improving conditions within a local dynamic (Baudelot and Rayna 2000; Baudelot et al. 2002; Musatti and Mayer 2003; Lazzari 2012; Pirard 2011). Their accompaniment is grounded in a global and systemic transformation process for key stakeholders (i.e. children, families, practitioners, elected post-holders, the local community), with associated transformation of actions (social and educational practice) and local environment.

17.6 Emergence of a Culture of Professionalization in Childcare Services: A Case Study

The following case study presents a cross-sectional analysis of responsibility levels in a competent system (Urban et al. 2012) and reveals the main characteristics of the culture of professionalization. This case study is not presented as a model in its own right but rather aims to shed light on the evolution of educational cultures and highlight trends in the emergence of a culture of professionalization. The case study was developed in a rural setting in the province of Luxembourg, situated in the Wallonia-Brussels Federation of Belgium. In this particular context, the qualifications and professional training opportunities available had failed to reach agreed professional standards (Pirard et al. 2012).

In this country, a curriculum for childcare services under 3 years ("Welcoming early years; taking up the challenge of quality") was published in 2002 (ONE 2002). This curriculum was produced via a participatory process and implemented by agents of the public institution in charge of authorizing, financing, evaluating and

accompanying childcare services (Office de la Naissance et de l'Enfance (ONE)). Implementation was developed for practitioners of childcare services through accompaniment processes, led by ONE coordinators and advisors in education (Pirard 2011). Trainers authorized and financed by ONE (working in line with a governmental guidance) also played a major role.

The new curriculum was published as a book and could be viewed as primarily belonging to the teaching culture, where knowledge and the role of specialists are viewed as paramount. The curriculum makes explicit a number of criteria to monitor during professional practice, forming a benchmark for childcare quality. These criteria are not presented as checklists but instead were formulated in an open way, allowing professionals to reflect on their practice and to co-construct contextualized meaning on the basis of these predefined criteria such as "freedom of movement" in everyday situations (activity, change of nappy, sleeping time, ect.), for instance.

The process of implementation and the effective use of the curriculum must also be analysed. More than 10 years on, the training culture can be observed in the field, where the curriculum has become a reference resource for subsidized trainers who have developed the organization of some specific learning spaces (generally based on childcare services) to cater for training needs for specific topics and new skills. The training process is viewed as a specialized space, where new skills and abilities can be acquired in a restricted time (generally 1–6 days), with the intention that this new knowledge is then applied to childcare services.

Professionalization culture can also be examined, thanks to participatory observation of a ONE process designed to implement the curriculum, conducted over a 10-year period in Luxembourg Province. From 2004 to 2013, an accompaniment process has been conceptualized, conducted and regulated both by ONE agents (coordinators and advisors in education) and their local partners and sometimes involving the intervention of specialists or advice to participate at further training sessions. This process combines accompaniment of each childcare service and the development of professional networks. The topics on which practitioners would like to be accompanied were first negotiated in project groups: freedom of movement (2004–2009), continuity of relationships in childcare services organized into defined age groups (2007–2010), managing mixed age groups (2007–2010) and relationships between professional and parents in childcare services (2011–2013). Meetings were organized every 1 or 2 months over several years, both within each service and between services coordinated by ONE agents. The aim was to develop, implement and adjust action projects that would improve service quality (freedom of movement, continuity and relationships with parents). Practitioners defined their goals and their action hypothesis to improve practice, experimented with some action in the field and then documented, analysed and evaluated the subsequent effects for children, families and themselves. This self-regulating participatory evaluation (Ballion et al. 1989), inspired by the work of "Centre de Recherche de l'Education Spécialisée et de l'Adaptation Scolaire" (CRESAS 1988, 2000; Hardy et al. 2011), allowed practitioners to adjust their actions and to understand the impact they were having. At regular, scheduled times in this process, the teams shared – through vid-

eos, posters and pictures – the results of their research/action with other professionals and with the families of service users at a local level.

The work performed in these different project groups is viewed as interdependent, creating opportunities to discuss the meaning of the curriculum criteria and to co-construct shared and contextualized meanings. They can generate a logic of framing ("référentialisation" – Figari 1994), that is, "a continual search for relevant markers (...) to explain and justify the design and evaluation of educational provision" (p. 48), which, not being content with results alone, continually raises new questions. This approach is grounded in local consultation with all stakeholders to jointly define and co-construct a quality service based on their own values, the analysis of their own experience and the knowledge they have collectively acquired (Pirard 2009, 2011).

Since the setup of these project groups in 2008, an inter-institutional change can be observed, primarily facilitated via the creation of a community of practice (Wenger 2005). Practitioners have proposed their own relevant topics and documented practice experience to share and reflect with other professionals. Professional experiences realized in one specific context have been analysed, with the help of accompaniers, through shared debate. The purpose is not to generalize or transfer practice but rather to explore new possibilities in different contexts in order to inspire other practitioners. The shared analysis of a singular experience can produce unforeseen learning and outcomes. For example, in 2008 a team presented a film of their project, showing babies autonomously exploring modelling clay on the floor, with tools, over an extended period of play; the children played quietly while the professionals carefully observed their exploration. Two years later, this experience inspired another team to experiment with a similar creative process in collaboration with a local artist, this time exploring painting. Over the next few years, other projects involving early years professionals and artists were realized, involving many different media and disciplines ranging from creative dancing to puppetry. In all these projects, practitioners documented the entire process of their experience through various media (i.e. photos, videos, etc.) in order to analyse the effects of practice and the conditions that make them possible and also to share the results with families, communities and other practitioners. The professional network has grown, joined by more and more practitioners in childcare and family day-care services, as well as teachers of initial training institutions, to learn together from this process of practice effect analysis.

The analysis of curriculum implementation in this case study shows characteristics of different educational action cultures coexisting in the same context. It additionally highlights several characteristics of an emergent culture of professionalization closely connected to accompaniment. Accompaniment is not monopolized by teachers, trainers or other specialists in education, although all these actors have a role to play in this process. Rather it is a shared function between actors whose combined action in the process has a global effect on training.

Accompaniers are, in practice, a variety of different workers rather than being characterized by one specific training role (e.g. ONE coordinators, educational advisors or other local partners). Together, they organize a variety of project groups

with the aim of transforming, collaboratively and in an interactive manner, both practice and practitioners. Working with local actors, they debate the predefined criteria of curriculum and contribute to the co-construction of shared, contextualized meanings through analysing the effects of their own practice. In this way, all these actors identify educational conditions to be taken into account when working with children, parents and other professionals. Accompaniers play a crucial role in project groups from the outset; their role broadens to help sustain a community of practice, of which they are themselves members. Although essential, accompaniers are not central figures in the community; instead they work to facilitate connections between other actors: between practitioners in a childcare team, between professional childcare teams, between practitioners, teachers and trainers, etc. They also facilitate external support, inviting specialists to provide essential knowledge to practitioners or to advise regarding participation in other specific training. In this case, knowledge and skills are considered an important resource, but not absolutely key, as specialist expertise can always be sought. Accompaniers can also collaborate with artists without either explicitly needing any educational competencies. None of these actors are specialist trainers, but their action with professionals embedded in an accompaniment system can meaningfully contribute to training and to transforming practice. This analysis shows that accompaniers sustain the development of individual and collective competences not only for the community members but also for themselves. This holistic process differs from a process rooted in the idea of knowledge transmitted through teaching or via the support of professional specialists in the field (teaching culture) and on skills acquired during training sessions (training culture).

Accompanied people are practitioners who play a central role in the identification of projects to be developed, their documentation and the analysis of practice on children, families and themselves, as well as their regulative evaluation. Through this process they can improve daily educational conditions, while simultaneously developing new individual and collective competencies for themselves and the community. They can therefore be viewed simultaneously as actors, learners, contributors and innovators of practice.

The manner in which accompaniers and accompanied people are viewed is contextualized in a framework where the borders between working and training have become blurred and where activity is consequently both "constructive" and "productive" (Rabardel and Pastré 2005). Relationships between workers may, therefore, evolve through the whole process; the hierarchical or vertical relationship inherent to all educational processes is coupled with the development of horizontal relationships in the professional network produced by accompaniment. This change can be observed particularly in the dynamic process of evaluation taking place between peers, transforming the traditionally vertical control system. It operates not only on the basis of an external control but also as an auto-evaluation led by workers' analysis of their practice and its effects (through documentation). Evaluation does not only lead to "the regularization" of practice according to the curriculum but also facilitates "the regulation" of practice based on shared, co-constructed

meanings (Vial 2001). This process opens up the possibility of different ways of acting and thinking, potentially leading to novel and unforeseen outcomes.

This work, involving a variety of actors, is driven by processes rooted in the principle of learning by doing, unfolding over time (e.g. through action training, project groups, action research, community of practice, etc.). The workspace, especially childcare services, can be viewed as a professional space where practitioners can collectively engage in problem solving. These practitioners are in essence starting to engage in primary research: working together to experiment with new practice, to document and analyse their effects and hence to co-construct both knowledge and action. In this way, the workspace intentionally transforms, becoming a new site for the active development of professional competencies.

This process requires an evolutionary view of workspace, learning space and environment. New developments that could not be anticipated at the beginning of a project can occur: these might include new topics, new key players, new actions and new networks that make a shared approach possible. The process addresses the paradoxes of accompaniment (Boutinet 2002), situated simultaneously in the evolutionary, the process itself, that which is unending, i.e. the trajectory and the transitory, having a beginning and an end, and not knowing where one is headed (the accompanied person can doubt his/her direction, having no certainty of finding his/her way, while simultaneously "knowing" that she/he is going somewhere) given the goals, procedures and the on-going accompaniment processes.

17.7 Conclusion

Professionalization is often addressed in literature with a view to improve practice and quality of services in the field of early childhood education. It implies different levels of responsibilities that interact and which require a systemic approach including initial training and continuing development of educators, leaders and coordinators, work conditions in childcare services and public policy. A firm understanding of professionalization requires a contextual approach that integrates different dimensions (actors, action and environment) in an evolutionary and longitudinal view.

For the purposes of this chapter, the authors have elected to frame their work in a practice-based research paradigm. To this end, they often propose the use of intelligibility tools without addressing underlying ways of thinking or acting. The three educational action cultures discussed in this chapter, and the case study presented above, do not provide any specific, practical requirements needed to increase professionalization in the sector. Rather, they are intended to support understanding of some important changes in the field of education and training and in shedding light on some consistencies in the various discourses about professionalization. More than a phenomenon or a discourse, "professionalization" can be viewed as a new action culture of education, alongside the teaching and training cultures observed more frequently in initial training systems and continuing professional development

actions. Professionalization emphasizes and clarifies various changes in practice: the importance of various aspects of practice according to competency development aims, the emergence of new professional functions as accompaniment, the bringing together of working space and training space, a new emphasis on different processes (documentation, analysis of practice, community of practice, action-training research, etc.) and less formal training methods included in the development of services and the transformation of staff roles, not always labelled as "training" or "teaching" actions. What characterizes a professionalization culture is the specific opening of new perspectives in order to understand different ways of transforming actors, actions and the learning/working environment in the context of a systemic approach.

The three action cultures of education can be viewed as supporting understanding of, rather than assessment of, training action systems with labelling risks. The challenge is to refrain from holding these cultures in contrast to one another and by doing so risk organizing them into a hierarchy. As the case study demonstrates, a culture of professionalization does not seek to replace the cultures of teaching and training; the three cultures can coexist in a new configuration. Action project groups and their accompaniment can be connected to teaching and the training of actors who conduct educational action in other contexts.

The three action cultures of education can be used to bring together traditionally separate frameworks, through studying the individual and collective levels holistically and by integrating questions about the development of competencies and services into the process of education design. This challenge is particularly relevant in countries where the structure of service supply is divided and where a lot of qualifications coexist without a common framework.

To conclude, these three educational action cultures could be viewed as a theoretical tool to discuss the notion of competent systems proposed by the European Core Study (Urban et al. 2011), not only as an objective configuration but also as a specific way of thinking. They go beyond the individual level, thanks to the analysis of educational work, links with the environment and the motivation for change. This cultural evolution demonstrates that actions previously considered to be disjoined can be linked and that relationships between actors can change at different levels of responsibility through local action projects where innovations (bottom up) and reforms (top down) are not in opposition. Furthermore, it emphasizes the importance of an action research process that simultaneously considers the co-construction of strategic/action knowledge and competencies, as well as the transformation of practice and its environment.

Notes In French, « Réseau Observatoire International sur la Professionnalisation dans les métiers relationnels et de l'interaction humaine » (ROIP) coordinated by Professor P. Maubant, University of Sherbrooke.

French-speaking part of Belgium.

Attribute given to an individual and/or collective subject through the attribution of characteristics constructed by inference made from his involvement in activities that are situated and finalized and result in a value attribution (Barbier 2011, 46).

Literally: Welcoming early years: taking up the challenge of quality.

Part III
Contemporary Research and Evidence – Early Childhood Education Globally: *Eastern Europe*

Elena Kravtsova, Nikolay Veraksa and Nikolai Veresov

Chapter 18
Contemporary Research in Early Childhood: Roots and Perspectives

Elena Kravtsova, Nikolay Veraksa, and Nikolai Veresov

Abstract This chapter examines common historical and theoretical roots of new areas and directions of contemporary research and unique innovative practices in early childhood education, which exist in Eastern European and post-Soviet countries. In many ways, they follow the academic tradition established in 1960s and developed in 1970s and 1980s in Soviet Union, which remains foundational for international contemporary studies and educational practices. Unique combination of traditional classical pedagogical research and strong "non-classical" developmental cultural-historical theoretical framework could be considered as a distinguishing feature, which predetermined both the foundations and directions of the history of early childhood studies in contemporary Russia, former Soviet republics and Eastern-European countries.

Keywords Early childhood research • Cultural-historical theory • Activity theory • Child development

18.1 Introduction: Back to the Future

New areas and directions of contemporary research as well as unique innovative practices in early childhood education and development presented in this section have, however, some common roots. In many ways they follow the academic tradition established in the 1960s and developed in the 1970s and the 1980s in Soviet Union by the generation of prominent academics whose research remains foundational for contemporary studies and educational practices. In some sense, these contemporary approaches, directions, and innovative practices in early childhood studies have historical unifying roots.

In the situation of the political and ideological pressure in Soviet Union in the 1960s, early childhood as a research field became an "island of relative freedom" for researchers working within the Vygotskian tradition. This space of freedom predetermined a unique distinguishing feature of early childhood studies in Soviet Union. On one hand, traditional, "classical," educational, and pedagogical studies were informed by main theoretical principles and concepts of the cultural-historical theory. In some sense, the early childhood studies were the territory of an application of main principles of the cultural-historical theory. This is mainly related to the understanding and theoretical underpinning of psychological development in early childhood as a process of sociocultural genesis of higher mental functions and the personality in child. On the other hand, a huge variety of empirical and experimental studies generated conditions for further development of the theoretical approaches within Vygotsky's tradition.

This unique combination of traditional classical pedagogical research and strong "nonclassical" developmental cultural-historical theoretical framework could be considered as a distinguishing feature, which predetermined both the foundations and directions of the history of early childhood studies in contemporary Russia, former Soviet republics, and Eastern European countries. This methodological heritage did not disappear; on the contrary, new research and immersing innovative educational practices demonstrate its incredible relevance in addressing demands, requirements, and challenges of twenty-first century. Chapters, presented in this section of the handbook, are research-based evidence of the strengths and power of methodological tools and theoretical principles of developmental research in early childhood.

However, it is true that it is hardly possible to understand fruits without looking at feeding roots; the difficulty is that roots are always hidden under the surface. Our chapter is an attempt to show these historical roots, which still feed contemporary research in early childhood.

Likely, these roots have clear chronological and institutional coordinates. 1960 is the year of the establishment of the Institute of Preschool Education[1] within the structure of the Soviet Academy of Pedagogical Sciences. That was a turning point of the development of early childhood studies in Soviet Union. The founder of the Institute, a famous Russian psychologist Alexander Zaporozhets, the academician who belongs to the Vygotsky's theoretical tradition, directed it for over 20 years until his death in 1981 (Zaporozhets 1986).

The variety of the Institute's research directions (the Institute consisted of many specialized units such as laboratories of cognitive upbringing,[2] ethical upbringing, physical upbringing, etc.) was one of the key factors that insured its integral approach to the discipline.

Interdisciplinarity was another unique feature of the Institute's organization. Along with psychologists and pedagogues, it employed physiologists, medical doctors, philosophers, psychophysiologists, and other experts from other scientific domains that facilitated many lines of research. Such unique ensemble of theorists and practitioners allowed synthesizing knowledge of various specialized areas of child development to create a holistic view of the child.

The analysis of issues that the researchers of the Institute were concerned with in their work allows distinguishing two major problems, which continue to shape the current state of early childhood studies in Russia and former Soviet republics – the problems of child's personality and the child's cognitive development.

Although the problem of child's personality development in early years were addressed in the Institute's studies for many years since its foundation in 1960, it was not until 1984 that this problem was assigned to a special laboratory. Inspired by the results of its research, N. Poddyakov, A. Zaporozhets' student, proposed the name for this laboratory – "Formation of child's personality in situation of social and family upbringing" (Poddyakov 1977).

The methodology of personality studies and problem of personal development were actively discussed during meetings of the Institute's Academic Council since the establishment of the laboratory and still are the subject of heated discussions.

The analysis of existing theoretical approaches to the study of personality and of the current early childhood curricula allowed concluding that many of the personality theories at that time were not about actual personality or the development in itself. Determinism inherent in traditional science employs formal logic. That is why internally conditioned developmental processes are outside of its scope. Therefore, Vygotsky's cultural-historical approach, which was widely advocated by

[1] Istitut doshkolnogo vospitania (Институт дошкольного воспитания), where, according to existing terminology of that time "preschool" meant age 3–6 years. However, a lot of research in the Institute was done with babies and toddlers which corresponds with contemporary term "early childhood" with division to early preschool (3–4 years), middle pre-school (4–5 years) and upper/senior pre-school (5–7 years).

[2] Upbringing is the translation of the Russian word vospitanie (воспитание) as it existed in official documents and educational frameworks at those times. However, the research at the Institute was focused on development as sociocultural process of the genesis of higher mental functions in child.

A. Zaporozhets, Vygotsky's student, was used as theoretical grounds in the Institute's research work.

Vygotsky (1987, p. 99) noted that the problem of child's personality was not even present in the old school of psychological thought because it lacked knowledge of the child's history of cultural development and theoretical framework of the higher mental functions. The cultural-historical conception is not just one of the theories in the psychological science. It is a scientific field of its own, with own methodology that is drastically different from traditional methods of scientific discovery.

The theory of sociocultural genesis of higher psychological functions is based on two premises. First, all mental functions are divided into two categories – elementary (natural) and higher (cultural). A child has elementary functions just as she has the body with all its functions. Higher mental functions are voluntary and consciously regulated.

The origins and development of higher functions require the use of psychological tools. Mediation, the key difference between natural and cultural mental processes, is the second premise of Vygotskian approach. The use of signs as psychological tools allows a child to control and master her cognitive processes. To realize, as Vygotsky writes, is to master. The notion of mastering is central to cultural-historical approach distinguishing it from all the other theories based on adaptation-homeostatic notions.

18.1.1 The Study of Child's Personality Development

Researchers of the Institute conducted their studies in several key directions.

18.1.1.1 Development of Motivation in Children

The problem of development of children's motivational sphere was being approached from the standpoints of the A. Leontiev's (2000) activity theory, which differentiates between operational and motivational components of the activity. Motives are related to objects satisfying needs, and the very activity itself can come as a motive. Motivation develops with shifts in the leading activity. For example, significant grown-ups come as the primary motive for babies in their first months. It is seen in baby's reactions – smiles, making of cooing sounds, and getting agitated whenever significant grown-ups come close or by, all to get their attention. In their bonding with babies, adults begin to introduce objects, such as toys, early on to organize communication; however, at this stage, a significant grown-up remains the main motive for a baby. A significant grown-up induces children's exploration of objects.

M. Лисина (1974) in her experimental work showed that baby's attention toward an object lasts much longer when it is held by an adult. Adult-baby interaction lays grounds for the transition to the next type of activity – object-oriented activity, where children's interest in objects becomes their main motive. At this stage the role of a significant adult changes, from being the one a child uses an object to get attention of to being the one who helps mastering this object. Objects begin to motivate children, attracting their interest. However, this motivation is situational. In their early years, children are easily switched from one object to another. As they are progressing in their object-related activity, children begin to separate actions with objects from adults performing them. This makes them realize and understand objective actions and become interested in reproducing them. At this point, as A. Leontiev noted, children's abilities are limited, and they are unable to participate in the activities of adults on equal terms. This contradiction is solved in play activity, where children performing the same actions in a make-belief manner using substitute objects for the ones used by adults. This activity results in the development of special play motivation. A. Leontiev (1983a, p. 303) wrote that the motive of a play is the play itself: a child plays simply to play. Because child play is a complex hierarchy of roles, children develop likewise hierarchy in their motivation. It can be seen in preschooler's favoritism of certain roles (captain, pilot, etc.) over the others. Thus appear motives with different strengths.

Ya. Neverovich (Neverovich and Zaporozhets 1986) studied this phenomenon in depth. She asked children to perform a monotonous, dull task and give them cubes of the same color but different in sizes and asked to sort them. The task varied in instructions, of which there were three types: “sort the cubes,” “sort the cubes for your mom to see how well you did,” and “sort the cubes for other children to play with them later on.” It turned out that young schoolchildren's performance on a task varied dependent on their motivation. The strongest motive was the latter, social one, oriented toward peers. This experiment demonstrates that children develop system of subordinated motives. Moreover, A. Leontiev, by his discovery of the famous “bitter candy” (Leontiev 1983a, p. 202) phenomenon, proved that motives not only incite activity but also create meanings. This phenomenon was observed in an experiment where children were given a difficult task that was impossible to solve abiding by the experimenter's instructions, but could be solved by cheating. The experimenter told the children that as a reward for solving a task, they will be given a candy, gave the task, and left the room. Children, having understood that the task was impossible to solve by the rules, were breaking them thus completing it successfully. Then the experimenter used to come back, praised the child's work, and rewarded them with the promised candy. It turned out that senior preschoolers demonstrated general dislike of the given candy, insisting it being “bitter” and not tasty. This phenomenon vividly demonstrated the presence of the two concurring motives – the one of getting the candy and the other of solving the task by the rules. The realization of the first motive didn't mean the realization of the other, which resulted in negative emotions: it was important not only to have a candy but also to deserve it.

L. Bozhovich (2008) in her works showed that moral motivation develops in the preschool age, resulting in the emergence of special system of emotionally backed norms. It guides moral behavior in various situations. Development of motivation in senior preschool age completes with the emergence of child's inner "personal stand" that marks their readiness for school. Children at this point make transition from preschool childhood with its play to a school childhood with social roles, responsibilities, and pertaining attributes.

18.1.1.2 The Role of Family in Development of Child's Personality

The second direction of the Institute's research work was guided by the principles of the Vygotskian approach that considers development a key in understanding human nature – a feature shared with the views of neoclassical psychology. It is impossible to understand features of one's personality or to create conditions for its development without viewing them in a broader context of other processes, functions, and social environment, such as friends and family.

Discourse of a preschool child's development cannot be limited to discussions of kindergarten's curriculum and activities, leaving child's home upbringing and emotional sphere outside the scope. Moreover, personality studies assume cooperation between researchers and participants, where both are subjects of personal ongoing development. This, in the context of the discussed problem – emergence and development of personality in preschool age – leads to conclude that only personal development of people interacting with children can assure purposeful development of children's personalities.

Intensive scientific inquiry into the field of family upbringing problem is the main example of practical implementation of the neoclassical psychology's principles. This line of research yield results that are being confirmed by scientists and practitioners worldwide: a family alone cannot successfully address formation of the harmonious personality in a child; moreover, families themselves are in need of the qualified psychological assistance because the nature of interrelations within a family can substantially affect the sound development of children's personality.

One of the serious problems in this matter was separation of parents from educational establishments. Kindergartens and school were not involving family members in the educational process, limiting their role to attendance of formal parental meetings. As the result, parents were unaware of their children's activity at school, and teachers had no knowledge of children's situations at home.

The situation began to change after multiple studies of the outcome of family education. It turned out that in preschool children's minds, family image is dependent on shared location. Families, in a preschooler view, are people who live in the same apartment or the same room. Grandparents or parents living in a separate location are not considered a part of the family. It also turned out that preschool children do not differentiate between an ideal and an actual image of a family, and, thus, there are no good or bad families in their view. All families are the same in the mind of a preschooler. This does not mean that interrelations within a family do not affect

child development. It is that a preschool child does not realize that parental neglect, their bad attitude, and conflicts between parents are something that characterizes their own family and not all the others as well. This distorts a child's perception and adversely affects their personality and cognitive development.

A shift in educational orientation toward family resulted in creation of qualitatively new educational programs of preschool development that, among other things, included parents in their children's kindergarten life.

This transition to family-centered pedagogy was supposed to ensure the creation of conditions for purposeful development of preschool child's personality. The distinctive features of this new pedagogy were the holistic view of a preschool child and their living environment and holistic understanding of the individual trajectories in preschoolers' development. Holistic view of the preschool child development acknowledges that preschool education is not limited to only kindergarten or only home, it asserts that classes cannot be planned apart from weekends and holidays, and children's leisure time must not be excluded. Any person, and especially a preschooler, learns a lot more outside of the classroom. Therefore, a variety of the child's life aspects need to be taken into consideration when developing system of preschool education. Otherwise, the educational program will not contribute to the development of the child and would simply be useless or downright harmful.

18.1.1.3 Social Psychology of Preschooler's Personality

The second direction of the Institute's research work was connected to studies of the social context of the formation of the child's personality. This aspect has been first studied in the laboratory of children's social psychology and then in the laboratory of identity formation in social and family conditions.

The results of studies of the communication can be divided into three groups. The studies of the first group were associated with identifying features and patterns of communication of preschool children, the structure of children's group, and specificity of interpersonal relationships between preschoolers (Repina and Sterkina 1990). The other line of research studied the individual characteristics of preschoolers' communication. They yielded unique results showing that beginning from the early preschool age, we can vividly see and distinguish conflict-prone children, children manipulators, children individualists, etc. At this, on the one hand, it was strongly emphasized that all these and many other types of communication had a right to exist, and on another, harmonization of communication necessary for the sound mental and personality development of children in preschool age was promoted.

Another group of studies analyzed communication and interaction of preschool children during various activities. For example, T. Antonova studied communication and interaction of preschool children during their play (Repina and Sterkina 1990).

Among the studies of interpersonal communication of preschool children, a special place belongs to the line of research that began in the Institute of Preschool

Education under the scientific guidance of A. Zaporozhets and continues to present day. In these studies, communication is seen as both a characteristic and a mechanism of the changes that happen to the child during the preschool age. For example, the results of a study by E. Kravtsova (Kravtsova and Kravtsov 2013), on the problem of psychological readiness for school, showed that somewhere between the senior preschool and early school age, child communication with others qualitatively changes. On the one hand, such change readies the child for school and, on the other, becomes a psychological cornerstone for the development of the next leading activity – learning at school.

18.1.1.4 Studies of the Emotional Development of Children

Another direction of supporting the realization of individual trajectory of child development focuses on the emotional sphere of preschool children. According to the cultural-historical theory, emotions are a central feature in the preschool period of child's development. This means that emotions play a special role in the personality development of children of preschool age, and this fact places specific requirements for the organization of the life of preschoolers. Studies of the preschool children's emotional sphere's development were carried out in the laboratory of psychology of emotions under the scientific guidance of A. Zaporozhets. It was found that the development of emotions changes qualitatively during the preschool age.

"I will be angry with you for a long time, for the whole of two weeks," says an 8-year-old boy to his mother. "We laughed equally long at first, but then I took a grip of myself and overlaughed my friend Misha" declares the hero of one of the stories by V. Dragunsky. K. Chukovsky in his famous book writes about a girl who says: "I cry not to you, but to my aunt Lida." All these illustrate the appearance of so-called anticipatory emotions (Zaporozhets) by the end of the preschool age.

The behavior of early preschool-age children (at the beginning of this period of development) is qualitatively different. For example, the younger preschooler gets angry, cries, and swears that he will never play football again (or take other people's things, be friends with that kind of kids, etc.). However, it takes a little time for a child at this age to head for the door and go play football again, take other people's things, etc., assuring his mother that this time things will be different.

Children of early and even middle preschool age often watch the same movie for many times sincerely hoping that suddenly this time it will end differently, and their favorite character will survive or defeat the enemies. In preschool period of their development children are spontaneous and direct, which is manifested in involuntariness and situational nature of their behavior. This is due to the specific integrity of their minds that does not differentiate between the inner and the outer world. Involuntariness and situational nature of their behavior shows that children are not aware of own inner states and emotions and have no means of controlling or comprehending them.

By the end of the preschool age, children acquire the ability to manage their emotions. At this point, two important features in the development of emotions in the preschool years appear. The first is related to the control mechanisms of the emotional sphere. Imagination, being, according to Vygotsky, a central psychological neoformation, is formed between the subject and its emotional manifestations. It ensures formation of the anticipatory emotions in senior preschoolers, or "generalization of sensations and intellectualization of affect," which, according to the father of cultural-historical theory, is a product of the crisis of 7 years of age.

The second feature of emotional development in the preschool years is connected with the emergence and rapid development of empathy, sympathy, and compassion (Strelkova 1989). Both of the highlighted features of emotional development in the preschool years are directly related to the leading activity of this period – child play.

18.1.1.5 Studies of Child Play

Such renowned psychologists, A. Usova, R. Zhukovskaya, D. Mendzheritskaya, N. Mikhaylenko, and others, studied child play, and there was not a single laboratory in the Institute that wouldn't study it.

However, at the same time there was no special department, which would specifically study play activity of preschool children. This largely is the reason why the Institute lacked an integral concept of play activity (some theories have emerged after the Institute was reorganized and restructured). At the Institute's Academic Council, where D. Elkonin presented his book "Psychology of play," he said that all his life he sought to create a tree of the child's play, but he succeeded in creating merely a bush (Elkonin 1978).

Research of child play had its ups and downs. Studies of play activity in the middle of the last century enjoyed wide interest resulting in a large number of various works, whereas at the end of the twentieth century, this interest was largely lost. For the past 5–7 years, the child play once again attracted attention of many researchers. This can be attributed to the fact that after a while theorists and practitioners realized that it is impossible to solve many issues without turning to child play. This is most vividly manifested in problems of psychological readiness for school. If in the 1990s the idea that psychological readiness for school depended on children's play activity seemed revolutionary and was rejected by many researchers, today no one seems to argue against this thesis. However, when it comes to the purposeful formation of psychological readiness for school, that is, creation of the conditions for the formation and development of child play, the situation begins to resemble that of the 1990s.

Studies of play activities conducted in the Institute before and after its reorganization yielded a number of important results. The fundamentally new (the first feature) to understanding of the child play was differentiation of its psychological criteria. Keeping in mind the Vygotskian approach to play activities, as well as his nonclassical psychology, we can define dual subjectivity as its key characteristic and its criterion. Dual subjectivity of child play describes situations when a child is

simultaneously a part of the game, and the one playing it, being at the same time in and out of its boundaries. The above can be illustrated by Vygotsky who noted that in the game of hospital, a child cries as a patient and at the same time is joyful because he is happy playing (Vygotsky 1966, p. 70).

This criterion qualitatively changes understanding of an imaginary situation as a criterion for play activities. According to Vygotsky, an imaginary situation is the space between the real (visual) and semantic (imaginary) field and not the content of the semantic field to which some researchers limited child play.

As shown in studies of E. Kravtsova (Kravtsova and Kravtsov 2013), child play encompasses relationships pertaining to the game (plot, characters) and to the reality (realm of a child's life). In some cases, these relationships do not coincide, for example, when a child in the game comes as an adult who takes care of a baby, played by an adult. In other cases, the relationship does not simply coincide but comes as the subject of a play, as in the case described by Vygotsky, when two brothers play two brothers. However, regardless of whether gaming and real relationships in child play coincide or not, if the player is dually subjective, he or she realizes play activity.

The second feature of the approach to child play that was beginning to take shape in the Institute was connected to the development of periodization of play at the preschool age. In the first approach to play a directed play, the child learns to create a plot by combining different objects. The second – figurative play – is aimed at development of the child's identification abilities. A child is changing walk, voice, and attitude depending on whom they identify themselves at the moment. By merging, the first and second approaches to playing (directed + figurative) form the basis for the formation and development of the role-play. Role-play allows realization of the skills gained in the previous kinds of games and creates conditions for the development of children's cognitive abilities. Thus, as a driver in a game, a child has to make decisions about what to do when their car brakes down or a wheel fells off. Or in another example, a child that is playing a salesman in a shop must think of how to weight products when there are no scales available or how to calculate the amount of change due.

Playing a game by the predefined rules, a close relative of the role-play comes in the senior preschool age. It is this kind of game that accounts for the development of voluntariness in preschool children. Moreover, given that the rules of the game must be learned prior playing it, we can conclude that playing by the rules facilitates development of psychological readiness for school.

The development of child play in preschool age concludes with the return back to the directed play, this time enriched with all the previous experience and knowledge gained in the previous types of games. This in many ways prepares for and ensures smooth transition to a next age period, new leading activity.

The third approach to play connects it to the other types of preschool activities. As it was mentioned before, the periods of child play development in the preschool age (developmental timeline for different types of games) were established. It should be noted that the emergence of new types of child play does not affect the

types a child already mastered, which only become more complex and rich in their content.

At this, each phase of the preschool period is characterized by a certain set of child play types with only one of them being new and newly formed at a time. Only this newly formed type of child play can be defined as a child's leading activity, which changes with the new phase of a child's development. For example, role-play is the leading activity in the middle preschool age, whereas in the senior preschool age, the leading activity becomes playing games with rules.

Leading type of play activity does not dominate the others, but by the end of preschool age, child play gets so advanced that it becomes a predominant type of children's activity. The types of child play that ceased to be their leading activity go from the center to the periphery of the process of cognitive development, becoming a form of organization of children's life.

Two things should be noted in this respect. First, until the child mastered play as an activity, it cannot be used for other developmental purposes. In other words, in this case, the use of play for educational purposes would not only be counterproductive, but will lead to substantial distortions, both in learning and in the development of play skills. Second, the child play can be used in various child activities by creation of situations where dual subjectivity can be realized.

The third approach to child play concerns conditions for development of play in early childhood.

Psychological readiness for play, on the one hand, reflects the continuity of the play as a purposeful activity, which is expressed in the fact that the child gains the ability to change their perception of an object and act according to it. At the same time, the psychological readiness for play involves the special situational forms of communication with an adult and the emergence of key actions with objects.

18.1.2 Studies of Cognitive Development

Studies in the field of cognitive development of preschool children conducted in the Institute had two main directions – the first led by A. Zaporozhets and the second by A. Usova.

18.1.2.1 Research on Learning Opportunities for Children

A. Usova advocated the general idea that preschoolers must have a system of knowledge that reflects basic laws and relationships between the various phenomena of reality. She explained her position by contrasting it to the approach, which posits that children are able to discover basic laws by themselves, by using own experience of interaction and communication with the outside world. Usova stressed that it is important not to overestimate the potential of children's autonomy: "You can often see how child's plain helplessness in some situations is interpreted by a grownup as

deliberation and planning. Child's autonomy develops gradually and requires serious help in this process" (Usova 1970, p. 55). Criticizing this approach, she emphasized that not all children develop speech, numeracy, drawing skills, etc. at the same pace. The division of preschoolers into groups according to the level of development of certain faculties creates large groups of children who did not reach that level and were labeled accordingly. The situation is exacerbated when such division is used in selection of children for school. Children of such groups are distributed to classes and schools of lower level that determines the future of these children.

Usova's research emphasized that there are two positions toward the child. According to the first position, the development of appropriate knowledge and skills may be regarded as desirable, but optional, and in this case, the child's mastering of the proposed content can remain on a relatively low level. According to another view, shared by A. Usova, children must master the proposed cultural content.

Usova offered to organize special classes for children within the system of preschool education that would help all of them to master the selected content. At the same time, the requirements for the organization of classes were formulated as follows: the classes must be interesting, full of activities, and accessible by all children and must get children emotionally involved. The classes should develop thought, speech, perception, etc. and at this let children lead their everyday lives. Along with the importance of classes, A. Usova stressed the importance of play and work, transforming into each other in some situations.

Usova singled out two types of skills and knowledge that children acquire. The first type is knowledge acquired through children's own experience. The second is the knowledge that deliberately transferred from an adult to a child. She insisted that the efficient educational process takes into account children's experience and relies on it. Classes should be organized in such a way that each child involved in the educational process achieves the results.

Thus, she mentions: "Children can acquire knowledge and skills in literacy, numeracy, drawing, construction and so on only when being taught these. Under these conditions, the experience in the form of knowledge and skills will be accessible to all children; will have an impact on their development. These tasks should not be linked to giftedness in children. All children are able to achieve a certain level of development when taught by an adult, considering and using activity" (Usova 1970, p. 53). When the classes are properly organized, there is an additional effect when children influence each other. Hence emerged the idea of daily group sessions conducted for 20–25 min twice a day in day care centers.

The sessions designed by A. Usova were based on the idea of imitation. The works of great number of researchers have shown that imitative behavior is common to preschool children. By giving a child a model to reproduce, adults reduce the chance of mistakes and lead child's activity directly toward the desired result, facilitating the development of knowledge and skills. On the other hand, children in their imitation must be active in own orientation to discover the key features to reproduce. In this case, the child comes as a subject of cognitive activity, not an object.

Usova considered educational sessions as a way of preparing preschool children for the transition to school. They seemed important to her, because she believed that

playing doesn't automatically entail learning, because learning is a result of special pedagogical impact: "One can cite numerous examples from educational practice showing how kids who are great at play, are far from performing the simplest and the basic requirements of learning activities: listening to adult, following instructions in their of mastering content, skills and methods of action. It has been shown in practice that children in the preschool age need to be taught in order to enable them to master skills required for their proper development and get them ready for school. Learning for a preschool child is a special activity that is formed during organized sessions" (Usova 1970, p. 67).

It should be noted that A. Usova welcomed the Montessori system. However, its autodidactic principle was main disadvantage to her, and therefore Usova favored learning sessions led by a grown-up.

Usova emphasized the importance of preschool education in the form of learning sessions. She also realized that children in their preschool years do not master the method of acquiring knowledge. Consequently, the learning activity itself does not develop, although children acquire certain qualities needed for the formation of educational activity in the future. Nevertheless, A. Usova considered learning sessions in kindergarten the only way of organizing developmental teaching, that is, to make sure that teaching would entail development.

The work of A. Usova resulted in many practical application of learning sessions on various subjects that were included in many different preschool educational programs.

18.1.2.2 Studies on Speech Development

One of the results of the Institute's work was development of system of classes for speech development for preschool children. The program was based on research conducted in the Institute's laboratory of speech development headed by F. Sohin (1984) and O. Ushakova (2002). Three research areas, structural (formation of structural levels of language – phonetic, lexical, grammatical), functional (development of coherent speech and communication), and cognitive (development of understanding phenomena of language and speech), were the main directions in studies of psychological-pedagogical problems of language development in preschool children. All three directions were intertwined, because awareness of speech and language phenomena is integral to all studies of preschoolers' speech development.

Studies have shown that the specially organized education system leads to substantial shifts in the speech and general cognitive development of preschool children. Children develop high culture of speech and a tendency toward its improvement, perfect accuracy, and expressiveness of their speech. Preschoolers begin to use appropriate means of artistic expression in their verbal creativity (by composing fairy tales, stories, riddles, poems).

According to A. Leontiev, any verbal expression requires a whole set of skills: a quick orientation in a situation of communication, an ability to plan speech and

choose its content, finding linguistic means for transmission, and an ability to provide feedback; otherwise communication will be ineffective and will not yield the expected results. It should be emphasized that the most important tool in acquiring verbal skills is the ease of transferring of linguistic units to the new, not yet encountered, combinations. This constitutes the so-called sense of the language, which enables the child to apply language skills to an unfamiliar language material, to distinguish the correct grammatical forms from the wrong ones.

The formation of linguistic abilities must include the development of a sense of language, which comes in use when a child needs to introduce linguistic units into a statement. We should point out the creative nature of such introduction. For one thing, the situations of verbal communication are constantly changing, which causes children to create phrases new to their linguistic experience and introduce them into new combinations. For another, changes of situations and creation of new combinations bring forth new ideas in child, causing the need of their expression with new speech forms. Children's linguistic skills develop in the very moment when they come to new linguistic solutions.

This ability is associated with the mastery of native language, development of linguistic skills; it develops by practicing communication as a system of verbal associations and can be purposefully formed.

The main objective of linguistic education is child's creative mastering of native syntax and its flexible application in specific situations, as well as mastering of basic communication skills. Individual differences in verbal fluency in children of the same age can be vast, so it is necessary to take into account individual characteristics of each child's speech development.

The main tasks in the development of speech, such as formation of phonetic culture of speech, enrichment of vocabulary, mastery of grammatical structure of speech and its coherence, and instillment of interest in artistic expression, are being solved throughout the preschool years, but in each age period these tasks gradually become more complex, with the subsequent changes in the teaching methods. Each of these tasks has a whole range of problems that must be addressed in a parallel and timely manner.

By assimilating native language, preschoolers master the most important form of verbal communication – spoken language. Communication in its full form – speech recognition and active speech – develops gradually. Therefore, language acquisition and language development are considered not only in terms of linguistics (phonetics, grammar, vocabulary) but also in terms of interpersonal communication skills with other children and adults, making it important to master not only the culture of speech but also the culture of communication.

In preschool education a close relationship of the structural components of communicative competence is seen as a relationship between communicational and speech abilities of the child, as the development of speech in the process of communication, assimilation of social experience, and development of creativity. All these skills give children an opportunity to anticipate communication in the elementary forms and orient with the conversational partner's status (a friend, a teacher, a parent, a strangers). Advanced culture of verbal communication is not mere proficiency

in native language; it is also an ability to use expressive means of native language in various contexts of communication. It is both speaking the right words and doing so in the right situational context.

Properly organized education and communication allow children to successfully acquire speech and communicative skills and develop their creative skills in various forms of artistic activity: art, music, theater, etc. A child can express her emotions and feelings with a spoken word, which should be figurative, concise, and to the point. Along with the culture of speech, the culture of communication and speech etiquette develops. However, teaching the culture of communication should not be limited to mere memorization of etiquette rules.

Speech skills include excellent verbal memory, general erudition, and feeling of the language, i.e., proper choice of linguistic means, logical construction and presentation of speech, and the ability to listen to other parties in a conversation. Communication skills include initiative in conversations, independence of judgment, the ability to engage in a conversation, activity, and emotionally evaluative responses.

Sufficient level of preschool speech includes:

Knowledge of literary norms and rules of the native language: the free use of vocabulary and grammar in expressing thoughts and compiling statements of any type
Well-developed culture of communication: the ability to establish contact with adults and peers (to listen, to respond, to argue, to ask questions, to explain)
Knowledge of the norms and rules of speech etiquette: the ability to use them depending on the situation

18.1.2.3 Development of Perception

As it has been noted, studies of cognitive development were conducted under the scientific guidance of A. Zaporozhets. Special attention was given to the research devoted to development of perception, thinking, and imagination, with studies of perception being common grounds for all the work in this field.

Zaporozhets believed that perception is a culturally conditioned process connected with the development of the sensory standard system that is carried out in the course of productive activities. He showed that the perception of a preschooler is of activity nature and represents a system of perceptual actions characterized by the use of sensory standards. At the preschool age, children become able to perceive the world not through innate properties of perception (as, e.g., a set of sensations as understood by associative psychology), but with a system of sensory standards, which have been developing by society throughout its history. Sensory standards are qualities according to which a child arranges objects around them. Those include shape, size, color, musical tones, phonemes, and so on.

Development of perception in terms of the activity theory is shaping child's mind with the properties of objects. However, as the development of child's system of sensory standards progresses, objects themselves begin to be interpreted (assimilated)

through the pertaining sensory standards. It was experimentally observed by L. Venger in the phenomenon where colors of objects were "elevated" to match the sensory standards (Venger 1969). For example, young preschoolers interpret the color orange as either red or yellow, because, as noted by L. Venger, they didn't yet master the whole system of sensory standards, only primary colors, and when faced with a complex color, they tend to search for a match in their system of sensory standards, among primary colors.

Together with L. Venger, A. Zaporozhets developed a system of sensory training within a preschool curriculum that offered a variety of activities aimed at development of an ability to use sensory standards in the analysis of various properties of objects. It turned out that the mechanism of visual perception is not limited to the irritation of the retina with reflected light from objects, it is perceptual activity related to the analysis of the object's perceived properties. In other words, perception is different from the process of distinguishing one object from the other. It is a process governed by the laws of human culture.

In an experiment by L. Venger, young preschool children were asked to retrieve objects through a wooden plank with holes similar to the shapes of objects. Thus, a child was required to pull an object through a hole of the similar shape. The task turned out to be difficult for children. Although they saw objects and openings, the decision required separating the shape of an object from its other properties, such as color, and relating it to the shape of the hole. In other words, young children had to solve a special perceptual task that was accessible only to senior preschool children. These studies resulted in the theory of child's perception development. According to this theory, the perception of a preschool child is a special process of analyzing objects with perceptual actions and sensory standards. First, in a child, there are only psychophysiological processes accountable for distinguishing one object from other. With an engagement in activities, the child begins to master perceptive actions and develop sensory standards. Children first master substandards. For example, a child may say "round like a cherry," or "similar to a cucumber" when referring to the oval. These definitions are based on the personal experience of interacting with these objects, and they are applied in the analysis of other objects. Along with the development of substandards form actions of perceptual identification, which is analysis of an object on the subject of similarity to one of the substandards. For example, a young preschooler may say that a bird is a creature that has a beak, but the beak in this respect is some definite, visual property. On the next stage of the preschool age, a child begins to develop the simplest sensory standards – color, shape, and size. This marks the beginning of the formation of cultural notions about shapes (circle, triangle, square), sizes (large, small), and color (red, blue, green, yellow). At this age, an action of referral to the standard is being formed: children are becoming able to analyze an object apart from its other properties in solving perceptual tasks. They become aware that a ball is round, ignoring the material it is made of, its color, or way of use.

By the age of four, children begin to develop understanding of the transformation of objects that means they become able to perform the action of perceptual seriation, for example, to arrange items in an order from the smallest to the biggest and vice

versa or sort color pictures according to the saturation of color, from the most vivid to the most bleak, and so on. That manifests the development of order notion of sensory standards. By the age of five, children have understanding of sensory standards and develop perceptive modeling, which allows consideration of an object as a set of various cultural properties. For example, a house can be represented as consisting of windows, doors, and roofs – a unified set of various culturally defined qualities. It is important to emphasize that such perceptional system only develops with appropriate training aimed at the development of sensory standards.

18.1.2.4 Development of Imagination

According to Vygotsky, imagination occurs when the child becomes independent of her own perception. When, for example, a child who sees the doll sitting is asked to say that the doll is standing (example by Vygotsky), they are unable to do that if they realize themselves as subjects of own speech and then employ a new cognitive function called imagination. Imagination allows the child to control the field of their own perception. In other words, the crisis of 3 years of age results in an ability of children to realize themselves as subjects of own speech and gradually, with the help of the speech, change their visual space. Irrespective of the objective reality, they become able to repeat the words of an adult – the doll is standing, the doll is sitting, etc.

Studies of imagination at the Institute were simultaneously conducted in two laboratories – the one under the supervision of L. Venger and the other under the supervision of V. Davydov (Kravtsova and Kravtsov 2013; Кудрявцев 1990 and others). These studies have provided data on the development of imagination on preschool years. Thus, a study by O. Dyachenko resulted in distinguishing two stages in imagination development – objectification and inclusion (Diachenko 2011). Important results were also obtained in experimental studies of imagination in the preschool years with respect to two different kinds of imagination – emotional and cognitive (Veraksa 2011).

Data were obtained on the structure of the imagination, which is implemented through the objective environment, past experience, and suprasituational internal position, on close connection of imagination to the development of creativity in the preschool years and on the role of imagination in the psychological readiness for school (Kravtsova and Kravtsov 2013; Кудрявцев 1990).

18.1.2.5 Development of Cognition

The studies of cognition's development, which components were cognitive actions, were carried out in the context of the activity theory. Three forms of cognition were singled out: visual-active, visual-figurative, and verbal-logical. N. Poddyakov studied visual-active form of cognition in early years child. It was shown that this type of cognition is characterized by the child's way of operating with objects. Initially

it is chaotic, disorganized. The child operates an object without expecting any result. This was experimentally studied using a special machine with holes in its top, through which by pushing buttons rods would pop up. At first, the child presses buttons at random without paying attention to the appearance of rods, but over time they begin to notice them, which happens spontaneously, not intended. The development of visual-active cognition happens when chaotic actions start to organize into probing, exploratory actions, where a child puts a theory forward and tests it, anticipating certain results. Here not only a connection between the action and the result establishes but also appears purposefulness of actions. For example, when children are faced with a task of making a ball roll off a hill and to stop at a certain place, they approach it differently at different age. Children of 2 years of age simply put the ball on the hill (regardless of how high or how low on the hill), release it, and watch what happens. Children of 3 years of age act fundamentally different: they begin to test different starting points on the hill to determine how far will the ball roll. Eventually they manage to establish the dependence of the ball's stopping point from its initial position that solves the task.

N. Poddyakov specifically studied the transition from visual-active to visual-figurative thinking, which is manifested not in the child's actions with objects in a situation, but in child's cognitive representation of the relations between them. He considered operational standards that reflect basic connections in a symbolic form to be essential in transition to visual-figurative cognition. The use of operational standards can be illustrated by the following experiment. A circle that rotates like a record is placed before a child. On this circle a figure of an animal is placed and above the circle there is a flat platform with another animal figure. A task is to place the animal figure on the circle in such a way that by rotating the latter, the two figures would meet at some predefined point. For children of early preschool age, this task is difficult to solve. Drawing rotation trajectories on the circle helps children to solve this task. In fact, these trajectories act as operational of standards, allowing children to anticipate the circle's rotation before actually rotating it. Another tool of figurative cognition is manipulating image, which is a representation of an outcome of own actions.

The use of manipulating image can be illustrated by the following experiment. N. Poddyakov introduced a special device to children consisting of a plank with a figurine which movement could be controlled by special buttons. The task was to move the figure from one point of the panel to another. Children's strategies in solving this task varied according to their age. Younger preschoolers used to immediately press buttons until desired result was achieved. Older preschool children would first try every button, watch the corresponding effect, and then solve the task very quickly. N. Poddyakov explained this result by the fact that the children had formed a special cognitive tool – manipulating image – which allowed them to anticipate movement of the figure depending on what buttons they press. Cognitive tools, such as operational standards or manipulating images, were central to development of child's cognition in the activity theory. Along them motivational side of cognitive activity was studied. N. Poddyakov discerned two types of cognition based upon two situations – solving of a task proposed by an adult or unguided

exploration of the objects and situations. Two of these motivations result in their own outcome. In the first case, adult-organized activity leads to the formation of distinct notions about the properties of objects. In the second case, where cognitive activity is initiated by the child, notions don't have that clarity because a child doesn't take into consideration main characteristics of the situation in which they act. Therefore children possess two types of notions – clear and schematized and uncertain and uncategorized. N. Poddyakov wrote that it was the second type of notions that constituted the child's zone of proximal development, being the source of their creativity, because they have a potential to eventually turn it into clear, distinct knowledge.

Studies of figurative cognition conducted under the scientific guidance of L. Venger revealed the important role of the so-called schematized representations – internal images of objects and the relations between their constituent elements that represent only the properties needed for solving particular tasks. This can be illustrated by an experiment in which a child was asked to find a toy in a room using a plan that represented only the main relations between the content of the room. To complete the task children were required to have a mental representation, which connected items on the plan to their referents in the real room. It is the ability to see the scheme (the schematized image) that makes this task solvable.

Studies by N. Veraksa discerned another form of preschool child's cognition – dialectical cognition. It has been shown that the development of dialectical cognition is a special independent direction of preschool children's cognitive development (Veraksa 2010).

We can see that in the work of N. Poddyakov, L. Venger and their colleagues descried above, cognition, as well as perception, is a culturally mediated process that can be purposefully developed through activities in the course of which the child develops cognitive tools. Such activities are mainly construction and art.

Concluding the description of the work of The Institute of Preschool Education of the Academy of Pedagogical Studies of USSR, it should be noted that it was practically oriented and resulted in creation of various educational programs for preschool children across all the countries of the former Soviet Union and others. Among such programs are "From birth to school" (Veraksa et al. 2010), "The Golden Key" (Kravtsov 2014), and "Razvitie" (Venger and Diachenko 2000), presented in Russia, Ukraine, Belarus, and Kazakhstan, "Tools of the mind" (Bodrova and Leong 2003) in the USA, and "Key to Learning" (Dolya 2010; Esteban et al. 2010) in the UK, the USA, Poland, and other countries.

Chapter 19
Symbolic Means in the Educational Programs for Preschool Children in Russia

Nina Salmina and Aleksander Veraksa

Abstract This chapter is devoted to the problem of the symbolic function development at the preschool age. J. Bruner, L. S. Vygotsky, and J. Piaget believed that the significant transformations of the child's mind are behind the symbolic function formation. L. S. Vygotsky stated that it is the sign or means of its use which are the basis of the psychological structure of the child consciousness. The problem of psychological process mediation by signs, possibilities of their use, and creation of signs by children became one of the most important in the Russian developmental psychology. In this chapter we will discuss three trends in symbolic tools for learning in preschool educational programs: play activity, drawing activity, and speech. Special attention is given to the comprehension of sign-symbolic systems and their acquisition during educational process. These areas are illustrated by the examples from the educational programs, which helps to see the logic of symbolic development understanding in the Russian early years education.

Keywords Symbolical function • Symbolical tools • Programmes of early childhood education • Programmes for symbolical function development

The problem of the symbolic function development at the preschool age has always attracted attention of researchers. J. Bruner, L. S. Vygotsky, and J. Piaget believed that the significant transformations of the child's mind are behind the symbolic function formation. J. Piaget understood the symbolic function to be "the ability acquired in the second year of life to represent absent object or event not apprehended directly by means of symbols or signs, i.e. those, which denote and which differ from those that are denoted" (Piaget 1976, 107).

According to Piaget, the symbolic function begins to appear in different types of representation – imitation, symbolic game, mental image, presentation, and speech.

In Piaget's works, the process of symbolization is shown as a special form of reflection of reality by a child achieved by virtue of an individual own activity as opposed to a sign of collective nature. J. Piaget emphasizes that a symbol carries an affective aspect and its application by a child is conditioned by the difficulties of subjection to external instructions and orders. The symbolic reflection is a special form of reality representation in the child's mind, which can precede the reflection of a world in the form of signs. At the same time, Piaget's attitude allows identifying a sign and a symbol as a part of a single process of symbolic function development. That is why the main discrimination in the psychological literature came to be associated with not so much by the sign-symbol line as by image and verbal representation line.

L. S. Vygotsky, who determined the range of problems and theoretical approach to analysis of the semiotic function development, proceeded from the assumption that in the higher psychological structure, "the entire functional determinant or the focus of the whole process is a sign or a means of its use" (Vygotsky 1983, 116–117). The problem of psychological process mediation by signs, possibilities of use, and creation of signs by children became one of the most important in the Russian developmental psychology. In this chapter we will discuss three trends in symbolic tools of learning in preschool educational programs: play activity, drawing activity, and speech.

19.1 Development of the Children's Play

According to Piaget, the symbolic play is a culmination of the development of child's play. A child, who is constantly forced to adjust to social and physical life of adults, which remains internal and difficult to appreciate, fails to satisfy affective and intellectual needs. Piaget emphasizes that for the purpose of affective and intellectual balance, it's necessary for a child to have an accessible area of activity, the motivation for which is not an adaptation to reality, but its assimilation without compulsions or orders. Such sphere is a play, which adapts reality by means of assimilation to the child's needs, while imitation acts as an accommodation to external models.

Traditionally, the sign-symbolic mediation development in Russian preschool education is associated with the play, child's speech development, and figurative activity. Speaking about child's play, L. S. Vygotsky assigned a huge part to it in development of imagination and creativity. In the creative process, Vygotsky singles out the specific type of children activity characterized by the process of the reference of images of one reality to another one. It is a peculiarity that distinguishes play from the other productive types of preschooler's activity. Vygotsky noted that each age has its own form of creativity connecting "activity of imagination with reality." The form of connection between activity of imagination and reality determined by Vygotsky as "an emotional" is of special interest. He emphasized that "every feeling, every emotion strive for taking shapes in the known images corresponding to this feeling" (Vygotsky 1967, 13). According to Vygotsky, an emotion

has a special ability to choose the corresponding impressions for it. Here "the principles of double expression of feelings" become apparent, according to which human internal states are reflected in the external products, and the image-fantasy acts as an internal language for our feelings. We see that Vygotsky, without any direct mentioning, pointed at the specific process of mediation between two different realities, one of which represents the cognitive processes and another one affective. In this case, it is necessary for us to emphasize an idea of the unity of affect, and intellect is an idea of the existence of specific relation between cognitive and affective human areas. This relation features the symbolic mediation. The symbolic mediation establishes relation between two reality chains – an emotional chain, "where the general feeling, general emotional sign form its basis" (Vygotsky 1967, 14) and a cognitive chain, which can be easily combined mentally. Vygotsky noted that emotional experiences represent the specific reality. Their interpreting through the cognitive area is based on the same mechanism as a child's play.

In fact, it is hardly lawful to think that a child acting with a stick has no other reality in his mind (acting with a horse). Here we can observe the same phenomenon as in the case with emotional imagination. Not knowing the real horse-riding method, a child acts with a stick, but refers his action exactly to the situation with a horse. In other words, we deal with the specific function of a symbol, when a child acts in space of a symbol, and the reality itself becomes to lose its mysteriousness when playing. It is clear why Vygotsky emphasizes that a playing child keeps two plans: a real plan and an imagined plan. To our opinion, it is connected exactly with the possibility of interpretation of one plan through another. When playing a game, the known closed field appears before the preschooler, but he does not simultaneously lose the concept of the real meaning of things. If a chair is a horse in this game, it does not prevent a child from moving a chair, although a horse can not be carried in one's arms (Vygotsky 1967, 51). To our opinion, having done this and the same actions, a child returns to the imaginary situation, which becomes more clear for him exactly due to the fact that an action with the real chair acts as a form of understanding action with a horse.

Such interpretation of a role of a game in the symbolic reflection development corresponds to the viewpoint of A. V. Zaporozhets, a follower of L. S. Vygotsky, who wrote that " … an important role of a game in the child's psychic development is explained by the fact that it equips a preschooler with accessible means of an active recreation, modeling by virtue of external object actions of such contents, which upon other conditions could be inaccessible and, therefore, could not be mastered properly" (Zaporozhets 1986, 214). When Zaporozhets speaks about the model nature of reality reflection in the play activity, he means "the systems of generalized, typical images of surrounding things and phenomena," which a child builds to "do its different mental transformations" (Zaporozhets 1986, 242). It seems to us that an imaginary situation is not so much characterized by the system of model (i.e., sign) relations, as by the system of symbolic actions, which in certain circumstances can be treated as sign.

The orientation specific character based on the symbolic reflection in the context of analysis of the child's play is presented in the works of A. N. Leont'ev. According

to Leont'ev, the play activity results from the conflict between the development of a need to act with things and "the development of operations by virtue of which these actions are carried out" (Leont'ev 2000, 475). Since a game is not productive, "the operations needed in the play action can be replaced by another operations, and its object conditions can be replaced by another object conditions; moreover, the content of an action itself remains. As a result, it is a play, where a child can learn a wider scope of reality directly inaccessible to him" (Leont'ev 2000, 475). It is this case for a play to become symbolic.

When analyzing a play process, A. N. Leont'ev paid attention to the method of carrying out the play operations. While considering an example of Vygotsky with a game of a child playing at horses, he wrote: "A stick comes into a game as a thing having its own meaning; a child uses it like a stick, but not like a horse. A stick has no symbolic meaning here. However, something changes: a stick acts in a game in a different way as opposed to the practical operation. This change can be explained as follows. A stick acquires not new symbolic functions, new meanings, but a certain personal sense for a child. This specific sense, a meaning for a subject is generated by peculiar motivation. The concrete motive corresponding to concrete need is both affective and affectogenic. An action with the play object reflects a concrete need and, therefore, I lay special emphasize on it, it acquires both known affective content, affective-subjective sense and subordinates the object meaning of the play object. A stick acts in the specific role, which is more instructive than a role of just a symbol or a second, temporal meaning" (Leont'ev 2000, 300–301).

We cited this extract from expression of Leont'ev as to our opinion it reveals the complex nature of the transformations of situation happening in space of a symbol sufficiently complete. From our viewpoint, the symbolic reflection, which develops during play, is represented here with all distinctiveness. Firstly, Leont'ev points at the concrete need satisfied in the play action. It seems that a child wants to ride a horse rather than a stick. But there is no horse actually. In other words, there is some motivational-need tension caused by the clear situation of uncertainty (a child has no horse at hand in reality). As a result the substitution of a horse with a stick happens. It is not a simple substitution, but also the reference of actions with a stick to a horse, i.e., the objectivation of a need in a stick. As a consequence, a new motive to play at horses occurs. This motive satisfies a need and generates a new sense: to ride a stick so as it is a horse. The sense, in its turn, structures the whole conditional game situation and determines the nature of a child's play actions.

We believe that the function of substituent in the play activity is transferred to something that is substituted, which results to that something that is substituted becomes clearer. Certainly, it is a peculiar, some kind of the primary means to comprehend reality. But due to the processes of symbolic mediation, it allows children building a model of relations of adults being studied, objectivating needs and displaying activity, though in naive form.

Since after the fundamental studies of Zaporozhets, Leont'ev, Usova, and Elkonin a play became to be considered as a leading activity, the development of the children's play activity was included into all preschool education programs in Russia as one of the major teachers' areas of work.

The development of play activity in the most widespread program in the Russian Federation "From Birth to School" (edited by Veraksa et al. 2010) begins at the age of 2. A teacher supports a child's interest in the play activity and forms skills to do several actions with one object, to transfer the known actions from one object to another and to use the object substituents. It should be specially noted that an object substituent fulfills a sign-symbolic function allowing representing an absent object. The symbolic function of an object substituent was noted by the majority of authors. Elkonin associated the possibility to substitute one object by another in a game, their renaming with an action: "The available data allows supposing that the renaming of objects by children is limited with those, which, by their properties, allow carrying out actions required by new names" (Elkonin 1989, 343).

The substitution development line remains in the educational work with children at the age of 4. Moreover, the participation of children in the joint games is encouraged. A teacher helps children to organize the game unions in pairs or by three based on the children's sympathies. The plots of children's games are based on the topics of day-to-day life and on the content of understandable literary works.

At the age of 5 the symbolization is supported through the development of ability to choose objects and attributes for the games. A teacher makes the process of distribution of roles and fulfillment of play activity in compliance with the rules and game concept more active. The interest of preschoolers in theatrical performances is supported. For this purpose children are involved into the process of playing simple performances based on the known literary works. Children create the expressive images using the means of expression (intonation, facial expression, gestures).

The play activity development at the age of 6 and 7 is associated with improvement and expansion of game concepts and skills of children. Demonstration of creative work, composing of new topics for the games, new roles, and new attributes, is encouraged. The special part in the teacher's work is assigned to formation of abilities in preschoolers to organize the joint play activity, to promote creation of the game unions of children. In theatrical games children master different roles presupposing the change of the child's role behavior.

In the "Development" program created under the guidance of L. A. Venger and O. M. Diachenko (1996), the play activity development is carried out during the preschool age for the period from the age of 3 to the age of 7. The creation of imaginary situation and ability to interact with the partner is of importance for children at the age of 4. For this purpose a child masters the conditioned object activity ("make-believe" actions) with the help of a teacher. Also a child is taught to take up the simplest roles and to interact in pairs with the partner, such as doctor-patient and driver-passenger. The object substituents (e.g., stick thermometer) are used for the development of conditioned play actions. The main task of a teacher in interaction with children at the age of 5 is to develop more complicated game interaction of preschoolers: to increase a number of children playing sociodramatic games, thus, a number of roles; to reveal the possibilities to children for changing the role behavior during the game; and to explain the necessity to agree roles during the game. The plots with numerous characters are used for that reason. The special attention is paid to the role dialog. When working with children at the age of 6, the main task of a

teacher is to develop flexible role behavior. The major direction for the play activity development is connected with the use of new roles in the plots known to children. For instance, in the "ship journey" game learned by children with the usual set of roles, captain, seamen, and passengers, there is a new conceptual character to be introduced, namely, Barmaley, a sea robber. In such a case the loosening of learnt schemes of preschoolers' game behavior occurs. Another direction of the game flexibility development is associated with invention of plots carried out orally only. A teacher offers any fairy-tale plot known to a child and discusses the possibilities for changing actions of characters under new conditions while it unfolds. The work with children at the age of 7 is aimed at the development of initiative and independency of preschoolers when realizing game concepts. The main task of a teacher is associated with the development of children's imagination. For this purpose children are offered to create various plots. The combination of characters from different conceptual spaces, Buratino and a spaceman, Baba-Yaga and a seller, etc., can be used as a way to unfold a new plot.

19.2 Development of Drawing Activity

According to the program "From Birth to School," a teacher begins to work on mastering necessary drawing skills (use of a pencil and a brush) with children at the age of 3. Children are motivated to depict known objects by offering them to outline objects. The work on improvement of drawing skills continues at the age of 4. Children are offered to draw simple objects: ribbons, roads, a fence, and a headscarf. Children are incited to convey a beauty of the world around in their pictures (a sky, varicolored leaves, falling snowflakes, etc.). At the end of the year, children draw certain objects and simple plots using necessary colors. At the age of 5 children draw objects by means of creation of distinctive forms and selection of color, convey easy plots, and use expressive means. At the age of 6 the children create pictures of objects from life and out of imagination using different compositional solutions. They use different colors and tints to achieve expressiveness of figurative images.

By the end of preschool age, children can create individual and collective pictures, decorative objects and narrative compositions on the topics concerning life, and literary works using different materials and methods of creating pictures.

According to the program "Development," the drawing activity is carried out during the whole preschool age, starting from the age of 3 (Venger and Diachenko 1996). One of the tasks set for children is aimed at mastering a combination of object representation and sheet coloring. When working with color, the stress is laid on its symbols. When working with an object graphic image, the task to master concrete drawing methods is not set. During drawing activity, children are incited to convey emotional state.

The object side of drawing activity is being developed and the composition plan tasks are set before children at the age of 5. A teacher introduces a preschooler to

the elements of image generation. At the same time, this work is organized so that not to prevent from the creative process of expressive image generation.

The task associated with transferring different human-world relationships in image is set for the children at the age of 6. This task is solved in the process of generating an expressive object-image composition. Children reflect pair relationships: human-object, human-animal, animal-animal, human-human, and I and world around me. The compositional tasks are solved, firstly, by virtue of the graphical image generation and then by its color score.

Children at the age of 7, who mastered the use of compositional and pictorial means of transferring relationships and personal mental outlook, solve more complex figurative tasks connected with the expressive image generation. An idea, which is put into the plot with further sketch elaboration searching for compositional and color score, is of particular importance. During the graphical image generation, the detailed elaboration of an idea is carried out; the image concept structure is defined more exactly; the symbolic content of a work enriches itself. The plot acts as a main structure element of children's literary works. The topics for plots can be chosen from the folklore (e.g., fairy tales where there is an opposition of good and evil).

19.3 Speech Development

An important social adaptation instrument is, according to Piaget, language, which is not invented by a child, but passed on to him as ready to use, compulsory and collectively.

The child's speech development in the preschool early childhood education system was singled out as a separate significant direction of the teacher's activity. In the Institute of Preschool Education of USSR (now Institute of Psychological and Pedagogical Problems of Childhood of Russian Academy of Education), there was a special laboratory of speech development in early childhood. F. A. Sokhin, its director, elaborated a theory of language acquisition in the preschool age. He showed that even without special training, starting from the very early childhood, children show huge interest in language reality, they "experiment" with words and create new words being guided by both sense and grammatical side of a language. Sokhin attributed the preschoolers' speech development to the consciousness of language phenomena, i.e., with the development of their metalinguistic activity (Sokhin 2002). He showed experimentally that the spontaneous immersion in speech environment does not guarantee the high level of language consciousness. In order to achieve it, one shall conduct special training. Firstly, the tasks of such training consist in formation of language generalization and consciousness of language phenomena. The interest in native language and speech creative work is based on that. The main strategy in the teacher's work on mastering language in preschool childhood early childhood shall consist in establishment of connection between

consciousness and child's speech functions as well as in formation of speech abilities and skills.

These provisions, advanced and substantiated by Sokhin, served as a benchmark for elaboration of detailed program for the speech development in early childhood executed under the guidance of O. S. Ushakova (2002). The program goal was the development of speech ability intending to master norms of language and speech. The development of speech abilities and skills in the field of phonetics, vocabulary, grammar, dialog, and monolog acts as its content. At the same time the different verbal, visual, and gaming methods and techniques were used at the group and individual classes. The classes were aimed at acquisition of knowledge of language and speech, including speech terms and concepts of the basics of linguistics. According to the program, the ability in four different types of speech activity (speaking, listening, writing, and reading) was developed in children. The teacher's work included the formation of ability to create and to apprehend texts as a result of speech activity.

The preschoolers practiced in resolving the following speech tasks:

To express the given sense by different means (ability to paraphrasing)
To extract the meaning from what was said and at the same time to differentiate expressions, which are outwardly similar but different by meaning (differentiation of homonymy) as well as to find the general meaning in the outwardly different expressions (proficiency in synonymy)
To differentiate the right sentences from the wrong linguistically
To choose among the thought expression means variety that, which corresponds to situation of communication mostly and which expresses personal characteristics of its participants to the fullest extent possible (selective ability)

In other words, the program is aimed at mastering all types of speech activity and basics of the spoken language culture, abilities to use language in communication situations, i.e., at the linguistic competence development. The linguistic competence came to be understood as a totality of speech abilities and skills developed in a child and allowing her to understand and to build new expressions according to speech situation and within the system of rules adopted in this very language for expression of thoughts. The linguistic competence development is closely related to the "speech culture" term (proficiency in the literary standards and ability to use them according to goals and speech situation) and also to the emotional sphere (ability to empathize, to understand your own feelings and the feelings of another person).

19.4 Mathematics Development

Highly appreciating the Piaget's studies on the symbolic function development, G. Vergnaud points to "the defects of Piaget's approach preventing from studying a problem of transfer and obtaining knowledge at school. One of them is absence of

analysis of learning the customary social instruments of representing terms (schemes, diagrams, drawings, pictures, and algebraic formulas), with the help of which a teacher tries to impart knowledge to pupils (including analysis, definitions and conclusions) worked out in a culture. Piaget pays considerable attention to the child's pictures, but this picture is rather treated as a product of a child's thought generation, while it is necessary to see mastering the means of representation and social communication by a child in it. It is also true towards an attitude to speech (language): absolutely accepting a Piaget's view point, according to which it is an action, but not a thing that is the most determinant factor in the operative thinking formation, it should be noted that there are a lot of action tasks laid and mediated in a speech. In such a way, if the study of something that is denoted is mostly important and it shall be carried out by observing an active behaviour of a subject in situation, than it is impossible to ignore the study of things that are denoted, particularly, social things, which denote and by means of which the things, which are denoted, are symbolized in communication and in the school communication in particular, which Piaget didn't pay attention to" (Vergnaud 1981, p. 9).

Despite the significant theoretical studies, this problem continues to remain open in many respects. The comprehension of sign-symbolic systems is acquired earlier than producing. The regularities of mastering the sign-symbolic systems are specific for each of them and are caused both by means of learning and functioning as well as by their semiotic characteristics. There is a conflicting material in literature regarding easiness-hardness of mastering signs and schemes by children. A.K. Zvonkin, when teaching math to preschoolers, has fixed great difficulties in using signs by them: "An idea of "signs" turned out to be extremely alien to children" (Zvonkin 1990, 97). N. Picard, in her fundamental study (Picard 1976) of process and results of realizing her basic math course, where the main means of learning the complex material by children was the use of symbols and work with different types of schemes ("tree," Venn-Euler diagrams, tables, different types of graphs), has discovered difficulties in using only some schemes (first of all, Euler diagrams when using it for the class intersection tasks). In principle, to her opinion, a schematization is a first stage of mathematization, which leads to preparation for learning math language. An analysis of children difficulties upon studying math shows that one of the reasons is a low level of symbolic development. The sign-symbolic preliminary instruction is presented in the early childhood programs in different ways, what influences the child's mental development and her further successfulness.

To prepare children for school and, above all, to the study of mathematics, a special preschool program mathematics was elaborated (Salmina and Tarasov 2000). The program is based on the assumption that the development of the symbolic function is its center line, because, on the one hand, mathematics and other subjects commonly use symbolic means (numbers, letters, symbols relationships, diagrams, tables, etc.) and learning difficulties of mathematics and other knowledge is often caused by a low level of development of the symbolic function as a whole. On the other hand, to operate with symbolic tools, you need to master the specific actions and systems of signs and symbols.

Despite the selection of the symbolic function as an independent unit, its formation is carried out in all the blocks of the program. The system of tasks associated with the creation of signs and symbols, and operation with them, was presented in all subsequent topics. Main feature of the tasks of the program is that they are all represented by drawings, signs, and symbols, with very little use of the verbal text. Drawings are used not for illustrative function, and they are the material for the formulation of the task, the implementation of children's activities (analysis, decoding, etc.), presenting the results of actions, i.e., symbols and signs are used for different functions. Presentation of tasks in symbols and signs on the material of all kinds of pictures, charts, and tables, using the same notations, makes the task clear for everyone, including children, poor in reading or not reading at all. In addition, the visualization allows to individualize the pace of the child tasks, which is especially important in the early stages of learning. The program uses symbolism created by children, with a gradual transition to a socially accepted symbolism. An important thing is that signs and symbols are included in work for the solution of practical problems (they are used for the solving of mathematical tasks, language tasks, arts acquaintance, etc.).

The main skills introduced in the program that are necessary for mathematical concepts are one-to-one correlation, the effect of the measurement using a label for the recording of the results of measurement and comparison, and relations being "more-less" and "equal, not equal" equalization of units. The process of mastering the course content is based on a psychological theory of gradual formation of mental actions (Galperin 1976), according to which the assimilation of new knowledge must begin with the operations with real objects, or their substitutes, and their subsequent transfer by means of signs and symbols in mental plan. For the organization of real objects, operation toys and real objects (buttons, beads, dolls, sticks, geometric shapes, and other objects that differ in shape, color, and size) are used (Salmina and Sokhina 1975; Salmina and Forero Navas 1994). Plot drawings and geometric shapes are introduced gradually. Attention is directed toward working out of a child's speech: group work with the sounded planning, pronunciation, and discussion of their own activities is used.

In accordance with the theory of the gradual formation of mental actions, learning is constructed in such a way that the finished solution approaches are not given; they are elaborated in a joint activity with an adult. The decision stands out as method that is applied to different situations and tasks. In each block of the program, children build and create not only methods to address the tasks but also the means (tables, diagrams, classifications, etc.). The consequence of all this is that the children do not memorize, but master necessary knowledge and skills during activities with real objects, diagrams, and symbols.

Chapter 20
Preschool Education in Ukraine

Roman Shyyan, Igor Shiyan, and Natalia Sofiy

Abstract The system of preschool education in Ukraine is described in the chapter: the legislation and policy, issue of coverage, the content of the preschool education, and some modern trends of development in Ukrainian preschool education are discussed.

According to Ukrainian legislation, preschool education is the primary stage of the whole structure of education system, while attendance to any preschool establishment of any jurisdiction, type, and ownership for children under 5 is not defined as obligatory and is granted to children at the parents' (or substitute persons) decision.

The content of the preschool education is regulated by three fundamental documents: State Law on Preschool Education of Ukraine, basic component of preschool education, and basic program of preschool education.

The basic component represents a certain compromise between acknowledgment of the necessity of following modern concepts of the quality of preschool education and traditional ways of work with preschool children.

Updating the content of education is gradually emerging in the traditional approaches. Since the mid-1990s, a significant impact on the system was provided by the programs of international organization "Step by Step." The other project "Learning to think" is implementing in Lviv and designed on the basis of Lev Vygotsky's doctrine.

Keywords Preschool education • Preschool education institution • Quality of education • Child development

20.1 Legislation and Policy

Preschool education[1] has been recently declared as one of the highest priorities of Ukrainian educational policy.

According to Ukrainian legislation, preschool education is the primary stage of the whole structure of education system, while attendance to any preschool establishment of any jurisdiction, type, and ownership for children under 5 is not defined as obligatory and is granted to children at the parents' (or substitute persons) decision.

The Law on Education[2], (1991) states:

Article 33. Preschool Education

Preschool education and training shall be carried out in a family and preschool institutions in cooperation with a family and shall be intended to ensure physical and psychological health of children, their comprehensive development, obtaining life experience, and acquisition of abilities and skills necessary for their further education.

Article 34. Preschool Educational Institutions

1. Preschool educational institutions shall include nurseries, kindergartens, nursery schools, family, promenade, preschool institutions of compensative (for children who require correction of physical and mental development) and combined types with a short-term, day, and full day stay of children, as well as kindergartens of a boarding school type, children's houses, and others.
2. Admission of children to preschool institutions shall be made according to the wish of parents or persons substituting them[3].

The Law on Preschool Education of 2001[4] defined preschool education as an obligatory primary component of the system of continuous education and listed three options to fulfill that obligation: family, institutions, and individuals. And only in 2010 amendment regarding an obligation to attend to preschool institution was adopted[5]. All Ukrainian citizens have the right to receive preschool education in preschool educational institutions as well as in the family or with proper individuals. The law describes preschool education as a wholistic process that should provide children with comprehensive development in accordance with their inclinations

[1] Doshkilna osvita (дошкільна освіта) is the term related to the system of education of children of age 3–7 which corresponds to "early childhood."

[3] The Law on Education of Ukraine http://planipolis.iiep.unesco.org/upload/Ukraine/Ukraine_Education_law.pdf

[4] The Law on Preschool Education in Ukraine. http://zakon4.rada.gov.ua/laws/show/2628-14

[5] The Law of Ukraine On Amendments to Legislative Acts on secondary and preschool education on the organization of the educational process http://zakon4.rada.gov.ua/laws/show/2442-17

and their individual, intellectual, and physical capabilities and cultural needs. According to the law, preschool educational institutions should ensure the physical, intellectual, and spiritual development of children and their social adaptation and readiness to continue their education. Preschool-age children include infants and junior, middle, and senior preschoolers.

The issue of state guarantee for accessibility of preschool education is controversial. The Constitutional Court finds[6] that “the provision of accessibility and gratuitousness of preschool education is assigned to the state only to the extent related to educational institutions of state and municipal ownership forms (Article 53.3 of the Constitution). In accordance with Article 3.2 of the Law ‘On the preschool education’ the state only renders assistance to the development and preservation of the preschool educational institution networks of other forms of ownership.”[7] In terms of “ensuring by the state of the opportunity to exercise the right of individuals for education,”[8] it means that preconditions for unequal opportunities for children in their preparations in their preparations for school exist.

As it is emphasized in a recent National Human Development Report[9], nonattendance of preschool education institutions (PSEIs) or any reason or attendance of an overcrowded PSEI limits a child’s important starting opportunities. Education of preschool-age (5 years old) children not in family, which became obligatory from 2010, is especially important to ensure an equal start in school. In the light of the shortage of places in PSEIs, general secondary educational institutions provide education to children of preschool age through special groups. In some instances, children visit traditional PSEIs temporarily (for a few hours). Almost 40 % of childcare institutions are located in modified and adapted buildings and therefore do not have the necessary infrastructure. Private or privileged institutions as well as third option mentioned in the Law on Preschool Education – proper “physical persons” – remain unaffordable for the majority of families.

A central place in the curriculum of preschool education is occupied by activities aiming at developing children’s moral qualities and aesthetic tastes and strengthening of their health. With older children more attention is paid to the development of their abilities, memory, thinking and language skills, etc.

A variety of preschool institution types is listed as nurseries, nursery-kindergartens, kindergartens, and school-kindergartens (the latter mainly in rural areas). Other institutions providing preschool education include orphanages, nursery-kindergartens of compensating type, kindergartens of a boarding-school type, nursery of a family type, child development centers, and orphanages of family type. Preschool educational institutions must be licensed. The average workload for children is 15 lessons per week (each lesson lasting 30 min).

20.2 Issue of Coverage

Coverage of relevant age children with preschool education[10] during the last decade of the twentieth century decreased in more than 2.5 times (from 2,428,000 in 1990 to 968,000 in 2001). Thus in 2001 the lowest level of coverage was reached. It was the only a year with less than a million children involved into preschool system. Subsequently, till 2004 the bottom line was reached for PSEI network, which was cut by 39.2 % (14,900 entities vs. 24,500 in 1990). A number of available places during the same time decreased from 2,277,000 to 1,040,000. In 2001, only 90 out of every 100 places available in the nation's preschools were filled, showing a reverse tendency compared to a ratio of 107:100 recorded in 1990. This ratio had dropped to 76:100 in 1995 and was about 70:100 in 1996–1998, while the number of children per teacher remains close to 1990 levels – 8:1 vs. 9:1. This implies that the actual teaching load has been reduced. In 2003, the number of children in preschool showed growth for the first time in 2 years. Enrollments rose by 5,000, pushing the proportion of such children up by 4 % and making it now 45 % of all children in that age group.

Decreased enrollment rates in preschool programs in Ukraine are mainly related to the consequences of the socioeconomic crisis in the 1990s, lower birth rates, and, as a result, a sharp decline in the network of PSEIs (Millenium Development Goals. Ukraine – 2010. National Report. Kyiv, 2010[11]).

The reduction of the network of preschool educational entities was caused by birthrate decreasing naturally followed by decreasing preschool-age children population. It was complemented with the abovementioned negative dynamics for coverage of children from relevant age group. Experts explain this tendency by several interrelated socioeconomic factors, such as the fall of production leading to transfer of preschool establishments to subordination of local self-governance authorities, which were not able to ensure their sufficient funding; general lack of budget resources for education reflected also at preschool level; low income of many families not allowing them to pay preschool fees; and high youth unemployment rate, particularly among women, not encouraging young families to send their children to preschool establishments. Another factor that encouraged parents to keep children at home was the Law on Public Assistance to Families with Children adopted in 1992, according to which financial support equal to the legally defined monthly living minimum for childcare was provided for families with limited incomes (but only until the child was 3).

The Multiple Indicators Cluster Survey 2005[12] found that 58 % of the children aged 36–47 months were attending early childhood education, and in the case of the

---

[10] Percentage of preschool children is calculated as the ratio of the number of children in preschool to the total number of children of appropriate age at the beginning of the year following the reporting one.

[11] Millennium development goals. Ukraine – 2010. National report. http://www.undp.org.ua/files/en_5521MilleniumDevelopmentGoalsReport2010.pdf

[12] Multiple Indicators Cluster Survey 2005. http://www.childinfo.org/mics3_surveys.html

children aged 48–59 months, the percentage was 67.2 %. About 65 % of the 6-year-olds attending the first stage of primary education had attended a preschool program the previous year.

The increase of children's involvement in preschool education in recent years is the result of the introduction of different forms of preschool education provision, such as full-time or part-time groups, multi-aged groups, play groups, consulting groups, compensative groups (specialized and sanatoria based), social rehabilitation groups, and development groups and centers at preschool educational establishments.

According to the Ministry of Education and Science in 2008, some 8,700 preschools were in rural areas, enrolling about 221,000 children. According to the State Statistics Committee, by the end of 2009, there were about 15,500 preschool education institutions (6,700 in urban areas and 8,800 in rural areas), of which some 1,100 were not in operation. The total enrollment was about 1,214,000 children (of whom 307,000 children in rural areas), representing 56 % of the children in the corresponding age group (68 % in urban areas and 33 % in rural areas) (State Statistics Committee 2010).

The Ministry of Economy reports that in 2008 the net enrollment ratio at the preschool level (children aged 3–5) was 88 % in urban areas and 47.6 % in rural areas. Overall, in 2008 there were 15,400 preschool institutions in the country (of which 1,200 were not operational) with some 1,195,000 children enrolled, representing 57 % of the children in the corresponding age group. (Ministry of Economy 2010)[13].

In the 1990s, almost 40 % of state-funded PSEIs were closed down, a significant number of them in rural areas, owing to the collapse of collective and state farms that funded those bodies before. As a result, 44 % of school-age children, including 33 % of children in rural areas, did not attend PSEIs in 2010. At the same time, in some rural regions, PSEIs are half empty. A number of factors contribute to such low enrollment rates: aging of the rural population, excessively high costs for rural inhabitants of placing a child in a PSEI, and traditions of bringing up children at home before they attend school. However, a significant share of children from rural areas cannot even attend these institutions as they do not exist – 71 % of villages with school-age children have no PSEI. In urban areas, there is a shortage of childcare places, from 113 in 1990 to 123 children per 100 spots in 2010.

To get a more objective appraisal of the preschool situation, it makes sense to study 3-, 4-, and 5-year-old children enrolled in preschools but the state statistics agency does not operate with this kind of data.

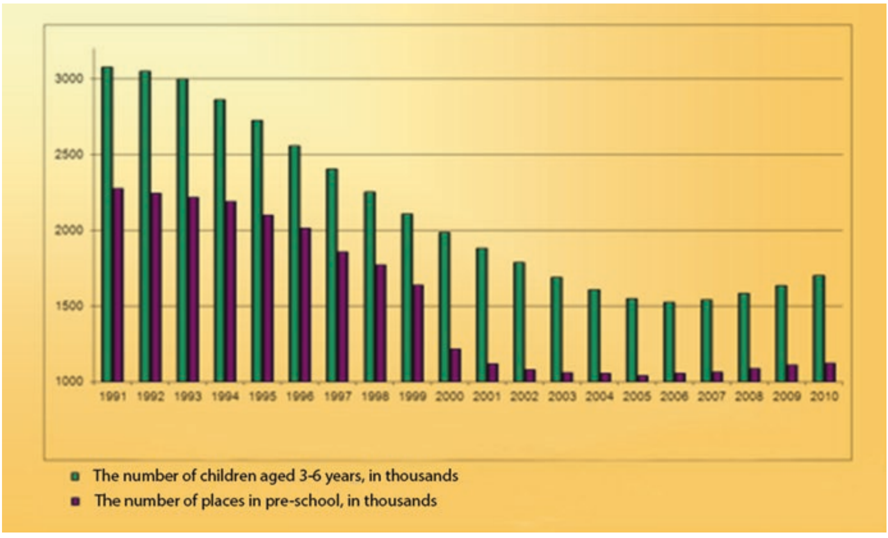
Millennium Development Goals (MDG) working group decided to change indicators for monitoring progress on the goals relevant to preschool enrollment measures. Indicators for monitoring progress on the goal's achievement, set up in 2003, inadequately reflect the situation in the education sector. Therefore, the matrix of indicators needs to be updated to take into account recent reforms in the educational

[13] Compiled by UNESCO-IBE (http://www.ibe.unesco.org/) World Data on Education, 7th edition, 2010/11

system. In particular, the net enrollment rate of children aged three to four in PSEIs and that of those aged five in PEIs should be combined but urban and rural data are separated: indicator 2.1 Net enrollment rate for children aged 3–5 in urban area and indicator 2.2 Net enrollment rate in rural area (see table below).

		2002	2003	2004	2005	2006	2007	2008	2009	2010	2011	2015
Indicator	1.2 (urban)	79.5	82.6	85.8	86.9	87.2	87.3	88.0	86.5	87.5	87.6	95
	2.2 (rural)	27.5	29.9	33.2	38.0	41.7	44.9	47.6	47.8	49.7	53.2	60

20.3 Availability of Preschool Education



The lack of available places in PSEIs and an absence of PSEIs altogether appear to be the most serious problems in some settlements. In response, some alternative solutions, such as short stay groups for children, weekend groups, family groups, child development centers, etc. have been implemented. In several regions of Ukraine, social and pedagogical patronage has been established.

However, the introduction of various forms of enrollment for children in preschool education (short stay groups for children, weekend groups, family groups, child development centers, etc.) remains a critical issue.

Problems of equal opportunities for all to access quality education, starting from preschool education, remain crucial. Quality of education is limited by problems of

staff, by retraining and teachers' skills, as well as by material, technical, scientific, and methodological issues in terms of providing education. Access to preschool education is problematic in big cities and in rural areas, whereas access to quality secondary education causes problems primarily in remote rural areas.

According to NHDR Conclusions[14], to further develop the preschool education system, it is important to ensure that the network of PSEIs is optimal and balanced enough to respond to the population's needs and demographic situation. In this direction, it is necessary to:

1. Increase the number of places within the PSEIs of communal property according to need and transfer ministerial PSEIs and those financed by collective agricultural enterprises to communal property
2. Develop the network of PSEIs of compensating and combined types owing to an increase in child morbidity and continue the development of child development centers
3. Strengthen scientific and methodological support to preschool education, update its standards, and introduce on wide scale a new generation of preschool education programs
4. Enhance functions of preschool institutions by introducing socio-pedagogical patronage by families who raise children of preschool age, including those with psychological impairments who, for different reasons, do not attend preschool institutions
5. Support the establishment of educational associations of "preschool institutions" – schools

20.4 The content of the preschool education in Ukraine

In accordance with the State Law on Preschool Education of Ukraine[15], the state standard called the basic component of preschool education has been established. The basic component determines state requirements as below:

To the level of development and social training of the preschool children.
To the conditions allowing those requirements to be met.
Basic program of preschool education should be designed with regard to this basic component.
Content-related analysis of the relation of those three fundamental documents (State Law on Preschool Education of Ukraine, basic component of preschool education, and basic program of preschool education) helps one to discover main tendencies of current preschool education in Ukraine and evaluate possible route of its development.

The abovementioned law presents the requirements to the general content of preschool education:

- Formation of the basis of social adaptation and life competence of a child
- Development of the elements of nature-aligned vision and positive emotional and axiological relation to the environment and the world in general
- Establishment of emotional and value-conscious attitude to the practical and spiritual activity
- Formation of the necessity of realization of his/her creative abilities

[15] The Law on Preschool Education in Ukraine. http://zakon4.rada.gov.ua/laws/show/2628-14

Such a statement of expected results of preschool education definitely reflects European trends existing in Ukrainian preschool professional community, the focus on positive experience of the childhood, acquirement of life competences, and development of creativity.

These requirements should be implemented in the framework of the state standard (i.e., basic component) and therefore, in the basic program of preschool education.

Let us look at the documents more closely.

There are seven main lines defined by the basic component:

Personality of a child
An individual in the society
The child in the natural environment
The child in the world of culture
The play of a child
The child in the sensorial and cognitive space
Speech of a child

Firstly, we should mention the preamble of the document naming expected educational results in the competence aspect.

Educational line called “Personality of a child” contemplates formation of positive self-concept, development of arbitrariness, independency, and responsibility by the end of preschool age.

The content of the line “A child in the society” is focused on the development of ability to orientate in the world of human relations, formation of the interest to understanding of other people, joined activity with peers and adults and development of relevant skills, as well as on correct evaluation of his/her own abilities, on respect to wishes and interests of other children.

In the part devoted to “A child in the natural environment,” one finds guidelines concerning emotional and axiological and responsible ecological attitude to nature.

Educational line named “A child in the world of culture” presupposes formation of aesthetical perception, acquirement of various objective and creative activity, positive motivation for achievements, development of the interest in products and process of artistic and practical activity, and formation of the culture of consumption.

The line called “Play of a child” is devoted to development of artistic capabilities, leadership, initiative, and independence. This educational line is meant to provide meeting of playing preferences and bring along friendly relations, partnership, and exchange of thoughts and also promote child’s improvization.

The goal of the line “A child in sensorial and cognitive space” is formation of representations, concepts, and models reflecting features, characteristics, and relations of different objects of the external world, as well as the ability to implement those models in activities. It is supposed that this formation results in development of thinking, research skills, elementary mathematical concepts, and competent behavior in everyday life.

The "Child's speech" is dedicated to acquirement of the culture of communicative speech and the rules of usage of language in different situations. Here the speech is regarded as a mean of cognitive development.

Each educational line included in the basic component will lead to generalized result of educational work, the document says, – which means formation of certain type of competence.

We do not consider the lines described above to be sequent and equal. They are divided in two groups: the first four lines are connected to different substantive areas of a child's development, and the last three are more about development of ways of acting providing the child with the opportunity to acquire those areas and formation of the competences mentioned there. Moreover, the most complicated line called "A child in the sensorial cognitive space" is simplified, above all, in the very name of the course.

Probably, those two aspects are the reasons why one can see domination of "formation of representations" over "formation of means" and "development of competences" in more detailed description. The following formulations are used mostly in order to describe performance of preschool education: "realizes," "wields the representations," "understands," "knows," and "distinguishes." On the one hand, competence-based results are defined for every area, but on another hand, the means and ways of their formation are not stated in supposed content of each educational line. For instance, it is not clear how the "sensorial cognitive competence" appears on the basis of acquirement of sensorial models and on which content cognitive competence should be grounded.

From our point of view, the basic component of preschool education represents a certain compromise between acknowledgment of the necessity of following modern concepts of the quality of preschool education for the professional community and traditional practical content and ways of work with preschool children, established long ago. We regard the variative part of the component as a compromise, too. This part proposes four additional educational lines which are IT skills, foreign languages, choreography, and chess.

This compromise results in "Confident start,"[16] the basic program of preschool education. This program consists of seven parts devoted to physical, cognitive, artistic, and aesthetical development and the development of speech as well as to play and labor activity. The program is almost totally focused on formation of knowledge, abilities, and skills in different areas. The only partial exception is the part describing the play motivating parents and teachers to promote development of play activity. The authors of the program prefer description of traditional kinds of activity implemented in kindergartens to conceptual design of the mechanisms of child development and ways of interaction of children and adults.

This basic program mostly preserves traditional ideas on the performance in preschool education instead of becoming a tool of its development. The moving force of such a development can be represented by alternative, partial, and

[16] Confident start. The basic program of preschool education in Ukraine. http://old.mon.gov.ua/images/files/doshkilna-cerednya/doshkilna/progr_rozv/1.pdf

experimental programs[17], designed on the basis of stable conceptual ground and with the view of modern understanding of development, opportunities of the preschool age, and performance of preschool education.

20.5 Some Trends of Development in Ukrainian Preschool Education

Along with many countries in the world, Ukraine has set ambitious goals to achieve: to increase both quantity and quality of early childhood development and education provisions for young families and their families. The rationale behind these goals is based on economic, as well as neurobiological, educational, and social arguments. At the individual level, early childhood experiences have been recognized as a key factor in building strong foundations for learning and successful participation in community throughout the life; at the societal level, this period in the life of the child and family plays a crucial role in promoting inclusion and strengthening social cohesion; from economists' point of view, the best return of investment comes from investments in the early years.

Updating the content of education is gradually emerging in the traditional approaches. Introduction of modern methods is often supported by partners from abroad. Since the mid-1990s, a significant impact on the system was provided by the programs of international organization "Step by Step." The network of "pilot" preschools was organized with the aim at the implementation and spread the idea of democracy in preschool education, involving families and communities to participate in the education of children.

20.6 Ukrainian Step by Step Foundation

Ukrainian Step by Step Foundation (USSF) is nongovernmental organization in Ukraine, which shares the vision of early childhood as a life space where educators and families work together to ensure access to early childhood services that promote well-being, development, and learning for each child based on the principles of democratic participation. Since 1994, the Step by Step program, an initiative of the Open Society Institute (OSI) strongly supported by George Soros, has been a symbol of change in the preschools, primary schools, and communities of Central, Eastern, and Southern Europe and Central Asia. It has been a symbol for empowering educators and other early years development professionals, families, and whole communities to support the development and learning of each child to his or her full potential. Equal access to education ad care opportunities, child-centered,

[17] About the creation of the programs on preschool education. The Ministry of Education and Science letter № 1/9–152. 28.02.2013 http://osvita.ua/legislation/doshkilna-osvita/34830/

individualized teaching, a holistic approach to child's development, inclusion, the significant role of parents and community involvement, and culturally appropriate learning environments and approaches have been the core principles of the program from its very beginning.

USSF is a national member of the International Step by Step Association (ISSA), which was established in 1998. One of its first activities was the development of the ISSA pedagogical principles. Educators that make a difference can be unofficial title of those teachers receiving the ISSA certificate of excellence based on assessment, using the ISSA pedagogical principles.

Being recognized as a source of innovation in the region, ISSA and USSF have always promoted professional discussions and encouraged educators, program managers, educational authorities, and other stakeholders to follow the development in the field and changing the situation and needs in the region. Establishing of ISSA pedagogical principles was an important step to demonstrate that the definition of quality and the way to improve it in practice is not a statistic, easily decided issue with one correct answer. The quest for quality is built on lively exchange of knowledge, experiences, and dispositions of all involved stakeholders. Competent Educators of the 21st Century: Principles of Quality Pedagogy document, developed by ISSA, encourages professional discussion, builds and expands the partnerships, helps to improve the practices, and brings change into the lives of young children in the countries of ISSA, including Ukraine.

There are a lot of discussions about quality of preschool education. However, what constitutes high quality in education still remains a complex, multifaceted matter, which includes structural conditions (e.g., group size, adult/child ratio, etc.), as well as a process factors (e.g., sensitivity of the adult, quality of interactions and curricula, etc.). Unfortunately, the language of quality, as well as initiatives and policies, sometimes creates unintended consequences as they legitimize the proliferating maze of regulations in early childhood education and often undermines, instead of providing support, professional autonomy. USSF enters this discussion from the point of view of a practitioner working with young children on a daily basis. Through its quality initiatives and pedagogical principles that describe quality practices, USSF has promoted the crucial role of the practitioner. We argue that while there is a solid amount of research findings, quality is still a concept that needs to be explored, developed, agreed upon, and implemented according to the cultural background and needs of the learning community, rather than presented as a universal solution for all situations and people. USSF believes that democracy forms the foundation of the preschool, and for this reason, early years activities should be carried out in accordance with fundamental democratic values.

Competent Educators of the 21st Century Principles consists of seven focus areas that reflect ISSA's main beliefs about quality pedagogy and identify ways to aspire to excellence:

Interactions
Family and community
Inclusion, diversity, and values of democracy

Assessment and planning
Teaching strategies
Learning environment
Professional development

USSF believes these areas are crucial to ensure high-quality support for children's development and learning. The seven areas promote practices that are guided by humanistic and socio-constructivist principles, emphasizing developmentally appropriate practices, individualized approach, and the idea that learning occurs in interaction and is a dialogue between children and adults, as well as between children, which is marked by respecting each other, stimulating and giving autonomy to the learner, and assuming that children are competent citizens even while they need support from adults. ISSA's principles of quality pedagogy recognize and promote the important role of the professional as a knowledgeable, sensitive individual who guides and scaffolds children in their journey of exploration and learning and works in close partnership with families as the first teachers of their children and communities as a natural resource for learning and inquiry.

In recent years, the Ukrainian Step by Step Foundation has been implemented in collaboration with Fontys University (Netherlands), a project aimed at the development of professional competencies of educators and leaders of preschool institutions (covered about 1,000 participants from each target group).

20.7 The Program "Learning to Think," Lviv, Ukraine

One of the projects focused on the development of new content and methods of early childhood education is implemented in three preschools in Lviv in collaboration with the Moscow City University and Moscow State University in Humanities. The main aim of this project is development of thinking in preschool children and implementation of the new methods of teaching and professional development of the preschool teachers.

Experimental preschool program implemented in the framework of this project has been designed on the basis of Lev Vygotsky's doctrine on development of higher mental functions and on psychological means of this development[18].

This program is focused on development of dialectical thinking (N.E. Veraksa) of preschool children and its application for solving controversial situations and productive creativity. The authors regard dialectical thinking as a system of dialectical mental acts[19]. Experimental works have confirmed the possibility of activation of dialectical thinking at the preschool age. Dialectical mental acts are formed and

[18]Vygotsky L.S. Mind in Society: The Development of Higher Psychological Processes. Harvard UniversityPress, 1978. 159 p

[19]Veraksa N.E. Structural approach to dialectic thinking. 14th International Conference on Thinking, 2009–210 p

used by children while discussing fairy tales, exploration of wild and inanimate nature, etc. Dialectical visual scheme appears to be one of the means of dialectical thinking.

Collaboration and work with preschool teachers is a special part of the project. During the seminars and webinars, the main emphasis is put on the development of professional reflection, the ability to work in the zone of proximal development, the creation of problematic situations during the lesson, and the ability to challenge children.

One of the methods used in the framework of seminars for the teachers is a group discussion on the video records of their lessons, planning of the next steps on the way of interaction between children and teachers.

The inertia of the system of training and in-service training of preschool teachers limits the spread of the new “child-centered” philosophy of early childhood education. Educational technologies and new content, developed in innovative projects, are implemented just partially.

The idea of education for life (lifelong learning) forms the basis of European education policy, forcing a new look at the importance of preschool education for further development. In this regard, the relevant competence development of teachers of preschool education is becoming a critical problem of educational policy in general.

Chapter 21
Pedagogical Center "Experiment": The Peculiarities of Preschool Education in Holistic Developing Education (HDE)

Bronislav Zeltserman, Margarita Dubina, Margarita Dragile, Maria Pekarskaya, Irina Maluhina, and Inta Baltina

Abstract The article represents best practices and inventions of preschool developmental approach in content, technology, and educator-child relationship carried out in the Educational Center "Experiment." It is based on the main principles of the holistic developmental education (HDE) having its ground in the theoretical teaching of L.S. Vygotsky, B.D. Elkonin and V.V. Davydov.

The article covers the following themes and issues: (1) particularities of the psychological guidance of the students as well as training of psychologists and educators. It presents some examples of learning tasks from lessons on math and logic for preschoolers.

This material is of a methodological character and is rather a recommendation for educators and psychologists working with preschool-age children.

It is highly recommended especially for those educators and psychologists who are interested in professional development, as well as in implementing innovational approaches for reaching netter qualitative results.

This could also be useful for parents, in order to organize a creative free time of their children or provide them with additional developing training at home.

Keywords Holistic Developing Education • Pedagogical center "Experiment" • Pre-school education

---

This chapter describes the peculiarities of preschool education in Pedagogical Center "Experiment," an authentic (authorship) school of Holistic Developing Education (HDE), situated in Riga, Latvia.

21.1 The Historical Context

Pedagogical Center “Experiment” was established in 1987 on the peak of discussions of the new school concept, which was developed into a project within the center during the next 2 years (till 1989). In the beginning the project was meant to be implemented within the school educational system, although already in 1989 new approaches were developed as an attempt to implement the concepts of the developing education system by Elkonin-Davydov for the preschool curriculum.

In 1991 the first class was formed mainly from children, who, at the age of 5, came to the studio of development by Pedagogical centre “Experiment.” In 2002 this class graduated after 12 years of school education. During the period two preschool institutions were run by the Pedagogical centre “Experiment” at the same time: the studio of development (for children from the age of 2 to 7 years old) and the kindergarten groups. At the beginning the main aim of working with preschool children was to prepare them for the developing education school; consequently, it had become the basis (core) of the preschool education.

The background for the process of development of new approaches and the implementation of the new content was the serious shifts of Latvian education system, which partly consisted of changes in public preschool and school education curriculum and standards, and transition from education in Russian to the state language. Moreover, the specification of Latvian inner policy also had its impact: the implementation of new approaches took its place during the period of general transition of the public preschool and school education system toward the Western standards, though, meanwhile, it had been changing its direction several times. Some of these changes related to the preparatory school and other innovations did not fit into our pedagogical and psychological perception of preschool-age children’s development.

Despite the fact, during the time period of formation and implementation of the Holistic System of Developing Education, we have successfully established institutions based on the main concepts of Russian psycho-pedagogical thought and Russian language.

The institution provides education for children of the age 15 months till 3 years old, as well as training for competence improvement for educators and psychologists.

The experience of establishment and development of the Pedagogical centre “Experiment,” especially of its preschool education, had proved that if the education system is grounded in main philosophical, scientific, and psycho-pedagogical ideas, high-quality results could be achieved, despite any outward circumstances. The outstanding achievements of personal and professional becoming of our graduates, who already are holding degrees from Latvian or any other universities of Western or Eastern countries, provide clear evidence that the stream of the developing education, emerged in the 1980s, had its scientific basis, methodological support, and successful implementation.

The system of HDE and its implementation are based on:

– Theoretical concepts of scientific school of L.S. Vygotsky (Выготский 1984, 1996; Veresov 2004);
– Theoretical, psycho-pedagogical, and methodological formulations of the system of developing education by B. D. Elkonin-V. V. Davydov (РОЭД or Developing Education by Elkonin-Davydov (DEED) (Давыдов 1996, 2000, 2005; Щедровицкий 2005; Эльконин 1989);
– Concepts of systematic thought activity (STA) methodology of G. P. Shchedrovitsky and STA pedagogy (STAp) (Акопова, Иванова 2006; Щедровицкий, Розин, Алексеев, Непомнящая 1993; Щедровицкий 2015);
– Conceptual foundations of preschool developing education project "Tropinki" ("Paths") by V. T. Kudryavcev (Кудрявцев 2007; «Стандартизация» дошкольного образования: путеводные звезды и подводные камни. http://obruch.ru/index.php?id=8&n=76&r=2);
– Author's developments by educators of Pedagogical Centre "Experiment" (Зельцерман 2007, 2002; Зельцерман, Рогалева 2000).

The fundamental difference between traditional and developing education, implemented in the Pedagogical centre "Experiment," is described by V. T. Kudryavcev (Kudryavcev, 2007): "The diagnosis for the traditional preschool education, formulated by B. D. Elkonin and V.V. Davydov, fairly enough describes the traditional preschool curriculum. The content and form of educator's work used in traditional early years education system are not relevant for development of children, because in their essence they are copying the experience that children had already (or were supposed to have) acquired through their everyday activities."

The chapter is based on best experience and practices of methodologists, psychologists, and educators of the center that reflect the developing approach toward content, technique, and relationship with children implemented in preschool education within the Centre "Experiment".

The following would be presented:

(1) the psychological and pedagogical grounds for developing practice (2) certain fragments of methods/instructions of exercises and abstracts of notes from classes and (3) several parts of transcript of classes or exercise

Before describing the practical aspect, we would stop on peculiarities of training for educators and psychologist working in preschool system of HDE.

21.2 Training of Psychological and Pedagogical Professionals

In order to fulfill its duties within the HDE system each educator is ought to participate in a certain advance professional training course to get acquainted with the peculiarities of the system. Moreover, in addition to the basic psychological and

educator's training and understanding of the fundamental doctrines of developing education system, each educator should possess performing skills and a good sense of humor in order to work in the system of HDE. It is necessary first of all because of the technology of the HDE, which perceives the participants of the education process as equal parties (student-educator). An educator should not pass his knowledge to a child, but to play a game with him, during which he would be able to receive new knowledge, tools, experience, etc.

21.2.1 Projecting Study Sessions as Project Workshops

Educators, working in various fields and with different age groups, are taking part in this kind of workshops together. During these workshops common issues of preschool group development are being discussed, and a holistic system of assignments/classes for creativity promotion, or work in pairs or groups, which individual educators systematically implement during their teaching time, is being developed.

The approach of exploring and zooming of an assignment would be described further on by an example of such tasks as "A boy and a drawing easel," "fairy tales," etc.

Another important aspect of these workshops is the development of inter-subject (cross-curriculum) classes, aimed for acquiring communication and group work skills in different age groups (4–6 years old). Leading educators of different similar fields, i.e., math-logics-science (the development of cognitive activity) or dance-music-sport-visual art, are participating in projecting and implementing these kinds of study sessions.

It is also possible to combine other study disciplines, if it is essential for reaching the aim of an educator while working with a certain group of preschool children.

A special attention is drawn to the use of various fragments of STA pedagogy for interdisciplinary classes' development, for an educator ought to have a clear understanding of correlation of aim of his class, psychological and pedagogical challenges, technology, and peculiarities of age psychology.

It is necessary to mention that the principle of "project workshops" applies not only to educators' teamwork on development of interdisciplinary classes but also to individual development and projecting of author's programs of developmental education.

In this case the approach of "master-apprentice," when "a young" (less experienced) educator is working on a project together with "a master" (more experienced educator), is used.

21.2.2 Workshops on Video Analysis of Lessons

During these activities psychological and pedagogical situations of a study session are being discussed in details.

It is an obligatory procedure for any new educator or any new approach for acquiring a competence or for usage of any new technology or an innovation developed in project workshops.

During the workshop on video analysis, extra attention is drawn to the analysis of the lesson's project (its aim, challenges, technology, and planned results), as well as to the actual psychological and pedagogical situation in the class itself. Actions and behavior of an educator and technologies he used are the subject for the analysis, as well as the process of new competence acquired by the students.

A psychological and pedagogical reflection is following the analysis, its goal is to detect the deficits of theoretical approach or model of the study session, and after another interaction a new concept of the study is being developed.

Each educator of HDE system should know the fundamental elements of systemic thinking activity (STA) pedagogy, including the peculiarities of organization and participation in communication, identification of own understanding and correct understanding by the conversation partner, self-reflection and reflection of the others.

During the special training, special attention is given to the acquiring of the competences mentioned above by the psychological and pedagogical professionals.

Only after pedagogical and psychological training educators are granted rights to develop and implement individual author's educational projects and developing games. Thus, a transparent program of visual art (from 3rd to 11th year), creative and intellectual extracurriculum events, etc. were created.

21.3 Psychological Guidance at Preschool Education Level

One of the main peculiarities of the HDE preschool education system is the psychological guidance, which purpose is to provide a psychological support for the subjects, children from 1 year old and educators, during the educational process. It is worthy to mention that the main feature of our psychological accompaniment is that it applies not only to the problem solving within the study process but also provides the management of psychological aspects of education. This kind of management demands a special training for both educational parties, children and educators, on psychological problem solving and personality development. In this case a psychologist is acting as an expert and an advisor.

The object of the accompaniment is the educational process, while its main subject matter is the situation of child development, which is understood as a system of child's relationship with the outside world, his parents, fellows, and himself.

The content of this article is the link from a diagnostic and correction of psychological difficulties to the management of the psychological aspect of the education. The main feature of this approach is the projecting of an activity (Зельцерман, Рогалева, 2000). Thus the first stage of working with a preschool group is the activity diagnosis of a group and individual development of children. The next step is the group division, according to the psychological peculiarities of the individual development situation of each child, based on the results of the diagnostics. This kind of

group division allows to set challenges and to find appropriate approaches for further developing activities in the group.

The desire to work in different groups and its skills are being developed in this kind of psychological activity.

During our classes children are playing various games. The search for the purpose of the game becomes the key aspect of development, which further allows the players to set their own challenges. Thus playing “the train” children of an elder age group define the purpose of the “interesting” game as an opportunity to learn “how to play together” and also “being sensitive to one another.”

21.4 From Socializing to Productive Communication

The shaping of socializing and communication skills takes a special place in the HDE system for preschool education.

Learning of socializing and communication technology is a common meta challenge, i.e., they are universal for any situation of interaction of a preschool-age child both within and outside the study process.

A program for preschool-age children support in the field of social interaction (“the ABC of socializing”) was developed for the preschool education level.

This program allows to guide a child into the sphere interaction, by forming the motivation for socializing, intention for communication, and necessity for socializing, thus removing the problem of child’s adaptation (localization) in the new social world, which expands rapidly for a preschool pupil.

At the early stage of development, it is his family (a mother and a father); later on as he grows up, the sphere of socializing expands to his fellows, new adults, new social conditions, and relations with other people.

Thus during the first classes, children are facing a situation of getting to know other children and their educator. The educator suggests that every child should say his name and that the others would name him in a gentle name. This way a child not only receives an opportunity to get familiar with other children and to memorize their names which are new to him but also to acknowledge (to realize) his own name, which he is able to harmonize, as well as to receive a new experience of socializing in an unfamiliar situation.

Besides the gaming acquaintance with new social world, during the classes a child receives a sense of belonging to a group and forms a positive attitude toward himself and other fellows, which enrich his emotional content. Moreover, these activities develop his skills of social behavior and culture and promote an ability for empathy and compassion.

For example, a game “an animal piano” awakens the sense of belonging to a group, attracts child’s attention to consciousness and comparison of his own emotional feelings, and develops the skill for interaction with other children.

In this game children are sitting in a line imitating the piano keys, which sound as different animal voices. During the activity an educator plays a role of a pianist, and he gives each child its piano key with a certain animal sound. When he presses a key, it should sound as an animal it represents.

During the activities, the juniors also acquire a social experience of communication.

During one of these classes, an educator using toys plays a tale about two hedgehogs, who found a green apple, but could not decide whether it was sweet or sour. Gradually, their conversation turned into a dispute and further into a fight. Children are asked to name the hedgehog’s situation, to predict (foresee) its various consequences, and to solve it in the best manner (by asking questions like: “What is going on between the hedgehogs? What could happen if the fight would not be stopped?”). In the result of the activity, children find their own approaches for conflict resolution (e.g., solving it by letting the hedgehogs to taste the apple or tasting it themselves, describing the taste to the hedgehogs, etc.)

In the process of solving the study situation, an adult assists a child in applying known action patterns in a new context. Frequently a new approach is necessary for the situation resolution; thus a child is testing samples, guided by an educator, who also helps to evaluate appropriate and inappropriate solutions.

Usually it becomes essential for the children to exchange opinions.

One of the possible techniques for the discussion is work in pairs.

In this case an educator asks a question that everyone could answer. Children are trying to do it, and time is given for their negotiations. “Face one another, and if you know the answer, share it with your partner. If he agrees and is nodding, take his hand and show that you are ready to reply the question together. If he disagrees, ask for his opinion, for may be you are not right, and he could help you?”.

For further successful education in our system, already in the preschool age, children are taught to think independently, to discuss, and to stand up for their opinion, as well as to raise questions and to initiate the obtaining of new knowledge.

Consequently an individual work guided by an adult is not sufficient enough for the task; working within a group of children is essential.

A dispute among children offering different approaches for the problem solving is a necessary condition for primal questions toward an educator. But for the disagreement full of content, the bodies involved should be able:

To formulate its own point of view
To find out the opinions of the others
To distinguish between own and other opinion
To solve the contradiction by argumentation, avoiding placing the conflict on the ground of interpersonal relations

In order to establish the primary coordination of actions, the etiquette of fair dispute is introduced:

after expressing your own opinion, ask others: “Do you agree? Do you mind? What do you think?”

If all agree, you can act. If there are different opinions, ask one another: “why do you think so? Can you prove it?”

Here is an example of a work in pairs:

You have infront of you an image of a human being. this man performs an unusual job. Please try both, you and your partner, to negotiate and to dress this man in a particular uniform. Afterwards you will exchange your drawings with another pair and they would try to guess this person’s occupation.

The establishment of a creative dialogue is a necessary condition for any activity. As a common issue for an interaction, implemented in a joint activity of children, we would suggest assignments for imagination development.

In our system the unique dialogues are implemented as an equal dialogue between a child and an educator and also as a specially organized dialogue on creative activity among the children.

21.4.1 Teamwork

A teamwork is being arranged by using special recommendations developed in the center, which, according to the teamwork aims, include socialization skills and tools of STA pedagogy (Цукерман 2000; Щедровицкий 2005; Танцоров 1997).

Various approaches for team building are used to develop a facilitator’s skills, as well as to teach children to work in a group.

Groups (teams) could be formed according to the wish of its participants. Thus, the main aim of the team could be the creative result by the group facilitators.

By the group facilitators. Usually an educator picks up a captain among those children who already by the end of the preparatory training seem to have inclination for facilitation and who are respected by their fellows.

Children are being divided into the groups by playing “a mirror.” It is the most complicated way to do it. A leader turns his back to the class, while an educator points at one of the students. The leader calls out a number. This group is being formed randomly. In this case the main aim of the group is to organize a communication.

According to the gender, girls are in one group and boys in another.

The acquiring of teamwork techniques by children is essential here (Зельцерман, Рогалева 2000; Танцоров 1997).

21.4.2 The Imagination Is a Central in Mental Growth of the Preschool Age

Creative imagination is a central psychological “achievement” of the preschool age (L. S. Vygotsky, V. V. Davydov). Its formation during various childhood activities promotes the establishment of children’s mentality.

During the preschool developing education, it is being actively formed by the means of specialized preschool activities, such as games, various types of artistic creativity, perception of fairy tales, independent creative writing, etc.

According to the hypothesis of V. V. Davydov and V. T. Kudryavtsev, the unity of the productive imagination and creative thinking is the basis for continuity of preschool and school developing education (Давыдов & Кудрявцевб 1997).

Imagination could not be formed from time to time; it demands a constant work and special attention within the study process.

It is being highly emphasized within our system of HDE.

It is not the prototypes of education activity are developed at the preschool level, but its universal psychological suppositions. One of the key suppositions and a priority in developing preschool education is the developed productive imagination, which represents the core of the creative potential of a preschool child and is related to the theoretical thinking of a junior (Кудрявцев 2007).

Imagination is not only the central mental process of the preschool age but also it is a common feature of a consciousness, it is “a universal ability” (E.V. Il’enkov), and consequently it is a backbone (systematically important) attribute of a human personality.

Psychological and pedagogical literature uses different terms to describe the process of development of imagination. In recent years the term creativity is widely used for this purpose in Latvia, and in the chapter we would use it to describe the activity for development of imagination, ability for imagination, creative thinking, dreamwork, and creativity.

In the center we have gathered and systematized more than 300 activities for development of creativity. The selection includes the concepts of J. Ranzulli (Гатанов 1998; Crutchfield 1966; Renzulli 1986; Torrance 1965), O. M. Dyatchenko (Венгер, Дьяченко 1989; Дьяченко 2007), and V. T. Kudryavcev (Кудрявцев 2007), the development of imagination ability (Акопова 2005; Акопова, Иванова 2006), developing verbal games (Зельцерман, Рогалева 2000), and fantasy (Кудрявцев 2012; Родари 2011), which are all different in their technique and mentality, but share the common aim of development of creativity.

The selection is arranged into a system, which allows to use them during activities in any field of knowledge.

The selection “mosaic” consists of several types of tasks and assignments:

Complete the drawing.
Verbal associations.
New ways of using.
Construction.
Unbelievable situations.

During the activity “complete the drawing,” children are intensively involved into the “transformation of a blot.” “What do I see, while transforming a blot into a good/bright/beautiful/ …?”

Verbal developing games are being implemented during the classes for speech development and at the same time promoting not only the speech improvement but also the development of creativity. Fairy tales are the best way to practice both speech and creativity by using different assignments:

misquotation of a fairy tale,
copying a fairy tale,
a new version of an old fairy tale,
a fairy tale upside down,
as well as,
making up a new ending of the story,
creating a new middle of the story,
making up a new beginning of a story.
The game “Misquotation of a fairy tale ”
Aim: Development of imagination and speech.

Instructions:

You all know the fairy tale “The little red ridding hood”. Now listen how it could be told by an old man from J. Rodari fairy tale.

once upon a time lived a little girl, named a Yellow ridding hood.

It is not yellow, it is red!

Oh, you are right! It is a red ridding hood. Once her mother called her saying: “Dear Green ridding hood …”

No! She is a Red ridding hood!

Sure! She has a red hood.

“Go to aunt Dionmira and bring her potato peels …”

It is obvious that he had misquoted the fairy tale completely. Please also try to misquote the fairy tale, i.e., to tell it with some changes of events and names of the heroes or even by mixing them. Meanwhile, others should sit and listen attentively and should correct the storyteller.

The following well-known Russian fairy tales could be used for the misquotation:

A speckled hen
A palace (“Teremok”)
A ginger bread
A rabbit’s house
Gooses-swans
The three bears

The following assignments are used for different age activities as a warm-up procedure.

Instructions: the activity could be divided into several stages: during the first one, an educator turns to children with a question “What do you see while looking at the figures (a circle, a triangle, a rectangle, a curved line)?” (Fig. 21.1).

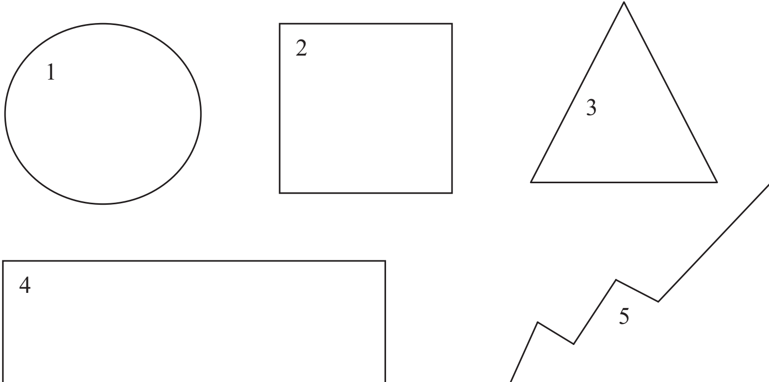

Fig. 21.1 Examples of figures 1

During the next classes, he might ask participants to complete the figure, or for advanced or elder group, he could suggest to make up something what no one else could draw.

This exercise is used for diagnostic.

Instruction: You have 2 min to draw a maximum amount of figures or to draw a comic strip (a cartoon) (Fig. 21.2).

This exercise is implemented within different age groups, and the sequence of assignments is based on the level of a group and its situation.

Instruction: Look at the picture, reflect for a while, and tell us what the boy is thinking about? If objects were able to think, what would be the thoughts of an easel, a sheet of paper, paints, a brush, toys, and birds behind the window? (Fig. 21.3).

All mentioned above gives a helicopter view of how various activities include exercises on various aspects of creativities being suitable for different age groups.

Some of the exercises are given to children of different age in a broader context, thus allowing us to follow the individual and group development dynamics.

Development of new activities for different age groups and knowledge fields is a special trend within the educator’s activity.

One of the main characteristics of the creativity development activities is the inclusion of elements of school education curriculum for the elder juniors, thus training them for the school studies.

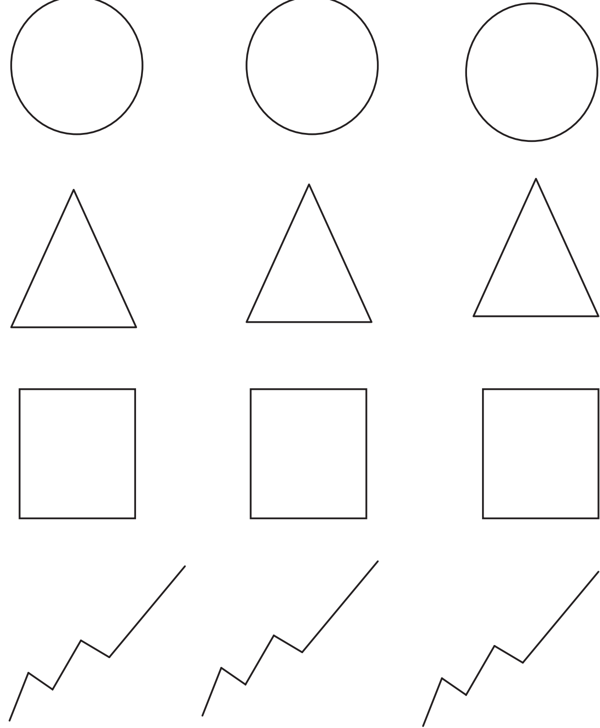

Fig. 21.2 Examples of figures 2

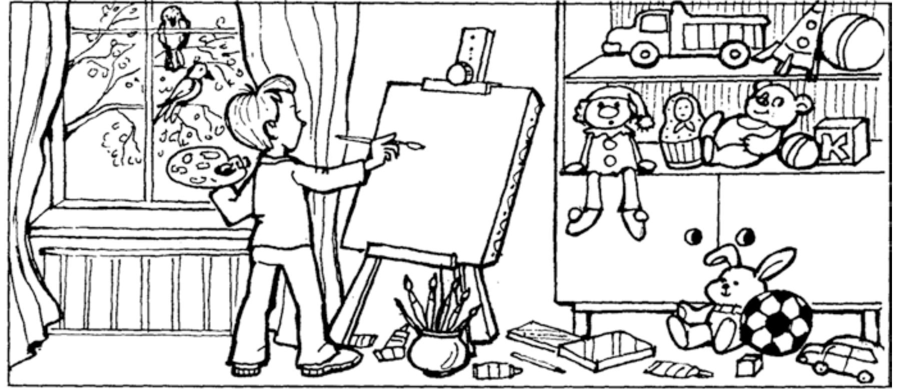

Fig. 21.3 What the boy is thinking about?

21.4.3 Development of Elements of Study Activity for the Preschoolers

One of the most important tasks is to develop certain technical procedures for introduction of study activity within different knowledge fields among the elder preschoolers.

Their aim is not only to facilitate the transaction from the preschool to school study activity for the elderly preschoolers, but it is mainly made to analyze psychological and pedagogical conditions, which allow to pass from play activity to the study activity and to teach "studying skills."

The ability to learn is an ability to self-transformation, implemented in a child's ability to put forward a certain aim for himself (this means that a child is able to acknowledge his ability limits), in his ability to find independently his own tools for problem solving, as well as in his ability to take a consequence of a certain steps and to acknowledge of its results.

The elements of study activity are being developed within a series of our preschool programs. One of these programs is the program for development of creative thinking, which includes various elements of study activity, such as planning, analysis of assignment conditions, action planning, modeling, control, and evaluation of self-taken activities.

Individual and collective forms of activities, as well as games, are being used during the program.

We would define the main approaches for development of study activity during classes:

– During the classes an educator is being attentive to formulate the assignment in such a way that he could test it if it was understood by the preschoolers and also that they would be able to transform it into an individual task.
– In all cases an educator is supposed to use various modes, modeling, and transformation by using various sign systems.
– Different types of work organization (work in pair or groups) should be used during an activity, in order to develop skills of productive communication among the preschoolers.
– For the course research assignments, various elements of research techniques of developing education should be used.
– Every class should end with an attempt to develop among the preschoolers an ability to reflect on the results of their thinking and activity.

The Evaluation of Understanding of an Assignment:

– Please draw in your notebooks a small triangle and a big circle under it. Now please add to the drawing several details in order to complete the picture. Please explain what it is and name it.

Action (or Story Plot) Planning:

Children, here are three images. Please look at them carefully and try to make up and to write down a story (you can ask you parents, who are present in the class, for an assistance). And now please tell us your story.

A Model Construction:

– Please imagine that today is a sunny day and it is a summer time (or a rainy day and it is fall time). Now please draw in your notebooks your desired activities during the season or weather.

Defining the Groups of Characteristics While Creating an Image or an Action

– Today we are going to fly to a fairy planet inhabited by children only. On this planet everything is meant and done for them. What do you think we can find there and how would it look like?

21.4.4 Evaluation and Self-Evaluation

Evaluation and self-evaluation are being formed during classes where the results of child's creative activity are finding their final shape in drawings, models, and texts.

Creative assignments have no wrong answers; all responses are accepted by an educator with a gratitude; he is to encourage a child for the independent evaluation of his own results, for an ability to see benefits and deficits of his work, for his courage, for fidelity to his principles, etc.

By implementing the approaches, one could practice various aspects of development of elements of study activity, such as planning, analysis of an assignment's suppositions, action planning, simulation, control, and self-evaluation. In this case a child's imagination and its development become the content.

All activities are developed preserving the main activity of preschoolers, thus learning through playing games.

21.4.5 The Peculiarities of Cognitive Activity Development

Our experience in working with pre-schoolers in HDE system proves that the development of the cognitive activity is the basis for successful studies at the school level. The organization of the study process within the school would not be effective if a child did not reach the appropriate level of cognitive activity maturity for his age group. Consequently, in our system of education, we start to develop the cognitive activity from the very early age of 1 year old, when mothers are required to transform their child's chaotic attempts to explore the surrounding world into a meaningful, thoughtful, and cognitive process. This approach is based on the peculiarities of the age-dependent development; for exactly at this early age, a child begins to show

curiosity for the outside world, seeing colorful objects, hearing different sounds, etc. This way a child acquires a primary orientation activity which is a physiological basis for the development of the cognitive activity.

Our main innovation in the development of cognitive activity among the preschoolers is the implementation of program "Together with your mother." In this case the aim of an educator is to transfer the approaches and tools for the development of child's main age-dependent peculiarities and skills, such as movement, sensor, inner speech, physical development, etc.

An activity with a different color pyramid is useful in this case. A mother is placing a pyramid in front of her child and draws his attention to the aspect that it has different colors. Rings of different colors, red, yellow, green, blue, etc., are being placed on a stick. A mother is to encourage her child to name the colors of the rings. If it is difficult for him, an adult provides an answer and asks from a child to repeat it after him. Afterward a mother encourages her child to place the rings in descending order on the stick. "Please show me the largest ring!" asks the adult and offers to place it on the stick. Further a child picks up another largest ring left and puts it on the stick. While collecting both a parent and a child name the color of a ring. As the result they create a pyramid, where in the bottom there is the widest ring and at the top the narrowest.

The development of cognitive activity begins at the early age by a child's interaction with different objects. This age-dependent peculiarity is taken into a serious account, while we are planning our developing activities with the early age group. During the activities children are learning how to differentiate shape, color, size of an object, as well as their quantity and orientation in the space.

In early childhood the cognitive development is build on the child's interest toward the outside aspects of the surrounding world.

Already by the age of 3 years old, a child is becoming more interested in hidden sides and connections of the world around him. It is a meaningful and active perception of the new aspect of the world; a child is taking his toys into pieces to investigate the unknown, he analyzes the objects and its purpose, and the more he finds out during the activity, the more he wants to stay in the situation of research and exploring. This consistent pattern is used during our classes and also for the individual child's playing activity. This developmental peculiarity enables us to create a field for research and experiment during our activities. Moreover it also enables a child to construct its own world view based on his own experience and observation.

At one of the activities, an educator presents a number of closed boxes to a group of children and explains that the three of them contain different objects, but one is empty. He asks them to find the empty box. He provides them with a clue of how to do it: "Shake the box to hear the sound." Children find the box that makes no sound, and thus the educator explains that "it means that it is empty." In the second part of the activity, children have to define the content of the box according to its sound. Which of the boxes contains a ringing bell or a rattle or stones? During the experimental activity, children learn that they can define the content of the box by the sound it makes.

According to our experience with preschoolers, using toys familiar to the child could also be productive. These kind of toys are used for playing activities for simulation of cognitive situations.

During the class the children are being visited by a familiar doll Masha and a teddy Mitya. The doll sees a mirror and wonders: “What is the shining object?”. A reply to the question could be given by children or by the teddy Mitya, who knows everything: “It is a mirror.” The doll goes on wondering: “Is it showing me?” “No,” replies a child or the teddy, “it is just your reflection!” Afterward, children are looking at themselves in the mirror, exploring the peculiarities of their appearance, and come to a conclusion that all people differ from one another.

By the end of the preschool age, it is possible to trace the features of self-consistency, self-control, and self-regulation of the cognitive activity within a child, which could be seen in his ability to set up goals, to find an approach, and to control the process of his activity and for an independent evaluation of his own result. The child begins to show his own initiative and conation in fulfilling assignments or in control of his own behavior. Our experience with preschoolers proves that at this age a child is already able to define his own activity and creativity, as well as to implement his own conation, interests, and necessities.

Elderly preschoolers are interested not only in the new object itself. Four-, 5-, and 6-year-old children want to know its structure, its purpose, its function, and its background. The cognitive interest becomes the motive for child’s manipulation with the object. This cognitive attitude is revealed in the peculiarities of childhood questions. A 4–5-year-old child always asks “why?” Thus an attitude of questioning the outside world is being developed. This age-dependent developmental peculiarity could be effectively used for activities arranged in a form of an independent research demanding from a child to explore its own way of fulfilling the assignment.

Two images obtaining two different objects are being presented to children during the class. One of the pictures contain the image with two kittens sitting by the table. There is a bowl on the table containing a branch of mimosa. The kittens are drawing a greeting card for their mother. Behind their backs there is a window with an icicle and the sun shining through it. The second image shows two kittens playing on the grass field full of dandelions. An educator explains that these two images are about spring and asks the group to name the features of the spring they see from the pictures. Children are usually surprised, because they see that the two images are completely different. They are divided into two groups in order to discuss and to find out the characteristics of the spring. At the end of the class, children discover that the images contain different stages of the spring season: at the beginning in March, the snow is melting and there are icicles and in the end in May, dandelions are blooming. Thus they reveal that each season consists of 3 months.

It is essential to mention that by the way of questioning and receiving an answer from his fellows or an adult, a child analyzes familiar facts and learns to generalize from the facts. Preschoolers are usually dismissed from any concrete problem specification, and thus they turn to its logical and generalized solution in their minds.

The most effective factor for the cognitive activity development for the age group is the providing of such conditions which enable a child to reveal himself as an actor of his own activity and his interaction with adult and fellows. The practical experience received enables him to acknowledge his own abilities, and this provokes his initiative in the cognitive activity and creativity.

21.4.6 The Development of Intellectual Abilities

Five – to – six year old children’s intellectual abilities are being developed by practicing various types of developing games:

Games developing manual dexterity by using methodological and didactic selections of Montessori materials (Материалы Монтессори n.d.)

Author’s development of verbal games consisting of various developing games, such as games for speech and speech skills development (Зельцерман, Рогалева, 2000)

“The Dragon” game:

For 5-year-old children.

Aim: To develop imagination and to form an ability to analyze information provided in the text and to use it for further development of its content and form.

Once upon a time there lived a bellicose rooster. He was very proud of his strong nib and sharp heels. Due to his qualities other birds in the yard called him a Bellicose. Every day he was offending someone by nibbing a duck, or by tearing a flock from a puppy’s tail, or by pushing aside hens from their meal bowls … The yard inhabitants were tolerating it for a long period of time. Although once they have gathered under the person and had decided to ….

21.4.7 Games for Mental (Thinking) Development

The cause game

Aim: To develop the ability to define cause-and-effect relations and to reflect them by syntactical structures, as well to promote open mind, creativity, and speech.

Instruction: Here I will describe the situation (an event that has already occurred), and your task would be to explain (or guess) why it happened.

An assignment for 5-year-old children:

1. A girl or a boy asked her or his grandmother for a forgiveness …
2. A boy or a girl got ill …
3. All birds flew away …
4. It is cold outside …
5. There is a rain of flowers …

The Link Game

Aim: To develop the ability to analyze and to make a synthesis, as well as an ability to define and to compare different characteristics of an object, and also to promote creativity.

Here I would bring up two objects. Your task is to find a similar object according to the similarities of one or more of its characteristics. It is a link between the two objects, e.g., a car and a spade. The missing link is an excavator (a digger), for it is a car and at the same time it is used for digging as a spade.

An assignment for 5-year-old children:

Shoes and an umbrella
Shoes and a rope
A printing machine and a calculator

21.4.8 The Development of Intellectual Abilities by the Means of Developing Computer Games

Already at the preschool level, computer technologies are being widely used by the center. Children of 3–3,5 years old are starting to learn how to use a computer. It is being used for learning of a selection of developing games, based on the methods of child's intellectual abilities' development and implemented as computer games (Зак, 1994, 1996).

Our long experience proves that the use of computer games and a process arrangement technique suitable for the age group provide the individualization of the development.

By playing computer games even at the early stage, a child realizes that objects on the screen are not real and that they are just symbols of the existing objects. It enables the development of symbolic function of child's consciousness, i.e., the understanding of different levels of the outside world as real (existing) objects, images, schemes, etc.

Computer practice provokes children's interest toward playing and consequently studying activity. This interest serves as a ground for development of such important structures as cognitive motivation, arbitrary memory, and concentration. All these features are essential for psychological (mental) maturity of a child to begin a study process.

The implemented approaches provide conditions for development of child theoretical thinking and problem solving:

Development of basic PC skills and spatial models and understanding of object characteristics (for 3–4-year-old children)
Development of abilities to comprehend the assignment, to question raising skills on the presupposition of an assignment and an ability to plan own activities, to analyze the results received as well as provide with skills for a constructive dia-

logue building, listening, and hearing the other (the partner), and to defend its point of view with arguments (for 4–6-year-old children)

A general approach for a problem description and an activity technique, from its collective problem review (explanation) for a group to individual guidance for typological problem solving, are methodologically tried and tested.

After the approach of problem solving is reviewed, explained, and written down on the blackboard, it is necessary to clarify to children the ways of “telling” the solution to the computer.

An educator has to show those ways on the computer while explaining.

All the solutions offered by the children, whether they were right or wrong, are being reviewed.

It is necessary to make sure that the child who had given an incorrect answer realizes his mistake.

Every child completes the assignment on the computer at his own pace.

If a child is experiencing difficulties fulfilling the task, an educator could provide him with clues by a chain of appropriate questions.

Starting from general questions (e.g., What could be the right solution? What has to be done?) and gradually going into the problem solving (What have you done so far? What should be done now? Is it possible to do it this way?)

At the end of the class, it is recommended to make a reflection (a feedback) on the activity, which should result in child’s comprehension of his acts and his record of understanding or misunderstanding.

For example, a developing game “how a caterpillar and an ant were visiting one another” (Зак, 1996)

Aim: To develop skills to explore statement of a problem and to plan and to control own activities.

To start the first activity one could say:

> once upon a time there lived a caterpillar and an ant. They loved visiting one another and also to riddle children. Today we will meet the caterpillar and we will try to solve some of her riddles.

The following drawing is to be provided on the blackboard (Fig. 21.4):

> Here is the house inhabited by: a Stick, Two Sticks, A circle and Two Circles. The caterpillar walks through the house visiting each of its inhabitants. To solve the riddle, you should always remember that the caterpillar walks by following straight lines only, i.e., it can move to a next square, up, down, to the right, and to the left. Here is the first riddle (Fig. 21.5).
>
> I, says the caterpillar, visited the Stick. Where did I go afterwards? What figure should we draw in an empty box? whom is the caterpillar visiting? The first square on the scheme above shows where the caterpillar was, but the second (the empty one) shows where she went afterward. Which figure we should draw in the empty square? Where did the caterpillar go to?

All children’s suggestions are being written down on the blackboard and later on discussed. If they wish, students could come out to the blackboard, in order to explain why this or that solution is right or wrong. The educator could move to

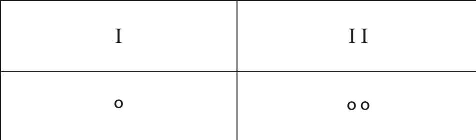

Fig. 21.4 Caterpillar riddles 1

Fig. 21.5 Caterpillar riddles 2

another type of problem solving, only after the educator makes sure that all children have understood the way of solving the previous problem.

Afterward, a student could move to the second and third type of the task resolution. In this case, it is known where the caterpillar has been and whom she had visited. A child should find the correct answer and mark it with ”+” or “-” if it is wrong. At the third stage, a child independently creates caterpillar's rout. There are similar tasks for an ant; however, he is not only able to move to the next cell but also diagonally. At the fourth type of tasks, the caterpillar and the ant act at the same time. This is a diagnostic to make sure if a child had accepted the rules of the game and if he is able to analyze the acts of the problem, as well as planning his actions for its resolution.

While solving the problem, an educator should watch the process and provide an assistance if it is necessary. He could help by asking certain type of questions: what is going wrong?, what should be done?, what are you doing?, why?, what are the rules?, etc., thus assisting a child to find his “own” solution.

By the end of the class, we ask children if:

They have learned something new during the activity
It was difficult to find the solution and why?
They have enjoyed the problem solving and why?

As result of regular activities of this kind by the age of 3–6, children are already able:

To accept and follow a study problem
To construct a discourse
To plan their activities according to the task given and the condition of its implementation
To include rules in their action planning and controlling
To compare, by choosing independently the basis and criteria for the logical operation

To correct their actions after its accomplishment, according to the evaluation and mistakes made
To provide argumentation for their position
To question (ask questions)

The main outcome of including developing computer games in the curriculum is that they provide the individualization of the learning process.

21.4.9 Development of Mathematical Concepts During Preparatory Training for the Developing Education

The peculiarities of the math learning, including elements of logic, and aim to development of logical thinking and understanding of mathematical concepts, are emphasized in the 6–7-year-old children curriculum.

According to our research data, a certain preparatory training is necessary in order to facilitate the child's introduction into the developing education system.

The technique for preschoolers' training in math consists of a specifically structured activities suitable for the preschoolers' age peculiarities, which stimulate the development of his thinking.

The program for introduction of mathematical concepts includes such topics as "Inverted divisor" ("Amount"), "A form," "Spatial orientation," and "Time knowledge."

Here we would like to discuss the main issue in the math preparatory according to V. V. Davydov (2000).

The beginning of learning of the concept of "Amount" as the basic concept of the math curriculum could be divided into three stages:

- Introducing to children the approach of measuring of an amount. At this stage the main concepts of dimension, measurement, and its functions, as well as finding an appropriate measurement of an object, are being developed. In this case children use the method of application and laying.
- Teaching children the indirect matching and the comparison of objects' sizes. In this case children compare objects that could not be necessarily compared to one another.
- Providing the development of concept of a number as the basis for measurement and relying on their own abilities to measure according to the conventional measurement, children are learning to form groups of objects on a certain ground, as well as unity and separation of different elements of plurality beginning with the counting foundation.

During an activity children learn how to compare two different objects by using a third one (a measure, a standard).

An educator places a piece of paper on the blackboard. This paper contains Christmas trees: one of them is found in the upper left corner, the other in the right lower corner, and the third one – in the right lower corner. The trees differ in their height for 1–1,5 cm. The educator asks children to determine whether the trees are of an equal height or one is higher or lower.

After hearing their responses, he is telling them a fairy tale: “Once upon a time a treasure was hidden under one of the Christmas trees. Two kind dwarfs would like to help a prince to find the treasure. A fairy revealed them a secret that the treasures are hidden under the highest tree. But the dwarfs can not decide which of the trees is taller than the others.” Children are getting involved into the process, but all their methods of determining the height (application) are not applicable in this case, for the trees are glued to the blackboard. Consequently, they understand the necessity of finding a new way to measure them. After a long discussion, they agree on introducing new subjects as substitutes. They reach the conclusion that if it is impossible to apply or attach, a size could be determined by the measure.

During another activity, children learn to use measure, equal to a part of an object, being able to fill it in several times. They are having on their tables two stripes of paper of equal width, but different in their length – one of them is as twice shorter as the other. The educator says: “We are all tailors. We have to cut into patterns and to sew napkins. Each of us has a piece of a material and it is the stripe, each measure is one napkin. We have to measure how many of the napkins we could make out of the material we have.” It is important that the children would be able to determine the sequence of the measurement rules and implement it correctly.

Since after a common discussion children usually are working independently or in pairs, they are unable to follow the rules, i.e., inarticulately applying the edges of the measure and the material, incorrectly marking the size of the measure and making measurements they forget to mark it with a sign. Consequently, after manipulating with the same objects, they receive different results. And that very moment is crucial for the development, because now they have an opportunity to analyze their activity by finding out what happened and why.

Consequently, the organized process of development of mathematical concepts enables children to pass successfully from the math course of the preschool level to school math course within the developing education.

21.4.10 Development and Artistic Activity Among the Elder Preschoolers

One of the innovations of the center is the complex thematic creative activities.

By playing a game, a child not only simulates the social behavior of adults but also makes experiments with their imaginary positions. V. T. Kudryavcev in his works (2007) defines two main mental growths of preschool age which are strongly connected and shaped by playing games, and they are an orientation toward position

of the other and creative imagination. It can be said that they are the two different faces of one of the same child's inclination as creativity.

In the history of the mankind, the universal ability to perceive the whole and general before its details had always been cultivated primarily by the means of art (E. V. Il'enkov).

Each child perceives the world through three main channels for perception, analyzing and keeping the information. All children see what is going on around them and could imagine various images, to hear different sounds and to experience a diversity of feelings, smells, and tastes. What matters is which of the three channels (visual, audial, or kinesthetic) he uses more often, because he primarily perceives the information received through the channel. What would be more important for a child: first to see, imagine, and then to hear and to taste, or the other way around, first to "try it on" and only then to imagine how it looks.

Our experience shows that during the first step of developing creativity, it is essential to "provide" a child with an opportunity and a tool for creative activity through his main perception channel.

What conditions should be provided according to the specification of each child? How to provide for the miscellaneous creative child development? How to transmit the tools to the creation of a holistic creative product?

In search for the reply to the questions stated above, the psychologists and educators of Pedagogical centre "Experiment" had developed its own methodology of complex thematic creative activities, which include classes of music, art, arts and crafts, move and dance, as well as of different similar types of creative activity.

The main aim of the complex thematically creative activities is to create presuppositions for development of individual creative skills, as well as for the acquirement of tools for individual and group creative product development, such as a dance, a drawing, a text, a handicraft, etc.

If an educator has a culturally rooted concept of the development process of individual creative skills by enriching a child through his experience of different art fields and interaction with other children, he would be able to achieve unique team and individual results in his professional activity.

It is essential to offer each child an opportunity for individual development.

Further, in this part, various elements of the activities for 5–6-year-old children would be provided. These children were already familiar with the main modalities of imagination and creative thinking. They already have a certain experience and an understanding of the process going on in the outside world, which they could use as a ground for imagination and creativity in order to supplement existing patterns and to construct their own models and views.

The technique for planning and implementation of the complex thematic activities:

> for planning the complex thematic activities it is important to pick up the correct thematic vector suitable for the imagination development of the age depending group. On the one hand it depends on the average level of development of the group and its type (logics, empirics, creators and etc), an, on the other, on the educator's understanding of psychological process within the child during the accomplishment of different creative tasks.

There are a few logical approaches to the issue-related activities:

if the group of children is able to follow the content/plot, the thematic activities could be based on fairy tales or well known stories. In this case the educator may offer to transform (to change) the original plot of the famous fairy tale or a story, or even to suggest to make up own plot/story/fairy tale.

Choosing the path, one should be aware of the fact that an imagination could possibly be substituted by memory and restoration of the original plot. During the activity, children are supposed to use their imagination, and memory, they are requested to create their own images and to express them orally, but not to reproduce the images and plot created once by an author.

If the majority of children in the group possess the visual thinking, they could be asked to reflect on the outside world filled with unpredicted and unique natural phenomena. Such topics as "an underwater world," "a magic forest," "a celestial adventure," "white and snowy winter," etc. could be used for the activity.

In this case the opportunity for children to involve their creativity is much higher, for they will use their experience and imagination to complete the missing parts of their perception (comprehension, feeling, cognition) of this or that natural phenomena. Moreover the risk that they would turn to their memory instead of the imagination is much lower than in the first case.

One of the main features of the complex content (thematic) creative activity planning is that it is based on a modified scheme of thinking activity by G. P. Shchedrovitsky (Щедровицкий 2005). The scheme is widely and often used by the educators and psychologists of the center in order to organize a productive communication within a group or just for producing a common creative product (Fig. 21.6).

According to the scheme, the particular role of an educator is to create a special and safe space for the teamwork, where he would be able to trace the culture of the content development and also to facilitate the group in order to receive a common creative product. In this case, both educator and children should go through three different stages:

At the first stage (thinking activity) – as we named it "creation and facilitation of a common space for the group work" – the educator is expected:

To introduce the norms of communication and teamworking process
To formulate the creative assignment (task) for the group
To motivate and to involve children in the problem solving

The second level (thinking-communication) is meant for communication, i.e., for exchange of opinions among children and their discussion on the problem solving and common creative product development. Here the educator should follow and examine the logic and the culture of the content and concepts used. At the same time he has to keep in mind his aim that the productive communication on the development of the creative product should result in acquiring a new knowledge by its participants.

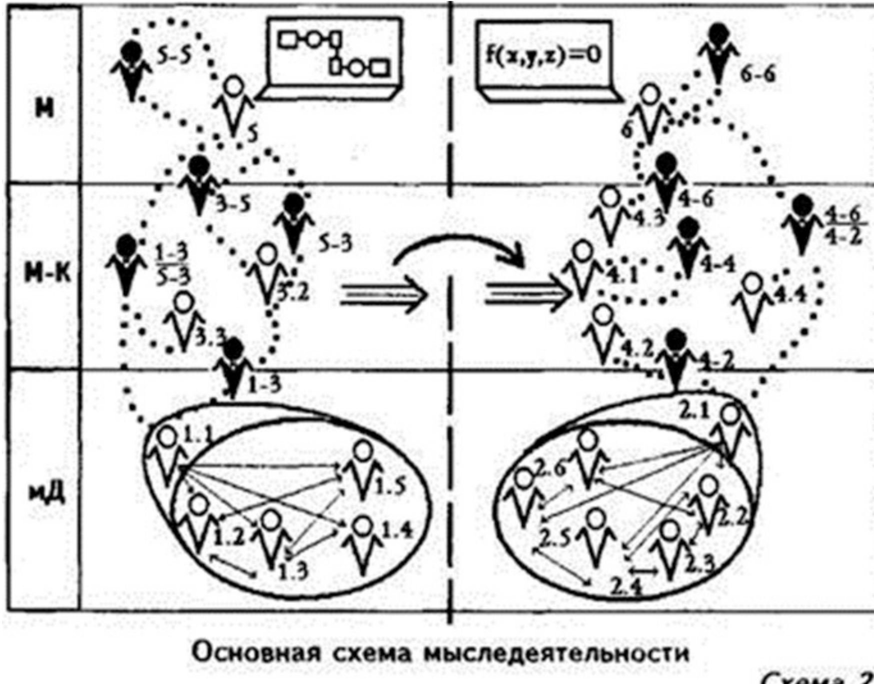

Fig. 21.6 General model of systematic thought activity (STA) methodology

The third level (thinking) is the final stage of discussion and development of the common creative product, as well as the right space for the record of collective and individual results.

Here is an example of planning and implementing of the complex thematic activity on the topic of the underwater world. It consists of several autonomous but at the same time connected thematic modules, such as:

> the main goal of the dancing module (containing music and movement) is to develop the ability to transmit the content (message) through movements. While accomplishing a thematic assignment given at the complex activity, children are able to discover an opportunity to express themselves through music (or special selection of music in order to create or play an image or natural phenomena) and movement (creation of an image or a hero through various motions).

A few examples of an activity assignments presented as an element of a facilitation technique of the first stage (the providing of a creative space):

> Greet children and invite them on a trip to an underwater world … Ask them to close their eyes, because in a few seconds they would hear music and each of them would go on his own trip. Also kindly ask them to remember the most interesting and exciting sight, events

and creatures they would meet in the underwater world, so that later on they would be able to share it with their fellows.

Choose a gentle fragment of the classical music that has changes in its flow, and put it on for 15–30 s. Depending on the reaction of children, you can use either compositions of Paul Moriah or classical music played by the symphonic orchestra for the children. Children often report on seeing fish, stones, shells, plants, etc. After the first immersion and its reporting, suggest for the children to immerse themselves into the underwater world for the second time, but this time to ask them to pay attention to the mood of the underwater world. The educator has to put on alarming music, which might remind a storm or a rapid flow.

After the second immersion, the children would report on being worried because of the waves. Follow the topic of the waves and suggest for the children to dance like ways, so they could play how the waves and the general mood in the underwater world changes because of the music. Provide them with the demonstration of certain wave movement and guide them through the activity …

One could also prepare an additional (supportive) material for the group, like giving each child “a wave” (a blue silk scarf attached to a stick that in a motion looks like a wave). If you see that each and every child is doing well, simulates waves, and follows the music, offer them to become a one big wave (a large piece of blue silk material which children hold and move to create a wave).

Only after the educator made sure that all children got involved into the general topic, he could suggest them to make up their own imaginary underwater world, thus passing from the first stage to the second. At the second stage, children have to discuss and create a collective creative product, based on the shared mood and thematic and creative space created. Invite them to discuss the mood of the underwater world, and put up the music according to their choice. Also ask them to pick up characters since they already have an experience of immersion and encountering there stones, shells, plants, etc.

After the second stage, and discussion before moving to the third one, in order to sum up (to close) the activity, invite children for another collective immersion into the underwater world in order to become a part of it. Everyone should turn into a being according to his taste and like. Also remind children that the mood of the sea and all its inhabitants depends on music and waves.

If you see that children are willingly going through the transformation and immerse themselves in the space of the underwater world, try to change the flow of the music. Watch and test how deep children could feel (experience) the mood and to reflect it in motion.

After the development of the collective creative product, in our case it is an underwater world’s dance, suggest to the children to discuss the common and individual results. What do they like or dislike, and what would they like to try next time? This is the third stage – the development of a common product – a new result of a group work. These reflections are useful for the educator to understand the level of the results and to prepare assignment for the next class.

The dance block promoted development of child’s:

Ability (sense, feeling) of transmission of a message-text through music or motion

Ability to use music and motion as additional strengthening means for an expression of a hero or the creation of a whole image or character

This music and dance development is a powerful tool for a deeper understanding of a natural image or phenomenon. Thus it provides more opportunities for self-expression. Children acquire tools for creating of an image through dance or motion. They could transform themselves into a created image or to assist the other to develop his image.

A creative perception of music and movement is being developed with a child, and it reveals itself in the following product sequences:

image – message (text) – music
music-message – motion

The creative block (consisting of visual art and handicraft) is aimed to provide tools for development and understanding of an image or a natural phenomenon through the means of visual art and handicraft.

The exploration of the underwater world could be followed by a drawing activity, when children are requested to describe their underwater world by the means of the visual art. The whole procedure is accompanied by the music.

One of the branches of the block is the activity of transformation of the space – decoration activity aimed on development of the ability to reflect the theme into spatial design.

Suggest children to transform the classroom space into the living underwater world by using materials on hand.

The creative activity of the block enables children to create a platform for a more holistic perception of the common theme of an image or natural phenomenon. Children express themselves and develop their perception of space, decoration, and interrelation of text, message, mag, character, plot, etc. Children learn to view and perceive message and space as a whole. Thus a creative perception of space is being developed and linked as a product from message (theme, subject, content, idea, image text) – creative design (a product of creative activity).

The main feature of the complex activities is the lack of time limit. Our experience proves that it is almost impossible to predict the pace of the creative activity both for the individuals and a group. It is completely unacceptable "to pull children out" of the process of creating the imaginary.

The complex activities could be arranged by using various techniques:

Synchronous – a common assignment is provided for the whole group and later it is divided into individual tracks according the child's inclinations, but providing an opportunity to change tracks.

Consistent – a group takes each block of the complex activity,e.g., every second day, children have "creative workshops" on the certain blocks of the complex activity.

The important factor of the complex thematic activity (or series of activities) is the final creative product.

The results of the complex activities:

Each of the thematic blocks mentioned above creates its own creative space, where each and every child could find himself an opportunity for individual development of his own

creativity. Although by immersing himself into a collective creative activity he is able to acquire tools for development of creative products from various creative spheres.

It is worth mentioning that the products received in the result of each block could also be viewed independently, e.g., a dance, a text, or a drawing.

They could be joined into one "perception" as a common collective product of the age-dependent group. For example, 5–6-year-old children played the fairy tale of "A palace" ("Teremok") by transforming themselves into different animals (according to their wish and taste), making up motions to distinguish them (gait, manner); they have also complemented the original text, and guided by the educator of design, they have decorated the stage for the performance.

All mentioned above shows clearly that a modification of the thinking activity could be used by an educator of a specific field, i.e., for developing a creative product both in the case of a certain subject and in a complex of subjects.

It is an absolute fact that in order to receive a higher quality of creative development of a child, it is necessary to implement the scheme for the creative activities more often.

21.5 Conclusion

The implementation of practices and methodological recommendations for the various aspects of preschool education described above are:

Training for psychological and pedagogical personal
Psychological accompaniment (tracking) of a preschool-age pupil
Usage of computer games
Development of creativity

All of them allow to prepare a child of 5–6 years old for study process in the DEC system (first year), but also promote the development of his skills of education activity that are essential for the success of his educational process in the future.

Despite the majority of "old" concepts and the establishment of new schools and traditions of child preschool training, the preschool education system still remains a disagreement battlefields for many scholars, educators, and psychologists. Recently, parents, as the main subjects and customers of education, had joined the discussion. Our 25-year-long experience, envisaged above, could promote the increase of quality of preschool education and the level of maturity for school study process.

Part III
Contemporary Research and Evidence – Early Childhood Education Globally: *Australasian and South Pacific*

Susan Grieshaber

Chapter 22
Introduction: Early Childhood in the Australasian Region

Jane Bone

Abstract This section of the handbook has contributions from authors who identify as part of Australasia as it extends from Australia and New Zealand to the Indian subcontinent. This area is characterised above all else by its variety. This introduction outlines changes and affiliations that characterise early childhood education in Australasia.

Keywords Australasia • Early childhood education • Quality • Curriculum

This section of the handbook has contributions from authors who identify as part of Australasia as it extends from Australia and New Zealand to the Indian subcontinent. This area is characterised above all else by its variety. The chapters written here reflect this, coming as they do from Bangladesh, Australia, New Zealand and Brunei.

Australasia is an exceptionally diverse area and this makes most generalisations about the region redundant. In most instances, areas of the world are linked to geographical location but at other times may be connected through ethnic links across borders or by political affiliations. Sometimes political decisions infiltrate education and are a deliberate way of strengthening ties, for example, Australia's wish to have stronger affiliations to Asia is made explicit through the school curriculum. In current curriculum documents, Asia is seen as a region with "cultural, religious, historical and language boundaries or commonalities" (Australian Curriculum 2014).

This diversity is evident in the chapters presented here, and of course even within each country, the authors do not claim to be representative but rather want to give a perspective from a particular direction. This might be seen most clearly in a country like Bangladesh, featured here in this handbook. Bangladesh is a country with a population of 153 million inhabitants and clearly it is impossible to represent the views of so many people. It may be assumed that Bangladesh would have little in common with New Zealand, population 4.5 million. In both countries, however,

there are contributions to be made and different agendas when it comes to early childhood education (ECE). This is the point made about Brunei, population 415,000 (approx.); despite being a small country, there is also a definite contribution to make in terms of international interest. The writers do not claim to be saying the last word but their chapters give historical background and represent contemporary viewpoints and as such are a valuable aspect of this handbook.

Professors Pramling-Samuelsson and Fleer (2009) suggest that despite differences "it appears, that all over the world, there are intentions to give children a good start in life…" (p.173). In an earlier handbook, they acknowledged "commonalities and distinctions" (Pramling-Samuelsson and Fleer 2009), and the important thing here is also to recognise that a multiplicity of perspectives will be addressed. The notion of difference and commonality can be equally applied to the chapters that follow. They give a unique and particular insight into early years' education from a part of the world that is seen by some to represent the future and to be key to future power relations in the world.

The role of children and childhood in these places is itself sometimes privileged and is also too often characterised by poverty and discrimination. In some countries in this vast region, for example, one might see children going into kindergarten in smartly pressed uniforms next to another child experiencing extreme poverty. It is a challenge for early years' education, and the policies that support it, to make it equitable and not a contributor to privilege and inequality. In Bangladesh the minimum wage per month is approximately the same as that for an Australian per hour (Minimum Wages by Country, np). In Australia the pay rate for many early childhood educators is nevertheless seen as discriminatory and marginalising. This is a reminder that all is relative to context and expectations, and despite these disparities, very different places in Australasia are interested in the potential of early childhood education. It is worth being aware though that in terms of rights and participation in education, there is still a drive to give all children a primary education in many countries, and in many places early childhood education is an unimaginable luxury. However, the goal is there and it may be possible one day to include all children in the benefits that flow from a quality early years' education (see, Smith and May).

The chapters here do not focus on the political context. Instead they try to give a current overview of the direction in which ECE is heading right now and there is an obvious emphasis on aspiration for the future. Grieshaber and Nuttall advocate for more research to support the comparatively mature field of early childhood education in Australia. Mohamed, Yaakub, Pearson and Sim describe the national vision put forward for Brunei, especially for the children and grandchildren who will be the recipients of this vision. They note that Brunei Darrussalam is the smallest country in Australasia, and like the curricula of other countries, there is an emphasis in the early years on developing a strong sense of identity. In early years' education, there has to be a broader understanding of education and as the authors note, an emphasis solely on the traditional three "r's" is too limiting. Brunei is focusing on increasing holistic approaches to early years' education.

A holistic approach and inclusive curriculum framework has always been a feature of early childhood education in Aotearoa New Zealand. Smith and May

chart advances made over time in New Zealand, and their analysis underlines that change and recognition of the importance of the early years do not happen quickly. Unhappily, since 2010, the attributes that made New Zealand early years' education an international leader have diminished due to changes in the government. This does highlight the importance of having a supportive government with a strong vision for the nation's children and a propensity for forward thinking. They make the point that a positive investment in the future through ECE is not the same as putting economic benefits before children's well-being. Smith and May show clearly that a respectful approach towards early years' education creates change plus a recognition that early childhood educators need to be well qualified, and they stress that it is not (as the Brunei authors mention) acceptable for teachers from primary education or with low-level qualifications to be educators of young children.

This is most obvious in international studies about quality and teacher qualification is a key contributor to quality early childhood education. Grieshaber and Nuttall review ECE in Australia and make the important point that "teachers can be either agents of cultural change or perpetuate inequality. This has particular implications for the preparation of early childhood teachers". Clearly this is something that deserves attention internationally as more and more children enter places of early learning, some as private clients and some as publicly funded citizens. Peter Moss (2014) has recently written about the old and new stories that underpin discussions of quality. Perhaps the attention given to preparing well-qualified teachers is part of the new story waiting to be given priority in terms of what young children deserve and the outcomes that are identified here by Smith and May.

In support of this contention, Sikder and Banu make the strong statement that in Bangladesh, too often, "in teaching, quality is absent". They identify the practices of teachers in pre-primary classrooms who educate in a way that does not acknowledge the developmental requirements or the strengths of young children in terms of play and imagination. Banu's (2012) research found that only too often "pre-school teachers focused on teacher directed teaching, coaching, memorising of facts through rote learning, and frequent testing to prepare children to pass primary school entrance examination". The argument made by all the chapters here is that when dealing with children in complex situations and when trying to foreground sound educational approaches, then the emphasis on well-qualified early childhood teachers has to be a focus.

All chapters have a historical perspective and take a long view of early childhood education in each place. These chapters will be a resource for future researchers and may influence policy makers who wish to review the state of early childhood education in these times when as Moss (2014) suggests, the emphasis remains on "high returns for social investment". Teachers, as Grieshaber and Nuttall emphasise, deal with cultural diversity in a changing world; they deal with health and well-being under challenging circumstances (Sikder and Banu); they deal with aversive changes in government support (Smith and May). When government support is forthcoming, then countries like Brunei may realise the "ambitious aims" that according to Mohamed, Yaakub, Pearson and Sim have the potential to support harmony and balance different beliefs and values.

Chapter 23
The Historical Emergence of Early Childhood Education Research in Australia

Joce Nuttall and Susan Grieshaber

Abstract This chapter of the handbook raises the question of whether early childhood education has reached the status of a mature field of research in Australian universities. It is organised around the discussion of three historical 'moments' between the 1930s and 2014. The authors argue these moments constitute turning points in the emergence of early childhood education research and scholarship in Australia, as distinct from research about children's learning and development that draws on medical and psychological perspectives. A glimpse of the present moment is provided through an analysis of the recent contents of two prominent international early childhood education research journals edited in Australia. The chapter concludes by reflecting on the conditions under which early childhood education researchers in Australia presently conduct their work and the relationship between these conditions and the implications of higher education policy for the continuing emergence of the field.

Keywords Research • Early childhood education • Historical moments • Higher education policy • Cultural diversity • Teacher education

23.1 Introduction

Visitors to Australia are often unprepared for its vastness. Australia is an island continent that ranges from its near neighbour, Indonesia, in the north to almost the sub-Antarctic islands in the south. Laid over the continent of Europe, it would spread from Portugal to Moscow. Yet its population is only around 23 million. The vast majority cling to the coastal edge where each of its state capitals is located.

Only the federal capital, Canberra, is inland. Most of these capitals are less than 200 years old, yet Australia is home to the world's oldest continuous indigenous culture, stretching back at least 50,000 years. Australia is also one of the most multicultural of countries. It has hosted successive waves of colonisation and migration since the late 1700s, including large numbers from Southeast Asia, New Zealand, the UK and the Pacific.

Within the last three decades, the advent of fast, regular air travel and reliable Internet-based communication has allowed scholars of early childhood education to communicate and collaborate across this vast geographical space. Our purpose in this chapter is to pause and take stock of these research endeavours and reflect on the extent to which early childhood education research in Australia displays the characteristics of a mature research field. By 'mature', in relation to research, we are interested in questions not only of scale and scope but questions of theoretical and methodological informants. We also understand early childhood education research to be situated within the broader field of education research, and early childhood academics as agents who understand the rules of the field and bring to it their own cultural and social capital (Bourdieu 1993). Furthermore, we understand it as a field distinct from other fields that pay attention to young children, such as medicine and psychology, a distinction that has not always been as evident as it is today.

In recent times, the field of early childhood education research in Australia has undergone rapid expansion. By tracing these developments since the first half of the twentieth century, we hope to show the richness and plurality of these research efforts in the early years of the twenty-first century. We do this by describing three 'moments' that we argue have been pivotal in this emergence. These moments were not necessarily characterised by dramatic events. At each of these moments, however, important trends emerged to the point where they could not be ignored. In tracing this historical story, our intention is to give a sense of development over time. In paying special attention to the contemporary moment, we use two main entry points to reflect on the extent to which early childhood education research in Australia has achieved the conceptual and methodological plurality expected of a mature research field. Our first entry point is via a convenience sample of research outputs from recent early childhood education research journals published in Australia, and edited by Australian academics. Our second entry point relates more specifically to the distinctive demands being placed on early childhood education in the early years of the twenty-first century as a consequence of contemporary policy moves. We have chosen to focus on the demand for the field to support and respond to Australia's cultural diversity. By taking this focus, we are able to give a sense of the wide variety of angles Australian early childhood education researchers are taking in engaging with this challenge, as well as the wide range of theories and methodological standpoints being brought to this important work. This is by no means the only challenge facing early childhood education researchers in Australia. We have selected it, in addition to reflecting on recent research publications, in order to illustrate the main claim of this chapter: that early childhood education research in Australia is now a mature field.

Our overall theme is one of emergence. We aim to show how research in early childhood education in Australia has developed as a culturally and historically accumulating phenomenon and how this emergence continues today. In the final part of the chapter, we reflect on the conditions under which early childhood education academics conduct research in Australia today and the implications of higher education policy for the continuing development of the field.

23.2 The Historical Emergence of Early Childhood Education Research in Australia

Research in early childhood education in Australia has both reflected and been influenced by the development of early childhood education services. Most services now called early childhood education had philanthropic beginnings in the early years of the twentieth century. This philanthropy aimed to provide 'necessary education and social training to compensate for poor environmental conditions' (Ashby and Grieshaber 1996, p. 131). There were close ties to the kindergarten movement in Europe, particularly the ideas of Friedrich Froebel. From these modest beginnings, and for the purposes of discussion in this chapter, we align research in early childhood education in Australia with three 'moments of discontinuity' or the emergence of 'something new' (Kendall 2001, p. 36). This discontinuity creates tension between what is and has been and what is new: 'between memory, fidelity, the preservation of something that has been given to us, and, at the same time, heterogeneity, something absolutely new, and a break' (Derrida 1997, p. 6). The success of what is new relies on whether and how it contradicts or is aligned with existing and established ways.

The 'first moment', itself an outgrowth of early philanthropy, occurred from 1939 to 1940. At this time, the Commonwealth Government made its first major investment in early childhood education. This paved the way for the services – and the research – that followed. The second moment saw pre-service early childhood teacher education move into universities in the early-to-mid 1990s. The third is the early childhood reform agenda, which began in 2007 and continues today. In the following sections, we discuss these three moments, focusing on how these points of cultural and historical discontinuity, and the subsequent emergence of something new, stimulated the development of early childhood education research in Australia.

23.2.1 The First Moment: Early Childhood Education Research as the Study of Growth and Development

The first moment begins in the late 1930s and ends in the 1980s. In the introduction, we identified early childhood education as a field distinct from, but historically related to fields such as psychology. This separation is recent. Fields with research

traditions such as medicine, health and developmental psychology characterised the first moment of early childhood education research. This was seen most emphatically in the establishment of a Lady Gowrie preschool centre in the capital city of each state in the late 1930s.

The Lady Gowrie centres were the first major investment by Australia's Commonwealth Government in early childhood education (Brennan 1994). The six centres were opened in 1939 and 1940 and located in industrialised inner-city areas where there was concern about the poor living conditions of families (Pendred 1964). These centres included major programmes of research into physical development: they were charged with the 'double purpose of the care and instruction of the young child and the study of growth, nutrition and bodily development' (Cumpston and Heinig 1945, p. iii). This focus reflected ongoing concern about the effects of the economic depression in Australia (1929–1933) on children's health. Details of individual children's age, weight, height, and other physical features were recorded for research and monitoring purposes. These practices are no longer featured in Australia's early childhood education services but remain a focus of Australia's field of maternal and child health.

As further evidence for this early reliance on medicine, health and psychology, in her account of the first 40 years of the *Australian Journal of Early Childhood*, Waniganayake (2001) noted the 'predominance of articles written by psychologists and medical practitioners' (p. 3) in the journal's predecessor publication, the *Australian Pre-School Quarterly*. This journal became the *Australian Journal of Early Childhood* in 1974 and is now the *Australasian Journal of Early Childhood* (AJEC). By the time the first group of external reviewers of submissions to the journal was established in 1988, the journal was attracting submissions from a wide range of disciplines beyond medicine and psychology, including sociology, anthropology and politics. We return to this journal later in this chapter as an entry point for understanding the third (contemporary) moment of emergence of early childhood education research in Australia.

Few early childhood education academics were employed in universities during this period. On the rare occasion that this occurred, their likely area of expertise was child development rather than early childhood education, and the sources of their ideas came from overseas, principally the USA and UK. Dr Anne Silcock, employed during the 1980s as a senior lecturer in education at The University of Queensland, is one example. Child developmentalists such as Silcock applied ideas from research in education and child development to early childhood education. In an article published for teachers in 1981, Silcock discussed the qualities of a responsible teacher. These included professional and personal qualities, influences on teacher-child interaction, and authoritarian and democratic teachers and teaching styles and their effect on academic progress. She cited eight references, none of which were Australian, ranging from 1946 to 1980. These included the now well-known Brophy and Good (1972) paper on 'Behavioral Expression of Teacher Attitudes', two articles published in the journal *Child Development* (in 1965 and 1968), and Lillian Katz's (1980) 'Mothering and teaching – some significant distinctions'.

Silcock's paper exemplified the lack of Australian research about early childhood education from the first historical moment in the late 1930s up until the early 1980s. Overall, the field during this time was characterised by reliance on overseas ideas, influences and practices, predominantly from the USA and UK. The paper by Silcock does foreshadow, however, the coming 'second moment', characterised by movement beyond ideas drawn principally from child development.

23.2.2 The Second Moment: Early Childhood Education Research Joins the Academy

The second moment covers the years in the 1990s. In the early 1990s, state-owned and state-controlled colleges of advanced education (CAEs) were amalgamated with federally funded and independent universities. This stimulated a second pivotal moment in the emergence of research in early childhood education in Australia and accelerated the growing discontinuity between the first and second moments. These amalgamations were part of a series of reforms of higher education instigated by John Dawkins, Commonwealth Minister for Employment, Education and Training from 1987 to 1991. The reforms included expansion of the Australian university sector and reintroduction of university fees. With the movement of early childhood pre- and in-service teacher education courses into universities, the focus of early childhood academics was no longer solely the preparation of teachers. They were now required to research and publish, as well as teach undergraduate and postgraduate students, and contribute meaningfully to their educational and professional communities. In their commentary at the time, Knight et al. (1994) contextualised these reforms within a wider post-war program of neoliberal reform, noting the shift from Keynesian economic principles to 'a new post-Keynesian competitive state approach' (p. 453).

This political and policy shift had important implications for early childhood education research. Up until the amalgamation of CAEs with universities, limited funds were available for research in early childhood education, and applications for competitive research funding depended upon employment in universities. An increasing number of doctoral dissertations in early childhood education appeared throughout this decade, and although the research base was small, it was growing. However the requirement to rapidly increase qualifications and up-skill research practices meant there were still only a few specialist early childhood researchers with the capacity to develop new research projects. A complicating factor was that research funding within universities and externally was (and still is) highly competitive. Time was needed to learn the genre of research grant writing and, if successful, how to lead and manage a research project alongside teaching, publication and engagement with the professional community. With a small number of recent postgraduate degree completions and little research experience, it was very difficult for early childhood education researchers to be competitive. During the 1990s,

postgraduate programs in early childhood education were also being developed, often as part of generic master of education programs. As well as the demands of completing higher degrees, researching and publishing, early childhood academics were now required to learn the skills of postgraduate teaching and research supervision.

Expectations of research participation and output by university academics continued to intensify during the 1990s. This second moment saw a steady growth of early childhood education research in Australia located firmly within education rather than related fields. The history of the content of the *Australasian Journal of Early Childhood*, noted above, is one way to trace the emergence of distinctively Australian research in early childhood education. A second important journal, *Contemporary Issues in Early Childhood*, appeared in 2000 with the aim of providing:

> …a context for presenting work that engages in alternative perspectives from those used traditionally in the field. As editors, we are delighted to have the opportunity to make available online and fully-refereed, current research and thinking that has emerged over the last decade. What makes this journal unique is that it contains current research and thinking that utilises different theoretical perspectives from those most frequently adopted in early childhood education. Some of the articles and colloquia published in *Contemporary Issues in Early Childhood* critique issues that many early childhood educators have accepted as unquestionable. We view this journal as an opportunity to showcase current challenges. It will exemplify the disquiet of some with traditional approaches and voice the reasons for such concern. It will also present some of the creative approaches that are being used to provide theoretical and practical ways ahead. (Grieshaber and Yelland 2000, p. 1)

The emergence of this journal, with its aim of presenting 'alternative perspectives', marked a maturing of early childhood education research in Australia and internationally. The conceptual frameworks available to researchers in early childhood education had multiplied and diversified since the dominance of the psychological and medical models of the 1970s seen in the *Australian Pre-School Quarterly*.

This diversification was further reflected in two scholarly conferences in early childhood education established during this second moment. The first, the Australian Research in Early Childhood Education (ARECE) conference, was established by Marilyn Fleer at the University of Canberra in 1993. ARECE (now International Research in Early Childhood Education) remains an important meeting ground for early childhood education researchers adopting sociocultural and cultural-historical perspectives on early childhood education, and its accompanying journal is a key outlet for doctoral candidates in ECE to begin dissemination of their work (Power 2010). By contrast, the other conference to emerge in the second moment – the annual conference of the Centre for Equity and Innovation in Early Childhood Education (CEIEC), established by Glenda MacNaughton in 2001 at the University of Melbourne – became known for its emphasis on postmodern and poststructuralist perspectives on research in early childhood education. These journals and conferences underscore the emergence of early childhood education as a field in Australia in this second moment, alongside (and not necessarily rejecting or subsuming) related fields such as child development. These examples of the work of Professors Fleer, MacNaughton and others also reflect the growing presence of early childhood academics among the professoriate in Australian universities during this period.

From its beginnings as an outgrowth of medicine and psychology in the first moment, a distinct educational strand in early childhood education research had emerged, focusing on curriculum, pedagogy and the education of early childhood teachers.

The transition to a research and teaching culture invariably took some time, but early childhood education research momentum grew steadily in Australia in this second moment. An important stimulus was the 2001 OECD report *Starting Strong*. This multi-country review of early childhood education provision recommended that countries create a stable framework for early childhood education research. As an OECD member country, the report had important implications for research in Australia. It could be used to leverage policy makers, politicians and funders. This was the opportunity for the field to identify long-term research agendas and necessary funding and training opportunities. The recommendations of *Starting Strong* included establishment of a long-term research agenda emphasising the connections between research, policy and practice. In keeping with changes already emerging in Australia in the second moment, the report recognised the dominance of methodologies associated with program evaluation and developmental psychology and suggested wider perspectives were needed. The disciplinary areas of anthropology, sociology, public policy, gender studies and learning theory were identified as appropriate theoretical bases from which policy and practice could be developed.

These recommendations came at the right time for early childhood education researchers in Australia. Several reviews of research in early childhood education had been undertaken locally (Centre for Community and Child Health 2000; Fleer 2000; Raban 2000; Yelland 2000). Three of these reviews were supported by the Australian Government Department of Education, Training and Youth Affairs (DETYA) (Fleer 2000; Raban 2000; Yelland 2000), an acknowledgement by the Commonwealth Government of the lack of research in early childhood education until that time. All four Australian reviews highlighted specific research directions for the field, and each recommended that the government fund longitudinal research. These reviews also positioned early childhood education, by the end of the second moment, as an emerging subfield of education research. By the early 2000s, researchers were adopting new conceptual informants such as post-structuralism and socioculturalism, or continuing to draw from established fields such as child development, or newer fields such as family studies and the sociology of childhood. There was also a growing body of Australian early childhood education research being reported in Australia. Early childhood education research in Australia was now well positioned for the third moment.

23.2.3 The Third Moment: Early Childhood Education Research as a Mature Field

In our description of the previous two moments, we have shown how the development of early childhood education research has co-evolved with government initiatives in early childhood education and developments in education policy, particularly

the reforms of higher education policy of the late 1980s. This co-evolution has been particularly noticeable since 2007, when the Council of Australian [state and federal] Governments (COAG) began implementing a large project of policy reform in early childhood education. These reforms, underpinned by theories of human capital (Heckman and Masterov 2005), are designed to improve access to services, increase rates of participation and raise the quality of early childhood programs (COAG 2009). They also break with Australia's history of state-based regulation of early childhood education and funding splits between state and federal budgets.

The COAG reforms present multiple entry points for research in early childhood education in Australia. Australia's early childhood education researchers are actively responding to these opportunities. A brief summary of the contents pages of recent issues, one from each of two major early childhood education research journals edited in Australia reflects the wide range of early childhood education research now being conducted and reported in Australia. Of particular interest in the context of this chapter is first, the wide range of topics being addressed by Australian researchers; second, the range of research approaches reported; and third, the growing range of theories informing early childhood education in Australia. A fourth feature is the publication of the work of overseas authors, a feature of the first and second moments but now drawn from a much wider geographical range beyond the USA and UK.

The contents of the two journal issues summarised here are from *Contemporary Issues in Early Childhood* [CIEC], 14(3), 2013 and the *Australasian Journal of Early Childhood* [AJEC], 38(3), 2013. The first of these contained seven papers, all original research articles; the second contained 25 papers, including those in its online supplement. All of the articles in both issues are firmly located in the field of early childhood education but the diversity of topics is considerable, including:

Professionalism
Professional development
Play
Research ethics
Transition to school
Early literacy
Programme evaluation
Early childhood policy
Leadership
Autism
Breastfeeding
Emotion regulation

Some of these topics are represented by two or more papers. Equally diverse is the range of methods and methodological choices made by authors, which include:

Ethnography
Literature review
Meta-analysis

Narrative
Oral history
Action research
Photo voice
Case study
Questionnaire
Clinical interviews
Content analysis via text analysis software

Again, several of these approaches (case study, content analysis) are reported in two or more of the papers across the 32 drawn from these two journal issues, and many articles report two or more methods. However, not all of these studies were conducted in Australia or by Australians. What is notable about the geographical reach of these journals in this 'third moment', when compared with pre-1980 publication patterns, is that the published overseas research is not confined to the USA and UK. Articles included in these two issues are principally by Australian authors but authors also come from New Zealand, Greece and Hong Kong.

Perhaps of greatest interest in the context of this chapter is the range of theories informing early childhood education research in Australia. These include those emerging in the second moment, principally post-structuralism, and continuing evidence of psychologically oriented developmental theories. However, an even wider range of theories of learning, development, education and society is evident through the inclusion of reports of research informed by activity theory, phenomenography, theories of policy formation and ecological theory. We acknowledge that this probe applies to only a small and very partial sample of research outputs among Australian early childhood education researchers in the contemporary moment. Nevertheless we argue that diversity of theory and method evident in this small selection reflects the emergence of early childhood education as a mature research field in Australia. This diversity has been both stimulated and enabled by the co-evolution of early childhood education policy (e.g., the COAG reforms), higher education policy (e.g., the amalgamation of universities and CAEs) and structures created by the field itself (e.g., the ARECE and CIECE conferences).

In the next section of this chapter, we accentuate this argument by focusing on one key element of the current policy reform program, that of responding to the cultural diversity of children and families in Australian society. This research focus is closely interwoven with contemporary policy moves. For example, *Belonging, Being and Becoming: The Early Years Learning Framework for Australia* (Department of Education, Employment and Workplace Relations [DEEWR] 2009), advises early childhood educators to respond meaningfully to diverse cultural backgrounds. An exhaustive review of current research on this topic is not the purpose of this chapter. Instead we point to selected examples, drawn from recent research, to demonstrate how early childhood education researchers in Australia are taking up a range of concepts, theories and methods in their attempts to understand and analyse cultural diversity.

23.3 Australian Early Childhood Education Research and Cultural Diversity in the Contemporary Moment

Concern with supporting the diversity of cultures, ethnicities and cultural and ethnic backgrounds of children and families in Australian society has been the focus of much recent research and policy work. Some of this research has been prompted by policies such as Investing in the Early Years – A National Early Childhood Development Strategy (the Strategy) (COAG 2009); *Belonging, Being and Becoming: The Early Years Learning Framework for Australia* (the Framework) (DEEWR 2009); and the Melbourne Declaration on Educational Goals for Young Australians (Ministerial Council on Education, Employment, Training and Youth Affairs [MCEETYA] 2008). All three documents are premised on human capital theory, with the strategy aiming to ensure that 'by 2020, all children will have the best start in life to create a better future for themselves and for the nation' (COAG 2009, p. 13). Specific policy objectives in the Strategy are directed towards '… greater social inclusion; improved outcomes for the majority of children but specifically Indigenous children and the most disadvantaged; and increased productivity and international competitiveness' (p. 13). All three documents exemplify the idea that education can transform society, making it more equitable and just. Moreover, early childhood education has a 'critical role' to play in 'closing the gap in educational achievement between Indigenous and non-Indigenous Australians within a decade' (DEEWR 2009, p. 6).

Early childhood educators in Australia have a long-standing philosophical and practical commitment to such principles of equity and social justice. Writing in 2007, Potter neatly encapsulated the field's commitments in the third moment of early childhood education research:

> With globalization, increased mobility of families, and the resultant changes to the social and cultural profiles of many countries, early childhood education is in an exciting, challenging, and, in some ways, uncomfortable position. For many years, teachers have been influenced by developmentalists as they have tried to respond to the diverse needs of individual children. They have been concerned with developing and implementing developmentally appropriate curriculum. While these goals are still important, we now face some harder questions in relation to children's sociocultural contexts and the many societal influences impinging on their lives and learning. (p. 64)

Early childhood education researchers have adopted a variety of entry points for interrogating these 'uncomfortable' questions. We touch on two of these here. First, we consider research about how parents experience practising teachers' responses to the cultural diversity of families; second, we draw from research concerning the preparation of early childhood teachers for working with culturally diverse families. As with our exploration of recent journal articles, our aim here is to reflect on the variety of foci, theoretical informants and methodological preferences that are evident even within a small sample of studies in just one area of early childhood education research.

23.4 Researching Teachers' Responses to Cultural Diversity in Early Childhood Education

One aspect of the policy directives aimed at greater social inclusion taken up by early childhood education researchers is the experiences of families and communities. Effective partnerships among parents, teachers and the community are idealised in the literature but can be difficult to achieve. Harris and Tinning (2012) report data from a study informed by feminist perspectives that used semi-structured in-depth interviews to seek the views of 49 parents and carers accessing childcare in northern regional Australia in 2009. Results revealed several concerns, including that parents worried about the difficulty of finding childcare, that the quality of care would be less than expected and that it would be culturally inappropriate. Similar concerns are found in many other regional and remote areas of Australia. However, an example of successful community consultation and collaboration aimed at providing culturally appropriate services is related by Lee-Hammond (2013), who described the processes involved in developing an integrated children and family centre for Aboriginal families in Western Australia. Ecological theory framed the study which involved data collection techniques of semi-structured interviews, focus groups and informal 'yarning'. Key elements of successful service delivery are identified and accompanying descriptions of these key elements illustrate what community members consider to be features of a culturally appropriate centre. Another success story in a remote Indigenous community resulted from creating a jointly constructed 'yarning space' as a way for parents (mostly mothers) to 'build and lead a literacy learning community' (Harris and Tinning 2012, p. 53). This case study used narrative inquiry and portraiture techniques to gather data. However, concerns about culturally appropriate environments are not limited to regional and remote parts of Australia. The supported playgroup initiative provides culturally safe environments for children and families from migrant backgrounds, specifically those whose first language is other than English and who are experiencing 'the 'triple jeopardy' of disadvantages associated with household, neighborhood and cultural circumstances' (Warr et al. 2013, p. 47). Data gathered through semi-structured interviews revealed barriers to families accessing early childhood services and strategies for supporting family engagement.

Disturbingly, several studies also reveal evidence of social exclusion. A project involving interviews with 30 sub-Saharan migrant parents living in Melbourne, Australia, confirmed that these parents felt their children were 'othered, labelled and denied citizenship' (Agbenyega and Peers 2010, p. 46). Parents related instances of children being treated differently from others such as not being provided with a blanket and pillow at rest time, runny noses not being wiped, and nappies not being changed frequently enough. Examples of labeling are alarming, with one parent reporting that her child was called a monkey by a teacher, and others upset by the failure of staff to recognise the heritage of children born in Australia, with children frequently told '…you are not Australian you are African, you are Sudanese because you are black' (p. 52). Parents were also anxious about their children's future in

Australia because of the racism the children experienced at preschools they attended. Other research with mixed findings involved a study that interviewed six migrant parents from India about their perspectives on Australian early childhood practice (Patel and Agbenyega 2013). While the parents generally preferred Australian early childhood education settings because of features such as small child-teacher ratios and holistic approaches, mothers favoured direct instruction and considered play 'a waste of time' (p. 52). The parents expressed concern that the Australian curriculum 'distanced their children from their culture' (p. 52) and reported 'mixed feelings' (p. 53) about the effectiveness of a curriculum that is supposed to be based on principles of diversity.

Being able to communicate effectively is significant in matters related to transition to school. Interviews with ten Bangladeshi parents in Sydney, Australia, confirmed that friendships with children of similar cultural and linguistic backgrounds and support from teachers helped create constructive transition experiences (Sanagavarapu 2010). Transition was more challenging for those children with limited English. Language barriers also prevented parents from communicating with teachers and from accessing written information about transition and the school curriculum. A project by De Gioia (2013) that investigated communication processes and expectations of continuity of care between home and early childhood settings drew on interviews with families from six childcare centres from 'macro culturally diverse parts of metropolitan Sydney, Australia' (p. 111). These families purposely chose a service that was different from their own culture because they wanted their children to improve their English and to 'benefit from learning the traits of the dominant macro culture of society' (p. 118). The importance of staff moving beyond basic information giving to developing meaningful relationships with parents was also emphasised.

These small-scale studies indicate that while some progress has been made, social justice matters about ethnicity, culture and diversity require further attention in early childhood education in Australia. One way of opening possibilities for change is a move from multicultural to intercultural approaches (Miller and Petriwskyj 2013). This would involve addressing the 'cultural understanding of Australian early childhood educators, particularly those who identify as Anglo-Australian, deeper policy enactment in pedagogic practice and negotiation with diverse families and communities' (p. 251).

23.5 Researching the Preparation of Early Childhood Teachers to Respond to Cultural Diversity

Implicit in efforts to understand the development of early childhood teachers in response to cultural diversity is the idea that teachers can be either agents of cultural change or perpetuate inequality. This has particular implications for the preparation of early childhood teachers. Research about the overlap between cultural diversity

and teacher preparation draws on a variety of conceptual informants. One set of related concepts includes notions such as 'self', 'identity', 'beliefs' and 'values'. These are broad psychological concepts that focus on the intra-mental worlds of early childhood teachers and which feature in the teacher education literature more widely. For example, Sims (2004) drew on concepts of beliefs and values in a study that sought to effect and evaluate change in the values held by students in pre-service children's service (childcare) programs through a specific model of early childhood teacher education pedagogy based on communities of practice. Likewise, Stamopoulos (2006) used a questionnaire and focus group or individual interviews with 101 pre-service early childhood teacher education students to show an increase in student teachers' acceptance of diversity through internships in community-based settings. A further example of an attempted intervention in student attitudes via practicum experiences is drawn from Lewis et al. (2006) in their account of a student undertaking a practicum placement in Cambodia. They adopted a poststructuralist theoretical perspective and a range of associated strategies to describe how the student was forced to confront the inadequacy of the normative discourses of child development she had encountered in her teacher preparation program, when faced with issues such as child trafficking and children's previous experience as beggars. In a chapter written for pre-service teacher education students, Martin (2012) explained the idea of relatedness that is at the centre of Indigenous peoples' ways of being and knowing, and which is 'critical to the formation of identity' (p. 27). She connects relatedness to all aspects of childhood and lifehood, making links to teaching and learning and in the process critiqued the western notion of schooling and all that it encompasses.

As an alternative to psychological models for understanding development, some early childhood education researchers are influenced by more broadly sociological concepts such as power and discourse. Diaz (2004) described working as an early childhood teacher educator in the context of her university's commitments to equity and social justice, adopting a method akin to self-study. A feature of the course Diaz described is the incorporation of post-structural theoretical perspectives to increase candidates' awareness and understanding of difference, inequality and social justice (thereby also signalling the close relationship between the conceptual informants of teacher education curriculum and the concepts being taken up by early childhood education researchers). However, in an earlier report about the course, Robinson and Jones Diaz (1999) showed how the course nevertheless had a strong emphasis on candidates' attitudes and values, how those values originate and can change, and how personal values connect with issues of inequality in the broader social context.

There is increasing evidence in early childhood education research in Australia that teacher education candidates themselves are also becoming more diverse. An important focus for early childhood education researchers in Australia, as distinct from studies of beliefs and values per se, is the experience of Aboriginal early childhood teacher education candidates. The work of Fleet and her colleagues (Fleet et al. 2012), grounded in a socio-constructivist framework, has made an important contribution to understanding these experiences. The assessment of diverse teacher

education candidates is a particularly complex area and, as Fleet and Kitson (2009) point out from focus groups with students and teaching staff, and interviews with graduates, 'good intentions' are not enough when working with Aboriginal students. Ortlipp and Nuttall (2011) also focused on assessment of culturally and linguistically diverse early childhood teacher candidates using a Foucauldian-inspired discourse analysis, with special emphasis on assessment of the teaching practicum. In a subsequent paper (Nuttall and Ortlipp 2012), they described the case of Sue, a highly successful Singaporean Chinese student, who almost failed her final practicum placement due to serious cultural misunderstandings between Sue and her supervising teacher, and the university's difficulty in accounting for issues of cultural difference when assessing Sue's practicum teaching.

Although unified by an interest in cultural diversity, these studies present a range of substantive foci including student beliefs, student experiences, evaluation of interventions in higher education and the experiences of teacher educators. A further unifying feature of these studies is their methodological similarity. Although these studies show some attempts to engage in quantitative methods (e.g., content analysis of university documents undertaken by Ortlipp and Nuttall (2011)), they are overwhelmingly qualitative in approach and rely heavily upon participant self-report. Both Lewis et al. (2006) and Nuttall and Ortlipp (2012) describe single-subject case studies, with interviews as the primary mode of data generation. We reflect further on this potential limitation in the final section of this chapter.

23.6 Future Directions

In this chapter, we have argued that early childhood education research in Australia has reached an important moment, reflected in the maturity of the field. The availability of fast technologies has enhanced this emerging maturity, particularly by supporting collaboration across vast distances. These technologies also offer the possibility of rapid developments in scale. This would address the most noticeable gap in the examples we have selected above, which is the consistently small sample sizes reported across a wide variety of studies. Small-scale and single-subject studies have considerable value in their own right. However, to claim that the field has reached maturity, these studies should perhaps be complemented by large-scale studies and research that allows researchers to compare the effects of specific interventions against non-intervention groups.

We have also argued that there is a close relationship between the realisation of this increased capacity and higher education policy (not just early childhood education policy), particularly exemplified in the second moment. As Rees et al. (2007) argue:

> …the starting point for developing new and perhaps more imaginative strategies for research capacity building is a much better understanding of the conditions under which educational researchers do their jobs and of the wider social relations within which these are situated. (p. 776)

It is to these 'wider social relations' – which in part explain the lack of large-scale and multi-site research – to which we turn in the last part of this chapter.

Most early childhood education researchers in Australia work in universities, with just a small number working in stand-alone institutes such as the Australian Council for Educational Research and the Australian Institute of Family Studies. Ideally, there should be a positive dialectical relationship between early childhood education research and university work: a co-evolution of research capacity and the development of practice across the early childhood education field. For university-based early childhood education researchers, however, the relationship between research activity and the realities of working in university environments is highly contradictory. These tensions are experienced by all university researchers in applied fields to some extent, but the rapid and simultaneous shifts in early childhood policy and higher education in Australia during the last four years have resulted in a particularly intense time for early childhood education researchers.

In 2009 the Australian government laid out an ambitious plan for the growth, credentialisation, re-credentialisation and professional development of the early childhood education workforce, driven in part by a desire to minimise risks to human capital (Productivity Commission 2011). The National Quality Framework for Early Childhood Education and Care (COAG 2009) increased expectations for qualified staff so that by January 2014, 50 percent of childcare staff were required to hold a diploma-level qualification (or higher), with a degree-qualified teacher employed by 2019 in all child care services with 25 or more children. These aims explicitly acknowledge the proven relationship between teacher qualifications and educational outcomes for young children, particularly those from diverse backgrounds. Although the present government has rolled back these target dates somewhat, an immediate result of these policies has been rapid growth in early childhood teacher education programs. With this has come an urgent need to increase the number of academic staff in early childhood education by at least 100 within a 3-year period (Nuttall 2012), and these staff need to be qualified to doctoral level. This level of qualification is important because higher education policy has simultaneously increased demands on universities for higher-quality research output through its Excellence in Research in for Australia (ERA) policy (Australian Research Council 2011).

The convergence of these two policy programs is creating a 'perfect storm' for early childhood education academics in Australia. At a time when unprecedented attention is being paid to the early childhood education field, related research should be flourishing, enabled by increased opportunities to collaborate. In reality, the pressures of meeting increased demands on early childhood teacher education, while also responding to the competitive and anti-collaborative nature of the ERA process, has the potential to work against capacity building in the early childhood education research field, which is principally located within the already stretched research field of teacher education. The reasons for these challenges have been described elsewhere (see, e.g., Nuttall et al. 2006) and include the number of education academics for whom academic work is a second or third career after teaching elsewhere. This means they often come to doctoral study late in their working lives

so that, in turn, the number of experienced researchers available to mentor early-career researchers is proportionately small (Cumming 2010).

Despite these pressures, early childhood education researchers in Australia continue to look beyond their immediate settings for research collaborators. A recent cross-institutional initiative in Australia was the creation of a Collaborative Research Network (CRN) in early years of education (involving Charles Sturt University, Queensland University of Technology and Monash University), which was specifically designed to build research capacity in early childhood education: in research supervision, leadership, administration, management and training. An important feature of the CRN was the wide range of research foci, methods, and theories adopted within its suite of projects. Recent work by the Australian Productivity Commission (2011) suggests Australia is learning from the experience of countries such as New Zealand and the UK about the need to address policy programs in an integrated way. One current large-scale Australian project, the E4Kids study, is another example of what can be undertaken when national and international collaboration, supported by substantial funding, is enacted. E4Kids is a 5-year study following approximately 2,600 children aged three and four years as they participate in childcare, kindergarten and preschool programs in two Australian states (E4Kds National Brochure 2014). It assesses the impact of participation in these programs as well as outcomes for children who do not attend programs. Growing Up in Australia: The Longitudinal Study of Australian Children (LSAC), which includes a longitudinal study of Indigenous children (LSIC), is a nationally representative study of child development that commenced in 2004. Data are being collected from children and their parents, carers and teachers. With these large-scale and longitudinal initiatives, researchers are ideally placed to take advantage of increasing opportunities to reach out to potential collaborators within early childhood education, across disciplines, and across national borders, not only to build research capacity but to contribute to the learning and development of young children, their families and their teachers in important ways. While we have suggested that early childhood education research in Australia has reached a stage of maturity, the progressive release of findings from these large-scale and longitudinal studies indicates that the field is currently poised for a fourth moment, a 'coming of age', where these results can be used to inform policy and practice, link with other state and national data and possibly make international comparisons.

Chapter 24
Connections Between Early Childhood Policy and Research in Aotearoa New Zealand: 1970s–2010s

Anne Smith and Helen May

Abstract This chapter summarises five eras of early childhood policy and research development in Aotearoa New Zealand. In the 1970s, there was a divided system of care and education, and the dominant view that childcare was primarily custodial and sessional care educational was questioned by research. In 1980s, policies moved towards integration, maintaining diversity and improving quality (especially through teacher education), while research explored the nature and long-term impact of quality. The 1990s saw the introduction of bicultural socioculturally based early childhood curriculum guidelines, *Te Whāriki*, and a wave of qualitative research followed to evaluate and support the curriculum and its implementation. During the 2000s, a strategic plan, *Nga Huarahi Arataki* (2002–2012), prioritised increased participation and quality and collaboration between services. In 2003, teacher-researcher partnership projects embarked New Zealand on an action research journey to explore, document and disseminate innovative teaching. In the recent era coinciding with a world economic downturn, a more conservative government approach to early childhood policy and cut backs to funding and programmes, research has, by political necessity, focused on the efficiency and effectiveness of taxpayer investment in the sector, increasing cost-effectiveness and promoting the participation of 'disadvantaged' children. The goal of improving quality has been put at risk by cutting funding for fully qualified staff.

Keywords New Zealand • Early childhood education policy • Early childhood education research

Early childhood education (ECE) in Aotearoa New Zealand has been shaped by strong partnerships between academic researchers, advocates for children and women, practitioners in the field and government agencies. The alliances are not always neatly aligned. Researchers have been proactive in shaping new policy directions for early childhood provision and pedagogy, interrogating its consequences and broadly defining uniquely New Zealand pedagogical directions. Themes of equity, social justice and the rights of children characterise the research agendas. The authors bring some shared and separate perspectives to this overview. Over several decades, we have both been engaged in policy advocacy and participated in a variety of committees, working parties and a task force during periods of major policy change. Anne Smith began her involvement in ECE by setting up a community childcare scheme in Dunedin in the 1970s (Smith 1980). Her observational research has focused on children's lived experiences in early childhood centres (Smith and Haggerty 1979; Barraclough and Smith 1996; Smith 1988, 1996, 1999), as well as children's rights and agency (Smith et al. 2005; Smith 2007, 2009). In the 1970s, Helen May was working in childcare and began documenting the New Zealand policy story as a research task itself (May 1985, 2001, 2009, 2013, 2014), later collaborating on the development of a national early childhood curriculum (Carr and May 1999).

This chapter summarises five eras of early childhood policy and research, from its fledgling beginnings in the 1970s when there were few doctoral scholars in ECE and no university early childhood programmes to the current time when New Zealand researchers have become a presence and voice in various world forums. New Zealand is a small country with 4.4 million people. Consequently, there is only a small research community spread thinly across seven university sites and several other providers of teacher education and, in earlier years, the New Zealand Council for Educational Research. Characteristic of this research community is its close personal relationships and collaborations and ongoing engagement in professional endeavours, policy development and advocacy. This overview chapter is also illustrative of expanding participation in ECE, from 1973 when 46% of 3- and 4-year-olds attended an early childhood service to 2012 when the comparable figure was 93% (Education Counts 2013).[1] Each era has shaped and/or been a catalyst to new research agendas and is illustrative of a particular configuration of the interwoven partnerships cited above. The political philosophy of successive governments also shaped each era, which in New Zealand swings between the left-leaning Labour Government and a right-leaning National Government. In global terms the political parties would be characterised as centre left and centre right. In broad terms, the significant advances for ECE have occurred under Labour Governments, whereas National Governments have tended to contain and sometimes curtail earlier development. The research cited in this chapter cannot be not comprehensive, but the examples are illustrative of the changing emphasis of the connections.

[1] The 1973 figure can only be indicative based on a census at the time. The latter figure is broadly accurate based on enrolment data but does include some dual enrolments. The school entry census showed 95% of 4-year-olds had attended ECE.

24.1 Early Policy and Research Beginnings: 1970s

In the 1970s, there were 'haves' and 'have nots', both in terms of types of ECE that received government support and accessibility for families. Despite a groundswell of advocacy for change supported by rafts of conference remits and reports, there was, however, no inclination by government to rethink its policy agenda (May 2001). Despite expanding coverage and funding support for part-day preschool programmes for 3- and 4-year-olds, under the Department of Education, a growing number of children attending childcare services under the umbrella of the Department of Social Welfare were excluded from government funding. This divided administration across government departments meant that childcare was the poor relation of early childhood services, both in terms of reputation and funding. Childcare was seen as suitable only for single parents where mothers 'had to' work or for other 'disadvantaged' families. The research cited in this section is indicative of the beginnings of changing understandings of the provision and role of ECE.

Early research questioned the dominant view that childcare centres offered primarily custodial care, and sessional preschool centres, kindergartens that were established in the late nineteenth century and staffed by teachers, and play centres, established in the 1940s and staffed by parents, provided educationally enriching experiences. Anne Smith and Heather Bain (1978) compared the type of interactions children from childcare centres and play centres had with each other and with staff. The study showed that there were similar interactions in both types of centre but that children attending childcare were engaged in significantly more interactive play (talking about an activity, questioning, planning or co-operative play) than children attending play centre, perhaps because the longer hours allowed those attending childcare to get to know each other better. Another observational study evaluated a high-quality early childhood centre (a Dunedin community childcare centre) and established that the centre incorporated high process quality in its programme – warm, sensitive and responsive interactions and joint involvement in meaningful activities – despite being under the auspices of the Department of Social Welfare and providing longer hours (Smith and Haggerty 1979).

Both of these studies helped support the argument that all ECE can and should provide both education and care, which was reflected in the reforms of the 1980s and 1990s and is outlined in the latter sections of this chapter. The research took a sociocultural and ecological perspective on ECE in New Zealand, viewing children's engagement in social interaction with others in cultural contexts as crucial for learning and development (Bronfenbrenner 1974; Vygotsky 1978). Urie Bronfenbrenner's visit to New Zealand and keynote address at a large cross-sectoral gathering of the ECE sector in 1979 (the Second Early Childhood Convention) were influential, emphasising the importance of the ecological context and the value of connections between children's worlds, and support for those who cared for them (May 2009).

Equity of access to early childhood services by children and families across class and ethnic divides was another issue that arose in the 1970s. This concern was

influenced by the War on Poverty in the USA, which lead to research suggesting that participation in high-quality early childhood programmes could break the cycle of poverty and underachievement for poor minority families (Lamb and Sternberg 1992). The study Who Gets to Preschool? (Barney 1975) provided evidence of the impact of geography, social class and ethnicity on the attendance of children across both childcare and preschool services in New Zealand. He showed that children from lower income and Māori families were less likely to participate in preschool programmes. During the 1960s and 1970s, there were various government-led policies to encourage the attendance of Māori children at preschool, which were based on a deficit rationale of 'compensatory education' and intended to redress the perceived poor home environment of Māori children (May 2001). Two projects illustrate the landscape of early childhood research in the 1970s. They were shaped around concerns for children missing out and touched upon questions concerning the best kind of early childhood programme for so-called disadvantaged children.

Geraldine McDonald's book Maori Mothers and Preschool Education (1973) documented the outcome of Māori community initiatives to establish preschools for Māori children, with a particular focus on the role of mothers and the kind of infrastructure support needed to maintain their viability. She showed that Māori cultural patterns were easily lost when preschool programmes were dominated by Pakeha (European New Zealand people) and suggested that Māori leadership and self-determination would encourage more Māori families to participate. The subtext of McDonald's findings was that community enthusiasm had been undermined by government political rhetoric louder than political action and by solutions that favoured the attendance of Māori children in mainstream preschool programmes.

In 1974, Jane Ritchie established Te Kohanga, a preschool for Māori children that operated as a research project until 1976 and in the same genre of compensation for 'cultural deprivation' as the US War on Poverty initiatives (Irwin 1989). In A Chance to be Equal, Ritchie (1978) challenged established notions of play-based ECE as the best preparation for school. These early research studies are significant in providing insights into the mix of culture, class and ECE of the era. Each study had longer-term policy implications. Smith and Swain (1988) later wrote: "There was little or no questioning of whether Pakeha (European NZ) institutions were appropriate or positive for Māori families" (pp. 117–18).

In 1983, with lessons learned from previous initiatives through both research and the experience of Māori participants, the first Kōhanga Reo, Māori language immersion ECE programmes, were established by Māori themselves, outside of the Department of Education whose preschool institutions were deemed to have failed Māori children and overridden aspirations for tino rangatiratanga [self-determination]. Similarly, government tardiness in addressing the issues of childcare funding and provision radicalised many women with childcare being a key plank of the 1970s women's movement (May 1985). A raft of community and national organisations emerged in support of childcare users, childcare workers and providers. This was the research and policy milieu in which the activism and research of the authors was seeded.

24.2 Before Five: 1980s–Mid-1990s

Characteristic of this second era is the imprint of different government philosophies on ECE policy and that the years of conservative cutback and curtailment sparked new research questions but also yielded an opportunity for a radical rethink of ECE curriculum. The 1984–1990 Labour Government initiated reforms across the education sector. Prior to the 1989 reforms, detailed for early childhood in the Before Five report (Lange 1988), the government shifted childcare from the Department of Social Welfare to unify all early childhood services under the Department of Education in 1986 and introduced an integrated early childhood teacher education qualification (combining the previously separate childcare and kindergarten training) in 1988. On the industrial front, the older Kindergarten Teachers' Association and the Early Childhood Workers Union for childcare formed the Combined Early Childhood Union of Aotearoa. Cumulatively, these changes were significant as a blueprint to remove entrenched divides between care and education. Before Five was premised on ideals of equity, addressing the interests of children, of women and of cultural survival, the latter being of particular importance to Nga Kohanga Reo [2] and the emerging centres for migrating Pacific Islands people. Overall, the reforms were intended to acknowledge the diversity of services in terms of philosophy, culture, structure and ownership, improve participation, address affordability, integrate care and education, support quality for children, improve the status of teachers and enable women to work in paid employment with improved childcare support. Despite resistance from the Treasury, ECE won additional funding to implement the new policies. Anne Meade, a significant architect of the reforms and a leading researcher, celebrated that the reforms enabled "Women and young children [to] gain a foot in the door" (1990, p. 96). Disappointment followed as the 'door' did not open fully (Dalli 1993). A National Government elected in 1990 curtailed the funding package. A shift towards deregulation and right-wing market ideals undermined some of the tenets of Before Five. Research projects of this second era reflected political concerns in a shifting policy landscape, with researchers seeking to provide hard data to convince policy makers about the best policy for quality ECE. The New Zealand research was influenced by US longitudinal intervention studies showing the lasting effects of participation in high-quality ECE (e.g. Schweinhart et al. 1993) and studies on the aspects of quality ECE that had an impact on children's development such as ratio, group size and training (Lamb and Sternberg 1990, 1992).

The Competent Children study, initiated by Anne Meade, helped persuade government that it was worthwhile investing in ECE. The study followed 307 children from 4 years of age and looked at the contribution that quality ECE and other variables (such as family and school) made to children's competence (Wylie et al. 1996). Participation in quality ECE influenced children's later competency in literacy and mathematics achievement at school as well as perseverance, communication

[2] Nga Kohanga Reo are language immersion early childhood centres for under 5-year-olds, designed to strengthen cultural and Māori language knowledge.

and logical problem-solving (Wylie and Thompson 1998). Better literacy and numeracy scores were associated with teachers asking open-ended questions, providing a print-saturated environment, engaging in children's play and providing age-appropriate resources and opportunities for co-operative activities (Wylie and Thompson 2003).

The visit of American researcher, Bettye Caldwell (1967) in the late 1970s, and her research on infant childcare had suggested that rich childcare settings for infants could be a particularly powerful positive influence on their development but that infants were very vulnerable to poor quality. Anne Smith's research in the early 1990s was influenced by Caldwell's work. Smith wanted to know what sort of quality was offered for infants in New Zealand early childhood centres and what its influence was. Her observational study of 200 under 2-year-olds in 100 childcare centres throughout New Zealand examined the influence of staff training qualifications and other aspects of structural quality (staff-child ratios, staff turnover, working conditions, salaries) on process quality, as measured by the nature of the interactions between staff and children (Smith 1996; Smith et al. 1995). The study showed an association between 3-year staff training and measures of quality (Smith 1996, 1999). Highly trained staff were more likely to be engaged in joint attention episodes with infants, suggesting that a more advanced level of training directly influenced quality processes (Smith 1999). The study also showed that the strongest predictor of high quality within centres was the wages of the staff and that working conditions were also important. The findings of this research fed directly into later debates and forums, fuelling calls for improved funding for early childhood (particularly childcare) centres, for better regulations to maintain quality and for widespread reforms towards a qualified early childhood workforce, a career structure and appropriate salaries for staff.

The first half of the 1990s was a time of extended debate and discussion about an appropriate philosophical and curriculum approach for ECE in New Zealand. This debate was particularly pertinent to the development of New Zealand's early childhood curriculum guidelines, Te Whāriki (Ministry of Education 1996), which began with Helen May and Margaret Carr from the University of Waikato winning a Ministry of Education contract, and their partnership with Māori leaders, Tilly Reedy and Tamati Reedy, in developing a bicultural, holistic curriculum (Smith 2010a). Sociocultural theory (Rogoff 1995; Vygotsky 1978; Wertsch et al. 1995) was becoming increasingly influential internationally because of the quiet revolution that had been taking place in developmental psychology. The rediscovery of Vygotsky puts much more focus on the importance of responsive social contexts as the crucible of thinking, in contrast to the traditional Piagetian approach of a free play curriculum with the teacher standing back and allowing children to explore.

A sociocultural approach linked with the ongoing debate in New Zealand about whether it was possible to separate care and education in environments for young children. Sociocultural theory suggested that a key element to promote learning was a shared frame of reference between adults and children (or between children) and that this was facilitated by caring and warm relationships. It reinforced Anne Smith's (1993) critique that there was a false dichotomy between education and care

institutionalized in New Zealand's separate types of early childhood services (child-care centres, kindergartens and play centres). She challenged the separation of education and care, and the laissez-faire free play approach, and suggested that instead teachers should jointly participate in activities and share meanings with children.

A sociocultural framework was also sensitive to the key issues of foregrounding of Māori world views, cultural practices and perspectives in ECE. These issues and many others were discussed and debated up and down the country during many consultations, meetings and amongst a diverse group of practitioners over an extended period between 1991 (at the beginning of the Ministry contract) and the introduction of the final curriculum to all early childhood centres in 1996 (Carr and May 1996). This was an era shaped by sharp political differences, considerable advocacy, turmoil and change in the ECE sector, alongside new theoretical paradigms which began a transformation of ECE policy and practice.

24.3 Te Whāriki: Mid-1990s–2000s

A significant wave of mainly qualitative research arose in the aftermath of Te Whāriki and the development of an associated narrative assessment approach called Learning Stories (Carr 2001; Carr et al. 2004–2009). This body of research was initiated by professional and researcher interests. Government agencies provided funding support, with the Ministry of Education managing the development of resources to support teachers in the implementation of Te Whāriki. This has been a long-term and ongoing process and a fruitful engagement across political and policy interests, research expertise and professional concern. The story of Te Whāriki's development as a bicultural partnership with Te Kohanga Reo Trust and the project co-ordinators, Margaret Carr and Helen May, has been well documented (Carr and May 1994, 1996, 1999; Smith 2010a; Nuttall 2013). This following section summarises the impetus Te Whāriki, as a curriculum document, has had on subsequent research agendas.

The theme of empowerment was important for Māori, and 'empowering children to learn and grow' became a foundation principle. Te Whāriki was about self-determination. A set of parallel Aims for Children in Māori and English were developed, as equivalent aspirations of empowerment in both cultures. Te Whāriki made a political statement about children: their uniqueness, ethnicity and rights in New Zealand. For people from the Pacific Island Nations (and other cultures), Te Whāriki provided a curriculum space where language and cultures could be in the foreground and not an add-on. The curriculum was envisaged as a whāriki, translated as a woven mat for all to stand on, and provided the framework which allowed for different programme perspectives to be woven with many possible 'patterns'. It provided signposts for individuals and centres to develop their own local curriculum through a process of talk, reflection, planning, evaluation and assessment. The aspirational principles of Te Whāriki construct children of New Zealand as both powerful and participating and are premised on principles of the rights of the child and

child agency. Te Whāriki's research journey became a tool to challenge older beliefs and reshape practice according to its ideals.

The curriculum emphasises the critical role of socially and culturally mediated learning and of reciprocal and responsive relationships with people, places and things. Children learn through collaboration with adults and peers, through guided participation and observation of others as well as through individual exploration and reflection (Ministry of Education 1996, p. 6).

Learning is conceptualised in Te Whāriki as arising out of the context of meaningful joint activity in cultural contexts using the tools of culture (language, stories, songs, rituals, family connections). Rather than assuming that there is one developmental pathway, development emerges from cultural goals with the guidance of community practice and expertise. Te Whāriki assumes that children will learn according to the opportunities they are given to participate and the guidance and stimulation provided by adults. The concept of learning dispositions, defined as 'habits of mind that dispose the learner to interpret, edit and respond to experiences in characteristic ways' (Carr 1997, p. 2), underlies Te Whāriki. Examples of learning dispositions are persevering with difficulties rather than giving up and avoiding failure, communicating with others and being imaginative. This approach suggests that teachers should avoid teaching fragmented skills but encourage and provide opportunities to exercise ongoing learning strategies and strengthen children's identities as competent learners in a range of different situations (Cowie and Carr 2009).

Researchers from Waikato and Otago universities (Carr et al. 2010) have investigated how children's learning dispositions are shaped by learning contexts over time (between the ages of 4 and 5 years). They focused on three dispositions – reciprocity, resilience and imagination – in 14 case studies, looking at the affordances offered by educational settings for children to develop learning identities and transfer learning strategies to new situations. The book presents a theoretical analysis of dispositions and the environmental characteristics that support them, illustrated by many learning episodes. For example, David, previously a reluctant writer, engaged in a story-writing session at school, and his teacher responded to his attempts by telling him that he is 'a clever writer' (Carr et al. 2010, p. 94). The teacher reflected that something 'clicked' for him on that day and he became much more eager to participate in writing.

A challenge in the implementation of Te Whāriki was to find a way of assessing its impact on learning, and this resulted in the development of a narrative, holistic bicultural approach to assessment, Learning Stories, which documented significant learning moments in children's everyday experiences (Carr 1997, 1998, 2001). Learning stories allow teachers to gain windows onto children's world views and assumptions, as well as allowing children to retain significant ownership of their stories and to share meaning and power with adults. Teachers documenting a child's learning story focus on five areas related to dispositions – finding something of interest, being involved, engaging with challenge, persisting when there are difficulties, expressing a point of view and taking responsibility – all of which align with the strands of the curriculum. The Ministry of Education contracted a team led by

Margaret Carr from the University of Waikato to capture exemplars in early childhood centres and to produce illustrated books documenting a variety of learning stories. These exemplars, known as Kei Tua o te Pae (Ministry of Education 2004–2009), are not prescriptive but illustrate a variety of ways to implement the curriculum and possible future learning pathways. The stories have been a powerful way of encouraging teachers to have positive constructions of children's competence, share stories with children and families and support teachers' confidence in trying out new ideas. Children also gain a strong sense of ownership and pride in their own learning and enjoy sharing the stories with family, friends and teachers (Carr et al. 2005).

More recent research has focused on developing a Māori approach to assessment, Te Whatu Pōkeka, to enable the assessment of children's learning journeys in their unique cultural contexts (Ministry of Education 2009; Rameka 2012). Te Whatu Pōkeka is a resource for teachers in Māori early childhood centres, produced by Māori researchers Lesley Rameka and Rita Walker, which gives exemplars of assessment that draw on children's history, cultural heritage and Te Ao Māori (Māori world views). Te Whatu Pōkeka is designed to help 'Māori children develop a strong and secure sense of identity that emphasises their connectedness to their ancestors, the universe and everything in it, and the spirit world' (Rameka 2011, p. 254). For example, whakapapa (genealogy and history) is incorporated into early childhood programmes through genealogical narratives layering generations of ancestors into the lifeline of those living today. The importance of whakapapa is the connection to land and other forms of life over time and space, establishing personal and collective identity (Rameka 2011). This section has provided some glimpses into a research agenda shaped by Te Whāriki although the era of 'Te Whāriki', its implementation and research story, is ongoing.

24.4 Early Childhood Strategic Plan: 2000s

In 1999, a Labour Government returned to power with an election platform agenda to recapture the impetus of the Before Five (Lange 1988) policies that had languished. In this era ongoing curriculum research initiatives (cited above) were entwined with policy-focussed research. The small research community was hard at work and supported by a growing number of new doctoral students and graduates.

Between 1999 and 2008, the government introduced equity funding to support participation in 'high-need' centres and services, delivered 20-h free ECE per week for 3- and 4-year-olds across all early childhood teacher-led services, and was on target to have teacher-led ECE centres staffed 100% by qualified teachers by 2012. These policies were embedded in the Labour Government's Strategic Plan, Pathways to the Future – Ngã Huarahi Arataki 2002–2012 and intended to provide a robust infrastructure for delivering high-quality, affordable ECE participation by all children (Ministry of Education 2002).

The Strategic Plan for Early Childhood (Ministry of Education 2002) was well founded in research and informed by the cumulative experience and dialogue of the previous 20 years within the early childhood sector. Immediately after the election in 1999, the Ministry of Education contracted a Children's Issues Centre team at the University of Otago to produce a literature review on ECE (Smith et al. 2000). The review showed that there were high participation rates in ECE (but lower for Māori or Pasifika children), that participation in EC was associated with cognitive gains and improved school performance and that in order to achieve positive outcomes, it was essential that children participated in quality programmes. Quality involves subjective components of what is valued in a society but also objective components linked to positive outcomes like staff training, staff-child ratios and group size, as well as sensitive and responsive adult-child interactions and joint engagement in meaningful activities. This research was used by the Ministry of Education and the Strategic Plan Working Group to develop strategic directions, which included increasing participation, improving quality and increasing collaboration between services.

The scope of New Zealand's early childhood policy directions received international attention. Peter Moss (2007) described New Zealand as 'leading the wave' of early childhood innovation, having 'confronted the wicked issues' (p. 33). Moss (2008) explained:

> New Zealand has developed a national framework, which brings some coherence to the system around issues of equity and access. One Ministry is responsible for all ECEC [Early Childhood Education and Care] services; there is a single funding system for services (based on direct funding of services rather than parents); a single curriculum; and a single workforce, which by 2012 will consist of early childhood teachers, educated to graduate level. Underpinning these structures, and perhaps the most radical change of all, New Zealand has an integrative concept that encompasses all services – 'early childhood education', a broad and holistic concept that covers, children, families and communities, a concept of 'education-in-its-broadest-sense' in which learning and care really are inseparable and connected to many other purposes besides. New Zealand has, in short, understood the need to rethink as well as restructure early childhood education and care. (pp. 7–8)

The Strategic Plan years created a fertile research environment, including evaluative studies addressing the new policy directions. The Ministry of Education contracted an evaluation of the implementation of the Strategic Plan between 2004 and 2009 (Mitchell et al. 2011). The study involved collecting data from 32 services in eight localities varying in geography and ethnic composition. Participation had increased markedly by 2009 (by 19%), children were participating for longer hours, affordability for parents had increased, and services were more viable. Quality was found to be good or very good in two thirds of centres but only fair or poor in about a third. Factors associated with high quality were teachers being involved in professional development, higher proportions of registered teachers being employed and use of Te Whāriki and associated resources. Linda Mitchell and colleagues (Mitchell et al. 2011) commented on the positive shifts on every indicator of teaching and learning associated with high usage of the Ministry of Education resources such as Kei Tua o Te Pae (the exemplars) (Ministry of Education 2004, 2007, 2009), the

Self-Review Guidelines and the Centres of Innovation reports (see later discussion).

In 2003, the government funded two new research initiatives, the Teaching and Learning Research Initiative (TLRI) and Centres of Innovation programme (COI), which have supported a range of early childhood projects around teaching, learning and curriculum (Meade 2010a, b; Nuttall 2010). Both initiatives were premised on the idea of partnerships between researchers and education professionals and encouraged the interrogation of practice towards richer weavings and understandings of Te Whāriki. The TLRI was a cross education sector-wide initiative intended to enhance the links between education research and teaching practices to improve outcomes for learners. A recommendation from the Strategic Plan (Ministry of Education 2002) was to establish early childhood centres that showcased innovation (COIs) that, on a 3-year cycle, would embark on an action research journey in partnership with experienced researchers to enable deeper exploration and documentation of innovative teaching and learning processes. The strategy was aimed at disseminating and showcasing quality practice across the sector. Anne Meade led the COI projects. Her task was to co-ordinate, support and build research capacity within the various COIs. From 2005, the various research journeys were documented and disseminated in a series of publications (Meade 2005, 2007, 2010a, b).

The COIs involved partnerships and collaboration between early childhood teachers and researchers. Meade (2007) points out that traditionally, teachers have been placed in a passive role in relation to research, but the COI projects gave teachers leadership experience and helped them to theorise, reflect and discuss their practice, as well as to disseminate their findings to networks of colleagues. The impact of these projects exceeded all expectations and played a critical role in enabling centres to flourish, improve their practice and engage in critical thinking (Ramsey et al. 2013). The funding for COI projects was terminated in 2008.

One of the earliest COI projects was to strengthen children's agency and increase their competence and confidence using ICT (computers, cameras, photocopier, laminator, etc.) in order to deepen learning and broaden assessment (Ramsey et al. 2005; Ramsey et al. 2013). It was undertaken at Roskill South Kindergarten and attended by mainly 3- and 4-year-old children prior to school entry. The project helped to develop a culture in the kindergarten where the children became competent with digital technology and could produce videos and narratives to incorporate into their Learning Stories. Teachers saw the technology as just another tool that helped them to notice, recognise and respond to children's learning. Teachers ran workshops, held visitor days and developed professional resources to disseminate the findings of the project.

Another project was carried out in a Samoan-language immersion centre in Auckland (Podmore et al. 2007). This innovation placed small groups of children together with their teacher (and primary caregiver) from the point of entry through to school with a strong focus on supporting language immersion and bilingualism. Children in the centre became capable, confident and competent in Samoan and engaged in meaningful conversations with peers and teachers. Children's sense of belonging was also enhanced by their participation in stable groups.

The TLRI recognises the value of involving practitioners in collaborative research with researchers. The programme is designed to strengthen the links between educational research and teaching practice, to improve learning outcomes and to build research capacity and leadership in the early childhood sector. Examples of these projects include a study of the role of visiting teachers in improving the quality of educators' practice in home-based care (Duncan et al. 2009), an investigation of teachers' understanding and recognition of infant learning and an articulation of the specialised nature of infant pedagogy (Dalli et al. 2011) and a project designed to strengthen bicultural strategies in ECE and increase the confidence and competence of teachers in Māori tikanga (cultural practice) in order to support the participation of Māori tamariki and whānau (Ritchie and Rau 2008).

Linda Mitchell and her colleagues were contracted by the Ministry to provide policy makers with a synthesis of research on the impact of ECE on children and their families (Mitchell et al. 2008). Like the earlier review (Smith et al. 2000), it showed consistent evidence of the influence of participation in ECE on short- and long-term cognitive and noncognitive outcomes for children (especially those from low-income families), that the key to achieving positive outcomes was quality ECE and that investing in good quality ECE brought about cost savings and benefits for societies and economies.

This era is illustrative of a particularly close synergy across professional, research and political domains. Research evidence supported policies that drove up the costs of ECE, but political opinion determined that these costs be carried by a supportive state, making quality ECE more affordable for parents. However, an incoming government was soon poised to redraft the policy and research landscape.

24.5 Early Childhood Taskforce: 2010s

The final era sketched for this chapter is illustrative of the division in New Zealand political opinion and policy. The election of a government led by the National Party in November 2008 caused a shift in ECE policy directions (Smith 2013; May 2014). Researchers are still midstream in adjusting to the new ethos. A worldwide economic downturn was used to justify a funding retrenchment. Cutbacks were made to fund for research, training and professional development programmes and the COI programmes. Labour's target of 100% of fully qualified teachers in early childhood centres was cut to 80%. Instead, the government's specific focus was to achieve 98% participation in ECE. There were new initiatives to improve early childhood participation in 'high-need' locations with mainly indigenous Māori children or Pasifika children. The cutbacks around quality were called 'a brutal blow' (Te Tari Puna Ora o Aotearoa -New Zealand Childcare Association 2010). The largest daily newspaper, *The New Zealand Herald* (24 May, 2010), summed up more conservative opinion with the 'Editorial: Preschool Budget cuts right move':

> Plainly National does not regard specialist teaching of pre-school children to be quite as important as Labour did. It is probably right. … Did childcare centres ever need to be fully staffed by trained teachers? Or is this a classic case of 'qualification inflation'. … It is easy to insist little children deserve nothing but the best. … but 'the best' at that level might not require professional training. The Government is right to direct more of its early education support to areas where children are missing out. … Contentious the decision may be but it seems educationally harmless, socially equitable and financially necessary.

The issue remains contentious, reflecting political divides over state interest in the universal funding of quality ECE for all children versus targeting funding towards those children and families deemed to pose risks to the economic and social infrastructure of the country. The focus on targeting disadvantaged children and families was also reflected in the government's welfare policies and especially their Green Paper on Vulnerable Children (Ministry of Social Development 2011) that viewed children in terms of their vulnerabilities and deficits.

Anne Tolley (2011), Minister of Education between 2008 and 2011, justified the government's position:

> Taxpayer investment in early childhood services has trebled over the last 5 years…Despite this growth in funding, too many children that the evidence tells us would benefit most from ECE are still missing out. They are at a disadvantage before they even start school. The economic reality is that money will be tight for the foreseeable future, so more than ever we must invest in the areas that will make the biggest difference to children and their families.

This shifting narrative became a catalyst for research investigating the links between qualifications, quality and outcomes for children and addressing political questions around the effectiveness of early childhood. The policy backdrop to these concerns was the establishment of an ECE Taskforce in 2010 (ECE Taskforce 2011). The terms of reference addressed Government concern over the rising expenditure on ECEC. The phraseology included 'effectiveness and efficiency of the Government's current early childhood expenditure', 'the value gained from the different types of investment' and determining 'cost effective and evidence-based ways to support children's learning in early childhood' (p.13). The report reiterated the evidence that there was a strong case for investment in high-quality ECE especially for low-income children, drawing heavily on economic analyses of benefit/cost ratios (p. 22). The Government asked the Taskforce to propose a new funding model 'without increasing current government expenditure' (ECE Taskforce 2011, p. 176). The funding recommendations were controversial, proposing a shift in emphasis from universal funding mechanisms towards targeting 'priority children'. Taskforce member Anne Smith (2011) released a minority report addressing the matter:

> The argument is that the new funding system will be better for low SES and Māori and Pasifika, but there is little information about how the new scheme will be able to accurately seek out and identify targeted groups. (pp. 2–3)

There were other worrying things in the Early Childhood Taskforce Report including the focus on economic development as opposed to child wellbeing or the rights of children, on getting parents into the paid workforce without

acknowledgement of the value of unpaid parenting work, and support for the unfettered market (Smith 2013). The current government has a strong drive towards coercing beneficiaries back to work, culminating in 2013 with the introduction of a policy to make it compulsory for beneficiaries to enrol their children in ECE for at least 15 h per week, with benefits cut as a sanction for noncompliance. This initiative was also connected to the government's goal of increasing the participation of vulnerable children in ECE.

The Taskforce had noted that 'one of the most important indicators of structural quality of an ECE service is the availability of appropriately qualified staff' (ECE Taskforce 2011, p. 45). The Taskforce, however, did not comment on whether it supported the government's policy of cutting funding for centres with 100% qualified staff, though it recommended increasing the regulated minimum from 50 to 80%. Minister Tolley claimed that there was no research evidence to show centres staffed 100% by qualified teachers were better than 80% of staff being fully qualified teachers. Conversely, Anne Smith (2010b) claimed that:

> Such research would be hard to do. (There are few countries that employ 100% qualified teachers in ECE). There isn't any research either which shows that 100% qualified staff isn't better than 80%. (p. 2, emphasis in original)

Smith said that there was plenty of research demonstrating that 'Qualified teachers provide more sensitive and responsive learning opportunities for children. … Logically the more qualified teachers…. the better outcomes there will be for children's well-being and learning' (p. 2).

Minister Tolley's challenge about the value of all early childhood staff being fully qualified teachers stimulated further research: the Early Childhood Teachers' Work Study (Meade et al. 2012). This research compared staff-child interactions in five centres staffed 100% by fully qualified teachers and five centres with 50–79% of staff who were qualified teachers. In the centres with 100% qualified staff, teachers interacted more and were more responsive to children, were more likely to model and encourage children, participate in children's play and activities, ask open-ended questions, foster language development and provide complexity and challenge for children. Children in the fully qualified centres were more likely to be involved in an education programme, work with symbols systems and to have access to more resources. One key indicator of quality processes is the amount of sustained shared thinking between adults and children, and this was higher in the centres where all staff were qualified teachers. Teachers also had greater pedagogical expertise and were better able to link theory to practice. Children in the centres with 100% of teachers had higher scores on indicators to do with independence and concentration (known to be associated with self-control, one of the strongest predictors of later success in life). The study added to a considerable volume of other research showing that teacher qualifications were a significant component of quality ECE. This final era outlined in this chapter is paused midstream at the time of writing because 2014 is an election year. It was unclear whether the National Government's redirection of ECE policy will become more entrenched or whether,

if elected, a Labour Government will as promised emphasise again the supportive state nudging towards universal provision funded by the state.

24.6 Summary and Conclusion

In almost half a century, radical changes have taken place in our ECE system in Aotearoa, from a divided and unevenly funded system towards a system with a coherent national policy framework, an integrated funding system, widespread improvements in quality, almost universal participation and the implementation of an innovative bicultural holistic curriculum. All of these policy changes have been connected to research agendas and programmes driven by a coalition of researchers, child advocates, parents and staff, concerned with the rights of children and their families to high-quality, accessible and affordable ECE. Initial research was sporadic and initiated by individual academics, but since the 1980s, research funding from government has provided significant support for important policy questions to be addressed by teams of researchers, including collaborative partnerships between practitioners and researchers. There is now a solid body of research evidence supporting the value of investment in high-quality ECE, although debates about the nature of quality continue and the political will to implement accessible and high-quality care have waxed and waned. The 2014 election will determine whether New Zealand's world-class ECE system will remain intact or whether it will be further eroded and move towards targeted funding approaches.

Chapter 25
Towards Wawasan Brunei 2035: Early Childhood Education and Development in Brunei Darussalam

Hanapi Mohamad, Rosyati M. Yaakub, Emma Claire Pearson, and Jennifer Tan Poh Sim

Abstract Asia's early childhood education policies and development are still relatively new compared to European countries. Brunei Darussalam is no exception. However, Brunei may be of interest to international readers because of recent developments in the provision of formalised early childhood care and education. Brunei's National Vision, known as Wawasan 2035, is an ambitious national agenda which supports the formal education system, among others, with specific emphasis on early childhood education and care as part of the strategic role of education. Brunei's national goals are unique due to its widespread consultation with the citizens, on which they are built, as well as their attempt to balance modernisation with parallel efforts to retain essential cultural and spiritual values. Government commitment to this particular agenda has been forthcoming both in terms of changes in policy, ongoing supported efforts to upgrade the quality of teaching and learning in existing government preschools and funding for innovative approaches to expanding early childhood care and education.

This chapter provides insight into past and current systems of early care and learning opportunities for young children in Brunei Darussalam, as well as describing future goals and innovative initiatives designed to strengthen and expand early childhood education and care in the nation, with particular reference to a national research and development project that aims to produce a Brunei-specific curriculum for 3–5-year-olds in the country. Part of the government's intention of expanding the current system of state-funded provision is to include children between 3 and 5 years of age.

Keywords Brunei's preschool education system

Brunei Darussalam is the smallest country in the Southeast Asian region. It is located on the island of Borneo and shares a common border with the states of Sarawak and Sabah in Malaysia. Despite its small size, Brunei Darussalam may be of interest to international readers because of recent developments in the provision of formalised early childhood care and education, resulting from changes in national policy. In the mid-2000s, the Brunei government introduced an ambitious national agenda for economic development, outlined in Wawasan 2035 (Brunei Govt. n.d.), otherwise known as the National Vision. Traditionally a relatively conservative nation with relatively high standards of living within the region, strong spiritual values and high dependency on oil exports for income, Brunei's National Vision is designed to support a strengthened economy by producing an 'educated, highly skilled and accomplished people…' and 'a dynamic and sustainable economy' (Brunei Govt., p. xiii). The formal education system, with specific emphasis on early childhood education and care as part of the strategic role of education, features as a key aspect of the government's framework, in moving towards achievement of the National Vision.

As a small country, there is potential in Brunei Darussalam to achieve ambitious aims. Brunei's national goals are unique due to both widespread consultation with the 'rakyat', or citizens, on which they are built, and their attempt to balance modernisation with parallel efforts to retain essential cultural and spiritual values. An opening message from His Majesty Sultan Haji Hassanal Bolkiah, Sultan and Yang Di-Pertuan of Brunei Darussalam, highlights the importance of connectivity between state and citizenship in achieving the National Vision:

> They (the Council) have looked ahead and recognised the needs of our future generation….. (T)hey have asked our people to describe what kind of country they wish Brunei Darussalam to be thirty years from now, when our children will be competing their careers and our grandchildren will be assuming responsibility for our country's affairs and for its people's fresh hopes…. As a result, they have identified many of the demanding personal, social, spiritual, cultural and economic challenges that will be set in the next three decades by the new world in which our young people will grow and become adults. (p. v)

The unique approach that is being taken to 'manage' the process of modernisation and development is also reflected in the words of His Royal Highness Prince Mohamed Bolkiah, Chairman of the Council for Long-term Development Plan and Minister of Foreign Affairs and Trade, who writes by way of introduction to the same document,

> (W)e have summarised these hopes as follows:
>
> To maintain the political stability Brunei Darussalam continues to enjoy.
> To preserve our social, culture, spiritual and historic values.
> To help our people meet the practical challenges of the modern world successfully.
> To give our families and communities confidence in the future. (p. ix)

As part of the nation's focus on upgrading national education systems, there is a considerable interest in the development and expansion in provision of formalised early childhood care and education. As this chapter highlights, government commitment to this particular agenda has been forthcoming both in terms of changes in

policy, funding for innovative approaches to expanding early childhood care and education, and ongoing supported efforts to upgrade the quality of teaching and learning in existing government preschools. Despite all these opportunities and gains, the country also faces considerable challenges in achieving some of the goals that have been set, most importantly in terms of introducing change to well-established systems that have been relatively untouched for some time, and expanding the current system of state-funded provision to include children between 3 and 5 years of age. This chapter provides insight into past and current systems of early care and learning opportunities for young children in Brunei Darussalam, as well as describing future goals and innovative initiatives designed to strengthen and expand early childhood care and education in the nation.

This chapter is divided into five sections. The first provides background information on Brunei Darussalam, including a brief overview of geography, demographics, people, history, philosophy, culture and values. The second section outlines current national policies that guide provision of formalised early childhood care and education in the country. The third section provides a historic overview and current situation of early childhood education in the country. The fourth section focuses on current challenges and opportunities in the provision of early childhood education and care in Brunei. The final section of this chapter looks at future and ongoing developments that are currently taking place, with particular reference to a national research and development project that aims to produce a Brunei-specific curriculum for 3–5-year-olds in the country.

25.1 Context of Brunei

Brunei is divided into four administrative districts, Brunei-Muara, Tutong, Belait and Temburong. The capital city, Bandar Seri Begawan, is situated in the Brunei-Muara District. The Brunei-Muara District is the most populated district in the country, followed by the Belait District, Tutong District and the Temburong District. As of July 2013, the total population of Brunei was estimated to be 415,717 of which 24.6% were between the ages of 0 and 14 years. The population growth rate is estimated at about 1.67%. Brunei is a multi-ethnic country, where in 2004, it was estimated that 66.3% of the population were Malays, 11.2% Chinese, 3.4% indigenous and smaller groups making up the rest. Islam is the official religion of Brunei, and two-thirds of the population adheres to Islam. Buddhism (13%), Christianity (10%) and other faiths (10 %, including indigenous beliefs) are also practised in the country (IndexMundi 2013).

The nation's official language is 'Standard' Malay, which refers to a formal, standardised version of Malay that is spoken across the Malaysian peninsula; however, English is also widely spoken. In addition to Malay, several other dialects are also widely spoken in the country. Locally, the most widely used local dialect of Malay is Brunei Malay although Standard Malay is used for formal purposes, for example, in government offices. Brunei Malay, Standard Malay and English, as well

as Chinese languages (Mandarin and local dialects), are likely to be encountered on a regular basis, especially in the towns. In government schools, teachers are required to use either Standard Malay or English as the language of instruction, depending on the subjects taught. The reasons for this are both pragmatic and historical (Brunei having been heavily influenced by British government administration in the past); however, this has resulted in a very marginal role for minority languages in Brunei beyond the family and local community (Coluzzi 2012).

Brunei Darussalam attained full independence from the United Kingdom on the first of January 1984. The reigning monarch, His Majesty Sultan Haji Hassanal Bolkiah Mu'izzaddin Waddaulah, is the 29th ruler of Brunei and occupies positions as Head of State and Head of Government. The Sultan embodies the executive, the legislative and the judicial branches of government. He both reigns and rules, with assistance from a Privy Council on matters concerning the royal household and customs, and by a cabinet and bureaucracy on most other matters. He also serves as the State's Prime Minister, Finance Minister and Defence Minister. Brunei is one of the largest oil-producing countries of the British Commonwealth (Hussainmiya 2002).

Upon independence from the British administration, efforts were made to promote a sense of national identity in the country. Melayu Islam Beraja (Malay Islamic Monarchy also referred in this chapter as MIB) was officially proclaimed as the 'national philosophy' of Brunei on the day of its independence by Sultan Haji Hassanal Bolkiah Mu'izzadin Waddaulah. Melayu Islam Beraja is described as 'a blend of Malay language, culture and Malay customs, the teaching of Islamic laws and values and the monarchy system which must be esteemed and practiced by all' (as cited in Brunei Government 2012). This national philosophy, which is incorporated as a mandatory component of the school and university curriculum, is aimed at forging a strong sense of identity as well as fostering unity and stability. While Brunei's official religion is Islam, the national philosophy is ostensibly one of respectful tolerance, allowing for the practice of other religions and beliefs. Melayu Islam Beraja thus forms the backbone of Bruneian cultural identity.

As an Islamic nation, Brunei observes special days in the Islamic calendar such as Hari Raya Aidil Fitri (a celebration after a month of fasting) and Hari Raya Aidil Adha (a celebration after the month of pilgrimage). Other religious holidays and celebrations observed in the country include the birth of Prophet Muhammad (peace be upon him (pbuh)), Hijrah (the migration of Prophet Muhammad pbuh and his followers from Mecca to Medina), Nuzul Al-Quran (the revelation of the Quran) and Isra' Mikraj (Prophet Muhammad's physical and spiritual journey from earth to heaven). The Brunei government supports staff during the fasting month of Ramadan by allowing all government officers and staff to work only 6 h daily (as opposed to the 7.5 h daily of normal working hours outside Ramadan), while all entertainment and sport activities are temporarily suspended. The government has taken measures to support the practice of Islam in the country, by closing all business premises between 12 and 2 pm during Friday prayers. In addition, 'doa' or prayers are incorporated in all official government functions. His Majesty also encourages the recital of the Holy Quran every morning prior to the start of work. The influence of Islam

extends to the school system, the curricula and the classroom practice, as highlighted by Hanapi (2006). Before classes begin, students assemble to sing the national anthem and recite a special school prayer seeking Allah's blessing for success in their academic and future endeavours. Additionally, daily greetings in Arabic are a common practice, for example, 'Assalamualaikum' (peace be upon you) and then followed by the usual Malay greetings 'Selamat pagi cikgu' (Good morning, teacher). Thus, Islam is inevitably significant in shaping the everyday lives of children in the country (Hanapi 2006).

25.2 Early Childhood Care and Education in Brunei: Current Policies

Brunei is a tax-free country, and its citizens have the privilege of free basic education and health services. The formal school system in Brunei Darussalam adopts the 7-3-2-2 pattern representing 7 years of primary education including a year of preschool, 3 years of lower secondary, 2 years of upper secondary or vocational or technical education and 2 years of pre-tertiary education. In terms of formal provision for young children, Brunei Darussalam's definition of 'early childhood' refers to the period between birth and 8 years of life. Formalised early childhood education and care comprises a combination of medical, developmental and educational services extended to children within this age range. The policies that underpin provision of these services are outlined below. Since 1979, the Brunei government has provided free preschooling for 5–6-year-olds, in the year before formal primary school begins. These state-funded preschools are attached to government primary schools and follow a curriculum that is geared towards supporting children in attaining basic learning skills required for successful entry into primary school. Historically, the majority of children aged below 5 years of age have been cared for at home, either by extended family members or by foreign domestic helpers, who are widely employed by families in Brunei Darussalam. To date, there has been little research to gauge the openness of families to formalised, out-of-home care. However, in response to increasing regional and global awareness of the possible social and educational benefits of high-quality formalised education and care, the government has begun to consider expanding the provision of formal early childhood education to younger children. Current moves in this direction include the development of a national quality framework for children aged between birth and 5 years, and a recent needs and costing analysis to inform the possibility of government provided services for children aged between 3 and 5.

Formal, centre-based early childhood education and care for children between 3 and 6 years of age includes a range of services and programmes provided by various ministries and private institutions. Currently, the Community Development Department (Jabatan Pembangunan Masyarakat (JAPEM)) in the Ministry of Culture Youth and Sports is responsible for services that relate to the social care and

development of children under 3 years of age, and the Ministry of Education is responsible for education and development of children above 3 years of age. In addition to that, the Ministry of Health is the lead agency in providing medical needs for children in Brunei.

In January 1996, Brunei Darussalam ratified the United Nations Convention on the Rights of the Child (UNCRC), indicating its commitment to fulfilling child rights. The Ministry of Culture Youth and Sports holds responsibility for preparing regular country report cards on the situation of children's rights in the country, for submission to the United Nations Committee on CRC. Brunei Darussalam's recognition that early childhood education and care is crucial in providing a strong foundation for building a nation, and its human capital has further strengthened in recent years, with the introduction of a series of legislative mechanisms designed to guarantee children's early education and well-being. In line with world trends on inclusive education, Brunei Darussalam also officially endorsed the concept of inclusion in 1994, with the introduction of the inclusive special education policy. As part of this policy, which is geared primarily towards supporting students who are struggling academically in mainstream settings, the Ministry of Education has in place 'special education' support services attached to primary (and a small number of secondary) schools (Koay et al. 2006). These support services are staffed by Special Educational Needs Assistance (SENA) teachers with specialist education and training.

While government schools offer preschooling for children aged 5–6 years, formalised early childhood education for children younger than 5 years old is currently provided by private, largely profit-making organisations. Cost can range between B$100 and B$200 per month, per child. However, these private organisations are mostly concentrated in the city and the surrounding areas. Only a few of these private schools are available elsewhere. The government provides an education allowance of B$120.00 per month for each child aged 5 years old and above, but only to citizens and permanent residents who are government employees who choose to send their children to private institutions. Citizens with low income can apply for extra support from the government for their children's schooling needs at government schools. These supports include subsidised uniforms, books, stationaries, school bags and so on. Not unlike many other countries (Rao and Jin 2010), ministries in Brunei Darussalam have traditionally functioned in relative isolation; however today there are a number of initiatives (some of which are outlined in this chapter) that are designed to strengthen inter-sectoral partnerships in the provision of early childhood care and education.

Legislation on the provision of early childhood care and education exists in the form of a number of acts or orders, several of which mandate responsibility for the provision and regulation of services. Education Order 2003 regulates the registration, supervision and inspection of all educational institutions for children 3 years and above. These regulations contain guidelines designed to ensure children's well-being, development, health and safety in all schools. The Ministry of Education is the registration authority for all educational institutions and coordinates related processes, in consultation with relevant government agencies.

The Education Order 2003 also mandates the provision of 1 year of free compulsory preschool education in government schools, for children aged between 5 and 6 years. Private preschools that cater for 5–6-year-olds are required to teach Malay and Islamic religious subjects based on the national preschool curriculum. The preschool curriculum framework is based on the Ministry of Education curriculum guidelines of the new twenty-first-century National Education System (SPN-21), which has been implemented since 2009. The Ministry of Education therefore supports private preschools by providing qualified and trained teachers to teach these two subjects (Brunei Government 2012).

Formal, centre-based provision for children younger than the age of 3 years is currently provided by private organisations. At present, there is no approved national curriculum for children aged under 3 years; however the Ministry of Education is currently developing a national quality framework to inform development of such a curriculum. Further details on plans for the development of this curriculum are provided in a later section of this chapter. All child care centres that operate in the country are required by law to obtain licences. The Community Development Department (JAPEM) under the Ministry of Culture, Youth and Sports is the licencing authority for child care centres and coordinates the registration process with relevant government agencies. The Child Care Centre Order 2006 regulates the registration, supervision and inspection of private child care centres that cater for children under the age of 5 years providing guidelines to child care centres on aspects such as hygiene and safety.

Mother and child health care is included under primary health care services provided by the government. Child health services begin at birth, with home visits conducted by midwives for mothers of newborn babies during the early weeks of the confinement period. The confinement period, during which mothers usually stay in the home to avoid exposing themselves or the newborn baby to germs and disease, starts after the mother gives birth and ends on the 40th day. Mothers who are government employees are also eligible for 105 days of fully paid 105 days maternity leave. Growth and developmental assessments are then carried out by health nurses during regular clinic visits. A comprehensive child immunisation programme also takes place during these early years. School health services, including dental services are provided to all children, whether they are in government or private schools. School health personnel from the Ministry of Health pay visits to schools yearly and monitor children's general health status, visual acuity, physical growth and recommend, if necessary, referrals to clinics.

25.3 Early Childhood Education in Brunei Darussalam: Historical Context and Current Situation

Until recently, the provision of early childhood education services in Brunei has been widely associated with the formal preschool settings that are attached to government primary schools, with little attention directed towards education and care services that cater for children below the age of 5. Despite the strong cultural values attached to children and families in Brunei, this has resulted until recently in early childhood care and education being a victim of what Sylvia Opper (1993) once referred to as the 'Cinderella' complex, where policies and programmes at this level are considered relatively unimportant in comparison to the more important business of formal, outcome-oriented teaching and learning that takes place in later school life. Education and training courses for early childhood professionals and practitioners, for example, have been largely geared towards preparing practitioners for this formalised preschooling.

In an attempt to upgrade early childhood education in line with international perspectives on best practice at the time, an 18-month certificate in Early Childhood Education (ECE) was introduced for the first time in 1993. Underpinned by principles of Developmentally Appropriate Practice (DAP, NAEYC 2009), the certificate was designed to upgrade teachers' knowledge of early learning and development in young children aged from birth to 8 years. The certificate aimed also to challenge teachers' tendency to adopt formal, traditional teaching methods and promote child-centred approaches (Hanapi 2006).

In 2009, significant changes to the education system associated with national reforms resulted in this course being discontinued, when the minimum qualification for teachers entering government preschools was upgraded to a Master of Teaching in Early Childhood Education and Care, in line with broader reforms within primary and secondary schooling. While upgrading preschool teacher qualifications in line with similar policies for primary and secondary school teachers is very important in terms of enhancing the status of preschool teachers, this change has presented several challenges. One of these is related to teacher supply, as the system adjusts to the new qualification requirements. A second challenge relates to ensuring that teachers of children under the age of 5 years, largely employed by private institutions, are also required to obtain minimum qualifications. A large number of preschool teachers employed by private institutions are school leavers who only have 'O' levels qualification. Currently in Brunei, 'preschool teachers' are assumed to be working for government as part of the formal education system. Reforms are also needed that address issues related to qualifications and supply of practitioners who are working in private centres with 3–5-year-old children.

A recent report on early childhood education and care in Brunei Darussalam prepared by independent consultants from the International Child Resource Institute (ICRI), representing the first comprehensive review of formalised provision of services for young children, provides valuable insights into areas of both strength and limitation of service delivery in the country. As the report indicates (ICRI 2013),

policies and strategies for the delivery of education for 5-year-olds is 'clear and straightforward' (p. 7). One benefit of having preschools attached to the formalised public schooling system, as outlined earlier, is that a range of standards widely considered as important for achieving quality, such as minimum teacher qualifications (Degotardi 2010) and structural factors (Rao and Jin 2010), are maintained. Hence, the ICRI report concludes that public programmes are, to a large extent, of 'high quality'.

A disadvantage of being closely related to formalised schooling is, as both Bruneian and international researchers have noted (Asmah and Kitson-Charleston 2006; Hanapi 2006; Rao and Jin 2010), the likelihood of both pressure to adopt formalised teaching and learning approaches, and the loss of a unique 'identity' for early childhood. Until recently, as mentioned, attention to early childhood education in the country has been directed primarily towards formalised preschooling. Having been adopted largely as part of the formal education system in Brunei (primary and secondary schooling), for many years, early childhood has operated without a unique set of goals or mandates that might distinguish early childhood from the later years of schooling. For example, until recently, curriculum planning from preschool to the final years of secondary schooling took place within the broader curriculum planning department within the Ministry of Education, with little input from staff qualified in early childhood education. Perhaps due in part to some of these challenges, teaching in preschool classroom has tended to be rather teacher directed (Asmah and Kitson-Charleston 2006). Traditionally, teachers have viewed the end product of learning as more important than the actual process, focusing on preparing children for formal learning in primary school. Until recently, preschools have been staffed largely by teachers with certification in primary school teaching. Their teaching has therefore tended to place strong emphasis on developing basic reading, writing and numeracy (the '3Rs'), rather than reflecting a more holistic, child-friendly approach that includes other areas of development, such as children's creative development (Hanapi 2006).

As part of the raft of reforms introduced in 2009, a new preschool curriculum was also introduced. The new curriculum, designed to align with the broader Ministry of Education curriculum guidelines for the new twenty-first-century National Education System (Sistem Pendidikan Negara Abad ke-21), was officially implemented in January 2009. The broader national curriculum is designed to promote a holistic approach to teaching and learning across the government education system, from preschool to secondary education. At preschool level, the curriculum highlights the importance of five domains of learning and development: self and social development, cognitive development (numeracy, literacy and early science), aesthetic and creative development (arts, handcraft, stories, drama and songs), physical development (safety and health and movement and games), and information and communication technology development (early ICT) in preparation for primary schools. The preschool programme also introduces early language skills in both Malay and English languages. Accompanying the curriculum is a set of early learning standards that covers the expected learning outcomes of preschool children at the end of their 1-year preschool education. These standards are designed to assist

teachers in monitoring children's achievement in five domains of the curriculum stated above.

As part of the National Vision's focus on enhancing and expanding provision of early childhood care and education services, in 2010, the first Early Childhood Care and Education (ECCE) Unit, focused specifically on the early childhood years, was established within the Ministry of Education. Over the past few years, the unit's mandate has revolved primarily around upgrading quality in existing early childhood care and education settings, via steps that are described below. The unit has therefore focused on implementing a range of measures designed to upgrade the quality of teaching and learning in preschool classrooms across the nation, building teacher networks and providing a range of professional development experiences for the 209 government preschool classrooms and 477 early childhood teachers working across the country.

Many of the initiatives taken up by the small, dynamic team of three staff in the Early Childhood Care and Education (ECCE) Unit within the Ministry of Education have been designed to bring formalised early childhood education programmes in Brunei in line with internationally recognised 'standards', as well as raising the profile and presence of early childhood care and education in the country. In the first 2 years of its establishment, these efforts involved the ECCE Unit in launching a nationwide 'Capacity Building Programme' for private and government preschool teachers, as well as introduction and implementation of a Preschool Quality Indicators Checklist. The 'Capacity Building Programme', conducted throughout 2011, aimed at strengthening the quality of teaching and general professional competencies by exposing existing preschool teachers across the country to child-centred philosophies and teaching and learning strategies. The programmes included hosting of workshops across the four districts in the country, as well as the appointment of facilitators and mentors for each catchment area and district across the country. After attending workshops on early childhood teaching and learning, these teacher networks were designed to strengthen and sustain the likelihood of positive change in preschool classroom, by assisting teachers in implementing new teaching and learning techniques (Brunei Government 2011).

A Preschool Quality Indicators Checklist, designed as a guide for teachers to use as a self-evaluation tool following attendance at the workshops, was also developed by the unit. All preschool teachers were advised to work towards achieving the requirements listed in the checklist and submit completed reports at the end of each school term. The checklist covered four key areas: teacher and child aspects (including specialised early childhood teacher's qualification and training, i.e. do teachers have early childhood teaching qualifications or have they followed any early childhood professional development programmes? Reflection on the use of appropriate classroom voices, collegiality and availability of a SENA teacher for special needs students are also found under this aspect), teaching and learning aspects (availability of learning through play activities, study corners, displays of children's work, student portfolios, student assessment and parent involvement), infrastructure aspects, and daily routine aspects. The collection of teacher reports based on the checklist was discontinued once it was felt that practising teachers were able to

recognise important aspects of quality in their classrooms (E. Yacub, personal communication, March 20, 2014).

In 2011, the ECCE Unit also introduced a 'Yearly School Readiness Programme', conducted every November, prior to the January start of preschool. Designed to ease the transition into preschool for new entrants, this programme was developed in response to concerns expressed widely by preschool teachers that many children struggle with the first few weeks of the academic year as they transition into formalised early learning contexts with which they are very unfamiliar. The programme involves children and families visiting schools during the month of November where children are enrolled to begin preschool in January. Children attend sessions in which they meet their preschool classroom and English language teachers, play games and tour the school campus, including canteens and playground areas (E. Yacub, personal communication, March 20, 2014).

In line with the country's focus on retaining essential cultural and spiritual values in the current moves towards upgrading and modernising education, the ECCE Unit has also coordinated preparation and nationwide distribution of a booklet of Bruneian traditional games and songs and children's religious songs for preschool teachers across the country. The launch of the book involved events held in communities across the country, where parents and children were encouraged to participate in and share their memories of traditional games and songs. As well as focusing on local communities, the ECCE Unit has initiated collaborations with counterparts across the region, and in 2011, the country held its first national Conference on ECCE, organised in collaboration with the South East Asia Ministers of Education Organisation (SEAMEO) and other regional partners (ECCE Unit n.d.).

25.4 Future Challenges and Opportunities

Achieving change in education contexts, as Fullan and Hargreaves (1992) have explained, takes time. Shifts in educational practice often require parallel shifts in societal/community perspectives on education. Since many of the teachers who are currently teaching in preschools across the nation are more comfortable with the systems with which they have become familiar, than they are with the new approaches that are currently being promoted, there has been a degree of resistance to change expressed by some (Norsusilawati 2014). This perhaps explains observations noted in the recent ICRI report that indicate the need for continued support to preschool teachers in achieving the shifts away from teacher-directed approaches that have been widely espoused through professional development workshops and teacher support networks:

> The teachers in Brunei public 5-year-old preschool have a role that includes a strong level of teacher direction of activities combined with an understanding that children need time to explore their early childhood environment on their own. Thus, a combination of activities has been selected that place the 5-year-old public programs at a somewhat unusual balance point. That balance point currently includes a level of teacher direction that would be

> beyond a typical emergent curriculum and a level of children's exploration that would be beyond a traditional teacher-directed curriculum approach. For example, teachers were observed to conduct marching activities with children, but for those programs observed, never relinquished control of the marching activity to a child or a group of children to lead or continue the activity. Another example is that excellent singing and music programs take place, led by various teachers, but some control all aspects of the music and movement activities and some allow children to choose songs and dances and begin to carry them out independently. In a similar manner, while the majority of the rooms observed had excellent activity zones within the room, some of the activity zones did not appear related to the teacher directed part of the program and some seemed clearly related. Thus, it is unclear whether a conscious decision has been made to call upon teachers to cede control of certain activities as children become ready for them and, at the same time, assure that children have true mastery over each of the activity zones over the room. (ICRI 2013, p.2)

These observations indicate that, while preschool teachers are open to the benefits of child-centred learning, they have yet to achieve consistency or alignment in their teaching. Similar challenges to achieving shifts in teaching practice for early childhood teachers have been reported previously (Lee and Tseng 2008; Ling 2003). Consistency in support for these teachers, in the form of both professional support and resources, will be key to sustaining the kinds of change envisioned by the ECCE Unit. Although educational policy in Brunei is not subject to the same political swings in priority that some other countries may experience, movements within the Ministry of Education may pose a risk to sustainability of some of the initiatives implemented in the ECCE Unit during the past few years. Maintaining the strong team that currently works within the ECCE Unit will be important for continuing the efforts that are described here.

With its seven native tribes of Malay people (Belait, Bisaya, Brunei, Dusun, Kedayan, Murut and Tutong) and two indigenous communities (Iban and Kelabit), Brunei's diverse population has inevitably resulted in a potpourri of speech communities with their own distinct dialects, languages and cultures, posing an additional challenge to early childhood teachers working with children in the year prior to entry into formal schooling. A significant challenge regularly discussed by students attending courses at the national university, where the authors of this chapter are based, is related to the language of instruction in schools and related implications for preschooling. Brunei is multi-ethnic and multilingual, so many children entering preschool are neither literate in Standard Malay, the language of instruction in government preschools, nor in English, which is the language of instruction in primary schools. By the time they enter primary school, young children are expected to have reached a high level of literacy in English as it is the medium of instruction for most subjects. A large number of children therefore spend their preschool year learning two 'new' languages, English and Standard Malay, as well as concepts and skills outlined in the national preschool curriculum.

In partial recognition of the challenges that both children and their teachers face for many 5-year-olds is their first year of formal learning, there is now a focus in the country on provision of early learning facilities for children aged between 3 and 5 years. The majority of countries across the Asia Pacific region are currently focused on expanding (or enhancing) the provision of early childhood care and education

'downwards' to include 3–5-year-olds (Pearson and Tan 2013). As part of this trend, Brunei is also considering the possibility of expanding current state-funded early childhood education services to include younger children.

Such a move requires careful consideration and planning, particularly since there is a lack of evidence to suggest that provision of formal learning for younger children would be demand driven. Many families in Brunei employ foreign domestic helpers who provide home-based care for young children. In other families, children have traditionally been cared for by extended family members. While it is important to be mindful of, and sensitive to, the possibility that parents are not comfortable with out-of-home, formalised care settings, private child care settings do exist in Brunei, and, for many years, the regulation of these centres has been relatively basic. As the government itself has acknowledged, it is crucial that expansion of formalised provision for younger children proceed with care and caution:

> It is important that Brunei Darussalam ensures that the current quality and standards of the social care and development of children under 3 years at the Community Development Department (JAPEM), preschool education offered to the 3–5 year-olds at the non-Government/private preschools as well as those offered at the Government preschools are of high quality and well-established, well-resourced and well-staffed by highly trained and qualified preschools teachers before attempting to lowering the starting age of preschool education from the current 5 years old to 3 years old. Such caution should be taken so that young children will not be taught by untrained teachers and be hurried to learn academic skills at an early age. (Brunei Government 2012, p. 7)

At present, educational and care services for children under the age of 5 are provided solely by private agencies. Anecdotal evidence suggests that some of the centres have adopted overseas approaches or models in their programmes. For example, some centres are known for offering a Montessori approach. However, due to the past focus on government – supported preschooling – there is currently a lack of research providing information about the types of programmes offered by private centres. According to statistics provided by the Ministry of Culture, Youth and Sports, only a small number of children throughout the country are attending licenced child care centres (a total of 295 children in 2011, Brunei Government 2012). Currently, while there is strong support for developing early childhood care and education provisions that are underpinned by national priorities, values and agendas, there is a need in Brunei for research designed to provide a cohesive national evidence, base from which to build contextually-appropriate, 'high-quality' early childhood education and care programmes. There is no national curriculum framework, for children below 5 years of age, and little data to indicate specific areas of priority or need for young children and families in the nation. The Brunei government has, thus, recently awarded researchers at the national university with funding to conduct nationwide research into national priorities, adopting a careful, measured approach to decisions regarding what types of programmes will be most likely to benefit children in this age group.

25.5 Focusing on 3–5-Year-Olds: Opportunities for Brunei

Following the introduction of the National Vision and its emphasis on early childhood care and education, former Minister of Education, Pehin Abdul Rahman Taib, referred in 2010 to the importance of investing in early childhood education to 'develop a strong foundation early in a child's development so that future learning can be built' (Thien 2010). At the same time, Ministry of Education (MoE) Deputy Permanent Secretary (Core Education) Hjh Suhaila Hj Abd Karim pointed to the need for greater attention to the provision of services for children aged under 5 years old. These sentiments reflect acknowledgment by the Ministry of Education that there is a need for greater focus on providing education and care for children in the younger age ranges. The Ministry of Education, therefore, is at the moment considering the possibility of investing in publicly funded early childhood education programmes for 3–4-year-olds and recently engaged the International Child Resource Institute (ICRI) to conduct a national assessment into the feasibility of including 3- and 4-year-old children in the national system of early childhood education. Among the initial general findings of the ICRI is a recommendation that the Ministry of Education pursue efforts to create high quality, publicly funded early childhood education programmes for 3- and 4-year-olds (ICRI 2013). This recommendation offers exciting opportunities for the country not only to expand and enhance early childhood care and education for children in Brunei but also for it to contribute to international innovations in early childhood care and education provision (ICRI 2013).

A common curriculum framework would help to ensure an even level of quality across different forms of provision and for different groups of children. It would also ensure continuity between early childhood education and care and primary schooling, as well as alignment with national values and customs. International evidence suggests that a strong, cohesive and relevant curriculum can provide the foundation for high-quality early childhood programming (OECD 2013). Indeed, this 'gap', given the current government commitment to expanding and enhancing early childhood care and education, offers opportunities for innovative approaches to development of 'quality' curriculum for 3–5-year-olds.

The importance of quality is widely espoused in international literatures on early childhood care and education. Less common is agreement on what can be seen to constitute 'quality' (Fenech 2011). Robin Alexander's (2008) recent analyses of references to quality in education, based on research conducted across five cultures, highlight current global developments and are relevant to the kinds of advances in early childhood education and care that Brunei is currently interested in. Alexander argues that conceptualisations of 'quality' are too often based on strict measurable inputs and outputs, rather than on broader, diverse social processes that underpin effective learning and teaching. Understanding these processes is necessary not only for high-quality teaching but is also of particular importance for early childhood programmes that seek to engage families and communities in children's early learning and development. As a nation, Brunei is well placed to respond to these

calls for innovative approaches to conceptualising quality. The country is well resourced and has expressed strong commitment to early childhood education and care. It has a rich national and cultural heritage which, as explained earlier, has been acknowledged as an important foundational aspect in the nation's development.

Services designed to support education and care for young children have long been recognised as requiring a holistic approach, and, increasingly, high-quality programming is associated with inclusive approaches that connect services to the specific needs and priorities of 'local' communities, including minority groups (Myers 2004). Programmes and services that are built upon evidence that reflects unique needs, strengths and cultural priorities, as well as documented knowledge regarding best practice, are now widely acknowledged as more effective than those that are shaped simply around a prescribed set of ideals, or by priorities for children that have been identified in very different contexts (Penn 2008). Such an approach, based on contextualised understanding, also contributes to environmental and cultural sustainability, an important priority for Brunei.

In response, a team based at the national university, Universiti Brunei Darussalam, has recently been awarded government funding to conduct nationwide research on Brunian values and priorities. The research is designed to support the development of early childhood care and education programmes and policies by providing a strong evidence – based on the values, priorities and needs that exist in Brunei Darussalam related to the care and education of young children. A final phase of the research project proposes development and field testing of a customised, Brunei-specific curriculum for children 3–4 years of age. Research, development and implementation of a Bruneian-branded curriculum that reflects the cultural diversity of the country would be favourable not only for children and families but would also reflect current early childhood education curriculum trends internationally.

25.6 Conclusion

In the last decade, Brunei Darussalam has seen considerable changes in improving the development of young children in the country. The core of these changes lies in its National Vision, more popularly known as Wawasan Brunei 2035. Brunei sees its education as an asset for the development of its human capital and its nation. Therefore, investing in early childhood care and education has become one of the nation's main agendas. What is unique about Brunei Darussalam is that in setting a national agenda of modernisation, it has also drawn attention to the importance of retaining essential cultural and spiritual values that are deeply rooted in the society. Within the field of early childhood care and education, achieving this combination of 'modernisation' and preservation of the various cultural 'traditions' that makes Brunei unique presents both challenges and exciting opportunities as the country expands and enhances service provision.

As this chapter has outlined, the Brunei government has considerable interest in the development and expansion in provision of formalised early childhood care and

education, with important implications for reviewing current systems as well as developing new innovations. Among the challenges for the current system that are currently under review are the difficulties posed to children as they enter preschool in mastering the Standard Malay language, which is different to the local Brunei Malay dialect that they encounter on a regular basis, as well as becoming literate in English as the medium of instruction in primary school. Related to this challenge, as reflected in the ECCE Unit's efforts to upgrade teaching and learning in preschools, is that the present system of teacher preparation may need to be revised and expanded, especially if the government decides to provide publicly funded early childhood education programmes for all 3–4-year-olds in the country.

Currently, increased focus has been directed in the development of services for 3–5-year-olds. These efforts include conducting assessment into the feasibility of including 3–4-year-old children in the national system of early childhood education. The government has also funded nationwide research on Bruneian values and priorities that will provide strong evidence-based data for the development of context-specific policies and programmes for children aged 3–4 years in the country. These initiatives reflect current international early childhood education trends and should give Brunei opportunities for contributing to important innovations in early childhood care and education provision in the coming years.

Chapter 26
Early Childhood Care and Education in Bangladesh: A Review of Policies, Practices and Research

Shukla Sikder and Laila Farhana Apnan Banu

Abstract Early Childhood Care and Education (ECCE) in Bangladesh is still in the preliminary stage compared to the significant developments made in the field across the globe. This chapter presents the summary of policies, practices and contemporary research, as well as challenges encountered in relation to ECCE in Bangladesh. Based on analysis of secondary data, the findings show that considerable progresses have been made in the policy arena. However significant gaps remain in implementation of policy commitments, particularly in relation to coverage and quality of ECCE services. More pronounced challenges in the sector are reported in the lack of reliable national dataset, poor service coverage, weak coordination among service providers, noncompliance of minimum quality standards, low parental awareness leading to low demand and utilisation and low research base to guide policy and programmatic decisions for optimum efficiency and effectiveness; which altogether contribute to the nonachievement of universal coverage of ECCE services of good quality for all. The authors argue that government and nongovernment organisations could work in a more harmonised manner for expanding the coverage and improving the quality of ECCE services in Bangladesh, with major emphasis on research to develop, test and scale cost-effective and affordable ECCE models, so that all children in Bangladesh could benefit from a fair start in life and reach their fullest potential.

26.1 Introduction

The importance of Early Childhood Care and Education (ECCE) for optimal child development is now internationally recognised. Coordinated birth-to-age-8 ECCE programmes help to prevent achievement deficits and produce better education, health, social and economic outcomes. Numerous research studies, including Nobel laureate Professor James Heckman's (2011) breakthrough research on early investments in quality early childhood development, have provided ample evidence of its individual, social and economic returns. At the individual level, early investment fosters valuable skills and establishes foundation for lifelong learning. At the societal level, with economically productive and socially responsible citizens, these investments strengthen the nation's workforce, grow the economy and reduce costly remediation and social spending, while increasing the value, productivity and earning potential of individuals. In fact, every dollar invested in quality ECCE programmes for disadvantaged children produces a 7–10% return, per child, per year (Heckman et al. 2010). Most importantly, ECCE interventions serve to create a level playing field for disadvantaged children. Research studies across the globe have proven that disadvantaged children, particularly girls, benefit most from ECCE services, who otherwise would not be able to access services at home and would not have been able to reach their potentials to the fullest (Heckman and Masterov 2007; Heckman 2011). An accumulating body of knowledge shows that ECCE interventions for disadvantaged young children is more effective than interventions that come later in life (Cunha and Heckman 2006).

ECCE means providing comprehensive and integrated supports necessary for a child to realise her/his right to survival, protection, care and education which will ensure optimal development from birth to age 8 (Ministry of Women and Children Affairs [MoWCA] 2009). Throughout this chapter, the term ECCE has been used to refer to activities related to early childhood care, development, stimulation and education that might elsewhere fall into categories referred to as ECD (Early Childhood Development), ECCD (Early Childhood Care and Development), ECE (Early Childhood Education), ECCED (Early Childhood Care, Education and Development) or other variants of this term. This also includes Pre-Primary Education (PPE) to mean the developmental and educational support provided to children of 5–6 years through play and other organised activities to foster physical, socioemotional, cognitive and language development.

Despite its highly beneficial role for economic and human capital development, ECCE has not been the top development agenda for Bangladesh. In a developing country like Bangladesh, awareness of ECCE is still emerging even among professionals, coupled with serious infrastructural and social constraints such as poverty, lack of trained educational and health professionals and resources. As a result, age and developmentally appropriate care, support and early learning opportunities for children, especially for the economically and/or socially disadvantaged ones, have been scarce, even though it has been 25 years since the Education for All (EFA) Goal 1 was adopted by Bangladesh, which highlights that early learning is fundamental to child development and lifelong learning.

Within this backdrop, this chapter aims to take stock of current policies, practices and research in ECCE in Bangladesh; identify challenges and gaps in current policies, programmes and service provisions; and recommend high-impact priority actions needed to address service gaps and quality. While this introductory section provides the rationale and scope of this chapter, the next section elaborates on the methodological approach taken to explore the ECCE context of Bangladesh. Providing a brief on the country context and the status of Bangladesh's children, the next section focuses specifically on the ECCE sector in Bangladesh, including developments in policies and programmes, social norms and practices, challenges and opportunities identified through research. The final section highlights policy and programmatic recommendations informed by the analysis in coverage and quality gaps.

26.2 Methodological Approach

The chapter is written based on a desk review of secondary data. Data were collected from published and unpublished academic research papers, programmatic research studies, government policy documents and other relevant grey literature available in the public domain. Thematic analysis was done to summarise key synopsis of the nature, scope and quality of policies and service provisions in the ECCE sector in Bangladesh. The analysis also incorporated authors' reflections of first-hand professional experiences to identify progresses made, challenges encountered and continuing gaps in service coverage and quality.

26.3 Bangladesh: The Country Context

Bangladesh, officially named as the 'People's Republic of Bangladesh,' is a South Asian country that appeared as a liberated nation in 1971 after achieving independence from Pakistan in the Bangladesh Liberation War (Raghavan 2013). Surrounded by India to its west, north and east; Myanmar to its southeast; and the Bay of Bengal to its south, it is divided from Nepal and Bhutan by the Chicken's Neck corridor (Islam 2003). The country's largest ethnic group Bengalis makes up 98% of the population, with 2% indigenous peoples such as the Khashea, the Jaintia and the Chakmas in northern and southeastern districts (Guhathakurta and Schendel 2013). Geographically, the country is ruled by the fertile Bengal delta, which earns the country the name of 'The Green Delta' and 'The land of rivers' (Iqbal 2010).

According to the Population Census 2011, the proportion of children under 18 in Bangladesh is about 40% of the 149.8 million population (Bangladesh Bureau of Statistics [BBS] 2011). A Child Poverty study indicated around 26.5 million of 63 million children in the country are living below the national poverty line, while 32 million are living below the international poverty line (UNICEF 2009). About one

quarter of them face persistent poverty and are typically deprived of four out of seven of the basic services of water, sanitation, nutrition, education, health, information and shelter. In terms of deprivation, 41% of children are deprived of shelter, 64% are deprived of sanitation, 71% of information, 57% of nutrition, 16% of health and 5% are deprived of education (UNICEF 2009). A recent survey by BBS and UNICEF (2014) reports that about 42% of children under five are stunted and 32% are underweight. Almost one-fifth of the children of primary education age (6–10 years) are deprived of formal education. About 40% of girls up to 18 years of age are already married. Among all children aged between 4 and 14 years, 13% are engaged in child labour and 97.5% of them are unpaid labourers (BBS and UNICEF 2014). Child malnutrition is almost twice as high in the poorest than in the wealthiest quintile (UNICEF 2009), which in linked with short adult stature and later in poor educational performance (Mason et al. 2014).

26.4 The Evolution of ECCE Concepts and Policy Developments in Bangladesh

Primary Education is compulsory in Bangladesh under the Compulsory Primary Education Act 1990 and is provided free of charge to children between the ages of 6 and 10 years (Islam 2003). Achievements in primary education have been impressive; however, ECCE is still in the emerging stage in Bangladesh. According to the Multiple Indicator Cluster Survey 2012–2013, only 43.5% of Bangladeshi children in primary grade 1 attended preschool during the previous year, and there are significant disparities in the participation pattern (BBS and UNICEF 2014). Gender disparities have nearly disappeared in PPE enrolments; however, children from ethnic minorities, children with disability or difficulty in learning and children from isolated communities or difficult geographies lag considerably behind their socially advantaged peer group in accessing quality preschool services. Only 13.4% of children of 3–5 years are receiving an early childhood education of any kind. Around 8.8% of children under 5 have three or more children's books at home, while playthings are available at 60.3% of households. Fathers' and mothers' role vary substantially when it comes to supporting their children in learning. While 40.8% of mothers provide support to children in learning, only 10.1% of fathers provide such support (BBS and UNICEF 2014).

26.4.1 The Evolution of ECCE in Bangladesh

ECCE as a comprehensive concept is fairly new in Bangladesh, though opportunities for early childhood education have existed in an informal and unstructured form. PPE has been an integral component and the most common form of ECCE service available in Bangladesh, which is defined as:

> The developmental and educational support provided to the child in the age range of 3 to <6 years in order to ensure the child's right to protection, care, survival and preparation for school education through play, amusement and introduction to literacy and numeracy, irrespective of the child's physical, mental and social status. (Ministry of Primary and Mass Education [MoPME] 2008, p. 8)

Baby class, permitted in 1994 in the Government Primary Schools (GPSs) of Bangladesh, was the first kind of ECCE service implemented by the government, although the National Curriculum and Textbook Board (NCTB) took the initiative to open baby classes in all rural and most urban GPSs in 1981–1982 (Education Watch 2013). For over 10 years, the private sector, nongovernment as well as government organisations have been implementing various PPE services with their own curricula, teaching-learning materials and methods, teacher training programmes, own monitoring and evaluation systems and support services to parents and community (Rich-Orloff 2010). Some nongovernment organisations (NGOs) run preschools on a large scale. BRAC, the largest NGO in Bangladesh, had 20,000 PPE centres (Shahjamal and Nath 2008) which enrolled both genders, minority groups, disadvantaged children from poor families, ethnic groups and children with disabilities (Ahuja and Ibrahim 2004). Apart from BRAC, numerous NGOs are operating learning centres that offer early learning and PPE. Privately, the Kindergartens and the English medium schools also provide PPE (Nath 2006), which are expensive and mostly serve the affluent segment of the society.

26.4.2 The Development of Policy Tools

Even though many NGOs are providing ECCE services for disadvantaged or excluded children (Ahuja and Ibrahim 2004), it was not part of the mainstream education provision. As a result of continued advocacy done by MoWCA and Bangladesh ECD Network (BEN), the Operational Framework for Pre-Primary Education was the first MoPME-endorsed policy tool that came into action in 2008. This set out the goal for universal PPE with quality. After this PPE framework was approved, the MoPME took systematic initiatives to implement PPE, such as starting a PPE class in all GPSs, initially on a pilot basis in 13 districts, with an interim curriculum, teaching-learning materials and teacher training programmes (MoPME 2011). The Operational Framework also provides guidelines for how parents and caregivers could provide age-appropriate care (MoPME 2008). The 2010 National Education Policy also called for putting a 1-year PPE programme in place with minimum quality and gradually moving onto offering a 2-year PPE programme.

Generally there is widespread sociocultural understanding and widely held social customs that view the infant and young children's need for development as more in terms of health and nutrition aspects relating to physical development. The comprehensive and complementary nature of holistic child development that recognises that children need balanced developmental readiness in different domains to be able to seize their fullest potential has come to the forefront only recently. There is a growing understanding that the first decade of children's lives is the most crucial

period for shaping their bodies and minds to help them become healthy, productive and functional human beings in terms of social, emotional, intellectual and physical development. These are the years, particularly the first 3 years, when the fastest development occurs, but they receive the least attention from service providers, policy planners and duty bearers. This is primarily because children have no voice, they cannot express their opinions and adults tend to interpret things from their own perspective. Primary attention is given to the physical development, as that can be seen and measured, but the socioemotional, linguistic and cognitive developments are subtle and not tangible enough to measure easily. To support caregivers, service providers, policy planners and practitioners alike to know what developmental milestones children should reach at certain age points, Early Learning and Development Standards (ELDS) are being adopted in Bangladesh context. Currently, the cultural validation process – which includes content as well as age validation – is going on under the leadership of MoWCA (2013). Once adopted, these developmental milestones will serve as development targets for children and assessment target for the service providers.

In November 2013, the Comprehensive Early Childhood Care and Development (CECCD) policy was approved, which lays the foundation for more concerted efforts guided by a set of priorities and principles across sectors relevant to ECCE (MoWCA 2013). Currently an implementation plan is under way under the leadership of MoWCA, which will guide practices and services and hold duty bearers accountable for children's holistic development.

26.4.3 The Development of Pre-primary Education National Curriculum

With sustained advocacy by MoWCA, the MoPME recognised the importance of organised PPE classes that provide children with necessary developmental readiness to cope with the formal academic environment of primary schools. After the pilot initiative kick-started in 13 districts with an interim curriculum arrangement, NCTB started to develop a competency-based national PPE curriculum in 2011–2012 that took a domain-based approach in organising the activities and the instructional process. It took the ELDS as a core-guiding tool to define domain-specific learning outcomes for the PPE age children. While most of the previous services were predominantly academic and therefore, not age-appropriate, the national PPE curriculum embraced the play-based approach, with some preliteracy and pre-numeracy skills to be provided at the later end of the 1-year programme. The curriculum is comprehensive, activity based and developmentally appropriate and addresses all necessary domains such as physical, cognitive, emotional, language and social needs.

The curriculum development process was unique in a way. In developing the primary curriculum, the NCTB usually did not consult NGOs for their experience and insights into running primary education services. However, development of the PPE curriculum involved all NGOs and other government bodies that had experience

and expertise in running PPE services. All the curriculum and materials of NGOs were collected and reviewed and served as entry points for the development of the national PPE curriculum of Bangladesh. All available best practices were integrated into the newly formed curriculum. Based on the curriculum, a learning package was developed by the NCTB that includes eight items: a primer, an exercise copy, a teachers' guide, vowel chart, consonant chart, a flip chart, flash cards (alphabet and number cards) and storybooks.

Though the curriculum was in place and materials were printed and distributed in bulk in 2013, the readiness on the ground for implementing the curriculum in classrooms using the newly designed materials package was considerably delayed. The DPE developed a 7-day Training of Trainers (ToT) in 2012 to train district level resource pool on concepts of ECCE; the goal, objectives and principles of the national PPE curriculum; the learning domains and expected learning outcomes defined in the competency framework; PPE materials, methods and standards; the daily, weekly and yearly lesson distribution plan; and expected roles of teachers and parents. Around 30% of the training time is dedicated to simulation sessions where trainers get a sense of how the learning sessions are to be organised and facilitated in the classrooms. The resource trainers then train teachers using a 15-day training manual. The training was rolled out in 2013 and 2014, reaching approximately 30,000 teachers (MoWCA 2013).

26.5 The ECCE Services in Bangladesh

The last two decades have seen tremendous growth in innovating and expanding cost-effective ECCE models and services through family-focused, centre and school-based programmes, with gradual endorsement of necessary policy and advocacy tools. The country has seen steady growth in organised ECCE services available to communities; however, the coverage is still inadequate, and policies, laws, legislation and minimum quality standards are yet to be put in place to hold the service providers and duty bearers accountable for quality services. The positive side is that noteworthy progress in the policy arena is under way as it relates to early education, though the issue of care and development is not yet a priority agenda in the national development scheme in terms of budgetary resource allocation. Table 26.1 exhibits what services are available in Bangladesh for various ECCE age groups from conception to age 8.

Table 26.1 Age-wise ECCE services available in Bangladesh

Age range	Services
0–3 years	Parenting education
3–5 years	Early learning
5–6 years	Pre-primary education
6–8 years	Early primary education

Adapted from MoWCA (2013)

26.5.1 Services for the 0–3 Age Group

Children up to 3 years are the most ignored group, both in the policy arena and services available on the ground. 'Parenting Education' is the only ECCE service available for reaching this age group (MoWCA 2013); however, current programming has a very limited coverage and suffers from low quality. Innovative approaches are required to reach parents and other primary caregivers to disseminate vital child care and development messages and particularly to reach semi- or nonliterate parents, speakers of minority languages and hard-to-reach (HTR) communities.

26.5.2 Services for the 3–5 Age Group

There are centre-based early learning sessions for the 3–5 years age group, which are known as 'Shishu Bikash Kendras (SBK)', mostly run by NGOs taking a play-based approach. While the NGO-run services have successfully reached some of the most HTR communities and have developed low-cost SBK models, these are heavily external aid dependent and are not sustainable in the long term. As a result, each year the number of centres and children reached vary as the aid flow varies. MoWCA and the Ministry of Chittagong Hill Tracts Affairs (MoCHTA) run some early learning centres that are comparatively more sustainable, as financing of these centres is shared with the government (MoWCA 2013). However, both government agencies and NGOs are in need of technical as well as financial support to run the early learning services.

26.5.3 Services for the 5–6 Age Group

Currently PPE is the most widely available ECCE service targeting the children of 5–6 years (6+ is the official age for enrolling in primary grade 1). With sustained advocacy and successful modelling by MOWCA, the MoPME finally recognised PPE to be a high-impact intervention for children's school readiness, which can increase school retention and lower dropout rates (MOWCA 2013). Accordingly, the Directorate of Primary Education (DPE) introduced the 1-year PPE programme for 5 year olds in all GPSs in 2010, with an interim arrangement for curriculum and teacher training. Introducing the organised PPE class in the mainstream primary schools was a major breakthrough, as this resulted in the lion's share of children being reached with PPE services. The national PPE curriculum materials are provided free of cost by MoPME to all eligible children/schools, including NGO-run centres. Also, each GPS is provided with a PPE grant of BDT 5000 per annum to buy play and other necessary materials to make the PPE classroom functional. However, anomalies are reported on the yearly allocation of PPE grant to schools and all providers' access to the MoPME provided PPE learning package in a smooth and efficient manner.

26.6 Research on ECCE in Bangladesh

ECCE has recently been receiving increasing attention worldwide (Education Watch 2013). However, there is very limited attention on research on ECCE, as most of the international research focuses on child psychology (Johanson 2011). Research on ECCE in Bangladesh began after 2000 (MoPME 2008). There is a long tradition of research on children's health, nutrition and wellbeing in Bangladesh from 1980s to present: Bairagi and Chowdhury (1994), Bhuiya et al. (1986), Black et al. (1984), Chen et al. (1980), Mitra et al. (1997), Roy (2000), Ardt et al. (2005), Black et al. (2007) and Islam (2010). The researchers mostly focused on how rural Bangladeshi children's malnutrition impacts their health and wellbeing. However, very little research has focused on the ECCE context in Bangladesh. The studies that have been done in this field so far are undertaken albeit sporadically.

26.6.1 Research on the Quality of Preschools

A small number of studies focused on the improvement of the quality of PPE programmes in Bangladesh. For instance, Aboud (2006) examined a preschool programme in rural Bangladesh in terms of cognitive and social outcomes. The children attending preschool performed better on measures of vocabulary, verbal reasoning, nonverbal reasoning, school readiness and the social aspects of play, whereas no difference was found on the cognitive aspects of play. This study provided knowledge for supporting implementation of preschool programme in rural areas for children's early years' development. Another experimental study (Moore et al. 2008) suggested to improve quality preschool programmes in developing countries such as Bangladesh. This study found that improved quality preschool programmes made a significant difference in the early years of children's development than the regular preschool programmes.

In 2011, Aboud and Hossain investigated how early years' education impacted on primary school achievement in the Bangladesh context. It was evident from the experimental study that children who attended preschool did better in all competencies (reading, writing, listening and speaking) than children who did not go to preschool. This study, including many others, recommended expanding high-quality preschool programmes with age-appropriate curriculum to support children to succeed later in primary education (Nath 2006; Shahajamal and Nath 2008).

26.6.2 Research on Teaching Practices in Preschools

Banu (2012) explored the classroom teaching practices in preschools in Bangladesh. Collecting data from three types of preschools: government, private and NGO-run preschools, the study found that the preschools were encouraging

memorising of facts and rote learning through teacher-directed teaching, coaching and frequent testing to prepare children to pass primary school entrance examinations. In teaching, quality was absent. There was no involvement of teachers and community members in developing curriculum and materials. Children's wellbeing was not prioritised, though this is one of the significant indicators in preschool education.

26.6.3 Research on Children's Language and Literacy Development

Few studies examined children's language and literacy development. A study conducted in formal and informal settings in Bangladesh found that picture dictionaries support young children's vocabulary and knowledge of the real world (Sharif 2012). A longitudinal research by Khanom et al. (2013) investigated the effectiveness of a comprehensive child development package, including children's (3–5 years) cognition, growth, school readiness and general health and hygiene practices in rural Bangladesh. The study found the implementation of the package through preschools as useful for certain areas such as maternal knowledge and children's language development. They emphasised on programme sustainability and improving quality of the package to gain benefits in all areas, including school readiness and parental engagement.

26.6.4 Research on Play Pedagogy

Play provides a vital role for children's holistic development in the early years (MoPME 2008). Play pedagogy is well recognised in the Western world for enhancing children's early years' education but yet to be optimally utilised in developing country contexts. Chowdhury and Rivalland (2011) examined how play as a pedagogical concept is understood, incorporated and practised in the ECCE practices of Bangladesh. The researchers conducted a sociocultural study to discover the understandings, views and perceptions of families and teachers of semirural public preprimary classes in Bangladesh. Play was defined as 'young children's active and interactive joyful activities, such as working with learning apparatuses, physical exercises, singing, acting, rhyming, games, outdoor plays and drawing' (p. 181). It was found that children did not get sufficient scope to learn through play activities in the class as it was directed by teachers who mainly focus on achievement and academic skills. Since the classroom environment is unfavourable, and there is limited access to play, play is reconceptualised in the Bangladesh context 'as joyful activities that involved young children in active and interactive behaviours with the

teacher and peers as a way of developing academic skills through imitating the teacher's steps in a correct way' (p. 184).

Chowdhury and Rivalland (2012) further explored the value of play in early learning in Bangladesh context. The qualitative study, based on the understandings of parents and early childhood educators in semirural Bangladesh, found that parents consider play to be a leisure activity and did not encourage children to play. On the other hand, teachers acknowledged that play accelerates children's early years' learning and supports young children's readiness for school. However, both teachers and parents emphasised play as a tool of achieving academic skills and neglected children's holistic development through play.

Concept formation can occur through play in children's everyday context (Fleer 2011), as emphasised in developed countries, such as Australia, European countries, the UK and the USA. Research has confirmed that infants-toddlers learn concepts, such as concepts of shapes, application of materials and rules of games through their everyday life. Small science concepts such as understanding of push, pull, floating-sinking, spinning and rolling can be understood by infants-toddlers through everyday activities and play. Sikder and Fleer's (2015a) case study research on concept formation, conducted in Bangladeshi family contexts for young children (10–36 months), found that there are possibilities to develop everyday concepts and scientific concepts through family practices in infants-toddlers regular activities and play. The same extended project found that these everyday concepts and small science concepts can be developed with the conscious collaboration of parents and infants-toddlers in the small science moments of their everyday life (Sikder and Fleer 2015b). Parents' perspectives on infants-toddlers' development of scientific concepts was also researched by Sikder (2015) which revealed that parents can create the environment for young children to learn everyday concepts and scientific concepts without any extra effort as part of children's everyday social situation of development. These research projects (Sikder and Fleer 2015a, b; Sikder 2015) contributed to the development of theoretical, pedagogical and empirical understanding in early years' education and how family as a first institution (Hedegaard and Fleer 2008) can create conditions for young children to learn everyday concepts and scientific concepts through play and regular activities.

Sharif (2014) explored the impact of play instruments in school playgrounds on preschool children's learning and development. Intervention schools under the experimental study created a joyful environment for children, with an anticipation that the children would be encouraged to go to school and the dropout rate would be reduced. The project also provided positive interventions for PPE children's school readiness. The study found that the intervention areas' primary education dropout rate decreased and 100% of students passed the primary school completion examination. Also the preschool children found school interesting because of the school playground, which enhanced their school readiness day-by-day (Sharif 2014).

The above research studies provide significant understanding on how play can create opportunities for children's learning and development either in formal or informal contexts. As evident from these studies, as well as highlighted in the PPE Operational Framework (MoPME 2008), play needs to be considered to make learning joyful and developmentally appropriate for PPE age children to ensure their holistic development.

26.6.5 Research on Different Aspects of Child Development

Saha et al. (2010) investigated children's (birth to 24 months) language development in relation to household food security in rural Bangladesh. The researchers collected data on household food security and socioeconomic status of the participant families during pregnancy period. They also gathered data on morbidity, weight and length of children in every month of the first year and quarterly in the second year of their life. The study found that early childhood language acquisition depends on household food security. They suggested that low-income countries need to enact appropriate policies to ensure household food security for children's language development in early years.

There are similar types of studies on the impact of food, nutrition and mothers' maternal health on young children's health and wellbeing. For example, infants' motor and explanatory behaviour development is related to iron and zinc levels (Black et al. 2004), mothers' depressive symptoms impact on infants' development and growth (Black et al. 2009), infants and young children growth depends on household food security (Saha et al. 2009) and under-5 children's stunting depends on a number of factors such as parents' education, household economic status and number of children (Rahman and Chowdhury 2007).

Moreover, parents' education also impacts on young children's growth and development in the early years. For example, Semba et al. (2008) studied children's stunting in a cross-cultural study between Indonesia and Bangladesh. They found that maternal and paternal education related to caregiving behaviours, immunisation, sanitation and use of iodised salts are important for children's growth and upbringing from birth to 5 years. Aboud et al.'s (2013) research examined the effectiveness of a parenting programme that included illustrative cards and discussion on hygiene, responsive feeding, play, communication, gentle discipline and nutritious foods. It was found that the participant parents could contribute more to children's cognitive and language development. However, there was no difference in children's health or growth between the participant and nonparticipant parents. Similar studies were conducted by Aboud (2007), Aboud and Akhter (2011) and Aboud et al. (2008) about parenting programmes or feeding interventions in rural Bangladesh for young children's health and growth.

The studies reviewed above strongly recommend the need for further research on children's learning and development at their early years. However, despite this strong-felt need, there is still a big gap in understanding the overall research context

for early years' learning in Bangladesh. Above all, the studies recommend that the quality of curriculum, teaching practices and programmatic strategies in ECCE in Bangladesh should be improved. The policy designs must consider research outcomes for improving current child care and education practices in Bangladesh, otherwise the goals of ECCD policy will not be achieved.

26.7 Challenges in Bangladesh ECCE Sector

Though the ECCE movement has come a long way in Bangladesh, many challenges and bottlenecks persist that prevent expansion of universal ECCE services with good quality for all. What follows is an account of key challenges facing the ECCE sector in Bangladesh.

Availability of reliable data is a key challenge. While there is no reliable national database for parenting education and early learning services, data related to PPE are available to some degree, but huge discrepancies remain between the sources. For example, BBS and MoPME data report different figures for PPE enrolment, making it difficult to make informed decisions to choose policy and programmatic options in a context that is substantially resource constrained and quality of services is of questionable standard.

Service coverage is another big problem. While there are few data on the coverage of different ECD services, DPE's PPE Expansion Plan indicated:

> Despite the increase in enrolment, there are still huge number (1.4 million as per mapping and 2.9 million as per BBS) of eligible children out of preschool coverage. It is estimated that 122,010 preschools at the rate of 30 children per school to meet teacher student ratio of 1:30 as set in the PPE Operational Manual by MoPME will be required to cover the total number of 3,660,286 PPE age children. However, the government, under PEDP3, has a plan to open one pre-primary class attached with 37,672 GPS. In addition 23,616 preschools with secured funding till 2015 are currently run by NGOs, meaning another 60,722 will be required for universal PPE coverage (DPE 2012, p. 13).

Therefore *GO-NGO collaboration* is needed to expand access for universal coverage of PPE services. However, coordination among service providers is nearly absent. As a result, some geographical areas, such as urban concentrations, are service-saturated, while isolated geographical pockets, such as remote rural areas, the hilly terrains of southeastern Bangladesh, islands and coastal belts, chars (riverbanks), haor (wetlands), baor (low-lying lands), tea gardens, brothels and jails for mothers who have committed crimes, suffer from service-famine, which denies the right of children from these particular backgrounds to survive, grow and learn. To address this issue, the MoPME developed a PPE Expansion plan in 2012 that identified areas with the highest needs. A GO-NGO collaboration guideline was approved in 2011, followed by an implementation plan for the GO-NGO collaboration. However, to date there has been no attempt from the government to implement these plans and guidelines. At least a few selected unions (lowest administrative units) could demonstrate collaboration models among different service providers, including government, NGOs and private providers to achieve universal coverage of PPE.

The *quality of services* remain a big challenge. In the absence of nationally defined quality standards, the existing ECCE services substantially vary in provision, scope, curricula, materials, methods, teaching and supervisory staff, training, infrastructure, indoor and outdoor play provisions and security issues related to children's wellbeing. As part of the PPE Expansion plan, a set of minimum quality standards was developed under the MoPME's guidance. The quality standards create a benchmark for all service providers to follow in assuring minimum standards in service provision. However after its development and endorsement, the MoPME has taken no initiative to disseminate the quality standards through circular or directive. Therefore, service providers have not yet been held accountable for not complying with the standards. Quite paradoxically, a small monitoring exercise done by UNICEF in 2013 using Tanahsahi model – a model widely used in health sector to examine bottlenecks in effective coverage – revealed that the majority of the GPS-based PPE classes do not meet quality standards for a dedicated space for PPE class, a trained teacher teaching PPE children and a teacher-student ratio of 1:30. While the centre-based facilities run by NGOs, MoWCA and MoCHTA follow the 1:30 teacher-student ratio, the GPSs take all children who come to seek enrolment in a PPE class, and this results in class sizes sometimes reaching 70–80 children in one classroom. This means the early experience of schooling for many children is not welcoming, as they can barely find a place to sit in the classroom, and individual attention and one-to-one support are seldom available.

Low parental awareness about the importance of early care, support and stimulation means that children do not receive age-appropriate interactive care in the homecare setting in their most formative years. Lack of stimulation delays children's cognitive, social, emotional and language development. By the time children come to school, their developmental potential is already lost to a great extent and children struggle to cope with the formal school environment with lack of school readiness skills. Low awareness also means low demand. While availability and accessibility of services are of major concern, utilisation of whatever services are available is also a problem. Utilisation falls sharply due to the fact that parents do not know the value of preschool education for getting the child ready for school. Timely enrolment is not done, as early learning remains a low priority agenda for many impoverished communities who struggle with poverty, illness and hardship of life. Even when enrolments are done, bringing children to schools/centres day after day is not ensured, because families are busy working, they have lack of transport and there is a ubiquitous cultural understanding that children from poor families have a low intellectual capability and therefore underperform in schools. NGOs and GPSs run parent meetings every month, but these meetings do not adequately highlight the agenda properly and take concrete mitigating measures to ensure children from disadvantaged/impoverished communities can access and utilise services to the extent that benefits them to learn, grow and transit to primary schools successfully and timely.

Though the concept of children learning through *Play* is acceptable in the contemporary world (Fleer 2011), and MoPME (2008) acknowledges the importance of play in children's holistic development, the evidence is not found in practices.

Bangladesh could benefit by incorporating a play-based learning approach not only into the curriculum framework but also in practices. Chowdhury and Rivalland (2011, 2012) provided research evidence that play can provide meaningful happy learning context that considers the sociocultural and educational realities of children of Bangladesh. Moreover, though NCTB considered age-appropriate developmental learning theories in designing the national PPE curriculum, there are multiple theoretical frameworks available, such as social learning, cultural-historical theory, post-development theories and the Reggio Emilia Approach to ECCE in the contemporary world. Also recent early childhood research studies (Banu 2012; Chowdhury and Rivalland 2011; Sikder and Fleer 2015a, b) show that preschool children's learning and development are influenced not only according to age but also by their family, society and culture. The inclusion of a multiple theoretical framework could provide a broader framework in developing the national PPE curriculum of Bangladesh.

Assessment of children's progress along the developmental milestones within the domains demands professionally skilled knowledge, skill and commitment from teachers and/or centre facilitators. Lack of appropriate tools, indicators and a culture of continuous assessment of more subtle developmental aspects than overt emphasis on academic achievement is still an area requiring further attention. Monitoring and evaluation of services are undertaken, but there is no common agreed set of monitoring indicators to assess the quality of PPE and ECCE services. The monitoring and supervision staff lack technical knowledge and skills and are hence unable to extend full support to the teachers in running PPE classes and other ECCE services. Though monitoring visits are carried out, there is no system for compiling the monitoring observations and then taking corrective measures to address current shortcomings and bottlenecks. While systematic evaluations that guide programmatic choices are rare, relevant research studies that inform policies and practices on what to do and how are rarer. Some discrete research studies are undertaken by academics, individuals and service providers; however, no systematic approach is being taken to compile a research depository or to undertake more applied research to see what works and what does not. Most importantly, research findings are seldom considered by policy planners while taking policy and programmatic decisions.

26.8 Conclusion

Although Bangladesh is still in the initial stages of establishing standard ECCE services and practices, government and NGOs continue to gradually work on further development of the ECCE sector in a more complementary manner. In some cases, both government and NGOs have worked collectively, such as developing the national PPE curriculum and materials package and the development of the CECCD policy framework (MoWCA 2009). However, to improve the coverage and quality of ECCE services in Bangladesh, both government and NGOs need to work in a

more coordinated manner to ensure efficient use of limited resources. While NGOs in Bangladesh have pioneered the implementation of ECCE, government has come forward to extend state support for sustainable expansion of the services. It would be wise for both government and NGOs to learn from each other and complement each other's strengths to overcome bottlenecks in access, equity and quality of ECCE service provisions so that all children can realise their fullest development potentials.

Additionally, Bangladesh perhaps needs more evidence-based research on ECCE. There is very little research that allows an understanding of the ECCE sector in Bangladesh. Conducting more research on the sector can inform the current practices on how to be more responsive to the realities and to develop cost-effective sustainable programme models and innovative solutions to address the current capacity and coordination gaps.

It is suggested that the implementation of policies is also vital, rather than making policies without practising them. Although there are many challenges in achieving success, it is hoped that the government of Bangladesh, along with other actors in the field, keep abreast of the recent developments in the field, and improve their practices accordingly, continuing to pay more attention to the quality of services reaching all children with state-of-the-art ECCE programmes that are cost-effective and affordable by all.

Chapter 27
Early Childhood Education Reform: Crisis and Changes

Liang Li, Yuejuan Pan, and Xiaoying Wang

Abstract The study and development of early childhood education (ECE) in Asian countries has been influenced by local cultural values, local government policies and Western education philosophy and pedagogical programs, and national and international economies. Early childhood education (ECE) in Asian countries has been through a dynamic history of educational reform. It is noticeably developed in the last two decades in many areas, such as teacher education, family education, and collaborations and curriculum development. This chapter will focus on the crises and changes during the early childhood education reform in Asian countries and conclude that it is essential to consider the interconnection and integration of Western early childhood practices into local traditional ideas and values during the process of contextualization and reform.

Keywords Early childhood education in Asia • Early childhood education reform • Crises and changes

27.1 Introduction

The study and development of early childhood education (ECE) in Asian countries has been influenced by local cultural values, local government policies and Western education philosophy and pedagogical programs, and national and international economies. Early childhood education (ECE) in Asian countries has been through a dynamic history of educational reform. It is noticeably developed in the last two

decades in many areas, such as teacher education, family education, and collaborations and curriculum development. However, the study has indicated that many Asian countries have challenges in ensuring equitable access to quality ECE services for all children, especially for minority ethnic groups and rural populations (Liu et al. 2004; Nanakida 2015; Harman et al. 2010; Phan 2012). How to improve the quality of ECE to meet families' and communities' needs is another important issue we need to address.

Within the last decades, along with the rapid development of Asian economy, the ECE in Asian countries has been through the dramatic change and development. These can be noted by the countries' policy reform, the implementation of the guidelines, and in particular the increasing enrolment rates in the kindergarten settings. These are explained by the authors in this volume (Pan, Wang, and Li; Lim; Liu and Lin; and Phan). We see an example of this in the writing of Pan et al., where it highlights the cause of early childhood education developed dramatically in China and explains where it shows the improvements in the enrolment rate of children, the quality of teachers, and research on ECE. Meanwhile, it needs to be noticed that the rapid development of early childhood education in Asian countries has also faced its developmental crises and challenges. Lenin (1914) develops the Marxism and sees the development in a dialectical way.

> A development…proceeds in spirals, not in a straight line; a development by leaps, catastrophes, and revolutions…inner impulses towards development, imparted by the contradiction and conflict of the various forces and tendencies acting on a given body, or within a given phenomenon, or within a given society. (cited in Anderson 1995, p. 24)

The development of human being, culture, and society is dialectical. The whole developmental process moves in a spiraling line. The upward spiral progress of development is a dialectical process which involves the conflicts, crisis, and challenges as the moving forces. The development of ECE in Asian countries exactly explains this dialectical process. It requires to make clarity of the key crisis before we take the further actions to move forward.

This chapter will highlight and discuss what key conflicts and changes the Asian ECE have faced in recent years and provide possible developmental trends in the future.

27.2 First Crisis: Cultural Traditions and Values in ECE

As Fleer and Hammer (2014) argue, cultural values are embedded in young children's learning, development, and education. Cultural values on education impact the way educators work with children and the way children participate in education.

Generally speaking, Confucian's beliefs and philosophy have been rooted in many Asian countries' ECE. The Confucian goal of harmony in social relationships influences on teaching and learning. For example, the collective ideology is the key value in education. The Confucian principles include filial piety, ancestral unity,

primogeniture, and lineage. It acknowledges the social obligations; respecting teachers, parents, and elders; and building harmony relationships with others (Pan et al.; Phan). These have significantly impacted on the philosophy of the kindergarten, including how to see children, how children learn, how teachers teach, and the relationships between teachers/adults and children (Zhu and Zhang 2008).

Compared to Western values in young children's independence and assertiveness, many Asian education values in mutual interdependence from an early age of children and family are considered as a first important and outweigh personal desires (Yunus 2005). The differences of cultural values have been noted by all the chapters in this volume.

Phan has discussed the ECE heritage and emphasized on great challenges of Vietnam's ECE teachers' deeply rooted Confucian beliefs about adult superiority, teacher authority, and child submission.

Similarly, Pan et al. have also mentioned that children's voice in China's context is ignored, and the adults make a lot of decisions on behalf of children such as the play environment, the interest classes, etc. The child in a Chinese family mostly is considered as the hope of family. This also impacts on early childhood education that ECE in China is deeply entrenched by the cultural traditions on collectivist orientation. The pedagogical approach highlights the teachers' direction and the group and collective work rather than individual child's demands and desires. As discussed by Pan et al., during the ECE reform recently happened in China, although the teachers start to look at children's perspective in the teaching practice and guided by the national curriculum, the adults still focus on their own agenda on child's learning and development.

This also has been discussed by Lim who explains and discusses the Singapore context of ECE. In particular, she has stated the ideologies in ECE in Singapore and explained that the "Our Shared Values" published in White Paper comprise five broad principles which have similarities to Confucian ideals. For instance, one of the principles describes "nation before community and society before self" which response to the neo-Confucianist idea of "community of self."

It can be seen that the Confucian's ideas have been embedded in ECE and teaching practices which show the cultural tradition influence on how the child looks like and how the education looks like. Adapting the Western educational philosophy and approaches, such as Montessori, Reggio Emilia approach, etc., which focus on child-centered teaching practice, it seems to be a dramatic philosophical shift for Asian EC educators with deeply rooted culturally shaped Confucians on superiority and teacher authority. This brings a critical question on how we develop a suitable early childhood education curriculum locally and globally. It brings a challenge into the ECE in Asian context on how to establish the cultural appropriate ECE educational system which on the one hand suits the local cultural traditions of collectivist orientation and the other hand meets children's needs and development.

As emphasized by Zhu and Zhang (2008), Confucianism has greatly influenced the educational ideas and philosophies in early childhood. They have proposed that it is not a good idea to give up the original traditional culture, but modify the tradi-

tional culture in the curriculum reform. During the curriculum reform, another crisis has embedded in EC teachers' pedagogical practices.

27.3 Second Crisis: Curriculum and Pedagogy

As Hedegaard (2012) argues, societal demands are considered as "the primary forces for human conducts" (p. 14). The top-down educational system from national government has initiated the curriculum reform. The national guidelines in Asian countries have driven and reinforced the fast speed of this reform in ECE. The policy and societal demands change the ECE teachers' pedagogical practices and approaches; however, this makes another conflict between educators' philosophy and beliefs and the translation of the child-centered practices.

Through interviewing the EC teachers, Phan has noticed the central problem of ECE reform in Vietnam is that the challenges the teachers have to face is how to implement the new EC approaches in the practices. The understanding of the new EC programs varies in Vietnam context which causes the problem in the implementation of EC curriculum.

The similar challenge, the translation of the new EC approaches, is also evidenced by Pan, Wang, and Li. In their work, the power of curriculum management decentralized results in many different curricula are able to be seen in the kindergarten practices in China from the adapted Western curriculum and models such as Reggio Emilia, High/Scope, and the ones created locally such as the Integrated Thematic model, etc. Many teachers do not have curriculum awareness and capacities. One particular change has been noted that teacher's teaching behaviors develop behind their beliefs. They identify that "Although teachers used key concepts advocated by the reform in their discussions, reflections, and documentations, they did not immediately transform the key concepts to appropriate practices." Their lack of understanding of the values and principles of the Western play-based learning enhance this enlargement of this conflict.

In explaining the challenges of ECE in Singapore, Lim amplifies the two different government agencies regulate the kindergartens and childcare centers, each with different priorities which make the challenges to educators' pedagogical practices as there is no standard national early year curriculum as a compulsory guideline for EC centers to adhere to. Lim has mentioned that Singapore's ECCE policy reform has moved as a cautious space, which needs to pay more attention to the professional images of ECCE and improve the quality of care and education to meet the needs of Singapore family and children.

The curriculum reforms in Japan have been discussed by Liu and Lin. There are two separate national curriculums to early childhood education in Japan, which are the Course of Study for Kindergarten for children over 3 years old and Guidelines for Nursery Care for children under 3 years old, respectively. Both are revised in 2008. These two curriculums provide the different goals and aims to the kindergarten and childcare centers which impact on educators' pedagogy. Guidelines for

Nursery Care focus on the caring rather than education, and the Course of Study for Kindergarten emphasizes on the education purpose to be ready for primary school education. The crucial crisis has been noticed by Liu and Lin, where enrolment rates of children in kindergartens are decreasing year by year because of low childbirth rate and long economic depression. This promotes the needs to integrate the nursery center with kindergartens during the ECE reform.

27.4 Changes and Creation in ECE

It can be noticed that ECE in Asian countries have been experiencing the crises. It is time to make quality changes. We need to rethink, rework, and create new possibilities to make sure that young children have increasing access to the quality of early childhood education and care. It needs to develop a concrete analysis of each specific crisis in the local social and cultural contexts.

27.4.1 Cultural Awareness and Appropriateness

It is required to develop the awareness of culture appropriateness when borrowing the EC curriculum models. Phan's work emphasizes Vietnam EC reform needs to consider how to bring borrow-from-outside educational model to local context. In China, as elucidated by Pan, Wang, and Li, in order to make a transformation of teachers' values and beliefs in practice, it is necessary to develop the cultural appropriateness in practice. This could be interpreted by two aspects: one is the appropriateness for the traditional culture, and the other is the appropriateness for the future culture a modern society will develop. They have argued that the educational reform should respect the local culture and be rooted in cultural context. It echoes Zhu and Zhang's (2008) argument that "there is no high-quality curriculum that can be effectively adopted in all different cultures" (p. 177). It is not an ideal form to give up the deeply rooted culture traditions.

27.4.2 Teachers' Education and Professional Development

With respect to children's rights and needs, the educational curriculum reform has been fast developed in Asian countries in order to improve the quality of early childhood education and care. The teachers' education and their professional development are paid great attention through the reform. According to Zhu and Zhang (2008), the curriculum reform requires the educators' high quality of professional knowledge to understand the child-oriented educational theory or the practical applications of child-initiated activities. As Pan et al. explained, the great sense of

teachers' identification and qualification needs to be established in China. In particular, the training of preservice teacher and in-service teacher needs to be more concerned about how to apply the theoretical understanding of the curriculum into the pedagogical practices. Phan examines the EC teachers' understanding of the borrowed curriculum and proposes the similar concern when discussing the teachers' professional development in Vietnam context. She has mentioned "the Vietnamese ECE reforms also highlight the need to align teacher education with ECE development." Lim has given her concern to the lack of research in teacher education to examine the effectiveness of teacher preparation programs in Singapore. In particular, she has noticed that one of the EC teacher training programs is offered by the private training agencies with overseas universities; however, there are no research evidences to show the efficacy of the EC degree courses provided by the private training agencies. Liu and Lin state that in Japan, teachers have conducted their own research to improve their knowledge of child development. This illustrates the importance of the research to develop the teachers' professional development.

27.5 Conclusion

The purpose of this chapter is to explore ECE reforms in Asian countries. Drawing upon Marx's theory of dialectical development, by investigating the ECE in China, Singapore, Japan, and Vietnam, this chapter reveals the key crises and challenges of ECE within Asia and provides relevant suggestions on how to cope with the crises at the local and societal level. It confirms that the development of ECE is progressing in an upward spiral. It also implies that curriculum reforms need to consider the important factor of contextualization. It should not ignore the local traditional values in ECE, but build upon contextual and conceptual ECE by adapting Western ideology in ECE. It is essential that the interconnection and integration of Western early childhood practices into local traditional ideas during this process of contextualization are considered.

Chapter 28
Early Childhood Education and Development in China

Yuejuan Pan, Xiaoying Wang, and Liang Li

Abstract In China, both the survival and development of children and the early childhood education have been improved greatly, but the development is uneven in different regions and groups. And child researches deepened and widened with the usage of new technologies and emergence of new topics and emphasize more and more research with children. The problems in early childhood education partly resulted from policy selection and system design. The policies in the past did not clearly define the role of the government and designated the main body responsible for funding at low level of government without strong capacity of public revenue, and the quality supervisory system did not work well. Since 2010, the government issued series of policies and redesigned the system through reforming public funding, teacher training, kindergarten management, etc. The most important change in policy is the shifts from emphasizing effects and efficiency to equity and equality. But lately, policies still exploit the old structure of funding bodies, and the local government could not keep abreast with the central government, and the implementation of policies was challenged. There had long lack of separate professional title system and rigid and explicit professional qualification management and sufficient staff establishment and valid and pertinent education and training system for kindergarten teachers, and it resulted in insufficient, instable, and low qualified staffing. To change teacher-controlled and subject-centered curriculum, the curriculum reform beginning in 1980s decentralized power of curriculum management and advocated beliefs about respecting children, active learning, play-based curriculum, etc. The physical environment and teachers' beliefs and behaviors changed a lot, but the

changes were not simultaneous and very unbalanced among kindergartens, which led into discussions about the cultural adaptation of the reform.

Keywords Child development and research • Policy on early childhood education • Kindergarten staffing • Curriculum reform

Early childhood education refers to education for 0–6 or 7 years old children and is treated as basic education within the education system. As the advance in social and economic development and the further of international communication and cooperation, the early childhood education in China has made great achievements since the Open Door Policy at the end of 1970s. Just under the influence of the special period of social, cultural, and economic transformation, the early childhood education in China faced particular problems and challenges.

28.1 Development of Children and Children Research

28.1.1 Survival and Development of Children

China government has made series of policies on and taken many measures of and increased public investment in children's health, education, legal protection, environment creation, etc. These efforts have dramatically reduced mortality rate of infants and under 5 year olds and basically universalized 9-year compulsory education and effectively suppressed violence against and criminal on children and thus effectively improved children's survival and development.

But the situation is uneven, and there still have many problems in the rural, remote, and poor areas, and it needs to strengthen protecting disadvantaged children's rights and profits (National Working Committee on Children and Women under the State Council 2005). Therefore, the priority of policies on children after 2005 obviously shifted from effects and efficiency to equity (Zhang 2011b). The China Development Research Foundation began to administer pilot projects such as "early nutrition intervention" and "deliver education to countryside" in Ledu county of Qinghai province and Xundian county of Yunnan province in 2009, which provided nutrition bags for 6–24 months old infants and early education for 3–5 years old children. Since 2012, the Ministry of Finance, the Ministry of Health, and the All-China Women's Federation invested one billion RMB to administer the Nutrition Intervention Project for pregnant woman and 6–24 months old infants in 100 counties in eight amassed and joined poor areas and Countryside Kindergarten Project in 640 countrysides of eight counties in Guizhou, Sichuan, Hunan, and Xinjiang provinces. And the Ministry of Education administered the Roving Education Project in countrysides of ten poor counties (People's Daily 2013). Nowadays, it has been widely recognized that improving survival and development of disadvantaged children in poor areas is an effective measure to eliminate poverty and advance social justice.

28.1.2 Awareness and Protection of Children's Rights

With the Open Door policy in 1978 and the communications with foreign countries, human rights and children's rights gained unprecedented attentions. The New Culture Movement in the mid of 1920s in China, which advocated humanity, human rights, and human agency and was disrupted by the National Salvation Movement (roughly from the mid of 1920s to the mid of 1940s), was resumed in the 1980s. Human rights and other humanity issues were no longer prohibited theoretic areas and became hot topics in the fields of culture, politics, education, and other areas (Guo and Tao 1999; Xu and Luo 2007). Education practices that treated children as passive learners were questioned and criticized. The ideology that children should be recognized and respected as active learners and that children have their own rights began to be in shape.

One cultural thread that has been deeply entrenched in Chinese culture for thousand years, simply to put, is the collectivist orientation which stresses the priority of group goals over individual goals and the importance of cohesion within social groups. Children in traditional culture were treated as the hope of family and future of country, and the value of children was defined by the profits of family and future, and the subjectivity of children as individuals is ignored. Reflected in a classroom, teachers paid attention only to the obscure needs and interests of group but not to individual child. Consequently, the most often observed classroom episode before the reform was that all children in the same class did all the activities including routines, play, and lessons at the same time and in the same way (Tobin et al. 1989).

The political breakthrough and philosophical reflection in human rights spurred the new concept of children. Children are viewed not only as having unique physical or psychological characteristics but also as being independent subjects with their own rights, needs, and interests. The Regulations on Kindergarten Education Practice – Trial Version (National Education Commission 1989a) and the Guidelines for Kindergarten Education Practice – Trial Version (MoE 2001) clearly propose that teachers should respect children including respecting their rights, learning needs and developmental characteristics, and individual difference and regulate that kindergarten education should promote each child's development in his or her own individual way. After decades of reform, the kindergarten practice changed a lot. Teachers in many classrooms began to listen to children's perspectives, care for needs of individual children, and allocate more time for free play, and give children more chances to make their own plan and choice (Liu et al. 2004, 2008, 2011a, 2012a, b).

But the protection of children's rights, especially rights to participate and play still needs to improve (Shi and Gao 2007; Pan 2011). It is often found that adults ignore children's rights and needs and arrange children's life according to their own needs in practice. For example, one investigation on children's life situation in Beijing found that most of children sampled attended interest classes, and many children joined more than one class (Zhang 2006). Otherwise, only few parents choose interest class according to children's needs and wills (Research team of

General Education Institute 2008). The free time belonging to children got less and less, and the whole life of the children was institutionalized. Meanwhile, the free public space for children's play and entertainment was shrunk as the process of industrialization and urbanization sped up. Many studies found that the reduction of natural play environment and public street and neighborhood space changed children's life and play behavior (Wang 2012; Shen 2008). In sum, children usually lose their own voices on many important affairs, and the environment was generally arranged according to adults' decisions.

28.1.3 Research on Child Development

The child development research has developed three aspects and greatly deepened the knowledge of a child.

First, many researchers tried to use new technology to study a child from different disciplines in recent years, which provide new research views and findings. For example, Zhou et al. (2006, 2007, 2009) studied the brain function and mathematical cognition using new brain imaging techniques including event-related potentials and functional magnetic resonance imaging, etc. and revealed that children learn addition and subtraction using mental number line and computation strategies and then form visual Arabic number representation and learn multiplication by oral recitation of multiplication table and then form auditory-language representation. Zhou and Liu (2010), Gao and Zhou (2010), and Liu et al. (2011a) studied young children's picture book reading and Chinese character awareness using eye movement analysis technique and found that Chinese-speaking children of 3–6 years old concentrated visually on information-loaded zone of the page and that children spent more time in looking at illustration in picture book than the print and that Chinese character awareness is one of valid predictor of children's literacy ability, and children's Chinese character judgment experience stages from picture as whole, element analysis to character as whole. These studies shed light on understanding children's learning and development in Chinese cultural context.

Second, the topics and contents of research were deepened and widened, especially influenced by the new phenomenon and problems emerging in the process of social development. The researches in the past treated children as a homogeneous collective group and mostly examined the abstract general law of development. As the class division getting more obvious and the gap between classes becoming larger, it has become hot topics whether children from families of different social status gain equal development and fair opportunity for development, and thus many studies after 1990s focused on school readiness, the effect of social resources on children's early development, and special group including children moving with parents and staying at hometown from family of migrant workers. For example, Yu et al. (2010), Gai and Zhang (2005) and Gai (2007) studied the structure, characteristics, influential factors, and assessment tools of school readiness in a deepgoing way. Xiao et al. (2009), Chen et al. (2009), Zhou et al. (2011), and Liu et al. (2012a)

examined the difference of school readiness of children from families with different social status, from minority nationalities, and in urban and rural areas. Lin and Liu and their colleagues investigated migrant children's social adaptation in urban cities, the relationship between their stigma perception and mental health (Lin et al. 2009; Liu et al. 2008). These studies proved that the gap in development between individual children has occurred in early childhood, and the difference of resources possessed by different social classes exerted main effects, which provide convincing proofs to understand the role of interaction between individual and environment in a child development, and important implications for reflecting and improving educational equality and social justice.

Third, it gains more attention to do research with children. Under the context of awareness of child rights, the status and role of children in research was reflected and reconstructed. It was recognized gradually that children were not only subjects of research but participants and coresearchers, and child research is not only on children but also for and with children. As a result, many studies began to shift their views of research and tried new research methods working with children. For example, Liu et al. (2005) studied young children's perceptive on play using material stimulation interview. Huang (2010) compared children experienced participation and teacher perceived children's participation and revealed there existed great difference. Liao and Li (2004) and Yan and Wei (2008) analyzed ideal curriculum and play and those experienced by children. These studies proved and acknowledged young children's ability to understand and judge their own affairs and revealed the difference of perspectives between children and adults.

28.2 Development of the Cause of Early Childhood Education

28.2.1 The Cause Made Advancement in a Twisty Road

As to the whole tendency, the cause of early childhood education developed dramatically. Compared to the situation in 1978, the total number of young children enrolled in kindergartens in 2016 rose to 44.14 million from 7.88 million, and the enrolment rate of eligible children in 3-year kindergarten education rose from 11.4 to 77.4% (MoE 2016). It means that the enlargement of quantity of kindergartens could satisfy more and more young children's needs for kindergarten education.

But the road of the development is not smooth. First, the total number of kindergartens rose steadily before the middle of 1990s and then decreased and did not go up again until 2003. Second, the total number of kindergarten teachers correspondingly rose gradually to 1.17 million in 1996 and then reclined to 0.63 million during the period in 1997–2001 and resumed after 2002. Third, the number and percentage of kindergartens sponsored by public enterprises and institutes dramatically

decreased; otherwise the number of private kindergartens increased. In the end of 1991, the number of private kindergartens across the whole country just was 12,000, which amounts to 7.29% of total number of kindergarten in the country but grew to 75.4 thousands in 2006, which amounts to 58% of the whole (Zhang et al. 2008, p. 65).

The curve of development of early childhood education mainly resulted from the economic reform in the 1990s. Before the middle of the 1990s, the majority of kindergartens were set up and managed by educational authorities and work units and provided as welfare for employees. In the 1990s, the reform of economic system began shifting from planning economy to market one. The public enterprise and institutes did not shoulder responsibilities by social sector anymore, and the schools, hospitals, etc. that sponsored by such kind of work units were separated from their original sponsoring bodies. In this context, many kindergartens of such kind were sold or closed. Meanwhile, the rural tax and fee reform gradually called off rural taxes and fees. Consequently, county or town governments have almost no financial capacity to fund early childhood education. Until 2003, the proposal on Reform and Development of Early Childhood Education (2003) clearly maintained that the government is the main body responsible for providing public kindergartens. After that, the development of early childhood education resumed.

The allocation of the resource of early childhood education is unequal and the development is uneven.

Two obvious problems should be noted in the process of development of early childhood education in China: On one hand, the resource of early childhood education as a whole was absolutely scarce while it made great achievements. On the other hand, the limited resource was allocated unequally which resulted in comprehensive, systematic, and multilevel uneven development among different geographical regions and social stratum between urban and rural areas.

First, the development of ECE in east advanced regions is better than that in middle and west regions. There are many children who have no access to basic kindergarten education in the middle and west regions, while the problem in east regions is how to provide quality kindergarten education for each child. For example, the enrollment rate for 3-year kindergarten education in Shanghai reached more than 98% (Shanghai Municipal Education Commission et al. 2011), while in Jiaozuo in Henan province only was 63% (Jiaozuo Municipal Education Commission 2011), which is only slightly higher than the national average of 56.6% in 2010 (Department of Development and Planning of MoE 2011). The total number of kindergartens was 1252 with 31.6% private ones, while that in Jiaozuo only was 501 with 93.2% private ones. And the average budgetary educational funding per permanent residential eligible children was 132.63 RMB in Shanghai, but that was only 3.02 RMB in Jiaozuo. Great gaps exist in budgetary educational funding, ratio of public kindergartens and the enrollment rate in Shanghai and Jiaozuo.

Second, the development of ECE in urban areas is better than that in rural areas. Currently, the quantity and quality of kindergartens, the enrollment rate, the number and educational degree, and qualifications of teachers in rural areas lagged far behind than in urban areas (Hong and Luo 2012). Liu et al. (2012a, b) observed 108 senior classes in kindergartens (including reception classes in primary schools) in cities, counties, and countryside in three provinces and found that the quality of physical environment, daily care, curriculum, etc. in kindergartens in the countryside was significantly worse than that in cities and counties. Such pattern of difference existed in three provinces sampled in east, middle, and west regions.

Third, the development of public kindergartens sponsored by educational authorities, government branches, and public enterprise and institutes is better than those sponsored by other bodies. Song (2011) analyzed the cost sharing by local government using data of 591 kindergartens in 25 counties in Hebei, Anhui, and Zhejiang provinces and found that only 8 of 218 private kindergartens gained public funding, otherwise 247 of 373 public kindergartens got public funding, and the government shared about 60% costs of these kindergartens. Kindergartens with different sponsoring bodies are different in funding raising mechanism, cost sharing model, and adequacy of non-personnel expenditure and thus difference in kindergarten conditions, staff qualification and stability, and classroom environment quality. For example, according to a large-scale investigation conducted in Hebei province, a province in the North China region, only 25.6% teachers in rural kindergartens have associate degrees or higher (Liu 2012). Liu et al. (2012a, b) and Pan and Liu (2008) found that the kindergartens in cities and sponsored by educational authorities performed better than those in town and countryside and sponsored by communities and private sectors.

Fourth, the families of higher social status more likely possess quality early childhood education than those of lower social status. The studies of Xu and Chen (2007) in Shanghai, Li (2010) in Wuhan, and Sun (2013) in Nanjing all revealed the same pattern of allocation of ECE resources among families of different social status that children from families of advantaged social status went into public kindergartens with higher quality. Zhang Yan found that the tuition fee of public and private kindergartens went far beyond the buying capacity of migrant workers, and their children either stay at home or enroll in illegal kindergartens without official registration (Jin et al. 2005). There were 1266 registered kindergartens in Beijing, but 1298 kindergartens without registration in 2009 (Political Consultative Committee Member investigation 2009). These kindergartens without registration scattered in the rural-urban fringe zone, and 95% children enrolled in these kindergartens were from migrant worker family (Zhang and Li 2010). In one word, most of quality public ECE resources are possessed by children from families of advantaged social status in cities.

28.3 Policy on Development of Early Childhood Education

28.3.1 The Problems in Past Policies on ECE

The problems of ECE in China resulted partly from the level of social economic development and partly from the policy selection and system design. Many scholars analyzed the policy on ECE and generally pointed out the problems as follows.

The responsibility of the government was not defined clearly, and the policies were not fully administered. The management system of ECE in China was established as "responsible by local government, managed by authorities at different levels, and coordinated by different branches with individual responsibility." Under such system, the responsibility of the government was defined ambiguously. And there are no concrete rules for implementation and no related mechanism and measures including average cost accounting, performance evaluation, funding guaranteeing, etc. Moreover, the policies on ECE are department regulations and then exerted little constraint on local government. As a result, many policies issued by central government just became a mere scrap of paper.

The level of the main body responsible for funding ECE is low, and the funding is not adequate and allocated unequally. The proposal on Reform and Development of Early Childhood Education (2003) reinforced and clearly maintained again that county governments are responsible for setting up public kindergartens in counties, and town governments are responsible for both setting town central kindergartens and raising funds for kindergartens in rural areas. However, after the establishment of the tax-sharing system in 1994, financial power was centralized with the powers of the county and town governments being weakened. Moreover, the rural tax and fee reform gradually called off rural taxes and fees. Consequently, county or town governments have almost no financial capacity to fund early childhood education. On the other hand, influenced by the urban-rural dual structure established since the establishment of the PRC in order to accelerate industrialization and urbanization, limited funding had been heavily invested in developing model kindergartens operated by public work units in cities, and kindergartens sponsored by private companies or communities and those in rural areas hardly received public funding.

The quality supervisory system is imperfect. The Kindergarten Management Regulations in 1989 (National Education Commission 1989b) stipulated that the local educational authorities should be responsible for supervising, evaluating, and guiding the care and education practice in kindergartens. Since that, many local educational authorities developed kindergarten rating standards and administered kindergarten evaluation, which positively promote kindergarten quality. But it could not guarantee objective and valid evaluation for public kindergartens, because the educational authorities play roles both of sponsoring, guiding, and evaluating bodies. And it lost effective control on quality of private kindergartens, because the private kindergartens charge tuition fee according to cost instead of quality, and the educational authorities have no power to fund and personnel private kindergartens.

28.3.2 Changes in Current Policies on ECE

The China government has been making efforts to improve accessibility, affordability, quality, and equality of ECE. Especially since 2010, the government held several summit meetings and issued series of policies and redesigned the ECE system in order to provide equitable and quality ECE.

Any change in policy is essentially kind of rearrangement of power and responsibility and reallocation of resources and profits among different bodies. The most obvious change of lately policies on ECE is the value orientation to equity and equality. The developmental goal of ECE is definitely proposed as establishing public provision system of ECE covering urban and rural areas with rational geographical distribution in order to provide basic and quality ECE for eligible children. And it emphasized that most kindergartens should be beneficial universally, which means that most of this kind of kindergartens funded by the government, and most eligible children could enroll in kindergartens, and most children from poor families could gain subsidy from the government. Thus, it requires that the public funding should be tilted to rural areas and remote poor areas and should establish subsidy system to help poor children and orphan and handicapped children receiving ECE. The central government will set special project to promote ECE in rural areas, and local government of every level should allocate special funding to construct kindergartens in rural areas.

To fulfill the goal, the policy reaffirmed the leading role of the government in developing ECE:

- Enrich resources of ECE in various ways including developing public kindergartens, supporting private kindergarten by buying service, awarding as subsiding, tax reducing, etc. and construct and plan community kindergartens in cities as a whole.
- Establish rational standard of teacher-children ratio, check and ratify establishment standard, improve the teacher qualification accreditation system, and issue teacher professional standard, improve teachers' status and remuneration, and the central and local government set training projects for teachers in rural areas.
- Enlarge funding in ECE by including ECE funding into financial budget, directing the increment of educational funding into ECE, establishing funding standard per student in public kindergarten, establishing ECE subsidy system, allocating special grants and increase funding to support rural areas in middle and west regions and minority and remote regions.
- Strengthen kindergarten management, strictly administer kindergarten accreditation, and establish standard for setting up kindergartens of different types and manage and guide kindergartens according to their types.
- Enhance management of kindergarten tuition fee charging.
- Make a 3-year development plan within the range of county (State Council 2010b).

The process of policy making is also more open, transparent, and evidence-based than before. Series of policy texts, including the Outline of China's National Plan for Medium- and Long-term Education Reform and Development (2010–2020) (abbreviated as the Outline, State Council 2010a), the Kindergarten Teacher Professional Standard (MoE 2011), the Kindergarten Staffing Standard (MoE 2013), etc., were worked out on the base of investigation and granted project study. After the draft of policy text was finished, it would be open to different groups at different levels within different ranges for comments. For example, the draft of the Outline was open to public comments through the website from February 28 to March 28 in 2010. The website of Ministry of Education received 18,474 comments and suggestions, and there are 3951 about ECE part, which is the biggest percentage among each education stage (Wang et al. 2010).

But these policies still have problems not solved and challenges in implementation. First, they still exploit the old structure of funding bodies though the focus of funding objectives was changed a lot. The policies stipulated the government should raise funding and construct rational cost sharing system, but the main funding bodies remain at local government mainly at the level of county and town and countryside, and the percentage of the government at different levels and families was not defined clearly. Within current revenue and tax system, the government at the lower level has weaker financial capacity, otherwise shoulder much heavier responsibilities for social welfare. To guarantee the funding as proposed by the policy, the funding bodies should be lifted to the government at a higher level with stronger financial capacity, if the macro revenue and tax system not be reformed. Second, the local government could not keep abreast with the central government in basic value orientation and management mode. China is centralized in politics and decentralized in administration. In many contexts, the local government could not accurately understand and implement the policy issued by central government. For example, the central policy required the government should play leading role and should energetically develop public kindergarten and form the setup that both public and private kindergartens develop simultaneously. But in a 3-year developmental plan, the local government invested most in building, rebuilding, or extending public kindergartens; therefore the number of public kindergartens grows dramatically. As to the social economic capacity, the government does not have enough public revenue to provide universal public kindergartens for all eligible children at this stage. Therefore, it is not a sustainable developmental mode to rely totally on the government's public revenue without employing market and volunteer mechanism.

28.4 Problems and Challenges in Kindergarten Staffing and Teachers' Living Conditions

A teacher directly and indirectly affects young children's learning and development and is one of critical factors influencing kindergarten quality. But problems in professional qualification and title, staff establishment, and teacher training have always been hindering kindergarten staffing and teachers' living conditions.

28.4.1 Professional Qualification and Title

The professional title for kindergarten teachers has long borrowed from title system for primary teachers. There were 48.2% teachers across the whole country who did not join the appraisal of professional title in 2002. Liu Xia (2011) found there were 64.23% among 21,179 kindergarten teachers who did not join the appraisal of professional title in Guangzhou. Also there is deficit in teacher qualification management system. The Regulations on Kindergarten Management in 1989 first proposed that kindergarten principal and teacher should have a degree of vocational kindergarten teacher training school or appraised as qualified by educational authorities. The Teachers Law of the People's Republic of China (Central People's Government of the People's Republic China 1993) proposed to administer teacher qualification management system and required that kindergarten teachers should have kindergarten teacher qualification and degree of vocational kindergarten teacher training school or upper or should pass the teacher qualification examination if not having such degree. But these policies accredited qualification only by educational degree and did not give explicit and concrete requirements on what knowledge and capacity should kindergarten teachers possess. As a result, kindergarten teacher as occupation has long been at low level of professionalization. And kindergarten teachers were called "auntie" or viewed as a babysitter who anybody could be or versatile young beauty.

The Teachers Qualification Regulations in 2000 made concrete regulations on kindergarten teachers' qualification standard, accreditation, and management. But it still had problems that the requirements are low and ambiguous, and the accreditation method is not scientific, and the qualification certificate is valid lifelong (Hong 2011). To improve the professional level, the Ministry of Education issued the Professional Standards for Kindergarten Teachers in 2011, which regulated what basic professional qualifications should a qualified kindergarten teachers have on aspects of professional beliefs and ethics, knowledge, and capacities. The issue of professional standards greatly promotes the professional level of this occupation and provides regulations and guidance to the accreditation, professional development, and education and training of kindergarten teachers.

28.4.2 Staff Establishment and Remuneration

The management of kindergarten teachers is based on staff establishment. Establishment is authorized size and structure of staff in government branches and public institutes. The salary of teachers having authorized establishment is totally or partly funded by the public revenue, which is the main way of public revenue investing in kindergarten education. Therefore, only public kindergartens, including kindergartens sponsored by educational authorities, government branches, and public enterprise and institutes, have an opportunity to apply for staff establishment. Majority of private kindergartens and those in rural areas do not have staff establishment. For example, there were 21,179 kindergarten teachers in Guangzhou, and only 1324 of them had establishment, which amounted to 6.25% (Liu 2011). But it is very difficult for kindergartens to get staff establishment, because the developmental emphasis is on 9-year compulsory education.

Establishment is the organizational identity of teacher, and teachers' profits including salary and welfare, training, and promotion are closely related to establishment. Teachers having establishment have higher salary from public revenue and more chances for training and promotion and then have stronger commitment to and recognition to this job, while teachers without establishment was paid by kindergarten at low level of salary and thus turns over frequently. Under such situation that the kindergartens severely lack staff establishment and teachers with and without establishment do same work but have different payment, kindergarten staff as a whole is insufficient, instable, and low qualified.

The Several Proposals on Development of Early Childhood Education (State Council 2010b) require that local government should check and verify staff establishment in public kindergartens and gradually personnel sufficient staff. But one basic content of the reform of government and public institutes is to reduce organizational size and staff and raise efficiency. The number and percentage of personnel paid by public revenue was reduced dramatically, and the staff establishment for kindergarten decreased more and more. In practical situation, some local government attempts to explore new management mode. For example, Hefei in Anhui province avoided the problem of staff establishment and exploited post management mode and provide teachers with and without establishment in the same post with the same salary and same conditions.

28.4.3 Teacher Education and Training

Many researchers studied kindergarten teachers' professional development, differences in beliefs and behaviors, etc., but there are many problems in preservice education and post-service training in practice.

The preservice education is administered at three levels of technical secondary school, 3-year college, and undergraduate university. And technical secondary

school had long played important role in training and delivering kindergarten teachers. During the Tenth Five-Year Plan Period, most technical secondary schools were transformed to a 3-year college. But the rash advancement incurred problems in adaptation of educational goals, training modes and curriculum arrangement, and sufficiency and qualification of teachers. As to curriculum, because of having long lacked professional standard and the cultivating goal is obscure, the education in technical secondary school had long emphasized music, dance, and art skills (Qin 2012) and ignored theoretical knowledge and teaching skills, while university contrarily stressed academic and ignored practice. The former aims to cultivate versatile teachers, but the latter aims to cultivate kindergarten teachers' academic attainment and research ability (Ye 2006).

Scholars studied learner community, kindergarten-based teaching research, and apprenticeship learning and their effects on teachers' development through action research, case study, and narrative study. But investigations showed that the in-service training in practice lack pertinent and effective content, participatory training method, and equal opportunity allocation (Li and Wang 2011; Qiu 2009; Research team of Song Qingling Development Center 2012; Shi et al. 2010; Tian and Zhou 2009; Wu and Wang 2012). Even the national kindergarten training project for teachers in rural kindergartens in middle and west regions also has these problems. Pang pointed out that the project did not rigorously examine and approve the qualifications of the training institutes and personnel; the trainees were not all teachers in rural kindergartens, and it lacked supervision and evaluation on the process and effects of project administration, and the content was not pertinent and appropriate; the training method was mainly the off-site group instruction (Wei and Pang 2013).

28.4.4 Living Conditions of Kindergarten Teachers

As a whole, the living conditions of kindergarten teachers were not optimistic under the influence of staff establishment, payment, and opportunity for training and promotion. Liu Xia's investigation found that the average salary of kindergarten teachers was significantly lower than that of non-private work units (Liu 2011). Li Hui compared the payment of kindergarten teachers in Shenzhen, Hong Kong, and Taipei and found that the level of payment in Taipei is the lowest, and the real purchasing power in Hong Kong is the lowest (Li et al. 2013). Li's investigation on kindergarten teachers' job pressure and living conditions implied that kindergarten teachers faced heavy work load and psychological pressure, felt a strong sense of job burnout and weak sense of success, and are not committed to this occupation (Li 2000). Liang and Feng questionnaired 447 teachers in kindergartens sponsored by different bodies and found that 48.4% teachers sometimes wanted to quit job, and 26.9% teachers regretted to choose this job, and some expressed to change job provided the payment is acceptable (Liang and Feng 2004).

The living conditions of teachers without establishment, in rural areas and private kindergartens, are even worse. Li found there is great difference in payment between teachers in public and private kindergartens, in urban and rural areas, and with and without establishment (Li 2012).

28.5 Achievements and Problems of Curriculum Practice and Reform

The early childhood education in China has gone through four major periods since the establishment of the first kindergarten run by the government in 1903 (Zhu and Wang 2005; Wang 2004). The history of kindergarten curriculum in mainland China has been an integrating process of learning from foreign countries and exploring native models. In the fourth period from the 1980s till present, the practice learned from the Soviet Union was criticized, and the curriculum management and beliefs and practice were reformed. Through three decades of efforts, the reform has made great achievements but still has essential problem waiting to solve.

28.5.1 The Power of Curriculum Management Decentralized

According to Zhang (2011a), power decentralization for kindergarten curriculum management has progressed through three phases. In the first phase, scholars and practitioners spontaneously explored new curriculum models. It is during this phase that the first kindergarten curriculum textbooks (Zhang 2011a) that were not issued by governmental institutes were published and marketed. In the second phase, the government formally decentralized the power of curriculum decision-making. Specifically, in 1999, the Central Committee of the CPC and the State Council co-held the third National Education Conference and proposed to reform the curriculum management system in primary education. A three-tier (national, local, and school) curriculum management system was established since then. Moreover, it was also agreed that local educational authorities and schools have more power in curriculum decision-making than national authorities. In the third phase, the Guidelines for Kindergarten Education Practice – Trial Version (MoE 2001) advocated that local authorities and kindergartens should create local curriculum reflecting and catering to local needs and culture, which substantially elevated the awareness and participation of kindergartens and teachers in curriculum decision-making. As a result, developing and designing school-based curriculum has become a hot issue in research and practice during this phase (Wang 2004). "Some local educational authorities require every kindergarten develop their own kindergarten-based curriculum, and some even use kindergarten-based curriculum as one important criterion for kindergarten quality rating" (Zhu 2006a). Therefore, the

decentralization of curriculum decision-making has directly led into the birth of curriculum models of a great deal of diversity and variety, which forever overturned the scene that all kindergartens across the country exploited one uniform curriculum. Many different curricula, from the ones borrowed from foreign countries such as Reggio Emilia or Project Approach to the ones created locally such as the Integrated Thematic model or Infiltration Model, can be seen in kindergartens.

But underneath the surface of diversity and autonomy is the disorder and uneven of kindergarten curriculum. Some studies pointed out that many principals and teachers do not have curriculum leadership and curriculum awareness and capacities to select and design curriculum and integrate curriculum resources (Yang and Zhang 2008; Zhang 2012). The quality of many curriculum kindergarten developed is low, and some kindergartens even thought developing kindergarten-based curriculum is to compile textbook or choose content totally on their own will (Yuan 2004). Jin (2012) investigated 15 kindergartens in Shenyang and found that the goals of the curriculum kindergarten developed were not comprehensive, and the contents of curriculum were too many and not integrated, and the way to implement curriculum was unitary, and the evaluation is weak. Zhao (2013) investigated 116 kindergartens in 14 cities and regions of Hunan provinces through interview and questionnaire on principals and teachers and found kindergarten teachers relied mostly on textbook or teacher guidebook, but the development of kindergarten-based curriculum is lagging. Therefore, it needs to improve teachers' capacity as well as delegate teachers' power.

28.5.2 Changes in Teachers' Beliefs and Behaviors

The reform in the range of the whole country was formally launched by the issue of the Regulations on Kindergarten Education Practice – Trial Version (National Education Commission 1989a), which symbolized the shifting from nongovernmental bottom-up exploration to government-directed top-down reform. The propagation and the mobilization of the reform were pushed forward from central to local government and then to kindergartens by administrative power. In 2001, the Ministry of Education (former National Education Commission) issued another national guideline, the Guidelines for Kindergarten Education Practice – Trial Version, to further carry on the curriculum reform.

The reform is "essentially a kind of self-conscious 'value-priori' cultural selection" (Liu and Feng 2005). The core values advocated by the reform included respect individual children, active learning, play-based integrated curriculum, etc. For decades, the reform efforts have been to transform the value-bearing fundamental principles to efficient education practice. And also the most obvious and greatest achievement of the reform was believed to be the change of educational values among practitioners (Liu and Feng 2005). Transforming educational beliefs (zhuan bian jiao shi guan nian) has become the most frequently used term in the reform literature (Liu et al. 2004; Huang and Liu 2006). In her dissertation study, Liu

(2007) interviewed different groups of stakeholders for kindergartens, which include teachers and principals, administrative officials, and scholars, and asked them to list the key concepts that they thought advocated in the reform and found that all the participants listed "respect children," "active learning," and "providing play as basic activity" as the key concepts for the reform. Yi and Pang's (2005) narrative study with one kindergarten teacher revealed similar results. Specifically, the teacher reported that she would respect and satisfy young children's needs as much as possible, would not pose too more rigid rules and discipline, and would encourage and engage children in classroom activities; the teacher also reflected that changes in her beliefs and teaching were resulted from learning the Guidelines for Kindergarten Education Practice – Trial Version (MoE 2001). Wang and Yu (2004) investigated kindergarten teachers in rural areas on their educational beliefs and found that teachers' beliefs had changed a lot and shifted from teacher-centered to children-centered.

The shift from rice-seedling-bed configuration to learning centers is obviously another noticeable achievement for the reform. Xiang (1995) investigated 407 kindergartens in six provinces and found that 50% of classrooms provided learning centers. Similarly, Liu and her team (2011b) evaluated qualities of kindergartens in 11 provinces, and one of the findings shows that learning centers were commonly adopted in kindergarten classrooms. In sum, after decades of reform, the setup of learning centers has become a common classroom configuration in Chinese kindergartens regardless of its variations in types or in quantity. Moreover, compared with classrooms in the past that only provided paper drill textbooks or sole type of manipulative, classrooms today provide a variety of hands-on manipulatives. For example, Liu and her colleagues (2004) found that all the 15 kindergartens they observed in Beijing provided some sort of play materials in learning centers and that classrooms of better qualities provided two to three types of materials in each learning center.

Another change is that teachers began to allocate more time for free play and give children more freedom and opportunities in choosing. Liu and colleagues (2012a, b) reported that 62% of classrooms in cities provided at least 30–45 accumulated or uninterrupted minutes of indoor free play on a daily basis, and some classrooms even allocated as much as an hour. During play, teachers would allow children to make autonomous choice for play theme, materials, or peers.

Meanwhile, teachers also began to teach and care for individuals. In the past, teachers usually paid too much attention on curriculum goals and lesson plans; as to children's needs, teachers only cared about them as a collective. For example, Zheng (2004) found that teachers mostly interacted with the whole group, and what teachers said and did was often directed to the obscure children as collective (i.e., teacher often said "ni men" [equivalent to the plural meaning of you]; "xiao peng you men" [equivalent to the meaning of "little friends"]). Liu et al. (2004) documented evidences that teachers began to care about children's individual needs, for example, children were allowed to go to toilet without asking for teachers' permission. Liu and colleagues' latest studies (Liu et al. 2008, 2012a, b) show that teachers allocated attention not only to individual child's basic needs such as eating, toileting, or

napping but also to the child's learning and developmental needs. For example, some teachers took anecdotal notes for individual child and gave accordingly individual scaffolding. Studies on teacher-child interaction also revealed similar patterns of change.

As to the entire tendency, the changes in abovementioned implied that the reform has made great achievements. But two phenomena should be noted when examined elaborately what kindergartens have made what changes at what aspects at what time.

First, it is easier to change physical environment than to change teaching behaviors. Physical environment, daily routine, and teaching interact with each other, but changes of these factors do not happen synchronically. The first made and most obvious achievements were those at the physical level. For example, learning centers had been observed in the early 1990s (Xiang 1995) which was just several years after the reform. In contrast, changes in teacher-child interactions and play did not obviously occur until mid and late 1990s (Liu 1995; note that the Xiang 1995 study was conducted earlier than Liu 1995, although they were published at the same year). In addition, teachers' teaching behaviors also lagged behind their beliefs. Although teachers used key concepts advocated by the reform in their discussions, reflections, and documentations, they did not immediately transform the key concepts to appropriate practice. Therefore, it was relatively easier to change physical environment than to transform teachers' practices.

Second is that the reform progressed to very unbalanced and great variations existed among kindergartens. Specifically, studies conducted by different researchers, in different years, or with different samples reached a similar finding that significant differences exist among kindergartens, especially in the domain of physical environment with public kindergartens in cities being generally better than private kindergartens or kindergartens in countryside. Moreover, there coexist curriculum models that popularized at different times – the traditional subject-based curriculum evolved from the establishment of the PRC as well as the most contemporary Project Approach or Reggio Emilia models. The impacts of the curriculum reform indeed landed upon different kindergartens at different extents (Pan and Liu 2008).

28.5.3 Cultural Appropriateness of Kindergarten Curriculum Reform

One important goal of the reform is to change the practice of group instruction which characterized as concentrated on subjects, centered on teachers and classrooms and textbooks, and based on talking and listening. But such kind of teacher-controlled knowledge-oriented group instruction still is prevalent in many kindergartens after decades. To this problem, there are many different answers. Some pointed to the difficulty in transforming teachers' beliefs and behaviors. And some discussed the cultural appropriateness of such wave of reform.

Zhu differentiated group teaching activity from group instruction and defined group teaching activity as that a couple of teachers organize teaching activities with many or whole children and generally ask all children do same activity or related tasks at same time. He asserted that group teaching activity could be either low-structured or high-structured; either teacher-preplanned or children-initiated; either integrated or subject-focused (Zhu 2006b). And he pointed out that "teacher-planned group teaching activity is main part of kindergarten curriculum, and most principals and teachers still treat group instruction as main activity in their kindergartens at present, and will do in future. It was shaped by our social culture and real situation." (Zhu 2006a) For example, the traditional culture in China admire collective spiritual, which is different from western culture. And the teacher-child ratio in China could not reach the standard in America, and teachers have no choice but group teaching activity when facing so many young children, but it is most effective (Zhu 2006b). Anyway group teaching activity is one particular kind of activity in kindergarten curriculum in China and should be reinforced and improved but not canceled or abolished. (Zhu 2006b).

Kindergarten curriculum reform should respect culture and be rooted in cultural context. But what are essentials of Chinese traditional culture which need to transmit? Is the group teaching activity that teachers selected in practice in context of high teacher-children ratio appropriate for the social ideal? Pan and Liu (2008) gave different explanations to these questions.

They thought Ming-Fen emphasis and examination orientation largely influenced the content and implementation of kindergarten curriculum. The pre-Qin Confucianism upheld benevolence, righteousness, propriety, wisdom, and integrity. Propriety means that people behave according to his or her social role to build a harmonious and orderly society. After the reinterpretation and reconstruction in post-Han dynasty and Song dynasty, however, the propriety evolved into the set of "Three Guides and Five Constants" (san gang wu chang), which strangles the development of humanity spirit. Liang (1987), a famous Chinese philosopher and social activist in the early twentieth century, maintained that Chinese culture was an ethics-based culture, in which individual identity was not defined by his/her capabilities and rights, but by his/her responsibilities and obligations for others and that individual's rights were not claimed by him or herself but imbued by others. Some scholars asserted that Ming-Fen was the essential of Chinese traditional culture, in which positions and roles in the society determined an individual's identity (Liang 1986; Qu 1981). Therefore, individuality was oppressed, and compliance to power and authority was promoted. The control of teachers on children just is the epitome of the macro social structure within kindergarten classroom.

The imperial examination system was firstly established in Sui dynasty, which was about 1400 years ago, and perfected in Tang dynasty, which was the successive dynasty after Sui, and had not been abolished until 1905. The imperial examination system had not been merely a political system for selecting cadres but also an open tunnel for the mass to upward their social status. The examination orientation has profoundly influenced Chinese's attitudes toward learning and the social wishes to examination. Affected by this orientation, learning means studying hard without

play, studying means preparing for examination, and examination is to change one's social status and gain advanced Ming-Fen. The beliefs of learning and studying for examination influenced by the imperial examination did not disappear but was reinforced after the abolishment in 1905. In nowadays, although there have been many critics about examination-oriented education and examination itself, examination is still viewed as the only equal and fair selecting measure. Because examination is treated as the sole pathway to gain Ming-Fen, teachers and parents highlight knowledge teaching and skills training, and treat play as a barrier for efficient learning.

However, culture appropriateness, however, should be interpreted from two aspects: one is the appropriateness for the traditional culture or cultural traditions, and second is the appropriateness for the future culture a society wishes to build. Curriculum reform therefore should balance its functions of cultural transmission and cultural selection/creation. Note that the obstacles encountered in the kindergarten curriculum reform reflect not only the conflicts between Western and Eastern cultures but also between traditional values and values pursued by the modern society. Therefore, there may not need to be too concerned about the loss of cultural identity, although the curriculum reform in China appears to be a product of learning from the West. On one hand, the ultimate purpose of the curriculum reform is congruent with the needs of the society. To fulfill modernization has long been the goal of social construction since the establishment of PR China in 1949, and to fulfill modernization, China needs autonomous and creative individuals. Moreover, in the West, child- or play-based curriculum was not the original kindergarten education tradition either. Lindon (2001) stated that "the focus on the value of spontaneous play grew in Western Europe from the 1930s to become established by about the 1970s" (p. 142). On the other hand, people usually interpret imported curriculum models from their own cultural lenses, add on their own interpretation, and select worthy elements from their own needs. Tobin et al. (2009) found that curriculums in different countries do not become totally the same even after decades of borrowing or learning from each other.

Chapter 29
History and Reform of Early Childhood Care and Education (ECCE) in Japan

Xiangying Liu and Chiafen Lin

Abstract The first regular kindergarten (1876) and the first permanent nursery center (1890) in Japan have established for more than 100 years. However, Japanese early childhood care and education (ECCE) system includes kindergarten and nursery center to develop the dual education system. This paper introduces some aspects of history and reform of ECEC in Japan. The aspects examined are as follows:

1. History of results of dual early childhood care and education system

Both kindergartens and nursery centers were set up in modern days, whereas kindergartens and nursery centers were established under different backgrounds and environments. For this reason, they were distinguished from service objects, service function, and service characteristics. After WW II, kindergartens and nursery centers were classified into different systems and caused a long-term dual early childhood education system.

2. Characteristics and development of kindergartens and nursery centers under dual education system

After WW II, according to the School Education Law, kindergartens were subsumed within school education system. Kindergartens offered children basic education and care, offered a proper environment for children to grow up, and promoted student's physical and mental development. Ministry of Education, Science and Culture managed affairs of kindergarten. Kindergartens enrolled children whose age was from 3 to 6 and mothers were unemployed. In contrast, according to Child Welfare Law, nursery centers were subsumed within the child welfare system. Nursery centers were for those mothers who must work for her family that lived under minimum living standards.

3. Curriculum reform of the kindergarten and nursery center in Japan after WW II

The curriculum standards both of kindergarten and nursery centers in Japan emphasize on children's development and classify five fields: health, relationship, environment, language, and expression.

4. Development of the early childhood teachers and children in Japan
5. Japanese attempts at child care support services in kindergartens and nursery centers
6. Trends in the early childhood care and education system reform of integrating kindergartens and nursery centers.

Keywords Japan • History and reform • System of ECCE • Kindergartens • Nurssery centers • Certified kodomoen

29.1 Introduction

Early childhood care and education (ECCE) in Japan already has an over 120-year history since the first regular kindergarten was established in 1876 and the first permanent nursery center opened in 1890. However, during these 120 years, a Japanese model of early childhood care and education has been completed to combine the traditional culture and new ways of thinking about children (Center for Women's Education and Development Ochanomizu University 2006) in the dual system that has been consisting of kindergartens and nursery centers (Liu and Nakata 2014).

This paper aims to provide the comprehensive view of the development of ECCE system in Japan from their foundation to their present situation. This paper is organized as follows:

1. History of the dual system of ECCE in Japan
2. Two types of Japanese preschool: Kindergartens and nursery centers
3. The curriculum reform of kindergartens and nursery centers after WW II
4. Teachers and children
5. Co-culture: Collaboration of home and kindergartens/nursery centers
6. Toward integrating kindergartens with nursery centers

29.2 History of the Dual System of ECCE in Japan

Both kindergartens and nursery centers were designed under different backgrounds and expectations. These two institutions were quite different in objects, functions, and characteristics. After WW II, kindergartens and nursery centers were more clearly differentiated from each other. This section explains how this dual system was constructed and what it caused.

29.2.1 Kindergartens as a National Policy of Modern Japan

The urgent goal of the Japanese government in the Meiji Era (1868–1912) after the long feudal times was to overtake and surpass the great powers of the West. One of the domestic policies that Meiji Government should deal with was to modernize its people: Education was a top priority. In 1871, Meiji Government constituted the Ministry of Education, Science and Culture and enacted an educational system in 1872. From 1879 to 1900, the compulsory educational system was devised and attempted. Thus, all Japanese children at the age of 6 became required to go to elementary schools in order to become the citizens of modern Japan.

An educational system also considered preschool education. Chapter 22 of An Educational System ordained that children under 6 must receive preparation education before going to elementary school (Ministry of Education, Science and Culture 1981). Under the government's active promotion, the first kindergarten in Japan was established in 1876 and affiliated with the Tokyo Woman's Normal School. The Tokyo Woman's Normal School, the antecedent of Ochanomizu University (the best national women's university in Japan), was the first higher educational institution for women established by the Meiji Government. This kindergarten was subsequently used as a model for the establishment of kindergartens in various regions around the country in Japan. By 1895, there were over 200 kindergartens nationwide. However, kindergartens were managed without the government's financial support (Japan Society of Research on Early Childhood Care and Education 2009); therefore in the 1890s, kindergartens gained the support of the upper-middle class, which included government officials and merchants who expected preparatory education for elementary school. This allowed kindergartens to flourish as institutions for preschool education to the children of the upper-middle class.

In light of the quantitative growth in kindergartens, the Ministry of Education, Science and Culture established a legal standard for them by drawing up the Regulation on Kindergarten Education and Facilities in 1899. These regulations established kindergartens as institutions for educating young children age 3 and above before they entered elementary school.

In the Taisho democracy period (from 1910s to 1920s), the pace of growth in kindergartens accelerated. Particularly, there was dramatic growth in private kindergartens, and they exceeded the number of public kindergartens. Educational curriculums and methods were also improved, having been influenced by educational philosophies in the United States and Europe, particularly with child-centered education methods and the Montessori Method. Under such background, in 1926, the ordinance relating to kindergarten was promulgated by the Ministry of Education, Science and Culture. In the regulations for carrying out the ordinance relating to kindergarten, the stated subjects were play, singing, observation, listening and talking, handwork, etc. (Center for Women's Education and Development Ochanomizu University 2006). This "ordinance" was the first independent one about kindergartens. It means that kindergartens were placed in the educational firman which was the best national regulation about education (Takatsuki 2010). In other words, the place for kindergartens within the country's educational system was established by it.

As abovementioned, we can assert that Japanese kindergartens were born under the control of the national government.

29.2.2 Nursery Centers Promoted by Nongovernmental Organizations

Quite different from kindergartens, nursery centers were set up by nongovernmental organizations as a charity for children whose family could not afford to take care of them.

Akazawa Atsutomi (1867–1937) and his wife opened the first nursery center affiliated to Niigata Seishu Private School. Akazawa Nursery Center enrolled children who were younger brothers and sisters of Niigata Seishu Private School students. Many of the students of Niigata Seishu Private School came from comparatively poor families. They were expected to take care of their younger brothers and sisters while their parents work out. Akazawa decided to open a nursery center in order to make his students study in Niigata Seishu Private School without worrying about their siblings.

Around the beginning of the twentieth century, the society had needed more nursery centers. Nursery centers provided care and education for poor children and burgeoned in major cities. In 1909, the government started to pay subsidiaries to nursery centers run by nongovernmental organizations. After WW I, the Ministry of Home Affairs founded Social Welfare Bureau in order to manage nursery centers and affairs for protecting children. From then, the nature of nursery centers changed from private charitable work to public social work. Public nursery centers appeared in many major cities (Takatsuki 2010). In 1938, the Ministry of Health and Welfare was established, and the Social Work Law was enacted. Under the law, nursery centers were legally positioned as a child protection activity (Center for Women's Education and Development Ochanomizu University 2006).

29.2.3 Dual System of ECCE After WW II

After the defeat of WW II, the Japanese government constituted and issued a new Japanese Constitution. Due to the spirit of the New Constitution—Peace, Gender Equality, and Democracy—integrating kindergartens with nursery centers was discussed in the Imperial Diet in 1946. However, it is hard to reach some agreement on providing free care and education for the poorest families.

In 1947, the Basic Act on Education and the School Education Law were enacted under the Allied General Headquarters. Meanwhile, the government also issued the Child Welfare Act. According to the School Education Law, kindergartens were subsumed within the school system. Kindergartens offered children basic education

and care, offered a proper environment for children to grow up, and promoted student's physical and mental development. Kindergartens became formally under the Ministry of Education, Science and Culture (from 2001 it is called Ministry of Education, Culture, Sports, Science and Technology). Kindergartens enrolled children from ages 3 to 6, whose mothers were home managers. In contrast, according to the Child Welfare Act (establishment in 1947 and the last change in 2014), nursery centers were subsumed within child welfare system. Nursery centers were for mothers who were paid workers for her family that lived under minimum living standards. However, from the 1950s to 1970s, owing to the movement to build more nursery centers, the great efforts of the women who acted to improve the care and education of children whose mothers work out, nursery centers became more popular and approved. Gradually, the quality of child care and education progressed (Liu and Nakata 2014). This was how the dual system of ECCE (the separation between kindergartens and nursery centers) was formed.

29.3 Two Types of Japanese Preschools: Kindergartens and Nursery Centers

This section is to reveal the difference between Japanese kindergartens and nursery centers by showing how the present kindergartens and nursery centers in Japan are managed.

29.3.1 Kindergartens

Japanese kindergartens are under the School Education Law, which provides that kindergartens offer education, care, and a proper environment for children to grow up, promoting their physical and mental development. As mentioned in Section 1, Ministry of Education, Culture, Sports, Science and Technology (the old name was Ministry of Education, Science and Culture) has been managing the affairs of kindergartens. Kindergartens enrolled children whose age was from 3 to 6.

Japanese kindergartens are divided into three types: (1) National kindergartens: These kindergartens are governed by the central government or Ministry of Education, Culture, Sports, Science and Technology. (2) Public kindergartens: These kindergartens are ruled by local governments or local education committees. (3) Private kindergartens: These kindergartens are established by legal persons; they are under the management of local governments (Morigami et al. 2013). As of 2013, the amount of kindergartens in Japan is 12,752, including 51 national kindergartens, 4695 public ones, and 8006 private ones (NPO Legal Person Kyouikusolution Company 2013a).

Japanese kindergartens start in April and end in March. Enforcement rules and kindergarten operation standards of School Education Law prescribe that annual

education weeks are more than 39 weeks even with a few exceptions. During the school year, children have spring break, winter vacation, and summer vacation. The day care time is 4 h a day. Japanese kindergartens are required to properly consider children's mental and physical development and their welfare.

Care and education in kindergartens are classified into five areas: health (physical and mental health), human relationships (the relationship between the child and other people), environment (children's surroundings and relationship to them), language (the process of language acquisition), and expression (feelings and expression). Japanese kindergartens place children at the same age bracket, and the class size is under 35 children. At least one full-time teacher is assigned exclusively to each class. Staffing allocation in a kindergarten is as follows: principal, head teacher, teachers, assistant teachers, special needs teachers, assistant special needs teachers, instructors, and educational assistants. A kindergarten teacher is qualified with an official teacher's certificate. As of 2013, there are 110,836 kindergarten teachers, including 354 national kindergarten teachers (0.32%), 23,799 public kindergarten ones (21.5%), and 86,703 private kindergarten ones (78.2%) (Ministry of Education, Culture, Sports, Science and Technology 2013).

School fees of Japanese kindergartens depend on each school. Needless to say, the fees of national or public kindergartens are lower than those of private ones. The government has been trying to minimize the gap of fees between private kindergartens and national or public ones. The Act on Subsidies for Private Schools issued in 1975 (enforced in 1976) assures that private kindergartens are subsidized by the government. A portion subsidy for private kindergarten expenses is offered to each private kindergarten through the following process: The government subsidizes prefecture governments; prefecture governments subsidize municipal governments; municipal ones subsidize each of private kindergartens.

29.3.2 Nursery Centers

Japanese nursery centers are under the Child Welfare Act. Nursery centers provide care service for children whose age is from 0 to 6 with lack of the care from family. Local governments manage affairs of nursery centers. The Ministry of Health, Labor and Welfare (the old name was the Ministry of Health and Welfare) supervises local governments. The Child Welfare Act provides that the nursery centers are for the children under the following situations:

1. Parents and relatives usually work out during daytime.
2. The child's mother is dead during or after childbirth.
3. One of the parents is sick, injured, insane, or disabled.
4. Parents need to take care of live-in relatives who are under long-term sickness, insanity, or disability.
5. Family just recovered from natural disasters like earthquakes, flood, and fire.
6. Other situations like above.

In these cases, children are allowed to enter nursery centers. When a family needs a great help about child care from others, parents can choose a nursery center and apply to municipal governments. Municipal governments inquire into to what extent each family needs the help about child care from a nursery center. After detailed investigation, municipal governments permit parents to entrust their children to their suitable nursery centers.

Nursery centers are classified into private ones and public ones. Local governments have jurisdiction over public nursery centers. Private nursery centers are supported by NPO or legal person of social welfare organizations, religions, schools, etc. As of 2013, there are 23,888 nursery centers in Japan, including 10,641 public ones and 13,247 private ones (NPO Legal Person Kyouikusolution Company 2013b).

School days are about 300 days a year, and nursery centers have no winter and summer vacation. Day care time is 8 h a day in principle, but nursery center directors can expand care time according to parent's work time. As of 2015, Japanese nursery centers offer a service of approximately 11 or 12 h a day on average. Yet longer care, temporary care, and night-time care are offered by many nursery centers.

The Ministry of Health, Labor and Welfare decides the content of education and care that nursery center are required to offer children. The content of education and care for over-3-year-old children is the same as that for the same-aged children of kindergartens: health, relationship, environment, language, and expressions. The staff of nursery centers consists of nursery teachers with official license, commissioned doctor, and cooks (may be contracted out). The standard ratio of a teacher and children is as follows: 0-year-old class is 1:3; 1-year-old class and 2-year-old classes are 1:6; 3-year-old class is 1:20; 4-year-old class and 5-year-old class are 1:30. More teachers are allocated to a class having children with disabilities. The statistical data of 2012 shows that the total number of formal staff members in Japanese nursery centers is 317,146; the number of the staff members in public nursery centers is 120,571; and those in private nursery centers are 196,575 (Ministry of Health, Labor and Welfare 2014).

Local governments support the expenditure for Japanese public nursery centers, though the support level depends on regions. Each nursery centers can use its subsidy from local governments for salary payment, operation expenses, administration expenses, office expenses, and so on. A private nursery center admitted by a local government is subsidized by the national government and its local government. Of the costs incurred by the municipality, the national government bears a half, the prefectural governments subsidize a quarter, and the municipal ones aid a quarter, after deducting the amount assumed by nursery center users.

Parents pay their children's care fees if they can afford to pay. How much parents pay depends on the amount of the income tax parents paid in the preceding year. The poorest families don't need to pay any children care expenses. Under the Children's Welfare Act, the poorest children are given opportunities to enjoy necessary care and education in nursery centers.

29.3.3 The Difference of Japanese Kindergartens and Nursery Centers

As abovementioned, we can assert that Japanese kindergartens are literal preschools or educational institutions for children whose families can afford to pay expensive fees of kindergartens and to have stay-at-home mothers. This situation has not changed since its foundation. On the other hand, since its foundation, Japanese nursery centers were regarded as social welfare institutions for poor children. Thus, we can safely say that the difference between Japanese kindergartens and nursery centers was decided by social and economic class.

But the situations around nursery centers in Japan have drastically changed. These days, the number of mothers working outside to build their own careers after their childbirth has been increasing also in Japan. It means that Japanese nursery centers have changed from social welfare institutions to indispensable preschools in which professional staff members offer appropriate care and education to children whose mothers contribute to their society as competent labor force. In this sense, the function of nursery centers in Japan is getting more significant.

29.4 Curriculum Reform of Kindergartens and Nursery Centers After WW II

This section examines some aspects of the curriculum reform that kindergartens and nursery centers underwent in the postwar Japan. Under the occupation of General Headquarters (GHQ), since the defeat of WW II in 1945, Japan was forced to change itself. Japanese government proclaimed the Japanese Constitution which based on democracy, new principles of new Japan, in 1946. Due to the spirit of the new Constitution, education reform in Japan after WW II started. Japanese preschool curriculum was also reformed. According to Tamiaki (2008) and the Center for Women's Education and Development at Ochanomizu University (2006), the circumstances of curriculum reform in kindergartens and nursery centers in Japan after WW II are as follows.

29.4.1 Curriculum Reform in Kindergartens

In 1948, Ministry of Education, Science and Culture issued Nursing Guidelines: Handbook of Early Childhood Care and Education which was composed by American specialists in GHQ and Japanese kindergarten education specialists. The handbook was intended to be applied to kindergartens, nursery centers, and the home.

The handbook emphasized the following issues: children's developmental traits, life instructions, living environments, daily living, happy experience, and the relationships between family and kindergartens.

For example, life instruction referred to children's growth, intelligence development, emotional development, and social development. Living environments mentioned about the playground, the building, and toys. The curriculum was based on happy experiences for children, such as field trip, rhythmic exercises, break, free play, music, storytelling, painting, handwork, nature observation, imitative play/dramatic play/puppet play, health care, and an annual calendar of events. The relation between family and kindergartens should be promoted through the following things: parent-teacher associations, parent education, instructions for parent education, and contact with elementary schools.
