345

The Names of Dietary Monoterpenpids and -Their Structure Numbers

A:

Actinidin	(**1**)
Actinidiolide	(**2**)
Actinidiolide (Dihydro-)	(**3**)
Actinidol	(**4**)
Artemisia ketone	(**5**)
Artemisia ketone (*Iso*-)	(**6a**)
Artemisia triene	(**6b**)
Artemisyl acetate	(**7**)
Artemisia alcohol	(**8**)
Ascaridole	(**9**)
Ascaridole (Dihydro-)	(**10**)
Ascaridole (*E-Iso*-)	(**11a**)
Ascaridole (*Z-Iso*-)	(**11b**)

B:

Bornane	(**12**)
Borneol	(**13**)
Bornyl formate	(**14**)
Bornyl acetate	(**15**)
Bornyl propanoate	(**16a**)
Bornyl iso-butyrate	(**16b**)
Bornyl angelate	(**16c**)
Bornyl isovalerate	(**17**)
Bornyl hexanoate	(**18**)
Borneol (*Iso*-)	(**19a**)
Bornyl formate (*Iso*-)	(**19b**)
Bornyl acetate (*Iso*-)	(**20**)
Bornyl isovalerate (*Iso*-)	(**21**)
Bornylene	(**22**)

C:

Camphene	(**23**)
Camphene hydrate	(**24**)
Camphenillol (3-Methyl-)	(**25**)
Camphenilone	(**26**)
Campholenol (α-)	(**27**)
Campholenal (α-)	(**28**)
Camphor	(**29**)
Carene (Δ^2-)	(**30**)
Carene (Δ^3)	(**31**)
Carene epoxide (Δ^2-)	(**32**)
Carene-4-ol [3(10)-]	(**33**)
Carvacrol	(**34**)
Carvacrol methyl ether	(**35**)
Carvenone	(**36**)
Carveol (Dihydro-)	(**37**)
Carveol (*E*-)	(**38a**)
Carveyl acetate *(E*-)	(**38b**)
Carveol (*Z*-)	(**39a**)
Carveyl acetate (Z-)	(**39b**)
Carveol *(Iso*-)	(**40**)
Carvomenthone	(**41**)
Carvone	(**42**)
Carvone (Dihydro-)	(**43**)
Carvone oxide	(**44**)
Carvotanacetol	(**45**)
Carvotanacetone	(**46**)
Chrysanthenol	(**47**)
Chrysanthenyl acetate (*E*-)	(**48**)
Chrysanthenyl acetate (*Z*-)	(**49**)

Chrysanthenone (*E*-) (**50**)
Cineole (1,4-) (**51**)
Cineole (1,8-) (**52**)
Cineole (2,3-Dehydro-1,8-) (**53**)
Citral [(Geraniol (**94**) & Nerol (**234b**)]
Citral (*E-iso*-) [(*Iso*-geranial (**113a**) & *Iso*-neral (**232**)]
Citronellal (Dihydro-) (**54**)
Citronellal (β-) (**55**)
Citronellic acid (**56**)
Citronellate (Methyl) (**57**)
Citronellol (**58**)
Citronellyl acetate (**59**)
Citronellyl formate (**60a**)
Citronellyl propanoate (**60b**)
Citronellyl butanoate (**61**)
Citronellyl isobutyrate (**62**)
Citronellyl 2-methylbutyrate (**63**)
Citronellyl pentanoate (**64**)
Citronellyl hexanoate (**65**)
Citronellyl heptanoate (**66**)
Cryptone (**67**)
Cumene (**68a**)
Cumenol (**68b**)
Cumene (Dehydro-) (**69**)
Cumin alcohol (**70**)
(= *p*-cymen-7-ol)
Cumin aldehyde (**71**)
Cumin aldehyde (Dihydro-) (**72**)
Cyclocitral (β-) (**73**)
Cyclocitral (β-Homo-) (**74**)
Cymene (*p*-Dehydro-) (**75**)
Cymene (*p*-Dihydro-) (**76**)
Cymene (*o*-) (**77**)
Cymene (*m*-) (**78**)
Cymene (*p*-) (**79**)
Cymene-7-ol (**70**)
(= Cumin alcohol)
Cymen-8-ol (*p*-) (**80**)
Cymen-9-ol (*p*-) (**81**)
Cymen-9-ol (*m*-) (**82**)
Cymenol (*p*-) (**83**)

D:

Damascenone(β-) (**84**)
Damascone (**85**)
Dill ether (**86**)

E:
Egoma ketone (*Iso*-) (**87a**)
Elsholtzia ketone (**87b**)
Eucarvone (**87c**)
F:
Fenchene (α-) (**88**)
Fenchyl alcohol (α-) (**89**)
Fenchyl acetate (α-) (**90**)
Fenchyl alcohol (β-) (**91**)
Fenchyl acetate (β-) (**92a**)
Fenchone (**92b**)
G:
Geijerene (**93**)
Geranial (**94**)
Geranic acid (**95**)
Geranate (Methyl) (**96**)
Geraniol (**97**)
Geranyl formate (**98**)
Geranyl acetate (**99**)
Geranyl propanoate (**100**)
Geranyl butanoate (**101**)
Geranyl iso-butanoate (**102**)
Geranyl pentanoate (**103**)
Geranyl isovalerate (**104**)
Geranyl 2-methylbutanoate (**105**)
Geranyl tiglate (**106**)
Geranyl hexanoate (**107**)
Geranyl heptanoate (**108**)
Geranyl octanoate (**109**)
Geranyl benzoate (**110**)
Geranyl acetone (**111**)
Geraniol (Hydroxy-) (**112**)
Geranial (*Iso*-) (**113a**)
Geraniol (β-*Iso*-) (**113b**)
Geranyl acetate (α-Cyclo-) (**114**)
Geyrene (**115**)
I:
Ionol (β-) (**116**)
Ionone (3-Oxo-α-) (**117**)
Ionone (3-Oxo-β-) (**118**)
Ionone (4-Oxo-α-) (**119**)
Ionone (α-) (**120**)
Ionone (α-Dihydro-) (**121**)
Ionone (β-) (**122**)

Ionone (β-4-Hydroxy-) (**123**)
Ionone (β-5,6-Epoxide) (**124**)
Ionone (β-Dihydro-) (**125**)
Ionone (δ-Dihydro-β-) (**126**)
Iridodiol (Dehydro-) (**127a**)
Iridodial (Dehydro-) (**127b**)
Iridomyrmecin (**128**)
Iridomyrmecin (*Iso*-) (**129**)
Iron (α-) (**130a**)
Iron (β-) (**130b**)
Iron (γ-) (**130c**)
Isophorone (**131**)

J:

Jasmine lactone (**132**)
Jasmone (*Z*-) (**133**)
Jasmonate (Methyl) (**134**)

L:

Lavandulal (**135**)
Lavandulol (**136**)
Lavandulyl acetate (**137**)
Lavandulyl pentanoate (**138**)
Lavandulyl 2-methylbutanoate (**139**)
Lavandulyl tiglate (**140**)
Lavandulol (Tetrahydro-) (**141**)
Lilac alcohol a (**142**)
Lilac alcohol b (**143**)
Lilac alcohol c (**144**)
Lilac alcohol d (**145**)
Lilac aldehyde 1 (**146**)
Lilac aldehyde 2 (**147**)
Lilac aldehyde 3 (**148**)
Lilac aldehyde 4 (**149**)
Lilac alcohol formate 1 (**150**)
Lilac alcohol formate 2 (**151**)
Limonene (**152**)
Limonene (*Iso*-) (**153**)
Limonene 1,2-oxide (*E*-) (**154a**)
Limonene 1,2-oxide (*Z*-) (**154b**)
Limonene diol (**155**)
Limonene-10-ol (**156**)
Limonene-4-ol (**157**)
Linalool (**158**)
Linalool (7*E*-8-hydroxy-) (**159a**)
Linalool (7*Z*-8-Hydroxy-) (**159b**)

Linalyl 8-acetate (**160**)
Linalool (8-Hydoxydihydro-) (**161**)
Linalool (Dihydro-) (**162**)
Linalool hydrate (**163**)
Linalool oxide (*E*-: furanoid) (**164a**)
Linalool oxide (Z-: furanoid) (**164b**)
Linalool oxide (*E*-: pyranoid) (**165a**)
Linalool oxide (*Z*-: pyranoid) (**165b**)
Linalool oxide (β-) (**166**)
Linalyl formate (**167**)
Linalyl acetate (**168**)
Linalyl propanoate (**169**)
Linalyl butanoate (**170**)
Linalyl pentanoate (**171**)
Linalyl iso-valerate (**172**)
Linalyl senecioate (**173**)
Linalyl hexanoate (**174**)

M:

Matatabiol (*Allo*-) (**175a**)
Matatabiol (*Neo*-) (**175b**)
Matatabi diether (5-Hydroxy-) (**176**)
Matatabi diether (7-Hydroxy-) (**177**)
Matatabi ether (**178**)
Matatabi diether (**179**)
Matatabi lactone (**180**)
Menthene (2-) (**181**)
Menthofuran (**182a**)
p-Mentha-3,9-oxide (**182b**)
Menthol (**183**)
Menthyl acetate (**184**)
Menthol (8-Hydoxy- *neo*-) (**185**)
Menthol (*Iso*-) (**186a**)
Menthol (*Iso*-) acetate (**186b**)
Menthol (*Neo*-) (**187**)
Menthol (*Neo-iso*-) (**188a**)
Menthol (*Neo-iso*-) acetate (**188b**)
Menthone (**189**)
Menthone (Iso-) (**190**)
Myrcene (**191**)
Myrcenol (**192**)
Myrtanal (**193**)
Myrtanol (*E*-) (**194a**)
Myrtanol (Z-) (**194b**)

Myrtenal (**195**)
Myrtenol (**196**)
Myrtenyl acetate (**197**)
Myrtenyl isovalerate (**198**)
Myrtenol (Dihydro-) (**199**)
p-Menth-2-en-7-ol (*E*-) (**200**)
p-mentha-1(7),8-diene (**201**)
m-Mentha-1(7),8-diene (**202**)
p-Mentha-1(7),8-dien-2-ol (*E*-) (**203a**)
p-Mentha-1(7),8-dien-2-ol (*Z*-) (**203b**)
p-Mentha-1(7),8-dien-2-yl-acetate (*Z*-) (**203c**)
p-Mentha-1,3,8-triene (**204**)
p-Menth-1-en-8-ol (**205**)
p-Menth-1-en-9-ol (**206**)
p-Menth-1-en-9-yl acetate (**207**)
p-Mentha-2,4(8)-diene (**208**)
p-Mentha-2,8-dien-1-ol *(E*-) (**209a**)
p-Mentha-2,8-dien-1-ol (*Z*-) (**209b**)
p-Mentha-2,8-dien-1-yl acetate (**210**)
p-Menth-2-en-1-ol (*E*-) (**211a**)
p-Menth-2-en-1-ol (*Z*-) (**211b**)
p-Menth-4(8)-en-9-ol (**212**)
p-Mentha-1(7),2-dien-8-ol (**213**)
p-Mentha-1(7),2-diene (**214**)
p-Mentha-1,3-dien-7-ol (**215**)
p-Mentha-1,4,8-triene (**216**)
p-Mentha-1,5-dien-9-ol (**217**)
p-Mentha-1,8-dien-4-ol (**218a**)
p-Mentha-1,8-dien-9-ol (**218b**)
p-Mentha-2,8-diol (*E*-) (**219**)
p-Menth-1-en-3-one (**220**)
p-Menth-1-ene (**221a**)
p-Mentha-3,8-diene (**221b**)
p-Menth-1-en-8-al (**221c**)
p-Menth-1-en-9-al (**221d**)
p-Menth-6-en-3-one (**221e**)
p-Menth-3-en-2-ol (**222**)
p-Menth-3-en-7-ol (**223**)

N:

Naginata ketone (**224**)
Nepetalactone(*Neo*-) (**225**)
Nepetalactone (Dihydro-) (**226**)

Nepetalactone (*Iso*-dihydro-) (**227**)
Nepetalactone (*E,Z*-) (**228**)
Nepetalactone (*Z,E*) (**229**)
Nepetalic acid (**230**)
Nepetalic anhydride (**231**)
Neral (*Iso*-) (**232**)
Neric acid (**233**)
Neral (**234a**)
Nerol (**234b**)
Neryl formate (**235**)
Neryl acetate (**236**)
Neryl *iso*-butanoate (**237a**)
Neryl *iso*-valerate (**237b**)
Neryl hexanoate (**238**)
Nerol (Hydroxy-) (**239**)
Neryl acetone (**240**)
Neryl oxide (**241**)
Nopol (**242**)
Norpinene (3,6,6-Trimethyl-2-) (**243**)

O:

Ocimene (*Neo-allo*-) (**244**)
Ocimene (*E-allo*-) (**245**)
Ocimene (*Z-allo*-) (**246**)
Ocimenol (*Z*-β-) (**247**)
Ocimenone (*E*-β-) (**248**)
Ocimenone (*Z*-β-) (**249**)
Ocimene (*E*-β-) (**250**)
Ocimene (Z-β-) (**251**)
Ocimene (*E*-dihydro-) (**252**)
Ocimene (*Z*-dihydro-) (**253**)

P:

Pinene (α-) (**254**)
Pinene (β-) (**255**)
Phellandrene (α-) (**256**)
Phellandrene (b-) (**257**)
Pinocarveol (*E*-) (**258a**)
Pinocarveol (*Z*-) (**258b**)
Pinocampheol (=3-pinanol) (**258c**)
Pinocarveyl acetate (**259**)
Pinocarvone (**260**)
Pinocamphone (*E*-) (**261**)
Piperitol (*E*-) (**262**)

Piperitol (*Z*-) (**263**)
Piperityl acetate (**264**)
Phellandral (α-) (**265**)
Phellandrol (**266**)
Pulegone (*Z*-) (**267**)
Pulegone (*Z-iso*-) (**268**)
Pinocamphone (*Iso*-) (**269**)
Phellandren-8-ol (α-) (**270**)
Perilla alcohol (**271**)
Perillyl acetate (**272**)
Perilla ketone (**273**)
Perillaldehyde (**274**)
Piperitenone (**275**)
Piperitenone (*Iso*-) (**276**)
Perillene (**277**)
Phellandrene oxide (**278**)
Piperitenol (*E- iso*-) (**279**)
Piperitenol (*Z-iso*-) (**280**)
Piperitone (**281**)
Piperitone (*Iso*-) (**282**)
Pulegol (*Iso-)* (**283**)
Pulegol (*Neo-iso*-) (**284**)
Piperitenone oxide (*Z*-) (**285**)
Pinene hydrate (*E*-) (**286**)
Pinene hydrate (*Z*-) (**287**)
Pinene oxide (β-) (**288**)
Piperitone oxide (Z-) (**289**)
Perilla ketone (*Iso*-) (**290**)

R:

Rose oxide (*E*-) (**291**)
Rose oxide (*Z*-) (**292**)

S:

Sabinene (Dehydro-) (**293**)
Sabinene (**294** & **295**)
Sabinene hydrate (*E*-) (**296**)
Sabinene hydrate (Z-) (**297**)
Sabinol (*E*-) (**298**)
Sabinyl acetate (*E*-) (**299**)
Sabinol (*Z*-) (**300**)
Santene (**301a**)
Santolina triene (**301b**)
Shisofuran (**302**)

Shisool (*E*-) (**303**)
Shisool (*Z*-) (**304**)
Sylvestrene (**305**)

T:

Terpinen-1-ol (**306**)
Terpinen-4-ol (**307a**)
Terpinen-4-yl acetate (**307b**)
Terpinene(β-) (**307c**)
Terpinene (α-) (**308**)
Terpinene (γ-) (**309**)
Terpineol (*Z*-β-) (**310**)
Terpinyl acetate (*Z*-β-) (**311**)
Terpineol (α-) (**312**)
Terpinyl acetate (α-) (**313**)
Terpinyl propanoate (α-) (**314a**)
Terpinyl pentanoate (α-) (**314b**)
Terpineol (δ-) (**315**)
Terpinolene (**316**)
Terpinolene (*Iso*-) (**317**)
Terpinolene-4,8-oxide (**318**)
Theaspirane (**319**)
Theaspirane-A (**320**)
Theaspirane-B (**321**)
Theaspirone (**322**)
Thuja-2,4(10)-diene (**323**)
Thujanol (*Z*-4-) (**324**)
Thujanol (*Neo*-3-) (**325a**)
Thujanol acetate (*Neo*-3-) (**325b**)
Thujyl alcohol (**326**)
Thujapricin (α-) (**327**)
Thujapricin (β-) (**328a**)
Thujapricin (γ-) (**328b**)
Thujene (α-) (**329**)
Thujene (β-) (**330**)
Thujone (α-) (**331a**)
Thujone (β-) (**331b**)
Thujone-2-ol (3-) (**332**)
Thymol (**333**)
Thymol methyl ether (**334**)
Thymoquinone (**335**)
Tricyclene (**336**)

U:

Umbellulone (**337**)
Umbellulone (Dihydro-) (**338**)

V:	
Verbanol (*E*-)	(**339a**)
Verbenyl acetate (*E*-)	(**339b**)
Verbanol (*Iso*-)	(**340a**)
Verbanyl acetate (*Iso*-)	(**340b**)
Verbenene	(**341**)
Verbenol (*E*-)	(**342a**)
Verbenyl acetate (*E*-)	(**342b**)
Verbenol (*Z*-)	(**343**)
(=2-pinen-4-ol)	
Verbenone	(**344**)
Y:	
Yomogi alcohol	(**345**)

Abstract

A number of foods, vegetables, fruits, and beverages (tea, coffee, and liqueur) contain many kinds of diterpenoids (mainly abietanes, cembranes, clerodanes, cyatanes, dolabellanes, fusicoccanes, kauranes, labdanes, pimaranes, taxanes, trachilobanes, totaranes) and their related compounds. This chapter summarizes the distribution of diterpenoids in dietary foods, vegetables, fruits, beverages, and processed foods, and their biological and pharmacological activity, effects, and application to our health, as well as metabolic pathways of several diterpenoids, which are widely distributed in dietary foods, by microorganisms and mammals.

Keywords

Diterpenoids · Coffee · *Ginkgo* · *Salvia* · *Stevia* · Biological activity · Biotransformation · Benefits

17.1 Introduction

In China, Korea, and Japan, a great number of higher and spore forming plants as well as mushrooms have been used as foods, including "functional foods," vegetables, fruits, and beverages as tea, coffee, and alcoholic drinks for human good health. In South-east and central Asia and Africa and South America, many different plants species from Europe and far east have been used as the same purpose as those in the above mentioned regions. Mediterranean region, the Aegean coast of Turkey, Greece and Balkan Peninsula as well as the central Asia, India, and Indonesia have been known as the origin of ancient medicines. Especially Greece and Turkey, the culmination of the knowledge in medicinal herbs and aromatic plants, morphology and anatomy have been developed.

In Mediterranean region, there are a great number of medicinal plants belonging to the Lamiaceae, for example, *Baccharis, Nepeta, Salvia*, *Stachys*, *Sideritis, Teineum*, and *Thymus* including diterpenoids (Carovic-Stanko et al. 2016). Madeira and Porto Santo Islands are ethnopharmacologically interesting because medicinal plants are recognized and many of which contain diterpenoids have been used as the herbal tea, infusion, or decoction used as antiasthmatic, antidiabetic, antirheumatic, antihypertensive, diuretic, insecticide, antibacterial, antifungal, antioxidant, sedative, emmenagogue or relieving coughs and fever, and many other diseases (Rivera and Obon 1995).

In this chapter, the distribution of diterpenoids and their related compounds in the representative foods, fruits, vegetables, and beverages including medicinal herbs, their biological and pharmacological activity and metabolism in mammalian body and benefits are summarized. Coffees, *Stevia*, *Ginkgo*, and *Zinger* species are focused as the dietary foods, food additives, beverage, and medicinal drugs in detail.

17.2 Distribution of Diterpenoids and Related Compounds in Foods Vegetables, Fruits, and Beverages

The diterpenoids are one of the most important secondary metabolites, widely distributed not only in terrestrial plants but also in marine organisms. Generally diterpenoids don't possess odorous properties, however, many diterpenoids indicate very bitter and pungent and some of which show potent sweet taste.

They are derived from geranylgeranyl pyrophosphate and are classified into several types, mainly abietanes, atisanes, bayeranes, cassanes, cembranes, clerodanes, cyatanes, daphnanes, dolabellanes, dolastanes, fusicoccanes, gibberellanes, halimanes, ingenanes, kauranes, labdanes, pimaranes, podocarpanes, rosanes, stemodanes,

stemaranes, taxanes, tiglicanes, trachilobanes, among which abietanes, clerodanes, kauranes, labdanes, and gibberellanes are the most popular and widely distributed as dietary phytochemicals.

In Charts 1 and 2, the most abundant diterpene skeletons found in the foods and beverages are shown.

Many abietanes contain an aromatic moiety in C-ring and they are widely distributed in terrestrial medicinal beverage plants especially in *Salvia* species and *Coffea* (Coffees). Cembranes, dolabellanes, and dolastanes have been mainly found in marine organisms, such as brown algae, *Dictyota* species, and even terrestrial plants, like some bryophytes. Taxanes have been isolated from almost only *Taxus* species, and paclitaxel (=taxol) (**1**) is now been used as clinically an important anticancer drug. Some fungi and liverworts produce cyatane diterpenoids. *Gibbellera fusikroii* mainly elaborates gibbellane diterpenoids. *Podocarpu*s species biosynthesizes podocarpanes as predominant metabolites. Connolly and Hill (1991) published the encyclopedia of di-, sester-, and triterpenoids in which more than 1000 of the structures of diterpenoids have been presented.

Hanson et al. (2017) reported the review article which covered the isolation and structure elucidation of terrestrial origin diterpenoids that include abietanes, cembranes, kauranes, labdanes, and their cyclic products including 228 references.

Li et al. (2016) reviewed naturally occurring clerodane diterpenoids with 533 references and 1317 structures, and their biological and pharmacological activity. The distribution of diterpenoids with typical biological and pharmacological properties was reviewed by Vasas and Hohman (2014) and Remy and Litaudon (2019). Islam et al. (2016) obtained plant-derived diterpenoids data from Science Direct, PubMed, Web of Science, Sopus, and various databases and described a total of 119 medicinal plants containing diterpenoids and their pharmacological activities (anticancer, antidiabetic, antifungal, antimicrobial, anti-inflammatory, antioxidant, antiviral, cardio-, chemo-, gastro-, hepato-, immune-, and neuroprotective, cytotoxic, genotoxic, and mutagenic with 232 references reported between 2005 and 2015).

A number of daphnane type diterpenoids have been found in species belonging to the Euphorbiacae and Thymelaceae families. Jin et al. (2019) reported a review article of structures of daphnanes, and their biological and pharmacological activities with 41 references. Appendino (2016) reported the distribution of ingenane type diterpenoids which are derived from daphnanes as seen in Chart 3, and their bioactivity with 221 references.

In Table 1, a number of different kinds of foods, fruits, vegetables, and beverages have been alphabetically listed, and the distribution of diterpenoids and their related compounds as well as their biological and pharmacological effects and benefits have also been briefly described. Up to now more than 3000 diterpenoids have been found in plants and mushrooms, and these constitute acyclic (phytane), monocyclic, bicyclic, tricyclic, and tetracyclic diterpenoids. They occur in nature widely as hydrocarbons, alcohols, ketones, and lactones. There are also many kinds of carboxylic diterpenoids at C-18 or C-19 (1,1-dimethyl group at C4 in A-ring) of abietanes, clerodanes, kauranes, and labdanes as well as their methyl and higher

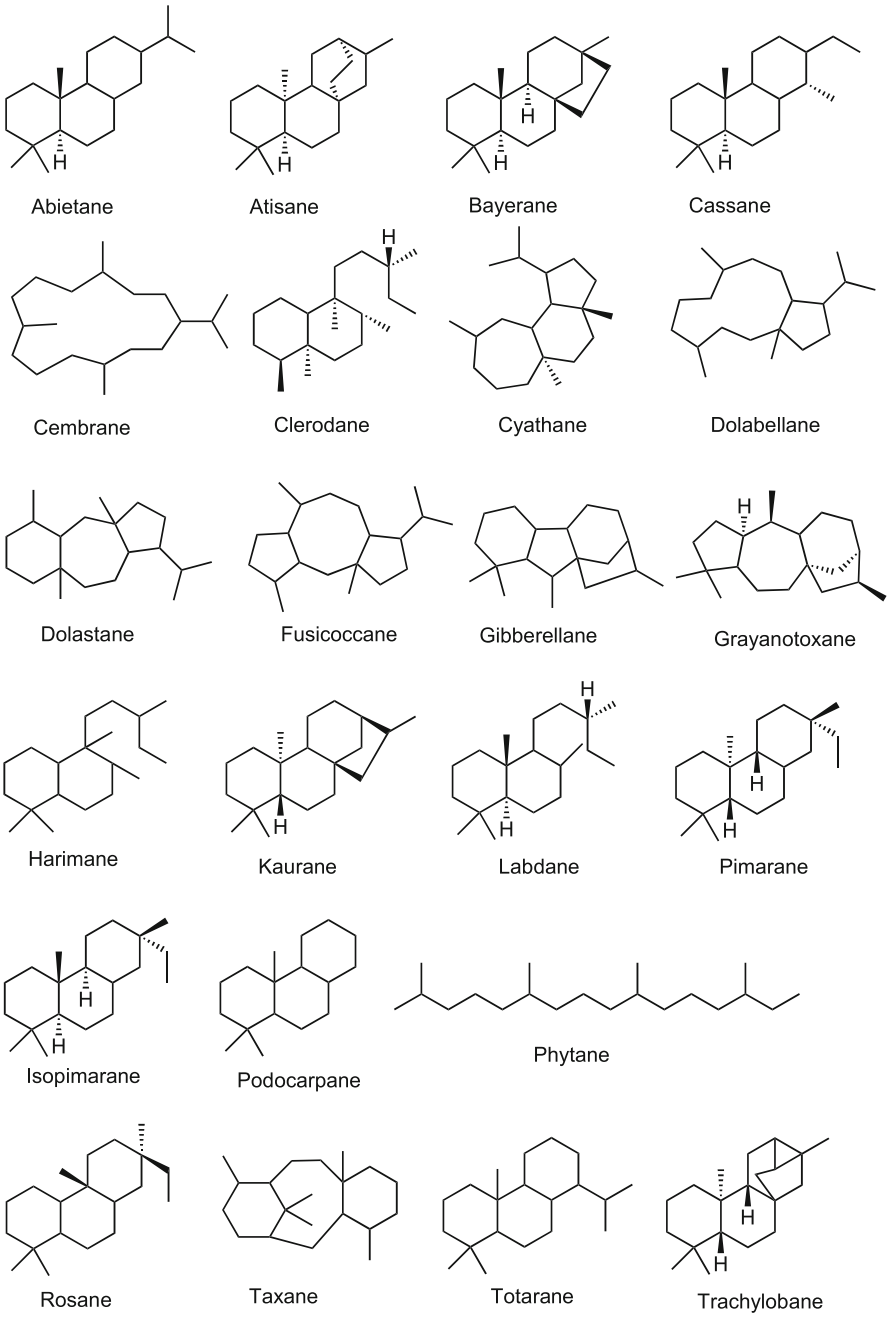

Chart 1 Main diterpene skeletons found in foods, fruits, vegetables, medicinal plants, and beverages

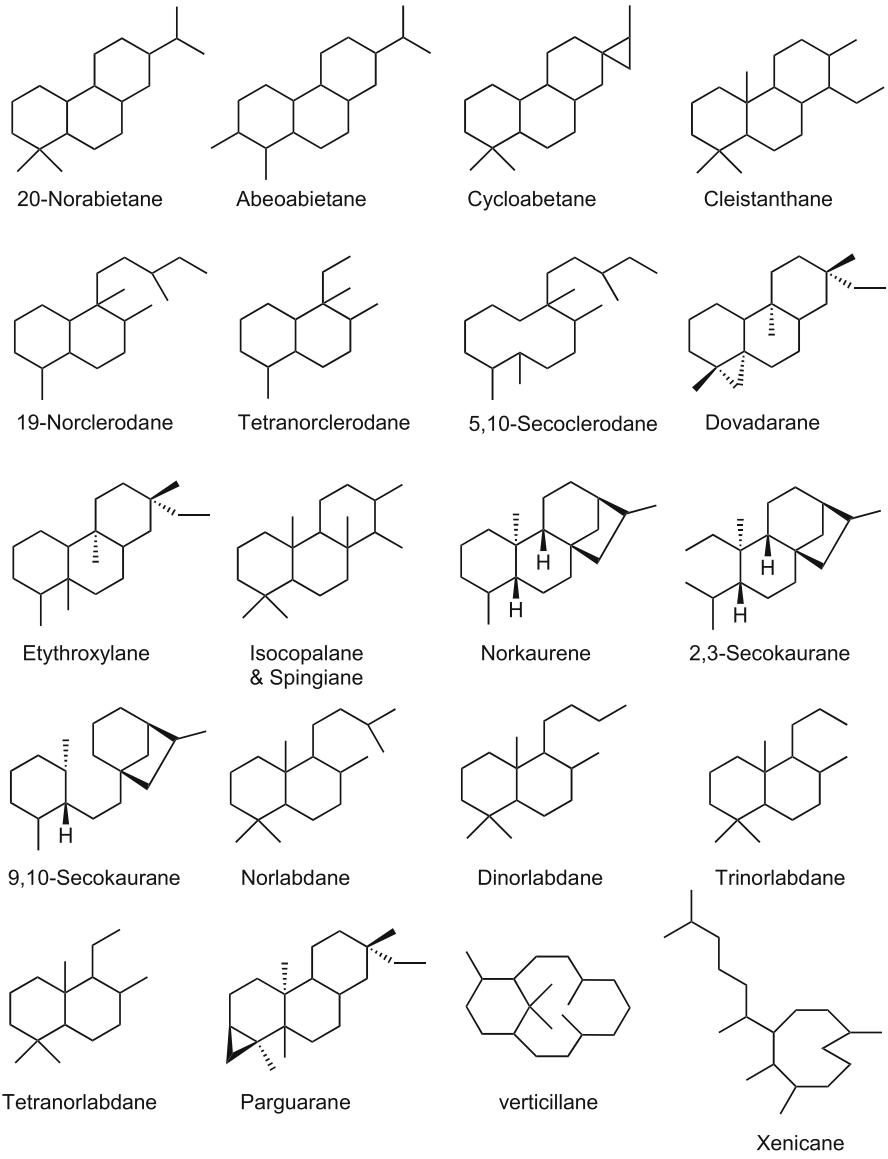

Chart 2 Minor diterpene skeletons found in foods, fruits, vegetables, medicinal plants, and beverages

fatty acid esters are also isolated from or confirmed in the dietary. One of the most characteristic features of naturally occurring diterpenoids is that a great number of furan and γ-lactone rings containing diterpenoids have been isolated and their stereochemistry elucidated using a combination of modern nuclear magnetic resonance (NMR), mass spectrum (MS), circular dichroism (CD) and X-ray

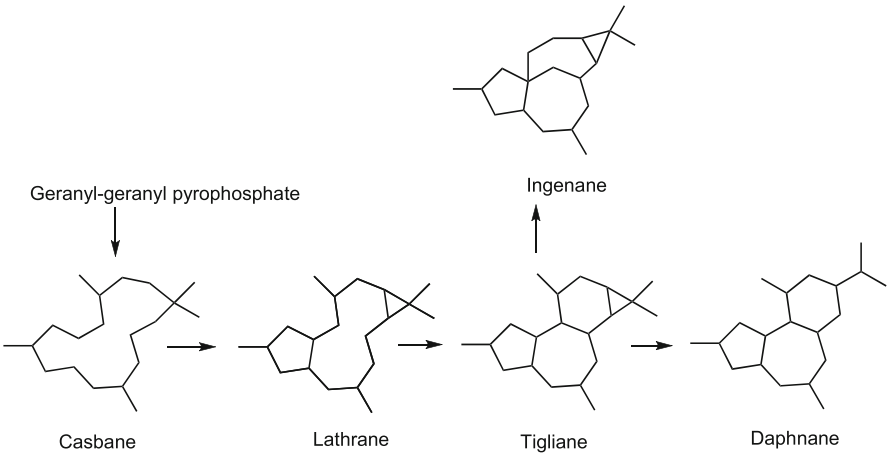

Chart 3 Diterpenpoid (casbane, latharane, tigriane, daphnane, and ingenane) skeletons found in foods, fruits, vegetables, medicinal plants, and beverages

crystallographic analysis. The second significant chemical profile of diterpenoids is that a number of isolated diterpenoids, such as clerodanes, kauranes, and pimaranes, possess the enantiomeric forms, although there are several exceptions.

As seen in Table 1, each dietary food and beverage contain only specific diterpenoids; however, the chemical profile of the others are so complex, including the different skeletal diterpenoids, and they are highly oxygenated.

Here, the species names and the distribution of diterpenoids in several well-known foods, beverages, and medicinal plants are surveyed.

In the following paragraphs, several representative genus and family including dietary diterpenoids have been discussed. In Charts 6–13 and Table 1, the representative diterpenoids (**60–185**) found in various foods and medicinal plants have been presented in addition to the diterpenoids (**1–59d**) which have been discussed in each paragraph.

17.2.1 *Agathis* (Kauri or Dammara) (Araucariaceae)

The *Agathis* grows in Oceanian region, mainly in Australia and New Zealand.

There are 22 species in these regions. These species belonging to this genus is one of the most valuable and sought after timber trees in Southeast Asia and it is traded on the international market. It also provides high-quality resins among which those from *A. borneensis*, *A. dammara*, *A. lanceolata*, *A. macrophylla*, and *A. philippinensis* are the most important commercially. 3α-Hydroxy-13*S*-16- nor-pimar-7-en-15-oic acid and 13*S*-pimar-7-en-3α,15,16-triol, and kaur-16-en-3α,13-diol, kauran-3α,13,16-α-triol, and (*E*)- and (*Z*)-communic acid have been isolated from the heartwood of the Fijian species *Agathis vitiensis* together with agatharesinol, abietic acid (**2**), and agathic acid. (Z)-communic acid indicates protective effects against UVB-induced

Table 1 The dietary plants and mushroom names used as foods, beverages, and herbal medicines including diterpenoids and their related compounds and application, benefits, and effects

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Abies georgei	7-Oxocallitrisic acid	Antiplatelet aggregation, antithrombic
Abies sachalinensis	Abieta-7,17-dien-12α-methoxy-18-oic acid, dehydroabietic acid (**43**), neoabietic acid, levopimaric acid	Foods, flavor source (soap, bath additive, deodorant) Antifungal, antioxidant, α-glucose inhibitory, humectants, skin conditioning
Abies siberica (Siberian Fir)	7,13-Abietadien-18-oic acid (=abietic acid) (**2**), 7,13-abitadien-18-ol (=abietinol), abietinal, abientol, iso-abienol	Antibacterial, antifungal, antihypertensive, anti-inflammatory, antioxidant, analgesic, expectorant, stimulant For arthritis, anxiety, colds, digestion, muscle recovery, pain, flu, wound healing
Acacia leucophloea	15*R*,16-Epoxy-8(14)-pimarene-1β,11α-diol (=leucophleoxol), 8(14)-pimarene-1β,15*R*,16-triol (=leucephaleol), leucoxol	Analgesic, antipyretic, antidote for snake bite, antimicrobial, anthelmintic, antipyretic, astringent, gastrointestinal and respiratory activity, expectorant For bronchitis, cough, demulcent, dental caries, diarrhea, dysentery, infection preventive, internal and external hemorrhages, intermittent fevers, skin diseases, stomatitis, styptic, ulcers, thermogenic, vulnerary, vomiting, wound healing
Acanthopanax koreanum	Acanthoic acid, *ent*-kaur-16-en-19-oic acid (**47**), 16β,17-dihydroxy-*ent*-kauran-19-oic acid (**4**), pimara-9(11),15-dien-19-ol,pimara-9(11),15-dien-19-oic acid (**60**), 19-acetoxy-pimara-9(11), 15-diene, pimara-9(11), 15-diene, 16α*H*,17-isovaleryloxy-*ent*-kauran-19-oic acid, 16α-hydroxy-17-isovaleryloxy-*ent*-kauran-19-oic acid, paniculoside-IV,16α-hydroxy-*ent*-kauran-19-oic acid, acanthol, acanthoic acid, 7β-hydroxy-*ent*-pimar-8(14),15-dien-19-oic acid, acantholoreoic acid A, *ent*-kaur-16-en-19-oic acid (**47**), 16α-hydroxy-*ent*-kauran-19-oic acid, 16α*H*,17-isovaleryloxy-*ent*-kauran-19-oic acid, 16α,hydroxy-17-isovaleryloxy-*ent*-kauran-19-oic acid	Hepatoprotective, TNF-α secretion inhibitory, tyrosine phosphate 1B inhibitory, sedative, tonic For diabetes, rheumatism

Acremonium luzulae	7,16-Isopimaradiene-2α,3β,19-triol (=virescenoside A), virescenoside E, virescenoside F, virescenside L	Immunomodulatory, immunostimulatory
Acritopappus confertus	16-Hydroxy-*ent*-labda-7, 13-dien-15-oic acid, 16,17-dihydroxy-*ent*-labda-7,13*E*-dien-15-oic acid, 16-hydroxy-17-oxo-*ent*-labda-7,13*E*-dien-15-oic acid,17-hydroxy-16-acetoxy-*ent*-labda-7,13*E*-dien-15-oic acid, 16-hydroxy-17-methoxy-*ent*-labda-7,13(14)-dien-15-oic acid, 7β,15-dihydorxy-*ent*-labda-8(17),13(14)-dien-16-oic acid lactone	
Acritopappus morii	7β-Hydroxypolyalthine, 17-hydroxyisopolyalthine, 7,15,16-trihydroxy-*ent*-labda-7,12(14)-diene	
Acritopappus teixeirae	16-Oxo-koval-3-en-15-oic acid	
Acritopappus pushagei	16-Acetoxy-18-hydroxy-kolavenic acid, 16,18-dihydroxykalavenic acid, 16-acetoxy-18-oxo-kolavenic acid, 16-hydroxy-18-oxo-kolavenic acid, 2β,15-didihydroxy-kolavenic acid, 15-hydroxy-2-oxo-kolavenic acid, acritoppusol, 16,18-dihydroxykolavenic acid lactone, 12,15,16-trihydroxy-*ent*-labda-7,13-dien-15-oic acid lactone, 12*S*,16-dihydroxy-*ent*-labda-7,13-dien-15,16-olide, 16,18-dihydroxy-3,13*Z*-clerodadien-15-oic acid (=16,18-dihydroxykolavenic acid), 2-hydroxy-3,13-clerodadien-16,15-olide (=2,15-diydroxykolavenic acid lactone), 2-oxo-3,13-clerodadien-16,15-olide, *ent*-18-acetoxy-3,13-kolavadien-16,15-olide	Anticancer
Aframomum aulacocarpos	Aulacocarpinolide, aulacocarpin A, aulacocarpin B, 8β(17)-epoxy-14,15,16-trihydroxylabd-12*E*-ene (=aulacocarpin C) (**61**), 15,16-epoxy-14*Z*,16*Z*-dimethoxylabda-8(17), 12*E*-diene (=aulacoparpin D), aframodial	Food, spice Antifungal, antimicrobial
Aframomum deniellii	8β,17-Epoxy-12*E*-labdene-15,16-dial (=aframodial)	Antifungal, antihypercholesterolemic, cytotoxic
Agathis australis	8,(14),15-Isopimaradien-18-ol (=isopimarinol), (*Z*)-communic acid, (*E*)-communic acid (**3**), levopimaric acid, sandaracopimaric acid, abietic acid (**2**), agathic acid	For wound healing

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Agathis lanceolata	19-Nor-8(17),13*E*-labdadien-15-oic acid (=19-noranticopalic acid), (*Z*)-communic acid, (*E*)-communic acid (**3**), dehydroabietic acid (**43**), abietic acid (**2**), neoabietic acid, agathic acid, agathalic acid	Edible (seed) Antiseptic For vulnerary
Agathis macrophylla	(*Z*)-Communic acid, (*E*)-communic acid (**3**), dehydroabietic acid (**43**), abietic acid (**2**), neoabietic acid, agathic acid, agathalic acid	
Agathis microstachys	Abietic acid (**2**), agathic acid, neoabietic acid	
Agathis robusta	Abietic acid (**2**), 8(14),12-abietadien-18-oic acid (=laevopimaric acid), agathic acid, neoabietic acid, communic acid	Edible (seed)
Agathis vitiensis	3-Hydorxy-13*S*-16-nor-pimar-7-en-15-oic acid, 13*S*-pimar-7-en-3α,15,16-triol, kaur-16-en-3α, 13-diol, kauran-3α,13,16α-triol, agatharesinol, (*Z*)-communic acid, (*E*)-communic acid (**3**), sandaracopimaric acid, dehydroabietic acid (**43**), abietic acid (**2**), neoabietic acid, agathalic acid	
Agerantia ixiocladon	4-Hydroxy-13-cleroden-15-oic acid	
Ageratina saltillensis	16-Hydroxy-3,4β-epoxy-5β,10β-*cis*-17α,20α-cleroda-13(14)-en-15,16-olide, 3α,4β,16-trihydroxy-5β,l0β-*cis*-17α,20α-cleroda-13(14)-en-15,16-olide, 3α,4β-dihydroxy-5β,10β-*cis*-17α,20α-cleroda-13(14)-en-15,16-olide, 3α-methoxy-4β-hydroxy-5β,10β-*cis*-17α,20α-cleroda-13(14)-en-15,16-olide, 3-oxo-4β-hydroxy-5β,10β-*cis*-17α,20α-cleroda-13(14)-en-15,16-olide, 2β-hydroxy-3,4β-epoxy-5β,10β-*cis*-17α,20α-cleroda-13(14)-en-15,16-olide, 2β-hydroxy-5β,10β-*cis*-17α,20α-cleroda-3,13(14)-diene-15,16-olide, 13*Z*-2β-hydroxy-5β,10β-*cis*-l7α,20β-cleroda-3,13(14)-diene-15-oic acid, 13*Z*-2-oxo-5β,10β-*cis*-17α,20β-cleroda-3,13(14)-diene-	For epilepsy, hypertension, mental disorders, schizophrenia, snake bite

	15-oic acid, 3,4β-epoxy-5β,10β-*cis*-17α,20α-clerodaα-l5-oic acid, 16-hydroxy-3,4β-epoxy-5β,10β-*cis*-17α,20α-cleroda-15-o1, 20-hydroxygeranylnerol, *ent*-3β,4α-dihydroxy-13-cleroden-15,16-olide, 3α,4α-dihydroxy-13-clerodanediol, *ent*-4α-hydroxy-3-oxo-13-cleroden-15,16-olide, *ent*-2α-hydroxy-3,13*Z*-clerodadien-15-oic acid, *ent*-3α,4α-epoxy-2α-hydroxy-13-cleloden-15,16-olide	
Aglaia odorata	3-Hydroperoxydolabella-4(16),7-dien-18-ol, 7,8-epoxydolabella-3-en-18-ol, 3,4-epoxydolabella-4(16),7-dien-3-one, 3,4-epoxy-dolabella-7-en-8-ol, 18-hydroxydolabella-3,7-dien, dolabella-3,4-dien-10,18-diol (**62**), dolabella-4(16),7-dien-3,18-diol, 3,4-epoxy-dolabella-7-en-18-ol, 18-hydroxydolabella-4(16),7-dien-3-one, dolabella-4(16),7,18-trien-3-ol	Anticancer, anti-leukemic, anti-HSV-1, cytotoxic (HL-60: human myeloid leukemia, SMMC-7721: hepatocellular carcinoma; A-549: lung cancer cells), insecticidal For bruises, febrifuge, heart disease, toxin by causing vomiting, traumatic injury, vomiting
Ajuga bracteosa	Ajubractin A (**63**), B-D, clerodin, 3-*epi*-caryoptin, ajugapitin, 14,15-dihydroclerodin, 3-*epi*-14,15-dihydrocaryoptin, ivain, 14,15-dihydroajugapitin, ajubratin E, 15-hydroxyajubractin, 14-hydro-15-hydroxyajugachin A, 14-hydro-15-hydroxyajugapitin, 15-*epi*-lupulin	Edible (leaves and roots) Antimicrobial, insect antifeedant
Ajuga chamaepitys	Ajugachin A, ajugachin B ajugapitin, 14,15-dihydroajugapitin, chamaepitin	Antioxidant, cytotoxic, diuretic, emmenagogue, stimulant For female disorders, gout, rheumatism
Ajuga ciliata	Neoclerodanes	Cytotoxic (SH-SY5Y: neuroblastoma cell), nitric oxide (NO) production inhibitory
Ajuga decumbens	Neoclerodanes	NO production inhibitory
Ajuga iva	Ivain I (=4,18:11,16:15,16-triepoxy-14-clerodene-2,3,6,19-tetrol), ivain II, ivain III, ivain IV	Antibacterial, anticancer, antidiabetes, antifeedant, antimicrobial, antioxidant, antipyretic, antitumor, insecticide For asthma, diarrhea, gout, malaria, rheumatism, ulcers, vulnerary

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Ajuga laxmannii		Anticancer antimicrobial, anti-inflammatory, antioxidant, antiprotozoal, galactagogic
Ajuga lupulina	Lupulins A-D	Antimicrobial
Ajuga macrosperma	Ajugaflorins A-F, ajugamacrin E, ajugatakasin B, ajugamarin F4, ajugalides B, C, ajugalin I	Edible part (whole plant) Expectorant For nephritis, *Pyricularia oryzae* cell cyclic inhibitory
Ajuga nipponensis	Ajugamarine (=4β,18-epoxy-1α-tigloyl-6β,19-diacetoxy-12R-hydroxy-13-cleroden-15,16-olide), dihydroajugamarine	Anti-inflammatory, antitumor, expectorant, diuretic, immunity, liver protective, rheumatism
Ajuga remota	Ajugarin I, ajugarin II (**64**), ajugarin IV (**65**), ajugarin III (**66**), V, ajuganin I, clerodin	Antidiabetes, insect antifeedant, antifungal, anthelminthic, antimalarial, antimycobacterial, antioxidant, anxiolytic, cytotoxic For fever, high blood pressure, infection, malaria, pneumonia, skin diseases, stomach pain, toothache
Ajuga reptans	Ajugarin II, ajugareptasone A (**67**), ajugareptansin, ajugatansin A, ajugatansin B_1, ajugatansin D_1, ajugavensin A	Edible (leave, young shoot) Antibacterial, antitumor
Ajuga turkestanica	Ferruginol, 4β-18-nor-kaur-16-ene**,** abieta-6,8,11,13-tetraen-12-yl acetate (=ferruginyl acetate), totarol (**180**), 14,15-dihydroajugachin, 14-dihydro-15-methoxy-ajugachin B, chamaepitin (=14-dihydro-15-hydroxy-ajugachin B), ajugachin B, ajugapitin, luplin A	Antibacterial, antimicrobial, antioxidant, antiproliferative, cytotoxic For heart disease, muscle and stomach aches
Aldama discolor (=*Viguiera discolor*)	*ent*-3*α*-Hydroxy-kaur-16-en-18-ol, *ent*-7-oxo-pimara-8,15-diene-18-ol, *ent*-2*S*,4*S*-2-19-epoxy-pimara-8(3),15-diene-7*β*-ol, *ent*-7-oxo-pimara-8,15-diene-3*β*-ol	Antiprotozoal, antimicrobial
Alpinia calcarata	Zerumin A (**69**), isocoronarin D, calcaratarins A-F, (*E*)-15,16-bisnorlabda-8(17),11-dien-13-one, laboda-8(17),11,13-trien-15,16-olide, (*E*)-labda-8(17),12-dine-15-al	Antimicrobial, anticancer, cytotoxic (KB cell) For cold

Alpinia chinensis	Labda-8(17),12-diene-15,16-dial (**29**), 14,15-epoxylada-8 (17),12-dien-16-al (**68**), coronarin E (**130**), 15-hydroxylabda-8 (17),11,13-trien-16-al, 15,16-epoxylabda-8(17), 11,13-trien-16-ol, 15-hydroxylabda-8(17),11,13-trien-16,15-olide, 14,15-dihydroxy-labda-8(17),12-dien-16-al, 12,15-dihydroxylabda-8(17),13-dien-16-al, 15-hydroxy-11,14-peroxylabda-8 (17),12-dien-16-al, dihydroxylabda-8(17),13-dien-16-al, coronarin C	Antiasthmatic, analgesic
Alpinia densespicata	Labdane glycosides: alpindenosides A-D, noralpindenosides A, B	NO production inhibitory
Alpinia formosana (pinstripe ginger)	12*E*,15,16-Bisnorlabda-8(17),11-dien-13-one, 12*E*-8(17)-labdadien-15-ol,16-al (**29**)	
Alpinia galanaga (galangal)	(*E*)-8β,17-Epoxylabda-12-ene-15,16-diol, galanolactone (**26**), galanal A (**28**), galanal B, isocoronarin D, galaganin, 8(17),12-labdadiene-15,16-dial (**29**)	Foods (flower, young shoots), for curries, soups. Beverage (herbal tea) Anticancer, antifungal, antimicrobial, cytotoxic, expectorant, α-glucosidase inhibitory, indigestion, stimulating digestion For cancers of mouth and stomach, colic, dysentery, respiratory and skin diseases
Alpinia japonica	Galanal A (**28**), B, pahangesin B	Antidiarrheal, antifungal antimicrobial, antipolyuria, antiulcer. cytotoxic, diuretic, Food preservative, NO production inhibition, tonic For aphrodiastic, hypertension
Alpinia katsumandai	Galanolactone (**26**)	Foods and beverage Antifungal
Alpinia nigra	*ent*-Labda-8(17),12-dien-15,16-dial (**29**), *ent*-8β,17-epoxylabda-12-ene-15,16-dial	Antimicrobial

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Alpinia oxyphylla	12*E*-Labda-12,14-dien-15(16)-olide-17-oic acid =	Antimicrobial, cytotoxic For abdominal disorders, anorexia, diarrhea, dementia, dieresis, α-glucose inhibitory, hypoglycemic, NO production inhibition, pain, spermatorrhea, urinary tract infection, uterine bleeding
Alpinia pahangensis	Pahangesin B	
Alpinia zermbet	Zerumin A (**69**), B, (*E*)-15,16-bisnorlabda-8(17),11-dien-13one	Beverage (herbal tea) Antimicrobial, aromatic stomachic
Ambergris	Ambroxide (**23a**) (=ambroxan, ambrox®)	Ambergris fragrance: high perfume and cosmetics for flavor Used as cosmetic flavor (skin hair, fabric flavoring spice)
Ambrosia arborescens	Diterpenoids	Cytotoxic (U937: monocyte leukemia
Amphiachyris dracunculoides (= *Gutierrezia dracunculoides*), (prairie broomweed)	18,19-Epoxy-19-hydroxy-3,13-clerodadien-15,16-olide (=amphiacrolide C), amphiacrolide A-D, gutierolide, 15,16-epoxy-7-hydroxy-8,(17),13(16), 14-labdatrien-19-oic acid (=17-hydroxyiso-lanbertianic acid)	For cold, cough
Andrographis paniculata (king of bitters)	Andrographolide A (**70**), andrographan, andrographosterin, andrographolactone, 14-deoxy-12*R*-sulfoandrographolide, neoandrographolide, 14-deoxyandrographolide, isoandrographolide, 14-deoxyandrographolide 19β-*D*-glucoside, homoandrographolide	Anticancer, angeogenic, antifertility, antimalarial, cardiovascular activity, cytotoxic (LoVor: colon cancer, NCI-H460: lung cancer), hepatorenal protective, hypoglycemic, immunological potential, liver enzyme modulatory, psychopharmacological activity, respiratory system benefit, sex hormone modulatory NF-κB inhibitory For cold, fever, hypertension, diabetes, herpes, helminth infection, peptic ulcer

Anisochilus carnosus	Coleon A, coleon Q (**71**)	Beverage (herbal tea) Anticancer, antimicrobial, antioxidant, gastric antisecretary, antiulcer, hepatotoxic, cytoprotective, stomachache
Anisochilus harmandii	4-*epi*-Triptoenzene (**72**), 12-*O*-deacetyl-6-*O*-acetyl-19-acetoxycoleon Q, pimaric acid, dehydroabietic acid (**43**), 9α,13α-*epi*-dioxyabiet-8(14)-en-18-oic acid, 7-oxo-dehydroabietic acid, 15-hydroxydehydroabietic acid, oxyabietan-18-oic acid, 12-*O*-deacetylcoleon A, 12-*O*-deacetyl-6-*O*-acetyl-18-acetyloxycoleon	Beverage (herbal tea), antimycobacterial, cytotoxic (NCl-H187 cell), tonic
Anisomeles indica	Ovatodiolide (**73**), 4-methylene-5β-hydroxyovatodiolide, 4-methylene-5β-hydro-peroxyovatodiolide, 4-methylene-5-oxo-ovatodiolide, 4α-hydroxy-5-en-ovatodiolide, 4α-hydroperoxy-5-en-ovatodiolide	Edible (tubers) Analgesic, anti-*Helicobacter pylori*, antihypertensive, anti-inflammatory, antiplatelet aggregation astringent, carminative, cytotoxic For eczema, pruritus, external afflictions, dyspepsia, fever, rheumatism, toothaches
Annona coriacea	3β,20-Epoxy-3α,16-dihydroxy-15-oxo-7-pimaren-19,6-olide	Fruit, ingredients in juices and desserts Laxative For dysentery
Annona glabra	Methyl 16β-acetoxy-19-al-*ent*-kauran-17-oate (=annoglabasin A), annoglabasin B (=16α-hyrdroxy-19-acetoxy-*ent*-kauren-17-oic acid), annoglabasin C (=16α-acetoxy-*ent*-kauran-19-oic acid-17-methyl ester), annoglabasin D (=16α-acetoxy-*ent*-kauran-19-al-17-methyl ester), annoglabasin E (=16α-hydro-19-ol-*ent*-kauran-17-oic acid, annoglabasin F (=16α-acetoxy-19-nor-*ent*-kauran-4α-ol-17-methyl ester), 16α-methoxy-*ent*-kauran-19-oic acid, 16α-hydro-*ent*-kauran-17,19-dimethyl ester	Beverage (herbal tea) Algaecide, antifungal, anti-HIV, cardiotonic infusion, insecticide sedative
Annona senegalensis	*ent*-3β-Hydroxykaur-16-ene, *ent*-kaur-16-en-19-oic acid (**47**), *ent*-16,17-deacetoxy-kauran-16-oic acid, *ent*-19-carbomethoxykauran-19-oic acid	Cytotoxic (MCF-7: breast, PC-3: prostate cancer cell)

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Annona squamosa (sugar apple, custard apple)	*ent*-17-Hydroxy-16β-kauran-19-al, *ent*-17-acetoxy-16β-kauran-19-al, 16-kauren-19-ol, *ent*-kaur-16-en-19-oic acid (**47**), 16β,17-dihydroxy-*ent*-kauran-19-oic acid (**4**) *ent*-11α-hydroxy-16-kauren-15-one (**5**), 4α-hydroxy-17,19-dinor-*ent*-kauran-16-one, 4β-hydroxy-16β*H*-18-nor-ent-kauran-17-oic acid, 4β,17-dihydroxy-16α-acetoxy-18-nor-*ent*-kaurane, annosquamosin Z, 16α*H*-*ent*-kaurane-17,18-dioic acid 17-methy ester	Fruits, ice cream, milk, beverage (herbal tea) Abortifacient, anticancer, antidiabetes, apoptosis inducing (HL-60 cell), cytotoxic (SMMC-7721, HepG2: human hepatoma cancer cells), expectorant, hypoglycemic, insecticidal, pesticidal, tonic For anemia, burning sensation, cold, cooling, diarrhea, dysentery, fainting spells, hysteria, sedative, stimulant
Annona vepretorum	*ent*-3β,19-Dihydroxy-kaur-16-ene, *ent*-3β-hydroxykaur-16-ene, *ent*-3β-acetoxykaur-16-ene, *ent*-3β-hydroxy-kaurenoic acid, kaurenoic acid	Cytotoxic (HepG2: human hepatoma; B16-F10, HL-60, non-tumor PBMC)
Aparisthmium cordatum	15,16-Epoxy-4-hydroxy-2,13(16)14-clerodatrien-17, 12-olid-18-oic acid (=cordatin), aparsthman	Antiulcer, gastroprotective
Aphanamixis polystachya	Aphanaperoxides	Cytotoxic (HepG2, MCF-7, A-549, AGS: human gastric carcinoma)
Aralia cordata	*ent*-7α-Hydroxy-8(14),15-pimaradien-19-oic acid, (**74**), *ent*-7-oxo-8(14),15-pimaradien-19-oic acid (**75**), *ent*-7β-hydroxy-8(14),15-pimaradien-19-oic acid, (**76**), *ent*-pimara-8(14),15-dien-15-oic acid, *ent*-kaur-16-en-19-oic acid, 18-nor-*ent*-pimara-8(14),15-dien-4β-ol, 18-nor-*ent*-kaur-16-en-14β-ol, *ent*-pimara-8(14),15-dien-19-ol, *ent*-pimar-15-en-8α,19-diol, 7-oxo-*ent*-pinara-8(14),15-dien-19-oic acid, 16α-hydroxy-17-isoveleroyloxy-*ent*-kauran-19-oic acid, 17-hydroxy-*ent*-kaur-15-en-19-oic acid, 15α,16α-epoxy-*ent*-kauran-19-oic acid, 16α,17-dihydroxy-*ent*-kauran-19-oic acid, 16α-methoxy-17-hydroxy-*ent*-kauran-19-oic acid, *ent*-continentalic acid, kaurenoic acid, 7-oxo-sandaracopimaric acid, pimaradienoic acid	Vegetable, salads Anti-Alzheimer, antiasthmatic, antibacterial, anti-inflammatory, antipyretic, antiulcer, COX-1, COX-2 inhibitory, Immune protective marginal acetylcholinesterase and β-site amyloid precursor protein cleaving enzyme (BACE 1) inhibitory, cytotoxic, diaphoresis, sedative For cold, sensitive constitution, lameness, lumbago, rheumatism

Araucaria angustifolia	7,13-Abietadien-18-al (=abietinal), (*E*)-communic acid (**3**)	Food (seeds), flowers, buds (medicinal use) Antidepressant, antigenotoxic, Anti-inflammatory, antioxidant, antiseptic, antiviral For anemia, fatigue, respiratory infection, rheumatism, scrofula
Araucaria araucana (pehuen)	Hibaene, kaurene, atisirene, labd-8(17)-en-15,19-diol (=imbricatadiol), 15-hydroxylabd-8(17)-en-19-al (=15-hydroxyimbricatolal), 15-hydroxylabd-8(17)-en-19-oic acid (=imbricatolic acid), 15-hydroxylabd-8(17)-en-19-oic acid methyl ester, 15-acetoxylabd-8(17)-en-19-ol, 15,19-diacetoxylabd-8(17)-ene, 15-acetoxyimbricatolal, 15-acetoxylabd-8(17)-en-19-al (=15-acetoxyimbricatolal), 15-acetoxylabd-8(17)-en-19-oic acid (=15-acetoxy-imbricatoic acid), 15-acetoxy-labd-8(17)-en-19-oic acid methyl ester, 15-methoxylabd-8(17)-en-19-oic acid methyl ester, labdanoic acid	Gastroprotective For cicatrization, contusions, ulcer, wound healing
Araucaria cookie	7,13-Abietadien-18-al (=abietinal)	Antimicrobial, antioxidant
Araucaria excelsis	7,13-Abietadien-18-ol (=abietinol)	
Araucaria heterophylla	Labda-18(17),14-diene, 13-epi-cupressic acid, 13-*O*-acetyl-13-*epi*-cupressic acid	Antiulcerogenic, cytotoxic (breast and colon cancer cell lines)
Arcangelisia flava	15,16-Epoxy-4,6-dihydroxy-2,13(16),14-clerodatrien-17,12:18,1-olide (=2-dehydroarcangelisinol), hydroxyarcangelisin, tinophyllol, 6-hydroxyarcangelisin, 2-dehydroarcangelisinol, tinophyllol, 6-hydroxyfibleucin, fibleucin, fibraurin, 6-hydroxyfibraurin, 2α,3α-epoxy-2,3,7,8α-tetrahydropenianthic acid methyl ester, 2α,3α-epoxy-2,3-dihydropenianthic acid methyl ester, fibraisin, 2α,3α-fibleucin, dihydroxy-2,3,7,8α-tetrahydropenianthic acid-2,17-lactone	Sap (sprue) antibacterial, antimicrobial, antiseptic, antitumoral, emmenagogue, expectorant, hypotensive, tonic, stimulate uterine contractions cause an abortion For indigestion, jaundice, intestinal complaints, stomach Antifungal, antimicrobial, antihypertensive cardiotonic, tonic For abortive, fatigue, hepatitis healing, malaria, worms

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Aristolochia brasiliensis	*ent*-2-Oxo-3-cleroden-15-oic acid (**77**), 17-chloro-16*R*-hydroxy-*ent*-kaurane, 2-oxo-kolavenic acid, 2-oxo-*ent*-3-cleroden-15-oic acid, kolavenic acid, *ent*-3-cleroden-15-oic acid, *ent*-clerd-3,13-dien-15-oic acid	Antioxidant, antipyretic cytotoxic (leukemia), diuretic, snake bite, tonic
Aristolochia cymbifera (Jarrinha)	Copaic acid, copalic acid, aristolochin, aristimic, arstolochic acid, aristolic acid, kolavelool, populifolic acid, 2-oxopoppulifolic acid, epi-populifolic acid, *ent*-8β-hydroxylabd-14-ene	Antimalarial, antimicrobial, antioxidant, antiprostate cancer, diuretic, sedative For menstruation
Aristolochia triangularis	*ent*-16β*H*-kaurane (=stevane A), (-)-*ent*-kaur-16-ene, (-)-*ent*-kaur-16-en-18-ol, *ent*-3β,19-dihydroxykaur-16-ene, (-)-kaur-16-en-18-al, (-)-*ent*-kaur-16-en-18-oic acid,16α,17-epoxykaurane*ent*-16β,17-epoxykaurane, *ent*-16β*H*-kauran-17-oic acid, *ent*-kauran-16α,17-diol, (-)-*ent*-kauran-16α-ol-18-al, (-)-kaur-15-en-17-ol, *ent*-15β,16β-epoxykauan-17-ol	Antifertility, antidote, antirheumatic, antiseptic, antitumor, diaphoretic, diuretic, emmenagogue For abortive, sore throats, skin diseases, snake bites, tuberculosis, wound healing
Austrocedrus chilensis	18-Hydroxyisopimar-15-ene, 18-acetoxyisopimar-15-ene, isopimara-8(9), 15-diene, isopimara-8(19), 15-dien-19-ol, sandaracopimaric acid, sandaracopimaric acid methyl ester, labda-8(17),14-dien-13-ol, 18-hydroxymanool, 18-acetoxymanool, torulosal, torulosic acid, torulosic acid methyl ester, 8(17),12,14-labdatriene, (*E*)-communic acid, (*E*)-communic acid methyl ester, (*Z*)-communic acid, (*Z*)-communic acid methyl ester, 12-oxolabda-8,13*E*-dien-19-oic acid, 12-oxolabda-8,13*E*-dien-19-oic acid methyl ester, ferruginol, dehydroabietic acid methyl ester, 7-oxo-ferruginol (= sugiol)	Antibacterial, antiprasmodial, antiproliferative, cytotoxic, diarrhea gastroprotective, sudorific

Avena strigosa	Avenaol	Food Germination stimulant
Azadirachta indica (neem)	8,11,13-abietatrien-3,7-dione (=margocin) (**78**), ninbodinin (**79**), nimosone, nimbidiol, nimbisonol, nimbione, nimbiol (**80**), nimbosone (**81**), nimbonolone (**82**), margolone, margolonone, isomargolonone, nimbosodione, 12-hydroxy-13-methoxypodocarpa-8,11,13-trien-3,7-dione (=ninbionone), 3,13-dihydroxy-13-methoxypodocarpa-8,11,13-trien-7-one (=nimbionol), 8,11,13-abietatrien-12,16-dihydroxy-3,7-dione (=margocinin) (**83**), 8,11,13-abietatrien-3β,12-dihydroxy-7-one (=margocilin) (**84**)	Antifungal, antimicrobial, to cause abortions For birth control, bloody nose, cardiovascular, diabetes, eye gum, (gingivitis), and liver problems, fever, increases immunity, intestinal worms, leprosy, loss of appetite, nature's toothbrush, skin stomach upset, skin ulcers, and blood vessels seeds: birth control, head lice, insecticide
Baccharis artemisioides	15,16-3α,4α-Diepoxycleroda-13(16),14-diene-20,12*S*-19,2β-diolide (=bartemidiolide), 15,16-epoxyclerada-3,13(16),14-triene-20,12S,19,2β-diolide (=deoxybartemidiolide)	Antirheumatism For treating traumatisms
Baccharis articulata *(= B. diptera)*	7-Oxo-16,19-dihydroxy-3,4-dehydroclerodan-15,20-diacid-dilactone, 8β-hydroxy-7-oxo-*ent*-cleroda-3-en-15,18-diacid-16,19-dilactone, 15,16-epoxy-7α,18-dihydroxy-15-methoxy-*ent*-cleroda-3-ene, *ent*-2α-hydroxy-3,13-clerodadien-15,16:18,19-diolide (=atriculin)	Antidiabetes, anthelmintic, Anti-inflammatory, antiviral, aphrodisiac, diuretic, febrifuge, gastric stimulant, tonic, digestive, hepatoprotective For male sexual impotence, female sterility, rheumatism, ulcers
Baccharis boliviensis	*ent*-3,13-Clerodadiene-15,16,17-triol (**85**), 16-hydroxybacchasalicyclic acid (**86**), 16-hydroxybaccasalicyclic acid-15-*O*-acetate (**87**), 15,16-dihydroxy-*ent*-3,13-clerodadiene-17-*O*-β-xylopyranoside (**88**), *ent*-2,4(18),13-clerodatriene-15,16-diol, *ent*-13(*Z*)-clerodene-2β,3β,4α,15,16-pentol, *ent*-3β, 4β-15,16-diepoxy-13(16), 14-clerodadien-2β-ol, *ent*-3β,4β-15,16-diepoxy-2β-methoxy-13(16),14-clerodadiene	Antibacterial, anti-inflammatory, COX-1, prostaglandin E2, (PGE2), 5-lipoxygenase (5-LOX) leukotriene C4 (LTC4), COX-2, nitric oxide (NO) and tumor necrosis factor-alpha (TNF-α) inhibitory, trypanocidal
Baccharis cassinaefolia	*ent*-15,16-Epoxy-2β-angeloyl-3β-(3-methyl-2-butenoyl)-13 (16),14-clerodadiene-18,19:20,12-diolide	

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Baccharis conferta (escoba)	Bacchofertin, bacchofetone, kingidiol	Beverage (herbal tea) Antibacterial, antiobesity, diuretic, laxative, spasmolytic For cold, cramps, cold, digestive disorders, insect bite, laxative, gastrointestinal disorders, insect bites, joint pain, seizures, stomachache, toothache
Baccharis crispa	Bacrispine, 1-deoxy-bacrispine	Antifungal, antibiotic, antifeedant, antimicrobial, antioxidant, antirheumatism, antiseptic, antispasmodic For digestive, fever, hepatoprotective, liver disorders
Baccharis eggersii	17-Hydroxy-13-labden-15,16-olide	
Baccharis flabellata	2,19:15,16-Diepoxy-neoclerodan-3,13(16),14-trien-18-oic acid, 15,16-epoxy-5,10-secoclerodan-1(12)-2,4,13(16),14-pentaen-18,19-olide, 15,16-epoxy-neo-clerodan-1,3,13(16),14-tetraen-18,19-olide	Antifungal
Baccharis gaudichaudiana	Baccharіol, 15,16-epoxy-15α-methoxy-*ent*-clerod-3-en-18-oic acid, 13-*epi*-15,16-epoxy-15α-methoxy-*ent*-clerod-3-en-18-oic acid, 7-oxo-16-hydroxy-*ent*-clerod-3-en-15-oic acid methyl ester-18,19-olide	Antidiabetes, antihypertensive, anti-inflammatory, antimicrobial, antileukemia, antiseptic, hepatoprotective, hypoglycemic, diuretic, tonic For digestive
Baccharis genistelloides (=B. trimera) (escoba)	15,16-Epoxy-7α,18-dihydroxy-15-oxo-*ent*-cleroda-3-ene, 7α,15,18-trihydroxy-*ent*-cleroda-3-ene, 15,16-diacetoxy-7α,18-dihydroxy-*ent*-cleroda-3-ene, 15,16-epoxy-7α,18-dihydroxy-15-methoxy-*ent*-cleroda-3-ene, 7-hydroxy-13,14,15,16-tetranor-3-cleroden-18,19-olide, 7-oxo-3-clerodene-15,16:18,19-diolide	Beverage (herbal tea) Anti-HSV-1/VSV, antibacterial, anti-inflammatory, antifungal, antimutagenic, antithermic, antiulcerogenic, effects on bile duct, bone marrow, cardiac function, liver, pancreas, serum lipids in diabetes For analgesic, anemia, aphrodiastic, cardiovascular, diabetes, diarrhea, digestive disorders, diuretic,

		gastrointestinal, hepatic, hypertension, indigestion, inflammatory, intestinal worms, liver, kidney, renal and spleen diseases, malaria, rheumatism, sexual impotency, sore throat, stomachic, ulcers, urinary
Baccharis grisebachii	Labda-7,13*E*-dien-3β,15-diol (**6**)	Traditional medicine Antibacterial, antifungal
Baccharis hytchisonii	Bacchalineol, barticulididol	
Baccharis illinita (cha ventura)	15β-Senecioyloxy-*ent*-kaur-16-en-19-oic acid, 15β-hydroxy-*ent*-kaur-16-en-19-oic acid, 17-hydroxy-*ent*-kaur-15-en-19-oic acid	Beverage (herbal tea) Anti-inflammatory, gastroprotective For gastric disorders, infection, skin and mucosal healing, stomach ulcers
Baccharis incarum	1α-Acetoxybacchotricuneatin A, hydroxybacchotricuneatin A, *ent*-18-acetoxy-3,13-clerodadien-16,15-olide	Anti-inflammatory antioxidant, antipyretic antiseptic, wound healing For digestion
Baccharis kingii	*ent*-15,16-Epoxy-3,13(16),14-clerodatrien-18,19-diol (=kingidiol)	Juvenile hormone antagonist
Baccharis latifolia	Labda-13-en-8,15-deiol, labd-13-en-8,15-diol	Antidiabetes, anti-inflammatory, antimicrobial, antioxidant, antirheumatic, pulmonary affections, tonic, vulnerary For disinfectant, emollient, inflammation, liver disorders, rheumatism, wounds, ulcers
Baccharis lejia	Bacchalineol-18-*O*-malonate ethyl ester, patagonol-18-*O*-malonic acid, 15-hydroxy-patagonol-18-*O*-malonic acid methyl ester, 16-hydroxy-iso-patagonol-18-*O*-malonic acid methyl ester, bacchalejin 1, bacchalejin 2, bacchalejin 3, bacchalejin 4	Antifeedant, insecticidal
Baccharis leptophylla	*ent*-3β,16β,19-Trihydoxy-kaurane, *ent*-16β,17-dihydroxykauran-19-al, 16β,17-dihydroxy-*ent*-kauran-19-oic acid (**4**)	Antibacterial, antiparasitic, HIV-inhibitory, platelet aggregation inhibitory

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Baccharis linearis	Baclinal, baclinepoxide, 13-*epi*-baclinepoxide, baclinic acid, triacetyl baclinic acid	Allelopathic, antifeedant, antirheumatic, cytotoxic, insect repellent For arterial blood, catarrh, headaches, inflammations, pyorrhea, respiratory ailments, rheumatism, spasmodic, urinary vulnerary, wound healing
Baccharis macraei	15,16-Epoxy-3,13(16),14-clerodatrien-19-hydroxy-18-oic acid (=hautriwaic acid acetate), *ent*-4α-hydroxy-isobacchasmacranone, bacchasmacranone, 2β-hydroxybacchasmacranone, (-)-hardwickiic acid	
Baccharis marginalis	*ent*-2β,3β,4α-Trihydroxy-15-cledrodanoic acid (=dihydrotucumanoic acid)	
Baccharis minutiflora	*ent*-16β-Acetyl-17-nor-19-kauranol, *ent*-15-kauren-17-ol, *ent*-19-hydroxy-16β-kauran-17-al, *ent*-16α-17-epoxy-19-karanal	
Baccharis multifolia	Furanoditerpenoids	For catarrhs, urinary problems
Baccharis myrsinites	Two clerodanes	
Baccharis paniculata	*ent*-18,19-Dihydroxy-3,13-clerodadien-15,16-olide (=paniculadiol)	Antifungal
Baccharis patagonica	*ent*-5β-3,13-Clerodadien-18-oic acid 16,15-olide (=patagonic acid)	
Baccharis pedicellata	*ent*-2β,3β,4α-13,14-Dihydro-15-clerodanoic acid (=dihydrotucumanoic acid), 3,13-clerodadiene-15,16:18,19-diolide	
Baccharis petiolata	2α,3α-Dihydroxy-8-labden-15-oic acid (=2α,3α-dihydroxycativic acid	
Baccharis pingraea	Angeloyl gutierrezianolic acid, furolabda-6,8-dien-17-oic acid, furolabd-7-en-17-oic acid, 10*E*-centipedic acid, gutierrezianolic acid	

Baccharis platypoda	Platypodiol	Anti-*Plasmodium falciparum*
Baccharis rufescens	*ent*-3,19-Disuccinyloxy-kaur-16-ene	Anti-inflammatory
Baccharis salcifolia (mule fat)	15,16-Epoxy-7,13(16)14-2α,3β-dihydroxylabda-triene, *ent*-2α,3α-dihydroxy-7-labden-15-oic acid (**89**), *ent*-15-hydroxy-3,13*E*-cleroda-dien-17-oic acid (=bacchasalicylic acid), *ent*-5-hydroxy-3,13*E*-clerodadien-17-oic acid 15-*O*-β-xylopyranoside, salicifolic acid, 5-hydroxy-6-hydrosalicifolic acid	Food (young shoot), Beverage (herbal tea) Anti-inflammatory, antirheumatic, antisyphilitic, diuretic, female germination inhibition, hygienic agent For bruise, colic, diarrhea, diaphoretic, dysentery, eye fevers, headache, inflammation, insect stings, wound healing
Baccharis salzmannii	6β,15,18,19-Tetrahydroxy-*ent*-cleroda-3-ene, 6β,15,18-trihydroxy-*ent*-cleroda-3-ene, *ent*-kaur-16-en-19-oic acid (**47**)	
Baccharis sarothroides	15,16-Epoxy-2,19-dihydroxy-3,13(16),14-clerodatrien-18-oic acid (=*ent*-2α-hydroxy-hautriwaic acid)	Seed: beverage (herbal tea) Cytotoxic (human carcinoma inhibitory), muscle relaxant For cold, refreshment
Baccharis scoparia	8β,13*R*-Epoxy-15-labdanal, *ent*-12α*H*,20:15, 16-diepoxy-7-oxo-3,13(16),14-clerodatrien-18,19-olide (=12-*epi*-conycephalide), baccharascoparone	
Baccharis sternbergiana	*ent*-8,17-Labdene-2α,15-diol, *ent*-15-hydroxy-8,17-labdene-2-one	
Baccharis thymifolia	6,10-(*E,E*)-Thymifodioic acid	
Baccharis tola	Erythroxylol-A, *ent*-bayer-15-en-18-ol, erythroxylol-A 14,15-oxide, 19-hydroxy-13-epi-manoyl oxide, *ent*-bayer-15-en-17,19-diol, *ent*-4α-hydroxy-19-norbeyer-15-ene, *ent*-beyer-15-en-18,19-diol, 15β,16β-epoxy-*ent*-beyeran-18-ol	Antibacterial, anti-inflammatory, protein synthesis
Baccharis tricuneata	Bacchotricuneatin A-D, *ent*-15,16-epoxy-3,13(16),14-clerodatrien-18-ol (=bacchalineol)	Antidiabetes, antianernic, antirheumatic, antiseptic, disinfectant For bronchitis, diabetes, headache, skin infections, wound healing

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Baccharis tucumanensis	*ent*-2β,3β,4α-Trihydroxy-13*Z*-cleroden-15-oic acid (=tucumanoic acid)	Abortive agent, anti-inflammatory
Ballota inaquidens	Hipanolone, ballonigrine (**90**)	Antibacterial, antifungal antispasmodic, antiulcer, sedative
Ballota saxatilis subsp. *saxatilis*	Hispanolone, dehydrohispanolone, ballonigrine	Antibacterial, antifungal
Barbacenia flava	Barbacenic acid, 3-deoxybarbacenic acid, 3-oxo-17-carboxy-3,18-secobarbacenic acid	
Beyria leshenaultii	*ent*-Kaurene-3β,19-diol	For tuberculosis
Bideus pilosa	Phytyl heptanoate	Beverage (herbal tea) Emmenagogue For abdominal troubles, dysentery, rheumatism, sore eyes, swollen, toothache, ulcers
Bifucaria bifurcate (brown algae)	Bifurcadiol (**91**), 12-hydroxygeranylgeraniol	Cytotoxic (A-549, HCT, SK-L-2, SK-OV-3, XF-498: human tumor cell lines)
Bowdichia nitida	6α,7α-Diacetoxyvouacapane	Anti-*Plasmodium falciparum*
Bromelia pinguin	7β,8β-Dihydroxypimar-15-en-3-one (**92**), 3-oxophyllocladan-16ξ-ol, phyllocladan-16α,19-diol	Fruit, edible (fresh shoot: cooked or raw), vinegar, beverage (refreshing drink) Antibacterial, cytotoxic
Bux sempervirens	Phytol	Decoction: antirheumatism Infusion: respiratory, sedative
Caesalpina echinata	Echinalides H-U	NK-κB inhibitory
Caesalpinia bonduc	Casalpinolide C-E, cassane furanoditerpene	Cytotoxic (MCF-7: DU145: prostate carcinoma, C33A: cervical carcinoma, Vero: fibroblast cells)
Caesalpinia decapetala	Caesaldecapes A, B	Cytotoxic (KB cell)
Caesalpinia echinata	Cassanes, echinalides H-U	Anti-*Leishmanial amazonensis*, NK-κB inhibitory
Caesalpinia furfuracea	Caesalfurfuric acid A	Antimicrobial

Caesalpinia minax (seed: kushilian)	Caesalmine A (**93**), B	Anti-*Plasmodium falciparum*
	Sucuriniranes (G-I)	Cytotoxic (Hela, HepG-2 cancer cell lines)
	Caesalmins C-G, caesalmanaxin A-L spirocaesalin, macrocaesalmin, neocaesalpins I-N, neocaesalpins S-U, neocaesalpins AA-AE, bonducellpin D, methyl 1α,7β-diacetoxy-5α,12α-dihydroxy-cass-13(15)-en-16,12-olide-17β-carboxylate, methyl 7β-acetoxy-1α,5α,12α-trihydroxy-cass-13(15)-en-16,12-olide-17β-carboxylate, 12α-ethoxy-1α,6α,7β-triacetoxy-5α,14β-dihydroxycass-13(15)-en-16,12-olide	Cytotoxic (Du145, K562 cancer cell lines) For cold, dysentery, fever
Caesalpinia pulcherrima	Pulcherrimins A-D, isovoiacapenol, 6β-cinnamoyl-7β-hydroxyvouacapen-5β-ol, pulcherrimin E-F, neocaesalpin E-G, 6β-hydroxy-isovouacapenol, 7β-acetoxy-6β-hydroxy-iso-vouacapenol, iso-vouacapenol monoacetate	Antibacterial, antifungal For liver disorders, mouth and throat ulcers
Caesalpinia sappan	Caesalsappanins O-S, morcaesalpinin, phanquinin A (**94**), B-K, phangininoxys B, C, 11-oxophanginin, phanginin U	Antibacterial, anthelmintic, anti-inflammatory, antimalarial, antineoplastic, antioxidant, antiplasmodial, antiproliferative, blood stagnation, complementary, cytotoxic (HCT: colon; MCF-7: breast cancer cell lines), dysmenorrheal, hepatoprotective, hypoglycemic, immunomodulatory, xanthine oxidase-inhibitory For diarrhea, dysentery, tuberculosis
	Cassanes, furanoditerpenoids, tomocinon, tomocinol	Antimalarial
Caesalpinia sylvestris	Casearin B	Cytotoxic (HePG2)
Calceolaria ascendens (topa-topa)	Dehydroabietinol, 19-malonyloxydehydroabietinol, 4-*epi*-dehydroabietic acid	Antibacterial, stomachache, sweeteners, tonic,
Calceolaria foliosa	*ent*-8,15-Isopimaradien-18-ol	
Calceolaria latifolia	*ent*-Isopimara-8(9),15-dien-18-ol,*ent*-isopimara-8(9),15-dien-19-ol, *ent*-stemara-13(14)-en-19-ol, *ent*-stemara-13(14)-en-18-ol	

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Calceolaria lepida	19-Pentyloxy-*ent*-pimar-15-en-9α-ol, lapidate, *ent*-pimara-9 (11), 15-dien-14-ol, *ent*-pimar-15-en-9α,19-diol, *ent*-stemar-13(14)-en-19-ol, methyl *ent*-stemar-13(14)-en-19-oate, methyl 19-malonyloxy-*ent*-pimar-15-en-9α-ol	
Calceolaria pinifolia	19-Malonyloxy-*ent*-iso-pimara-8(9),15-diene, methyl 19-manoyloxy-*ent*-iso-pimara-8(9),15-diene, 4-*epi*-dehydroabietinol, *ent*-iso-pimara-9(11),15-dien-19-ol, dehydroabietic acid (**43**), dehydoabietinol, malonyloxy-8,11,13-abietatriene, 8,15-iso-pimaradien-19-ol, methyl 19-malonyloxy-*ent*-iso-pimara-9(11),15-diene,19-malonyloxy-*ent*-iso-pimara-9(11),15-diene	Antimicrobial, antiMRSA, astringent, bactericidal, stomachic, sweeteners
Calceolaria talcana	Diterpene mixtures	Insecticide
Callicarpa candicans (fish killing dynamite)	Callicarpone	Antiasthma, antimicrobial, fish-killing, insecticidal For abdominal troubles, amenorrhea, depuration, fever, emmenagogue, skin diseases
Callicarpa macrophylla	Macrophypene A (**95**), B-E, calliphyllin, 14α,18-dihydroxy-7,15-iso-pimaradiene, 8α,9α,13α,14α-diepoxyabietan-18-oic acid, 7α-hydroxydehydroabietic acid, 7-oxodehydroabietic acid, abieta-8,11,13,15-tetraen-18-oic acid, 17-acetoxy-16β-hydroxykaur-3-one, *ent*-16α,17-dihydroxy-kauran-3-one, 3-oxoanticopalic acid	Fruit (sweet and succulent) Nervous growth factor stimulant For diarrhea, dysentery, fever, gastrointestinal bleeding, indigestion, rheumatism, stomachic
Callitris columellaris	Sandaracopimaric acid (**35**), (*Z*)-communic acid, (*E*)-communic acid (**3**), isopimaric acid, 7-oxo-4-epidehydroabietic acid, labda-8(17),13(16), 14-trien-19-oic acid	Cosmetic, perfumery Antianxiety For aromatherapy, cold, cramps, cuts, sores, stomachic
Callophycus serratus (red algae)	Bromophycolides A-U, debromophycolide A, callophycoic acids A-H, callophycols A, B	Antibacterial, anticancer, antifungal antimalarial, antitubecular

Calocedrus formosana	(*E*)-Communic acid (**3**) isocuressic acid, 15-acetoxycommunic acid, agathoral, pinosolide acid, 13S-labda-8(17),14-dien-13*Z*-*p*-hydroxy cumanoxy-19-ol, 16-hydroxylabda-8(17),13-diene-15,19-dioic acid butenolide, sugiol	Anti-inflammatory, antitumor
Calocedrus macrolepis	Calomacrins A-C, labdanes, 15-methoxy-pinusolidic acid, lambertianic acid, agatholol, 15,16-dihydroxy-8(17), 13*E*-labdadien-19-oic acid	Antifungal, cytotoxic (A-549, HL-60, MCF-7, SMMC-7721, SWe80 cancer cell lines)
Canabalia gladiata	Gibberellin A_{21}, gibberellin A_{59}, canavalisoide, gladiatosides A_1-A_3, B_1-B_3 C_1, C_2	Vegetables, beverage (herbal tea) Anti-inflammatory For abdominal dropsy, ache, asthma, atopic coughs, dermatitis, dysentery, epilepsy, headache, inflammatory diseases, intercostal neuralgia, kidney disease, kidney-related lumbago, obesity, schizophrenia, stomachache, swelling vomiting
Canistrocarpus cervicornis	4*R*,9*S*,14*S*-4α-Acetoxy-9β,14α-dihydroxydolast-1(15),7-diene (**96**)	Antitoxin (snake venom)
Caryopteris divaricata	Clerodin-I, caryoptin, dihydrocaryoptin, cledorin hemiacetal, caryoptin hemiacetal, caryopinol	Antifeedant
Caryopteris terniflora	*ent*-7β,11α,14-Trihydroxy-11β,20-epoxy-kaur-16-en-15-one-18-al, *ent*-7β, 14-dihydroxy-11α-methoxy-11β-20-epoxy-kaur-16-en-15-one-16-al	Antifungal, antitumor For cold, headache, rheumatic pains, scrofula
Casearia corympsa	18,19-Diacetoxy-3,13(16), 14-clerodatrien-2-one	
Casearia graveolens	Graveospene A -I	Cytotoxic (HepG2)
Casearia grewiifolia	Caseargrewiins A-D, *rel*-(2*S*,5*R*,6*R*,8*S*,9*S*,10*R*, 18*S*,19*R*)-18,19-diacetoxy-18,19-epoxy-6-methoxy-2-(2-methylbutanoyloxy)-cleroda-3,13(16),14-triene, *rel*-(2*S*,5*R*,6R,8S,9S,10R, 18S,19R)-18,19-diacetoxy-18,19-epoxy-6-hydroxy2-(2-methylbutanoyloxycloreda-3,13 (16),14-triene	Antifungal, antimicrobial antitumor, cytotoxic (KB, BC1, NCI-H187), febrifuge, tonic
Casearia pitumba	18,19-Epoxy-3,13(16),14-clerodatriene-2,6-hydroxy-18,19-diacetate (=pitunbin)	

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Casearia sylvestris	Casearins B, G, U, V, *ent*-kaurane glucosides, sylvestrisides A, B, (−)-hardwickic acid, (−)-patagonic acid, *ent*-kaur-16-ene-3*β*,18-diol, 15-hydroxy-3-cleroden-2-one	Analgesic, anticlastogenic activities, anti-inflammatory, anti-snake venom, antitumoral, antiophidian, antiulcer, DNA-modifying activities For appetite suppressant, diuretic, weight loss product, snake bite, **t**rypanocidal
	Casearins B	Reaction oxygen species (ROS) production inhibition
	Oxygenated tricyclic clerodanes	Cytotoxic (Sarcoma 180, B-16/F-10)
Casimiella ampla	Humirianthol	
Casimiella rupestris	Humirianthenolide A-F, casearupestrins A−D, 2,7-di-*O*-acetyl-casearupestrin A, 2,6-di-*O*-acetyl-casearupestrin D, doxorubicin	Cytotoxic (MDA/MB-435: melanoma; SF-295 glioblastoma cancer cell lines)
Caulerpa brownie (green algae)	Cyclic, acyclic diterpenoids	
Caulerpa lentillifera (green algae: Umibudo)	Phytol, phytadienes, unidentified terpenoids	Foods, salads Antimicrobial, antioxidant
Cedrus atlantica	Sandaracopimaric acid, abietic acid (**2**), iso-pimaric acid, levopimaric acid, palustric acid, dehydroabietic acid (**43**), neoabietic acid, 18-norabieta-8,11,13-trien-4-ol, 7-oxodehydroabietinol, 8,11,13-abietatriene-15,18-diol, 7α-hydroxydehydroabietinol, 8,11,13-abietatriene-7α-ol	Flavoring agent Antibacterial
Cedrus deodora	8,11,13-Abietatriene-7α, 18-diol, 7β,15-dihydroxy-8,11,13-abietatrien-18-oic acid	
Celastrus hypoleucus	7-Deoxynimbidiol	Cytotoxic (A549, CNE, MCF, HCT116, HeLa)
Ceriops tagal	Tagakenes A-F	Cytotoxic (a panel of tumor cell lines)
Chamaecyparis formosensis	Formosanoxide, formosanolide, formosanone, formosanic acid, 12-hydroxy-6,7-seco-8,11,13-abietatriene-6,7-dial (**97**)	Compound flavor Antifungal, antimicrobial, larvicidal (mosquito), NO production inhibitory
Chamaecyparis nootlatensis	8-epi-Manoyl oxide, 8,13-diepimanoyl oxide	

Chamaecyparis obtusa	(*E*)-communol, ferruginol, hamaecydin, 12-hydroxy-6,7-secoabieta-8,11,13-triene-6,7-dial, hinokione, 13-*epi*-trulosal, 13-*epi*-cupressic acid, 13-*epi*-truolsol, hinokiol, 3-*epi*-triptobenzene, 1α,2α-epoxyhinokione (**98**), camaecydin (**99**)	Compound flavor, soap flavor, bath additives Anticancer, antifeedant, antifungal, cytotoxic (BGC-323, Hela, A549 cancer cell lines), bactericidal, insecticide
Chamaecyparis pisifera	8,11,13-Abietatriene-12,15-diol (=15-hydroxyferruginol), 20-nor-1(10),2,8,11,13-abietapentaen-12-ol, 8,11,13-abietatriene-12,20-diol, pisiferol, pisiferal, pisiferic acid, *O*-methoxypisiferic acid, pisiferanol, pisiferadiol (=20*S*-hydroxypisiferanol), 12-deoxypisiferanol, pisiferin, iso-pisiferin, 1β-hydroxyisopisiferin, 12-hydroxy-20-*nor*-abieta-1(10),2,8,11,13-pentaene, (10*S*,12-dihydroxy-9(10 → 20)-*abeo*-abieta-8,11,13-triene), 1β-hydroxy-iso-pisiferin (=1*R*,12-dihydroxy-9(10 → 20)*abeo*-abieta-8,10(20),11,13-tetraene), dimethylamine salt of *O*-methylpisiferic acid, rel-(8*R*,10*R*,20*S*)-8,10,20-trihydroxy-9(10→20)-abeo-abieta-9,3-dien-12-one, 8(14),15-pimaradien-19-oic acid	Antibacterial, antimicrobial
Chasmanthera dependens	1β,4α,5α,12α*H*,15,16-Epoxy-4,8-dihydroxy-2,13(16)-clerodatriene-17, 12:18,1-diolide (=8β-hydroxycolumbin)	Androgenic anticoagulant, antimicrobial, antioxidant, fertility enhancing, larvicidal, thrombolytic
Chiliotrichium rosmarinifolium	*ent*-15,16-Epoxy-3,4-seco-4,13(16)14-halimatrien-3-oic acid (=secochilotrin), 8-hydroxy-7-labdan-15-oic acid, geranyl geraniol derivatives, 3-iso-labdanes, 3-seco-iso-labdandes, *Z*-clerodanes	
Chloranthus henryi	Henrilabdane C	Cytotoxic (BEL-7402: hepatoma; BGC-823: gastric carcinoma; HCT-8: colon cancer cell lines)
Chrisothamnus nauseosus	9,13-Epoxy-18-hydroxy-7-labden-15-oic acid (=18-hydroxygrindelic acid), 9,13-epoxy-18-oxo-7-labden-15-oic acid (= oxogrindelic acid), 9,13-epoxy-18-(methylpropanoyl)-7-labden-15-oic acid, 9,13-epoxy-18-succinoyl-7-labden-15-oic acid, 3α-hydroxy-7,13*E*-labdadien-15-oic acid, sempevirenic acid, 3β-hydroxy-7,13*E*-labdadien-15-oic acid, 3α-hydroxy-7,13*E*-labdadien-15-oic acid, 3-oxo-7,13*E*-labdadien-15-oic acid	Chewing gum For chest pains, colds, coughs, diarrhea, fevers, internal injuries, menstrual cramps, stomachache, toothache

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Chromodoris kuniei	Spogiane diterpenoids	Cytotoxic (NBT-T2)
Chromolaema laevigata	*ent*-6β,7α-Dihydroxy-3,13*Z*-clerodadien-15-oic acid (=6β,7α-dihydroxykolavenic acid), *ent*-6β-angeloyl-7α-acetoxy-3,13*Z*-clerodadien-15-oic acid	Analgesic, antifungal, anti-inflammatory, purgative For influenza, intestinal disorders, itching, menstrual regulator, stomatitis, swelling, toothache, thrush, pruritus, ulcerative
Cinnamomum cassia	Cinncassiol A (**100**), cinncassiol-A-19-*O*-β-*D*-glucoside (**101**), anhydrocinnazeylanol, anhydrocinnazelanine, cinnacassiol C (**102**), cinncassiol C-19-*O*-β-*D*-glucoside, cinncassiol C_2 , cinncassiol C_3, cinncassiol D_4 **(103)**, cinncassiol D_4-19-*O*-β-*D*-glucoside (**104**), cinncassiol D_1, cinncassiol D_1-19-*O*-β-*D*-glucoside, 4β-hydroxycinncassiol cinncassiol D_2, 4β-hydroxycinncassiol D_2-19-*O*-β-*D*-glucoside, cinncassiol D_3, cinncassiol E	Food flavor, beverages (herbal tea), cookies, bread, chewing gum, crude drug Analgesic, antibiotic, antiinfectious, anti-inflammatory, antineuralgic, antiseptic, antispasmodic, antiviral, aphrodisiac, bactericidal, cholagogues, cicatrisant, decongestant, expectorant, digestive, emmenagogue, febrifuge, hepatic, hypotensive, insecticide, muscle relaxant, nervine, sedative, stimulant, stomachic, sudorific, tonic, vermifuge
Cinnamomum zeylanicum	Cinnzeylanol, cinnzeylanine, cinncassiol B, cinnzeylanol-19-*O*-β-*D*-glucoside	Beverages, food flavor, and flavor and aroma enhancer for beverage, cookies, bread, chewing gum, source, spice Analgesic, anti-Alzheimer's disease, antiaging, antibiotic, antidiabetic, antifungal, antioxidant, antiparasitic, antiseptic, antispasmodic, aphrodisiac, astringent, bactericide, cardiac, carminative, emmenagogue, insecticide, nephropathy, stimulant, stimulating appetite, stomachic, tonic, vermifuge For cold, diarrhea, headaches, respiratory complaint, muscular aches and pain, stomach upset

Cistus albidus	13-*epi*-Manoyl oxide	Antimicrobial
Cistus creticus	Manoyl oxide, 13-*epi*-manoyl oxide, 8,13-epoxy-15,16-dinorlabda-12-ene, 3β-hydroxy-13-*epi*-manoyl oxide, labd-7,13-dien-15-ol, labd-7,13-dien-15-yl acetate, 3β-acetyl-13-*epi*-manoyloxide, labd-13-en-8α,15-diol, labd-13-en-8α-ol-15-yl acetate	Anthelmintic, antibacterial, antifungal, antioxidant, cytotoxic (cervix, breast, melanoma cancer cell lines)
Cistus incanas (Ladano)	(5,8,9,10*R*)-Labd-13*E*-ene-8α,15-diol, (5,8,9,10*R*)-labd-7,13*E*-dien-15-ol, (5,8,9,10*R*)-labda-7,13*E*-15-yl acetate, 8,13-epoxylabd-14-ene, 13-*epi*-8,13-epoxylabd-14-ene, labd-14-ene-8,13-diol, 13-*epi*-sclareol	Beverage (herbal tea) Antibacterial, antifungal, antiviral, antioxidant, antiviral, cytotoxic (KB, P-388, NSCLC-N6 cancer cell lines), myorelaxant
Cistus labdaniferus	Dehydroabietic acid (**43**), 8-abieten-18-oic acid (**105**)	Antimicrobial, anti-leishmanial, antimultidrug resistant For malarial symptoms, fatigue, muscular aches
Cistus ladanifer	6-Acetoxy-7-oxo-8-labden-15-oic acid, 7-oxo-8-labden-15-oic acid, oxocativic acid	Antibacterial, antifungal, antioxidant, antiviral, analgesic effects, spasmolytic
Cistus laurifolius	6β,8-Dihydroxy-*ent*-13*E*-labden-15-oic acid (=laurifolic acid), salmantidiol, salmantic acid, methyl salmantiate	Antioxidant
Cistus monspeliensis	Cistodiol, cistodioic acid	Antiaging, antibacterial, anticancer, antioxidant, fatigue, isogenic, malarial symptoms, muscular aches, myorelaxant, spasmolytic
Cistus mospeliensis	13-*epi*-Manoyl oxide, manoyl oxide	Cytotoxic
Cistus palhinhae	*ent*-5β,10β,13ξ-2-keto-3-cleroden-15-oic acid	For dementia, dental decay, elephantiasis, epilepsy, fatigue, filariasis, gastrointestinal, malarial symptoms, muscular aches, parasitic infections, respiratory disorders
Cistus parviflorus	Manoyl oxide, 13-*epi*-manoyl oxide	Antioxidant
Cistus populifolius	*iso*-Dehydropopulifolic acid (**106**), *epi*-hydroxy-populifolic acid (**107**), β-methoxypopulifolic acid (**108**), hydroxypopulifolic acid (**109**), α-methoxypopulifolic acid (**110**)	Analgesic, antibacterial, antioxidant, antiviral, spasmolytic

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Cistus salviifolius	Manoyl oxide, 13-*epi*-manoyl oxide, *Z*-ferruginol, iso-dehydro-populifolic acid, epi-hydroxypopulifolic acid, β-methoxypopulifolic acid, hydroxypopulifolic acid, α-methoxypopulifolic acid	Antibacterial, anticancer, antifungal, antioxidant For colds, diarrhea, digestive, fevers, inflammatory, rheumatism, skin diseases
Clerodendron brachyathum	Clerodinin A, B, D, clerodin, clerodinion C, clerodiol	Antihypertensive, diuretic
Clerodendron calamitosum	*ent*-4β,18:11*R*,16:15,16*R*-Triepoxy-14-clerodene-3α,6β,19-triol (=3-epicaryoptin), caryopinol, caryoptin, *ent*-4β,18:11*R*,16:15,16*R*-triepoxy-14-clerodene-3α,6β,19-triacetate	Antifeedant
Clerodendron inerme	*ent*-3,13-Clerodadien-16,15-olide-18-oic acid (=clerodermic acid, inermes A, inermes B, 14,15-dihydro-15β-methoxy-3-epicaryoptin, 14,15-Dihydro-15-hydroxy-3-*epi*-caryoptin	Antiplasmodial, antifeedant (mosquito)
Clerodendron infortunatum	4β,18:11*R*,16*R*;15,16*R*-Triepoxy-14-clerodene-6β,19-diacetate (=clerodin)	Anticonvulsant, antidandruff, antidiabetic, antifeedant, antihyperglycemic, antipyretic, ascaricide, insecticidal, laxative, colic, tumors, vermifuge For diarrhea, gravel, headache, liver disorders, malaria, scabies, scorpion, sting and snake bite, skin diseases sores, spasm, tumors
Clerodendron trichotomum	Clerodendrin A (= (2*R*,3*S*,4*R*,5*R*,6*S*,9*R*,10*R*, 11*S*,13*S*,16*R*)-6,19-diacetoxy-3-[(2*R*)-2-acetoxy-2-methylbutyryl-oxy]-4,18:11,16:15,16-triepoxy-7-clerodene-2-ol (=clerodendrin A) (**111**), 15,16-dehydro-teuvincenone G, trichotomin A, 2α-hydrocaryopincaolide F, villosin C, 15-dehydro-17-hydroxycyrtophyllone A, demethylcryptojaponol, 6β-hydroxydemethylcryptojaponol	Foods (leaves) Analgesic, antihypertensive, anti-inflammatory, antioxidant, antirheumatic, NO production inhibitory, sedative
	Trichotomone	Cytotoxic (A549, GC-832, Jurkat, 293T WT)

Clerodendrum bungei	Abietane diterpenoids, uncinatone	Insect antifeedants, cytotoxic (B16: murine melanoma, HEK-293: human epithelial kidney; HGC-27: human gastric cancer cell lines) For beriberi, boils, cuts, eczema, hemorrhoids, hypertension, pesticidal, postpartum hemorrhage, prolapse of the uterus, rheumatism, wounds healing
Clerodendrum kiangsiense	Abeoabietan	Cytotoxic (A-549, HL-50, MCF-7, SMMC-7721)
Cloranthus serratus	Serralabdanes	Antioxidant, NO production inhibitory
Cluytia richardiana	Cluytene C-E, saudin	Antidiabetes, hypoglycemic
Cneorum tricoccon (=Spurge olive)	Cneorubin U, W1, X, Y	Purgative, rubefacient
Coffee seeds	Cafestol (**7**)	Phosphorylation and NO production inhibitory
	Kahweol (**9**)	Cytotoxic (HepG2) Antinociceptive COX-II, inducible NO synthase (iNOS) inhibitory, peripheral
	Cafestol palmitate	
Coffea arabica	Cafestol (**7**), 16-*O*-methylcafestol (**8**), kahweol (**9**), 16-*O*-methylkahweol, cafemines A-G, cafemides A-G, mazambioside (**112**), cafestol palmitate	Beverage (coffee) Antiangiogenic, anticancer, anti-inflammatory, antinociceptive, antiosteoporosis, antitumorigenic, chemoprevention, cytotoxic (HePG2), α-glucosidase inhibitory, hypercholesterolemia, COX-2 and NO synthase (iNOS) inhibitory, NO production, and phosphorylation inhibitory
Coffea canephora (= *Coffea robusta*)	Cafestol (**7**), kahweol (**9**), 16-*O*-methylcafestol (**8**), cafestol palmitate	Food, beverage (coffee) Analgesic, anorexic, antidotal, aphrodisiac, cardiotonic, CNS-stimulant, counterirritant, COX-II and NO synthase (iNOS) inhibitory, cytotoxic (HePG2), diuretic, galactagogic, α-glucosidase inhibitory, hypercholesterolemia, hypnotic, nervine immune protective, NO production and phosphorylation inhibitory, uretic effects, vomiting

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
		controls For asthma, atropine poisoning, fever, flu, headache, immune protective, jaundice, malaria, migraine narcosis, nephrosis, opium poisoning, sores, vertigo
Coffea congensis	Cafestol (**7**), kahweol (**9**)	Beverage (coffee) Anticarcinogenic, serum cholesterol raising
Coffea liberica var. *dewevrei*	Cafestol (**7**), kahweol (**9**), 16-*O*-methylcafestol (**8**)	Beverage (coffee) Anticarcinogenic For serum cholesterol raising
Coffea liverica var. *liberica*	Cafestol (**7**), kahweol (**9**)	Beverage (coffee) Anticarcinogenic For headaches, serum cholesterol raising, sore eye
Coffea pseudozamguebariae	Cafestol (**7**), kahweol (**9**), mazambioside (**112**)	Beverage (coffee), bitterness Anticarcinogenic For headaches, serum cholesterol raising
Coffea racemsa	Cafestol (**7**), kahweol (**9**),	Beverage (coffee) Anticarcinogenic For headaches, serum cholesterol raising
Coffea salvatrix	Cafestol (**7**), kahweol (**9**),	Beverage (coffee) Anticarcinogenic For headaches, serum cholesterol raising
Coffea sessilifora	Cafestol (**7**), kahweol (**9**),	Beverage (coffee) Anticarcinogenic For headaches, serum cholesterol raising
Coffea stenophylla	Cafestol (**7**), kahweol (**9**), 16-*O*-methylcafestol (**8**), 16-*O*-methylkahweol	Beverage (coffee), Anticarcinogenic For headaches, serum cholesterol raising

Coffea vianneyi	Mascarol (**113**), mascaroside (**114**)	Beverage (coffee)
Coleus aquatic	6,11,12,14,16-Tetrahydroxy-5,8,11,13-abietatetraen-7-one (=coleon C), 11,12,14,16-tetrahydroxy-8,11,13-abietatriene-6,7-dione (=coleon D), 6,11,12,14-pentahydroxy-5,8,11,13-abietatetraen-7-one (=coleon U)	
Coleus argentatus (=*Plectranthus argentatus*)	6β-Formoxy-7,12-trihydroxy-8,12-abieta-diene-11,14-dione (=6β-formoxy-7α-hydroxyroyleanone, 6β,7α,12-trihydroxy-8,12-abietatriene-11,14-dione (=6β,7α-dihydroxyroyleanone), 7α-acetoxy-6β,12-dihydroxy-8,12-abietadiene-11,14-dione (=7α-acetoxy-6β-hydroxyroyleanone), 7α-fromyloxy-6β-hydroxyroyleanone, 8α,9α-epoxy-6,12-dihydroxy-5,12-abietadiene-7,11,14-triene (=8α,9α-epoxycoleon U quinone)	Antimicrobial For sensor
Coleus aromaticus (*Karpurvalli*)	Phytol	Functional foods, flavoring for stuffing of meat and poultry beef and lambs Antimicrobial, antioxidant
Coleus carnosus (=*Plectranthus amboinicus*)	6β,20-Epoxy-6,11,12-trihydroxy-8,11,13-abietatrien-7-one (=carnosolone), 3β,6,11,12,14-pentahydroxy-5,8,11,13-abietatetraen-7-one (=coleon S), coleon U, royleanone, 6,7-dehydroroyleanone, 7α-acetyloxyroyleanone, horminone, 6β-hydroxyroyleanone, 7α-acetyloxy-6β-hydroxy-royleanone, 6β,7α-dihydroxyroyleanone, 7α-acetyloxy-6β,20-dihydroxyroyleanone, coleon V, 6α-carnosolone, 12-trihydroxy-6,20-epoxymethanoabieta-8, 11, 13-trien-7-one	Food (raw or cooked, spice, poterb) Anti-inflammatory, antimicrobial, antiseptic, antitumor, antiviral, antituberculosis, bronchodilator, insect repellent For asthma, bronchitis, burns, cholera, colds, congestive, convulsions, cough, digestive problem, epilepsy, fevers, headaches, heart failure, meningitis, menstrual pain, skin allergy, sore, ulcers, urinary diseases, wound healing
Coleus coerulescens	Coleon O, 12-deacetoxycoleon R, 17(15→16)abeo-3α,18-diacetoxy-6β,7α,16-trihydroxyroyleanone, 17(15→16),9(4→3)-bisabeo-6,7,16-trihydroxy-royleanone, 3α,18-deacetoxy-6β,7α,16-trihydroxyroyleanone	
Coleus forskohlii	Forskolin (**10**), coleonone, 8α,13*R*-epoxy-14-labden-15-one, 8,13-epoxy-9α-hydroxy-14-labden-15-one (=coleol), coleonol F, coleonols B, D, F, coleonol E (**115**), 8,13-epxy-6β-hydroxy-7β-acetoxy-14-labden-11-one, 8,13-epoxy-6β-hydroxy-14-	*Herbal medicines Adenylyl cyclase effect, antiasthma, antibacterial, antidepressant, antidiabetic, antidrepanocytary, antihistamine, antihypertensive, anti-inflammatory, antimetastatic, antiproliferative,*

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
	labden-11-one, coleosol, folskolins G-J, 13-episclarenol, folskoditerpenosides A, B, 14-deoxycoleon U, demethylcryptojaponol	*antioxidant, breast milk-stimulant, bronchodilation, cancer prevention, cardiovascular ailments, cardiovascular cloning and molecular genetics, cytochrome P450 and nuclear receptor effect, fat burning supplement, hepatoprotective effect, insulin and thyroid hormone secretion increasing, NO scavenging, platelet aggregation, relaxative, renal, thyroid effects, vaculogenic properties* *For angina, eczema, hypothyroidism, heart health, psoriasis, weight loss*
Coleus fredericii	Fredericones A-D	
Coleus igniarius	Coleons A, B	For inflamed eyes, pain, skin condition
Coleus kilimandschari	Coleon F	Antifungal, antimicrobial
Coleus somaliensis (=*Plectranthus somaliensis*)	3β-Acetoxy-6,11,12,14, 16-tetrahydroxy-5,8,11,13-abietatetraen-7-one (=coleon H), 3β-acetoxy-11,12,14,16-tetrahydroxy-8,11,13-abietatriene-6,8-dione (= coleon I), coleon J, 3β,17-diacetoxy,11,12,14,16-tetrahydroxy-8,11,13-abietatriene-6,8-dione (=coleon K), coleon O, 19-acetoxycoleon Q	
Coleus xanthanthus	Coleon U-11-acetate, 16-acetoxycoleon U-11-acetate, xanthathusins F-K, coleon U, 16-O-acetylcoleon C, coleon U quinone, 8α,9α-epoxycoleon U-quinone, xanthanthusin E	Cytotoxic (K562 human leukemia cell line) For arthritis, colds, coughs, injuries, neurasthenia, rheumatism, scabies, snake bites, tuberculosis
Coleus zeylanicus	6β,7β-Dihydroxy-royleanone,7β-acetoxy-6β-hydroxyroyleanone, 7α-acetoxy-6β-hydroxyroyleanone	For diarrhea
Conyza aegyptia	16,15-Epoxy-3β,4α,7β, 10β-tetrahydroxy-12β*H*,13(16),14-clerodadien-20,12-olide	
Conyza blini	14,15-Dinor-labdan-13-one-8-*O*-*α*-L-arabinopyranosyl-2,8,19-trihydroxy-3,13-cleroda-dien-15,16-olide (=blinin)	For chronic bronchitis and other inflammatory diseases, gastroenteritis

Conyza pyrifolia (=*Microgrossa pyrifolia*)	1-Acetyl-6*E*-geranygeraniol-19-oic acid, 6*E*-geranylgeranyol-19-oic acid , (*E*)-phytol, 3α,4α:15,16-dieoxy-10-oxo-5,10-seco-13(16),14-clerodadien-20,12-olide (=10α-angelyoyl-10-desoxopyrrhopappolide	Antimalarial, anti-inflammatory For fever, diarrhea, sores
Conyza scabrida	*ent*-19-Acetoxy-15,16-epoxy-5,10-seco-1,3,5,19*Z*,13(16),14-clerodapentaen-18-oic acid (=19-acetoxyseco-nidoresedaic acid), 5α-hydroxy-5,10β-dihydro pintzianic acid, 5α-hydroxy-1,2-dehydro-5,10-dihydropintzianic acid	
Conyza stricta	Labda-8(17),13-dien-15-dioic acid butenolide, 16-hydroxylabda-8(17), 13-dien-15,19-dioic acid butenolide, *ent*-15,16-epoxy-5,10-seco-1,3,5(19),13(16),14-clerodapentaen-18-oic acid (=strictic acid), 12*R*-hydroxystrictic acid	Anti-inflammatory, anthelmintic, diuretic For cancerous, liver, and urinary disorders, chickenpox, diarrhea, dysentery, small pox, stomach ulcers
Conyza welwitschii	15,16-Epoxy-5,10-seco-1,3,5(19),13(16),14-clerodapentaene-17,18-dioic acid, 12*R*-hydroxystrictic acid, 17α-hydroxy-12β,17-epoxystrictic acid	
Copaifera cearensis	Epuruic acid, cativic acid, kolavenic acid, crolechinic acid, haplociliatic acid, labdanolic acid, patagonic acid, (-)-hardwickiic acid	NO production inhibitory
Copaifera coulteri	15,16-Epoxy-2-hydroxy-3,13(16),14-clerodatrien-18-oic acid (=2β-hydroxyhardwickiic acid	
Copaifera duckei	(-)-Hardwickiic acid, kaur-16-en-19-oic acid (=kaurenic acid), *ent*-polyalthic acid	Anti-inflammatory, antinociceptive, antiproliferative, antitrypanosomal
Copaifera langsdorffii	(-)-Hardwickiic acid , kaur-16-en-19-oic acid (=kaurenoic acid), *ent*-8(17)-13*E*-labdadien-15-oic acid (=copalic acid), acetoxycopalic acid (=3α-alepterolic acid acetate, *ent*-agathic acid, hydroxycopalic acid (=3α-alepterolic acid), 3-hydroxy-14,15-dinorlabd-8(17)-en-13-one, kaur-16-ene, manool (**34**), sclareol (**22**)	Food additive, flavoring agent in foods and beverages Anodyne, antacid, antibacterial, antifungal, anti-inflammatory, antileishmanial, antimicrobial, antiproliferative, antipsoriatis, astringent, astroprotective, cytostatic, demulcent, digestive, disinfectant, diuretic, expectorant, insecticidal, laxative, smooth muscle relaxant, vermifuge, vulnerary, wound healing
Copaifera lucens	Copalic acid, *ent*-polyalthic acid	Antibacterial, antileishmanial

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Copaifera martii	Kovalenic acid, kaur-16-en-19-oic acid (=kaurenic acid)	Antibacterial, anticancer (cervical carcinoma), anti-inflammatory, antileishmanial
Copaifera multijuga	Copalic acid, 3-hydroxycolalic acid, acetoxycopalic acid, 18-hydroxy-8(17),13-labdadien-15-oic acid (=copaiferolic acid)	Antibacterial, antiblenorragic, anticancer, anticough, anti-inflammatory, antileishmanial, antinociceptive, antiproliferative, antirheumatic, antiseptic, antitetanis, diuretic, insecticidal, laxative
Copaifera officinalis (Copaiba balsam)	15,16-Epoxy-3,13(16),14-clerodatrien-18-oic acid (=copaic acid), (-)-hardwickiic acid, kaur-16-en-19-oic acid (=kaurenic acid), copalic acid	Food additive, flavoring agent Antibacterial, anticancer, antifungal, anti-inflammatory, antimicrobial, antileishmanial, antiproliferative, astringent, cytostatic, demulcent, digestive, disinfectant, diuretic, expectorant, laxative, vermifuge, vulnerary. topical wound healer For bronchitis, chilblains, eczema, insect bites, psoriasis, sinusitis, sores, urinary tract and reproductive system conditions such as cystitis, kidney, bladder infections, vaginal discharge and gonorrhea, and tonsillitis, tuberculosis
Copaifera paupera	Copalic acid, kaur-16-en-19-oic acid (=kaurenic acid), methyl copalate, agathic acid 15-methyl ester, agathic acid 15,19-dimethyl ester, *ent*-polyalthic acid, *ent*-pinifolic acid, methyl 3β-hydroxylabda-8(17),13-dien-15-oate, methyl 18-hydroxycopaiferolate, 14,15-bisnorlad-8(17)-en-13-one, 16β-kauran-19-oic acid	Antibacterial, antileishmanial, antiproliferative
Copaifera reticulata	14-Clerodatrien-18-oic acid (=hardwickiic acid), *ent*-kaur-16-en-19-oic acid (**47**), *ent*-8(17)-13*E*-labdadien-15-oic acid (=copalic acid), acetoxycopalic acid (=3α-alepterolic acid acetate), *ent*-agathic acid, hydroxycopalic acid (=3α-alepterolic acid), 3β-hydroxylabdan-8(17)-en-15-oic acid, *ent*-	Acaricidal, antibacterial, antinociceptive, antifungal, anti-inflammatory, antileishmanial, antiproliferative, antitrypanosomal, anxiolytic, insecticidal (mosquito larvicidal), neuroprotective

	15,16-epoxy-13(16),14-clerodadien-18-oic acid, 13*S*-7-labden-15-oic acid, *ent*-8(17),13-labdadien-15,19-dioic acid (=agathic acid)	
Copaifera scabrida	19-Acetoxy-1,2-dehydro-hautriwaic acid	
Crossopetalum gaumeri	Crossogumerin B, nimbiol	Cytotoxic (HeLa)
Crossopetalum uragoga	Salvadoriol, ferruginol, triptinin, hypolide, carnosol (**16**), carnosol diacetate	Antitumor promoting, antioxidant
Croton argyrophylloides	15,16-Epoxy-4-hydroxy-13(16),14-clerodadiene-3,12-dione, 15-oxo-kaur-16-en-18-oic acid	Antispasmodic, cytotoxic (HL-60: leukemia; MPAMB-435: melanoma; SF-295: glioblastoma; HCF8: colon cancer cell lines)
Croton cajucara	Cajucarin A, (*E*)-cajucarin B, (*Z*)-cajucarin B, *ent*-(4α*H*,5β-12β*H*)-5,16-epoxy-19-nor-2-oxo-13(16),14-clerodadien-20,12-olide (=(*E*)-crotonin), (*E*)-dehydrocrotonin	Analgesic, antidiabetes, antihypercholesterolemic, antileishmanial, antinociceptive, antiulcerogenic, gastroprotective, cytotoxic for Ehrlich carcinoma, human K52 leukemia and peripheral blood mononuclear cell, antilipotropic, NO production inhibitory For diarrhea, liver inflammation
Croton californicus	(-)-Methyl barbascoate, *ent*-(5β,12α*H*)-15,16-epoxy-3,13 (16),14-clerodatrien-17,12-olid-18-oic acid (=barbasoic acid)	Antimalarial For rheumatic pain Stupefy fish
Croton campestrs	*ent*-15,16-Epoxy-20-hydroxy-2-oxocleroda-3,13(16),14-triene (=velamolone), *ent*-15,16-epoxy-2-oxocleroda-3,13 (16),14-triene (=velamone)	
Croton caudatus	Crotoncaudin, *ent*-8*S*,10*R*-15,16-epoxy-19-norcleroda-4,11,13(16),14-tetraene-18,6α:20,12-diolide (=isocrotocaudin), teucvidin, *ent*-(5β,12α*H*)-15,16-epoxy-19-nor-4,11, 13(16),14-clerodatetraene-18,6α:20,12-diolide (= 3,13(16),14-clerodatrien-17,12-olid-18-oic acid), crotocaudin, isocrotocaudin, crotusins A-C	Cytotoxic (A549, Hela, Hep G2, MPA-MB 231, MCF-7 human tumor cell lines) For colds, diuretic, fever, hypothermic, hypotensive, insecticidal, smooth muscle relaxant, stomach disorders, toxicity assessment
Croton caudatus var. *tometosus*	Crotontomentosins A-F, *ent*-15,16-epoxyhalim-5(10),12 (16),14-trien-18-oic acid, margocin, pomiferin D, E, 15-hydroxy-7-oxoabieta-8,11,13-triene	Cytotoxic (A549, Hela, Hep G2, MDA-MB-231 cancer cell lines)

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Croton corylifolius	Corylifuran, *ent*-(4α*H*,12α-)-15,16-epoxy-3-oxo-13(16),14-clerodadien-20,12-olide-18,19-dioic acid (=corylifuran)	
Croton crassifolius	Crassifolin A-G, spiro[furan-3-(2*H*),1'(2'*H*)-naphthalen)]-5'-carboxylic acid, chettaphanin, penduliflaworosin, 1,4-methano-3-benzoxepin-2(H)-one, isoteucvin, teucvin, crassifolin A-D, J-O, clerod-5(10)-ene-19,6β; 20,12-diolide, chettaphanin I, chettaphanin II, crassifolusin A	Anti-Herpes simplex, antiangiogenic
Croton damayeshu	Crodamoids A-J, 13-*O*-(2-methylbutyryl)-4-deoxy-4α-phorbol, 12-*O*-tigloyl-4-deoxy-4α-phorobol-13-acetate, 12-*O*-tigloyl-4-deoxy-4α-phorbol-13-2-methylbutyrate, 12-*O*-angeloyl-4-deoxy-4α-phorbol-13,2-methybutyrate, 4α-deoxyphorbol-12-tiglate-13-isobutyrate	Antiangiogenic, cytotoxic (A549: lung carcinoma; HL-60: human acute myeloid leukemia cell lines)
Croton draco	12,10:15,16-Diepoxy-2-hydroxy-20-oxocleroda-3,13(16),14-trien-18-oic acid, draconin, 15,16-dihydroxy-18-oxocleroda-3,13-diene, 9-acetoxy-vomifoliol, 9(11)-dehydrokaurenic acid, hardwickiic acid	Antitumoral For cough, cut, diarrhea, flu, herpes infections, open sores, oral sores, stomach ulcers, wound healing
Croton eleuteria	*ent*-15,16-Epoxy-7β-acetoxy-3β,4α,12*S*-trihydroxy-13(16),14-clerodadien-20-al (=cascarillin), *ent*-4α*H*-5,16-epoxy-13(16),14-clerodadien-2-one, cascarillin A, C, E-I, eluterins A-J	Antifungal, gastric acid secretion For digestion
Croton haumanianus	Crotocorylifuran, *ent*-15,16-epoxy-3(16),4,14-clerodatrien-20,12-olide 18,19-dioic acid, dimethyl ester, crotocorylifuran, crotohaumanoxide	Edible (stem bark, leaves, fruits) Aphrodisiac, antiepileptic antihypertensive For abortion prevention, blennoragy, constipation, diuretic, edema of the legs and abscesses, epilepsy, gastric diseases, gonorrhea, headache, pain, heartburn, hernia, hypertension, purgative, rheumatism, and painful urination, urinary infections, worm

Croton joufra	Plaunol A, C, swassin	Histaminergic effect, smooth muscle stimulant
Croton lacciferus	*ent*-Kaur-15-en-17-ol, *ent*-kaur-15-en-17-hydroxy-3β-yl acetate, *ent*-kaur-3β,16β,17-triol, *ent*-kauran-16β,17-diol, *ent*-15-kaurene-3β,17-diol	Antifungal, colds, dysentery, fever, skin diseases and lung diseases, tuberculosis
Croton laui	Crotonolide A (**116**), B-J, isocrotonolide B-D, 12-deoxycrotonolide H	Cytotoxic (HL-60, P-388), antimicrobial
Croton lechleri	Korberin A, korberin B, bincatriol, crolechinol	Antibacterial, antifungal, antioxidant, antitumoral, antiviral, CNS depressant, crown gall tumor inhibitory, cytotoxic (CA-9KB), wound healing
Croton lucidus	15,16-Epoxy-19-nor-2-oxo-13(16),14-clerodadien-20,12-olide (=crotonin)	
Croton macrostachys	Crotomacrine	Antibacterial, antifungal, early antigen viral induction stimulation, anti-inflammatory, fish poison, insecticide, laxative, mitogenic
Croton mauritianus	2-*O*-Decanoylphorbol-13-acetate, 12-*O*-decanoyl-7-hydroxy-peroxyphorbol-5-ene-13-acetate	Cytotoxic (chikungunya virus-induced cell death)
Croton megalocarpus	15,16-Epoxy-3,4-dihydroxy-12-oxo-13(16)14-clerodadien-17-oic acid methyl ester (=chiromodine)	Early antigen viral induction stimulation, Epstein-Barr virus activation, mitogenic, molluscicidal
Croton nepetaefolius	1,4-Dihydroxy-2*E*,6*E*, 12*E*-casbatrien-5-one	Antimicrobial
Croton niveus	*ent*-8(17),13-Labdadien-16,15-olid-18-oic acid (=nivenolide)	
Croton nublytatus	15,16-Epoxy-3,8(17), 13(16),14-clerodatetraene-18,19:20,12-diolide (=plaunolide)	
Croton oblongifolius (=*C. roxburghii)*	Labda-7,12*E*,14-triene-17-al, 17-hydroxylabda-7,12(*E*),14-triene, 17-acetoxylabda-7,12*E*, 14-triene, 15-hydroxylabda-7,13*E*-diene-17,12-olide, labda-7,13*E*-diene-17,12-olide, 12,17-dihydroxylabda-7,13*E*-diene	Antimicrobial, antispasmodic, hepatoprotective, histaminerigic, hypotensive, smooth muscle stimulant, tonic For fever, flat worms, dysentery, dysmenorrhea, dyspepsia, infertility, purgative, snake poisoning, wounds

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Croton schiedeanus	12*R*-12-Hydroxy-cascarillone, (*E*)-dehydrocrotonin, (Z)-dehydrocrotonin, 5β-hydroxy-(*Z*)-dehydro-crotonin, methyl (-)-16-hydroxy-19-nor-2-oxo-*Z*-cleroda-3,13-dien-15,16-olide-20-oate, (-)-12,16-dihydroxy-15,16-olide-*Z*-cleroda-3,13-dien-15-oic acid, floridolide A, (+)-15-methoxyfloridolide A, haplopappic acid, (+)-15-hydroxy-*cis*-cleroda-3,13-dien-15-oic acid	Antihypertensive, vasodilator effect
Croton sonderianus	*ent*-(10β,12α*H*)-3,13(16), 14-Clerodatrien-20,12-olid-18-oic acid methyl ester (=sonderianin), 15,16-epoxy-12-hydroxy-3,13(16)14-clerodatrien-18-oic acid (=12-hydroxyhardwickiic acid)	Antimicrobial
Croton sublyratus	2,19-Dihydroxy-3,8(17), 13(16),14-clerodatetraene-18,6:20,12-diolide, (=plaunol C), plaunol A, B, D (=plaunol), plaunol E (=plaunol acetate)	Analgesic antibacterial, antifungal, anticholinesterase, antiulcerogenic, hemorrhagic, toxicity assessment
Croton tonkinensis	*ent*-1α-Acetoxy-7β,14α-dihydroxy-kaur-16-ene-15-one, crotonkinin A, crotonkinins C-J, (16*S*)-*ent*-18-acetoxy-7β-hydroxykaur-15-one, *ent*-18-acetoxy-7α-hydroxykaur-16-en-15-one, *ent*-14β-acetoxy-7α-hydroxykaur-16-en-15-one, *ent*-7α,14β-dihydroxykaur-16-en-15-one, crotonkinensin A, *ent*-7β,18-dihydroxykaur-1-en-15-one, *ent*-15-oxokaur-16-en-18-oic acid, *ent*-18-acetoxykaur-16-en-15-one, *ent*-7β-hydroxykaur-16-en-15-one, *ent*-14β-hydroxykaur-16-en-15-one, *ent*-11α-acetoxykaur-16-en-18-oic acid, *ent*-18-hydroxykaur-16-en-15-one, *ent*-18-acetoxy-7α-hydroxykaur-6-en-15-one, *ent*-18-acetoxy-7,14β-dihydroxykaur-16-en-15-one	Elastase release, superoxide radical inhibition
Croton urucurana	Sonderianin, methyl 12-*epi*-barbascoate	Antidiarrheal
Croton zambesocus	Crotozambefurans A-C, crotocorylifuran	Antibacterial, antifungal, antiviral, protease inhibitory

Croton zambesocus	*ent*-18-Hydroxy-trachyloban-3-one	NO production inhibition
Cryptomeria japonica	8,(14),15-Isopimaradien-18-ol (=isopimarinol), 11-hydroxy-12-methoxy-8,11,13-abietatrien-7-one (=cryptojaponol), ferruginol, 7-oxoferruginol, xanthoperol, sandaracopimaradien-18-ol, 15-kaurene, sandaracopimaric acid, sandaracopimaradiene-3β-ol, sugiol, secoferruginol, sandaracopimaric acid, sandaracopimaradiene-3β-ol	Antimicrobial, immune protective For depurative, gonorrhea
Cunninghamia lanceolata	Lanceolatanol hydroperoxide, epilanceolatanol hydroperoxide, lanceolatanoic acid hydroperoxide, epilanceolatonic acid hydroperoxide, lanceolatanol, lanceolatanoic acid, 11-acetoxylanceolatanoic acid methyl ester	Cytotoxic (PC-3: human prostate cancer cell line)
Cupressus sempervirens	6-Deoxytaxodione (=11-hydroxy-7, 9(11), 13-abietatrien-12-one), taxodione, ferruginol, sugiol, manool (**34**), 1,3-dioxoferruginyl methyl ether, sempervirol, 13-hydroxy-8,11,13-totaratrien-1,3-dione (=1,3-dioxototarol)	Antimicrobial, antileishmanial antiparasitic
Cupressus torulosa	Manool (**34**)	Antiseptic For inflammatory wound healing
Curcuma amada (*mango ginger*)	12β-Hydroxy-15-norlabda-8(17),13(14)-dien-16-oic acid, (*E*)-15-ethoxy-15-methoxylabda-8(17),12-dien-16-al, (*E*)-15α-ethoxy-14α-hydroxylabda-8(17),12-dien-16-olide, 15-ethoxy-12β-hydroxylabda-8(17), 13(14)-dien-16,15-olide, (*E*)-15,16-bisnorlabda-8(17),11-dien-13-one, coronarin C ethyl ester, coronarin D methyl ester, (*E*)-15,15-diethoxylabda-8(17),12-dien-16-al, (*E*)-labda-8(17),12-diene-15,16-dial (**29**), (*E*)-14-hydroxy-15-nor-labda-8(17),12-dien-16-ol, (*E*)-labda-8(17),12,14-trien-15,16-olide, zarumine, methyl 12*E*,16-epxolabda-8(17), 12-dien-15-one, 16-oxolabda-8(17),12-dien-15,11-olide, (*E*)-14,15,16-trinorlabda-8(17),11-dien-13-oic acid (16), (*E*)-labda-8(17),12-dien-15-ol-17-al, (*E*)-14-hydroxy-15-norlabda-8(17),12-dien-16-al	Food (dippig vegetable) Analgesic, anticancer, antifungal, antimicrobial, antioxidant, antiplatelet, antitubecular, antiulcer, anti-inflammatory, CNS depressant, cytotoxic (A549: lung; HeLa: cervical; MCF7:human breast cancer; PANC-1 and PSN-1, pancreatic cancer cell lines), larvicidal, insecticidal For cough, inflammation, rheumatisms

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Curcuma domestica (=*C. longa*)	(*E*)-Labda-8(17),12-diene-15,16-dial (**29**)	Foods, food additive, beverage (herbal tea) α-Amylase inhibitory, antiallergic, anti-Alzheimer's disease, antiarthritic, anticarcinogenic, antidiabetes, antifungal, anti-inflammatory, antiobesity, antioxidant, antiviral, hypoglycemic, hypolipidemic, neurotoxin inhibitory
Curcuma heyneana	(*E*)-15,16-Bisnorlabda-8(17),11-dien-13-one, (*E*)-labda-8(17),12-dien-15,16-dial (**29**)	Anti-inflammatory, antimicrobial, antioxidant, cancer prevention For anthelmintic in skin scrub, body sliming, diarrhea, wound healing
Curcuma mangga	(*E*)-15,16-Dinorlabda-8(17),11-dien-13-one, communic acid, labda-8(17),13-diene-15-oic acid (copallic acid) (**30**), 14,15,16-trinorlabdan-8,12-diol, (*E*)-labda-8(17),12-diene-15,16-dial (**29**), zerumin A (**69**), B	Foods, beverage (herbal tea) Analgesic, antiallergic, antioxidant, NO production inhibitory, lipid peroxidation, antiproliferative, antimicrobial, antitumor, apoptotic, cytotoxic (A549, Ca Ski, HT-29, MRC-5, KB, cancer cell lines)
Curcuma zedoaria	Curcuminol	Food, beverage (herbal tea) Antiamoebic, antifungal, antimicrobial, antiulcer, digenetic, hepatoprotective For cold, infection, diarrhea, leukoderma, leucorrhea, menstruation, stagnation, stomachache, toothache, tuberculosis, vomiting
Cussonia racemose	Cussoracosides A (**19i**)-F, β-D-glucopyranosyl *ent*-16β,17-dihydroxykauran-19-oate, paniculoside IV	Antispasmodic For acne, diarrhea, mental diseases, malaria, rheumatism, syphilis
Cyathus africanus (mushroom)	Neocyathins K-R, three known congeners	Antineuroinflammatory, NO production inhibitory
Cyathus earlei (mushroom)	3,13-Cyathadien-11α,14β,15-triol (=cyathatriol), 3,13-cyathadien-14β-acetoxy-11α,15-diol, 3,13-cyathadien-15-acetoxy-11α,14β-diol, 3,13-cyathadien-11α,15-diacetoxy-14β-ol	Antibacterial, antifungal

Cyathus helenae (mushroom)	Cyathin A_3, B, B_2, Q, allocyathin, neoallocyathin A_4, cyahookerins A-F, (12*S*)-11α,14α-epoxy-13α,14β,15-trihydroxy-cyath-3-ene, (12*R*)-11α,14α-epoxy-13α,14β,-15-trihydroxycyath-3-ene, cyathin E, erinacol, cyathatriol, 4-oxo-cyatha-3,12-diene	Antibacterial, neurite out growth promoting, NO production inhibitory
Cymbopogon citratus	α-Camphorene (**136**)	Flavoring agent in foods, drinks and in perfumes, baked goods and beverage (herbal tea) Analgesic, antimicrobial, antifungal, anti-inflammatory, antimutagenic, carminative, sedative For arthritis, febrifuge, digestion problems, cramping flatulence, immunity booster, mosquito repellent
Cystoseira abiesmarina	Cystoazorols	Antioxidant
Cystoseira myrica	Dictyone acetate, dictyol F monoacetate, isodictytriol monoacetate, cystoseirol monoacetate	Cytotoxic (KA3IT: murine cancer cell line)
Cystoseira sp. (algae)	Meroterpenoids	Antibacterial, anticancer., antidiabetes, antifungal, anti-inflammatory, antioxidant, antiparasitic, cholinesterase inhibitor, cytotoxic
Cystoseira usneoides	Cystodiones A-F	
Dacrydium biforme	Labda-8(17),14-dien-13-ol (=manool) (**34**)	
Dacrydium cupressinum	Podocarpic acid, totarol	Anti-influenza, anti-LAV, astringent
Daphne genkwa	Genkwadaphnin	Anti-influenza, antiviral [hepatitis B and C virus (HBC|V, HCV); HIV]
	Genkwadanes	Cytotoxic (HT-1080 cell line)
Dicraropteris dichotoma	18-Hydroxyaylthonic acid (**117**), 18-oxo-aythonic acid	Anti-HIV
Dictyota acutiloba (brown algae)	Acutilols A, B, acutilol A acetate, dictyolene	Feeding deterrent
Dictyota bartayresii	8β-Hydroxypachydictyol A	Antiviral, cytotoxic
Dictyota binghamiae	Dictyoxide A, dictyotriol A diacetate	
Dictyota caribaea	Dictyol B acetate, pachydictiol A, isopachydictyol A	Antialgal, antifouling, antiherbivory, antiproliferative, antithrombotic, cytotoxic

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Dictyota cervicornis	8,14β-Epoxy-7β,8-dihydroxy-8,9-seco-1,15-dolasten-9-one	Antifeedant, antifouling, antimalarial, antiviral, enzyme inhibitory
Dictyota ciliolata	Dictyol B acetate, pachydictyol A, xenicane diterpenoids	Antialgal, antimicrobial, antifouling, antifungal, antiproliferative, antithrombotic, cytotoxic
Dictyota crenulata	Dictyodial	Antibiotic, antifouling, antifungal
Dictyota dentata	Dictyol C, H (**119**)	Antioxidant, antitumor, protection for DNA damage
Dictyota dichotoma	Dictyol A (**118**), B-F, J, dictyol B acetate, dictyol-D 2β-acetate, dictyol I acetate, pachydictyol A-C, isopachydictyol A, (*Z*)-pachydictyol, (*E*)-pachydictyol, 8α-dihydroxypachydictyol A, 8β-hydroxypachydictyol A, 3,4-epoxy-13-hydroxypachdidctyol A, dictyoxide, dictytriol, dictyone, dictyone acetate, dictyotadiol, dictyohydroperoxide, isopachydictyolal, dictyotins A-C, *ent*-ergorgiaene, dolabellatrienol, amijiol, amijiol acetate, dichotenol B, dichotone, acetyldictyolal, dictyotalides A, B, nordicytotalide, 4-acetoxydictyolactone, crenulacetal C, acetoxycrenulide, sanadaol, 13-epidictyol, dictyone, dictyriol, isodictyriol, dictyriene A, dictytriene, epoxypachydictyol A (**120**), 9α,15-epoxy-7(17)-fusicoccene (=epoxydictyotene), norxenicanes 3*E*,7*E*,18-dolabellatrien-14-one (**31**), secodolastanes, dictyoxetanes (Group 2), xenicanes, 4,18-dihydroxy-1(9),6,13-xenicatrien-19-al (**33**)	Food, animal feed, make beer, frozen food, fruit juices, pastries, ice cream, jellies, in meat and flavor sauces, milk shakes, salad dressings Acyltransferase and diacylglycerol inhibitory, algicidal, antibacterial, antifouling, antifungal, antiherbivory, antioxidant, antithrombotic, antitumor, antiviral, cytotoxic, fish antifeedant, protection of DNA damage, pesticide
Dictyota divaricata	Dictyol C, H (**119**), 2-hydroxydictyoxide, dilophol, 3β-hydroxydilophol, 7β-acetoxy-1(15),8-dolastadiene-14-ol	Antifouling, antioxidant, antitumor, protection for DNA damage
Dictyota flabellata	Dictyodial	Antibiotic, antifungal

Dictyota linearis	Dictyodial, 4α-acetyldictyodial, 11(15),8,13-dolastatriene-4-diol, 11(15),8-dolastadiene-2,14-diol (=amijitrienol), dolastanes, 1(15),8-dolastadiene-2β, 14β-diol (=isoamijiol) (**32**)	Antibacterial, antifungal
Dictyota menstrualis	Pachydictyol A, isopachydictyol, dictyol A, 6*R*-6-hydroxydichototomo-3,4-diene-1,17 isoamijiol -dial, 6*R*-acetoxydicitotomo-3,4-diene-1,17-dial	Antithrombotic, antifouling, cytotoxic, anti-HIV-1, antithrombin, antifeedant, antiretroviral
Dictyota mertensii	Dictyol H (**119**), epoxypachydictyol A (**120**)	
Dictyota pfaffii	Dolabelladienols A, B, dolabellanetriol, dolabelladiene, 8-hydroxy-2,6-dolabelladiene	Antifeedant, antiviral, antimalarial, antiviral, anti-HSV-1, antithrombin antifeedant, pasture weeds inhibitory
Dictyota plectens	8α,11-Dihydroxypachydictyol A, 8β-hydroxypachydictyol A, 9α-hydroxydictyol, isodictyol E, 3β-acetoxydilophol, acetoxypachydiol, 4α-hydroxypachylactone	Anti-inflammatory, antimalarial, antioxidant, antiviral, cytotoxic
Dictyota prolificans	1(9)*E*,6*E*12*E*,14-xenoicatetraene-17,18:19,18-diolide, 12,15-didehydro-1,9*E*,6*E*-13-xenoicatriene-17,18:19,18-diolide	
Dictyota sp.	Xenicane-type diterpenoids, 18-hydroxydolabella-3,7-dien-2-one, 3,4-epoxy-2α,18-dihydroxydolabella-7-ene, 3,4-epoxy-18-hydroxydolabella-7-ene-3β-hydroxydilophol, dictyol C, E, hydroxycrenulide, 9-acetoxy-15-hydroxy-1,6-dolabelladiene, hydroxyacetyldictyolal, 4,8-dihydroxydictyo-lactone, 8α,11-dihydroxypachydictyol	Antifoulants, cytotoxic (NCI-H189)
Dictyota spinulosa	Hydroxydictyodial	Antibiotic, antifeedant
Dictyota valubilis	Pachydictyol	Antifouling, antithrombotic cytotoxic
Dilophus dentata	Dictyol H	
Dilophus fasciola	Dictyol C, E, dolabellanes, neodictyolactone, sanadaol, 2*E*,4βH,7*E*-dolabelldiene-5β,6β,10α,18-tetrol, 7,18-fascioladien-17-al	Acyltransferase inhibitory, algicidal, antifouling, cytotoxic, ichthyologic, phytotoxic

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Dilophus ligulatus	Dictyol E, dictyoxide	Acyltransferase inhibitory
	Epoxyoxodolabelladiene, acetyldictyolal, dictyotalide, neodictyolactone, dictyolactone, 6,13-xenicatrien-19-al (=fukurinolal), pachylactone, acetoxycrenulide, acetylcoriacenone, isoacetylcoriacenone, grenuladial, dilophol, dictyoxide	Antifungal, antimicrobial, cytotoxic
Dilophus marginatus	Secospatane-types, cubebanes, 13,17-spatadien-10β-ol	Antimicrobial Feeding deterrent
Dilophus mediterraneus	Dictyol C	Antifouling
	Dictyol E	Acyltransferase inhibitory
	Dictyodial, sanadaol	Antibacterial, algicidal
Dilophus okamurai	Secospatane-types 15, 17, 18-dictyolactone dikamural, pachydictyol A, 6,13-xenicatrien-19-al (=fukurinolal), cubebane type, dictyoterpenoids A, B, 4-hydroxy-18-acetoxy-1(9),6,13-xenicatrien-19-al (=fukuinolal)	Antimicrobial, cytotoxic, feeding deterrent
Dilophus prolificans	Dilopholone, 7α-acetoxydilopholone, (1, 7β-acetoxydilopholone, epoxydilopholone	
Dilophus spiralis	Pachydictyol A, isopachydictyol A, dictyoxide, dolabellanes, neodictyolactone, acetyldictyolal, pachylactone, dilospirane B	Antibacterial, antithrombotic, antifouling, antitumor, feeding deterrent, cytotoxic
Dilophus ugandensis	Dictyol E	Acyltransferase inhibitory
	Dilophic acid	Antibacterial

Dioscorea bulbifera	Diosbulbin N (**121**) diosbulbins A-D, F, G, O, P	Food Analgesic, antifungal, anti-inflammatory, antimicrobial, antioxidant, antitumor, gastroprotective functions
	8β,12α:15,16-Diepoxy-9-*nor*-13(16),14-clerodadiene-16,6β:18,2α-diolide (=diosbulbin B), diosbulbioside F, diosbulbin E	Anti-inflammatory, cytotoxic (A-549, HL-60, MCF-7, SMMC-7721, SW-480 human cancer cell lines), hepatoprotective For leprosy, tumor
Dioscoreaphyllum cumminsii	Isocolumbin	
Dodonaea angustifolia	2-Hydroxy-15,16-epoxycleroda-3,13(16),14-trien-18-oic acid, *ent*-16-hydroxylabdan-3α,8β-dihydroxy,13(14)-en-15,16-olide	Antibacterial, hypotensive, cardiac depressant, coronary-constricting, phagocytosis enhancing, analgesic, molluscicidal, intestinal smooth muscle contraction, anodyne, antipruritic, astringent, diaphoretic, febrifuge, odontalgic, vulnerary For fevers, malaria, swellings, wounds A decoction: for digestive system disorders, including indigestion, ulcers, diarrhea, and constipation
	Dodonic acid (**122**), 2β-hydroxyhardwickiic acid, *ent*-3β,8α-dihydroxy-15,16-epoxy-13(16),14-labdadiene, hautriwaic acid, hautriwaic acid lactone, neoclerodan-3,13-dien-16,15:18.19-diolide, 15α-methoxy-neoclerodan,3,13-dien-16,15:18,19-diolide, 15β-methoxyneoclerodan-2,13-dien-16,15:18,19-diolide	Antifungal, antimicrobial For tuberculosis, pneumonia
Dodonaea attenuata	*ent*-17-Acetoxy-15,16-epoxy-19-hydroxy-3,13(16),14-clerodatrien-18-oic acid	
Dodonaea polyandra	polyandric acid A, B, 13,17-epoxy-13-methyl-15-oxo-labda-7-ene (**123**), 17-hydroxy-13-methyl-labda-7,13*Z*-dien-15-oic acid, 13-methyl-17-oxo-labda-7,13*Z*-dien-15-oic acid, 15,16-epoxy-3β-hydroxy-labda-7,13(16),14-triene	Anti-inflammatory, toothache

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Dodonaea viscosa	`*ent*-15,16-Epoxy-3β,8α-dihydroxylabda-13(16),14-diene, *ent*-15ξ-ethoxylabdan-3β,8α-dihydroxy-13(14)-en-15,16-olide (**124**), *ent*-16ξ-hydroxy-labdan-3β,8α-dihydroxy-13(14)-en-15,16-olide, 8α-hydroxy-3-*O*-β-glucopyranosyl *ent*-labda-13-en-15,16-olide	Antiviral (anti-herpes) For fever, hepatoprotective, hyperpigmentation-associated diseases, inflammation, insecticide, rheumatism, pain
	Hautriwaic acid, 2α-hydroxyhautriwaic methyl ester, *ent*-15,16-epoxy-9αH-labda-13(16),14-diene-3β,8α-diol, dehydro hautriwaic acid, methyl dodonates A-C, donolide, *ent*-15,16-epoxy-6-hydroxy-3,13(16),14-clerodatrien-18-oic acid (=dodonic acid)	Cytotoxic (THP-1 cell line)
Elettaria cardamomum	8(17),12-Labdadiene-15,16-dial (**29**)	Food flavor, cookies, source, liqueurs, luxury spices Antifungal, antimicrobial, antiviral, carminative, stomachic, tonic For asthma, colic, constipation, diarrhea, diuretic, dyspepsia, epilepsy, hypertension, muscle pain
Elodea canadensis	9α,13α-Epidioxy-8(14)-abieten-18-oic acid	
Elsholtzia bodinieri	Hinokiol, ludongnin, sandaracopimar-15-en-8β,12β-diol, 6-hydroxy-(-)-hardwickiic acid 2'-β-*O*-glucopyranosyl-benzyl ester, 6,7-dihydroxy-(-)-hardwickiic acid 2'-β-O-glucopyranosyl-benzyl ester	Analgesic, antibacterial, anti-HCV, anti-inflammatory, antipyretic, sedative For respiratory disorders
Eremophila aff. drummondii	8,16-Dihydroxyserrulat-19-oic acid, 7,8,16-trihydroxyserrulat-19-oic acid, 7,8-dihydroxy-16-caffeoyl-serrulat-19-oic acid, 7,8-dihydroxy-16-feruloyl-serrulat-19-oic acid, 7,8-dihydorxy-serrulat-14-en-19-oic acid, 7,8-	α-Glucosidase and PTP1B inhibitory, antimicrobial

	dihydroxy-16-butanoyloxyserrulat-19-oic acid, 7,8-dihydroxy-16[(3-methylbutanoyl)-oxy]-serrulat-19-oic acid, 8-hydroxyserrulat-4-en-19-oic acid, 8-hydroxy-16-acetoxyserrulat-14-en-19-oic acid, 3,7,8-trihydroxy-16-oxoserulat-14-en-19-oic acid, 3,7,8-trihydroxyserrulsat-14-en-19-oic acid, 7,8,16,18-tetrahydroxy-19-serrulatanoic acid, 7,8,16-trihydroxy-18-acetoxyserrulat-19-oic acid, 7,8,16-trihydroxyserrulat-19-oic acid	
Eremophila cuneifolia	5,14-Dihydroxy-3-visiciden-20-oic acid, 5-hydroxy-4-oxo-3-visciden-20-oic acid, 5-hydroxy-3,14-viscidadien-20-oic acid	Colds
Eremophila dempsteri	15-Hydroxy-3,7,11-cembratrien-19-oic acid	
Eremophila dicipiens	2(4),14-Decipiadiene-1,18-triol, 18-hydroxy-1(4)14-decipiadien-1-oic acid	
Eremophila duttonii	Serrulat-14-en-7,8,20-triol, serrulat-14-en-3,7,8,20-tetraol	Antibacterial, antilisterial
Eremophila falcata	8,16-Dihydroxyserrulat-14-en-19-oic acid	α-Glucosidase and PTP1B inhibitory
Eremophila flaccida	Serrulat-14-ene-8,18-diol	
Eremophila freelingii	5,15,17-Erematrien-19,16-olide (=eremolactone)	Tea, sugar substitute Antidiarrheal, antiseptic For chest pain, cold, headaches, wash for sores
Eremophila georgei	3,15-Epoxy-18-hydroxy-7,11-cembradien-19-ol	
Eremophila gibossa	8,16-Dihydroxyserrulat-14-en-19-oic acid, 8-hydroxy-16-oxoserrulat-14-en-19-oic acid	α-Glucosidase and PTP1B inhibitory
Eremophila glabra	8,16-Dihydroxyserrulat-19-oic acid	α-Glucosidase and PTP1B inhibitory
	8-Hydroxy-16-cinnamoyl serrulat-19-oic acid, 4-methylpent-3-enoylserrulat-19-oic acid	PTP1B inhibitory
Eremophila granitica	14-Serrulatene-2α,7,8,20-tetraol, 2-deoxy-14-serrulatene-7,8,20-triol	

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Eremophila lucida	(3Z,7Z,11Z)-15-Hydroxycembra-3,7,11-trien-19-oic acid, 5α-hydroxyviscida-3,14-dien-20-oic acid	Antimicrobial
Eremophila microtheca	Microthecaline A (**125**)	Antimalarial (*Plasmodium falciparum*)
	2-Acetoxy-7,8-dihydroxy serrulat-14-en-19-oic acid, 3,7,8-trihydroxyserrulat-14-en-19-oic acid, 3,19-diacetoxy-8-hydroxy serrulat-14-ene	Antibacterial
Eremophila neglecta	8-Hydroxyserrulat-14-en-19-oic acid, 8,19-dihydroxyserrulat-14-ene, 8-Hydroxyserrulat-14-en-19-oic acid	Anti-inflammatory, antimicrobial
Eremophila rotundifolia	5,8-Dihydroxyzerrulat-14-en-18-al	
Eremophila serrulata	20-Acetoxy-8-hydroxyserrulat-14-en-19-oic acid, 8,20-dihydroxy-serrulat-14-en-19-oic acid, 8,20-diacetoxyserrulat-14-en-19-oic acid, dihydroxyserrulatic acid	Antimicrobial
Eremophila sturtii	3,8-Dihydroxyserrulatic acid, serrulatic acid	Antibacterial, cyclooxygenase (COX-1, COX-2) inhibitory
Eremophila virens	5,16-Dihydroxy-3-visciden-20-oic acid	Antimicrobial
Erythrophleum fordii	Erythrophlesin H	Cytotoxic (PC-3: human prostate cancer cell line)
Erythrophleum ivorense	Erythroivorensin	Antioxidant
Erythroxylon monogynum	Monogonol, hydroxymongonol, (+)-hibaene, atisirene, isoatisirene, (-)-pimaradiene, 8(14),15-pimaradiene	Food (cooked or row), fruits (pleasant flavor: for perfumery) Antimicrobial
Erythroxylum passerinum	14-*O*-Methylryanodanol	Anti-Aedes (aegypti larvae)

Espelelia schultentzii	15β-Hydroxy-16-kauren-19-oic acid (=grandiflorolic acid)	
Eugenia uniflora		Fruits: beverage (herbal tea) For bronchitis, cough, influenza, intestinal trouble
Eunicea asperula	Asperketal	
Eunicea fusca	8,10,13(15),16-Lobatetraen-18-ol (=fuscol), fuscoside E	Antifouling
Eupatorium glutinosum	15-Hydroxy-7-labden-17-oic acid, 15-acetoxy-7-labden-17-oic acid	Antimicrobial
Eupatorium obtussmum	Uasdlabdanes A-F	Antiproliferative, cytotoxic (A549, lung, HBL-100 and T-45D: breast, HeLa, cervix lung: SW1573: lung, WIDR: human colon cancer cell lines)
Eupatorium turbinatum	19,20-Epoxy-7α,12,20-trihydroxy-8,12-abietadiene-11,14-dione (=conacytone), turbinatone	
Eupatorium salvia	7-Hydroxy-8(17)-labden-15-oic acid (=salvic acid), 7-acetoxy-8(17)-labdan-15-oic acid	Antimicrobial, antiseptic
Euphorbia caducifolia	8,1,3-Epoxy-17-hydroxy-11,13(15)-abietadien-15, 12-olide (=caudicifolin)	
Euphorbia dendroides	Jatrophanes	Cytotoxic (NCI-H460/R: multidrug resistant cancer cell line)
Euphorbia falcata	Cyclomyrsinane	Cytotoxic (HeLa, MCF-7 cancer cell lines)
Euphorbia fidjiana	*ent*-13*R*-Hydroxy-3,14-dioxo-16-atisene, *ent*-3,14-dioxo-16-atisene, *ent*-13*R*:14*R*-dihydroxy-3-oxo-15-atisen-17-al, *ent*-17-hydroxy-8(14),13(15)-abietadien-16-al, *ent*-16-hydroxy-8(14)-pimarene-3,15-diene	

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Euphorbia fischeriana (lang-du)	Prostratin 20-*O*-(6'-acetoxy)-β-*D*-glucopyranoside, langduin A_6, deacetyllangduin A_6, langduin A_6 13-*O*-β-*D*-glucoside	Antibacterial, anti-inflammatory, antituberculosis, cytotoxic (AGS, Hep-G2 cancer cell lines) For abdominal distension, edema, cancer, intestinal parasites, psoriasis scrofula
	Fischerosides A-C, prostratin, 12-deoxyphorbol-13,20-diacetate, 12-deoxyphorbol-13-hexadecanoate, 12-deoxyphorbaldehyde-13-hexadecanoate, langduin A, langduin D, *ent*-13*S*-hydroxy-16-atisene-2,14-dione, jolkinolide A, 17-hydroxyjolkinolide A, jolkinolide B, 17-hydroxyjolkinolide B	Anti-HIV-1 For ascites, edema, cancer
	Euphonoides A-G, fischeriabietane, 25 known analogues: *ent*-abietanes, *ent*-pimaranes, *ent*-kaurenes	Cytotoxic (C-4-2B, C-4-2B/ENZR: human prostate. HCT-15, RKO: colon; MDA-MB-231 breast cancer cell line)
	Euphorin A-H, *ent*-3β-hydroxyrosa-1(10),15-diene, *ent*-3β,19-hydroxyrosa-1(10),15-diene (=ebractenoid C), *ent*-2α,3α-dihydroxyrosa-1(10),15-diene (=yuexiandajisu F, *ent*-2,3-hydroxy-18-*nor*-rosa-1,3,5(10),15-tetraene (=ebractenoid F), fischeria A, jolkinolide B, yuexiandajisu E, *ent*-11α-hydroxyabieta-8(14),13(15)-dien-16,12α-olide, *ent*-16α,17-dihydroxykauran-3-one, ingenol, ingenol 3-palmitate, ingenol 3-myristinate, *ent*-rosanes, *ent*-abietanes, *ent*-kaurane, ingenane, lathyrane	Cytotoxic (MCF-7: human breast cell line)
Euphorbia guyoniana	Guyonianins E, F.	Cytotoxic (HEK293: human embryonic kidney 293 cancer cell lines)

Euphorbia helioscopia	Jolkinolide A, 11β,12β-epoxy-jolkinolide A (=jolkinolide B), 16-hydorxypseudojolkinolide B, pesudojolkinolide A, jatrophane diterpenes, euphcopenoids A, B, known analogues	Tea substitute Antiasthmatic, anthelmintic, antibacterial, antifungal, anti-inflammatory, antiallergic, antinociceptive, antipyretic, antitumor, antiviral, cytotoxic (A549, HePG2: lung; HL-60, LA795), febrifuge, insulin secretagogue, NO production inhibitory, vasodepressors, vermifuge, skin eruptions
Euphorbia jolkini	Ingenol, jolkinolide A-F	Antifeedant, anti-respiratory, antiviral, anti-RSV, cathartic, respiratory *syncytial* virus (RSV)
Euphorbia kansuensis	Euphoanoid A	NO production inhibition
Euphorbia kansui	Ingenanes	Anti-*Nilaparvata lugens*, anti-*Tetranychus urticae*
Euphorbia lathyris	Iathyrane diterpenoids analogues	Cytotoxic (MCF-7/ADM), NO production inhibition
Euphorbia lunulata	Jatrophanes	Cytotoxic (MCF-7; NCI-H460)
Euphorbia mellifera	Euphomelliferine, euphomelliferenes A, B, ingenone, jatrophane diterpenes	Antitumor (Colo 320: adenocarcinoma cells)
Euphorbia neliscopia	Jatrophane diterpenoids, 16 known related compounds, nelicoscopinolide, euphornin	Cytotoxic (HeLa, MDAMB-231 cancer cell lines)
	Euphoscopoids A-C, jatrophanes, lathyrane	Antifeedant, cytotoxic (NCl-H1975, HepG2, MCF-2)
	Euphorhelipanes A, B	Triglyceride lowering
Euphorbia neriifolia	Ingol type: euphorantins S, T, *ent*-atisan type: euphorneroides A-D 11 known diterpenoids	Anti-HIV-1
	ent-Isopimaranes: eupnerias J-P, 3β-hydroxysandaracopimaric acid	Anti-inflammatory, anti-influenza, anti-HIV-1, NO production inhibitory For cold, cough, fever
Euphorbia osyrides	2,3,5,7,8,9,14,15-Octahydroxyjatropha-6(17),11*E*-diene	Cytotoxic (Cao-4, OVCAR-3 cancer cell lines)
Euphorbia pallasii	Pseudojolkinolide A, B, 16-hydroxypseudojolinolide B, 18-hydroxy-pseudojolkinolide B	

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Euphorbia paralias	Paralianone	NO production inhibitory
Euphorbia pekinensis	Diterpenes, new abietane	Cytotoxic, anticomplementary
	Casbane-type diterpenoids: pekinenin C-F, pekinenal, pekinenin A, yuexiandajisu B	Cytotoxic (A549: lung; MGC-803: gastric; Ketr-3: kidney; MCF-7: breast; HL-60: leukemia; SW620: colon; SMMC-7721: liver; KB: nasopharyngeal cancer cell lines)
	Euphpekinensin	Cytotoxic (HO-8910: ovarian; KB: nasopharyngeal, NCL-H490: lung carcinoma, SGC7901: gastric cancer cell lines)
	Pekinenal	Cytotoxic (C4-2B, C42B/ENZR, MDA-MB-23 human prostate cancer cell lines)
	Euphopanes A-C	Cytotoxic (NCI-H460: lung, KB: nasopharyngeal, HO-8910: ovarian; SGC7901: gastric cancer cell lines)
Euphorbia piscatoria	Jolkinol D, L derivatives	Cytotoxic (EPG85-257: gastric, EPP85-181: pancreatic, HT-29 cancer cell lines)
Euphorbia plumerioides		Purgative, vermifuge vomiting inducing
Euphorbia prolifera	Myrsinol diterpenes	NO production inhibitory
Euphorbia royleana	Euphoroylean A (**126**), euphoroyleans B-H, phanginin A (**127**) (including 2 cembranes, 3 ingenanes, 2 atisane, 1 kauranes) + 22 known compounds:	Anticancer, cytotoxic (A-549, BEL7402, HCT 116, MDA-MB-231 cancer cell liens)
	3β-*O*-Angeloyl-17-tigloyloxy-20-deoxyingenol, 3β-*O*-angeloyl-17-benzoyloxy-20-deoxyingenol, *ent*-19-acetoxy-16α,17-dihydroxyatisan-3-one, *ent*-16α,17-dihydroxy-19-noratisan-3-one, *ent*-16α,17-dihydroxy-19-(2*Z*-methylbutanoyloxy)-kauran-3-one, *ent*-16α,17-dihydroxy-19-tigloyloxykauran-2-one, 1-acetoxy-*ent*-abieta-8(14),13(15)-	NO production inhibitory For inflammation, rheumatism

	dien-12α,16-olide, 18-hydroxy-*ent*-abieta-8(14),13(15)-dien-12α,16-olide, *ent*-18-nor-8(14),15-iso-pimaradiene-3β,4α,12β-triol, antiquorine A, sandaracopimaradienal, 3α,12α-dihydroxy-*ent*-8(14),15-iso-pimaradien-18-al, *ent*-13*S*-hydroxyatis-16-ene-3,14-dione, *ent*-3β,13*S*-dihydroxyatis-16-en-14-one, *ent*-3α,13*S*-dihydroxyatis-16-en-15-one, *ent*-3β,19-dihydroxykaur-16-ene, eurifoloids D, E, 7-angeloyl-12-acetoxy-8-methoxyingol, 3,7,12-triacetoxy-8-benzoylingol 3,12-diacetoxy-7-hydroxy-8-methoxyingol	
	Quamurolide C, euphorantins M, *ent*-atis-16-ene-3,14-dione, eurifoloids E, G, J, L, antiquorine A	Chemoreversal activities on $P\text{-}_{8p}$ high expressed HepG2/DOX cells
Euphorbia sogdiana	6(17)-Epoxylathyranes, lathyrane, myrsinane, tigliane	Cytotoxic (EJ-138: bladder cancer cells, Jurkat T-leukemia cell lines)
Euphorbia stacheyi	Euphstrachenols A-C, 5,15-diacetoxy-3-benzoyloxy-14-oxoathyr-6(17),12*E*-diene, 3,5,25-triacetoxy-14-oxo-lathyr-6(17),12*E*-diene, jolkinol A, B, jolkinoate I, 3β,5α,20-trihydroxy-15β-cinnamoyloxy-14-oxolathyra-6Z,12*E*-diene, ingenane, 20-*O*-acetyl-[3-*O*-(2'*E*,4'*Z*)-decadienoyl]ingenol, 3-*O*-(2'*E*,4'*Z*)-decadienoylingenol, (3β,12α,13a)-3,12-dihydroxypimar-7,15-dien-2-one, (5β,9β,10α)-2-hydroxypimara-1,7,15-trien-3-one, yuexiandajisu C, *ent*-(3α,5β,8α,9β,10α,12α)-3-hydroxyatis-16-en-14-one, *ent*-atis-16-ene-3,14-dione, joljinolide E, *ent*-11β-hydroxyabieta-8(14),13(15)-dien-16,12-olide, stracheyioid C (22)	Cytotoxic (HGC-27: stomach cancer, MV4-11: leukemia, H460 lung, Skvo3: murine ovarian cancer cells, BaF3: lymphocyte cancer cell line)
	Stacheyioids A-C	Cytotoxic (A-549, Hela, HePG2, MCF-7, P388 cancer cell lines)
Evenia prunastri (Oak moss: lichen)	Rimuene	Fragrances Antiseptic, emollient, expectorant, fixative

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Evodia floribunda	3,13-Clerodadien-16,15-olid-18-oic acid (=floridiolide A), floridiolide B, 15,16-dihydroxy-3,13-clerodadien-18-oic acid (=floridiodic acid)	Anticancer, antiobesity
Fibraurea chloroleuca	6-Hydroxyfibraurin	
Fibraurea tinctoria	epi-8-Hydroxycolumbin, fibaruretin A-F, epi-12-palmatoside G, floribundic ester, fibraurin, fibraurinoside, fiblecin, fibreucinoside, chasmanthin, fibrauretinoside A, epi-fibrauretinoside A	Anti-inflammatory, antimalarial, diuretic, NO production inhibitory, sedative For diabetes, dysentery, eyes and stomach diseases
Fritillaria ebeiensi	6α,7β-Dihydroxylabda-8(17),12(*E*),14-triene, 6-oxo-2-hydroxylabda-7,12(*E*),14-triene	Neuroprotective
Fuerstia africana	11,15-Dihydroxy-5,7,9(11),13-abietatetraen-12-one (=fuerstione), abietanes	Anti-*Plasmodium falciparum,* cytotoxic
Gelonium aeguoreum	17-Abietanes: gelomulide, gelomulide A-G, K-X, 6β-acetoxy-1-one-8β,14α-dihydroxy-*ent*-abieta-2(3),13(15)-dien-16,12-olide, *ent*-kauranes	Cytotoxic (A549: lung, MDA-MB231, MCF-7: breast, HepG2: liver cancer cell lines)
Gelonium multiflorum	Gelomulide A-F	
Ginkgo biloba	ginkgolides A (**11**), B (**12**), C (**13**), J, M	Food (fruit), beverage (herbal tea) Altitude sickness, anticancer, anxiety, Alzheimer's disease, blood pressure problems, dementia, depression, erectile dysfunction, fatigue, macular degeneration, neuropathy, premenstrual syndrome, schizophrenia
Globba pendula	16-Oxo-8(17),12-labdadien-15-olide	Cytotoxic (H-460, MC-7, PC-3 cancer cell lines)
Glossocarya caicicola	Clerodanes	Cytotoxic (Sf9 human carcinoma)
Glyptostrobus pensillis	Gryoensin A	Cytotoxic (K562: human chronic myeloid leukemia cell line)

Gnidia glauca	Gndiglaucin	Antibacterial, antifungal, antioxidant, mosquito larvicidal, ovicidal
Gochnatia decora	7β,15β-Dihydroxykaur-16-en-19-oic acid	NO production inhibitory, neutrophil elastase inhibitory For asthma, cough, wounds
Gochnatia glutinosa	*ent*-8(14),15-Pimaradiene-3β,19-diol, *ent*-8(14),15-pimaradiene-3β,18-diol	
Gomphostemma crinitum	Cleroda-12,17-diacetoxy-17-hydroxy-3,13*E*,(14)-dien-2-one	Edible (leaves) Antimicrobial, antimalarial
Goschnatia paniculata	*ent*-6β-15,17-Trihydroxy-3-cleroden-18-oic acid (=gochnatol), gochnatoic acid	
Goyazianthus tertrastichus (=*Symphopappus casarettoi*)	*ent*-3α,4α-Epoxy-13*E*-cleroden-2β,15-diol, kolaverol derivatives	Anticancer
Grangea maderaspatana	Gramaderins A-D, 18-carboxy-16α-hydroxycleroda-3,13-dien-16,15-olide, 15-deoxypulic acid, *ent*-14,15.16-trinor-5,10-seco-11,3-(19)-cledratriene13,18-dioic acid (=norstrictic acid), 15,16-dihydro-15-methoxy-16-oxostrictic acid, norhardwickiic acid	Analgesic, acetylcholinesterase inhibitory, anti-implantational, anti-inflammatory, antioxidant, elastase release inhibitory, cytotoxic, estrogenic, superoxide anion generation inhibitory For hepatitis herpes, mastitis, snake bites
Green Vegetables, foods, ruminant meat	Phytol, 3*RS*,7*R*,11*R*-phytanic acid	Antidepressant, antimicrobial, antinociceptive, antioxidant, anxiolytic, apoptosis inducing, autophagy, anti-inflammatory, cytotoxic, hypolipidemic, immunomodulatory
Green coffee beans	*ent*-9,16β,17-Trihydroxy-19-kauranoic acid (=cofarol), *ent*-9,16β,17-trihydroxy-19-kauranoic acid β-*D*-glucopyranosyl ester (=cofaryloside)	
Gutierrezia texana	10 *cis*-Clerodanes: 6α,18-dihydroxy-*cis*-cleroda-3,13(14)-diene-15,16-olide, 18,19-dihydroxy-*cis*-cleroda-3,13(14)-dien-15,16-olide, 18,19*R*-epoxy-19-hydroxy-3,13-clerodadien-15,16-olide	

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Haldwickia pinnata	*ent*-15,16-Epoxy-3,13(16),14-cerodatrien-18-oic acid (= (-)-hardwickiic acid), kolavic, kolavenolic, kolavonic acids	
Halimeda scabra	Halmendalactone	Food
Halimeda tuna	Halmendalactone, halitunal	Food Anti-coronavirus
Haliminum viscosum	13,14,15,16-Tetranor-12-hydroxy-1(10)-*ent*-halimen-18-oic acid, 14,15,16-trinor-1(10)-*ent*-halimen-13,18-dioic acid, 3β-methoxy-8-labden-7β, 15-diol, 3,11-18-sphenolobadiene-4,13,17-triol, 13,17-diacetoxy3(11)-sphenolobadien-4-ol, trimesolanone, valparene	Neurotrophic
Haplopappus baylahuen	18-Hydroxy-labda-7,13*E*-en-15-oic acid, 18-acetoxy-labda-7,13*E*-en-15-oic acid	Antioxidant, antiseptic antispasmodic For digestive
Haplopappus ciliatus	3-Cleroden-15,18-diol (**128**), 3-clerodene-15,18-dioic acid (=haplociliatic acid) (**129**)	Antiseptic
Haplopappus remyanus	18-Acetoxy-*Z*-cleroda-3-en-15-oic acid	Beverage (herbal tea)
Haplopappus unicinatus	18-Acetoxy-*Z*-cleroda-3-en-15-oic acid	Antimicrobial, digestive stimulant For gastrointestinal infection, infected wound, wound healing
Hedychium coronarium	Coronarin E (**130**), ethoxycoronarin D, isocoronarin D, methoxycoronarin D, labdanes	NF-kB, COX-I, COX-II inhibitory, cytotoxic (A549: lung, HepG2: hepatoblastoma, HL-60: promyelocytic leukemia, HeLa: cervical, HuCCA-1: *cholangiocarcinoma*, KB: epidermoid, MDA-MB231: hormone independent breast, MOLT-3: T-lymphoblast, S102: hepatocellular, T-47D: hormone dependent breast cancer cell lines)

Hedychium coronarium	Labdanes, coronarin E (**130**)	A-549: lung, HeLa: cervical, MCF-7: breast cancer cell lines
Hedychium longipetalum	Hedylongnoids A, B, C	Cytotoxic
Hedychium spicatum	Labdanes	Cytotoxic (A-549: lung, A-431: skin, Colo-205: colon cancer, MCF-7: breast cancer cell lines)
Helianthus annuus (Sunflower)	*ent*-Kaurane-2α,16α-diol, *ent*-kaurane-15α,16α-epoxy-17-al-19-oic acid, phyllocladan-16β-ol, *ent*-atisan-16α-ol, angeloylgrandifloric acid, *ent*-kaurane-16-en-19-oic acid, *ent*-kaurane-17-hydroxy-15-en-19-oic acid, *ent*-kaurane-16β, 17-dihydroxy-19-oic acid, ciliaric acid, gibberellin A_{67} (**131**), gibberellin A_{76} (**132**)	Foods (seeds and flowers) Antioxidant, astringent, cytotoxic (HepG2, MCF-7, SF-268 cancer cell lines), expectorant, diuretic For fever, sores, spider snake bites, swellings
	ent-Kauran-16α-ol (**36**), *ent*-atisan16α-ol, *ent*-kaur-16-en-19-oic acid (**47**), thujyl *ent*-kaur-16-en-19-oate, 19-trachylobanoic acid (**133**), thujyl *ent*-trachyloban-19-oate (**134**), ent-kaur-16-en-19-al, *ent*-trachyloban-19-al, *ent*-kauran-16β-ol, *ent*-kauran-l6α-ol, *ent*-kauran-16β, l9-diol, *ent*-atisan-16α-ol, *ent*-atisan-16β-ol	Antimicrobial, insecticidal, oviposition stimulants for the banded sunflower moth (*Cochylis hospes*)
	Grandiforolic acid (**135**), kaurenic acid	Antioxidant
Helianthus atrobubens	*ent*-12,16-Dihydroxy-17-angeloyl-19-kauranoic acid	Food (seed), made into sunflower butter or used to make seed yoghurt, used in salads, margarines, or in cooking, roasted seed: coffee and drinking chocolate substitute, Beverage (herbal tea) Astringent, diuretic, expectorant For febrifuge, high fever, malaria, lung ailments, nutritive, poultice on sores, pulmonary complaints, rheumatic aches and pains, snakes and spider bites, stomachic swellings
Helianthus debilis (beach sunflower)	*ent*-15β,16β-Epoxy-7-hydroxy-19-kauranoic acid, *ent*-15-kaurene-17,19-dicarboxylic acid	Food (seed), vegetable Bronchial and other pulmonary problems, cold, diuretic, expectorant For snake bites, sunstroke

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Helianthus strumosus	*ent*-7-Oxo-8,15-pimaradien-19-oic acid, *ent*-7,15-pimaradien-19-oic acid	Roots (decoction): used to get rid of worms in both adults and children
	ent-Pinara-7,15-dien-19-oic acid, *ent*-7-oxopunara-8,15-dien-l9-oic acid	Roots (infusion): used in the treatment of lung problems
Helichrysum dendroideum	*ent*-15-Kaurene-17,19-diol, 16-kaurene-3α-acetoxy-19-oic acid, *ent*-kauren-3α-(3-methylbutenoyl)-19-oic acid, 15-beyrene-3β,19-diol (=15-stachene-3β,19-diol)	
Helichrysum foetidum	Kaurene-16-en-18-oic acid	Psychoactivity
Helichrysum formosissinum	7,13-Abietadien-12-ol	
Helichrysum heterolasium	9-geranyl-α-terpineol, 16-hellicallenal	
Helichrysum italicum	12-*O*-Tetradecanoyl-phorbol-13-acetate	Antifungal, anti-inflammatory, antimalarial Flowers/Leaves: For allergies, colds, cough, fragrance industries, gallbladder disorders and skin lover, infectious and sleeplessness
Helichrysum obconicum	Geranyl *p*-cymene	Anti-inflammatory, COX-II and lipase enzyme inhibitory, NO production inhibitory
Helichrysum oligocephalum	*epi*-Manoyl oxide	Anti-inflammatory For gastrointestinal complaints
Helichrysum refluxum	3,15-Erythroxyladien-18-oic acid	
Helichrysum species (600 species)		Antiallergic, anti-inflammatory, antimicrobial, antioxidant, antipsoriasis agents, diuretic, hepatoprotective For colds, cough, digestive problem, hysteria, infection, nervousness, respiratory complaints, wound healing
Helichrysum tenax var. *tenax*	15-Kauren-18-ol, *ent*-beyer-15-en-19-ol	Antimicrobial
Helichrysum chinosphaerum	*ent*-7,13-Abietadiene	

Hericium abietis (mushroom)	Erinacine P (=helical) (**42a**)	Food
Hericium erinaceum (=H. erinaceus) (mushroom)	Erinacine A (**39**), B (**40**), C (**41**), K, P (**42a**), Q (**42b**), R, cyatha-3, 12-diene, cyatha-3(18), 12-diene, erinacol, 11-*O*-acetyl-cyathatriol, 15-*O*-acetyl-cyathatriol, 11-O-acetyl-cyathin A_3, Four erinacine related compounds	Food, Chinese medicine Antibacterial, nerve-growth-factor (NGF) synthesis stimulatory, NGF like activity, κ-opioid receptor agonist
Hericium ramosum (mushroom)	Erinacine E (hericin), erinacine P (=helical) (**42a**)	Food Antibacterial, κ-opioid receptor agonist, NGF synthesis stimulatory
Hoffmannia strigillosa (tepecajeta)	*ent*-15-Hydroxy-3,13-clerodadien-16,15-olid-19-oic acid, 19-hydroxy-3,13-clerodadien-16,15-olide	Anti-inflammatory For stomach illness
Horminum pyrenaicum (dragon's mouth)	Horminone, 7-O-acetylhorminone, agastaquinone, 15,16-dehydro-inuloyleanol, 15,16-dehydroagastol, inuroyanol, agastol, 3-deoxyagastaquinone, 7α,12-dihydroxy-8,12-abietadiene-11,14-dione (=7α-acetoxyroyleanone)	Beverage (herbal tea)
Humulus lupulus	α-Camphorene (**136**), metacamphorene (**137**)	Beverage (herbal tea) Anticancer, antifungal, anti-inflammatory, antimicrobial, antioxidant, atherosclerosis, diuretic For anxiety disorders, appetite, bladder related problems, insomnia, nervous tension reduction, relaxant and sleep aid, urinary boosts T3 and T4 production
Hypoestes forskalei	Hypoestenonols A, B, verticillarone, hypoestenone (**59d**), deoxyhypoestenone, dehydrohypoestenone, hypoestene, fusicoplagin D, 8α,9α-epoxydeoxyhypoestenone, 8α,9α-epoxy-hypoestenone (**59e**)	East African folk medicine Anti-*Plasmodium falciparum,* anti-*Leishmania infantum,* anti-*Trypanosoma cruzi, T. brucei*
Hypoestes purpurea	Hypopurins A-D	Taiwanese folk medicine Anti-phlogistic, antipyretic, liver protective, vasorelaxant

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Hypoestes rosea	Hypoestoxide, isoroseanolone, roseanolone, roseadione	For typhoid, malaria
Hypoestes serpens	Fusicoserpenol A, dolabeserpenoic acid A, 7β-hydroxyisopimara-8,15-dien-14-one, 14α-hydroxy-iso-pimara-7,15-dien-1-one, 1β,14α-dihydroxy-iso-pimara-7,15-diene, 7β-hydroxyisopimara-8(14),15-dien-1-one, 7β-acetoxyisopimara-8(14),15-dien-1-one, serpendione	Traditional Malagasy medicine Antifungal, antihypertensive
Hypoestes verticillaris	Verticillarone	For tuberculosis, chest complaints, dry cough, pneumonia, wound healing, hypertension, gonorrhea, cancer
	13-Hydroxy-7-oxo-labda-8,14-diene	Antimalarial
Hyptis fasciculata	15β-Methoxyfaciculatin, 15α-methoxyfaciculatin, methoxyneoetaefolin	Expectorant For fever, gout
Hyptis fructicosa	12,16-Epoxy-11,14-dihydroxy-8,11,13-abietatrien-7-one (=hyptol)	Analgesic, anticonvulsive hypotensive, larvicidal, vasorelaxant
Hyptis suaveolens	13-*epi*-Dioxiabiet-8(14)-en-18-ol, 8-abietene-14α,18-diol, 8-abietene-14α-hydroxy-18-oic acid	Antimicrobial, antiplasmodial, carminative For stimulant, stomachic
Hyptis umbrosa	Umbrosone	Analgesic, anti-inflammatory For cramps and fever, gastrointestinal disorders, nasal congestion, skin infection
Icacina claessensis	*ent*-3α,20:14β,16-Diepoxy-3,14α,15α-trihydroxy-7-pimaren-19,6β-olide (=icacinol)	Food
Icacina guesfeldtii	Icacinlactone, icacintricholide, icacine, icaneine, De-N-methylicaceine	Analgesic, anticonvulsant, antimicrobial, anti-Epstein-Barr virus, anti-HSV-1, anti-HSV-2, sedative For food poisoning, constipation, malaria

Icacina trichantha	Icacinol, humirianthenolide C, 2β-hydroxyhumiriantholide, 14α-methoxy-humirianthjone, 17-hydroxyicacinol, icacenone, 7α-hydroxyicacenone, 12-hydroxyicacinlactone, 2β-hydroxyicacinlactone B (=icacinlactone H), 7α-hydroxyicacinlactone, 7β-hydroxyicacinlactone B, icacinlactone A-G, I-L, icacintrichanone, icacintrichantholide, icacine, icaneine, De-N-methylicaceine, (9β*H*)-pimarane, (9β*H*)-norpimarane	Food, soup Antiasthma, antihypertensive, antimicrobial. antioxidant, aphrodisiac, diarrheal effect, soft tumor For constipation, induction of emesis and abortion malaria, poisoning, rheumatism, toothache
Illicium jiadifengpi	Jiadifenoic acids	Antiviral (Coxsackie virus B2, B3, B4, B6)
Inula royleana	Inuroyleanol, 7-ketoroyleanone, 11,14-dihydroxy-12-methoxyabieta-8,11,13-trien-7-one, 12-hydroxyabieta-8,12-dien-7,11,14-trione (=royleanone), 6,7-dehydroroyaleanone, 12-hydroxy-8,12-abietadiene-7,11,14-trione (=7-oxo-royleanone), 11,12,14-trihydroxy-8,11,13-abietartien-7-one	Beverage (herbal tea) Insecticidal, parasiticide
Isodon amethystoides	*ent*-7β,14α-Dihydroxy-16-kauren-2,15-dione (=umbrosin B), *ent*-3α,7β,14α-trihydroxy-16-kauren-15-one (=wangzaozin A), leucamein F, glaucocalyxin A, B	Antimicrobial, antitumor, antioxidant, anticoagulative, antithrombotic, antifibrotic, antineuroinflammatory For abscesses, swollen sores, pneumonia, lung abscess, pulmonary tuberculosis
Isodon effusus (=*Rabdosia effusus*)	Effusin, *ent*-7,20-epoxy-1β,6α-7-trihydroxy-16-kauren-15-one (= effusanin A), *ent*-7,20-epoxy-1β-acetoxy-6α,7-dihydroxy-16-kauren-15-one (= effusanin B), effusanin C, D	Antibacterial
Isodon eriocalyx (=*Rabdosia eriocalyx*)	*ent*-15α-Acetoxy-3,20-epoxy-6α-hydroxy-16-kaurene-1,7-dione (=maoecrystal A), *ent*-7,20-epoxy-16-kaurene-1α,3α,6α,15α-tetra-hydroxy-19-*O*-β-D-glucopyranoside (=1α,3α,6α,15α-rabdoside 2), *ent*-19-acetoxy-7,20-epoxy-1α,3α,6α,7-tetrahydroxy-16-kauren-15-one (= maoecrystal I) neolaxiflorin A, B, eriocalyxins C−E, laxiflorins J−M, maoecrystal P, maoeriocalysins A-D	Cytotoxic, inhibitory effects on human tumor K562 and T24 cells

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Isodon excisoides	1α,7α,14β-Trihydroxy-20-acetoxy-*ent*-kaur-15-one, 1α,7α,14β,18-tetrahydroxy-20-acetoxy-*ent*-kaur-15-one, 1α-acetoxy-14β-hydroxy-7α,20-epoxy-*ent*-kaur-16-en-15-one, henryin, kamebanin, reniformin C, kamebacetal A, B, oridonin (**139**)	Cytotoxic
Isodon flavidus	Flavidusin A, B, glutinosin, *ent*-kaur-16β,17-diol, siegebeckiol, 16-hydroxyferrugiol, hinokiol, maslinnic acid, fladin A, lophanic acid	Antifungal
Isodon glutinosa	Four kaurenes, one abietane: glutinosin C	Anti-inflammatory, antitumor
Isodon glutinosa	Glutinosin C	
Isodon inflexus (=*Rabdosia inflexa*)	15-Acetyldemethyl kamebacetal A, six known kaurenes, 3α,6β-dihydroxy-7,17-dioxo-*ent*-abieta-5(16)-ene, kamebacetal A, kamebakaurin, excisanin, inflexin, inflexanin C (=1α-acetoxy-7β,18-dihydroxyabieta-9(11)-en-12-one, inflexanin D (=1α-acetoxy-18-hydoxyabita-7,9(11)-dien-12-one), inflexuside A (=1,11,13-trihydroxyabieta-8-en-7-one-1-*O*-β-D-glucopyranoside, inflexuside B (=1,11,13-trihydroxyabieta-8-en-7-one-1-*O*-(2-*O*-coumaroyl)-β-*D*-glucopyranoside	Anti-inflammatory, NF κB and NO production inhibitory
Isodon japonicus (=Rabdosia japonica, Isodon japonica)	Isodonteroenes I, II, oridonin (**139**), hebeirubescensin H, rabdternin E, F, enmein (**15**), nodosin, isodocarpin, serrin, isodonal, *ent*-3,15-dioxo-7β,14α-dihydroxy-kaur-16-ene (**138**), *ent*-7β,20-epoxy-kaur-16-ene-1β,6α,7α,14α,15α-pentanol-1-*O*-β-*D*-glucopyranoside, enmein-3-acetate, isodotrisin, epinodosin, sodoponin, eponodosinol, trichodonin, hikiokoshins A-I, *ent*-6α,17-Diacetoxy-7,20:15β,16-diepoxy-7,14α-kaurenediol, maoyerabdosin, rabdosin A-C, maoyecrystal F, rabdophyllin G	Beverage (herbal tea) Antibacterial, antifungal, anti-HBV, antiindigestion, anti-inflammatory, antimicrobial, antioxidant, antitumor, melanogenesis, cytotoxic (L1210: murine lymphoma, KB cancer cell lines) For gastrointestinal disorders, indigestion

Isodon lasiocarpus	*ent*-7,20-Epoxy-1β,6α,7,11α-tetrahydroxy-16-kauren-15-one (=ladiodonin), oridonin, lasiodin	
Isodon longitubus	Nodosin, isodocarpin, 1-acetyloridonin, diacetyloridonin	
Isodon lophanthoides	Lophanic acid, 8(17),12,14-labdatriene-19-oic acid, 11β-hydroxy-isopimara-8,15-dien-3-one	Anti-inflammatory, antimalarial, cytotoxic
Isodon parvifolius	Epinodosinol, lasiodpnin, parvifolines C-N, Z, rabdoternin G, adenolin E , lasiodonin, lushanrubescensin F, parvifoliside, effusanin A, B, E, taibaihenryiin A, shikokianin, maoyecrystal J, lasiodonin acetonide, rubescensin C, I, J, P, enanderianin P, 14β,16-dihydroxy-3α,18[1-methylethane-1,1-diyl] dioxy]-*ent*-abieta-7,15(17)-diene parvifoline AA, AB, X, Y, hebeirubescensin L, trichokaurin	Cytotoxic (A-549, HT-29, K526 cancer cell lines)
Isodon pharicus	Pharicin C, R	
Isodon rubescens	Rubesanolides A, B, 9 known kaurenes, ponicidin, xindongnin	Antiangiogenic, antibacterial, anticancer, anti-inflammatory For bacterial infections, cancer, inflammation, gastrointestinal and respiratory disorders, sore throat
	Atisane, isorubesins A-E, oridonin	Cytotoxic (A549, Jurkat, MCF-7, NB4, PC3, SHSY5Y human cancer cell lines)
Isodon sculponeta	Sculponeatin A-C	
Isodon shikokianus (=*Rabdosia shikokianus*)	Isodomedin, oridonin, shikokianin, shikokianidin	
Isodon trichocarpus	Enmein (**15**), dihydroenmein, isodocarpin, nodosin, isodotrisin, oridonin, trichokaurin, trichodonin, enmedol, enmenal, emerol, ememodin	Antitumor
Isodon umbrosus (=*I. kameba*)	Isodomedin, *ent*-1β,7β,14α-trihydroxy-kauren-15-one (=kamebanin), *ent*-2β,7β-14α)-trihydroxy-16-kauren-15-one (=mebadonin), *ent*-3α-acetoxy-7β,14α-dihydroxy-16-*ent*-kauren-15-one, *ent*-1β,7β,14α,20-tetrahydroxy-16-kauren-15-one (=kamebakaurin), kamebakaurinin, *ent*-2α,3α,7β,14α-	Beverage (herbal tea) Antimicrobial

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
	tetrahydroxy-16-auren-15-one (=leukamenin A), leukamenin B-D, rabdolatifolin rabdoumbosanin, shikoccin, shiokoccidin, *ent*-7β,14α-dihydroxy-16-kaurene-2,15-dione (=umbrosin A), umbrosin B	
Isodon xerophilus	(11β)-6,11-Dihydroxy-7,20-dioxo-*ent*-abieta-5,8(14)-dien-16-oic acid-δ-lactone (=xerophilusin R), (11β,15*S*)-6,10,17-trihydroxy-7,20-dioxo-*ent*-abieta-5,8(14)-dien-16-oic acid δ-lactone (=xerophilusin S), xerophilusin G, I, J, K, enanderianin, rosthorin A, longikaurin B, rabeoterunin D, *ent*-abieta-7-ene-3α,16,17,18-tetraol (=xerophilusin XIV) (**140**), 15,16,17-trihydroxy-3α-18-[1-methylethane-1,1-dyl]dioxy]-*ent*-abieta-7-ene (XV), 3α,15,18-trihydroxy-16,17-[(1-methylethane-1,1-diyl)]-*ent*-abieta-7-ene (=xerophilusin XVI)	Antibacterial, anti-inflammatory, antitumor, cytotoxic (K562, MKN45, HepG2 cancer cell lines)
Isodon yunnanenis	*S-trans*-8(17),12*E*,14-labdatrien-20-oic acid, *S-trans*-12*E*,14-labdadien-20,8β-olide, hinokiol	
Itoa orientalis	13-Deoxyitol A, itol A	Antifeedant
Jatropha curcas	Jatrophalactone, curcusecone A (**141**), B-E, curcusones F-J, 4-epicurcusone E, 3-dehydroxy-2-epicaniojane, jatrogrossidion, 2-epi-jatrogrossidione, rhamnofolanes,	Cytotoxic (A-549, CNS, HL-60, MCF-7: breast, NCI-H460: lung, SF-268, SMMC-7721: SW480 cell lines) For dysentery, eczema, gonorrhea, gum bleeding, ringworm, scabies, toothache
Jatropha dioica	Riolozatrione, 6-epiriolozatrione, jatrophatrione, citlalitrione, jatropholone A, B, jatrophatrione, citlalitrione, riolozatrione	Antibiotic, antifungal, antioxidant, antiviral
Jateorhiza palmata (=*Jateorhiza columba*)	2α,3α:15,16-Diepoxy-4α-hydroxy-2,13(16),14-clerodatriene-17,12:8,1-diolide, isojateorinyl glucoside, 15,16-diepoxy-4-hydroxy-2,13(16),14-clerodatriene-17,12:18,1β-diolide (columbin), 2β,3β-15,16-diepoxy-13(16),14-clerodadiene-17,12β:18-diolide-1β-*O*-β-*D*-glucopyranoside diolide (=columbinyl glucoside), 2β,3β:15,16-diepoxy-4α-hydroxy-	Herbal mixture, herbal bitters Anthelmintic, antipyretic, laxative For diarrhea, dysentery, dyspepsia, hernia, ruptures, snake bites, weak stomach, vermifuge, gastric irritability, vomiting during pregnancy

	2,13(16),14-clerodatriene-17,12β:18,1β-diolide (=jateorin), 15,16-diepoxy-4α-hydroxy-2,13(16),14-clerodatriene-17,12α:18,1β-diolide (=palmarin), chasmanthin, palmatosides A, G	
Juniperus cedrus	Isoabienol, sandaracopimaradiene, (*E*)-totarol (**180**)	Insecticides, insect repellent
Juniperus communis	15,16-Epoxy-12-hydroxy-8(17),13(16),14-labodatrien-19-oic acid, imbricatolic acid, isocupressic acid, sandaracopimaric acid, isopimaric acid, 13*S*-8(17)-labdene-15,19-dial (=junicedral), 6,7-dehydro-8,11,13-abietatrien-12α-ol (=Δ^6-dehydroferriginol, (5α)-12-hydroxy-8,11,13-abietatriene-6,7-dione, 5β,12-hydroxy-8,11,13-abietatriene-6,7-dione, 7-oxo-8,15-isopimaradien-18-oic acid	Beverage (gin)
Juniperus oxycedrus	13*S*-8(17)-Labdene-15,19-dioic acid (=mercusic acid), 8,11,13-abietatrien-7α-ol	
Juniperus phoenicea	7,13-Abietadien-3-one, , 4-epi-abietic acid (=7,13-abietadien-19-oic acid), 8,13-abietadien-19-oic acid (=4-epi-palustric acid), 7α-hydroxy-8,11,13-abietatriene-19-al	
Juniperus rigida	8,11,13-Abietatriene-7β,11,12-triol	
Juniperus savina	8,13-Abitadiene (=palustadiene), saviperone A (**142**), sabiperones B-F, juniperolide, 3β,7α-dihydroxyabieta-8,11,13-triene, labda-13*E*-ene-8α,15-diol	Abortifacient, cytotoxic (HL-60: human promyelocytic leukemia, A549: lung adenocarcinoma, MCF7: breast adenocarcinoma, HepG2: hepatocellular carcinoma, HCT116: colorectal adenocarcinoma cell lines)
Juniperus thurifera	13*E*-Labdane-8α-hydroxy-18-al, 13Z-labdane-8α-hydroxy-18-al	
Laetia thamnia	*ent*-Kaur-16-en-19-oic acid (**47**), *ent*-β-hydroxykaur-16-ene, *ent*-kaur-16-en-3α,19-diol, *ent*-17-hydroxykaur-15-en-19-oic acid, methyl *ent*-kaur-16-en-19-oate, *ent*-kaur-16-en-3α,19-diol (acetate diester)	Cytotoxic (HT29, HCT116, MCF: breast, SW480, SW620: colon, 22Rv1, LNCaP: prostate)
Laurencia glandulifera (red algae)	Neorogioltriol	NO production and COX-II inhibitory, tumor necrosis factor-α expression inhibitor

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Laurencia intricata (red algae)	Laurencianol	Food
Laurencia irieii (red algae)	Iriediol, 7-deoxyiriediol, 7-deoxy-1β,11β-epoxy-iriediol, irieol F, 10-acetoxyiriediol, 7-deoxyirieol (=irieol E), 11-deacetoxy-pinnaterpene A (=ireol C)	
Laurencia obtusa (red algae)	Laurecianol, obtusadiol	
Laurencia pinna (red algae)	Pinnaterpene A, 18-hydroxy pinnaterpene A (pinnaterene B), pinnaterpene C	
Laurencia saitoi (red algae)	Parguerol, parguerol 7-acetate, parguerol 16-acetate, parguerol 17-acetate,	Feeding-deterrent activity against young abalone and sea urchins
Lavandula angustifolia		Edible (leaves, petals, flowering tips) Analgesic, antianxiety, antibacterial, anticancer, antifungal, anti-inflammatory, antimicrobial, antioxidant, cardiovascular, hypolipidemic, neurologic/CNS and spasmolytic effects, sedative
Lavandula multifida	15,16-Dihydroxy-7,11-dioxopimar-8(9)-ene (**143**), 15*S*,16-dihydroxy-7-oxo-pimar-8,9-ene, 15,16,17-trihydroxy-7-oxo-pimar-8,9-ene, 5,16,17-trihydroxypimar-8(9)-ene, glutinosin (=15*S*,16-dihydroxy-iso-pimar-8(9)-ene)	Edible (aerial part) Antibacterial, antifungal, anti-inflammatory, antimicrobial, antioxidant For rheumatism
Lavandula officinalis	Megastigmatrienone, gibberellin A_3	Analgesic, antibacterial, antifungal, anti-inflammatory, antiseptic, wound healing
Leonotis nepetaefolia [mota, (marijuana) in Maxico]	Bis-spirolabdanes: leonepetaefolin A-E, 15-epi-leonepetaefolin A-E, methoxynepetaefolin, nepetaefolin (**144**), nepetaefuran, dubiin, leonotinin, leomotin, nepetaefuranol	Inflorescence (leaves). marijuana substitute (flowers) Antiasthmatic, antibacterial, antidiarrheal, antifungal, anti-inflammatory, antioxidative, antispasmodic, spasmolytic, tonic For burns, cough, fever, dysmenorrhea, kidney dysfunction, rheumatism, skin infections, scalds stomachache

Leonurus marrubiastrum	*ent*-5α,10β,12*S*-12α-Hydroxy-3,13-clerodadiene-15,16:18,19-diolide (=marrubiastrol), 3,13-clerodadiene-18-oic acid β-D-glucopyranosyl ester (=marbiaside), *ent*-demethylmarrubiaketone	
Leonurus sibiricus (marihuanilla)	Preleosibirone A (**145**), 13-epi-preleosibirone A, isopreleosibirone A, leosibirone A, B, 15-epi-lepsibirone B	Marijuana substitute (leaves and roots) Antibacterial, febrifuge, respiratory stimulant
Lepechinia bullata	7-Methoxy-12-hydroxy-8,12-abietadiene-11,14-dione (=7-O-methyl-horminone)	
Letharia vulpina (Lichen)	Manool (**34**), sanadaracopimaric acid (**35**)	Beverage Stop bleeding, stomach disorder, poultice for swelling
Leucas aspera	Leucasperone A-C, leucasperol A, B, leucasperoside A-C	Antifungal, antimicrobial, antinociceptive, antioxidant, antipyretic, antirheumatism, aperient, chronic, cytotoxic, diaphoretic, emmenagogue, expectorant, hepatoprotective, insecticide, prostaglandin inhibitory, psoriasis, skin eruptions. stimulant
Leucas linifolia	8(14),15-Isopimaradien-7-one-3-*O*-[α-L-rhamnopyranosyl (1→2)]-*O*-β-*D*-glucopyranoside (=linifolisoide)	
Leucas zeylanica	12-*O*-β-D-glucopyranosyl-11,16-dihydroxyabieta-8,11,13-triene (=leucasinoside), 19-*O*-β-*D*-carboxyglucopyranosyl-12-*O*-β-*D*-glucopyranosyl-11,16-dihydroxyabieta-8, 11,13-triene, 12,19-*O*-β-D-diglucopyranosyl-11,16-dihydroxyabieta-8,11,13-triene	Leaves: cooked and eaten as a pot herb Anthelmintic, diaphoretic, sedative For headache, itch, stimulant, poultice, vertigo, wound healing
Leucothoe grayana	1α,3β,5β,6,12β,14β,11α-10(20)-Grayanatoxene-3,5,6,12,14,16-hexol	
Liatris laevigata	8,15-Epoxy-3,12,16-pimaranetriol (=*ent*-3β,8β,12α,15R)-form), *ent*-5β-epoxy-12α,16-dihydroxy-3-pinanone	
Libocedrus formosana	Shonanol (=12-hydroxy-2,8,11,13-totaratetraen-1-one	
Linaria japonica	Linaridial (=3,13-clerodadiene-15,16-dial (=*ent*-5α,13*E*)-form, linarienone (=3,13-clerodadiene-15,16-dial12,15-dihydroxy-3,13-clerodaiene-3-one)	

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Linaria saxatilis	4(18),13-Clerodadiene-12,15-diacetoxy-16-ol, 11,15-epoxy-15-hydroxy-4(18),12-clerodadiene-16-al	
Linum usitatissimum	Ustatissimin A	Hepatoprotective
Litophyton viridis	(1*R*,3*E*,7*E*,11*E*)-Cembratrien-15-ol (=nephthenol)	
Litsea glutinosa		Fruit Antipyretic, astringent, furunculosis For demulcent, diarrhea, dysentery, swelling
Lobophytum compactum	Lobocompactol A, B	Cytotoxic (A549: lung, HL-60: human cancer cell lines)
Lobophytum pauciflorum	Cyclolobatriene, fuscol, lobatriene	Cytotoxic (A-431: human epidermoid skin carcinoma)
Lobophytum sp.	17,18-Epoxy-8,10,13(15)-lobatriene	Oil
Lycopodium lucidulum	12,16-Epoxy-11,14-fihudroxy-5,8,11,13-abietatetraene-7-one	
Lycopus europaeus	Euroabienol (**146**), methyl 1α-acetoxy-7α,14α-dihydroxy-8,15-iso-pimaradien-18-oate, methyl 1α,14α-diacetoxy-7α-hydroxy-8,15-iso-pimaradien-18-oate, 1α,14α,18-trihydroxy-7α-acetoxy-8,15-iso-pimaradiene, methyl 1α,14α-dihydroxy-8,15-iso-pimaradiene-18-oate, 5,9-dihydroxygeranyl linalool, methyl 7α,14β-diacetoxy-1α-hydroxy-8,15-pimaradien 18-oate, methyl 1α-hydroxy-7α,14α-diacetoxy-8,15-iso-pimaradien-18-oate, methyl 1α,7α,14α-triacetoxy-8,15-iso-pimaradien-18-oate, methyl 1α,7α-diacetoxy-14α-hydroxy-8,15-iso-pimaradien-18-oate, methyl-7α,14α-diacetoxy-8,15-iso-pimaradien-18-oate, methyl 7α,14α-diacetoxy-11α-hydroxy-8,15-iso-pimaradien-18-oate, methyl 7α-acetoxy-11α,14α-dihydroxy-8,15-iso-pimaradien-18-oate, methyl 1α,7α-aeceoty-14-oxo-8,15-isopimaradien-18-oate, methyl 14α-acetoxy-7α,11α,-dihydroxy-8,15-iso-pinaradiene-18-	Antifungal, antigonadotropic, antimicrobial, antioxidant, hyperthyroidism, immunomodulatory

	oate, methyl 7α-acetoxy-11α,hydroxy-14-oxo-8,15-iso-pimaradien-18-oate, methyl 7α-acetoxy-1α,11α,14α-trihydroxy-8,15-iso-pimaradien-18-oate, 5,9-dihydroxygeranyl linalool	
Lycopus lucidus	3*S*,5*R*,10*S*-7-Oxo-8,11,13-abietatriene-3,11,12,14-tetraol-2-*O*-β-glucopyranosyl-(1→2)-β-glucopyranoside A (= lucihirtin)	Antiviral (hepatitis virus), dilate blood vessels
Macaranga tarius	*ent*-12β-Hydroxy-8(14),15-pimaradien-2-one (=macarangonol)	
Malvastrum coromandelianum	Neophytadiene, Phytol,	Analgesic, antifungal, anti-inflammatory, antimicrobial, antioxidant, antipyretic For dysentery
Manihot esculenta (cassava)	*ent*-8α,14α-Epoxy-3β-hydroxy-9(11),15-pimaradiene-2,12-dione, *ent*-8(14)-pimaradiene-3β,12β-diol, *ent*-15-beyerene-3β,12β-dihydroxy-2-one, *ent*-1β-hydroxy-3-nor-15-beyerenone-1,12-dione, *ent*-8(14),15-pimaradiene-3β,12β-diol (=yucalexin P21)	
Marchantia polymorpha	*ent*-Labda-7,13*E*-dien-15-ol	Beverage (herbal tea) antifungal, antimicrobial, antioxidant, antitrypanosomal, antiviral, diuretic muscle relaxant
Marrubium friwaldskyamum	9α,13*R*:15,16-Diepoxy-3-oxo-14-labden-19,6β-olide	
Marrubium vulgare (white horehound)	12*S*-Hydroxymarrubiin (**147**), 3-dehydro-15-methoxyvelutine C, marrubin, peregrinin, thessaline D, marrubinone B, deacetylvitexilactone, verbascoside, leucosceptoside A, martynoside, anisofolin A, ternifolin A, 9,13*S*:15,16-diepoxy-14-labden-19,6β-olide, 9,13*R*:15,16-diepoxy-14-labden-19,6β-olide (=premarrubiin), preperegrinine	Beverage (herbal tea) horehound beer Antibacterial, antifungal, antidiabetic, gastroprotective, vermifuge-respiratory-purgative For appetite, common cold, coughs, dyspepsia, indigestion, persistent cough, shortness of breath
Maytenus cuzcoina	Cuzcol, 6-dehydroxycuzcol	Antifeedant, anti-HIV17, antitumor promoting, cytotoxic, immunosuppressive, insecticidal

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Maytenus dispermus	Maytenone, 12,13-dihyroxy-8,11,13-totaratrien-7-one (=dispermone), 13-hydroxy-7,9(11),13-totaratriene-6,12-dione (=maytenoquinone)	
Microglossa pyrrhopappa	6-Hydroxyisochilolide, 6-hydorxy-incanpteroniolide, 3α,4α:15,15-diepoxy-10-oxo-9,10-seco-13(16),14-clerodadien-20,12-olide (=pyrrhopappolide)	
Microlepia marginata	*ent*-3β,15*S*,16-Trihydroxy-7-pimaren-3-one (=fumotoshidin A), *ent*-3β,15*S*,16-trihydroxy-7-pimaren-2-one, fumotoshidin B, *ent*-16β,17,18-kauranetriol, *ent*-16β,17-kauranediol-18-*O*-(4-*O*-methyl-β-*D*-glucopyranoside) (=epimicroplepin)	
Mikania alvimii	*ent*-15-Nor-14-oxo-8(17), 12*E*-labdadien-18-oic acid	
Mikania sessilifolia	*ent*-16β,17-Epoxy-kauren-19-al, *ent*-kauren-19-oic acid 2-hydroxyethyl ester	
Milleria quinqueflora	*ent*-8(14)-Pimamarene-2α,3α,15*R*,16-tetrol, *ent*-8(14)-pimamaren-15-oxo-2α,3α,16-diol	
Momordica charantia	Geranyllinalool, phytol, isophytol	Food, vegetables, beverage (herbal tea) Antidiabetes, antihypertension
Monarda brevipes	18-Acetoxy-3,13(16),14-clerodatrien-2-one	
Monarda sp.		Beverage (herbal tea) Arthritis stimulate For colds, delirium rheumatism, colic, digestive, febrifuge, flatulence, headache, indigestion, menstruation, nausea, respiratory problem, sudorific

Montanoa tomentosa	Pretomentol (**148**), pretomexanthol (**149**), prezoapatanol (**150**), tomentanol (**151**), zoapatlin (**152**), zoapatanol, montanol, tomexanthin, tomentol	Traditional herbal medicine Aphrodisiac, ejaculation, sexual stimulant
Mulium crassifolium	Isomulinic acid, mulinic acid	
Myroxylon pereirae (Peru balsam)		Foods, hygiene products, perfumes For asthma, catarrh, external wounds, rheumatism
Myroxylonn balsamum (Tolu balsam)		For common cold, scabies, ulcers, wounds
Myrtus communis		Beverage
Nardophyllum lanatus	15,16-Epoxy-3β,4α-dihydroxy-7-oxo-13(16), 14-clerodadien-20,12-olide, *ent*-15,16-epoxy-3,4-seco-4(18),13(16),14-halimatriene-3,5β:20,13β-diolide	
Nasutitermes gracilirostris	1(15),8(19)-Trinervita-diene-2β,3α,9α,11-tetraacetate	
Nepeta obtusicreana	14α-Acetoxy-6-oxoabieta-7-ene, euroabienol, obtusicrenone (**153**)	Anti-Alzheimer, anticholinesterase activity
Nepeta sauvis	Nepetolide	Antiasthmatic, antispasmodic, diaphoretic, diuretic, sedative, tonic, vulnerary For abdominal spasm, calcium antagonist
Nepeta septemcrenata	1α,14α,18-Trihydroxy-7α-acetoxy-8,15-isopimara-diene, 1α-hydroxy-7α,14α, 18-triacetoxy-8,15-iso-pimaradiene	Antimicrobial
Nepeta sorgerae	14α-Acetoxy-18-hydroxy-iso-pimara-8,15-dien-7-one, sorgerolone	Acetylcholinesterase and butyrylcholine esterase inhibitory, antioxidant
Nepeta teydea	8,11,13-Abietatriene-1α, 18-diol (=teideadiol), netidial, netidiol A 7α-monoacetate, netidiol A 18-monoacetate, netidiol B, netidiol B 14α-monoacetate, netidiol B 18-acetate, netiol, 13α-isopropyl-8(14)-podocarpen-14α,18-diol, 13α-isopropyl-7(8)-podocarpen-14α,18-diol	Aphrodisiac, diuretic, hyperglycemic For catarrhal

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Nepeta tuberosa subsp. *beticulata* (cat mint)	Isopimaryl 2β[(1'-methyl-2'-al)ethyl]-5α-methyl-cyclopenta-β-carboxylate, isopimaryl 2β-acetyl-5α-methyl-cyclopentane-β-carboxylate, 3α-isopimaryloxy-4α,7α-dihydronepetalactone, isopimaryl-4β[(3'α-methyl-2'β-methoxy-carbonyl) cyclopentyl]-2-pentanoate, isopimaryl 3β -methylencarboxylate-4α,7α-dihydro-nepetalactone, iso-pimaryl-2α-methylencarboxylate-4α,7α-dihydro-nepetalactone, iso-pimaryl 3-methylencarboxylate-4-hydroxy-4α,7α-dihydronepetalactone, di-isopimaryl malonate, isopimaryl malonic acid, 7-oxo-isopymara-8,15-dien-18-ol, iso-pimaryl acetate, iso-pimarol, isopimaric acid, 8(14),15-iso-pimaradien-7α,18-diol, myrceocomunic acid, 8,11,13-abietatrien-3β-ol, iso-pimara-8,15-dien-7β,18-diol, 7α-hydroxy-iso-pimara-8(14),15-dienyl malonate, acetyl isocupressic acid	
Nidorella agria	19-Hydroxy-3,13-cloredadien-16,15-olide	
Nidorella auriculata	15,16-Epoxy-1,3,13(16), 14-clerodatetaraen-18-oic acid methyl ester (=methyl nidoresedate)	
Nigella sativa	Nigellamines A_1-A_5, B_1, B_2, B_3, C, D	Cytotoxic (HepG2: hepatoblastoma cancer cell line) For asthma, abdominal pain, flatulence, kidney stones, polio
Nothopanax simplex	α-Camphorene	
Oidiodendron truncatum	8β*H*,12*R*,13*R*,14*R*-13,16-Epoxy-3-cleroden-12,14, 15,18-tetrol	

Olea europaea var. *maderensis*	Geranyl geraniol, phytol	Beverage (herbal tea), Infusion: antihypertensive
Oospore virescens	Virescenol A, 7,15-Isopimaradiene-3,19-diol (=virescenol B), 7,15-isopimaradiene-3-hydroxy-12-*O*-β-*D*-altropyranoside, virescenoside F, G, 19-hydroxy-7,15-isopimaradien-3-one (virenosol C), virescenoside C	
Oryza sativa	Momilactone A (**154**), B (**155**), C (**156**), D, E, 6,19β-epoxy-3β-hydroxy-5α,9β-pimara-7,15-diene, (9β*H*)-pimara-7,15-diene-3β,6β-19-triol, ineketone (**157**), gibberellin A_1, A_4, A_9, A_{19}, A_{20}, A24, A_{29}, A_{34}, A_{44}, A_{51} and A_{53}, *ent*-copalyl diphosphate, *ent*-sandaracopimaradiene, oryzalexin S, stemar-13-ene, *syn*-copalyl diphosphate, oryzalexin A-F and S, *ent*-kaur-16-ene, *ent*-cassa-12,15-diene, phytocassane A-E, oryzadione	Food (rice), brown and germinated brown rice Anticancer, antidiabetes mellitus, antidiarrheal, antifungal, antimicrobial, antioxidant, antitumor, antiviral, cytotoxic, germination inhibitory For cardiovascular
Osimum labiatum (pink sage)	Labda-8(17),12*E*,14-tetrene-2*R*,18-diol	Anticancer (breast cancer), anti-inflammatory, antimicrobial, antituberculosis, cytotoxic
Osmunda japonica	*ent*-Kauran-16*S*,17-hydroxy-19-oic acid (**37**)	Food Cytotoxic (HeLa, HePG2)
Pachdictyon coriaceum	6-Acetoxydilophol, 3β-hydroxy-6β-acetoxy-dilophol	
Pachydictyon coriaceum oil	Pachydictyol	
Palafoxia arida	*ent*-7-Pimarane-2α,15,16,18-tetrol, *ent*-7-pimarane-2α,15,16,18-tetrol, *ent*-7-pimarane-2α,15,18-trihydroxy-16-*O*-β-*D*-glucopyranoside, *ent*-3α,15*S*-hydroxy-pararosane, *ent*-3β,15*S*-hydroxypararosane, *ent*-7-pimarane-2α,15,18-trihysroxy-16-*O*-β-*D*-glucopyranoside, darutigenol	
Palafoxia rosea	*ent*-7-Pimarene-3α,15*S*,16-triol, 3-hydroxypalarosane	
Palafoxia texana	jesromotetrol, 3β-acetoxy-jesromotetrol, 3β,19-diacetoxy-jesromotetrol	

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Peltodon longipes	Abietanes	Cytotoxic (MIAPaCa-2: human pancreatic, MV-3: melanoma tumor cell lines)
Perovskia scrophularifolia	Rosmanol (**17**), epi-rosmanol, carnasol, 12-*O*-methyl carnosic acid	For dermatitis, intestinal parasites
Petalostigma pubescens	Pimaranes, sonderianol	Cytotoxic (L1210, P388 cell lines)
Phaieria nisidai	Simplexin	Immune protective
Phlomidoschema parviflorum	1(10),15-Rosandien-18-oic acid (**158**), 1(10),3,15-rosatrien-18-oic acid methyl ester	Muscle relaxant, sedative For cancerous ulcers, diarrhea, fever, heart genital tumors, inflammatory, internal bleeding, liver disorders, sclerosis of the spleen, sore mouth and throat, tumors
Phlomis betonicoides	Phlomoidesides A, phlomisosides III, V, baiyunol (=15,16-epoxy-8,13(16),14-labdatrien-3-ol, baiyunoside (=baiyunol-3-*O*-[β-*D*-glucopyranosyl-(1-2)-β-*D*-xylopyranoside	Cytotoxic (NCl-H, 1975, HepG2, MCF-7: human tumor cell lines)
Phlomis lychnitis	Phlomisosides II-IV (2-*O*-(6-desoxy-α-mannopyranosyl)-β-glucopyranoside)	Beverage (herbal tea) Anti-inflammatory, antioxidant, antipyretic, cold, digestive, gastrointestinal disorders, sedative, throat pain
Phlomis medicinalis	Baiyunoside, phlomisoside II, III.	Beverage (herbal tea) Antipyretic, sedative, For cold, digestive, gastrointestinal disorders, throat pain
Phlomis tuberosa	14-Hydroxyabieta-8,11,13-triene-11-carbaldehyde-18-oic-12-caboxy-13(1-hydroxymethylethyl)-lactone, 14-hydroxyabieta-8,11,13-triene-17-oic-12-caboxy-13-(1-hydroxy-1-methyl ethyl)lactone, 14,16-dihydroxyabieta-8,11,13-triene-15,17-dioic acid, 15,16-epoxy-8,13(16),14-labdatrien-19-oic acid (=phlomisol), phlomisoic acid (=15,16-epoxy-8,13(16),14-labda-trien-19-oic acid), 15,16-epoxy-8,13(16),14-labdatriene	Antimicrobial, α-Glucosidase inhibitory, intoxication, rheumatoid arthritis For cardiovascular and pulmonary diseases, tuberculosis

Phlomis younghusbandi	Phlomisoic acid phlomisosides III (=phlomisoic acid β-*D*-xylopyransyl-(1→2)-β-*D*-glucopyranoside), IV (=phlomisoic acid α-L-rhamnopyranosyl-(1-2)-β-D-glucopyranoside)	Beverage (herbal tea)
Physcomitrella patens	*ent*-Beyerene, 16-hydroxy-*ent*-kaurene *ent*-kaur-16-ene, *ent*-sandaracopimaradiene	Antimutagenic
Picea abies	8,11,13-Abietatriene-15-hydroxyl-18-oic acid methyl ester	
Picea jezoensis	7,13-Abietadien-18-oic acid (=abietic acid) (**2**), 8(14),12-abietadien-18-oic acid (=levopimaric acid)	
Pieris japonica	2β,3β-Epoxy-5β,6β,7α,9β,10α,14β,16α-grayanotoxaneheptol	
Pinus banksina	18-Nor-8,11,13-abietatrien-4α-ol, 18-nor-8,11,13-abietatrien-4β-ol	
Pinus caribaea	8,13-Abietadien-18-oic acid	
Pinus contorta	(13*S*)-Labda-8(17),14-diene-13β,18-diol, 18-norlabda-8(17),13-diene-4α,15-diol, 8(14),15-pimaradien-18-al, 7,15-isopimaradien-18-al, 8(14),15-pimaradien-18-ol, 7,15-isopimaradien-18-ol	Edible (inner bark, sap, seed, gum) Antiseptic, diuretic For colds, coughs consumption, gonorrhea, rheumatic affections, rubefacient, stomach pains, vermifuge, vulnerary, wound healing
Pinus koraiensis	Dehydroabitane, dehydroabitanal, dehydroabietic acid methyl ester, pimara-7,15-dien-3-one	Edible (seed)
Pinus lambertiana	15,16-Epoxy-8(17),13(16),14-labdatrien-19-oic acid (=lanbertianic acid), 12-oxolanbertianic acid	
Pinus monicola	8,11,13-Abietatrien-7-ol, 8,11,13-abietatrien-7-one, 9,10β-epoxy-6,12-dihydroxy-6,7-seco-8,11,13-abietatriene	
Pinus morrisonicola (=Pinus formosana)	15-acetoxy-7-oxo-dehydroabietic acid, picealactones A-C, 7-oxodehydroabietic acid	Antihypertension, antioxidant, lipid-lowering
Pinus pallasiana	8,13-Abietadien-18-oic acid, dehydroabitane	
Pinus palustris	8,13-Abietadien-18-oic acid (=palustric acid)	Flavor Antiseptic, bactericides, disinfectant, diuretic, vermifuge For chronic, cold, colic, cough, diarrhea, worms

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Pinus pimaster	Abietatriene, abieta-7,13-diene, dehydroabietal, iso-abienol, labda-8(17)-13*E*-dien-19-al, labda-8(*17*),13*E*-dien-15-ol, labda-8(17),13*Z*-dien-15-al, neoabietadiene	Lipid for food, beverage (herbal tea) Anti-inflammatory, antimicrobial, antioxidant, antiviral, cholesterol lowering effect, endometriosis For allergy, asthma, cardiovascular, menstrual and venous disorders, pregnancy associated pain
Pinus pityusa	8,13-Abietadien-18-oic acid	
Pinus pumila	*ent*-12,15-Epoxy-8(17),12,14-labdatrien-7α-ol (=pulmiloxide) *ent*-7β-hydroxypumiloxide	
Pinus radiata	13β-Hydroxy-18-abietanoic acid	
Pinus strobus	12*E*,14-Labdadien-8α-ol (=abienol), strobal	
Pinus sylvestris	8α,13*R*-Epoxy-14-labden-19-oic acid, (= dehydropinifolic acid), 8(17)-labdadiene-15,18-dioic acid, 13(16),14-labdadien-8α-ol (=iso-abienol), 13*S*,8(17)-labdane-15,18-dioic acid (=pinifolic acid), 7,13-abietadien-18-ol (=abietinol), 7,13-abietadien-18-al (=abietinal), 8,11,13-abietatrien-19-acetate (=dehydroabietinol acetate), 8α-hydroxy-12-oxo-13-abieten-18-oic acid, 7,15-isopimaradiene (=isopimaradiene), 19-nor-8(14),15-iso-pimara-dien-3-one, 15-ethyl-18-methyl pinifolate, 18-hydroxylabda-8(17), 13*E*-dien-15-acetate	Edible (pine nut) Cytotoxic (BEL-7402, HeLa, SK-N-SH cancer cell lines), improves vision, maintains weight stability, lowers bad cholesterol, and benefits bone strength, reduces the risk of heart attack and boost energy levels
Pisum bulgaris	Gibberellin A_{44}	
Pisum sativam	Gibberellin A_{44}	
Piteris livida	*ent*-9α-Hydroxy-15-oxo-16-kauren-19-oic acid β-*D*-glucopyranosyl ester, *ent*-6α,9α-dihydroxy-15-oxo-16-kauren-19-oic acid β-*D*-glucopyranosyl ester, *ent*-6α,11α-dihydroxy-15-oxo-16-kauren-19-oic acid β-*D*-glucopyranosyl ester	

Piteris longipes	*ent*-11α,15α-Epoxykaura-19-oic acid, *ent*-9α,15α-dihydroxy-16-karen-19-oic acid, *ent*-11α,15α-hydroxy-15-oxo-19-kauren-19-oic acid, *ent*-11α,15α-hydroxy-15-oxo-19-kauren-19-oic acid β-*D*-glucopyranosyl ester, *ent*-11α-hydroxy-15-oxo-19-kauranoic acid	
Pittisporum undulatum	8β,13β-Dihydorxykaur-16-ene	
Pityrodia lepidota	6α,18-Dihydroxy-2,13*E*-clerodadien-15-oic acid methyl ester	
Plantago lanceolata	Phytol, phytone	Beverage (herbal tea) Antidote, Anti-inflammatory, antimicrobial, antioxidant, antispasmodic, antitumor, cytotoxic, respiratory tract disorders For conjunctivitis, furunculosis, decoction or juice: eye drops for conjunctivitis, poultices for cleansing open sores
Plathymenia reticulata	*ent*-5α-3,14-Clerodadien-13-ol (= platyterpol)	
Platycaete aucheri	*ent*-7-Oxo-3,13*E*-clerodadien-15-oic acid, 6β-hydroxy-7-oxo-3,13-clerodadiene-15-oic acid, *ent*-6β-hydroxy-7-oxo-3,13-clerodadien-15,16-olide	
Plectranthus barbatus (=*Coleus barbatus, Coleus forskohlii*)	7,20-Epoxy-8,11,13-abietatriene-11,12-diol (=20-deoxocarnosol), cariocal, 6,11-epoxy-6α,12-dihydroxy-6,7-seco-8,11, 13-abietatrien-7-al, 19(4β→3β)abeo-6,11-epoxy-6α,12-dihydroxy-6,7-seco-4(18),8,11,13-abietatetraen-7-al, barbatusol, coleon E, F, 9(10→20)abeo-8,11,13-abietatriene-10β,11,12-triol, 6,11-epoxy-6α,12-dihydroxy-6,7-seco-4 (18),8,11,13-abietatetraen-7-al, cyclobutatusin, cyclobarbatusin	Beverage (herbal tea) Acetylcholinesterase inhibitory, antiprotozoal
Plectranthus ernstii	*rel*-15ξ,16-Epoxy-7α-hydroxypimar-8,14-ene, *rel*-15ξ,16-epoxy-7-oxopimar-8,14-ene, 1*R*,11*S*-dihydroxy-8*R*,13*R*-epoxylabd-14-ene	Antibacterial

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Plectranthus fruticosus	*ent*-Labda-8(17),12*Z*-trien-2α-ol, *ent*-2α-acetoxylabda-8 (17),12*Z*,14-trien-3β-ol, 3β-acetoxylabda-8(17), 12*E*,14-trien-3α-ol, *ent*-15β,16β-epoxykauran-19-oic acid, *ent*-15β,16β-epoxykauran-19-ol	Antimicrobial
Plectranthus nummularis	Parvifloron E, parvifloron F, 19-*O*-3,4-dihydroxybenzoyl)-11,12-dihydroxy-20(10→5)-abeoabieta-1(10),6,8,11, 13-tetraene, 12-*O*-(3-methyl-2-butenoyl)-19-*O*-(3,4-dihydroxybenzoyl)-11-hydroxyabieta-8,11,13-triene	
Plectranthus barbatus	Prectrin, 15*S*,6β,12α-acetoxy-7α-hydroxy-13β,16-cycloabieta-8-ene-3,11,14-trione (=barbatusin), 15*S*,19(4→3)-abeo-6β,7α,12α-trihydroxy-13β,16-cycloabieta-4(18),8-diene-11,14-dione (=7,12-bis(*O*)-desacetyl) coleon N, 19(4→3),17 (15→16)bis-abeoabieta-11,12,14,16-tetrahydroxy-3,5,8,11,13-pentene-2,7-dione (=plectrione A)	Anti-Alzheimer disease, antifeedant, antifungal, anti-inflammatory, antileishmanial, antimicrobial, antioxidant For dental caries, digestive, fever, genitourinary, heart blood and circulatory, infection, musculoskeletal disorder, pain, poisons treatment, respiratory, sensory
Plectranthus caninus	3β,6,11,12,14-Pentahydroxy-5,8,11,13-abietatetraen-7-one (= coleon S), coleon T, 7,12-diacetylcoleon J, coleon Q (**71**), coleon R	For digestive, respiratory conditions
Plectranthus coesta	3α,7β,14α,20-Tetrahydroxy-16-kauren-15-one (=coestinol)	
Plectranthus ecklonii	Plavifloron D	Antioxidant, cytotoxic (breast, colon, glioma, leukemia, lung, melanoma, pancreatic, cancer cell lines, P-glycoprotein-over expressing cells) For skin condition
Plectranthus edulis	Edulone A-11,12-diacetate , 6β,7α-dihydroxyroyleanone, lanugone A, 3α-formyloxy-6β,7α,12-trihydroxy-17(15→16) abeoabieta-8,12,16-trinene-11,14-dione, 3α-formyloxy-12-hydroxy-17(15→16)abeo-abieta-6,8,12,16-tetraene-11,14-dione,17(15→16), 19α(4→3) bisabeo-6β,7α,12,16abietatetraene-11,14-dione	For digestive, respiratory conditions

Plectranthus elegans	11-Hydroxy-7,9(11),13-abietatriene-12-one, 7α,11-dihydroxy-12-methoxy-8,11,13-abietatriene	Antimicrobial For genitourinary condition
Plectranthus ernstii		Antimicrobial
Plectranthus grandidentatus	11,14-Dihydroxy-7,9(11), 13-abietatriene-6,12-dione, grandidone A, B, 7-*epi*-grandidone A-D, 12-Hydroxy-8,12-abietadiene-11,14-dione (=royleanone), 7α,12-dihydroxy-8,12-abietadine-11,14-dione (=horminone), 6β-hydroxyroyleanone, 6β,7α-dihydroxyroyleaonone, 7α-acetoxy-6β-hydroxyroyleanone, 6,7-dehydroroyleanone, 6,11,12,14-tetrahydroxy-5,8,11,13-abietatriene-7-one (=coleon U)	Antimicrobial (methicillin and vancomycin resistant), antiproliferative (human lymphocytes), antitumor (breast, lung, renal melanoma, CNS) For blood and heart circular, respiratory condition
Plectranthus hadiensis	6β,7α-Dihydroxyroyleaonone, 7α-acetoxyroyleanone, 7α-formyloxy-6β-hydroxy-royleanone	Antifungal, anti-inflammatory, antimicrobial, antioxidant For digestive, respiratory conditions, skin disorders
Plectranthus hereroensis	7α,12-Dihydroxy-8,12-abietadine-11,14-dione (=horminone), 16-acetoxy-7α,12-dihydroxy-8,12-abietadiene-11,14-dione	For digestive condition
Plectranthus incanus (=*P. mollis*)		Vegetable Anticancer, antidote, astringent, anti-inflammatory, antioxidant, antirheumatism, antitumor, cardiac depressant, cytotoxic, febrifuge, muscle relaxant, mosquitocidal, mosquito repellent, respiratory stimulant, tonic For bleeding stop, fever, snake bites, vasoconstriction
Plectranthus lanuginosus	Lanugone A-S, K', K"	Anti-Alzheimer disease, antioxidant For digestive condition
Plectranthus madagascariensis	7α-Acetoxy-6β-hydroxyroyleanone, 6,7-dehydroroyleanone, 7α-fromyoxy-6β-hydroxy-royleanone, 7α-acetoxy-6β-hydroxy-royleanone, 6,11,12,14-Tetrahydroxy-5,8,11,13-abitatetraen-7-one (=coleon U), 7β,6β-dihydroxyroyleanone, parvifloron D	Cytotoxic (CCRF-CEM: human leukemia, A549: lung adenocarcinoma cell line) For asthma, chest complaints, colds, coughs, enema

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Plectranthus myrianthus	Coleon U, 7α-formoxy-6β,12,16-trihydroxy-8,11,13-abietatrien, 11,12,14-trihydroxy-8,11,13-abietatriene-6,7-dione (=coleon V), epi-grandidone A, grandidone B, C, D, 7-epi-grandidone B, 3-epi-grandidone	
Plectranthus nilgherricus	11,15-Dihydroxy-5,7,9(11),13-abietatetraene-12-one (=fuerstione)	
Plectranthus parviflorus	11-Hydroxy-19-(3-methyl-2-butenoyl)-5,7,9(11),13-abietateraen-12-one (=paviflorone A) parviflorone D, 11-hydroxyl-19-(3,4-dihydroxybenzoyl)-5,7,9(11),13-abietateraen-12-one (=parviflorone E), 2-(3,4-dihydroxybenzoyl)-11-hydroxy-5,7,9(11),13-abietatetraen-12-one (=paviflorone F)	For fever, infection
Plectranthus puberulentus	4*R*,19*S*-7,12,19α-Trihydroxy-1,5(10),6,8,12-abietapentene-11,14-dione (=coleon A), 7,12-dihydroxy-1,5(10),6,8,12-abietapentaene-11,14,19-trione (=coleon A lactone)	Antifeedant, antimicrobial
Plectranthus scutellaioides	Spiroscutelone A (**159**), B, C	Cytotoxic (Hela, MCF-7, PSN-1) For abdominal pain, emmenagogue, skin disorders
Plectranthus sanguineus	7α,12-Dihydroxy-8,12-abietadiene-11,14-dione (=horminone), 7α-formyloxy-12-hydroxy-8,12-abietadiene-11,14-dione (=7-O-formylhorminone), sanguinone A, 6β-hydroxyroyleaonone (=6β-hydroxyroyleanone), 7α-acetoxy-6β,12-dihydroxy-8,12-abietadiene-11,14-dione (=7α-acetoxy-6β-hydroxyroyleanone), 7α-formyloxy-6β-hydroxyroyleanone, 5,6-dihydrocoleon U, coleon U quinone, 8α,9α-epoxycoleon U quinone, grandidone A, B, 7-*epi*-grandidone A, B	
Podocarpus cupressina	12-Hydroxy-8,11,13-podocarpatriene-19-oic acid	

Podocarpus dacrydioides	5β*H*,12-hydroxy-8,11,13-abietatriene-6,7-dione, 12,16,17-trihydroxy-8,11,12-abietartrien-19-oic acid (=pododacric acid)	
Podocarpus ferrugieus	Kaur-16-ene	
Podocarpus ferrugineus	8,11,13-Abietatriene, 12-hydroxy-8,11,13-abietatriene-2-one (=2-oxoferruginol), 8,11,15-abietatrien-12-ol (=ferruginol), 8,11,13-abietatriene-12,19-diol, 12-hydroxy-8,12-abietadiene-11,14-dione (=royleanone), cupresol, cupresol methyl ether, kaur-16-ene	
Podocarpus gracilior	Podlide	
Podocarpus hallii	Hallactone A, podolactone C S-oxide, 8,14-isopimarene-2,15,16,18-tetrol (=hallol)	
Podocarpus lambertius	8,11,13-Abietatrien-19-oic acid (=lambertic acid), macrophyllic acid	
Podocarpus macrophylla	Macrophyllic acid, podototarin	
Podocarpus macrophyllus (Japanese yew)	Podocarpone E 7α,8α-epoxide (=inumakilactone B), inumakilactone A, E, ponalactone A, E	Edible (Fruits) Fruit: carminative. pectoral and stomachic, seeds: cholera, heat ailments, stomach diseases, for sweet Leaves: (decocted) For rheumatism, joint painful Fruits (decocted) Antiseptic, astringent, carminative, tonic For arsenic poisoning, fever, heart, kidney, lung, stomach, skin and ulcer diseases
Podocarpus mannii (*Afrocarpus mannii*)	Podototarin, 8,11,13-totaratriene-13,19-diol (=hydroxytotarol), 13-hydroxy-8,11,13-totaratrien-19-al, 13-hydroxy-8,11,13-totaratrien-19-oic acid	
Podocarpus milanjiamus	Milanjilactones A, B, milanjilactone B 7α,8α-epoxide	
Podocarpus nagi	Nagilactones A (**14**), B-D, podototarin, 15-methoxycarbonylnagilactone D	Antitumoral
Podocarpus nakaii	Ponalactone A, ponalactone A β-D-glucopyranoside	
Podocarpus neriifolius	Podolactone C, D	

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Podocarpus nubigena	Nubilactone A	
Podocarpus polystachyus	Podocarpone E 7α,8α-epoxide (=inumakilactone B)	
Podocarpus saligna	Salignone A, B, D, I-L	
Podocarpus sellowii	Sellowin A, B, 2β,3β-epoxysalignone H	
Podocarpus spicatus	16-Kaurene	
Podocarpus totara	Podocarpic acid, totarol (**180**), 8,11,13-abietatrien-12-ol (=ferruginol), podototarin, 8,11,13-totaratriene-13,19-diol (=hydroxytotarol), 13-hydroxy-8,11,13-totaratrien-19-oic acid, 8,11,13-podocarpatriene-12,19-diol (=podocarpic acid)	Anti-influenza, *anti*-microbial
Podocarpus urbanii	Urbalactone	
Polyalthia longifolia	16*R*-Hydroxy-3,13-cloerodadien-15,16-olide, 16-oxo-3,13*E*-clerodadien-15-oic acid, 16-hydroxycleroda-3,15-dien-16,15-olide, 16-oxocleroda-3,13*E*-dien-15-oic acid, 3,16-dihydroxy-cleroda-4(18),13,14*Z*-dien-15,16-olide,16α-hydroxy-cleroda-3,13,14*Z*-dien-15,16-olide	Antiadipogenic, antimicrobial, antiobesity, anti-*Plasmodium falciparum*
Polyalthia viridis	*ent*-16-Hydroxy-2-oxo-3, 13-clerodadien-15,16-olide (=2-oxo-3,13-kolavadien-15,16-olide), (4→2)-abeo-16-hydroxy-3-oxo-clerodadien-15,16-olide (= (4→2)-abeo-3-oxo-2,13-kolavadien-15,16-olide	
Polygonum aviculare	Diterpene alkaloid: 6-hydroxy-11-dexoy-1,3-dehydrohetisane (= panicudine) (**160**)	Beverage (herbal tea) For antirheumatism Infusion: diuretic, antimicrobial

Portulaca cv. jewel	3,13*Z*-Clerodadiene-15,16,18,19-tetrol (=jewnol A), *ent*-15,16-dihydroxy-17-oxo-3,13-clerodadien-18,19-olide (=portulide D), *ent*-7,15,16,19-tetrahydroxy-3,13-clerodadien-18-oic acid (=portulide C), portulide B, *ent*-15,16-dihydroxy-3,13*Z*-clerodadien-18,19-olide	
Portulaca grandiflora	*ent*-15,16,17-Trihydroxy-3,13Z-clerodadien-1,18-olide (=portulide, 3-hydroxyportulol ether, portulal	Vegetable (used in salads, cooked like spinach) For burns, cirrhosis of the liver, eczema, hepatitis, insect bites, snake bite, scalds, swelling and pain in the pharynx
Portulaca oleracea	Potulene	Antifungal, antimicrobial, hepatoprotective
Premna herbacea	Sirutekkone	Edible (fruits), Beverage (juice from roots and rhizomes) For dropsy, cough, asthma, fever, cholera, and rheumatism
Premna integrifilia	11,12,16-Trihydroxy-5,8,11,13-abietatetraen-7-one, 12,16-epoxy-11,14-dihydroxy-5,8,11,13-abietatetraen-7-one, 12,16-epoxy-11,14-dihydroxy-5,8,11,13-abietatetrane-7-one	
Premna latifolia	6α,11,12,16-Tetrahydroxy -8,11,13-abietatrien-7-one (=nellionol), 11,12,16-trihydroxy-5,8,11,13-abietatetraen-7-one	Cytotoxic (A-431, A-549, ACHN, B-16, F10, Hep-G2, HT-29, MCF-7, PC-2 cancer cell lines)
	Icetexanes, premnalatifolin A	Cytotoxic (MCF-7: breast, HT-29 cancer cell lines
Premna obtusifoloa	Acanthoic acid analogues, pimaranes, rosanes, abietanes, icetexanes, rearranged icetexanes,	Antimicrobial, NO production inhibitory
Premna schimperi	5*R*,8*R*,9*S*,10*R*-12-Oxo-*ent*-3,13(16)-clerod-15-oic acid, 16-hydroxy-clerod-3,13(14)-dien-15,16-olide, *ent*-12-oxolabda-8,13(16)-dien-15-oic acid, andrographolide, *ent*-12-oxo-3,13 (16)-clerodadien-15-oic acid	Antibacterial, antileishmanial

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Premna tomentosa	Icetexanes	Antioxidant, α-glucosidase inhibitory
Printzia laxa	Printzianic acid, isoprintzianic acid	
Prioria balsamifera (=Gossweilerodendron balsamiferum)	*ent*-15,16-Epoxy-4(18),13(16),14-cleroda-trien-3β-ol (=agbaniol)	
Propolis	Manoyl oxide, labda-8(17),12,13-triene, 13-*epi*-manool, communal, sempervirol, ferruginol, 14,15-dinor-13-oxo-8 (17)-labden-19-oic acid, copalol, 18-hydroxyabieta-8,11,13-triene, communic acid, totarol, 13-*epi*-torulosal, neoabietic acid, pimaric acid, imbricatoloic acid, 13-*epi*-torulosol, abietic acid (**2**), dehydroabietic acid (**43**), 13-*epi*-cupressic acid, dihydroxyabieta-8,11,13-triene, isoagatholal, 2-hydroxyferruginol, hydroxydehydroabietic acid, agathadiol, totarolon, isocupressic acid, 6,7-dihydroxyferruginol, ferruginolon, junicedric acid, acetylisocupressic acid, 13(14)-dehydrojunicedric acid, 13-succinyloxy-abietadiene, 13-succinyloxyabieta-8,11,13-triene, 13-succinyloxyabietadiene isomer, 13-succinyloxyhydroxy abietadiene	Foods Antibacterial, anti-inflammatory, antimycotic, antioxidant, antiviral, cytotoxic, immunomodulating For burns, wound healing
Prumnopitys andina	2β-Acetoxyferrugiol	Antimicrobial
Prunella vulgaris	Vulgarisins A-D	Antibacterial, anticancer, antidiabetes, anti-inflammatory, antiviral (for Helpes), cytotoxic (A549: human lung carcinoma cell line) For wound healing
Pseudopterogorgia bipinnata	Bipinnapterolide	Antimicrobial

Psidium cattleynum (=*P. cattleinum*)	3β-Kauren-18-yl acetate, phytol, thunbergol	Food, syrup, ice cream, jams, jellies, beverage (herbal tea) Infusion: antidiabetes, antineoplastic, antioxidant, astringent
Pteris cretica	2β,15α,19-Trihydroxy-*ent*-kaur-16-ene 2-*O*-β-glucopyranoside, 2β,6β,15α-trihydroxy-*ent*-kaur-16-ene 2-*O*-β-*D*-allopyranoside, 2β,6β,16α-trihydroxy-*ent*-kaurane 2-*O*-β-*D*-allopyranoside, 2β,16α,19-trihydroxy-*ent*-kaurane 2-*O*-β-allopyranoside	
Pteris dipar	5β,11β,12β-Trihydroxy-15-oxo-*ent*-kaur-16-en-19-oic acid (**38**), 7β,9-dihydroxy-15-oxo-*ent*-kaur-16-en-19,6β-olide, (16*R*),11β-hydroxy-15-oxo-*ent*-kaur-19-oic acid, (16*R*)-11β-hydroxy-15-oxo-*ent*-kaur-19-oic acid 19-β-*D*-glucoside	Cytotoxicity (KB cell)
Pteris livida	*ent*-9α-Hydroxy-15-oxo-16-kauren-19-oic acid β-*D*-glucopyranosyl ester, *ent*-6α,11α-dihydroxy-15-oxo-16-kauren-19-oic acid β-*D*-glucopyranosyl ester	
Pteris longipes	*ent*-9α,15α-Dihydroxy-16-kauren-19-oic acid, *ent*-9α-hydroxy-15-oxo-16-kauren-19-oic acid (=pterokaurene L_1), *ent*-12α,15α-dihydroxy-16-kauren-19-oic acid (=pterokaurene L_4), 11α,16α-epoxy-19-kauranic acid (=pterokaurene L_5)	
Pteris multifida	*ent*-2α,6α,15β-Trihydroxykaur-15-ene (**161**), *ent*-2α,15β-dihydroxykaur-15-ene, *ent*-2α,16β-dihydroxy-kaurane, 2α-*O*-β-*D*-glucopyranosyl-15β-hydroxylkaur-15-ene	Chinese medicine Antidysenteric, anti-inflammatory, antioxidant, antipyretic, antirheumatism, detoxicant, acne, appendicitis, bleeding
Pteris plumbaea	*ent*-2α,14α,15β,16β,17-Kauranepentol	
Pteris purpureorachis	*ent*-9α-Hydroxy-15-oxo-16-atisen-19-oic acid (=pteriatisene P_1), *ent*-9α,15α-dihydroxy-16-atisen-19-oic acid (=pteriatisene P_2)	

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Pteris semipinnata	*ent*-11α-Hydroxy-15-oxo-kaur-16-ene (**5**)	Chinese medicine Anticancer, apoptosis, cytotoxic (HT-29 and MNK-45 human colon cancer cells), snake bites
Pteronia divaricata	3-Hydroxypteronialacone, 3-oxopteronialacone	
Pteronia eenii	19-Hydroxypteronia dilactone (=pteroniatrilactone), 15,16-Epoxy-3α,4β,8β,10β,-tetrahydroxy-13(16),14-clerodadien-20,1-olide, 15,16-epoxy-3α-oxo-4β,8β,10β,-trihydroxy-13(16),14-clerodadien-20,1-olide, pteroneeniol, secoeeniolide	
Pteronia incana	15,16-Epoxy-3α,4β,10β-trihydroxy-13(16),14-clerodadien-20,1-olide, 15,16-epoxy-3α-acetoxy-4β,8β,10β,-trihydroxy-13(16),14-clerodadien-20,12-olide, 3α,4α:8β,12:15,16-triepoxy-10-hydroxy-13(16),14-clerodadien-20,1β-olide, incanpteroniolide	
Pteronia paniculata	7-Oxo-3-cleroden-15-oic acid (=7-oxo-13,14-dihydrokolvanic acid), 3-cleroden-15-oic acid	
Pulicaria gnaphaloides	15,16-Epoxy-3,13(16),14-clerodatrien-18,6-olide	Antioxidant
Pulicaria salviifolia	*ent*-15,16-Epoxy-6β,7α-dihydroxy-3,13(16),14-clerodatrien-18-oic acid, *ent*-15,16-epoxy-3,13(16),14-clerodatrien-18,6-olide (=salvin)	Antioxidant
Pycnocycia spinosa	3,7,10,15-Pentaacetyl-5-butanoyl-13,17-epoxy-8-myrsinene	Antispasmodic
Pygmaecopremna herbacea	3β,11-Dihydroxy-5,7,9(11),13-abietateraene-2,12-one (=isobharangin), bharanginin, pimaeocin A, pytmaoecin C	
Pyllostachys edulis (bamboo shoot)	Gibberellin A_{21}	

Rabdosia adenantha	*ent*-1β,7α,11α-Triacetoxy-3α-hydroxy-16-kaurene-6,15-dione (=adenanthin)	Anti-inflammatory, bacteriostatic
Rabdosia amethystoides	ent-7β,14α,20-Trihydroxy-16-kaurene-11,15-dione (=amethystoidin A)	Chinese medicine For treating acute lymphocyte leukemia, cervical cancer
Rabdosia coetsoides	Plecostonol, *ent*-3α,7β,14α),20-tetrahydroxy-16-kauren-15-one (=coestinol)	Beverage (herbal tea), cooked with meat (Potherb)
Rabdosia effusus (=*Isodon effusus*)	*ent*-7,20-Epoxy-1β,6α,7-trihydroxy-16-kauren-15-one (= effusanin A), *ent*-7,20-epoxy-1β-acetoxy-6α,7-dihydroxy-16-kauren-15-one (= effusanin B), effusanin C, D	Antibacterial
Rabdosia eriocalyx (=*Isodon eriocalyx*)	*ent*-15α-Acetoxy-3,20-epoxy-6α-hydroxy-16-kaurene-1,7-done (=maoecrystal A), *ent*-7,20-epoxy-16-kaurene-1α,3α,6α,15α-tetrahydroxy-19-*O*-β-D-glucopyranoside (=1α,3α,6α,15α-rabdoside 2), *ent*-19-acetoxy-7,20-epoxy-1α,3α,6α,7-tetrahydroxy-16-kauren-15-one (= maoecrystal I), neolaxiflorin A, B, eriocalyxins C−E, laxiflorins J−M, maoecrystal P, maoeriocalysins A-D	Cytotoxic (K562, T24 human tumor cells)
Rabdosia excisa	Excisanin H-K, kamebakaurin *ent*-1β,7β,12β,14α-tetrahydroxy-16-kauren-15-one (=excisanin A), ent-1β,7β,14α-trihydroxy-12β-acetoxy-kaur-16-en-15-one (=excisanin B)	Anti-inflammatory cytotoxic (P-388: murine leukemia cell)
Rabdosia flexicaulis (=*Isodon flexicaulis*)	*ent*-20-Acetoxy-7β,11α,14α-trihydroxy-kauren-15-one, flexicaulin A, *ent*-1β,7β,14α-trihydroxy-20-acetoxy-16-kauren-15-one (=henryin A)	
Rabdosia henryi (=*Isodon henryi*)	*ent*-1β,7β,14α-Trihydroxy-20-acetoxy-16-kauren-15-one (=henryin A), *ent*-1β,7β,14α,20-tetrahydroxy-16-kauren-15-one (=kamebakaurin), *ent*-7β,14α,18-trihydroxy-16-kaurene-11,15-dione (=4-epihenryin A), exidonin, dophyllin G, lasiokaurin, epi-nodosin, isodonhenrins A-E	Chinese Folk medicine Cytotoxic (HL-60, SMMC-7721, A-549, MCF-7, SW480 human tumor cell lines)

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Rabdosia inflexa (=*Isodon inflexus*, Plectranthus *inflexus*)	*ent*-1β,3α-Diacetoxy-16-kaurene-6β,11α,15-triol (= inflexarabdonin A), inflexarabdonin B, E, 1α,3α-diacetoxy-6β,11β-dihydroxy-16-kauren-15-one (=*ent*-inflexinol), *ent*-1α,3α-diacetoxy-11β-hydroxy-16-kaurene-6,15-dione (=inflexin)	Anti-inflammatory, gastroprotective, NF κB and NO production inhibitory For inflammatory diseases
Rabdosia kunmingensis	*ent*-7β,11α,12β-Trihydroxy-14α-acetoxy-16-kauren-15-one (= rabdokunmin A) *ent*-7β,11α,12β,14α,18-pentahydroxy-16-kauren-15-one (=rabdokunmin E), rabdokunmin B-D, *ent*-7β,11α,12β,14α-tetrahydroxy-16-kauren-15-one (= rabdoloxin B)	
Rabdosia latifolia	*ent*-1β-Acetoxy-3β,7β,14α-trihydroxy-16-kauren-15-one (=reniformin B), *ent*-1β,7β,14α-trihydroxy-20-acetoxy-16-kauren-15-one (=henryin A)	Cytotoxic (A-549, HepG2, MCF-7, BCG-823, HeLa cancer cell lines)
Rabdosia liangshanica	7β,14α-Dihydroxy-1,16-kauradiene-3,15-dione (=liangshanin A), liangshinin B-F, *ent*-11α,16α-epoxy-17-kauranol	Anti-hepatitis virus
Rabdosia longituba	Effusanin B, *ent*-1β,7β,14α,20-tetrahydroxy-16-kauren-15-one (=kamebakaurin), *ent*-7,20-epoxy-6α,7,24α-trihydroxy-16-karen-15-one (=longikaurin A), longikaurin B, *ent*-6α,15α,20-triacetoxy-2,16-kauradiene-1,7-dione (=longirabdosin), isolongirabdiol, lasiokaurin, oridonin (**139**), rabdokaurin B, C (**162**), D (**163**), rabdophyllin G	Antimicrobial, antitumor
Rabdosia lophanthoides	6β,12-Dihydroxy-7α-methoxy-16-acetoxy-8,12-abietadiene-11,14-dione (=lophansthoidin A), 6β,12-dihydroxy-7α,16-diacetoxy-16-kauren-8,12-abietadiene-11,14-dione (=lophansthoidin B), lophansthoidin C-F	For hyperlipidemia

Rabdosia macrocalyx	*ent*-7,20:14,20-Diepoxy-1β-6α,11α,16-kauren-15-one (=macrocalin B), *ent*-1β,7β,12β,14α-tetrahydroxy-16-kauren-15-one, *ent*-1β,7β,12β,14α-tetrahydroxy-16-kauren-15-one (=excisanin A), *ent*-1β,7β,14α-trihydroxy-12β-acetoxy-16-kauren-15-one (=excisanin B), macrocalin A, macrocalysin	
Rabdosia macrophylla	*ent*-7β,14α,20-Trihydroxy-16-kaurene-11,15-dione (=amethystoidin A), *ent*-1β-acetoxy-7,20-epoxy-6α,7,14α-trihydroxy-16-kauren-15-one (=lasiokaurin)	Antitumor
Rabdosia nervosa	*ent*-6α,15α-Diacetoxy-7,20-epoxy-3α,7-dihydroxy-16-kauren-1-one, 3β-hydroxy-1α,7β,11β, 15β-tetraacetoxy-*ent*-kaur-16-en-6-one	For acute hepatitis, snake bites
Rabdosia parvifolia	*ent*-Isopimarene-6β,7β,8β-triol, *ent*-iso-pimar-15-en-6α,7α,8α-triol, parvifoline A, B, *ent*-3α-acetoxy-iso-pimar-15-en-8α-ol	
Rabdosia phyllostachys	Phyllostachysin A, B, 6β,11β,14β-trihydroxy-15α-acetoxy-*ent*-kaur-16-en-7-one-20-al	Antineoplastic
Rabdosia pseudo-irrorata	*ent*-3β,7β,14α-Trihydroxy-16-kauren-15-one (=pseurata A), *ent*-3β,7β,11β,14α-tetrahydroxy-16-kauren-15-one (=pseurata B), pseurata D-F	For eye inflammatory, round worm killing
Rabdosia rosthornii	*ent*-11α,19-Diacetoxy-7β,13β-dihydroxy-16-kauren-15-one (=rosthornin B), A-D, *ent*-7,20:14,20-diepoxy-1β,6α,7-trihydoxy-16-kauren-15-one (=ponicidin), *ent*-11α-acetoxy-13β,19-dihydroxy-16-kauren-15-one (=rosthorin)	Antibacterial
Rabdosia rubescens	*ent*-7,20-Epoxy-16-kaurene-6α,11α,14α,15α-tetraol (=rubescensin C), *ent*-2α,3α,6α,7α,11β-tetraacetoxy-7-hydroxy-16-kauren-15-one (=lushanrubescensin), lushanrubescensin B-E, *ent*-7,20:14,20-diepoxy-1β,6α,7-trihydoxy-16-kauren-15-one (=ponicidin), 3α,6β,11β,12β,-tetrahydroxy-16-kauren-15-one (=xindongnin B)	For prostate cancer, oral infection, enlarged prostate, prostatic hyperplasia

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Rabdosia serra	*ent*-7,20:18,20-Diepoxy-1β,14-dhydroxy-16-kauren-15-one (=rabdoserrin A), *ent*-1β,7β,12β,14α-tetrahydroxy-16-kauren-15-one (=excisanin A), *ent*-1β,7β,14α-trihydroxy-12β-acetoxy-16-kauren-15-one (=excisanin B), *ent*-1β,7β,14α,20-tetrahydroxy-16-kauren-15-one (=kamebakaurin), *ent*-1α,7β,14α-trihydroxy-12β-acetoxy-16-kauren-15-one (=rabdoserrin D)	Antimicrobial, anticancer (HepG2), anti-hepatitis B virus (anti-HBV)
Rabdosia shikokiana	Shikoccin (**164**), shikoccidin (**165**), *ent*-7,20-Epoxy-16-kaurene-6α,7α,11β,15α-tetrahydroxy-1-*O*-β-*D*-glucopyranoside (=shikokiaside A), rabdosichuanin D, rabdosianin A, B, shikokianoic acid, 11-acetoxyshikokianoic acid-6-al	Cytotoxic (anti-Ehrlich carcinoma)
Rabdosia ternifolia	*ent*-7,20-Epoxy-1β,6α,7,11α-tetrahydroxy-16-kauren-15-one (=lasiodonin), rabdoternin A, ternifolin, isodonoic acid, isodonal, longikaurins A, E	
Rabdosia trichocarpa	Tricholabdal A, H, 3-deoxytrichorabdol D (=trichorabdal B), trichorabdal D, 11-deoxytrichorabdal D (=tricholabdal C)	Deodorizing effect Antibacterial, antimutagenic, antitumoral, bitter stomachic, deodorizing
Rabdosia weissiensis	*ent*-1β,3α,6β,7α,11α-Pentahydroxy-16-kauren-15-one (=weissiensis A)	
Radix miltiorrhizae	Miltionins A-D	Anti-influenza A
Ramalina hierrensis (Lichen)	(-)-*ent*-kauran-16α-ol (**36**), (-)-Sandaracopimaric acid (**35**)	Anti-inflammatory, cytotoxic
Ramalina tumidula (Lichen)	(-)-*ent*-kauran-16α-ol (**36**), (-)-Sandaracopimaric acid (**35**)	Anti-inflammatory, cytotoxic

Relhania calycina	*ent*-3α,15-Dihydroxy-8,14-pimarene-16-*O*-β-*D*-glucopyranoside, 2α,16β-17-trihydroxy-3-kauranone, *ent*-2α,16β-dihydroxy-3-kauranone-17-*O*-β-*D*-glucopyranoside	
Relhania corymbosa	*ent*-Nor-3,5-clerodadien-15-ol, 19-nor-3-oxo-4-cleroden-15-oic acid	
Relhania genistifolia	3α,4α-Dihydroxy-15-clerodanoic acid, *ent*-3α,4α-dihydroxy-13-cleroden-15-oic acid, *ent*-3,7α-dihydroxy-2-oxocleroden-15-oic acid, *ent*-3α-hydroxy-7α-acetoxy-cleroden-15-oic acid methyl ester, *ent*-7α-acetoxy-5-oxo-4(19)-cleroden-15-oic acid	
Relhania squarosa	*ent*-2-Hydroxy-3-oxo-1,4(19)-clerodadien-15-oic acid, *ent*-3-oxo-4(19)-cleroden-15-oic acid	
Rhododendron japonicum	2,3-Epoxy-6β,14β-diacetoxy-5β,10α,16α-grayantoxanetriol (=rhodojaponin I), 2,3-epoxy-6-acetoxy-5β,10α,14β,16α-grayanotoxatetrol (=rhodojaponin II), 2,3-epoxy-5β,6β,10α,14β,16α-grayantoxanepentol (=rhodojaponin III), rhodojaponin IV, 2,3-epoxy-14-acetoxy-5β,6β,10α,16α-grayanotoxatetrol (=rhodojaponin V), rhodojaponin VII	Cytotoxic
Rhynchospermum verticillatum	*ent*-15,16-Epoxy-3,13(16),14-clerodatrien-18,19-olide-12*R*-*O*-β-*D*-glucopyranoside (=rhynchospermoside A), *ent*-15,16-epoxy-3,13(16),14-clerodatrien-18,19-olide-12*S*-*O*-β-D-glucopyranoside (=rhynchospermoside A), *ent*-15,16-epoxy-1-oxo-2,13(16),14-clerodatriene-17,12:18,19-diolide (=rhynchosperin A), rhynchosperin B, C	
Roylea calycina	Calyone (=3-acetoxy-15,16-epoxy-9-hydroxylabdα-13(16),14-dien-7-one), calyenone [=3-acetoxy-15,16-epoxylabdα-8,13(16)-trien-7-one], precalyone (=3-acetoxy-9,13;15,16-diepoxylabda-14-en-7-one)	Antitumor (lymphocytic leukemia)

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Rubus chingi	Labdanes	Cytotoxic (A549, A2780, BGC-823, HCT-8, MCF-7, M231, NP14, NTUB1 cancer cell lines)
Rubus orchorifolius	*ent*-Kaur-2-oxo-16β,17-dihydroxyacetoneketal	Beverage (herbal tea), cytotoxic (HCT 116: human colon cancer cell)
Rubus suavissimus	Rubsoside (=steviol-13,19-di-*O*-β-*D*-glucoside) (**19**), stevioside (**20**), rebaudioside A (**25**), suavioside A (**19a**), steviol monoside (**19b**), suaviaside B (**19c**), suaviosaide G (**19d**), suavioside J (**19e**), suavioside H (**19f**), suavioside I (**19g**), *ent*-3-oxo-16β-kaurane-17-*O*-β-glucopyranoside (**19h**), panicloside IV, *ent*-16α,17-dihydroxykauran-19-oic acid	Beverage (herbal tea) Antiangiogenic, antiallergic
Ryonia speciosa	Ryanodine, dehydroryanodine, ryaniaditerpene esters A-D	Calcium transport blocker, insecticide
Salvia aegyptiaca	(*E*,*E*,*E*)-cembrene A	
Salvia aethiopsis	Manool (**34**),15-nor-hydroxy-13-epi-manoyloxide-14-oic acid, salvipisone, 4,5-seco-5,10-friedo-4(18),5(10),6,8,13-arucadiol (=1-ketoaethiopinone)	Antibacterial
Salvia africanalutea	Carnosol (**16**), carnosic acid	Anticancer (breast), anti-inflammatory, antimicrobial, antioxidant, serum triglyceride elevation inhibitory
Salvia amplexicaulis	7-Oxo-abietα-9,12,14-triene, horminone, 7-acetyl-horminone, sugiol, ferruginol	Antihypertensive, cardioactive, vasorelaxant
Salvia anastomosans	Anastomosine	
Salvia apiana	11,12,16-Trihydroxy-8,11,13-abietatrien-20-oic acid (=16-hydroxycarnosic acid)	

Salvia argentea	1*R*-Hydroxy-20-nor-5(10),6,8,13-abieta-tetraene-11,12-dione (=1*R*-hydroxymiltirone), 11,12-dihydroxy-20-*nor*-5 (10),6,8,13-abietatetraen-1-one (=arucadiol), 4,5-seco-5,10-friedo-4(18),5(10),6,8,13-arucadiol (=1-ketoaethiopinone), isopimara-8(9),15-diene, salvipisone, ferruginol, aethiopinone, isocembrene, manool (**34**), sclareol oxide	Foods, basal leaves Acetylcholinesterase and *butyrylcholinesterase* inhibitory, antibacterial, antioxidant, hemostatic, mosquito larvicidal
Salvia atropatana	Atropatanene, 7α-acetoxyroyleanone, saprothoquinone, aethiopinone	Cytotoxic (PC3: prostate cancer cell line)
Salvia austraca	7α-Acetoxyroyleanone, 7α-hydroxyroyleanone	
Salvia ballotaeflora	19,20-Epoxy-7α,12,20-trihydroxy-8,12-abietadiene-11,14-dione, icetexine, romulogarzone	
Salvia barrelieri	Barreliol, royleanone 12-methyl ether, 7-episalviviridinol, iguestrol, ferruginol, taxodione, viridone, demethylinuroyeanol, isomanool, 7-oxo-royeanone-12-methyl ether, 7α-acetoxy-royleanone-12-methyl ether, royleanone, horminone, 7-acetylhorminone, cryptojaponol, inuroylenol	Antioxidant, antibacterial, diuretic, emmenagogue, spasmodic
Salvia bicolor	8,11,13-Abietatriene-7α,11,12-triol	
Salvia bleapharochelana	Psiferic acid derivatives, *O*-methylpisiferic acid, *O*-methylpisiferic acid methyl ester	Antibacterial, antifungal
Salvia bracteata	Bractealine	Antibacterial
Salvia breviflora	*ent*-2β,18-Epoxy-19-hydroxy-3,13-clerodadien-16,15-olide	
Salvia broussonetii	Brussonol	Cytotoxic, insect repellent (sting bag)
Salvia canariensis	7α-Ethoxy-12-hydroxy-8,17-abietadiene-20,6β-olide (=canariquinone), dexoycarnosol methyl ether, rosmaquinone, 7-ethoxyrosmanol, salvicecanaric acid, 7,11,12-trihydroxy-20-*nor*-5,7,9,11,13-abietapentaen-1-one (=arucatriol)	

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Salvia candelabrum	Candesalvone, candesalvone A [11, 12, 14-trihydroxy-19 (4→3)-abeo-3, 8, 11, 13-abietatetraen-7-one], candesalvone B [11, 12, 14-trihydroxy-7-oxo-3, 4-seco-4 (18), 8, 11, 13-abietatetraen-3-oic acid] 12,14-trihydroxy-8,11,13-abietatriene-3,7-dione (=candelabrone)	
Salvia candidissima	Candidissiol, manoyl oxide, pachstazone, 20-deoxocarnosol, aethiopinone	
Salvia cardiophylla	Cardiophyllidin, 2,12-dihydorxy-8,11,13-abietarien-7-one (=2α-hydroxysugiol)	
Salvia carnosa	11,12-Dihydroxy-8,11,13-abietatriene-20,7β-olide (=carnosol) (**16**)	
Salvia castanea	Tanshinone II (A), tanshinone II (B), hydroxytanshinone II (A), tanshinone I (**21**), dihydrotanshinone I, cryptotanshinone I, neotanshinone A, neotanshinone B, tanshinone aldehyde, przewaguinone A, przewaguinone B, sugiol	Antioxidant
Salvia chinensis	Salvianol acid, methyl salviano acid, methyl salvianate A, dimethyl lithospermate, salvianoic acid	
Salvia chinopeplica	19-Hydroxyroyleanone, carnosol (**16**), 16-hydroxycarnosol, 16-hydroxy-20-deoxocarnosol, 16-hydroxycanosic acid, 16-hydroxyrosmanol, 11,12,16-trihydroxy-20-*nor*-labdan-5 (7),8,11,13-tetraen-1-one	
Salvia chionantha	Horminone, 7-acetyl horminone	
Salvia chrysephylla (golden leaf sage)	sclareol (**22**)	Antioxidant, acetylcholine esterase and butyrylcholine esterase inhibitory
Salvia cinnabarina	3,4-Secoisopimar-4(18),7,15-triene-3-oic acid	Hypotensive, intestinal spasmolytic activity, intestinal motility

Salvia clevelandii	Rosmadial, 16-hydroxycarnosol, abieta-8,11,13-triene, taxodone, carnasol, rosmanol (**17**), carnosic acid	Anticancer, cytotoxic
Salvia clinopodioides	Clinopodioides A-D	Antilipido-peroxidative, antiamoebic, antigiardial, antioxidant, antipropulsive, antiprotozoal
Salvia coccinea	Clerodatetraene-17,12:18,19-diolide (=salviacoccin)	
Salvia columbariae (Chia)	Tanshinone II A, cryptotanshinone (**45**)	Food (seeds) Cytotoxic
Salvia corrugata	Fruticuline A, C, demethylfruteculine A	Antimicrobial, bacteriostatic
	7α-Methoxy-19-acetoxyroyleanone, 7α,19-diacetoxyroyleanone, 7-dehydroxyconacytone	Chemopreventive
Salvia cryptantha	6,8,11,13-Abietateraene-11,12,14-triol (=cryptanol), 2β,12-dihydroxy-8,12-abietadiene-11,14-dione (=2β-hydroxyroyleanone), fruticuline C, 7α-methoxy-19-acetoxy-royleanone, 7α,19-diacetoxy-royleanone, 7-dehydroxyconacytone	Chemopreventive
Salvia divinorum (psychoactive mint)	Salvadoran A (=divinorum A), B, salvinorin C-G, divinatorins A-D, hardwickiic acid, salvinicin A , B, salvidivin A, C, H	Anti-inflammatory, recreational drug, agonistic activity to opioid receptor For headache, diarrhea, hallucinations
Salvia elegans	Pimara-7,15-dien-3-one, sclareol (**22**), totarol, 13β-methylvinylpodocarp-7-en-3β-ol	Antianxiety, antidepressant, antihypertensive, antioxidant For hypertension
Salvia eremophila	Carnasol, carnosic acid	Beverage (herbal tea), flavoring agent Antimicrobial, antioxidant
Salvia eriophora	Ferruginol, aethiopinone, 1,2-dihydroxysapi-paraquinone, 6,7-didehydroroyleanone, 4,14-dihydroxysaprotho-quinone	Antihypertensive, cardiovascular activity, vasorelaxant
Salvia euphratica	8,11,13-Abietatriene-2α,11,12-triol (=eupharatricol), 11,12,15-trihydroxy-8,11,13-abietatrien-20-al (=euphracal)	
Salvia farinacea	*ent*-10βH-7β,20:12, 20:15, 16-Triepoxy-1,2,13(16), 14-clerodatetraen-18,19-olide	
Salvia forskahlei	Forskalinone, multicaulin	Antibacterial

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Salvia fruticosa	Carnosol (**16**), dehydroabietic acid (**43**), carnosic acid	Antibacterial, antioxidant Infusion: For headache, circulatory system diseases
Salvia fruticulosa	11-Hydroxy-2-methoxy-19,20-dinor-1,3,5(10), 7,9(11),13-abietahexaene-6,12-dione, fruticulin A, demethylfruticulin	Anticholinesterase, antimicrobial, antioxidant
Salvia fulgens	Salvifulgenolide, (*E*)-1,2-dihydro-salvifaricin, *ent*-19-acetoxy-15,16-epoxy-3,13(16),14-clerodatrien-6,18-diol, *ent*-19-acetoxy-15,16-epoxy-6-hydroxy-3,13(16),14-clerodatrien-18-al, 10β-hydroxy-bacchotrieneatin A	Culinary herb Hallucinogenic For stomach ailments
Salvia gilliessi	5-*epi*-Icetexone	Antimicrobial, antiproliferation, antitrypanosomal (*Trypanosma cruzi*)
Salvia glutinosa	12-Deoxydanshenxinkun B, dihydroisotanshinone II, isotanshinone II	Anticholinesterase, antimicrobial, antioxidant
Salvia grandifolia	Grandifolia A-F, tanshinone VI, tetrahydrotanshinone, tanshinone II B, danshenol B, salvianolic acid, nepetoidin B	Hepatoprotective, vasorelaxant
Salvia greggii	Salvigresin, salvigresides A-D, 15,16-epoxy-10-hydroxy-13(16),14-clerodadiene-17,12:18,19-diolide (=7,8β-dihydrosalviacoccin)	
Salvia herbacea	Tehuanin A-H	
Salvia hispanica (chia)	Hispanin A (**166**), B-F, G (**167**), I, J, 12-hydroxyhautriwaic lactone, bacchotricuneatin, rhynchospermoside, (*E*)-1,2-dihydro-salvifaricin, 8-hydroxysalviarin, 12-hydroxyhardwickic acid	Food (seeds) Antidiabetes, anti-inflammatory, cardioprotective For cardiomyocyte injury, cardiovascular diseases, nervous system disorders
Salvia hypargeia	6β,12-Dihydroxy-8,11,13-abietatriene-1,7-dione (=hypargenin A), 12,15-dihydroxy-8,11,13-abietatrien-7-one (=hypargenin B), 12-hydroxy-8,11,13-abietatrien-6,7-dione (=hypargenin C) hypargenins D-F	Antibacterial, antimicrobial

Salvia infuscata	Infuscatin	
Salvia jamensis	15,16-Epoxy-cleroda-3-en-7α,10β-dihydroxy-12,17:19,18-diolide, Isopimaric acid	Increase adenosine-5'-diphosphate induced platelet aggregation inhibitory
Salvia keerlii	7α-Acetoxy-12*R*-hydroxy-*neo*-cleroda-3,13(14)-diene-15,16:18,19-diolide (=kelinolide), 7β,12-dihydroxy-3,13-clerodadiene-15,16:18,19-diolide (=kerlinolide), *ent*-8α,12R-epoxy-3,13*S*(14)-clerodadiene-15,16:18,19-diolide (=kerlin), *ent*-15,16-epoxy-6β-hydroxy-3,13(16),14-cleroda-trien-19-oic acid (=kerlinic acid)	
Salvia kronenburgii	Horminone, 7-acetyl horminone	
Salvia lanata	7α,12-Dihydroxy-8,12-abietadiene-11,14,20-trione (=desacetylnemorone), 7α-acetoxy-12,20-dihydroxy-8,12-abietadien-11,14-dione	
Salvia languidula	Languiduline	
Salvia lanigera	Langierol, 11,14-dihydroxy-8,11,13-abietatrien-20,7-olide	Antimicrobial
Salvia lasiantha	*ent*-10β-Acetoxy-2-oxo-3,13-clerodadien-15,16-olide	
Salvia lavandulifolia	Galdosol	Beverage (herbal tea, liqueur), condiment Antimicrobial, antioxidant, cytoprotective
Salvia leriaefolia	8(17),12*E*,14-Labdadien-6,19-olide	Antimicrobial
Salvia leucantha	Salvoleucalon B	Cytotoxic
Salvia limbata		Antioxidant, antiviral
Salvia lineata	*ent*-15,16-Epoxy-1,3,13(16),14-clerodatetraene-17,12:18, 19-diolide (=linearifolin), *ent*-15,16-epoxy-1(10),2,13(16),14-clerodatetraene-17,12:18, 19-diolide (=dehydrosalvianin)	
Salvia macrophylla	Corsonic acid, salvimacrophyllin A-D, 17-methoxycarnosic acid, 7-oxo-8(14),15-iso-pimaradien-18-oic acid (=7-oxosandaracopimaric acid), 7-oxo-sandaradomimaric acid methyl ester	Antimicrobial
Salvia macrosiphon	13-epi-Manoyl oxide, savigenin	Cytotoxic, laxative For cough, sore throat

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Salvia melissodora	Melisodoric acid, *ent*-2α,7β-dihydroxy-3,13-clerodadiene-16,15:18,19-diolide, *ent*-2α-acetoxy-7β-hydroxy-3,13-clerodadiene-16,15:18,19-diolide, *ent*-2α-hydroxy-7β-acetoxy-3,13-clerodadiene-16,15:18,19-diolide, *ent*-2α-acetoxy-7-oxo-3,13-clerodadiene-16,15: 18,19-diolide, 7α,18,19-trihydroxy-3,13-clerodadien-16,15-olide, *ent*-6β-hydrocy-3,13-clerodadien-15,16-olide-19-oic acid	Antifeedant
Salvia miltiorrhiza	Tanshinone I (**21**)	Anti-inflammatory, apoptosis (MCF-7: breast cancer, MDA-MB-231: estrogen receptor negative estrogen receptor positive), cytotoxic (MCF-7, MDA-MB-231 cancer cell lines) NO production inhibitory Apoptotic inducing effect (rat primary cortical cells)
	Tanshinone I (**21**), tanshinone II, tanshinone II B, tanshinoic acid, militibetin A, yunnannin A, ferruginol, miltionones II, 15,16-dihydrotansinone I	Enhance activity of insulin on the tyrosine phosphorylation of the insulin receptor (RI) β-subunit Cytotoxic (HONE-1, HT-29, P388 cancer cell line) For angina, heart attack, stroke
	Sibiriquinone A, B cryptotanshinone (**45**)	Anticancer (HIF-1: gastric, Hep 3B human cancer cell lines)
	Tanshinone II A (**168**)	Apoptotic inducing effect on a large variety of cancer cells, osteoclastogeneis inhibitory
	Cryptotanshinone (**45**) Tanshinone II B, tanshinone lactone A	Anti-Alzheimer's disease, antiproliferative, immunomodulatory
	8,11,13-Abietatriene-2α, 12-diol (=salviol), 2α-hydroxyferruginol), 7β-hydroxy-8,13-abietadiene-11,12-dione, 11-hydroxy-8,11,13-abietatrien-7-one (=sugiol), 12,6-epoxy-20-*nor*-5,7,9,12,15-abietapentadiene-11,14-dione, danshenspiroketal lactone, 13-epidanshen-spiroketal lactone,	

	3,16-dihydroxy-2-isopropyl-8-methyl-1,4-phenanthraquinone (=danshexinkun A), danshexinkun B, C, 1,2-dihydro-1,6-dimethylfuro[3,2-c] naphtha[2,1-e]-oxepine-10,12-dione, formyltanshinone, isotanshinone I, methylenedihydrotanshin-quinone, 4-methylenemiltirone, miltinone I, miltinone II, miltirone, 1,5,7,9,13-abietapentaene-11,12-dione (=didehydromiltirone), neocryptotanshinone, tanshindiols A-C, tanshinlactone, 1,2,15,16-tetrahydro-tanshinone I, tanshinone II, 3α-hydroxytanshinone II A, tanshinone II B, tanshinonic acid methyl ester, 6,7,8,9-tetrahydro-1,6,6-trimethylfuro[3,2-c] naphtha[2.1-e]oxepine-10,12-diene, salviolone, 7β,20-epoxy-13-methyl-8,11,12-podocarpatrien-12-ol (=norsalvioxide)	
Salvia moorcrofiana	11β-Hydroxy-5,7,9(11), 13-abietatetraen-12-one, 11-hydroxy-5,7,9(11),13-abietatetraen-12-one (=deoxyfuersitone)	
Salvia multicaulis	12-Demethylmulticaulin, multiorthquinone, 2-demethyl-multiorthquinone, 12-methyl-5-dehydro-acetylhorminone, salvipinarone	Antibacterial, anticholinesterase, antioxidant
	12-Methyl-5-dehydrohorminone	Antifungal
Salvia nemorosa	7,12-Dihydroxy-8,12-abietadiene-11,14,20-trione (=desacetylnemorone)	
Salvia officinalis	Carnosol (**16**), 12-*O*-methyl carnosol, isorosmanol (**18**), columbaridione, carnosic acid (**169**), 12-*O*-methylcarsonic acid, rosmanol (**17**), epi-rosmanol, galdosol, atunzensin A, rosmadial, miltirone, (*5S,6S,7S,10R,12S,13R*)-7-hydroxyapiana-8,14-diene-11,16-dion-(22,6)-olide, (*5S,6S,7S,10R,12R,13S*)-7-hydroxyapiana-8,14-diene-11,16-dion-(22,6)-olide, (*5S,6S,7S,10R,12R,13S*)-7-hydroxyapiana-8,14-diene-11,16-dion-(22,6)-olide, rosmanol-7-ethyl ether, 6,7-O-dimethyl-epi-rosmanol (**170**), abietane-7-oxoroyleanone-12-methyl ether, 7-acetoxyroyleanone-12-methyl ether, royleanone, horminone, 7-acetylhorminone,	Foods, food flavor (sausage, pickles, soup, canes, vine), beverages (herbal tea), crude drugs, spice Anthelmintic, antibacterial, antifungal, anti-inflammatory, antioxidant, antiobesity, antisecretary, antiseptic, antispasmodic, antiviral, astringent, carminative, central nervous system (CNS) activity, cytotoxic (Caco2: colonic carcinoma, HepG2; hepatoma cancer cell lines), diuretic, emmenagogue, gastroprotective, hemostatic, hypoglycemic, insect repellent, NO production and NF-κB transcription factor inhibitory, sedative, strengthen bones and

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
	cryptojaponol, inuroyleanol (=7-oxo-11,14-dihydroxy-12-methoxy-8,11,13-abietatriene, 20-norabietanes: safficinolide (**171**), sageone (**172**), 7-methoxyrosmanol, galdosol, royleanone, horminone, acetylhorminone, manool (**34**)	immune system, tonic, tranquilizer, wound healing For cough, hot infusion: for bronchitis, stomachic
Salvia oxodon	3α-Hydroxy-dehydroabietic acid, 3β-acetoxy-abieta-8(14)-en-18-oic acid 9α,13α-endoperoxide, 3β-hydroxyabieta-8(14)-en-18-oic acid 9α,13α-endoperoxide	
Salvia pachphylla	Carnasol, 20-deoxocarnasol, carsonic acid, iso-rosmanol (**18**), 7-methoxyrosmanol, 5,6-didehydro-*O*-methylsugiol, 8β-hydroxy-9(11),13-abietadien-12-one, 11,12-dioxoabieta-8,13-dione, 11,12-dihydroxy-20-*nor*-abieta-5(10),8,11,13-tetraen-1-one, pachyphyllone	
Salvia pachstachys	2,12-Dimethoxy-8,11(13)-abietatriene (=salvinol dimethyl ether)	
Salvia phlomoides	11,12-Dihydroxy-8,11,13-arbietatrien-7-one (=demethyl-cryptojaponol), 6α,7β-dihydroxy-8,13-abietadiene-11,12-dione, 6,11,12trihydroxy-5,8,11, 13-abietatetraen-7-one	
Salvia plebeia	Plebeianiol, carnosol (**16**), isocarnosol, saficinolide (**171**), 2,11,12-trihydroxy-7,10-epoxy-8,11,13-abietatriene, 2β,3β:18,19-diepoxy-10-hydroxy-7,13(16),14-clerodatriene-17,12:18,19-diolide	Anti-inflammatory, antimicrobial, antioxidant, antitumor, urinary tract infection For bronchitis
Salvia polycephala	20-Hydroxy-3,13*Z*-clerodadien-15-oic acid (=stephalic acid)	
Salvia polystachia	linearolactone	Antiprotozoa
Salvia pomifera		Antioxidant

Salvia pratensis		Antimicrobial, antioxidant
Salvia prionitis	4-Hydroxy-saprorthoquinone, 3-keto-4-hydroxy-saprorthoquinone, 11,12-dihydroxy-5,8,11,13-abietatetraen-7-one (=salvinolone), 4,5-seco-5,10-friedo-3,5,6,8,13-abietapentaene-11,12-dione (saprorthoquinone), sapriparaquinone, 3-oxo-sapriparaquione, 4-hydroxysapripara-quinone, pionitin, salvinolacone	Cytotoxic (HL-60: leukemia, SGC-790 and MK-28): stomach cancer cell lines
Salvia przewalskii	Tanshinone II, Cryptotanshinone (**45**), 18-deoxy-3α-hydroxy-tanshindiol A (=tanshinodiol B), 18-deoxy-3β-hydroxy-tanshindiol A (=tanshinodiol C)	Induce CYP3A4 at transcriptional level, by activating human pregnane X-receptor on HepG2 cells, vasorelaxant
Salvia puberuda	Isosalvipuberulin	
Salvia pubescens	19*R*-acetoxy-19-deoxoicetexone, 3β,11,12-trihydroxy-8,11,13-abietatrien-7-one (=3β-hydroxydemethylcryptojaponol), 19(4→3)abeo-11,12-dihdyroxy-4(18)-8,11,13-abietatetraen-7-one	Antibacterial
Salvia recognita	12-Methyl-5-dehydro-horminone	Antifungal
Salvia reflexa	8-Hydroxysalviarin, 7,8-didehydrorhyacophiline, 15,16-epoxy-8α-hydroxy-*neo*-cleroda-2,13(16),14-triene-17,12*R*:18,19-diolide, 7,8-didehydrorhyacophiline, salviarin, 6β-hydroxysalviarin	Antioxidant
Salvia regla	7α,12,20-Trihydroxy-11, 14-dioxo-8,12-abietadien-19-oic acid (=diacetyl sessein)	
Salvia rhytidea	1-Deoxoaurocadiol, ferruginol, taxodione, arucadiol, deoxyneocryptotanshinon, 7α-ethoxyroyleanone, microstegiol, 12-hydroxysapri-paraquinone	Antibacterial, antifungal, anti-inflammatory, antioxidant, antiproliferative, anti-tumor, cytotoxic For digestive and healing

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Salvia rosmarinus (=*Rosmarinus officinalis*)	Carnosol (**16**), rosmanol (**17**), isorosmanol (**18**), 7-methoxyrosmanol, epi-rosmanol, rosmadial, cryptotanshinone (**45**), carnosic acid, methyl carnosate, 7-methoxy-*epi*-rosmanol	Aerial part: Flavoring food, cosmetic, perfume, spice, spray, crude drug, beverages (herb tea) Anticancer, anticarcinogenic, Antidepressant, antidiabetes, anti-inflammatory, antimicrobial, antiobesity, antioxidant, antiseptic, antispasmodic, antiulcerogenic, carminative, GI irritant, hepatoprotective, neuroprotective, neurotrophic, acetylcholine stevase inhibitory For brain aging and muscular degradation protection, enhancing memory and concentration, hair growth, hepatic, improving digestion, intestinal renal, neurological, respiratory affections, skin health
Salvia santolinifolia	Carnasol, carnosic acid	Beverage (herbal tea), flavoring agent Antibacterial, antioxidant hemorrhoids, hypercholesterolemia For diarrhea
Salvia sapinae	8β,11,13-Abietatriene-7,15-diol	
Salvia sclarea	Ferruginol, salvipisone, microstegiol, candidissiol, 2,3-dehydrosalvipisone, aethiopinone, 1-oxo-aethiopinone, salvinolone, cryptojaponol, Δ^7-manool, 14-Labdene-8α,13*S*-diol (=sclareol (**22**)), manool (**34**), dehydrosalvipisone, 7-oxoroyleanone	Food flavoring, salads, beverages (herbal tea) Antibacterial, antidepressant, anti-inflammatory, antispasmodic, antiviral, appetizer, aromatic, astringent, bactericidal, bacteriostatic balsamic, carminative, tonic For circulation, indigestion, kidney disorders, pectoral, pain and pre-menstrual problems, stomach, stress relief
Salvia semiatrantha	2α-Hydroxy-3,13-clerodadiene-15,16:18,19-diolide (=semiatrin)	

Salvia sessei	7α-Acetoxy-12,20-dihydroxy-11,14-dioxo-8,12-abietadien-19-oic acid (=sessein)	
Salvia shannoni	Sepulturin A-F, infuscatin	Anti-inflammatory antiprotozoal, cytotoxic
Salvia splendens	Salvinolin A, *ent*-15,16-epoxy-2,13(16),14-clerodantriene-17,12: 18,19-diolide (=salviarin), *ent*-15,16-epoxy-10α,11-dihydorxy-2,13(16),14-clerdatriene-17,12:18,19-diolide	Antifeedant
Salvia staminea	Manoyl oxide	Antimicrobial
Salvia syliaca	Ferruginol, candidissiol, 4-dehydrosalvilimbinol, viridone, salvisyrianone	Antihypertensive, vasorelaxant
Salvia texana	6,8,11,13-Abietatetraene-2α,12-diol (=6,7-didehydroalviol), 2α,11-dihydroxy-5,7, 9(11),12-abietatetraen-12-one (=6-deoxo-2α-hydroxy-taxodione), 11-hydroxy-7,9(11),13-abietatrien-2,6,12-trione (=2-oxo-taxodione), 2α,6,7,11-tetrahydroxy-5,7,9(11),13-abietatetraen-12-one (=5,6-didehydro-2,7-dihydroxytaxodione), 2α,6α,7,11-tetrahydroxy-7,9(11),13-abietatrien-12-one (=2α,7-dihydorxytaxodione, 2α,6α,11-trihydroxy-7,9(11),13-abietatrien-12-one (=2α-hydroxytaxodione), 2α-hydroxysalvicanaric acid, salvicanaric acid, 2α,11,12-trihydroxy-6,7-seco-8,11,13-abietatriene-6,7-dial-11,6-hemiacetal	
Salvia tilifolia		Anticholinesterase, antioxidant
Salvia tiloaefolia	Isosalvipuberulin, trifodiolide	
Salvia tomentosa	7α-Acetoxyroyleanone, 7α-dihydroxyroyleanone, 6,7-dehydroxyroyleanone, 3β-hydroxydehydroabietic acid (=3β-hydroxy-8,11,12,15-abietatetraen-18-oic acid)	Beverage (herbal tea), condiment (leaf) Antimicrobial, antioxidant
Salvia verticillata (purple sage, lilac sage)	7α-Acetoxyroyleanone, 7α-hydroxyroyleanone	Antibacterial, antioxidative For anxiety, depress in epilepsy

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Salvia viridis	*epi*-13-Manoyl oxide	Antibacterial, antifungal, antioxidant, antiviral
Salvia wiedemanii	8,11,13-Abietatrien-3-one, 9α-hydroxy-7-oxo-15-abieten-18-oic acid	
Salvia yunnanensis	Yunnanin A, danshenol, 7,8-seco-para-ferruginone	Antimicrobial, antitumor (BIU87: bladder, K-562: erythromyeloblastoid, Me-180: cervical, T-24: bladder carcinoma cell lines)
Sargassum macrocarpum (algae)	Tuberatolide B (TTB)	
Sargassum micracanthum	2-Geranyl geranyl-6-methyl-1,4-benzoquinone	Antioxidant, cytotoxic (colon 26-1.5 cell line)
Sargassum siliguastrum (algae)	sargachromenol E	
Satureja hortensis (savory)	Carnosol (**16**), carnosic acid	Antibacterial, antidiarrheal, anti-inflammatory, antinociceptive, antioxidant, antispasmodic, hepatoprotective insecticidal, pesticidal, sedative
Satureja montana		Beverage (herbal tea, liqueur), spice Antibacterial, antifungal, antimicrobial, antioxidant, cytotoxic
Sceptrum labdalactone		Antimicrobial
Sciadopitys verticillata	15,16-Dihydroxy-8(17),13*E*-labdadien-19-oic methyl ester (=sciadopic acid methyl ester), 12S,20:15,16-diepoxy-8(17),13(16), 14-labdtrien-19,20-olide (=sciadin), *ent*-15-kaurene, *ent*-kaur-16-ene, 15-phyllocladene (=isophyllocladene), verticillol	
Scoparia dulcis	Dulcinol, scopadulcic acid A, 4-*epi*-scopaduli acid A (=scopadulic acid B)	
Scutellaria alpina	Scutalpin	

Scutellaria baicalensis	Scutebaicalin (**173**)	Antifungal, anti-inflammatory, antioxidant, cardiovascular, insect antifeedant, kidney, liver diseases
Scutellaria galericulata	*ent*-2β,19:18,11,16:15,16-Tetraepoxy-14-clerodene-1α-tigloyl-19-acetoxy-6β-ol (=jodrellin T), *ent*-2β,19:18,11,16:15,16-tetraepoxy-14,15-dihydroclerodene-1α-tigloyl-19-acetoxy-6β-ol (=dihydrojodrellin T), 4,18:11,16:15,16-triepoxy-3α-tigloyl-6β,19-diacetoxy-14-cleroden-2α-ol (=galericulin)	
Scutellaria indica		Anticancer, anti-inflammatory antioxidant, antipyretic, antitumor
Scutellaria rivularis	3β,4β-Epoxy-6β-benzoyl-8-hydroxy-11,13-clerodadien-15,16-olide (=secutellone F), *ent*-8,13-epoxy-3α,4α-dihydroxy-6β-benzoyl-11α-acetoxy-15,16-clerodanolide, *ent*-3α,4α,8α-trihydroxy-6β-benzoyl-11*E*,13-clerodadien-15,16-olide (=scuterivulactone D)	
Scutellaria woronowii	*ent*-2β,19:4β,18:11*R*, 19*S*:15,16S-Tetraepoxy-14-cleroden-6β,19-diacetate (=jodrellin A), *ent*-2β,19:4β,18:11*R*,19*S*:15,16S-tetraepoxy-6β-acetoxy-19-(2-methyl-propanoyl)-14-clerodene (jodrellin B)	
Scyopholepia hookeriana	*ent*-8(14)-Pimarene-3β-*O*-[3-*O*-methyl-α-*L*-rhamnopyranosyl-(1→2)-α-*L*-arabinopyranoside], 12β-(3-*O*-methyl-β-*D*-quinovopyranoside (=hookeroside A), *ent*-8(14)-pimaradiene-3β-*O*-[3-*O*-methyl-α-*L*-rhamnopyranosyl-(1→2)-α-*L*-arabinopyranoside], 12β-*O*-β-(fucopyranoside (=hookeroside B), *ent*-8(14)-pimaradiene-3β-*O*-[β-*D*-fucopyranosyl (1→2) β-*D*-fucopyranosyl (1→2)-α-*L*-arabinofuranoside], 12-*O*-β-D-fucopyranoside (=hookeroside C), hookeroside D	
Selaginella denticulate	*ent*-Labda-7,13(*E*)-dien-15-ol	Beverage (herbal tea) Antihypertensive For cough

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Sequioia sempervirens	20-Hydroxyferruginol, 6α-hydroxysugiol	Anticancer (breast, colon, lung)
Sida rhombifolia	Some diterpenoids	Decoction: for cleansing open sores Infusion: for dysentery Cytotoxic, antibacterial
Sideritis angustifolia	*ent*-15-Beyerene-7α,12α, 17-triol (=conchitriol), *ent*-13-atisene-7α,16α,17-triol (=isosideritol)	
Sideritis arborescens	*ent*-16-Kaurene-11β,18-diol	
Sideritis asora	7α,18-Dihydrokaur-16-ene	Antifungal
Sideritis biflora	*ent*-15β,16β-Epoxy-3β,7α,18-kaurenetriol	
Sideritis canariensis	*ent*-7α,18-Trachylbanediol	
Sideritis candicans	*ent*-Kaurene-7β,18-diol (=candicandiol), *ent*-kaurene-7α,18-diol (=*epi*-candicandiol), *ent*-kaurene-18-acetoxy-7β-ol, 17-nor-7α,18-dihydroxy-*ent*-kaur-16-one (=adejone), *ent*-16-kauren-7α-ol (=candol *A*), *ent*-16-kauren-18-ol (=candol *B*), *ent*-7α-acetoxy-16-kauren-18-ol, epicandicandiol	Beverage (herbal tea) For bronchitis, cough, digestive, intestinal diseases
Sideritis chamaedryfolia	8β,15,19-Trihydroxy-13-labden-7-one (=villenatriolone), 16-kaurene-7α,18-diol (=*epi*-candicandiol)	
Sideritis condensata	Linearol, isolinearol, siderol, sideridiol, sideloxol, 7-acetylsideroxol, candol B	Beverage (herbal tea) Acaricidal, insecticidal
Sideritis funkina	*ent*-15-Kaurene-3α,6α,7α,18-tetrol (=sidofunkiol)	
Sideritis leptoclada	Sideroxol, *ent*-7α,18-dihydroxy-15β, 16β-epoxykaurene	Antimicrobial, anticancer, malignant melanoma, antioxidant
Sideritis leucantha	*ent*-15-Kaurene-3β,7α,17, 18-tetrol (=isoleucanthol), 16-kaurene-3,7,15,18-tetraol, *ent*-15-kaurene-3β-acetoxy-7α,18-diol (=isosidol), foliol, sidol	Antioxidant

Sideritis linearifolia	Foliol, sidol	Antioxidant
Sideritis lycia	Linearol, 7-epicandicandiol, siderol, sideridiol, sidol	Anticancer, cytotoxic
Sideritis niveofomentosa	Siderol, sideridiol, 7-epicandicandiol, sidol, eubotriol, eubol, anthonolone, linearol	Anti-inflammatory, antimicrobial, antioxidant, antirheumatism, antiseptic, insecticide For cold, cough, gastrointestinal disorders
Sideritis paulii	*ent*-15α,16α-Epoxy-kaurene-3β,7α,18-triol	
Sideritis perfoliata	13-*epi*-Manoyl oxide	Antimicrobial
Sideritis pullulans	1α,3α,7β,18-Tetrahydroxy-*ent*-kaur-16-ene (sideripullol A), 3α,11α,18-trihydroxy-*ent*-kaur-16-ene (sideripullol B), 3α,7β,18-trihydroxy-17-*nor*-*ent*-kauran-16-one (sideritone A), 3α,7β-dihydroxy-18-acetyloxy-17-*nor*-*ent*-kauran-16-one (sideritone B), 3α,7β,16α,17-tetrahydroxy-18-acetyloxy-*ent*-kaurane (sideripullol C), 7β,16α,17,18-tetrahydroxy-*ent*-kaurane (sideripullol D)	Cytotoxic (HeLa, PC-3)
Sideritis pusilla	15-Beyerene-7,14,18-triol (=pusillatriol), 13-atisene-11,16,17-triol	
Sideritis raeseri	Bayerene, pimara-8(14),15-diene, *ent*-15-kaurene, manoyl oxide	Beverage (herbal tea)
Sideritis scardica	Beyerene, pimara-8(14),15-diene, *ent*-15-kaurene, manoyl oxide	Beverage (herbal tea) Anti-inflammatory, antioxidant, cytotoxic, expectorant, gastroprotective, immunostimulant, pulmonary emphysema, urogenital diseases
Sideritis serrata	*ent*-15-Beyerene-7α,17-diol, *ent*-15-beyerene-12α,17-diol (=tobarrol)	
Sideritis sicula	*ent*-15-Kaurene-7α-hydroxy-18-acetate (=sideripol)	
Sideritis sipylea	Epoxyisolinearol	Antifungal
Sideritis sp.	Royleanone, linearol, foliol, siderol, 7-*epi*-candicandiol	Antifungal

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Sideritis stricta	*ent*-1β-Hydroxy-7α-acetoxy-15β,16β-epoxykaurane (**174**), sideroxol, 7-*epi*-candicandiol, linearol, *ent*-7α,15β,18-trihydroxykaur-16-ene, *ent*-7α-acetoxy-15,18-dihydroxy-kaur-16-ene, foliol, sideridiol, siderol 2,3-dehydrosalvipinone, 7-oxo-royleanone epoxyisolinearol	Antibacterial, antifungal
Siegesbeckia orientalis	*ent*-12α,16-Epoxy-2β,15α, 19-trihydroxypimar-8-ene, *ent*-12α,16-epoxy-2β,15α, 19-trihydroxypimar-8(14)-ene, *ent*-2α-15,16,19-tetrahydroxypimar-8(14)-ene,*ent*-15-oxo-2β,16,19-trihydroxypimar-8(14)-ene, *ent*-2-oxo-15,16-dihydroxypimar-8(14)-en-16-*O*-β-*D*-glucopyranoside, *ent*-2-oxo-15,16,19-trihydroxypimar-8(14)-ene, *ent*-2-oxo-3β,15,16-trihydroxypimar-8(14)-en-3-*O*-β-*D*-glucopyranoside, *ent*-2β,15,16,19-tetrahydroxypimar-8(14)-en-19-*O*-β-*D*-glucopyranoside, *ent*-8,13-pimarene-3β-*O*-β-*D*-glucopyranosyl-15*S*,16-diol	Food (young leaves) For hypertension, malaria, neurasthenia, rheumatic arthritis, snake bite
Siegesbeckia pubescens	*ent*-8(14)-Pimarene-2α,15,16,19-tetrol (=kirenol), *ent*-8(14)-pimarene-6β,15,16,19-tetrol, *ent*-16β,17-dihydroxykauran-19-oic acid	Chinese folk medicine Antithrombic
Silphium perfoliatum	8α,12*R*-Epoxy-13*E*-labdene-15,16-diol (=16-hydroxycarterochaetol)	
Sinularia flexiblis	1*R*,3*S*,4*S*-Epoxy-11*R*-hydroxy-7*E*,15(17)-cembradien-16,12*R*-olide (11-*epi*-sunulariolide), 1*R*,3*S*,4*S*-epoxy-11*S*-hydroxy-7*E*,15(17)-cembradien-16,12*R*-olide (=sunulariolide), 2,6,6,9,13-pentamethyl-1,4,8,12-cyclopentadecatetraene (=flexibilene)	

Sinulasria mayi	2*E*,4*Z*,7*E*,11*E*,15-Cembrapentaene (=cembrene), (1*R*,2*R*,3*E*,7*E*,11*E*,15-cembratetraen-2-ol (=mayol)	
Solenostemon monostachys	2-*O*-Acetyl-17-acetoxy-15-epicoleon Z, 12-*O*-acetyl-15-epicoleon *Z* (=mon A), mon B, mon C	
Solenostemon sylvaticus	12-*O*-Acetyl-17-acetoxy-15-epicoleon *Z*, 12-*O*-acetyl-17-formyl-15-epicoleon *Z*, coleon Z, 6-*O*-acetyl-17-acetoxy-12-*O*-desacetylcoleon P (=syl A), 19-acetoxycoleon O (=syl C), coleon *Z*, 2-*O*-desacetyl-7-*O*-acetyl-19-acetoxycoleon P	
Solidago altissima	*ent*-1β-Acetoxy-3,13-clerodadien-15-oic acid (=solidagonic acid), 6β-hydroxy-3,13-clerodadiene-15,16-olide (=5α,6β,8β*H*-elongatolide, 3β,4β-epoxy-6-angeloyl-13-cleroden-15,16-olide (=elongatolide E), 3β,4β-epoxy-6-tigloyl-13-cleroden-15,16-olide (=solidagolactone VIII)	
Solidago arguta	*ent*-15,16-Epoxy-3,13(16)-,14-clerodatriene, 15,16-epoxy-3,13(16)14-clerodatrien-18,6β-olide	
Solidago canadensis	15,16-Epoxy-9α-hydroxy-7,13(16),14-labdatrien-6-one (=solidagenone)	
Solidago elongata	6β-Hydroxy-3,13-clerodadiene-15,16-olide (=elongatolide A, 6β-acetoxy-3,13-clerodadiene-15,16-olide (=elongatolide B), 6β-angeloyl-3,13-clerodadiene-15,16-olide (=elongatolide C), D	
Solidago juncea	*ent*-15,16-Epoxy-3,13(16),14-clerodatrien-20-oic acid (=junceic acid), 8(14)-abietene-7α,13-ol (=junceanol V), 8 (14)-abietene-6α-(3-ethyl-2-butenyl)-7α,13-diol	
Solidago leongata	6β-Hydroxy-3,13-clerodadien-15,16-olide (=elongatolide B)	
Solidago missouriensis	*ent*-7,13-Abietadiene, 7,13-abietadien-2β-ol, (+)-*ent*-7,13-abietadien-3-one, (+)-*ent*-7,13-abietadien-3α-ol, 8(14)-abietene-3-oxo-13β-ol (=missourienol) A, 8(14)-abietene-3β,13β-ol (=missourienol) B	

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Solidago nemoralis	*ent*-20-Oxo-3,13-clerodadien-16,15-olide (=rugosolide), *ent*-7,13-abietadien-18-oic acid (=*ent*-abietic acid), *ent*-7,13-abietadien-5α-ol	
Solidago serotina	*ent*-15,16-Epoxy-3,12(16),14-clerodatrien-19-oic acid, solidanoic acid A, *ent*-15,16-epoxy-18-hydroxy-3,13(16),14-clerodatrien-19-oic acid (=solidagoic acid B)	
Solidago shortii	*ent*-3α,4α-Epoxy-13-cleroden-15,16-olide, *ent*-3α,4α-epoxy-16-hydroxy-13-cleroden-15,16-olide	
Solidago virgaurea	Clerodanes	Antimicrobial
Spinacea olerocea	Gibberellin A_{53} (**175**)	Vegetable For fatigue, intestinal and stomach complaints, stimulating growth in children, recovery from illness
Stachys aegyptiaca (Egyptian mountain tea qourtom)	Stachaegyptin A, F-H, stachysperoxide	Beverage (herbal tea) Antifungal, antimicrobial
Stachys affinis		Food tonic
Stachys alopecuros		Antibacterial antifungal
Stachys anisochila	Abietatriene	Antifungal, antimicrobial, antioxidant
Stachys annua	*ent*-7β,13-Dihydroxy-3,14-clerodadien-2-one (=stachysolone), *ent*-7β,13-diacetoxy-3,14-clerodadien-2-one	Anti-inflammatory, hepatoprotective
Stachys atherocalyx		Beverage (herbal tea) Anti-inflammatory
Stachys balansae		Beverage (herbal tea) Antibacterial, antifungal
Stachys bayburtensis		Beverage (herbal tea) Antibacterial, antifungal

Stachys bithynia		Beverage (herbal tea) Antibacterial, antifungal
Stachys byzantina	Phytyl nonadecanoate	Beverage (herbal tea) Anticancer, anti-inflammatory For ulcers Infusion: for antiasthmatic, circulatory system diseases, varicose veins
Stachys candida		Antimicrobial
Stachys carduchrorum		Beverage (herbal tea) Antibacterial, antifungal
Stachys cretica subsp. *anatorlica*		Beverage (herbal tea) Antibacterial, antifungal
Stachys cretica subsp. *bulgarica*		Antibacterial, antifungal
Stachys euboica		Beverage (herbal tea) Antifungal, antimicrobial
Stachys floridana (yinmaiao)		Food Antifungal
Stachys geobombycis		Food Tonic
Stachys germanica	Abieta-8,11,13-triene	Leaves, flower-tops (herbal tea) Antifungal, anti-inflammatory, antimicrobial, antioxidant, antiproliferative, cytotoxic For ulcers
Stachys germanica subsp. *heldreichii*	Abietatriene, *ent*-laurenene	Beverage (herbal tea) Antibacterial, antifungal
Stachys glutinosa	Dehydroabietane	
Stachys hubermorathii		Beverage (herbal tea) Antibacterial, antifungal
Stachys huetii		Beverage (herbal tea) Antibacterial, antifungal

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Stachys inflata		Beverage (herbal tea) Anti-inflammatory, infective and rheumatic disorders
Stachys iva	Isoabienol, sclareol (**22**), *cis*-totarol, methyl neoabietate, labda-13(*E*)-en-8α,15-diol	Beverage (herbal tea) Antimicrobial, antioxidant
Stachys lavandulifolia		Beverage (herbal tea) For cold, cough, stomach ailment
Stachys longispicata		Beverage (herbal tea) Antibacterial antifungal
Stachys mentifolia	Abietatriene, abieta-8,11,13-trien-7-one, 13-epi-manoyl oxide, labd-13-en-8,15-di-ol, 16-kaurene	Antibacterial, antifungal
Stachys obliqua		Beverage (herbal tea) Antibacterial, antifungal
Stachys officinalis (=*Betonica offocinalis*)	Betonicoside A-D,	Beverage (herbal tea) Antibacterial, antifungal
Stachys palustris	Abietol, abietatriene, stachysic acid, sclareol, 6β-hydroxy-*ent*-kaur-16-ene, 6β,18-dihydroxy-*ent*-kaur-16-ene, kaur-16-ene, 13-*ent*-manoyl oxide, stacylone, stachone, 13-*epi*-manoyl oxide	Food (leaves, tubers), beverage (seed, herbal tea) Antibacterial, antifungal, antimicrobial, antioxidant, antiradical, antiseptic, antispasmodic, cytotoxic, emetic, emmenagogue, expectorant, homeostatic, nervine, sedative, tonic, vulnerary agent For anxiety, headache, menopausal problems, nervous tension
Stachys parviflorum (=*Phlomidoschema parviflorum*)	Stachysrosane, stachyssaponin A, B, parviflorosides A, B	Antidiarrheal, muscle relaxant, sedative
Stachys persica	Sclareol (**22**)	Leaves, flower-tops: Antifungal, antimicrobial anti-inflammatory, antioxidant

Stachys pinetorum		Beverage (herbal tea) Antibacterial, antifungal
Stachys plumosa	6-Deoxyandulusol, 13-epi-jbugodiol, dehydroabietane, kaurene, biformene, pimaradiene, 3*Z*-cembrene A, manoyl oxide, thumbergol, totarol, abieta-2,11,13-trien-7-one, dehydroabietol, 13-epi-manoyl oxide, sclareol (**22**), abieta-8,11,13-triene, dehydroabietal, methyl neoabietate, dehydroabietane, labd-13*E*-en-8α,15-diol	Leaves, flower-tops: Beverage (herbal tea) Antioxidant, antifungal, antimicrobial
Stachys pumila	Kaur-16-ene, manoyl oxide	Leaves, flower-tops: Beverage (herbal tea) Antifungal, antimicrobial, antioxidant
Stachys recta	11α,18-Dihydroxy-*ent*-kaur-16-ene, kaur-16-ene, stachysolone diacetyl and monoacetyl derivative	Leaves, flower-tops: Beverage (herbal tea) Antifungal, antimicrobial, antioxidant
Stachys scardica	Abieta-8,11-13-triene, dehydroabietol, sclareol (**22**), dehydroabietal, dehydroabietic acid methyl ester	Leaves, flower-tops: Beverage (herbal tea) Antifungal, antimicrobial, antioxidant
Stachys schtschegleevii		Tea Cancer, ulcers, anti-inflammatory, antibacterial
Stachys sericantha		Leaves, flower-tops: Beverage (herbal tea) Antifungal, antimicrobial
Stachys setifera		Leaves, flower-tops: Beverage (herbal tea) Antifungal, anti-inflammatory For cancer, genital tumors, ulcers
Stachys spectabilis	Cembrene	Leaves, flower-tops: Beverage (herbal tea) Antifungal, antimicrobial
Stachys spinulosa		Leaves, flower-tops: Beverage (herbal tea) Antifungal, antimicrobial, antioxidant
Stachys sylvatica	Abietol, abietatriene, stachysic acid, sclareol, 6β-hydroxy-*ent*-kaur-16-ene, 6β,18-dihydroxy-*ent*-kaur-16-ene, kaur-16-ene, 13-*epi*-manoyl oxide, stacylone, stachone, betolide	Leaves, flower-tops: Beverage (herbal tea) Antifungal, antimicrobial, anti-inflammatory, Antioxidant, antispasmodic

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Stachys thirkei		Leaves, flower-tops: Beverage (herbal tea) Antifungal, antimicrobial
Stachys tmolea		Beverage (herbal tea) Antifungal, antimicrobial
Stachys viticina		Beverage (herbal tea) Antifungal, antimicrobial
Stachys yemenensis		Beverage (herbal tea) Antifungal, antimicrobial
Stemodia maritima	Stemolide	
Stenochlaena palustris	Phytol, phytadienes	Food, raw as salad or cooked, soup Antibacterial For fever, skin diseases, stomachache, ulcers
Stevia aristata	*ent*-12β-Hydroxy-15-beyeren-19-oic acid, *ent*-7α-hydroxy-15-beyeren-19-oic acid	
Stevia eupatoria	12-Hydroxy-9(11),16-kauradien-19-oic acid, 12β-ethoxy-*ent*-kaur-9(11),16-dien-19-oic acid	
Stevia lineata	15,16-Epoxy-1,3,13(16)-clerodatetraene-17,12;18, 19-diolide (=*ent*-8β*H*, 12α*H*)-form, sterebin E, 11*E*,13*E*-labdadien-6α,7β,8α,15-tetraol, 8α,11*E*, 13*E*-labdadien-6α,7β,8α, 15-tetraol (=6α,7β-brebin F)	
Stevia lucida	*ent*-Kaurenoic acid, stevionolide	
Stevia monadaefolia	6α-Angeloyloxynidrellol	
Stevia ovata	Paniculoside IV	
Stevia paniculata	Paniculosides I-V, crispiloside B	

Stevia phelbophylla	Stevioside (**20**)	Antihypertensive, anti-inflammatory, organoleptic
Stevia polycephala	stephalic acid (=20-hydroxy-3,13-clerodadien-15-oic acid	
Stevia rebaudiana	Steviol (**24**) sclareol (**22**), 11*E*,13(16)-labdadiene-6α,7β,8α,14,15-pentol, 14-epi-11*E*,13(16)-labdadiene-6α,7β,8α,14,15-pentol, stevioside (**20**), dulcoside A **(20a)**, rebaudioside A (**25**), rebaudioside B (**25a**), rebaudioside C (=dulcoside B) (**25b**), isosteviol, steviolbioside, rebaudioside D (**25c**), rebaudioside E (**25d**), rebaudioside F (**25e**), dulcoside A (**25f**)	Food additive (sweetener) anticancerous, antihyperglycemic, antihypertensive, anti-inflammatory, antimicrobial, contraceptive, diminishing cramps, hot flashes, night sweats and pain Beneficial: for balancing, organoleptic
Stevia salicifolia		Antimicrobial, effective: in diminishing pain, cramps, night sweats, and hot flashes, Beneficial: for balancing hormone
Stevia samapatensis	2β-Hydroxy-7-labda-15-oic acid	
Stevia subpubescens	Subpubescensoside	
Stoechisoermum marginatum (algae)	5*R*,19-Diacetoxy-15,18-(*R*,*S*)-dihydrospata-13,16-diene	
Suegada multiflora	*ent*-16β,17-Dihydroxy-3-kauranone (=abbeokutone), *ent*-16-kaurene-3β,15β,18-triol, *ent*-3-oxo-16-kaurene-15β,18-diol, *ent*-kaurene-3β,15β-diol, helioscopinolide A, C, I	Antiallergic
Symphiopappus compressus	*ent*-2α-Hydroxy-3,13-kolavedien-15,16-olide	
Symphyopappus reticulatus	3,13-Clerodadiene-15,17-diol (=*ent*-3,13-kolavadiene-15,16-diene)	
Syzygium fluviatile	Acetyl incensole, cassipourol, cassipouryl formate, 4',5'-dehydrodiodictyonema	
Syzygium jambos	Phytol	Beverage (herbal tea) Antidiabetes, antioxidant
Tagetes gracilis	Isocimenone, 14,15-dihydro-bisocimenone	
Tawanaia cryptomeroides	Hinokiol	

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Taxodium districhum	7β,12-Dihydroxy-8,12-abietadiene-11,14-dione (=taxoquinone, 7β-hydroxyroyleanone), 6α,11-dihydorxy-7,9,11(13)-abietatrien-11-one (=taxodone), 11-dihydorxy-7,9,11(13)-abietatrien-6,12-dione(=taxodione) 12-hydroxy-5,8,11,13-abietatetraen-7-one (=5,6-dehydrosugiol), sugiol, Δ^5-dehydrosugiol	Tumor inhibitor
Taxodium mucronatum	15-Pimarene-8β,19-diol	
Taxus baccata	2α,5α,7α,9α,10β,13α,-Hexaacetoxy-11-taxen-1β-ol (=1β-hydroxybaccatin I), 2α,4α,7α,9α,10β,13α-hexaacetoxy-5β,20-epoxy-11-taxen-1β-ol (baccatin IV), 4α,10β-diacetoxy-2α-benzoyloxy-5β,20-epoxy-1β,6β,13-trihydroxy-11-taxen-9-one (=baccatin III) (**53**), baccatin V-VII	Tumor inhibitor
Taxus brevifolia	Paclitaxel (=taxol) (**1**), 7-epitaxol,10-deacetyl-10-oxo-7-epitaxol	Tumor inhibitor
Taxus cuspidata	1β-Hydroxy-7β-acetoxytaxinine, 1β,3β-dihydroxytaxinine	Tumor inhibitor
Taxus mairei	1β,2α,7α,9α,10β,13α-Hexaacetoxy-4β,20-epoxy-11-taxen-5α-ol (=1β-acetoxy-5-deacetylbaccatin I), 1-dehydroxy-4-deacylbaccatin IV	Tumor inhibitor
Taxus sumatrana	Taxanes	Cytotoxic (Hepa59T/VGH: liver carcinoma, NCI: lung carcinoma; HeLa;DLD-1: colon cancer, Med: human medulloblastoma cell lines)
Taxus wallichiana	5,1α-Epoxy-1,2,3,7,10,13,19-heptahydroxy-11-taxen-9-one, 10-deacetyltaxol, cephalomannine (**52**), deacetylcephaloannine	Tumor inhibitor
Taxus yunnanensis	5,20-Epoxy-2,4,7,10,13-pentahydroxy-11-taxen-9-one (=1-dehydroxybaccatin III, 5,20-epoxy-11-taxen-2,4,7,9,10,13-heptaacetate (=1-acetylbaccatin IV)	Tumor inhibitor

Tedania ignis	Tedanol	COX-II inhibitory
Tetraclinis articulate	8,11,13-Abietatriene-3-oxo-12-ol (=hinokione), 8,11,13-totaratrien-13-ol (=totarol) (**180**)	
Tetraclinis sp.	8,11,13-Abietatriene-3β,13-diol	
Tetradenia riparia (=Iboza riparia) (ginger bush)	7α-Hydorxyroyleanone (=ibosol), 8(14),15-sandaracopimaradiene-7α,18-diol, 8-abieten-7β,13β-diol	Beverage (herbal tea) Antifungal, antileishmanial, antimicrobial, antispasmodic, antiviral For cough, diarrhea, dengue fever, headaches, malaria, toothache
Teucrium abutiloides	*ent*-4β,18:12,20:15,16:19, 20-Tetraepoxy-13(16),14-clerodadien-6β-ol (=teubutilin A, *ent*-4β,18:12,20:15,16-triteepoxy-13(16)14-clerodadien-6β,19,20-triacetate (=teubutilin B)	
Teucrium bicolor	*ent*-15,16-Epoxy-9-hydroxy-3,13(16),14-clerodatrien-19,6:20,12β-diolide (=*ent*-12α*H-epi*-teuscordonin)	
Teucrium botrys	*ent*-15,16-Epoxy-6α,12*R*, 18-trihydroxy-3,13(16), 14-clerodatrien-20,19-olide (=teubotrin), 15,16-epoxy-6α,18,19-trioxy-3,13(16),14-clerodatrien-20,12-olide (=tausalvin C)	
Teucrium buxifolium	*ent*-4β,18;15,16-Diepoxy-3α-hydroxy-6-oxo-19-acetoxy-12(16),14-clerodadien-20,12-olide (=19-acetylteulepicin)	
Teucrium canadense	Teuflin, teuevidin, isoteyflin	
Teucrium capitatum	*ent*-15,16-Epoxy-6α,7α, 18,19-tetrahydroxy-3,13(16),14-clerodatrien-20,12β-olide (=lonin)	Flowered aerial part: Beverage (herbal tea, liqueur "Terbert" and seasoning olives or soups)
Teucrium chamaedrys (Germander)	Teucrin A (**176**), dihydroteugin, isoteuflidin, teuflin, teuevidin, teuflidin, teuerun, 12(*S*)-15,16-epoxy-19-hydroxy-neocleroda-13(16),14-dien-18,6α:20, 12-diolide, teuchamaedrin, (12*S*)-15,16-epoxy-2β,6β-dihydroxy-neocleroda-13(16),14-dien-18,19:20, 12-diolide (=dihydroteugin), *ent*-4α,6α:15,16-diepoxy-2α-hydroxy-13(16),14-clerodadiene-18.19:20,12-olide (=chamaedroxide), *ent*-15,16-epoxy-2α,6α-dihydroxy-3,13(16),14-clerodatriene-18.19:20,12-olide (=teugin), *ent*-	Flower aerial part: Beverage (herbal tea, bitter alcoholic, bitters and liqueurs, flavored wine) Antibacterial, antioxidant, astringent, hepatotoxicity For abscesses, digestion, gout, respiratory disorders, infusion on the gums, wounds healing

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Teucrium scorodonia	*ent*-15,16-Epoxy-6α-hydroxy-19-acetoxy-3,13(16),14-clerodatrien-18-al-20,12β-diolide, *ent*-15,16:18.19-diepoxy-6-oxo-18α-hydroxy-13(16),14-clerodadien-20,12-olide (=teukotschyn), *ent*-15,16-epoxy-9-hydroxy-3,13(16),14-clerodatrien-19,6:20,12α-diolide (=teuscorodonin), *ent*-15,16-epoxy-6α,18-dihydroxy-19-acetoxy-3,13(16),14-clerodatrien-20,12β-diolide (=teuscoradol), *ent*-15,16-epoxy19-*nor*-4,6,13 (16),14-cleroda-tetraenehydroxy-18:6:20, 12-diolide (=teuscorolide), *ent*-15,16-epoxy-2α-hydroxy-19-nor-4,6, 13 (16),14-clerodatetraene-18:6:20,12-diolide (=2-hydroxyteuscorolide), 19-acetoxy-6α-hydroxy-4α, 18: 15,16-diepoxy-neoclerodane-13(16),14-dien-20,12*S*-olide (=eupolin I), 19-acetoxy-6β-hydroxy-15,16-epoxy-*neo*-clerodane-3,13 (16),14-trien-20,12*S*-olid-18-al (teuscorodal)	Beverage (herbal tea) Leaves and flowers: a hop substitute for flavoring beer Astringent, carminative, diaphoretic, diuretic, emmenagogue, tonic, vulnerary
Teucrium spinosum	*ent*-15,16-Epoxy-4β,19-dihydorxy-13(16),14-clerodadien-19,6α:20,12-diolide, teuspinin, 19-acetylteuspinin	
Teucrium viscidum	*ent*-15,16-Epoxy-19-*nor*-3,13(16),14-clerodatrien-18,6a:20,12-diolide (=teucvidin), teucvisins A-E, teucvin, teuflin, kinalborin C, teuspinin, 19-acetyl-teuspinin, isoteuflin, 2-deoxychamaedroxide, teuscordal, 6α-acetoxyteuscordin, teuvisone, biteuvisone A, B	Acetylcholinesterase inhibitory, antidiabetes, antifeedant, anti-inflammatory antimicrobial Chinese folk medicine Hematemesis, pulmonary abscesses, traumatic injuries, and bites from rabid dogs or venomous snakes
Teucrium webbianum	*ent*-15,16-Epoxy-2α-hydroxy-19-*nor*-3,13(16), 14-clerodatriene-18,6:20, 12-diolide (=*ent*-2α-hydroxyteucvidin), teuflidin, teucrin A, *ent*-2α-hydroxyteucvidin	
Thuja occidentalis	Beyerene, dehydro-abietane, neothujic acids III, IV, (+)-7-oxo-13-*epi*-pimara-14,15-dien-18-oic acid, (+)-7-oxo-13-*epi*-pimara-8,15-dien-18-oic acid, (+)-isopimaric acid	Food: Pith of young shoots Leafy branchlets: beverage (herbal tea) Anthelmintic, anti-inflammatory, antiseptic, antiviral, benzo(*a*)pyrene-protein binding inhibitor

Thuja plicata	18-Nor-8(14),15-iso-pimaradien-4-ol, 19-nor-8(14),15-iso-pimara-dien-4-ol,*syn*-stemod-13(17)-ene, sandaracopimaradiene, levopimaradiene, rimuene, beyerene, beyerene-1β-ol, kaur-15-ene, (*E*)-totarol, totaradiol, ferrugiol	Food: Inner bark used as a thickening in soups etc. or mixed with cereals when making bread, chewing gum Leaf: for various internal pains Stem and root: for colds Seeds and twigs: for fevers Antimicrobial
Thuja standishii	15-Isopimaren-8β-ol, 15,16-bisnor-13-oxolabda-8(17),11*E*-dien-19-oic acid, (E)-communic acid (**3**), 15-oxolabda-8(17),11*Z*, 13*E*-trien-19-oic acid, 15-oxolabda-8(17),11*Z*,13*Z*-trien-19-oic acid, 12-oxo-11-nor-drim-8-en-14-oic acid, 15-oxolabda-8(17),13*Z*-dien-19-oic acid, 15-nor-14-oxolabda-8(17),12*E*-dien-19-oic acid, ferruginol, sugiol, isocupressic acid, sandaracopimaric acid, standishinal (=8-formyl-6(7→11)*abeo*abietane)	Antitumor, aromatase, and EBV-EA inhibitory
Thujopsis dolabrata	16-Hydroxyferruginol (**178**), (15*R*)-12,16-epoxy-8,11,13-abietatriene (**179**), totarol (**180**), 7α-hydroxytotarol (**181**), 7β-hydroxytotarol (**182**), rimuene, rosa-5,15-diene, 13-*epi*-dolabradiene, hibaene, dolabradiene, isoagatholal-15-*O*-β-*D*-xylopyranoside	Soap flavor, aroma retaining agents Antibacterial, antifungal, anti-inflammatory, antiproliferative, antiviral For hypertension, jaundice rheumatoid, liver and kidney disorders
Thymus pulegioides (leaf thyme)		Flowered aerial part: beverage (herbal tea, liqueur: ratafia) liqueur (ratafia), for seasoning stews For sedation, blood purification, renal stones, bronchitis, stomach spasms, asthma, diarrhea, flatulence, fever, airway decongestant, gastrointestinal disinfectant, depurative, disinfect wounds, ulcers, cold, digestive
Thymus serphyllum (wild thyme)		Beverage (herbal tea) Antibacterial, antidiarrheal, antimalarial, antioxidant, antiproliferative, antihypertensive, antiseptic, anthelmintic, antitussive, bronchitis, expectorant, sedative, spasmolytic, tonic For eczema, menstrual disorders, rheumatism, wounds

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Thymus vulgaris	Carnosol (**16**), epirosmanol (**183**), methyl carnosate, carsonic acid (**169**)	Flowered aerial part: beverage (herbal tea), spice Analgesic, anthelmintic, anti-bronchiolitis, anticatarrhal, antifungal, antihypertensive, anti-inflammatory, antimicrobial, antioxidant, antitussive, antispasmodic, carminative, diuretic, expectorant For acne, gastrointestinal, stomatitis
Thymus zygis (Spanish thyme)		Aerial part (flowered): Beverage (herbal tea), spice Antibacterial, anti-inflammatory, antioxidant
Tinomiscium philippinense	Tinophyllone	Foods, beverage (Herbal tea), cosmetics, pharmaceutics Antimicrobial, antitumor, insecticide, mosquito repellent
Tinospora cordifolia	Epoxyclerodanes	Gastroprotective
Tinospora cordifolia (=*T. sinensis*)	2β,3β:15,16-Diepoxy-4α,6α-dihydroxy-2,13(16),14-clerodatriene-17,12:18,1β-diolide, 15,16-epoxy-4α,8β-dihydroxy-2,13(16),14-clerodatrien-17,12:18,1β-diolide, *ent*-15,16-diepoxy-4α-hydroxy-2,13(16),14-clerodatriene-17,12:18,1β-diolide (=columbin), tinosporafuranolactone, 15,16-epxy-6α-hydroxy-19-nor-4,13(16),14-clerodatrien-17,12-olide-18-oic acid *O*-β-*D*-glucopyranosyl ester, 15,16-epoxy-4α-hydroxy-18-nor-1-oxo-2,13(16),14-clerodatrien-17,12-olide, cordifoliosides A-E, tinocordioside, cordioside	Stem: used as Ayurveda, folk medicine Antiallergic, antiarthritic antidiabetic, anti-inflammatory, antileprotic, antimalarial, antioxidant, antiperiodic, antispasmodic, antistress, hepatoprotective, immunomodulatory
Tinospora malabarica (=*Tinospora sinensis*)	10α-Hydroxycolumbin, malabarolide, 1-acetyltinosinenoside D, E, tinosinenoside D-F, K	Stem: used as Ayurveda, Folk medicine, Traditional Chinese Medicine (TCM) Antiarthritic, antidiabetes, anti-inflammatory, immunomodulatory

Tinospora tuberculate (=*T. crispa, T. rumphi)*	15,16-Epoxy-3β,4α-dihydroxy-13(16),14-clerodadiene-17,12:18,6-diolide (=borapetol A), borepetol B, borapetosides A-F, columbin, rumphioside A-F, tinotufolin A, B	Stem: used as a folk medicine Antidiabetes, anti-inflammatory, antimicrobial, antioxidant, cardiotonic
Torreya nucifera	8(17),13-Labdadiene-15,18-diol, torreferol, 8-hydroxyferruginol, 6-hydroxydehydroabienol, hinokiol, 4-*epi*-agathadiol, 18-hydroxy-13-epi-manool 18-methyl ester, ferruginol, 18-dimethoxyferruginol	Food, seed: edible oil Anthelmintic, antioxidant
Trachylobium verrucosum (=*Hymenaea verrucosa*)	13*S*,8(17)-Labden-15-oic acid	
Trigonastemon heterophylla	Trigonostemome, trigonochinene B	Antimicrobial
Triticum aestivum	Gibberellin A_{60}, gibberellin A_{61}, gibberellin A_{62}	Foods, beverage (herbal tea) Anticancer, anti-inflammatory For childhood asthma, preventing gallstones, post-menopausal symptoms, chronic inflammation
Trogopterus xanthipes	Manool **(34)**, 12*R*,13*R*-8,12-epoxy-14-labden-13-ol, pomiferin A, B, 11,13-abitatrien-7α,18-diol, 7-oxocallitrisic acid	Antithrombotic
Trupterygium wilfordii	triptolide, tripdiolide, triptobenzenes A-G	Root (also known as thunder god vine) Anti-inflammatory, antirheumatism, cartilage protective immune suppressive
Turbina corymbosa	6α,16β,17-kauranetriol	Seed: psychedelic drug
Turraeanthus africanus	Terraeanin	Antimicrobial
Udotea flabellum	Udoteatrial, udoteal, udoteafuran	Antimicrobial, antitumoral
Udotea petiolata (=*Flabellia petiolata*)	Udoteal	Induced feeding avoidance in the herbivorous fish (*Eupomacentrus leucostictus*)
	Udoteal B	Antibiotic, cell division inhibitory of fertilized sea urchin egg, toxicity against herbivorous damselfish

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Ulva lactuca	Labda-14-ene-3α,8α-diol, labda-4-ene-8-hydroxy-3-one	Food Anticancer, antimicrobial, antioxidant
Vellozia candida (=*Vellozia maritima, Vellozia tertia*)	5α,10α-Epoxy-7,11-dihydroxy-7,15-rosadien-6-one	
Vellozia piresiana	8β-Hydorxy-15-isopimaren-3-one (=epoxyvellozin), compactone, 7β,8β-dihydroxy-3-oxopimar-15-ene, 8β-hydroxy-3-oxopimar-15-ene, 8,11,13-cleistathatrien-3,7-dione, 1,8,11,13-cleistanthatetraen-3,7-dione	
Viburnum odoratissimum	Vivsonins A-C, E, F	Fruit
Vicia faba	Gibberellin A_{53} (**175**)	Food Antioxidant, bones strengthen, diuretic For anemia, lithotriptic
Viguiera arenaria	Kauranes, *ent*-Pimara-8(14),15-dien-19-oic acid, its sodium salt, *ent*-8(14),15-pimaradien-3β-ol, 3β-acetoxy-*ent*-15-8β,19-diol, *ent*-3β-acetoxy-8(14),15-pimaradiene	Antimicrobial, vascular contractility inhibitory
Viguiera robusta	Kauranes, pimaranes	Vascular contractility inhibitory
Vitex cauliflora	3-Oxo-15,17,18-triacetoxylabda-7,13*E*-diene	Anti-*Plasmodium falciparum*
Vitex negundo	Negundoins A-G	Antioxidant
Vitex rotundifolia	15,16-Diepoxy-14-labden-6β-ol, (*rel*-5*S*,6*R*,8*R*,9*R*,10*S*)-6-acetoxy-9-hydroxy-13(14)-labden-16,15-olide, (*rel*-*S*,6*S*,8*R*,9*R*,10*S*)-6-acetoxy-9-hydroxy-13(14)-labden-16,15-olide, (*rel*-*S*,6*R*,8*R*,9*R*,10*S*)-6-acetoxy-9-hydroxy-15-methoxy-13(14)-labden-16,15-olide, (*rel*-*S*,6*R*,8*R*,9*R*,10*S*,13*S*,16*S*)-6-Acetoxy-9,13-epoxy-16-methoxylabdan-15,16-olide, (*rel*-5*S*,6*R*,8*R*,9*R*,10*S*,13*R*,16*S*)-6-Acetoxy-9,13-epoxy-16-methoxylabdan-15,16-olide, (*rel*-*S*,6*R*,8*R*,9*R*,10*S*,13*S*)-6-Acetoxy-9,13-epoxy-15-	Fruits “Viticis Fructus”: colds, eye pain, headaches, migraine Edible leaves: relieve illnesses such as wella (burning sensation), and nalulu (dull headache, dull pain in stomach, queasy) Antihyperlipidemia, antiplasmodial

	methoxylabdan-16,15-olide, (*rel-S*,6*R*,8*R*,9*R*,10*S*,13*R*)-6-acetoxy-9,13-epoxy-15-methoxylabdan-16,15-olide, (*rel-*5*S*,8*R*,9*R*,10*S*,13*S*, 15*S*,16*R*)-9,13;15,16-Diepoxy-15,16-dimethoxylabdane, (*rel-*5*S*,8*R*,9*R*,10*S*,13*S*,15*R*,16*S*)-9,13;15,16-diepoxy-15,16-dimethoxylabdane, vitexilactone, viterofolins A-H	
Vittadinia gracilis (=Vittadinia cuneate, Eurybiopsis gracilis)	*ent*-12α,20α:15,16-diepoxy-3,13(16),14-clerodatriene-17,20:18,19-diolide	Eaten regularly but not preferred by livestocks and wild animals
Xenia membranacea	Branacenal, 7,8:17,18-diepoxy-1(17),6(20),13-xeniatetraene-11,12,18-triol (=bisdioxyhavannahin)	
Xenia novaebrittanniae	Novaxenicins B, xenioide I	Antimicrobial
Xenia obscuronata	4(18),8(19)-xeniaphylladiene-5,14,15-triol (=xeniaphyllantriol), obscuronatin	
Xestospongia vanilla	xestenone	
Xylopia aethiopica	*ent*-15α-Acetoxy-kaur-16-en-18-oic acid (= xylopic acid) (**184**), 2-oxo-kolavenic acid (**185**)	Fruit: coffee drink, soups Biliousness and febrile pains, bronchitis, dysenteric Steeped bark in palm-wine: asthma, bronchitis, biliousness and febrile pains, dysenteric, rheumatism, stomachaches Macerate leaves in palm-wine: a locally popular intoxicating drink Analgesic, antiallodynic, antibacterial, antifungal, antihyperalgesic, condiments, cytotoxic (leukemia, pancreatic cells) For colic pain, headache, neuralgia, rheumatism
Xylopia aromatica	*ent*-13,16-Dihydroxy-8(17),14-labdadien-18-oic acid, *ent*-trachyloban-3β-ol, *ent*-atisan-16α,18-diol, *ent*-atisan-16α-ol-18-oic acid	Fruit: febrifuge Seeds: Flavor cooked foods, poisonous, and kill rats Shoots and stem-bark: aromatic and tonic Flowers: carminative tonic Beverage (herbal tea): strong diuretic for swellings of the legs

(continued)

Table 1 (continued)

Dietary plant and mushrooms names	Diterpenoids and related compounds	Applications, benefits, effects
Zingiber mioga	Galanal A (**28**), B, 8β,17-epoxylabd-12*E*-ene-15,16-dial (=miogadial) (**27**), mioganal, labd-12*E*-ene-15,16-(8β),17-trial (=miogatrial), geranyllinalool	Food (young flower shoot), food additives Anticancer, antihypertension, anti-inflammatory, antiviral, platelet aggregation, and 5-lipoxygenase inhibitory For abnormal and irregular digestion, blood flow improvement, fever, hematemesis, hypotension, menstruation, skin health, TR, PA1 activation
Zingiber officinale	Galanolactone (**26**)	Food, vegetable, food additives, spice and beverage (herbal tea) Antagonist at 5-HT3
Ziziphora clinopodioides (wild basil, wild calamint)	Phytol	Spice, vegetable, beverage (herbal tea) Antibacterial, anti-inflammatory, antioxidant, antiseptic carminative, expectorant, sedative For migraine, depression, fever, gastrodynia, heart disorders, vomiting
Ziziphora tenuior	Manool (**34**)	Beverage (herbal tea) Antidiarrheal, antifungal, antimicrobial, antioxidant, antiseptic, expectorant, febrifuge, pectoral effects For bladder stones, cough, diarrhea, dysentery, fever, gut inflammatory, painful menstruation, stomach tonic, uterus infection, wound healing
Zealandia guidonia	Cinnamoyloxy-6β-hydroxyzuelanin, zuelaguidins E, G	Anticancer For amenorrhea, emetic

skin aging by suppressing UVB-induced MMP-1 expression. (*E*)-Communic acid (**3**) shows considerable cytotoxicity against four human cancer cell lines in vitro. It also shows good antibacterial activity against *Mycobacterium aurum.*

17.2.2 *Ajuga* [Lamiaceae (=Labiate)]

The Lamiaceae is widespread family of about 220 genera comprising 400 species distributed in the most of the world. More than 400 species *Ajuga* are cited in the Index Kew-ensis. *Ajuga* species are rich sources of clerodanes and neoclerodanes. The presence of clerodane diterpenoids have been reported in less than 20% of the above mentioned number of the species. Many clerodanes and neoclerodanes isolated from the *Ajuga* show antifungal, antimicrobial, cytotoxic, hypotensive, hypoglycemic, and insect antifeedant activities (Coll and Tandron 2008).

17.2.3 *Annona* (Annonaceae)

The Annonaceae is a very large family, occurring about 120 genera and more than 200 species. The family is an economically important source of edible fruits and oils. Seed oils of some *Annona* species are used as edible oils and cosmetics such as soap products. Flowers of *Annona* are also used in perfumery and used as folk medicines for cancer prevention. *A. squamosa* (sugar apple) which has been used as snack or dessert indicates the presence of antiviral, anti-inflammatory, antidiabetic, analgesic, and antioxidant compounds. Its bark and fruits show antidiarrheal activity and hematinic, cooling, sedative, stimulant, expectorant, maturant tonic, and antiviral properties, respectively (Vanitha et al. 2011; Wu et al. 1996). Among 14 kauranes isolated from this species, 16β,17-dihydroxy-*ent*-kauran-19-oic acid (**4**) indicated significant activity against HIV-replication in H9-lymphocyte cells (Wu et al. 1996). *ent*-11α-Hydroxy-16-kauren-15-one (**5**) was found to show apoptosis in human promyelocytic leukemia HL-60 cells. 4α-Hydroxy-17,19-dinor-*ent*-kauren-16-one, 4β-hydroxy-16β*H*-18-nor-*ent*-kauren-17-oic acid, and their 4β,17-dihydroxy-6α-acetoxy-nor-*ent*-kaurene and two more kaurene derivatives showed cytotoxicity against SMMC-7721 and HepG2 cancer cell lines (Chen et al. 2020).

17.2.4 *Baccharis* (Asteraceae)

The *Baccharis* is a genus of very large plants, with 400–500 species, belonging to the Asteraceae which distributed mainly in the Neotropical regions, South America, and Mexico. Many of the *Baccharis* species have been used as traditional medicines for the treatment of pain, wounds, ulcers, gastrointestinal disorders, as spasmolytic, diuretic, and analgesics, and in the treatment of high fever, diabetes, and bacterial and fungal infections. *Baccharis* flowers are rich in nectar and several species are

good honey plants. Some *Baccharis* species have been used as beverages in the form of decoction and infusion of the whole plants.

The major diterpenoids in the *Baccharis* are the neoclerodanes. In addition, kaurane and labdanes have also been found in this genus. Labda-7,13*E*-dien-3β,15-diol (**6**) possesses antifungal activity against a few fungi, such as *Trichophyton mentagrophytes* and *T. rubrum*. A unique kaurene, *ent*-3,19-disuccinylkaur-16-ene from *B. rufescens*, shows anti-inflammatory activity (Abad and Bermejo 2007).

17.2.5 *Caesalpinia* (Fabaceae)

The *Caesalpinia* is a genus of flowering plants belonging to the Fabaceae family. It contains tropical or subtropical woody plants and about 160 species have been known. The genus mainly produces the cassane type diterpenoids which indicate potent cytotoxicity against human cancer cell lines.

17.2.6 *Callicarpa* (Verbenaceae or Lamiaceae)

The genus *Callicarpa* have more than 40 species in China and Southern Asia, two representative of which are native or naturalized to the southeastern United States, namely *C. americana* and *C. dichotoma* (=*C. purpurea*). Many of the species have been ethnomedically used in the treatment of cancer, hepatitis, rheumatism, fever headache, indigestion, and the other ailments. Jones and Kinghorn (2008) reported the review article of *Callicarpa* constituents with biological active natural products including diterpenoids.

17.2.7 *Casearia* (Salicaceae)

The genus *Casearia* grown in South America comprises about 180 species most of which contain clerodane and kaurene diterpenoids with significant bio- and pharmacological activity, such as antifungal, antileishmanial, antiplasmodial, antitumor, trypanocidal, and antimalarial activity (Vieira-Junior et al. 2011).

17.2.8 *Cistus* (Cistaceae)

The *Cistus* is a genus of flowering plants in the rockrose family Cistaceae, containing about 20 species. They are perennial shrubs found on dry or rocky soils throughout the Mediterranean region, from Morocco and Portugal through to the Middle East, and also on the Canary Islands. Many labdanes possessing antimicrobial and cytotoxic activity, including manoyl oxide, have been found in this genus.

17.2.9 *Clerodendrum* (Verbenaceae)

The *Clerodendrum* is a genus of about 400 species in the family of the Verbenaceae which mainly grows in the tropic and warm temperature zone including southern Asia and Africa. It is currently classified in the subfamily Ajugoideae, being one of several genera transferred from Verbenaceae to Lamiaceae in the 1990s, based on phylogenetic analysis of morphological and molecular data. The genus is native to tropical and warm temperate regions of the world, with most of the species occurring in tropical Africa and southern Asia. The type species for the genus is *Clerodendrum infortunatum*. It is native to Sri Lanka and the Andaman Islands. The leaf aqueous extract of *C. glandulosum* has been used by the North-East Indian to alleviate symptoms of diabetes, obesity, and hypertension. Many insect antifeedant diterpenoids are distributed in this genus.

17.2.10 *Coffea* (Rubiaceae)

Coffee and tea are the two most important and consumed beverages in the world. About 80% of people in the world population take coffee marketed in the blended form of *Coffea arabica* and *C. canephora* (Novaes 2018).

Brazil, Colombia, Costa Rica, Elsalbador, Ethiopia, Guatemala, Honduras, Indonesia, Venezuela, and Vietnam are coffee export countries, and each country consumes 6.02 kg/one person/year, 1.91. 2.66. 2.59, 2.27, 1.29, 2.51. 0.099, 3.21, and 1.31, respectively. On the other hand, EU, Japan, Norway, Russia, Switzerland, Tunisia, Turkey, and the United States are coffee import countries and each county consumes 4.90 kg/one person/year, 3.54, 8.59, 1.70, 7.56, 2.48, 0.74, and 4.42, respectively. The presence of diterpenoids in green tea, English and Oolong tea is negligible while coffee beans contain pentacyclic diterpenoids which have not yet been isolated from or detected in the other foods, fruits, seeds, and vegetables. Since 30 years, the chemical and pharmaceutical studies of coffees were carried out from view point of food and beverage sciences.

Several observational studies indicate that coffee drinkers have a much lower risk of type 2 diabetes, a serious condition that affects millions of people in the world; anti-Alzheimer disorder, which is a leading cause of dementia, anti-Parkinson's disorder, the second most common neurodegenerative disease; and lower risk of liver and colorectal cancers. One of the most important discoveries of secondary metabolites from the coffees is the presence of the specific diterpenoids, cafestol (**7**), 16-*O*-methylcafestol (**8**), and kahweol (**9**) as the major components.

Arabic and Robusta coffee contain cafestol. 16-*O*-Methylcafestol has been found only in Robusta coffee. Arabica coffee also contains kahweol as predominant component; however, Robusta coffee produces kahweol as very minor diterpene. Filtered coffee does not contain cafestol or kahweol, because they are retained in filter paper. Instant coffee also does not contain diterpenoids. Diterpenoids in coffee beans' oil are present in free form. They are esterified with fatty acid, mainly palmitic acid, and linoleic oleanolic, stearic, arachidonic, and behenoic acids as major constituents. Up to

now, 100 *ent*-kaurane diterpenoids have been found in coffee. There are different kinds of diterpenoids produced during the process of fruit development and green bean roasting, although cafestol and kahweol are the main skeletons of coffee diterpenoids. Hu et al. (2020) reported the *ent*-kaurane diterpenoids including a lactam ring in roasted beans of Arabica coffee which inhibit α-glucosidase. Higher risk of heart disease has been known by up-taking of diterpenoids rich coffee. Although cafestol included unfiltered coffee, like Scandinavian-type decocted coffee, French-press cafeteria and Turkish coffee raise plasma triglycerol and LDL-cholesterol concentration in human in vitro and in vivo experimental results (Urgert and Katan 1997; Roos et al. 2001). Cafestol and kahweol shows pharmacological effects such as hepatoprotective, anti-inflammatory, antidiabetic, antiosteoclastogenesis, anticarcinogenic, and colon cancer inhibitory activities (Ren et al. 2019; Roos et al. 1997; Gross et al. 1997; Kurzrock and Speer 2001; Novaes 2018; Higdon and Frei 2007).

Kahweol inhibits COX-II expression, MCP-1 secretion, and NF-kB/STAT-1 pathway. In Japan population, habitual coffee drinking may be associated with reduced risk of hepatocellular carcinoma (HCC) (Inoue et al. 2005). Trinh et al. (2010) reported that decaffeinated coffee provided neuroprotection in *Drosophila* models of Parkinson's disease. Cafestol and its related diterpenes demonstrate their potential as multiple functional food and multiple target alternative medical drugs.

17.2.11 *Coleus* (Lamiaceae)

The *Coleus* grows in tropical to subtropical region. There are about 150 species and more than 500 varieties of the genus in cultivation all over the world. *Coleus eluteria* bark is used to flavor of the liqueur Campari and Vermouth.

One of the most important species of *Coleus* is *C. forskohlii* (=*Plectranthus barbatus*). The root of this plant has been used to treat heart disorders such as high blood pressure and chest pain (angina), as well as respiratory disorders such as asthma in Hindu and Ayurvedic traditional medicine from ancient times. Since its major labdane diterpene epoxide, forskolin (**10**) was found to have positive inotropic, antihypertensive, and adenylate cyclase-stimulating activities, and it has ever aroused a great deal of scientific interest, and a number of 8,13-epoxy-labd-14-en-11-one diterpenes have been obtained. Forskolin is also used to treat allergies, eczema and psoriasis, obesity, painful menstrual periods, irritable bowel syndrome (IBS), urinary tract and bladder infections, advanced cancer, blood clots, insomnia, and convulsions. Healthcare providers sometimes give forskolin intravenously for heart failure. Forskolin drops are used in the eyes to treat glaucoma.

17.2.12 *Conyza* (Asteraceae)

The *Conyza* (horseweed) has 150 species belonging to the Asteraceae family. It grows in tropical and subtropical regions. The representative diterpenes of this genus are clerodanes.

17.2.13 *Croton* (Euphorbiacae)

The genus *Croton* belonging to the Euphorbiacae family, one of the largest genera of higher plants, comprises more than 1300 species which distribute in tropical and subtropical areas of the world. Many species in this genus contain the secondary metabolites which show antibacterial, antidiabetic, antidiarrheal, antifungal, anti-inflammatory, antimalarial, antipyretic, antihypertensive, antispasmodic, antiulcer antiviral, insecticides, vermifuges, diuretic, cytotoxic, gastrointestinal disease, etc.

Diterpenoids are very rich in *Croton*, corresponding to clerodanes 800 of which have been isolated and their structures elucidated. In addition, it contains cembranes, halimanes, kauranes, labdanes, trachylobanes, sarcopetalanes type diterpenoids as well as phorbol esters (Xu et al. 2018; Palmeira et al. 2006; Salatino et al. 2007).

17.2.14 *Copaifera* (Fabaceae)

This genus belongs to the family the Fabaceae has about 70 species distributed in the central and South America especially in Brazil. Copaiba oil was approved in the United States as a food additive and is applied to a small amount as a flavoring agent in foods and beverage. The oleoresin or bark decoction has been used as an anti-inflammatory and contraceptive by native Brazilian people. Copaiba has a number of ethnophamacological indications for the treatment of respiratory ailments such as bronchitis, strep throat, hemoptysis, pneumonias and sinusitis, and skin and mucosa diseases, such as dermatitis, eczema, psoriasis, wounds, ulcers and lesions of the uterus, leishmaniosis and leucorrhea, anemia, headaches, etc. The oil is also used for syphilis, bronchitis, cough, rheumatism, aphrodisiac, stimulant, antiseptic, anti-herpetic, anthelminthic, anticancer, antiparalytic, and antitumor properties. Tea from the seeds of copaiba is also used as a purgative and for treatment of asthma. Copaiba oil is now used in the cosmetic industry as a fixative for perfumes and perfuming soaps and shampoo. *Copaifera* oleoresins contain not only sesquiterpenoids but also much amount of diterpenoids especially, clerodanes, kauranes, and labdanes among which copalic and kaurenoic acids indicate antibacterial, anti-inflammatory, antileishmanial, antitrypanosomal, cytotoxic, and wound healing properties (Trindade et al. 2018; Arruda et al. 2019; Vargas et al. 2015; Leandro et al. 2012; Custodio and Veiga 2012).

17.2.15 *Eremophila* (Scrophulariaceae)

The *Eremophila* is a genus of more than 260 species of plants in the figwort family, Scrophulariaceae all of which are endemic to mainland Australia. The *Eremophila* are widespread in the arid areas of Australia, especially Western Australia and range in size from low-growing shrubs to small trees. The major diterpenoids found in this genus are naturally rare serrulatanes possessing α-glucosidase inhibitory activity.

17.2.16 *Euphorbia* (Euphorbiacae)

The *Euphorbia* is a genus of plants in the Euphorbiacae family (7500 species and 275 genus) and there are 2100 species. It is one of the most diverse groups of flowering plants on the Earth. A great number of the species produce many highly oxidized different type of diterpenoids including abietanes, atisanes, casbanes, daphnane, euphanes, ingenanes, jatrophanes, kaurenes and lathlanes, myrsinane, rhamnopholanes, and tigliane. Their contents are very high in some species and their bioactivity is also very diverse. Since the discovery of anti-HIV activity in the early 1990s, macrocyclic diterpenoids in all plant groups have attracted many phytochemists and pharmacologists, and a number of papers concerning anti-HIV potential through PKC activation have been published. Not only such antiviral phytochemicals but also a number of diterpenoids found in this genus show potent cytotoxic activity against several human cancer cell lines, antimicrobial and antifungal activities.

17.2.17 *Ginkgo biloba* (Ginkgoaceae)

Every year about 8000 t of dried leaves of *Ginkgo biloba* are produced and widely sold as phytomedicine in Europe and as dietary supplement as beverage (tea). Now, about 50 millions of *G. biloba* tree are grown in Europe, China, France, the United States (South Carolina), and Japan. In Japan *G. biloba* seed is used as food and planted especially at roadside and as fire prevention tree. The acetone-water extract from the dried leaves contains structurally complex diterpene trilactones, ginkgolides, and bilobalides whose structures were established by Nakanishi and his coworkers (Nakanishi 2005, Strømgaard and Nakanishi 2004). Ginkgolides possess improvement of memory, increased blood circulation, and beneficial effects to suffer of Alzheimer's disease. This class of the molecules has been studied for its potential to act as a platelet-activating factor receptor antagonist. Ginkgolide B (**12**) has been studied for its potential to reduce migraine frequency and it functions as a selective antagonist of glycine receptors based on noncompetitive inhibition for neurological system that this compound forms and is used in treatment for cerebrovascular disorders. Ginkgolides A-C (**11**–**13**) are platelet activation factor antagonists which are considered to contribute to their effects on cognitive disorders and these trilactones inhibit NF-kB signaling and iNOS activation. Ginkgolide A (**11**) could be explored for a potential role in managing vascular complications in diabetes, since it improved high glucose-induced vascular inflammation via modulation of the STAT-3-pathway.

17.2.18 *Helianthus* (Asteraceae)

Four species belonging to this genus are listed in Table 1. The representative species is the sunflower (*H. annuus*). The seeds of the *Helianthus* have been used as foods and food additives. This genus is a rich source of kaurene diterpenoids possessing anti-inflammatory activity.

17.2.19 *Helichrysum* (Asteraceae)

The genus *Helichrysum* consists of an estimated 600 species of flowering plants in the family Asteraceae. The type species is *Helichrysum orientale*. This genus is also a rich source of kaurane diterpenoids.

17.2.20 *Hypoestes* (Acantaceae)

The *Hypoestes* is a flowering plant genus with 150 species which are widely distributed in the tropical and subtropical region around the Indian Ocean. Many species that belong to this genus have various bio- and pharmacological activities, such as antimicrobial, antifungal, antioxidant, antitrypanosomal, and antileishmanial, and used as folk medicines, for treating many diseases, breast, liver, heart, and respiratory infection, anemia, scabies, skin disorders, typhoid, hypertension, and gonorrhea. The *Hypoestes* are rich sources of diterpenoids, labdanes, furanolabdanes, isopimaranes, dolabellanes, and especially fusicoccanes, such as hypoestenonols from *H. forskalei* which exhibited antifungal and antimalarial activity (Al Haidari 2018).

17.2.21 *Isodon* (Lamiaceae)

The *Isodon* is a group of flowering plants in the family Lamiaceae described as a genus in 1840. It is native to tropical and subtropical parts of the Old World, primarily Asia but two species are from Africa. Many of the species are endemic to China. Of 150 species of *Isodon*, nearly 70% is distributed in tropical and subtropical Asia. The *Isodon* is a genus of mint relatives whose member species has also been called *Rabdosia* or *Plectranthus*. Primarily Asian in origin, *Isodon* consists of about 100 species of *Salvia*-like plants a few of which have potential in the woodland garden. Ndoile (2020) reported 131 of diterpenoids from *Isodon* species. Sun et al. (2006) and Liu et al. (2017) described the review articles concerning diterpenoids from the *Isodon* species and their biological activity with 469 *ent*-kaurene as well as ent-gibberellanes, abietanes, and *ent*-abietanes, and the other bicyclic and tricyclic diterpenoids and the *ent*-kaurane structures categorized as 1) C-20 non oxygenated *ent*-kauranes, 2) C-20 oxygenated kauranes, (mono-epoxy-kauranes, diepoxy-*ent*-kauranes, C-20 oxygenated non-epoxy ring ent-kauranes), 3) 6,7-seco-*ent*-kauranes (enmein type, spiro-lactone type), 4) 8,9-seco-*ent*-kauranes, 5) 8,15-seco-*ent*-kauranes and 15,16-seco-*ent*-kauranes, 6) 7,20-cyclo-*ent*-kauranes, 7) *ent*-kaurane dimers, and 8) miscellaneous *ent*-kauranes, and 290 references. The isolated *ent*-kauranes and their related compounds possess antimicrobial, cytotoxic, antitumor, and antiviral activity.

17.2.22 *Nepeta* (Lamiaceae)

The *Nepeta* is native to Asia, Africa, and Europe, and North America and Mediterranean regions with over 250 species known. Several *Nepeta* species have

traditionally been used as diuretic, diaphoretic, antitussive, antibacterial, antifungal, antispasmodic, antiasthmatic, febrifuge, sedative, spice and herbal tea, as well as food and food supplements, an ingredient of vegetable soup, traditional foods, and used for colds, flu, and bronchitis. Nepetalactones are characteristic monoterpenes for some *Napeta* species as discussed in the dietary monoterpenoids (▶ Chap. 16, "Dietary Monoterpenoids"); however, a number of this species produced different diterpenoids, mainly abietanes and pimaranes (Yilmaz et al. 2016).

17.2.23 *Phlomis* (Lamiaceae)

The *Phlomis* is a genus of over 100 species of herbaceous plants, subshrubs, and shrubs in the family Lamiaceae, native from the Mediterranean region east across central Asia to China. Common names include Jerusalem sage and lamp wick plant. The *Phlomis* mainly produces abietanes and labdanes, and several species have been used as herbal tea.

17.2.24 *Pinus* (Pinaceae)

The Pines are any conifers in the genus *Pinus* of the family Pinaceae. The *Pinus* is the sole genus in the subfamily Pinoideae. About 126 species belonging to this genus have been known with 35 unresolved species. Pine is one of the more extensively used types of wood used as lumber. Almost all of the pine trees elaborate not only mono- and sesquiterpenoids but also diterpenoids of which abietanes and kaurenes are predominant constituents. The hexane extracts of the leaves of some of pine trees contains 80% of *ent*-kaurene in total yield. Some pine nuts are edible and leaves used as herbal tea.

17.2.25 *Plectranthus* (Lamiaceae)

The *Plectranthus* is a group of flowering plants in the family Lamiaceae. This genus grown in Southern and tropical Africa and Madagascar has 300 species of which 62 species are reported to be used as medicines, ornamentals, foods, flavors, and fodder (Lukhoba et al. 2006). Many species are rich sources of abietanes and their related compounds indicating antioxidant, antimalarial, antifungal, and cytotoxic effects.

17.2.26 *Podocarpus* (Podocarpaceae)

The *Podocarpus* is a genus of ever green or shrubs conifers, the most numerous and widely distributed of the podocarp family, Podocarpaceae, brightly colored receptacle at maturity. There are about 100 species in the genus depending on the

circumscription of the species. The *Podocarpus* species produce nagilactone diterpenoids, such as nagilactone A (**14**) which are naturally very rare constituents, restricted in this genus, together with abietanes. In spite of the presence of such nagilactone compounds and the other diterpenes found in this genus, little has been known of their bio- and pharmacological activity except for the constituents of *P. nagi* and the Japanese yew, *P. macrophyllus*.

17.2.27 *Premna* (Lamiaceae)

The *Premna* is a genus of flowering plants in the mint family, Lamiaceae, first described for modern science in 1771. It is widespread through tropical and subtropical regions in Africa, southern Asia, northern Australia, and various islands in the Pacific and Indian Oceans. The main diterpenoids of this genus are highly oxidized abietanes, clerodanes, and labdanes possessing antimicrobial activity.

17.2.28 Propolis (Bee Glue)

Propolis is one of rich sources of pharmacologically active diterpenoids in nature. It is a resinous material that is mostly collected by honey bees (*Apis mellifera* L.). Propolis has been used as many functional foods and cosmetics. Propolis collected in the different locations possess different diterpenoids, especially abietanes and labdanes, which show antimicrobial, antiviral, antifungal, antiparasitic, anti-inflammatory, cytotoxic effect, and immunomodulatory effect (Aminimoghadamfarouj and Nematollahi 2017).

17.2.29 *Rabdosia* (Lamiaceae)

The *Rabdosia* includes over 100 species mainly found in Japan, China, eastern Africa, Indian, Himalaya, and southern Asia. Many species of this genus have been used as the traditional medicine for the treatment of several diseases, such as respiratory and gastrointestinal bacterial infection. *R. japonica,* which has been used for treatment of hepatitis, gastricism, mastitis, and coughing, was highly studied phytochemically by Japanese and Chinese researchers and shown to have antitumor, antioxidant, anticoagulant, antimicrobial, and anticomplementary activities . It contains a bitter principle, enmein (**15**) and many other related kaurene type diterpenoids (Xiang et al. 2015).

17.2.30 *Rosmarinus* (Lamiaceae)

Salvia rosmarinus, commonly known as rosemary, is a herb with woody perennial fragrant, evergreen, needle-like leaves and white, pink, purple, or blue flowers, native to the Mediterranean region. Until 2017, it was known by the scientific

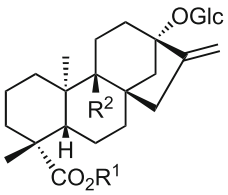
name *Rosmarinus officinalis*, now a synonym. It is a member of the mint family Lamiaceae, which includes many other herbs. The aerial parts have been used as spice and herbal tea as well as cosmetics and flavoring foods. It contains carnosol (**16**), rosmanol (**17**), and isorosmanol (**18**) and their related compounds which have various kinds of bio- and pharmacological activity such as anticancer, antifungal, and antidiabetic.

17.2.31 *Rubus* (Rosaceae)

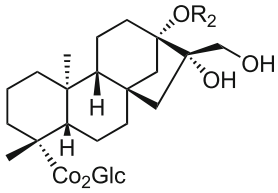
In Guan Xi province in Main China, the Chinese tea plant, *Rubus suavissimum* belonging to the Rosaceae is grown. Its leaves possess strong sweet taste and used as beverage (sweet tea, tian-cha). Its sweet taste is responsible for the diterpene glycoside, named rubsoside (**19**) whose aglycone is the same as that of stevioside (**20**); however, one glucose is absent. Enzymatic transformation of stevioside gives rubusoside which is 130 times sweeter than sucrose. Rubusoside is an excellent solubilizing agent. It can enhance the solubility of important pharmaceutics, such as curcumin, liquiritin, teniposide, and etoposide. In addition to rubusoside, *R. suavissimum* elaborates rubusoside-related glucosides (**19a–i**) (Chart 4) (Kinghorn et al. 2010).

17.2.32 *Salvia* (Lamiaceae)

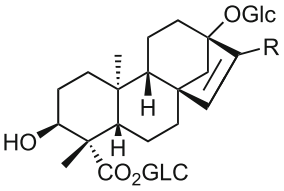
The *Salvia* is the largest genus in the family of the Lamiaceae plants and they are distributed mainly in South and Central America (500 species), central Asia and Mediterranean region (250), and eastern Asia (90). Wu et al. (2012) reported that 730 constituents were isolated from 134 *Salvia* species of the over 1000 species. *Salvia* species produce an incredible numbers of diterpenoids, abietanes (365), possessing simple structures and its derivatives are highly oxygenated, together with clerodanes (138), pimaranes (20), and labdanes (18) and among others. *Salvia* also elaborates with sesqui-, C-23-, C-25-terpenoids and triterpenoids and flavonoids. *Salvia officinalis* grown in the Mediterranean regions has fully been studied chemically and a number of diterpenoids especially abietanes were isolated and their structures as well as bio- and pharmacological activity such as anticancer, anti-inflammatory, antinociceptive, antioxidant, antimicrobial, antimutagenic, antidementia, hypoglycemic, and hypolipidemic effects were reported (Ghorbani and Esmmaeilizadeh 2017). In China, a number of *Salvia* species have been used in Traditional Chinese Medicine (TCM). *Salvia miltiorrhiza* known as red sage (丹參; pinyin: *dānshēn*) has been used for the treatment of cardiovascular and cerebrovascular disorders. It has also been used for circulation problems, chronic liver disease, sleeping trouble, and wound healing as well as skin problems, for example, acne, psoriasis, and eczema. This herb produces many abietanes, such as tanshinones (**21**) many of which possess *ortho* or *para*-quinone moieties in the molecule, and show significant pharmacological activity such as anticancer, antioxidant, antibacterial, neurodegenerative, anti-inflammatory, kidney and liver



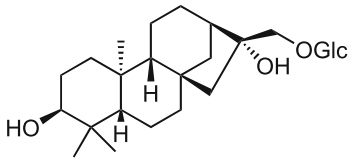
rubusoside (**19**): R^1=Glc, R^2=H
steviol monoside (**19b**): R^1=R^2=H
suavioside B (**19c**): R^1=Glc, R^2=OH



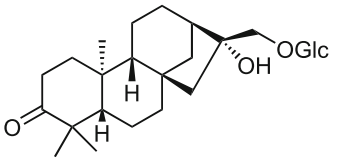
suavioside G (**19d**): R^1=H, R^2=Glc
suavioside J (**19e**): R^1=OH, R^2=H



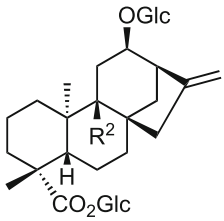
suavioside H (**19f**): R= CHO
suavioside I (**19g**: R= CH_2OH



suavioside A (**19a**):



ent-3-oxo-16β-hydroxy-kaurane-17-*O*-β-glucoside (**19h**)



cussoracoside (**19i**)

Glc= β-D-glucopyranosyl

Chart 4 Sweet diterpene glucoside, rubusoside (**19**) and its related compounds (**19a**–**h**) from the leaves of *Rubus suavissimus*, and cussoracoside (**19i**) from *Cussonia racemosa* (Kinghorn et al. 2010)

protective, anti-HIV, and antidiabetic activity (Jiang et al. 2019). *S. hispanica* (Chia) which began to be used in human food ca 3500 BC is distributed in Mexico to Guatemala. It is now cultivated in America, Australia, and Southeast Asia to obtain seeds which have been used as "Chia" as foods and seed oil. *S. hispanica* contains neoclerodane diterpenoids named hispanins A-J and salvihispin A-G and their related compounds. Hispanins D, F, I, and 12-hydroxyhautriwaic lactone and bacchotricuneatin A as well as salvihispin F show cardioprotective effects (Fan et al. 2019, 2020).

Sclareol (**22**) which was isolated from *Salvia sclarea* has been used major as a raw material for fragrance industry to produce cosmetics and food flavor (Fahlbusch

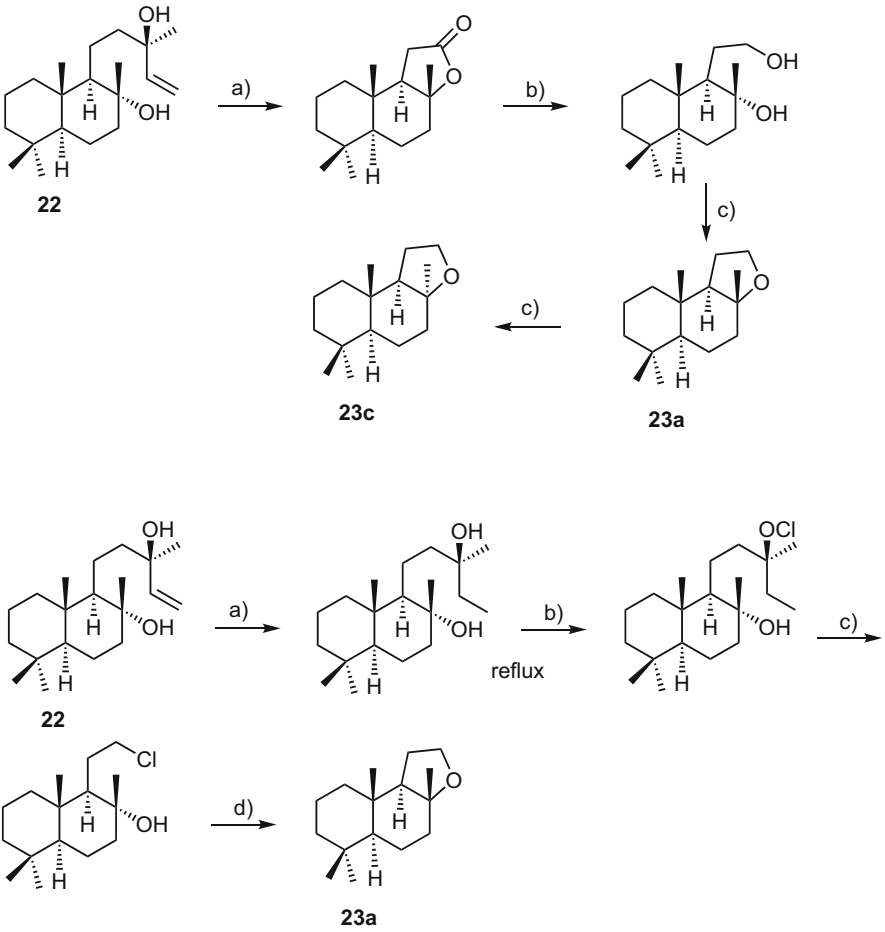


Fig. 1 Two hemisyntheses of ambrox (**23a**) from sclareol (**22**) (Decorzant et al. 1987). (**a**) CrO_3/AcOH, (**b**) LiAlH4/Ether, (**c**) 3-naphthalenesulfonic acid. (**a**) 5% Pd-C/EtOH, (**b**) aq.NaOCl/CCl_4, (**c**) 30–35 °C/3 h/reflux, (**d**) NaH/THF/3 h

et al. 2007). Sclareol is an important starting material to make ambrox (=ambroxide) (**23a**) originated from ambrain (Decorzant et al. 1987) (Fig. 1). The liverwort, *Porella perrottetii* produces a large amount of a labdane diterpenoids (**23b**) from which ambrox (**23a**) was synthesized in very good yield (Fig. 2) (Asakawa et al. 2013).

17.2.33 *Sideritis* (Lamiaceae)

The genus *Sideritis* contains more than 320 perennial and annual vegetable species widely distributed in the Mediterranean, the Balkans, the Iberian Peninsula and

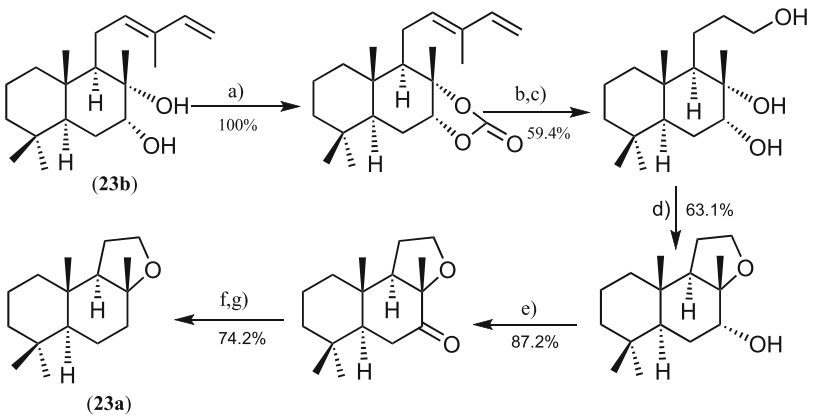

Fig. 2 Hemisynthesis of ambrox (**23a**) from labda-12,14-diene-7α,8α-diol (**23b**) isolated from liverwort, *Porella perrotteniana* (Asakawa et al. 2013). (**a**) $CH_3COCOOCCl_3/Py/CH_2Cl_2$, (**b**) O_3/CH_2Cl_2, (**c**) $LiAlH_4$, (**d**) $H^+/CH_3NO_2/p$-TsOH, (**e**) CrO_3-H_2SO_4, (**f**) $TsNHNH_2$, (**g**) $NaBH_3CN$

Macaronesia, Central Europe, and temperate Asia region. They are traditionally used "tea" for feeding, flavoring agents, and folk medicine as anti-inflammatory, anti-ulcerative, antimicrobial, antioxidant, antispasmodic, anticonvulsant, analgesic, and carminative agents (Burgos et al. 2011). The *Sideritis* produces *ent*-kauranes as predominant diterpenes.

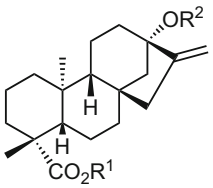
17.2.34 *Stachys* (Lamiaceae)

The *Stachys* is one of the largest genera in the family Lamiaceae and there are about 350–450 species. The type species for the genus is *S. sylvatica.* The distribution of the genus covers Asia, Africa, Australasia, and North America. *S. officinalis* was the most important medicinal herb in England. *S. affinis* is grown for its edible tuber. Several species are cultivated as ornamentals. The abietanes, kauranes, and labdanes have been found as the major constituents from the *Stachys*.

17.2.35 *Stevia* (Asteraceae)

In recent decades, the request for no caloric natural sweeteners in the food industry has increased the extraction of polysaccharides and other sweeteners isolated from plants, fungi, and algae due to their various biological activities. One of the most important no caloric plant sweeteners are several ent-kaurene glycosides with steviol (**24**) as a common aglycone isolated from *Stevia rebaudiana* belonging to the Asteraceae which is native to subtropical and tropical South and Central America. Among glycosides, stevioside (**20**) is the most abundant followed by rebaudioside A (**25**). The former diterpene glycoside is 140 times sweeter than sucrose, while the

Chart 5 Stevioside (**20**) and its related compounds (**20a**, **24**, **25**–**25f**) from the leaves of *Setevia rebaudiana* (Kinghorn et al. 2010). Glc = β-D-glucopyranosyl, Rha = α-L-Rhamnopyranosyl, Xyl = β-D-xylopyranosyl



stevioside (**20**): R^1=Glc, R^2=Glc-Glc (2-1)

steviolbioside (**20a**): R^1=H, R^2=Glc-Glc (2-1)

steviol (**24**): R^1=R^2=H

rebaudioside A (**25**): R^1=Glc, R^2=Glc-Glc (2-1), Glc (3-1)

rebaudioside B (**25a**): R^1=H, R^2=Glc-Glc (2-1), Glc (3-1)

rebaudioside C (**25b**): R^1=GLc, R^2=Glc-Rha (2-1), Glc (3-1) (=dulcoside B)

rebaudioside D (**25c**): R^1=Gluc-Gluc (2-1), R^2=Glc-Glc (2-1), Glc (3-1)

rebaudioside E (**25d**): R^1=GLc-Glc (2-1) R^2=Glc-Glc (2-1)

rebaudioside F (**25e**): R^1=GLc-Glc (2-1) R^2=Glc-Xyl (2-1), Glc (3-1)

dulcoside A (**25f**): R^1=GLc, R^2=Glc-Rha (2-1)

latter compound is 240 times sweeter than sucrose. Rebaudioside A possesses a better quality of sweetness. Now it is widely and legally consumed by millions of people from China, Korea, Israel, and especially Japan where the herb and the extract have been used since 1970s in numerous food products with an extensive safety taste, including soy sauce, pickles, boiled fish paste, and soft drink without any health risk. In 2006, Japan consumed more *Stevia* than any other country with stevia accounting for about 40% of the sweetener market. Steviosides are stable to remain sweet taste in processed foods and in hot soft drink like coffee (Goyal et al. 2010). *S. rebaudiana* produces not only stevioside (**20**), but also many similar *ent*-kaurene glucosides (**20a, 24, 25a–f**) (Chart 5) (Kinghorn et al. 2010).

17.2.36 *Solidago* (Asteraceae)

The aerial parts of *Solidago* species contain not only mono- and sesquiterpenoids while their roots are a rich source of clerodane diterpenoids. However, these

species are only used as the medicinal herbs and their bioactivity remained to be clarified.

17.2.37 Taxus (Taxaceae)

The *Taxus* is known as "Yews" a genus of evergreen coniferous trees belonging to the family Taxaceae mainly distributed in the northern hemisphere. All species of yew contain highly poisonous taxine alkaloids, although ripe fruits are sweet and edible. *Taxus brevifolia* (Pacific yew) and *Taxus canadensis* (Canadian yew) were the initial sources of paclitaxel (taxol) (**1**), possessing taxane diterpene skeleton which is one of the most important chemotherapeutic drug used in breast and lung cancer treatment. Since the discovery of paclitaxel and its related compounds, the chemical studies on secondary metabolites of different *Taxus* trees have resulted in the isolation of a great number of new taxoids possessing the interesting pharmacological activity (Wani et al. 1971; Suffness 1995; Kingston et al. 1993; Appendino 1995). Other yew species, for example, *Taxus mairei, T. wallichiana*, and *T. yunnanensis*, contain many similar taxane compounds with anticancer activity. Docetaxel, an analogue of paclitaxel, originated from *Taxus baccata* (European yew). The Japanese yew has been used to treat diabetes and promote diuresis and as an emmenagogue. From *T. cuspidata* about 120 taxoids have been isolated. Among the isolated toxoids, several non-taxol type compounds have been shown to reduce calcium chloride induced depolymerization of microtubules, increase cellular accumulation of vincristine in multidrug-resistant tumor cells, and showed strong cytotoxicity (Shigemori and Kobayashi 2004). Wang et al. (2011) reported a review article entitled "Natural taxanes: developments since 1823" which cited 513 references with more than 500 taxoid compounds and their bio- and pharmacological activity.

17.2.38 *Taxodium* (Cupressaceae)

The *Taxodium* species belongs to the Cupressaceae family and they are closely related morphologically to the Japanese *Cryptomeria japonica* and Chinese swamp cypress, *Glyptostobus pensilis*. Only a few *Taxodon* species have been known, *T. mucronatum, T. ascendens*, and *T. districhum* which produce cytotoxic abietane diterpenoids, taxodion, taxodone, taxoquinone (=7β-hydroxyroyleanone), sugiol, Δ^3-dehydrosugiol as well as labda-8(20),13-dien-15-oic acid and metasequoic acid which indicate antifilarial activity.

17.2.39 *Teucrium* (Lamiaceae)

About 300 species of the *Teucrium* belonging to the Lamiaceae are distributed in the northern temperate and subtropical regions, mainly in the Mediterranean region.

Many species of this genus have been used for over 2000 years in traditional folk medicines as diuretic, diaphoretic, hypoglycemic, hypolipidemic, antioxidant, antipyretic, anti-inflammatory, antiulcer, antitumor, and antibacterial crude drugs. Several species have been used as tonic and to treat stomachic, intestinal disorders, and colds, and for feminine sterility. One of the most common and highly studied species in this genus is *T. chamaedrys* named germander which is native to Europe and used in the treatment of digestive and respiratory diseases, abscesses, gout as well as astringent infusion on the gums and for wound healing.

Hydro-alcoholic extract has been used as approved substances in the preparation of flavored wines, bitters, and liqueurs. More than 220 diterpenoids all of which clerodane or neoclerodane skeleton have been isolated from the *Teucrium*. Many of them possess clerodane 20,12β-lactone moiety. The extracts of some species were exhibited to potentiate the cytotoxic and proapoptotic effects of anticancer drugs vincristine, vinblastine, and doxorubicin, against a panel of carcinogenic cell lines (Rajabalian 2008).

17.2.40 *Alpinia, Amonum, Elettaria, Curcuma*, and *Zingiber* (Zingiberaceae)

The *Alpinia, Amonum, Elettaria, Curcuma*, and *Zinger* belong to the Zingiberaceae family. The *Alpinia* is the largest genus in this family, with about 230 species many of which have been used as foods and spices as well as flower decoration. In Table 1, several *Alpinia* species having bio- and pharmacologically active diterpenoids are listed. *A. galanga* exhibited potent antimicrobial activity which is responsible for 8(17),12-labdane-15,16-dilal (**29**) (Widyowati and Agil 2018).

The seeds of cardamon or cardamom originated from the *Amonum* or *Elettaria* species have been used as foods, food additives, spices, and herbal tea. *E. cardamomum* (小豆蔻) and *A. villosum* var. *xanthioides* (縮砂) have been used as Kampo medicines. 8(17),12-Labdadien-15,16-dial (**29**) obtained from *E. cardamomum* and *Curcuma mangga* indicates potent antimicrobial activity. Calcaratarin A, communic acid (**3**), and copallic acid (**30**) also inhibit COX-II expression. In Korea, *A. villosum xanthioides* and *A. tsaoko* have been used as traditional tea.

Many *Curcuma* species possess food and nutritional value and are chemically studies extensively. The rhizomes of *Curcuma angustifolia, C. caulina, C. leucorrhiza*, and *C. xanthorrhiza* are good sources of food supplements. The rhizomes of *C. aeruginosa, C. amada, C, aromatica C. longa, C. pirreana, C. pseudomontana, C. purpurascens, C. xanthorrhiza*, and *C. zedoaria* are also used as dye, spice, and food flavoring, and coloring agent in food preparation. In fluorescence, tuberous roots, and rootstocks of *C. angustifolia, C. amada, C. australis, caulina,* C. *manga*, *C. pierreana*, and *C. pseudomontana* have been reported to be used as food appetizers, vegetables, and culinary preparations or making pickles, flavoring against steamed and baked fishes (Rajkumari and Sanatombi 2017). The crude extract of *C. manga* shows cytotoxic effects against MCF-7, KB, A549, Ca Ski, and HT-29 cell lines. The isolated diterpenoids, (*E*)-labda-8(17),12-diene-15,16-dial (**29**) and zerumin A (**69**) possessed

high cytotoxic effects against all six cancer cell lines (Malek et al. 2011). *C. heyneana* also produces the same labdane dial (**29**) which shows antimicrobial activity.

Zingiber officinale is the most widely used species as foods, vegetables, food additives, spices, and beverage among the Zingiberaceae family. This plant has been used as medicinal plant to cure many diseases. The first biologically active compound, galanolactone (**26**), a labdane epoxy-γ-lactone, possessing antagonist at 5-HT3 receptor was isolated from *Z. officinale* (Huang et al. 1991). The same lactone was found in some *Alpinia* species *A. galanga* and *A. katsumandai* which have been used as foods and beverage including antimicrobial, antifungal, and other pharmacological activity (see Table 1).

The rhizome of another *Zinger* species, *Z. mioga*, which is smaller than that of *Z. officinale* is also used as foods, vegetables, and food additives. The whole plant exhibited anticancer, antihypertensive, anti-inflammatory, and antiviral activity and used to treat abnormal and irregular digestion, fever, and hematemesis and so on. The flower buds of *Z. mioga* have been used as spice or pickles in Japan because of its characteristic pungent and pleasant odor. Abe et al. (2004) reported the isolation of three labdane dialdehydes, miogadial (**27**), which is responsible for the pungent flavor, galanal A (**28**) and B from the flower buds of *Z. mioga*. These three diterpene dialdehydes showed antimicrobial activity against Gram positive bacteria.

17.2.41 *Ziziphora* (Lamiaceae)

The *Ziziphora* is a genus of annual or perennial herbs or subshrubs in the family Lamiaceae and there are about 20 species distributed in Southern and Eastern Europe, North-West Africa, and Asia to the Himalayas and Altai mountains. *Ziziphora* has aromatic leaves which contain antimicrobial compounds and used as herbal tea.

17.3 Distribution of Diterpenoids and Related Compounds in Spore-Forming Plants and Mushrooms

17.3.1 Algae

Many types of sea algae (=sea weeds) are used as food, food additives, processed foods, and even beverages (algal tea with crude extract of *Plunus mume*) especially Japan, China, and Korea. They are also rich source of biological and pharmacological constituents with therapeutic properties. They have been established as healthy foods and food additives that are rich in dietary fibers and minerals. Many of them have been used as traditional folk medicines and drugs.

The common edible green, brown, and red algae are as follows:

Green algae: *Caulerpa lentillifera* (sea grape or green caviar), *Chlorella, Monostroma nitidum* (Hitoegusa* Japanese name), *Ulva compressa* (Aonori*), *U. intestinalis*, and *Ulva* species (sea lettuce, Aosa*)

Brown algae: *Alaria esculenta, Cladosiphon okamuranus* (Mozuku*), *Ecklonia cava, Eisenia bicyclis* (Arame*), *Fucus spiralis, F. vesiculosus, Himanthalia elongate, Laminaria digitata, Mastocarpus papillatus, Nereocystis luetkeana, Pelvetia canaliculata, Postelsia palmaeformis, Saccharina japonica* (Konbu*), *S. latissima, S. cinetum, Sargassum echinocarpum, S. fusiforme* (Hijiki*), *S. myriocysum, S. swartzii, S. vulgare, Undaria pinnatifida* (Wakame*), and *U. undarioides*

Red algae: *Chondrus crispus, Eucheuma spinosum, E. cottonii, Gelidiella acerosa, Gelidium crinale* (Tengusa*), *Gracilaria edulis, G. corticata, Mastcarpus papillatus, Mastocarpus stellatus, Neopyropia tenera* (Asakusanori*), *Palmaria palmata, Porphyra laciniata, P. umbilicalis*

El Gemal (2010) reported the review entitled "biological importance of marine algae" with 272 references and 386 structures among which 46 of diterpenoids and their biological activities were described. The similar review article concerning algal benefits; nutrition, medicine, pharmaceutics and cosmetics, and historical story of algae as foods, medicines, food industries and nutrition (polysaccharides, fifer, proteins and amino acids, lipids and fatty acids, minerals, vitamins and cosmetics), as well as classification of algae and pharmacological activity of each isolated secondary product including diterpenoids with mostly antibacterial, antiviral, and cytotoxicity of 102 species has been reported using 37 references (Anis et al. 2017).

17.3.1.1 *Ulva* (Green Algae)

Ulva fasciata, a green algae, contains seven labdane diterpenoids among which two labda-14-ene-3α,8α-diol and labda-14-ene-8α-hydroxy-3-one showed antibacterial activity against *V. alginolyticus* and *Vibrio parahaemolyticus* (Chakraborty et al. 2010). *Caulerpa lentillifera* is tasty green algae which grows in Okinawan cost. It contains unidentified terpenoids and steroids which showed antioxidant and antimicrobial activity (Asakawa unpublished results).

17.3.1.2 *Dictyota* (Brown Algae)

It is a genus of brown seaweed in the family Dictyotaceae. The species are predominantly found in tropical and subtropical seas, and are known to contain numerous chemicals (diterpenes) which have potential medicinal value. As at the end of 2017, some 237 different diterpenes had been identified from across the genus. Among the brown algae, *Dictyota* belonging to the Dictyotaceae are rich sources of diterpenoids and some of them are edible, such as *D. dichotoma*. Chen et al. (2018) summarized the distribution of diterpenoids with 90 references up to the end of 2017. A total of 233 diterpenoids were described, and they are divided into three groups: prenylguaianes, germacranes, cadinanes and epielemanes (Group 1), dolabellanes, such as

3*E*,7*E*,18-dolabellatrien-14-one (**31**) *from D. dichotoma,* dolastanes, 1(15),8-dolastadiene-2β,14β-diol (**32**) from *D. linearis,* secodolastanes, dictyoxetanes (Group 2), xenicanes, 4,18-dihydroxy-1(9),6,13-xenicatrien-19-al (**33**) from *D. dichotoma*, crenulidane, dichotomane, and crenulane (Group 3), among which the group 2 (120) is composed of almost 50% of the total diterpenoids (233) of the *Dictyota* species, and most of the isolated diterpenoids that originated from *D. dichotoma* possess antibacterial, antifungal, antiviral, cytotoxic, anti-inflammatory activity.

17.3.1.3 *Dilophus* (Brown Algae)

The *Dilophus* is distributed in the tropical zone of both hemispheres. Most of diterpenoids found in this genus share the same structural skeleton with those of *Dictyota* because the *Dilophus* is taxonomically similar to *Dictyota* mentioned above. The most characteristic chemical feature of this genus is the presence of cubebane-skeletal diterpenoids which show potent antibacterial and antifeedant activities. Xia et al. (2020) reported the review article of this genus including 124 diterpenoids and 63 references.

17.3.1.4 Red Algae

One of the most consumable red algae in the world is *Gelidium crinale* from which agar-agar is produced and it has been used as many foods, food additives, and processed foods; however, it does not contain any diterpenoids. The *Laurencia* species are rich sources of mono-, sesqui-, and diterpenoids, many of which possess chlorine and bromine atoms; however, these algae have not been used as foods.

17.3.2 Lichens

There are about 20,000 species of lichens in the world; however, several species, such as *Bryoria fremontii* (wila), *Cetraria islandica* (Iceland moss), *Cladonia rangiferina*, *Parmelia perata* (Kalpasi or black stone flower), *Umbilicaria esculenta*, are edible foods and some of them have been used as beverage (herbal tea). *C. islandica* was an important source of food for northern European, and was cooked as a salad, soup bread, or pudding. *B. fremontii* was an important food in North America. *Umbilicaria esculenta* is rare lichen which is used as traditional food in Japan and Korea. However, these edible lichens lack diterpenoids, and many aromatic compounds have been found as major components and their antioxidant property and cytotoxicity are reported. Only one edible lichen *C. rangiferina* produced several diterpenoids, abietanes and labdanes, and a pimarane derivative of which only abietane derivatives, hanagokenols A and obtuanhydride, sugiol and monbretol showed antimicrobial activity (Yoshikawa et al. 2008). Huneck and Yoshimura (1996) reported that rimuene containing lichen, *Evernia prunastri* (oak moss), shows antiseptic, emollient, and expectorant activity. Decocted *Letharia vulpina* (wolf lichen) which contains manool (**34**) and sandaracopimaric acid (**35**) was used as beverage to stop bleeding, stomach disorder, and poultice for swelling. *Ramalina hierrensis* and *R. tumidula* contain (-)-*ent*-kauran-16α-ol (**36**) and (-)-sandaracopimaric acid, respectively.

17.3.3 Bryophytes

Bryophytes are divided into three classes, Marchantiophyta (6000), Bryophyta (14,000), and Anthoceratophyta (300 species), among which Marchantiophyta (liverworts) contains cellular oil bodies. About 24 species of bryophytes have been used as medicinal plants especially in China. Among bryophytes, clerodanes, kaurenes, labdanes, cembranes, cyathanes, dolabellanes, fusicoccanes, pimaranes, phytanes, sacculatanes, sphenolobanes, trachylobanes, verticillanes, vibsanes, and viscidanes diterpenoids have been found in liverworts as major components and their absolute configuration and biological activity are reported; however, nobody knows whether these diterpene containing liverworts are edible or not. Only one large thalloid liverwort, *Marchantia polymorpha* which shows various biological activity: antimicrobial, antifungal, antioxidative, diuretic, potent antitrypanosomal, muscle relaxant, and tubulin polymerization and nitric oxide production inhibitory activity, is edible liverwort, and it is used as herbal tea and liqueur. It contains only labda-3,13(*E*)-dien-15-ol as a minor component (Asakawa 1982, 1995, Asakawa et al. 2013).

17.3.4 Ferns

Ferns comprise more than 12,000 species spread among 250 different genera. Baskaran et al. (2018) described in their review article entitled "A review of the use of pteridophytes for treating human ailments" 66 species including bio- and pharmacological activity citing 300 references. The young shoots of several ferns, *Athyrium esculentum*, *A. filix-femina*, *Matteuccia struthiopteris, Osmunda cinnamomea*, *O. japonica*, *O. regalis*, *Polystichum munitum*, *Pteridium aquilinum*, and *Stenochlaena palustris* are edible as a cooked leaf vegetable. Among which *O. japonica* biosynthesizes three *ent*-kauranes, such as *ent*-kauran-16(*S*),17-hydroxy-19-oic acid (**37**) possessing cytotoxic effects against HeLa and HepG2 cancer cell lines (Bowen et al. 2020) and *P. munitum* shows anti-inflammatory and anticancer activity for dandruff (Cao et al. 2017).

Flavonoids, hydroxycinnamic acid, and anthocyanin antioxidants have been found in some edible and many inedible ferns. The sprophyte of *Equisetum arvense* and roots of *P. aquilium* have been used as cooked vegetable and production of highly qualified starch, respectively. However, these species do not contain diterpenoids. On the other hand, the bitter fern, *Gleichenia quadripartita* contains 15 new labdane diterpene glycosides (Socolsky et al. 2007).

Dicranopteris dichotoma (=*Dicranopteris linearis)* has been used for parasites, skin ulcer, cut, and cold. It produces three tetranorclerodanes, such as aylthonic acid, and five *ent*-clerodanes such as 6(*S*),13(*S*)-cleroda-3,14-dien-6,13-diol which shows HIV inhibitory activity (Li et al. 2007).

The fern species, *Pteris* belonging to the Pteridaceae, are rich sources of kaurenes and kauranes and their glycosides. In addition, a few labdanes have been also confirmed as a small amount (Cao et al. 2017). Especially *P. cretica, P. dipar, P. plumbaea*,

and *P. semipinnata* contain these diterpenoids possessing various biological activities. For example, *P. dipar* contains 5β,11β,12β-trihydroxy-15-oxo-*ent*-kaur-16-en-19-oic acid (**38**) indicating potent cytotoxicity against KB cell. *ent*-11α-Hydroxy-15-oxokaur-16-ene (**5**) which was isolated from the Chinese medicinal fern *P. semipinnata* used for the treatment of venomous snake bites shows significant cytotoxicity and anticancer activity (Cao et al. 2017). It also indicates apoptosis in human colon cancer HT-29 and MNK-45 cells as well as cytotoxicity on the gastric cancer. The same kaurenoic acid also inhibits the proliferation of the human lung cancer cell lines (A549, NCH23, and CRL-2066), hepatocellular carcinoma (HCC), and lung adenocarcinoma cells. 7,9-Dihydroxy-15-oxo-*ent*-kaure-16-en-19,6-olide and 7,11-dihydroxy-15-oxo-*ent*-kaur-16-en-19,6-olide also inhibit lung adenocarcinoma cells. *P. multifida* which show antidysenteric, anti-inflammatory, antioxidant, antipyretic, antirheumatism, and detoxicant activity has been used for acne, appendicitis, and bleeding as the Chinese medicine contains 2β,16α-dihydroxy-*ent*-kaurane, 2β,15α,18-trihydroxy-*ent*-kaur-16-ene, and 2β,6β,16α,17-tetrahydroxy-*ent*-kaurane (Ge et al. 2008).

17.3.5 Mushrooms

More than 15,000 mushrooms are distributed in the world. Among them, 10 to 14% of the total mushrooms are edible as foods, vegetable, beverages, and processed foods in East Asian counties, China, Japan, and Korea. The others are nontoxic but inedible (too hard to chew) and toxic. Some nontoxic and inedible mushroom contains a big amount of spider-female pheromone and antimicrobial and antiviral compounds (Quang et al. 2006). About 700 species of the mushrooms have been used as traditional medicines and crude drugs. The distribution of diterpenoids is rare in mushrooms and fungi; however, a number of cyathane diterpenoids have especially been found in edible and inedible mushrooms belonging to the *Cyathus* and *Sarcodon* species. *Hericium* species are mushroom belonging to the family Hericiaceae and have been known as Chinese medicine or food without harmful. In particular, *Hericium erinaceum* (Yamabushitake, in Japanese) which is marketed as supplement, contains erinacine A-C (**39–41**), P (**42a**), and Q (**42b**) which exhibited nerve-growth-factor synthesis stimulatory and κ-opioid receptor agonist activities (Kawagishi et al. 1994, 1996a, b, 2006; Kenmoku et al. 2000, 2001, 2002, 2004).

The review concerning structural elucidation and bioactivity of erinacines from the fruiting body and mycelium of *Hericium erinaceum* have been reported by Ma et al. (2010). Xia et al. (2012) reported the structures of 109 cyatanes and its related compounds from *Cyathus* species with 96 references and their biological activities such as antimicrobial, anti-Methicillin-resistant bacterial, *Staphylococcus aureus*, osteroclast-forming suppressing agonistic toward the κ-opioid receptor, anti-inflammatory, and cytotoxic effect as well as stricture activity relationship in detail. The similar review concerning secondary metabolites of mushrooms including cyathane diterpenoids with 43 structures has been reported by Duru and Cayan (2015).

17.4 Biological and Pharmacological Activity of Dietary Diterpenoids and Their Related Compounds

A great number of flower plants including terpenoids have been used as foods, spices, vegetables, and beverages (tea, coffee, juices). Each crude extract including some diterpenes possesses a number of different biological and pharmacological activities. The most frequently recognized activities of diterpenoids are antimicrobial, antifungal, anti-inflammatory, antioxidant, and cytotoxic effects as seen in monoterpenoids (▶ Chap. 16, "Dietary Monoterpenoids").

As shown in Table 1, dietary foods and beverages contain a great number of highly oxygenated diterpenoids possessing γ-lactone and furan rings and almost all of them possess some kind of bio- and pharmacological activity, especially cytotoxic, antimicrobial, antifungal, antioxidant, and anti-inflammatory activity.

Cafestol (**7**) which was obtained from unfiltered coffees indicates hepatoprotective and a potent cholesterol elevating effect in mice (Van Cruchten et al. 2010). In India the major medicinal spices of *Coleus* is the tuberous *C. folskohlii, C. amboinicus, C. blumei, C. tuberosus, C. malabaricus*, and *C. scutellaroides* among which *C. forskohlii* is widely used in different counties. Forskolin (=7β-acetoxy-8,13-epoxy-1α,6β,9α-trihydroxylabd-14-en-11-one) (**10**) and its analogues included in *C. folskohlii* has been used for the treatment of heart diseases, abdominal colic, respiratory disorders, and many others and they have been totally synthesized by many organic chemists and their pharmaceutical activities tested. On the other hand, *Coleus carnosus*, which has been used as foods and spice, elaborated abietane diterpenoids, possessing antibacterial and anti-HIV, antiseptic, and potent cytotoxic activity. Kavitha et al. (2010) summarized the history, morphology, phytochemistry, and pharmacological aspects of *C. folskohlii* and forskolin and its analogues in detail. Asakawa et al. (2013) reported the hemisynthesis of forskolin (**10**) and 1,9-dideoxyforskolin (**11b**) from the labdane diterpene, ptychantin A (**10a**) (Fig. 3).

Many species belonging to the Zingiberaceae are rich sources of labdanes of which (*E*)-labda-8(17),12-dien-15,16-dial (**29**) isolated from *Alpinia* and *Curcuma* species which have been used as foods, spices, and beverages shows potent anti-inflammatory and antimicrobial activity. *Andrographis paniculata,* king of bitters, which biosynthesized a number of andorgrapholides, exhibits potent cytotoxic,

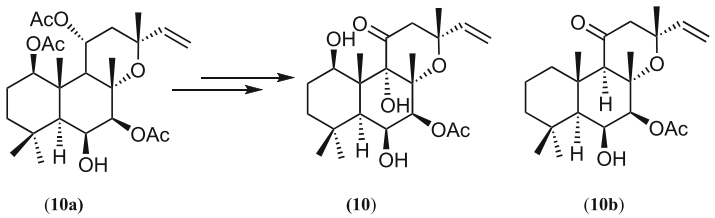


Fig. 3 The preparation of forskolin (**10**) and 1,9-dideoxyforskolin (**10b**) from the labdane diterpene, ptychanitin A (**10a**) isolated from the liverwort, *Ptychanthus striatus* (Asakawa et al. 2013)

cardiovascular, hepatorenal protective, and psychopharmacological activity. The *ent*-kauranes and *ent*-norkarurane-containing *Annona glabra* and *A. squamosal* (sugar apple) indicate antifungal, anti-HIV, cardiotonic activity, antidiabetic, and hypoglycemic, respectively. *Azadirachta indica*, the neem tree, which contains various podocarpa diterpenoids, possesses antidiabetic, antimicrobial, antifungal, and causes abortion, and used for cardiovascular, fever, liver, and skin disorders.

Baccharis species that have been used as beverages are rich sources of clerodane and neoclerodanes. For example, *B. genistelloides* possessing 15,16-epoxy-*ent*-clerodanes and *ent*-cleroda-18,19-olides exhibits antiviral, activity against HIV-1/VSV, antimutagenic, anti-inflammatory, and antidiabetic and have effects on bile duct, bone marrow, and uses for analgesic, anemia, and diarrhea, and so on. There are many *Croton* species beneficial for human health and they mainly produce clerodanes, and some of them are also rich sources of kauranes and labdanes, For example, *C. haumanianus* indicates aphrodisiac, antiepileptic, antihypertensive, and antidiabetic.

Curcuma species belonging to the Zingiberaceae family have been used as foods, foods additives, spices, beverages, and processed foods world widely. They are very rich of sesqui- and diterpenoids and pigment, like curcuminoids. Especially, *C. amada* (mango ginger) which produces a number of labdanes indicates various pharmacological activity, such as cytotoxicity against many cancer cell lines, anti-platelet, antifungal, and antimicrobial effects.

Ginkgo biloba and *Zingiber officinale* are very important crude drugs and ginkgolides (**11**–**13**) indicates anti-Alzheimer activity.

Dioscorea bulbifera, a Traditional Chinese Medicine (TCM) and food, contains several clerodane diolides, such as cleroda-16, 16β:18,2α-diolide (=diosbilbin B), which demonstrates cytotoxic activity against several cancer cell lines, fungi, and bacteria.

Eremophila species are chemically very characteristic since their major components are serrulatane type diterpenoids indicating α-glucosidase inhibitory activity as shown in *E.* aff. *drummondii*, *E. falcata*, and *E. glabra*.

The species belonging to the *Euphorbia* biosynthesize a number of different types of diterpenoids, and some species, such as *E. fischeriana*, elaborate highly oxidized phorbol esters which show antiviral activity against HIV-1 and rosane and abietane types possessing potent cytotoxic against human breast, colon, and prostate cancer cells. *E. helioscopisa* used as tea substitute contains jorkinane type diterpenoids indicating antiasthmatic, anthelmintic, antifungal, antimicrobial, and cytotoxic against lung cancer, and NO production inhibitory activity. *E royleana* elaborates various types of diterpenoids, euphanes, ingenols, kauranes, abietanes, and isopimaranes, possessing cytotoxicity against several human cancer cells.

The presence of diterpenoids in mushrooms is very rare. *Hericium* species are exceptional, since they produce many cyatane diterpenoids which show nerve growth factor synthesis stimulatory activity.

A few *Icacina* species, such as *I. trichantha* which has been used as food, produces various icacinane diterpenoids having antiasthma, antihypertensive, antimicrobial, and antioxidant.

The *Isodon* species are very rich sources of *ent*-kauranes. Up to now, more than 300 of this type of compounds have been isolated, and many of them indicate various biological activity. *I. japonica* used as beverage contains enmein (**15**), nodosin, isodocarpin, and their related compounds which indicate cytotoxic effect, murine lymphoma and antioxidant and antimicrobial activity. *Lycopus europaeus* is a rich source of isopimaranes possessing antifungal, antigonadotropic, antimicrobial, and antioxidant.

Oryza sativa (rice) produces a few characteristic pimaranes, such as momilactone A and its analogues as well as various gibberellins which inhibit germination inhibitory activity.

Rubsoside (**19**) and stevioside (**20**) isolated from *Rubus suavissimum* are significant kaurene-type sweet substances. They are widely used as food additives and sweeteners for many beverages and cooked foods and many other processed foods (Kinghorn et al. 2010). *Salvia* are rich sources of diterpenoids which show a number of different types of bio- and pharmacological activity. Tanshinone (**21**), and its analogues from *Saliva miltiorrhiza* show apoptosis in human breast cancer and are anti-inflammatory.

Salvia rosmarinus (=*Rosmarinus officinalis*) which has been used as flavoring food, spice, cosmetics, beverage, and crude drug produces phenolic abietanes, rosmanol (**17**), isorosmanol (**18**), and carnosic acid. Rosmanol has anti-inflammatory, antioxidant, antidepressant, and significant cytotoxic activity against the neuroblastoma and human colon adenocarcinoma cells, and antiulcerogenic activities. Isorosmanol (**18**) also exhibits antioxidant, neuroprotective, and neurotrophic effects and acetylcholinesterase inhibitory activity. Carnosic acid is more efficient antioxidant than vitamin E. *Salvia officinalis* used as foods, food flavor, crude drugs, and spice elaborates the same abietanes lactones (**17, 18**) from *S. rosmarinus*, and many other abietanes show many significant pharmacological activity, antimicrobial, antifungal, antispasmodic, antioxidant as well as cytotoxic, hemostatic, and hypoglycemic activity.

Many *Stachys* species have been used as beverages (herbal tea). *Stachys* species produces a number of different diterpenoids. *S. palustris* which elaborates abietanes and *ent*-kauranes indicates antibacterial, antifungal, antioxidant, antispasmodic, and antiseptic activity.

Stevioside (**20**) is the major *ent*-kaurane glucoside from *Stevia rebaudiana* together with its various analogues (**20a–f**) as shown in Chart 5 (Kinghorn et al. 2010). Stevioside is one of the most significant food additive (sweetener) for various kinds of foods, especially for non-calorie sweetener for beverage (coffee), cakes, cookies, and sources.

Since Wani et al. (1971) isolated paclitaxel (=taxol), one of the most significant clinically used anticancer drugs, from *Taxus brevifolia*, its total synthesis, isolation, and structural elucidation as well as biodegradation and biotransformation have been carried out and more than 200 taxane products have been obtained in the last century.

Teucrium chamaedrys (Germander), *T. montanum, T. pilum*, and *T. scorodonia* which mainly produce clerodanes and neo-clerodane lactones have been used for beverage (herbal tea, liqueurs, and flavored wine). These diterpenoids indicate antibacterial, antioxidant, diuretic, and hepatotoxic effects. *Vitex rotundifolia*,

which biosynthesizes a number of highly oxygenated labdanes, show anti-hyperlipidemic and antiprasmodial activity.

Cembrane-type diterpenoids are a large and structurally varied group of natural products isolated from both terrestrial and marine organisms. Especially, the Greek tobacco elaborates different types of cembranes many of which contain a γ-lactone group (Connolly and Hill 1991). Interestingly, some liverworts produce highly oxygenated cembranes (Asakawa et al. 2013). From a biomedical perspective, cytotoxicity is the most remarkable property of this class of diterpenoids, represented by sarcophytol originated from soft coral (Connolly and Hill 1991).

17.5 Microbial and Mammalian Biotransformation of Diterpenoids and Their Related Compounds

Every day, we take consciously take foods, vegetables, fruits, processed foods, spices, beverages (tea and herbal tea, coffee, cocoa) as well as processed foods including secondary metabolites, terpenoids, steroids, aromatic compounds and acetogenins, alkaloids, and so on. Little attention has been payed to fetal (metabolic pathways) of these compounds in our body, although many secondary metabolites were biotransformed by microorganisms and enzymatic treatment to produce the different functional compounds than the original products.

Recently, a numerous diterpene synthase and cytochrome P450 enzymes which generate different diterpenoids have been identified. Such enzymatic catalysts and their profound knowledge of specialized terpenoid metabolism may be applied to modern microbial and photosynthetic production systems which offer alternative production of different type of phytochemicals for human health (Mafu and Zerbe 2018).

A number of the papers concerning bioconversion of terpenoids, especially mono-, sesqui-, and diterpenoids, have been reported (Asakawa and Noma 2010, 2020; Bhatti and Khera 2014; Frij et al. 2011; Monteiro et al. 2017; Noma and Asakawa 2020; Rajamanikyam et al. 2017; Silva et al. 2013; Sultana and Saify 2012). Abietanes, cembrane, clerodanes, kauranes, labdanes, pimaranes, and taxanes and some minor skeletal diterpenoids have been carried out by enzymatical and in situ biotransformation in mammals in order to know the fetal (pathway of substrate) in our body and to obtain some functional substances for application to cosmetics, medicinal, and agricultural drugs as well as food additives and beverages.

In the following figures, the biotransformation pathways of some representative dietary diterpenoids have been shown.

17.5.1 Abietanes

Rodents, especially wild hares, like to eat conifer plants including diterpenoids, such as abietane and its derivatives, and kaur-16-ene. In order to understand the fetal of such simple diterpenoids, abietic acid (**2**) was orally administered directly into rabbits for 24 h, followed by the enzymatic degradation of urine to give C-16

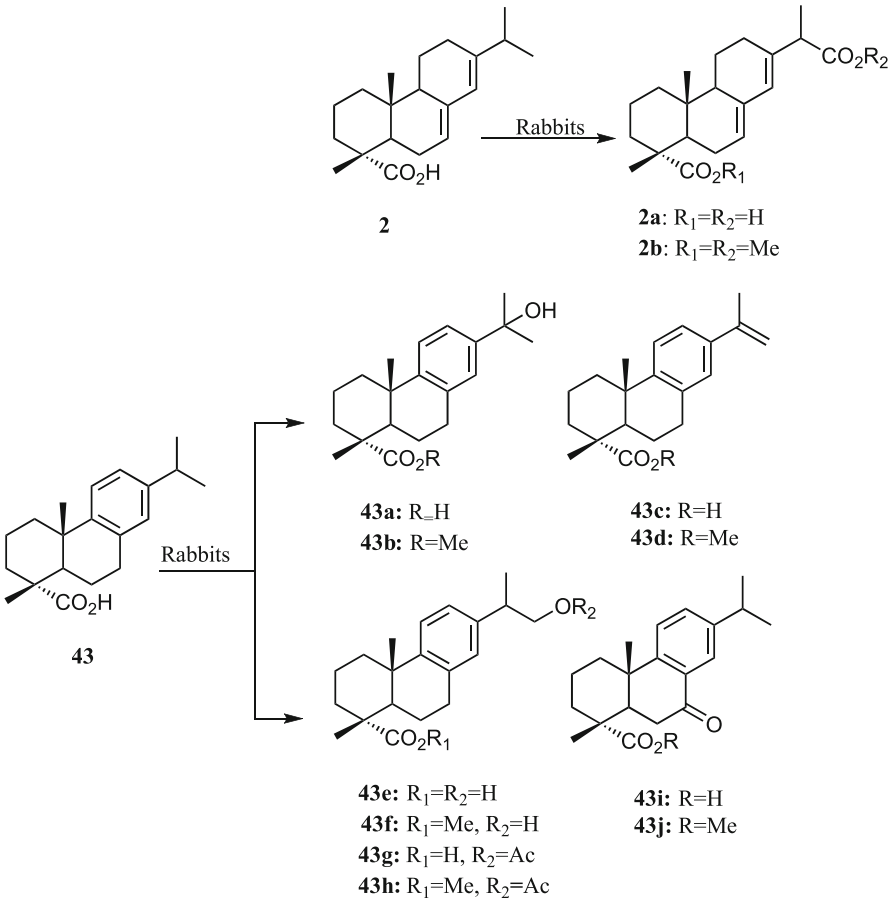

Fig. 4 Biotransformation of abietic acid (**2**) and dehydroabietic acid (**43**) by rabbits (Asakawa and Noma 2010)

carboxylic acid (**2a**) (Asakawa and Noma 2010, 2020) (Fig. 4). Dehydroabietic acid (**43**) was treated in the same manner as described above to give the metabolites (**43a–d**). Hydroxylation at an isopropyl group and oxidation at C-7 position and dehydration of the metabolic product (**43b**) were found in this case. 8,11,13-Abietatrien-18-ol (**44**) was treated in the same method as mentioned above to form seven metabolites (**44a–g**). Oxidation and hydroxylation at C-2 were observed together with the same hydroxylation at an isopropyl group seen in dehydroabietic acid (Fig. 5) (Asakawa and Noma 2010, 2020).

Cryptotanshinone (**45**) possessing an orthquinone group from *Salvia* species was treated by two microorganisms, *Cunninghamella elegans* or *Mucor rouxii.* The former fungous directly introduced stereo- and regiospecifically a hydroxyl

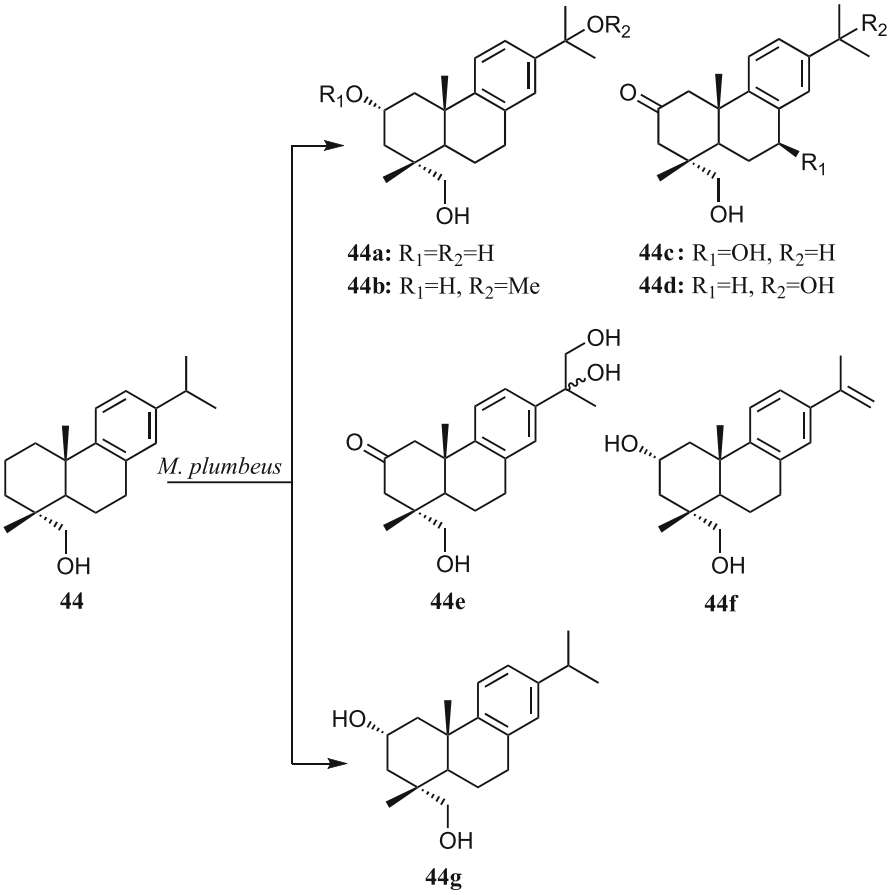

Fig. 5 Biotransformation of 8,11,13-abietatrien-18-ol (**44**) by *Mucor plumbeus* (Asakawa and Noma 2010)

group at C-3 and C-18 position to give 3α- (**45a**), and 3β- (**45b**) and 18-hydroxydated cryptotanshinone (**45c**) (Martinez et al. 2014) and the latter microorganism gave totally different metabolites than those obtained from the same substrate mentioned above. It produced three anhydrides (**45d–f**) and four spiro lactones (**45g–j**), two of which have 3α- (**45g**) and 3β-hydroxyl group (**45h**) (Fig. 6) (De Sousa et al. 2018).

17.5.2 Ginkgolide B

Ginkgolide B (**12**) obtained from *Ginkgo biloba* exhibits significant pharmacological effects against ischemic brain injury, platelet aggregation, and thrombosis as

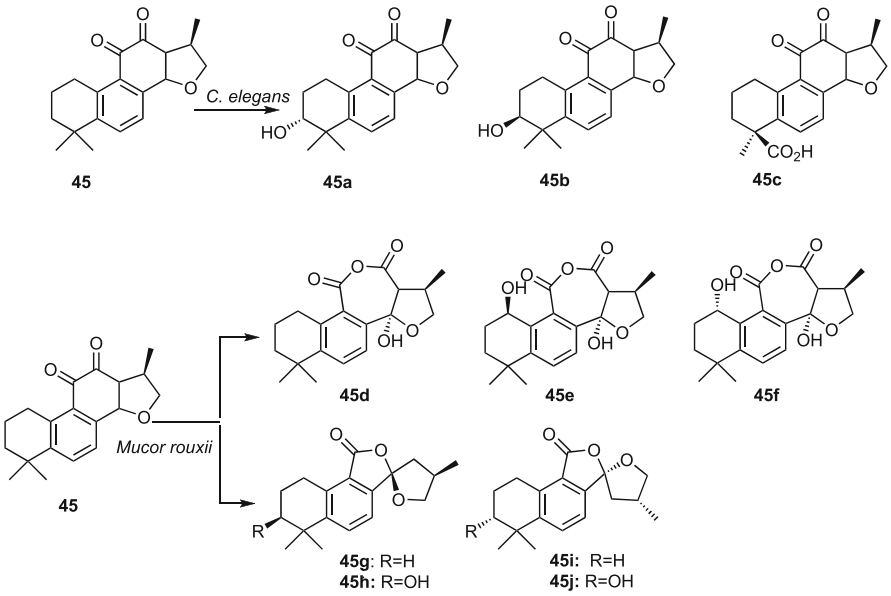

Fig. 6 Biotransformation of cryptotanshinone (**45**) by *Cunninghamell elegans* (De Sousa et al. 2018) and *Mucor rouxii* (Martinez et al. 2014)

well as inflammatory and central nervous disorders, post-ischemic neuronal damage, dementia, and Alzheimer's disease. Wang et al. (2008) administered ginkgolide B (**12)** to rats in order to understand its metabolite pathway. The rat biotransformed to ginkgolide B to a hydroxy ginkgolide B (**12a**) and an A-ring hydroxylated ginkgolide B monool **(12c**) via **12b**. This conversion was confirmed by rat liver incubation in vitro and the CYP2D6 isozyme was identified as the major CYP450 enzyme responsible for ginkgolide B metabolism in the rat liver microsomes (Fig. 7).

17.5.3 Cembranes

Since discovery of cembrane type diterpenoids in marine organisms, especially from soft corals, a number of cembranoids have been found not only in marine animals and algae but also in higher plants mainly from some tobacco species and liverworts. A cembrene diol, 2,7,11-cembratriene-4α,6α-diol (**46**) was converted by two microorganisms, *Cunninghamella elegans* and *Mucor ramannianus* to afford 11,12-epoxy-6α-acetate (**46a**). 4α-Hydroxy-6α-acetoxy-2,7,11-cembratriene (**46b**) was biotransformed by *Bacillus megaterium* to furnish a cembrene triol (**46c**) (Fig. 8) (Asakawa and Noma 2010, 2020).

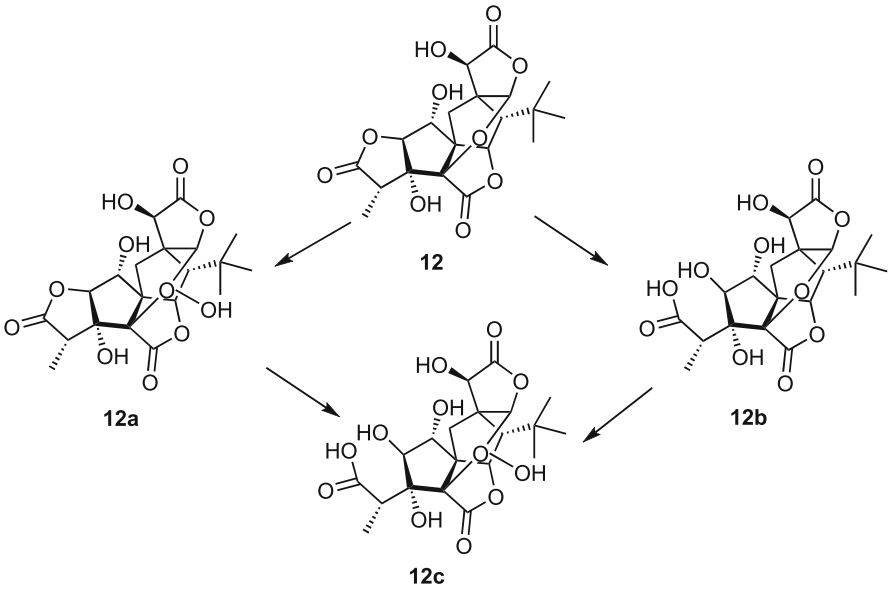

Fig. 7 Biotransformation of ginkgolide B (**12**) in rat (Wang et al. 2008)

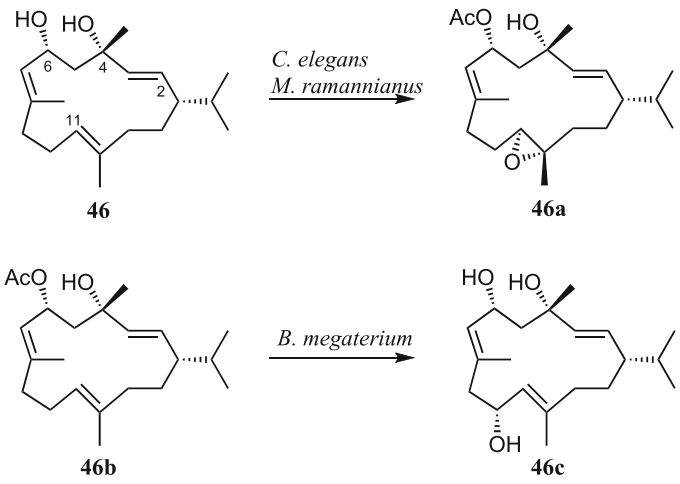

Fig. 8 Biotransformation of 2,7,11-cembratriene-4,6-diol (**46**) and 6-acetoxy-2,7,11-cembratrien-4-ol (**46b**) by *Cunninghamella elegans*, *Mucor ramannianus*, and *Bacillus megaterium* (Asakawa and Noma 2010)

17.5.4 Kauranes

Cafestol (**7**) which is one of a furano-kaurane 16,17-diol, from coffee extract was biotransformed to 2-hydroxycafestol (**7a**), followed by epoxidation and successive epoxidation on one of the double bond of a furan ring to give an epoxide (**7b**) and then to glutathione conjugate (**7b**) by liver P450 enzyme (Fig. 9) (Van Cruchten et al. 2010). When a sweet dietary diterpene glucoside, stevioside (**20**) was orally taken in human body, it was converted to steviol glucuronide (= steviol 19-*O*-β-glucopyranosiduronic acid) (**24a**) in human urine via steviol (**24**) (Geuns et al. 2006). On the other hand, some microorganisms, *A. niger*, *M. recurvatus*, and *B. emgaterium* converted steviol (**24**) to *ent*-7α-hydroxy- (**24b**), *ent*-19-oic acid β-glucopyranosyl ester (**24c**), *ent*-16β,17-dihydroxy- (**24d**), 7-oxo- (**24e**), and 7α,11β-dihydroxysteviols (**24f**) (Fig. 10) (Asakawa and Noma 2010, 2020). *ent*-Kaur-16-en-19-oic acid (**47**) which is one of the representative kauranes widely distributed in dietary foods and medicinal plants was incubated by *C. blakesleeana* to give four metabolites, *ent*-7α- (**47a**), *ent*-16α-hydroxy- (**47b**), *ent*-16β,17-dihydroxy- (**47c**), and *ent*-7α,16β-dihydroxykauranes (**47d**) (Fig. 11). *Ent*-kaur-16-en-7β-ol (**48**) was treated in the same manner as mentioned above by *Gibberella fujikuroii* to furnish *ent*-7β,16β,17-triol (**48a**) and unique secokaurene anhydride (**48b**). Further biotransformation of *ent*-7β,18-dihydroxykaur-16-ene (**49**) and *ent*-7β,15β,18-trihydroxykaur-16-ene (**50**) by *G. fujikuroii* gave *ent*-7β,18,19-trihydroxykaurene (**49a**) and *ent*-7β,11α,15β,18-tetrahydroxykaur-16-ene (**50a**), respectively (Fig. 12) (Asakawa and Noma 2010, 2020).

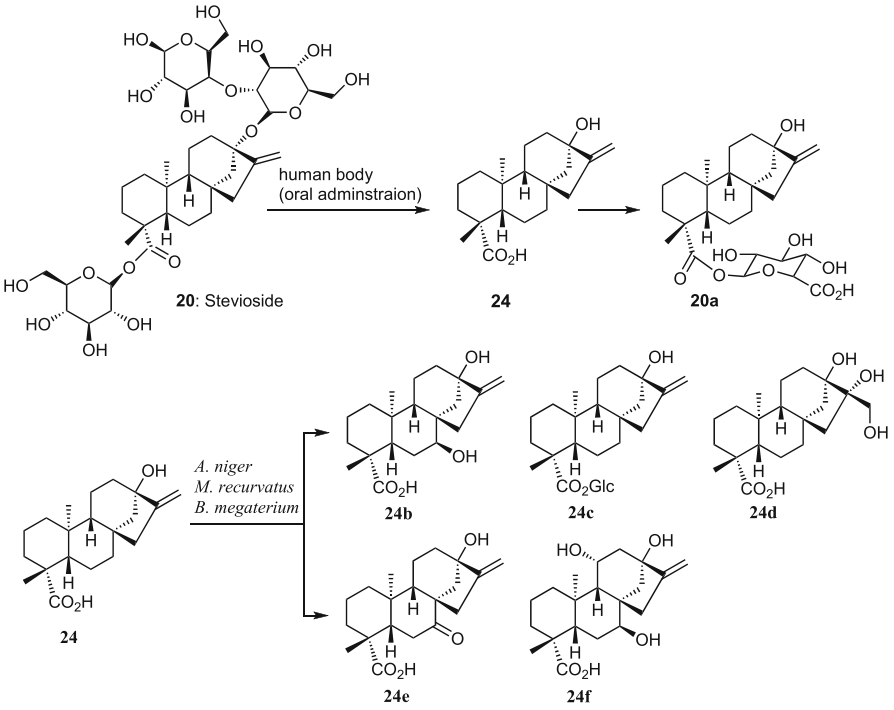

Fig. 10 Biotransformation of stevioside (**20**) by human body (Geuns et al. 2006) and steviol (**24**) by *Aspergillus niger*, *Mucro recurvatus*, and *Bacillus megaterium* (Asakawa and Noma 2010)

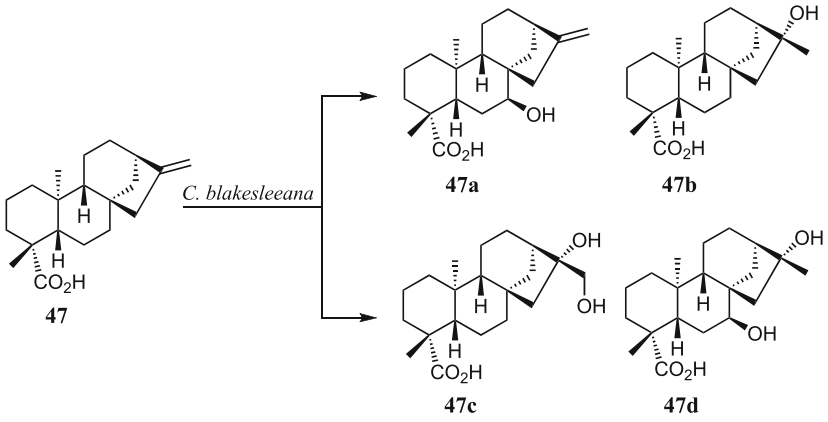

Fig. 11 Biotransformation of *ent*-kaur-16-en-19-oic acid (**47**) by *Cunninghamella blakesleeana* (Asakawa and Noma 2010)

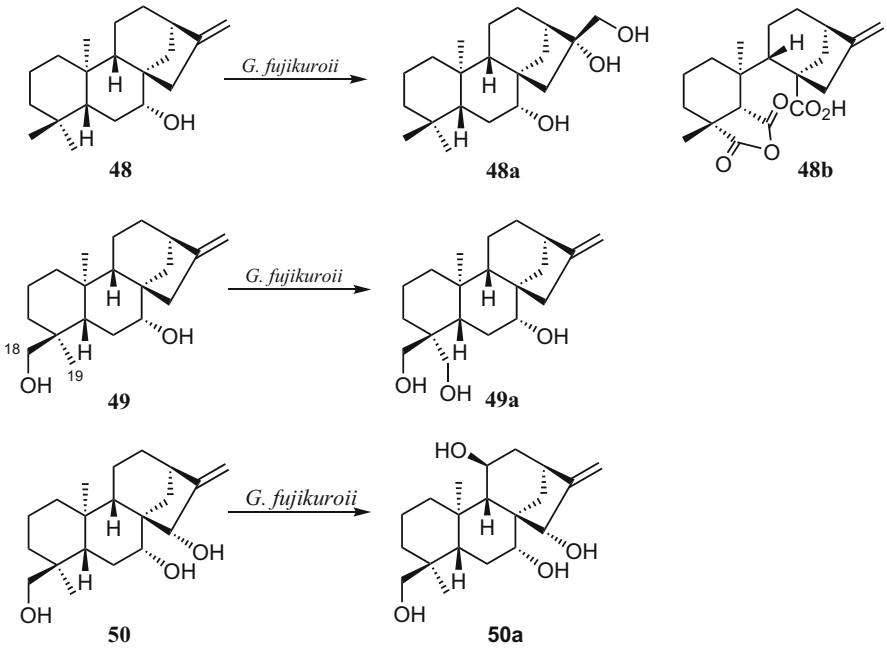

Fig. 12 Biotransformation of *ent*-kaur-16-en-7β-ol (**48**), *ent*-7β,18-dihydroxy-kaur-16-ene (**49**), and *ent*-7β,15β-trihydroxy-kaur-16-ene (**50**) by *Gibberella fujikuroi* (Asakawa and Noma 2010)

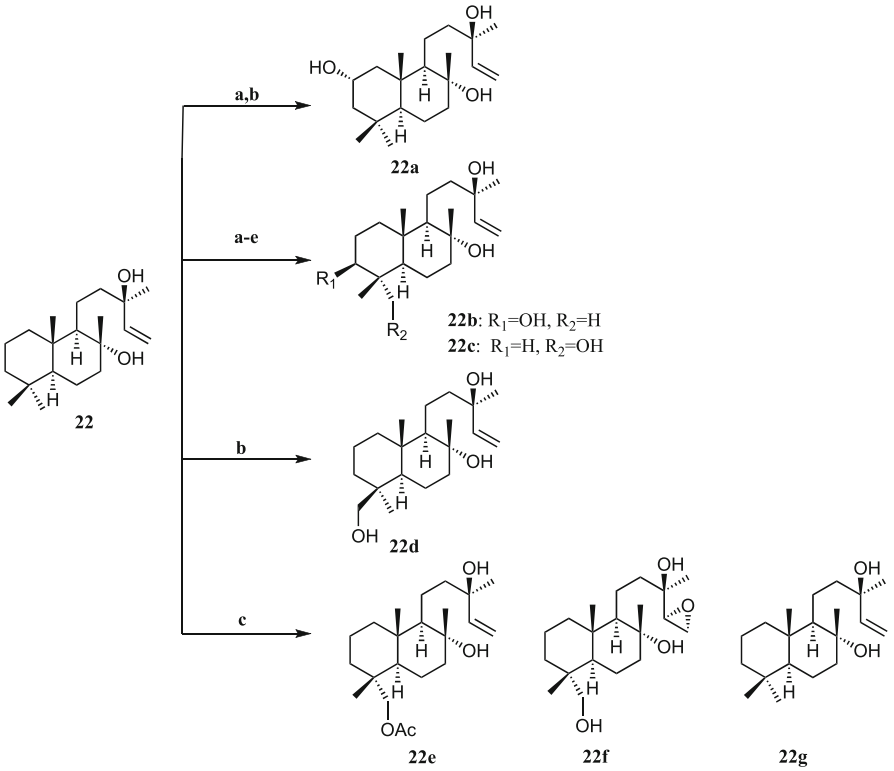
17.5.5 Labdanes

Sclareol (**22**), a labdane type diol, from some *Salvia* species was biotransformed by four microorganisms as shown in Fig. 13. Each microorganism regio- and stereo-selectively gave 2α-hydroxy- (**22a**), 3β-hydroxy- (**22b**), 19-hydroxy- (**22c**), 18-hydroxy- (**22d**), 19-acetoxy- (**22e**), and 15,16-epoxy product (**22f**) of 19-hydroxy compound (**22c**) (Asakawa and Noma 2010, 2020). Manool (**34**) and 7α-hydroxymanool (**51**) were also treated by *Mucor plumbeus* to afford the similar hydroxylated products (**34a–d**) and **51a–c**, respectively, as those from sclareol (**22**) (Fig. 13) (Asakawa 2010; ► Chap. 16, "Dietary Monoterpenoids").

17.5.6 Taxanes

In order to obtain paclitaxel (=taxol) like more potent and safe anticancer reagents, a number of biotransformation experiments of taxoids have been carried out. The biotransformation of paclitaxel (=taxol) (**1**), cephalomannine (**52**), and baccatin III (**53**) by *Nocardioides albus* is shown in Fig. 14. Firstly hydrolysis of **1** at C-13 occurred to afford baccatin-III, followed by hydrolysis at C-10 to furnish



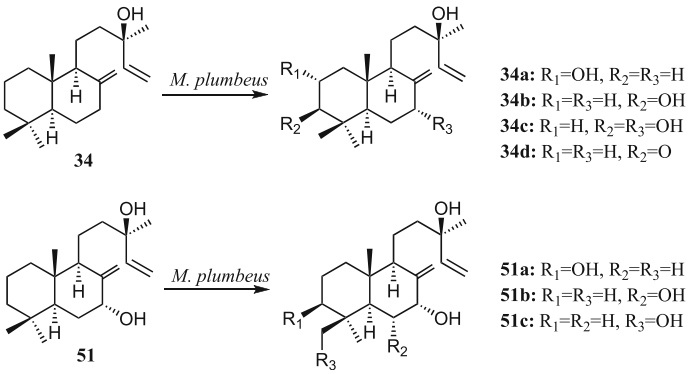


Fig. 13 Biotransformation of sclareol (**22**), manool (**34**), and 7α-hydroxymanool (**51**) by various microorganisms (Asakawa and Noma 2010)

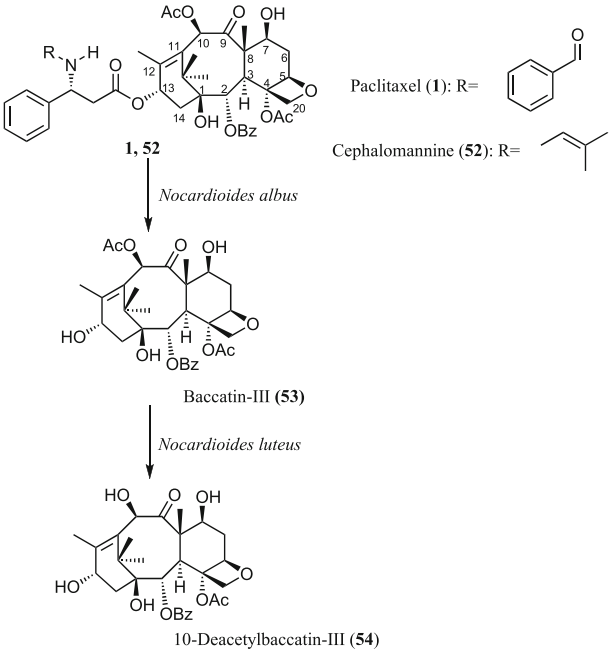

Fig. 14 Biotransformation of paclitaxel (= taxol) (**1**), cephalomannine (**52**), and baccatin III (**53**) by *Nocardioides leteus* (Asakawa and Noma 2010)

10-deacetylbaccatin III (**53a**). 10-Deacetyl-7-epi-taxol (**54**) was treated with two microorganisms, *Microsphaeropsis onychiuni* and *Mucor* species gave 10-desacetylpaclitaxel (**53a**) and two C-10 hydrolyzed products (**54b, c**) (Fig. 15).

Sinenxan (taxuyunnanine C) (**55**) was incubated with *Abisidia coerulea* to afford C-10 deacetyl (**55a**) and four hydroxylated products (**55b-e**) at B- and C-rings, respectively (Fig. 15) (Asakawa and Noma 2010, 2020).

17.5.7 Clerodanes

A furanoclerodane lactone (**56**) isolated from *Dodonea viscosa* was incubated with a plant pathogen, *Rhizopus stolonifera* to afford a furan-ring cleaved lactone (**56a**) and *ent*-2β-hydroxy introduced product (**56b**), while a furanocleroda-19-oic acid methyl ester (**57**) was treated in the same manner as that described above to furnish two γ-lactones (**57a, c**) and two γ-lactone cleaved metabolites (**57b, d**). Among all of the metabolite, 15-hydroxy-13-oic acid (**57d**) indicated antimicrobial activity against Gram negative bacteria (Fig. 16) (Choudhary et al. 2013).

17.5.8 Pimaranes

When *ent*-13-epi-Pimara-9(11),15-dien-19-oic acid (**58**) was fed with the fungous *Gibberella fujikuroii*, *ent*-1-oxo-2β, 9β-dihydroxy- (**58a**) and its C-2-epimer (**58b**),

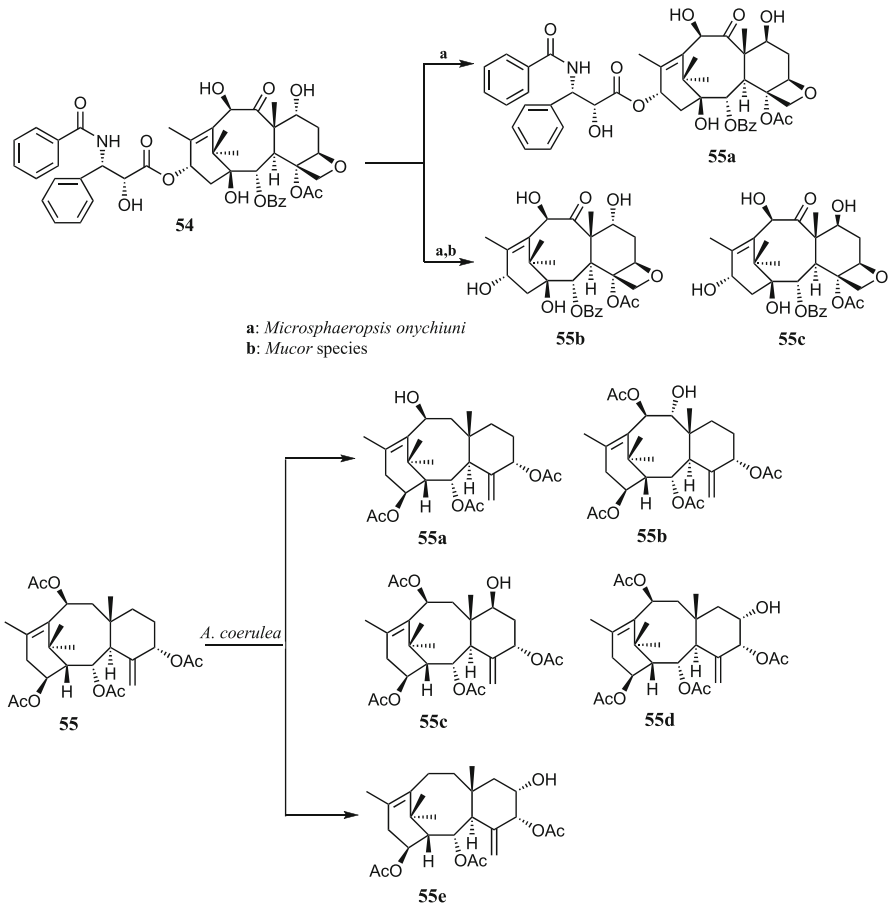

Fig. 15 Biotransformation of 10-deacetyl-7-epi-taxol (**54**) by *Microsphaeropsis onychiuni* and *Mucor* species, and Sinenxan **(55)** by *Abisidia coerulea*

1-oxo-12β-hydroxy derivative (**58c**) were obtained together with a Baeyer-Villiger oxidative product (**58d**). On the other hand, two *ent*-8β-hydroxy-9,11-epoxy derivatives (**59a, d**) were obtained along with two *ent*-7-oxo-11β derivative (**59b, c**) were obtained from *ent*-13-epi-pimara-9(11),15-dien-19-ol (**59**) (Fig. 17) (Martinez et al. 2014).

17.5.9 Fusicoccanes

Hypoestes forscalei is a rich source of fusicoccane diterpenoids. Al Haidari (2018) reported the biotransformation of hypoestenone (**59d**) by fungous, *Mucor ramannianus* ATCC 9628. An epoxidation occurred in this case to give 8α,9-α-epoxyhypoestenone (**59e**) (Fig. 18).

Only several examples of enzymatical biotransformation of some diterpenoids by several fungi and rabbits have been demonstrated. A number of diterpenoids were

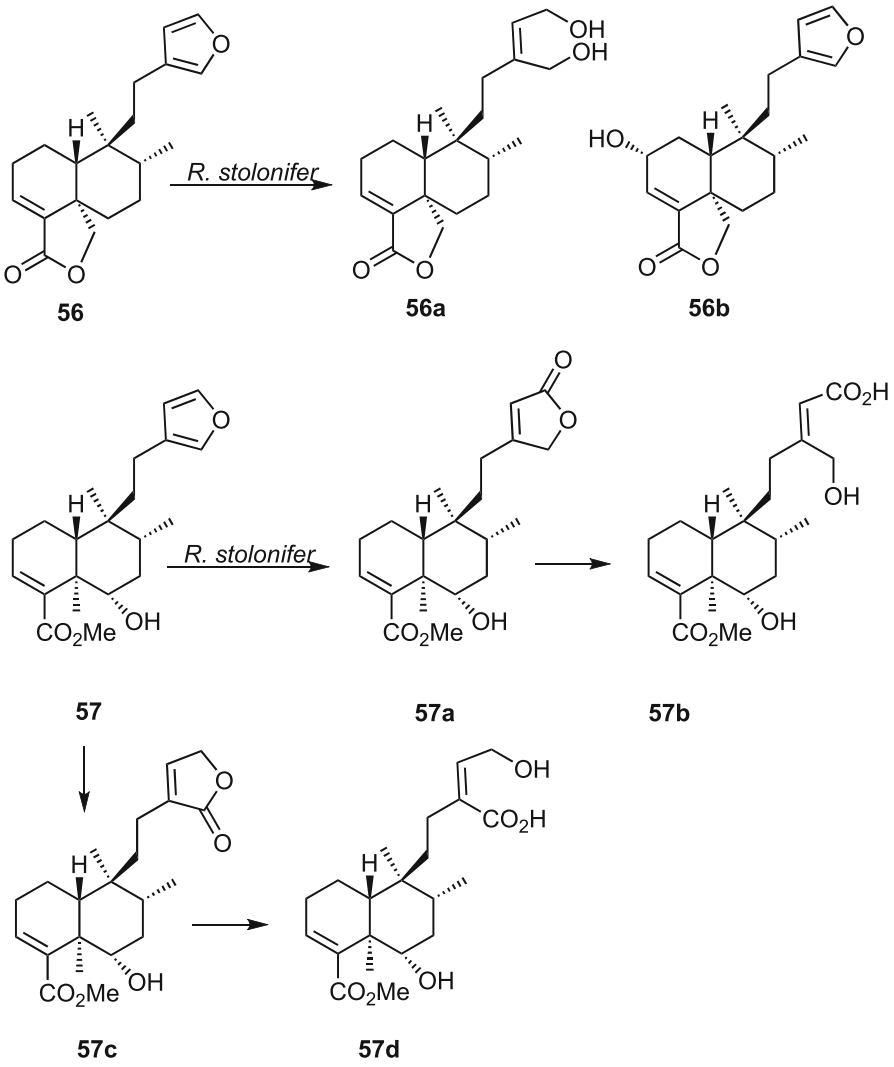

Fig. 16 Biotransformation of clerodane lactone (**56**) and clerodane methyl ester (**57**) isolated from *Dodonaea viscosa* and *Pulicaria wightiana*, respectively, by a plant pathogen fungus *Rhizopus stolonifera*

biotransformed by various fungi and mammals to give various metabolites, many of which showed antimicrobial, antifungal antiobesity, cytotoxic, and enzyme inhibitory activity. In the microbial and mammalian biotransformation, oxidation (direct introduction of hydroxy and carbonyl group at non-active carbon atom and carboxylation), reduction (double bond and ketone), epoxidation (double bond), esterification (including lactonization), and glycosidation have been found. The present methods are environmentally very friendly because a substrate is soluble in water with some nutrients, like peptone, simple one step reaction, non-hazard, and very

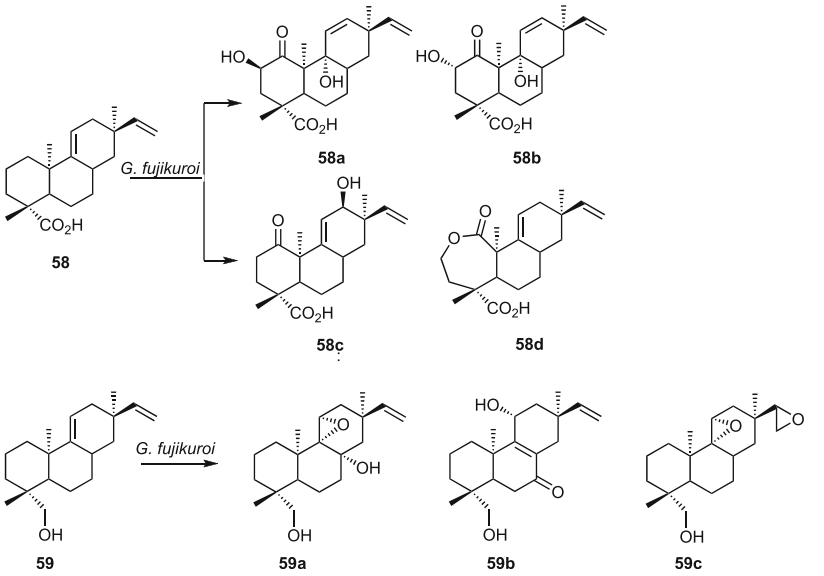

Fig. 17 Biotransformation of 13-epi-*ent*-pimara-9(11),15-dien-19-oic acid (**58**) and its 19-ol (**59**) by *Gibberella fujikuroi* (Martinez et al. 2014)

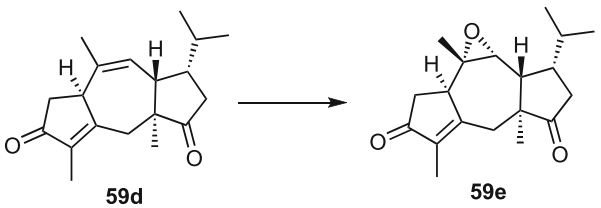
Fig. 18 Biotransformation of hypoestenone (**59d**) by *Mucor ramannianus* (Al Haidari 2018)



cheap, and it gives many valuable metabolites possessing different bio- and pharmacological activity from freely selected dietary diterpenoids and those from many medicinal and aromatic plants.

17.6 Conclusion

Three major dietary diterpenoids found in coffee, *Ginkgo*, and *Stevia* species and many other medicinal plants and one animal originated aroma, ambrox, have been discussed from viewpoint of foods, beverages, foods additives, and supplements as well as their bio- and pharmacological activity. Furthermore, the biotransformation of dietary diterpenoids including coffee, *Ginkgo biloba*, *Salvia*, *Taxus*, etc. and the other specific diterpenoids using enzymes and in situ mammals, such as rabbits was demonstrated in detail. In this chapter, more than 900 higher plants and 50 spore-forming plants (ferns, bryophytes, algae, lichens) and some mushrooms species

producing diterpenoids have been given to fields of foods, beverages, food additives, and medicinal sources. So many diterpenoids were tested against cancer cell lines, harmful microorganisms such as bacteria, viruses, and fungi. One of the most significant discoveries of anticancer drug from plant is taxol from *Taxus brevifolia* and *T. canadensis*. In order to find more active anticancer drugs, many taxane compounds have been biotransformed using tissue culture and bioconversion technique and hemisynthesis. A great amount of stevioside, non-calorie sweetener have been consumed in the world without any serious side effect, and *Ginkgo* extract containing ginkgolides having a unique tertiary butyl group in the molecule has been used as the effective drug for Alzheimer's diseases. It is absolutely difficult for the authors to get all of dietary diterpenoids references from the world. The authors think that a number of significant foods, vegetables, beverages, food additives, and processed foods including diterpenoids using in each country are lack in Table 1; however, the authors believe that Table 1 could be used as an Encyclopedia to understand how each plant and fungous, but not many animals (used as foods, vegetables, tea and coffee, and alcoholic beverages), biosynthesizes so many different types of diterpenoids, several of which exhibit incredible bitter and sweet tastes. Recent computer's development, analytical techniques, molecular biology, and omics studies will create more significant and valuable nutrients, medicinal drugs as well as food additives, supplement, and cosmetics for our humane life.

17.7 Structure Numbers and Names of Diterpenoids Including This Chapter

(**1**) Paclitaxel (= taxol)
(**2**) Abietic acid
(**3**) (*E*)-Communic acid
(**4**) 16β,17-Dihydroxy-*ent*-kauran-19-oic acid

Abstract

Tea, a water infusion of leaves from *Camellia sinensis* (L.) Kuntze, is the oldest, most consumed beverage worldwide. Archeologists have recently discovered traces of tea drinking dating to around 206 B.C. There are five major types of tea, differing in production processes and, therefore, in chemical composition: green tea, white and yellow teas, oolong tea, black tea, and dark tea. Compounds identified in green tea are involved in several biological activities and can have various health-promoting functions, which can include antioxidant, anti-inflammatory, antiviral, anticancer, antidiabetic, and anti-obesity activities, as well as activities against CVD and neurodegenerative diseases, and many others. These beneficial effects are mainly ascribed to tea catechins, bioactive constituents belonging to the flavonoid family (flavan-3-ols subclass), which represent approximately 70% of all polyphenols in tea. However, the maximal concentrations of the catechins detected in blood in human subjects or animals after oral ingestion are in submicromolar or low micromolar levels, which indicate that only small amounts are absorbed and passed into the blood. Chapter "Tea Catechins" describes the chemical composition of *C. sinensis* leaves and the beneficial effects on human health upon tea consumption, focusing on tea catechin bioactive constituents. This chapter also takes into account their bioavailability, toxicological aspects, and safety profiles. Furthermore, recent applications of tea catechins in the food market are presented.

Camellia sinensis · Tea catechins · Phytochemistry · Bioactive compounds · Health properties · Bioavailability

18.1 Introduction

Tea is the most consumed beverage worldwide, and tea plant from which it is derived, *Camellia sinensis* (L.) Kuntze, is currently grown in over 50 countries of the world. The main producers of tea are China and India, with 2,473,443 t and 1,325,050 t harvested, respectively, in 2017 alone, followed by Indonesia, Iran, Turkey, Vietnam, Kenya, and Sri Lanka (FAOSTAT 2019).

18.1.1 Botanical Description

According to its botanical classification, *C. sinensis* belongs to the *Theaceae* family which are woody plants with simple leaves, which may be more or less leathery and have smooth or toothed edges, widespread in temperate regions. *C. sinensis* is a small, highly branched tree, standing at 5–10 m tall, characterized by spaded oval evergreen leaves with toothed edges, which are soft and velvety when young and coriaceous when they are ripe. The shape and size of the leaves are distinctive characteristics in establishing the variety of the plant. The flowers have six to nine petals, are creamy white, and are solitary or grouped in twos or threes, while the fruit consists of a small woody capsule with a few dark, flattened seeds. The oil pressed from these seeds is used in cooking, due to its sweet taste. The plants are cultivated to the height of 1 m to facilitate harvesting, which occurs almost exclusively by hand in order to obtain the finest products and provides for the collection of unopened terminal buds, called pekoe, and the first leaves, young and soft, which produce one of the highest quality tea infusions. Shortly preceding the first harvest, which takes place between April and May, it is traditional practice to obscure the plant to encourage an increase in the content of flavonoids, sugars, and other molecules, which are representative of the quality of the tea, creating the necessary conditions for obtaining a sweeter and more precious product. The products of the first harvest differ from later harvests as they may include both the first leaves of the new season and the remaining leaves of the previous season.

The varieties of tea plant with commercial value are *C. sinensis* var. *sinensis* (called China type) and *C. sinensis* var. *assamica* (called Assam type, deriving from the Northeast state of India). Recent publications on the genetic profiling of tea have clarified that other tea varieties, e.g., *C. assamica* subsp. lasiocalyx Planch (called Cambod type), which have been considered to be synonyms of China and Assam tea types, are actually hybrids. Indeed, as breeding techniques have evolved, artificial pollination and hybridization are also steadily growing in importance.

18.1.2 History

A Chinese legend states that tea was discovered accidentally by Emperor Shen Nong in 2700 B.C., when camping under a tree after a long trip, some tea leaves fell in his pot of boiling water. However, tea as a beverage was first mentioned in Erh Ya,

a Chinese book dating from 350 B.C. Archeologists have recently discovered evidence of tea drinking in the excavation of "Han Yang Ling Mausoleum" in the Shaanxi province of China, revealing the diffusion of tea in the Han dynasty (206 B.C.). Tea drinking spread to Japan around the sixth century, as a privilege of high society, and became more widely popular about 700 years ago. The occidental consumption of tea arose from the tea trade between China and Holland, from which the English first gained an appreciation for drinking tea. In the seventeenth century, England was the first player in tea commerce imported from India, imposing restrictive trade conditions and strict taxation on the colonies. That is why, following the approval of the Tea Act in 1773, American colonials threw the tea cargo of British ships overboard off the coast of Boston (Boston Tea Party). Globally, tea consumption differs in the types of tea consumed and in the manner of consumption. Traditionally, green tea or oolong tea is preferred in Asia, whereas black tea is the customary beverage in much of the rest of the world, especially Europe, North America, and North Africa. Black tea is usually taken hot with milk in the Anglo-Saxon regions, whereas Americans prefer ice tea, introduced in 1904 at the St. Louis World's Fair, as a result of a particularly hot season.

18.1.3 Traditional Medical Application

Although the diffusion of tea drinking primarily occurred due to its sensorial properties, tea was initially consumed for its health properties, as with other herbal remedies in traditional Chinese medicine. In fact, it was mostly consumed for its digestive and detoxifying properties. Nevertheless, scientific investigation on this topic only began in the last decade of the eighteenth century. Even in India, tea was used traditionally as a medicinal plant before British colonization, after which tea was used as a drink for pleasure.

18.1.4 Tea Classification and Production Processes

Although the properties of tea differ between plant cultivars, climatic conditions, and producing regions, the post-harvest conditions have the highest impact on the variability of its chemical profiles and, consequently sensorial properties. Tea beverages are divided into five types: green tea, white and yellow teas, oolong tea, black tea, and dark tea (or pu-erh tea). Contrary to popular belief, every type is made from *C. sinensis* leaves. In fact, this classification is only based on the different production processes: non-fermented (green tea), lightly fermented (white and yellow teas), semi-fermented (oolong tea), fully fermented (black tea), and post-fermented (dark tea) (Fig. 1) (Tenore et al. 2015). Generally speaking, it's possible to subdivide the production process into a number of principal steps as reported below.

Picking: the operation in which the operator chooses buds or young or mature leaves.

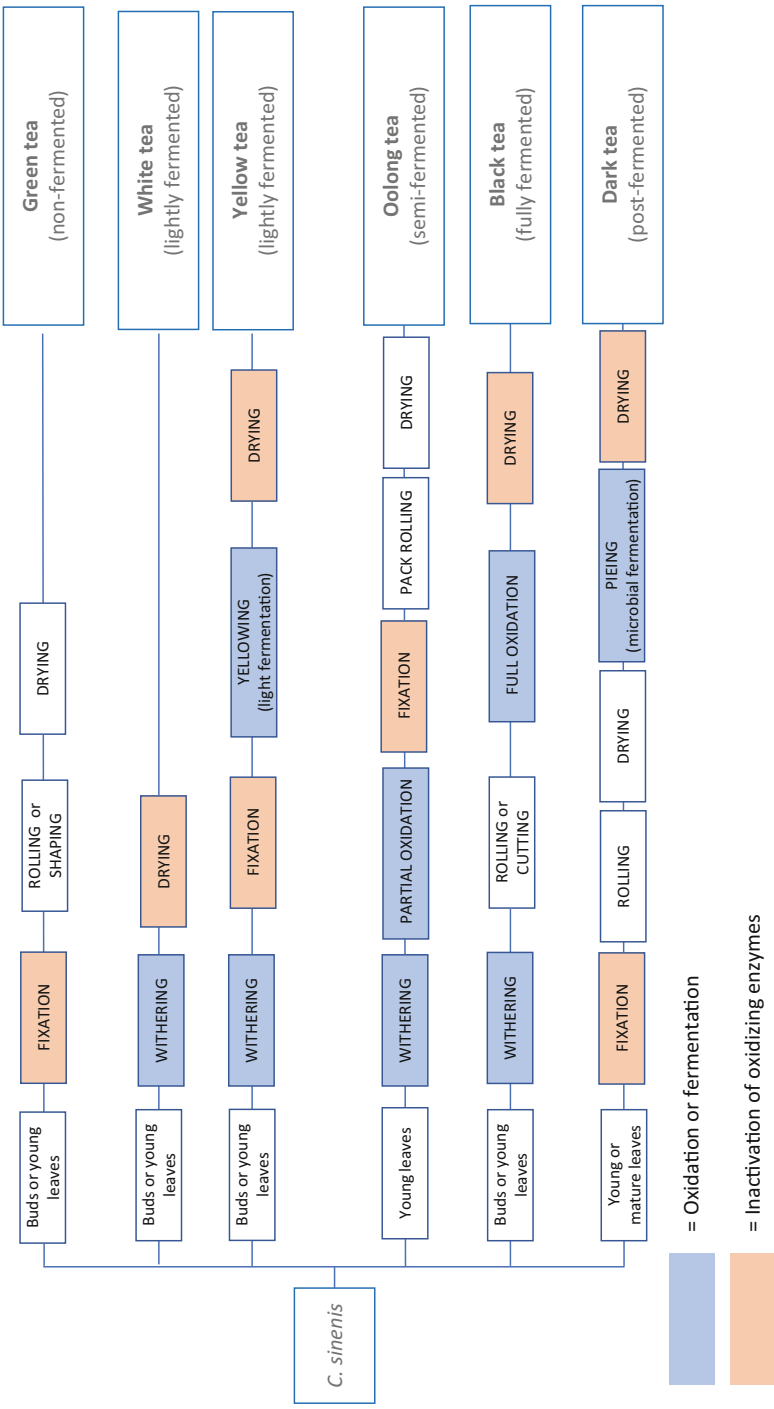

Fig. 1 Tea production processes

Withering: in this operation the tea leaves are spread in a series of enclosed or open troughs fitted with perforated trays under forced air circulation. During this period, the leaves lose some of their moisture, from approximately 70–80% to 60–70% of fresh weight and become more flexible for rolling. The withering operation has a strong impact on the chemical profile of the end product, as it catalyzes oxidative reactions resulting in slight oxidation of the leaves.

Fixation: is a step in the production of green tea, leading to the inactivation of enzymes and cessation of oxidation, with a significant impact on color and taste. To do this, leaves are slightly warmed to approximately 85 °C for short time (min) under dry or wet conditions.

Rolling: the shaping of tea leaves by hand or rolling machines. This operation leads to the release of essential oils from cell walls.

Pieing: this step involves the microbial fermentation of the leaves, induced by incubation at about 30 °C under moist conditions.

Crushing or cutting: the process that allows a greater intensity of oxidative reactions by increasing the exposed surface.

18.2 Bioactive Constituents

The chemical composition of tea leaves varies broadly on the basis of plant cultivar, growing environment, harvest season, and manufacturing conditions. The main bioactive constituents of tea leaves are polyphenols and methylxanthines, including catechins (25–35% D.W.), caffeine (3.5% D.W.), theobromine (0.15–0.2% D.W.), and theophylline (0.02–0.04% D.W.). Furthermore, organic acids (1.5% D.W.), chlorophyll (0.5% D.W.), theanine (4% D.W.), and free amino acids (1–5.5% D.W.) are present in tea leaves, in addition to a variety of other bioactive components in small amounts, such as flavones, flavonols (mainly quercetin, kaempferol, myricetin), phenolic acids, carbohydrates, minerals, vitamins, and enzymes.

It has been long established that the oil obtained from tea seeds is rich in antioxidant compounds. Recent studies have identified a significant amount of catechins in tea seed oil, suggesting that this product could be a promising source of bioactive compounds, such as catechins. In particular, George and colleagues showed that the total catechin content is about 4.8 ± 0.9 to $9.8 \pm 0.25 \times 10^{-3}$ (expressed as % of flavonoids) in seed oil from various tea clones (George et al. 2015).

18.2.1 Tea Catechins

Taking into account evidence presented in scientific literature, beneficial effects of tea are mainly attributable to tea catechins, which represent approximately 70% of all polyphenols in tea. Tea catechins, which are abundant in the young leaves and buds of tea plants, belong to the flavonoid family and to the subclass of flavan-3-ols. The main tea catechins are (−)-epicatechin (EC), (−)-epicatechin-3-gallate (ECG), (−)-epigallocatechin (EGC), and (−)-

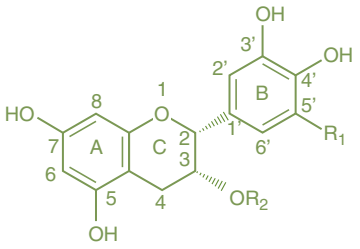
epigallocatechin-3-gallate (EGCG). Furthermore, tea contains (+)-catechin (C), (+)-gallocatechin (GC), (−)-gallocatechin-3-gallate (GCG), and (+)-catechin-3-gallate (CG).

These eight molecules are derived from the absence or presence of a gallyl substituent on the following four catechins: (+)-catechin, (−)-epicatechin, (+)-gallocatechin, and (−)-epigallocatechin.

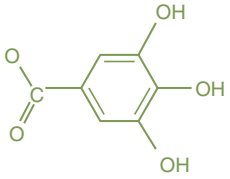
18.2.1.1 Chemical Structure of Tea Catechins

The structural basis of catechin molecules consists of two benzene rings, the A- and B-rings, which are similar to resorcinol and catechol moieties, respectively. Furthermore, catechins contain a dihydropyran heterocycle with a hydroxyl group on carbon 3, the C-ring. Catechins show two chiral centers on the C-ring against carbons 2 and 3. Hence, it has four diastereoisomers, of which two stereoisomers are in a *trans* configuration (referred to as catechin) and the other two in a *cis* configuration (referred to as epicatechin), as shown in Fig. 2.

The results obtained from in silico and in vitro studies on structure-activity relationships reveal that the molecular structure of catechins plays an important role in its antioxidant properties. As stated in these investigations, the antioxidant activity of tea catechins is mainly determined by the number and position of hydroxyl groups. Moreover, an increase in antioxidant activity could be linked to the presence of several structural elements, such as an o-dihydroxyl catechol structure in the B-ring, and the presence of unsaturation and a 4-oxo group in the



Main catechin structure



Gallate group

	R1	R2
EC	H	H
EGC	OH	H
ECG	H	Gallate group
EGCG	OH	Gallate group

Fig. 2 Catechins molecular structure

C-ring. In addition, the antioxidant activity of catechins could be facilitated by the 2,3-double bond in the C-ring, together with 4-oxo function in the C-ring, since these enable electron delocalization from the B-ring, or by the hydroxyl groups at positions 3 and 5, since these provide the hydrogen bonding to the 4-oxo group in the C-ring.

18.2.1.2 Biosynthesis of Tea Catechins

Catechins are synthetized through the flavonoid pathway, starting from 4-coumaroyl CoA, which, in turn, is derived through the phenylpropanoid pathway. The first enzyme involved in the flavonoid pathway is *chalcone synthase* (CHS) which catalyzes the condensation of 4-coumaroyl CoA and three units of malonyl-CoA, to form chalcone, also called naringenin chalcone. Subsequently, *chalcone isomerase* (CHI) catalyzes the isomeration of chalcone to naringenin, the corresponding flavanone. From this point the flavonoid pathway branches in different ways, which result in the synthesis of different classes of flavonoids: flavones, flavonols, flavan-3-ols, and anthocyanins.

Where flavan-3-ols are concerned, non-esterified catechins (C, EC, GC, and EGC) are produced in steps involving sequential reactions catalyzed by leucoanthocyanidin 4-reductase (LAR), anthocyanidin synthase (ANS), and anthocyanidin reductase (ANR), while esterified catechins (EGCG and ECG) are produced from EGC and EC by flavan-3-ol gallate synthase (FGS). The detailed flavonoid pathway is reported in Fig. 3.

18.2.2 Factors Determining a Modification of Tea Catechin Profile

There are various factors which may modify the profile of tea catechins, through epimerization, hydrolysis, oxidation or condensation, and oligomerization reactions. These factors, which are reported in further detail below, can occur during the growth of the plant, during post-harvest operations or even during infusion.

18.2.2.1 Growing Conditions: Impact on Tea Catechin Profile

The impact of growing conditions on the chemical profile of tea leaves is significant. Therefore, this section briefly covers the effects of shade techniques and the influence of an ethylene modified atmosphere on tea plants.

Shade

The production of shade-grown green teas was developed in Japan, following the spreading of tea from China at the hands of Buddhist monks in the sixteenth century. Tea bushes are progressively kept under rice-straw screens in April, the time corresponding with the opening of the first leaves. After 20 days, tea leaves are harvested by hand, immediately steamed to inactivate oxidative enzymes, and then dried in a specific tunnel. At this point, if the dried leaves are pulverized, matcha tea is produced, while in cases where the leaves are kept whole, the final products are generally named *shade teas* (e.g., gyokuro tea). Matcha, known as the "ceremony

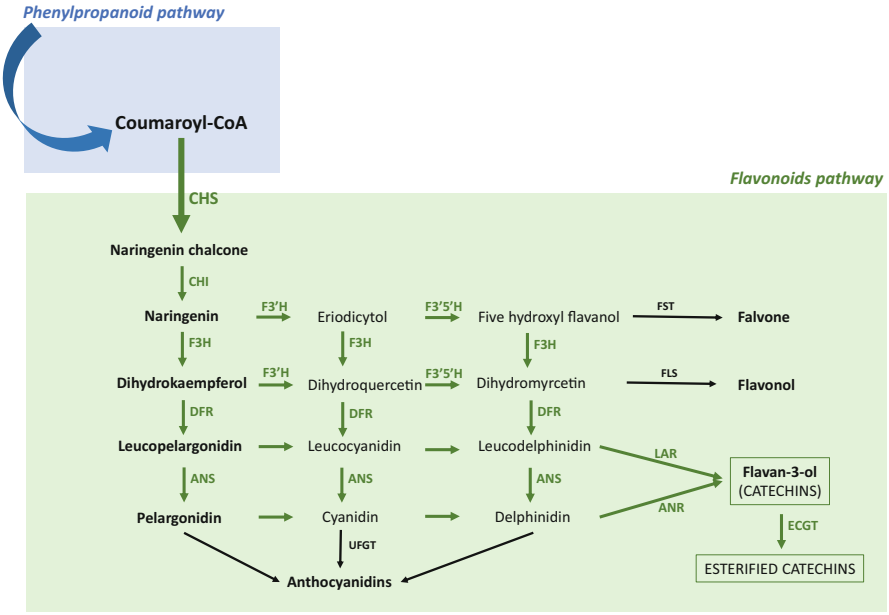


Fig. 3 Biosynthesis of catechins. CHS, chalcone synthase; CHI, chalcone isomerase; F3H, flavanone 3′-hydroxylase; F3′H, flavonoid 3′-hydroxylase; F3′5′H, flavonoid 3′, 5′-hydroxylase; DFR, dihydroflavonol 4-reductase; ANS, anthocyanidin synthase; UFGT, UDP-glucose flavonoid 3-O-glucosyltransferase; FST, flavonol 4′-sulfotransferase; FLS, flavonol synthase; LAR, leucoanthocyanidin reductase; ANR, anthocyanidin reductase; ECGT, epicatechin glucosyltransferase

tea," and the other *shade teas* are characterized by a brilliant light green color, which actually derives from the shade process. Tea plants, as with other species, are able to enhance their photosynthetic apparatus when grown under shade conditions. Indeed, young leaves grown in shade conditions accumulate a greater amount of chlorophyll than in other teas (called *light teas*). Another interesting characteristic of *shade teas* is their high content of amino acids, such as theanine, which gives them a unique sweet taste. On the other hand, it is well-known that the solar radiation regulates the biosynthesis of phenylpropanoids. So, the flavanol content of *shade teas* is lower than that of *light teas*, from about 10% to 13.1% of flavonoids, respectively. The amount of catechins of matcha (*shade tea*) compared to green tea (*light tea*) is reported in Table 1, which shows data from a research article carried out by Weiss and Anderton (Weiss and Anderton 2003). While Japan remains the leading consumer of matcha tea, followed by China, consumption of matcha in the United States and Europe is expected to grow due to its recent use in different kind of smoothies, hot milk beverages, and alcoholic beverages such as matcha beer. It also important to note that while normally tea leaves are infused with water and the extract is consumed, in the case of matcha tea, powdered tea leaves are added to water and the leaves are thus consumed as part of the beverage. For

Table 1 Amount of catechins in matcha (shade tea) compared to green tea (light tea) (Weiss and Anderton 2003)

Compound	Green tea (mg/g)	Matcha tea (mg/g)
Caffeine	3.9 ± 0.35	23.9 ± 0.34
Catechin	6.2 ± 0.01	Under limit of detection
EGC	6.2 ± 0.05	0.75 ± 0.04
EGCG	0.42 ± 0.05	0.32 ± 0.03
EC	4.4 ± 0.30	2.4 ± 0.11
ECG	0.10 ± 0.02	0.25 ± 0.03

this reason, the intake of bioactive constituents is higher for matcha than in other types of tea, assuming the same drug-solvent ratio.

Ethylene

Ethylene, a plant hormone that affects the growth and development of plants, plays a crucial role in plant signal transduction. In some plant species, ethylene signalling is involved in plant defenses by inducing the accumulation of secondary metabolites and enhancing polyphenol oxidase activity. A recent research article aiming to elucidate the effects of ethylene on the synthesis of phenolic compounds in tea seedlings showed that this plant hormone significantly enhanced the total content of catechin. In more detail, tea seedlings were exposed to a modified atmosphere, which presented a large amount of 1-aminocyclopropane-1-carboxylic acid (ACC), a direct precursor of ethylene. The results of chromatographic analyses indicate that this ACC treatment increases the galloylation of EGC and EC. Furthermore, ACC exposure enhances anthocyanin synthesis. However, the antioxidant enzyme activity assay showed that the activity of catalase (CAT), superoxide dismutase (SOD), and total peroxidase (POX) decreases, while ascorbate peroxidase (APX) activity is increased.

These findings elucidate that ethylene signalling is involved in the modulation of the accumulation of secondary metabolites and could thus be useful in increasing the healthy properties of tea products.

Post-Harvested Conditions: Impact on Tea Catechin Profile In general, it can be stated that post-harvest conditions have the largest influence on tea catechin profile, since the various processes yielding the various types of teas belong to these kinds of operations.

Anaerobic Conditions

In 1987, a Japanese scientist, named Dr. Tsushida Tojiro, accidentally discovered that freshly picked tea leaves exposed to anaerobic conditions in a nitrogen-rich modified atmosphere accumulated GABA, synthetized from glutamic acid. Thanks to Dr. Tojiro's discovery, a new type of tea, GABA tea, was created. According to the standards defined by the Japanese authorities, GABA tea must have a GABA amount of at least 150 mg/100 g of dry tea. Today, the GABA tea

Table 2 Content of polyphenolic compounds in GABA and green teas (Wang et al. 2006)

Compound	Green tea (mg/g)	GABA tea (mg/g)
Caffeine	3.22 ± 1.14	3.34 ± 1.36
Catechin	0.76 ± 0.31	0.73 ± 0.46
EGC	2.85 ± 1.67	3.71 ± 2.06
EGCG	4.69 ± 1.55	3.26 ± 1.78
EC	0.62 ± 0.23	0.44 ± 0.67
ECG	0.85 ± 0.64	0.66 ± 0.58
GC	2.48 ± 1.24	3.17 ± 2.01

production process also involves the shade operation of tea, derived from the observation that shade growing tea plants have increased glutamic acid content. GABA tea is appreciated for its unique sensorial properties and especially for the great deal of evidence for its health properties, such as sleep-promoting effects, antihypertensive activity, and antidepressive-like effects (Di Lorenzo et al. 2016; Daglia et al. 2017). A recent study explains the mechanisms by which anoxia increases GABA concentration by about 20 times that of untreated tea. The results suggest that the increase in GABA is due to the increase in activity of the enzymes glutamate decarboxylase and diamine oxidase, and the increase of putrescine and spermine, two substrates for GABA production (Liao et al. 2017). In addition to its influence on GABA content, the exposure of picked tea leaves to anaerobic conditions leads to a variation in the catechin profile of GABA tea. Wang et al. reported that, compared to green tea, GABA tea shows significantly lower levels of EGCG and EC, while GC, C, EGC, and ECG do not differ (Table 2) (Wang et al. 2006).

Decaffeination

As in the case of coffee, various processes exist to yield a decaffeinated tea. Nowadays, ethyl acetate or methylene chloride assisted solvent extraction and supercritical fluid extraction are the most used methods for producing decaffeinated tea, as these avoid toxic organic solvents, such as chloroform, ethyl hexanoate, and propyl acetate or organochlorine solvent. Other processes include the separation of caffeine by the use of resin and charcoal. An innovative approach for the degradation of caffeine is by microbial treatment with *Pseudomonas* and *Aspergillus* spp. However, it is important to take into account that these environment-friendly processes are characterized by a high cost. Furthermore, some methods, such as decaffeination processes using hot water or cosolvent-assisted supercritical fluid extraction, lead to the loss of tea catechins. Park and colleagues first elucidated this phenomenon, observing that during the extraction of caffeine using the supercritical CO_2 extraction method, the loss of catechins was high in decaffeinated tea, while the loss was low in semi-decaffeinated tea, with low degree of decaffeination (Park et al. 2007). Therefore, the decaffeination process represents a challenge to the crucial retention of catechins.

Withering

As explained in Sect. 1.4, withering is a process aimed at reducing the moisture in tea leaves, which leads to an increase in the concentration of cell enzymes, resulting in activation of catechol oxidase and phenol oxidase. These enzymes trigger the oxidative reaction responsible for decreasing the amount of catechins, and increasing the concentrations of theaflavins and thearubigins. This is why white, oolong, and black teas, which are subjected to withering processes, are characterized by low catechin levels. Furthermore, withering results in the enhancement of caffeine, amino acids, and sugar content, while the concentration of chlorophyll decreases.

Fermentation

As with withering, the fermentation of tea leaves involves the oxidation process, mostly induced by the activity of endogenous and exogenous enzymes, which in this case also cause the formation of polymeric theaflavins and thearubigins. Oolong tea is a partially fermented tea, which requires the inactivation of enzymes after about an hour of fermentation. Oolong tea contains a mixture of monomeric polyphenols and higher molecular weight theaflavins. Black tea is produced by the extensive oxidation of polyphenols, with the inactivation of enzymes being induced following 3–6 h of fermentation, resulting in the accumulation of a great amount of thearubigins and theaflavins. As green tea is non-fermented, this contains a relatively unmodified quantity of monomeric catechins, with the polyphenols-oxidase enzymes being immediately inactivated after picking by means of dry heat or steam as part of the fixation process.

18.2.2.2 Brewing Methods: Impact on Tea Catechin Profile

Even the infusion methods for tea have a significant impact on the catechin profile, mainly due to differences in stability of pH, temperature, and storage time.

Tea catechins solubilized in water are stable at 37 °C for 7 h, while at 98 °C there is a 20% decrease after the same time. When EGCG is submitted to the temperature of 120 °C for 20 min, the epimerization of EGCG to (−)-gallocatechin gallate (GCG) is observed. EGCG, ECG, EGC, and EC are most stable at pH 4–5 with decreasing stability at lower and higher pH. At higher pH, the epimerization into GCG and CG increases. Thus, the relatively high amount of GCG found in some drinks is most likely due to epimerization of EGCG. A progressive decrease in total levels of catechins was reported during storage of green tea bags at 20 °C for 6 months. This phenomenon is due in part to losses in the most abundant catechins. Indeed, EGCG decreased by 28% and ECG by 51%, probably due to auto-oxidation reactions which increase with pH. So, it is essential to take into account the degradation of tea catechins during production, storage, and transport.

In addition, the number of infusions influences the catechin profile of brewed tea. In a study conducted by Yang and colleagues, the highest catechin extraction yield was obtained from the first or second infusion, depending on the applied temperature (Yang et al. 2007).

Another factor is the water quality, the subject of a recent research article considering the extraction yield of EGCG and EGC. These results indicated that

the choices of reverse osmosis water, packaged drinking water, and ultrapure water are the best, instead of tap water and soft water.

A particularly remarkable phenomenon takes place when tea beverages cool down, known as *creaming*, that consists of the precipitation of an insoluble catechin-caffeine complex, resulting in a decrease in the total catechin content of the beverage. A study from Ishizu and colleagues revealed that the esterified forms of catechins (EGCG and ECG) are more subject to creaming (Ishizu et al. 2016). Colon and Nerin observed that catechins and caffeine are re-solubilized at low pH values (Colon and Nerin 2014).

Moreover, Xu et al. found that the addition of sugars (30 g/mL), such as sucrose and fructose, decreases the creaming phenomenon (Xu et al. 2017).

18.2.3 Catechins Distribution in Tea Products

The content of catechins in a given tea beverage is strictly related to its subtype (green, white, oolong, and black) due to the strong impact of the fermentation process on catechin molecules. Green tea, which is produced without fermentation, has the highest amount of catechins: approximately 130 mg/100 g of green tea brewed (1 g dried tea leaves per 100 mL boiling water), subdivided as reported in Tables 1 and 2, of which the most representative catechin is EGCG (70.2 ± 4.08 mg/100 g) (USDA 2007). The catechin content of the other tea subtypes decreases with the degree of fermentation. So, considering EGCG as the most abundant catechin, an analysis of literature and market data conducted by the US Department of Agriculture (USDA) showed that white tea infusion contains an average of 42.45 ± 15.47 mg/100 g of EGCG, oolong tea infusion contains an average of 34.48 ± 4.76 mg/100 g of EGCG, and black tea infusion contains an average of 9.36 ± 0.46 mg/100 g of EGCG (USDA 2007). As discussed above, the fermentation process increases the aerobic oxidation catalyzed by enzymes, which is then followed by a succession of chemical condensations.

18.3 Bioavailability and Metabolism

Metabolism is the main limiting step in the beneficial activities of phenolic compounds on human health. The bioavailability and metabolism of tea molecules, especially tea catechins, has been studied since the early 2000s. However, human data are still lacking at present.

18.3.1 Absorption

The absorption of tea catechins occurs mainly in the small intestine and also in the colon, thanks to the metabolism of microbiota. The uptake rate is low, corresponding to about 1.68% in humans, a similar value was found in rats, in comparison with about 14% in mice. The low absorption of tea catechins is partially attributed

to their chemical conformation, which presents a large hydration shell, due to the presence of many hydroxyl groups. In vitro studies on $Caco_2$ cell line models suggest that the behavior of tea catechins in the intestinal epithelium is complex. Transepithelial transport is supposed to occur via paracellular diffusion. However, there are growing hypotheses on the presence of other polarized transport mechanisms for the absorption of tea catechins.

18.3.2 Metabolism

The bioavailability of tea catechins is strictly related to their metabolism at intestinal, microbial, and hepatic levels. In the small intestine, catechins are absorbed as glucuronide and sulfate conjugates, and methylated metabolites, to facilitate their transport to the liver. Catechins and their metabolites present in the intestinal lumen reach the large intestine which are intensely metabolized into small phenolic acids and valerolactones through microbiota activity. In particular, the microbial metabolism can be summarized as follows: (1) the C-ring is opened via the cleavage of an ether bond -O- by hydrogenation, and gallated catechins are degallated; (2) lactones are formed with partial dehydroxylation on the B-ring; (3) phenolic acids and some of their conjugate derivatives are formed; and (4) benzoic acids and some of their conjugates are further formed by oxidation and conjugation. The end metabolites include phenolic acids, benzoic acids, and some of their conjugates.

An in vitro study reported that human serum albumin is able to transport EGCG through the circulation system. Furthermore, this blood protein could prevent the oxidation of EGCG in alkaline conditions, stabilizing it in bloodstream. Indeed, the differences in serum albumin levels in humans may be one of the reasons for the interindividual variability in response to administration of catechins (Ishii et al. 2011).

Catechin metabolites are excreted in feces and urine, through the metabolism in the liver and kidneys, which is less intense than gut metabolism. In more detail, the liver cytosolic catechol-O-methyltransferase quickly catalyzes methylation of the catechins, which decreases their hydrophilicity. Subsequently, sulfurylation and glucuronidation occur in the liver and kidneys to allow the elimination of the methylation products. Another factor that can influence the interindividual variability in response to administration of catechins could be the polymorphisms of catechol-O-methyltransferase.

Several in vitro and in vivo *studies* have allowed a hypothesis of the steps involved in catechin metabolism in humans, as presented in Fig. 4.

As anticipated at the beginning of this section, the human studies on catechin bioavailability yield different and controversial results. In particular, the detected urinary excretion values of catechin metabolites range from traces to about 10% of the ingested amount. However, Del Rio et al. observed that by extending focus from catechin conjugates to include the colonic microflora-derived poly-hydroxyphenyl-g-valerolactones, the urinary excretion reaches 39% of the ingested catechin amount (Del Rio et al. 2010).

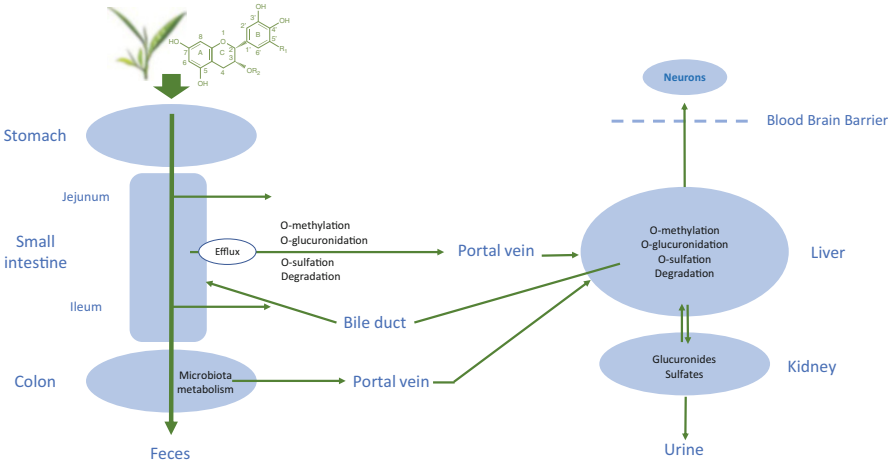

Fig. 4 The proposed metabolism fate of tea catechins in human

18.3.3 Factors Influencing Tea Catechins Bioavailability

Some studies have also assessed the impact of different factors on bioavailability of catechins.

18.3.3.1 Diet

Vitamin C, Omega-3 polyunsaturated fatty acids, and piperine have been found to improve the bioavailability of catechins by preventing their oxidation or glucuronidation. Moreover, clinical studies show that the bioavailability of catechins is enhanced in fasted subjects.

18.3.3.2 Brewing Methods

The use of hard water in tea brewing could affect the bioavailability of catechins due to its higher concentration of metals, especially Ca^{2+} and Mg^{2+} (Ishii et al. 2011).

The results of studies on the bioavailability impact of adding milk in tea beverages, a typical British habit, are unclear. In spite of a relatively recent in vitro study demonstrating that the intestinal absorption of catechins was significantly enhanced in milk added tea, two older human studies showed that adding milk to tea does not increase the bioavailability of tea catechins (Xie et al. 2013).

18.4 Bioactivities

Compounds identified in green tea are involved in several biological activities and can have various health-promoting functions. These include anticancer, antiobesity, and antidiabetic activities, as well as protective effects against cardiovascular disease (CVD) and neurodegenerative disease, and many others (Sanlier

et al. 2018). The therapeutic potential of green tea has been directly linked with its polyphenol content, and particularly for the catechins, which include EGCG as the most abundant, and most investigated, tea catechin (Granja et al. 2017; Pastoriza et al. 2017). There are several mechanisms involved in the protective actions of these phytochemicals. However, as many health disorders are related to oxidative stress and overproduction of inflammatory markers, the protective effects of tea catechins appear to be mainly related to their antioxidant and anti-inflammatory activities.

18.4.1 Neuroprotective Activity

Neurodegenerative diseases are a heterogeneous group of disorders that are characterized by progressive degeneration of the structure and function of the central or peripheral nervous systems (http://www.nature.com/subjects/neurodegenerative-diseases). The progressive degeneration of neurons leads to changes in behavior and cognitive function (e.g., dementia) and to motor dysfunction. Alzheimer's disease constitutes approximately 70% of all dementias, and its incidence increases with age, with a doubling every 5–10 years. Treatments for neurodegenerative diseases represent a great economic burden, and they already contribute US$20 billion to a market that, according to the World Health Organization, is expected to grow and to become the second leading cause of death by 2040, after CVD (Gammon 2014).

Accumulating evidence has implicated oxidative stress in the initiation and progression of such neurodegenerative diseases, and therefore considerable attention is now being paid to the possibility of using nature antioxidants for prevention and treatment. There is an increasing interest in the health properties of tea and a significant rise in scientific studies on the medicinal properties and health benefits of tea (Cooper et al. 2005). Green tea has a better neuroprotective role than other teas from *Camellia sinensis* due to the higher amounts of catechins (phenolic compounds with powerful antioxidant activities) and iron-chelating and anti-inflammatory agents (amazon, Mandel et al. 2012). The mechanisms of action of tea catechins still remain to be fully defined. As well as antioxidant and free radical scavenging effects, their modulation of cell apoptosis and neuroplasticity, attenuation of inflammatory responses, and anti-aggregation effects are likely to have roles here (Sutherland et al. 2016, Ortiz-López et al. 2016).

Some recent studies have shown that catechins from green tea can promote neuroprotection against oxidative and inflammatory stressors in obese rats supplemented with a cafeteria diet (Macedo et al. 2017). The antioxidant properties of green tea are also useful for the protection of memory against deficits due to aging and to brain insults like ischemia reperfusion (Schimidt et al. 2017). Recently, the neuroprotective potential of green tea was also reported in a model of Alzheimer's-like disease (Schimidt et al. 2017).

As well as EGCG, the other major catechins in green tea are: (−)-epicatechin, ECG, and EGC. EGCG is the major catechin isolated from the polyphenolic fraction of green tea, and it can account for 50% to 80% of the catechin content. As well as

its antioxidant properties, many beneficial biological actions of EGCG are known to be mediated through further specific mechanisms, which include its interactions with cell surface membrane proteins and specific receptors and its regulation of signalling pathways and transcription, DNA methylation, mitochondrial function, and cell autophagy (Kim et al. 2014). In vivo studies in mice have demonstrated that EGCG can reduce β-amyloid generation, modulate amyloid precursor cleavage, and reduce cerebral amyloidosis, with inhibition of β-amyloid-induced cognitive dysfunction, through modification of secretase activity (Lee et al. 2009). Aktas and co-workers demonstrated that EGCG mediates T-cell nuclear factor (NF)-κB inhibition and has neuroprotective effects in autoimmune encephalomyelitis, an animal model for multiple sclerosis (Aktas et al. 2004). EGCG can induce down-regulation of the pro-inflammatory cytokine tumor necrosis factor (TNF)-α and can thereby inhibit microglial activation (Anandhan et al. 2013). Islet amyloid polypeptide formation is inhibited by EGCG, and preformed amyloid fibrils are disaggregated (Schrag et al. 1998). Similar to EGCG, catechin has shown neuroprotective properties in neurodegenerative diseases, such as Alzheimer's disease and Parkinson's diseases, via its transitional metal chelating property (iron, copper) and its antioxidant activity (Mandel et al. 2008). Catechin also has anti-inflammatory properties (Hirao et al. 2010). This suggests that catechin might also have a neuroprotective role in brain injuries. In a rat model of middle cerebral artery occlusion, pretreatment with catechin hydrate resulted in neuroprotective effects through NF-κB-mediated downregulation of inflammatory responses (Ashafaq et al. 2012).

18.4.2 Anticancer Activity

In carcinogenesis, critical roles are played by increased levels of reactive oxygen species (ROS), and modulation of oxidative stress (i.e., an imbalance between increased ROS and cell antioxidants) might be the key mechanism through which phytochemicals act in tumorigenesis and cancer chemoprevention (Chikara et al. 2018). ROS include superoxide anion radicals, hydrogen peroxide (H_2O_2), and hydroxyl radicals, and these are generated not only during mitochondrial oxidative phosphorylation but also during inflammation, infection, mechanical and chemical stress, and exposure to ultraviolet and ionizing radiation. Oxidative stress in the first phase of cancer development (i.e., initiation) can lead to mutations in oncogenes and tumor-suppressor genes that are often related to the formation of oxidative stress-associated DNA adducts. In the promotion stage of cancers, oxidation of cysteine and methionine residues result in changes in protein structures and enzymatic activities, which results in dysregulation of signalling pathways and expansion of transformed cells. Furthermore, increased levels of lipid peroxidation products (e.g., 4-hydroxynonenal) that can interact with and modify proteins and DNA have also been shown to be associated with carcinoma progression.

The therapeutic properties of catechins in the prevention and treatment of cancers are mainly attributed to their free-radical scavenging properties and their metal ion

chelation (especially of iron). Several studies have demonstrated the antioxidant capacity of EGCG and shown that EGCG has stronger antiradical activity compared to other green tea catechins and to vitamin E and vitamin C (Granja et al. 2017). However, beyond simple antiradical actions, additional mechanisms appear to be involved in the protective effects of these phytochemicals (Bernatoniene and Kopustinskiene 2018). Green tea catechins can modulate the cellular ROS levels through inhibition of pro-oxidant enzymes, such as cyclooxygenase, inducible nitric oxide synthase, lipoxygenase, and xanthine oxidase, and by induction of the expression of superoxide dismutase, catalase, and glutathione peroxidase, the major enzymes that protect the cell against oxidative damage.

The molecular mechanisms responsible for this induction of antioxidant enzymes by EGCG have been extensively investigated. Catechins, and particularly EGCG, can bind to various molecules and modulate their activities, and thus modulate cell-signalling pathways (Rahmani et al. 2015). It has been shown that EGCG can activate nuclear factor erythroid 2-related factor (Nrf2), which is considered to be an important target for cancer prevention. In this way EGCG can induce expression of antioxidant enzymes. Further, EGCG appears to be involved in phosphorylation of the serine and threonine residues of Nrf2 that are responsible for Nrf2 activation. The effects of tea catechins on lipid peroxidation in liver carcinoma cells were studied. It was reported that EGCG suppressed H_2O_2-mediated cytotoxicity by increasing the levels of cellular glutathione (Chikara et al. 2018). As estrogen is believed to be responsible for breast cancer development, the anti-breast cancer efficacy of tea polyphenols has been ascribed in part to inhibitory activities on the enzymes involved in estrogen biosynthesis (Capellino et al. 2014).

Some studies have also reported that EGCG has protective effects against cancer cells through induction of their cell cycle arrest and apoptosis. Indeed, EGCG has been shown to induce p53-dependent apoptosis in a human lung carcinoma cell line (Yamauchi et al. 2009). Yamauchi et al. (2009) examined cell growth/proliferation and apoptosis with the addition of catechin, epicatechin, ECG, EGC, and EGCG to A549 cells. They showed that at 48 h after treatment, catechin and epicatechin had no suppressive effects on cell viability at up to 100 μmol/L, while ECG had some effect, and EGC and EGCG significantly suppressed cell viability. When a mixture of these compounds was applied, cell viability was decreased even at 10 μmol/L. Also, they evaluated caspase 3/7 activity, which is an indicator of cell apoptosis, and they reported that only EGCG at 100 μmol/L significantly induced caspase 3/7 activity in these A549 cells.

Santos et al. (2018) optimized the formulation of white tea, fermented rooibos, and roasted mate. The antiproliferative activities were evaluated in human hepatoma carcinoma (HepG2) cells and human colorectal adenocarcinoma epithelial (Caco-2) cells. The optimized tea formulation that contained various catechins demonstrated antioxidant effects through its inhibition of ROS generation in the HepG2 cells. In cell viability tests of these tea extracts in this in vitro study, some cytotoxicity against both of these cell lines was seen. The concentration needed to kill 50% of the cells was 500 μg/mL and was similar for both of these cell types.

In another study carried out on the A549 human lung carcinoma cell line, where these cells were treated with EGCG at 10 μmol/L to 100 μmol/L, reduced formation of capillary tube-like structures was observed (Li et al. 2013). They also reported downregulation of expression of some signalling molecules in the presence of EGCG, including hypoxia-inducible factor (HIF)-1α and vascular endothelial growth factor (VEGF). This confirmed the inhibitory effects of EGCG on tumor angiogenesis: the growth of new blood vessels that are needed to ensure nutrient and oxygen supplies to tumor cells.

The efficiency of EGCG for inhibition of metastasis formation has also been investigated. As reported by Takahashi et al. (2014) for human lung cancer cell lines, EGCG inhibited phenotypes of epithelial-mesenchymal transition (EMT) in a dose-dependent manner. Cell invasiveness and the metastatic activity of cancer cells are strongly related to EMT, and EMT activation can be stimulated by a number of biological factors, such as TNF-α and tumor growth factor-β, as well as by mechanical stimuli. They also showed that EGCG can cause alterations to cell membrane organization, which result in inhibition of cell motility and increased cell stiffness.

The chemopreventive potential of green tea catechins has been investigated in several in vivo studies. The prevention of DNA oxidative damage in lymphocytes, colonocytes, and hepatocytes has been reported, where rats were fed a green tea extract for 5 days at the equivalent human dose of 500 mL/day, with no effects seen with the lower dose of 100 mL/day (Kager et al. 2010). The therapeutic activity of EGCG for inhibition of growth and metastases of colon tumors in mice has also been studied. Protective effects of EGCG on preneoplastic lesions in the mouse colon were explained to be due in part to upregulation of the Nrf2-uridine 5′-diphosphate-glucuronosyltransferase 1A (UGT1A) signalling pathway (Yuan et al. 2008). Zhu et al. (2014) demonstrated that skin treatment with EGCG can reduced ROS in skin cells via upregulation of superoxide dismutase 2 and heme oxygenase, which thereby protected the mitochondrial DNA from damage caused by ionizing radiation.

18.4.3 Activity Against Cardiovascular Diseases

Tea consumption has been suggested to be associated with a variety of physiological functions that might be responsible for protection against CVD. CVD is characterized by the development of atherosclerosis, which is an inflammatory condition that is associated with increased levels of ROS and with vascular endothelial dysfunction, accumulation of fatty deposits, oxidation of plasma low-density lipoprotein (LDL), atherosclerotic plaque formation and rupture, platelet aggregation, and obstructions to the arterial blood flow (Santhakumar et al. 2018).

Initially, the reduction of CVD risk by green tea consumption was attributed mainly to the antioxidant and anti-inflammatory properties of the tea catechins. However, recent evidence suggests that the protective role of tea catechins against

CVD appears to be due to their regulation of lipid metabolism, improvements to vascular endothelial dysfunction, effects on cell proliferation, modulation of platelet aggregation, and antithrombotic activity. Animal studies have shown that tea catechins can reduce blood levels of total cholesterol, LDL, and triglyceride and can slow the development and progression of atherosclerosis (Santhakumar et al. 2018).

The modulation by the tea catechins of endothelial cell activation, which contributes to alterations to endothelial function, was evaluated in vitro by Carnevale et al. (2014). In their study, treatment with catechin and EC was accompanied by reduced markers of endothelial cell activation, which was induced by activated platelets from patients with peripheral artery disease. Furthermore, in another study, it was shown that treatment of a human retinal pigment epithelial cell line with EGCG suppressed inflammatory effects induced by TNF-α, including induction of ROS, upregulation of intercellular adhesion molecule (ICAM-1) expression, and increased monocyte adhesion to retinal pigment epithelial cells. These data indicated that this TNF-α inhibition was mediated via the NF-κB pathway (Thichanpiang and Wongprasert 2015). In another in vitro study on human neutrophils, a catechins mixture (including EC, ECG, EGC, EGCG) suppressed the release of pro-inflammatory cytokines, and also the expression of NF-κB and myeloperoxidase activity, and the production of HOCl (Marinovic et al. 2015). Decreased ROS levels were ascribed to increases in antioxidant enzyme activities, which they attributed to induction by these catechins. They also reported increases in phagocytic activity of the neutrophils.

Gallate is a pyrogallol moiety that can act as a strong antioxidant. It is esterified at position 3′ on the C-ring of EGCG, GCG, and ECG, and it enhances the antiplatelet and antithrombotic activities of these phytochemicals, compared to their counterparts, EGC, GC, EC, respectively, and to catechin. This confirmed that their antioxidant activities might be involved here, although not as a determining factor. However, the antiplatelet and antithrombotic activities of these catechins can be attributed to their modulation of various cellular targets. ECCG can suppress collagen-induced platelet aggregation by inhibition of arachidonic acid liberation from membrane phospholipids (Jin et al. 2008).

Epigallocatechin-3-gallate has been shown to reduce myocardial damage induced by cigarette smoke in rats (Gokulakrisnan et al. 2011). The protective role of this in vivo EGCG treatment was confirmed by decreased pro-inflammatory markers, which have a key role in atherosclerosis, such as NF-κB, TNF-α, cyclooxygenase-2, and inducible nitric oxide synthase in the cardiac tissue of the rats. Furthermore, the EGCG treatments resulted in fewer lipidemic pathologies (i.e., high cholesterol, fatty acids, triacylglycerols) and decreased lipid-metabolizing enzyme activities in the serum and cardiac tissue (Gokulakrisnan et al. 2011). In a study in mice, EGCG administration (40 mg/kg/day for 18 days) significantly reduced the size of atherosclerotic plaques in the aortas, and increased high-density lipoprotein (HDL), decreased LDL, and had little effect on triglycerides in plasma. Also, EGCG significantly inhibited hepatic lipid accumulation and suppressed inflammatory processes, whereby across six cytokines examined, the levels of TNF-α and

interleukin (IL)-6 were reduced, while those of IL-10 were increased (Wang et al. 2018a). As they surmised, the increased IL-10 might promote anti-inflammatory conditions and thus protect against the development of atherosclerosis. In the same study, it was suggested that EGCG eventually activated gene expression to promote hypolipidemic effects.

18.4.4 Antidiabetic Activity

It has been demonstrated that in diabetes prevention and treatment, tea catechins can be beneficial through a number of actions, including regulation of insulin secretion of pancreatic β-cells, control of blood glucose levels, inhibition of insulin resistance, and control of inflammation markers (i.e., expression of pro-inflammatory cytokines) and oxidative status (Granja et al. 2017). The protective actions of these phytochemicals in diabetes are regulated through various mechanisms. Studies on pancreatic β-cell lines showed that EGCG improves glucose-stimulated insulin secretion through stimulation of insulin receptor substrate-2 signalling. It has also been suggested that EGCG administration can significantly reduce glucose levels by decreasing the formation of "advanced glycation end products" (AGEs), whereby AGEs formation is suppressed via the regulation of Nrf2 function (Sampath et al. 2017). Therapeutic properties have also been ascribed to the inhibitory activities of the tea catechins on α-amylase and α-glucosidase. An in vitro study showed that tea catechins and EGCG alone more strongly inhibited α-glucosidase than α-amylase. Based on half maximal inhibitory concentration, tea catechins showed up to 1000-fold the efficacy of the antidiabetic drug acarbose (Gao et al. 2013). In an in vivo study of sucrose loading in rats, Satoh et al. (2015) demonstrated that an aqueous extract of tea leaves resulted in dose-dependent lowering of plasma glucose, with no effects on insulin levels. In the same study, they showed inhibition of α-glucosidase and α-amylase by this treatment.

An investigation carried out by Alves et al. (2015) showed that in prediabetic rats, 2 months consumption of white tea improved their overall metabolic status. Here, as well as higher insulin sensitivity and lower glucose intolerance, they also showed improved protein oxidation status for these rats. A similar in vivo study where diabetic mice were fed with a green tea extract that contained high levels of EGCG (>94% EGCG; <5% other catechins) confirmed these pronounced anti-diabetic effects of these phytochemicals (Ortsäter et al. 2012). Their data also indicated that EGCG exerts its antidiabetic activity through reduction of insulin resistance and preservation of pancreatic β-cells. EGCG treatment resulted in fewer islets of Langerhans that showed pathological changes. There was also a reduction in the levels of the oxidative stress markers, and this was linked to the antioxidant effects of EGCG. Thus, they suggested that EGCG is a potential therapeutic agent for prevention and treatment of diabetes mellitus. In addition, Ahmad et al. (2015) reported that in rats the interventions with catechins and EGCG resulted in significantly lower serum glucose and lipid levels (i.e., cholesterol, LDL) than those that received a high cholesterol and sucrose diet. Here, EGCG was more effective

against hyperglycemia than the other catechins, which reduced hypercholesterolemia more effectively.

Epigallocatechin-3-gallate has been shown to provide this beneficial modulation of glucose and lipid metabolism through downregulation of genes involved in gluconeogenesis and synthesis of fatty acids, triacylglycerol, and cholesterol. Studies provided evidence that green tea catechins change the redox state of the cells and affect the activity of several kinases involved in gluconeogenesis (Granja et al. 2017). An in vitro study by Yasui et al. (2010) provided evidence that in H4IIE rat hepatoma cells, green tea catechins can decrease gene expression of the glucose-6-phosphatase and phosphoenolpyruvate carboxykinase.

Chronically elevated levels of free fatty acids in plasma may also have a profound role in insulin resistance. Indeed, treatment with EGCG and ECG in a mouse skeletal muscle cell model improved free fatty acid-induced insulin resistance through suppression of phosphorylation of serine 307 in insulin receptor substrate-1, with regulation of the protein kinase activation pathway in dose- and time-dependent manners (Deng et al. 2012).

18.4.5 Anti-obesity Activity

Investigations have demonstrated that tea catechins have potent efficiency in obesity treatments, via a direct impact on adipose tissue, and that they can promote decreased adipocyte differentiation. It has been shown that these phytochemicals have suppressive effects on the enzymes involved in the synthesis of fatty acids, triacylglycerols, and cholesterol, and on the other hand, tea catechins have been shown to stimulate the enzymes involved in fatty acid mobilization (Suzuki et al. 2016).

In rats induced to obesity, Rocha et al. (2016) demonstrated that daily consumption of green tea extract (500 mg/kg body weight) significantly inhibited the gain in body weight (by 24% versus control), decreased adipose tissue (i.e., subcutaneous, retroperitoneal fat) and adiposity index, reduced hypertrophy of adipocytes, and decreased triacylglycerols and cholesterol contents in blood and liver tissue. Increased levels of adiponectin in the plasma after consumption of green tea extract suggest that green tea catechins can also promote secretion of this adipokine by adipocytes. It has also been reported that treatment with green tea catechins decreases plasma levels of the inflammatory cytokines, such as IL-6 and TNF-α (Rocha et al. 2016). However, in the course of this green tea treatment, the biochemical parameters of uric acid and creatinine did not differ significantly among the treatment groups (obese rats, without and with green tea consumption), which suggested that this green tea consumption did not cause any kidney or liver damage. In the same study with obese rats, green tea modulated gene expression of key proteins involved in lipid metabolism in their adipose tissue. This was seen as a significant decrease in adipocyte differentiation and downregulation of mRNA expression of several lipogenic enzymes: fatty acid synthase, pyruvate dehydrogenase, stearoyl-CoA desaturase 1, and diacylglycerol acyltransferase. On the other

hand, mRNA expression levels of the main lipolytic enzymes (i.e., hormone-sensitive lipase, adipocyte triacylglycerol lipase, lipoprotein lipase) and the protein perilipin were significantly increased (Rocha et al. 2016). According to the so-called AMP-activated protein kinase (AMPK) hypothesis, it has been postulated that the effects of green tea catechins on genes are mediated through AMPK, which is an enzyme that has a key role in downregulation and upregulation of the expression of various genes (Yang et al. 2016). Catechins are known to activate AMPK, which can result in inhibition of the expression of the lipogenic enzymes, and suppressed differentiation of adipocytes.

Other studies have suggested that green tea catechins can interfere with the emulsification of lipids, which leads to suppressed fat digestion. This might thus be an additional way in which these phytochemicals influence obesity. It has been proposed that this interference is due to increased particle size and decreasing surface area of the emulsified lipids and that these changes will influence lipase activity and slow down lipid hydrolysis. A study performed with green, white, and black tea infusions showed that white tea was more effective in inhibition of pancreatic lipase activity in vitro than green tea, with half-maximal concentrations for inhibition of 22 μg gallic acid equivalents (GAE)/mL and 35 μg GAE/mL, respectively. Here, black tea was inactive even at 200 μg GAE/mL (Gondoin et al. 2010). The inhibitory effects of these catechins were ascribed to the formation of a complex with the lipase, which modifies its conformation and leads to decreased catalytic activity.

Green tea catechins can also stimulate thermogenesis through inhibition of the enzymes that metabolize noradrenaline. This has been suggested as an additional mechanism by which catechins regulate the balance between lipid anabolism and catabolism and increase energy expenditure. In addition, tea catechins have been shown to inhibit starch digestion by inhibition of α-amylase. In vitro inhibitory activities against pancreatic α-amylase of EGCG and oolong tea were indeed confirmed, with half-maximal inhibitory concentrations of 0.350 mg/mL and 0.375 mg/mL, respectively (Fei et al. 2014).

18.4.6 Other Activities

Other health-promoting effects of tea catechins have also been described, such as anti-inflammatory, antiviral, antibacterial, antifungal, anti-osteoporosis, anti-allergenic, anti-estrogenic, and photoprotective activities. As reviewed by Siddiqui et al. (2016), tea can inhibit growth and multiplication activity of different bacteria, such as *Bacillus cereus*, *Campylobacter jejuni*, *Clostridium perfringens*, *Escherichia coli*, *Salmonella typhi*, *Staphylococcus aureus*, *Listeria monocytogenes*, and *Helicobacter pylori*. Activities against human pathogenic yeast, such as *Candida albicans*, have also been reported, with these effects not being lethal against intestinal microbiota. Furthermore, beneficial effects for *Bifidobacterium* spp. have also been reported for tea.

Several mechanisms have been proposed for the actions of tea catechins against viruses: antioxidant activity, enzyme inactivation, cell membrane disruption, prevention of viral attachment and penetration into cells, and induction of the self-defense mechanisms of the target cells. The efficiency of the antiviral activity against influenza virus infection in chicken was confirmed (Lee et al. 2012), and EGCG was shown to inhibit in vitro entry of Zika virus into host cells (Sharma et al. 2017). Furthermore, EGCG is involved in dose-dependent mechanisms that inhibit HIV-1 infectivity of human T cells and macrophages, whereby at physiological concentrations of EGCG (<10 μmol/L) it significantly inhibited HIV-1 p24 antigen production (Nance et al. 2009). For this inhibition of HIV, the green tea catechin appears to act by adhering to the target cells, which prevents the virus from anchoring and entering the host. As EGC, ECG, and catechin were ineffective here, this indicated that both the pyrogallol and galloyl groups are required for this activity. Furthermore, evaluation of cytotoxicity in HIV-1-infected cell cultures demonstrated that at physiological concentrations, EGCG did not significantly inhibit cell viability, proliferation, and apoptosis. Inhibitory activities of EGCG against other viruses have also been confirmed, such as against hepatitis C virus, adenovirus, and Herpes simplex virus (Pastoriza et al. 2017).

Tea catechins can protect bone health and modulate the regulation of bone formation and loss. Studies carried out on cell lines and in animal models have shown positive effects of tea catechins on osteoporosis. As reviewed by Đudarić et al. (2015), EGCG can influence the signalling pathways involved in osteoblastogenesis and osteoclastogenesis, which in rodents results in increased bone mineralization, inhibition of osteoclast differentiation, and decreased formation of calcium stone deposits. This protective role of tea catechins in bone health has again been ascribed to their antioxidant properties and their reduction of the production of inflammatory mediators.

Wang et al. (2018b) showed recently that when rats with diabetic retinopathy were treated with catechins by intravitreal injection (50–200 mg/kg/day) for 8 weeks, there was inhibition of activation of NF-κB and decreased production of inflammatory factors (i.e., IL-1, IL-6, TNF-α), which weakened the pathological changes in the retinal tissues. Furthermore, as reviewed by Rahman et al. (2018), green tea polyphenols also have significant roles in the treatment of inflammatory bowel disease, through their regulation of Toll-like receptor 4, which blocks NF-κB activation, and thus inhibits TNF-α production.

18.5 Benefits

Many clinical studies have been carried out to examine the health-promoting functions of green tea catechins. A large number of studies have shown that green tea consumption is associated with health benefits, with confirmation of the protective role and therapeutic potential of tea catechins in the treatment of several diseases.

18.5.1 Neurodegenerative Diseases

Due to their antioxidant activities and anti-amyloidogenic properties, green tea catechins are being investigated as dietary phytochemicals for their beneficial effects in neurodegenerative diseases (Rigacci and Stefani 2015). We previously evaluated the brain accessibility of EGCG in relation to its potential neuroprotective effects (Pogačnik et al. 2016). Primary cortical neuron cultures were exposed to oxidative insult in the absence and presence of the catechins, and neuroprotection was assessed through evaluation of apoptotic-like and necrotic-like cell death. EGCG rapidly crossed the blood-brain barrier model, and in doing so, it protected against oxidation-induced neuronal necrotic-like cell death by ~40% and in apoptosis by ~30%. Also, EGCG effectively inhibited α-synuclein fibrillation over the relevant timescale. Based on the effects of the catechins studied, we concluded that EGCG is the most promising neuroprotective compound (Pogačnik et al. 2016).

18.5.2 Cancers

It has been suggested that a diet rich in tea catechins is inversely associated with incidence of a variety of cancers (Chikara et al. 2018). Diet enriched with green tea led to significant reduction in urinary 8-hydroxy-2′-deoxygunosine, which is an oxidative stress-related DNA adduct that has been associated with precancerous and cancerous tissues. Consumption of green tea catechins (1.3 g/day for 6 weeks) in a phase II clinical trial with men suffering from prostate cancer resulted in reduced serum levels of hepatocyte growth factor (HGF, a prostate-specific antigen) and VEGF (an angiogenic stimulus for tumors) (McLarty et al. 2009).

Beneficial effects of green tea on ovarian cancer were ascribed to induction of apoptosis and to suppression of expression of proteins involved in inflammation, cell motility, and angiogenesis. Studies have shown that in premenopausal and postmenopausal women, green tea consumption can decrease serum estrogen levels (as a risk factor for ovarian cancer) potentially through modification of estrogen metabolism or conjugation (Fuhrman et al. 2013). Black tea consumption has been shown to both increase and decrease (Sanlier et al. 2018) ovarian cancer risk.

Zhang et al. (2012) tested the activity of EGCG supplementation on parameters related to cell proliferation, invasion, and angiogenesis in patients with breast cancer undergoing radiotherapy treatment. In comparison to those receiving radiotherapy alone, the serum levels of VEGF and HGF were significantly lower with radiotherapy plus EGCG (400 mg, for 2–8 weeks). Then in the same study, in vitro treatment of cancer cell lines with EGCG resulted in cell cycle arrest, suppression of cell proliferation and invasion, reduction of activation of metalloproteinase-9 and metalloproteinase-2, and reduction of NF-κB.

As reviewed by Sanlier et al. (2018), some studies have reported no correlations between green tea consumption and cancer risk, while others have reported significant positive correlations, or that green tea consumption significantly effects its protective actions. According to a recent systematic review of 11 cohort studies, 9

case-control studies, and 1 clinical trial, it cannot be concluded that green tea intake can reduce incidence of breast cancer (Najafi et al. 2018). Guo and co-workers (2017) carried out a dose-response meta-analysis and concluded that high doses of tea consumption (7 cups/day) reduced the risk of prostate cancer. Then an inverse association between tea consumption and skin cancer risk was reported in a case-control study carried out by Rees et al. (2007), while Asgari et al. (2011) reported that there was no such association. In a further dose-response analysis, here of observational studies, it was suggested that green tea consumption decreased the risk of lung cancer, while black tea consumption did not have any effects (Wang et al. 2012).

A large prospective cohort study was performed over 15 years in China on 165,000 adult male participants aged >40 years and free of pre-existing diseases (Liu et al. 2016). This showed that regular green tea consumption was associated with reduced risk of all-cause mortality, and of CVD-specific and cancer-specific mortality, compared to those who did not drink green tea. For non-smokers, non-regular alcohol drinkers, and rural residents, this inverse association for green tea consumption was further strengthened. Indeed, these data for all-cause and CVD mortality are in line with most previous studies. However, the observations for cancer mortality are not consistent. The results from a meta-analysis of 11 prospective cohort studies that focused on cancer mortality indicated that green tea consumption was not associated with cancer mortality, while black tea consumption was shown to be inversely associated with all-cancer mortality (Tang et al. 2015). Finally here, other studies have reported no associations between green tea consumption and cancer mortality (Kuriyama 2008).

18.5.3 Cardiovascular Diseases

High incidence of CVD has an enormous socioeconomic impact and is associated with incorrect diet and lifestyle. Several epidemiological studies have investigated the relationships between tea consumption and the development of CVD. Generally, it has been indicated that tea catechins are protective against CVD through actions on a number of different systems, including regulation of intestinal absorption and serum levels of cholesterol; activation of antioxidant and inhibition of pro-oxidant enzymes; improvements to vascular endothelial function; suppression of platelet adhesion; reduction of the risk of inflammation and oxidative damage; antithrombotic activity; regulation of the blood lipid profile; and lowering of blood pressure (Sanlier et al. 2018). Indeed, Jowko with co-workers (2015) showed that supplementation with a green tea extract (980 mg polyphenols daily for 4 weeks) protected against exercise-induced oxidative stress. In their randomized, double-blind, placebo-controlled study, there were higher total polyphenols and total antioxidant capacity in the blood plasma of male sprinters before a sprint, with lower plasma values of the oxidation product malondialdehyde after the sprint. At the same time, there were no effects on the muscle damage marker creatine kinase compared to placebo (i.e., no green tea consumption). Furthermore, a double-

blind clinical study on 60 mildly hypercholesterolemic subjects showed that drinking catechin-enriched green tea (as 781 mg catechin daily) or oolong tea (640 mg catechin daily) for 12 weeks provided hepato-protection (Venkatakrishnan et al. 2018). Here, significance was seen for increased expression of antioxidant enzymes (e.g., superoxide dismutase, catalase, glutathione reductase, glutathione peroxidase), as well as decreased body weight and plasma lipid profile.

A population-based prospective cohort study on 40,530 people showed that green tea consumption was inversely associated with all-cause mortality, with a stronger inverse association with CVD mortality, and stroke mortality in particular (Kuriyama 2008). These inverse associations were more pronounced in women. Consumption of 500 mL green tea per day compared to 100 mL/day reduced the risk of CVD death by 31%. This was particularly seen for cerebral infarction, whereby the women who consumed 500 mL green tea per day had 62% lower risk from cerebral infarction compared to those consuming 100 mL/day. Also, a meta-analysis of prospective observational studies defined protective effects against CVD for increased green tea consumption (Pang et al. 2016).

In contrast, several studies have failed to show favorable effects of green tea consumption against CVD. In an earlier Japanese study, there was no association seen between tea consumption and CVD in men, while in women, there was an almost 40% lower risk (Mineharu et al. 2011). Ikeda and co-workers carried out a prospective cohort study that included almost 30,000 men and women aged 40–69 years and evaluated the association between plasma levels of the tea catechins (i.e., epicatechin, ECG, EGC, EGCG, total) and incidence of stroke or coronary heart disease (Ikeda et al. 2018). They found no significant associations. However, when the analysis was stratified by smoking status, positive correlation was found between plasma levels of EGCG and reduced risk of stroke for the group of male non-smokers.

18.5.4 Diabetes

Green tea has been recognized as a potential nutritional strategy associated with positive effects for prevention and control of diabetes mellitus. It has been shown that catechins can control hyperglycemia and reduce complications associated with type 2 diabetes mellitus (Alipour et al. 2018). Indeed, a double-blind controlled study on 52 patients with type 2 diabetes showed that 12 weeks of 583 mg green tea catechins per day significantly increased insulin levels, whereas no significant difference was seen for glucose levels and glycated hemoglobin (Nagao et al. 2009). Furthermore, meta-analysis of 22 randomized controlled trials that included 1,584 subjects revealed that consumption of green tea catechins decreased fasting blood glucose (Zheng et al. 2013). The results of subgroup analyses here suggested that the beneficial effects were more pronounced when the green tea catechins consumption was longer than 12 weeks. However, as was indicated, the limited data available did not support a positive effect on fasting blood insulin and glycated hemoglobin levels. Another meta-analysis confirmed that daily consumption of tea

(>3 cups) reduced the risk of type 2 diabetes (Yang et al. 2014). Here, they also noted differences between different regions around the world and differences with regard to sex. Significant association between tea consumption and diabetes risk was shown for an Asian population, but not for the European and American populations. This was explained on the basis that green tea is mainly consumed in Asia, while black tea is preferred in European countries and the USA.

In a randomized controlled crossover trial of overweight male subjects, no effects were seen on serum glucose, insulin, cholesterol, and triacylglycerol levels after 6-week administration of 400 mg (twice daily) decaffeinated green tea, despite significantly increased levels of serum EGCG and urinary EGC and its metabolites (Brown et al. 2011). Another randomized, placebo-controlled crossover study showed that a green tea extract (EGCG, 257.6 mg) ingested with a test meal limited digestion and absorption of starch in humans without causing any side effects, as estimated by $13CO_2$ excretion in the breath (Lochocka et al. 2015). This finding demonstrated that tea catechins can act as inhibitors of glucoside hydrolase enzymes, and it suggested their use as viable alternatives to pharmaceuticals for weight control and treatment of type 2 diabetes mellitus.

18.5.5 Obesity

As reviewed by Sanlier et al. (2018), there have been several epidemiological studies that have confirmed that green tea consumption interferes with dietary lipid absorption and digestion, and thus lowers lipid levels in the blood and lipid accumulation in the tissues. It has been shown that green tea catechins have inhibitory effects on expression of genes for proteins involved in adipogenesis and lipogenesis, and these effects of tea on fat metabolism can be highly relevant for weight management protocols. Indeed, different studies have shown beneficial effects of exercise-induced anti-obesity treatments (e.g., abdominal fat loss, decreased plasma lipid levels, increased lean body mass, and muscle strength) that are enhanced when combined with green tea consumption (Suzuki et al. 2016). An epidemiological study conducted on 6,472 women and men in the United States reported that black, oolong, and green tea consumption was inversely associated with body mass index and other markers of metabolic syndrome (Vernarelli and Lambert 2011). In this study, inflammatory markers (e.g., serum levels of C-reactive protein) were lower in tea consumers of both sexes, with higher HDL-cholesterol for the male tea consumers, and for both the female and male tea consumers, there was no association with tea consumption for LDL-cholesterol and total cholesterol.

Many randomized, placebo-controlled clinical studies conducted on obese subjects with metabolic syndrome showed significant reduction of abdominal fat, waist circumference, body weight, body mass index, LDL-cholesterol, LDL-cholesterol/HDL-cholesterol ratio, and oxidative stress markers (i.e., malondialdehyde, hydroxynonenal, myeloperoxidase, oxidized LDL) in the subjects who consume daily green tea catechins, compared to the controls (Suzuki et al. 2016). In a randomized, double-blind, placebo-controlled clinical study, 115 women received

high-dose green tea extract for 12 weeks. The results here showed significant weight loss and decreased waist circumference and serum levels of total cholesterol and LDL-cholesterol (Chen et al. 2016). Another clinical trial showed that 12 weeks consumption of a catechins-rich beverage (583 mg green tea catechins per day) for patients with type 2 diabetes resulted in decreased waist circumference and increased adiponectin levels, which is negatively related to visceral adiposity (Nagao et al. 2009). The therapeutic effects of drinking black tea in terms of inhibition of fat absorption were examined in a randomized, placebo-controlled, double-blind cross-over study, where 10-day consumption of 55 mg black tea polyphenols three times per day resulted in increased fecal lipid excretion (Ashigai et al. 2016). As examined recently in a pooled analysis of six human trials, continual consumption of green tea (as a beverage with 540–588 mg catechins) significantly reduced abdominal fat (total, visceral, subcutaneous fat) and improved blood pressure, body weight, body mass index, and waist circumference (Hibi et al. 2018). These observations suggested a protective role of the tea catechins in the development of diseases associated with metabolic syndrome disorders.

However, there have also been indications that have not supported anti-obesity effects of these tea catechins. For example, a cross-sectional survey of 554 participants in Japan did not find any correlation between tea consumption (even for those drinking >4 cups/day) and metabolic syndrome disorders (e.g., increased weight and waist circumference, hypertension, elevated serum triglycerides) (Takami et al. 2013). They proposed some possible explanations for this lack of correlation, such as small variations in the green tea consumption among these individuals, different dietary habits, presence of chronic diseases, lack of information on added sugar, milk, or cream, and the relatively small number of participants. Also, a randomized, double-blind, placebo-controlled trial conducted over 12 weeks on 83 obese premenopausal women who received 300 mg EGCG/day showed no significant effects on body weight, adiposity, energy expenditure, blood lipid levels, and C-reactive protein (Mielgo-Ayuso et al. 2014). However, the EGCG intake had no adverse effects on liver function markers. A similar trial of 937 healthy or obese postmenopausal women who consumed a green tea extract (843 mg EGCG/day) also did not show any changes in body weight, body mass index, or waist circumference after 12 months, and with no changes seen for serum levels of leptin, ghrelin, or adiponectin (Dostal et al. 2016). Finally here, as shown in a randomized clinical trial that included 63 patients with type 2 diabetes, drinking four cups of green tea/day resulted in significant decrease in body weight and systolic blood pressure but no significant changes in blood lipid profile and oxidative stress parameters (i.e., malondialdehyde level) (Mousavi et al. 2013).

18.5.6 Osteoporosis

Several studies on bone health in postmenopausal women showed that green tea consumption increased bone formation, decreased deterioration of bone microstructure, and improved bone strength and quality (Pastoriza et al. 2017). A

systematic review of 11 cross-sectional studies, 4 case-control studies, and 2 prospective cohort studies suggested that tea consumption can reduce the risk of osteoporosis (Sun et al. 2017). In another meta-analysis that included eight cross-sectional studies, four cohort studies, and one case-control study, tea consumption was shown to be beneficial for bone mineral density and to prevent bone loss (Zhang et al. 2017).

18.6 Applications in Food

At present, the importance of food naturalness continues to grow with consumers. For most consumers in developed countries, it is very important that food products be natural. A 2017 review, aiming to draw up the concept of "natural food" held by consumers, shows the importance of freedom from synthetic additives, preservatives, or other artificial ingredients for the perceived naturalness of foods. These consumer expectations represent a big challenge for the food industry and are currently at the forefront of the search for natural-based substitutes for food additives of synthetic origin.

In the last few years, the isolation of catechins from tea has allowed the use of these compounds in food technology, as antioxidants, preservatives, coloring, or flavoring agents. Furthermore, isolated catechins are employed as bioactive ingredients in food supplements, pharmaceutical, and cosmetic products.

The employment of tea catechins in food technology is based on their physical and chemical properties, among which the most important are:

(a) Ability to form precipitates.
As shown in Sect. 2, catechins have the ability to form precipitates, interacting with proteins, but also caffeine. This phenomenon is called *creaming*. The inhibition of the activity of some enzymes, such as lipase, lipoxygenase, amylase, pepsin, and trypsin, attributed to catechins, derives from their ability to form precipitates with protein, as the precipitating enzymes are inactivated. EGCG and ECG contain ester bonds, so have shown a greater ability to form precipitates than other catechins. The precipitation of catechins is also used in the catechin isolation process, which is explained in more detail in the following section.

(b) Scavenger ability.
The antioxidant ability of catechins is well-known. This property is due to the presence of hydroxyl groups in the catechin structure, which can scavenge reactive oxygen species (ROS). Moreover, catechins can trap peroxyl radicals, suppressing free radical chain reactions and terminating the lipid peroxidation process. EGCG and ECG are shown to be the most effective catechins in preventing lipid peroxidation, followed by EGC and EC. Food technologists take advantage of these catechin properties, especially in foods with high fat content or oils.

On the other hand, some precautions must be taken in employing tea catechins in food technology, on the basis of other physical and chemical properties such as:

(c) Temperature and pH sensibility.
As explained above, catechins are unstable at high temperature and pH values. Briefly, when the temperature exceeds 95 °C, EGCG, EGC, ECG, and, EC epimerize into their respective nonepistructured forms (GCG, GC, CG, C). Moreover, catechins are stable in acidic conditions (pH < 4), but when pH values rise above 4, the stability of catechins decreases, and when exceeding a pH value of 8, catechins become extremely unstable.

(d) Oxidizing enzymes sensibility.
The production processes involved in producing the various types of tea are based in part on the sensitivity of catechins to oxidizing enzymes, such as polyphenol oxidase and peroxidase, that oxidize catechins in theaflavins and thearubigins. However, the adjustment of temperature and pH values can contribute to the reduction of oxidizing enzyme activity. In fact, the optimum conditions for their activity are at a temperature of 40 °C and pH of 5.5.

(e) Ion-binding ability.
Catechins are able to bind iron, due to their galloyl group. When this phenomenon occurs in foods, it inhibits iron absorption in the body. Nevertheless, the ion-binding ability of catechins could be useful in the prevention of oxidative damage in foods. Indeed, catechins are able to chelate iron and copper, two metals that catalyze the lipid peroxidation reaction, inhibiting the initiation and propagation phases.

(f) Bitterness.
Catechins are characterized by a bitter taste which is a limiting factor for their use in food technology, as recent studies have shown that bitter taste is one of the main reasons for the rejection of food products by consumers. So, a balance between the active dose of catechins and bitterness is need.

18.6.1 Tea Catechins Isolation

As explained in more detail above, tea leaves contain a wide variety of soluble chemical compounds such as catechins, caffeine, organic acids, chlorophylls, theanine, and others, of which catechins are present in largest amounts. However, the isolation of tea catechins can be difficult due to their nonsignificant difference in solubility or molecular size, and for this reason several isolation methods have been developed. Green tea is considered to be the better starting matrix for catechin extraction and isolation, over other teas, due to its higher concentration of catechins.

Generally speaking, there are three types of catechin isolates reported below.

- The *crude tea extract* contains catechins together with other tea compounds, e.g., caffeine, chlorophyll, and theanine. The production process of crude tea extract involves three main steps: (1) the extraction of soluble compounds into a tea

infusion, (2) the concentration of the obtained solution, and (3) the drying process.

Because of its content of other tea compounds, crude tea extract might be inconvenient for use in foods. For example, the yellowing color of the extract could give an unwanted color to certain foods. Moreover, caffeine could give an unwelcome bitter taste.

- The *catechin mixture extract* contains a high-purity catechin mixture. The crucial step in the production of catechin mixture extract is the decaffeination process, starting from crude tea extract or directly from a tea infusion. Tea leaves themselves are characterized by a high caffeine content, of about 5% d.w., even more than coffee which contains about 1.5% of caffeine d.w. The caffeine content of tea extracts might not be agreeable to consumers, in addition to contributing to creaming phenomena, which makes catechins unstable in aqueous solution.

  As shown in the previous subsection dedicated to this process, several methods are used for tea decaffeination, including organic solvent extraction, synthetic resin absorption, and supercritical fluid extraction. Nowadays, while the extraction of caffeine through organic solvents is very effective, the risk of solvent residuals remaining in the final product has become almost unacceptable. Thus, supercritical fluid extraction and synthetic resin absorption are the most used techniques, despite high setup costs.
- The *individual catechin extract* contains a high concentration of a single type of catechin and is widely used in food supplements or as food-preserving agent, especially in the case of EGCG extract. The isolation of individual catechins represents a big challenge, because of their similar chemical conformation and molecular weight. To approach this critical issue, countercurrent and column chromatography methods have been developed. These two separation methods are based on the differences between catechins in their affinity to solvents and column materials, used in countercurrent chromatography and in column chromatography, respectively.

18.6.2 Tea Catechins as Food Additives

As discussed at the beginning of this section, in addition to their employ in food supplements and fortified foods, tea catechins are used as replacements for synthetic food additives. In particular, tea catechins are used as antioxidants, preservatives, coloring, and flavoring agents.

18.6.2.1 Antioxidant Agents

Catechins are used in foods as antioxidant agents, especially in meat and fish products, due to their ability in preventing lipid peroxidation. Synthetic antioxidants, such as butylated hydroxytoluene (BHT), butylated hydroxyanisole (BHA), and tertiary butyl hydroquinone (TBHQ), are commonly used in food. It has been shown that a chronic consumption of these synthetic compounds, even if in small doses, could have a toxic effect in the body, especially in infants and children.

Some studies have elucidated the effectiveness of catechins in preventing lipid peroxidation, comparing results with those obtained from commonly used antioxidants. Catechins, especially EGCG, are 20 times more active than vitamin E and 4 times more active than BHA. In other studies, catechins have shown a synergic effect with antioxidant agents, such as vitamin C. The greater the level of unsaturation of fats, the more the foods containing them are subject to peroxidation. For example, vegetable oil and fish oil are more susceptible to lipid peroxidation than meat. The use of tea catechins to prevent lipid peroxidation shows positive results in meat (catechin dose used: 300 mg/kg), fish (catechin dose used: 250 mg/kg), and soybean oil (catechin dose used: 40 mg/kg) (Vuong et al. 2011).

18.6.2.2 Preservative Agents

In addition to preventing lipid peroxidation, which leads to food spoilage and lowers shelf life, tea catechins have shown inhibitory activity against microbial growth. Hara-Kudo and colleagues have shown that a crude catechin extract could exert a significant effect on the growth, toxin production, and spore germination of certain species of bacteria. In particular, a crude catechin extract containing a catechin concentration of about 250 μg/mL was found to inhibit the spore germination and vegetative growth of *Clostridium botulinum* and *Bacillus cereus*, whereas *Escherichia coli* O157 serotype appears to be more resistant. Nevertheless, a crude catechin extract containing a catechin concentration of about 500 μg/mL is able to inhibit the vegetative growth and the production of Vero cytotoxins of *Escherichia coli* O157. The mechanisms proposed by the authors for the inhibition of spore germination from catechins are (1) damage to spore membranes, observed through fluorescence microscopy, and (2) interaction between catechins and calcium-binding proteins on the spore surface, hypothesized by authors. These proteins, which allow the cellular absorption of calcium, are in fact fundamental in the germination phase of the spores (Hara-Kudo et al. 2005).

18.6.2.3 Coloring and Flavoring Agents

Some studies have shown the potential effects of tea catechins as coloring and flavoring agents. However, of these, catechins provide contradicting results in terms of their coloring activity. Tang et al. showed that the addition of tea catechins at 200 mg/kg and 300 mg/kg to beef improved color stability and discoloration, respectively (Tang et al. 2006). The mechanism of action proposed by Tang and colleagues was that catechins maintained oxymyoglobin levels during refrigerated storage, retaining the bright red color of meat, and inhibited metmyoglobin production, which confers the brown color to meat. Meanwhile, Martinez et al., using the same concentration of tea catechins on pork meat, found no color-preserving effect, hypothesizing that catechins could actually have had a negative effect on color (Martínez et al. 2005). This meat discoloration could be related to the ability of catechins to bind the iron present in myoglobin. A more recent study, on the other hand, found improved conditions for the stabilization of meat color in the application of a mixture composed by catechins (3 to 19%), carnosine (78 to 94%), and α-tocopherol (0 to 12%) (Liu et al. 2010). The reason for this discrepancy in the results

obtained in studies of the coloring properties of catechins may be ascribed to variability in the experimental conditions.

The flavoring properties of tea catechins have been demonstrated in meat products at a concentration of 200 mg/kg and 300 mg/kg, inhibiting the off-flavors formed during food storage. This effect is ascribed to both the antioxidant and the antimicrobial properties of tea catechins (Martínez et al. 2005).

18.6.3 Tea Catechins Regulatory Status

Despite it having been well established that tea catechins could be used in food supplements as components of *C. sinensis* extract, the community regulations of the various countries are not harmonized regarding the use of tea catechins alone as a bioactive ingredient in food supplement, as is often the case. This occurs because the safety of tea catechins has not yet been clarified. For example, at the European level, the European Commission has asked EFSA to perform this evaluation, and the EFSA scientific opinion was published in 2018. This document established the safe consumption values for tea catechins (with detailed discussion reported in the dedicated section of this review). Some nations have covered this regulatory gap with national rules, as in the case of Italy. Indeed, the Italian Ministry of Health has allowed the use of EGCG from green tea as a bioactive ingredient in food supplements, with a maximum daily intake limit equal to 300 mg, with use discouraged during pregnancy (Ministero della Salute. ALTRI NUTRIENTI E ALTRE SOSTANZE AD EFFETTO NUTRITIVO O FISIOLOGICO, publication date: 6th August 2009).

As happens for food supplements, even in food, the use of extracted tea catechins is not allowed. In the United States, tea extract may be used as natural flavoring agent with antioxidative properties in foods characterized by high amounts of fat. According to the United States Code of Federal Regulations (21 CFR 101.22, and 21 CFR 182.10), the term "natural flavoring" means the *essential oil, oleoresin, essence or extractive, protein hydrolysate, distillate, or any product of roasting, heating or enzymolysis, which contains the flavoring constituents derived from a spice, fruit or fruit juice, vegetable or vegetable juice, edible yeast, herb, bark, bud, root, leaf or similar plant material, meat, seafood, poultry, eggs, dairy products, or fermentation products thereof, whose significant function in food is flavoring rather than nutritional*. In the European Union, the definition of "natural flavoring" substances, as stated in Council Directive 88/388/EEC, is: *a flavoring substance obtained by appropriate physical, enzymatic or microbiological processes from material of vegetable, animal or microbiological origin either in the raw state or after processing for human consumption . . . Natural flavoring substances correspond to substances that are naturally present and have been identified in nature.* This definition is applied to the preparation of all foods, excluding those that require specific additional regulations. Some tea extracts are also considered to be traditional foods in Europe; however, the market classification of tea extracts depends on the intended use as well as the product profile. For example, if the

primary function relates to its antioxidant properties, the tea extract is regulated as an antioxidant agent and must be specifically approved.

18.7 Safety: Toxicity and Side Effects

The interest in tea catechins shown by the scientific community concerns both aspects related to their beneficial activity on human health and aspects related to their safety. The need for the evaluation of the safety of tea and tea catechins derives from case reports of adverse effects related to the consumption of green tea extracts or food supplements, and, in rarer cases, tea beverages. In 2009, in response to a request from the European Commission, EFSA published a safety assessment on green tea, focusing on dried extracts and traditional infusions consumed as foods, including beverages and food supplements in Europe. In 2018, the EFSA published a scientific opinion on the safety evaluation of green tea catechins (EFSA 2018). However, there are many gaps in the evaluation of the safety of tea catechins. These are due to various critical issues reflected in the collection and processing of data, such as the heterogeneity of the chemical composition of tea products or extracts, or of tea food supplements, tested in both toxicological and human intervention studies, and the lack of chemical characterization of these products, as well as a limited understanding of the mode of action or adverse outcome pathway for the observed toxicity.

The registered adverse effects in animal toxicological studies are hepatotoxicity, gastrointestinal toxicity, reduced weight gain, epicardium inflammation and myocardial necrosis, pancreatic necrosis, renal proximal tubular necrosis, nasal and olfactory toxicity, and thyroid dysfunction. The severity of injury is strictly related to the exposure (dose levels), the chemical composition of tea beverages or extracts, route of administration, and feeding state (fasting or bolus). In human intervention studies, gastrointestinal toxicity, hepatotoxicity, reduced body weight or weight gain, nasal-olfactory toxicity, and cardiotoxicity have been observed. This evidence is derived from a 2018 systematic review, which takes into account 104 peer-reviewed human clinical studies. The authors showed that only liver toxicity and gastrointestinal toxicity have a high relevance in humans, albeit with a very low incidence. While gastrointestinal toxicity was observed at lower dose levels than hepatotoxicity in most animal studies and all human studies, it was not considered to be a critical effect, because it is a local effect which could be readily prevented through consumption of tea products with or after a meal. Moreover, the authors reveal that tea catechins are not genotoxic or carcinogenic based on results from carcinogenicity and genotoxicity assays in experimental animals, corroborated by the lack of documented evidence from human epidemiological studies reporting any association between tea consumption and increased cancer risk (Hu et al. 2018).

In the 2018 EFSA opinion on the safety of tea catechins, the Panel considered that tea catechins cause a dose-dependent hepatotoxicity and that the consumption of tea catechins for 4 months or longer at a dose of about $>$800 mg EGCG/die is associated with an increase in the serum concentration of hepatic enzymes alanine

and aspartate aminotransferases, which are recognized indicators of liver injury (EFSA 2018).

In agreement with the opinion of EFSA, the United States National Institutes of Health stated that: "*Green tea extract and, more rarely, ingestion of large amounts of green tea have been implicated in cases of clinically apparent acute liver injury, including instances of acute liver failure and either need for urgent liver transplantation or death.*"

From the evidence gathered in the literature, it seems that among the different tea-based products taken into consideration, solid food supplements were found to be the most subject to adverse reactions. This finding is further confirmed by the PlantLIBRA study, a European project which studied the adverse effects of plant food supplements involving 2359 adults from six European countries (Finland, Germany, Italy, Romania, Spain, and United Kingdom). The self-reported adverse effects were registered in poison centers. The obtained results showed that the adverse effects deriving from the consumption of food supplements containing *Valeriana officinalis* and *Camellia sinensis* are the most diffused. The bias of this survey is that clinical evidence supporting the self-reported toxicity was not assessed.

The proposed mechanisms of liver toxicity reported in the literature are the loss of mitochondrial membrane potential, with the consequent increased production of reactive oxygen species and reduced glutathione contents. Another hypothesized mechanism is the pro-oxidative activity of tea catechins administered in high doses, which is mediated via formation of EGCG o-quinone, which reacts with protein thiols to form a compound with stress-generating properties. Moreover, hepatic toxicity may be induced by decreasing expression of heat shock proteins, which are synthetized in stress conditions, and antioxidant enzymes. Furthermore, genetic polymorphisms and pre-existing health conditions or concomitant medication use, such as nonsteroidal anti-inflammatory drugs, paracetamol or statins affecting mitochondrial membrane integrity, may predispose certain individuals to tea catechin-induced hepatotoxicity (EFSA 2018).

18.8 Marketed Products

Food supplementation can provide concentrated sources of nutrients or other substances that can have nutritional or physiological effects. The purpose is to supplement the normal diet. Food supplements are generally marketed in dose forms, e.g., as pills, tablets, capsules, or liquids in measured doses. Supplements can be used to correct nutritional deficiencies or to maintain an adequate intake of certain nutrients (http://www.efsa.europa.eu/en/topics/topic/supplements).

Antioxidants have been extensively used more recently to counter or overcome the effects of the excess ROS that are involved in several pathologies, including diabetes and obesity. Many over-the-counter dietary supplements that are used for "treatment" of obesity, neurodegenerative diseases, diabetes, and related metabolic disorders have insufficient medical information and support from scientific evidence.

Green tea has gained tremendous popularity as an all-round health "elixir," where it is described as burning fat and protecting against an array of illnesses, including cancers and CVD. With enticing names such as Green Tea Triple Fat Burner and Green Tea Slim, many people are drawn to such supplements with green tea for weight loss. Consumers spent about $140 million on these in 2015, according to data available from the Nutrition Business Journal (https://www.consumerreports.org/dieting-weight-loss/truth-about-green-tea-for-weight-loss). Indeed, the year 2019 is expected to remain strong for market growth of green tea extracts, primarily due to widening applications and strengthening buyer power. New growth opportunities will emerge across the green tea extract market value chain, with both suppliers and distributors focusing on adapting to the shifting consumer preferences. On the other hand, more intense competition and the demand for high-quality products at low cost will act as challenges for market growth to 2025 (https://www.marketresearch.com/OG-Analysis-v3922/Future-Global-Green-Tea-Extract-12199295/). On the eBay platform (https://www.ebay.com) at the time of writing, there were 335 products available from a search for green tea extracts under "dietary supplements" and 28 products that were said to contain tea catechins. Similar results were found on amazon.com (https://www.amazon.com/). Under "health and household," "vitamins and dietary supplements," "nutritional supplements" (295 products for this alone), "antioxidants," and "green tea extract," there were 163 products available.

These nutritional supplements that are said to contain green tea extracts can be found in the form of capsules, tablets, powders, or liquids. Based on the product information, these green tea extracts indicate the following claims: help to boost metabolism when combined with a reduced calorie diet and exercise plan (https://www.amazon.com/); a plant-based supplement that contains several antioxidants (and most importantly, polyphenols and EGCG) that have been shown to naturally increase resistance to diseases and degeneration; and more importantly for obese people, to support weight-loss and weight-maintenance goals. This last represents a staple for anyone looking to decrease their body fat. Some products contain more health claims, such as: Advanced Green Tea Formula, Zenwise Health Green Tea Extract (https://www.amazon.com/Green-Extract-Supplement-EGCG-Vitamin/dp/B00RH5I8U0), which claims to contain a blend of green tea extract (with EGCG and polyphenols) and vitamin C, to support weight loss, provide energy, and stimulate immune responses, cognition, and heart health for men and women; Metabolism Booster for Weight Loss, which claims that when combined with a healthy diet, the green tea extract (with EGCG catechin) is an effective fat burner that promotes slimming by giving the body metabolic function a natural boost; Antioxidant Immune System Support, which claims that with its 98% polyphenols, the green tea extract (*Camellia sinensis*) works with the vitamin C in this formula for a powerful source of antioxidants to bolster immune function to help you feel your best; No Caffeine for Jitter-Free Energy, which includes 725 mg green tea extract per serving and claims that this nature-inspired decaffeinated formula provides a pure and gentle boost of energy to get you through your day without any jitters or caffeine crashes; and Supports Brain & Heart Health, which as a daily green tea extract claims that this supplement promotes healthy cardiovascular function.

Although numerous in vitro and in vivo studies and clinical studies that have been reported here show the various beneficial effects described above, overall the data remain conflicting. More studies to validate their efficacy and safety are warranted, and large, well-designed, double-blind, placebo-controlled clinical studies need to be carried out before use of such preparations can be recommended for treatment and/or prevention of neurodegenerative diseases, diabetes, and other diseases. Some reports have also identified an association between hepatotoxicity and health supplements that contain green tea extract (Bonkovsky 2016; Garcia-Cortes et al. 2016; and references therein).

18.9 Patents

The various patents around these green tea extracts generally relate to the extraction methods used, along with the encapsulation of the tea catechins and the associated health claims. These patents also generally discuss the evidence found in the literature for the pharmacological activities of green tea. Indeed, as health-promoting products and disease-preventing applications, these green tea extracts, or compounds isolated from green tea extracts, are the subject of many patents. Using the Google Patents Searching Browser, more than 12,300 hits can be obtained for tea catechins (priority, 2002, granted, WO) (https://patents.google.com/). Here, we will restrict ourselves to only a few of what we see as the more important ones.

A US patent for methods and compositions for improving bioavailability of EGCG through administration of a nanoparticle complex to treat neurological diseases such as Alzheimer's disease or HIV-associated dementia was granted in December 2014 (US8906414B1). This invention was made with government support under Grant No. 5K08 MH082642-02 awarded by the National Institute of Mental Health (NIMH); Grant No. R43AT004871 awarded by the National Center for Complementary and Alternative Medicine (NCCAM); and Grant No. R21AG031037 awarded by the National Institutes on Aging. This patent is owned by Natura Therapeutics Inc., University of South Florida. The government has certain rights in this invention.

More recently, in December 2015, a patent application was filed with the US patent office for inhibition of neurodegenerative diseases using a "Grape seed extract, green tea extract and probiotic bacteria" (US20160106789A1), where the green tea extract is primarily EGCG. George Robertson filed a patent application (April 2015; WO2015154192A1) for use of a composition that comprises a flavan-3-ol, a flavonoid and a fatty acid in the treatment of oxidative injuries due to mitochondrial dysfunction. The disorders to be treated are indicated as neurodegenerative disorders, which include Parkinson's disease, Huntington's disease, amyotrophic lateral sclerosis, Alzheimer's disease, and multiple sclerosis; neurological damage due to stroke; and ototoxicity arising from chemotherapy with cisplatin. EGCG is one of the possible flavan-3-ols present in the composition here.

Another patent defines "Agents for downregulation of the activity and/or amount of Bcl-xl and/or Bcl-w" (April 2013; WO2014174511A1; filed by Krizhanovsky V,

Pilpel N, Yosef R). This method comprises a therapeutically effective amount of an agent from a green tea extract that can downregulate an activity and/or an amount of Bcl-x L and/or Bcl-w and/or p21, with the proviso that the inflammatory disease is not cancer. In another patent (US6410061B1; filed by Morré DM, Morré JD, Purdue Research Foundation) defined for "Tea catechins as cancer specific proliferation inhibitors," the method and compositions for treating cancers or solid tumors comprise administration of a therapeutically effective amount of catechins, a group of polyphenols found in green tea, to a mammal in need of such therapy. These compositions of the catechins include, but are not limited to, epicatechin, ECG, EGC, and EGCG. This invention also covers the various modes of administration of the therapeutic compounds. Another patent (2014; US8906414B1; filed by Shytle RD, Tan J, Smith A, Giunta B, Sanberg CD) describes the compositions and methods of increasing the bioavailability of catechins by their encapsulation within nanoparticles, along with the compositions of the nanoparticle complex that are formed between the catechin and the nanoparticle. Each of these compositions was shown to increase the bioavailability of EGCG. This is defined as useful for treating diseases such as Alzheimer's disease and HIV-associated dementia.

Then there is "Topical liposome compositions containing phenolic anti-inflammatory agents and their methods of preparation" (June 2014; WO2014085914A1; filed by Simmons DL), where liposomal topical compositions containing phenolic anti-inflammatory agents, and methods for making thereof, are presented. These compositions are generally used to help to prevent solar radiation-induced skin damage and to help to prevent and/or treat inflammatory dry skin conditions caused by eczema and contact dermatitis. In the patent "Composition and method for improving cognitive function and brain bioavailability of ginseng and ginsenosides and treating neurodegenerative disease and neurological disorders" (February 2017; WO2018148821A1, filed by Kay DG & Maclellan A), the invention is directed to methods and compositions for improving cognition or rejuvenation of the brain of an individual using an active combination of at least one phospholipid and at least one substance selected from a group consisting of ginseng, green tea, catechin, ginsenoside, essential fatty acids, and combinations thereof. (https://patents.google.com/).

18.10 Perspectives

Tea obtained from the leaves of *C. sinensis* is one of the most popular beverages around the world. Several in vitro and in vivo studies have suggested that tea catechins can provide beneficial effects, which can include antioxidant, anti-inflammatory, antiviral, anticancer, antidiabetic, and anti-obesity activities, as well as activities against CVD and neurodegenerative diseases, among many other claims. However, the maximal concentrations of the catechins detected in blood in human subjects or animals after oral ingestion are in submicromolar or low micromolar levels, which indicate the small amounts that are absorbed and pass into the blood. These appreciably lower in vivo quantities compared to the effective concentrations

determined in in vitro studies suggest the poor stability of these compounds in the gastrointestinal tract.

The bioavailability of tea catechins has been extensively studied, and many so-called delivery systems have been proposed to improve their stability and promote their membrane permeability across the intestine. However, there are large differences in the conclusions from studies that have investigated the association between tea consumption and health benefits. In this respect, the solubility, structure, bioavailability, permeability, shelf life, safety aspects, and exact mechanisms responsible for the actions of tea catechins should be additionally examined in well-controlled human trials. Long-term dietary intervention trials in large populations with detailed information on lifestyle, dietary habits, and health status of participants have been proposed.

Many over-the-counter dietary supplements have insufficient medical information and support from scientific evidence if they are to be used for the treatment of diseases and metabolic disorders. Although numerous in vitro and in vivo studies, and also clinical studies, have reported beneficial effects of these tea catechins, the results have been, and remain, conflicting. More research is needed to validate their efficacy and safety and large, well-designed double-blind, placebo-controlled clinical studies need to be carried out before the use of such preparations can be recommended for treatment and/or prevention of health disorders.

Abstract

Tea, except water, is the most widely consumed beverage across the world. It contains many active substances, among which polymeric polyphenols (theaflavins, thearubigins, and theasinensins) are dominant in fermented teas. Theaflavins and thearubigins are the major polyphenolic compounds in black tea, whereas theasinensins are the most characteristic for oolong tea. All of these classes of polyphenols have complicated structure and complex route of synthesis, in which polyphenol oxidase is a crucial enzyme. The aim of the present chapter is to provide a summary on the current knowledge on theaflavins, thearubigins, and theasinensins associated with chemical structure, molecular action pathways, and health benefits based on the scientific evidences available on the literature.

Keywords

Black tea · Catechins · Theaflavins · Thearubigins · Theasinensins

19.1 Introduction

Tea is a very popular drink in the world, and after water, it is the most frequently consumed beverage. The annual production of tea is estimated to around 2.9 billion tons. Every day almost 70% of the global population drinks 18–20 billion cups of tea. *Camellia sinensis* (L.) Kuntze belongs to the family Theaceae and is cultivated in over 45 countries from all continents, except North America and Antarctica. Subtropical and tropical climate with high precipitation and little acidic soil are the most preferable conditions for tea cultivation (Barua 2008). Young leaves, immature buds, and delicate stalks of tea bush are processed to produce tea as a food product. Taking into account the production process, tea can be divided into several types, of which green and black teas are the most popular ones. In the scientific literature, different classifications can be found; however recently Yi and co-workers (2015), based on the production process, divided tea into seven sub-types, namely, black, green, white, yellow, oolong, aged Pu-erh, and ripened Pu-erh. Green and white teas are non-fermented products, while the latter one is considered high-quality tea produced from young leaves and buds harvested before their maturation, mostly in spring. The tea leaf contains over 4000 active constituents. Table 1 summarizes the composition of tea according to the leaf and to the tea infusion.

Polyphenols are the main and most widely distributed secondary metabolites present in plants. They can be divided into several subclasses of which flavonoids are the most complicated and widespread in the plant kingdom (Fig. 1).

The basic structure of flavonoids, so-called flavan skeleton, consists of two aromatic rings linked by a three-carbon atom heterocyclic ring. All flavonoids contain OH groups in the positions 5- and 7- in the A ring and in the position 3- in the B ring; however the differences in location and character of other OH groups and the presence or absence of a double bond between carbon atoms 2 and 3 in the C

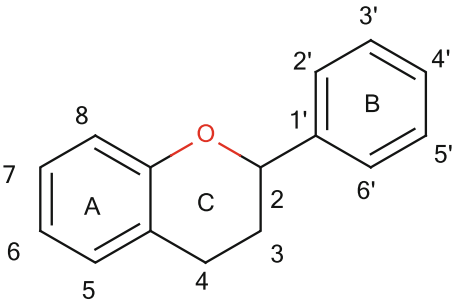

Fig. 1 Flavan skeleton – a basic structure of flavonoids

ring are the reasons for the division of this group of compounds into several subclasses: flavanones, flavonols, flavones, isoflavones, anthocyanidins, and flavan-3-ols. The latter one, also called catechins, are the main active constituents of tea. A characteristic feature of these substances is the presence of the -OH group in position 3 in the C ring (Fig. 2).

The major catechins present in the tea leaves, alongside with their abbreviations used in the literature, are (−)-gallocatechin (GC), (−)-epicatechin gallate (ECG), (−)-epigallocatechin (EGC), (+)-catechin (C), (−)-epicatechin (EC), (−)-gallocatechin gallate (GCG), and (−)-epigallocatechin-3-gallate (EGCG). Their structures were presented below (Fig. 3).

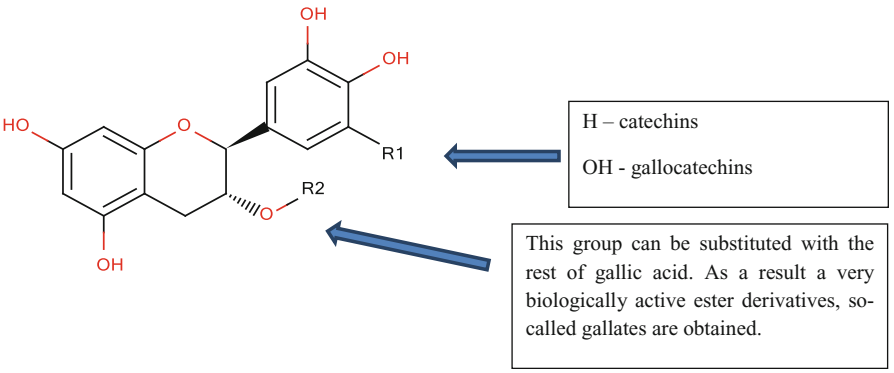

Fig. 2 The structure of flavan-3-ols

During the fermentation, which is the main process in the production of black tea, over 75% of catechins are transformed into complicated polymers, such as theaflavins (TFs), thearubigins (TRs), and theasinensins (TSs).

19.2 Theaflavins

19.2.1 Biosynthesis and Structure

The composition of black tea was presented in Table 2.

Theaflavins and thearubigins are the major polyphenolic compounds in black tea. The first accounts for 2–6% of solids in the dry matter of the brew of the black tea. TFs are synthesized during the dimerization process of catechins. So far more than 25 theaflavins were found in the black tea. The main element of their structure is the seven-membered benzotropolone ring, which is formed due to the oxidation of the epigallocatechin ring B or epigallocatechin gallate, followed by decarboxylation and simultaneous fusion with the epicatechin ring B or epicatechin gallate (Beecher 2003). The most important theaflavins found in black tea are theaflavin (TF_1), theaflavin-3-gallate (TF_2A), theaflavin-3′-gallate (TF_2B), and theaflavin-3,3′-digallate (TF_3). In literature some other signatures of TFs can be found, namely, TF_1 as TF, TF_2A as TF_1, and TF_2B as TF_2. Theaflavin-3,3′-digallate is always marked as TF_3 (He 2017). In addition to theaflavins in tea infusions, the presence of other compounds that are derivatives of benzotropolone, among others theaflagalline or theaflavin acids, was proofed. The structures of four main TFs alongside with the basic monomers were illustrated in Fig. 4.

The relative proportion in which particular theaflavins are present in black tea was reported to be as follows: theaflavin (18%), theaflavin-3-gallate (18%), theaflavin-3′-gallate (20%), theaflavin-3,3′-digallate (40%), and minor derivatives such as theaflavic acids.

	R_1	R_2
(+)-catechin	H	H
(−)-gallocatechin	OH	H
(+)-catechin gallate	H	Gallic acid
(−)-gallocatechin gallate	OH	Gallic acid

	R_1	**R_2**
(-)-epicatechin	H	H
(−)-epigallocatechin	OH	H
(−)-epicatechin gallate	H	Gallic acid
(−)-epigallocatechin-3-gallate	OH	Gallic acid

Fig. 3 Structures of the tea catechins

The reactions of oxidation and polymerization of catechins probably occur with the participation of two enzymes: polyphenol oxidase and peroxidase. It is believed that mainly polyphenol oxidase is responsible for the oxidation of flavanols to

Table 2 The composition of black tea

Compounds	Content (% of dry matter)

Pigments (mainly chlorophyll and carotenoids)	2
Volatiles	0.1
Minerals	5

	R_1	R_2	Monomers
Theaflavin (TF_1)	OH	OH	EC+EGC
Theaflavin-3-gallate (TF_2A)	Gallic acid	OH	EC+EGCG
Theaflavin-3'-gallate (TF_2B)	OH	Gallic acid	EGC+ECG
Theaflavin-3,3'-digallate (TF_3)	Gallic acid	Gallic acid	ECG+EGCG

Fig. 4 Structures of tea theaflavins (Lambert and Yang 2003)

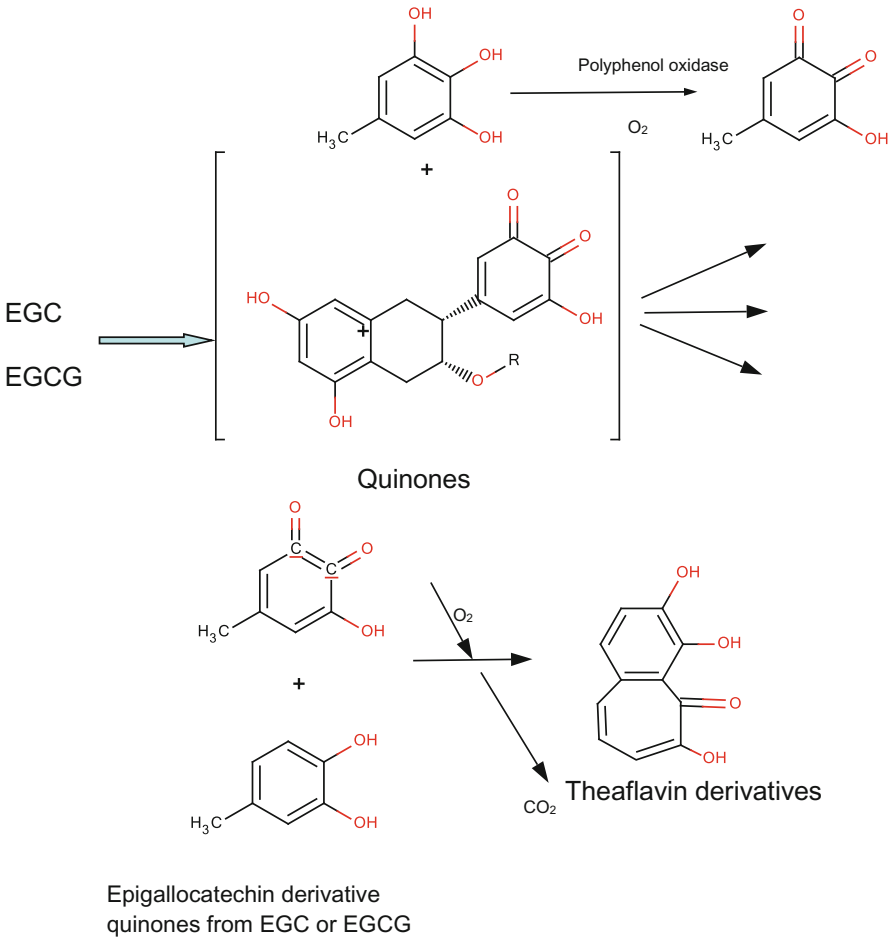

Fig. 5 The probable mechanism of synthesis of theaflavins during the fermentation process (Haslam 2003)

theaflavins and thearubigins (Haslam 2003). Peroxidase activity, which catalyzes the oxidation reaction of phenols to quinones with the participation of hydrogen peroxide, has been shown to be five times higher in fresh tea leaves compared to the oxidase, and its activity increases during the production process. However, its role in the synthesis of complicated polymeric polyphenols of black tea has still not been fully explained (Mahanta et al. 1993) (Fig. 5).

19.2.2 Organoleptic Properties

Theaflavins are orange or orange-red pigments, which determine the specific color and taste of black tea infusion. TFs were called a "golden molecules," because of

their wide biological properties. Very often they are associated with the grade and quality of black tea, the most consumed tea in the world. Although both theaflavins and thearubigins are responsible for the specific taste and aroma of black tea, the first one are considered as the major group of compounds used to assess the market value, clonal variations, and seasonal quality variations of black tea (Yao et al. 2006). Theaflavins have astringent properties and give specific mouth-coating and long-lasting oral sensation at the back of the throat. However their astringent properties are much lower, compared to catechins, and account for about 0.1% of the total astringency of all tea constituents (He 2017).

19.2.3 Absorption and Metabolism of Theaflavins

Bioavailability of theaflavins is very poor. Based on the plasma and urine concentrations, Mulder and co-workers established the intake rate at 0.0006%, and Pereira-Caro and co-investigators obtained even lower value of 0.000001% after oral ingestion of a mixture of theaflavins, which was an equivalent of ~10 cups of black tea (Mulder et al. 2001; Pereira-Caro et al. 2017). Ingested TFs pass through the gastrointestinal tract unchanged to the colon, where they are subjected to the action of the resident microbiota. As a result low molecular weight degradation products are formed, mainly hydroxybenzene derivatives, particularly pyrogallol-1-sulfate, pyrogallol-2-sulfate and 3-(4′-hydroxyphenyl)propionic acid. Probably theaflavins are catabolized in the two pathways – first by colon microbiota and second by mammalian cell enzymes during phase II metabolism. Because of a very low TFs bioavailability, the beneficial role associated with the consumption of black tea is linked to their circulating metabolized products, which are mainly of microbial origin (Pereira-Caro et al. 2017).

19.2.4 Bioactivity of Theaflavins

In recent years many beneficial effects of TFs were revealed including in vitro and in vivo studies. Below some of the most important biological activities were described (examples were limited to animals and human studies).

19.2.4.1 Antioxidant Activity

It is already well-known and was confirmed in numerous studies that tea infusions possess strong antioxidant activity. Black tea infusions are now considered as a major source of dietary polyphenols for a general population. For many years this product was thought to be a weaker dietary antioxidant agent, compared to green tea, which seemed obvious, because over 75% of simple catechins are decomposed during fermentation process. However, recent findings revealed that the new compounds (e.g., theaflavins), which arise, are also characterized by strong radical scavenging activity. The ability to quench DDPH (2, 2-diphenyl-1-picrylhydrazyl) radical by theaflavins can be expressed as follows: $TF_3 > TF_2B = TF_2A > EGCG > TF_1$

(He 2017). This comparison shows that three major theaflavins are stronger antioxidants than EGCG, which is considered one of the most active antiradical molecules present in food. The randomized, double-blind, crossover study performed by Arent and co-workers on humans subjected to acute anaerobic interval training revealed beneficial effects of TFs intake. The study showed that the consumption of black tea enriched in theaflavins led to better recovery and reduced the oxidative stress. Moreover it reduced muscle pain caused by long anaerobic periods (Arent et al. 2010).

19.2.4.2 Antimutagenic Activity

The study performed on bone marrow cells of mice showed significant decrease in chromosomal aberrations and sister chromatin exchange caused by benzo[a]pyrene, after oral administration of black tea extract, which was equal to the consumption of five cups per day. This activity was mostly due strong antioxidant activity, which inactivated direct carcinogenesis (desmutagenicity) outside the cell. Other proposed mechanism linked this activity with the induction of P450 cytochrome enzymes, which results in the activation of intracellular detoxification of carcinogens. Moreover induction of DNA repair, inactivation of reactive forms of mutagens and carcinogenesis, as well as inhibition of promutagen activation, promotion, invasion, and metastasis of tumor cells are also mechanisms which underline the antimutagenic activity of theaflavins (Halder et al. 2005).

Wang and co-workers proved protective effects of theaflavins on cadmium-induced (0.4 mg/kg body weight, s.c., once a day) testicular toxicity in male Sprague-Dawley rats. The animals received 50, 100, and 200 mg/kg of TFs per body weight, orally, once a day during 5 weeks. The study revealed dose-dependent reduction of cell damage in testis and DNA damage, increased serum testosterone levels, and improved sperm characteristics. The authors also observed other beneficial effects of theaflavins administration, e.g., decrease in the production of MDA caused by Cd; reduced concentration of this metal in the liver, testis, and blood; and increased excretion of cadmium with feces and urine (Wang et al. 2012).

19.2.4.3 Influence on Blood Lipids

Theaflavins were proved to inhibit the lipase and amylase and suppress the expressions of lipopolysaccharide-induced intercellular adhesion molecule and vascular cell adhesion molecule by blocking the activation of NF-κB and JNK in the epithelial cells of the intestine. Additionally TFs suppress lipogenesis by inhibiting fatty acid synthase, through downregulation of epidermal growth factor and receptor/PI3K/Akt/Sp-1 signal transduction pathway. As a result of all of these mechanisms, significant hypolipidemic effect was observed.

TFs were also shown to have strong effects toward the prevention of obesity by inhibition of hepatic lipid storage, reduction of lipid accumulation, and production of fatty acids and stimulation of their oxidation. After oral administration of TFs, increased energy expenditure and expression of metabolic genes were proved. Theaflavins are also considered to improve liver steatosis, oxidative stress, and inflammation and as a result decrease hepatocyte apoptosis (He 2017).

19.2.4.4 Anti-inflammatory Activity

Gosslau and co-workers proved TF_2B to have strong anti-inflammatory effect by the suppression of the 12-O-tetradecanoylphorbol-13-acetate-induced COX-2 gene expression and downregulation of TNF-α, inducible nitric oxide synthase (iNOS), ICAM-1, and nuclear factor κB (NF-κB). They have also reported that TF_2B significantly reduced ear edema in mouse, by producing similar pattern of gene downregulation to that observed in the cell model (Gosslau et al. 2011). TF_3 was shown to have protective effect in colitis. Theaflavin derivatives were also proved to decrease the expression of the inflammatory cytokine IL-6, one of the most important mediators of inflammation (He 2017).

19.2.4.5 Antimicrobial Activity

Theaflavin-3,3′-digallate (TF^3) during the epidemiological studies was shown to be strong inhibitor of 3C-like protease, related to severe acute respiratory syndrome (SARS). TFs were proved to have strong inhibitory effects against influenza and HIV viruses, by blocking the initial steps of infection through attenuation of neuraminidase and hemagglutinin activity (He 2017).

Other studies, performed using six clinical isolates of herpes simplex virus type 1 (HSV-1) and two clinical isolates of HSV-2, have shown that the combination of TF_3 and lactic acid significantly reduced the infection caused by these viruses in the pH spectrum of 4.0–5.7, which mimic the conditions found in the female reproductive tract (Isaacs and Xu 2013).

Betts and co-workers revealed strong antibacterial effect of various concentrations of theaflavins toward eight clinical isolates of *Stenotrophomonas maltophilia* and *Acinetobacter baumannii*, important nosocomial pathogens, resistant to multiple antibiotics. They also proved significant synergism of action with epicatechin; however the mechanism of such activities was not elucidated (Betts et al. 2011).

19.2.4.6 Anticancer Activity

TFs were shown to have strong anticancer activity in numerous studies performed on human cancer cell lines, by blocking extracellular signal transmission and cell proliferation and improving cell shrinkage, membrane blebbing, and mitochondrial clustering. As a result of these mechanisms, the induction of cancer cells apoptosis was observed (He 2017).

Oral administration of theaflavin-enriched black tea extracts (40% of TFs) to Sprague-Dawley rats with dimethylnitrosamine-induced liver fibrosis reduced necrosis, bile duct proliferation, inflammation, and elevated levels of serum GOT (glutamate oxaloacetate transaminase) and GPT (glutamic pyruvic transaminase). Studied extract was efficient at the dose of 50 mg/kg as well as 100 mg/kg per day. Hepatic fibrosis is a high-risk factor of developing hepatocellular carcinoma (HCC), which is the fifth most common cancer in men and the seventh in women globally (Weerawatanakorn et al. 2015a). Thus drinking black tea may have beneficial role in the prevention of HCC.

Tea polyphenols (including theaflavins) were observed to suppress the activation of aryl hydrocarbon receptor (AhR) induced by 2,3,7,8-tetrachlorodibenzo-p-dioxin

(TCDD) ex vivo in rats. Conjuncted and intact forms of catechins and theaflavins were present in the plasma and liver of animals. These results confirmed that polyphenols from tea can be incorporated in the liver and through the AhR activation pathway may inhibit the activity of cytochrome P450 1A1 enzyme. Tea phenolics are also a promise chemopreventive agent in human prostate cancer. The relative bioavailability of theaflavins in the prostate tissue was 70% higher compared to EGCG. It was proved that tea polyphenols (catechins and theaflavins) are bioavailable in prostate, where they can act as anticancer agents (He 2017).

Lee et al. reported that theaflavin gallates are hydrolyzed by salivary esterases, which were proofed in either in vitro or in vivo studies, and high concentrations of theaflavins were observed in saliva in the first hour after oral administration of black tea brew. This might reflect that black tea infusions may play beneficial role in the prevention of oral cancer and dental carries (Lee et al. 2004).

19.2.5 Safety: Toxicity and Side Effects

Theaflavins should be considered as a safe and nontoxic natural product. In the literature there is no information on toxicity of TFs. The only information which might be found is that TF_2A and TF_2B could act as a prooxidants and increase oxidative stress. However it was observed in relation to cancer cells, which must be considered a beneficial activity (Babich et al. 2008).

19.2.6 Marketed Product

Theaflavins are present on the market as dietary supplements containing black tea extracts. *Theaflavin Standardized Extract*® produced by LifeExtension® contains 350 mg of black tea extract, which is standardized to 25% of theaflavins per one capsule. The product is protected by US patent Nos. 6,811,799 and 6,602,527 and can be bought on the US market. The producer does not inform what are the proportions of particular theaflavins in the extract.

Theaflavin® produced by Seeds® is also a dietary supplement which contains black tea extract, together with green tea extract and vitamin E. However, the producer does not provide any information on the composition of this extract, except that it was produced from premium black tea. This product is also offered in the US market.

19.2.7 Perspectives

Taking into account lack of toxicity and side effects, numerous beneficial effects to the organism, which was presented above, and high daily intake with very popular black tea infusions, theaflavins can be potentially used in functional foods and nutraceuticals in the prevention of several lifestyle diseases, e.g., obesity, cancers,

or diabetes. Other potential applications include liver diseases, dental carries, and reduction of toxicity caused by heavy metals (e.g., cadmium). Theaflavins are consumed every day by a large population of the world with black tea, so probably they are still acting, although we do not note or measure the effects of their action. Except that, TFs can be used as isolated compounds or purified extracts from tea as dietary supplements.

19.3 Thearubigins

19.3.1 Biosynthesis and Structure

Thearubigins (TRs) are the next polymeric polyphenols present in black tea, which (together with theaflavins) are responsible for specific brown color and aroma of the infusions. In the past TRs were considered as the insoluble fraction of ethyl acetate extraction of the black tea (Yao et al. 2006). Their content in black tea is about 12–18%, and therefore they comprise the biggest part of all active constituents. TRs are synthetized during the same process as TFs, in which polyphenol oxidase and peroxidase are involved.

Thearubigins are compounds with a red-brown or dark brown color. Although the majority of catechins during fermentation are likely to be transformed into thearubigins, the structure and formation of these substances are still poorly understood. They are believed to be heterogeneous flavan-3-ols and their gallate derivates (Fig. 6). Some authors also suggest that theaflavins are involved in the formation of thearubigins (Haslam 2003). It seems that the pathway of TRs synthesis mainly involves EGC and EGCG and in the next steps quinone and then theaflavins and other benztropolones. Another route suggests participation of theasinensins.

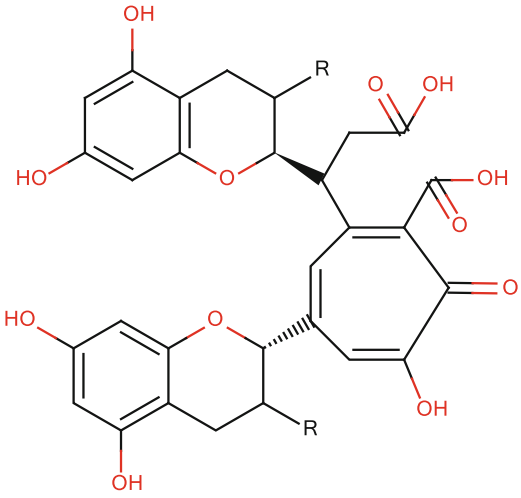

Fig. 6 The proposed structure of thearubigins (Khan and Mukhtar 2007)

The process of thearubigins synthesis resembles "the browning" – very often observed in nature, during which the plant tissues are damaged and oxidized, based on the quinone tanning, the Maillard reaction, or caramelization. TRs are a group of very closely structurally related polymeric compounds, which range from dimeric and trimeric to tetrameric and even greater structures and average molecular weight of ~700–2000 (Haslam 2003).

19.3.2 Organoleptic Properties

Some of the authors suggest that most of the catechins present in fresh tea leaves are transformed into thearubigins during the fermentation process and therefore they constitute the final group of compounds during the production of black tea. TRs are water-soluble, acidic compounds, primarily responsible for rust brown color of the infusion. They are characterized by ill-defined chromatographic behavior, and since many years, little progress has been made toward an understanding of their chemical nature. It is proposed that thearubigins are mainly responsible for the red-brown color of the tea infusion; however its specific taste and aroma are mostly due to the presence of theaflavins (Khan and Mukhtar 2007). Due to their very high water solubility, thearubigins account up to 30–60% of the solids in black tea infusion. TRs are very often associated with the richness of taste and therefore called a "body" of black tea (Yao et al. 2006).

19.3.3 Biological Activity

There are very few data on biological properties of thearubigins. Since their structure was not fully elucidated, there are no standards on which studies toward their activity may be conducted. Because there are very few information on that subject, below some studies on biological activities of TRs were presented, which can be found in the scientific literature.

Halder and co-workers proved significant antimutagenic effect of thearubigins. Fraction of TRs was extracted from black tea infusion by n-butanol liquid-liquid partition. Particular compounds were not separated and identified, but the total fraction was described as "thearubigins." For chromosome aberration assay (CA), the animals were fed by gavage and obtained three different concentrations of TRs (40, 80, and 160 mg/kg body weight). Immediately after the gavage, the animals were administrated benzo[a]pyrene (B[a]P) (100 mg/kg body weight). For the analysis of CA, the animals received colchicine, and 2 h later they were killed, and their bone marrow was expelled and subjected to the analysis. The study revealed significant reduction in CA in all the three different concentrations of thearubigins with B[a]P compared to the control group. The treatment with TRs significantly reduced both the chromatid and chromosome types of aberrations (Halder et al. 2005).

The same authors performed in vivo sister chromatid exchange (SCE) test in mice using TR fraction. All the steps of the treatment were the same as in CA analysis. Obtained results showed significant anticlastogenic effect of orally administrated thearubigins as measured by SCE against B[a]P – a strong mutagen. All three tested concentrations of TRs showed significant reduction toward the frequency of SCE (Halder et al. 2005).

TRs showed significant antimutagenic properties against B[a]P in the in vitro plate test using four different Salmonella strains (TA97a, TA98, TA100, and TA102). Obtained results showed significant antimutagenic activity of thearubigins.

The authors concluded that in the CA assay, TRs showed two times lower protective effects compared to TFs fraction, and in the SCE study, TFs revealed about three times more protective effects compared to TRs. Interestingly thearubigins showed different activity in two different test systems. Their activity was much higher in in vivo mammalian cells than in in vivo bacterial systems. Antimutagenic and anticlastogenic activity of thearubigins is the same as in the case of theaflavins, probably due to their antioxidant properties, which inactivate the extracellular activity of direct carcinogens. Thearubigins also increase the activity of cytochrome P450, which results in the enhancement of the intracellular detoxification of carcinogens.

Catterall and co-workers investigated antimutagenic effects of theafulvins (a fraction of thearubigins) in vivo using male Wistar albino rats, against several dietary carcinogens (heterocyclic amines, polycyclic aromatic hydrocarbons, and nitrosamines). The study showed concentration-dependent significant reduction of the mutagenicity of 2-amino-3-methyumidazo-[4,5-f]quinoline, 2-amino-l-methyl-6-phenylimidazo[4,5-fc]pyridine, benzo[a]pyrene, 7,12-dimethylbenz[a]anthracene, nitrosopyrrolidine, and nitrosopiperidine. However the mutagenicity of aflatoxin B1 was increased (Catteral et al. 1998).

The antioxidant activity of black tea is well-known and is due to the simple phenolics like catechins, as well as theaflavins and thearubigins. All of these groups of compounds, because of their phenolic nature, have strong antioxidant properties. However the knowledge and studies on this subject for particular polyphenols of black tea may be classified as follows: catechins>TFs> > TRs. The antioxidant activity of thearubigins is definitely the least well-known.

Study on the antioxidant activity of TRs rich fraction, performed using different in vitro and in vivo systems (e.g., DPPH, ABTS, FRAP, or hydrogen peroxide assays and protection of different biomolecules against oxidative stress in rats), revealed similar activity of both thearubigin- and theaflavin-rich fractions. Once again it was proofed that strong antioxidant potential of black tea is the resultant of activity of all compounds of phenolic nature present in black tea leaves. Thus in some situations, black tea is described as a more potent antioxidant agent compared to green tea (e.g., stronger lipid peroxidation inhibitor) (Sinha and Ghaskadbi 2013).

Imran and co-workers studied the influence of theaflavins and thearubigins on antioxidant status and lipid peroxidation in rats. They have proved that TFs exhibited higher antioxidant activity. Animals receiving a diet rich in both TFs and TRs were characterized by significant reduction in lipid profile, glucose content, and renal

function. Moreover this study revealed that animals receiving TFs were characterized by lower values in the TBARS test (thiobarbituric acid reactive substances), which is one of the most widely used assays for measuring lipid peroxidation end product – malondialdehyde and lipid profile, compared to thearubigins or a mixture of TFs and TRs (1:1). On the other hand, theaflavins+thearubigins diets caused the highest glucose, urea, and creatinine decrease and maximum level of insulin and antioxidant parameters compared to diets containing theaflavins or thearubigins alone (Imran et al. 2018).

The antioxidant activity of particular constituents of black tea can be characterized as follows: TF_3 > EGC > the mixture of TF_2A and TF_2B > thearubigins>TF_1. It should be also noted that studies regarding the antioxidant activity of particular black tea polyphenols are inconclusive, mainly because of different systems and parameters used. However many data suggest that the strongest active compound is TF3, followed by simple catechins. Thearubigins, although considered as strong antioxidant agents, are classified much less active compared to catechins or theaflavins.

19.3.4 Conclusion

Because of the limited data and only few scientific studies regarding thearubigins, it is not easy to predict a future perspective for this group of compounds. There are no information on toxicity of these compounds, but taking into consideration that they are a basic constituent of black tea, thus a significant ingredient of human daily data, their toxicity and side effects should be considered low.

Except dietary supplements containing total extracts from the black tea or isolated theaflavins, there are no products on the market with isolated thearubigins or fractions rich in these compounds. However majority of people consume TRs every day while drinking black tea infusions. Taking into account how popular is this beverage, thearubigins should be considered significant constituent of human diet, being simultaneously one of the most important non-nutrients.

19.4 Theasinensins

Black tea is definitely the most popular type of tea, which accounts for almost 78% of the global production. It is mainly consumed in the United States and Europe. Green tea is mostly preferred in Asian countries, and its market share is estimated to be ca. 20%. The third most popular type is oolong tea, consumed mainly in Taiwan, southern China, and many Eastern countries. Although its production is only 2% of the global market and thus it is far below the most popular types, namely, black and green, its popularity is still increasing. During the last two decades, its production in China has almost doubled, from 67.6×10^3 metric tons in 2000 to 254×10^3 metric tons in 2014 (Weerawatanakorn et al. 2015b).

Table 3 The composition of oolong tea beverage (Sajilata et al. 2008)

Compound	Content (mg/100 mL)
Catechin	1.65
Gallocatechin	6.65
Epigallocatechin	16.14
Epicatechin	5.08
Catechin gallate	0.6
Epicatechin gallate	5.73
Epigallocatechin gallate	25.73
Gallocatechin gallate	1.85
Gallic acid	2.19
Caffeine	23.51
Polymerized polyphenols	33.65
Total polyphenols	99.32

Oolong is a semi-fermented type of tea, and the degree of catechin oxidation is in a wide range of 10–80%, depending on the consumer requirements. Apart from the degree of fermentation, all three types of tea are also differentiated based on its amino acid content, mainly L-theanine but also alanine, leucine, serine, or glutamic acid. Oolong tea has specific taste and aroma, depending on several parameters like smell of volatile fragrance, umami (specific taste, hard to explain), and degree of astringency versus sweetness (Alcazar et al. 2007).

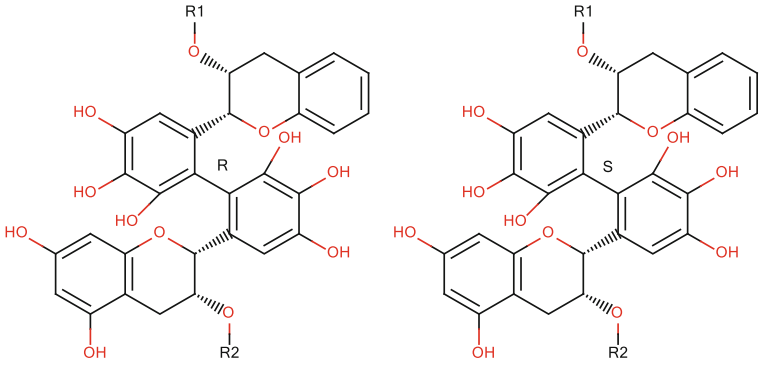
Major components of oolong tea can be divided into two groups: simple catechins and polymeric polyphenols. Since this type of tea is a semi-fermented product, the degree of catechin degradation changes, and thus the concentration of polymeric compounds differs. Sajilata and co-workers characterized the composition of oolong tea beverage as follows (Table 3).

Major secondary polyphenols in black tea are theaflavins and thearubigins, which were previously described. However oolong tea contains another class of polymeric polyphenols, known as theasinensins.

19.4.1 Biosynthesis and Structure

In 1958 Robert discovered a new group of compounds, known as bisflavanols A, B, and C, which were formed by linkage of two EGCG molecules. Later, in 1984, this group of polymeric oxidized flavan-3-ols was isolated from oolong tea and identified as theasinensins A, B, and C. In 1988 Nonaka and Hashimoto confirmed the presence of other compounds of this type, which were named using the letters D, E, F, and G (Weerawatanakorn et al. 2015b).

Theasinensins are considered as bioactive flavonoids of oolong tea. They are formed by the coupling of two catechins at their B rings through a C-C molecular bond. Its structure was presented in Fig. 7.



R stereoisomers		S stereoisomers	
Theasinensin A	R1=R2=Galloyl	Theasinensin D	R1=R2=Galloyl
Theasinensin B	R1=Galloyl R2=H	Theasinensin E	R1=R2=H
Theasinensin C	R1=R2=H		

Fig. 7 The structures of theasinensins (Weerawatanakorn et al. 2015b)

The structures of theasinensins A, B, and C contain the biphenyl bonds in the configuration R, whereas in D and E, it is R-biphenyl configuration (Fig. 7). Some authors suggest that theasinensins D and E are just stereoisomers of A and C. If we consider basic monomers which build particular TSs, it visible that theasinensins A and D are dimers of EGCG with an R- and an S-biphenyl bond and theasinensin B is the dimer formed by the conjunction of EGCG and EGC, whereas theasinensin C is a dimer of EGC (Tanaka et al. 2003; Matsuo et al. 2006).

Theasinensins can be found in fermented teas, namely, black and oolong. They are synthetized during the fermentation process, in which the two dominant catechins in fresh tea leaves – EGCG and EGC – are oxidized by polyphenol oxidase. As a result corresponding quinone derivative is produced, which undergoes stereoselective dimerization to produce theasinensin (Tanaka et al. 2003).

The pathways in which TSs are formed are very interesting. Hashimoto concluded that theasinensins are much more easily synthetized by polyphenol oxidase, compared to theaflavins (Hashimoto et al. 1992). The crucial point during the formation of TSs is the enzymatic oxidative coupling of pyrogallol rings of EGCG. This reaction could be also conducted using chemical agents. There are different pathways in which theasinensins and theaflavins are formed. The latter one are formed during the oxidative condensation reaction between catechol moiety of EC or ECG and a pyrogallol moiety of EGC and EGCG, which was described

previously. The pathway in which theasinensins are formed involves conjunction of pyrogallol-type B rings of EGCG and EGC. TFs are synthetized in the first step of black tea production, when leaves are crushed and kneaded. At this point TSs are not observed. They are formed when the leaves are heated in the temperature of 80 °C. One of the most important intermediates during the synthesis of TSs is unstable dehydrotheasinensins. They are formed from the oxidation of pyrogallol-type B ring catechins. During the final stage of black and oolong tea production (heating and drying process of the tea leaves), dehydrotheasinensins undergo redox dismutation to form corresponding theasinensins. It was elucidated that the transformation of dehydrotheasinensin A gives theasinensins A and D. Moreover it was implied that this process may be a nonenzymatic process, which spontaneously occurs during heating and drying of the tea leaves. Such a process may be also conducted in vitro in the nonenzymatic way (Weerawatanakorn et al. 2015b). Shii and co-workers obtained dehydrotheasinensin A by a nonenzymatic oxidation of EGCG by copper salts at the room temperature and pH 4–5. The efficacy of the reaction increased with the elevated temperature (Shii et al. 2011).

19.4.2 Biological Properties of Theasinensins

Although the scientific literature is rich in information on the biological properties of green and black teas, the data regarding oolong tea and its main active compounds – theasinensins – are still limited. Because majority of experiments evaluating biological activity of theasinensins are in vitro experiments, and oolong tea is the tea most equated with theasinensins, below in vivo studies on the activity of the pure compounds as well as its main source were presented.

19.4.2.1 Antioxidant Activity

It is obvious that, taking into account, that the main active ingredients of oolong tea are polyphenols, this product will be strong antioxidant agent – similar to green and black teas. In vivo study revealed that the consumption of oolong tea temporarily moderately increased the antioxidant capacity of human plasma. It was further observed that oolong tea reduced oxidative stress and DNA damage caused by free radicals (Higdon and Frei 2003). Study performed on athletes revealed that the consumption of oolong tea for 30 days significantly reduced the levels of malondialdehyde at rest and after exercise. The resting levels of SOD (superoxide dismutase) were also reduced. Moreover it was found that oolong tea decreased the level of lipid peroxidation and normalized the cholesterol profiles (Tsai et al. 2005). Theasinensin C, among all theasinensins isomers, was considered as the strongest antioxidant agent against lipid peroxidation (Weerawatanakorn et al. 2015b).

19.4.2.2 Anti-inflammation

Several studies demonstrated anti-inflammatory activity of oolong tea and its active constituents. It was shown that ethanol extract from oolong tea increased angiogenesis and adiponectin gene expression in epididymal fat, which was considered as

anti-inflammatory effect. Moreover this extract was proofed to have beneficial effects on metabolism and inflammation through pro-angiogenic activity during adipose tissue expansion (Weerawatanakorn et al. 2015b). On the molecular basis, it was shown that ethanol extract from oolong tea reduced the concentration of monocyte chemoattractant protein-1 (MCP-1) in serum, a small cytokine responsible for gathering monocytes, memory T cells, and dendritic cells to the site of injury (Tchernof and Despres 2013). Moreover it was elucidated that theasinensins A and D reduced LSP-induced COX-2 and PGE_2 synthesis, and this effect was stronger in the case of theasinensins B, C, and E. It was proposed that the galloyl moiety (present in the isomers A and D) plays an important role in anti-inflammatory activity of this group of compounds (Hou et al. 2010). It was also discovered that theasinensin A caused changes in 1382 genes responsible for chemokines, interleukins, and interferons production, thus strongly interfering in the immune defense system (Chen et al. 2011). Continuation of experiments elucidated new molecular pathways of the influence of theasinensins on immune defense components – theasinensin A significantly reduced the levels of inflammatory mediators like inducible oxidase synthetize (iNOS), nitric oxide (NO), interleukin-12 (p70) (IL-12), tumor necrosis factor alpha (TNF-α), and MCP-1. Cell signaling pathways were also modified through the action of theasinensin A – downregulation of MAPK/ERK kinase (MEK)-extracellular signal-regulated kinase (ERK) signaling through a direct binding to MEK-ERK was proofed (Weerawatanakorn et al. 2015b). These findings were confirmed in the mouse paw edema model – theasinensin A inhibited the production of IL-12 (p70), TNF-α, and MCP-1 and attenuated the inflammation in mouse paw edema caused by lipopolysaccharide LPS (Hisanaga et al. 2014).

19.4.2.3 Anti-obesity Activity

Oolong tea was proofed to possess significant activity toward the reduction of weight. Although such experiments were not conducted for particular theasinensins, a study performed on high-fat diet-induced obese mice revealed reduction of fat production through the inhibition of pancreatic amylase. This caused significant decrease in lipid absorption and increased lipid excretion into the feces. Another study demonstrated that the supplementation with oolong tea reduced the concentration of LDL-cholesterol, total cholesterol, and triacylglycerols in serum plasma in rats and decreased their weight. Oolong tea was also proofed to strongly decrease the levels of triacylglycerols in comparison to green tea. Oolong tea was also proofed to increase plasma levels of SOD and weight ratios of the liver to epididymal adipose tissue in rats. The fact that oolong tea reduces the levels of MCP-1, a protein which concentration is positively associated with higher incidence of obesity, indicates that active constituents of oolong tea may play a beneficial role in the prevention of this disease (Weerawatanakorn et al. 2015b).

19.4.2.4 Anticancer Activity

Several studies reported that oolong tea may be characterized by strong cancer-chemopreventive properties, similar to green or black teas. Some authors suggested that catechins play a dominant role and were mostly responsible for this activity.

However there are not much research performed to investigate anticancer activity of theasinensins. In theory since initiation and/or prolongation of different types of cancers is connected with inflammation and generation of free radicals, significant anti-inflammatory and antioxidant properties of theasinensins may play a crucial role in cancer prevention caused by oolong tea and its active constituents. In vitro studies revealed molecular basis of potential anticancer activity of TSs. Using two cell lines – human histolytic lymphoma (U937) and acute T-cell leukemia (Jurkat) – it was shown that theasinensin A, extracted from oolong tea, induced apoptosis through the release of cytochrome c into the cytosol and activation of caspase-9 and caspase-3, loss of mitochondrial transmembrane potential, and elevation of free radicals production (Pan et al. 2000). Maeda-Yamamomota and co-workers investigated potential role of tea polyphenols in the inhibition of metastasis using human fibrosarcoma HT1080 cells. The study revealed weak antimetastatic activity of theasinensin D in comparison to theaflavin and ECG, which was considered as the most active (Maeda-Yamamoto et al. 1999).

There are limited data on anticancer activity of particular theasinensins in the in vivo model. Study performed by Zhang and co-workers revealed that oolong tea, similar to black and green teas, induced apoptosis and arrested cell cycle in male Donryu rats (Zhang et al. 2000). However no particular theasinensins were used in this experiment, so it is not obvious if this activity was caused by catechins, TSs, or other active compounds present in oolong tea extract. Oral administration of theasinensin A in mice with carbon tetrachloride (CCl4)-induced fibrosis relieved liver injury and ameliorated liver functions. Immunohistological staining has shown that supplementation with theasinensin A reduced collagen deposition and inhibited inhibition of transforming growth factor β (TGF-β). It was concluded that theasinensin A may be considered as a potential bioactive compound from oolong tea, which prevents liver fibrosis (Hung et al. 2017). Based on previous studies, it could be concluded that chemopreventive effects of oolong tea extracts are due to its anti-inflammatory, antimutagenic, and anti-genotoxic activity; however there are still not many experiments performed on pure theasinensins in the in vivo model (Weerawatanakorn et al. 2015b).

19.4.2.5 Hypoglycemic Effect

Aqueous extract from oolong tea, similar to green and black teas, was proofed to increase insulin activity by 15-fold in an epididymal fat cell assay (Anderson and Polansky 2002). No impact of oolong tea on Na^+-dependent glucose cotransporter (SGLT1) was shown in frogs (Xenopus oocytes) compared to tea catechins (Hossain et al. 2002). A study performed on 20 people (women and men, average age of 61.2 years) suffered from diabetes since almost 5 years, which have obtained 1500 mL of oolong tea per day for 30 days, revealed significant decrease of plasma glucose from 229 to 162.2 mg/dL and fructosamine from 409.9 to 323.3 μmol/L. Water was used as control. It was also proofed that the combination of oolong tea and hypoglycemic drugs can cause stronger effects toward reducing

blood glucose than taking the drugs alone (Hosoda et al. 2003). It was indicated that crucial compounds of oolong tea responsible for this activity are theasinensins. Studies performed in mice and rat models revealed that theasinensin A reduces serum glucose levels by over 30%, inhibits glucose production and absorption in the intestine through suppression of α-glucosidase activity, and induces antihyperglycemic responses by suppressing fat absorption. Other studies performed using cell lines have shown that theasinensins A and B can promote glucose cell uptake and improve insulin resistance by regulation of GLUT 4, which is insulin-regulated glucose transporter present predominantly in adipocyte and striated muscle tissue. It was also revealed that this mechanism differs from EGCG, which can also regulate the activity of GLUT 4 (Weerawatanakorn et al. 2015b).

19.4.2.6 Prevention of Cardiovascular Diseases

There are epidemiological studies which have proofed beneficial effects of oolong tea consumption toward the cardiovascular system. An epidemiological study was performed on 1507 subjects from Taiwan. The study revealed that 600 were habitual tea drinkers (green or oolong tea) who consumed at least 120 mL of tea infusion per day during the period of 1 year or more. The study revealed that in the group of habitual tea drinkers, the risk of developing hypertension was reduced by 46% for those who drank 120–599 mL of tea per day and was further reduced by 65% for those who drank 600 mL or more. Unfortunately the study did not separate people who drink green from oolong tea (Yang et al. 2004). Since high-fat and cholesterol diet was proved to increase the risk of atherosclerosis and coronary heart disease, activities leading to decrease lipid intake and absorption and causing higher energy expenditure (EE) are considered crucial in decreasing the risk of cardiac diseases. Hsu and co-workers have shown that the consumption of polyphenol-enriched oolong tea increases fecal lipid excretion in patients taking high-fat diet (Hsu et al. 2006). Moreover, a study performed on 11 healthy Japanese women proved beneficial effects of oolong tea drinking for the increase of energy expenditure. This experiment showed that oolong tea increased EE by 10% and green tea by 4%. Since green tea contains on average two times more caffeine and EGCG in comparison to green tea, the authors suggested that polymerized polyphenols present in oolong tea, of which theasinensins are the major fraction, are responsible for this activity (Komatsu et al. 2003). Study performed by Rumpler and co-workers revealed similar results, oolong tea consumption increased EE and fat oxidation. Its consumption can help to maintain low body weight and reduce the risk of atherosclerosis and hypertension (Rumpler et al. 2001). Oolong tea was proved to reduce the atherogenic index and increased the HDL-total cholesterol ratio in rats fed with high-fat diet (Yang and Koo 1997). Above findings confirmed beneficial effects of oolong tea consumption on the prevention of cardiovascular diseases; however there is still lack of data on the bioactivity of theasinensins toward heart diseases which could be found in the literature.

19.4.2.7 Antimicrobial Activity

Several studies have reported the activity of oolong tea extracts or particular theasinensins toward the inhibition of pathogen growth. Among them the following strains may be mentioned: *Streptococcus sobrinus* 6715, *Bacillus subtilis*, *Escherichia coli*, *Proteus vulgaris*, *Pseudomonas fluorescens*, *Salmonella* sp., *S. mutans MT8148R*, and *Staphylococcus aureus* (Weerawatanakorn et al. 2015b). All of these studies were performed in vitro, and no in vivo studies for antimicrobial activity of theasinensins can be found in the scientific literature at the moment.

19.4.3 Conclusions

Theasinensins are still poorly understood. There is a need to continuing studies on the content of particular TSs in black and oolong teas. As for now there are some reports which showed that the major theasinensin is theasinensin A, which concentration was higher compared to theasinensins B and D. It was also proved that the concentration TSs in oolong tea is 0.65% and was much higher compared to green tea (0.05%). More studies regarding the activity of particular theasinensins in the in vivo model, as well as scientific data regarding their absorption, metabolism, and microbial degradation, are needed to extend the knowledge on these polymerized polyphenols.

19.5 Patents

The screening for patents regarding polymeric polyphenols from tea gives over 7,000 of results. The biggest part regards theaflavins (almost 5,000 results), which are the best-studied from all condensed tea polyphenols. The majority of these inventions disclose the production process, biological activity, and usage as food components or dietary supplements. The table below shows selected patents regarding theaflavins, thearubigins, and theasinensins (Table 4).

19.6 Summary

Tea contains a large number of active substances. Its positive influence on the human organism is known since centuries. During production process of fermented and semi-fermented teas (mainly black and oolong), simple catechins are oxidized to form polymeric polyphenols. These substances have not been fully understood yet, and studies on understanding their structure, synthesis pathways, and biological properties are still carried out. Currently, it is known that they have many beneficial

Table 4 Selected patents regarding polymeric polyphenols from tea

Patent number	Country	Title	Brief description	Year
Theaflavins				
CN101096693A	China	*Method for preparing theaflavin and thearubigin from fresh green tea*	The invention discloses a making method of theaflavin and Congo red element from fresh green tea, without using toxic and harmful organic solvents	2007
US7157493B2	USA	*Methods of making and using theaflavin, theaflavin-3-gallate, theaflavin-3′-gallate and theaflavin 3,3′-digallate and mixtures thereof*	The invention discloses methods of making a mixture of theaflavin, theaflavin-3-gallate, theaflavin-3′-gallate, and theaflavin 3,3′-digallate, usage in pharmaceutical industry and production of dietary supplements	2003
CN1729807A	China	*Process for preparing keemun black tea with highly concentrated theaflavin and thearubigins*	The invention discloses a process for preparing keemun black tea rich in theaflavins and thearubigins	2004
US5532012A	USA	*Process for preparation of purified tea components using preconcentration by cream separation and solubilization followed by medium pressure chromatography and/or preparative HPLC*	The invention describes a method of obtaining selected tea polyphenols, including theaflavins, using liquid/liquid extraction and chromatographic techniques	1995
CN101808529A	China	*Process for extracting theaflavins from tea*	The invention describes process of extraction of theaflavins from tea leaves using water and ethyl acetate simultaneously or sequentially. As the result ethyl acetate extract rich in theaflavins is obtained	2007
US20090098224A1	USA	*Metabolic-enhancing properties of theaflavins and thearubigins*	The invention discovered that theaflavins and thearubigins reduce appetite and adipose tissue, increase metabolism and energy expenditure, and enhance lean body mass	2007

Table 4 (continued)

Patent number	Country	Title	Brief description	Year
CN102524536A	China	*Application of theaflavin as feed additive and corresponding feed*	Application of theaflavin as the food additive in the concentration of 0.015–0.045% in different foods, e.g., fish meal, bean pulp, or peanut meal	2011
JP2009268420A	Japan	*Functional food composition*	The purpose of the invention is to produce a functional food with an inhibitory potential toward α-glucosidase and lipase containing different theaflavins in the concentration of 2–10%	2008
Thearubigins				
CN101473880B	China	*Method for extracting and separating thearubigins from black tea*	The invention describes method for separation of thearubigins from black tea using simple extraction equipment. The biggest advantages of the proposed method are low costs, high efficiency, and low impact on the environment	2009
CN101518597A	China	*Application of thearubigins to pharmacy*	The invention describes a new purpose of thearubigins in the field of pharmacy as natural products which can be used for treating or preventing type II diabetes, lipogenous diabetes, and adiposis. Moreover the invention proves that thearubigins have no toxic side effects and are safe and reliable to take	
CN108522674A	China	*Processing method of high-quality black tea*	The invention describes the production process of high-quality black tea. One of the advantages is the promotion of theaflavin and thearubigin	2018

(continued)

Table 4 (continued)

Patent number	Country	Title	Brief description	Year
			formation through the increased oxidation of simple catechins by polyphenol oxidase and beta-D-glucosidase	
CN106509478A	China	*Feed additive for improving immunity and antioxidation ability of river crabs and preparation method thereof*	Composition of food additive, containing among others 20–40 parts of thearubigin, for improving the immunity and antioxidation ability of river crabs	2016
CN107156310A	China	*Instant health-care antiaging soybean milk powder*	The invention relates to the technical field of production of instant health-care antiaging soybean milk powder containing among others thearubigin	2017
CN105285189A	China	*Making method of black tea cakes*	The invention describes the production of black tea cakes rich in thearubigins with the reduced amounts of theaflavins	2015
CA2762665A1	Canada	*A prebiotic composition comprising thearubigin*	The invention proposes the usage of black tea polyphenols (containing 82% of thearubigins) as a prebiotic and/or for the treatment or prevention of conditions associated with poor gut health or low immunity	2010
CN106578219A	China	*Method for highly efficiently purifying thearubigins prepared through chemical oxidation of tea polyphenol*	The invention describes purification methods of thearubigins obtained through chemical oxidation of tea polyphenols. The method removes sodium chloride with high efficiency and allows to obtain high-purity thearubigins	2016
Theasinensins				
KR101296418B1	South Korea		The invention provides food and beverage	2005

Patent number	Country	Title	Brief description	Year
		Lipase inhibitor containing theasinensins	containing lipase inhibitor based on a mixture of theasinensins (A, B, and D)	
US20110064851A1	USA	*Method of producing fermented tea drink rich in theaflavins*	The invention describes the method for preparing a fermented tea drink rich in theaflavins and theasinensins A and B, characterized by little bitterness and astringency, characterized by excellent taste and sweetness	2009
JP2010138103A	Japan	*Method for producing theasinensin*	The invention presents method for producing theasinensin by oxidizing EGC and/or EGCG in the presence of a nonhomogeneous catalyst and then reducing the obtained product. The method provides higher efficiency compared to the conventional methods	2008
CN104621291A	China	*Method for extracting and preparing theasinensin from tea leaves*	The invention discloses solid-liquid extraction of theasinensins from tea leaves using acetone solution	2015
JP2010189321A	Japan	*Cholesterol-lowering agent*	The invention describes cholesterol-lowering agent based on natural products, which contains theasinensin	2009

effects on the body and in the future they can be used in the pharmaceutical and food industry on a much larger scale than at present.

J. Xiao et al. (eds.), *Handbook of Dietary Phytochemicals*,
https://doi.org/10.1007/978-981-15-4148-3_21

Abstract

Stilbenoids are naturally occurring polyphenols, found in several edible plants, such as berries, peanuts, and grapes, which have been attracting increasing interest owing to their potential benefits for human health, namely, to prevent and treat chronic diseases related with aging. They can be constitutively expressed or biosynthesized as phytoalexins. Structurally characterized by a C6–C2–C6 scaffold, they can be found as monomers, dimers, trimers, or very complex oligomers. In this chapter, the focus will be on dietary stilbenoids found in the *Vitis vinifera*, namely, in grapes and wine, which are the principal dietary source of stilbenes. Among them, *trans*-resveratrol is the most extensively investigated stilbene. The main bioactive constituents, bioavailability and metabolism, the *in vivo* biological properties of the major constituents, and their role in human health, application in food, as well as issues related with safety and marketed and patented products will be also discussed.

Keywords

Stilbenes · *Vitis vinifera* · Wine · Polyphenols · Oligostilbenes · *Trans*-resveratrol · *In vivo* studies · Bioavailability · Metabolism · Clinical trials

20.1 Introduction

Stilbenes or stilbenoids are plant-derived polyphenols, occurring in several plant families being particularly abundant in Gnetaceae, Pinaceae, Cyperaceae, Fabaceae, Dipterocarpaceae, and Vitaceae (Rivière et al. 2012). They have been attracting increasing interest due to their diverse biological activities and potential benefits for human health, namely, cardioprotection, neuroprotection, antidiabetic properties, anti-inflammation, and cancer prevention and treatment, making them important lead compounds in drug discovery and development. An important example of this is *trans*-resveratrol (*trans*-3,4′,5-trihydroxystilbene, **1**), commonly known as resveratrol, which has shown several biological activities, including strong antioxidant effects, thus providing cardiovascular protection by reducing oxidative stress. The cardioprotective effects of resveratrol have been connected to the "French Paradox." The term is related to the paradoxical epidemiological observation that French population has a low incidence of coronary heart disease, despite the high intake of saturated fats. It was hypothesized that French paradox might be owing to the consumption of red wine, which may contradict the negative effects of a diet rich in saturated fat. This conclusion fostered the interest in the overall phenolic constituents of red wine and particularly in resveratrol that has been extensively investigated (Akinwumi et al. 2018).

In plants, stilbenoids can be constitutively expressed or can be synthetized as phytoalexins in response to fungal and bacterial pathogens and/or to other environmental stress factors (Xiao et al. 2008). This class of secondary metabolites derives from phenylpropanoid and acetate-malonate pathway with a chemical structure

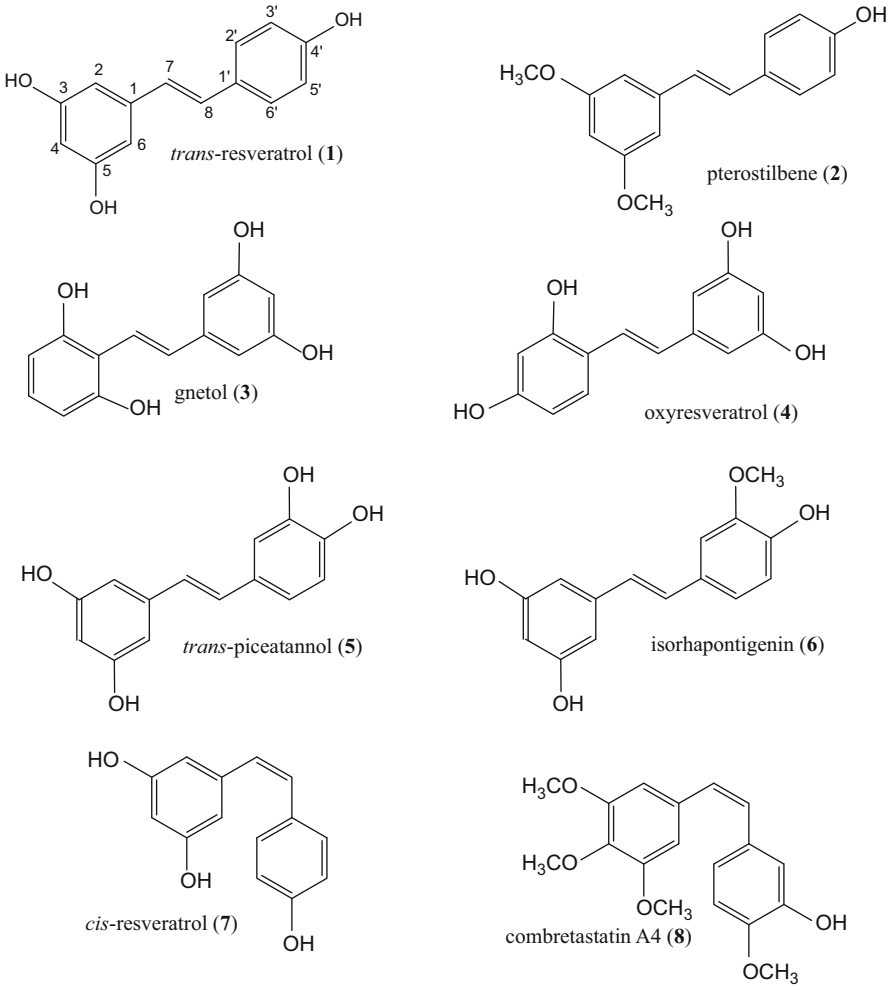

Fig. 1 Examples of monomeric *trans*-stilbenes (**1**–**6**) and *cis*-stilbenes (**7** and **8**) with hydroxyl and methoxyl substituents

based on a C6–C2–C6 backbone, where two phenyl rings are joined by an ethylene bridge. They can assume both a *trans* (*E* isomers, **1**–**6**, Fig. 1) and a *cis* configuration (*Z* isomers, **7** and **8**, Fig. 1), which elicits different pharmacological activities, being the *trans* isomer the most common and stable configuration in naturally occurring stilbenes. Structural variations in stilbenoids include different substituent patterns in the aryl groups, which may bear different hydroxyl, methoxyl, prenyl, or geranyl moieties and may also appear as glycosides (Figs. 1 and 2). They can be found as monomers and as very complex oligomers, which may result from oxidative coupling of monomeric stilbenes through C–C or C–O–C bonds of resveratrol (**1**), oxyresveratrol (*trans*-2,3′,4,5′-tetrahydroxy-stilbene) (**4**), piceatannol *(trans*-

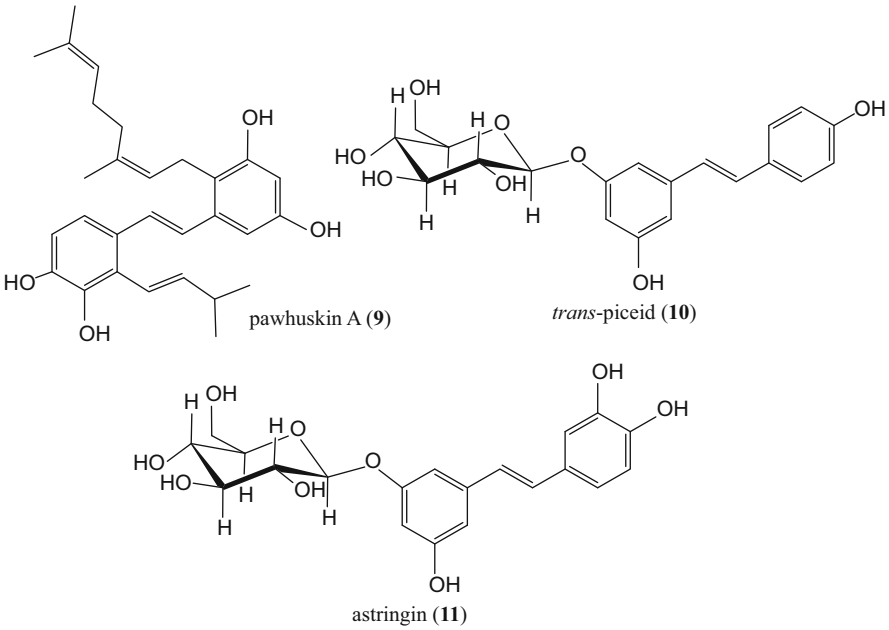

Fig. 2 Examples of monomeric stilbenes with prenyl, geranyl, and glycosyl substituents

3,3′,4,5′-tetrahydroxy-stilbene) (**5**) or isorhapontigenin (*trans*-3,4′,5-trihydroxy-3′-methoxystilbene) (**6**) (Pawlus et al. 2012; Rivière et al. 2012; Shen et al. 2009).

Vitis vinifera L. (Fig. 3) belongs to the Vitaceae family and is the main dietary source of stilbenes, which are consumed in the form of grapes, grape juice, and wine. The therapeutic and health-promoting properties due to the consumption of grapes and related products have been attributed to the presence of a complex combination of polyphenolic compounds, which includes not only monomeric stilbenes such as resveratrol (**1**) but also simple phenolics and flavonoids among others, being the latter the largest group (Georgiev et al. 2014).

In this review, the focus will be on the beneficial health effects of the dietary stilbenoids found in the *V. vinifera*. The activities of the main stilbenoids, found in grapes and wine, on relevant animal assays and clinical trials will be discussed in terms of bioavailability and metabolism, principal biological activities, and their role in human health. Application in food, as well as issues related with safety and marketed and patented products, will be also discussed.

20.2 Stilbenes in *Vitis vinifera*

Structurally characterized by a C6–C2–C6 scaffold, stilbenes are secondary metabolites derived from a mixed biosynthetic pathway (Fig. 4). In this way, one *p*-coumaroyl-CoA starter molecule, derived from the shikimate pathway, is

Fig. 3 *Vitis vinifera* (Pixabay 2019; Wikimedia commons 2019)

condensed to three malonyl-CoA molecules derived from the acetate pathway, giving rise to a polyketide chain (Dewick 2009). Stilbene synthase enzyme catalyzes the folding and subsequent cyclization through an aldol condensation reaction that generates the basic skeleton of stilbenes, represented by resveratrol (**1**). Further methylation, glucosylation, and prenylation reactions give rise to a myriad of stilbenoid derivatives.

Stilbenoids, found in several edible plants, such as berries, peanuts, and grapes, are considered promising compounds to prevent and treat chronic diseases related with aging (Khawand et al. 2018). More than 1000 stilbene derivatives have been identified (Pawlus et al. 2012), ranging from monomers to octamers and different substituent patterns. In Vitaceae family, they are found in several species, including *V. vinifera*, the most important species for wine production. In fact, red wine and grapes are the main dietary source of the most known and studied stilbene resveratrol (**1**). Resveratrol (**1**) and its derivatives, with several patterns of oligomerization and glycosylation, are also found in the whole plant, such as leaves, canes, wood, and roots of the grapevine and in larger amount than in grape berries (Gabaston et al. 2017).

Oligomeric stilbenes were previously classified into two main groups, according to the presence or not of at least one five-membered oxygen-containing heterocycle (Sotheeswaran and Pasupathy 1993). Owing to its limitation, there have been several attempts to improve this classification, by dividing first oligomeric stilbenes according to their monomeric moieties and heterogeneous coupling and then further classifying these based on the presence (group A; e.g., ε-viniferin, **12)** or absence (group B; e.g., pallidol, **13**) of oxygen-containing heterocycles (Fig. 5) (Shen et al. 2009).

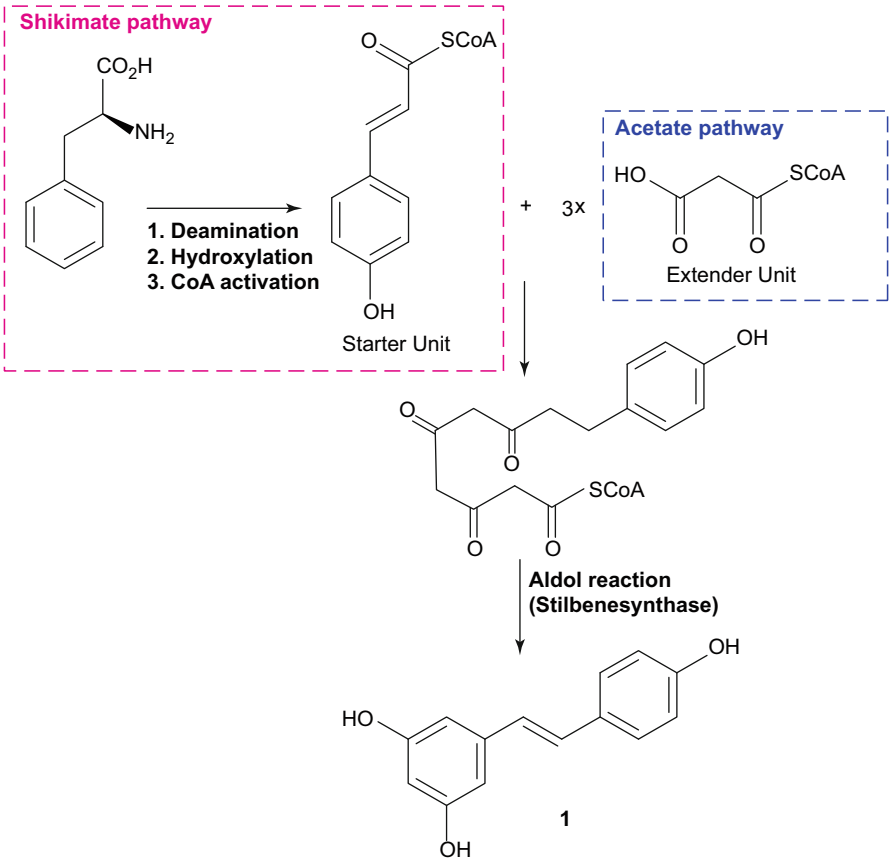

Fig. 4 Biosynthesis of stilbenes

Most of the stilbenes found in *Vitis* species as monomers are methoxylated and predominantly glycosylated derivatives of resveratrol (**1**) and piceatannol (**5**). The monomers can be found as *trans* and *cis* isomers such *trans*- and *cis*-piceid [*trans*-(**10**) and *cis*-resveratrol-3-*O*-β-D-glucopyranoside], pterostilbene (*trans*-3,5-dimethoxy-4′-hydroxy-stilbene) (**2**), and astringin (**11**), the 3-β-D-glucoside of piceatannol (Figs. 1 and 2). In *V. vinifera*, the number of these stilbenes is lower in wine than in grapes (ISVV database 2017).

Concerning the dimeric forms of stilbenes found in wine, most of them bear resveratrol (**1**) as monomer. They are essentially derivatives of viniferin and pallidol (**13**), being the most frequent ε-viniferin (**12**) (Fig. 5), the major oligomer found in *Vitis* species. While several trimers and tetramers (**13**) have been also found in *Vitis* species, including in different plant parts of *V. vinifera*, only one of these oligostilbenes, namely, the tetramer hopeaphenol (**13**, Fig. 6), has also been reported in wine. Two pentamers were isolated from *V. amurensis* roots, but there is no report for the presence of this type of oligomers in *V. vinifera*. Conversely, more recently,

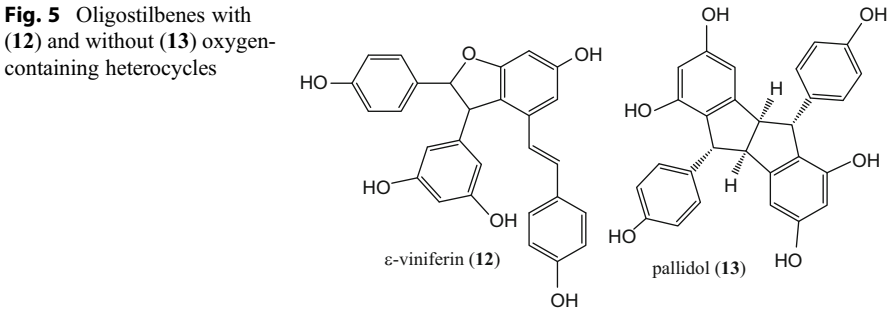

Fig. 5 Oligostilbenes with (**12**) and without (**13**) oxygen-containing heterocycles

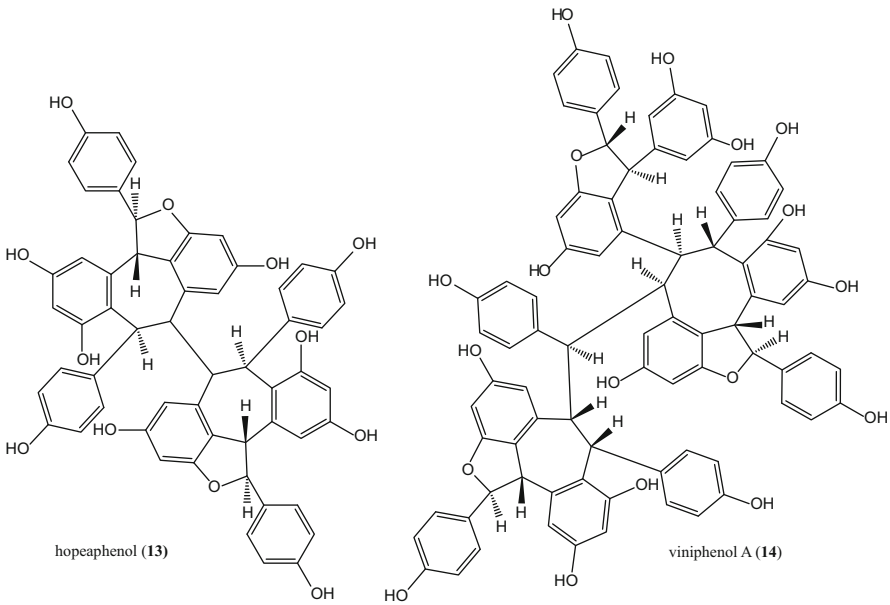

Fig. 6 Examples of oligostilbenes found in *V. vinifera*

the resveratrol hexamer viniphenol A (**14**) (Fig. 6) was isolated from the vine stalks of *V. vinifera* (Pawlus et al. 2012; Shen et al. 2017).

20.3 Bioavailability and Metabolism

In the last two decades, extensive studies have been conducted in order to find out the biological effects of stilbenes. Concomitantly, bioavailability and other pharmacokinetic preclinical studies have been performed in animal models and humans. In this regard, the most studied stilbene is resveratrol (**1**), although in recent years, pterostilbene (**2**) and piceatannol (**5**) have also begun to be explored. Unfortunately,

and notwithstanding all the promising biological effects reported for several disease models, the pharmacokinetic properties and bioavailability of these stilbenes are not so satisfactory, a fact that may limit their application in clinical use.

Despite its low water solubility (< 0.05 mg/mL), resveratrol (**1**) is rapidly absorbed at the small intestine by passive diffusion and undergoes a promptly and extensive phase II metabolic reactions catalyzed by uridine 5′-diphosphoglucoronyltransferases (UGTs) and sulfotransferases (SULTs) in the intestinal epithelial cells and liver. It is reported that after an oral administration of resveratrol, its plasma half-life is about 8–14 min and consequently only about 1–2% of its free form may be found in plasma (Dvorakova and Landa 2017). Resveratrol-3-*O*-glucoronide (**15**), resveratrol-4′-*O*-glucoronide (**16**), their sulfate analogues (**17**, **18**), and resveratrol-3,4′-*O*-disulfate (**19**) have been reported as the major phase II metabolites (Fig. 7). The conjugation to sulfates and glucuronic acid increases water solubility and allows the excretion by the kidneys, being these metabolites mainly eliminated in urine (Singh et al. 2015).

On the other hand, *in vitro* studies using human liver microsomes demonstrated the formation of two tetrahydroxylated resveratrol metabolites, piceatannol (**5**) and another one that was putatively identified as 3,4,5,4′-tetrahydroxystilbene (**20**), which resulted from phase 1 metabolic reactions. This study suggested the major role of cytochrome P450 (CYP), particularly the isoform CYP1A2 in this metabolic

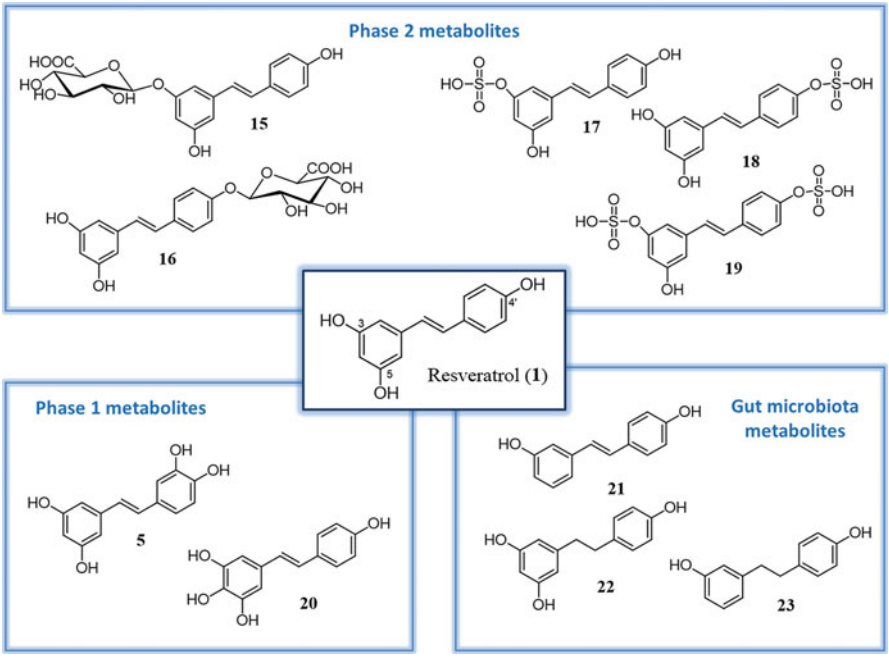

Fig. 7 Resveratrol metabolites resulting from phase 1 and 2 metabolic reactions and microbial biotransformation in gut

process (Piver et al. 2004). Other metabolites have been identified, in fecal samples, such as 3,4′-dihydroxy-*trans*-stilbene (**21**), dihydroresveratrol (**22**), and 3,4′-dihydroxybibenzyl (lunularin, **23**), highlighting the important function of gut microbiota in resveratrol metabolism (Fig. 6) (Wang and Sang 2018). The extensive metabolism of resveratrol decreases circulating levels of the free molecule; thus, it is suggested that biological effects could be also attributed to resveratrol metabolites or probably to the enterohepatic recycling involving biliary secretion, which may result in some deconjugation by gut microflora in the small intestine and reabsorption of the original molecule (Akinwumi et al. 2018).

However, the absorption and metabolic processes appear to be dependent on different factors, such as specific inter-individual variability, administration routes and doses, species, gender, disease status, and mode of consumption (fasting or with food or wine). Several studies carried out both on animals and humans compared the pharmacokinetics of resveratrol regarding different doses and treatment regimens and administrations routes (oral and intravenous). To study the influence of the administration routes on resveratrol pharmacokinetics in humans, ^{14}C-labeled resveratrol was administered orally or intravenously with doses of 25 and 0.2 mg, respectively (Walle et al. 2004). A high absorption rate was observed followed by an extensive biotransformation in both types of administration, resulting in only trace amounts of free resveratrol in the systemic circulation. After an oral dose of 25 mg, a total radioactivity of 491 ± 90 ng/mL (resveratrol and metabolites) was reached at about 1 h after the dose. Curiously, at around 6 h after consumption, a second peak plasma total radioactivity was observed, which was suggested to be a result of the enterohepatic recirculation of conjugated metabolites. The urinary excretion was assessed and indicated at least 70% of absorption and a recovery of total radioactivity ranging from 53.4% to 84.9% in urine after oral consumption. Similar results were obtained after the i.v. dose of 0.2 mg of ^{14}C-labeled resveratrol. One hour after the bolus injection, a rapid decrease of total radioactivity was observed on plasma, but the second plasma peak was not detected (Walle et al. 2004).

In a study performed in healthy volunteers that took orally low doses of resveratrol (5 or 50 mg), the main metabolites found in plasma were glucuronides. On the other hand, when high doses were administered (> 250 mg), resveratrol-3-*O*-sulfate (**17**) was the main identified metabolite. Interestingly, in plasma samples collected 11–21 h after intake, the main identified metabolite was the derivative conjugated with both glucuronide and sulfate moieties (Wang and Sang 2018).

In order to study the influence of different doses of resveratrol, a pharmacokinetic study was conducted by orally administering single doses of 0.5, 1, 2.5, or 5 g, in 10 healthy volunteers per dose level (Boocock et al. 2007). The rapid absorption of resveratrol was corroborated in this study, achieving a peak plasma concentration in the 0.83 h–1.5 h post-dose. Peak plasma levels of resveratrol at the highest dose were 0.54 ± 0.38 μg/mL achieved in the 1.5 h post-dose. Two monoglucuronides and resveratrol-3-*O*-sulfate (**17**) were the main identified metabolites, and their concentration exceeds those of resveratrol by up to 20-fold. The study also concluded that excretion rates were highest in the 4 h post-dose, and when the lowest dose was consumed, 77% of all urinary species were excreted within this period. In the 24 h

post-administration of the 0.5 g dose level, the amount of resveratrol excreted in the urine was below 0.04% of the dose, whereas urinary excretion of the three resveratrol conjugates ranged from 0.51% (one of the glucuronides) to 11.4% of the dose (resveratrol-3-*O*-sulfate, **17**). This study proved that only traces of resveratrol could be found in plasma even after high-dose consumption, suggesting that ingestion of resveratrol equivalent to the amount contained in several hundred bottles of red wine is not enough to elicit the biological effects associated with this compound (Boocock et al. 2007). The concentrations used in *in vitro* or *in vivo* studies with resveratrol supplements are too high to be reached in the organism after wine consumption. A very interesting research was conducted aiming at study resveratrol bioavailability after a moderate consumption of red wine (300–600 mL) associated with fasting and different meals: a standard meal and meals with high and low amount of lipids (Vitaglione et al. 2005). It appears that resveratrol bioavailability is not influenced by fasting, the type of meal, or the amount of lipid content. Moreover, it was demonstrated that resveratrol absorption and metabolism after wine consumption are highly variable, being found in the serum of roughly half of the subjects in free or in glucuronidated form and in very low concentrations. Other studies were carried out to study the matrix effects on the absorption and bioavailability. Theoretically, the absorption rate of resveratrol may increase when administered with a matrix that promotes its solubility (Peng et al. 2018). These researches comprised the moderate consumption of red wine, grape juice, resveratrol tablets, and different doses of resveratrol dissolved in different matrices, including white wine, grape juice, vegetable shakes, and diluted ethanol or whisky. Controversial results were obtained since some studies concluded that there were no significant differences wherever the type of matrix, whereas other studies claimed that absorption and bioavailability of resveratrol were higher when pure compound was administered (Peng et al. 2018).

It was also found that there is no significant difference between a single high-dose treatment and repeated administrations of resveratrol. In a double-blind, randomized, placebo-controlled study to investigate the multiple-dose pharmacokinetics, four groups of 10 healthy volunteers received 25, 50, 100, or 150 mg of resveratrol, six times/day (every 4 h), for 2 days (Akinwumi et al. 2018; Wang and Sang 2018). Similarly to other studies, peak plasma concentrations were reached at 0.8–1.5 h post-dose. Despite the multiple administrations, the degree of resveratrol accumulation in plasma was not significant even for the highest dose. However, high inter-individual variability and circadian variations were observed, being the residual plasma concentration highest after morning administration and lowest during the night (Akinwumi et al. 2018).

Although much less studied than resveratrol, the bioavailabilities of pterostilbene (**2**) and piceatannol (**5**) are nowadays beginning to be unraveled. In comparison with resveratrol, pterostilbene (**2**) has two methoxyl groups located at C-3 and C-5, which confer higher lipophilicity improving the cell permeability and increasing oral absorption. Moreover, pterostilbene (**2**) is considered to be more metabolically stable since it has only one free hydroxyl group available for phase 2 metabolic reactions; therefore, pterostilbene-4′-*O*-glucuronide (**24**) and pterostilbene-4′-*O*-sulfate (**25**) were characterized as its main metabolites (Fig. 8). Consequently, it seems that

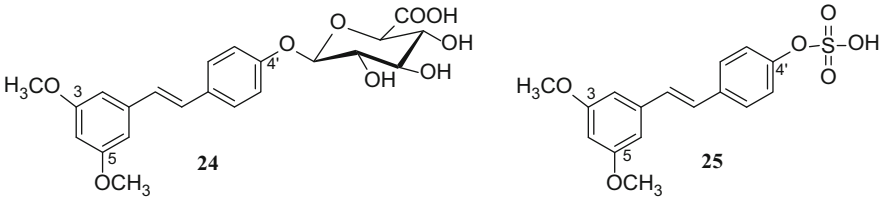

Fig. 8 Main metabolites of pterostilbene (**2**)

pterostilbene is tenfold more bioavailable than resveratrol (Akinwumi et al. 2018; Peng et al. 2018; Wang and Sang 2018).

Regarding piceatannol (**5**), the vast majority of studies is yet rather limited to cells and animal models. *In vitro*, piceatannol is considered to be a product of CYP450 metabolism of resveratrol. This was corroborated by *in vivo* studies, where piceatannol was also detected in plasma and liver of athymic mice, 5 min after oral administration of resveratrol (Kershaw and Kim 2017). Concerning piceatannol metabolism, *in vitro* studies using human liver cytosol and microsomes described the existence of sulfation and glucuronidation metabolic reactions and identified piceatannol disulfate, two monosulfated, and three monoglucuronide metabolites, although the exact location of the conjugated groups was not possible to be determined (Fig. 9) (Kershaw and Kim 2017).

After i.v. administration in rats, glucuronides seem to be the main metabolites. After intragastric administration, a piceatannol-monoglucuronide was found to be the most abundant metabolite, but other ones were also observed, such as sulfated and methylated metabolites, in particular isorhapontigenin (**6**) and rhapontigenin (**26**) (Fig. 9). Rhapontigenin (**26**) was also found in urine, as well as piceatannol mono- and diglucuronides, *O*-methylpiceatannol-monoglucuronide, and *O*-methylpicetannol-monosulfate. In contrast to piceatannol (**5**), methylated compounds were not found as metabolites of resveratrol (Kershaw and Kim 2017).

As mentioned above, oral bioavailability of resveratrol is highly compromised by its extensive metabolism and elimination rate (Peng et al. 2018). Currently, these factors are trying to be overcome by using drug delivery systems employing nanotechnology for resveratrol encapsulation, which comprise liposomes, polymeric nanoparticles, solid lipid nanoparticles, lipospheres, and cyclodextrins (Summerlin et al. 2015). Studies performed in animal models showed that these novel nanocarriers possess several advantages, including improved solubility, physicochemical stability, and protection from metabolic reactions thus overcoming first-pass effects. Moreover, such nanoformulations could enhance transport across the membranes, increasing concentration of resveratrol in tissues such as the brain, liver, and kidney, enabling targeted and controlled drug release (Siddiqui et al. 2015).

Recently, a clinical trial was designed by Calvo-Castro et al. (2018) in order to assess the improvement of the oral bioavailability of resveratrol from vineatrol by micellar solubilization (registration number: NCT02944097). Vineatrol is a standardized ethanolic extract of grapevine shoots that contains 33.3% resveratrol

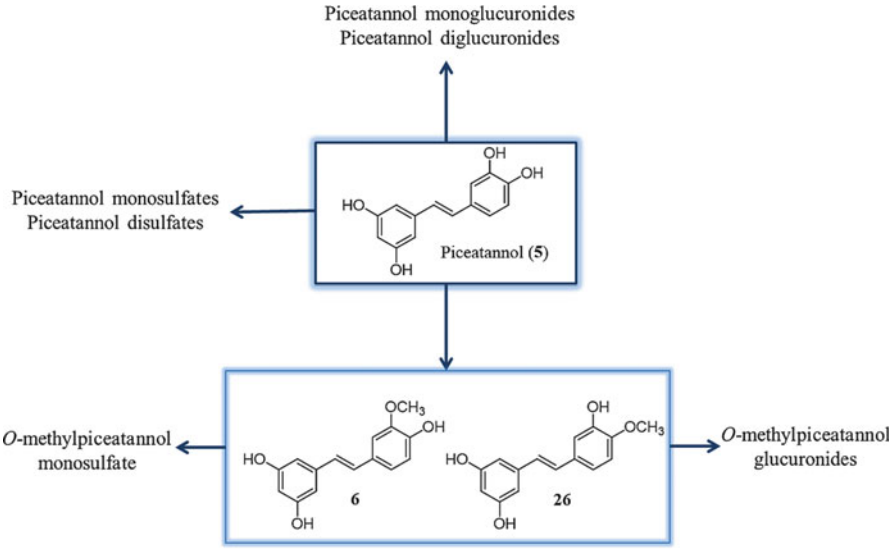

Fig. 9 Piceatannol metabolites

monomers and oligomers, including 5.8% resveratrol (**1**), 14.5% *trans*-ε-viniferin (**12**), and minor amounts of ampelopsin (2.4%), hopeaphenol (**13**) (2.2%), piceatannol (**5**) (0.5%), R2-viniferin (1.2%), R-viniferin (1.8%), miyabenol C (2.3%), and E-omega-viniferin (2.6%). Thus, twelve healthy volunteers (six women, six men) randomly ingested a single dose of 500 mg vineatrol (30 mg resveratrol, 75 mg ε-viniferin) as native powder or liquid micelles (placebo uncontrolled). Oral ingestion of the soluble vineatrol micelles improved the relative systemic bioavailability with of total resveratrol when compared to the native powder, without any indication of adverse effects. The mean maximum total plasma resveratrol concentrations after the intake were 300 and 28 nmol/L, respectively. The authors conclude that a micellar microemulsion provides a safe delivery of resveratrol in order to reach relevant bioactive concentrations to systemic circulation (Calvo-Castro et al. 2018).

20.4 Bioactivities of Stilbenoids: *In Vivo* Studies

Considering the bioactivities of stilbenes, using *in vivo* studies, there are several works describing the large benefit effects on different human health areas, such as hypolipidemic action, obesity, type 2 diabetes, and dementia prevention and anti-inflammatory, antioxidant, antiaging, anticancer, depigmentation, and cardiovascular effects. Several works, focusing on wine and grapes, have been reviewed regarding stilbenoids *in vivo* studies, emphasizing not only the well-studied resveratrol (**1**) but also pterostilbene (**2**), oxyresveratrol (**4**), piceatannol (**5**), piceid (**10**), (Figs. 1 and 2), and oligostilbenes (Table 1).

Table 1 Bioactivities of stilbenes from wine and grapes and main conclusions of recent works regarding animal studies

Stilbenes	Animal study	Main conclusions	References
Resveratrol (**1**), pterostilbene (**2**), oxyresveratrol (**4**) piceatannol (**5**), and *cis*-piceid (**27**)	Bioactivities review which includes animal studies in mice	Stilbenoids have different biological properties such as cardioprotection, neuroprotection, antidiabetic properties, depigmentation, anti-inflammation, cancer prevention and treatment	Akinwumi et al. (2018)
Resveratrol (**1**), pterostilbene (**2**), and piceatannol (**5**)	Anti-inflammatory activity review of animal studies in mice	Anti-inflammatory activity of natural stilbenoids as a promising group of potential anti-inflammatory drugs	Dvorakova et al. (2017)
Oligostilbenes found in grapes and wine	Review work in mice	Antioxidant, anti-inflammatory, anticancer, antimicrobial, antiviral, cardioprotective, neuroprotective, and hepatoprotective activities of grape stilbenes	Georgiev et al. (2014)
Resveratrol (**1**), piceatannol (**5**), and pterostilbene (**2**)	Review study in mice	Effects of stilbenoids: as antitumor, antiplatelet, antioxidant, antimicrobial, anti-inflammatory, analgesic, anesthetic, and a behavior of membrane-interactive drugs	Tsuchiya (2015)
Resveratrol (**1**)	Animal study in mice and rats	Resveratrol and other stilbenes: potential inhibitory effect on transient receptor potential (TRP) channels and modulation of TRP channel activity	Yu et al. (2013)
Resveratrol (**1**), piceatannol (**5**), and *cis*-piceid (**27**) astringin, resveratroloside, *cis*-resveratroloside	Animal organ study in mice	Stilbenoids: potential inhibition of cyclooxygenases and preneoplastic lesions	Waffo-Téguo et al. (2001)

In a previous study involving animal organs, Waffo-Téguo et al. (2001) indicated that resveratrol (**1**) directly inhibits the activity of COX-2. The authors investigated the inhibitory effects of grape phenols on carcinogen-induced precancerous lesions in mouse mammary grand organ cultures. In this study, 12 phenols isolated from grape plant cell cultures were used to evaluate the potential of inhibition of cyclooxygenases and preneoplastic lesion formation in carcinogen-treated mouse mammary glands in organ culture. This report showed the potential cancer-chemo-preventive activity of astringin (**11**), a plant stilbenoid found in wine. Astringin (**11**) and its aglycone piceatannol (**5**) revealed activity in the mouse mammary gland

organ culture assay but displayed no activity in COX-1 and COX-2 assays. Resveratrol (**1**) presented bioactivity in the same bioassays indicating that astringin (**11**) and piceatannol (**5**) may act as potential cancer-chemopreventive agents using a different mechanism from that of resveratrol (**1**) (Waffo-Téguo et al. 2001).

Yu et al. (2013) investigated whether resveratrol (**1**) and other stilbenoids could modulate TRP (transient receptor potential) channels in sensory neurons *in vitro* and had analgesic effects *in vivo*, using whole-cell patch-clamp techniques and behavioral analysis. This study showed that resveratrol (**1**) and other stilbenoids have a potential inhibitory effect on TRP channels, exerting its activity in different ways. TRP is a family of ion channels that are activated by physical (temperature and mechanical force) and chemical stimuli. Sensory TRP channels are sensitized by pro-inflammatory agents and mediate heightened pain sensitivity.

Studies on obesity and diabetes and using animal models have concluded that, in addition to the known anti-inflammatory and antioxidant activities, grape seed extract prevents metabolic syndrome, type 2 diabetes, and obesity (by modulating the metabolic endotoxemia and by improving the gut barrier integrity; Georgiev et al. 2014).

In 2017, Dvorakova and Landa reviewed the anti-inflammatory activity of resveratrol (**1**), pterostilbene (**2**), and piceatannol (**5**). Resveratrol (**1**) was described to inhibit the expression of cyclooxygenase-2 (COX-2) *in vivo* models using rats. Its analgesic properties against pain (acute or chronic) could be assessed through alterations of the expression of serum tumor necrosis factor-alpha and whole brain nitric oxide in the diabetic rat model, reduction of expression of COX-2 in inflammatory pain model, or inhibition of cyclin-dependent kinase 5 activity in primary afferent neurons.

Recently, Akinwumi et al. (2018) reviewed the biological properties of stilbenoids such as resveratrol (**1**), pterostilbene (**2**), oxyresveratrol (**4**), piceatannol (**5**), and *cis*-piceid (**10**). The biological activities covered were from cardioprotection, neuroprotection, antidiabetic properties, depigmentation, and anti-inflammation to cancer prevention and treatment. The properties described are thought to be mediated by different universal signaling pathways. The hypolipidemic effect of the dietary resveratrol (**1**) was studied in hepatoma-bearing rats where the antitumor growth and anti-metastasis effects were also determined. In addition, resveratrol (**1**) was studied on isolated rat hearts from ischemia reperfusion injury, and its potential cardioprotective effects were attributed to its peroxyl radical scavenging activity (Akinwumi et al. 2018).

20.5 Human Benefits

The potential biological activities of wine stilbenes have been the subject of several *in vitro* and *in vivo* studies. However, the link between these preclinical studies and the beneficial effects in humans is not totally clarified yet. At the time of this review, there were 152 trials registered in ClinicalTrials.gov dealing with resveratrol (**1**). A recent review covered some of the latest clinical trials using this stilbene (Ramírez-Garza et al. 2018). However, only a few studies deal with the effects of

resveratrol or other stilbenes from grapes or wine. Herein, examples of relevant clinical trials using stilbenes and grape extracts are reviewed (Table 2).

The first clinical trial dealing with the potential beneficial effects of grape powder in patients with colon cancer was published in 2009 by Nguyen et al. (registration number NCT00256334). This pilot trial was performed as a four-dose cohorts study. Eight patients, preselected due to colon cancer diagnosis, were randomly assigned to each cohort, being treated orally every day until surgery (14 days). Thus, two patients ingested 120 g/day of grape powder (0.114 mg of resveratrol); three patients ingested 80 g/day of grape powder (0.073 mg of resveratrol); one patient had 80 mg/day of plant-derived resveratrol tablets (15.5 mg of resveratrol); and two patients ingested 20 mg/day of plant-derived resveratrol tablets (3.9 mg of resveratrol). At the times of diagnostic colonoscopy and surgery, cancer and normal colonic mucosa tissues were obtained. These samples were evaluated by Wnt (wingless/integrated) pathway-specific microarray and quantitative real-time polymerase chain reaction (qRT-PCR), comparing pre- and postexposure to resveratrol or grape powder. The Wnt signaling pathway activates mutations essential for the development of colon cancer. On the cancerous tissues, the treatment with resveratrol or grape powder had no change in the composite Wnt target gene expression. However, on normal colonic mucosa, the treatment with 80 g/day of grape powder inhibited the expression of cyclinD1 and axinII (Wnt target genes). This had the lowest resveratrol content of all the cohorts but also had many other bioactive components (other polyphenols) not present in the plant-derived resveratrol capsules. This clinical trial presented some limitations such as a small sample size and no control of the dietary intake of the patients nor control of medication that could affect Wnt pathway. But despite the limitations, the authors suggest that low doses of resveratrol or consumption of grapes may have a beneficial role in colon cancer prevention.

Besides cancer chemopreventive activity, consumption of wine and grapes has often been associated with benefits for cardiovascular system. In this regard, a clinical trial was designed to investigate the effects of a dietary resveratrol-rich grape supplement in primary and secondary prevention of cardiovascular disease (registration number: NCT01449110).

For primary prevention of cardiovascular disease studies, 75 patients on statin treatment and at high risk of cardiovascular disease (diabetes mellitus or hypercholesterolemia plus arterial hypertension, active tobacco smoking, or overweight/obesity) took part of this trial. The subjects were randomly distributed through the three parallel arms (triple-blinded and placebo controlled): grape extract containing 8 mg of resveratrol and other resveratrol derivatives piceid (**10**) and viniferins in trace amounts (group A; $n = 25$), a grape extract with a similar polyphenolic content but lacking resveratrol (group B; $n = 25$), and placebo (group C; maltodextrin; $n = 25$). The treatments were encapsulated, and the patients consumed 1 capsule/day for the first 6 months and 2 capsules/day for the next 6 months to assess possible dose-response effects. Therefore, to evaluate the effects on the atherogenic markers, the authors only used data after the first 6 months of treatment (Tomé-Carneiro et al. 2012a). Group A showed significant decreases in the low-density lipoprotein cholesterol (LDLc; −4.5%), apolipoprotein B (ApoB; −9.8%), oxidized LDL (LDLox;

Table 2 Summary of clinical trials using stilbenes and grape extracts

Condition	Study design	Dosages	Biomarkers	Effects	References
Colon cancer	Randomized four-dose cohorts ($n = 8$) No placebo Duration 14 days	120 g/day of grape powder ($n = 2$) 80 g/day of grape powder ($n = 3$) 80 mg/day of plant-derived resveratrol tablets ($n = 1$) 20 mg/day of plant-derived resveratrol tablets ($n = 2$)	Wnt pathway: inhibition of expression of cyclinD1 and axinII	Beneficial for prevention of colon cancer	Nguyen et al. (2009)
Cardiovascular disease(CVD) primary prevention	Randomized three parallel arms, placebo controlled ($n = 75$) Duration 12 months	1 capsule/day for 6 months +2 capsules/day for the next 6 months Group A: grape extract with 8 mg of resveratrol ($n = 25$) Group B: grape extract without resveratrol ($n = 25$) Placebo ($n = 25$)	Atherogenic markers: reduced levels of ApoB, LDLox (group A) Inflammatory and fibrinolytic markers: reduced levels of TNFα, hsCRP, and PAI1 and increased IL-10 (group A)	Beneficial for prevention of CVD on patients with statin medication	Tomé-Carneiro et al. (2012a, b)

Cardiovascular disease secondary prevention	Randomized three parallel arms, placebo controlled ($n = 75$) Duration 12 months	1 capsule/day for 6 months +2 capsules/day for the next 6 months Group A: grape extract with 8 mg of resveratrol ($n = 25$) Group B: grape extract without resveratrol ($n = 25$) Placebo ($n = 25$)	Inflammatory markers in PBMCs: increased levels of adiponectin and downregulation of Kruppel-like factor 2, NF-$_K$B, activator protein-1, c-Jun, activating transcription factor 2, and CREB-binding protein (group A)	Beneficial	Tomé-Carneiro et al. (2013a)
Diabetes mellitus type 2	Randomized three parallel arms, placebo controlled ($n = 35$ male type 2 diabetic and hypertensive medicated patients) Duration 12 months	Same as Tomé-Carneiro et al. (2013a)	Inflammatory markers: alteration of miR-21, miR-181b, miR-663, miR-30c2, miR-155, and miR-34a and reduction of CCL3, IL-1, and TNF-α (group A)	Beneficial	Tomé-Carneiro et al. (2013b)
Cardiovascular	Randomized 2 × 2 block design ($n = 80$, patients with hypercholesterolemia with or without cholesterol medication), placebo controlled. Duration 6–8 weeks	Twice a day Group A:50 mg pterostilbene Group B:125 mg pterostilbene Group C:50 mg pterostilbene +100 mg grape extract Placebo	Increase of LDL levels (groups A and B) Reduced blood pressure (group B)	Beneficial for hypertensive population	Riche et al. (2013)

−20%), and LDLox/ApoB (−12.5%). On the contrary, no significant changes were observed for both groups B and C. In conclusion, the intake of one capsule/day of resveratrol-rich grape supplement significantly reduced LDLox and ApoB in patients undergoing primary prevention of cardiovascular disease with statin medication (Tomé-Carneiro et al. 2012a). Furthermore, for the evaluation of inflammatory and fibrinolytic markers, Tomé-Carneiro et al. (2012b) measured serum levels of interleukin (IL)-6, IL-10, IL-18, tumor necrosis factor-α (TNFα), soluble intercellular adhesion molecule-1 (sICAM1), high-sensitivity C-reactive protein (hsCRP), adiponectin, and plasminogen activator inhibitor type 1 (PAI1). After 1-year treatment, the key findings of this study were that the resveratrol-rich grape supplement (group A) significantly decreased the inflammation-related markers hsCRP (−26%), TNFα (−19.8%), PAI1 (−16.8%), and IL-6/IL-10 ratio (−24%) and increased anti-inflammatory IL-10 (19.8%). No significant effects were observed for the placebo and grape extract without resveratrol groups. The authors concluded that 1-year consumption of grape supplement enriched in resveratrol improved the inflammatory and fibrinolytic status in patients who were on statins for prevention of cardiovascular artery disease (Tomé-Carneiro et al. 2012b).

For the secondary prevention of cardiovascular disease studies, 75 patients who coronary syndrome, cerebrovascular accident or peripheric arteriopathy event occurred at least 6 months or more, before the recruitment took part of this trial, which followed the same design as described above, using the same treatment groups and duration (Tomé-Carneiro et al. 2013a). After 1-year treatment, the transcriptional profiling of inflammatory genes in peripheral blood mononuclear cells (PBMCs) was explored using microarrays and functional gene expression analysis. The main outcomes were observed for the group treated with resveratrol-containing grape supplement (group A). The increased levels of adiponectin levels (10%) prevented the increase of PAI1 levels, and downregulation of pro-inflammatory transcription factors (Kruppel-like factor 2, NF-$_{\kappa}$B, activator protein-1, c-Jun, activating transcription factor 2, and CREB-binding protein) was found to be modulated in PBMCs. The non-high-density lipoprotein cholesterol load was reduced in both groups A and B. In contrast, the placebo group showed significant decrease of the levels of adiponectin and IL-10 and increase of PAI1. The authors concluded the presence of resveratrol in the grape supplement was essential for the observed benefic effects and pointed toward further research on this nutraceutical as a possible safe coadjuvant food supplement in the follow-up of coronary artery disease patients (Tomé-Carneiro et al. 2013a).

These human studies have evidenced the cardioprotective benefits of resveratrol and grape extracts through the amelioration of inflammatory and atherogenic markers. Nevertheless, many of these biochemical markers are also involved in the development of type 2 diabetes mellitus (T2DM). Therefore, Tomé-Carneiro et al. (2013b) further investigated the molecular changes associated to the regular intake of the resveratrol-containing grape extract in PBMCs isolated from

hypertensive patients with T2DM. A subset of 35 male type 2 diabetic and hypertensive medicated patients, which took part in the larger clinical trial previously described (Tomé-Carneiro et al. 2013a), were analyzed in this study. The authors evaluated the changes in genes and microRNAs involved in the inflammatory response. The supplementation of these patients with resveratrol-rich grape extract during 1 year highly correlated with the alteration of a group of miRNAs involved in the regulation of the inflammatory response (miR-21, miR-181b, miR-663, miR-30c2, miR-155, and miR-34a) as well as with the reduction of the expression of pro-inflammatory cytokines (CCL3, IL-1, and TNF-α) and increase of the transcriptional repressor LRRFIP-1 (leucine-rich repeat flightless-interacting protein). Although the authors conclude that long-term supplementation with a grape extract containing resveratrol has beneficial immunomodulatory effects in circulating immune cells of T2DM hypertensive medicated patients, they do not discard the hypothesis of the combined action of resveratrol with other phenolic compounds present in the grape extract or with some of the specific medication administered to these patients (Tomé-Carneiro et al. 2013b).

On the subject of benefic cardiovascular effects of stilbenes, another clinical trial concerning the activity of pterostilbene (**2**) on metabolic parameters was conducted (registration number, NCT01267227). Eighty subjects with hypercholesterolemia (total cholesterol $\geq$200 mg/dL and/or baseline low-density lipoprotein cholesterol $\geq$100 mg/dL) were randomized in a 2 $\times$ 2 block design for presence of cholesterol medication into one of four groups: 50 mg pterostilbene, 125 mg pterostilbene, 50 mg pterostilbene plus 100 mg grape extract, and placebo. The treatments were taken orally, twice a day for 6–8 weeks. The endpoints of this study were high-density lipoprotein (HDL), low-density lipoprotein (LDL), triglycerides, blood pressure, and weight. In both groups treated with pterostilbene (**2**), there was an increase of LDL levels (17.1 mg/dL). This effect was not observed for the combination of pterostilbene (**2**) and grape extract. The presence of a baseline cholesterol medication appeared to attenuate LDL effects. Regarding the triglyceride levels, no significant results were observed for any group. Neither pterostilbene significantly affected HDL levels. Nevertheless, both systolic (−7.8 mmHg) and diastolic blood pressure (−7.3 mmHg) were reduced with 125 mg dose of pterostilbene. In conclusion, pterostilbene was able to increase LDL levels and reduce blood pressure when used in doses of 250 mg/day. The authors call the attention for future studies to evaluate high-dose pterostilbene (**2**) with grape extract in a hypertensive population (Riche et al. 2014). This clinical trial was also used to evaluate the effects on the safety of long-term pterostilbene administration in humans (Riche et al. 2013). Since some of the patients that took part on the clinical trial were taking statins, it was important to evaluate if there were any possible drug-drug interactions. It was concluded that pterostilbene did not demonstrate any biochemical hepatic adverse drug reactions nor had a direct effect of on measures of renal or glucose markers. In conclusion, pterostilbene was considered generally safe for use in humans up to 250 mg/day (Riche et al. 2013).

20.6 Application in Food: Wine Derivatives as Dietary Supplements and Related Products

Due to the health benefits attributed to polyphenolic compounds present in wine, during the last years, other options have been investigated. These include non-alcoholic wines, grape juices, powders, extracts, and other products obtained from grapevine, which show the same biological benefits but are devoid of the alcoholic content (Georgiev et al. 2016).

Regarding nonalcoholic wines, they can be an option for some social groups (as young adolescents, nondrinkers, drivers, etc.) who normally do not consume wine because of their content in alcohol. However, due to wine dealcoholization techniques, the quality, and, more importantly, the sensory characteristics are modified or even reduced. To overcome this setback, different techniques have been investigated in order to protect the organoleptic properties of nonalcoholic wines, for example, the membrane contactor and distillation under vacuum methods (Motta et al. 2017).

Without alcoholic content, powders obtained by freeze-dried wine and encapsulated in a maltodextrin matrix are being used as a source of wine polyphenols that can be added to other foods. This new product showed to have 3.7-fold more polyphenols than the same amount of red wine (Rocha-Parra et al. 2018).

A rich phenolic content powder can be also obtained from the pomace, the grape biomass discarded after the vinification process. A method to produce the dry pomace extract without using organic solvents was recently described. This extraction, based on aqueous cyclodextrins, showed to be an effective process to recovering phenolic compounds from food-derived products (Georgiev et al. 2016). It is known that pomaces obtained from red wines have higher content of phenolic and other natural compounds with antioxidant activity. Recently, Beres et al. (2017) reviewed the main applications of this powder grape pomace extract not only in food but also in pharmaceutical and cosmetic industries (Fig. 10).

By using a sieve, it is possible to separate the grape seeds from the pomace. Grape seeds have become increasingly popular on markets in different countries, such as the United States (Yamakoshi et al. 2002). From the seeds, it is possible to produce grape seed powder or grape seed oil or even dry grape seed extracts (Georgiev et al. 2016). These products are important due to their high polyphenolic content ranging from 60% to 70% of total extractable compounds and attract the interest of the pharmaceutical, cosmetic, and food industry as a cost-effective source of natural antioxidant compounds (Fig. 10). In market, it is possible to buy MegaNatural®-Gold Grape Seed Extract (Polyphenolics, USA) and Citricidal® grapefruit seed extract (NutriBiotic, USA) (Teixeira et al. 2014).

From the pomace, it is also possible to separate the grape skins by vibrating sieves. The powder obtained by prior dried and ground of the skins can be used as a nutraceutical or as a source to obtained pure antioxidant compounds, as the stilbenoid compound resveratrol (Georgiev et al. 2016). The pomace is also the origin of the so-called antioxidant dietary fibers. These soluble fibers are obtained by extraction of grape pomace using different techniques (Beres et al. 2017). Regarding their application (Fig. 10), some studies have shown the use of grape pomace and

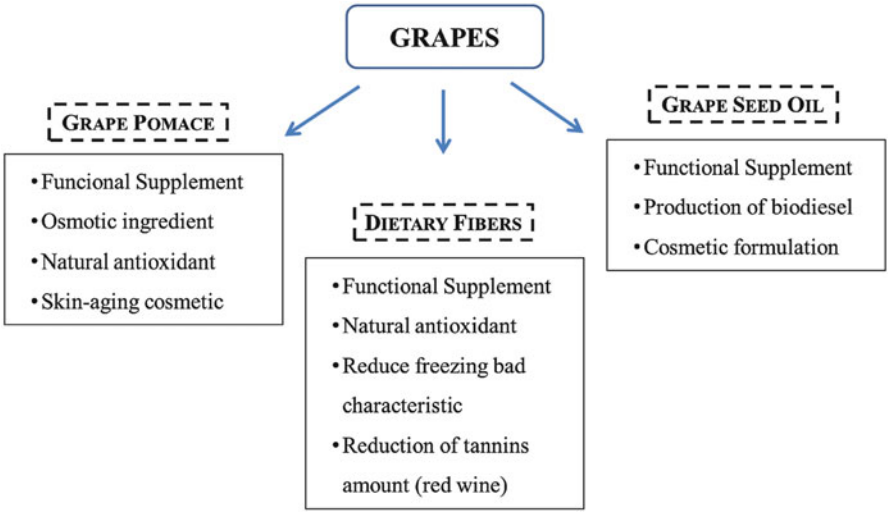

Fig. 10 Selected applications of grape derivatives

seed flours in different food products such as popsicles, cereal bars, biscuits and cookies, and muffins, in order to improve their content in antioxidant compounds (Beres et al. 2017). In order to prevent alterations such as flavor changes, color, texture, and lipid oxidation during freezing storage of some food products, for example, association of codfish or seafood with the extracted fibers obtained from pomace is being studied (Zhu et al. 2015; Beres et al. 2017). Moreover, studies in chicken breast hamburger are also being carried on (Beres et al. 2017).

20.7 Safety: Toxicity and Side Effects

During the last years, a high interest in natural product consumption and in particular resveratrol and related stilbenoids has been highlighted. The toxicity of resveratrol (**1**) has been exhaustively studied not only in animal models but also in humans. Regarding animal studies, the acute, subchronic, and chronic toxicity of resveratrol, synthesized by DSM Nutritional Products Ltd., was highly studied in multiple *in vitro* and *in vivo* animal assays (Williams et al. 2009). It revealed to be well tolerated and nontoxic, being a NOAEL (no-observed-adverse-effect level) for resveratrol defined as 0.75 g/kg bw/day dose (Edwards et al. 2011). In relation to its safety in humans, several studies have shown that at low doses, resveratrol is well tolerated; however more information is needed especially regarding its long-term use (Akinwumi et al. 2018). An important data is the acceptable daily intake (ADI) in humans for resveratrol, which was calculated by using data from animal toxicity studies and a standard default safety factor of 100 which gives an ADI of 0.45 g/day for a 60 kg individual (Edwards et al. 2011).

In a recent review (Wahab et al. 2017), it was reported that there are a small number of dose-independent adverse effects such as nephrotoxicity and gastrointestinal problems associated with administration of resveratrol in humans. It is highlighted that 0.45 g/day of resveratrol is a safe dose for a 60 kg person; however, its supplementation in higher doses could be slight toxic (Wahab et al. 2017). In fact, using daily doses of 2.5 g or higher amount of resveratrol, some minor side effects may occur, for example, nausea, vomiting, diarrhea, and liver dysfunction in patients with nonalcoholic fatty liver disease (Salehi et al. 2018). In another study, it is pointed that resveratrol was found to be safe and well tolerated and without any other new side effect when used in a long-term experiment or in doses up to 5 g/day (Ramírez-Garza et al. 2018). It is important to note that the results mentioned above were obtained in healthy population; therefore, caution must be taken concerning the results obtained in people that have some pathology (Salehi et al. 2018). Some of the last clinical trials using resveratrol are summarized in a recent review (Ramírez-Garza et al. 2018); however, further investigation is needed to evaluate the safety of resveratrol for long-term treatment.

It should be pointed that some adverse effects were also found for resveratrol. In fact, some studies have shown that resveratrol may act as a pro-oxidizing agent, contrarily to its widely known chemopreventive and antioxidant properties (Salehi et al. 2018).

It is extremely important to pay attention to possible interactions between resveratrol and other stilbenoid derivatives and conventional medicines. In fact, resveratrol may interact with several medical drugs (Salehi et al. 2018). In this regard, it was observed that high doses of resveratrol (1000 mg/day or above) inhibit cytochrome P450 isoenzymes such as CYP3A4, CYP2C9, and CYP2D6 and can induce CYP1A2, being responsible for a number of drug interactions, by changing drug clearance and consequently their bioavailability and toxicity (Wahab et al. 2017; Salehi et al. 2018). The interaction between resveratrol and anticoagulant, antiplatelet, or even nonsteroidal anti-inflammatory drugs could be a possibility, especially due to an intensification of both bruising and bleeding risk, associated to the reduction of human platelet aggregation activity showed by resveratrol when tested in *in vitro* assays (Salehi et al. 2018).

A recent review conducted by Zha (2018) showed also interaction between resveratrol and transporter proteins, especially with ABC transporter membrane proteins. In fact, it was reported that this natural compound could inhibit P-glycoprotein (P-gp), multidrug resistance-associated protein 2 (MRP2), and organic anion transporter 1/3 (OAT1/OAT3) and consequently could enhance the exposure of patients to some anticancer drugs.

It is also important to emphasize the interaction of red wine polyphenols with human microbiota. A study conducted by Queipo-Ortuño et al. (2012) indicated that consumption of red wine significantly increase the growth of some important microbiota bacteria identities, namely, *Enterococcus*, *Prevotella*, *Bacteroides*, *Bifidobacterium*, *Bacteroides uniformis*, *Eggerthella lenta*, and *Blautia coccoides* suggesting its possible prebiotic benefit.

20.8 Marketed Products

Wine is the most popular and widely discussed nutritional grape product with proven beneficial health effects on human body, when moderately consumed. However, it is important to highlight the different content of resveratrol/stilbenoids among different wines. On the other hand, it is known that the effective concentration of resveratrol in order to achieve the claimed biological activities may be higher than that obtained from wine drinking or food consumption. These reasons led to the constant search of new food sources and emphasized the potential of nutritional stilbenoid supplements (Navarro et al. 2018). Nowadays, the number of new food supplements containing pure resveratrol or this in a mixture of compounds is growing. However, mainly due to inadequate industry quality control, the majority of these supplements do not have the claimed concentration of resveratrol. This issue is highlighted by the work of Rossi et al. (2012). Resveratrol is also used by cosmetic industry. One promising and famous example is the cosmetic trademark Caudalie®, whose products contain as main ingredients resveratrol and other grapeseed polyphenols and stilbenoids. Its first patent is dated from 1999 and was related with compositions which are essentiality resveratrol esters, in the form of monomers and/or oligomers (Vercauteren et al. 1999). However, the search for new derivatives and methods to improve its cosmetic products is intense and constant as highlighted by a recent patent presented by the same industry. This patent is related with a new process for stimulating hyaluronic acid synthesis using resveratrol monomers and/or oligomers (Thomas et al. 2016). As showed above, the selection of the source of resveratrol is very important in order to obtain high amount of resveratrol and related stilbenoids with a realistic price. From the different strategies known, namely, the chemical synthesis and the use of by-products derived from tropical foods (mango pulp or even the guava) or from plants with little economical values or even from by-products of harvesting or wine production, the use of biotechnology and genetic engineering is increasingly attracting attention in the last years (Navarro et al. 2018). In fact, there are different engineering techniques that have been studied, namely, the production of resveratrol and related compounds, using microorganisms and enzymes. Kuo et al. (2017) described a successful approach to have mass production of resveratrol by using a small portion of extract of *Polygonum cuspidatum* and the wine yeast *Dekkera bruxellensis*. In this way, a repeated fed-batch fermentation process was scaled up to 1200 L in order to produce 35 mg of resveratrol per hour, liter, and round (Kuo et al. 2017). To produce higher quantity of resveratrol and other natural compounds, the genetic engineering, namely, transgenic organisms, is being used with very good results. A recent review summarized current progresses made in resveratrol biosynthesis, using bacterial hosts (Braga et al. 2018).

Regarding biotechnological approaches, plant cell biotechnology of grapes and mainly grape cell suspensions are seen as promising and alternative methods for producing bioactive nutraceuticals. In fact, the growth of grape cells in bioreactors for their production displays advantages when compared to the conventional breeding. In order to increase yields of these phytochemicals, several optimization

strategies have been used, as exemplified for the non-resveratrol-producing grapevine cell suspension of a grape hybrid, which produced resveratrol in the presence of methyl jasmonate. When scaling up the culture to a laboratory bioreactor, it achieved a yield of 230 mg/L (Georgiev et al. 2014).

20.9 Patents

Resveratrol is widely known as possessing a highly variety of biological benefits, including antitumor, antioxidant, anti-inflammatory, cardioprotective, neuroprotective, and other activities. Due to all beneficial activities, the number of food supplements containing resveratrol increases every day, and their study, as medicines, is a reality. However, their therapeutic use has been hindered by a number of factors that need to be solved. On one hand, until now, it is not known the real cellular or molecular targets of resveratrol. On the other hand, its low bioavailability and possible oxidative degradation during preparation for biological applications hamper the finding of a therapeutic dose that can benefit human health. These main reasons led to the development of different resveratrol derivatives with the objective of improving the therapeutic potential of resveratrol-based compounds (Li et al. 2016).

In a recent review, a total of 29 patents and over 200 resveratrol derivatives were reported. These derivatives were studied mainly to cancer, cardiac diseases, metabolic disorders, and neurologic diseases. The cited review also refers some studies regarding the application of resveratrol derivative patents in nutraceutical compositions and cosmetics (Li et al. 2016). In another review of patents, made from 2009 to 2012, these two classes of applications have been also discussed together with findings in the main therapeutic areas referred above (Pezzuto et al. 2013).

In a search of new patents from the last year, the same areas of research are pointed. As an example, a German patent describes the process for producing a skin care formulation containing dimers of resveratrol. This formulation could be used to topical application or pharmaceutical preparation of cosmetic skin care (Merryvital 2018).

20.10 Conclusions and Perspectives

Summarizing, stilbenoids are plant-derived polyphenols with several biological activities, which have been attracting increasing interest due to their potential benefits for human health. They can be found as monomers or very complex oligomers resulting from oxidative coupling of monomeric stilbenes, whose structural variations include different substituent patterns in the aryl rings. In human diet, the principal sources of stilbenes are grapes and wine. Despite the beneficial evidences of stilbenes on human health, there is still some ambiguity between high bioactivity and low bioavailability, namely, for resveratrol, the most studied stilbene. Consequently, further studies are crucial for evaluating the bioavailability and

other pharmacokinetic parameters of stilbenes, thus providing evidence for their therapeutic importance in human health. Their potential biological activities have been the subject of several *in vitro* and *in vivo* studies. Despite the reduced number of registered clinical trials addressing the human benefits of stilbenes from wine or grapes, the ones reviewed herein point to an increasing evidence that resveratrol and pterostilbene exert beneficial cardioprotective effects in medicated patients. Nevertheless, further studies are needed to unveil the underlying mechanisms by which this may occur and to establish correlations between the promising effects observed in animal models.

Due to the health benefits attributed to stilbenes in human health, the number of food supplements, medicines, and cosmetics in the market is increasing every day. However, in order to increase the number of stilbenes in health-promoting products, there are still some issues that need to be solved, namely, the source of resveratrol and quality control in industry production.

Abstract

Chlorogenic (CGAs), caffeic (CA), and ferulic acids (FA) are ubiquitously exist in plant foods, especially in coffee which is the most consumed beverages with fascinating economic, botanical, and historical significances. In the recent 20 years, there was an increase of interest in the health benefits of coffee in which CGAs, CA, and FA are considered important contributors for the bioactivities. Numerous scientific evidences exhibit that these phenolic components render a number of diverse biological activities including antioxidant, antimicrobial, anti-inflammatory, antiviral, anti-carcinogenicity, and antiaging effects. They are used as functional component in foods and various commercial products. This chapter reviewed the bioactive constituents, bioavailability, and metabolism of CGAs, CA, and FA and their derivatives in food, especially in coffee. We also summarized the biological activities of these phenolic acids in animal and human studies along with their toxicity and side effects, application in food, marketing products, as well as related patents.

Keywords

Coffee · Green coffee bean · Chlorogenic acid · Caffeic acid · Ferulic acid · Bioavailability · Bioactivity

21.1 Introduction

Clinical and epidemiological investigations have led to basic research for unraveling the chemistry and mechanisms of action of dietary phytochemicals. These studies have established the relationship between food or diet and health status. Natural health products and functional foods encompass a wide range of food/ingredients, with a variety of bioactive molecules which accountable for their efficacy in disease prevention and health promotion. Chlorogenic (CGAs), caffeic (CA), and ferulic acids (FA) are a significant group of secondary plant metabolites and are of substantial interest due to their perceived advantageous effects on health.

Plant origin foods such as coffee, yerba mate tea, fruits, and vegetables are rich in CGAs, CA, and FA (Table 1), among which coffee, especially green coffee bean, is one of the richest sources for CGAs (Saeed et al. 2019; Bagchi et al. 2016). Green

Table 1 Content of CGA, CA and FA in various sources of food

Sources	Foods	Content (mg/100g fresh weight)

Source: Adopted from Andres-Lacueva et al. 2010; Bagchi et al. 2016; Butiuk et al. 2016; Chen 2019; Gao et al. 1994; Hernandez et al. 1997; Marks et al. 2007; Mattila et al. 2005; Micard et al. 1997; Nakatani et al. 2000; Nishizawa et al. 1998; Risch and Herrmann 1988; Sakakibara et al. 2003; Saeed et al. 2019; Slimestad and Verheul 2009; Spanos and Wrolstad 1992; Zhao and Moghadasian 2008.

coffee bean contains 5–12 g/100 g CGAs (Sanlier et al. 2019), and the content of CGAs in roasted coffee depends on the degree of roasting and the type of beans. The loss of CGAs in roasted coffee beans ranges from 60% to 98% during the light or very dark roasting process. Daily intake of phenolic compounds ranges from less than 100 mg to over 2 g (Clifford 2004). In western countries, daily intake of coffee provides more than 1 g of CGAs, which is considered as the major contribution for the dietary phenolics (Del Rio et al. 2013). Except for coffee beans, coffee leaves, the by-product of coffee plants, have been made into tealike beverage which also contains abundant CGAs, CA, and FA. The content of these phenolic compounds depends on the species and cultivar of coffee plants, age of leaves, and the processing methods (Campa et al. 2012; Chen 2019; Chen et al. 2018b). *Coffea arabica* leaves contain higher (3.9% of dry leaves) CGA compared with that of *Coffea canephora* (robusta) leaves (2.4% of dry leaves) (Campa et al. 2012). Japanese-style-green tea-processed young coffee leaves retained greater CGAs than that of black tea-processed mature leaves (Chen et al. 2018b).

CA, the most common hydroxycinnamic acids, accounts for up to 70% of total hydroxycinnamic acids in fruits (Lafay and Gil-Izquierdo 2008). FA exists widely in cereal grains. FA is a commonly used food preservative that exhibited a wide range of biological applications such as antioxidant, immune-modulatory, growth-

enhancing, and antibacterial activities. They are generally esterified with quinic and tartaric acids or form conjugate with sugar. CGAs, CA, and FA are known to possess various bioactivities including antioxidant, anti-inflammatory, antimicrobial, anti-allergic, antidiabetic, antilipidemic, cardioprotective, neuroprotection, and hepatoprotective effects (Wianowska and Gil 2019; Espindola et al. 2019). Clinical studies also showed that consumption of CGA-, CA-, and FA-rich foods or administration of those pure phenolic acids has positive effects on Alzheimer's disease, Parkinson's disease, neurological behavior (infant hyperactivity), psychoactive responses, diabetes, gonad and liver function, cancer, and blood pressure (Dorea and Da Costa 2005). However, overdose of CGAs, CA, and FA also showed toxicity and side effects, such as causing hypotension, cardiovascular diseases, genotoxicity, and reproductivity problem (Butt and Sultan 2011).

In order to show efficacy in vivo, bioactive food components need to be bioavailable first. From a nutritional perspective, bioavailability is used to quantify the proportion of intake food that can be utilized by the human body and thus show efficacy. Bioavailability is a multistep process that involves releasing of bioactive components from the food matrix, absorption through the intestine, distribution to the circulation system and different organs, metabolism by phase I and II enzymes, and thus elimination out of body (Rein et al. 2013). Bioavailability is influenced by the bioaccessibility, composition of food matrix, structure and polarity of bioactive components, the transporters and enzymes, and gut microbiota. In food, the majority of phenolic compounds exist as conjugate form with other macromolecules, instead of free form. In the human body, after metabolization, phenolic compounds turn into different metabolites that possess different bioactivities compared with their parent compounds. Therefore, understanding the bioavailability of bioactive compounds from different food matrices and the efficacy of metabolites are very crucial for the utilization of food bioactivities.

The aim of this chapter is to summarize the bioactive constituents, bioavailability, and metabolism of CGAs, CA, and FA with their derivatives in food with an especial focus on coffee, as well as on their unique biological activities on animal and human, the toxicity and side effects, the marked product, and patents that related to those compounds.

21.2 Bioactive Constituents

Chlorogenic acid (CGA) was discovered in 1837 and was introduced in 1846 to describe a rich component in the green coffee bean, which was first recognized as 3-O-caffeoylquinic acid (3-CQA) and later as 5-O-caffeoylquinic acid (5-CQA) by the IUPAC. The term "chlorogenic acids" (CGAs) issued to described a group of esters that are formed between quinic acid and hydroxycinnamic acids (ferulic, caffeic, p-coumaric acids, and sinapic acid). Therefore, in the present chapter, CGA is used to represent 5-CQA, and CGAs is used to denote chlorogenic acids and their

derivatives. Currently, over 300 major and minor CGAs have been described in coffee and other plant materials (Farah and Lima 2019). These compounds include caffeoylquinic acids (CQAs: 3-CQA, 4-CQA, and 5-CQA), dicaffeoylquinic acids (diCQAs: 3,4-diCQA, 3,5-diCQA, and 4,5-diCQA), feruloylquinic acids (FQAs: 3-FQA, 4-FQA, and 5-FQA), diferuloylquinic acids (diFQAs: 3,4-diFQA, 3,5-diFQA, and 4,5-diFQA), *p*-coumaroylquinic acid (*p*CoQAs: 3-*p*CoQA, 4-*p*CoQA, and 5-*p*CoQA), di-*p*-coumaroylquinic (di*p*CoQAs: 3,4-di*p*CoQAs, 3,5-di*p*CoQAs, and 4,5-di*p*CoQAs), sinapoylquinic acids (SiQAs: 3-SiQA, 4-SiQA, and 5-SiQA), dimethoxycinnamoylquinic acids (DQAs: 3-DQA, 4-DQA, and 5-DQA), caffeoyl-feruloylquinic acids (3F-4CQA, 3C-4FQA, 3F-5CQA, 3C-5FQA, 4F-5CQA, and 4C-5FQA), trimethoxycinnamoylcaffeoyl- or feruloylquinic acids (4T-5CQA, 3T-5CQA, 3T-5FQA, 3T-4FQA, and 4T-5FQA), caffeoyl-dimethoxycinnamoylquinic acids (3D-4CQA, 3D-5CQA, and 4D-5CQA), feruloyldimethoxycinnamoylquinic acid (3D-4FQA, 3D-5FQA, and 4D-5FQA), sinapoyl-caffeoylquinic acids (3Si-5CQA, 3Si-4CQA, and 4Si-3CQA), sinapoyl-feruloylquinic acids (3Si-5FQA, 4Si-5FQA, and 4Si-3FQA), and related compounds. Majority of them that existed in coffee and coffee leaves belong to three subclasses: CQAs, di-CQAs, and FQAs (Fig. 1) (Chen 2019; Clifford et al. 2003).

The major dietary sources of CGAs are vegetables (e.g., eggplant, tomato, carrot, and sweet potato), fruits (e.g. apple, pears, cherry, blueberry, and strawberry), and beverage (e.g., coffee and tea) (Rohit and Rao 2013). Green coffee is the major source of CGAs in nature, the content is about 5–12 g/100 g (Farah and Donangelo 2006), and CGA content is affected by the species and cultivars. For example, CGA contents in green coffee beans of *C. canephora* and *C. arabica* are 5.17–14.4% and 3.40–7.24%, respectively (Narita and Inouye 2015). After roasting, CGA contents significantly decrease to 1.7–2.5 g/100 g and 1.0–4.3 g/100 g in the medium roasted *C. canephora* and *C. arabica* beans, respectively (Farah and Lima 2019). Among CGA derivatives, 5-CQA has been reported as the most predominant compound in coffee beans and leaves and most of the plants (Chen et al. 2018b; Chen 2019).

CA, the most abundant hydroxycinnamic acids, presents mainly in coffee beans, fruits, olives, carrots, potatoes, propolis, and olives. CA (3,4-dihydroxycinnamic acid) consists of phenylpropanoid (C6-C3) configuration with a 3,4-dihydroxylated aromatic ring attached to a -COOH through a trans-ethylene wire (Fig. 1). It exists in various forms such as monomers (glycosides, amides, organic acid, and sugar esters), dimmers, trimers, and flavonoid derivatives. Further, these compounds are found in the cell wall of vegetables in the bound form with proteins or polymers (Espindola et al. 2019).

Similar to CA, FA is also a hydroxycinnamic acid in which 3-OH is substituted with methoxy group (Fig. 1). FA is also an abundant phenolic acid in plants, e.g., 5 g/kg in wheat brain and 50 g/kg in corn kernel. In coffee, FA content is about 9.1–14.3 mg/100 g (Saeed et al. 2019). FA occurs as free form or covalently conjugated to polysaccharides, polyamines, hydroxyl fatty acids, lignin, and glycoproteins in the plant cell wall. In cereals, it is esterified to the arabinoxylans of the grain cell walls.

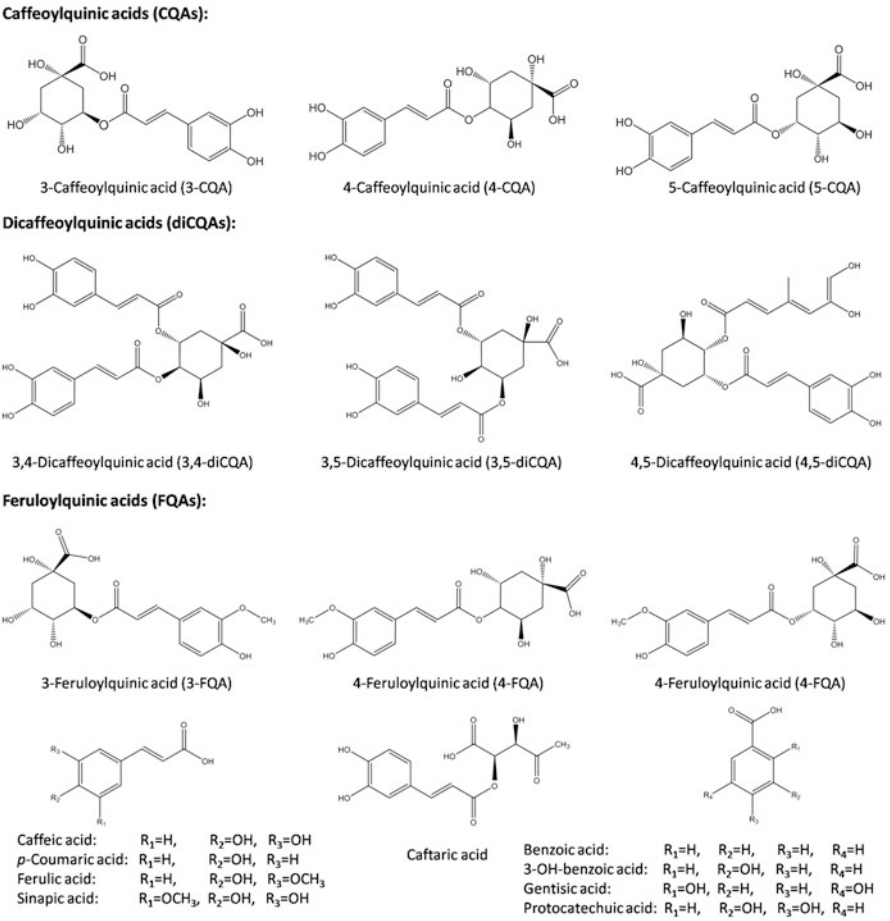

Fig. 1 Chemical structures of major CGAs, CA, and FA in coffee

21.3 Bioavailability and Metabolism

Food matrix is a very complex system that affects the bioaccessibility and bioavailability of phenolic compounds. CGAs, CA, and FA widely present in plants as conjugated forms instead of free forms. They exist as low-molecular-weight, water-soluble components in cytosol as well as lipid-soluble compounds in the waxes of the plant surface (Karakaya 2004). The conjugation results in less bioaccessibility as well as enhanced hydrophilicity and molecular weight, which cause reduced bioavailability. After oral injection, phenolic compounds undergo an intestinal transformation before absorption and entering the circulation toward the liver and other organs. The nonabsorbed fraction is enzymatically metabolized by gut microbiota to produce various metabolites.

21.3.1 Chlorogenic Acid

The bioavailability and metabolite of CGA have been better studied compared with other phenolic acids due to its abundance in foods, especially in coffee. Understanding of CGA metabolism in human body is essential to reveal the fate and efficacy of CGA in vivo. The studies of bioavailability and metabolism of CGA and CA started in the 1950s. Previously, it was thought that the bioavailability of CGAs is very poor. Less than 1% of oral intake CGA was absorbed by animal and human, and most of it was metabolized by gut microbiota. However, thanks to the improved detection techniques, nowadays, it is known that about one third of injected CGAs is absorbed by human gastrointestinal (GI) track (Farah and Lima 2019). The absorption of CGA starts at the upper session of GI track, the stomach, but mostly happens in the small intestine through passive diffusion (Monteiro et al. 2007). Monocarboxylic acid transporter and bilitranslocase are also considered involved in the absorption of CGA.

About 30% intake of CGA is absorbed in the small intestine, and the rest of it reaches the colon and utilized by gut microbiota (Stalmach et al. 2009). Colonic microflora hydrolyzed the unabsorbed CGA to CA and quinic acid in the colon. Further, it is dehydroxylated to form 3-hydroxyphenylpropionic and benzoic acid, and then the hippuric acid is formed when conjugated with glycine. As a consequence, half of the ingested CGA appears as urinary hippuric acid (Olthof et al. 2001). It was previously found that there were only $<1\%$ of CGAs ingested identified and quantified in murine or human plasma and urine due to digestion and metabolized process (Monteiro et al. 2007; Gonthier et al. 2006). Farah et al. (2008) identified the considerable amount of CGA, CQA, diCQA, and FQA compounds in human plasma after consumption of roasted and green coffee extracts. After absorption, CGA undergo phase II metabolism to form sulfate and glucuronide conjugates. The schematic representation of the main metabolic pathway of CGAs is shown in Fig. 2. It can be noticed that the major FA and CA metabolites like dihydro ferulic acid-4-O-sulfate, dihydro caffeic acid-3-O-sulfate, and caffeic acid-3-O-sulfate are found in the blood circulation of CGA metabolism (Marin et al. 2015; Naveed et al. 2018). Due to limited studies available on the biological properties of CGA, FQA, FQA, p-CoQA, CFQA (caffeoyl-feruloylquinic acid), and other minor CGA compounds, more studies are needed to establish the mechanisms involved in the metabolism and absorption of individual major/minor CGA compounds from coffee.

The bioavailability of CGAs was largely dependent on the food matrix and varied among individuals. It was reported that CGA absorption was not affected by milk or sugar that were added during coffee consumption. The transition of CGA in the upper part of the gut is very rapid in food-deprived rats or fasting humans when administrated with coffee or pure CGA; therefore, no CGA was detected in plasma or urine (Azuma et al. 2000). However, when volunteers consumed prune or coffee with breakfast, CGA appeared in urine (Ito et al. 2005).

In summary, the fate of CGA in vivo can be divided into three parts: a part of it was absorbed from the stomach intact; some of it is absorbed by small intestine

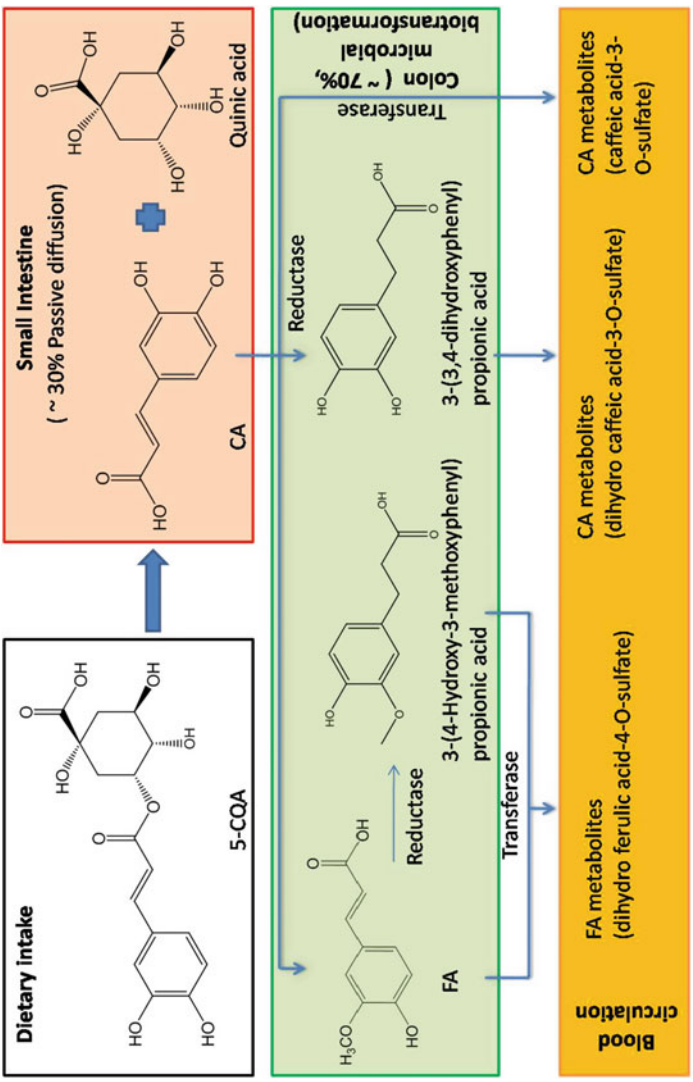

Fig. 2 Major metabolic pathway of 5-CQA and CA (Adapted from Naveed et al. 2018)

followed by hydrolyzed by the enterocytes before entering circulation; the last fraction of the not absorbed CGA reached caecum and metabolized by gut microbiota.

21.3.2 Caffeic Acid

When rats administrated CA through gastric intubation, CA, FA, and their sulfates or glucuronides were found in plasma 30 min after administration, and the metabolites reached maximum 2 h later (Azuma et al. 2000). CA was also found to be absorbed in the stomach (Konishi et al. 2006) and distributed in the portal vein and aorta 10 min after its administration (Konishi et al. 2005). About 19.1% of CA can be absorbed in rat small intestine, whereas 11% of the ingested dose was found in urine of ileostomy volunteers (Olthof et al. 2001). However, only 0.3% of CGA excreted in urine, indicating that esterification of CA with quinic acid markedly decreased the absorption of CGA. CA can also be metabolized by gut microbiota. The two key microbial metabolites of CA are 3-hydroxyphenylpropionic acid and benzoic acid, which are produced by the action of *Bifidobacterium lactis*, *Lactobacillus gasseri*, and *Escherichia coli* (Gonthier et al. 2006). Isoferulic acid has been found as a specific metabolite of dietary CA derivatives. It was revealed as a useful biomarker for the metabolism of CA derivatives from dietary sources (Rechner et al. 2001).

21.3.3 Ferulic Acid

The physiological significance of FA is affected by its bioavailability for absorption and subsequent interaction with target organs. It is found that after 24 min of oral administration, free FA reached highest concentration in plasma level (Zhao and Moghadasian 2008). The metabolic pathway of FA feruloyl monomer, oligomer, and polymer are summarized in Fig. 3. Feruloyl monomers get hydrolyzed to form free FA in the intestinal lumen or mucosa, and then FA-glucuronides are generated in the intestinal mucosa. In the liver, free FA and FA-glucuronides are metabolized into several metabolites including FA-sulfate, FA-glucuronide, and FA-sulfoglucuronide which is the FA diconjugate form with glucuronide and sulfate, feruloylglycine, dihydroferulic acid, m-hydroxyphenylpropionic acid, vanillic acid, and vanilloylglycine (Zhao et al. 2003; Zhao and Moghadasian 2008). Further, vanillin is changed into oxaloacetate and pyruvate by protocatechuate (PCA) 4,5-cleavage pathway. Finally, FA catabolism end products enter into the tricarboxylic acid cycle and generate energy in the biological system. In addition, it is also reported that the administration of FA in the intraperitoneal to rats excretes 3-hydroxyphenyl propionic acid as a major urinary metabolite (Zhao et al. 2003; Zhao and Moghadasian 2008).

The bioavailability of FA is greatly affected by food matrix as well. For example, FA was detected in plasma of volunteers shortly after consumption of beer and the urinary excretion reached maximum at 7 h after injection (Bourne et al. 2000). Only

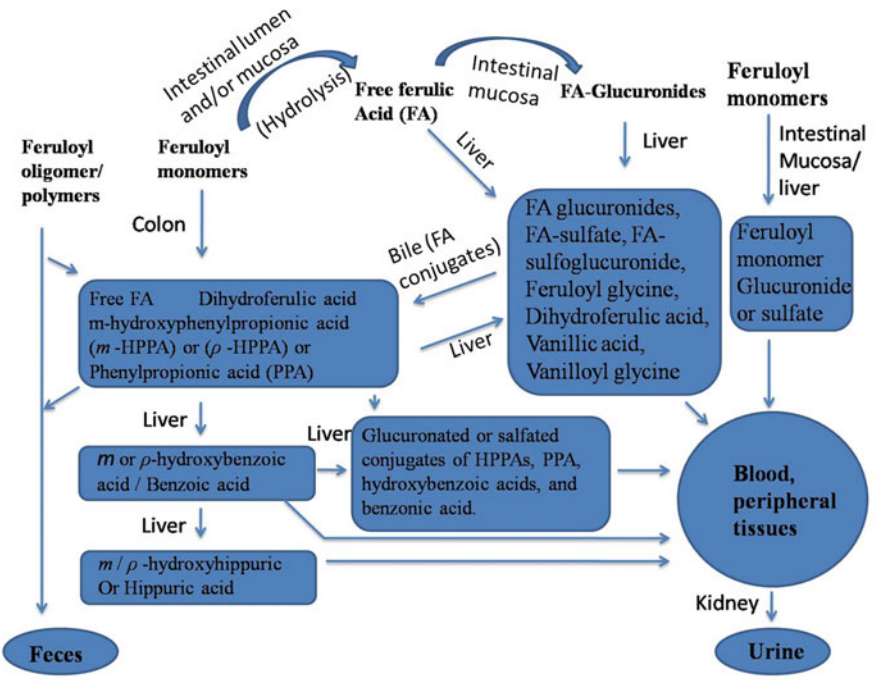

Fig. 3 Proposed possible metabolic pathways of dietary FA, reprinted with some modification from the ref. Zhao and Moghadasian 2008, copyright 2008, with permission from Elsevier

3% of ingested FA through cereals was detected in rat urine; however, the urinary exertion reached 50% of intake when free FA was administrated (Adam et al. 2002). This is because in the whole grain foods, FA is esterified with araboxylans and hemicelluloses, which resulted in the decreased bioavailability. Free FA was absorbed in the upper part of the gut, whereas the esterified FA metabolized in the caecum (Zhao et al. 2003). Moreover, the major microbial metabolites of FA are vanillin and 3-(4-hydroxyphenyl)-propionic acid (Andreasen et al. 2001). It is to be noticed that the bioavailability of FA varied in human and rats. For example, Yang et al. (2007) found the rapid absorption of FA upon oral administration, whereas FA has been reported to have very low oral bioavailability in humans because of its extensive metabolism.

A recent study compared the bioavailability of four hydroxycinnamic acids including CGA, CA, FA, and *p*-coumaric acid in non-fasted rats under physiological conditions. The injected CA, FA, and p-coumaric acid mainly excreted in the urine within 0–6 h as free form or glucuronide and/or sulfate conjugates, whereas CGA metabolites including CA, FA, *p*-coumaric acid and their conjugates were detected at 6–24 h and 24–48 h in the urine. The order of overall urinary excretion at 48 h was as followed: ferulic acid (73.2%) > caffeic acid (61.6%) > p-coumaric acid (54.1%) >> chlorogenic acid (4.9%). The percentages of the conjugates followed a

descending order as: 96% for ferulic acid >83% for caffeic acid >74% for chlorogenic acid >68% for p-coumaric acid. The results indicated that CGA was much poorly bioavailable and slower excretion compared with FA, CA, and p-coumaric acid due to the esterification of CA with quinic acid (Kishida and Matsumoto 2019).

21.4 Bioactivities (Animal Aspects)

CGA, CA, and FA are phenolic acids that are widely distributed in the human diet. Therefore, increasing research interest focuses on their enormous health benefits in human. There are numerous in vitro and animal studies related to the biological activities of CGA, whereas the clinical studies are relatively scant. Most of the human studies are related to coffee and much less used pure CGA, CA, and FA. Due to the lack of commercial availability of most minor CGAs derivatives, CGA is the most widely researched.

The possible mechanism of action and various beneficial activities of CGA are shown in Fig. 4. CGA reduces reactive oxygen species (ROS) and

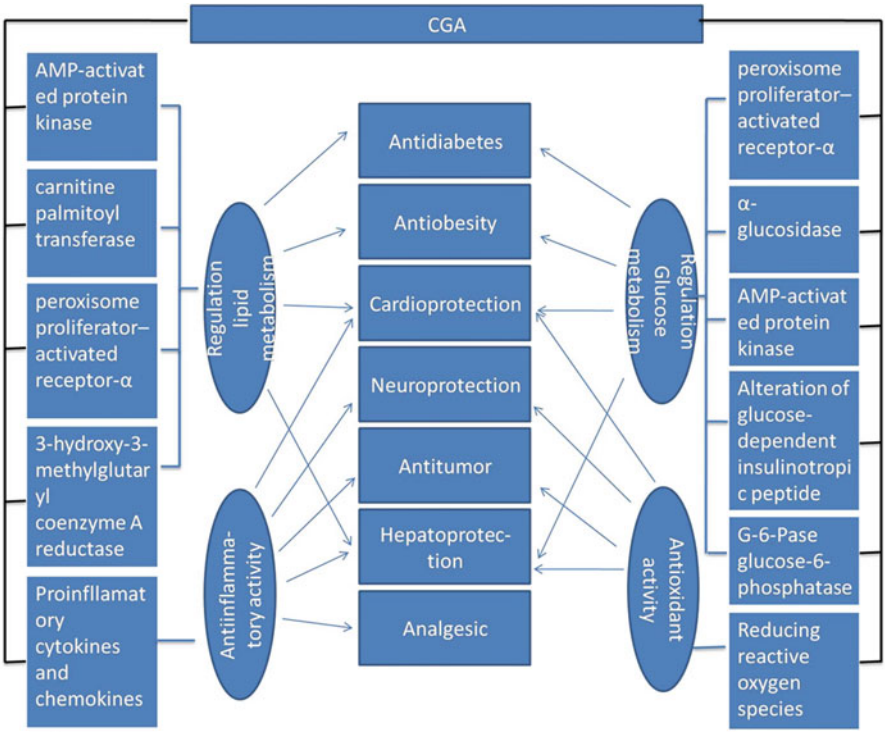

Fig. 4 Mechanisms of action of CGAs and its various health benefits (Adapted from Tajik et al. 2017)

proinflammatory cytokines or chemokines, and thereby it shows antioxidant and anti-inflammatory activity, respectively. Due to the antioxidant and anti-inflammatory activity of CGA, it has exhibited several promising applications including antidiabetes, anti-obesity, cardioprotection, neuroprotection, antitumor, hepatoprotection, and analgesic activities. CA and FA have also showed various biological applications. The recent animal studies on the bioactivities of CGA, CA, and FA and its derivatives are displayed in Table 2.

21.4.1 Antioxidant Activity

Oxidative stress is related to several chronic diseases, degenerative diseases, cancer, and aging. Antioxidants are valuable compounds that inhibit/reduce the effects activated by free radicals and oxidizing agents. Phenolic compounds are well-known antioxidants that show various health benefits. CGA is of special interest due to its unique properties and is able to fight oxidative stress by acting as a metal chelator, reducing lipid peroxidation, inhibiting NAD(P)H oxidase activity, and scavenging free radicals (Clifford 1999; Tajik et al. 2017). Animal studies indicated that the antioxidant and anti-inflammatory activities of CGA contribute to the health effects of coffee. Chen et al. (2018a) found administration of CGA to weaned pig reduced the oxidative stress, increased the intestinal absorption and digestion function, thus ameliorated weaning stress-induced diarrhea, and enhanced the growth performances of weaned pigs. Bao et al. (2018) proposed that dietary intervention rich in CGA has been used as an effective therapeutic agent for the treatment of diabetic nephropathy which is associated with the antioxidant effect of CGA. When diabetic rats fed with CGA, the lipid hydroperoxide was decreased, and the antioxidants such as reduced glutathione and vitamins C and E were increased (Karthikesan et al. 2010; Pari et al. 2010). In the methamphetamine-treated rats, CGA was able to reduce the oxidative stress by increasing liver superoxide dismutase and glutathione peroxidase activities and inhibiting lipid oxidation (Koriem and Soliman 2014).

CA was found to reduce oxidative stress in mouse hippocampus. A dosage of 300 mg/kg of CA significantly decrease the levels of an oxidative stress biomarker, 4-hydroxynonenal, in the mouse hippocampus and the activated microglia indicating that CA has potential to maintain brain health through its antioxidant capacity (Koga et al. 2019).

The biological activity of FA was first found in 1970, and now the antioxidant activity of FA is one of the most well-known activities. Because of the extended side chain and phenolic nucleus present in FA, it easily forms resonance-stabilized phenoxy radicals that mainly responsible for the free radical scavenging activity (Zhao and Moghadsian 2008). This facilitates FA to protect lipids and deoxyribonucleic acid against oxidation through ROS. In addition to ROS, FA is also reported to enhance the expression level of superoxide dismutase, catalase, and antioxidant enzyme. Recently, scientists reported the high efficacy of FA and its derivatives in reducing cyclooxygenase (COX) activity and xanthine oxidase effect.

Table 2 Selected bioactivity studies of CGA, CA, and FA and its derivatives in animals

Compounds	Animal model	Key findings	References
Chlorogenic acid (GCA)	Rat	Treats diabetic nephropathy by inhibiting oxidative stress and inflammation through modulation of the Nrf2/HO-1 and NF-κB pathways	Bao et al. (2018)
	Pig	CGA reduced weaning stress-induced diarrhea It enhanced the growth performances of weaned pigs through maintaining antioxidant capacity and intestinal digestion and absorption function	Chen et al. (2018a)
	Mice	CGA significantly decreased serum triglyceride, cholesterol, hepatic lipids, fasting blood glucose, inflammation, hyperinsulinemia, and hyperglycemia It increased insulin sensitivity It improves high-fat diet-induced hepatic steatosis and insulin resistance in mice	Ma et al. (2015)
	Rat	CGA showed its beneficial role on wound repair and diabetes under diabetic conditions	Bagdas et al. (2015)
	Rat	CGA effectively inhibited isoproterenol-induced hypertrophy in neonatal rat myocytes	Li et al. (2014)
	Mice	Showed protective effect on tetrachlorobenzoquinone-induced liver injury	Xu et al. (2014)
	Rat	It controlled high levels of cholesterol considerably by upregulating the gene expression of PPAR-α in hypercholesterolemic rats induced with a high-cholesterol diet	Wan et al. (2013)
	Mice	CGA reduced heart triglyceride levels and ameliorate cardiovascular disorders It exhibited anti-obesity property and improved lipid metabolism in high-fat diet-induced obese mice	Cho et al. (2010)
Caffeic acid (CA)	Rat	CA exhibited antidiabetic nephropathy effect and mechanism of action Reactivation of autophagy pathway by suppression of autophagy regulatory miRNA	Matboli et al. (2017)
	Rat	CA suppressed hepatic inflammation, oxidative damages, hepatocyte apoptosis, and microcirculatory disturbance caused due to I/R in rat liver	Mu et al. (2015)
	Rat	CA and CGA prevented diabetic-induced brain disorder by inhibiting acetylcholinesterase activity, reducing anxiety, improving memory in diabetic rats	Stefanello et al. (2014)
	Mice	CA and 5-CQA inhibited P-selection expression on platelets and decreased the	Park (2009)

(continued)

Table 2 (continued)

Compounds	Animal model	Key findings	References
		platelet activation 5-CQA and CA inhibited COX-1 and COX-2 enzyme activity	
Ferulic acid (FA)	Rat	FA in a combined form with metformin alleviated the symptoms of diabetes in obese rats FA alleviated lipid peroxidation in diabetic rats by changing the expression of pro-inflammatory cytokines, apoptosis, and altering oxidative stress	Nankar et al. (2017)
	Rat	FA showed antidiabetic effects by modulating insulin signaling molecules in the liver of high-fat diet and fructose-induced type 2 diabetic rats	Narasimhan et al. (2015)
	Isolated rat hepatocytes (Ex vivo)	Polyphenols including CA, FA, ethyl ferulate, methyl ferulate exhibited hepatoprotective effects in different models of rat hepatocytes	Maruf et al. (2015)
	Rat	FA-treated wounds epithelized faster in an excision diabetic wound model	Ghaisas et al. (2014)
	Rabbits	Sodium ferulate inhibited atherosclerogenesis in hyperlipidemia rabbits	Wang et al. (2004)

Hence it is believed that FA lessened a number of oxygen species produced by the enzyme-catalyzed transformation (Nile et al. 2016). Moreover, FA also shows promising effects for the treatment of disorders associated with oxidative stress such as Alzheimer's. These wide ranges of antioxidant capacity seem to impel CGA, CA, and FA to act as an effective nutritional supplement for human and animal health.

21.4.2 Antimicrobial Effect

The researches related to the antimicrobial effect are mostly in vitro study. Various studies showed that CGA inhibited microorganisms that grow throughout human GI track, from the mouth to colon (Farah and Lima 2019). Generally, the antimicrobial activity of CGA, FA, and CA on different microorganisms depends on the position and number of substitutions in the benzene ring and the saturated side chain length. Phenolic acids and their derivatives with longer alkyl chain showed greater antimicrobial activity. CGA and CA present in coffee showed inhibitory effect against pathogens such as *Staphylococcus aureus*, *Enterococcus faecalis*, *Listeria monocytogenes*, *Pseudomonas aeruginosa*, *Escherichia coli*, and *Salmonella choleraesuis* (Martinez-Tome et al. 2011). CGA also effectively inhibited the growth of bacterial strains such as *Shigella dysenteriae* and *S. pneumonia* by provoking

irreversible permeability changes in the cell membrane, causing cell death (Lou et al. 2011; Barbieri et al. 2017). Suarez-Quiroz et al. (2013) found that green coffee CGAs have an important antibacterial, antifungal, and anti-mycotoxigenic effects. FA showed bacteriostatic and bactericidal activities against *Escherichia coli*. The antimicrobial mechanisms of CGA included binding to and disruption of the outer cell membrane followed by the release of cytoplasm macromolecules which leading to cell death (Lou et al. 2011).

21.4.3 Cardioprotection Ability

Cardiovascular diseases (CVD) have claimed the first spot as the leading cause of death in many countries across the world and particularly in developed countries. CVD is a chronic disease that remains prevalence for decades, and the phenolic acids such as CGA, CA, and FA have found as a remarkable role to ameliorate such diseases. Oral administration of CGA and CA to mice inhibited P-selection expression on platelets, which in turn decreased the platelet activation. In addition, CGA and CA were able to inhibit COX-1 and COX-2 enzyme activity (Park 2009). Cho et al. (2010) found that CGA reduced heart triglyceride levels and ameliorated cardiovascular disorders. CGA effectively inhibited isoproterenol-induced hypertrophy in neonatal rat myocytes (Li et al. 2014). CGA has the capacity to control high levels of cholesterol considerably when it was consumed as a dietary supplement (Cho et al. 2010; Wan et al. 2013). FA has been reported for the treatment of the number of chronic diseases including cardiovascular diseases. Sodium ferulate, a salt of FA, has been used in China to treat cardiovascular and cerebrovascular diseases (Wang et al. 2004).

21.4.4 Neuroprotection Effect

Oxidative stress has been known as responsible for the neurotoxicity and pathology associated with various neurodegenerative diseases (Alzheimer's disease), wherein the free reactive nitrogen species (RNS) and ROS generated in the brain can lead to lipid peroxidation or RNA, DNA, and protein oxidation and neuronal dysfunction or even death (Gohil et al. 2012). Coffee constituents such as CGA, CA, and FA are known potent scavengers of ROS and RNS, thereby inhibiting the free radical attack DNA/RNA/proteins, hence preventing their oxidative modification in the brain. CGA and CA demonstrated the ability to prevent diabetic-induced brain disorder evidenced by inhibiting acetylcholinesterase activity, reducing anxiety, and improving memory in diabetic rats (Stefanello et al. 2014).

FA could be potentially used as a therapeutic molecule for nucleus pulposus (NP) regeneration. Protective effects of FA ethyl ester against the amyloid beta peptide (1-42)-induced oxidative stress and neurotoxicity have been evaluated (Sultana et al. 2005). They reported the potential importance of FA ethyl ester to treat Alzheimer's disease and other oxidative stress-related diseases. Another study showed the

neuroprotective effects of FA toward oxidative stress-related apoptosis after cerebral ischemia/reperfusion injury by inhibiting ICAM-1 mRNA expression in rats. These results infer the promising neuroprotection effect of CGA, CA, and FA in various in vivo and in vitro systems (Cheng et al. 2008).

21.4.5 Hepatoprotection Capacity

CGA has protective effects on tetrachlorobenzoquinone (TCBQ)-induced liver injury. Xu et al. (2014) found that pretreatment of CGA relieved TCBQ-induced oxidative stress and liver damage significantly indicating the hepatoprotective nature of CGA. Sun et al. (2014) reported a protecting ability of CGA in a dose-dependent manner toward carbon tetrachloride (CCl_4)-induced acute liver injury in male Sprague Dawley rats.

Mu et al. (2015) has described the therapeutic role of CA against I/R-induced hepatic injury in rats. They found that CA suppressed hepatic inflammation, oxidative damages, hepatocyte apoptosis, and microcirculatory disturbance in rat liver. Phenolic constituents such as CA, FA, and their derivatives showed efficient hepatoprotective effects against methylglyoxal/glyoxal provoked oxidative damage and cytotoxicity (Neelam and Sharma 2019). The hepatoprotective effect follows the order: CA > FA > ethyl ferulate > methyl ferulate in different models of rat hepatocytes (Maruf et al. 2015). FA has also been found to have a hepatoprotective effect against CCl_4-induced acute liver injury through suppression of inflammatory signaling pathways and oxidative stress (Kim et al. 2011). These results implied that CGA, CA, and FA can serve as potential hepatoprotective candidates for liver injury.

21.4.6 Antidiabetic and Antilipidemic Activity

Noncommunicable diseases are the most common causes of morbidity or premature mortality, and diabetes is one of them. It is the 4th or 5th leading cause of death in many countries. CGA is a potential antidiabetic candidate. It has been reported that coffee consumption lowered the possibility of type 2 diabetes (Van Dam 2008). Ong et al. (2013) found that the chronic administration of CGA inhibited hepatic glucose-6-phosphatase expression and activity, improved lipid profiles, attenuated hepatic steatosis, and enhanced skeletal muscle glucose consumption, which in turn enhanced insulin sensitivity, dyslipidemia, glucose tolerance, and fasting glucose level in $Lepr^{db/db}$ mice. Green coffee bean extract reduced visceral fat and body weight in mice. High-fat diet rats fed with CGA (100 mg/kg) significantly decreased serum triglyceride, cholesterol, hepatic lipids, fasting blood glucose, inflammation, hyperinsulinemia, and hyperglycemia and increased insulin sensitivity (Ma et al. 2015). Another study found that high-fat diet rats fed with green coffee bean extract had a significantly lower fat mass and body weight compared with control group (Choi et al. 2016).

Recently, Matboli et al. (2017) examined the antidiabetic nephropathy effect of CA and proved its mechanism of action that occurred by reactivation of autophagy pathway via suppression of autophagy regulatory miRNAs. FA showed antidiabetic effects by modulating insulin signaling molecules in the liver of high-fat diet and fructose-induced type 2 diabetic rats. FA-treated rats illustrated the downregulation of glucose 6-phosphatase, phosphoenolpyruvate carboxykinase, and gluconeogenic enzyme genes, thereby reducing gluconeogenesis (Narasimhan et al. 2015). FA promoted wound healing effect in streptozotocin-induced diabetic rats. FA also was found to alleviate the symptoms of diabetes in obese rats and reduce lipid peroxidation in diabetic rats through changing the expression of pro-inflammatory cytokines, apoptosis, and altering oxidative stress (Nankar et al. 2017).

21.4.7 Anti-inflammatory Activity

Coffee promotes a lower risk of chronic conditions such as reducing inflammation, oxidative stress, and increasing serum levels of anti-inflammatory factors like adiponectin and interleukins (Cadona et al. 2019). The role of CGA in controlling oxidative and inflammatory conditions has been reported (Liang and Kitts 2016). Chauhan et al. (2012) found that oral administration of 40 mg/kg CGA to lipopolysaccharide (LPS)-induced arthritis rat inhibited pro-inflammatory cytokines, thereby exhibiting the enhanced healing of tissue damage caused by inflammation. CGA protected against trinitrobenzene sulfonic acid-induced colitis in mice through decreasing neutrophil infiltration and inhibiting nuclear factor kappa B (NF-κB) pathway (Zatorski et al. 2015).

Caffeinated and decaffeinated coffees act as anti-inflammatory agents in therapeutic processes in various pathological situations. Coffee's therapeutic potential results from its bioactive substances including caffeine, CGA, and CA. Together, these compounds have been exhibited to modulate inflammatory, to accelerate wound healing in neuropathic pain and to reduce inflammation in animal models (Leon et al. 2019). An anti-inflammatory activity of CA in cardiac tissue of diabetic mice has been evaluated by Chao et al. (2009). They reported that CA could provide anti-inflammatory, antioxidative, triglyceride-lowering, and anticoagulatory protection in cardiac tissue of diabetic mice. Hence, the supplement of CA is helpful for the prevention/attenuation of diabetic cardiomyopathy. In an excision wound model, FA-treated wounds were found to epithelize faster compared with diabetic wound control group (Ghaisas et al. 2014).

21.5 Benefits (Human Studies)

21.5.1 Antioxidant Activity

Coffee constituents like CGA, CA, and FA have been revealed to be an effective antioxidant in human studies. The possible reason for the potent activity of these phenolic acids is due to its capability to induce upregulation of cytoprotective

enzymes (extracellular signal-regulated kinase ½, heat shock protein 70, Akt, and heme oxygenase-1), to scavenge free radicals, and to lessen the activity and expression of cytotoxic enzymes (COX-2, inducible nitric oxide synthase (iNOS), and caspases) (Chen et al. 2014). A clinical study conducted by Hoelzl et al. (2010) showed that individuals injected instant coffee that included green and roasted coffee bean extracts which contained 300 mg CGA significantly decreased two of the oxidative stress biomarkers in urine, 8-isoprostaglandin F2α and 3-nitrotyrosine, by 15.3% and 16.1%, respectively, when compared with the control group who only consumed water.

21.5.2 Antidiabetic Activity

Prospective cohort investigations of coffee intake and risk of type 2 diabetes mellitus have been studied widely in various countries including the United States, Sweden, Finland, and the Netherlands. These studies have established a significant inverse association between coffee consumption and risk of type 2 diabetes mellitus (Higdon and Frei 2006). A cohort including more than 193,000 men and women showed that those who consumed 6 cups or 2 cups of coffee daily reduced the risk of type 2 diabetes mellitus 35% and 28%, respectively (Van Dam and Hu 2005). The antidiabetic activity of coffee is strongly related to the presence of phenolic compounds especially CGAs in coffee, and the mechanisms included the reducing glucose production from the liver by phenolic acids; inhibiting glucose-6-phosphate translocase thus reducing glucose absorption; inhibiting gut incretin hormones; and protesting pancreatic β-cells against oxidative stress (Gokcen and Sanlier 2019; Van Dam and Hu 2005).

It was found that green coffee extract which contains mainly CGAs reduced glucose-6-phosphatase hydrolysis and inhibits the generation of hepatic glucose, thereby showing antidiabetic effect (Henry-Vitrac et al. 2010). Cheng et al. (2011) reported that consumption of CA can hinder the misfolding of human amylin polypeptide, thus potential for ameliorating type 2 diabetes. A few clinical pharmacokinetics studies of FA in humans have been reported in the literature to show its antidiabetic activity (Mancuso and Santangelo 2014).

21.5.3 Anti-obesity Activity

CGA, CA, and FA show anti-obesity activity by decreasing cholesterol level as well as fatty acid biosynthesis (Gokcen and Sanlier 2019). Further, it altered the plasma adipokine levels while enhanced fatty acid oxidation and PPAR alpha expression in the liver (Cho et al. 2010). A study demonstrated that compared with normal instant coffee, CGA-enriched instant coffee had a significant role in the utilization and absorption of glucose from the diet and reduced body fat and body mass, remarkably (Thom 2007). Another study elaborated on the differences in insulin, gastrointestinal hormone profiles, and plasma glucose and further confirmed the antagonistic effect of CGA on glucose transport (Johnston et al. 2003). Overweight and

obese individuals who consumed coffee containing green coffee bean extract have a decline body weight, and 80% of the weight loss was due to the fat loss (Thom 2007).

21.5.4 Antiviral Activity

CGA, quinic acid, and CA have been reported to possess anti-hepatitis B virus activity, and CGA derivative, caffeoyl 5,6-anhydroquinic acid, exhibited significant anti-HIV capacity (Chaves-Ulate and Esquivel-Rodríguez 2019).

21.5.5 Anticancer Activity

Although many studies have found the positive association between coffee consumption and the risk of various cancers, epidemiological studies investigating the role of coffee consumption on cancer still could not obtain a conclusive answer. Human studies have revealed that coffee consumption has the efficiency of preventing breast cancer, prostate cancer, colon cancer, hepatocellular carcinoma, and rectal cancer. In vivo and in vitro investigations have established the anti-carcinogenic activity of CA against hepatocellular carcinoma (HCC) which is the most common type of primary liver cancer, considered to be of vastly aggressive, high incidence and causing substantial mortality across the world. In addition, these studies elaborated that the intake of CA-abundant foods showed a protective activity toward carcinogenesis by inhibiting the generation of nitrosamides and nitrosamines. These nitro compounds are the major inducers of pathology. The anticancer ability of CA is connected with its antioxidant effect which is ascribed to its molecular structure that has double bond in the carbonic chain, number of hydroxyl group, different positioned hydroxyls in catechol group, and free phenolic hydroxyls (Espindola et al. 2019).

21.5.6 Antihypertension

The impacts of CGA-enriched green coffee on blood pressure have been summarized by Sanlier et al. (2019). Kozuma et al. (2005) found that when mild hypertension Japanese subjects consumed 93 mg or 185 mg green coffee bean extract, which equivalent to 50 mg or 100 mg CGA for 28 days, their systolic and diastolic blood pressures were reduced. The possible antihypertension reasons are that bioactive component such as CGA in green coffee inhibited 11β-HSD1 enzyme activity, thus decreasing the ratio of cortisol/cortisone (Revuelta-Iniesta and Al-Dujaili 2014); CGA increase nitric oxide bioavailability; the metabolite of CGA, ferulic acid, reduced oxidative stress by attenuating superoxide (Watanabe et al. 2006).

21.6 Application in Food (Including Correctly Cooking Foods Rich in Phytochemicals)

Owing to the enormous biological applications of CGA, CA, and FA, they gained considerable attention in food industries. As a result, several dietary foods that have these major phenolic acids both in combined with other compounds and individual forms are commercially available in the market. Due to its antimicrobial and antioxidant potential, it has been used as a food preservative as well. Green coffee extracts which is rich in CGAs, CA, and FA have been used to fortify different foods or make dietary supplements. Ground coffee bean powder was added into the bread to make phenolic enrich products that retained greater antioxidant activities (Dariusz et al. 2015). Green coffee extract enriched soy milk was found to have increased antioxidant activity, high bioaccessibility, and increased protein and starch digestibility (Seczyk et al. 2017). CGAs, the main precursors of coffee flavor and colors, contribute to the final acidity and bitterness of coffee. During roasting of coffee beans, CGAs undergo dehydration, fragmentation, Strecker degradation, and Maillard reactions to produce CA, low-molecular-weight compounds, and quinolactones which cause the increase of bitterness of coffee. The beans of *C. arabica* contain lower CGAs compared with *C. canephora*, which causes the better cup quality of *C. arabica* bean. However, CGAs in coffee leaves are more abundant in *C. arabica* than in *C. canephora*, thus tending to produce greater bioactivity tealike beverage when using the former source. Therefore, the selection of coffee species and the administration of roasting conditions are crucial in order to produce high quality of coffee. When production of green coffee extract as supplement is considered, it is a good choice to use the *C. canephora* beans that contain more CGAs.

CA was used to modify ovalbumin, which can reduce the allergenicity of ovalbumin (Tong et al. 2018). CA-incorporated film showed a 6-fold increased antibacterial activity and 20-fold enhanced antioxidant activity compared with CA-free composite films (Yu et al. 2013). The releasable CA exhibited considerable inhibitory ability on lipid oxidation of menhaden oil-in-water emulsion. CA and FA effectively inhibited the lipid oxidation which plays a key role to produce rancidity and off-flavor in frozen minced fish (Medina et al. 2009). Takahashi et al. (2013) reported that FA had the ability to inhibit the growth of *L. monocytogenes* (food-borne pathogenic bacteria) in cheese and smoked salmon. A soy protein isolate-based edible coating containing FA controlled browning index, weight loss, and firmness of fresh-cut apples when stored at the temperature of 10 °C and the relative humidity of 50%; therefore FA prolonged the shelf life and enhances the quality of freshly cut apple (Alves et al. 2017). In Japan, FA has been permitted as a food preservative and additive antioxidant due to its antioxidant and antimicrobial properties. FA has been added to sports foods to enhance athletic performance. For example, as a sport supplement, FA can reduce fatigue and muscle tenderness due to its free radical scavenging activity (Tee-Ngam et al. 2013). Due to the unique properties and applications, FA has received considerable interest in oriental

research where it widely used as an efficient antioxidant. Dietary supplementation with FA enhanced the meat quality and the antioxidant activity of poultry by decreasing serious level of MDA and increasing the hepatic activity of GSH-Px (Saeed et al. 2019).

21.7 Safety: Toxicity and Side Effects

The researches related to the toxicity and side effects of CGA, CA, and FA are very scant, especially for animal and clinical studies. A study done by Moridani et al. (2001) using isolated rat hepatocytes showed that CA and CGA can metabolize into cytotoxic o-quinone by cytochrome P450 and CA has higher cytotoxicity than CGA. Although the health benefits of CGA-rich coffee or green coffee bean have been widely reported, there are studies also related these compounds to the risk of chronic diseases to coffee consumption (Sanlier et al. 2019). Excessive consumption of coffee leads to the possibility of cardiovascular disease that is probably due to the occurrence of cholesterol-raising agents (Butt and Sultan 2011). Healthy individuals supplement with 2 g CGA per day for 7 days were found to have higher (>12%) total homocysteine in the postprandial plasma compared with placebo group, indicating the possible risk of CGA to the cardiovascular diseases (Olthof et al. 2001b). Although researchers have found that green coffee could reduce blood pressure in the mild hypertension Japanese patients (Kozuma et al. 2005), consumption of green coffee extract which contains 140 mg CGA for 12 weeks significantly decreased systolic and diastolic blood pressure in health individuals, suggesting the possible hypotension risk (Watanabe et al. 2006). Liu et al. (2019) found that mice consumed 5 or 150 mg/kg/day of caffeic acid before gestation affected implantation of embryos and the higher dose caused the low fetal weight. Although CGA is generally considered as an antioxidant, it can turn into prooxidant at high concentration and in the presence of transition metal ion.

21.8 Marketed Products

A wide range of dietary supplements containing green coffee extracts is commercially available in the market. They are offered in various forms which include powder, tablet, and capsule. Green coffee extract supplements generally contain about 50% CGAs and have claimed to help weight loss, suppress appetite boosts, control blood sugar level, and maintain heart health. For example, Svetol® (Naturex) is a decaffeinated green coffee extract supplement that has a specific ratio of CGA and its derivatives with a claimed slimming function (Dellalibera et al. 2006; Henry-Vitrac et al. 2010). Body fat and weight-reduced coffee extract supplements are also available (Thom 2007). Other products contain green coffee bean extract which exhibits antihypertensive potential are available in the combined form of Svetol® with olive leaf extract and beet powder (Wong et al. 2014). Lisopresol® is a chewing gum containing green coffee extract, L-carnitine, and nutraceutical

products that might aid in the control over snack intake and reduce hunger sensations (Bobillo et al. 2016). Green coffee bean extract has also been made into GRECOBE-Green Coffee Bean Extract sachets which can be consumed with hot water infusion. Ground green coffee bean powder can also be packed in sachets to make green coffee infusion. The concentration of CGAs ranged from 628 to 1040 mg/L in *C. arabica* hot water infusion and from 682 to 1210 mg/L in *C. canephora* infusion when 3 g green coffee bean powder infused with 200 ml boil water (Macheiner et al. 2019). Coffee leaves are also made into different types of coffee leaf teas (Chen et al. 2018b) and Kombucha with different flavors. FA has the ability to neutralize free radicals in muscle tissue; thereby it treats muscle fatigue, and hence it is widely used as a sports supplement.

21.9 Patents

CGA, CA, FA, and their derivatives are subjects of numerous patent submissions around the world. The search engine for patents by Google patent showed more than 55,000 patents related to them. The preparation of phenolic compounds particularly CGA, CA, and FA from green coffee extract with various forms has also been widely patented (US20160030350A1, US20180235251A1, TW201440781A, KR101999108B1, CN1813556A, US10335444B2, CN105175266A). The patents list a wide range of extraction protocols of these polyphenolic compounds from green coffee bean (CN106278891A, CN101404891B, KR102047346B1, JP5295559B2), roasted coffee bean (JP2017093301A, JP6139724B2), coffee (JP2018529378A, US10449225B1), coffee fruit extract (KR20180054660A), coffee decaffeination with caffeic acid (CA1320658C, US4767634A, EP0340354A1), guava leaf (CN108498582A), tobacco leaves (CN109696514A), apple (CN109123321A), olive (CN109030664A), kiwifruit (CN108680660A), and other plant residues (ES2569132B1).

A number of patents are available to describe the various applications of phenolic acid that consist of CGA, CA, and FA in coffee especially antioxidant activity (CN105494825B). An effect of a decaffeinated green coffee extract on body weight control has been developed by regulation of glucose metabolism (US9358264B2). CGAs were often used as active agents for slimming in cosmetics (FR2883472A1), flavor modifier (ES2247339T3, TWI283168B), and taste modification (WO2019040989A1, JP5766173B2) in beverages. Water-soluble green coffee bean extract consists of 70% CGAs, and $<1\%$ caffeine has been developed as an antioxidant supplement and is effective in healthy weight management (PCT/IN2015/000236). Antioxidant containing these phenolic acids as an effective ingredient was described widely (KR20050110186A, JP3855293B2, WO2006103515A1, CN105494825B). Antihypertensive agent (JP4119629B2) that containing those bioactive constituents showed a significant effect in hypertension (US7939563B2, US7351436B2) or preventing a rise in blood pressure (EP1186294A2).

In pharmaceutical field, these bioactive compounds show various health benefits, including the treatment of aging, age-related disorders, and/or age-related manifestations including atherosclerosis, peripheral vascular disease, coronary artery disease, osteoporosis, arthritis, type 2 diabetes, dementia, Alzheimer's disease, and cancer (US20060275294A1, US20190374489A1, WO2014048888A1, JP4713765B2, CN105076916A, CN103068359A, CA2685031A1, US20060172012A1, JP6406730B1, US20160296490A1, US20160193306A1).

21.10 Perspectives

CGAs, CA, and FA received considerable attention due to their wide distribution in plant foods and potential health benefits. Although a number of in vitro studies have shown various biological activities of these compounds, the in vivo human studies are still scant. Most of the clinical studies focus on the health benefits of coffee or green coffee beans and lack of the researches on the in vivo bioactivity of pure compounds. Among this group of phenolic acids, majority of the researches are related to the CGA (5-CQA), and researches related to other minor CGA derivatives are very scant. Since food is a very complex system, food matrix has a great impact on the bioaccessibility, bioavailability, and bioefficacy of bioactive compounds. Coffee contains different groups of bioactives; therefore, it is hard to make a conclusive proof for the health benefits of CGA alone in the clinical studies when individuals are administrated coffee. Therefore, understanding the physical and chemical characteristics of macromolecules such as polysaccharide- and protein-phenolic acid conjugates in different food systems, the interaction of other groups' phytochemicals with phenolic acids, and the impacts of macromolecules and other bioactives to phenolic acids are crucial to better utilize CGAs, CA, and FA and to guide the processing methods. Moreover, the bioefficacy of bioactives is largely varied in individuals. Therefore, precision impacts of bioactives need to be considered in future researches using more advanced analytical techniques and data processing methods.

Processing, especial thermal processing, not only affects the organoleptic characteristics of food but also influences the content and structure of phenolic compounds. For example, about 60–98% of CGA is isomerized or transformed into quinolactones in different roasting processes. Thus, a large quantity of thermal processing products such as 3-caffeoylquinic-1, 5-lactone (3-CQL), and 4-caffeoylquinic-1, 5-lactone (4-CQL) produced in roasted coffee bean. Therefore, more attentions need to be paid to the bioavailability and bioefficacy of the major processing products in order to better understanding the benefit and risk effects of injected foods. Moreover, the injected CGAs, CA, and FA undergo extensive transformation to produce various metabolites; thus it is difficult to distinguish the efficacy of parent phenolic compounds from the metabolic compounds. More researches are needed to be done using the metabolites to elucidate the protective mechanisms of food origin bioactives in human body.

Caffeoylquinic Acids

22

Dorota Woźniak, Izabela Nawrot-Hadzik, Weronika Kozłowska, Sylwester Ślusarczyk, and Adam Matkowski

Contents

Abstract

Caffeoylquinic acids (CQAs) are a large family of phenylpropanoids (chemically esters) found in large amounts in coffee beans but typically occur in many other edible plants, and as such, they belong to the most widespread polyphenols in plant kingdom. They are also associated with significant health benefits resulting from the consumption of beverages such as coffee and yerba maté as well as some popular vegetables such as globe artichoke or endive. Also, many medicinal herbs

J. Xiao et al. (eds.), *Handbook of Dietary Phytochemicals*,
https://doi.org/10.1007/978-981-15-4148-3_23

owe their properties to their CQA content. Here, we focused on the importance of these compounds for functional properties of healthy foodstuff, summarizing such well-studied aspects as bioavailability, in vitro and in vivo pharmacological effects, and potential for lifestyle disease prevention and management. The chemical diversity and analytical approaches are also outlined.

From the literature review, it is concluded that CQAs count as the most essential healthy constituents of various foods and beverages and should be included in characterization of edible consumer products. At the same time, one should remember that caution is necessary in claiming unfounded properties to cure diseases. Therefore, more research is necessary, especially on human subjects, as well as further development of affordable and reliable analytical methods in an ultimate goal to understand their distribution, diversity, and function.

Keywords

Chlorogenic acids · Antioxidant · Coffee · Artichoke · Asteraceae · Hydroxycinnamate

22.1 Introduction: What Are Caffeoylquinic Acids?

Phenolic acids are widely distributed in various foodstuffs of vegetables, but a significant proportion of them occurs as esters or depsides. Among them, one of the best known groups is conjugates with (−)-quinic acid, known collectively as chlorogenic acids (coming from chlorogenic acid, CGA, the most widespread and the first to be described compound of their kind). A number of related structures formed with other hydroxylated organic acids are sometimes being included in this category. The diversity and distribution of various hydroxycinnamic-acyl conjugates have been extensively studied, discussed, and reviewed by Clifford and co-workers in several papers that have been appearing since more than two decades (Clifford 1999, 2000, 2017; Clifford et al. 2007, 2017; Abrankó and Clifford 2017).

They occur in fruits, vegetables, and beverages such as coffee, yerba maté, and wine. Chlorogenic acids are extremely widely distributed among higher plants and in some cases are found in surprisingly high concentrations (Azuma et al. 2000; Clifford 2017).

Many of these compounds, like other polyphenols, are also associated with important health benefits, especially in the context of lifestyle disease prevention. Consequently, a lot is being spoken about how coffee is good for you and why people should consume a lot of vegetables from the Compositae (Asteraceae) botanical family – artichokes, endive, radicchio, etc.

Chlorogenic acid, contained in almost every studied higher plant species, is the most typical example and one of the most intensively studied plant dietary

polyphenols. In fact, most of the pharmacological and physiological activities of CQAs were described for CGA.

22.2 Chemistry of CQAs

They are formed by condensation between (−)-quinic acid [1 L-1(OH),3,4/5-tetra-hydroxycyclohexane carboxylic acid according to IUPAC and certain *trans*- acids, usually caffeic (CQAs) (see Table 1). Quinic acid has axial hydroxyl groups on carbons 1 and 3 and equatorial hydroxyl groups on carbons 4 and 5. During processing or upon UV-irradiation, *trans* isomers of cinnamic derivatives may be partially converted to *cis* form (Clifford 1999). CQAs are categorized according to the number or the position of caffeoyl groups and their additional modifications (Miyamae et al. 2011). Among all CQAs, 5-*O*-caffeoylquinic acid (5-CQA) is the most ubiquitous compound in the plant kingdom, known as chlorogenic acid. 3-*O*-

Table 1 Positional variants of caffeoylquinic and caffeoylshikimic acids

Name and abbreviation		R1	R3	R4	R5

1,4,5-Tri-*O*-caffeoylquinic acid	1,4,5-triCQA	C	H	C	C
1,3,4,5-Tri-*O*-caffeoylquinic acid	1,3,4,5-tetraCQA	C	C	C	C
		R1	**R3**	**R4**	**R5**
Shikimic acid	SA				
3-*O*-Caffeoylshikimic acid	3-CSA	–	C	H	H
5-*O*-Caffeoylshikimic acid	5-CSA	–	H	H	C
4-*O*-Caffeoylshikimic acid	4-CSA	–	H	C	H
3,4-Di-*O*-caffeoylshikimic acid	3,4-diCSA	–	C	C	H
3,5-Di-*O*-caffeoylshikimic acid	3,5-diCSA	–	C	H	C
4,5-Di-*O*-caffeoylshikimic acid	4,5-diCSA	–	H	C	C

caffeoylquinic acid (3-CQA), also called neochlorogenic acid, and 4-*O*-caffeoylquinic acid (4-CQA), known as cryptochlorogenic acid, frequently accompany the former compound.

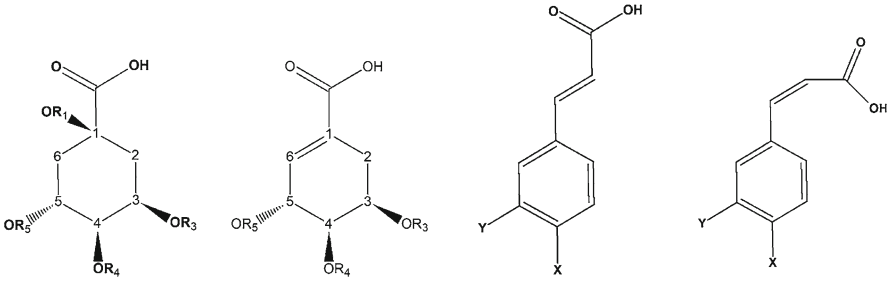
Moreover, (−)-quinic acid can be esterified with more molecules of caffeic (or other hydroxycinnamic) acid, and the following subgroups are known: dicaffeoylquinic acids (diCQAs), for example, in *Lonicera japonica* (Yang et al. 2018) or *Artemisia campestris* (Pereira et al. 2018); tricaffeoylquinic acids (triCQAs) in *Ipomoea aquatica* (Lawal et al. 2017) or in *Solidago* sp. (Abdel Motaal et al. 2016; Woźniak et al. 2018); and even tetraCQAs in *Bridelia ferruginea* stem bark (Cimanga et al. 1999). We also know mixed diesters of caffeic and ferulic acids, i.e., caffeoyl-feruloylquinic acids (CFQAs), which are characteristic of robusta coffee (*Coffea canephora*, Rubiaceae) or caffeic and sinapic acids, i.e., caffeoyl-sinapoylquinic acids (CSiQAs), as found in *Gardenia jasminoides* (Rubiaceae) (Nishizawa et al. 1987), *Broccoli* sprouts (Moreira-Rodríguez et al. 2017), or *Ilex paraguariensis* (Jaiswal et al. 2010). Mixed esters involving various combinations of one to three residues of caffeic acid with one or two residues of a dibasic aliphatic acid like glutaric, oxalic, or succinic are also known, especially in the Asteraceae family (Clifford et al. 2008; Maruta et al. 1995). Galloyl conjugates of quinic acids and cinnamoyl conjugates of quinic acid derivatives such as shikimic acid methyl or butyl quinate, and 4-deoxyquinic acid also occur in certain plant species. For example, caffeoylshikimic derivatives 3-QSA and 4-QSA are found in nectar of many flowering plants, among them *Vaccinium corymbosum* L., where they serve as a natural pathogen defense and influence plant-pollinator interaction (Egan et al. 2018).

Another kind of hydroxycinnamate conjugates forms when quinic acid is replaced by:

1. Other hydroxylated organic acids, mainly α-hydroxyhydrocaffeic, malic, and tartaric but also galactaric, glucaric, gluconic, hydroxycitric, methoxyaldaric, phenylpyruvic, and tartronic.
2. Amides of amino compounds including aromatic amino acids, choline, anthranilic acids, and diamines.
3. Esters of polysaccharides, simple sugars, and sugar alcohols including glycerol and *myo*-inositol. Especially chlorogenic acid glycosides were described with glucosyl or rhamnosyl carbohydrate moiety, glycosides including those of anthocyanins, flavonols, and diterpenes.
4. Esters of lipids including alkanols, alkandiols, u-hydroxy-fatty acids, and sterols (Zhang et al. 2013; Clifford 2000; Baeza et al. 2016; Alonso-Salces et al. 2009; Vo et al. 2014).

Different methoxy derivatives such as mono-, di-, or tri-methoxycinnamic and sinapic acid residues are described too (Kargutkar and Brijesh 2018; Sytar et al. 2018; Zengin et al. 2018). Chlorogenic acids are relevant coffee quality markers, and more than 70 chlorogenic acid derivatives have been detected so far in green coffee (Alonso-Salces et al. 2009; De Rosso et al. 2018). As we mentioned before, these

classic CGAs may be subdivided by the identity, number, and position of acyl residues as follows (Nagy and Abrankó 2016):



QA = quinic acid **SA**-shikimic acid **C** = cinnamic acid (trans) (cis)

X = H, **Y** = OH p-coumaric acid;

X = **Y** = OH caffeic acid;

X = OCH3, **Y** = OH ferulic acid

It is widely accepted that the known biosynthetic pathway produces *trans* form of cinnamic derivatives, and these dominate in most extracts; also it has been long known that conversion to the *cis* form occurs readily, especially after UV light exposure (Clifford et al. 2008).

22.2.1 Identification of CQAs

More and more stringent requirements for determining the quality of food products, including those of vegetable origin, have made analytical techniques used for this purpose important and increasingly used as a standard quality control method. Nowadays, there is a general trend in food science that link food and health, considering food as not only alimentation but also an affordable way to prevent future diseases and provide health benefits. Depending on the type and availability of CQAs from the different matrices, various extraction solvents are suggested in the literature; specifically, lower molecular weight polyphenols, such as hydroxycinnamate derivatives, are preferably extracted using methanol (Mané et al. 2007). Methanol use eliminates such extracts from consumption, and for this purpose ethanol or water is more suitable. Non-acidified methanol, ethanol, or water together with suitable extraction time and solid-to-liquid ratio is often chosen to allow a complete extraction of the CQA pool, reducing the risk of their degradation.

Among all analytical techniques, the LC-MS (liquid chromatography-mass spectrometry) is considered well-suited for CQA analysis and identification. To obtain better mass spectra and high-resolution mass spectra, negative ionization mode is recommended for CQA identification (Clifford 2000). Similar spectral behavior and UV detection with maximum absorbance around 300–320 nm and a shoulder around 290–310 nm, characterizing hydroxycinnamic acids and derivatives, facilitate the quick identification of most chlorogenic acids as a class and allow for more

affordable instrumentation to be applied in routine analysis (Crupi et al. 2018). In mass spectrometry-based detection, the typical fragmentor voltage (FV) is varied between 60 and 320 V; values in the range between 60 and 150 V are recommended for small molecules, whereas values above 350 V are only used to fragment large molecules. Cleavage of the hydroxycinnamic acid residue requires less energy if the esterification of QA occurs closer to the carboxyl group, and hydroxycinnamic acid is cleaved easier from position 5 than 3. As a result, regioisomeric monocaffeoylquinic acids (CQAs) and dicaffeoylquinic acid (diCQAs) showed different tandem mass spectra in negative ion mode (Table 3), e.g., producing fragment ions at m/z 191 and 173 corresponded to S1 [quinic acid – H]$^-$ and S2 [quinic acid – H_2O – H]$^-$ ions, respectively, and ions at m/z 179 A1 [caffeic acid –H] characteristic for CQA derivatives with molecular ion (*m/z* 353 λ_{max} 325 nm). Appropriate molecular ions are assigned as follows: for coumaroylquinic acid (*m/z* 337 λ_{max} 315 nm), producing fragment ions at *m/z* 172 and *m/z* 191, 163 corresponded to [quinic acid – H]$^-$ and [coumaric acid – H]$^-$ ions, respectively, feruloylquinic acids (*m/z* 367 λ_{max} 325 nm), sinapic (*m/z* 379 λ_{max} 325 nm), and dicaffeoylquinic acids (*m/z* 515 λ_{max} 325 nm). See (Table 2; Nagy and Abrankó 2016). Conformation *cis* preferably the hydrophobicity compared with *trans* form due to hydrogen bond inside the structure (Clifford et al. 2008).

22.3 Natural Sources of CQAs

Although coffee beans are the most widespread dietary source of these compounds, they are also present, for example, in several vegetables belonging to the Asteraceae (Compositae) family. Globe artichokes and cardoons (*Cynara cardunculus* subsp. *scolymus, C. cardunculus* subsp.*flavescens*) contain cynarin along several other CQA but Jerusalem artichokes (*Helianthus tuberosus*) contain mainly 3,4diCQA isomers.

However, these compounds are ubiquitous among land plants (put together by Clifford 2017), starting from bryophytes, which would be the phylogenetically first plants to contain them, through ferns and horsetails, gymnosperms, and of course flowering plants – angiosperms as the most diverse and advanced group. From cryptogamous taxa (a few mosses; a horsetail, *Equisetum arvense*; several fern species from different families), the most often reported isomer was 5-CQA (neochlorogenic acid). Surprisingly, there are rather few reports on CQAs' presence in gymnosperms, including *Ginkgo biloba* and juniper, and also in berries which are edible and used as spice (Fierascu et al. 2018). Selected examples of plant foods (spices, vegetables, fruits and nuts, beverages) containing CQAs are listed in Table 4, based on Clifford (2017) and some more recent publications (Dillenburg Meinhardt et al. 2019, Jaiswal et al. 2010, Kahle et al. 2005, Maruta et al. 1995, Sytar et al. 2018). Among flowering plants, the monocots seem to be less abundant in CQAs, and their occurrence is rather sporadic.

Table 2 MS^3 data of selected common monoacyl and diacyl hydroxycinnamoyl-quinic acids in negative ion mode

		MS^1			MS^2			MS^3

Table 4 Selected dietary (vegetable/beverages) sources of CQAs – based on Clifford et al. (2017) and references cited in the main text (content given as per dried mass unless indicated otherwise)

Family	Species	Organs consumed	Identified compounds	Content
Aquifoliaceae	Yerba maté – *Ilex paraguariensis*	Leaves (tea)	CQAs and diCQAs in similar proportions	92 g/kg total CQAs
Asteraceae	*Arctium* sp. (burdock)	Tap roots	Over 30 CQAs and diCQAs	Exceeding 15 g/kg
	Cynara scolymus/ cardunculus – Globe artichokes and cardoons	Flower heads/ leaves	Over 30 various CQA isomers, 5-CQAs, and 1,5-diCQAs dominate depending on the season and variety	Flower heads – Over 5 g/kg
	Cichorium endivia and *C. intybus* – Endive – Various forms	Vegetative parts – Whole vegetable	3-CQA, dominant diCTA (chicoric acid – Dicaffeoyltartaric)	Up to 1 g/kg
	Lactuca ssp. – Lettuces	Whole vegetable	3-CQA	Up to 25 g/kg depending on variety and conditions
	Scorzonera hispanica – Black salsify	Tap roots	5-CQA and 3,5-*O*-diCQA dominating, several other diCQAs	Up to 130 g/kg
	Tragopogon porrifolius – Salsify	Tap roots		
	Stevia rebaudiana	Leaves	Several CQA and diCQA isomers – 4-CQA dominating	70 mg/kg
	Helianthus annuus – Sunflower	Seeds or fruits – Achenes	5-CQA dominating, followed by 3-CQA, 3,5-diCQA, 4,5-diCQA, 4-CQA, and several minor compounds of this class	Up to 30 g/kg
Convolvulaceae	*Ipomoea batatas* – Sweet potatoes	Tubers	5-CQA and 3,5-diCQA predominating	2 g/kg
Ericaceae	*Vaccinium myrtillus* – Bilberry	Fruits (berries)	5-CQA	500 mg/kg fresh fruit
Moraceae	*Ficus carica* – Figs	Fruits	5-CQA dominant	Up to 5.8 g/kg (peel)

(continued)

Table 4 (continued)

Family	Species	Organs consumed	Identified compounds	Content
	Jackfruit – *Artocarpus heterophyllus*	Fruits	5-CQA (dominant) and 4-CQA	Up to 14 g/kg
	Mulberry – *Morus alba*	Fruits	5-CQA (dominant)	500 mg/kg fresh fruit
Poaceae	Rice – *Oryza* sp.	Grain	3-CQA	10–20 mg/kg
Rosaceae	*Prunus armeniaca* – Apricot	Fruits/ kernels	3-CQA and/or 5-CQA dominant + several other in fruits	Few hundred mg/kg
	Prunus domestica – Plums and prunes	Fruits	5-CQA dominant, several other present	Total CQAs over 4 g/kg in prunes depending on variety
	Cydonia oblonga – Quince	Fruits	5-CQA dominant	Up to 3.2 g/kg
Rubiaceae	*Coffea arabica*, *C. canephora* – Arabica and robusta coffee	Grain (dehulled fruits)	5-CQA major compounds, dozens of other forms, including CQA and diCQA	Total CQa can exceed 100 g/kg
Solanaceae	*Solanum tuberosum* – Potato	Tubers	5-CQA major compound	Up to 6 g/kg, depending on variety and conditions
	S. melongena – Eggplant	Fruits	Several CQAs and diCQAs	3-CQA 0.4–3.0 g/kg, significant increase in grilled or baked fruit
	S. lycopersicon – Tomato	Fruits	3-CQA, 5-CQA and some diCQAs; content very variable; increases in grilled eggplant, tomato paste, etc.; but results are inconsistent (sometimes decreases)	Up to 1.5 g/kg

22.4 Metabolism and Bioavailability

Given the fact that phenolic acids are rarely present in foods in free forms, the evaluation of systemic availability of potential bioactive plant constituents is a major prerequisite for the interpretation of in vitro pharmacological testing.

Absorption of orally administered chlorogenic acid (5-*O*-caffeoylquinic acid) in rats was studied to obtain plasma pharmacokinetic profiles of their metabolites. Merely traces of metabolites, supposedly caffeic acid conjugates, caffeic acid glucuronides, caffeic acid sulfates/glucuronides, and ferulic acid sulfates/glucuronides, for 6 h after chlorogenic acid administration were observed. These metabolites reached their maximum concentrations of 0.12–0.34 μM within the first 0.5–1 h after administration; then their plasma levels decreased. However, no chlorogenic acid and its conjugates were detected. On the other hand, almost the whole amount of ingested chlorogenic acid was found in the small intestine for 6 h after oral administration. These results suggest that the intestinal mucosa or intestinal microflora may not possess esterase activity that would be able to cleave chlorogenic acid into caffeic and quinic acids which would decrease absorption of chlorogenic acid from the digestive tract (Azuma et al. 2000). Previous data from the literature also showed in an in vitro model using the small intestine from rats that only very little absorption of chlorogenic acid (0.1%) occurred (Spencer et al. 1999). Moreover, a study reported no evidence of enzymatic hydrolysis of chlorogenic acid by the intestine, liver, or human plasma but revealed that chlorogenic acid ingested by humans is most likely cleaved into caffeic acid and quinic acid by an esterase enzyme provided by the colonic microflora (Plumb et al. 1999). Strong evidence exists that the majority of chlorogenic acids are not absorbed in the proximal part of the gastrointestinal tract, unless transformed to caffeic and ferulic acids before being absorbed (Lafay et al. 2006). Generally, esterification of caffeic acid with quinic acid, as in chlorogenic acid, markedly reduced its absorption like the other esters. In fact, urinary excretion of chlorogenic acid represented 0.3% after a clinical trial with ileostomized patients. Other data showed that the metabolite concentration of chlorogenic acids was 100 times lower than that obtained with caffeic acid in the same conditions (Lafay and Gil-izguierdo 2008).

On the other hand, a few further studies providing data on CQAs metabolites in human plasma failed to detect other compounds than either conjugated or free hydroxycinnamic acids (DuPont et al. 2002; Nardini et al. 2002). Caffeoylquinic acids were detected in human plasma and urine only in form of conjugated and nonconjugated hydroxycinnamates such as caffeic acid, its methylated derivates ferulic acid and isoferulic acid, and the hydrogenation products dihydrocaffeic acid and dihydroferulic acid (Wittemer et al. 2005).

By contrast, a study on the absorption in humans of phenolic acids from coffee, a common beverage lacking free phenolic acids but particularly rich in bound phenolic acids, predominantly the mono-CQAs, indicates that hydrolysis of chlorogenic acid occurs early in the gastrointestinal tract. At 1 h after coffee brew consumption (actual intake of chlorogenic acids), a significant increase (91.1 $\pm$ 33.2 ng/mL) in free caffeic acid levels was found in plasma samples compared to time 0 (20 $\pm$ 10 ng/mL) (Nardini et al. 2002). The data clearly suggest that due to the absence of free caffeic acids in coffee brew used in the experiment, the level of plasma caffeic acid detected in the study represents the amount of caffeic acid absorbed following the in vivo release of free caffeic acid from bound complexes. Chlorogenic acid from administered coffee is not absorbed as such, but it undergoes hydrolysis in the

gastrointestinal tract by the action of cytosolic esterases in the gut mucosa or gut microflora. The study suggests that caffeic acid, even if present in the diet in bound forms, such as chlorogenic acids, is still bioavailable to humans.

However, Monteiro et al. (2007) found chlorogenic acids in human plasma samples after coffee consumption suggesting that the rapid transit through the stomach was not a critical point. The three main chlorogenic acids (3-caffeoylquinic, 4-caffeoylquinic, and 5-caffeoylquinic acids) and three dicaffeoylquinic acids were identified in plasma. Maximum concentration of total CGA reached 7.66 ± 2.5 μmol/l. Two plasma concentration peaks were observed, the first at 0.5–1.0 h and the second at 1.5–4.0 h after coffee consumption.

Studies on intestinal absorption and metabolism of chlorogenic acid revealed that around one-third of ingested chlorogenic acids in foods are absorbed and enter the bloodstream from the small intestine, with a possible contribution from the stomach; in healthy subjects with a functioning colon, the remaining two-thirds reach the large intestine (Stalmach et al. 2010). Experiments conducted in a rat model showed that chlorogenic acids are not hydrolyzed in the stomach but partially absorbed in an intact form; this could explain the early detection thereof in plasma, within 30 min after coffee consumption (Lafay et al. 2006).

Chlorogenic acid in parent form has been identified in human urine and plasma by several authors after ingestion of coffee; however, other authors failed to detect this phenolic acid in plasma or urine after the same consumptions. Farah et al. (2008) studied the pharmacokinetic profile and bioavailability of caffeoylquinic acids in healthy human subjects and found that the apparent bioavailability of them from a green coffee extract was approximately 33%. Urine was not the major route for excretion of caffeoylquinic acids in the human trial, but the smaller metabolites recovered suggested that the metabolism and excretion of esters, which influence the overall elimination kinetics in humans, could be quite variable and related to genetic polymorphisms.

To sum up, experiments that have been in place until now, carried out on humans and animals, have demonstrated that chlorogenic acids are bioavailable at physiological level and the variety of phenolic acids as circulating forms was very numerous thanks to the absorption as such and following metabolization and the occurrence of the microflora phenolic acid metabolites (Lafay and Gil-izguierdo 2008). During absorption, caffeoylquinic acids are conjugated in the small intestine, and later in the liver, where methylation, sulfation, and glucuronidation, as the main conjugation reactions, take place. This is a very important process not only in detoxification, to avoid any potential toxic effects, but also in eliminating them via the biliary or the urinary route by increasing their hydrophilicity (Heleno et al. 2015).

22.5 Bioactivities In Vitro (Cell Lines) and In Vivo (Animal Studies)

Despite of the large amount of data concerning in vitro bioactivity of phenolic acids, very little is known about the phenolic acid's bioactive forms in vivo and the mechanisms by which they may contribute toward disease prevention. Similarly,

only a few studies deal with the bioactive properties of their metabolites (Piazzon et al. 2012; Rechner et al. 2002), especially as most of those molecules are not commercially available. After absorption from the gastrointestinal tract, these molecules suffer conjugation reactions causing several changes in their initial structure and circulate in human plasma in their conjugated forms, such as glucuronide and methylated and sulfated derivatives. These changes in their structures may increase or decrease the bioactivity of the initial phenolic acids. Moreover, several studies dealing with the biological effects of phenolic acids have ignored the question of their achievable concentrations in the circulation after ingestion as well as the possibility of metabolism. As we have known from bioavailability study, caffeoylquinic acids, which are naturally esterified, are not or in little amount cleaved in the gastric lumen or the small intestine, but mostly they are cleaved in the colon by esterase activity of the gut microflora. Therefore, the urgent issue to be estimated is whether the identified conjugates and metabolites are physiologically relevant or can only be regarded as biomarkers of a phenolic acid-rich diet. So, detailed knowledge concerning the conjugative and metabolic events and resulting plasma levels following the ingestion of a hydroxycinnamates-rich diet is crucial for understanding their bioactivity.

22.5.1 Antioxidant and Antimutagenic Activity In Vitro

Several experimental and epidemiological studies suggested that chlorogenic acids of daily diet contributed to the protection against various degenerative diseases (Liang and Kitts 2016). Their effects on health have been more particularly attributed to their antioxidant properties. The underlying mechanism(s) for specific health benefits attributed to chlorogenic acids involve(s) mitigating oxidative stress and hence the related adverse effects associated with an unbalanced intracellular redox state.

The base of antioxidant action of chlorogenic acids (CGAs) is their ability to donate hydrogen atoms to reduce free radicals and to inhibit oxidation reactions. After donating hydrogen atoms, chlorogenic acids are oxidized to their respective phenoxyl radicals, and these phenoxyl radicals are quickly stabilized by resonance stabilization (Liang and Kitts 2016). The chlorogenic acid is an excellent natural scavenger among many polyphenol compounds, because the one electron oxidation product of CGA formed by reaction with free radicals is rapidly broken down to further products that cannot generate any free radicals (Shibata et al. 1999).

Although a majority of isomers of chlorogenic acid – such as caffeoylquinic acids (CQAs): 3-CQA, 4-CQA, 5-CQA, 3,5-diCQA, 3,4-diCQA, and 4,5-diCQA – are potent antioxidants (Xu et al. 2012), chemical-based or cell-based assays directed at characterization of the antioxidant capacity have been focused mostly on the 3-CQA isomer (chlorogenic acid). Chlorogenic acids react with different sources of free radicals at different rate constants; they have the capacity to scavenge 1,1-diphenyl-2-picrylhydrazyl (DPPH) radicals, superoxide anions ($^{\cdot}O_2^-$), hydroxyl radicals ($^{\cdot}OH$), 2,21-azino-bis(3-ethylbenzothiazoline-6-sulphonic acid) ($ABTS^{\cdot}$) radicals,

lipid oxidation, and peroxynitrite ($ONOO^-$). The efficiency of 5-CQA isomer reacting with free radicals such as superoxide, hydroxyl radical, peroxyl radical, and peroxynitrite is species-specific, as has been determined by the second-order rate constants $0.96 \pm 0.01 \times 10^6$ $M^{-1}s^{-1}$, $3.34 \pm 0.19 \times 10^9$ $M^{-1}s^{-1}$, $1.28 \pm 0.11 \times 10^5$ $M^{-1}s^{-1}$, and $1.6 \pm 0.7 \times 10^5$ $M^{-1}s^{-1}$, respectively (Liang and Kitts 2016).

This antiradical activity of chlorogenic acids has been attributed to important action such as DNA-protective mechanism against the radical damage caused to DNA, including DNA strand breakage. Six CGA isomers, including three caffeoylquinic acid isomers 3-CQA, 4-CQA, and 5-CQA and three dicaffeoylquinic acid isomers 3,5-diCQA, 3,4-diCQA, and 4,5-diCQA, were shown to exhibit a protective effect against DNA plasmid chromosome breaks induced by H_2O_2. Dicaffeoylquinic acids demonstrated better protective antioxidant activity than caffeoylquinic acids against the radical damage caused to DNA, mostly because they have more hydroxyl groups (Xu et al. 2012).

On the other hand, the redox cycling of chlorogenic acids in the presence of oxygen and transition metals takes place to form reactive oxygen species that are capable to damage macromolecules, such as DNA and lipids (Sakihama et al. 2002). So, in systems containing redox-active metals such as Cu and Fe, prooxidant activity of hydroxycinnamates occurred. Chlorogenic acids are relatively weaker pro-oxidants compared to caffeic acid; the reason for this difference is that caffeic acid is a simpler p-coumaric derivative, where CGA is esterified and contains a quinic-carbohydrate moiety. Moreover, CGAs in the presence of Cu ions are relatively short-lived radicals; nevertheless they can result in a prooxidant effect, such as DNA single-strand breaks (Liang and Kitts 2016).

Many examples of antioxidant properties of chlorogenic acids, attributed to prevention of crucial biomolecules, have been shown in vitro on **chemical-based assays**. The research by Shibata et al. (1999) studied protective effect of CGA against detrimental activity of hypochlorous acid (HOCl), a secondary byproduct of oxidation of chloride by H_2O_2, which initiate a mutagenic response as a reaction with amines to produce chloramine (NH_2Cl). Chloramine is an oxidant and potent mutagen. CGAs, specifically 5-CQA, have been able to protect against NH_2Cl-induced DNA breakage due to its good ability to scavenge HOCl and other intermediates of oxygen. Additionally, the antioxidant reaction occurs more rapid in acidic than neutral pH; thus CGAs from diet could be excellent protectors from *H. pylori*-induced gastric mucosal lesions, partially caused by intermediates of oxygen produced by activated neutrophils (Shibata et al. 1999). The anti-peroxidative activity of CGA showed experimental study where the protected substrate was LDL. Protection against LDL oxidation is crucial for prevention of the initial step in the development of many disorders such as atherosclerosis. Studies based on incubating isolated LDL with oxidizing agents in vitro showed that 3-CQA was effective at mitigating both copper-induced LDL oxidation and ferryl myoglobin-induced LDL oxidation (Liang and Kitts 2016). These results correspond to other studies in rat brain in vitro that reported reduced malondialdehyde (MDA) content by chlorogenic acid. The mechanisms through CGA exert its neuroprotective

properties were inhibiting AChE and BChE activities as well as preventing oxidative stress-induced neurodegeneration (Oboh et al. 2013).

22.5.2 Cell Lines and In Vivo Studies

Further type of experiments focused on characterization of the antioxidant capacity of CGAs used **cell-based models**. The oxidative stress was stimulated by various oxidative stressors (e.g., t-BHP, H_2O_2, $FeSO_4$) in PC12 cells, and for its evaluation diverse biomarkers such as the reduction of lipid peroxidation product, the extent of ROS formation, and GSH depletion were used. Genomic DNA integrity is also an important biomarker of redox status because reactive species continuously attack DNA structure and cause different kind of DNA lesions. The results showed the utility and effectiveness of CGA isomers to mitigate intracellular oxidative stress (Liang and Kitts 2016).

3-CQA reduced the DNA oxidative damage caused by X-ray irradiation by 4.49%~48.15%. In addition to this direct effect, this compound reduced UV photo-lesions in human blood lymphocytes, mouse epidermal cell line or human HaCaT keratinocytes (Cha et al. 2014; Feng et al. 2005).

The **animal-based assays** have confirmed antioxidant activity of CGAs based on evidence from in vitro chemical and cellular-based assays. Observations from animal experimental models examined the redox status after exposition thereof to a variety of forms of oxidative stress when animals were pretreated with 3-CQA. In diabetic rats feeding 3-CQA, it was observed effectively reduced lipid hydroperoxide production and increased level of non-enzymatic antioxidants such as reduced glutathione and vitamins C and E. This ability of CGAs is attributed to prevention of environmental toxicity, for instance, caused by heavy metal pollution. Pretreatment of rats with 3-CQA before Cd exposure significantly restored the depleted levels of GSH, vitamin C, and vitamin E and attenuated harmful MDA levels in brain tissue (Liang and Kitts 2016). Other studies have shown that affinity of 3-CQA to reduce lipid peroxidation and free radical scavenging activity can alleviate the oxidative stress induced by methamphetamine or scopolamine and prevent the accumulation of MDA in the central nervous system (Liang and Kitts 2016). The 3-CQA also protects against oxidative stress through its activation of Nrf2 nuclear translocation and upregulation of cellular antioxidant enzymes, suppression of ROS-mediated NF-κB, AP-1, and MAPK activation. These results could be attributed to chemopreventive effects of chlorogenic acid and its protection against environmental carcinogen-induced carcinogenesis (Feng et al. 2005).

CQAs are able to attenuate harmful impact on intracellular redox balance caused not only by chemical but also by physical factors, such as UV or γ-irradiation. Topical delivery of 3-CQA in guinea pigs during exposure to UVB reduced photo-oxidation-induced damage of skin. Moreover oral administration of 3-CQA to mice at a concentration of 100 mg/kg body weight before exposure to gamma radiation significantly reduced chromosomal damage (Liang and Kitts 2016).

In conclusion, there is strong evidence that CGAs are effective antioxidants that will protect against excessive oxidation reactions in vivo by upregulating redox-related nuclear transcription factors involved in the expression of antioxidant enzymes (Magielse et al. 2014).

22.5.3 Anti-Inflammatory Activity

Similarly to other bioactivities, anti-inflammatory properties of caffeoylquinic conjugates are represented mostly by the chlorogenic acid (3-CQA) studies. Also, similarly to antioxidant properties, anti-inflammatory actions are thought to be a basis for broader therapeutic/preventive effects. Inflammation processes when occur chronically or excessively may lead to developing of lifestyle diseases and complications or even severe malignancies. Chlorogenic acids target multiple signaling pathways involved in generating inflammatory response on different levels, such as NFκB pathway inhibition, scavenging ROS, and direct inhibition of enzymes such as COX, NOS, and LOX, as well as normalizing the levels of circulating cytokines and balancing the associated gene expression (Clifford et al. 2017; Naveed et al. 2018; Yamagata 2018).

For example, suppressing of Toll-like receptor in Con-A challenged mice leads to amelioration of hepatitis (Yuan et al. 2017). So, the effects are indeed pleiotropic and cannot be dissected from other pathophysiological processes, such as dyslipidemia and other symptoms of metabolic syndrome.

Several recent reviews on the pharmacology of chlorogenic acids unanimously conclude that anti-inflammatory properties are well-documented in vivo (Clifford et al. 2017; Santana-Gálvez et al. 2017; Naveed et al. 2018; Yamagata 2018). These properties result in protection against neuroinflammatory injury, damage of the vascular system by reducing hypertension and atherosclerosis, damage of hepatocytes and other tissues in the GI tract, against promotion of tumors, and finally in reducing inflammation-related pain.

22.6 Disease Prevention

Recent basic and clinical research studies have mentioned about reduction in the risk of a variety of diseases following CQA consumption. It is postulated that CQAs are able to exert significant roles in prevention development of many diseases as cardiovascular diseases, type 2 diabetes mellitus, obesity, cancers, hepatic steatosis, stroke, and Alzheimer's disease.

22.6.1 Cardioprotective Properties

Cardiovascular diseases (CVDs) continue to be the leading cause of morbidity and mortality in the industrialized world and account for 15.2 million deaths worldwide

in 2016 (WHO 2018). The molecular mechanisms underlying CVD are closely linked to cellular oxidative stress and inflammation, which contribute to LDL oxidation, endothelial dysfunction, atherosclerotic plaque formation, plaque rupture, vascular remodeling, and atherothrombosis (Pashkow 2011; Hajjar and Gotto 2013; Hussain et al. 2016).

Natural products containing CQAs could play an important role in regulation of ROS and glutathione level in the cells. Clinical evidences have shown an association between GSH level and CVD. Low GSH level was observed in patients with the most severe cases of heart failure, and patients with cardiac diseases showed 21% depletion in blood GSH than healthy controls (Damy et al. 2009). 3-*O*-caffeoylquinic acid (CGA) has been shown to induce glutathione-linked enzymes via Nrf2 signaling pathway; it increases the transcriptional expression of γ-GCL, HO-1, and GSTA1 (Boettler et al. 2011).

Recent clinical studies have shown that artichoke (*Cynara scolymus*) extract containing chlorogenic acid, 1,5- and 3,4-di-*O*-caffeoylquinic acid, and cynarin as the predominant polyphenolic compounds among hydroxycinnamates and apigenin and luteolin, and their glycosides as the main flavonoids, may favor CVD prevention by acting on different factors, which is increasing HDL-C as well as decreasing LDL-C, triglycerides, and total cholesterol (Rondanelli et al. 2013; Rangboo et al. 2016; Bundy et al. 2008; Lupattelli et al. 2004; Englisch et al. 2000). Not all clinical trials showed consistent results which may be elucidated by a slightly different methodology and different purification and standardization, as well as the stability of the supplements consisting artichoke extracts. However, in a report about artichoke leaf extract (ALE) for treating hypercholesterolemia created by Cochrane Database of Systematic Reviews, which is the leading journal and database for systematic reviews in health care, authors concluded that there is an indication that ALE has potential in lowering cholesterol levels, but the evidence is, as yet, not convincing (Wider et al. 2013). One of the most likely explanation of ALE impact on HDL cholesterol increase is associated with chlorogenic acid which protects paraoxonase-1 (PON-1) activity in HDL-C, which was demonstrated in in vitro study (Gugliucci and Bastos 2009). Paraoxonase 1 (PON-1) is a high-density lipoprotein (HDL)-associated serum enzyme, and it has been shown to protect against CVD, by preventing the formation of oxidized HDLs and low-density lipoproteins (LDLs) (Aviram et al. 1998); by hydrolyzing the thiolactone form of homocysteine, which alters proteins in the arterial wall (Jakubowski 2000); and by hydrolyzing platelet-activating factor, a bioactive phospholipid which is involved in vascular disease development (Rodrigo et al. 2001). Decreasing total cholesterol and LDL-C was observed also in other studies carried out with ALEs in animal models (Küskü-Kiraz et al. 2010; Qiang et al. 2012).

Some of the studies attribute luteolin impact on decreasing total cholesterol and LDL-C by inhibition of the 3-hydroxy-3-methylglutaryl coenzyme A (HMG-CoA) reductase activity, which is a key enzyme in the liver cholesterol biosynthesis pathway (Gebhardt 1996, 2002). Even though cynarin did not show inhibition of HMG-CoA reductase activity in the abovementioned studies, some older studies showed its effect on lowering plasma lipids (Montini et al. 1975; Kraft 1997;

Fintelmann and Menssen 1996; Lietti 1977; Wójcicki 1978; Thompson Coon and Eernst 2003). Impact of other CAs on lipid profile was also analyzed. In a 2002 study, Rodriguez de Sotillo and Hadley found that in obese, hyperlipidemic, and insulin-resistant Zucker rats which were infused with chlorogenic acid via intravenous infusion, fasting plasma cholesterol and triacylglycerol (TG) levels were significantly reduced, similar to liver triacylglycerol levels (Rodriguez de Sotillo and Hadley 2002). More recently, in addition to improve plasma lipid profiles, chlorogenic acid was shown to inhibit lipoprotein lipase (LPL) activity in vivo and elevate peroxisome proliferator-activated receptor-α (PPARα) expression in the liver (Li et al. 2009; Cho et al. 2010). In a 2014 in vivo study, Huang et al. (2014) by using real-time polymerase chain reaction revealed that chlorogenic acid altered the mRNA expression of the transcription factors peroxisome proliferator-activated receptor-α (PPARα) and liver X receptor-α (LXRα) and targeted genes involved in hepatic fatty acid uptake, β-oxidation, fatty acid synthesis, and cholesterol synthesis. They concluded that chlorogenic acid may improve lipid metabolism disorders by altering the expression of PPARα and LXRα. Taking into account recent evidence, it is believed that cholesterol-lowering effects of chlorogenic acid in SD rats are most likely mediated by increasing fatty acid utilization in the liver via the upregulation of PPARα mRNA (Wan et al. 2013).

22.6.2 Antidiabetic Activities

Type 2 diabetes mellitus (T2DM) is a chronic metabolic disease characterized by insulin resistance, pancreatic β-cell dysfunction, and hyperglycemia (Dada et al. 2017). Studies have shown contrary association between consumption of product containing CAs and lower risk of type 2 diabetes. For example, it is reported that there is reduction of risk of T2DM by 30% for those who drink 3–4 cups of decaffeinated coffee containing high contents of CAs (Huxley et al. 2009). In randomized crossover trial conducted on 15 overweight men, it was observed that chlorogenic acid and trigonelline ingestion significantly reduced early glucose and insulin responses during an OGTT (oral glucose tolerance test) (van Dijk et al. 2009). Several other human studies have been done to assess the antidiabetic activity of chlorogenic acid-rich foods and supplements or pure chlorogenic acid (Thom 2007; Ahrens and Thompson 2013; Iwai et al. 2012; Johnston et al. 2003). Some of them demonstrated that caffeinated and/or decaffeinated coffees (rich in chlorogenic acid) significantly decreased glucose-dependent insulinotropic polypeptide (GIP) and increased glucagon-like peptide 1 (GLP-1) secretion after consumption. Authors suggested that chlorogenic acid might have an antagonistic effect on glucose transport (Johnston et al. 2003). Another randomized, double-blind, placebo-controlled trial, performed in 55 overweight subjects with impaired fasting glycaemia, showed that supplemented group with extract from *Cynara scolymus* had significant decreases of FBG (fasting blood glucose), HOMA (homeostatic metabolic assessment), glycosylated hemoglobin, ADAG (A1c-derived average glucose), and lipidic pattern (Rondanelli et al. 2014). Furthermore, in vitro evidence demonstrated that

chlorogenic acid increased cell insulin secretion and insulin sensitivity (Tousch et al. 2008). By investigating the mechanisms of chlorogenic acid activity, we learn that it inhibited glucose-6-phosphate translocase 1 and reduced the sodium gradient-driven glucose transport in the intestine (McCarty 2005). What is more, it suppresses hepatic gluconeogenesis through the inhibition of glucose-6-phosphatase (G6P-ase) activity (Bassoli et al. 2008) and stimulates glucose uptake in myotubes (Prabhakar and Doble 2009) and adipocytes (Alonso-Castro et al. 2008). A study of Ong et al. (2013) demonstrated that chlorogenic acid regulates glucose and lipid metabolism via the activation of AMPK (5′-adenosine monophosphate-activated protein kinase). It inhibited hepatic G6P-ase expression and activity, attenuated hepatic steatosis, and improved lipid profiles and skeletal muscle glucose uptake, which in turn improved fasting glucose levels, glucose tolerance, insulin sensitivity, and dyslipidemia.

22.6.3 Hepatoprotective Activity

Several studies have shown the beneficial impacts of caffeoylquinic acids and products that contain them on liver disorders. One of them is nonalcoholic steatohepatitis (NASH), a multifactorial disorder, characterized by fatty infiltration in the liver and steatosis that may culminate in cirrhosis and hepatocellular carcinoma. Oxidative stress, hepatocellular inflammation, and insulin resistance play an important role in the pathogenesis of NASH. Rangboo et al. (2016) decided to carry out a randomized double-blind clinical trial in which patients suffering NASH were randomly assigned to receive *Cynara scolymus* extract or placebo for 2 months. Significant reduction of triglycerides and total cholesterol was observed, as well as a decrease in serum ALT and AST (effective biomarkers in the diagnosis of hepatic damage) in the group receiving the extract in comparison with the placebo group. The authors suggested that this effect could be attributed to the antioxidant ingredients in *Cynara scolymus* extract, in which chlorogenic acid is the most active antioxidant (Gebhardt 1998). Also, several in vitro and animal studies evaluated the antioxidative and free radical scavenging potential of *Cynara scolymus* extracts in the protection of hepatocytes from oxidative stress (Heidarian et al. 2013; Metwally et al. 2011; Mehmetçik et al. 2008; Miccadei et al. 2008). Moreover, four dicaffeoylquinic acid derivatives isolated from the water extract of propolis have been shown to be effective against carbon tetrachloride (CCL4) liver injury in an in vitro assay (Basnet et al. 1996). Wang et al. (2009) reported anti-hepatitis-B virus activity of chlorogenic acid, quinic acid, caffeic acid, and coffee rich in chlorogenic acid in vitro and in animal models. Recent study indicated that roasting levels of coffee correspond to total chlorogenic acid contents as well as antioxidant and anti-inflammatory activities (Jung et al. 2017). Data suggest that these activities are negatively correlated with roasting levels in the cell models. Total chlorogenic acid contents were higher in lightly roasted coffee extract than other roasted groups. In addition, lightly roasted coffee extract had the highest antioxidant activity. Intracellular glutathione (GSH) concentration and mRNA expression levels of genes related to GSH synthesis were negatively related to roasting levels.

22.6.4 Neuroprotective Activity

Studies have shown that excessive oxidative stress in the brain leads to accelerated aging and impacts the severity of neurodegenerative diseases like Alzheimer's disease, Parkinson's disease, and autism spectrum disorder (ASD) (Frandsen and Narayanasamy 2018). Caffeoylquinic acids are known for their antioxidant activities (Clifford 1999; Cao et al. 2010), and their metabolites may impact on redox processes in the brain (de Paulis et al. 2002). Soumyanath et al. (2012) demonstrated that treatment with water extract of *Centella asiatica* improves learning and memory deficits in Tg2576 mice, an animal model of Aβ (amyloid-β) accumulation, where the accumulation of amyloid-β (Aβ) is a hallmark of Alzheimer's disease and is known to result in neurotoxicity. In the next study, researchers confirmed the neuroprotective effects of caffeoylquinic acids and that isochlorogenic acid A and 1,5-dicaffeoylquinic acid were the most active in protecting MC65 cells from Aβ-induced cell death (Gray et al. 2014). Each compound was also able to attenuate Aβ-induced alterations in tau expression and phosphorylation in both cell lines (Gray et al. 2014). Many studies have found that chlorogenic acid has the ability to attenuate oxidative stress in numerous neurological disorders (Kwon et al. 2010; Kim et al. 2012). Moreover, the recent study revealed that chlorogenic acid acts as a protective agent against glutamate-induced cortical neuron injury, where glutamate excitotoxicity has proven to play a key role in several neurodegenerative disorders, including Huntington's disease and multiple sclerosis, Alzheimer's disease, and Parkinson's disease, as well as other neurological disorders (Rebai et al. 2017). In the latest review article about cognitive and neuroprotective effects of chlorogenic acid, it was summarized that preclinical and clinical studies provide evidence that chlorogenic acid supplementation could protect against neurological degeneration and the resulting diseases associated with oxidative stress in the brain; however, no formal, well-controlled studies have been performed to date (Heitman and Ingram 2017). Also, in a second review from 2017 about chlorogenic acid and mental diseases, the authors concluded that chlorogenic acid possesses neuroprotective effects under both in vitro and in vivo models (Nabavi et al. 2017).

22.7 Chlorogenic Acids: Epidemiological Studies

There are no specific epidemiological studies concerning use of CGAs and morbidity on certain diseases. For this paper the epidemiological analysis was led by a comparison of CGA-rich nutrition product consumption with analysis of potential disorders within CGA activity. As CGAs mainly act in the gastrointestinal tract, especially on the liver, this organ was selected for further studies. The activity against colorectal cancer was also analyzed.

Liver disorders, according to WHO report, are at the forefront of most often cause of death in the world. These include hepatitis virus infection, mainly B and C, liver cancer, cirrhosis, and chronic liver diseases of different etiologies, among them excessive alcohol consumption or obesity. Other nonfatal liver disorders significantly

affect health and life quality and mostly depend on diet and lifestyle. This second class includes nonalcoholic fatty liver disease (NAFLD) and nonalcoholic steatohepatitis (NASH). NAFLD is defined as a presence of $\geq$5% of hepatic steatosis due to causes other than alcohol use, viral infections, or certain medicine intake. It is recognized as the liver component of a metabolic syndrome (MetS) often appearing in obesity (Younossi et al. 2016). NASH occurs when significant fibrosis is present due to inflammatory process that may lead to cirrhosis or liver cancer. It is estimated that about one of five people with NAFLD has NASH (Pimpin et al. 2018).

Simple fatty liver, as NAFLD is called, is associated with a high burden of metabolic comorbidities including obesity, type 2 diabetes, hyperlipidemia, hypertension, and MetS. NAFLD is the most common liver disease in the world affecting 25.24% of global population with the highest prevalence in the Middle East and South America and lowest in Africa (Younossi et al. 2016). Estimated prevalence of NAFLD in Europe is 23.71%, while NASH reaches up to 11.9% counted by liver transplantations for cirrhosis from 1988 to 2016 (ELTRA). Coexistence of diabetes or obesity is an important risk factor of NAFLD/NASH morbidity. It is known that for one unit of body mass index (BMI), risk of occurrence of NAFLD increases by 13–38%, while for 1 cm more in waist circumference, its change reaches 3–10%.

Chlorogenic acid is known for its antioxidant, anticarcinogenic, and anti-inflammatory properties. It is a common constituent present in human diet in products like coffee, artichokes, potatoes, berries, peach, apple, anise, fennel, etc. (Clifford 1999). Despite many sources, most of them cannot be considered in epidemiological studies, because the dosage is too low or consumption is occasional and difficult to determine. Seasonal availability of most products causes even more considerable fluctuations. Potato tubers, due to their year-round availability and wide consumption, might be an epidemiologically interesting source of CGAs reaching 17.3 mg/100 g of fresh weight, but the cooking and baking processes cause 60% and 100% of their loss, respectively (Dao and Friedman 1992).

Apples were the most produced fruit in EU in terms of quantity, with 12.7 million tons harvested in 2015 (or almost 25 kg per EU inhabitant) (Eurostat). Among other fruits apples have the highest amount of free phenolics which can be easily absorbed into the bloodstream. Pure 5-*O*-caffeoylquinic acid is recovered from the intestine reaching even 60.8% of intake (Borges et al. 2013). It is also the main phenolic acid found in apples, with the second highest antioxidant activity among all other compounds, except rutin which ranks first. 100 mL of apple juice contains about 3.5 mg of pure 5-*O*-caffeoylquinic acid (Borges et al. 2013), while that of the fruit and peel reaches 12.6 mg/100 g FW and 0.26 mg/g FW, respectively (Kalinowska et al. 2014). CGA concentration is not constant, and factors like cultivar type, maturity of the fruit, conditions of cultivation, rising, harvest, and storage significantly affect those values.

In turn artichokes provide about 450 mg/kg of chlorogenic acid and are rich source of cynarin, an isomer of 1,5-diCGA formed spontaneously in water and constituting about 800–1400 mg/kg dry mass of capitula (Clifford 1999). Global consumption of artichokes in 2015 reached 1,637 tons, and nearly one-third out of it was eaten in Italy (511,000 tons). That gave 8.55 kg per person per year which is

impressive compared with global average of 1.07 kg/year. In the USA according to USDA, Economic Research Service in 2017, artichoke consumption per capita was 1.43 pounds, equivalent to 0.648 kg per year. An average Italian eats about 23 g of artichokes per day compared with 1.8 g for an average American. However, the consumption trend is rising; this cannot be taken into epidemiological consideration, since the highest Italian consumer eats about 10 mg of CGA daily through artichokes (Parr et al. 2018).

Compare with a single espresso that can contain up to 116 mg of chlorogenic acid, potatoes are rather poor source of this polyphenol (Ludwig et al. 2014). Therefore, for further epidemiological studies, coffee was selected as a most valuable source of CGAs in a human diet.

Coffee is one of the most frequently consumed beverages in the world with about 500 billion coffee cups drank annually. In 2017/2018, the world's total coffee consumption was estimated to be 9.72 million tons, with almost one-third of which was in Europe. According to the International Coffee Organization (ICO) statistics, coffee consumption varies significantly across Europe. The highest coffee consumption is estimated in Scandinavian countries reaching annually 12 kg per person in Finland or 9.9 kg in Norway compared with 5.8 kg in Italy or 5.1 kg in France. In several countries like Denmark, the USA, Brazil, and Japan, coffee is the major source of dietary phenolic antioxidants (Komes and Belščak-Cvitanović 2014).

The CGA content in coffee varies depending on species and roasting, grinding, or brewing conditions (Perrone et al. 2010). In commercial coffee industry, two species are the most valuable: *Coffea arabica* with fine, mild aroma and *Coffea canephora* var. *robusta* with more distinctive taste. Generally arabica contains less CGAs than robusta and about 50–60% less of caffeine. The second main factor influencing CGAs content is roasting, which causes progressive destruction of CGAs. Coffee beans roasted in 220 °C for 6, 7, 8, 13, and 15 min lose about 25%, 60%, 70%, 98%, and 99% of CGAs, respectively (Antonio et al. 2010), which remain consistent with other papers (Ludwig et al. 2014; Farah et al. 2005; Priftis et al. 2018). Both of those components significantly influence the taste of coffee and can be seen in regional preferences. People from South European countries generally drink darker roasted coffee and blends with robusta varieties as a basis, while North European consumers favor mild arabicas and a lighter roasting (Ludwig et al. 2014).

Coffee drinking is very popular around the world, and many techniques of brewing are used, listing filter coffee, French press, instant, Italian, Turkish, or high-pressure espresso. Filter coffee provides the lowest content of beneficial polyphenolic compounds, while most was found in the instant one. By now 40% of instant coffee is made from robusta beans from *Coffea canephora*, which explains the higher content of CGAs compared with classical brewed coffee. Relatively high amount of chlorogenic acid is present in espresso coffee reaching 0.43–4.31 mg/mL which on average volume about 35 mL gives 15.05–150.85 mg per serving. Filter coffee consists 0.41–1.57 mg/mL making about 41–157 mg per 100 mL serving. In this case differences are caused by different times of brewing which directly affect the extraction process (Ludwig et al. 2012; Jeon et al. 2017). Grain grinding degree

affects the content of CGAs in accordance with the principle that the smaller the particles are taken, the more effective the extraction process is (Jeon et al. 2017). Reheating of coffee to boiling temperature elevates CGA and caffeine content on approximately 23% (Niseteo et al. 2012).

As the roasting and brewing time significantly changes CGA content in coffee, other coffee additives change the bioavailability of polyphenols. Addition of milk significantly decreases polyphenolic content and antioxidant capacity of coffee which may be caused by potential interactions between polyphenols and milk proteins (Niseteo et al. 2012). Interestingly Ludwig et al. did not confirm those findings in his study showing that CGA content in espresso and espresso-based latte or cappuccino is comparable (Ludwig et al. 2014). Duarte and Farah (2011) found that instant coffee dissolved in milk has about 19% less CGA metabolites compared to one dissolved in water and that addition of milk causes reduction of coffee metabolite amount in urine. Unfortunately, there is no additional data about "milk" used in all referred experiments.

Decaffeination process can be done by several methods based on organic solvents used or nonorganic-solvent-based processes. Dichloromethane or ethyl acetate is the most popular organic solvent used in decaffeination process. Other methods without organic solvent are based on water decaffeination or carbon dioxide caffeine extraction (Lack and Seidlitz 2012). In methods using organic solvent, some of chlorogenic acid is lost because of repeated heating process to evaporate the solvent. Lima et al. show that about 60% of chlorogenic acid is lost in decaffeination using dichloromethane in the case of green coffee, while in roasted coffee its content decreased only at about 5% compared with normal caffeinated coffee. Chlorogenic acid content for green coffee reached (g/100 g of ground coffee) 4.95 ± 0.043 and 1.95 ± 0.041 for caffeinated and decaffeinated, respectively, while for roasted coffee those values were 0.40 ± 0.017 and 0.38 ± 0.008 (Lima et al. 2013). In turn, when decaffeination is performed using a method without organic solvent like in water, coffee brews contain higher total content of chlorogenic acids than its regular coffee counterparts. Farah et al. (2005) report an average increase of about 18% in total CGAs in coffee decaffeinated with this technique. Green coffee steaming prior decaffeination is often used to moisten the bean and cause it to swell which makes subsequent caffeine extraction easier. Steaming causes about 10–20% loss of CGAs (Steinhart et al. 2001; Budryn et al. 2015). Most decaffeinated coffees available is decaffeinated using organic solvents. Coffees usually defined as "bio" are mostly decaffeinated with water.

Considering the above, determining the average amount of specific constituents is ineffective, considering the number of variables that appear within one "cup of coffee." Each cup of coffee consists relatively high amount of chlorogenic acid that possesses many health-promoting properties. Most of them are related to the treatment of metabolic syndrome including antioxidant, anti-inflammatory, antilipidemic, antidiabetic, and antihypertensive activities. Benefits of coffee drinking strictly overlap them suggesting that the range of coffee activities results from its high content of chlorogenic acid. However coffee is also the major natural dietary source of caffeine, a purine alkaloid, exerting stimulatory effect on sympathetic

nervous system. Kahweol and cafestol, the coffee diterpenes, are also reported to administer liver protective action (Muriel and Arauz 2010). Coffee drinking health benefits therefore cannot be linked just with CGAs, as every single cup possesses a number of active constituents which may act simultaneously or in contrary to polyphenols. Studies investigating the relationship between coffee consumption and different disease morbidities are of interest to many research groups. However, such studies are too often restricted to testing an influence of a 'cup of coffee' without quantitative analysis of active constituents.

Caffeine role in liver protection remains unclear although some efforts are taken to explain this issue. Caffeine-containing beverages including coffee, decaffeinated coffee, tea, chocolate, and Coca-Cola were investigated on the risk of symptomatic liver cirrhosis. No evidence of significant trends was observed in examined beverages except in coffee. In this case inverse association was noticeable with dose-dependent manner starting with one cup of coffee a day. Liver cirrhosis odds ratios decreased from 1.0 for control group of non-coffee drinkers to 0.47, 0.23, 0.21, and 0.16 in 1, 2, 3, 4, or more cups of coffee drinkers, respectively (Corrao et al. 2001). That remains consistent with Kennedy et al.'s findings who noticed the association between high coffee consumption and reduction of hepatocellular carcinoma risk. In this case in turn caffeinated and decaffeinated coffee were examined, both showing downward risk trend, but to a lesser extent for decaffeinated one (Kennedy et al. 2017). As decaffeinated coffee consists less CGAs, and no additive data determining "coffee" is provided, fluctuations between coffee brewing might occur causing significant differences in CGAs concentration. After all the abovementioned findings may suggest the positive role of constituents other than caffeine in hepatocellular carcinoma risk reduction.

Basically, most of the research confirm the finding that coffee drinking has a positive impact on liver enzymes. These phenomena were firstly observed in 1985, and since then numerous studies confirmed it. It may be a surprising fact that coffee drinking is generally linked with less healthy lifestyle including cigarette smoking, less physical activity, and less healthy diet. The reduction of transaminases (alanine transaminase (ALT), aspartate transaminase (AST)), alkaline phosphatase (ALP), and gamma-glutamyltransferase (GGT) is significant and dose dependent. In 1999–2010, in US National Health and Nutrition Examination Survey, 27,793 participants were examined for association of coffee drinking and level of enzyme activity. It was confirmed that drinking of three or more cups of coffee a day lowers the level of liver enzymes with OR = 0.75 (95% CI: 0.63–0.89), 0.82 (95% CI: 0.68–0.98), 0.73 (95% CI: 0.55–0.95), and 0.69 (95% CI: 0.57–0.83) for ALT, AST, APT, and GGT, respectively. The similar inverse association was observed also in case of decaffeinated coffee. Drinking of two or more decaffeinated cups of coffee a day compared with non-coffee drinkers had OR = 0.62 (95% CI: 0.41–0.94), 0.74 (95% CI: 0.49–1.11), and 0.70 (95% CI: 0.49–1.00) for ALT, AST, and GGT, respectively (Xiao et al. 2014). Serum levels of ALT and AST were also lower for coffee drinkers in dose-dependent manner in recent prospective cohort study of European Prospective Investigation into Cancer and Nutrition (EPIC). However, some of those observations were more significant after adjusting to sex. ALT and

AST were lower for men by 6.3% and 9% while in women by 3% and 5%, respectively. Generally compared with nonconsumers, high coffee consumers had statistically significant lower mean levels of liver enzymes and higher serum albumin (Gunter 2017). Ikeda et al. and Danielsson et al. (2013) observed that inverse association of coffee intake and liver enzymes activity is even more significant in people who consume alcohol compared with nonalcoholic drinkers (Ikeda et al. 2010; Danielsson et al. 2013). This phenomenon seems to have general application, as research around the world considering all human races, Caucasians, Black, White, Latinos, and others, confirm those findings. Setiawan et al. (2015, 2017) in recent multiethnic studies noticed that the reduction of liver enzyme activity and fibrosis is inversely associated with coffee consumption. This association was mainly observed in alcoholic liver disease when cirrhosis has already occurred, but in case of NAFLD, the association was significant for both cirrhosis and non-cirrhosis cases.

Due to recent EPIC studies, coffee drinking is strictly related with all-cause lower mortality in dose-dependent manner. In big cohort study lasting for 16.4 years, 520,000 participants from 10 European countries were investigated in case of mortality of any reason. Participants were divided into five groups depending on the coffee drinking amount: nonconsumers (NC) and drinking <1 (L), 1 – <2 (M-L), 2 – <3 (M-H), and 3+ (H) cups of coffee a day. Other factors were considered, like BMI, physical activity, smoking status and its intensity, education, menopausal status, ever use of oral contraceptives or menopausal hormone therapy, alcoholic drinks, total energy, and eating habits including red, processed meat, fruit, and vegetable intake. Strong inverse associations were observed between high coffee consumption and deaths of specific diseases. Mostly visible was mortality limitations due to deaths from diseases of gastrointestinal tract including liver disease, NASH, and alcoholic cirrhosis. Medium-low (M-L) coffee consumption reduced digestive diseases by about 30% in both men and women, while medium-high (M-H) coffee consumers reached 54% and 33% less for men and women, respectively. High (H) coffee consumers died of digestive diseases relatively 59% and 40% less frequently for men and women, respectively (Gunter 2017).

Coffee drinking health benefits have been repeatedly reported and analyzed in numerous studies including meta-analyses and reviews. Most of them are consistent proving that drinking of three to four cups of coffee a day significantly reduces morbidity and mortality of liver diseases including NAFLD, cirrhosis, and chronic liver diseases secondary to HBV and HCV like hepatocellular cancer. Regardless to the etiology of hepatocellular carcinoma, coffee drinking inversely reduces the morbidity which was documented in several studies (Setiawan et al. 2015; Gelatti et al. 2005; Larsson and Wolk 2007). All observations are convergent and report about 40% risk reduction for people who drink about three to four cups of coffee a day.

Moreover, coffee consumption appears to have an association with decreased risk of colorectal cancer. Coffee, as well as its individual constituents caffeine, caffeic acid, chlorogenic acid, and kahweol, has shown a potentially protective action in colorectal cancer – the third leading cause of cancer-related death in the USA. Epidemiological studies confirm strong sex dependency in colorectal morbidity

and coffee intake. In this case clear results are hard to obtain as reports are often contradictory and results are significant only in well-defined groups. In a recent report, Bułdak et al. compiled current research presenting analysis of coffee impact on colorectal cancer morbidity. Out of 21 epidemiological studies presented, more than half showed no significant association between coffee drinking and colorectal cancer incidence (Bułdak et al. 2018). Dose dependency was not observed even in Finland where coffee consumption reaches even ten cups a day (Bidel et al. 2010). The inverse association was reported in seven studies, while dose-dependent increased risk was observed in three studies. Sex dependency was reported in some studies, but information was inconclusive. Japanese studies of 96,162 people with 50,139 women report that risk of invasive colon cancer in woman who regularly drink three or more cups of coffee a day reach RR of 0.44 (95% CI = 0.19–1.04; p for trend = 0.04) compared with RR = 1.00 for non-coffee drinkers (12). In turn, in European research, a positive association was observed with HR = 1.12 (95% CI = 1.03–1.23) and HR = 1.33 (95% CI = 1.22–1.46) for three and four cups of coffee per day, respectively (Gunter 2017). It is difficult to confirm if ethnical differences are significant as inaccuracies occur even within homogeneous groups. Yamada et al. showed high risk of colon cancer in men, but not in women, drinking more than three cups of coffee a day with HR of 1.26 (95% CI 0.93–1.70), while Nakagawa-Senda et al. in the same dosage of three cups of coffee a day report of lower cancer risk of OR = 0.78 (95% CI: 0.65–0.92) (Yamada et al. 2014; Nakagawa-Senda et al. 2017).

The bioavailability and pharmacokinetic aspects of coffee may play an important role in colorectal cancer activity. In humans, one third of chlorogenic acid is absorbed in the small intestine, and the undigested rest is reaching the colon where it is hydrolyzed to caffeic acid by colon cancer cells. In turn caffeine is absorbed in the stomach and small intestine, and its oral bioavailability reaches 99% (Tian et al. 2019; Liguori et al. 1997). Caffeine present in serum is significantly inversely associated with colorectal cancer, but inverse association for decaffeinated coffee and colorectal cancer indicates that caffeine impact in vivo is lower as it is in in vitro studies. Kahweol in humans is absorbed in about 70% and plays a great role in carcinogenesis as protective agent against severe toxins like aflatoxin B1 or 2-amino-1-methyl-6-phenylimidazo(4,5-b)-pyridine. In fact, epidemiological studies focus on the entire coffee drink without precise qualification of individual constituents (Stalder et al. 1990; Lee and Jeong 2007).

Moreover, it is documented that chlorogenic acid may reduce intestinal glucose absorption and significantly affect glucose administration and its blood level. It becomes relevant as development of type 2 diabetes is strictly associated with liver diseases: in NAFLD and NASH patients it is estimated to be 22.51% and 43.63%, respectively (Younossi et al. 2016). It has been proved that coffee consumption is inversely associated with risk of type 2 diabetes regardless of caffeine presence. Drinking of six cups of coffee a day may lower the type 2 diabetes risk even on 33% with no statistical significance between caffeinated and decaffeinated one. This association may be even stronger, while high coffee drinking is usually connected with less healthy lifestyle. Ding et al. in his meta-analysis findings on

1,109,272 participants and 45,335 cases of diabetes had also noticed high dose dependency. For each cup of coffee per day, irrespective of caffeine content, the type 2 diabetes risk was lower at about 6–10%. This would indirectly imply health benefits of coffee distinguishing other compounds rather than caffeine (Ding et al. 2014).

22.8 Patents, Marketed Products, and Perspectives

Being well-known and important constituents of coffee and several vegetables, chlorogenic acid and related phytochemicals have been subjects of an immense number of patents around the world. A database search using "chlorogenic acid" yields over 12,000 hits, thereof 3500 are from the World Patents Office. Their scope is from isolation and purification from various materials (mainly coffee, though) to pharmaceutical and nutraceutical applications.

The pharmaceutical/therapeutic indications include polycystic ovary syndrome (WO2014025864A2), conjunctivitis (WO2009045054A2), metabolic syndrome (WO2008115723A1), fibroblast stimulation (WO2016150356A1), transglutaminase inhibition (WO2008153318A2), and many others. CGA was also patented by global corporations as ingredient of sweeteners that were supposed to prevent and combat inflammation, diabetes, and related disorders (e.g., WO2007061803A1, WO2008057968A2, WO2007061912A2).

Certainly, there is also a huge number of marketed products, claiming a lot of extraordinary health benefits. Most of the so-called "green coffee" supplements include chlorogenic acid activities in their advertisements. However, there are also products that are marketed as true herbal medicines, following the country-specific regulations. Chlorogenic acid or other compounds such as cynarin are quality markers in products from several herbal drugs, including pharmacopoeial ones. Such herbs include, for example, those listed in European Pharmacopoeia monographs: artichoke leaf, narrow-leaved coneflower root, nettle leaf, pale coneflower root, purple coneflower herb, and purple coneflower root. In Turkey, the bark from *Viburnum opulus* is used for manufacturing chlorogenic acid-enriched herbal drugs. Cardoon (artichoke) leaves are used in several European countries to prepare herbal medicines with indications for digestive and liver disorders.

This trend, however, does not imply that all these inventions and products indeed contribute to the importance of CGA and other CQAs as public health-relevant compounds. Nevertheless, it confirms the worldwide interest in these phytochemicals which will most likely continue in the future along with more insightful data on the mechanisms at work in the pharmacological and dietary properties attributed to consumption of coffee, Compositae vegetables, or, more recently, blueberries and bilberries. The latter have been not so intensively studied with respect to CQAs as important phytochemicals, contributing to their beneficial properties along with much more conspicuous anthocyanins.

As a closing remark, we suggest that instead of introducing too many preparations with unverified therapeutic or preventive properties, the future direction should

rather be to popularize CQA-rich foodstuffs, especially vegetables and herbal teas, in which CQAs could act in concert with other dietary polyphenols, therefore providing the consumers with broader scope of benefits. The concentrated extracts, with proper validation for CQA content, could also benefit the public health by preventing lifestyle diseases, improving longevity, and alleviating stress-related deterioration of health.

Whether this would be achieved by increased coffee consumption only is rather doubtful (depends on the local traditions and economic situation), and focus should be on change of dietary habits toward higher intake of selected vegetables and fruits such as blueberries and bilberries.

However, more epidemiological studies are needed population-wide to prove these beneficial effects of CQAs.

Abstract

Cinnamic and coumaric acids belong to the large family of phenylpropanoids with C6-C3 skeleton. Main biosynthetic route involves deamination of phenylalanine into trans-cinnamic acid, followed by hydroxylation into coumaric acids. In plants, *p*-coumaric acid is a predominant isomer that is preferentially bound to cell wall polysaccharides by ester bond. Food processing in general results in the release of bound acids that can be absorbed in the gastrointestinal tract. The maximum plasma concentration of coumaric acid is reached in minutes after ingestion, and halftime in blood circulation is longer than that of more hydroxylated cinnamates. Pure compounds as also complex plant extracts with high cinnamic and coumaric acid content have beneficial effects in amelioration of diabetes, carcinogenesis, or uncontrolled inflammation. Additionally normal physiological functioning of lipid and bone metabolism and neuroprotective and eye-protective effects were confirmed. Most experimental results were obtained on model animals and human and animal cell cultures; there is nevertheless lack of human intervention studies with pure compounds. Low acute toxicity in mammals and pronounced toxic effect on certain pathogenic microorganism, together with antioxidant activity of the molecules, point to the potential application for food conservation. A large number of patents related to the production and application of cinnamic and coumaric acids in food and other sectors were issued in the recent years.

Phenylpropanoids · Phenolic acids · Cinnamic acid · Hydroxycinnamic acids · Oxidative stress-related diseases

23.1 Introduction

We would like to start this chapter by quoting Hippocrates "Let food be the medicine and medicine be the food." Historically, natural products have played an important role in drug discovery to combat a variety of diseases. An oxidative stress, resulting from the imbalance between reactive oxygen and nitrogen species (ROS or RNS) and antioxidants, has been recognized as a major contributing factor in the pathogenesis of various diseases. Phenolic compounds are well-known antioxidants that scavenge and therefore potentially protect against ROS- or RNS-induced in vivo damage. Numerous studies have been performed to explore the positive role of polyphenols in the prevention and treatment of oxidative stress-related diseases, such as neurodegeneration, cardiovascular diseases, and cancer.

Phenolic acids are diverse group of secondary plant metabolites that are widely distributed through the plant kingdom and are an integral part of human diet. In food plants, they are occurring as esters or glycosides conjugated with other natural compounds such as flavonoids, alcohols, hydroxy fatty acids, sterols, and

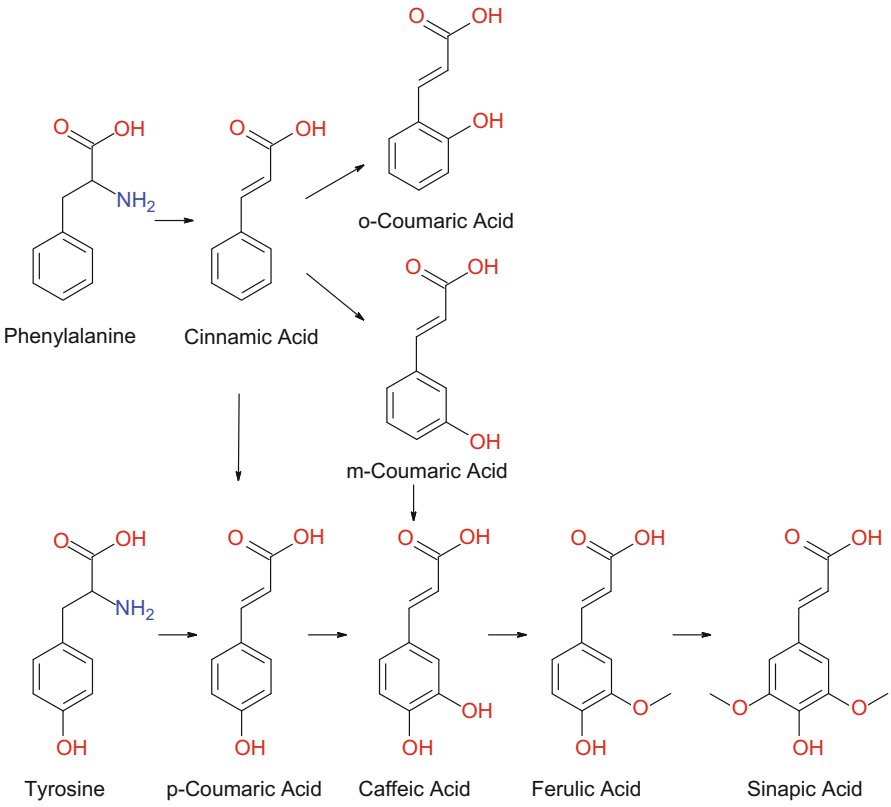

Fig. 1 Biosynthetic pathway of the phenylpropanoids in plants

glucosides. Although the role of phenolic acids in plants still remains unknown, they have been associated with diverse functions, including nutrient uptake, protein synthesis, enzyme activity, photosynthesis, structural components, and allelopathy (Naczk and Shahidi 2006). Phenolic acids can be divided into two major groups: hydroxybenzoic acids and hydroxycinnamic acids. Chemically, phenolic acids have at least one aromatic ring in which at least one hydrogen is substituted by hydroxyl group. The hydroxycinnamic acids are a series of trans-phenyl-3-propenoic acids that differ in their ring substitutions and include caffeic acid (3,4-hydroxycinnamic acid), ferulic acid (3-methoxy, 4-hydroxy), sinapic acid (3,5-dimethoxy, 4-hydroxy), and *p*-coumaric acid (4-hydroxy) (Fig. 1). There are three isomers of coumaric acid, *o*-coumaric acid (*o*-CouA), *m*-coumaric acid (*m*-CouA), and *p*-coumaric acid (*p*-CouA), that differ by the position of the hydroxy substitution of the phenyl group. *p*-CouA is the most abundant isomer of the three in nature and the most studied one. *p*-CouA exists in two forms, trans-*p*-CouA and cis-*p*-CouA. In different foods the derivatives of *p*-CouA such as *p*-coumaroyl glucose, *p*-coumaroyl malic acid, *p*-coumaroyl glycolic acid, *p*-coumaroyl tartaric acid, *p*-coumaroylquinic acid, and some others can be found (Fig. 2).

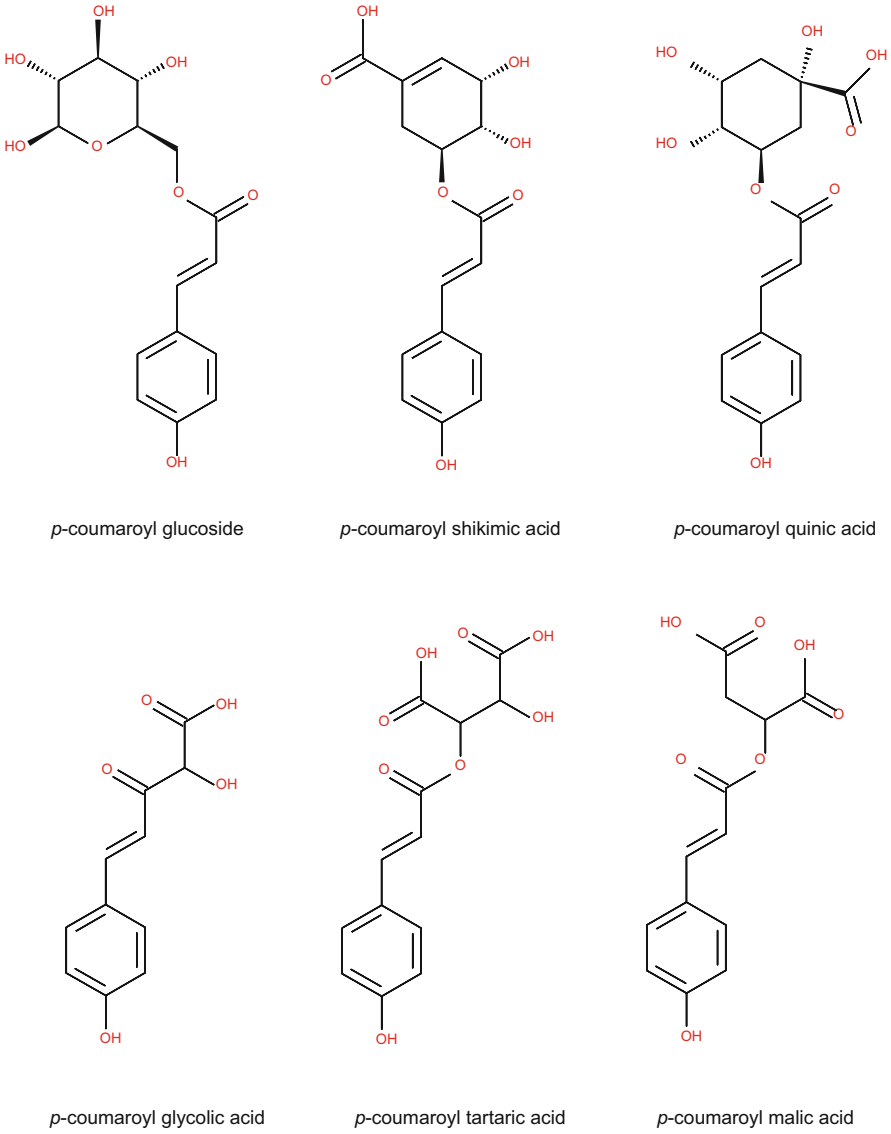

Fig. 2 Derivatives of *p*-coumaric acid

In Tables 1 and 2, the selected foods from Phenol-Explorer database which contain the highest amount of *p*-CouA and cinnamic acid (CinA) are listed, respectively. Detailed inspection of Tables 1 and 2 reveals that the content of CouA and CinA increased after hydrolysis process indicating that the *p*-CouA is conjugated (Neveu et al. 2010; Rothwell et al. 2012; Rothwell et al. 2013). Food processing as freezing, steaming, (pressure) boiling, frying, sterilization, and fermentation releases the cell wall-bound phenolic acids.

Table 1 Content of coumaric acid in foods. (The data were obtained in March 2019 from the http://phenol-explorer.eu/contents/polyphenol/454)

Food	Content of free *p*-coumaric acid	Content of *p*-coumaric acid after hydrolysis

Olive (green), raw	14.33 mg/100 g FW	21.00 mg/100 g FW

Presence of phenolics in foods may have important effects on the oxidative stability and microbiological safety of products. In addition, many phenolics in raw or processed foods have important biological activity related to their inhibitory

effects on carcinogenesis and other diseases. The *p*-CouA acid has beneficial effects on human health through the prevention of degenerative pathology, such as cardiovascular diseases and cancer (Kadoma and Fujisawa 2008). The beneficial effects of cCouA and CinA will be discussed in this chapter.

23.2 Bioactive Constituents

23.2.1 Biosynthetic Pathway

The phenylpropanoids are a diverse family of organic compounds that are synthesized by plants from the amino acids L-phenylalanine and L-tyrosine. Among the most widely distributed phenylpropanoids in plant tissues are the cinnamic acid (CinA) and hydroxycinnamic acids or hydroxycinnamates (HCAs) – a class of aromatic acids having a C6-C3 skeleton. The typical examples of HCAs are coumaric acid (hydroxycinnamic acid), caffeic acid (3,4-dihydroxy-cinnamic acid), ferulic acid (4-hydroxy-3-methoxy-cinnamic acid), and sinapic acid (4-hydroxy-3,5-dimethoxycinnamic acid) which are produced from the shikimate pathway from L-phenylalanine or L-tyrosine as shown in Fig. 1. The most common HCAs are not present in plants in a free state but are predominantly associated with other molecules to form glycosylated derivatives or esters of tartaric acid, quinic acid, shikimic acid, glucose, or coenzyme A. Glycosylation takes place on carboxyl and not at the phenolic hydroxyl groups (Fig. 2).

L-Phenylalanine and L-tyrosine act as C6-C3 building blocks and are precursors for a wide range of natural products. In plants elimination of amino group from phenylalanine leads to formation of CinA, while elimination of amino group from tyrosine could yield *para*-coumaric or 4-coumaric (*p*-CouA) as shown in Fig. 1. All plants appear to have the ability to deaminate phenylalanine via phenylalanine ammonia lyase (PAL) enzyme and hydroxylate CinA into *o*-, *m*-, or *p*-CouA via cinnamic acid hydroxylase enzymes. On the other hand, the corresponding transformation of tyrosine yields only *p*-CouA and is mainly limited to members of the grass family (the Gramineae/Poaceae) (Pereira et al. 2009). *p*-CouA can be further oxidized via *p*-coumaric acid 3-hydroxylase (also called *p*-coumaroyl ester 3-hydroxylase) leading to formation of caffeic, ferulic, and sinapic acid. The most representative HCA is caffeic acid, which occurs in fruits, vegetables, and coffee, mainly as an ester with quinic acid (chlorogenic acid or 5-caffeoylquinic acid) (Croft 1998; Fingerman and Nagabhushanam 2006).

23.2.2 Mechanism of Antioxidant Activity

Oxygen is necessary for aerobic respiration to break down food molecules and to release energy. But aerobic respiration is also accompanied with generation of series of reactive oxygen species (ROS). Reduction of oxygen through addition of electrons (often during mitochondrial electron transport) leads to formation of a number

of ROS including superoxide anion radicals ($\bullet O_2^-$), hydroxyl radicals (•OH), hydrogen peroxide (H_2O_2), hydroxyl ion (OH^-), and nitric oxide (•NO). ROS are continuously produced and can have a role in cell signaling pathways (Hancock et al. 2001), but they can also cause damage to cells or crucial biomolecules, thus leading to disease conditions. It has been established that simple phenolic acids, such as benzoic or cinnamic acids, and their derivatives have antioxidant and radical scavenging properties (Kilic and Yesiloglu 2013). Antioxidant and radical scavenging potency of molecules depend on the electronic structure. For example, caffeic, sinapic, ferulic, and coumaric acids have an additional -CH=CH- group between phenyl and carboxyl group when compared to protocatechuic, syringic, vanillic, and p-hydroxybenzoate. This additional double bond makes caffeic, sinapic, ferulic, and coumaric acids more potent antioxidants and radical scavengers than their analogues without -CH=CH- group between phenyl and carboxyl group. It may be that the -CH=CH-COOH linked to the phenyl ring plays a role in stabilizing the radical by resonance (Cuvelier et al. 1992; Natella et al. 1999; Mathew et al. 2015). According to the literature, the quasi-planar geometry of the molecule contributes to a better stabilizing effect through delocalization of the π-electron between aromatic ring and C=C bond (VanBesien and Marques 2003).

CinA and HCAs share a lot of properties and characteristics with polyphenols. Similar to polyphenols, CinA and HCAs are able to act as antioxidants and/or chemoprotectants. The mechanism of antioxidant activity can follow one (or combination) of several pathways shown in Fig. 3.

In the case of free radical scavenging, CouA can break free radical chain reaction. Hydroxyl group on benzene ring can react with reactive oxygen and nitrogen species by donating hydrogen and forming a radical form of CouA with unpaired valence

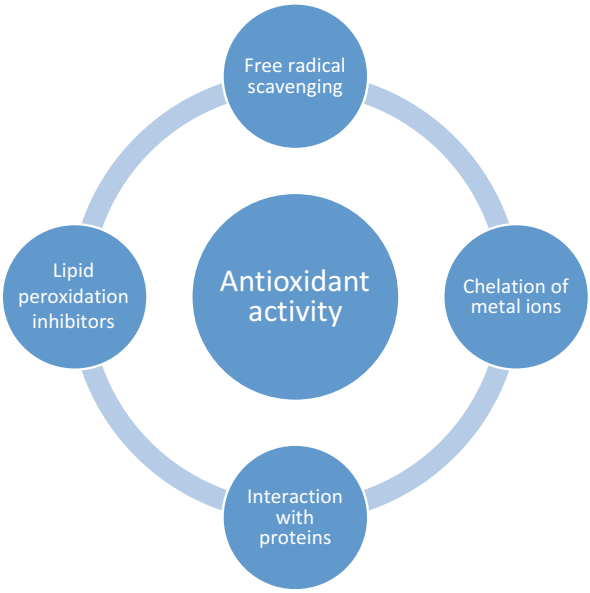

Fig. 3 Different mechanisms of antioxidant activity

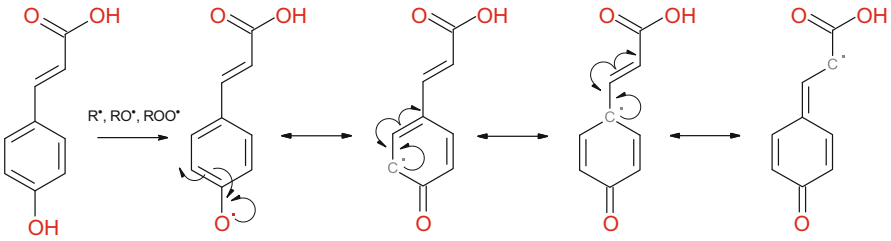

Fig. 4 Proposed mechanism of *p*-coumaric acid antioxidant activity

electron on oxygen atom. Radical form of CouA is more stable than reactive oxygen and nitrogen species because of the interaction of the hydroxyl group with the π-electrons of the benzene ring. Namely, radical form of CouA is stabilized by delocalization and resonance (Fig. 4). The formation of these relatively long-lived radicals is able to modify radical-mediated oxidation processes (Pereira et al. 2009; El-gizawy and Hussein 2017). The antioxidant activity of phenolic acids is related to the number and position of hydroxyl groups in the molecule. Even though CinA lacks any hydroxyl groups on benzene ring, it still possesses some radical scavenging activity. The ability to scavenge free radicals increases by adding hydroxyl group to benzene ring, thus obtaining CouA. Radical scavenging activity of CouA can be further optimized by placing hydroxyl group on *para*-position and/or adding second hydroxyl or methoxy group, thus obtaining other HCAs. Regardless of the position of hydroxyl group, CouA has lower antioxidant activity when compared to other HCAs (Briante et al. 2003) and can even behave like prooxidants, depending on their concentration (Fukumoto and Mazza 2000; Kristinová et al. 2009). The antioxidant efficiency of monohydroxylated compounds is strongly enhanced by the introduction of a second hydroxyl group at the ortho (e.g., caffeic acid)- or para-positions and is increased by one or two methoxy substitutions in ortho-position (e.g., ferulic or sinapic acid) with respect to the hydroxyl group (Fukumoto and Mazza 2000).

Exposure to environmental chemical carcinogens may be responsible for large number of human cancers. Nitrites from food and water are precursors in the formation of N-nitroso compounds, which are genotoxic compounds consisting of nitrosamines and nitrosamide. Formation of N-nitroso compounds can be blocked by all HCAs, including *p*-CouA. *p*-CouA can react with nitrites and thus function as chemoprotective agents to inhibit N-nitrosamine formation. Figure 5 shows the beginning of the mechanism of reaction of *p*-CouA with nitrite in H_2O that can lead to different products depending on the conditions. *p*-CouA is most reactive at acidic pH, but it might also serve as a nitrite scavenger at higher pH values (Torres y Torres and Rosazza 2001).

Due to absent hydroxyl group(s) on phenyl ring, the ability of CinA to scavenge free radicals is lower when compared to HCAs. Nevertheless, it can boost antioxidant response by elevating antioxidant enzyme levels. Consequently, the pretreatment with CinA can provide protection to normal cells from the toxic effects of the widely used anti-cancer drug by significantly reducing the lipid peroxidation.

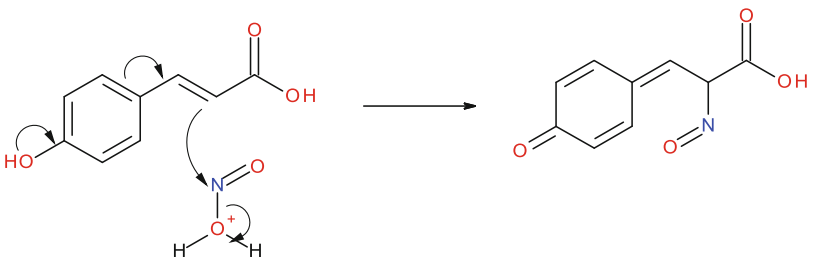

Fig. 5 Reaction of p-coumaric acid with nitrite in water which can lead to different products depending on conditions likely to be found in living systems. (Adapted from Torres y Torres and Rosazza 2001)

The details of protection mechanism offered by CinA are still under investigation (Patra et al. 2012). Although antioxidant activity of HCAs is most often linked to their hydrogen donating ability, other mechanisms have been suggested. The antioxidant capacity of HCAs is also attributed to their ability to chelate transition metals, like copper or iron, which act as catalysts in the production of free radicals leading to lipid peroxidation, protein modification, and DNA damage (Vaya and Aviram 2001; Andjelkovic et al. 2006; Gaspar et al. 2009). Catechol group seems to be crucial for complex formation, so CinA and CouA should not be unable to chelate metals. This seems to be true for CinA, but there are reports describing the ability of *p*-CouA to form complexes with several metals (Swislocka et al. 2012; Shen et al. 2018).

CinA and HCAs exhibit amphoteric properties due to their hydrophobic phenyl ring, and hydrophilic hydroxyl groups thus have the potential to interact with proteins. Interaction with proteins is important because it can modulate (a) nutrient uptake by solute-binding protein transportation (Tan et al. 2013), (b) quality of a food product during production and subsequent storage (Kaur et al. 2018), and (c) the activity of some specific enzymes, such as various cytochrome P450 isoforms, lipoxygenases, cyclooxygenases, and xanthine oxidases (Cos et al. 1998; Pereira et al. 2009). CinA and CouA can reversibly bind to serum albumins using them as carriers, thus increasing their uptake and overcoming low aqueous solubility.

23.3 Bioavailability and Metabolism

Most bioavailability studies concern caffeic acid and ferulic acid although there are other dietary important HCAs like rosmarinic acid or caftaric acid. Cereals, coffee, fruits, and vegetables are main sources for dietary CinA and HCAs including *p*-CouA; ferulic, caffeic, and sinapic acid; and their esterified/etherified conjugates. Table 2 shows that the highest amounts of CinA can be found in cinnamon and green olives. High amounts of CouA are present in eggplant, olives, broccoli, and asparagus; other sources are sweet cherries, plums, blueberries, cranberries, citrus peel and seeds, and orange juice. Daily intake of total HCAs can be as high as 2000 mg

(Clifford 2004), but this number varies depending on country, personal dietary habits, and geographic location (Bravo 1998). Due to their high consumption, cereals, coffee, and tea seem to be the most important sources of HCAs. Kern et al. showed that consumption of a 40 g portion of commercial high-bran breakfast cereal provides ~120 mg of hydroxycinnamates (Kern et al. 2003), and Clifford estimated that a single cup of coffee may contain 70–350 mg of hydroxycinnamates (Clifford 1999). Main food contributors to HCA intake are mostly represented by coffee since a coffee drinker usually drinks more than one cup of coffee per day and consequently ingests on average 630 mg of hydroxycinnamates per day just from coffee (Grosso et al. 2014). In Western countries, coffee and products derived from this drink are consumed regularly, thus representing the main food source of HCAs.

HCAs are usually covalently bound to the cell wall by forming ester bond with polysaccharides or can be found in plants as esters of tartaric acid, quinic acid, shikimic acid, glucose, or coenzyme A. The free form is also present in plants, but its amount is always lower than the amount of esterified form. For example, the amounts of free HCAs in coffee pulp were as follows (in%): *p*-coumaric acid 2.8, caffeic acid 5.6, chlorogenic acid 23.1, and ferulic acid 26.6 with respect to total content of individual HCA(Teresa Torres-Mancera et al. 2011). Feruloyl esterases represent a diverse group of carboxyl esterases that catalyze the hydrolysis of ester bonds between HCAs and plant cell wall polysaccharide. These enzymes have been mostly studied from microbial sources as potential biocatalysts in a wide variety of applications such as in biofuel, food and feed, pulp and paper, cosmetics, and pharmaceutical industries, but they are also present naturally in plants (Dilokpimol et al. 2016). There are no esterases in human tissues able to break these ester links, but Couteau et al. showed that certain gut bacteria, including some already recognized as potentially health-promoting (i.e., species belonging to the genera *Bifidobacterium* and *Lactobacillus*), have feruloyl esterase activity and are involved in the release of free HCAs in the human colon (Couteau et al. 2001). Because esterified HCAs exhibit lower absorption and bioavailability than free HCAs, the esterase activity of gut bacteria is crucial for transport of HCAs into human bloodstream. Although the main site for metabolism of esterified HCAs is colonic microbiota, up to one third of their absorption can also take place in the small intestine (Borges et al. 2013; Marin et al. 2015). Unabsorbed esterified HCAs that reach the colon are metabolized by the colonic microbiota into free HCAs (Deprez et al. 2000; Ou and Gu 2014; Neilson et al. 2017). Over the length of the colon, esterified HCAs are slowly metabolized, and gradient of native compounds and their microbial metabolites is likely established (Tsang et al. 2005).

To explain the in vivo effects of these compounds, it is very important to know the fate of phenolic compounds in the human body. The bioavailabilities of phenolic compounds vary widely, which depend on their chemical structures, metabolism, and biological activities (Ota et al. 2011). In situ or ex vivo absorption models suggest that, unlike covalently bound, free HCAs can be absorbed in all sections of the rat gastrointestinal tract, including the stomach, jejunum, ileum, and colon (Zhao and Moghadasian 2010). The exact mechanism for absorption of CinA and HCAs is not entirely clear due to the complexity of the processes affecting the absorptive

processes including diffusion and gut transporters. Since monocarboxylic acid transporters (MCTs) are expressed in many tissues and have an important role in the intestinal absorption, they might be involved in the absorption of CinA, HCAs, and their derivatives. Intestinal absorption of various compounds is usually studied with the human colorectal adenocarcinoma cell line (Caco-2), which represent a useful model since the cells are morphologically and functionally similar to human small intestinal epithelial cells. Uptake of CinA and some of the HCAs has been studied, and it was discovered that the uptake of di-hydroxycinnamic acid was markedly lower than that of mono-hydroxycinnamic acids and that the uptake of mono-hydroxycinnamic acids was lower than that of CinA. In general, hydroxylation, particularly di-hydroxylation, decreased the affinity for MCTs, probably due to decreased lipophilicity (Tsukagoshi et al. 2018). There are evidences suggesting that the uptake of HCAs might involve passive diffusion (Poquet et al. 2008; Zhao and Moghadasian 2010). If this is the case, then bioavailability of free HCAs should be correlated with their polarity because large polar substances are unable to cross lipid bilayers. The results published by Ota et al. (2011) and Nardini et al. (2009) on bioavailability of the free HCAs show that *p*-CouA which is less polar than caffeic and ferulic acids has the highest effect on the structure of the membrane lipids. Caffeic and ferulic acids, both more polar than *p*-CouA, had smaller effects on rigidity and dynamics of phospholipid chains in the cell membrane structure.

In order to determine bioavailability of CinA and HCAs, their concentration is measured in plasma and urine after ingestion. Analysis of *p*-CouA from blood and urine confirmed that *p*-CouA was absorbed well in the gut and excreted in its original form. Bioavailability of *p*-CouA was estimated to be between 70% and 75%, which is relatively high (Konishi et al. 2004; Zhang et al. 2007). It takes only couple of minutes to reach maximum plasma concentration of *p*-CouA after oral administration. It takes a little longer for ferulic acid to reach maximum plasma concentration meaning that *p*-CouA is absorbed more rapidly than ferulic acid. *p*-CouA is absorbed throughout the digestive tract with passive transport being the major pathway by which *p*-CouA enters bloodstream. On the other hand, an extensive absorption of CinA by the duodenum, jejunum, ileum, colon, and cecum has been associated with active transport system and indication that MCT may play a part in CinA absorption. It seems that absorption of CouA is slower and less efficient than that of CinA (Garrait et al. 2006). The metabolism of CinA and HCAs may occur in the liver, intestinal mucosa, and kidney and/or by intestinal microflora. HCA may undergo several enzymatic reactions during its metabolism, including O-methylation, sulfation, glucuronization, GSH conjugation, glycination, dehydroxylation, demethylation, dehydrogenation, and hydrogenation. After the free acid is released by bacterial esterases, it is then metabolized to reduce the double bond. The reduction of double bond yields phenylpropionic acid, which is then decarboxylated to produce phenylacetic acids. In the next step, dehydroxylation removes the hydroxyl at the 4th C-atom of the HCA phenyl ring. Methyl groups can also be removed from phenyl ring through demethylation at different stages of degradation (Tomás-Barberán et al. 2009). However, majority of *p*-CouA stays in free form after absorption and doesn't seem to become glucuronated by the jejunum

cells (Spencer et al. 1999). Ten minutes after oral administration of *p*-CouA, 58% of free form is still present in plasma. This percentage drops to 50% within 60 min of oral administration (Konishi et al. 2004). By contrast, free ferulic acid decreases to 15% within 15 min and to 1% within 60 min after oral administration (Zhao et al. 2003); thus the conjugation of *p*-CouA appears to be slower than that of ferulic acid. This can be confirmed by comparing urinary excretion rate of free *p*-CouA (24%) and free ferulic acid (5.4%) in rat urine. Plasma metabolites of ferulic acid were mainly sulfates or sulfoglucuronides regardless of the form under which ferulic acid was administered (free or combined with different carbohydrates). Absorbed free *p*-CouA can also be conjugated with glucuronide, sulfate, and sulfoglucuronide in the liver (Pei et al. 2016).

23.4 Bioactivities

23.4.1 General

Bioactivity of CinA and HCAs related to health has been subject of many reviews in the recent years. This is not surprising as research within this field is extremely active. Recently there was a shift from a study of general antioxidant properties to a specific influence on the different pathological processes, mostly on chronic and systemic disorders. In the case of coumaric acid, a relative proportion of word "coumaric acid" as also health-related words in the abstracts of manuscripts published in journals with impact factor is higher in last few years (Table 3). Experiments performed on human and animal cell cultures and dietary interventions with animals have shown many health-related benefits. Addition of CouA resulted in slower growth and spreading of tumors, often related to induced apoptosis of cancer cell and antiangiogenic activity. CouA has also antidiabetic and antihyperlipidemic activity and is therefore a potentially useful dietary component to ameliorate the negative effects of type 2 diabetes and obesity. Studies on various cell lines and dietary interventions on model animals have shown that coumaric acid possesses immunomodulatory and anti-inflammatory properties. The neuroprotective effects

Table 3 Comparison of particular word usage related to coumaric acid and health-related properties in the abstracts of manuscripts published in journals with impact factor. The data were obtained in February 2019 from the Web of Science database for indicated time periods

	All years	2014–2018	2016–2018
All manuscripts	33,723,429	10,190,679	6,301,026
Coumaric	5708	2084	1360
Cancer	294	161	109
Inflammation	98	68	49
Apoptosis	119	72	55
Diabetes	61	38	32
Health	402	234	163

mostly related to amelioration of ischemia were also confirmed. Those and some other health beneficial properties are presented in this section. The bioactivity-related properties of CinA were less analyzed; nevertheless some beneficial effects were also observed.

23.4.2 Cancer

23.4.2.1 Animal Cell Cultures and Model Animals

Certain phenolic compounds have anticancer properties. They can influence various stages of cancer development: transformation of normal cell into cancer cells, growth of tumors, and spreading of tumors from primary site to other sites within the organism (Anantharaju et al. 2016).

p-CouA can form hydrogen bonds to a heterocyclic aromatic amine that is formed during thermal treatment of foods and reduce its binding to DNA that could result in frameshift mutations (Ferguson et al. 2003). At 150 μmol/L *p*-CouA induce apoptosis of mouse neuroblastoma cancer cells lines. Large enhancement of ROS production resulted in structural changes of mitochondrial membrane and induction of caspase-8 mRNA (Shailasree et al. 2015). Angiogenesis is a crucial factor for tumor growth and migration. Methyl ester of *p*-CouA showed a dose-dependent anti-angiogenic activity on human umbilical vein endothelial cells inhibiting proliferation and tube formation in submillimolar range. Same compounds were tested on zebra fish embryos where a potent inhibition of vessel formation and inhibition of angiogenesis in zebra fish tumor cell line were observed already at 5–20 μmol/L range (Zhang et al. 2018). Mechanism of anticancer activity of *p*-CouA could be related also to the inhibition of indoleamine 2,3-dioxygenase expression that is overexpressed in various types of human cancers.

Animal feeding studies with *p*-CouA included in diet show mixed results. Rats fed with high-fat diet and incorporated *p*-CouA (0.1% w/w) developed less colorectal carcinomas and more adenomas induced by dimethylhydrazine in comparison to control; however, none of the effects was statistically significant (Femia et al. 2005). Later it was shown that *p*-CouA at a daily dose in a range 50–200 mg/kg of body weight statistically significantly inhibit formation of preneoplastic lesions induced by dimethylhydrazine. The onset of carcinogenesis is most likely attenuated by dose-dependent induction of antioxidant enzymes superoxide dismutase, catalase, and glutathione peroxidase (Sharma et al. 2017). Stabilization of redox status in normal cells that are affected by anticancer therapy is one of the benefits of *p*-CouA. Cisplatin is the potent anticancer agent that increases oxidative stress. *p*-CouA fed to adult Wistar rats was shown attenuate nephrotoxicity and hepatotoxicity, by increasing the expression of antioxidant enzymes that were down regulated by cisplatin (Akdemir et al. 2017). Such action of *p*-CouA can nevertheless be a double-edged sword, as improved redox status help to survive not only normal cells but also cancers cells and could therefore in principle promote carcinogenesis.

Cinnamic acid intragastrically administered to mice (150 mg/kg; 6 doses in 2 weeks) efficiently reduced the growth of colon carcinoma xenografts without having

the influence on body weight. The antitumor effect was attributed to the inhibition of histone deacetylases (Zhu et al. 2016).

23.4.2.2 Human Cell Cultures

Redox imbalance is one of the key mechanisms in cancerogenesis. High concentration of ROS can lead to mutagenesis, but also trigger necrotic or apoptotic death of cancer cells. On the other hand, lower concentration of ROS inhibits cell migration and proliferation but also increases the survival rate of cancer cells. In this regard anticancer potential of molecules that can alter the redox status of cells should be taken with care (Helfinger and Schroder 2018).

Experiments on human cell cultures have shown that *p*-CouA can inhibit growth of colon cancer and lung cancer cell lines in micromolar and millimolar range. Interestingly at millimolar range, the inhibition of growth was attributed to the induction of apoptosis through overproduction of ROS in mitochondria (Jaganathan et al. 2013), whereas, in hundred micromolar range, lower cell viability was attributed to the decreased concentration of superoxide anion that is crucial for normal functioning of cancer cells (Bouzaiene et al. 2015). Addition of *p*-CouA to the cell culture growth media resulted in lower antiangiogenic potential of endothelial cells (Kong et al. 2013). The viability of two different treated human cancer cell lines was significantly reduced from 10 micromolar to millimolar concentration range of *p*-CouA in growth media. Under these conditions, *p*-CouA downregulated the expression of molecular chaperone Grp78, concentration of which is increased in cancer cells. Lower concentration of Grp78 led to apoptosis (Sharma et al. 2018). Findings on cell cultures were confirmed on model animals. Male albino Wistar rats fed on a daily dose of *p*-CouA (100 mg/kg) showed significantly lower number of colon tumors induced by dimethylhydrazine and similarly to cell cultures lowered expression of Grp78. Anticarcinogenic effect on human breast cells was shown also for *o*-CouA that is positional isomer of *p*-CouA; nevertheless the IC_{50} value was relatively high (5 mmol/L) (Sen et al. 2013). Glucoside of *p*-CouA that is found in Chinese traditional herb decrease the viability of various human cancer cell lines with IC_{50} values in hundred micromolar range. The effect was attributed to mitochondria-mediated apoptosis. Same compound fed to mice at 50 mg/kg resulted in substantial reduction of tumor size (Peng et al. 2015). Alky esters of *p*-CouA that can be found in the roots of some edible plants as sweet potato are extremely cytotoxic to certain human cancer lines. The IC_{50} values for lymphoblastic leukemia cells are in sub micromolar range, even an order of magnitude lower than cisplatin, a chemotherapeutic agent. They induce apoptosis and activate caspase-3 enzyme (Menezes et al. 2017).

Cinnamic acid decreases the viability of human cancer stem cells that are often resistant to drug treatment. Incubation of human colorectal cancer cells in the presence of cinnamic acid at concentration higher than 10 mM resulted in reduced cell viability (IC50 13.6 mM). Nevertheless such concentrations cannot be obtained in vivo and are also for two to three orders of magnitudes higher than those of some common chemotherapy drugs (Soltanian et al. 2018).

23.4.2.3 Results Obtained on Complex Mixtures of Polyphenols with High p-CouA Content

Anticancer potential was also shown for various complex mixtures of phenolic compounds in which *p*-CouA is one of the major compounds. Cell wall-bound polyphenols of foxtail millet increased the sensitivity of human colorectal cancer cells to various chemotherapeutic agents. The mechanism is attributed to the lower expression of some drug resistance proteins, inhibition of cell proliferation, and promotion of apoptosis (Lu et al. 2018). Onion peel extract (100 mg/L) with high content of *p*-CouA had a strong cytotoxic effect on human colon carcinoma cells. Additionally onion peel extract lowered the synthesis of some antioxidant enzymes that were induced by exogenous oxidative stress and have an anti-inflammatory activity (Kim et al. 2013b). The extract of the herb *Salicornia freitagii* has a cytotoxic effect on human colon carcinoma cells. The mechanism is attributed to modulatory effect on the expression of enzymes involved in detoxification pathways and xenobiotic activation (Altay et al. 2017). Propolis, a complex mixture of phenolic compounds, where *p*-CouA is a mayor phenolic acid constituent, showed an apoptotic effect on human tongue squamous cell carcinoma cells. The ethanolic extract of propolis activated caspases 3, 8, and 9 in a dose-dependent manner. Mixture of constituents phenolic compounds was more potent inducer of apoptosis in comparison to particular compound indicating a synergistic effect (Czyzewska et al. 2016). Further experiments revealed that induction of apoptosis by phenolic compounds in propolis is related to increased mitochondrial proline degradation and decreased proline availability for collagen biosynthesis (Celinska-Janowicz et al. 2018).

Cinnamomum cassia bark extract, where cinnamic acid is a major constituent, induced apoptosis in human and mice oral cancer cells already at concentration of 25 mg/L. The extract supplied to mice by oral gavage (250 mg/day) efficiently reduced the tumor growth in mice, without having influence on weight (Yu et al. 2019).

23.4.3 Diabetes

23.4.3.1 Animal Cell Cultures and Model Animals

Diabetes mellitus is a metabolic disorder characterized by chronic hyperglycemia with disturbances of carbohydrate, fat, and protein metabolism. *p*-CouA has been shown to ameliorate some of the negative impacts of high glucose level and also interferes with some signaling pathways that are involved in the onset of type 2 diabetes. At 25 μM *p*-CouA improved glucose uptake by adipocytes in combination with hypoglycemic drug and increased expression of glucose transporter GLUT4 by threefold. Additionally expression of fatty acid synthase and HMG-CoA reductase, key enzymes in fatty acid, and cholesterol biosynthesis was reduced (Prabhakar and Doble 2011).

Incorporation of *p*-CouA into diet of rats resulted in the amelioration of certain complications of diabetes. Diabetic rats consuming 40 mg/kg of *p*-CouA for 6 weeks have statistically significant lower glucose and glycosylated hemoglobin and higher

insulin levels. Intake of *p*-CouA also resulted in decreased level of proinflammatory signal molecule TNF-α (Abdel-Moneim et al. 2018). Same treatment of diabetic rats also resulted in lower brain oxidative stress and declined inflammation and apoptosis in hippocampus region that is important for short- and long-term memory and is one of the first regions of the brain that is damaged in dementia (Abdel-Moneim et al. 2017). Daily administration of *p*-CouA (100 mg/kg) to rats with the experimentally induced diabetes led to reduced levels of blood glucose and higher insulin and also higher activity of glycolytic enzymes and lower activity of gluconeogenic enzymes in the liver. Statistically significant decrease in cholesterol and triglycerides in the kidney and liver was also observed (Amalan et al. 2016). Incorporation of mulberry leaves (5%) that are used for culinary purposes and brewing of tea into the diet of diabetic rats resulted in significant decrease in blood glucose levels and improved kidney function. Feeding on mulberry leaves resulted in reduction of the PPAR-gamma levels in kidneys and increase in phosphorylation of regulatory important Ser112, the receptor that regulates fatty acid and glucose metabolism. Incorporation of mulberry leaf extract (20 μM gallic acid equivalent) and its main phenolic constituent p-CouA (5 μM) into growth media resulted in the increased phosphorylation of Ser112 in PPAR-gamma expressed in the canine kidney cell line. Such experiment undoubtedly shows that *p*-CouA can interfere with inflammation and diabetes (Gurukar and Chilkunda 2018).

CinA have even more pronounced antidiabetic properties than *p*-CouA. Diabetic rats fed orally with CinA (10 mg/kg) 1 h prior to glucose intake (3 g/kg) had much lower increase in blood glucose in comparison to control. The magnitude of the effect 2 h after glucose intake was of the same range as 5 mg/kg intake of antidiabetic drug glibenclamide (Hafizur et al. 2015). As intake of cinnamaldehyde that is aside from CinA the major constituent of cinnamon bark extracts did not result in lower blood glucose, the antidiabetic properties of cinnamon could be related to cinnamic acid. Beneficial effects of CinA in type 2 diabetes are not related only to regulation of blood glucose level. CinA is also an efficient antiglycation agent. At 1 mmol/L concentration, it significantly inhibited formation of advanced glycation end products in vitro. The magnitude of the effect was much more pronounced in comparison to all three positional isomers of CouA (Adisakwattana et al. 2012).

23.4.4 Lipid Metabolism

23.4.4.1 Animal Cell Cultures and Model Animals

p-CouA and some complex plant extracts with high content of *p*-CouA interfere with lipid metabolism and can ameliorate some negative impacts of obesity and hyperlipidemia. *p*-CouA has a large impact on metabolism of rat skeletal muscle cell lines above 10 μM concentration. It promotes beta-oxidation of fatty acid, suppressed triglyceride accumulation, and enhanced glucose uptake (Yoon et al. 2013). Incubation of mouse preadipose and muscle cell lines at submillimolar concentration of *p*-CouA suppressed differentiation of these cells by downregulating

many transcriptional factors. It was also cytotoxic to preadipocytes above 500 μM concentration. Specifically the expression of PPAR-gama2 was decreased, and it was shown by molecular modeling that *p*-CouA could hydrogen bond to PPAR-gama2 (Ilavenil et al. 2016).

p-CouA at (18 mg/kg) added to diet of male rats fed on high-fat and high-fructose diet resulted in lower total blood cholesterol and triglycerides and better HDL/LDL ratio. Hepatic triglyceride was also reduced in comparison to control (Guo et al. 2017). Supplementation of *p*-CouA (100 mg/kg) to high-fat diet in rats showed reduction on body mass and adipose tissue in particular. Markers of oxidative stress and blood lipid composition were also significantly improved (Hsu et al. 2009). Dietary *p*-CouA (0.2 w/w) lowered plasma and liver lipid levels and promoted the fecal excretion of sterols (Yeh et al. 2009).

Not only pure *p*-CouA but also some complex plant extracts with high content of *p*-CouA can regulate lipid metabolism. Daily administration of pineapple leaf extract (200–800 mg/kg) rich in polyphenols and particularly *p*-CouA (1.5%) significantly reduced accumulation of abdominal fat and accumulation of lipids in the liver. Expression of carnitine acyltransferase 1 (CAT1: catalyze essential step in beta-oxidation) and also some other enzymes is included in mitochondrial catabolism. Experiments on human liver cell cultures revealed that also pure *p*-CouA has similar effect on induction of CAT-1 and inhibited intracellular accumulation of fat (Xie et al. 2014). Similar results were obtained for aqueous extract of hulled barley. When injected intraperitoneally (15–50 mg/kg) barley extract in dose depended manner inhibited differentiation of adipocytes, fat mass and body weight gain in mice. Oral intake for 8 weeks (15 mg/kg) also resulted in lower weight gain. Anti-adipogenic effect of pure *p*-CouA (already at 1 μM) was confirmed on cell murine preadipocytes (Seo et al. 2015). *p*-CouA (28 mg/g) is the major phenolic compound in the extracts of kenaf (important fiber crop) seed meal. Incorporation of the extract (2.3–4.6%) or meal itself into high-fat diet of rats resulted in improvement of hepatic and kidney function, lower accumulation of liver fat, total and LDL serum cholesterol, and higher HDL cholesterol (Chan et al. 2018). Dwarf bamboo extract (100–1000 mg/L) and its major constituent *p*-CouA (4 μM) attenuated accumulation of lipids in human-cultured liver cells by induction of phosphorylation of AMP-activated protein kinase and expression of CAT1, resulting in activation of catabolic pathways of lipid metabolism and inhibition of lipogenesis (Kim et al. 2013a). Welsh onion extract (50–400 mg/L) and its major phenolic constituent *p*-CouA (20–40 μM) interfered with cholesterol metabolism in human hepatic cell cultures. Both pure compound and extract contributed to the prevention of LDL receptor degradation at low concentration of lipoproteins. Therefore they are potentially effective in reducing hypercholesterolemia (Choi et al. 2017).

Trans-CinA at hundred micromolar range in growth medium has a significant influence on the preadipocyte differentiation. It induced brown-like phenotype in white adipocytes and activated brown adipocytes, resulting in increased beta-oxidation and thermogenesis and reduced lipogenesis. Therefore trans-CinA could be potentially useful in treatments of obesity (Kang et al. 2019).

23.4.5 Inflammation

Inflammation is a normal protective response to a certain stimulus as pathogens or damaged tissue. The functions of inflammation are to eliminate the invading microbes and necrotic cell and to initiate process of tissue repair which are all beneficial to the survival of organism. There is however a darker side of inflammation where it became a chronic process that plays an important role in many systemic disease as rheumatoid arthritis, atherosclerosis, cancer, diabetes, and others. *p*-CouA have an immunomodulatory and often an anti-inflammatory properties and could ameliorate the outcome of some chronic diseases.

23.4.5.1 Animal Cell Cultures and Model Animals

Proliferation of mice splenocytes (suspension of different white blood cells) was decreased by *p*-CouA in hundred-micromolar range (Kilani-Jaziri et al. 2017). Extracts of edible fern, an important wild vegetable in China with high content of *p*-CouA, decreased expression of interleukins, the important mediators of inflammatory response in mice macrophages (Dion et al. 2015).

Induction of intestinal inflammation in rats was suppressed when *p*-CouA was administered in daily dose of 50 mg/kg. The effect was attributed to the reduced expression of proinflammatory cyclooxygenase COX-2 (Luceri et al. 2004). *p*-CouA fed to rats 100 mg/kg per day showed an immunosuppressive properties and lowered expression of inflammatory mediator TNF-α in arthritic rats (Pragasam et al. 2013). Medicinal herb *Bambusae Caulis* extracts and its major phenolic constituent *p*-CouA, supplied by oral injection, inhibit cigarette smoke-induced inflammation in mice. Downregulation of the expression of proinflammatory molecules was observed (Kim et al. 2018). Atherosclerosis that can lead to severe cardiovascular complications was attenuated in rats on a high fat and high-sucrose diet, when daily dose of *p*-CouA (75 mg/kg) was supplied. Improvement in HDL/LDL ratio and hypoglycemic effect was found, and lower degree of histopathological alternations of aorta wall was observed (Omar et al. 2018). Excessive accumulation of urate in joints can lead to inflammation and arthritis. Daily consumption of *p*-CouA (100 mg/kg) by rats with urate-induced inflammation resulted in improved biochemical markers, lower inflammation, and better histopathology of ankle joint (Pragasam and Rasool 2013). Natural herb *Oleandia diffusa* and its major phenolic compounds *p*-CouA (14 mg/kg) fed to rats with induced arthritis have anti-inflammatory effects. Serum levels of inflammation mediators TNF-α and IL-6 decreased as also swelling, joint redness, and deformability (Zhu et al. 2018). Rats with induced rheumatoid arthritis benefited from the consumption of *p*-CouA (100 mg/kg). *p*-CouA significantly suppress joint edema and expression of inflammatory mediators. Enhanced bone mineral density and suppression of bone destruction and cartilage degradation were confirmed by radiological scans.

23.4.5.2 Human Cell Cultures

On the contrary to some experiment with mouse white blood cells where *p*-CouA showed inhibition of proliferation, viability of human monocytes was not affected

by *p*-CouA or propolis. The reason for such observations may be related to the two orders of magnitude lower concentration (0.5 μM) in study with human leukocytes. Even at such low concentration, statistically significant induction of some inflammatory mediators was observed after incubation in *p*-CouA and propolis. Additionally fungicidal and bactericidal activity of monocytes was improved (Cardoso et al. 2017). Incubation of human umbilical vein endothelial cells stimulated with lipopolysaccharides in *p*-CouA (10 μM) or red wine polyphenolic extracts (1–50 mg/L) resulted in lower endothelial inflammatory gene expression and reduced intracellular ROS generation, indicating that *p*-CouA have anti-atherosclerotic properties (Calabriso et al. 2016).

Application of cinnamon extract (containing approx. 0.25% of CinA) at concentration up to 100 mg/L to the coculture of human intestinal Caco-2 cells and macrophages ameliorated intestinal cell damage induced by lipopolysaccharide. Additionally treatment with cinnamon extract resulted in lower levels of inflammatory cytokines and could therefore be potentially useful in improving the symptoms of inflammatory bowel disease (Kim and Kim 2017).

23.4.6 Neuroprotective Effects

23.4.6.1 Animal Cell Cultures and Model Animals

Both *p*-CouA and *m*-CouA have neuroprotective effects in rat and mouse neuronal cell cultures. Incubation of rat neuronal cell lines in the presence of neurotoxic B-amyloid peptide, with 5–50 μM *p*-CouA, resulted in lower expression of proinflammatory enzymes cyclooxygenase-2 and inducible nitric oxide synthase (Yoon et al. 2014). *p*-CouA already at concentrations lower than 1 μM and also champagne wine extracts rich in *p*-CouA and other phenolic compounds protected mouse neurons in cell cultures from toxicity induced by 5-S-cysteinyl-dopamine (Vauzour et al. 2010). Feeding of mice with positional isomer of *p*-CouA, *m*-CouA (3 mmol/kg), which is a metabolite of chlorogenic acid, showed improved locomotor activity of mice, and further experiment on mice neurons showed that incorporation of 10 μM into growth media promotes neuronal differentiation and growth (Ito et al. 2008).

Main neuroprotective action of *p*-CouA is nevertheless related to the amelioration of the damages caused by anoxic conditions followed by restoration of blood circulation and oxygenation, which is accompanied by induction of oxidative stress (Szwajgier et al. 2017). The single intraperitoneal injection of *p*-CouA 100 mg/kg of body weight prior to induction of 20-min ischemia of the spinal cord followed by reperfusion resulted in significantly lower amount of formed malondialdehyde (marker of oxidative stress) and higher amount of antioxidant enzyme superoxide dismutase and respiratory factor 1 that activates expression of genes required for respiration. Additionally histopathological analysis of tissues reveals higher numbers of normal neurons 24 h after ischemia (Guven et al. 2015b). Similar effects of *p*-CouA were observed after ischemia/reperfusion of the sciatic nerve (longest nerve in the leg) (Guven et al. 2015c). Administration of 100 mg/kg of body weight

prior to occlusion of middle cerebral artery resulted in lower level of oxidative stress in ischemic brain tissue. Levels of malondialdehyde were decreased, whereas levels of superoxide dismutase and respiratory factor 1 were increased. *p*-CouA significantly improved neurological deficit scores (Guven et al. 2015a). The positive effects of *p*-CouA were observed also as a result of 2-week daily intake (100 mg/kg) together with normal diet. Mice fasted for 2 h prior to 30-min inclusion of both carotid arteries, followed by 45-min reperfusion, were sacrificed and their brains analyzed. Inclusion of *p*-CouA into the diet resulted in lower brain infarction volume and neuronal death. Similar to rats, content of malondialdehyde was decreased and level of antioxidant enzymes increased (Sakamula and Thong-asa 2018).

CinA has been shown to protect mouse dopaminergic neurons from damage induced by 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine and is therefore a potentially useful dietary molecule that could delay the onset of Parkinson's disease. Daily dose of CinA (100 mg/kg) fed to mice for a week improved locomotor activities most likely due to the activation of peroxisome proliferator-activated receptor alpha in astrocytes (Prorok et al. 2019).

23.4.7 Psychological Effects

23.4.7.1 Model Animals

Influences of *p*-CouA not only are limited to the neuroprotective function but also modulate learning and have anxiolytic (reduced anxiety) and antidepressant effects on model animals. Feeding of male Wistar rats with *p*-CouA (3–90 mg/kg) 60 min prior to testing significantly reduced anxiety. In vitro GABAergic assay revealed that *p*-CouA can bind to the receptor in micromolar range ($EC_{50} = 6.9$ μM), stronger than caffeic or cinnamic acids (Scheepens et al. 2014). Intraperitoneal administration of *p*-CouA (50–100 mg/kg) 1 day prior to behavioral experiments improved despair and apathy-related symptoms induced with lipopolysaccharide in rats. Biochemical analysis also revealed lower brain accumulation of proinflammatory cytokines cyclooxygenase-2 and TNF-a in the rats fed with *p*-CouA (Lee et al. 2018b). Rats with administered *p*-CouA (30 mg/kg) 30 min prior to injection of scopolamine, which impairs learning and memory, attenuated scopolamine-induced effects. *p*-CouA improved avoidance memory and long-term spatial recognition memory (Kim et al. 2017).

23.4.8 Bone Metabolism

23.4.8.1 Animal Cell Cultures, Model Animals, and Human Cell Cultures

Abnormal activation of osteoclast, which is normally involved in the process of bone remodeling, results in bone destruction in the diseases as rheumatoid arthritis. Incorporation of *p*-CouA into mannosylated liposomes (targeted to macrophages) injected into rats (10 mg/kg) resulted in significant inhibition of osteoclast differentiation and lower expression of inflammatory cytokines. Additionally incubation

of excised bones (with induced osteoclastogenesis) in the media containing 25 μM *p*-CouA resulted in significantly lower loss of bone calcium content (Neog and Rasool 2018). Oral administration of *p*-CouA 100 mg/kg for 10 days on the other hand significantly improves longitudinal bone growth in rats. Growth is most likely induced due to increased expression levels of insulin growth factor and growth hormone (Lee et al. 2018a).

Experiments on human osteoblastic cell cultures revealed that *p*-CouA already at submicromolar range increased proliferation of osteoblast for more than 10%. Induction effect was also observed when phenolic extract of olive oils containing *p*-CouA was added into the cell culture growth media (Garcia-Martinez et al. 2016). The influence on proliferation induced by *p*-CouA or phenolic extract was nevertheless not concentration dependent over the range of three orders of magnitude.

23.4.9 Hypoxia

23.4.9.1 Animal Cell Cultures and Model Animals

p-CouA is a quantitatively important constituent of Tibetan turnip that is traditionally used in local communities as food and folk medicine that ameliorates the symptoms of hypoxia. Experiments on model mice force-fed with *p*-CouA 100 mg/kg showed that symptoms of hypoxia (9.5% O_2 for 24 h) were significantly improved as less water was accumulated in lungs. On molecular level, concentration of NO was increased, redox status improved, and concentration of protein occludin that is crucial for alveolar stability increased (Li et al. 2018a). *p*-CouA (8 mg/kg administered daily for 1 week) was also shown to be efficient in improving the negative impacts of induced myocardial infarction in model mice as less edema and necrosis of heart tissue were observed. On molecular level, less oxidative damage was observed, and higher concentration of antioxidant enzymes was determined, which together with lower level of caspase expression resulted in lower degree of apoptosis (Prince and Roy 2013).

Interestingly *p*-CouA was also identified as a putative marker of oxidative stress per se. *p*-CouA was accumulated in human lobar bronchial cells, when cell culture was exposed to anoxic conditions. During 1-week incubation, an almost linear increase in *p*-CouA accumulation inside cells was observed. It is hypothesized that *p*-CouA is generated as a result of coenzyme Q10 degradation under anoxic conditions or downregulation of coenzyme Q10 biosynthesis for which *p*-CouA is precursor (Silina et al. 2016).

23.4.10 Eye Protection

23.4.10.1 Human Cell Cultures and Model Animals

Daily drops of *p*-CouA (164 ng) into the rabbit eye significantly reduced negative effect of UVB irradiation related to vessel damage. Concentration of marker typical for oxidative DNA damage (8-oxodG) was reduced, whereas concentration

of antioxidant enzyme superoxide dismutase was increased (Lodovici et al. 2009). Protective effect of *p*-CouA in the mixture with hydroxycaffeic acid (5 + 5 μM) was observed also in human conjunctival epithelial cell culture as synthesis of 8-oxodG was significantly reduced. Levels of proinflammatory prostangaldins and malondialdehyde that is formed as a result of lipid oxidation were reduced when daily dose (50 uL) at abovementioned concentration was administered to the rabbit eye (Larrosa et al. 2008). *p*-CouA (3–30 μM) included in growth media for human lens epithelial cells was protective against hydrogen peroxide-induced apoptosis. *p*-CouA downregulated expression of caspases and mitogen-activated protein kinases that were induced by hydrogen peroxide, suppressed intracellular ROS production, and increased concentration of antioxidant enzymes leading to lower level of cellular death (Peng et al. 2018).

23.4.11 Skin Pigmentation (Melanin Synthesis)

23.4.11.1 Animal Cell Cultures and Human Cell Cultures

Melanogenesis is the process of melanin formation in melanocytes that leads to skin pigmentation. Uncontrolled melanogenesis may result in undesired and aesthetically problematic skin pigmentation. Rice bran that is rich in *p*-CouA has been traditionally used for hypopigmentation treatment in East Asia. *p*-CouA and complex plant extracts with high content of *p*-CouA can interfere with melanin formation. Melanin formation and tyrosinase activity were significantly reduced already when *p*-CouA was added to murine melanoma cell culture at concentration lower than 10 mg/L. The inhibitory effect of *p*-CouA was much more pronounced than that of other structurally similar phenolic compounds (An et al. 2008). Further experiments revealed that inhibition of melanogenesis is the result of competitive inhibition of tyrosinase by *p*-CouA (Park et al. 2008) and that *p*-CouA is better inhibitor of human tyrosinase in comparison to those isolated from mice or mushrooms. Additionally *p*-CouA decreased expression of enzymes involved in melanogenesis due to inactivation of transcription factor (cAMP)-responsive element-binding protein (Jun et al. 2012).

23.4.12 Other Effects

23.4.12.1 Animal Cell Cultures, Model Animals, and Human Cell Cultures

p-CouA also influence some other physiological and pathophysiological processes. Administering a daily dose (50 mg/kg) to mice for 1 week significantly attenuated the hepatotoxic effect of acetaminophen, a popular antipyretic and analgesic drug, indicated by lower blood levels of aminotransferases. *p*-CouA protected from hepatic apoptosis, by attenuating ROS-mediated DNA modification and inflammation through the modulation of mitogen-activated protein kinase signaling (Cha et al. 2018). Negative effects of ethanol that induced reproductive toxicity in model rats

were suppressed by daily consumption of *p*-CouA (50–200 mg/kg). Antioxidant status, sperm parameters, and testis characteristics that were deteriorated by ethanol were improved by co-administration of *p*-CouA. Decreased level of pro-inflammatory molecules and apoptotic caspases was also observed (Nishi et al. 2018). Doxorubicin is an efficient chemotherapeutic yet cardiotoxic agent. *p*-CouA (380 μM) has a cardioprotective effect on cultured rat myoblast cells (from myocardium). The protective mechanism of *p*-CouA could be related to the upregulation of genes associated with autophagy that is crucial for the removal of nonfunctional organelles/proteins that are accumulated in cardiomyocytes as a result of doxorubicin treatment. Additionally *p*-CouA stabilized redox status and induced expression of antioxidant enzymes (Sunitha et al. 2018). *p*-CouA was also effective in preventing the oxidative damage of rat colonic mucosa. Daily administration (50 mg/kg) resulted in lower levels of 8-oxydG, better results of comet test, and induction of glutathione-S-transferase. Interestingly vitamin E administration of the same dose resulted in statistically significant increase of oxidative stress (Guglielmi et al. 2003). Oral administration of *p*-CouA (100 mg/kg per day for 3 weeks) proved to be efficient in protecting from cadmium-induced nephrotoxicity. Histopathological analysis of the rat kidney reveals that co-administration of *p*-CouA with cadmium halved the cadmium content in kidneys in improving their function. Higher content of metal-binding protein and improved redox status and lysosomal integrity were also observed (Luceri et al. 2007). Further experiments revealed that *p*-CouA attenuated synthesis of proinflammatory cytokines that were induced by cadmium and stabilized level of mitochondrial enzymes crucial for energy metabolism (Navaneethan and Rasool 2014).

p-CouA fed to rabbits at relatively low doses (5 mg/kg) inhibited ADP-induced platelet aggregation and thromboxane A2 (eicosanoid with prothrombotic properties), without negatively affecting other blood parameters (Luceri et al. 2007). Five consecutive administrations of *p*-CouA (20 mg/100 g) every third day significantly protected the spleen, liver, and bone marrow cells of mice from large radiation dose (5 Gy). Levels of blood serum aminotransferases and antioxidant enzyme that were changed as a result of irradiation were normalized in rats taking *p*-CouA. Positive effect were observed even 2 months after irradiation as lower levels of mitochondrial superoxide anions were detected in spleens and livers of mice that took *p*-CouA prior to exposure (Kook et al. 2017).

23.5 Benefits

p-CouA is on the crossroads of important biochemical pathways and can be formed by hydroxylation of trans-cinnamic acid or deamination of tyrosine by tyrosine ammonia lyase. It is the precursor of other cinnamic acids as caffeic, ferulic, and sinapic that are often present in food matrices at higher concentration than coumaric acid. There is large variety of soluble conjugates of cinnamates, including glycosides, ethers, and ethers of amides, depending on the compound that is bound to

hydroxyl or carboxylic group of particular cinnamic acid. Additionally cinnamates can be bound to the cell wall components with ether of ester bonds. Foods of plant origin are therefore a complex mixture of cinnamic acids and their derivatives. CouA and CinA (free or bound) and conjugates are rarely the predominant compounds. As no human nutrition studies with pure *p*-CouA or its conjugates were performed, data about benefits of *p*-CouA can be only extrapolated from the animal feeding studies (Sect. 4) that were performed mostly with rodents.

Despite lack of studies with pure compounds, there are some data obtained from dietary interventions with foods high in coumaric acid, to support findings on animal studies that food high in *p*-CouA and structurally similar compounds may have positive influence on human health.

In the randomized control studies, supplement of 50 g of oat flour per day in the duration of 8 weeks resulted in statistically significant higher potassium level and albumin, whereas some other markers of kidney function were not influenced by diet or even potentially negative factor as higher blood urea level was found in the "oat" group (Rouhani et al. 2018). Oat is a rich source of *p*-CouA and avenanthramides that include conjugates of *p*-CouA. The authors concluded that incorporation of oat into diet could be beneficial and speculate that some of the observed effects could be related *p*-CouA that also protects against nephrotoxicity in rats.

For Japanese apricot that is traditional food in Japan and is a rich source of *p*-CouA, it was shown that incorporation of this fruit into diet significantly reduce the level of allergic symptoms in rhinitis (Kono et al. 2018) especially in women. Within the same study, it was shown that oral administration of ume extract to mice attenuated mast cell degranulation led to lower response to allergen exposure. The same effect was also observed for the pure *p*-CouA.

Cinnamon as a spice has been used in human nutrition for centuries. There are a large number of tree species that are used as source for bark in which trans-cinnamic acid is one of the major constituents. Recently it was indicated that cinnamon consumption has beneficial effect related to diabetes due to lower blood glucose level. The systematic literature review published in 2016 (Costello et al. 2016) analyzed results of 11 randomized controlled trials. The conclusion was that consumption of cinnamon resulted in modest decrease of fasting glucose level as also lower level of hemoglobin glycation, indicating that it is a potentially useful supplement to standard therapy for type 2 diabetes. Additionally the randomized double-blind controlled trial on individuals with metabolic syndrome revealed that 3 g of cinnamon daily in the duration of 16 weeks resulted in significant improvements of markers of metabolic syndrome in the intervention group (Jain et al. 2017).

23.6 Application in Food

Food processing has large influence on the content and availability of polyphenols. Enzymatic and nonenzymatic oxidation, release of cell wall-bound polyphenols, de novo biosynthesis, leakage into the aqueous phase, and type of treatment are important factors.

23.6.1 Thermal Treatment

Parboiling of rice (five varieties) and bran from these varieties result in higher free and bound *p*-CouA content. Absolute increases in contents after parboiling were higher for the bran samples, whereas larger relative increase was found for milled rice (Pal et al. 2018). Thermal treatment of the sorghum bran (10 min boiling in water) prior to chewing or stimulation of gastric phase also resulted in improved bioaccessibility of *p*-CouA (Salazar-Lopez et al. 2018). By adding adzuki beans (20% w/w) to polished rice, the content of *p*-CouA can be increased. Availability of *p*-CouA from such mixture can be further increased, if cooked in high-pressure rice cooker in comparison to normal rice cooker (Woo et al. 2018). Higher availability of free *p*-CouA after high pressure cooking can on the other hand result in lower content of bound *p*-CouA. The content of bound *p*-CouA in cranberry beans that account for 80% of all *p*-CouA decreased for 40%, followed by only marginal increase of free *p*-CouA (Chen et al. 2015). Also thermal treatments of black rice bran at lower water contents like extrusion (120 °C, 12–17% moisture) can lead to higher free and bound p-CouA contents; nevertheless same treatment of polished and unpolished rice, where absolute p-CouA contents are lower, did not results in better availability (Ti et al. 2015b). Booth cooking and in vitro digestion positively affected availability (extractability) of cell wall-bound coumaric acid in brown rice that accounted for over 90% of all p-CouA. In polished rice, where initial p-CouA content is lower, cooking and digestion resulted in lower yields (Ti et al. 2015a). Booth cooking and in vitro digestion positively affected availability (extractability) of cell wall-bound coumaric acid in brown rice that accounted for over 90% of all *p*-CouA. In polished rice, where initial *p*-CouA content is lower, cooking and digestion resulted in lower yields (Ti et al. 2015). Thermal treatment at temperatures lower than 100 °C resulted in better retention of *p*-CouA in *Brassica* vegetables. The levels of *p*-CouA and some other phenolic acids were more stable in vegetables processed by sous-vide method (incubation at 90 °C, 45 min) in comparison to boiling and steaming (Florkiewicz et al. 2019). Microwave treatment (Zeb et al. 2019) significantly improved availability of *p*-CouA from chicory leaves. The fivefold increase of free *p*-CouA after 20 min of microwave treatment (650 W) was attributed to the release of cell wall-bound *p*-CouA. *p*-CouA is predominant phenolic in domestic garlic (Pedisic et al. 2018), and its content was reduced by crushing to the similar degree as blanching. Largest losses were observed for frying where only 40% of initial *p*-CouA remained after 10 min. Sorghum grains are excellent sources of free *p*-CouA (35 mg/kg), and processing like steaming and roasting results in substantial loss (up to 75%) of free *p*-CouA (Wu et al. 2013). Interestingly authors observed higher bound *p*-CouA, and such results could be interpreted more as an improved extractability due to processing as attributed to actual increase of bound *p*-CouA.

23.6.2 Sprouting and Fermentation

Sprouting and fermentation are relatively old techniques with renewed interest in relation to food processing and preparation. Here intensive transformation of matrix

takes place, which is accompanied by change in the content of bioactive constituents, as are phenolic compounds. Sprouting of wheat is accompanied by few-fold increase of free *p*-CouA content (few mg/kg range). Even higher contents are accumulated in the wheatgrass that is a popular garnish in high cuisine. Not only free but also the content of bound *p*-CouA that accounts for over 99% of *p*-CouA can be increased. Contents of bound *p*-CouA can be as high as 3500 mg/kg (Stagnari et al. 2017) that is more than order of magnitude higher than in the bran of cereals. Sprouted and kiln-dried wheat and barley malts are modest sources of free *p*-CouA (range of mg/kg) that can be extracted into beer. Here *p*-CouA serves as a precursor of 4-vinylphenol that is an important aroma compound in mature beer. Depending on the yeast strain, the *p*-CouA content in beer can be in the range of mg/L or can be decreased for the two orders of magnitude when yeast strains with high conversion potential are applied (Langos and Granvogl 2016). Free *p*-CouA content is increased also during germination of bean sprouts. For an order of magnitude, higher contents (200 mg/kg) were found in sprouted in comparison to raw beans. Accumulation of *p*-CouA and other polyphenols was significantly increased by elicitors of plant defense (Mendoza-Sanchez et al. 2016). In peanuts, where *p*-CouA is present in sub-mg/kg quantities and CinA in much higher content, (50 mg/kg) germination resulted in lower contents of both acids. Oven roasting and microwave heating also resulted in lower content of *p*-CouA and CinA (Aljuhaimi and Özcan 2018).

23.6.3 Other Treatments

Technological operations that result in change of structural integrity of plant matrix have also a large influence on available *p*-CouA. Preparation and roasting of cornflakes from flanking grits (large endosperm particles) result in decrease of bound *p*-CouA for all hybrids analyzed and three- to fourfold increase in soluble *p*-CouA. Total *p*-CouA content was nevertheless lower, as loss of bound *p*-CouA was not fully compensated by increase of soluble fraction (Butts-Wilmsmeyer et al. 2018). Defatted soybean flour contains few hundred mg/kg of bound *p*-CouA. Choosing the appropriate parameters of microwave or ultrasound treatment can result in the release of bound *p*-CouA, and soluble content can reach almost 100 mg/kg, which accounts for 20% of initially bound *p*-CouA (Jez et al. 2018). High-pressure treatment (up to 650 MPa) on the other hand did not result in higher soluble *p*-CouA content in tomato puree. For all treatments and varieties, even losses of *p*-CouA up to 40% were observed (Durovic et al. 2018). Similar was found for mulberry juice where ultrahigh pressure processing resulted in almost 50% loss from initial 80 mg/L. Addition of ascorbic acid into the juice prior to processing resulted in complete retention of *p*-CouA indicating that oxidation is possible mechanism of loss (Yu et al. 2014). Prolonged storage of tomato juice results in loss of *p*-CouA and other phenolic compounds. It was nevertheless shown that moderate-intensity pulsed electric field treatment of juice prior to storage improves initial content and retention of *p*-CouA during storage (Vallverdu-Queralt et al. 2012).

23.7 Toxicity and Side Effects

In principle anticancer properties of coumaric acid, as increased production of ROS, induction of caspases and apoptosis, and lower expression of enzymes involved in detoxification pathways, can be in broader terms related to toxicity and undoubtedly result in side effects. Despite the abovementioned cytotoxic effects, the acute toxicity of *p*-coumaric acid is relatively low (LD_{50} for mice = 2850 mg/kg). The content of free-*p*-CouA in food of plant origin is rarely above 100 mg/kg DW and in certain edible mushrooms in the order of 1000 mg/kg DW. Glycosylated forms (conjugates) in certain berries reach 1000 mg/kg DW range. The highest contents are found for cell-bound *p*-coumaric acid and in not edible parts as the corn straw and cob or residue of sugarcane extraction (bagasse) where the contents can be as high as 20,000 mg/kg of DW. The bioavailability of such *p*-CouA is much lower, and the kinetics of the release in gastrointestinal tract relatively slow. Therefore, with normal daily nutrition, it is hard to obtain doses that are even for two orders of magnitude lower than LD_{50} found for mice.

One of the important characteristics of *p*-CouA is that influence on ROS formation significantly depends on concentration and can attenuate or stimulate the level of oxidative stress. Incorporation of 0.5 μM *p*-CouA into growth media for human endothelial cells resulted in statistically significant lower levels of ROS and increased metabolic activity, whereas at 20-fold higher concentration (10 μM) formation of ROS was increased and cell viability decreased (Posadino et al. 2013). Experiments on rat liver mitochondria revealed that *p*-CouA inhibit pyruvate transport and carboxylation and in sub-100 μM range inhibit certain enzymes involved in gluconeogenesis (Lima et al. 2006). This is the concentration range of *p*-CouA that can be found in plasma of rodents few minutes after oral ingestion of doses around 100 μmol/kg (Pei et al. 2016). The half-life of *p*-CouA in plasma is nevertheless short (range of minutes), and therefore the concentration is relatively fast decreased to low micromolar range. Potentially the most problematic effect of *p*-CouA is its goitrogenic activity (Khelifi-Touhami et al. 2003). The mass of the thyroid glands of rats with ad libitum access to standard laboratory chow with sufficient level of iodine that received by gastric tube a 40 mg/kg of *p*-CouA for 3 weeks was doubled in comparison to control. The goitrogenic effect was confirmed by a significant decrease of triiodothyronine and thyroxine hormones in blood. Importantly the goitrogenic effect of *p*-CouA was much more pronounced than that of caffeic and ferulic acids fed in the same amount (based on molar intake). No further experiments related to potential goitrogenic effect at lower doses in rodents of human intervention studies were performed.

p-CouA is much more toxic toward certain bacteria and fungi than toward mammals. Antimicrobial action of *p*-CouA can therefore be used for stabilization of food matrix in order to reduce microbial load. In the millimolar range, *p*-CouA can completely inhibit *Staphylococcus aureus* growth in the chicken soup even at room temperature (Stojkovic et al. 2013). In submillimolar range, *p*-CouA significantly increased the permeability of bacterial cell membrane and also intercalated the groove in bacterial DNA double helix, which might affect DNA replication and

transcription (Lou et al. 2012). *p*-CouA showed a synergistic antibacterial effect against both gram-positive and gram-negative bacteria with nisin (Bag and Chattopadhyay 2017), antibacterial peptide that is used as a food additive. The mechanism of action is most likely related to the inhibition of surface attachment and biofilm formation. Combination of nisin and *p*-CouA could therefore find the application in the food industry. Lower microbial loads can also be related to quorum sensing inhibition. The statistically significant effect was nevertheless observed at 3 mmol/L or higher *p*-CouA concentration, which limits practical application (Bodini et al. 2009). Analysis of mechanisms of tolerance studied on bacterium *Pseudomonas putida* revealed that improved membrane stability, secretion, and exclusion of toxic compounds outside the cell were crucial for survival (Calero et al. 2018).

CinA is a potent inhibitor of quorum sensing and potential antivirulence agent for control of bacterial infection. At sublethal concentration, it effectively inhibited biofilm development and production of quorum sensing-dependent virulence factor of *Pseudomonas aeruginosa*. Modeling in silico and in vivo analysis on *C. elegans* revealed that CinA interferes with the binding of natural autoinducers to the quorum-sensing receptor proteins (Rajkumari et al. 2018). Aquaculture industry is under a large pressure to find the alternative to the application of antibiotics that are undesired pollutants. It was shown that CinA has potent inhibitory effect (mg/mL range) against certain fish pathogens, whereas the majority of nonpathogenic isolates from fish intestines were resistant to trans-CinA (Yilmaz et al. 2018). Photochemical isomerization of trans-CinA to cis-CinA have large influence on antimicrobial activity. The minimum bactericidal concentration of cis-CinA against multiple drug-resistant *Mycobacterium tuberculosis* is as low as 2.5 mg/L, which is more than two orders of magnitude lower than that of trans isomer (Chen et al. 2011).

Viability of fungi is also influenced by *p*-CouA and its derivatives. Ethanolic ester of *p*-CouA at 1 mmol/L increased plasma membrane permeability and induced oxidative damage of cellular structures of fungus *Alternaria alternata* that can produce mycotoxins on the surface of fruits and vegetables (Li et al. 2018b). Acidic and relatively nonpolar *p*-CouA can diffuse through the cellular membranes. In phytopathogenic fungus *Botrytis cinerea*, *p*-CouA (1.5 mM concentration in growth media) can act as a mitochondrial uncoupler of proton gradient (Morales et al. 2017), resulting in the increase of oxidative metabolism, accompanied by relatively low ATP synthesis, offering the alternative way for the control of this pest, that can significantly affect yield and quality of grapes.

Structural isomer of *p*-CouA, the *o*-CouA, is a potent phytotoxin. Already in the submillimolar concentrations, it reduced the germination of *Arabidopsis* seeds, inhibited root elongation, and induced cell death, whereas other two isomers, *p*-CouA and *m*-CouA, had no effect in this concentration range. It is hypnotized that *o*-CouA can play the important role in the spreading of the invasive plant *Eupatorium adenophorum*, where *p*-CouA is a major phenolic compound (Zheng et al. 2012).

p-CouA can be used as an antimicrobial agent also in human body ecosystems. Adhesion of oral pathogens to the cells of connective tissue was significantly

inhibited by *p*-CouA already at concentrations lower than 100 μmol/L (Esteban-Fernandez et al. 2018). Importantly most of bacterial pathogens found in oral cavity do not metabolize *p*-CouA, and its concentration remains relatively stable.

23.8 Marketed Product

In the recent years, a lot of efforts have been put into the research areas related to the study of influence of various processing and cooking parameters on the bioavailability of micronutrients, including coumaric acid. This research effort will undoubtedly result in the marketing of food products with optimized content of such bioactive constituents. With the normal diet, milligram quantities of positional isomers of coumaric acid are consumed on a daily basis. Apart from food, coumaric acids can be consumed with dietary supplements, where they contribute to the functional and health-related properties of the products. For vast majority of such products, detailed composition of micronutrients is not reported, and therefore the actual impact of coumaric acids to the characteristics of the product can be only estimated from scientific sources where composition of phenolic compounds in similar matrices was determined. For some products that are advertised on the Web, actual content of *p*-CouA is nevertheless reported. The propolis extract enriched with astaxanthin (https://www.naturalhealthyconcepts.com/dr-ohhiras-propolis-plus-30.html) contains 730 μg of *p*-CouA/g or 1320 μg in a serving (three capsules). There are also scientific manuscripts reporting the compositions of particular dietary supplements. Certain *Vitis vinifera* extracts that are sold on the EU market contain 100–600 ug/g of *p*-CouA, which in particular supplements also the major phenolic compound (Filipiak-Szok et al. 2013). Potential health-related benefits of such extracts could be related to *p*-CouA. Dietary supplement prepared from *Moringa oleifera* seeds by fermentation, which contains 3000 ug of *p*-CouA/g, modulates HDL and LDL cholesterol ratio, and has immunological properties (Adedayo et al. 2018), is a promising product with market potential. Application of *p*-CouA is undoubtedly not limited only to the food and dietary supplement sector. Due to antityrosinase activity (prevents skin pigmentation), it is one of the most important ingredients of products with cosmeceutical application (Taofiq et al. 2017).

Cinnamon bark, pulvers, or extracts are used as spices and dietary supplements. Alcoholic extracts of cinnamon are available from various suppliers mostly as food-flavoring products. Dried extracts are often packed into gelatin capsules and sold as dietary supplements. They are advertised as products that support insulin function and maintain optimal glucose level. The actual composition of the extracts is typically not reported, and therefore the efficiency of the products cannot be related to the experimental results published in scientific literature that were obtained with chemically defined samples. Large variations in the bioactive constituents in different cinnamon species and type of solvents used for extraction result in large variations in the composition of extracts (Costello et al. 2016).

23.9 Patents

As already mentioned in the previous section, *p*-CouA and its derivatives have a large potential as antipigmentation agent for the skin. In relation to this property, in the Google Patents base (https://patents.google.com/), patents in the USA (US9089499B2) and elsewhere were issued. *p*-CouA and other CinA derivatives are also the compounds with two functional groups, which can form ester bonds, and are as such appropriate compounds for polymerization reaction and formation of bioplastics. The patent related to formation of *p*-CouA-based polymers (US20190002630) was issued in 2019. *p*-CouA is abundantly available from non-food agricultural wastes as bagasse or corn stover. Plastics made from CinAs could be interesting for packaging of food items due to antioxidant properties based on hydroxyl groups on aromatic rings. Apart from agricultural waste products, *p*-CouA can be obtained also biotechnologically by deamination of tyrosine. In 2016 patent (WO/2016/008886) related to microbial transformation based on tyrosine ammonia lyase activity was published.

One of the patents related to CouA has also important implication in food products. In the recent years, there is a large interest for reduction of sugar content in food products. In order to retain sweet taste in food with reduced sugar content, artificial sweeteners or steviol glycosides from plant extracts can be added. Sweet taste of sugar substitutes is nevertheless different from that of mono- and disaccharides. Often a slightly bitter aftertaste, metallic, and even rancid impressions in the oral cavity are produced. Certain substances can mask this aftertaste and improve the acceptance of sweet products with low sugar content. The EU patent "Aroma composition comprising *o*-coumaric acid to reduce or suppress undesirable taste impressions of sweeteners" (EP2340719B1) related to the application of *o*-CouA as compound that can modify the unpleasant aftertaste of non-sugar sweeteners was granted in 2014.

Antimicrobial activity of cinnamic acid forms the basis for few patents that were issued in relation to its application as preservative in nonalcoholic beverages. The Japanese patent (JP4267814B2) granted in 2009 is related to the use of Cinn as a preservative in tea-based drinks that could be prepared in the process of cold filling. The European patent (EP2768326B1) related to the application of vanillin and CinA as preservative in carbonated and juice-containing beverages was granted in 2018.

23.10 Perspectives

Due to the advanced analytical techniques, there is an increasing amount of data of polyphenolic composition of foods, metabolic products, and their pharmacokinetic effects. The data are becoming unmanageable, so there is a need for up-to-date databases with required deposition of the new data. There is a need for standardization of analytical methods and reference materials so that the data from different laboratories can be compared. For some classes of dietary polyphenols, there are

now sufficient intervention studies to indicate the type and magnitude of effects among humans in vivo, on the basis of short-term changes in biomarkers. However, a large number of polyphenolics remain unexplored with respect to their antioxidant and other human beneficial properties. Furthermore, substantial evidence is needed to elucidate the molecular mechanisms of different classes of phenolic compounds involved in the potential protective effects against oxidative stress. HCAs have significant antioxidative activity, anti-inflammatory, anticancer, and many other beneficial roles. To follow their activity in vivo, there is a need for plasma biomarkers (for the antioxidative activity, energy metabolism, carcinogenesis). The effects of phenolic acids including *p*-CouA and CinA (found in raw and processed foods such as red wine, cereals, cranberries, and some supplements) are mostly studied in vitro; knowledge about the effects in vivo, although they are significant, is more limited. The reasons are (i) the lack of validated in vivo biomarkers, especially in the area of carcinogenesis; (ii) lack of long-term studies; and (iii) lack of understanding or consideration of bioavailability in in vitro studies, which are subsequently used for the design of in vivo experiments. It is time to rethink the design of in vitro and in vivo studies, so that these issues are carefully considered. To more closely reflect the long-term dietary consumption of polyphenols, the length of human intervention studies should be increased.

Contents

Abstract

Ellagitannins (ETs) are widely distributed secondary metabolites classified as hydrolyzable tannins found mainly in berries such as raspberries, blueberries (BBs), black raspberries (BRBs), strawberries, and pomegranates. A plethora of reports tend to show that ETs can impact positively on human health by

promoting therapeutic activities such as being an antioxidant, antimicrobial, anti-inflammatory, and anticancer. Studies showed that ETs found in the seeds of black raspberries (BRBs) increase the functional activity of juices or wines which used BRBs as ingredients. It has been reported that berries have the potential to reduce the systolic and diastolic blood pressure and increase superoxide dismutase activity after the consumption of BBs. Numerous studies showed that ETs isolated from pomegranates possess good antimicrobial activities against a panel of microbes including human pathogens such as *Escherichia coli*, *Salmonella enteritidis*, *Staphylococcus aureus*, *Bacillus subtilis*, *Klebsiella pneumoniae*, *Pseudomonas aeruginosa*, *Yersinia enterocolitica*, *Listeria monocytogenes*, and *Candida albicans*. Interestingly, it was shown that these therapeutic values are attributed to the presence of ETs. Furthermore, ETs are also distributed in various nuts, namely, pecans, cashews, walnuts, pistachios, or hazelnuts. It is known clinically that frequent nut intake is associated with protective effects against cardiovascular diseases. Although it is mentioned that ETs can also be found in vegetables, however as far as our literature search could establish, there are no scientific validation of ETs in vegetables. Thus, it is proposed that more scientific investigations be geared to shed light on the potential of ETs found in vegetables. Overall, foods containing ETs are recommended to be consumed on a regular basis since a panoply of scientific investigations showed that they are associated with promising health benefits.

24.1 Introduction

Phytochemicals are non-nutritive secondary plant compounds often with health-promoting and disease-preventive properties, mainly found in fruits, vegetables, grains, herbs, spices, and other plant foods (Afrin et al. 2018). For many decades ago till date, plants have been the center of interest for many scientists across the globe solely due to their curative nature. The therapeutic value of edible plants and fruits is linked to the metabolites they produced and has indeed proved their worth on many occasions. For instance, biguanide compounds present in various plant parts such as dry fenugreek seeds (*Trigonella foenum-graecum* L.), fresh green curry leaves (*Murraya koenigii* L.), fresh green bitter gourd (*Momordica charantia* L.), garlic (*Allium sativum* L.), orange-fleshed sweet potato (*Ipomoea batatas* L.), and white-fleshed potatoes (*Solanum tuberosum* L.) exhibited good insulin sensitivity and thus control glucose level significantly (Raigond et al. 2018; Perla and Jayanty 2013). Plants are considered as a major storehouse of metabolites production of various phytochemical classes. It is found that phenolic contents or polyphenols are the most ubiquitous metabolites widely distributed in the kingdom *Plantae*, and the

most common polyphenols include phenolic acids, tannins, and flavonoids (Sytar et al. 2018; Ksouda et al. 2018).

Polyphenols form the integral part of most human diets and even animal diets since many among them are herbivores (Ovaskainen et al. 2008). Recent interest in food phenolics has increased due to their role as antioxidants which act as a prevention barrier against numerous diseases, namely, cardiovascular diseases, cancer, Alzheimer's disease, and age-related diseases (Basanta et al. 2018; Bravo 1998). Tannins are medium-sized phenolic compounds of up to 30,000 Da. They are subdivided into two major categories: (1) hydrolyzable and (2) condensed tannins. Additionally, a third minor group of tannins exist known as phlorotannins usually found in marine brown algae but are not edible (Bravo 1998). Hydrolyzable tannins, as their names indicate, are readily hydrolyzed in weak acid, alkali, or hot water to form polyhydric alcohol and phenylcarboxylic acid (Shirmohammadli et al. 2018). Based on this chemical property, hydrolyzable tannins are further subdivided into two groups: (1) gallotannins (released gallic acid) and (2) ellagitannins (released ellagic acids) (Shirmohammadli et al. 2018; Bravo 1998) (Fig. 1). Ellagitannins (ETs) are hydrolyzed to ellagic acids (EAs) under physiological conditions in vivo, and the latter is then metabolized by the microbiota in the intestine to produce an array of different urolithins such as urolithins A and B (Sánchez-González et al. 2014; Landete 2011).

ET is characterized by the presence of a unit, biarylic dehydrodigalloyl so-called hexahydroxydiphenoyl (HHDP), often linked to 1,2,3,4,6-hydroxy of glucose (Yang et al. 2018). In 1996, the first total synthesis of ellagitannin was identified as pedunculagin (Fig. 2) and was performed by Feldman and Smith in the Pennsylvania State University.

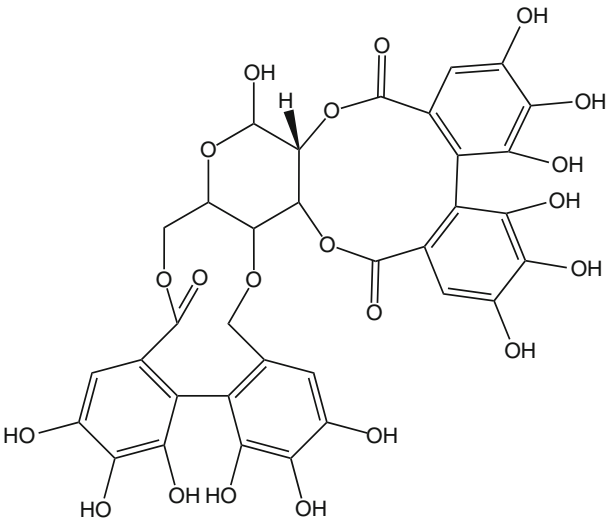

Fig. 1 Pedunculagin

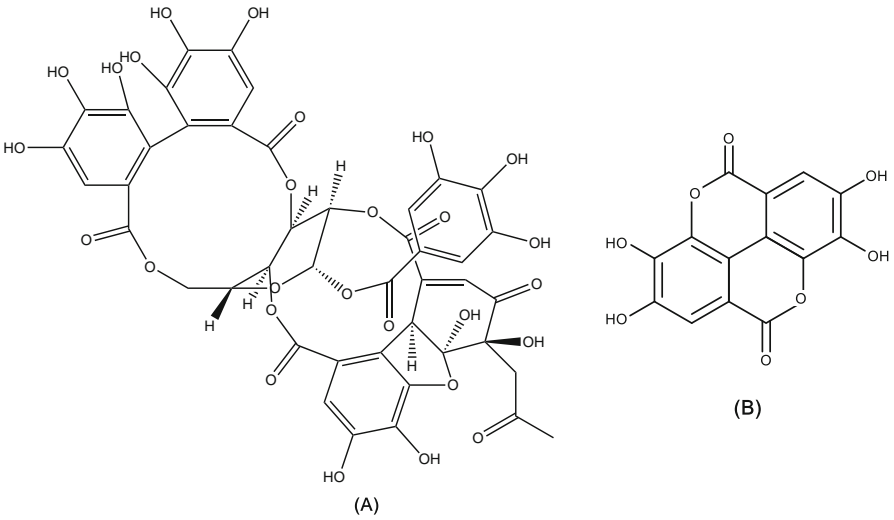

Fig. 2 (**a**) Ellagitannin, (**b**) ellagic acid

During the past decades, researches were mainly focused on phenolics, flavonoids, and anthocyanins but less on ETs. The reason was linked to the occurrence of ETs, and EAs are mostly found in fruits, few berries, and nuts (Törrönen 2009). Numerous vegetables and fruits possessed many therapeutic values due to their high consistency of a variety of phytochemicals. The most important dietary phytochemicals considered are isothiocyanates, indoles, flavonoids, retinoids, tocopherols, and ellagitannins (ETs) (Ismail et al. 2016). Various studies have confirmed that diets rich in fruits and vegetables reduce the risk of many types of cancer, namely, colorectal cancer (Afrin et al. 2018; Bansal et al. 2018), breast cancer (Sayeed et al. 2017), lung cancer (Kasala et al. 2015), and skin cancer (Iqbal et al. 2019) and also neurodegenerative diseases (de Rus Jacquet et al. 2017).

24.2 Bioactive Constituents

Ellagitannins are a type of polymer formed by EA and a hydroxyl group, like glucose, bind together (Fig. 2). They are characterized by the presence of biarylic dehydrodigalloyl so-called hexahydroxydiphenoyl (HHDP) units which are frequently linked to 1,2,3,4,6-hydroxy of glucose. As a diverse class of hydrolyzable tannins, ETs are different from gallotannins, which are characterized by the presence of depsidically linked galloyl units. Ellagitannins generally form macrocycles, while gallotannins do not. Considered a type of antioxidant, ETs can be found in various fruits. Some of them exhibit remarkable bioactivities as discussed in the next sections of this chapter, such as potent antibacterial and antiviral activities, inhibition of mutagenicity of carcinogens and tumor promotion, as well as remarkable host-mediated antitumor effects (Yang et al. 2018).

24.3 Bioavailability and Metabolism

Ellagitannins are polyphenols that possessed significant biological activities in vitro and relevant pharmacological properties and nutritional values in vivo. The promising biological activities are related to the scavenging ability that ETs possessed. Nevertheless, it is equally important to understand the bioavailability and metabolism of ETs in the gastrointestinal (GI) tract to understand the physiological or nutritional role of these polyphenols.

Ellagitannins and ellagic acids are found abundantly in fruits, namely, pomegranates, berries, peaches, and cherries, vegetables, and nuts such as walnuts, cashews, and pecans (Landete 2011). A fresh weight of 100 g of raspberries can serve approximately 263–330 mg ETs, eight walnuts can provide an amount of 802 mg, a liter of pomegranate juice contains 2020–2660 mg, and a liter of oak-aged red wine contains about 9.4–50 mg of ETs. Table 1 illustrates the amount of ETs and EAs recorded from different types of foods. The amount of EAs in foods is determined as free EA or

total EA after acid hydrolysis (Landete 2011). High content of ETs and EAs is reported in mainly all of the berries (strawberries, raspberries, blackberries) (Koponen et al. 2007; Aaby et al. 2007; Clifford and Scalbert 2000) as shown in Table 1.

Pomegranate juice is a rich source of ETs and exerts a protective property against a panel of diseases especially cardiovascular diseases, hypertension, blood lipid profile, and oxidative stress. Pomegranate juice was used for 3 years to treat patients suffering from carotid artery stenosis which may lead to decreased atherosclerotic lesion size. This effect is attributed to potent antioxidant ability of pomegranate juice which contains large amount of ETs. Bianca Fuhrman (2006) reported a decline in collagen-induced platelet aggregation in patients after they consumed pomegranate juice for 2 weeks.

Dietary foodstuffs containing ETs and EAs have promising anticancer property. However, for research purposes, it is important to know the bioavailability and metabolism of these polyphenols for a better selection of cell lines. For example, if ETs and EAs are poorly absorbed from the gut, it is then inappropriate to test these polyphenols at very low concentrations. For instance, a large amount of the tested compounds would be needed to reach the target organs (e.g., breast, brain). Numerous studies have demonstrated the significant anticancer property of ETs found in pomegranates, raspberries, and strawberries among others against different types of cancer.

Generally, ETs are relatively stable in the physiological conditions of the stomach. Acidic conditions (pH 1.8–2.0) and enzymes do not hydrolyze ETs, and thus no EA formation is observed in the stomach. However, under the physiological conditions of the stomach, a small amount of EAs is converted from ETs due to the physiological conditions with pH 7.0–7.3 (neutral conditions). Several human gastrointestinal (GI) cell lines are normally used to evaluate the uptake, metabolism, transport, and excretion of ETs and EAs. Numerous studies used predigested ETs (Caco-2 cells) for a close simulation of the in vivo conditions. Whitley et al. (2003) reported a high accumulation of EA in Caco-2 cells giving an indication that EAs are easily absorbed across the apical membrane. Around 93% of EAs are irreversibly bound to macromolecules; hence it appears to accumulate in the epithelial cells in the aerodigestive tract.

ET and EA are metabolized further by the intestinal microflora to form urolithins A and B. Cytochrome P-450 hydrolyzed urolithin A to increase the possibilities of glucuronidation and consequently increase the excretion of the metabolite. Two experiments have been carried out to understand the bioavailability and absorption of ETs in the human body. Firstly, the pharmacokinetic of the absorption of pomegranate juice is studied for several hours after consumption, and secondly the bioavailability and metabolism is evaluated by studying the metabolites present in the urine and plasma samples. Seeram et al. (2004) reported a concentration of 31.9 ng/mL of EA in plasma in the first 4 h after consumption. A second study investigating on ET bioavailability and metabolism was carried out with other dietary source of ET, namely, strawberry, raspberry, walnut, and oak-aged red wine (Cerda et al. 2005). These foodstuffs differ in the content and type of ETs. However, urolithin A was detected in all participants ($n = 40$). This led to the proposal of the microbial metabolite urolithin A as a biomarker for human exposure to dietary ETs.

Ellagitannins are large polar polyphenols poorly absorbed in the bodily system. Some pharmacokinetic studies show that EA can be absorbed within 30–60 min after the intake of several foods (Seeram et al. 2004). This indicates that absorption of EAs starts in the stomach and is detectable in peripheral blood. Generally, EAs disappear from plasma 2 h after consumption. Nevertheless, several pharmacokinetics have shown that after the intake of different foods containing the same amount of EAs, no apparent detection of EA was observed in plasma indicating that no absorption of EA took place. However, it is important to note that different individuals have different absorption pattern.

One of the most important steps in bioavailability and metabolism of ETs is the conversion of ET into different hydroxylated dibenzopyranone derivatives, namely, urolithins A–D. Urolithins are the gut microbial metabolites of ETs. The conversion starts in the small intestine and continues in the GI tract. Urolithins A and B are the two most important types of hydroxylated dibenzopyranone derivatives. Urolithins are absorbed in the small intestine and excreted in the bile after methylation and conjugation with glucuronic acid (Espin et al. 2007). Experimental testing conducted in animals showed that the reason why the formation of these metabolites starts in the small intestine could be due to the presence of anaerobic bacteria. The metabolism continues along the GI tract to end with the production of urolithins A and B. Differences in the production of these metabolites by human volunteers show that they may be produced by the activity of specific microorganisms present in the gut. If these microbial metabolites, which are more bioavailable than native ETs and EA, were the true active principles responsible for the biological activity associated with ET- and EA-rich foods consumption, then this would bring up the possibility of developing new functional foods in which specific ET-metabolizing microorganisms could be included together with the ETs (Fig. 3).

Furthermore, in the GI tract and in other tissues (mainly in the liver), EA and ETs microbial metabolites are further metabolized either through Phase I (hydroxylation) or Phase II (methylation, glucuronidation, and sulfation) enzymes to render them more soluble for better excretion in urine. Hydroxylation of urolithin A, and probably B, renders them more reactive with additional

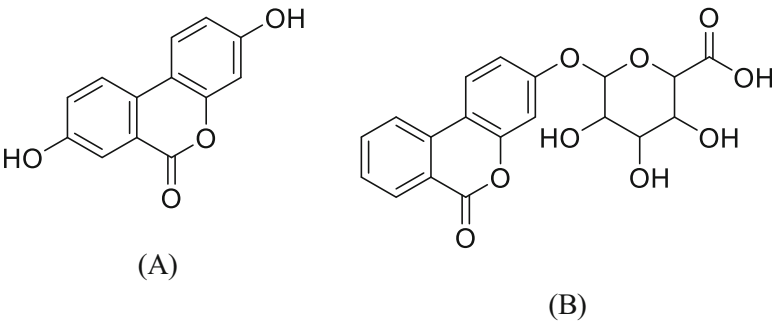

Fig. 3 (**a**) Urolithin A, (**b**) urolithin B 3-*O*-glucuronide

functions for conjugation, which hence facilitates their excretion. Thus, monohydroxydibenzopyran-6-one (urolithin B) can be hydroxylated to produce a dihydroxylated derivative, and urolithin A (3,8-dihydroxydibenzopyran-6-one) can be further hydroxylated to produce trihydroxylated derivatives (Quideau 2009). A study showed that both urolithins A and B can induce the expression of cytochrome P-450 in Caco-2 cells by 15- and 20-fold explaining the abundance of urolithin B-derived dihydroxylated compound in urine, plasma, and liver tissues. Phase II products are also produced together with methyl ethers and different glucuronide conjugates and are detected in different tissues and in urine. The sulfate conjugates of the metabolites of ETs are more abundant in animals and humans compared to glucuronide conjugates. These sulfate conjugates are initially produced in the intestinal cells before being further metabolized in the liver and finally excreted in urine or bile.

In order to understand the biological activity of ETs and EA, it is important to know the metabolites present and their respective concentrations in the target organs. For instance, in rats, no EA, ET, or derived metabolites have been detected in muscle, adipose, heart, lung, or brain tissues. However, a minute amount of microbial metabolites were detected in the liver and kidney. The biological activity and physiological effects of ETs and EA have to be consistent with their bioavailability and metabolism. Thus, results obtained from in vitro studies using cultured cells that would not be in direct contact in vivo with food ETs should be considered with caution.

24.4 Bioactivities (Animal Aspects)

There are also a number of reports regarding the in vivo chemopreventive activity of EA and ETs, mostly in animal models. These studies started in the early 1960s, when it was shown that EA was able to inhibit induced lung tumors in mice upon oral administration. It has been observed that EA and ETs can disappear when in contact with animal cells or tissues, and this has been attributed to irreversible linkage of these compounds with proteins or other cell structures. The bioavailability studies of EAs in animals showed that EA is released from ET in the small intestine followed by absorption of EA in the cells. EA is then easily metabolized in the intestinal cells to form methyl and dimethyl ethers and glucuronic acid conjugates. These metabolites are detectable in bile and in peripheral blood; however no free EA was detected (Quideau 2009).

Prostate cancer is the second leading cause of cancer among men across the globe. Numerous studies suggested pomegranate juice as good cancer-chemopreventive as well as cancer-chemotherapeutic agents against prostate cancer. A study conducted by Malik et al. (2009) mentioned that anthocyanins present in pomegranate juice are responsible for the anticancer effect in athymic mice. Two different groups of mice were administered with pomegranate fruit extract (PFE) as and water as drinking fluids, respectively. Eight days after consumption, it was observed that small solid tumors were formed in mice drinking water. PFE in

different percentages, namely, 0.1% and 0.2%, were administered orally in mice 1 day after implanting tumor cells. It was observed that both 0.1% and 0.2% PFE significantly inhibited tumor growth.

24.5 Benefits (Human Studies)

Consumption of dietary ETs has been associated with different health benefits. Nonetheless, ETs are not bioavailable as such and are metabolized in vivo. They are partially converted into EA in the upper gastrointestinal (GI) tract, but this first metabolite is also poorly bioavailable. In the lower GI tract, EA and residual ETs are metabolized by gut microbiota to produce urolithins, which, together with their conjugate relatives, persist at relatively high concentrations in plasma and urine for days after ingestion of dietary ETs. Thus, ETs and EA may exert local health benefits on the GI tract, but systemic health benefits are more likely to result from urolithins (Garcia-Munoz and Vaillant 2014). Many beneficial effects are related to the presence of EA, ETs (including punicalagins), punicic acid and other fatty acids, flavonoids, anthocyanidins, anthocyanins, estrogenic flavonols, and flavones, which seem to be its most therapeutically beneficial components. However, the synergistic action of the pomegranate constituents appears to be superior when compared to individual constituents. Promising results have been obtained for the treatment of certain diseases including obesity, insulin resistance, intestinal inflammation, and cancer. Although moderate consumption of pomegranate does not result in adverse effects, future studies are needed to assess safety and potential interactions with drugs that may alter the bioavailability of bioactive constituents of pomegranate as well as drugs (Viladomiu et al. 2013).

24.6 Pharmacological Properties of Dietary Ellagitannins

Numerous food products, medicinal plants, and nutraceuticals contain hydrolyzable tannins mainly ETs which are known to possess potential benefits on cardiovascular diseases (Larrosa et al. 2010). From a study reported by McDougall and Stewart in 2005, it was mentioned that ETs inhibited α-amylase activity and thus have the potential to show synergistic effects on starch degradation after ingesting berries particularly raspberries and strawberries (McDougall and Stewart 2005). Additionally, a study conducted by Ismail et al. (2016) showed that ETs play a primordial role in the prevention of cancers, namely, cervical, skin, liver, colon, breast, prostate, and esophageal and oral cancers. Ellagitannins are found in abundance in fruits mainly raspberries, strawberries, pomegranates, blackberries, and longan and nuts especially almonds and walnuts (Heber 2011). Interest in ETs and EA has increased over the past few years due to its properties as a micronutrient (Bakkalbaşi et al. 2008).

Bioactive compounds from berries have potent antioxidant, anticancer, antimutagenic, antimicrobial, anti-inflammatory, anti-neurodegenerative (Nile and

Park 2014), and antiaging properties (Avalos-Llano et al. 2018). The oxidative properties of ETs vary depending on their chemical structures. In a study conducted by Gyamfi and Aniya (Gyamfi and Aniya 2002), it was found that ETs are better metal chelators rather than radical scavengers. Additionally, ETs can also be effective prooxidants in the absence of ascorbic acid. It is hence difficult to draw conclusion on the oxidative property of ETs since various studies have mentioned both the prooxidant and antioxidant capacity of ETs.

24.6.1 Ellagitannins in Fruits

Ellagitannins and ellagic acids are polyphenols mostly abundant in berries, namely, raspberries, strawberries, black raspberries, or pomegranates. Ellagitannins are known to possess many health benefits and provide protection against various chronic diseases, namely, cardiovascular diseases, cancers, and neurodegenerative diseases (Augustin et al. 2005; Erdman et al. 2007). The intake of polyphenol with the aim to prevent diseases is promising but not conclusive as more human clinical trials are required to reach a proper scientific evaluation (Törrönen 2009). Considering the fact that ETs are hydrolyzed to EAs which are further metabolized in the gastrointestinal tracts to form urolithins, it is thus of paramount importance to highlight that the healthy benefits are mainly attributed to those urolithin compounds (Garcia-Munoz and Vaillant 2014).

24.6.2 Pomegranates

The global increase in the consumption and production of pomegranates is associated to the health promising facet of the fruit (Türkyılmaz et al. 2013). The bright red color of pomegranate juice is attributed to the presence of the main constituents which are anthocyanins. The most prevalent tannins present in pomegranates are hydrolyzable tannins (HTs) including ETs and gallotannins in contrast to condensed tannins (CTs) which are rarely found (Gil et al. 2000; Teng et al. 2017). Numerous studies showed that ETs isolated from pomegranates possess good antimicrobial activities against a panel of microbes, namely, *Escherichia coli*, *Salmonella enteritidis*, *Staphylococcus aureus*, *Bacillus subtilis*, *Klebsiella pneumoniae*, *Pseudomonas aeruginosa*, *Yersinia enterocolitica*, *Listeria monocytogenes*, and *Candida albicans*. It is known that the therapeutic values of pomegranates are attributed to the presence of ETs (Henning et al. 2017). For instance, a study conducted by Henning et al. (2017) on pomegranate (*Punica granatum* L.) concluded that *Akkermansia muciniphila* play an important role in the hydrolysis of ETs to EAs in the intestine and thus contribute to the health benefits of that particular fruit. Al-Zoreky (2009) evaluated the antimicrobial properties of the fruit peel of pomegranates both in vivo and in vitro. Antimicrobial screening was performed against nine strains of microbes, namely, *Listeria monocytogenes* ATCC 7644, *Staphylococcus aureus* ATCC 6538, MRSA (*Methicillin-resistant*

Staphylococcus aureus), *Bacillus subtilis* ATCC 6633, *Klebsiella pneumoniae* ATCC 10031, *Escherichia coli* ATCC 10536, V517, *Salmonella enteritidis* ATCC 4931, and *Yersinia enterocolitica* ATCC 23715, reporting the highest MIC value with *Salmonella enteritidis* ATCC 4931 (4 mg/mL). Furthermore, pomegranate juice was assessed for its antimicrobial property. Out of the 12 microorganisms tested, only 4 microbes including *Bacillus megaterium*, *Bacillus subtilis*, *Staphylococcus aureus*, and *Pseudomonas* sp. showed good antimicrobial property (Türkyılmaz et al. 2013).

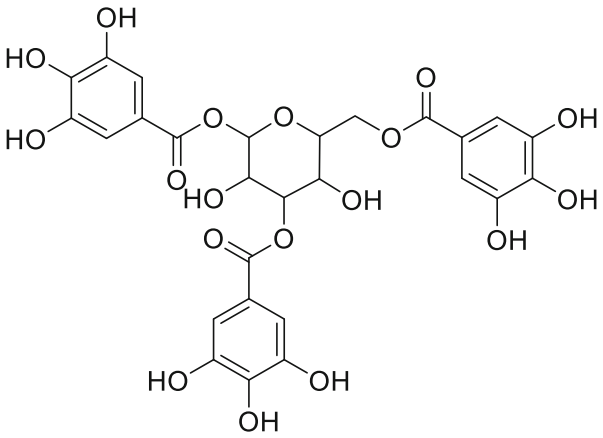
Through various studies pomegranate is found to be a potent anticancer agent that contains many bioactive components such as EA, punicic acid, and punicalagin. The extracts obtained from this plant have been found to suppress tumor cell proliferation and induce cell cycle arrest and apoptosis through modulation of various transcription factors, signaling pathways, and the expression of various genes in both in vitro and in vivo settings. Clinical studies reported pomegranate juice intake aids in the control and stabilization of prostate and colon cancer. However, very few clinical studies have been undertaken and encouraged scientists to scrutinize this promising fruit more in depth (Khwairakpam et al. 2018). Recently, for the first time, the team of Berdowska et al. (2018) evaluated the modulatory impact of selected ETs, namely, agrimoniin, sanguiin H-6, rugosins D and A, tellimagrandin I, and pedunculagin, on human breast cancer cells showing resistance to Adriamycin (MCF-7/Adr). Results showed that the highest inhibitory impact was reported with agrimoniin followed by pedunculagin, rugosins D and A, and lastly tellimagrandin I (Berdowska et al. 2018).

24.6.3 Berries

Berries are represented by a number of small fruits in a variety of colors, namely, red, blue, or purple. The most common berries are blueberry, bilberry, cranberry, blackberry, raspberry; black, white, or red currant; and strawberry, and less common include lingonberry, cloudberry, elderberry, honeyberry, whortleberry, and chokeberry. They contain high levels of polyphenols including flavonoids (anthocyanins, flavonols, flavanols), condensed tannins (proanthocyanidins), hydrolyzable tannins (ETs, gallotannins), phenolic acids (hydroxybenzoic acid, hydroxycinnamic acids, chlorogenic acid), stilbenoids, and lignans (Vendrame et al. 2016; Nile and Park 2014; Manganaris et al. 2014).

Raspberry also known as nature's candy has been consumed by the world population since thousands of years ago. They are consumed in different ways: fresh, frozen, dried and in yoghurts, desserts, cakes, juice, or jellies. Raspberries are known to be a good source of polyphenols such as anthocyanins, flavonols, and ETs which have the capacity to reduce the risk of oxidative damage caused by free radicals and have the potential to reduce the risk of chronic diseases including cancer and heart disease (Megan 2018). According to the US Department of Agriculture (USDA) National Nutrient Database, one cup of raw raspberries equivalent to 123 g contains 64 g energy, 1.48 g protein, 0.80 g fat, 14.69 g carbohydrate, 31 mg

Fig. 4 Gallotannin



calcium, 0.85 mg iron, 32.2 mg vitamin C, and 1.87 mg niacin (USDA National Nutrient Database, 2019). The two horticulturally valuable raspberries are the red (*Rubus idaeus* L.) and the black raspberries (*Rubus occidentalis* L.) (Yazdanpour et al. 2018).

The bioavailability of red raspberry anthocyanins (ATs) and ETs was studied by Ludwig et al. (2015). A total of eight ATs, two EA conjugates, two ETs, one hydroxycinnamate, and one phenolic acid were identified and quantified in the raspberry supplement using HPLC-PDA-MS. Figure 4 illustrates the chemical structures of some major compounds of interest. In the same study, volunteers were fed with red raspberries, and their plasma and urine samples were tested by UHPLC-MS. It was found that ATs and ETs undergone extensive degradation while passing through the digestive system of body to produce a variety of metabolites including methyl, glycine, glucuronide, and sulfate derivatives of phenolic acids, phenylpropanoids, ellagic acid, and urolithins. It is with respect to the produced metabolites that the red raspberries possessed the underlying protective effects on the human health. In a review compiled by Teng et al. (2017), it was suggested that future studies should be focused on the absorption of anthocyanins and how it can be used in chemotherapy and anti-inflammation treatment.

Black raspberries (BRBs), the sister berry of red raspberries, locally known as "Bokbunja" in Korea, are largely cultivated in the southern parts of Korea, China, and Japan. The cultivation area of this species has increased due to the huge demand by the population for their usage as a traditional herbal medicine. BRBs are rich in flavonoids, tannins, triterpenosides, and phenolic compounds, and these metabolites possess multiple pharmacological properties, namely, cell proliferation inhibition and apoptosis stimulation in HT-29 human colon cancer cells and anti-fatigue, anti-gastropathic, anti-inflammatory, antirheumatic, and antioxidant activities (Jeong et al. 2010). At the time of writing, due to its extraordinary functionality, different types of processed products, such as sugar extracts, wine, and vinegars, have been actively produced to create high-value added Bokbunja food products (Song et al.

2016; Kim et al. 2005). Black raspberries are heavily screened in terms of their anticancer property.

BRBs harbor a wide array of bioactive metabolites, namely, flavonols, anthocyanins, hydroxycinnamic acids, as well as ETs (Teegarden et al. 2019; Paudel et al. 2013). BRBs and other sources of dietary anthocyanins are attributed to many health-promoting benefits especially preventing eyestrain, improving night vision, and preventing macular degeneration, possess anti-inflammatory properties, and act as a protection barrier against DNA damage and anticancer and anti-neurodegenerative among others (Yousefi et al. 2015; Rezaee Kivi and Sartipnia 2013). A team of scientists in Korea studied the effects of BRBs on oxidative stress and plasma oxidant capacity in health male smokers, and the results were promising. Thirty-nine male volunteers were given 30 g of freeze-dried BR or placebo for 4 weeks. There was no age difference, neither smoking history or anthropometry nor nutrient intake between groups. It was found that the BRB supplementation had no effect on plasma lipid profiles, LDL oxidation, and DNA damage. However, the activity of the antioxidant enzymes increased drastically together with glutathione peroxidase and catalase and reduced plasma lipid peroxidation. Thus it was concluded that BR supplementation might decrease cigarette smoke-induced oxidative stress through increase of endogenous antioxidant enzyme activities (Park et al. 2015).

The seeds of BRBs are known to contain a large quantity of ETs. As mentioned earlier, ETs are hydrolyzed by the system of the body to subsequently form ellagic acids (EAs) which are further metabolized into urolithin A (UA) and urolithin B (UB) known to be bioavailable in the colon and prostate. Cho et al. (2015) conducted an interesting study on those compounds (ETs, EAs, UA, UB) in relation to their anticancer activities using HT-29 colon cancer cells. Results showed that EA caused a slight but significant cell cycle arrest at the G1 phase, and both urolithins caused cell cycle arrest at the G2/M phase and upregulated p21 expression. Apoptotic cells were detected by annexin V-FITC/PI assay when treated with the compounds. ET, EA, UA, and UB showed anticancer activity by arresting the cell cycle and inducing apoptosis on the HT-29 human colon cancer cells. Therefore, this study suggested that the BRB seeds could be a potential source of anticancer ETs.

Interestingly, BRBs exhibited good antioxidant properties due to the presence of anthocyanins and phenolic acids. The ethanolic extract (70%) containing compounds 9, 11, 16, and 17 has the highest antioxidant potential with IC50 <0.1 μg/mL, while the ethanolic extract (30%) containing compounds 8, 9, 11, and 17 showed an activity with IC50 value 2.80 μg/mL (Xiao et al. 2017). A study was conducted on the level of polyphenolic contents with respect to the maturation stages of Java plum (*Syzygium cumini* Lam.). Data showed that the level of gallotannins, ellagitannins, flavonols, gallic acid, and ellagic acid decreased as the fruit ripened (Lestario et al. 2017).

Strawberry (*Fragaria x ananassa* Duch.) is one of the most popular and appreciated berries consumed by most people either fresh or dried or processed. It is reported that strawberries help to prevent inflammation; fight against oxidative stress and obesity; reduce risk of heart disease, diabetes, and neurodegenerative disorders;

and also act as a preventive barrier against different types of cancers (Afrin et al. 2016). According to previous studies, the ET contents of raspberry and strawberry were 160 and 25–59 mg/100 g in fresh samples, respectively. However, Koponen et al. (2007) reported a lower content value ranging from 2 to 66 mg/100 g. EA is the main phenolic acid in strawberries (from 300 mg to 600 mg/100 g) (Vendrame et al. 2016). ETs and EAs are reported to play a primordial role in controlling hyperglycemia and hypertension in diabetic patients. Recently, a study conducted by Nowicka et al. (2019) demonstrated that ETs and procyanidins play an important role in terms of antioxidant properties of strawberries. Strawberry has good anti-inflammatory property, and the compound pelargonidin-3-*O*-glucoside (P3G) is the major anthocyanin responsible for this property (Duarte et al. 2018). Fumagalli et al. (2016) investigated anti-inflammatory activity after simulated gastric digestion conducted in vitro. It was concluded that strawberry tannins exerted the same anti-inflammatory property even after digestion. To the best of our knowledge, very few studies have been conducted on strawberries in relation to the compound ET and thus require more investigation.

Blueberry (*Vaccinium corymbosum* L.) is among the most commonly consumed berries in the United States. Along with blackberries and strawberries, blueberries (BBs) are rich sources of ETs (up to 600 mg/100 g), followed by chokeberries, cloudberries, and red raspberries (approximately 260 mg/100 g) (Zanotti et al. 2015). Of much interest, it is important to highlight that from a study conducted by Seeram et al. (Bianca Fuhrman 2006), the phytochemical profiling of BBs revealed that the predominant types of tannins present in them are condensed tannins (proanthocyanidins) rather than hydrolyzable tannins (namely ETs) which are the most abundant compounds in strawberries, blackberries, and raspberries. Johnson et al. (2015) conducted various studies on 480 mL blueberry juice which is equivalent to a cup of fresh BBs. Results showed that these fruits have the potential to reduce the systolic and diastolic blood pressure and increase superoxide dismutase activity after the consumption of BBs. It was thus concluded that daily consumption of BBs can potentially reduce blood pressure and arterial stiffness. Basu et al. (2010) also confirmed the health benefits of BBs in terms of cardiovascular diseases and metabolic syndrome. Johnson et al. (Johnson and Arjmandi 2013) reviewed the anticancer property of BBs and mentioned that these berries showed promising anticancer effects by preventing carcinogenesis and DNA damage. However, further clinical trials are required with respect to their cancer-preventive ability.

24.6.4 Ellagitannins in Vegetables

Vegetables are of minor importance to polyphenol intakes. Carotenoids are obtained mainly from vegetables and sterols from margarines, bread, and fruit. Isoflavonoids came from soy products, and lignans were derived from seeds, soy

products, rye bread, and other cereal products (Ovaskainen et al. 2008). Koponen et al. (2007) screened various vegetables, namely, eggplant, lettuce, red paprika, potato, red beet, red cabbage, red onion, red radish, rhubarb, and tomato, for the total content of anthocyanins and ETs. Results showed the content that total anthocyanins ranged from 3 to 75 mg/100 g of fresh weight and the total ellagic acid content varied from 1 to 330 mg/100 g of fresh weight. As far as our literature search could establish, there are very few articles reading ETs present in vegetables. Most of the research articles revolve around pharmacological properties of ETs present in berries. As a consequence more scientific investigation should be carried out in order to better clarify on the pharmacological properties and health benefits of ETs in vegetables.

24.6.5 Ellagitannins in Nuts

Nuts are considered as highly nutritious foods in many parts of the world and are easily found in many dishes and even salads (Sanchez-Gonzalez et al. 2017). Common edible tree nuts are almonds, Brazil nut, cashew, hazelnut, macadamia, pecan, pine nut, pistachio, and walnut (Chang et al. 2016). Nuts are nutrient-rich foods and have been a regular constituent of mankind's diet. Nuts are convenient and tasty snacks that contribute to a healthy dietary pattern. They are usually consumed as whole nuts (as raw, roasted, or salted) (Alasalvar and Shahidi 2008). It is known that frequent nut intake is associated with protective effects against cardiovascular diseases. In addition to the generally high contents of unsaturated fatty acids and polyphenol, compounds seem to be also implicated in health-promoting effects of nuts due to their antioxidant properties (Abe et al. 2010).

Le et al. (2014) conducted a study on cytotoxic effects of ETs derived from walnuts. The targeted human cancer cells were MDA-MB-231, MCF7, and HeLa cells. Interestingly, the methanolic extract revealed good cytotoxic activity against all of the cancer cells tested and suggested that this effect was attributed to the presence of compounds isolated from the extract. The compounds were identified as tellimagrandin I and tellimagrandin II considered as members of the ET family (Fig. 5). Anthocyanins and ellagitannins derived from nuts and berries were considered to be potent cardiometabolic biomarkers as they significantly reduced the cholesterol level compared to pomegranates and grapes (Garcia-Conesa et al. 2018).

US pecans and Chinese hickory nuts are known to possess a panel of different phytochemicals including phenolic acids and proanthocyanidins attributed to health promising benefits to human beings. Gong and Pegg (2017) conducted a study on the isolation of ellagitannin-rich phenolics from those nuts and found that US pecans possess more proanthocyanidins in contrast to Chinese hickory nuts. Comandini et al. (2014) analyzed the complete profile of tannins along with other phenolic compounds present in commercial chestnut bark samples using HPLC-DAD/ESI-

MS method. A total of seven compounds, namely, vescalin, castalin, gallic acid, vescalagin, 1-*O*-galloyl castalagin, castalagin, and EA, were isolated, and the compound, 1-*O*-galloyl castalagin, was tentatively identified and found for the first time in chestnut bark samples (Fig. 6).

24.7 Application in Foods

ETs have attracted the interest of numerous researchers because of their recently recognized role as promising chemotherapeutic agents. There are also recent studies on their occurrence in fruit–vegetable and processed products. Berries are very popular among fruits. They are widely consumed in fresh forms and as food products such as preserves, jams, yoghurts, and ice creams. In China, longans (*Dimocarpus longan*) are consumed as fresh, dried, or canned in syrup. They are equally used in liqueurs or drinks. The seeds of longans possess therapeutic values since they contain tannins in the form of galloyl-HHDP-glucopyranose and pentagalloyl-

HHDP- glucopyranose. Fruit juices are popular products, and a large variety of new products based on fruit juices have recently appeared in the market. In particular, pomegranate and berries juices are mixed with other juices because of their intense flavor and color. These fruit juices are a very rich source of ETs and other phenolic compounds. ETs are important for fruit juices due to their strong antioxidant activity. On the other hand, these compounds cause serious defect such as haze and sediment formation in fruit juice (Bakkalbasi et al. 2009).

The health benefits offered by probiotic fermented milks can be increased by adding native fruit pulps. Red fruits containing EAs and ETs exhibit powerful antioxidant properties and other beneficial biological properties, namely, cardioprotective effects, prevention of human pathogenic bacteria, α-amylase inhibition of angiotensin I-converting enzyme, and proliferative activities against various cancer cells. A study conducted by Bueno and team aimed at improving the physical properties of symbiotic yoghurts through their supplementation with a mixture of red berry pulps: strawberry, raspberry, and "pitanga." The simplex-centroid design was used for mixture modelling. The design included seven batches/trials: three supplemented with each type of fruit pulp, three corresponding to the binary mixtures, and one supplemented with the combination of the three pulps. A control experiment was prepared without addition of fruit pulp. Processed milk bases were fermented at 42 °C until pH 4.7 by using a starter culture blend that consisted of *Streptococcus thermophilus* (TA040), *Lactobacillus bulgaricus* (LB340), and *Lactobacillus acidophilus* (LA140). Subsequently, milk base (80%) was blended with a pulp preparation (20%) and other ingredients according to the experimental design. Physicochemical analyses, enumeration of viable bacteria, and color and rheological characteristics of the yoghurts were evaluated 36 h after preparation and 21 days after cold storage. Three regression models were adjusted to the results (linear, quadratic, and cubic special). The results showed that the addition of a mixture of red fruit pulps affected pH and counts of probiotic bacteria, which slightly decrease during storage. Addition of the three red berry pulps simultaneously enhanced the color and rheological properties of probiotic yoghurts when compared to the control. It was possible to estimate the optimum mixture compositions of the three fruit pulps that increase EA contents in probiotic yoghurts (Luciana et al. 2014).

Trigueros et al. (2014) conducted a study on the antioxidant activity and protein–polyphenol interactions in a pomegranate (*Punica granatum* L.) yoghurt. Pomegranate juice (PGJ) is rich antioxidants; however phenolics easily interact with proteins. A yoghurt fortified with 40% PGJ made from arils was studied (PGY) to determine the antioxidant activity and to estimate the phenolics–proteins interaction during 28 days of cold storage. Juice, yoghurts, and protein-free permeates were analyzed for phenolic composition. It was observed that the anthocyanin profile was changed by the fermentation of the yoghurt, especially the content in cyanidin-3-*O*-glucoside. However, during storage, the anthocyanin content in the fortified yoghurt decreased, but no color change in the yoghurt was noted. The analysis of permeates revealed that the degree of phenol–protein interaction depends on the type of phenolic, EA, and delphinidin 3,5-*O*-diglucoside being the least bound phenolic compounds. The presence of PGJ in yoghurt enhanced radical scavenging performance, whereas all the observed ferric reducing power ability

of PGY was attributed to the presence of PGJ. The 84.73% of total anthocyanins remained bound to proteins at the first day of storage and 90.06% after 28 days of cold storage, revealing the high affinity of anthocyanins for milk proteins.

Another study by El-Said and team on the antioxidant activities and physical properties of stirred yoghurt fortified with pomegranate peel extract (PPE) was conducted. Stirred yoghurt was prepared from reconstituted skim milk powder fortified with 5%, 10%, 15%, 20%, 25%, 30%, and 35% of the pomegranate peel extract (PPE). Results showed that yoghurt fortified with PPE demonstrated higher antioxidant activities compared to the negative controls. Addition of PPE had no significant effects on the sensory attributes (appearance, body and texture, or flavor) as compared to the control sample. Increasing the percentage of the added PPE resulted in decrease in the viscosity of the stirred yoghurt, but samples containing 20% and 25% PPE led almost the same viscosity (El-Said et al. 2014).

Ice cream is one of the most consumed dairy products in the world. Ice cream is rich in macronutrients, i.e., carbohydrates, fats, and proteins, and some micronutrients, i.e., vitamins A, D, and E and calcium mineral. However, commercially available ice creams are generally poor in natural antioxidants like vitamin C, colors, and phenolics. Addition of pomegranate peel phenolics at 0.5 and 1.0% (w/w) showed significant improvement of the antioxidant and α-glucosidase inhibitory activities of the enriched ice creams compared with control sample. Antioxidant activity as EC_{50} and α-glucosidase inhibitory as IC_{50} of 1.0% phenolic-enriched ice creams were 133.3 and 22.9 μg/mL, respectively. More than 75% of the panelists accepted the phenolic-enriched ice creams in sensory evaluation, which lends supports to such products for commercial introduction to the general public with the potential as functional foods (Çam et al. 2014). Sagdic et al. (2012) studied the interaction between some phenolic compounds and probiotic bacterium in functional ice cream production. The radical scavenging activity supplemented with EA, gallic acid (GA), PPE, and grape seed extract (GSE) was higher compared to the control. It was observed that the highest radical activity was attributed to PPE due to its high phenolic content. The study concluded that EA, GA, PPE, and GSE could be used to enhance the phenolic content of ice cream and to gain antioxidant property.

Kushwaha et al. (2015) suggested an economical approach for the production of purified ETs powder from fresh and fermented peels of pomegranate fruit. The method involved the inoculation of about 500 g of fresh pomegranate peel with *Aspergillus niger* culture (3. 8 × 109 spore per ml/100 g fresh peel) and incubated at 26 °C for 7 days in an incubator. In five conical flasks of 500 mL, about 100 g of fermented pomegranate peel was added to 200 mL distilled water and shaken for 18 min at 90 °C. Each flask was centrifuged and the supernatant was collected. The supernatant was subjected to different analysis, namely, antioxidant activity and ET content. The antioxidant activity of ETs powder from fermented peel was slightly lower than ETs powder from fresh peel. It may be due to the oxidation degradation of phenolic compounds during fermentation. After purification of ETs extract from fresh and fermented peel, content of TEC and respective antioxidant activity increased in ETs powder. So, ETs powder may be considered as an ultimate product for its further application, e.g., as biopreservatives, nutraceutical, additives, and antioxidative agent in different food, pharma, and cosmetics products. The most economical approach

proposed was from 1 kg fresh peel; approximately 37–38 g of purified ETs powder can be produced of worth Indian rupees 25,441 in the international market.

24.8 Safety: Toxicity and Side Effects

Oak leaves have a high concentration of ETs. These phytochemicals can either be beneficial or poisonous to animals. For instance, beef cattle are often intoxicated after consuming oak leaves. The severity of the poisoning has recently been associated with the ruminal microbiota, as different bacterial populations were found in animals that tolerated oak leaves and in those that showed clinical and pathological signs of toxicity. Intoxication has previously been linked to the production of phenolic metabolites, particularly catechol, phloroglucinol, and resorcinol. It was projected that the microbial metabolism of ETs could be linked to the different tolerance level or intoxication in different animals. Consequently, it is important to understand the metabolism of ETs in cattle. Different urolithins were detected in ruminal fluid, feces, urine, and plasma. Oak leaf ETs were noticed to decrease as they were converted to urolithins, namely, isourolithin A and urolithin B, by the ruminal and fecal microbiota. Urolithin aglycons were observed in rumen and feces, while glucuronide and sulfate derivatives were detected in plasma and urine. Sulfate derivatives were the main metabolites detected in plasma, while glucuronide derivatives were the main ones in urine. The main urolithins produced in cattle were isourolithin A and urolithin B. Low molecular weight phenolics of the benzoic, phenylacetic, and phenylpropionic groups and metabolites such as catechol, resorcinol, and related compounds were also detected. There was a large variability in the kinetics of production of these metabolites in individual animals, although they produced similar metabolites in all cases. Further studies are needed to demonstrate if the efficiency in the metabolism of ETs by the microbiota could explain the differences observed in susceptibility to intoxication by the different animals (González-Barrio et al. 2012).

24.11 Conclusion and Perspectives

The pharmacological aspects, health benefits, chemistry behind ETs, application of ETs in foods, and toxicity discussed in this chapter, are yet another example of the remarkable impact of natural products on human activities. It is very fascinating to

realize that natural products derived from the metabolism of plants for their protection against pathogens and herbivores, then identified as active principles of plant extracts used in folk medicines and later as promising drug leads, end up being investigated for their role in the elaboration of the biophysicochemical and organoleptic profile of a beverage particularly wine. The biological activity and physiological effects of ETs and EA have to be consistent with their bioavailability and metabolism. Thus, results obtained from in vitro studies using cultured cells that would not be in direct contact in vivo with food ETs should be considered with caution. This is, for example, the case of studies testing activity of ETs on liver or breast cancer cell lines. The metabolic transformation of ETs into urolithins A and B is a widespread phenomenon in nature. According to the present knowledge, berries of *Rubus*, *Fragaria*, and *Rosa* species, as well as pomegranate and muscadine grape products and walnuts, are the best dietary sources of ellagitannins. Due to limited food sources, the dietary intake of ETs and EA is probably low compared to many other polyphenols. Experimental studies on ellagitannin-rich foods have demonstrated potential for health benefits, and dietary interventions are being conducted in patients at increased risk for cancer development. In addition to high levels of ETs, berries, pomegranates, and walnuts also contain a variety of other phytochemicals, essential fatty acids, and other nutrients and may therefore be regarded as "health foods" or even "superfoods." Research is progressing in many laboratories and will eventually provide new evidence on the health effects of dietary ETs. Meanwhile, increased consumption of the delicious ET-rich foods and beverages as a part of a balanced diet can be recommended. For example, pomegranate fruit (*P. granatum* L.) yields the richest source of ETs among other fruit juices and is recommended to consume frequently. The ellagitannins found in pomegranate fruit are very potent antioxidants, and pomegranate juice exceeds the in vitro antioxidant potency of other common commercial fruit juices. Pomegranate peel is a rich source of phenolics which contain unique phenolic compounds called punicalagins in significant amounts. Utilization of pomegranate by-product as a source of functional ingredient in food industry is an ideal objective. This study clearly showed that phenolics of pomegranate peels in microencapsulated form would be a suitable ingredient for improving the functional properties, precisely antioxidant and α-glucosidase inhibitory activities of ice cream. Future studies are necessary to investigate the interaction of phenolics with other food components in ice cream.

Gallotannins in Food

25

Ipek Suntar, Fabiana Labanca, and Luigi Milella

Contents

Abstract

Tannins are natural polyphenolic components found in fruits such as grapes, apples, pears, plums, peaches, strawberries, and cranberries as well as in beverages including wine and tea. Other sources of tannins are *Acer ginnala* Maxim., *Caesalpinia spinosa* (Molina) Kuntze, *Caesalpinia brevifolia* Baill., *Hamamelis virginiana* L., *Quercus infectoria* Oliv., *Terminalia chebula* Retz., *Eucalyptus sieberiana* F. Muell., and *Schinopsis* Engl. species. Tannins can be classified into hydrolyzable and nonhydrolyzable (condensed) tannins. Hydrolyzable tannins possess a polyhydric alcohol group in center and hydroxyl groups that are esterified by gallic acid or hexahydroxydiphenic acid,

called gallotannins and ellagitannins, respectively. Medicinal plants containing gallotannins, *Rhus chinensis* Mill. and *Terminalia chebula* Retz., have been prescribed for the treatment of cough, constipation, dysentery, and dysfunctions of the liver and kidney in traditional Chinese medicine. Gallotannins, belong to antioxidant class of polyphenols, seems to be involved in a wide variety of mechanisms linked to human health. Despite their important biological activities, ingestion of large quantities of these compounds may cause some adverse effects. The number of clinical studies on gallotannin containing natural sources is not adequate; therefore, further studies on the potential adverse effects that might be associated with high gallotannin consumption are needed. Consequently, it can be concluded as tannins in optimal doses have promising effects for human health; however, high amount of tannins is not recommended due to its possible risk in cancer induction, anti-nutritional effects, and other adverse reactions.

25.1 Introduction

Tannins are the most complex group of polyphenols. They comprise condensed tannins (or proanthocyanidins), phlorotannins, and hydrolysable tannins. This last class includes soluble chemical compounds of molecular weight comprised between 500 and 5000 Da and characterized by the presence of a core polyol, generally D-glucose. Among them, gallotannins and ellagitannins are the most representative. Their distinctive feature, important in food quality, is the astringency, a sense of dryness extended to all mouth, due to the hydrogen bonds formation between phenolic hydroxyls and salivary proteins responsible of their precipitation as complexes (Arapitsas 2012). The case of tannins is the most representative example of secondary metabolites role in plants. On one side, their astringency and bitterness ensure the defense against herbivores; on the other, their effectiveness in human health makes them recognized beneficial compounds and allows their large use in natural medicine. Although the aim of this book is not the analysis of phytochemicals in medicinal plants but, instead, in food plants, it is interesting to note what large use of these compounds has been done in the past in the care of many diseases. Traditional Chinese medicine prescribes several medicinal plants, containing gallotannins, to treat a large variety of conditions, as well as the galls of *Rhus chinensis* Mill. to dysentery and the fruits of *Terminalia chebula* Retz. that represent the main components of Ayurvedic remedy "Triphala," to care liver and kidney dysfunctions. They are also used in dry form for cough and constipation (Tewari et al. 2017). The fruits of *Cornus officinalis* Siebold & Zucc. are useful in erectile dysfunction (Sieniawska and Baj 2016). *Paeonia suffruticosa* Andrews is

Fig. 1 Main traditional uses of gallotannin-rich plants

highly revered in Chinese culture, and its root bark is used to improve liver function and to reduce fever, just like *Sanguisorba officinalis* L., known as Di Yu, that presents the same qualities and, moreover, shows antihemorrhagic and wound curative properties (Bensky et al. (1993) Chinese Herbal Materia Medica. Eastland pr). Gallotannins in *Hamamelis virginiana* L. have been used for the first time by Indians in North America, for their anti-inflammatory and astringent properties and to care hemorrhoids and diarrhea (Okuda and Ito 2011), while *Caesalpinia spinosa* (Molina) Kuntze pod infusion is used as gargle for inflamed tonsils. A summary of mostly recognized medicinal properties of gallotannin-rich plants is reported in Fig. 1. The application of gallotannins could be extended also to other fields, i.e., the use of tara gum in food industry for the emulsification and stabilization properties (Wu et al. 2015) or in chemical industry as antifouling against undesirable accumulation of marine organisms on boat hulls (Bellotti et al. 2012). In textile sector, the treatment of cotton with oak gall extract provides antibacterial tissues, useful in Candida infections' reduction (Tayel et al. 2013). Furthermore, gallic acid (GA), deriving from gallotannins metabolism, shows an important pharmaceutical application in the production of trimethoprim, an antibacterial drug used in association with sulfonamide in the treatment of various infections (Sarıözlü and Kıvanç 2009).

25.2 Bioactive Constituents

Gallotannins originate from the esterification of the hydroxyls of the sugar core with gallic acid (3,4,5-trihydroxyl benzoic acid) that was discovered for the first time in the middle 1700s by a German chemist, Carl Wilhelm Scheele (Arapitsas 2012). The biosynthetic origin of gallic acid was disputed for long time between an early

derivate of shikimic acid and phenylalanine, a later product of shikimate pathway (Fig. 2). Dewick and Haslam (1968, 1969) through radioisotope tracer experiments proved the maintenance of carboxylic group of shikimic acid in gallic acid, confirming the first theory. In the formation of gallotannins, the esterification of glucose with gallic acid by glucosyltransferase provides the first intermediate, the glucogallin (1-galloyl-β-glucose) that has a pivotal role in subsequent esterifications as acyl donor (Daglia et al. 2014) (Fig. 3). The simplest gallotannin is pentagalloyl glucose (β-1,2,3,4,6-pentagalloyl-*O*-D-glucopyranose) or PGG that presents five ester linkages between sugar hydroxyl groups and carboxylic groups of gallic acid. More complex gallotannins are derived from galloylation of this unit to yield hexa-, hepta-, octa-, and galloderivatives. The enzymatic acylation of pentagalloylglucose

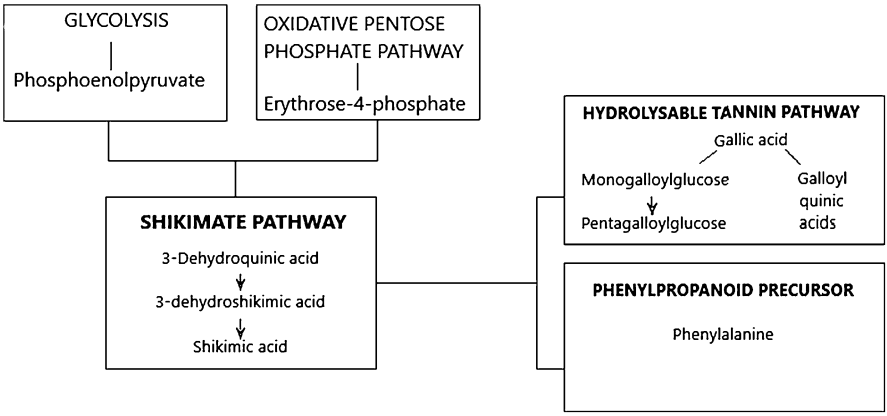

Fig. 2 Shikimate pathway. (Romani A, Lattanzio V, Quideau S (2014). John Wiley & Sons)

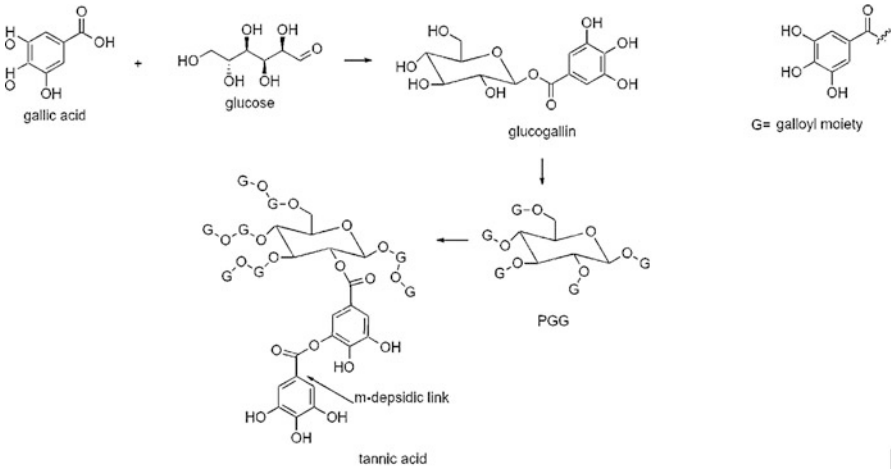

Fig. 3 Proposed biosynthetic pathway for gallotannins

was demonstrated in vitro. In particular, four galloyltransferases have been identified in sumac leaves (Zhang et al. 2009). Further esterification with another five molecules of gallic acid results in the most known gallotannin, the tannic acid. In the eighteenth century, studies on tannic acid led Adolph Strecker to establish that it could be hydrolyzed in gallic acid and glucose and to provide its first formula $C_{27}H_{22}O_{17}$ (Arapitsas 2012). Today it has been revised in $C_{76}H_{52}O_{46}$. Thus, its chemical structure should be represented by that of a decagalloyl glucose, but instead in nature it is variable, depending by species, ranging from 2 to 12 galloyl residues per molecule (Sieniawska and Baj 2016). It is a largely used food flavoring, according to European Union regulation (EC) No. 2232/96 (Arapitsas 2012). Its antioxidant activity revealed stronger than that of vitamin E by DPPH and ABTS radical assays, making it an appreciated preservative in food (Badhani et al. 2015).

Polygalloyl esters were firstly identified more than 100 years ago by Fischer, together with Freudenberg. They formation proceeds by *meta*- or *para*-depside bonds that involve galloyl units' addition to phenolic hydroxyls in *meta* or *para* position with respect to galloyl carboxyl group. It must be highlighted that the nature of sugar hydroxyls is different from that of phenolic hydroxyls. For this reason, they are more simply hydrolysable than ester bonds, and it is easy to isolate PGG from a mixture of polygalloyl esters. The degree of polymerization and galloylation, as reported below, is important because it affects the chemopreventive properties of gallotannin-rich extracts. The presence of several chiral centers in all gallotannins is responsible of the existence of many isomers, characterized by the same molecular weight, but by different susceptibility to hydrolysis and different elution times during chromatography. Also their ability to precipitate proteins is related to structure. The occurrence of numerous structures and their variability is due to oxidative coupling of other gallic acid molecules or to phenolic oxidation. As told above, it has been shown that the shikimic acid plays a central role in the biosynthesis of gallotannins. Even from its hydration, it is possible to obtain the quinic acid that combines with gallic acid to provide a new class of gallotannins, the galloquinic acids (Fig. 2) (Karas et al. 2017). In these molecules, the hydroxyls of quinic acid are esterified with gallic acid to provide differently substituted galloquinic acids. The major limit of gallotannins and, in general, of hydrolysable tannins isolation and quantification is represented by the absence of commercially available standards and specific detectors that lead to the use of nonselective methods to isolate them, with less accuracy (Arapitsas 2012). Another consideration derives from the high susceptibility to hydrolysis of *meta*-depside gallotannins that makes them not extractable by acid methods or with high temperatures (i.e., Soxhlet extraction), because they are promptly hydrolyzed in PGG (Barreto et al. 2008). The classic method for hydrolysable tannins extraction is methanolysis that causes the release of methyl gallate that could be overestimated (Gan et al. 2018). However, given the importance of gallotannins for human health, their occurrence among plants and their extraction have been studied since ever, as reported by Okuda et al. (1993) who investigated on the presence of hydrolysable tannins in herbaceous and woody plants, in the attempt to find a correlation with plant evolution. In more recent studies, they correlated progressive oxidation of compounds with morphological

evolution (Okuda et al. 2000) and proved that, in herbaceous plants, gallotannins structures remain invariant, but in woody plants, they transform in the early part of season, sometimes even changing from gallotannins to ellagitannins, as in *Liquidambar formosana* Hance (Okuda and Ito 2011). Indeed, not all compounds are stable and isolable. Among all gallotannins that have been isolated, the food interesting compounds are numerous.

- *Hamamelitannin.* This digalloylhamamelose has been originally isolated from a *Hamamelis* species, in particular from *Hamamelis virginiana* L. (Hamamelidaceae). Its galloyl esters are present also in *Castanea* species (Fagaceae) and *Sanguisorba* species (Rosaceae), the first consumed cooked as autumnal fruit, or in jam preparations, the second eaten raw or cooked in salads or soups (Okuda and Ito 2011).
- *3,4-; 4,11-; 3,4,11-tri-O-Galloylbergenin*. This C-glycosidic gallotannin is present in *Mallotus japonicus* (L.f.) Müll.Arg. (Euphorbiaceae). This plant is often called "The food wrapper plant" because of the large leaves that are used to wrap food in Japan. They are edible once they are cooked (Saijo et al. 1990).
- *Penta-O-galloyl-glucoside* and its analogs (*hexa-* to *nona-* gallosydes) (Luo et al. 2014) and *methyl gallate* (Barreto et al. 2008) in *Mangifera indica* L., commonly known as mango. Although these active compounds have been detected in major amounts in peel and kernel, their presence has been revealed in traces (<0.2%) also in the pulp (Kiss and Piwowarski 2016).
- *1,2,3-tri-O-Galloyl-β-D-glucose, geponin, penta-O-galloyl-β-glucose, and 2,6-di-O-galloyl-β-glucose* from *Geum japonicum* L. (Rosaceae). Tea of leaves and flower is used for astringent properties in order to treat cough and hemorrhages (Yang et al. 2011).
- *3-Galloylgallic and 4-galloylgallic acid, tri-, tetra-, penta-, hepta-, and nona-galloylglucose* from *Rhus chinensis* Mill. (Anacardiaceae). The seeds can be eaten for stomachache, mushroom poisoning, and indigestion; the buds boiled are useful against diarrhea, as well as fruit decoction, while dried fruits also in case of constipation, vomit, and indigestion. Fruit powder is used as antitoxin (CRC World Dictionary of Medicinal and Poisonous Plants (2012) Umberto Quattrocchi. CRC Press).
- *1,2,4-tri-O-Galloyl-β-glucopyranose and 1,3,4-tri-O-galloyl-β-glucopyranose* (Sahar et al. 1997)*, PGG, and β-1-O-galloyl-3,6-(R)-hexahydroxydiphenoyl-D-glucose* (Corilagin) (Xiao et al. 2013) from seed and leaves of *Punica granatum* L., better known as pomegranate.
- *Turkish gallotannins (penta-, hexa-, and hepta-galloylglucose)* from *Quercus infectoria* Oliv. (oak tree). The galls are used, in addition to other cereals, to make bread (Stashia 2013).
- *Hexa- and hepta-galloylglucose* from *Rhus typhina* L. (sumac). The fruits, big red cones consisting of individual drupes, are the ingredients of a lemon tasting drink, the "sumac-ade," used in the Middle East Mediterranean area to care gastrointestinal diseases (Kossah et al. 2011).

- *1,2,6-tri-O-Galloyl-glucose* and *1,2,3,6-tetra-O-galloyl-glucose* in *Ceratonia siliqua* L. pods, characterized by a sweet flavor. It is appreciated for gelling and thickening properties of flour deriving from seeds and for the low glycemic index that allows using it in diabetic food manufacture (Kiss and Piwowarski 2016).
- *Monogalloyl to hexagalloyl hexosides* in *Canavalia gladiate* (Fabaceae) red beans. This peculiar coat color is attributable to these compounds. Although this type of legume is the richest in antioxidant, especially in gallotannins, among other 42 Chinese edible beans evaluated, it is rarely used. The tender pods could be consumed as vegetable as a great natural source of gallotannins, but this plant is not commercially cultivated (Gan et al. 2018).
- *Gallic acid, methyl gallate,* and *ethyl gallate* in *Toona sinensis* (Juss.) M. Roem. (Meliaceae). The leaves are edible and are often employed in Chinese vegetarian cuisine (Hseu et al. 2008).
- *Gallic acid, 5-O-galloyl, 3,5-O-digalloyl,* and *3,4,5-O-trigalloyl quinic acid derivatives* are the main gallotannins in edible oil from *Pistacia lentiscus* L. (Anacardiaceae) (Romani et al. 2002).
- Galloylquinic acid, galloylshiquimic acid, galloylhexoside acid, digalloylquinic shikimic acid, digalloylquinic acid, and other mono-, di-, and tri-derivatives have been founded in different amounts in fruits and leaves of strawberry (*Arbutus unedo* L.) of various areas of Mediterranean (Miguel et al. 2014). These compounds seem to be present exclusively in this plant, providing an extra value to these precious red gems.
- Uncommon polyphenols called glucitol-core containing gallotannins (GCGs) in *Acer* L. species, *Acer rubrum* L., and *Acer saccharum* Marsh. that represent the major source of maple syrup, largely used as topping for cakes and sweets. They are formed by galloyl groups attached to a 1,5-anhydro-D-glucitol core (Ma et al. 2016).
- Free gallic acid has also been found in red fruits, *Vitis aestivalis* Michx. and *Vitis vinifera* L., in black tea (about 125 mg/L) and in green tea (about 6 mg/L). It is also present in *Oryza sativa* L. (between 17 and 35 mg/Kg) and in oat flour (*Avena sativa* L.) (Daglia et al. 2014).

25.3 Bioavailability and Metabolism

The development of potential natural therapeutic drugs requires detailed knowledge about pharmacokinetic parameters. The bioavailability of vegetable compound is never free from trouble. It depends by the complexity of phytocomplex that at the same time might be responsible both for an incremented general beneficial effect and for floating absorption of a compound, caused by the concomitant presence of anti-nutrient (i.e., matrix or non-soluble tannins). In fact, many differences could be observed after administration of the pure compound or the whole extract (Jiamboonsri et al. 2015). Given the structure similarity among gallotannins, the most common gallotannins that occur are simplest gallic acid derivatives: tetra- and

penta-*O*-galloyl-glucoses (Kiss and Piwowarski 2016). Data about the bioavailability of some of them are derived from studies on oral administration of mango seed kernel extract in rats (Jiamboonsri et al. 2015). Gallic acid is rapidly absorbed after oral ingestion, raising the maximum concentration in blood after 60 min, with a half-life of 24 min. In humans, the maximum concentration reaches 2 μmol/L, and the half-life is 1 h. No strong differences may be detected between pure compound and extract administration, differently from the two other major metabolites of mango extract: methyl-gallate and PGG. The comparison between their concentrations in rats blood after intraperitoneal injection (35 and 6 μM, respectively) and after oral administration of high dose (under the detectable limit) leads to the conclusion that they might be widely influenced by intestinal permeability and transformed by gut microflora and hepatic metabolism (Jiamboonsri et al. 2015). However, the level of bioavailability in blood of hydrolysable tannins is limited because of the complete hydrolysis in gut (Karas et al. 2017). The bioavailability might also vary between different gallotannins based on the different degrees of solubility. From spectrometric measurements of di-, tri, tetra-, and penta-galloylglucosides, it has been demonstrated that the number of galloyl groups has an inverse relationship with the water solubility, due to the hydrophobic nature of galloyl groups (He et al. 2006).

Although tannins have complex structures and a well-known toxicity against various organisms, they are metabolized and degraded in their derivatives by some microorganisms. As regards gallotannins, they have the simplest chemical structure, and their degradation occurs quite easily by biological enzymatic way through bacteria, yeast, and fungi or by chemical hydrolysis, under acid or base conditions, providing gallic acid and glucose. The main enzyme that play a pivotal role in gallotannins metabolism is tannase that catalyzes, firstly, the cleavage of depside bonds and, secondly, the hydrolysis of ester linkages, thanks to the strong esterase and depsidase activities (Karas et al. 2017). It has been isolated for the first time from strains of *Aspergillus* and *Penicillium*, and nowadays, it is largely used in food industry as stabilizer in various products, as wine and fruit juice (Sarıözlü and Kıvanç 2009). Its action results in the production of glucose and gallic acid that is decarboxylated in pyrogallol by a specific decarboxylase. From pyrogallol it is possible to gain pyruvic acid, which is converted in *cis*-aconitic acid and then in 3-hydroxy-5-oxo-hexanoate before get into Krebs cycle (Karas et al. 2017).

The rate of gut microbial hydrolysis of simple galloyl esters, like methyl-, ethyl-, and propyl-gallate, mono- to hexa-substituted galloyl-β-D-glucoses, and depsides is faster rather than the higher substituted gallotannins, as octa- to dodeca-galloyl-β-D-glucoses. From in vitro studies, miming the low-acid conditions of gastrointestinal tract on mango and strawberry GT-rich extracts, it emerged that higher molecular weight gallotannins are converted into lower weight gallotannins in 4 h, with a concomitant increase of PGG from 200% to 500%, confirming PGG as a transformation product of higher molecular weight gallotannins.

Specifically, Kiss and Piwowarski (2016) revised literature about gallotannins metabolism in humans. They recovered information on urinary gallotannin-deriving metabolites after gallotannin-rich food intake. They found that the most common are pyrogallol-1-*O*-glucuronide, *O*-methylpyrogallol-*O*-sulfate, pyrogallol-*O*-sulfate,

deoxypyrogallol-*O*-sulfate, 4-*O*-methylgallic acid, and 4-*O*-methylgallic acid-3-*O*-sulfate after mango pulp ingestion and catechol sulfate, catechol glucuronide, pyrogallol sufate, methyl pyrogallol sulfate, and pyrogallol glucuronide from strawberries (Kiss and Piwowarski 2016).

25.4 Bioactivities (Animal Aspects)

Gallotannins seem to be involved in a wide variety of mechanisms linked to human health. The explanation of the bioactivity of gallotannins lies in their chemical structure that presents many hydroxyls, with different chemical roles and properties. In fact, phenolic hydroxyls, thanks to their ability in charge stabilization by resonance, are different from sugar core hydroxyls. As belonging to antioxidant class of polyphenols, gallotannins exhibit a strong antioxidant and antiradical activity, deriving by the ability of phenolic OH to donate a hydrogen or transfer an electron to transform into a more stable radical, as shown in Fig. 4. The two mechanisms occur simultaneously, with a prevalence of first way. SAR studies on radical scavenging activity of gallic acid derivatives demonstrated a clear correlation with the number of hydroxyl groups along with steric freedom and the influence of substituents. The presence of a carboxylic group in gallic acid, with respect to pyrogallol, is responsible of the higher antioxidant activity of the first molecule. In fact, it could be explained by the hydrogen donation propensity of this acid group (pKa∼4), together with the presence of an electron withdrawing group at *para* position that makes the corresponding OH more prone to donate hydrogen. Furthermore, the deriving radical O• is stabilize through two intramolecular hydrogen bonds with *ortho*-hydroxyl groups (Badhani et al. 2015). Basing on these criteria and according to Badhani et al. (2015), gallic acid exhibits the highest antioxidant capacity among various polyphenols. Evidences have demonstrated the role of co-planarity of the molecule and hydroxyls, with a better capability in charge delocalization, in the increment of antioxidant potential.

Gallotannins, as previously told, are promptly hydrolyzed in gallic acid and glucose, demonstrating the importance of gallotannins as diet source of precursors of such a powerful antioxidant compound. As regards gallotannins from *Galla*

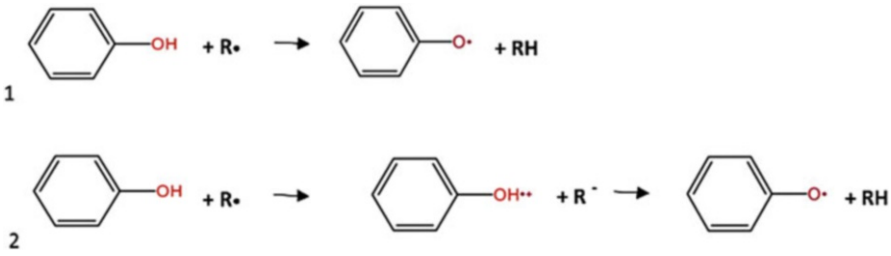

Fig. 4 Antioxidant mechanisms of action of gallotannins. Phenolic OH donates a hydrogen (1) or transfers an electron (2) to transform into a more stable radical

chinensis, studies have demonstrated a clear positive correlation between the degree of polymerization and the antioxidant activity, through different methods (hydroxyl radical scavenging, FRAP, β-carotene-linoleic acid system, and DPPH radical assays), perfectly in line with the evidences about gallic acid (Kiss and Piwowarski 2016). From monogalloylated glucopyranose to deca-galloylated, the antioxidant potential gradually increases, with the exception of di- and tetra-galloylglucopyranose that show an unexpected low activity. It seems that the availability of hydroxyls to hydrogens transfer is reduced by a bond occurring between the galloyl groups. Although some exceptions, the high antioxidant power of gallotannins makes them the perfect substitutes to artificial preservatives in food to prevent oxidation, as well as BHA and BHT, considered as potential carcinogens and severely restricted by Food and Drug Administration.

A comparison between artificial additives and gallotannins has demonstrated the better effectiveness of gallotannins with respect to BHA and BHT (He et al. 2006). The limit of utilization of these compounds as preservatives in food is due to their anti-nutritional effect owing to the interactions with macronutrients that could affect their absorption. The main interactions that occur are both hydrophobic and hydrophilic. The firsts take place between galloyl groups and aliphatic side chains of amino acids, while the seconds between phenolic group of gallotannins and carbohydrates' hydroxyls or polar groups of amino acids, like carboxylic and amino groups. The linkage of gallotannins with polar proteins increases their solubility (He et al. 2006). The capability of gallotannins to interact with biological molecules is responsible of their antimicrobial properties, considered an additional value to their use as food preservatives. The antimicrobial potential is led to the number of pyrogallol rings. Gallic acid, with only one pyrogallol ring, shows a modest antimicrobial activity, but it is able in prevention of biofilm forming by bacteria, in particular by *S. aureus*, *P. aeruginosa*, *E. coli*, and *L. monocytogenes* (Marín et al. 2015).

To translate traditional medicine to modern useful drugs, it is necessary understand the mechanisms that underlie to various bioactivities attributable to gallotannins:

– **Neuroprotective.** Thanks to the hydrophobicity and the antioxidant properties, gallotannins appear as valuable neuroprotective agents (Lu et al. 2006). Oxidative stress and inflammation, with all related pro-inflammatory cytokines release, are the principal events responsible of neurodegenerative diseases occurrence (Daglia et al. 2014). In this context, PGG-rich extracts have an important role, thanks to their lipophilic profile that allows to cross the brain membrane (Lu et al. 2006). Alzheimer disease is characterized by a progressive loss of cognition and memory, and a body of evidences demonstrated the role of accumulation of β-amyloid protein in disease's progression. PGG isolated from *Paeonia suffruticosa* through HPLC analysis showed a great amelioration in the formation of β-amyloid aggregates and also in destabilization of already formed ones. After oral administration of PGG, brain sections of treated and untreated mice have been compared through immunoreactive method, showing a 20% decrease of β-amyloid

aggregates. An improvement in memory deficit was observed in treated mice (Kujawski et al. 2016). This effect might be explained through the antioxidative properties of PGG but also by a new hypothesized method: from in vitro observations on rat neuronal cells, it seems that heme oxygenase-1, a stress response protein, plays a central role in oxidative stress resistance, but further investigations are necessary (Zhang et al. 2009). Although these evidences are derived from PGG of *Paeonia suffruticosa* root extracts (an inedible plant, except for its flowers), Fujiwara et al. (2009) have in vitro demonstrated that this effect is attributed to only PGG molecule that is widely present in other edible plants. Indeed, it is confirmed by Hartman et al. (2006) that observed a great behavior amelioration in mice after pomegranate juice intervention. Treated mice showed an approximately 50% reduction in β-amyloid deposition, compared to untreated mice (Hartman et al. 2006). The neuroprotective activity of gallotannin-rich food might be attributable also to inhibitory activity of tannic acid against β-secretase enzyme, a specific protease that is frequently overactive in Alzheimer disease, with a mitigation of its effects in transgenic mice (Kujawski et al. 2016). The value of gallotannins in the neuroprotection regards also the alleviation of brain damages after ischemia. It is recognized that reperfusion after an ischemic event is associated with severe alterations, as well as inflammation mediator recruitment, radical oxygen species release, and necrosis of brain tissue. Mango leaves-PGG pretreatment to rats subjected to ischemia followed by reperfusion is associated with a mitigation of brain injuries as compared with not pretreated group (Viswanatha et al. 2013).

- **Antidepressant.** The adverse reaction and the tolerance to the modern antidepressant drugs drive to the investigation of antidepressant potential of natural compounds. Among them, gallic acid exhibits a significant activity, proven by forced swim test. The immobility period of mice treated with 60 mg/kg of gallic acid is lower than that of the untreated group, as occurs with target drug, fluoxetine. It acts through a unique mechanism of action, increasing both serotonin and catecholamine levels in the synaptic clefts of the central nervous system. Further interactions with adrenergic, serotonergic, and dopaminergic receptors are also responsible of its antidepressant activity. These results fortify the conclusions of a previous study, conducted on Swiss albino mice, subjected to mild stress. Observing mice behavior under 5, 10, 20 mg/kg doses of gallic acid, Chhillar and Dhingra (2013) concluded that gallic acid reduced immobility time and prevented and restored the stress-induced decrease in sucrose preference. This last evidence might be traced back to the GA-dependent decrement of corticosterone levels in blood. Mild stressed mice present higher plasma nitrite and brain malondialdehyde levels and an increased brain MAO-A activity compared to the control, as well as a decrement of glutathione and catalase activity, as a consequence of the increment of oxidative stress. High doses of gallic acid are associated with the prevention of these alterations (Can et al. 2017).
- **Anti-obesity.** Mango (*Mangifera indica*) seed kernel extract has been identified as a powerful source of anti-obesity compounds. Mice groups following high-fat diet, with and without mango seed kernel extract supplementation, were

monitored. Results showed a reduction in weight gain, fat and visceral fat accumulation, and adipocytes size in treated group, with respect to the control. Hepatic steatosis was observed only in untreated group, while liver sections of treated mice did not reveal histological modifications. These evidences depend on the inhibition power of mango seed kernel extract against intracellular triglycerides accumulation, through the inhibition of the central enzyme of triglycerides biosynthesis. Comparisons with another in vivo study with mango pulp supplementation led to worst results, concluding that mango seed kernel extract contains more anti-obesity bioactive molecules rather than pulp (Kobayashi et al. 2013).

- **Antidiabetic and anti-platelets action.** The increment of obesity is associated with many correlated diseases, first among them, diabetes. In the continuous attempt to find new strategies in diabetes care and maintenance, PGG appears as a valuable lead compound for further therapeutic developments. Gallotannin-rich extracts from *Mangifera indica* L. have been screened in order to identify the antidiabetic compound. Ex vivo studies on the liver and adipose tissues demonstrated the ability of PGG in inhibition of 11β-hydroxysteroid dehydrogenases, a specific oxidoreductase enzyme that plays a central role in the regulation of the levels of glucocorticoids in the body (Mohan et al. 2013). Starting from this result, Mohan et al. (2013) evaluated the activity of PGG on male C57BL/6 mice receiving high-fat diet to induce diabetes. The treatment with different oral doses of PGG (10, 25, and 50 mg/kg) exhibited a clear amelioration of glucose blood levels and fat profile, together with a dose-related decrement of body weight compared to the control (Mohan et al. 2013). In vivo studies on diabetic and obese mice revealed that α-PGG decreases resting blood glucose concentration, with higher glucose tolerance than β-PGG. It could be ascribed to the in vitro demonstrated insulin-mimicking activity of α-PGG that binds to insulin receptors and induces GLUT-4 membrane translocation (Zhang et al. 2009). As insulin receptors are present also on platelets and play an anti-platelets action, Perveen et al. (2011) tested the effects of α-PGG on blood aggregation. Oral treatment with α-PGG (0.02 g/kg) on wild-type mice blocked ex vivo induced platelet aggregation, demonstrating that PGG inhibit platelets activation (Perveen et al. 2011).
- **Hepatoprotective.** As liver damage is correlated with oxidative stress and inflammation, in vivo investigation on the hepatoprotective activity of PGG has been carried on. After treatment with carbon tetrachloride to induce liver injury in rats, a dose of 0.5, 1, and 2 g/kg/day of mango seed kernel extract has been administered. Serum transaminases in treated group showed a decrease stronger than that of rats group treated with the standard drug silymarin, highlighting the hepatoprotective effectiveness of mango seed kernel extract. Furthermore, rats' liver sections presented a remarkable mango seed kernel extract dose-depending improvement in chemical-induced necrosis (Nithitanakool et al. 2009).
- **Nephroprotective.** As hyperoxaluria is associated with an increment of oxidative stress, cell apoptosis, and lipid peroxidation, the antioxidant properties of gallotannins led to investigate their putative effects against kidney stones. In particular, PGG has been tested on hyperoxaluric rats, and it appears to be a

valuable aid in nephrolithiasis prevention, reducing calcium oxalate crystals and oxidative renal cells damage (Lee et al. 2011).

- **Gastrointestinal.** Ulcerative colitis and Crohn's disease are the most common inflammatory diseases that affect the gastrointestinal system. Corilagin, thanks to its immunomodulatory properties, showed therapeutic effect in acute colitis treatment. It has been evaluated by acute colitis model induced by dextran sulfate sodium (DSS) in mice. Intraperitoneal daily doses of 7.5, 15, and 30 mg/kg of corilagin have been associated with an attenuation of colon tissue histological damage and a decrement of pro-inflammatory factors, associated with colitis inflammatory status, by the inhibition of pro-inflammatory action mediated by myeloperoxidase enzyme (Xiao et al. 2013). The limit of this study is represented by the administration route that does not take into account the bioavailability of an oral dose. However, the efficacy of gallotannins in gastrointestinal disease treatment is well recognized as demonstrated by Rajan et al. (2012) who proved the effect of water mango seed kernel extract on castor oil-induced dysentery on Swiss albino mice, confirming its utilization in traditional Chinese medicine. Mango seed kernel extract turned out to be active in altered intestinal motility reduction and in inhibition of prostaglandins, responsible for the unbalanced intestinal permeability in diarrhea (Rajan et al. 2012).
- **Reproductive system.** The treatment of rats with pomegranate juice for 7 weeks has been associated with an improvement of sperm cell density, sperm concentration in epididymis, and sperm quality and motility, thanks to the antioxidant properties of its gallotannins (Türk et al. 2008). Although the responsible molecule of these effects remains uncertain, the same amelioration has been observed also on Leydig cells of male B6 mouse after *Toona sinensis* administration. In this case, the improvement in sperm motility proved not to be induced by an increment of testosterone, confirming the hypothesis of the involvement of antioxidant mechanism tied to gallotannins (Ling Poon et al. 2005).
- **Cholesterol lowering.** Despite its physiological role, high cholesterol level in blood is associated with an augmented cardiovascular risk. The in vivo evaluation of cholesterol lowering potential of gallotannins in pomegranate and mango provides powerful results. In particular, the treatment of albino Wistar rats with an oral dose of mango leaves extract (90 mg/kg for 42 days) showed a reduction in total cholesterol and triglycerides levels in blood (Gururaja et al. 2017). Given the well-known positive role of apolipoprotein E in maintenance of cholesterol and triglycerides levels and in atherosclerosis lesion development, Aviram et al. (2000) tested the pomegranate juice on apolipoprotein E-deficient mice. They observed a 20% reduction in native LDL and oxidized LDL uptake by peritoneal macrophages and by 90% in the oxidation of LDL associated with a decrement of cellular lipid peroxidation and superoxide release by the same cells after pomegranate juice administration. Furthermore, the size of mice atherosclerotic lesions is reduced by 44%, with a concomitant reduction in foam cells number rather than control (Aviram et al. 2000). The anti-atherogenic effects of pomegranate juice, due to its antioxidative properties, have been confirmed by De Nigris et al. (2005). The progression of atherosclerosis is remarkably reduced in

hypercholesterolemic mice, as well as the number of foam cells (De Nigris et al. 2005). In pigs, endothelial damages, induced by dyslipidemia, have been attenuated by commercial skin pomegranate-extract intake (Wang et al. 2018).

- **Antihypertensive.** Evidences of gallotannins-related antihypertensive action are derived from the evaluation of blood pressure in hypertensive mice after intervention with pomegranate juice. Results showed an antagonism toward angiotensin II enzyme, the main regulator in the renin-angiotensin-aldosterone system, involved in blood pressure balance. The mechanism of action is led to the antioxidant properties of gallotannins that avoid the decrement of antioxidant enzymes level, associated with angiotensin II release (Waghulde et al. 2010). Hypertension is correlated with an augmented shear stress, with an underexpression of eNOS and an overexpression of pro-oxidative genes, *p*-JUN and ELK-1, activated by reactive oxygen species. The treatment of mice with doses of pomegranate juice showed an increment of eNOS activity, together with a decrement of oxidative stress-related genes expression (De Nigris et al. 2005).
- **Immunomodulatory.** The term immunomodulatory refers to both immunostimulation and immunosuppression. In autoimmune diseases, an over activity of immune system occurs. PGG appears an effective immunoregulator from in vivo studies. It reduces TNF-α response to LPS stimulus in rats in a dose-dependent manner (Feldman et al. 2001). In contrast, alcoholic mango extract increases humoral antibody and delayed type hypersensitivity in Swiss albino mice, revealing immunostimulant properties, probably attributable to mangiferin (Makare et al. 2001).
- **Antiallergic.** The allergic response is mediated by IgE. PGG exhibits antiallergic properties, due the capability to inhibit B cell signal pathway, with the suppression of IgE production. Ovalbumin-sensitized mice have been utilized in order to evaluate IgE levels after the oral treatment with PGG. It revealed active in the reduction of expression levels of a specific chemokine involved in eosinophil recruitment by IgE receptors. In addition, there is a decrement of the expression of TNF-α and insulin-like growth factor binding protein-3, both involved in IgE production. The antiallergic effect of PGG is enhanced by the immunosuppressive activity of T regulatory cell, which showed an increment, mostly in mice spleen (Kim et al. 2015).
- **Anticancer and anti-inflammatory activity.** The physiopathology of cancer involves several modifications, starting from a primary cancer lesion, with cells over-proliferation and angiogenesis, associated with an inflammatory status. The immunomodulatory, anti-inflammatory, and antioxidative properties of gallotannins put a new perspective on their use as anticancer agents, as demonstrated by many studies. In particular, PGG exhibited in vivo anticancer action against lung cancer, skin cancer, sarcoma, breast cancer, and prostate cancer through different mechanisms that have been in vitro clearly elucidated. However, the way in which PGG exerts the in vivo reduction of tumor remain unclear, because of the lack of in vivo experiments. As regards lung cancer, the intraperitoneal administration of PGG is associated with a dose-dependent decrement of growth, and the maximum dose of 20 mg/kg showed a 91% growth

reduction (Huh et al. 2005). This effect is associated with the suppression of angiogenesis mediated by both the inhibition of pro-angiogenic factors released by COX-2 and the blocking of VEGF binding to VEGF receptor, involved in new blood vessel formation. PGG has been shown a reduction of percentage of skin tumor-presenting mice to about 50% and the average number of tumors per mouse to about 33% (Sieniawska and Baj 2016). A potentiation of immunitary system is at the basis of the effectiveness of PGG or its metabolites against sarcoma. The life expectancy is augmented to 81.9% in sarcoma-bearing mice when they have been treated with intraperitoneal doses of PGG (Zhang et al. 2009). The in vivo efficacy of orally administered PGG on the growth of triple negative breast cancer could be explained through different mechanisms. Zhao et al. (2013) demonstrated the role of both intraperitoneally and orally gallotannins intake in mouse xenograft models in the inhibition of poly (ADP-ribose) glycohydrolase, an enzyme involved in modulation of gene expression (Zhao et al. 2013). Downregulation of estrogen receptors and ErbB family receptors has been proposed as mechanism of action of PGG on this type of cancer by in vivo test on nude mice. The administration of PGG showed a breast cancer regression more pronounced than paclitaxel drug dosing (Zhang et al. 2009). PGG has been revealed a repressor of prostate cancer bone metastasis. It inhibits the expression of metalloproteinase induced by the binding of epidermal growth factor to its receptor in bone, responsible for metastasis. Nude mice treated with 25 mg/kg of PGG three times a week showed lower tumor dimensions and less osteolytic lesions, after prostate cancer cells injection into the bone marrow cavity of tibia, with respect to the control (Kuo et al. 2009). Although PGG showed the highest activity among gallotannins in cancer prevention, also gallic acid and tannin acid demonstrated to be active against cancer. The first has been tested on long-cell lung cancer, after the cell has grafted in mice. The treatment with anticancer drug has been revealed enhanced by the co-administration of gallic acid, with a higher number of apoptotic cells (Kawada et al. 2001). The reduction of tumor growth is also observable in small-cell lung cancer. This efficacy might be explained through the caspase-3-mediated apoptosis induction (Bin-Chuan et al. 2009) and the reduction of inflammatory status, due to the scavenging activity of GA against the reactive oxygen superoxide anion. Its effects on prostate carcinoma xenograft growth have been evaluated on nude mice. They presented a dose-dependent decrement of tumor cell proliferation, associated with a lower angiogenesis rather than untreated mice (Kaur et al. 2009). From in vivo studies, tannic acid appears as a valuable chemopreventive agent. Its activity is explained also when low doses were used: 4.44% of mice receiving tannic acid developed hepatic carcinomas, while 33.3% of cases have been reported in the control group (Nepka et al. 1999). As regards skin tumor progression, tannic acid revealed more potent than GA. It reduces ornithine decarboxylase activity, induced by tumor-promoting agents by 85%. As this enzyme is involved in tumor promotion, it is possible to suppose a putative utilization of tannic acid as anti-promoting agent in many cancer types (Gali et al. 1991).

25.5 Benefits (Human Studies)

In literature, there are several preclinical and clinical studies about the biological effects and pharmacokinetics of simple phenolic compounds; however, human studies are rare, and research findings are controversial on tannin-type compounds (Smeriglio et al. 2017). It has been reported in systematic reviews, and meta-analysis studies that consuming tannin-type compounds found in leaves, fruits, barks, and rhizomes of medicinal plants could avoid chronic diseases (Wang et al. 2014; Turati et al. 2015). Human studies in tannins are on mainly elagitannins and grape seed proanthocyanidins. The outcome of these studies has revealed a reduction in lipid peroxides and enhancement of SOD and CAT activities, GSH and paraoxonase levels, as well as total antioxidant capacity (Horvathova et al. 2014; Deáková et al. 2015). The clinical trials on gallotannin containing medicinal plants were summarized in Table 1.

- **Antimicrobial activity**. The antimicrobial effect of *Hamamelis virginiana* L. distillate and urea (5%) formulation was evaluated in 15 healthy volunteers. The distillate exhibited significant antimicrobial effect on aerobes which are involved in the pathogenesis of atopic dermatitis and intertrigo (Gloor et al. 2002).
- **Anti-inflammatory activity.** In a randomized, placebo-controlled study, vasoconstrictive activity of an aqueous propylene glycol extract of hamamelis was investigated in 30 healthy volunteers. The extract caused a decrease in skin temperature (Diemunsch and Mathis 1987). A mild anti-inflammatory activity of a hamamelis ointment (25 g aqueous distillate/100 g ointment base) was reported in five patients with dermatoses and 22 healthy volunteers. In another study, anti-inflammatory activity of hamamelis distillate was investigated in comparison with chamomile and hydrocortisone (1%) cream and 4 base preparations in two randomized double blind studies in 24 healthy volunteers. The outcome of the study revealed the anti-inflammatory activity of hamamelis PC-cream (Korting et al. 1993). Anti-inflammatory effect of 10% hamamelis distillate lotion was evaluated in 30 healthy volunteers using a modified UVB erythema test model, suggesting that the lotion relieves the symptoms of sunburn inflammation (Korting et al. 1993).
- **Anti-aging activity.** The effect of hamamelis ointment on dry aging skin was investigated in an open-label clinical study in 89 patients at the age of minimum 50 years. Hametum ointment which contains 6.25 mg distillate from fresh leaves and twigs of *H. virginiana* (1:1.6) as the active ingredient was applied to patients were twice daily during 4 weeks. Sebumetric and corneometric measurements and dryness symptoms including tautness, roughness, or itching were recorded. Clinically relevant improvement of skin sebum content and moisture was detected in 4 weeks of application (EMEA 2009).
- **Changes in the gut microbiome.** In a randomized pilot study, potential role of *mango* intake in changes of the gut microbiota, bioavailability of galloyl metabolites, and anti-inflammatory activities in 12 lean and 9 obese (averages

Table 1 Available clinical trials on gallotannin and gallic acid containing natural sources by US National Institutes of Health (www.clinicaltrials.gov)

Number ID	Title	Subjects enrolled
NCT02295293	The effects of *Rhus coriaria* L. on serum lipid levels of patients with hyperlipidemia (SomaghLipid)	74 participants, both sexes, 20–65 years
NCT02891031	The effects of *Rhus coriaria* L. on serum uric acid levels (SomaghUricA)	76 participants, both sexes, 20–65 years
NCT02754089	The effects of *Rhus coriaria* L. on body weight (SomaghWeight)	50 participants, both sexes, 18–60 years
NCT01643096	The effect of thyme and sumac on the thermic effect of food and comparison between warm and cold temperament people	40 participants, both sexes, 18–40 years
NCT02330029	Pinaverium and herbs for irritable bowel syndrome treatment: An onset and offset study (PHIBEST)	800 participants, both sexes, 18–70 years
NCT01641224	A randomized, double-blind, and placebo-controlled study on the treatments of irritable bowel syndrome	800 participants, both sexes, 18–70 years
NCT02511899	Investigation of the influence of careless™, a *Mangifera indica* fruit powder, on microcirculation and endothelial function	10 participants, both sexes, 40–70 years
NCT00935948	Efficacy and safety evaluation of the Imescard compound water smartweed ointment	60 participants, both sexes, 18–70 years
NCT01890070	Study of the nutraceutical properties and health benefits of traditional components of the Mediterranean diet	50 participants, both sexes, 18–75 years
NCT02663492	Transcutaneous electrical Acupoint stimulation for non-small cell lung Cancer patients	300 participants, both sexes, 20–75 years
NCT01501305	Influence of carob and probiotics on acute diarrhea in children	100 participants, both sexes, 3–18 years
NCT02935829	Short-term effects of a carob snack on postprandial glycemic responses and energy intake and satiety	140 participants, both sexes, 18–50 years
NCT02227615	Absorption of mango in healthy individuals	30 participants, both sexes, 20–40 years
NCT02005939	Effect of biophenol-rich pomegranate extract intake on blood pressure, hormones, body composition and quality of life in healthy volunteers. (POM-01Expl)	29 participants, both sexes, 18–65 years
NCT02532101	Modulating effects of oil palm Phenolics in uncontrolled insulin-treated type 2 diabetes mellitus (UNIDOPP)	8 participants, both sexes, 18–70 years
NCT01775384	Polyphenols, exercise, and metabolomics	34 participants, both sexes, 18–55 years
NCT02532088	Modulating effects of oil palm Phenolics in subjects with pre-diabetes (PREDOPP)	268 participants, both sexes, 18–70 years
NCT02328339	Tea and forearm blood flow	20 participants, both sexes, 45–75 years
NCT02273323	Flow mediated dilation in response to black tea (T)	30 participants, both sexes, 18–65 years
NCT02800967	The effects of Aronia juice polyphenols on cardiovascular disease risk (AMARCord)	84 participants, both sexes, 30–50 years

(continued)

Table 1 (continued)

Number ID	Title	Subjects enrolled
NCT03485885	Bioavailability of Maqui Berry extract (MBE) in healthy subjects	12 participants, both sexes, 18–50 years
NCT03214276	Effects of polyphenols supplementation on cycling endurance	48 participants, both sexes, 25–45 years
NCT03805139	Role of Ajwa derived polyphenols in Dyslipidaemias	60 participants, both sexes, 18–70 years

BMI are 22.34 and 33.42, respectively) subjects was evaluated. 400 g of mango was administrated daily for 6 weeks. At the end of 6 weeks, plasma levels of galloyl metabolites enhanced in all subjects, and this was 2.4 times higher in lean subjects. The pyrogallol producing microbiota levels including *Aspergillus oryzae* and *Lactococcus lactis* were significantly lower in obese subjects than in lean subjects. No changes were recorded for *Bifidobacterium* spp. levels. The outcome pointed out that obese individuals do not show the same level of adaptive absorption and metabolism as lean subjects (Kim et al. 2017). *Punica granatum* L. (pomegranate) contains a rich source of biophenols; the most abundant are ellagitannins, anthocyanins, ellagic, and gallic acids. In a study performed on 20 healthy volunteers consuming 1000 mg/day of *P. granatum* extract for 4 weeks, an increase of *Actinobacteria* and *Verrucomicrobia phyla* and a decrease of *Firmicutes* were detected. *Enterobacter*, *Escherichia*, *Lactobacillus*, *Prevotella*, *Serratia*, and *Veillonella* genders also increased, while *Collinsella* decreased significantly. The authors suggested that health benefits may be attributed to the changes in the microbiota (Li et al., 2015).

- **Effect on cholesterol levels:** A two-arm, double-blind placebo-controlled randomized clinical study was carried out on a gallotannin containing medicinal plant *Rhus coriaria* L., also consumed as spice all over the world. Eighty patients with primary hyperlipidemia were randomly assigned and were given 500 mg *R. coriaria* twice daily for 6 weeks. The study indicated significant enhancement in HDL-C and Apo-A1 concentrations with *R. coriaria* supplementation in patients with hyperlipidemia (Hajmohammadi et al. 2018).
- **Antidiarrheal effect.** Antidiarrheal effect of tannic acid-based medical food, Cesinex®, was investigated in six children (18 months to 8 years old) and four adults (55–71 years old) with diarrhea. Two pediatric patients were found to be positive for rotavirus, while in adult patients, no specific cause was found. Diarrheal symptoms were relieved in nine of ten patients receiving Cesinex®. In conclusion, the outcome showed that the tannic acid-based medical food, Cesinex®, was found to be active in managing diarrhea and has a good safety profile (Ren et al. 2011).
- **Effect on irritable bowel syndrome (IBS).** A randomized controlled clinical trial was performed on 1044 adult patients with IBS at 5 hospitals in China, from August 2012 through January 2015. Subjects were randomly assigned (1:1:1) to groups given tongxie (a combination of A macrocephalae, *Paeonia lactiflora*

Pall. along with other herbs), placebo, or pinaverium (50 mg) three times daily for 4 weeks. Significant greater reductions in abdominal pain were detected in patients given tongxie when compared with patients given placebo or pinaverium. It was suggested that tongxie can be considered an alternative therapy for patients with IBS who do not respond well to conventional therapies (Fan et al. 2017).

– **Antiallergic Effect**. A double-blind, placebo-controlled study was carried out to assess antiallergenic activity of Lowal, mixture of 1% benzyl benzoate and 1% tannic acid against dust mites (HDM), Dermatophagoides pteronyssinus and *D. farinae* in carpets. 30 homes (showing more than 400 ng/g of *D. pteronyssinus* and *D. farinae* in carpet dust) of children with HDM sensitization and asthma were enrolled. On day 0 group 1 ($n = 15$) received active treatment, group 2 received placebo treatment ($n = 15$). Two and 8 weeks later, dust samples were collected to determine the amount of mite allergens. After a 2-week washout period, the second treatment was applied as the same manner. A significant decrease was detected for active treatment when compared to placebo treatment after 2 and 8 weeks. It was concluded that slight mite allergen reduction effect was obtained with *Lowal* treatment (Lau et al. 2002)

25.6 Application in Food

Gallotannins are found only in some woody and herbaceous dicotyledons. Cereals are also natural producers of hydrolyzable tannins. *Rhus chinensis* Mill. (Chinese gallnuts) and *Rhus coriaria* L. (sumac) and are rich in gallotannins. β-Glucogallin was reported to be present in *Mangifera indica* L. (mango fruit) pulp (Oliveira et al. 2016). The fruits of sumac are powdered and consumed directly as spice in foods especially in some Mediterranean countries (Lu et al. 2013). Tannic acid is a bitter-tasting substance that binds and precipitates proteins. It is a component found in daily consumed several foods as well as in red wine or unripe fruit and is astringent when taken orally or applied topically. Tannic acid is important in making wine, since it ensures the balance and complexity of wine's palate, color, and aging. Green tea is another source of tannic acid. Tannic acid is also found in the nutgalls which are formed by insects on twigs of *Quercus infectoria* Oliv. Tannic acid is used as a flavoring agent in beverages and foods. Tannic acid was previously used for absorbing poisons in combination with activated charcoal and magnesium oxide. Tannic acid has medicinal applications such as for dysentery, diarrhea, coughs, painful joints, and cancer when taken orally or for bleeding when applied topically. Indeed, it has a protective effect on the skin. It is used for leukorrhea by vaginal application. Tinctures and aqueous extracts are prepared from the fresh leaves of *Hamamelis virginiana* L. by extracting with water and ethanol mixtures in different ratios. Comminuted herbal substances, dry or liquid extracts prepared from the cortex of *Quercus robur* L., and rhizomes of *Potentilla erecta* (L.) Raeusch. are used for medicinal purposes.

25.7 Safety: Toxicity and Side Effects

Polyphenols in food and medicinal plants are presumed to play an essential physiological role in the maintenance of good health. However, due to participating proteins and inhibiting digestive enzymes, tannins are considered as nutritionally undesirable components, resulting in detrimental action on vitamin and mineral absorption. According to published reports, tannins were involved in the incidences of cheek and esophageal cancers, however also recorded as antimutagenic and anticarcinogenic in other studies. Despite their important biological activities, ingestion of large quantities of these compounds may cause some adverse effects.

Tannin toxicity is based on three main mechanisms. The first one is inhibition of microbial enzymes including cellulases, pectinases, xylanases, GPx, laccase, and glycosyltransferase. The second one is their effect on membranes, i.e., inactivation of membrane-bound proteins, inhibition of oxidative phosphorylation, and electron transport system. And the last one is their metal ion chelation effect (Guil-Guerrero et al. 2016). Genotoxicity, short-term, and repeat-dose toxicity studies have been performed on tannic acid. Dietary intake of 2.5% grape seed or grape skin extract caused no-observed-adverse-effect level (NOAEL) in female rats (Serrano et al. 2016). In another study, subchronic oral toxicity of GSE was assessed; the NOAEL of dietary GSE was found to be equal to 1.4 g/kg in male rats and 1.5 g/kg in female rats (Fiume et al., 2014). Moreover, LD_{50} of grape seed and skin extract ingestion was found to be higher than 5 g/kg in rats. Long-term exposure to high concentrations of tannic acid dust may cause lung function changes due to the particles less than 0.5 μm penetrating and remaining in the lung. The symptom is breathlessness and lung shadows. Tannic acid also caused liver tumors in rats following subcutaneous injection (Chemwatch 2008). Despite many studies on the mutagenicity and genotoxicity are available, they are not adequate in evaluating genotoxic risk; therefore, further investigations are highly required (Lluís et al. 2011). Moreover, potential adverse effects cannot be assessed in detail due to lack of information regarding the consumption of these compounds by pregnant and lactating women. In addition, no studies on reproductive toxicology are available (Smeriglio et al. 2014).

25.8 Marketed Products

A Tannic Acid-based Medical Food, **Cesinex**®

Brewtan B, **Brewtan C**, and **Brewtan F** are 100% natural gallotannins specially designed for the brewing industry.

Hametan® cream contains standardized *Hamamelis virginiana* L. extract and is used for wound healing and places in the dermatologic products category.

25.9 Patents

Published patents were searched by using the links (https://worldwide.espacenet.com; https://patents.google.com; https://patentscope.wipo.int/search/en/search.jsf; http://online.turkpatent.gov.tr/EPATENT/servlet/PreSearchRequestManager) with the keywords "gallotannin" and "tannic acid" which have revealed the information presented in Table 2.

25.10 Perspectives

Tannins are natural biologically active components found in edible and medicinal plants. More recently, studies have been conducted on the possible implications of tannin consumption to prevent diseases and provide therapeutic effect by using its derivatives. In in vitro and in vivo studies, tannins were reported to have antimicrobial activity by inhibiting the growth and invasion of fungi, bacteria, and viruses in food plants. Therefore, they can serve as natural regulators of the microbial population in gastrointestinal system. However, biological activity studies as well as activity mechanism studies are still scarce. A preliminary correlation has been reported in clinical studies between potential health effects and dietary intake of tannins, so far. In some epidemiological studies, it was reported that a dietary intake of more than 1 g/day is associated with a reduced many chronic diseases (Sieniawska 2015). Tannins were also reported to display other beneficial activities on immune response, hepatotoxicity, and lipid metabolism. One of the commercially available tannins is tannic acid, which was previously used as antidote against poisons. Nowadays, it is administered topically for the treatment of diaper rash, cold sores, fever blisters, and poison ivy and is also taken orally and applied directly for bleeding, chronic diarrhea, dysentery, bloody urine, painful joints, persistent coughs, and cancer. On the other hand, regarding the safety of gallotannins, potential dangers of diets containing high levels of gallotannins together with food-based polyphenol enrichment and supplements with pure compounds or mixtures have not been studied in detail (Marginǎ et al. 2015). However, the risk related to dietary ingestion of gallotannins is low owing to their poor bioavailability. Nevertheless, the number of clinical studies on gallotannin containing natural sources is not adequate. Further studies on the potential adverse effects that might be associated with high gallotannin consumption are needed. For making certain claims about the health effects in humans, some aspects should be taken into account while conducting clinical studies. Standardized test material should be used in such clinical studies, and the findings should be evaluated by considering individual variations in microbiota. Further clinical studies on human volunteers are warranted to confirm the preliminary findings obtained so far. Absorption and metabolism of tannin-type compounds should be assessed in detail to find out their bioavailability, which is an important

Abstract

A vitamin is an organic substance necessary, in small quantities, for the correct functioning of the metabolism of a living organism. It is an essential nutrient because this substance cannot be synthesized in sufficient quantity by this organism and thus must be provided through the food intake. Each organism has specific needs: a molecule can be a vitamin for one species and not be it for another. It is the case for example of Vitamin C. Some vitamins are water-soluble compounds, including all vitamin Bs (B1, B2, B3, B5, B6, B7, B9, B12) and vitamin C. Others are fat-soluble compounds and encompass vitamins A, D, E, and K. In this chapter, we have chosen to provide an overview of recent literature data only about vitamins provided exclusively or significantly by plant food, in particular vitamins A (as provitaminic carotenoids), B1, B9, C, E, and K1. Vitamins provided by animal food, such as vitamin D or vitamin B12, will be not discussed in this chapter.

Keywords

Bioactivity · Bioavailability · Diet · Plant kingdom · Food sources · Vitamin A · Vitamin B1 · Vitamin B9 · Vitamin C · Vitamin E · Vitamin K1

26.1 Provitamins A

26.1.1 Bioactive Constituents

The main active form of vitamin A is retinol (Fig. 1) but this compound is rarely found in plant kingdom. Astonishingly, while retinol is produced from plant compounds belonging to the carotenoid group, animal retinoids, and vegetal carotenoids have largely distinct biological roles.

In order to reduce and simplify the field of discussion, this part is strictly restricted to a limited number of carotenoid derivatives that can be attributed provitamin A activity, owing to structural specificities enabling their transformation into it, which requires:

- A mostly linear structure containing numerous double bonds, all encountered as their (*E*) isomer.
- A carbon number that is a multiple of that of retinol, enabling their cleavage into up to 2 retinol moieties: as retinol is a 20C derivative, it would require 40C carotenoids.
- At least one ring system, at an end of the molecule, which is identical to that of retinol. This feature can be referred to as a β-ionone ring system (because it resembles β-ionone, a fragrant degradation product of these compounds) which implies one more conjugated double bond than those present in the linear chain.

While the first two criteria are easily met, being common features in plant carotenoids, the last requirement is much more unusual, making three compounds (Fig. 2) as candidates possibly encountered in the diet at significant levels:

- **β-carotene** (formally β,β-carotene) can yield two retinol molecules.
- **α-carotene**, which is β,ε-carotene – Greek letters here indicate the proper designation for both cycles in the carotenoid nomenclature –yields only one retinol molecule.
- **β-cryptoxanthin**, also called β,β-hydroxy carotene, a xanthophyll (oxygenated carotenoid derivative), also yields one retinol molecule.

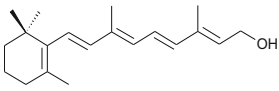

Fig. 1 Structure of retinol

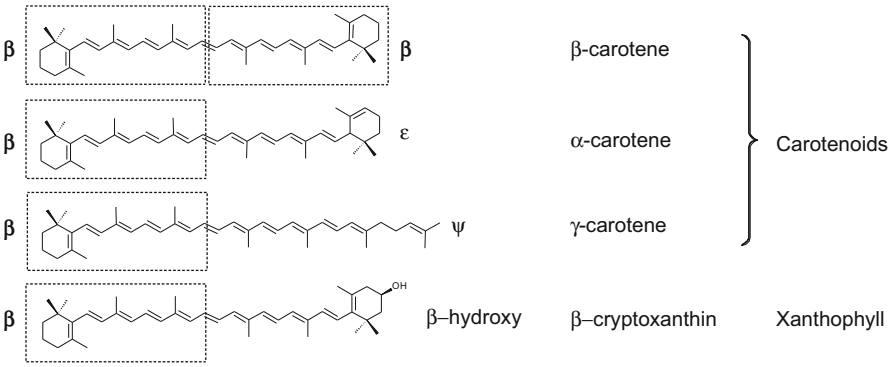

Fig. 2 Carotenoids that are precursors of retinol. β moieties are shown

γ-carotene, the precursor of β-carotene with only one β cyclization, while theoretically a provitamin A, seems to be rare in the diet and has been little studied.

In plants, carotenoids are synthesized in plastids, specially chloroplasts and chromoplasts. Carotenoids are tetraterpenic derivatives produced by the condensation of two geranylgeranyl pyrophosphate molecules (produced from isopentenyl pyrophosphate and dimethylallyl pyrophosphate in the methylerythritol phosphate pathway) by phytoene synthase, considered as the rate-limiting enzyme in the carotenogenic pathway. Phytoene is submitted to desaturation and isomerization reactions to produce the linear compound all-(*E*) lycopene, which can be cyclized and hydroxylated to yield compounds of interest (see Fig. 3). In chloroplasts, most enzymes involved in carotenogenesis have been localized in envelope membranes while, because of their importance in photosynthesis, carotenoids are mostly encountered in thylakoid membranes; in chromoplasts storage forms differ according to the predominant compounds and plant species (Alagoz et al. 2018; Sun et al. 2018). Stabilization of carotenoids involves vitamin E as a radical scavenger protecting them from oxidation and their esterification, for hydroxylated compounds, that is, xanthophylls (Watkins and Pogson 2020).

26.1.2 Bioavailability and Metabolism

26.1.2.1 Bioavailability

Because of their almost strict terpenic origin and hydrocarbon structure, carotenoids are fat-soluble. Their processing in the digestive tract involves their dissolution in the fat phase of the meal. As a xanthophyll, β-cryptoxanthin can be found as esterified derivatives which are hydrolyzed before its absorption, predominantly by cholesterol ester hydrolase (Breithaupt et al. 2002), of pancreatic origin, which differs from retinyl esters (which are hydrolyzed by pancreatic lipase and pancreatic

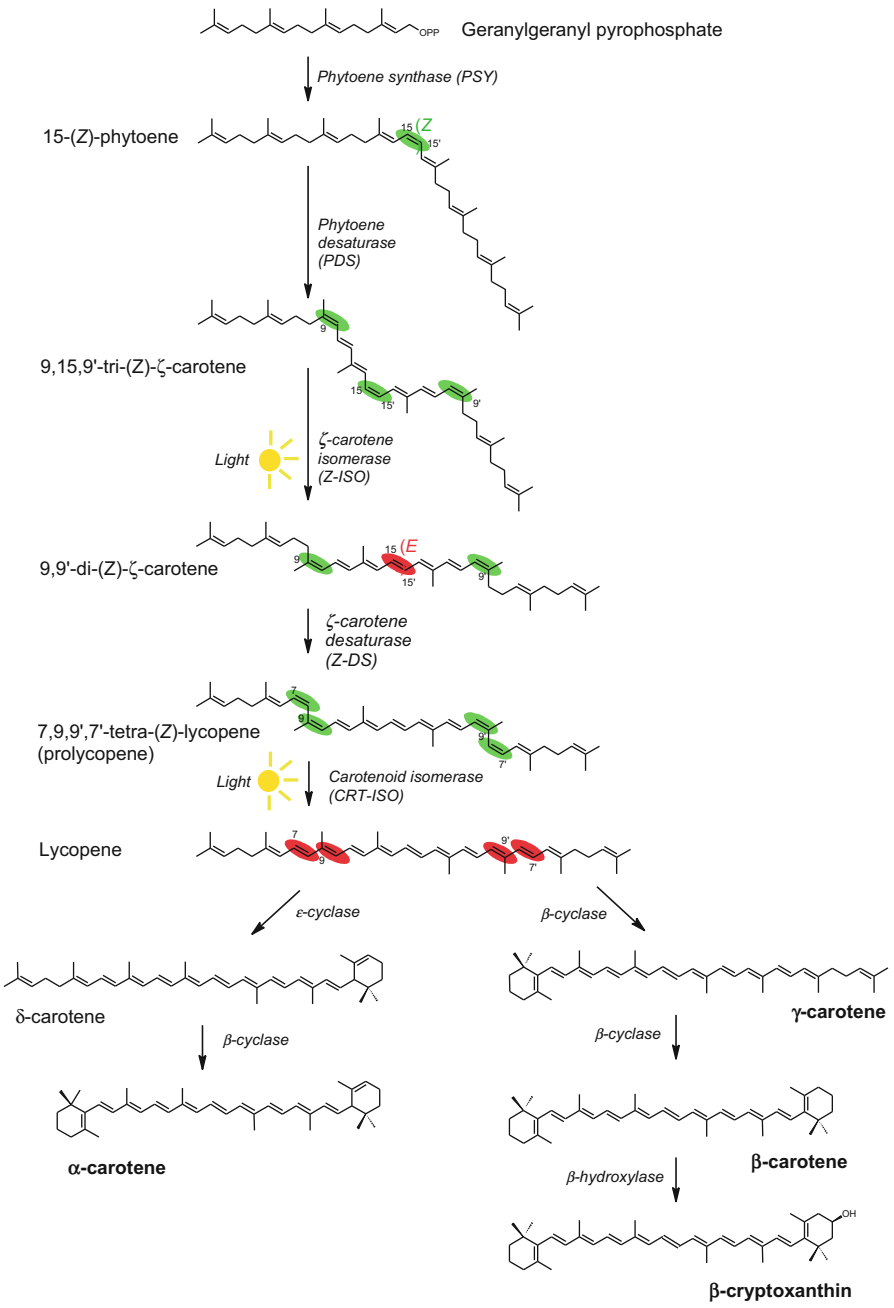

Fig. 3 Biosynthesis of provitamins A in plants

lipase-related protein 2) (Reboul 2013). Free compounds are incorporated to mixed micelles or may be bound to some proteins from the diet (Reboul 2019a). Provitamin A, as other carotenoids, can be absorbed through the apical brush border membrane by a process that has long been attributed to sole passive diffusion, while recent studies have increasingly shown the implication of transporters for lipophilic compounds with low substrate specificity: Scavenger Receptor class B type I (SRBI) (During and Harrison 2007; Borel et al. 2013a), CD36 (van Bennekum et al. 2005; Borel et al. 2013a), and possibly NPC1-like transporter 1 (NPC1L1) (During et al. 2005). The bioavailability of β-carotene was reported with high variability but seems to range between 10% and 30% of the dose typically (Reboul 2019a). β-cryptoxanthin displays better bioavailability, as do xanthophylls in general, which has been attributed to their greater polarity, enhancing incorporation in mixed micelles, enabling location at their outer surface but also to improve solubility in hydrophilic compartments (Burri et al. 2016).

Efflux mechanisms are likely to contribute to the incomplete bioavailability of provitamins A (Reboul 2019a).

26.1.2.2 Metabolism

Even after absorption, only 60–70% of provitamins A are converted into retinoids (Castenmiller and West 1998). This is performed by the cytosolic mucosal enzyme β-carotene 15,15′-dioxygenase BCO1, while minor eccentric cleavage reactions are performed by mitochondrial β-carotene 9′,10′-dioxygenase BCO2 (Amengual et al. 2013). In spite of its name, BCO2 can cleave 9–10 or 9′–10′ double bonds of the carotenoids and xanthophylls (Kelly et al. 2018), yielding apocarotenoids, ionone, and apo-10-carotenal derivatives that depend on the substrate of the enzyme (see Fig. 4). Non-hydroxylated β-10-apocarotenal can be cleaved again by BCO1 and converted to a retinoid. The direct cleavage product is retinal (Leuenberger et al. 2001), which can be further oxidized to retinoic acid (see Sect. 6.3) or reduced to retinol, which can be esterified by lecithin retinol acyl transferase (LRAT) at low doses requiring its binding to intracellular retinol-binding protein, type II (CRBPII); and some acyl-CoA acyl transferases (ARAT), predominantly diacylglycerol acyltransferase 1 (DGAT1) at higher doses (Wongsiriroj et al. 2008).

Retinoic acid exerts negative feedback on its own production in the enterocyte by induction of the transcription factor ISX, repressing both precursor resorption by SRBI and cleavage by BCO1 (Lobo et al. 2010).

Carotenoid derivatives are predominantly secreted through the basolateral membrane of enterocytes, both as free carotenoids and retinyl esters by chylomicrons into the blood via the lymphatic circulation; an ApoB-independent pathway has also been suggested to explain free carotenoid secretion (During and Harrison 2007). It has been attributed to the ABCA1 transporter, which is strongly expressed at the basolateral side of enterocytes (Mulligan et al. 2003) because its expression has been correlated with carotenoid and β-carotene transport (During et al. 2005; Borel et al. 2015) and may enable carotenoid transport by HDL. In both cases carotenoids and retinyl derivatives, once they reach the liver, are stored predominantly in stellate cells (Moriwaki et al. 1988; Blaner et al. 2009), by an LRAT-dependent process for

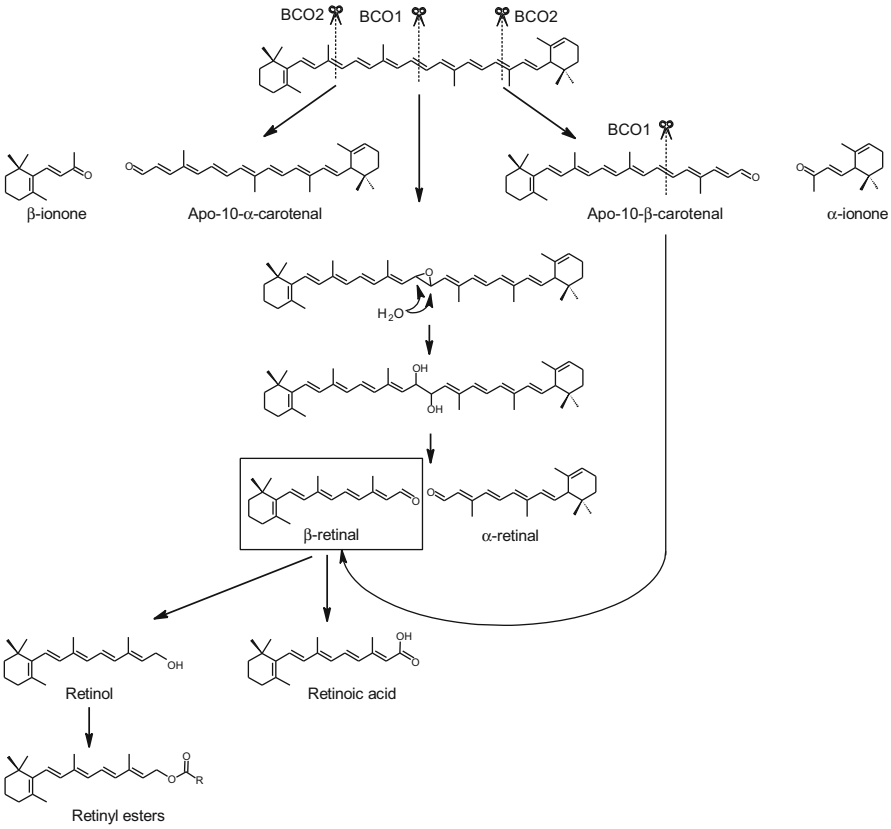

Fig. 4 Conversion of a provitamin A into retinoids in mammals

the latter (Batten et al. 2004; O'byrne et al. 2005). In blood, retinol (obtained by hydrolysis of retinyl esters) is transported by retinol-binding protein (RBP4), which forms a complex with transthyretin, while carotenoids are distributed by LDL. Cellular uptake of retinol relies on STRA6 (Vitamin A receptor, Stimulated by retinoic acid 6 – except in the liver) and RBPR2 (RBP4 receptor-2, primarily expressed in the liver and intestine) (Alapatt et al. 2013), while carotenoids may be transported by LDL receptor and SRBI (Harrison 2019). For a global view of carotenoid transport, see Fig. 5.

26.1.3 Bioactivities

26.1.3.1 General Role

Functions of vitamin A can be attributed to two distinct mechanisms, which explain its general effect and more specifically its importance for vision.

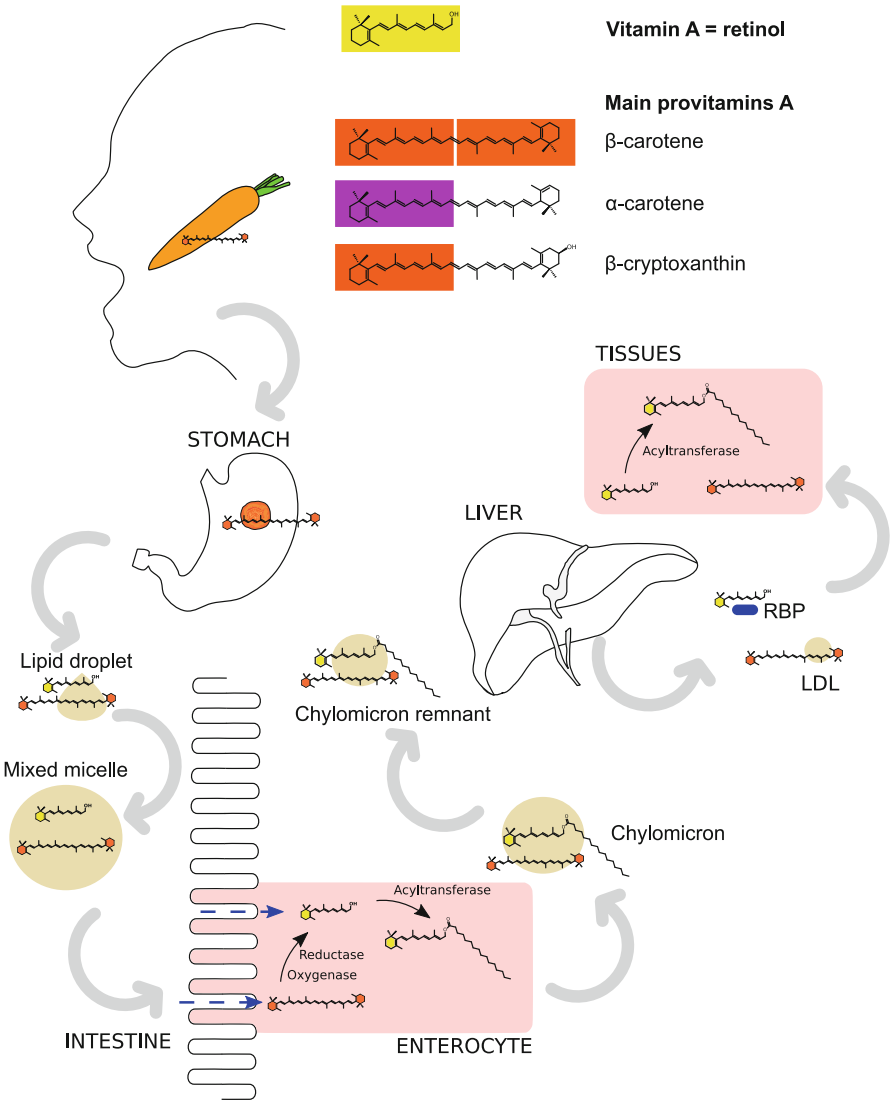

Fig. 5 Global features of vitamin A absorption and distribution in man

Retinoic Acid and Metabolism

Most of the effects of vitamin A are in fact explained by its acidic derivative retinoic acid, acting as a ligand for nuclear receptors that are transcription factors. Various types of such receptors were characterized primarily because of their affinity for retinoids (Fig. 6). Retinoid X receptors (RXR), with three subtypes (α, β, γ), are central because they can act on gene transcription as homodimers or as heterodimers, interacting with other nuclear factors (McGrane 2007), with different potential

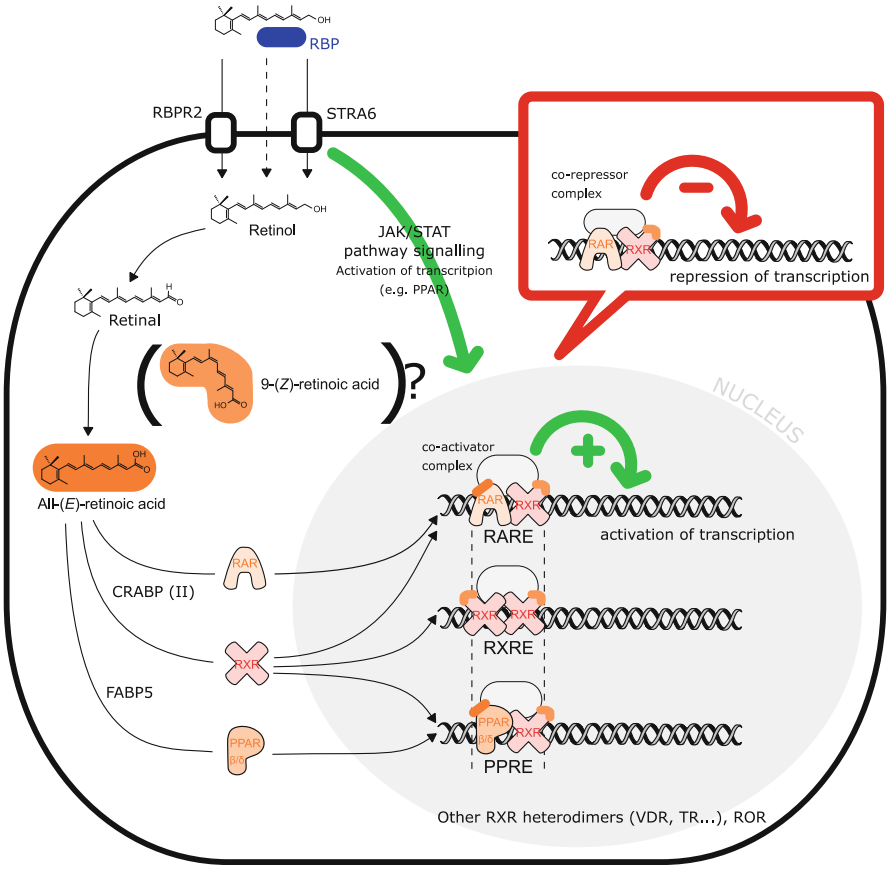

Fig. 6 Effects of retinoic acid on transcription

effects because the activation can be triggered by the RXR ligand, the partner nuclear receptor ligand or both (García et al. 2020).

Two of them have all-(*E*)-retinoic acid as a ligand:

- Retinoic acid receptors (RARα, β, γ) are important in organogenesis and can exert activating or repressing effects (depending on retinoic acid binding or not, respectively) on genes such as *Hox* genes, which are highly conserved for anteroposterior positional patterning information (Marlétaz et al. 2006).
- Peroxisome proliferator-activated receptors (PPAR), particularly of the β/δ type, modulate cell proliferation and differentiation (Michalik et al. 2006).

Another isomer of retinoic acid, 9-(Z)-retinoic acid has been identified as a ligand for RXR and suggested as its natural activator (as shown in Fig. 6) (Allenby et al. 1993). Nevertheless, its biological relevance is unclear (Dawson and Xia 2012). More recently, 9-(*Z*)-13,14-dihydroretinoic acid was detected in several organs and

proposed to be of physiological importance (Rühl et al. 2015), at least in mice, yet its origin remains to be elucidated. RXR ligands are named "rexinoids" and are not necessarily retinoids. Long-chain PolyUnsaturated Fatty Acids (PUFAs), for example, DHA, are RXR ligands (García et al. 2020).

RXR complexes implicate interaction with specific DNA regions called responsive elements, which are named after the distinctive nuclear receptor they interact with: RARE, RXRE, PPRE, or generically RARE. They also require coactivators or corepressors. Retinoic acid transport to nuclear receptors relies on Cellular Retinoic Acid Binding Protein II for RAR and RXR and Fatty Acid Binding protein (FABP5) for PPAR β/δ. The expression of these binding proteins in cell types participates in the pro-apoptotic or proliferative effects of retinoic acid locally (Schug et al. 2007).

Faster, non-canonical (i.e., cytosolic non-RAR-mediated), mostly CRABP(I)-mediated effects on cell cycle have also been reported (Nhieu et al. 2020).

These mechanisms underlie differential effects on cell differentiation, exerting stimulation or inhibition according to specific cell types or conditions (Asson-Batres and Norwood 2020).

In Europe, EFSA Panel on Dietetic Products, Nutrition and Allergies recognized that "Vitamin A has a role in the process of cell specialisation" (EFSA NDA Panel 2009a).

Finally, it is interesting to note that β-cryptoxanthin was identified as a RAR agonist, with distinct effects from all-(*E*)-retinoic acid. This is not directly related to provitamin A activity, as the non-provitamin A xanthophyll lutein displayed similar effect (Matsumoto et al. 2007).

Retinoids in Vision

Vitamin A is involved in the process of vision and light perception (Fig. 7), after its conversion into its aldehyde derivative retinal, which enables light-initiated signal transduction, when coupled to specific transmembrane proteins called retinylidene proteins or opsins s.l.:

- Rhodopsin is the light-sensor of rods, the most numerous photoreceptors in the retina (hence the name "retinal purple"), that permit scotopic (low-light) and peripheral vision.
- Photopsins are located in cones, which are less numerous, but concentrated in the fovea and are dedicated to photopic vision (i.e., vision in well-lit conditions). Three different "cone opsins" with distinct optimal operating wavelength enable color perception.

In both cases, signal transduction involves a (Z) to (E) isomerization and release of retinal, linked to a lysine residue in opsin sequence as a Schiff base, a process called "bleaching." The reversal of this operation requires, after the reduction of retinal by retinol dehydrogenases, the intervention of other retinal cell types in addition to the photoreceptors. The classical visual cycle involves retinal pigment epithelium (RPE) cells in which:

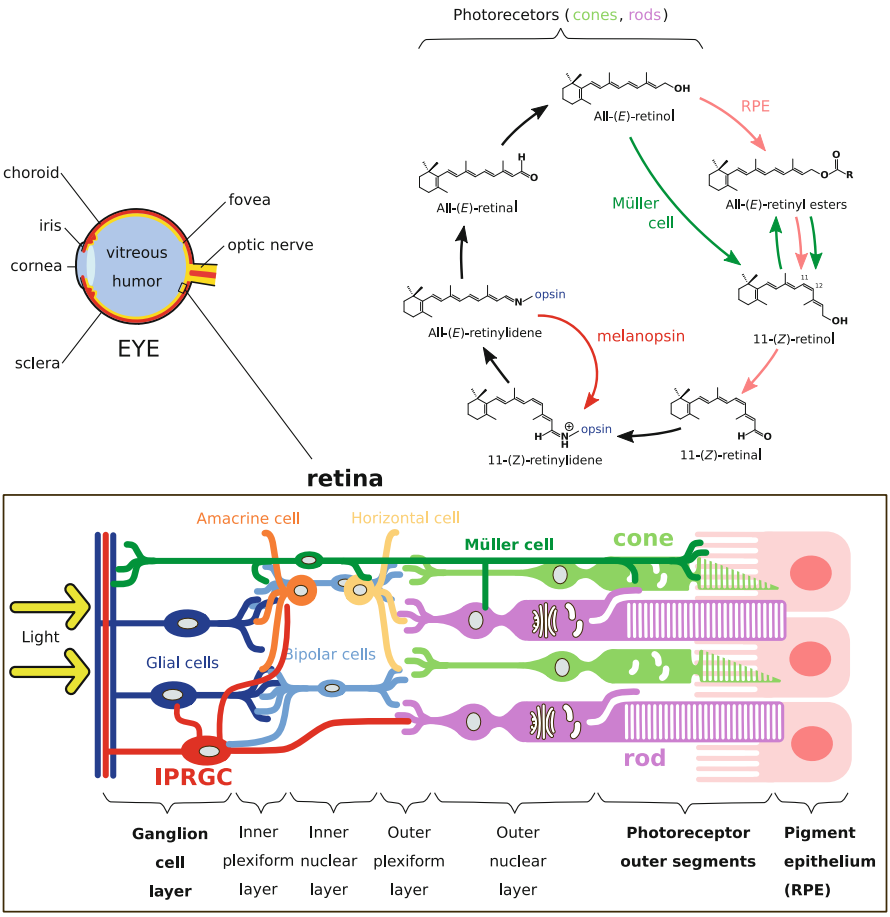

Fig. 7 Vitamin A, eye, and vision

1. All-(*E*)-retinol is converted into retinyl esters by LRAT (Sears and Palczewski 2016).
2. A retinol isomerohydrolase, RPE65 (Retinal Pigment Epithelium-specific 65 kDa protein), both isomerizes the 11,12 double bond and releases free 11-(*Z*)-retinol (Wolf 2005).
3. 11-cis Retinol Dehydrogenase then oxidizes 11-(*Z*)-retinol into 11-(*Z*)-retinal, the active chromophore (Simon et al. 1995).

The linkage between the two parts of this visual cycle (bleaching and all-(*E*)-retinal reduction in photoreceptors; 11-(Z)-retinal regeneration in RPE) appears to rely on Interphotoreceptor Retinoid Binding Protein (IRBP) (Pepperberg et al. 1993).

There is evidence that cones, in addition to this visual cycle, can use another pathway for 11-(*Z*)-retinal regeneration, explaining an increased rate for this process when compared with rods, and maintained signaling even at high light levels (Saari 2012). This cone visual cycle involves Müller cells and differs from the first pathway by the direct conversion of nonesterified all-(*E*)-retinol by dihydroceramide desaturase-1 (DES1) (isomerase-2), presumably (Kaylor et al. 2013) into 11-(*Z*)-retinol, but also, to a large extent, 9-(Z)-retinol. Cellular Retinal-binding Protein (CRALBP or RLBP1) appears to be responsible for 11-(Z) selectivity of the output of Müller cells (Sato and Kefalov 2016). Moreover, cones can uptake 11-(Z) retinol as well as 11-(Z)-retinal, while rods exclusively rely on 11-(Z)-retinal (Wang and Kefalov 2009).

Other retinylidene proteins exist. In the eye, melanopsin is found in Intrinsically Photosensitive Retinal Ganglion Cells (IPRGC) and in low amounts in photoreceptors (Tri Hoang and Yau 2010). It is involved in non-image forming vision, circadian rhythm, and may contribute to mood regulation by light, as mutations have been detected in some cases of Seasonal Affective Disorder (Roecklein et al. 2009; Roecklein et al. 2012; Lazzerini Ospri et al. 2017).

26.1.3.2 Animal Studies

Studies on animals played a prominent role in the study of vitamin A and carotenoids in general, so that a full account might be unreasonable for a book chapter. Some important historical notions can be reminded here:

- While most of the early studies on vitamins were driven by concern over well-identified human diseases (beriberi for thiamin, scurvy for ascorbic acid), it was not the case with vitamin A. The concept of a "fat-soluble A" compound has emerged over the observation that identified macronutrients did not suffice to ensure normal growth of rodents and had to be added some specific fat ingredients. Of course xerophthalmia or night blindness had already been described in Man and treatment by liver had already been suggested several times in history, but the rational route to vitamin A identification hugely relied on animal feeding experiments (Carpenter 2003a, b).
- Retinal pigment and the process of bleaching are very factual observations that could be made only thanks to animal studies, mostly led by the German physiologist Kühne on frog eyes, making it possible to identify the chemical nature of light transduction (Lanska 2010).
- Although the process of retinol identification as "true" vitamin A was quite long, it did not hamper the identification of vitamin A activity of "carotene," neither its conversion to vitamin A in vivo in animals, between 1928 and 1930. Indeed, as the chemical structure was determined more than a decade **before** that of retinol – a surprisingly long delay and obviously a painful experience for researchers of the time) – β-carotene was one of the first vitamin compounds to be characterized (Moore 1930; Pawson 1982).

Noteworthy, not all animal species are able to convert provitaminic carotenoids: in most carnivorous species, this pathway is inefficient or insufficient (Green et al. 2011).

26.1.4 Benefits (Human Studies)

Vitamin A is a recognized immunomodulator. In general, its physiologic affect is to inhibit inflammatory Th1/Th17 and promotes humoral Th2 and Treg response profiles, while this action may be reversed in inflammatory conditions, thus contributing both to tolerance and defense mechanisms, through RXR modulation of RAR effects (Elmadfa and Meyer 2019).

The efficacy of vitamin A supplementation for preventing overall morbidity and mortality in children between 6 months and 5 years of age was confirmed by a meta-analysis. In particular, vitamin A lowers the incidence and risk of mortality from (but not of hospitalization for) diarrhea (Imdad et al. 2017). According to the WHO (2017), diarrhea is the second leading cause of death in children under 5 years old (ca. 525,000 deaths per year) WHO 2017. The efficacy of interventions in babies aged 0–1 or 1–6 months could not be ascertained (Imdad et al. 2016; Haider et al. 2017). A mechanistic explanation for the protective role of vitamin A derivatives in gut infection was recently brought: in a model of salmonella infection in mice, vitamin A stimulates IL-18 production, which acts both on early stages of infection (by promoting cell shedding, i.e., renewal of epithelial barrier and elimination of contaminated cells) and on later stages through Th1 and Th17 responses of immune cells and IFN-γ production, for pathogen clearance. Not surprisingly, this is a RAR-mediated transcriptional effect (Iyen et al. 2020).

No effect was found on mortality from measles, respiratory disease, and meningitis, yet a reduction of incidence was observed for measles. Vitamin A supplementation did not reduce hospitalization for pneumonia, either (Imdad et al. 2017).

Bitot's spots, important early manifestations of vitamin A deficiency in the eye, include infiltration of *Corynebacterium xerosis*, the gas production of which explains their typical foamy appearance (Krishna et al. 2016).

The health claim "*Vitamin A contributes to the normal function of the immune system*" is authorized in Europe (EFSA NDA Panel 2009a, 2011).

Classically, skin and mucosal alterations have been attributed to vitamin A deficiency. Mori (1922) reported xerosis of the trachea and larynx; Wolbach and Howe (1925) described atrophy and keratinization of various glandular organs but found "no striking changes" on skin, with slight atrophy of the hair follicles and sebaceous glands in rats and the sole human case alluded to displayed epithelial modification in various locations, but no specific cutaneous signs.

A frequently mentioned trouble is phrynoderma, which is follicular hyperkeratosis with numerous minute rough-textured papules, yet it is now frequently discussed that this may not be a specific sign of vitamin A deficiency, involving vitamins of the B-complex and/or other nutrients such as essential fatty acids (Heath and Sidbury 2006; Yan and Jen 2012).

On the basis of classical textbooks, the EFSA Panel on Dietetic Products, Nutrition and Allergies stated that

- "*Vitamin A contributes to the maintenance of normal mucous membranes*" (EFSA NDA Panel 2009a, 2010a).
- "*Vitamin A contributes to the maintenance of normal skin"* (EFSA NDA Panel 2009a, 2010a).

Although the description of skin or mucous membranes are not frequently reported in the current medical description of vitamin A deficiency, the interest of retinoids used orally or topically, including natural tretinoin (i.e., all-(E)-retinoic acid) in a variety of dermatological conditions (Chen et al. 2019b) such as acne vulgaris (Kolli et al. 2019), psoriasis (Menter et al. 2020), and eczema (Halioua et al. 2019; Kim et al. 2019), tends to confirm this physiological function.

Resistin-like molecule α (RELMα), a cysteine-rich protein produced by keratinocytes was suggested as the mediator of vitamin A protecting effect against skin infection (Harris et al. 2019).

The possible conversion of topical β-carotene to retinol in human skin was established (Antille et al. 2004).

Vitamin A deficiency is well characterized for causing blindness associated with xerophthalmia and/or keratomalacia (Fig. 8) (Sommer 1998) and the benefit of vitamin A supplementation has been confirmed (Vijayaraghavan et al. 1984). Night blindness is an early manifestation that has intrigued scientists since Antiquity and Galen already recommended liver consumption to treat it (Lanska 2010). Blindness cases are still reported in low-income countries (Daba et al. 2019; Wadhwani and Singh 2020) and xerophthalmia can be observed in Western countries (Lai et al. 2014). Eye defects are both related to retinal-associated vision metabolism and to a loss of transcriptional effects of retinoic acid (Blomhoff and Blomhoff 2006). The possible conversion of circulating β-carotene to vitamin A was demonstrated in human retinal epithelium cells (Chichili et al. 2005).

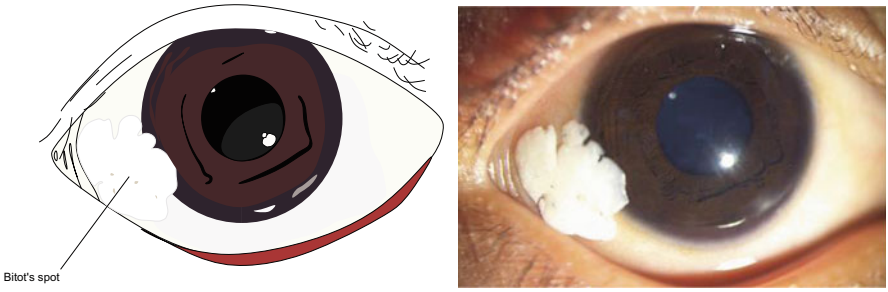

Fig. 8 Bitot's spots in a 4-year-old boy in Indian. (Adapted from Ram and Jinagal 2018)

In Europe, the health claim "Vitamin A contributes to the maintenance of normal vision" is authorized (EFSA NDA Panel 2009a, 2010a).

The positive correlation between vitamin A and iron status has long been evoked and studied. Vitamin A-associated anemia was described as differing from pure iron deficit, with decreased in serum iron, low Total Iron-Binding Capacity, and transferrin saturation, as well as high serum ferritin concentration, because of a lower mobilization of Fe stores, while iron deposits in the liver and spleen. Most clinical trials assessing the benefit of vitamin A supplementation on anemia tend to confirm this observation, yet contradictory data exist. Vitamin A affects erythropoiesis. Its action may also be explained by regulation of ferritin stores and enhanced resistance to infections (Michelazzo et al. 2013).

In Europe the health claim "Vitamin A contributes to normal iron metabolism" is authorized (EFSA NDA Panel 2009a).

As for other vitamins studied here, we focused on European Dietary Reference Values (Table 1) because of their more recent assessment. Vitamin A values are Population Reference Intakes, that is, they could be calculated from an Average Requirement to maintain a concentration of 20 μg retinol/g liver, a threshold suggested by Olson in 1987 (EFSA NDA Panel 2015a). Corresponding provitamin A requirements are discussed in the next part.

Causes for insufficient vitamin A include reduced intake (because of inadequate food supply, alcoholism, mental illness or dysphagia), impaired absorption linked to inflammatory causes (IBD, celiac disease), shortening of the digestive tract (short bowel syndrome, bariatric surgery), and chronic diarrhea. Pancreatic insufficiency is also a possible cause but it does not hinder carotenoid absorption (pancreatic juice is required for retinyl esters hydrolysis). Disordered transport (in abetalipoproteinemia) and reduced storage (in liver disease or cystic fibrosis) can also be observed (Krishna et al. 2016).

Table 1 Dietary reference values of vitamin A (RE) from EFSA, expressed in μg/day

Infants	
0–6 months	–
7–11 months	250
Children

Pregnancy	700
Breastfeeding	1300

26.1.5 Applications in Food

The contribution of provitamins A to the presence of retinol in the body depends on the number of provitaminic moieties they contain, but also to their interaction with plant tissue and food matrix (Institute of Medicine 2000, 2001), time spent in the intestine, and the efficiency of cleavage into retinol, submitted to interindividual variations and not restricted to the sole enterocytes (Chichili et al. 2005), which make precise measure tricky. The necessity of a conversion tool for taking provitamins into account was expressed by a Joint Expert Group of FAO and WHO as soon as 1967. Two main methods are used nowadays for the estimation of total retinol available from food, without a clear consensus on the best option:

- RE (retinol-equivalent) = retinol + β-carotene/6 + (α-carotene + β-cryptoxanthin)/12 (FAO/WHO 1967)
- RAE (retinol activity equivalent) = retinol + dietary β-carotene/12 + (α-carotene + β-cryptoxanthin)/24 + β-carotene in oil/2 (US Institute of Medicine 2001)

Table 2 presents plant foods that may be considered rich in vitamin A according to European law (Regulations n° 1924/2006 and 1169/2011) and to the definition of RE used by EFSA. To provide at least 240 μg RE/100 g, they should contain ≥1440 μg/100 g β-carotene.

Amounts in α-carotene and β-cryptoxanthin have been recorded only in the USDA database (https://fdc.nal.usda.gov/index.html), to our knowledge. They were not included in Table 2 because there is scarcely any identified food ingredient that may qualify as rich in vitamin A because of them. The most important remarkable foods providing β-cryptoxanthin are paprika (6186 μg/100 g), butternut squash (3471 μg/100 g), which may be considered as rich in vitamin A for these amounts alone (≥12 × 240 = 2880 μg RE/100 g), and persimmon (1447 μg/100 g), which may qualify as a source of vitamin A on the same basis (≥12 × 120 = 1440 μg RE/100 g). We identified no food ingredient that may be recognized as a source of vitamin A because of its α-carotene content. Butternut squash, again, had the highest amount of this compound with a maximum value of 935 μg/100 g.

Provitamins A like other carotenoids can be quite stable in plants and their availability may be enhanced by cooking (Liu et al. 2004) because heat contributes to their release from their accumulation forms in plastids (Sun et al. 2018). While their measured amounts are little affected by short heating conditions (Khachik et al. 1992), heat as well as light causes isomerization that results in an equilibrium between (E) and (Z) forms (Pesek et al. 1990; O'Neil and Schwartz 1995). This is also observed in fresh foods, to varying extents depending on the species considered (Chandler and Schwartz 1987). The oxidative degradation of carotenoids exists naturally and contributes to food flavor and fragrance but can be enhanced by processing (Vervoort et al. 2013). All these reactions may finally lower vitamin A activity in the product (Zechmeister 1949; Rodriguez-Amaya and Tavares 1992).

Table 2 β-carotene content of plant products which may qualify as rich in vitamin A (ANSES 2017). Only food ingredients with confidence levels A–C were reported. Min–max values, when available, were discarded for clarity purpose

Category	Food	β-carotene (μg/100 g)	RE (μg/100 g) based on β-carotene exclusively
Algae	Bladderwrack (*Fucus vesiculosus*, *F. serratus*), dried	12,400	2067

	Watercress	1910	318

26.1.6 Safety: Toxicity and Side Effects

The toxicity of retinoids is well known, with possible consequences on the liver, hypertriglyceridemia (with possible pancreatitis), headache, skin and mucosal abnormalities, bone resorption, and fractures. Teratogenicity is probably the most feared side effect, with possible craniofacial, cardiac, nervous, and thymic defects (Olson and Goyal 2020). Unfavorable benefit-risk assessment of vitamin A supplementation has been evoked in children under 6 months of age with an increased risk of bulging fontanels (Imdad et al. 2016; Haider et al. 2017).

The toxicity of β-carotene, which has been the most studied provitamin A, is still in inconclusive and the EFSA SCF and NDA Panel could not derive an upper limit for its consumption. Provitamins A have not been found responsible for teratogenicity or fœtal toxicity, to this date (Olson and Goyal 2020). The enhanced risk of lung cancer found in some trials along with high doses of β-carotene was attributed to possible cytochrome or retinoid pathway interactions (EFSA SCF and NDA Panel 2006).

High intake of carotenoids (presumably β-carotene) may lead in some people to yellow-orange coloration of the skin, carotenoderma (or carotenemia) (Yan and Jen 2012).

26.1.7 Marketed Products

β-carotene has been marketed as a drug to prevent vitamin A deficiency, although vitamin A itself is generally preferred. Several studies tend to confirm the possibility of using β-carotene or even foods containing carotenoids instead of retinoids such as retinyl esters to cure vitamin A deficiency, with likely better tolerance (Carlier et al. 1993; Ncube et al. 2001; Vuong et al. 2002). Yet these findings are contested (de Pee and West 1996). The importance of plant source to reach a correct vitamin A intake is admitted (Haskell 2012) but pure β-carotene is not marketed as a curative agent for vitamin A deficiency at present.

Although some drug retinoids have names suggesting parenthood to carotenoids (bexarotene), we identified no carotenoid derivative (bexarotene, tazarotene), their chemical structure do not specifically recall the typical carotenoid structure, and they are not detailed here as they cannot be considered as retinoid derivatives.

Various dietary supplements contain β-carotene as a supply of vitamin A, as it is altogether considered as safer than actual vitamin A. Its origin is supposed to be synthetic in numerous cases but some supplements claim their natural and vegetal origin. β-carotene may also be marketed for preparation of the skin to sun exposure, although it is not clear whether the intended effect relies on the retinoid pathway, sunscreen effect, or only on mild carotenoderma ("suntanning effect"). The traditional prescription of β-carotene in erythropoietic protoporphyria (Urbanski et al. 2016) is in favor of a possible efficacy of such products.

26.1.8 Patents

A variety of patents have been submitted on carotene or cryptoxanthin production. It appears that scarcely any has been dedicated recently to novel uses.

26.1.9 Perspectives

Carotenoids represent an important source of vitamin A, a structurally simple yet fascinating vitamin and their study and uses are intertwined, while the difference between animal and plant origins is more clear-cut than usual in vitamins. The understanding of retinoid pathway and its subtle influence on cell differentiation and protection is obviously still under development even though a lot has been done. Possible beneficial effects of vitamin A and carotenoids on cardiovascular diseases and cancer (Bhatt and Patel 2020) require better knowledge. The feasibility of reaching higher amounts in plants (Watkins and Pogson 2020) with conserved bioavailability is a challenge for the future. A first step would be to define more efficiently its equivalence to retinol, a piece of data that is still elusive.

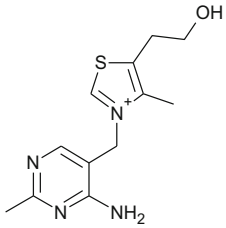
26.2 Vitamin B1: Thiamine

26.2.1 Bioactive Constituents

Thiamine (Fig. 9) is a rather simple vitamin. It contains a pyrimidine and a thiazolium ring.

As usual with vitamin compounds, the biosynthetic origin of this compound is rather mixed and involves a diversity of pathways. In plants, as can be seen in Fig. 10, the pyrimidine derives from 5-aminoimidazole ribotide (Roje 2007), an intermediate compound in purine biosynthesis, through a complex rearrangement that may be similar to that described in some bacterial species such as *Escherichia coli*

Fig. 9 Structure of thiamine



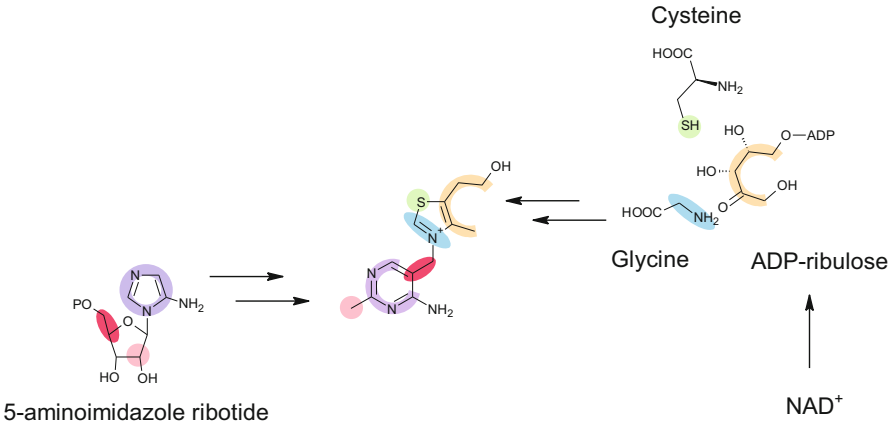


Fig. 10 Likely biosynthetic origin of thiamine in plants

(Begley 1996) and involves S-adenosylmethionine radical-dependent reactions (Coquille et al. 2013).

In contrast, the alkylated thiazole originates mainly in an ADP-ribulose (which is produced from NAD^+), with contributions from two amino acids: glycine, which brings the nitrogen atom as well as its neighboring carbon, and cysteine (a conserved residue in thiamine synthase), which provides sulfur (Goyer 2017). This differs from the bacterial pathway that involves 1-deoxy-D-xylulose-5-phosphate for the backbone, and tyrosine instead of glycine (Begley 1996), but appears to be similar to what was described in yeasts (Chatterjee et al. 2011).

In plants, the pyrimidine and thiazole moieties react as their pyrophosphate and phosphate derivatives, respectively, to afford thiamine phosphate (ThMP). While all the aforementioned steps take place in the chloroplast, ThMP is transported to the cytosol for its conversion into thiamine pyrophosphate (ThDP), the main active form and predominant (up to 90%) vitamer in wild-type plant tissue (Mangel et al. 2017),

through a dephosphorylation-pyrophosphorylation process (Ajjawi et al. 2007; Hasnain et al. 2016).

26.2.2 Bioavailability and Metabolism

26.2.2.1 Bioavailability

Thiamine is predominantly absorbed in its free form, whereas ThMP and ThDP are hydrolyzed by intestinal alkaline phosphatases, according to animal studies (Schaller and Höller 1975; Gastaldi et al. 1988; Rindi et al. 1995). Free thiamine is transported by cation carrier proteins, the specific solute carrier proteins SLC19A2 (ThTr1) and SLC19A3 (ThTr2) (Said et al. 2004) or the more generic organic cation transporter proteins OCT1 and OCT3 (Lemos et al. 2012) in the body, but their respective role in intestinal absorption of thiamine has been diversely reviewed (Brown 2014; Manzetti et al. 2014). ThMP (SCL19A1, RFC1) and ThDP transport exist through anion carriers (Zhao et al. 2002; Nabokina and Said 2012), although their quantitative importance is unclear at this time. Specific transport enables efficient ($\geq$ 95%) absorption of dietary doses of thiamine (Tomasulo et al. 1968; Ariaey-Nejad et al. 1970), but is saturable. Intestinal absorption of thiamine also appears to rely on passive diffusion when high doses are used, with dramatically diminished efficacy (Hoyumpa et al. 1982; Davis et al. 1984).

After oral administration, thiamin reaches its peak concentration in plasma within 1 h and has an elimination half-life of about 150 min (Tallaksen et al. 1993). It is distributed into other compartments and transported into cells, including blood cells : its concentration in plasma (free thiamin + ThMP $\approx$ 16 nM) is 10 times lower than that of whole blood (Thiamine + its mono-, di-, and triphosphate esters $\approx$ 165 nM) (Gangolf et al. 2010), and erythrocytes are usually reported as representing $>$ 80% of blood thiamine (Whitfield et al. 2018). Total thiamine concentration is high in all vital organs. Its liver storage is limited in humans, in comparison with rodents (Gangolf et al. 2010) and liver failure may trigger thiamine deficiency (Butterworth 2009).

26.2.2.2 Metabolism

Thiamine is phosphorylated inside the cells, by thiamine diphosphokinase, into ThDP, which is by far its major form. Pyrophosphokinase can produce ThMP from ThDP, for elimination. To a lesser extent ThDP can also be phosphorylated, becoming ThTP. Some adenylylated derivatives (AThTP and AThDP) can be produced, mainly in fast growing cells (Gangolf et al. 2010). Free thiamine itself and THMP are the main forms encountered in urine, with low amounts of ThDP. Up to 30 degradation products may be found in urine, mostly uncharacterized in humans. Ariaey-Nejad et al. (1970) identified 4-methylthiazole-5-acetic acid and possibly the thiazole moiety of thiamin. A 25-kDa peptide conjugate of thiamine was also reported.

26.2.3 Bioactivities

26.2.3.1 General Role

The most important structural feature in thiamine is the lability of the hydrogen atom between the heteroatoms of the thiazolium. The carbanion thus formed is stabilized by the vicinity of the ammonium, making it an ylid (Fig. 11).

As a coenzyme, ThDP uses this nucleophile to attack carbonyles within various biomolecules, with a constant outcome: the cleavage of one C-C bond next to the carbonyle (see Fig. 12). It is a factor of:

- Dehydrogenase complexes: in these multienzymatic complexes, ThDP is the cofactor of E1 and enables the decarboxylation of ketoacids and the acylation of lipoic acid (the latter, as its amide derivative lipoamide, is a cofactor of the E2 component, which will transfer the acyl residue to coenzyme A). The reactions following this mechanism are summed up in Table 3. All these complexes are located in the inner mitochondrial membrane. The exact mechanism of E1 has been elucidated in pyruvate dehydrogenase by Ciszak et al. (2003). Its general pattern is described in Fig. 12 (green box).
- Transketolase: this enzyme belongs to the pentose phosphate pathway. As described in Fig. 12 (red box), it transfers a C2-unit from a ketose to an aldose in two distinct reactions (Mittschke et al. 2010). Pentose phosphate pathway enables the synthesis of NADPH, a reducing agent in cells as well as that of ribose-5-phosphate, a precursor of nucleotides.
- 2-hydroxyacyl-CoA lyase : this peroxisomal enzyme enables the α-oxidation of 2-hydroxy fatty acids that cannot be catabolized by β-oxidation. It catalyzes their cleavage to produce the corresponding 1C-shortened fatty aldehyde and formate as formylCoA, which involves a nucleophilic attack of the α-keto group by the ylid carbanion of ThDP (blue box in Fig. 12, Casteels et al. 2007).

European Food Safety Authority (EFSA) authorized the health claim "Thiamine contributes to normal energy-yielding metabolism," owing to the dehydrogenases and transketolase roles and the contribution of thiamine in their action. Moreover, this role in energy metabolism (in all cells, including those of the cardiac and nervous systems) has been used to justify two additional claims:

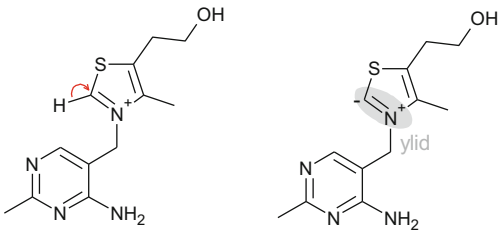

Fig. 11 Formation of the ylid in thiamine

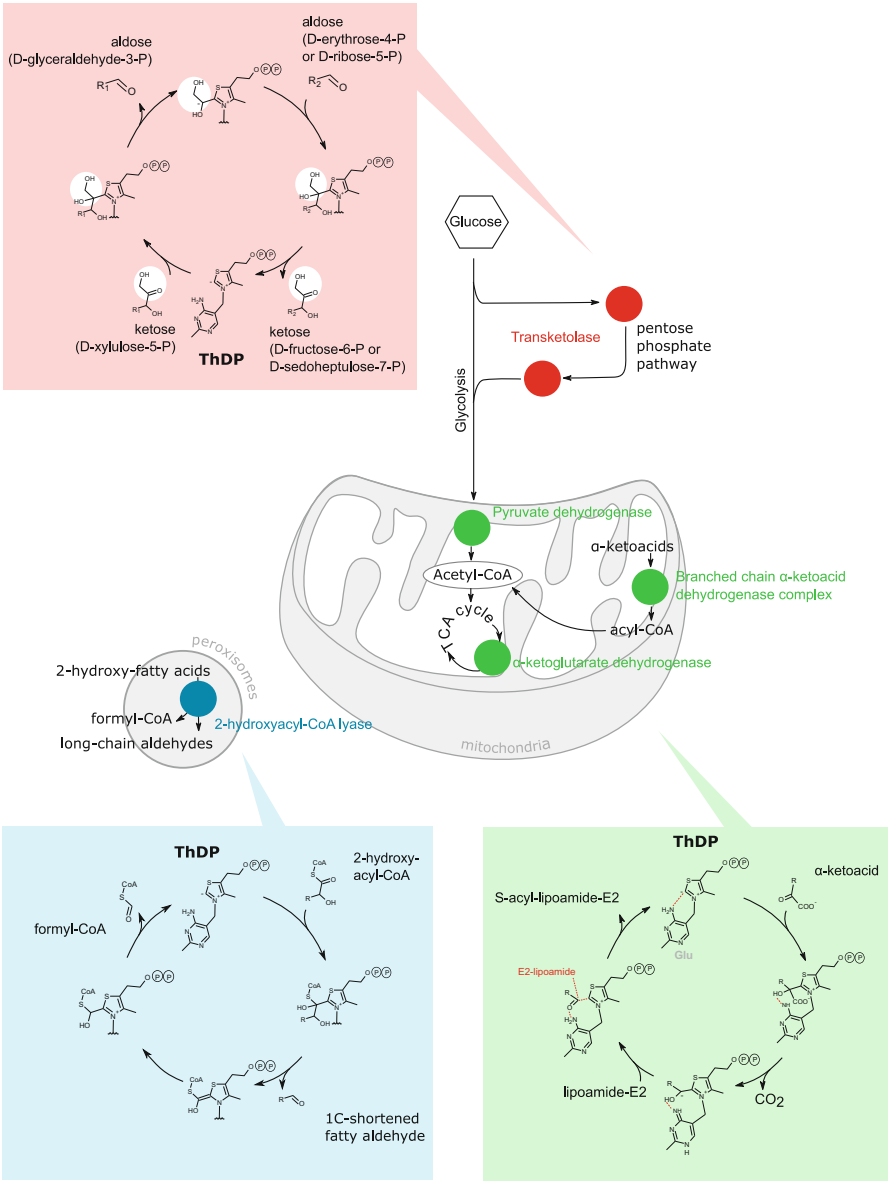

Fig. 12 Enzymatic reactions involving TPP as a cofactor

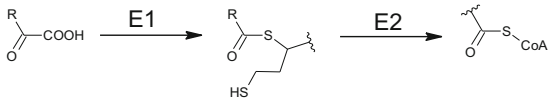
- "Thiamine contributes to the normal function of the heart" (EFSA NDA Panel 2009b), which may also be linked to the NADPH-mediated antioxidative properties of thiamine.
- "Thiamine contributes to the normal function of the nervous system" (EFSA NDA Panel 2009b), which may involve the importance of thiamine in glucose-

Table 3 Dehydrogenase complexes using ThDp as a cofactor, their substrates and products



Enzymatic complex	Substrate	Structure (R=)	Final product	Role
Pyruvate dehydrogenase	Pyruvate	Me	Acetyl-CoA	Krebs cycle
α-ketoglutarate dehydrogenase	α-ketoglutarate	HOOC	SuccinylCoA	
Branched-chain ketoacid dehydrogenase	α-keto-isovalerate (from deamination of valine)		IsobutyrylCoA	Branched-chain amino acid metabolism
	α-keto-isocaproate (from deamination of leucine)		IsovalerylCoA	
	α-keto-β-methylvalerate (from deamination of isoleucine)		α-methyl-butyrylCoA	

derived neurotransmitters acetylcholine (that requires acetylCoA), glutamate, and GABA (that require α-ketoglutarate) (Butterworth et al. 1986), but also little known ThTP-mediated neuromuscular phosphorylation processes (Bettendorff et al. 2014).

26.2.3.2 Animal Studies

Thiamine is a ubiquitous enzymatic cofactor and is important for numerous animal species. A determinant criterion for the choice of animal assays has been the delay required to achieve observable symptoms with animals on a low-thiamine diet. Historically, birds have been the model of choice that enabled the identification of foods containing thiamine, as well as its purification and structural elucidation. Christian Eijckmann determined the possible location of thiamine in rice bran by its observations of chickens given different meals (Carpenter 2003a). Jansen and Donath (1926) obtained the first pure, crystallized thiamine by means of a bioassay-guided fractionation of rice polishing that relied on the onset time of symptoms in bondol ricebird (cited as "munia maja," presumably *Lonchura maja*, that is, white-headed munia, Fig. 13) fed with polished and washed-off rice supplemented with defined amounts of bran extract fractions (active fractions delayed this onset time which was normally below 15 days). They also used pigeons, which were preferred by other researchers to confirm and continue their work (see for instance Williams et al. 1930).

Fig. 13 Polyneuritis in bondol as depicted by Jansen and Donath

26.2.4 Benefits (Human Studies)

Benefits of thiamine consumption can be easily established by observation of the consequences of a thiamine-depleted diet. This condition has been long known as beriberi without clear insight into its cause until Kanehiro Takaki demonstrated, in the end of the nineteenth century that the use of polished rice alone as food in the Japanese navy was the culprit. More diverse meals resulted in a reduced number of cases, although Takaki's explanation was that beriberi was caused by a protein-deficient disease (Bay 2008). Vorderman, in 1897, observing the diet of prisoners in Indonesian prisons, afforded a hint at the difference between polished and complete rice (Vandenbroucke 2013) (Fig. 14).

Other prominent human studies were those that enabled the definition of what may be accepted as a correct thiamine status. This definition still relies to this day on the measure of erythrocyte transketolase activity, based on papers published in the middle of the twentieth century (Brin 1962; Sauberlich 1967; Wood et al. 1980) because clear cut-off values have not been defined for other markers such as ThDP erythrocyte concentration (EFSA NDA Panel 2016).

Beriberi and more generally thiamine deficiency may cause various symptoms, of which the most prominent are:

- **Neurologic** (thiamine was initially described as antipolyneuritis factor; the name "aneurin" was also used): Mental changes have been admitted as a clear symptom of thiamine deficiency by EFSA, making possible the health claim "Thiamine contributes to normal psychological functions" (EFSA NDA Panel 2010b). Thiamine deficiency or diminished thiamine-dependent enzyme activities have been documented in Wernike-Korsakoff syndrome (Chandrakumar et al. 2018), Alzheimer (Gibson et al. 2016), and Parkinson disease (Lu'o'ng and Nguyễn 2013).
- **Cardiovascular** (cause of death in beriberi; "wet" beriberi was thus named because of dropsy (congestive heart failure) inconsistently occurring in the course of the disease): thiamine deficiency is more prevalent in the heart failure

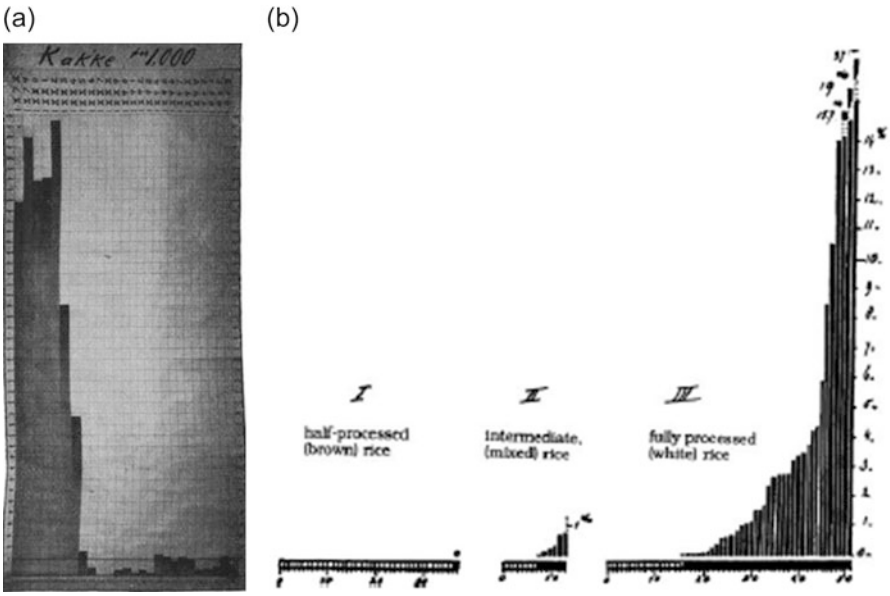


Fig. 14 Historical charts illustrating the effect of dietary intervention on the number of cases of beriberi. (**a**) Takaki's depiction of the dramatic fall in cases thanks to a change in diet (From Funk 1924); (**b**) Vorderman's account of the effect of the processing of rice on the health of prisoners. (From Carpenter 2003a)

population (Jain et al. 2015) and supplementation is beneficial in some cases (DiNicolantonio et al. 2013). Thiamine deficiency may contribute to the pathophysiology of various cardiovascular disorders, especially in the context of diabetes mellitus, because of alternative pathways of glucose metabolism (DiNicolantonio et al. 2018; Eshak and Arafa 2018).

- **Digestive** (anorexia), possibly because of alteration of hypothalamic AMPK activity (Liu et al. 2014). Gastrointestinal symptoms including anorexia may be encounterezd as the only clinical signs of thiamine deficiency (Prakash 2018).

Definition of what may be accepted as correct intakes of thiamine has been a subject of investigation for numerous national and international entities with various outcomes. We focused on EFSA dietary reference values (DRVs), because of their international elaboration, transparency, and recent publication (2016). Data supporting these values and their selection are not discussed here but can be accessed in the corresponding document (EFSA NDA Panel 2016). EFSA set a DRV of 0.1 mg/MJ (0.4 mg/1000 kcal) for all groups of populations. For convenience, estimations of daily requirements in mg/day are presented in Table 4.

Table 4 Dietary reference values of thiamine from EFSA, expressed in mg/day

Population	Male	Female
Infants		
0–6 months	–	–
7–11 months	0.27–0.31	0.24–0.28
Children		
1–3 years	0.33–0.49	0.30–0.46
4–6 years	0.53–0.77	0.49–0.72
7–10 years	0.64–1.02	0.58–0.96
11–12 years	0.86–1.15	0.81–1.06
Adolescents		
13–14 years	0.99–1.32	0.89–1.15
15–17 years	1.14–1.55	0.94–1.20
Adults		
18–39 years	0.96–1.41	0.77–1.13
Pregnancy		
1st trimester[a]	–	0.99–1.05 (1.16)
2nd trimester[a]	–	1.07–1.13 (1.24)
3rd trimester[a]	–	1.17–1.23 (1.34)
Breastfeeding[a]	–	1.17–1.23 (1.34)
≥40 years	0.84–1.35	0.69–1.08

[a]Daily values are provided by EFSA except for pregnancy and lactation values, where recommendations are originally provided as average requirement in addition to values of nonpregnant nonlactating values. Values between brackets correspond to high physical activity level (PAL=2) that was supposed little likely in case of pregnancy or breastfeeding (FAO 2001)

26.2.5 Applications in Food

Thiamine is present in several food categories, including animal-based products. As regards plant sources, it is mainly found in grains (preferably wholemeal grains), legumes, and nuts, as well as spices (which are supposed to be consumed in lesser amounts). Table 5 sums up major plant food sources of thiamine, according to the EFSA Food Composition database (https://www.efsa.europa.eu/en/data/food-composition), selected on the ground of established regulatory thresholds for any food to be considered a source of thiamine (>0.165 mg/100 g) or rich in thiamine (>0.33 mg/100 g).

Thiamine is well-known for its losses in cooking processes. This can be explained by its fragility to various conditions that are summed up in Fig. 15 (Gregory 2017).

It should be kept in mind that, although thiamine disulfide is a possible explanation for reduced thiamine absorption by concomitant polyphenol absorption, its absorption is possible, and it does retain thiamine activity. Naturally occurring reaction products of the sulfhydryl form of thiamine, such as allithiamine, may hinder thiamine detection or quantification, while preserving vitamin status of

Table 5 Thiamine content of plant products which are at least sources of thiamine

Category	Food	Thiamine content (mg/100g)				
Grains		Flour	Groats	Grain or rolled grain	Bran	Germ
	Barley	0.25		0.12 (pearled)-0.15	-	-
	Buckwheat	**0.36**	0.52	-	-	-

	Cumin seed	**0.61**				
	Dill seed	**0.42**				
	Fennel seed	**0.41**				
	Fenugreek seed	0.32				
	Garlic and similar, dill leaves	0.16-0.17				
	Juniper berry	**0.38**				
	Thyme	0.22				
	Vietnamese mint	**0.53**				

–: not available; gray box: amount below threshold defining food sources of thiamine in Europe (<0.165 mg/100 g); bold: amount above threshold defining food rich in thiamine in Europe (>0.33 mg/100 g).

consumers (Fujiwara et al. 1954). On the other hand, thiaminase activity, resulting in vitamin losses, may be encountered in foods such as ferns (Fujiwara and Matui 1953), and tannins probably react with thiamine, producing non-vitamin, non-soluble compounds that were not described (Ventura et al. 2013; Yoshida et al. 2012).

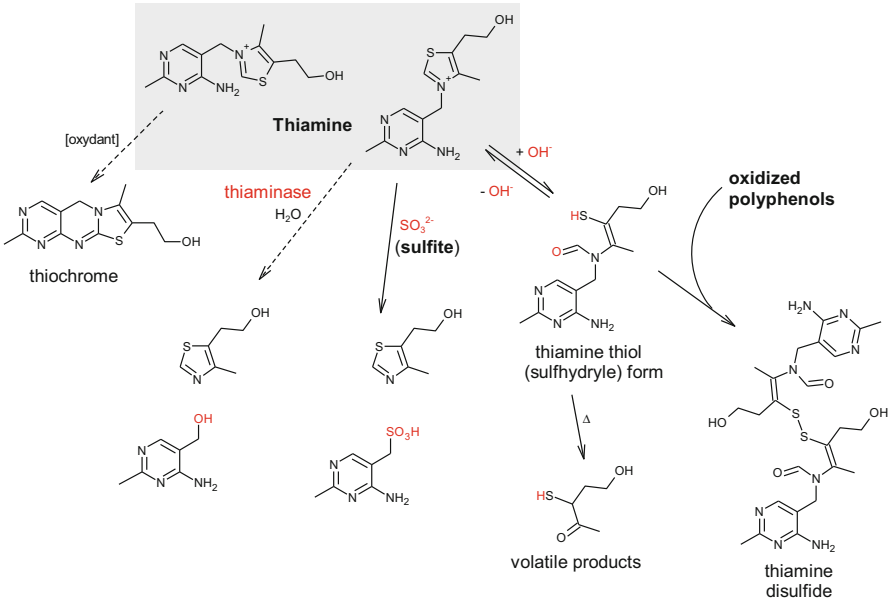

Fig. 15 Degradation reactions described for thiamine

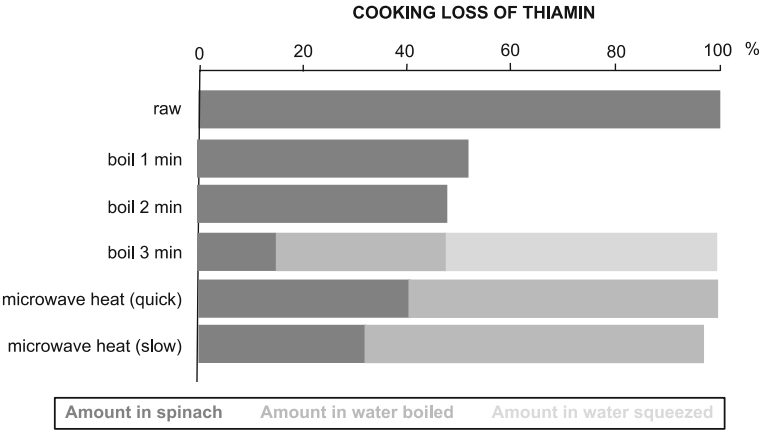

Fig. 16 Changes in thiamine content in spinach cooked by various methods (thiamine content of raw material showed as 100%) according to and adapted from Kimura et al. (1990).

While these degradations may cause considerable thiamine losses in food products or affect significatively its bioavailability, it appears that the most important point is its hydrosolubility, all the more if considering cooking methods at home. This is illustrated by experiments by Kimura et al. (1990), which show that for short cooking times, most of lost spinach thiamine can be found in the water used for boiling it (Fig. 16).

Accordingly, thiamine content tends to diminish dramatically with food processes, in particular cooking. Table 6 shows the impact of cooking in some examples, with calculation of reference dietary intakes (RDI) coverage for suggested portions.

Table 6 Thiamine amount and percentage of RDI covered for defined portions of thiamine-containing plant foods.

		Thiamine amount (mg/100 g)	Portion size[a]	Thiamine amount (mg/portion)	% RDI for one portion
Grain-based products					
Rice grain, parboiled	Raw	0.35	cup 48 g	0.17	15
	Cooked in water	0.09	cup 155 g	0.14	13
	Steamed	0.09	cup 155 g	0.14	13
Pasta wholemeal	Dry	0.54	cup farfalle 81 g	0.4374	40
	Cooked in water	0.10	cup farfalle 107 g	0.107	9.7

[a]portions are mostly inspired by those proposed by USDA (https://ndb.nal.usda.gov/ndb/search/list)

26.2.6 Safety: Toxicity and Side Effects

There is no data about toxicity from excessive thiamine consumption. As seen above, high doses of thiamine are little absorbed. No toxicological threshold has been established for thiamine (EFSA NDA Panel 2016).

26.2.7 Marketed Products

Thiamine is marketed alone mainly as a curative agent for Wernicke encephalopathy or beriberi, at high doses (e.g., 250 mg). It may have encountered in multivitamin preparation registered as drugs or dietary supplements for specific purposes (asthenia or prevention of B vitamin deficiency in specific conditions such as weight loss surgery). Injectable drugs are available for parenteral nutrition. Marketed thiamine is of synthetic origin.

26.2.8 Patents

A variety of lipid-soluble derivatives have been developed, presumably to ensure bioavailability in cases of high dose administration and enhance restorative action in Wernicke encephalopathy. A part from the naturally occurring allithiamine, some sulfhydryl (benfotiamine, acefurtiamine) or disulfide (sulbutiamine) derivatives have been marketed for ailments in relation with fatigue or neural disorders.

26.2.9 Perspectives

The ongoing interest for thiamine-related disorders in major health concerns such as neurodegenerative or cardiovascular diseases show that there are still good reasons for reflexion about this molecule, its transport in human body, and means to protect it in food. Additionally, plant-sourced (or at least naturally occurring) thiamine may be of interest for dietary supplements as consumers are increasingly fond of natural ingredients.

26.3 Vitamin B9: Folate(s)

26.3.1 Bioactive Constituents

Vitamin B9 is a group of structurally related compounds, which are usually grouped under the term “folate.” Their common structural features consist in a pterin moiety, a *para*-aminobenzoic acid (PABA), which is linked to the pterin by its amino group, through a methylene bridge (forming what is called pteroic acid), as well as a

minimum of one glutamoyl residue, establishing an amide bond with the acyl group of PABA.

While folic acid (i.e., pteroylmonoglutamic acid, Fig. 17) is commonly accepted as the main known form of vitamin B9, it should be kept in mind that it is not a natural compound. Instead, molecules in plants will display two major features of structural variation:

- The pterin moiety is found as reduced forms (dihydrofolate or mainly tetrahydrofolate) which may be substituted by diversely oxidized one carbon units on the N5 and N10 positions (methyl, formyl, formimino) or both (methylene, methenyl); these forms will be discussed in the Sect. 3.3.
- The number of glutamoyl residues varies, affording polyglutamoylated compounds (Fig. 18)

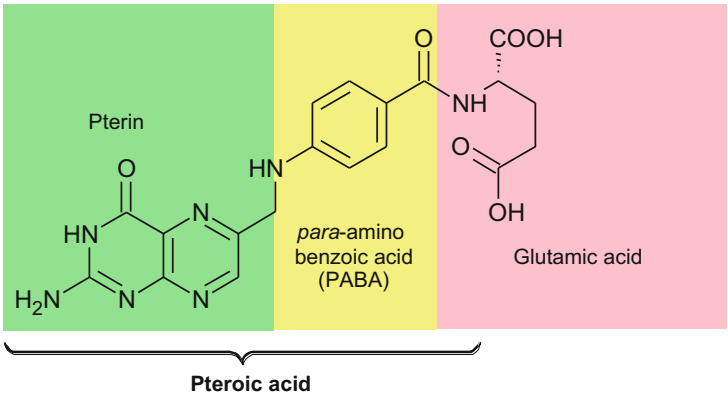

Fig. 17 Structure of pteroylmonoglutamate aka folic acid

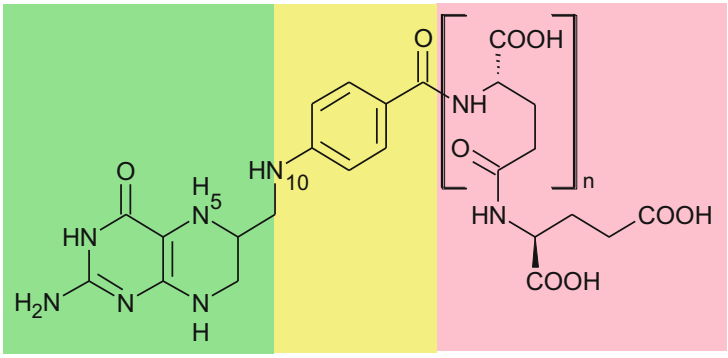

Fig. 18 Structure of naturally occurring folate

Fig. 19 depicts folate biosynthesis in plants (Basset et al. 2002; Ravanel et al. 2001; Sahr et al. 2006). The hydroxymethylpterin moiety is formed as its dihydrogenated state by retroaldolization of dihydroneopterin, the rearrangement product of GTP by GTP cyclohydrolase I (GCHI). The condensation of the pyrophosphorylated form of 6-hydroxymethyl-dihydropterin with PABA, a chorismate derivative, affords dihydropteroate, which may be subsequently glutamoylated and reduced. These biosynthetic steps are common to prokaryotes and eukaryotes, while some specificities exist. In plants they are highly compartmented, with three subcellular contributors; as frequently observed in eukaryotes, steps converting hydroxymethyldihydropterin into dihydropteroate are performed by a same bifunctional enzyme (Mouillon et al. 2002).

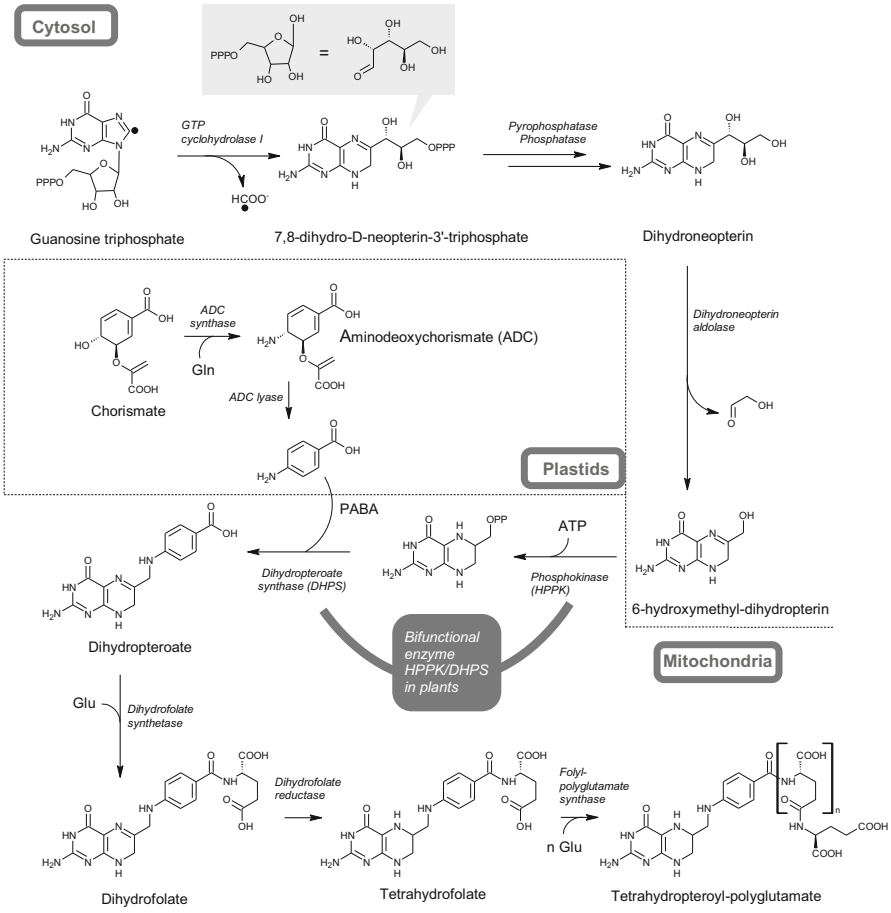

Fig. 19 Folate biosynthesis in plants

26.3.2 Bioavailability and Metabolism

26.3.2.1 Bioavailability

While folates display variations as regards their glutamoylation in food (polyglutamates representing usually more than 50% of total folates), only monoglutamoyl derivatives are absorbed. The hydrolysis of polyglutamates to monoglutamates is predominantly performed by the enzyme folate hydrolase, which is located on the jejunal brush border and encoded by the glutamate carboxypeptidase II (GCPII/FOLH1) gene, in humans and pigs (Bernstein et al. 1970; Chandler et al. 1986). This is not the case in rats where a distinct folate hydrolase (γ-glutamyl hydrolase, γ-GH) is released by pancreatic secretions in the intestinal lumen (Shafizadeh and Halsted 2007). These enzymes operate at different optimal pH values and with different mechanisms, with GCPII sequentially cleaving terminal glutamates and γ-GH being able to catalyze hydrolysis of both internal and terminal glutamates (Chandler et al. 1986; Wang et al. 1986).

Absorption of monoglutamates across the apical brush border is performed by Proton-Coupled Folate Transporter (PCFT) in normal, slightly acidic, conditions, although the Reduced Folate Transporter (RFT), which is present at the same location, may predominate functionally in the case of an increase in pH value (Zhao et al. 2009). RCF operating at suboptimal pH value, colonic transport as well as passive diffusion in the small intestine may contribute to the absorption of folates in some conditions (Zhao et al. 2009; Aufreiter et al. 2009).

26.3.2.2 Metabolism

The involvement of folates in one-carbon metabolism is directly related to its biological activities and interest, so it will be discussed in the following part. Other interesting aspects of folate metabolism are:

- Reconjugation, as polyglutamoylation is used to prevent folate from exiting the cells, making an important difference between a short-lived pool of monoglutamoylated folates and an intracellular polyglutamoylated pool with slow turnover (Stites et al. 1997), located in liver and other tissues (Lin et al. 2004)
- C9-N10 hydrolysis, which is not reversible and accounts for the possible detection of folate breakdown products such as pterin, isoxanthopterin, p-aminobenzoylglutamate, and its acetylated derivative p-acetamidobenzoylglutamate (McPartlin et al. 1993)

26.3.3 Bioactivities

26.3.3.1 General Role

Folate is implicated in a variety of physiological reactions which are strongly intertwined with its biological forms and their interconversion. They are shown in Fig. 20, along with the enzymes involved and spontaneous (nonenzymatic) reactions. The role of tetrahydrofolate (THF) is central:

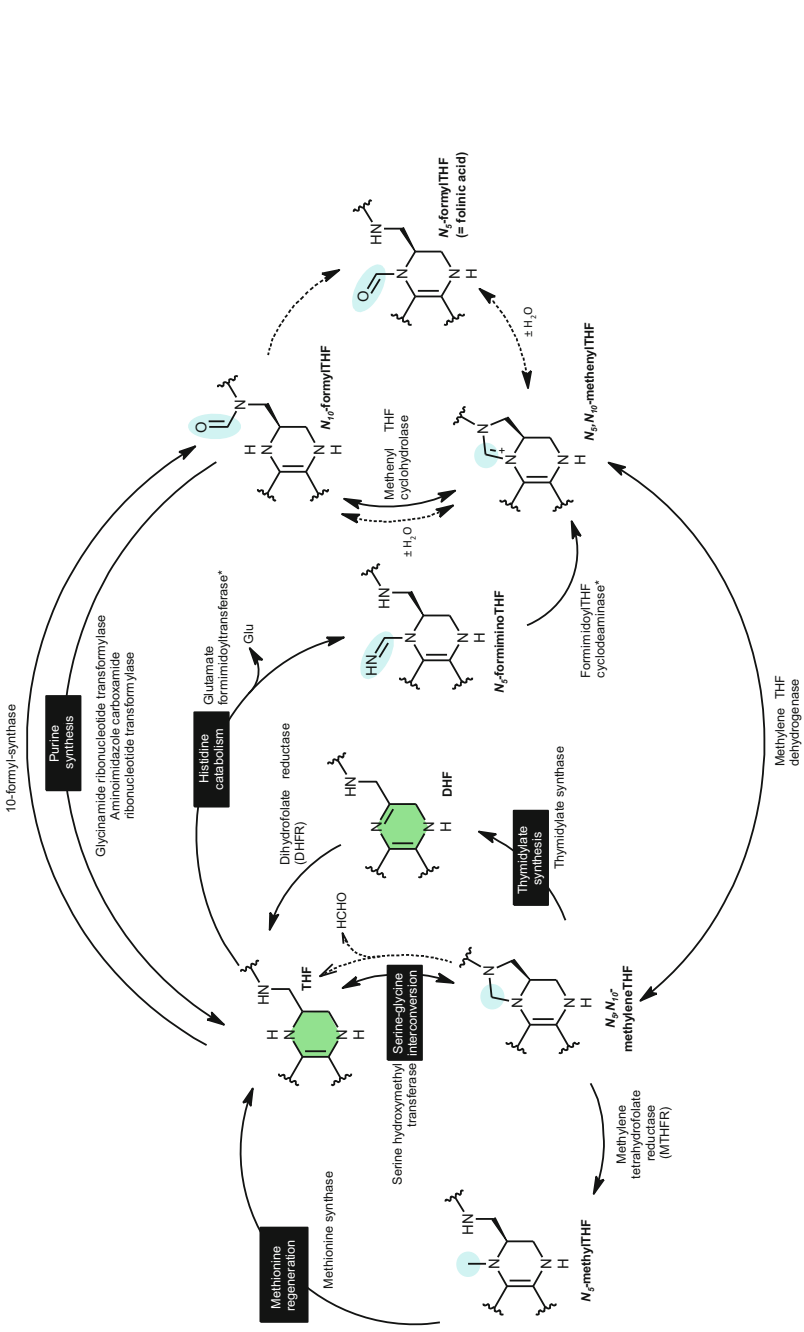

Fig. 20 Interconversion of variants of the pteridine ring of folate. Bold characters: folates; full arrows: enzymatic reactions; dotted arrows: spontaneous reactions; black boxes: biological function

- It can be converted to methylene THF by a serine hydroxymethyl transferase with a one-carbon unit afforded by serine, a dispensable amino acid. Methylene THF is reduced to the more stable N5-methyl THF by methylene tetrahydrofolate reductase (MTHFR). N5-methyl THF is used for transport (its monoglutamate is the major form encountered in plasma (Combs and McCLung 2017); it is also used by methionine synthase for the regeneration of methionine, with the contribution of vitamin B12 (Krebs et al. 1976). Methionine, once adenosylylated, is the universal **methyl donor** in the body. Methylene THF is also the donor of the methyl group in the methylation of uridine monophosphate into thymidine monophosphate by thymidylate synthase (Wahba and Friedkin 1961; Pastore and Friedkin 1962).
- Another contribution of THF is achieved through its receiving a formimino group from formiminoglutamate in the process of histidine degradation into glutamate. Formimino THF is little available as it is immediately transformed by another domain of the same bifunctional enzyme (formiminotransferase-cyclodeaminase) into methenyl THF with an ammonium ion loss (McKenzie et al. 1980; Kohls et al. 2000). THF thus plays some direct part in the **metabolism and interconversion of various amino acids**: serine, glycine, histidine, glutamic acid, and methionine.
- N10-formyl THF can be obtained from THF, directly by 10-formyl synthase or indirectly, after hydration of N5,N10-methenyl THF, a product of methylene THF dehydrogenase. N10-formyl THF is the carbon donor of two transformylases belonging to the purine biosynthesis pathway, implying its own conversion back to THF. Hence, folates are important contributors to the **synthesis of both purines and pyrimidines**, enabling **cell proliferation**. Questions have arisen about the different incorporations of labeled carbon sources (histidine, serine/glycine, and formate) into purines by transformylases leading to the suggestion of possible distinct 10-formyl folate pools by these two enzymes as well as a possibly significant role of N10-formyl DHF as a substrate for aminoimidazole carboxamide ribonucleotide transformylase (Baggott and Tamura 2001, 2015).

All these described enzymatic reactions involve polyglutamoylated forms, which contribute to folate molecular recognition and handling. For instance, substrate channeling (i.e., transfer of the intermediate substrate) in the bifunctional formiminotransferase-cyclodeaminase is optimal with pentaglutamate (Kohls et al. 2000).

In Europe, EFSA authorized four health claims that are related to the roles of folate described above:

- “Folate contributes to a normal function of the immune system” (EFSA NDA Panel 2009c).
- “Folate contributes to normal cell division” (EFSA NDA Panel 2009c).
- “Folate contributes to normal maternal tissue growth during pregnancy” (EFSA NDA Panel 2009c).
- “Folate contributes to normal amino acid synthesis” (EFSA NDA Panel 2010c).

26.3.3.2 Animal Studies

Folate is important for all living organisms, but animals particularly rely on exogenous supply because they lack several enzymes for its biosynthesis. Nevertheless, because the digestive microbiota can synthetize folates, a deficiency is not expected in ruminants, and can be limited or delayed by practices such as coprophagy in rodents.

Historically, the first animal model used for reproduction observed in human folate deficiency was rhesus monkey, leading to the obsolete name "vitamin M" at a time when its chemical identity was not established (Carpenter 2003b).

As microbes provided convenient models for studies on metabolism, animal studies found their major contribution in the comprehension of folate bioavailability mechanisms (Bayes et al. 2019): deconjugation (Bernstein et al. 1970) and transport (Zhao et al. 2009).

26.3.4 Benefits (Human Studies)

As is usual with vitamins, the discovery of vitamin B9 was a direct consequence of the observation of a vitamin B9-deficient diet, making some of its health benefits obvious from the start. Although numerous conditions may be linked to folate deficiency or suboptimal intake, the most important and recognized are:

- **Blood cell defects** – Lucy Wills was the first reporter of "tropical macrocytic anemia" in mothers on what would be later defined as a low folate diet (Carpenter 2003b). Megaloblastic anemias are nowadays known to be related to impaired DNA synthesis, explaining a prominent role of vitamin B9, implicated both in thymidilate and purine de novo synthesis (see Sect. 3.3). Erythroid macrocytosis is an early change in this disease, but neutropenia and thrombocytopenia may develop in severe cases and all fast proliferation cells are affected. Folate-associated megaloblastic anemia is less clearly associated with neurological troubles than those linked to vitamin B12 deficit, nevertheless exhaustion and a depressed mood can be observed (Carmel 2019).
  EFSA authorizes two health claims based on this knowledge:
  "Folate contributes to normal blood formation" (EFSA NDA Panel 2009c).
  "Folate contributes to normal psychological functions" (EFSA NDA Panel 2010c).
  "Folate can contribute to the reduction of tiredness and fatigue" (EFSA NDA Panel 2010c).
- **Impairment of foetal development** – Abnormal folate status has been linked with an increased risk of neural tube defects (NTD). It was at first a suggestion (Smithells 1982), which was subsequently confirmed at high doses (4 mg) and in multivitamin preparation (MRC Vitamin Study Research Group 1991), then at lower doses (Czeizel and Dudás 1992) and as a single ingredient. Other birth defects were supposed to be related to low folate status, with no clear evidence to this day (De-Regil et al. 2015). EFSA authorized the following health claim:

"Supplemental folate intake increases maternal folate status. Increasing maternal folate status contributes to the reduction of the risk of NTD"
if 400 µg supplemental folate is consumed daily for at least one month before and up to three months after conception. (EFSA NDA Panel 2013a)

Folate status in Man can be assessed by folate concentration measurement in serum, where it depends on short-term changes, or in erythrocytes, where it is considered to reflect tissue stores. In both cases analytical methods include microbiological methods relying on the stimulation of the growth of bacteria (generally *Lactobacillus rhamnosus*) by folates, competitive binding to proteins (immunological methods, most of which rely on ligand-labeled folates and chemoluminescence) or liquid chromatography, noteworthily isotope dilution LC/MS/MS (Pfeiffer et al. 2009).

The role of folate in methionine synthesis has directed attention toward indirect consequences of folate deficiency as a biomarker: a defect in methionine regeneration by methylation of homocysteine leads to **hyperhomocysteinemia** (Fig. 21), which has been linked to various conditions including cardiovascular diseases, cancer, and Alzheimer's disease (Kim et al. 2018). The admitted beneficial effect of correct homocysteine remethylation led EFSA to authorize the health claim "Folate contributes to normal homocysteine metabolism" (EFSA NDA Panel 2009c). Nevertheless, the correction of hyperhomocysteinemia by B-group vitamins has not been shown to reduce cardiovascular events, cancer risk, or global mortality (Martí-Carvajal et al. 2017).

More recently, attention was drawn to cystathionine, an intermediate product of cysteine synthesis from homocysteine by vitamin B6-dependent transsulfuration. Elevated plasma cystathionine was found to be correlated with stroke and global mortality in the context of coronary heart disease (Dhar et al. 2018, 2019).

Dietary reference values provided by EFSA (2014) are reported in Table 7. Population Reference Intakes (PRI) calculated from Average Requirements based on biomarkers of folate status could be proposed except in the cases of neonates <6 months and of pregnancy. In the latter, an Adequate Intake based on a study where the intake was sufficient to maintain folate status was observed (Caudill et al. 1997) while the possibility of reaching the same result with lower doses cannot be ruled out. In comparison with other vitamins, the calculation of PRI involved higher coefficient of variation, taking heed of numerous genetic polymorphisms (e.g., MTHFR) possibly increasing requirement for folates in some people.

Other causes for increased requirement in folates may include drug therapy with products described in part 7, but also metformin or phenytoin, alcohol consumption, and various causes of decreased intestinal area or efficiency such as bariatric surgery (McNulty and Pentieva 2009).

26.3.5 Applications in Food

The first successful treatment of folate deficiency was quite immediately proposed by Lucy Wills: it was the famous yeast extract Marmite®. At the time the

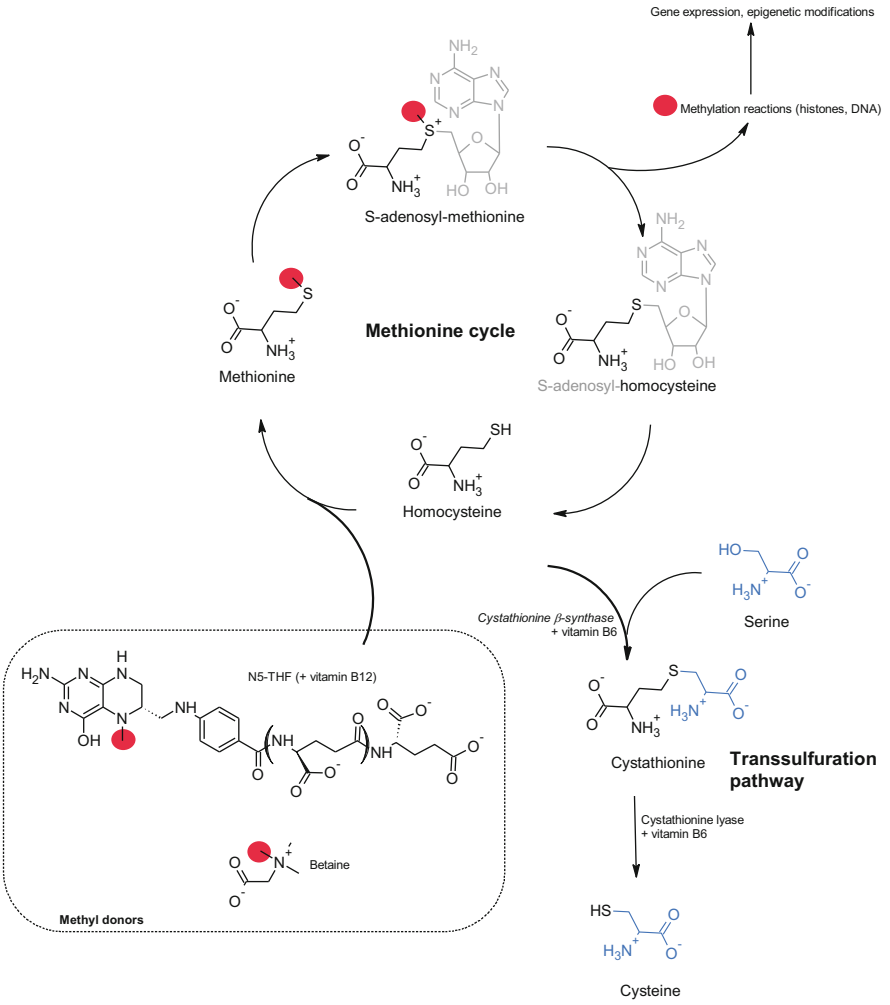

Fig. 21 Methionine cycle and transsulfuration pathway

molecular basis of the disease was not known and the proof of concept was challenged but Wills confirmed the successful treatment of correctly diagnosed pernicious anemia of pregnancy or tropical macrocytic anemia (Fig. 22, Wills 1933).

Folates are present in various foods, noticeably in liver and yeast products. The presence of folates in various plant products is reported in Table 8. We focused on foods that could be defined as "rich in folates" according to European law (Regulations n° 1924/2006 and 1169/2011), that is, ≥60 μg/100 g. Mushrooms and spirulina are also non-animal foods rich in folates.

In spite of their original success as food ingredients, dietary folates were found to have flaws for their intended reproducible use as curative agents in medicine:

Table 7 Dietary reference values of folate from EFSA, expressed in mg/day.

Infants	
0–6 months	-
7–11 months	80
Children

Pregnancy	600
Breastfeeding	-

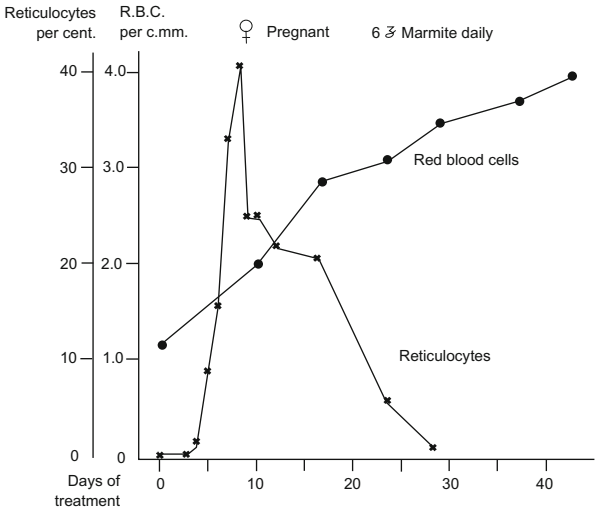

Fig. 22 Marmite yeast extract curative effect on macrocytic anemias as reported by Lucy Wills (right)

- Their diversity, making it difficult to quantify them; Table 9 shows a transcription of several recent attempts at folates in different plant foods: N5-methyl THF is generally the main compound but formyl vitamers can be present in significant amounts or even predominate, for example, in pak-choi.

- Their lack of stability. Fig. 23 sums up reactions described for the degradation of major vitamin B9 vitamers in food, N5-methyl THF, N10-formyl THF, and THF. The oxidation of the tetrahydropyrazine ring is reversible but other oxidative reactions are possible (Blair et al. 1975). Breakdown products are also created by

Table 8 Folate content of plant products which are rich in folates (ANSES 2017). Only foods with confidence levels A–C were reported

Category	Food	Total folate (μg/100 g) (min–max values when available)
Algae	Carragaheen (*Chondrus crispus*), dried	866
	Dulse (*Palmaria palmata*), dried	92
	Kombu (*Laminaria japonica*), dried	127
	Wakame (*Undaria pinnatifida*), dried	237
Fruit	Strawberry, raw	72

hydrolysis (Jägerstad and Jastrebova 2013); as described for N5-methyl THF, thermal treatment of food can induce formation of rearrangement or glycation products (Verlinde et al. 2010). N5-formyl THF is a rather stable form but can be chemically converted into the less stable N10-formyl THF (see Fig. 20).

- Their limited bioavailability (Hannon-Fletcher et al. 2004). Although polyglutamoylation may be suspected for that, it seems that it is not usually limiting in the intestinal absorption of folates (McKillop et al. 2006). The decisive reasons would be matrix effect, as folates bind to proteins and sugars, which justifies the use of various treatments for quantifications in food and biological samples (heat, acid, acetone and/or enzymes) (Pfeiffer et al. 2009). Conjugase inhibitory activity may also explain lowered polyglutamate bioavailability in some foods (Bhandari and Gregory 1990).

For these reasons, folic acid, a very minor form of natural vitamin B9 which is fully oxidized on the pyrazine ring, has long been considered the best form of administration: it is a single chemical entity, the simplest form (without one-carbon unit and monoglutamoylated), chemically stable, and used as a synthetic derivative without the risk of matrix effect. The Institute od Medicine (1998) has suggested the use of dietary folate equivalents (DFE), where foof folates are considered to be considerably less bioavailable than folic acid:

μg DFE = μg food folates + μg folic acid × 1,7
1 μg DFE = 1 μg food folate = 0.6 μg folic acid from fortified food or as a supplement consumed with food = 0.5 μg of a folic acid supplement taken on an empty stomach

[a]Estimation from addition of reported formyl vitamers in charts

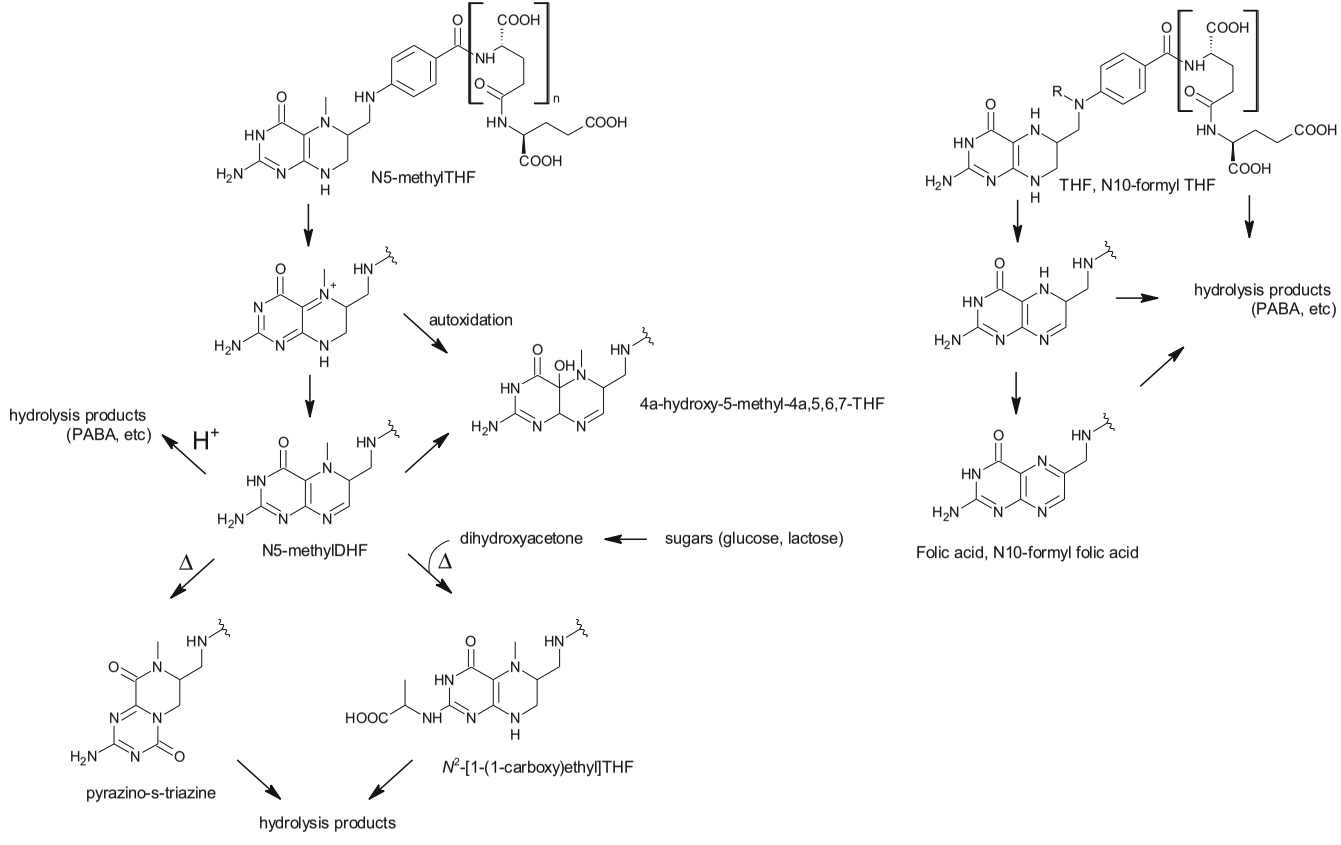

Fig. 23 Degradation reactions of major food tetrahydrofolates in food

Yet, this assumption is still debated, with numerous papers suggesting higher bioavailability for food folates, while the effectiveness of food fortification with folic acid, which is mandatory in some countries and has been described as "highly effective in decreasing NTD cases in populations where it has been implemented" (Caffrey et al. 2018), has recently been more cautiously addressed in a meta-analysis (Centeno Tablante et al. 2019).

As usually reported for water-soluble vitamins, folate loss by plain extraction should not be overseen. It is possibly important in industrial processes (Delchier et al. 2013) as well a cooking methods (Leichter et al. 1978) and can involve any natural or synthetic folate form.

26.3.6 Safety: Toxicity and Side Effects

Direct toxicity of folates is considered to be negligible within normal range of consumption, but may be lethal at very high folic acid doses (Devnath et al. 2017). A specific risk must be considered in the context of vitamin B12 deficiency, as folate can correct megaloblastic anemia and make it difficult to identify. High dose folic acid may be correlated with an increased detection of some (prostate) cancers, while it clearly prevents others (e.g., colorectal cancer) (Patel and Sobczyńska-Malefora 2017). This may be explained by a stimulation of cell proliferation in cancer tissue. It is not clear whether any of the above applies to natural folates.

26.3.7 Marketed Products

The predominant form used for vitamin B9 supplementation is folic acid. N5-methylTHF has been suggested as an alternative, because it does not require MTHFR processing (MTHFR polymorphism is the most frequent cause for enhanced folate requirement in the general population) (Guéant-Rodriguez et al. 2006) and cannot mask vitamin B12 deficiency (it depends on cobalamin for conversion into methylene THF, thus does not apparently corrects the effects of cobalamin deficiency as folic acid does) (Scaglione and Panzavolta 2014). Foods can be promoted on the basis of their amount in folates and possible health benefits in Europe (see Sects. 3.3 and 3.4). Recently, natural extracts have been marketed as natural vitamin B9.

Inhibitors of specific enzymes in folate metabolism have been developed and used as antimicrobials and anticancer agents. Their use is frequently associated with supplementation in N5-formyl THF in order to enhance their activity or lower their toxicity to humans. They are summed up in Table 10.

26.3.8 Patents

Enhanced bioavailability is a subject of interest for folate. A registered glucosamine salt folate salt has been reported to have grater bioavailability than folic acid in rats (Miraglia et al. 2016).

Table 10 Drugs affecting folate metabolism

Compound	Target (effect)	Intended use	Associated folate form and aim
5-fluoro uracile (5FU, fluorouracil)	Human thymidylate synthase inhibitor	Cancer chemotherapy	N5-formyl THF (folinic acid), enzyme cofactor enabling suicide inhibition
Methotrexate (MTX, amethopterin)	Human dihydrofolate reductase inhibitor (folate analogue)	Cancer chemotherapy, immunodepressant	N5-formyl THF (folinic acid), diminishes MTX toxicity – not affected by DHFR inhibition
Pyrimethamine	Parasite dihydrofolate reductase inhibitor	Toxoplasmosis treatment	N5-formyl THF (folinic acid), diminishes MTX toxicity – not affected by DHFR inhibition
Sulfamethoxazole	Dihydropteroate synthase inhibitor in bacteria	Antibacterial (synergism with trimethoprime)	-
Trimethoprime	Bacterial dihydrofolate reductase inhibitor	Antibacterial (synergism with sulfamethoxazole)	N5-formyl THF (folinic acid), diminishes MTX toxicity – not affected by DHFR inhibition

26.3.9 Perspectives

While the effects of defects in folate status or metabolism are clearly established, choices for supplementation are still debatable. Difficulties in analysis, links between specific ingested forms, biomarkers, and health effects explain the need for further work and standardization in assessment methods.

26.4 Vitamin C: Ascorbic Acid

26.4.1 Bioactive Constituents

Ascorbic acid, also known as vitamin C, is a 6-carbon hydroxylactone biogenetically derived from glucose with a molecular mass of 176.12 Da. It is a water-soluble vitamin, which is sensitive to heat and light (EFSA NDA Panel 2013b). It was first isolated by Albert Szent-Gyorgyi in 1928 and identified by Norman Haworth in 1933 (Carpenter 2012; Padayatty and Levine 2016). It has two pKa, with the first at 4.2 and the second at 11.6. Thus, at pH = 7, vitamin C is mostly present in its ionized form, ascorbate (99.9%) (Du et al. 2012). This molecule is often in the form of salts, among them sodium ascorbate and calcium ascorbate are the most common. A resonance form exists for this deprotonated anionic form in particular due to the presence of the two conjugated double bonds (Linster and Van Schaftingen 2007). Ascorbic acid, the functional in vivo form of the vitamin, is the enolic form of an α-ketolactone with an asymmetric carbon atom. Only one of its stereoisomers is sufficiently active, *L*-(+)-ascorbic acid. The two enolic hydrogen atoms confer the

acidic character to the molecule and provide electrons for its function as antioxidant. In solution, vitamin C can be oxidized and give a mixture of ascorbate and dehydroascorbate (EFSA NDA Panel 2013b; Institute of Medicine (US) Panel on Dietary Antioxidants and Related Compounds 2000; Linster and Van Schaftingen 2007; Smirnoff 2018) (Fig. 24).

The first oxidation step of vitamin C is the loss of one electron to provide the derived resonance-stabilized MDHA (monodehydroascorbate) radical, which is central to its biological activities. Its half-life is longer (many seconds or even minutes) than many others radical species, depending on absence of oxygen and electron acceptors such as iron. If many redox reactions are common in plants and mammals, this step can be managed by specific enzymes in plants, in particular ascorbate peroxidase (APX) and ascorbate oxidase (AO). DHA (dehydroascorbate) and ascorbate are then produced by dismutation of MDHA with an equilibrium in favor of ascorbate and DHA. The tri-carbonyl structure of DHA is particularly instable and is present in the hydrated hemiacetal form in solution (Du et al. 2012; Linster and Van Schaftingen 2007; Smirnoff 2018) (Fig. 24). Hence, vitamin C is a good free radical scavenger in vitro and in vivo by both its ability to act as an electron donor with a redox potential and the relative stability and unreactivity of MDHA (Paciolla et al. 2019). By its capacity to donate reducing equivalents, vitamin C also contributes to several biochemical reactions. It is a cofactor for several enzymes involved in the human metabolism, in particular Cu^{+}-dependent

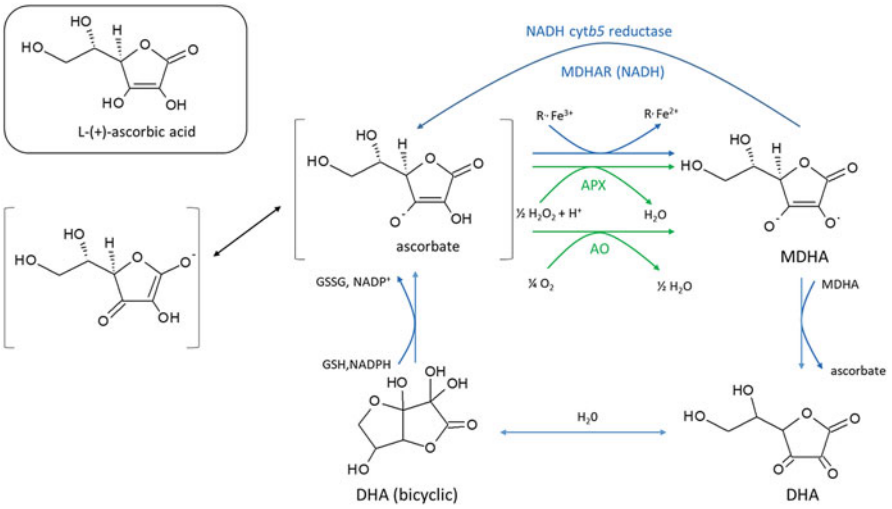

Fig. 24 Structure of L-(+)-ascorbic acid and its redox states (Adapted from (Linster and Van Schaftingen 2007; Smirnoff 2018). Ascorbate, fully reduced form; MDHA, monodehydroascorbate, resonance-stabilized ascorbate radical; DHA, dehydroascorbate, fully oxidized form. Reactions occurring both in plants and mammals are shown in blue and plant specific reaction are shown in green. In plants, MDHA and DHA reduction are catalyzed respectively by NADH- and GSH-dependent enzymes families and in mammals by a variety of enzymes

monooxygenases and Fe^{2+}-dependent dioxygenases. It is particularly involved in the biosynthesis of collagen, carnitine, and some neurotransmitters. It also contributes to iron absorption, immune stimulation, and epigenetic regulation (Institute of Medicine (US) Panel on Dietary Antioxidants and Related Compounds 2000; Paciolla et al. 2019).

Vitamin C is an essential nutrient involved in the normal metabolism of humans and many other mammals. If some animals are able to synthetize it from D-glucuronate, derived from UDP-glucuronate, in some organs such liver or kidney, others including humans, nonhuman primates, guinea pigs, or bats have lost this capacity. They no longer have the last enzyme of the pathway, L-guluno-1,4-lactone oxidase, due to an accumulation of mutations in its coding gene. No evolutionary explanation is satisfactory yet (Fenech et al. 2019; Linster and Van Schaftingen 2007).

Plant-derived ascorbate is the major source of vitamin C in the human diet. Indeed, L-ascorbate is abundant in plants, but with contents significantly different among plant species and cultivars (Paciolla et al. 2019; Smirnoff 2018). Ascorbate concentrations vary between the organs, with highest contents in the aerial parts such as leaves and flowers and lower contents in less photosynthetically organs such as roots and stems. Ascorbate concentrations can reach 1–5 mM in leaves. In seeds, ascorbate accumulates during early germination and disappears at maturity and when they are deshydrated. Vitamin C occurs in all cell compartments, with concentrations up to 20 mM in chloroplasts. It is also found in the apoplast (cell wall and extracellular space) but with lower contents and in a more oxidized form than in the intracellular pool. Different environmental changes, and in particular light, can impact the regulation of vitamin C levels (Paciolla et al. 2019; Smirnoff 2018; Smirnoff and Wheeler 2000; Wheeler et al. 1998).

L-ascorbate has several roles in plant (Fenech et al. 2019; Paciolla et al. 2019; Smirnoff 2018):

- It contributes to the smooth running of photosynthesis by different ways and slows down leaf senescence: as a ROS scavenger limiting ROS-mediated damage; as an enzyme cofactor, in particular as a cofactor of violaxanthin de-epoxidase, an enzyme involved in preventing photodamage, by converting violaxanthin to zeaxanthin, thus dissipating excess excitation energy; as donate electrons when photosystems are damaged by stress conditions.
- It is involved in the synthesis of plant hormones as an enzyme cofactor.
- It is implicated in the control of plant growth and development, as well as in the plant defense response against pathogens.
- It is involved in transmembrane electron transport and it favors iron uptake and transport in plants.
- It is particularly involved in the control of cell division; the ascorbate redox state has a major role in the cell cycle progression.
- It also plays a role in the programmed cell death induced among others by H_2O_2 formation of heat shock. It is to note that APX, an enzyme family limited to green plants and photosynthetic protists, contributes to the high capacity of plants to

remove H_2O_2 produced by photosynthetic electron transport and photorespiration, by converting it to H_2O and O_2.

The biosynthesis of ascorbate in higher plants is subject to discussion by different researchers. Unlike the animal pathway, in higher plants, no carbon conversion is observed. The carbon 1 in the D-glucose remains as the carbon 1 in ascorbate after conversion.

The predominant pathway of vitamin C biosynthesis seems to be that proposed by Smirnoff and Wheeler in 1998 (Wheeler et al. 1998). The **Smirnoff-Wheeler pathway** (**D-mannose/L-galactose pathway**) involves D-mannose and L-galactose (Fig. 25). The two initial steps begin by the conversion of D-glucose-6-phosphate into D-mannose-6-phosphate, which is then transformed into D-mannose-1-phosphate by the action of a phosphomannose mutase (PMM). GDP-D-mannose is formed from D-mannose-1-phosphate by the transfer of guanosine monophosphate from GTP by GDP-D-mannose-pyrophosphorylase (GMP). GDP-L-galactose is further produced from GDP-D-mannose by a GDP-D-mannose epimerase (GME) through a 3′,5′-epimerization. In the Smirnoff-Wheeler pathway, GDP-L-galactose is converted into L-galactono-1,4-lactone in several steps in the cytosol. Several enzymes are implicated: GDP-L-galactose-phosphorylase (GGP), L-galactose-1-phosphate phosphatase (GPP), and L-galactose dehydrogenase (LGal-DH). L-galactono-1,4-lactone must then move from cytosol to mitochondria where the L-galactono-1,4-lactone dehydrogenase is localized and allows the conversion into ascorbate transferring electrons to cytochrome c. It is interesting to note that this last step of oxidation is managed by a deshydrogenase instead of an oxidase as occurs in animals (L-guluno-1,4-lactone oxidase). This deshydrogenase allows not to release H_2O_2 and does not affect the redox state of the cell during the formation of ascorbate (Fenech et al. 2019; Paciolla et al. 2019).

The other ascorbate biosynthetic pathways are (Fig. 25):

- The **gulose pathway** (**Wolucka-Van-Montagu pathway**) starts from the 5′-epimerization of the GDP-D-mannose with the formation of GDP-L-gulose. Indeed, GME is also able to catalyze the 5′-epimerization instead of 3′,5′-epimerization described in the Smirnoff-Wheeler pathway (Major et al. 2005). GDP-L-gulose could be converted into L-guluno-1,4-lactone in several steps, but some enzymes are not clearly identified. Then, the gulunolactone oxidase (GulLo) could be transformed L-guluno-1,4-lactone into ascorbate (Paciolla et al. 2019). Other authors hypothesize that ascorbate could be directly synthetized from GDP-L-gulose, due to its scarcity in plants and its lack of structural function (Fenech et al. 2019).
- The **myoinositol pathway**, following a pathway similar to animals, could also lead to the formation of L-guluno-1,4-lactone. First, myoinositol is oxidized in D-glucuronate by the myoinositol oxygenase (MIOX). Then, D-glucuronate is converted into L-guluno-1,4-lactone in two steps by glucoronate reductase and aldono lactonase (Paciolla et al. 2019; Valpuesta and Botella 2004). However, the contribution of the myoinositol pathway in the ascorbate biosynthesis remains still unclear (Fenech et al. 2019).

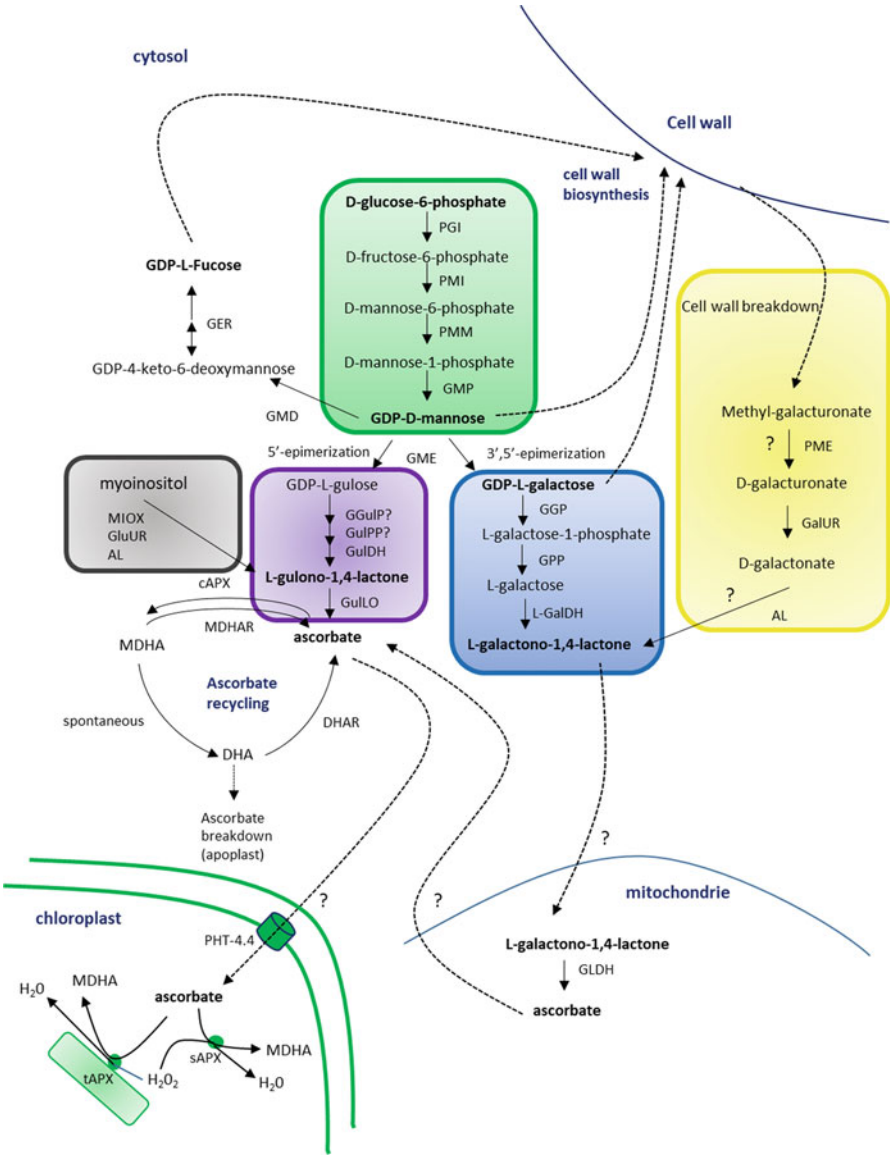

Fig. 25 Biosynthetic pathways of ascorbate in the plant cells (Adapted from Fenech et al. 2019; Paciolla et al. 2019). Different colors indicate different pathways. In gray, the myo-inositol pathway; in violet, the gulose pathway (Wolucka-Van-Montagu pathway); in blue, the D-mannose/L-galactose pathway (Smirnoff-Wheeler pathway); in yellow, the galacturonate pathway. In green are represented the initial steps leading to GDP-D-mannose. Solid lines represent the dedicated reactions within a pathway. Dashed lines represent the translocation of a molecule from a cellular compartment to another. A question mark indicates enzymes not identified in plants. Abbreviations of enzymes: AL, aldono reductase; cAPX, cytosolic ascorbate peroxidase; DHAR, dehydroascorbate reductase; GalUR, D-galacturonate reductase; GGP, GDP-L-galactose-phosphorylase; GGulP, GDP-L-gulose pyrophosphatase; GLDH, L-galactono-1,4-lactone dehydrogenase;

- The **D-galactorunate pathway**, mainly active during fruit ripening in some species, uses methyl-galacturonate released by the degradation of pectin during the cell wall breakdown. Methyl-galacturonate is converted into D-galacturonate by a pectin methyl esterase. D-galacturonate is then used by a D-galacturonate reductase (GalUR) to produce D-galactonate that is converted by an aldone-lactonase into L-galactono-1,4-lactone, the last intermediate within the Smirnoff-Wheeler pathway (Agius et al. 2003; Fenech et al. 2019; Paciolla et al. 2019).

In addition to its biosynthesis, the ascorbate pool can also come from its recycling (Foyer-Halliwell-Asada cycle) and depend on its degradation (Fenech et al. 2019). Moreover, several ascorbate derivatives, including glucosides, have been identified in plants (Smirnoff 2018).

26.4.2 Bioavailability and Metabolism

26.4.2.1 Bioavailability

Absorption

Oral route of administration is privileged for vitamin C that comes from food, mainly fruits and vegetable, or supplements. In general, typical human diet provides sufficient amount of vitamin C in healthy population. However, this dietary intake can be inadequate in the case of some pathologies or in smokers (Lykkesfeldt and Tveden-Nyborg 2019). Absorption of ascorbate and DHA mainly occurs in the enterocytes of the small intestine. Three modes of membrane transport are possible: active transport, passive, and facilitated diffusion. At low gastrointestinal concentrations, ascorbate is absorbed through specific sodium-dependent active transporters belonging to nucleobase transporters and named SVCTs (Sodium-Dependent Vitamin C Transporters). The high capacity/low affinity transporter of vitamin C, SVCT1, is particularly implicated. This transport process in intestinal epithelium is saturable and highly dose-dependent. On the other hand, its release into the blood stream is less elucidated. DHA is accumulated in cells through facilitated diffusion via sodium-independent facilitative glucose transporter (GLUTs), in particular GLUT 1 and GLUT3. Once inside the cell, DHA van be converted to ascorbate by

Fig. 25 (continued) GluUR, glucoronate reductase; GMD, GDP-D-mannose-4,6-dehydratase; GER, GDP-4-keto-6-deoxymannose,3,5-epimerase-4-reductase; GME, GDP-D-mannose epimerase; GMP, GDP-D-mannose-pyrophosphorylase; GPP, L-galactose-1-phosphate phosphatase; GulDH, L-gulose dehydrogenase; GulPP, L-gulose-1 phosphate phosphatase; GulLO, gulonolactone oxidase; L-GalDH, L-galactose dehydrogenase; MDHAR, monodehydroascorbate reductase; MIOX, myoinositol oxygensase; PGI, phosphoglucose isomerase; PME, pectin methyl esterase; PMI, phosphomannose isomerase; PMM, phosphomannose mutase; sAPX, stromal ascorbate peroxidase; tAPX, thylakoidal ascorbate peroxidase. Abbreviations of substrates: DHA, dehydroascorbate; MDHA, monodehydroascorbate.

intracellular reduction or transported to the blood stream by GLUT1 and GLUT2. Finally, a passive diffusion could play a potential role in its absorption, in particular at high concentrations. Indeed, at pH 5 in the small intestine, the proportion of unionized ascorbic acid goes from 0.1% to 15% (Du et al. 2012; Lykkesfeldt and Tveden-Nyborg 2019; Padayatty and Levine 2016). Eighty percent of ascorbic acid is absorbed for a dietary intake of 100 mg/day and about 75% for an intake of 1g/day; however, efficiency of absorption gradually decreases at higher intakes and falls to about 50% or less with doses above 1 g/day. The bioavailability of vitamin C from foods and supplements does not seem to be significantly different (EFSA NDA Panel 2013b; Institute of Medicine (US) Panel on Dietary Antioxidants and Related Compounds 2000).

After absorption, vitamin C is transported in plasma predominately in the free reduced form as ascorbate. No specific binding protein is known (EFSA NDA Panel 2013b). The peak plasma of vitamin C concentrations is reached 120–180 min after ingestion (Padayatty and Levine 2016). Negligible amount of oxidized vitamin C is present in plasma (Lykkesfeldt and Tveden-Nyborg 2019). A difference can be noted between women and men, because women reach the plateau of plasma ascorbate concentration at lower vitamin C intake. Moreover, the plasma ascorbate concentration decreases in pregnant women. Smokers have lower plasma ascorbate concentration than non-smokers (EFSA NDA Panel 2013b). In humans, plasma concentrations are firmly controlled when ascorbate is taken orally (Graumlich et al. 1997; Levine et al. 1996). The normal range for ascorbate in blood plasma is 40–80 μmol/L. Due to homeostatic regulation, steady-state plasma concentrations do not exceed 220 μmol/L even if the maximum tolerated oral dose is taken (3 g 6 times daily). By contrast, when ascorbate is administered parenterally, for a 50 g intravenous dose, plasma concentrations can reach 15,000 μmol/L (Padayatty et al. 2004). At these extracellular concentrations, vitamin C could be toxic for cancer cells, hence clinical research studies are conducted on the use of vitamin C by the IV route in the supportive care of cancer patients (Du et al. 2012; Fritz et al. 2014; Klimant et al. 2018; Ngo et al. 2019).

Distribution

Vitamin C is distributed from blood stream to all tissues. This distribution is highly compartmentalized. The cellular transport of ascorbate and DHA is mediated by active and facilitative transport systems respectively. SVCT1 and more specifically SVCT2 contribute to the cellular transport of ascorbate in various tissues and maintain intracellular levels of ascorbate under normal physiologic conditions. These transporters have different tissue distribution and vary by cell type. The low capacity/high affinity of vitamin C transporter, SVCT2, is expressed in a lot of tissues (EFSA NDA Panel 2013b; Lykkesfeldt and Tveden-Nyborg 2019). The cellular transport of DHA is mediated by facilitative transport by means of glucose transporters, in particular GLUT1, GLUT 3, and GLUT 4. In some cell types, the uptake of DHA is inhibited by physiological concentrations of glucose. To maintain the ascorbate pool, DHA is efficiently converted into ascorbate intracellularly by several cell types (Du et al. 2012; EFSA NDA Panel 2013b). In healthy individuals,

intracellular concentrations of ascorbate are higher than extracellular fluids. Tissue concentrations are in the range of mM, while they are in the range of μM in plasma. These concentrations are higher than those necessary for some biological activities of vitamin C, such as its actions as coenzyme, suggesting that vitamin C could have other yet unknown functions. Only erythrocytes have no SVCT transporters and have ascorbate level similar to that of plasma. Human erythrocytes have a recycling capacity of ascorbate from DHA (Du et al. 2012; Lykkesfeldt and Tveden-Nyborg 2019; Padayatty and Levine 2016). Adrenal glands and pituitary glands reveal the highest ascorbate concentrations. Liver and brain also show high concentrations (Du et al. 2012; Padayatty and Levine 2016).

26.4.2.2 Metabolism

In the body, the metabolism of ascorbate is closely related to its biological roles as free radical quencher and as cofactor, leading to its oxidation to DHA. Since DHA is readily reduced in ascorbate intracellularly by a number of cell types to maintain the ascorbate pool, relatively small amounts of the vitamin are lost during the catabolism. A part of DHA is irreversibly hydrolyzed to 2,3-diketogulonic acid, which can then be decarboxylated to L-xylonic acid and L-lyxonic acid. In some animals, these metabolites may enter in the pentose phosphate pathway (Lykkesfeldt and Tveden-Nyborg 2019). Other metabolites products have been identified as L-xylose, L-threonic acid, and oxalic acid. In humans, oxalic acid is the main metabolite produced from 2,3-diketogulonic acid and clinically identified in the urine. Indeed, urine is the main route of elimination of unchanged ascorbate and its metabolites. In the kidneys, due to its hydrophilic nature and low molecular weight, ascorbate is filtered by glomerulus through a hydrostatic pressure gradient and concentrated in the urine. Due to the formation of oxalic acid from DHA, in particular with high doses of vitamin C, its consumption could lead to calcium oxalate accumulation in the urinary space in individuals with impaired renal function (EFSA NDA Panel 2013b; Levine et al. 1996; Padayatty and Levine 2016). Likewise, with large intakes of vitamin C, unabsorbed ascorbate is degraded by the intestinal microflora, which may cause diarrhea and intestinal discomfort sometimes reported by consumers of large doses of vitamin C (EFSA NDA Panel 2013b; Institute of Medicine (US) Panel on Dietary Antioxidants and Related Compounds 2000).

In addition to dose-dependent absorption, a renal reuptake of ascorbate contributes to the regulation of body ascorbate content. This renal reuptake, highly concentration-dependent, takes place in the proximal renal tubules mainly by means of saturable active transport through SVCT1 transporters. Ascorbate could then release in the blood stream by a poorly understood diffusion mechanism. Passive reabsorption of vitamin C does not seem to play an important role. DHA formed from ascorbate in the renal epithelium is released in the blood stream by GLUT2 transporters located in the basolateral membrane. Under saturated conditions, ascorbate will be preferentially excreted, whereas at very low ascorbate intakes, no ascorbate will be excreted to limit the loss (EFSA NDA Panel 2013b; Institute of Medicine (US) Panel on Dietary Antioxidants and Related Compounds 2000; Lykkesfeldt and Tveden-Nyborg 2019).

Vitamin C is secreted in breast milk and the mean of vitamin C concentration in human milk from lactating women without vitamin C supplementation is in the range of 35–50 mg/L (EFSA NDA Panel 2013b).

26.4.3 Bioactivities

26.4.3.1 General Role

The two main functions of vitamin C are:

- To be a cofactor of enzymatic reactions
- To be a reducing and antioxidant agent

Vitamin C as a Cofactor of Enzymatic Reactions

By its capacity to donate reducing equivalents, vitamin C is an enzyme cofactor for several biochemical reactions mainly catalyzed by monooxygenases and dioxygenases, including those in which it is an actual cosubstrate. In mammals, vitamin C is the cofactor of more than 15 dioxygenases and at least three monooxygenases. These enzymes are the more often copper or iron-dependent proteins. Vitamin C reduces the active center metal ion of these enzymes and maintains the formed metal ions in a reduced state for their optimal activity (EFSA NDA Panel 2013b; Padayatty and Levine 2016):

- Vitamin C is particularly important for the biosynthesis of collagen, the most abundant protein in mammals, which represents approximately 25% of the total protein content. Collagen is the major component of the extracellular matrix that supports most tissues in particular connective tissues. This protein is found in skin, cartilage, ligaments, tendons, bone, and teeth. Its amino acid composition is atypical for proteins due to its high hydroxyproline content. Vitamin C is particularly implicated in the hydroxylation of the amino acids proline and lysine of the procollagen, a crucial step for later glycosylation and the formation of the triple helix structure of collagen. Vitamin C acts as a cofactor of three dioxygenases implicated in procollagen hydroxylation: procollagen-proline dioxygenase (three isoenzymes of **the collagen prolyl 4-hydroxylase** and **collagen prolyl 3-hydroxyase**) and procollagen-lysine 5-dioxygenase (**lysyl hydroxylase)**. A deficiency in vitamin C for a long period results leads to impaired collagen synthesis and scurvy (Du et al. 2012; Pullar et al. 2017).
- Vitamin C also contributes to the regulation of the activity of the hypoxia-inductible factors (HIFs), in particular HIF-1. Ascorbate is the cofactor of three isoenzymes of the **HIF prolyl 4-hydroxylase**, which regulate the activity of HIFs by the hydroxylation of specific proline residues on HIF-α, the regulatory oxygen-sensitive subunit of the heterodimeric HIF. Under normal conditions, HIF-1α is hydroxylated and degraded by proteasomes leading to the decrease of HIFs activity, whereas under hypoxia conditions or ascorbate depletion, the hydroxylation is inhibited, HIF-1α is stabilized, and forms a heterodimer with the oxygen-

insensitive subunit HIF-β leading to the activation of HIF activity. HIF-1 is also negatively regulated by FIH-1 (factor inhibiting HIF) or **asparaginyl hydroxylase** which also requires vitamin C as cofactor. So, ascorbate availability will mainly have an impact of immune cell function in hypoxic inflammatory and tumor surroundings by the regulation of HIFs activation. Because of more than 60 gene products are regulated by HIF, ascorbate availability may also have an significant impact on several cell functions among others erythropoiesis, angiogenesis, cell proliferation and survival, glucose and iron metabolism (Ang et al. 2018; Padayatty and Levine 2016).

- Vitamin C is also a cofactor for the **lysine-specific demethylase 1** (LSD1), a JmjC domain-containing histone demethylase belonging to the superfamily of the flavin adenine dinucleotide (FAD)-dependent amine oxidases. LSD1 is a Fe^{2+}-2-oxoglutarate dioxygenase. This enzyme is able to demethylate trimethylated lysines of histone via a redox process. LSD1 could play a significant role in different biological processes as cell proliferation or tumor progression. Ascorbate is also a cofactor for **ten-eleven translocation (TET) methylcytosine dioxygenases** that catalyze DNA demethylation. Ascorbate availability can influence the demethylation of histone and DNA. Due to the correlation of DNA hypermethylation and cancer development, as well as the impact of TET DNA demethylases and some histone demethylases on epigenetic remodeling of immune cells, ascorbate could have an impact in immune cell function and prevention of cancer (Ang et al. 2018; Camarena and Wang 2016; Chen et al. 2012; Du et al. 2012).
- Vitamin C plays a role, at least in vitro, in the biosynthesis of carnitine, a quaternary ammonium compound implicated in energy catabolism. It mainly contributes to the transport of fatty acids in mitochondria for ATP formation. Vitamin C is as a cosubstrate of two dioxygenases, **trimethyllysine hydroxylase** and **γ-butyrobetaine hydroxylase**. The role of vitamin C in the biosynthesis of carnitine in-vivo is more difficult to characterize (Dunn et al. 1984; Rebouche 1991a, 1991b, 1995).
- Vitamin C is a cosubstrate for the 4-hydroxyphenylpyruvate dioxygenase, a Fe (II)-containing non-heme oxygenase that catalyzes the second reaction in the catabolism of tyrosine (Moran 2005).
- Vitamin C is a cosubstrate for catecholamine biosynthesis, in particular the conversion of dopamine to noradrenaline in nervous system and in the adrenal glands. This conversion implicates the monooxygenase known as **dopamine β-hydroxylase** (Menniti et al. 1986).
- The activity of another monooxygenase, the **peptidylglycine α-amidating monooxygenase**, located in secretory vesicles, is also known to be dependent on vitamin C and also other electron donors. This enzyme catalyzed the first step of peptide amidation that is essential for the activity of several hypothalamic and gastrointestinal hormones such as oxytocin, vasopressin, cholecystokinin, and α-melanocyte-stimulating hormone (Kolhekar et al. 1997; Prigge et al. 1999, 2000).
- Vitamin C is implicated in the transformation of cholesterol to bile acids via the enzyme **cholesterol 7α-monooxygenase**, known also as cholesterol 7α-

hydroxylase. Reduced cholesterol conversion to bile acids induces cholesterol accumulation in the liver and blood and atherosclerotic modifications in coronary arteries (EFSA NDA Panel 2013b; Ginter 1989; Turley et al. 1976). Vitamin C also contributes to the regulation of steroid metabolism and steroidogenesis in the adrenal glands. These reactions require the microsomal enzymatic system containing cytochrome P-450 hydroxylase. It is also to note that reducing agents such as vitamin C may enhance the hydroxylation of aromatic drugs and carcinogens by hepatic cytochrome P-450 (EFSA NDA Panel 2013b).

These many enzymatic functions have been established in vitro but not usually in vivo (Padayatty and Levine 2016).

Vitamin C as a Reducing and Antioxidant Agent

Apart from its implication in several biochemical reactions as a cofactor, vitamin C is well-known to be a reducing agent or electron donor and may exert beneficial activities as a water-soluble antioxidant agent. As an electron donor with redox potential and by the relative stability and unreactivity of the ascorbate radical MDHA, vitamin C is a good free radical scavenger both in vitro and in vivo of reactive oxygen species and reactive nitrogen species, as well as singlet oxygen and hypochlorite. The one- or two-electron oxidation products, MDHA and DHA, are relatively nontoxic and are easily regenerated in vivo. This chemical and enzymatic regeneration goes through glutathione and NADH or NADPH reductases (Fig. 24).

Vitamin C could be part of the antioxidant defense system directly. It could for example protect the eye against oxidative damage, in particular against photoinduced free radicals, or the neurophils against ROS produced during phagocytosis. Vitamin C also inhibits the low-density lipoprotein (LDL) oxidation by scavenging ROS before the initiation of lipid peroxidation, reducing atherosclerosis (Garland 1991' Institute of Medicine (US) Panel on Dietary Antioxidants and Related Compounds 2000; Jialal and Devaraj 1996; Moser and Chun 2016). Vitamin C is also responsible for antioxidant protection indirectly by the regeneration of other biological antioxidants such as glutathione and β-carotene from their respective one-electron oxidation products. It is able to recycle vitamin E by reducing α-tocopheroxyl radicals produced via scavenging of lipid radicals (Edge and Truscott 1997; EFSA NDA Panel 2013b; Institute of Medicine (US) Panel on Dietary Antioxidants and Related Compounds 2000; Kagan et al. 1992).

Vitamin C can also improve dietary non-heme iron gastrointestinal absorption (Bendich and Cohen 1990; EFSA NDA Panel 2013b).

Vitamin C is commonly called as antioxidant, but this term seems to be misleading. Indeed, if some antioxidant functions have been demonstrated in vitro or in some cases in vivo, they are unproven in humans. Supplementation with vitamin C does not seem to display benefits in diseases caused by oxidative stress (Padayatty and Levine 2016).

Moreover, vitamin C could also exert a prooxidant effect in the presence of catalytic metals by reducing ferric to ferrous iron and by releasing ferrous iron from ferritin, which can lead to the formation of free radicals through the Fenton

reaction. However, the link between these effects and an excess of vitamin C intake is not clearly established (Du et al. 2012; EFSA NDA Panel 2013b).

Based on its different biological roles and on different symptoms linked to vitamin C deficiency, European Food Safety Authority (EFSA) authorized several health claims for food and food supplements containing at least 12 mg of vitamin C per 100 g, including (EFSA NDA Panel 2009d, 2010d):

- Vitamin C contributes to the protection of cell constituents from oxidative damage.
- Vitamin C contributes to normal collagen formation and the normal function of bones, teeth, cartilage, gums, skin, and blood vessels.
- Vitamin C contributes to the normal function of the nervous system.
- Vitamin C contributes to the normal function of the immune system.
- Vitamin C increases non-heme iron absorption.
- Vitamin C contributes to normal physiological functions.
- Vitamin C contributes to normal energy-yielding metabolism.
- Vitamin C can contribute to the reduction of tiredness and fatigue.
- Vitamin C contributes to the regeneration of the reduced form of vitamin E.

Moreover, EFSA authorized the claim "Vitamin C contributes to maintain the normal function of the immune system during and after intense physical exercise" only for food which provides a daily intake of 200 mg in addition to the recommended daily intake of vitamin C.

The health claims "Vitamin C contributes to the normal function of the immune system" and "Vitamin C contributes to the protection of cell constituents from oxidative damage" were also authorized for infants and young children from birth to 3 years of age (EFSA NDA Panel 2015b, 2017a).

26.4.3.2 Animal Studies

Like plants, the vast majority of animals are able to synthetize vitamin C through successive reactions which convert D-glucose-1-phosphate to L-ascorbic acid (Fig. 26). This biosynthesis of ascorbate takes place in the liver in mammals, while it is produced in the kidney in fish, amphibians, and reptiles. An inversion of configuration is observed during the biosynthesis due to the formation of a hydroxymethyl group in L-gulonate from the aldehyde function of D-glucuronate. The last step of the biosynthesis leads to the release of H_2O_2, which is not the case in plants. As discussed above, only humans and some animals, among other primates, guinea pigs, bats, and some birds, have lost the ability to synthetize vitamin C due to the highly mutation of L-gulonolactone oxidase that catalyzes the last step in the biosynthesis (Linster and Van Schaftingen 2007; Smirnoff 2018).

A lot of in vivo studies were performed to evaluate the biological activities and bioavailability of vitamin C. Different animal models were employed. For example, rabbits were formerly used to study the effect of ascorbic acid in atherosclerosis, whereas guinea pig was used to elucidate the role of ascorbic acid in the regulation of cholesterol metabolism. The development of model of chronic latent scurvy in the

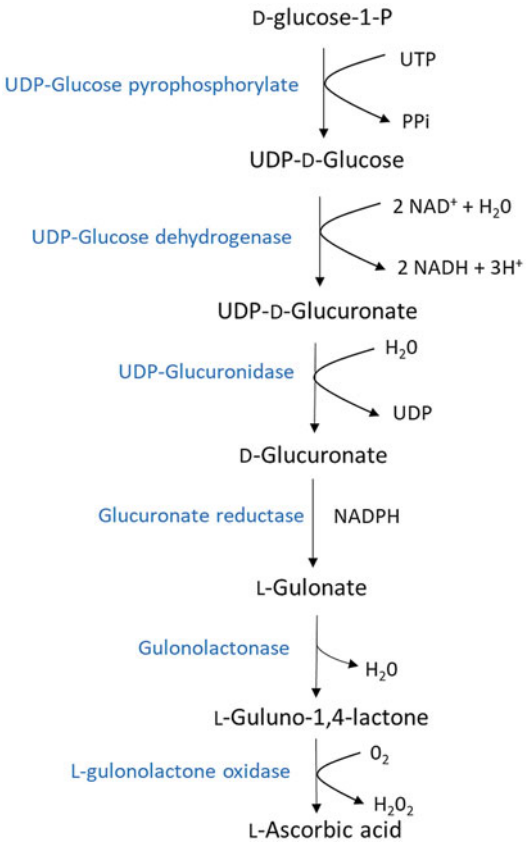

Fig. 26 Biosynthetic pathway of ascorbate in animals. (Adapted from (Linster and Van Schaftingen 2007; Smirnoff 2018))

guinea pig in the 1970s led to significant scientific advances in this domain (Turley et al. 1976). The naturally vitamin C-deficient guinea pig is the model of choice to bioavailability studies. But, genetically scorbutic animal models, such as the Osteogenic Disorder Shionogi (ODS) rats, the L-gulono-γ-lactone oxidase (Gulo−/−) knockout mouse, and the spontaneous bone fracture (sfx) mouse, were developed (Carr and Vissers 2013; Maeda et al. 2000; Mizushima et al. 1984; Mohan et al. 2005). More recent models such as SMP30 (Senescence Marker Protein 30) knockout mice are also employed. These mice develop symptoms of scurvy when subjected to a vitamin deficient diet (Ishigami 2010; Son et al. 2018).

26.4.4 Benefits (Human Studies)

The role of vitamin C in Humans was studied at least since the eighteenth century with the spread of **scurvy** among sailors during the age of exploration. However, this pathology was already known in antiquity. Scurvy is the consequence of a vitamin

Fig. 27 Painting showing some sailors infected by scurvy

C-depleted diet, but the symptoms appear after approximately 1 month of privation. It was precisely the case of long sea travels with a prolonged lack of fresh vegetables and fruits in food diets (Padayatty and Levine 2016). Two million sailors would have been affected by this disease. In 1747, James Lind conducted the first "clinical trial" on several sailors and showed that Citrus were effective in the treatment of scurvy (Fig. 27). At present, this disease is rare but continues to exist, in particular in people affected by malnutrition. It also occurs in adults and children with mental disorders, people with bad eating habits or alcoholism, and older people without medical supervision (Agarwal et al. 2015; Fiorini et al. 2018; Kothari et al. 2020; Marik and Liggett 2019; Urueña-Palacio et al. 2018). Scurvy symptoms can be linked to a total body pool of less than 300 mg and a plasma ascorbate concentration below 10 μM (EFSA NDA Panel 2013b; Institute of Medicine (US) Panel on Dietary Antioxidants and Related Compounds 2000). However, physical signs could only appear at lower plasma ascorbate concentration, as low as 3 μM (Padayatty and Levine 2016).

Many symptoms of scurvy seem to match with recognized roles of ascorbate in enzyme reactions, even if no experimental evidence has really established the link. The earliest symptoms of scurvy include fatigue, lassitude, and weakness that could be due to insufficient carnitine biosynthesis, as well as muscle weakness, anemia, and aching joints (EFSA NDA Panel 2013b; Padayatty and Levine 2016). The main symptoms are skin impairments and injuries by deterioration of elastic tissue, which underline the major role of ascorbate in stability of collagen in connective tissues. Scurvy is then associated with impaired bone growth and ossification in infants; tooth loss, joint pain, bone and connective tissues disorders, and poor wound healing with multiple clinical features in adults such as: bleeding into the skins, subcutaneous tissues, joints, muscles; breakdown of old wounds; bruising; gingival inflammation and bleeding; erythema, purpurea: arthralgia and joint effusions (Fig. 28). People infected by scurvy can also develop depression, mood changes, and

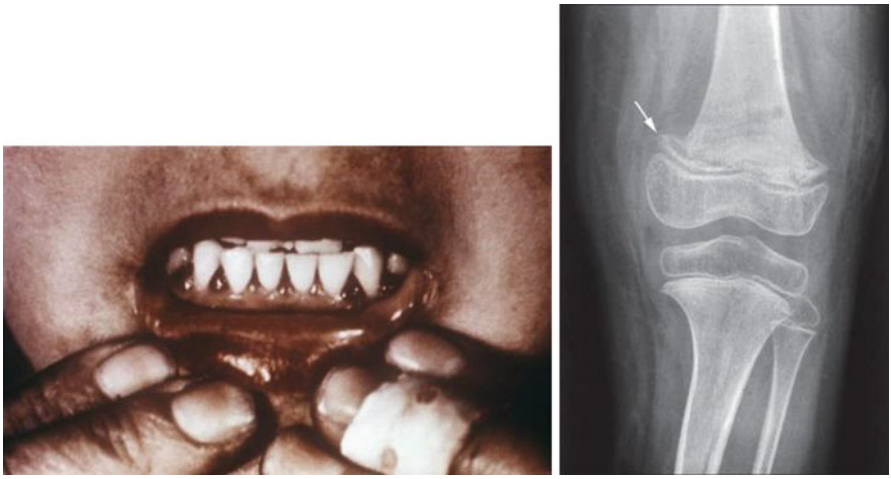

Fig. 28 Scorbutic gums in a patient and scurvy line indicated by an arrow on an X-Ray radiograph of the knee joint (wikipedia)

hypochondriasis, probably due to the impact of ascorbate in dopamine hydroxylation. A dyspnea can be also observed in some cases. The diagnosis is a clinical examination, radiographs with X-rays, and improvement after treatment (Fig. 28). A useful mnemonic for memorize symptoms of scurvy is 4H: hemorrhagic signs, hyperkeratosis, hematologic abnormalities, and hypochondriasis. Multiple vitamin deficiencies, as well as some other diseases such as osteomyelitis, can be confusing. The issue of scurvy is fatal without therapeutic care. The children are treated with vitamin C 100–300 mg daily and adults 500–1000 mg daily for at least 1 month or until symptoms disappear (Agarwal et al. 2015; EFSA NDA Panel 2013b; Padayatty and Levine 2016).

European Food Safety Authority established an Average Requirement (AR) of 90 mg/day for men and 80 mg/day for women, as well as a Population Reference Intake (PRI) of 110 mg/day for men and 95 mg/day for women. The PRI for other populations are specified in the Table 11 (EFSA NDA Panel 2013b). These references are determined on the basis of a plasma concentration around 50 μmol/L of ascorbate, indicative of an adequate status.

The Recommended Dietary Allowance (RDA) was estimated to be 90 mg/day for men and 75 mg/day for women in the USA and Canada. These values were set to maintain near-maximal neutrophil concentration with minimal urinary excretion of ascorbate. The requirement for smokers is increased by 35 mg/day due to the increasing of oxidative stress and metabolic turnover of vitamin C with smoking. The median dietary intakes of vitamin C for adults are estimated to 102 mg/day in the United States and 72 mg/day in Canada (Institute of Medicine (US) Panel on Dietary Antioxidants and Related Compounds 2000).

A significant number of in vitro studies have underlined the physiological role of vitamin C on cellular functions and enzymatic reactions. However, these effects have

Table 11 Dietary reference values of vitamin C from EFSA, expressed in mg/day (EFSA NDA Panel 2013b)

Population	Population references intakes (mg/day)

Breastfeeding		+60

not been clearly demonstrated in vivo and remain unclear in clinical conditions, physiologic or pathologic, mainly due to the choice of the employed dose and the sigmoidal dose-concentration relationship of vitamin C (Padayatty and Levine 2016). As we discussed previously in the part "bioavailability," plasma concentrations in humans are firmly controlled when ascorbate is taken orally because of homeostatic regulation. The steady-state plasma concentrations do not exceed 220 μmol/L even if the maximum tolerated oral dose is taken (18 g daily), which may limit the differences between control and treatment groups in clinical trials in terms of plasma and tissue vitamin C concentrations (Graumlich et al. 1997; Levine et al. 1996; Padayatty and Levine 2016).

A significant number of clinical trials exist, however, but with often small effects. The effect of vitamin C has been studied in particular for its role in the prevention, duration, and severity of the **common cold**. A Cochrane meta-analysis concluded that vitamin C was not effective in the prevention of the common cold when taken on a regular basis, at least 200 mg/day, and even at higher doses 1000 mg/day. However, taking vitamin C on a regular basis could reduce, according to the studies, the severity and the average duration, by 8% in adults and 14% in children, of the common cold. A vitamin C supplementation would have more impact on the reduction of incidence of colds among great athletes exposed to brief periods of severe physical exercise such as marathon runners (Hemilä and Chalker 2013). A more recent meta-analysis conducted on children underlined that vitamin C intake has no preventive effects but reduces the duration of upper respiratory tract infections (URTI) (Vorilhon et al. 2019). Due to the low cost and safety of vitamin C, its supplementation could be justified to reduce the duration and severity of common colds in children and adults, as well as upper respiratory tract infections especially in children under 6 years of age and/or submitted to high frequency of URTI (Hemilä and Chalker 2013; Vorilhon et al. 2019). Moreover, EFSA estimated that the dietary

intake of vitamin C contribute to the normal function of the immune system in adults and in children under 3 years of age (EFSA NDA Panel 2009d, 2015b).

Other clinical trials focus in particular on the interest of vitamin C in the prevention and treatment of **cancer**. Some studies deal with the potential interest of a diet rich in vitamin C, through a normal food intake or oral supplementation, on the reduction of the risk of developing cancer. The conclusions of the different meta-analysis are not systematically converging and are rather in the demonstration of the absence of a relationship between dietary vitamin C intake and risk of cancer (Fang et al. 2015; Fulan et al. 2011; Harris et al. 2014; Hua et al. 2016; Long et al. 2019). However, an increasing fruit and vegetable intake, source of vitamin C, not antioxidant supplement use, could globally reduce the risk of chronic diseases such as total cancer and prevent premature deaths. Optimal intakes for chronic diseases prevention could be about 800 g/day for fruits and vegetables, 225 g/day for whole grains, and 15–20 g/day for nuts (Aune 2019; Aune et al. 2018). Other clinical trials relate to the interest of high doses of vitamin C intravenously in the treatment of cancer. Indeed, as already discussed in the part "metabolism," intravenous administration bypasses the homeostatic regulation and plasma concentrations can reach much higher values than by oral route, until 15 mmol/L. At these extracellular concentrations, vitamin C could be toxic for cancer cells, by a prooxidant process via the production of H_2O_2. But, other researchers postulate that vitamin C could act as an antioxidant and reduce then the secondary effects of radiotherapy and chemotherapy (Du et al. 2012; Fritz et al. 2014; Jacobs et al. 2015; Parrow et al. 2013; Wilson et al. 2014). In the current state of the knowledge, no sufficient evidence allows to suggest that ascorbate supplementation by the IV route can be recommended outside of a clinical trial (Jacobs et al. 2015; Wilson et al. 2014). However, recent studies showed a role of vitamin C in regulation of the cancer epigenome. Ascorbate also contributes to enzymatic reactions of histones demethylation and DNA demethylation (Camarena and Wang 2016; Du et al. 2012; Gillberg et al. 2018; Ngo et al. 2019). Prominent preclinical studies supported by well-elaborated clinical trials could bring valuable data to confirm the use of vitamin C by the IV route in the supportive care of cancer patients (Du et al. 2012; Ngo et al. 2019; Vissers and Das 2018).

Vitamin C could also prevent **postoperative atrial fibrillation in cardiac surgery** (Hemilä and Chalker 2019; Hemilä and Suonsyrjä 2017; Putzu et al. 2019; Shi et al. 2018). On the other hand, the results of clinical trials are not conclusive, and sometimes controversial, in the current state of knowledge, concerning the relationship between vitamin C intake and cardiovascular diseases (Al-Khudairy et al. 2017; Ashor et al. 2014, 2019) and between vitamin C intake and cognitive function (Crichton et al. 2013; Li et al. 2012; Travica et al. 2017).

26.4.5 Applications in Food

Vitamin C is mainly provided by plant species, in particular edible fruits and vegetables. Table 12 sums up major plant food sources of vitamin C, mainly according to the French Agency of Food Security (ANSES 2017), selected on the

Table 12 Vitamin C content of plant products, which are rich in vitamin C (ANSES 2017). Only vitamin C content superior to 24 mg/100 g and foods with confidence levels A–C are reported. In some cases, vitamin C content provides from other sources than ANSES 2017. The sources are then specified in footnotes

Category	Food	Total vitamin C (mg/100 g) (min–max values when available)
Algae	Ao-nori (*Enteromorpha* sp.), dried	35.4 (9.24–53.8)
	Dulse (*Palmaria palmata*), dried	83.6 (15.9–187)
	Nori (*Porphyra* sp.), dried	57.3 (2.18–193)
	Rockweed (*Ascophyllum nodosum*), dried	94.8 (0.21–239)
	Sea lettuce (*Ulva* sp.), dried	54.6 (0.28–267)
	Sea thong (*Himanthalia elongata*), dried	62.8 (27.5–133)
	Wakame (*Undaria pinnatifida*), dried	28 (2.84–137)
Fruits	Acerola (*Malpighia emarginata*), raw	**1677**[a]
	Baobab fruit pulp	**280–300**[b]
	Blackberry, raw	36.4
	Blackcurrant, raw	181 (113–255)
	Breadfruit, raw	29
	Camu-camu (*Myrciaria dubia*), raw	**2800 (2400–3000)**[c]
	Cauliflower, frozen, cooked	31.3
	Currant, raw	45 (25–70)
	Ditax fruit pulp (*Detarium senegalense*), raw	**1200–2200**[d]
	Elderberry, berries, raw	32.5 (29–36)
	Goji berries (*Lycium barbarum*, *Lycium chinense*), raw	55.29 (33.15–113.8)[e]
	Gooseberry, raw	29 (18–56)
	Grapefruit, pulp, raw	33.3
	Guava pulp, raw / nectar	**228** (173–283) / 36
	Indian gooseberry (*Phyllanthus emblica*), raw	445[f]
	Kakadu plum (*Terminalia fernandinia*), raw	**3000 (1000–5300)**[g]
	Kiwi, pulp and seeds, raw	92.7 (77.4–118)
	Kumquat seedless, raw	45 (41–49)
	Lemon, zest, raw / pulp, raw / pure juice / homemade juice	**129** / 51 (49–53) / 24.8 / 42.4 (32.1–46)
	Lime, pulp, raw / homemade juice	29.1 / 30 (27.3–33.8)
	Litchi, pulp, raw	71.5
	Mandarin, pulp, raw	26.7 (22.1–34)
	Mango, pulp, raw	32.1 (13.2–92.8)
	Orange, pulp raw / homemade juice / pure juice	57 (53.2–60.8) / 52.6 (45.6–61.7) / 37 (19.1–69)
	Papaya, pulp, raw	61.4 (24.6–93.1)
	Passion fruit, pulp and seeds	30
	Pineapple, pulp, raw	36.4 (7.9–70.7)
	Pink grapefruit, pulp, raw	31.2 (22.6–36.3)

ground of established regulatory thresholds for any food to be considered a source of vitamin C (>12 mg/100 g) or rich in vitamin C (>24 mg/100 g). The most common edible fruits in Europe with higher content of vitamin C are blackcurrant, guava, kiwi, litchi, strawberry, and citrus (orange, lemon, pomelo). Some wild fruits, such are Sea buckthorn and rose hips, are more rich in vitamin C with about 400 mg of vitamin C per 100 g. However, less common tropical fruits have much higher contents, including kakadu plum fruits (3000 mg of vitamin C per 100 g), Camu-Camu fruits (2800 mg of vitamin C per 100 g), and Ditax fruits (with a mean of 1700 mg of vitamin C per 100g). Some of these species are found in supplement foods as source of vitamin C. The most common edible vegetables are peppers (Solanaceae) and different cabbages (Brassicaceae) (Chuah et al. 2008; Domínguez-Perles et al. 2014). Another Brassicaceae species (*Cochlearia officinalis* L.) was commonly named *scurvy-grass*, because it was historically used to cure scurvy on board ships (Chauvet 2018). Some herbs such as parsley and some algae contain also significant contents of vitamin C (ANSES 2017).

Prolonged storage and cooking methods may reduce vitamin C content in food (Zhao et al. 2019). Among different home cooking procedures (boiling in water, steaming, pressure steaming, microwave heating and stir-frying without using water), the less suitable method seems to be boiling, which leads to high loss of vitamin C, in particular due to the high solubility of ascorbic acid in water. Microwave heating and stir-frying without using water seems to be more appropriate to preserve ascorbic acid (Bureau et al. 2015; Chuah et al. 2008; Lee et al. 2018). Indeed, thermal treatment can accelerate the conversion of ascorbic acid to dehydroascorbic acid, followed mainly by the hydrolysis of 2,3-diketogulonic acid (Barros et al. 2011; Chuah et al. 2008). Before cooking, it is best not to thaw frozen vegetables in order to prevent vitamin C to degradation (Nursal and Yücecan 2000).

26.4.6 Safety: Toxicity and Side Effects

The Panel on Dietary Antioxidants and Related Compounds in the USA and Canada determined a Tolerable Upper Intake Level (UL) for adults at 2 g/day. This UL is based on some adverse effects such as osmotic diarrhea and gastrointestinal disturbances (Institute of Medicine (US) Panel on Dietary Antioxidants and Related Compounds 2000). On the other hand, EFSA did not determine a UL. Vitamin C seems to be a low acute toxicity according to available studies conducted in animals. The agency also notes that the most defined side effects at high doses (3–4 g/day) are reversible gastrointestinal intolerance and diarrhea, due to the degradation of unabsorbed ascorbate by the intestinal microflora. Some renal effects can be observed due to the urinary excretion of oxalic acid, in particular in individuals with impaired renal function. As discussed above, vitamin C also could exert a prooxidant effect in the presence of catalytic metals leading to the formation of free radical through the Fenton reaction. However, the link between these effects and an excess of vitamin C intake is not clearly established (Du et al. 2012; EFSA NDA Panel 2013b).

26.4.7 Marketed Products

According to reference website for healthcare professionals in France, ascorbic acid can be marketed orally in some pharmaceutical specialties alone at a dose of 1 g per tablet or in association with sodium ascorbate sodium to treat asthenia or vitamin C deficiency. But, ascorbic acid can be also associated, at doses varying between 100 mg and 500 mg per tablet, with other active ingredients to manage different diseases such as for example quinine to take care muscle cramps, with arginine aspartate to manage asthenia, with paracetamol and antihistamines to manage fevers and nasopharyngitis, and with citroflavonoids or rutoside/α-tocopherol to treat hemorrhoids and venolymphatic insufficiency. Ascorbic acid can be also proposed in solution for intravenous injection (1 g/5 ml) to treat vitamin C deficiency (Vidal 2013).

Ascorbic acid can also be found in food supplements, alone, in combination with other vitamins and minerals or in combination with antioxidant plant extracts. The proposed doses are in general 500 or 1000 mg per tablet. Vitamin C can be synthetic or with natural origin. Different fruits with high content of vitamin C are marketed in food supplements, such as acerola, rose hips, camu-camu, and goji fruits.

Unlike animal studies, all bioavailability studies conducted in humans have demonstrated no differences between synthetic and natural vitamin C, whatever the methodology used (subject population, study design, intervention used). The few differences observed in pharmacokinetic studies in humans seem to have a minimal physiological impact (Carr and Vissers 2013).

Oral liposomal vitamin C formulations have been developed to improve its stability and enhance its bioavailability (Caritá et al. 2020; Davis et al. 2016; Łukawski et al. 2019).

26.4.8 Patents

A considerable number of patents have been filed on vitamin C since its isolation and identification in the 1930s. The patents relate in particular to optimization of its synthesis, development of methods of extraction from natural sources, microbial production, biotechnological production, development of analytical methods for detection and identification of vitamin C in different matrix, development of galenic formulations to improve the stability, and the bioavailability of vitamin C for pharmaceutical, agro-food, or cosmetic applications.

26.4.9 Perspectives

The ongoing interest for ascorbic acid-related disorders in major health concerns such as cancer show that various aspects in its biological roles are still to be deepened and underline the potential of vitamin C intake intravenously. Moreover, the sigmoidal dose-concentration relationship of vitamin C when taken orally should not to be overlooked in clinical trials. More fundamental research is also needed to provide evolutionary features to explain the lack of vitamin C synthesis in some mammals, in particular humans.

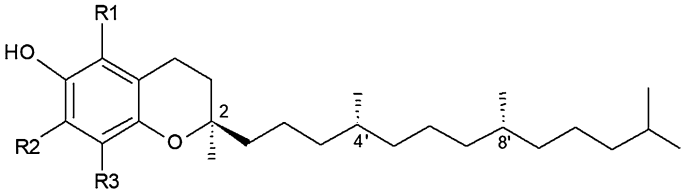
26.5 Vitamin E: α-Tocopherol

26.5.1 Bioactive Constituents

Vitamin E is a liposoluble vitamin which can be considered as a mixture of eight naturally occurring forms, including four tocopherols (α, β, γ, δ) and four tocotrienols (α, β, γ, δ), called tocochromanols. Their structure, relatively simple, is composed of a polar hydroxylated ring system (chromanol ring) and a long apolar isoprenoid side

chain. The hydroxyl group carried by the chromanol ring can donate a hydrogen atom to reduce free radicals, whereas the hydrophobic side chain permits the penetration of the vitamin into biological membranes. The different forms (α, β, γ, δ) are determined by the number and position of methyl groups on the chromanol ring. Tocopherols differ from tocotrienols only by the nature of the hydrophobic chain. The saturated phytyl side chain of tocopherols is replaced by a geranylgeranyl side chain, an unsaturated chain with three double bonds. Tocopherols have three chiral centers in positions 2, 4′ and 8′, leading to the formation of eight possible stereoisomers, but only the *RRR* stereochemistry of tocopherols occurs naturally in plants (Fig. 29). The naturally occurring *RRR*-α-tocopherol (formerly and incorrectly named *d*-α-tocopherol) is the unique physiologically active form because is maintained in human plasma by means of its preferential interaction with liver α-tocopherol transfer protein (α-TTP). Thus, some agencies, such as EFSA, consider vitamin E as being α-tocopherol only, with a molecular mass of 430.71 Da. Synthetic vitamin E, all racemic- (*all rac*)-α-tocopherol (formerly and incorrectly called *dl*-α-tocopherol), contains the eight stereoisomers of α-tocopherol in equal amounts. Only 2*R*-stereoisomeric forms (*RRR*-, *RSR*-, *RRS*, and *RSS*-α-tocopherol) are maintained in human plasma; the 2*S*-stereoisomeric forms (*SRR*-, *SSR*-, *SRS*, and *SSS*-α-tocopherol) have low affinity to α-TTP and are rapidly metabolized in liver (Azzi 2019; EFSA NDA Panel 2015c; Fritsche et al. 2017; Institute of Medicine (US) Panel on Dietary Antioxidants and Related Compounds 2000). Tocotrienols in plants are found with one asymmetric center in the R configuration (2R) and three double bonds, two of them, in positions 3′ and 7′, are in the "E" configuration. Historically, vitamin E was discovered in 1922, isolated in 1935, identified and first synthesized in 1938. Because the first activity for this vitamin was recognized as essential for fertility and fetal development in rats, the name "tocopherol" was given and comes from the Greek *tókos* meaning "birth" and *phérein* meaning "to bear or carry" (Evans and Bishop 1922; Fernholz 1938; Karrer et al. 1938). However, the essentiality of this function has never been confirmed in humans, except for one case report reporting the successful birth in woman with recurrent spontaneous abortions after administration of tocopherol nicotinate 300 mg/day (EFSA NDA Panel 2015c; Harada et al. 2005).

By its hydroxyl group on the chromanol ring, vitamin E has the ability to capture and stabilize by resonance the electron of free radicals in membranes and in plasma lipoproteins. It is a chain-breaking antioxidant and a peroxyl radical scavenger which mainly preserves the integrity and thus the bioactivity of long-chain polyunsaturated fatty acids in membranes of cells. It protects fatty acids from lipid peroxidation (Traber and Atkinson 2007). Thus, α-tocopherol scavenges lipid peroxyl radical ($LOO^{\bullet}$) before it attacks lipids. α-tocopherol is converted to α-tocopheroxyl radical ($E^{\bullet}$), which is resonance-stabilized, and a lipid peroxide (LOOH) is formed. The resulting vitamin E radical ($E^{\bullet}$) may attack lipids and react with another radical such as $LOO^{\bullet}$ or $E^{\bullet}$ to provide an adduct or a dimer. Vitamin E radical ($E^{\bullet}$) may also react with ascorbate or other hydrogen donors to form α-tocopherol to its reduced state, illustrating the vitamin E recycling (Fig. 30). Due to the fact that vitamin E to its reduced state is continuously restored, oxidized tocopherols emphasized in vitro are usually not found in vivo (Buettner 1993; Niki 2014; Traber and Stevens 2011).



α-tocopherol : R1 = CH_3; R2 = CH_3; R3 = CH_3

Fig. 29 Structures of tocopherols and tocotrienols. All tocopherols are represented in the *RRR*-forms. (Adapted from (Institute of Medicine (US) Panel on Dietary Antioxidants and Related Compounds 2000)

Vitamin E is an essential dietary constituent, because it cannot be produced in humans and in animals. As plants biosynthesize tocochromanols, the major sources in human nutrition are vegetable oils. Cereals, nuts, and green leafy vegetables can also provide vitamin E in diet. Tocochromanols occur exclusively in photosynthetic organisms including plant species, green algae, and some cyanobacteria (Mène-Saffrané and DellaPenna 2010). Tocochromanols also include plastochromanol-8 (PC8) which is not covered in this chapter, because it is not directly included in vitamin E (Kruk et al. 2014). The most abundant form of tocopherol isolated from photosynthetic tissues of many plant species, in particular in eudicots, as well as in cyanobacteria, is α-tocopherol in the *RRR* stereochemistry. However, α-tocopherol can be accumulated in seeds of some eudicots species, such as *Arabidopsis thaliana*. Unlike α-tocopherol, tocotrienols are less widespread in the plant kingdom. They are most abundant in monocot species, such as Poaceae and Arecaceae species, and are rare in eudicots. They are relatively rare in photosynthetic tissues and are more abundant in seeds and in latex. The tocochromanol biosynthetic pathway has been particularly studied in *Arabidopsis* and *Synechocystis* species. The major subcellular localization of tocochromanols in plant cells is plastids, such as leaf chloroplasts and seed plastids, even if other localizations have been highlighted including seed lipid bodies and mesophyll cells. As in animals, the major role of vitamin E is to maintain

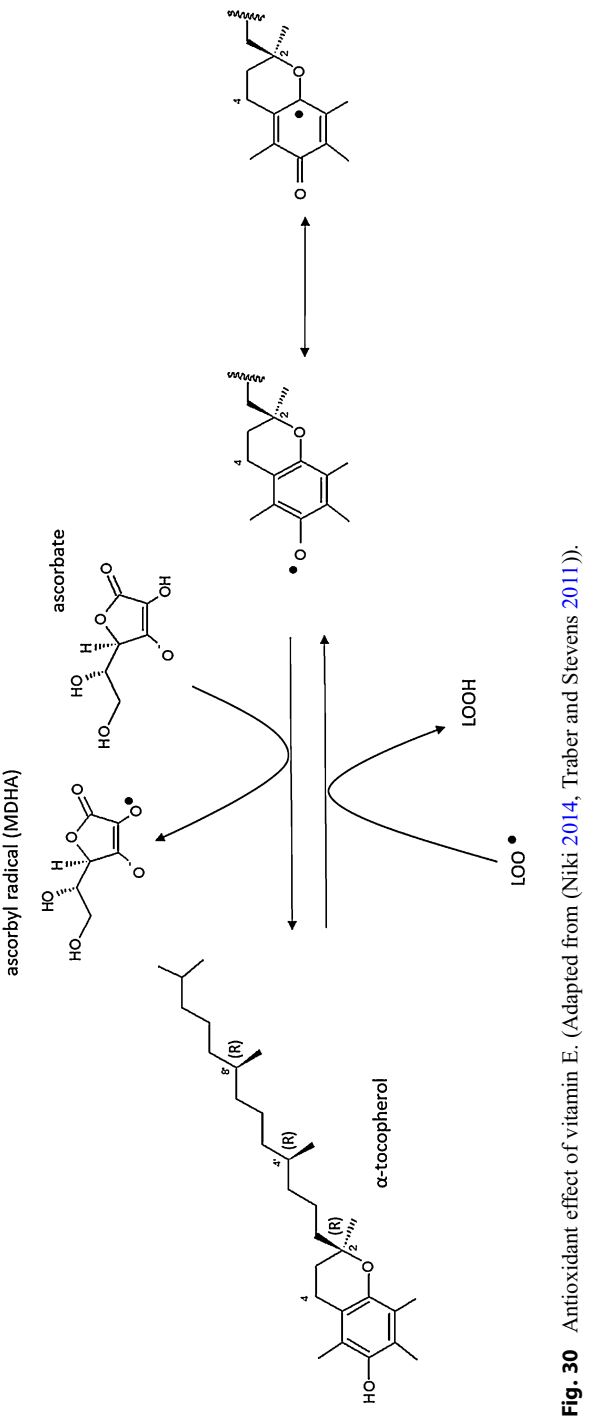

Fig. 30 Antioxidant effect of vitamin E. (Adapted from (Niki 2014, Traber and Stevens 2011)).

membrane integrity and stability by its protective effect against propagation of lipid peroxidation. Vitamin E can also contribute to the modulation of ROS accumulation and then play a role in photoprotection when leaves are subjected to photo-oxidative stress. This effect associated with modulation of lipid peroxidation can be linked to the role, recently underlined, of vitamin E in stress sensing and intracellular signaling (Muñoz and Munné-Bosch 2019).

Tocochromanol biosynthesis takes place in the plastids of plant cells, except for the first step that can be initiated in the cytoplasm (Fig. 31). This first step, common to all tocochromanols, derives from the shikimate pathway and consists of converting *p*-4-hydroxyphenylpyruvate (HPP) to homogentisate (HGA) via the *p*-4-hydroxyphenylpyruvatedioxygenase (HPPD) (Dörmann 2007; Fritsche et al.

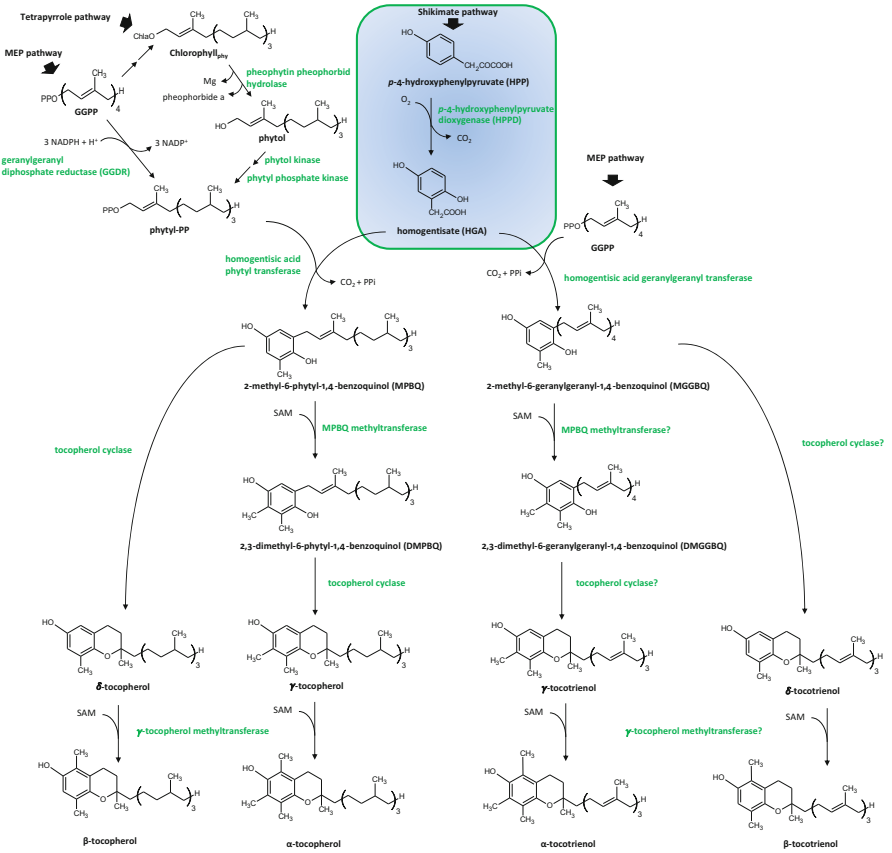

Fig. 31 Tocopherol and tocotrienol biosynthesis pathways. Adapted from (Fritsche et al. 2017; Mène-Saffrané and DellaPenna 2010; Muñoz and Munné-Bosch 2019). The first step framed in green is common of the two classes of tocochromanols. Enzymes implicated in tocopherol biosynthesis pathway were identified in *Arabidopsis thaliana*. The enzymes involved in the last steps of tocopherol synthesis, in particular methyltransferases and tocochromanol cyclases, could be the same as that involved in tocotrienol synthesis.

2017). The tocochromanol biosynthesis differs at the second step where a polyprenyl side chain is attached to HGA. This polyprenyl side chain derives mainly from isopentenyl diphosphate (IPP) from the methylerytrithol phosphate pathway (MEP) from 1-deoxy-D-xylulose 5-phosphate. Geranygeranyl diphosphate (GGPP) will be at the origin of the side chain of tocotrienols. On the other hand, phytyl-PP involved in tocopherol biosynthesis may have two origins. It can be provided by the reduction of GGPP by a geranylgeranyl diphosphate reductase or mostly by the recycling of free phytol derived from chlorophyll degradation. Phytol is released during chlorophyll breakdown via the intermediate chlorophyll$_{phy}$, chlorophyll linked to a phytyl moiety. This alternative metabolic way, known as the phytol recycling pathway, occurs in plants both in responses to environmental stresses and during developmental processes such as leaf or flowers senescence, seed maturation, or ripening of fruits (Fritsche et al. 2017; Mène-Saffrané and DellaPenna 2010; Muñoz and Munné-Bosch 2019; vom Dorp et al. 2015). In tocopherol biosynthesis, HGA is condensed with phytyl-PP by means of homogentisic acid phytyl transferase to form 2-methyl-6-phytyl-1,4-benzoquinol (MPBQ), which will be the common precursor to all tocopherols. MPBG can then be directly cyclized by a tocopherol cyclase to form α-tocopherol. It can also be methylated in position 3 by the MPBQ methyltransferase to form 2,3-dimethyl-6-phytyl-1,4-benzoquinol (DMPBQ) which will then be cyclized by a tocopherol cyclase to form γ-tocopherol. Finally, δ- and γ-tocopherols are methylated at the position C-5 by the γ-tocopherol methyltransferase to form β- and α-tocopherols, respectively.

In tocotrienol biosynthesis conducted mainly in seeds of monocots, HGA is condensed with GGPP by means of homogentisic acid geranylgeranyl transferase to form 2-methyl-6-geranylgeranyl-1,4-benzoquinol (MGGBQ), which will be the common precursor to all tocotrienols (Yang et al. 2011). The enzymes responsible for the methylation of MGGBQ into DMGGBQ, the cyclization of MGGBQ, and DMGGBQ into δ- and γ-tocotrienols, respectively, as well as their following methylation into β- and α-tocotrienols have not been yet reported from tocotrienols producing species. The enzymes involved in the last steps of tocopherols synthesis, in particular methyltransferases and tocochromanol cyclases, could be the same as that involved in tocotrienols synthesis (Fritsche et al. 2017; Mène-Saffrané and DellaPenna 2010; Muñoz and Munné-Bosch 2019).

26.5.2 Bioavailability and Metabolism

26.5.2.1 Bioavailability

Absorption

After ingestion, vitamin E is released from its food matrix, dissolved in the lipid phase of the bolus at gastric and duodenal levels, and then incorporated into lipid droplets. In the duodenum, vitamin E is combined by bile salts with other lipid digestion products mostly into mixed micelles, which can be diffused through the

unstirred water layer of the glycocalix area to reach the apical membrane of the enterocytes. Several factors can impact the vitamin E transfer to mixed micelles such as food matrix, as well as quantity and quality of fat and fat-soluble micronutrients provided by the meal (Borel et al. 2013b; EFSA NDA Panel 2015c; Reboul 2017, 2019b). Along with free tocopherols, tocopherol esters can be also provided by food supplementation and must be hydrolyzed in the lumen of the small intestine before absorption. This hydrolysis could be led by some pancreatic enzymes whose activity requires the presence of bile salts such as cholesteryl ester hydrolase, also known as bile salt-dependent lipase. Other pancreatic enzymes, including pancreatic lipase and pancreatic lipase-related protein 2, are not able to contribute to this hydrolysis. The absorption of the free and esters forms are similar in healthy subjects even in absence of digestive enzymes and bile salts, suggesting that other enzymes from enterocytes, such as endoplasmic reticulum esterases, could contribute to the hydrolysis of tocopherol acetates in an efficient manner (Desmarchelier et al. 2013; Lombardo and Guy 1980; Mathias et al. 1981; Nagy et al. 2013; Reboul 2017). Until fairly recently, vitamin E was thought to be absorbed only by passive diffusion, after dissociation of mixed micelles, through enterocyte apical membrane by transporters non-specific to tocopherols. However, after vitamin E intake, postprandial responses are very variable in humans. Some recent advances show that the absorption of α- and γ-tocopherol is in reality more complex and involves at least partially different receptors and transporters, in particular Scavenger Receptor Class B Type 1 (SR-B1), CD36 molecule, and NPC1-like intracellular cholesterol Transporter 1 (NPC1L1) (Reboul 2017, 2019b). No studies determine precisely the quantification of α-tocopherol in humans. Former studies using radioactive or deuterium-labeled α-tocopherol give variable results with a large range of reported mean α-tocopherol absorption, from about 10% to 80% for different fat intakes. In 2015, on the basis of some studies, the EFSA Panel estimated an average α-tocopherol absorption from a normal diet about 75% (Borel et al. 2013b, 2015; Traber and Stevens 2011). However, new insights underline the need to deepen our knowledge on vitamin E absorption in humans.

After intestinal absorption, tocopherols are incorporated in intestinal epithelial cells into nascent chylomicrons or into high-density lipoproteins (HDL) via the ATP-binding cassette transporter ABCA1. However, only α-tocopherol is maintained in plasma and tissues. α-tocopherol is secreted into the systemic circulation from chylomicrons along the lymphatic pathway. The plasma half-life of α-tocopherol is long, between 48 h and 60 h. By contrast, the plasma half-life of synthetic form is much shorter. The long plasma half-life of *RRR*-α-tocopherol is partly due to its rapid recirculation from the liver to the plasma. Remaining chylomicrons, containing newly absorbed vitamin E, are first captured by the liver. Vitamin E is then secreted from the liver in circulating lipoproteins, by its incorporation thanks to α-tocopherol transfer protein (α-TTP) into nascent very-low density lipoproteins (VLDL) in particular and in high density lipoproteins (HDL) (Galli et al. 2017; Institute of Medicine (US) Panel on Dietary Antioxidants and Related Compounds 2000; Kayden and Traber 1993; Traber and Stevens 2011). The selective accumulation of α-tocopherol and the facilitated exchange between liver and plasma is thus

explained by preferential affinity of α-TTP, a hepatic cytosolic protein, for α-tocopherol. The relative binding affinities of α-TTP for tocopherols are 100% for natural α-tocopherol, 38% for β-tocopherol, 9% for γ-tocopherol, and 2% for δ-tocopherol (Hosomi et al. 1997). α-TTP also protects α-tocopherol from excessive catabolism mediated by cytochrome P-450, in particular the degradation of α-tocopherol to α-carboxyethyl hydroxychromanol (α-CEHC) mediated by tocopherol-ω-hydroxylase. α-tocopherol bound to α-TTP will be less subject to metabolic degradation by tocopherol-ω-hydroxylase in comparison with other non-α-tocopherol congeners (Galli et al. 2017). Once secreted into the bloodstream, VLDL are converted into intermediate-density lipoproteins (IDL) and low density lipoproteins (LDL) by means of a lipoprotein lipase. The excess of VLDL surface constituents, including α-tocopherol, is moved to high-density lipoproteins (HDL) (Fig. 32) (EFSA NDA Panel 2015c).

Distribution

From lipoproteins, vitamin E is distributed into human extrahepatic tissues. α-tocopherol is the vitamin E form found at highest concentrations, followed by γ-tocopherol. Tocotrienols are habitually not detected in tissues (Galli et al. 2017). α-tocopherol is particularly detected in adipose tissues with more than 90% of the total body *RRR*-α-tocopherol pool. The α-tocopherol delivery to peripheral tissues can be explicated by at least two mechanisms: the release of α-tocopherol during the hydrolysis of triglyceride-rich lipoproteins by lipoprotein lipase and a receptor-uptake of LDL- and HDL-bound α-tocopherol (Fig. 32) (EFSA NDA Panel 2015c; Galli et al. 2017; Rigotti 2007).

26.5.2.2 Metabolism

The liver plays an essential role in the recirculation and metabolism of vitamin E, in particular α-tocopherol. In phase I, tocopherols and tocotrienols are metabolized by ω-hydroxylation in endoplasmic reticulum, followed by ω-oxidation and β-oxidation in peroxisome and mitochondrion to provide long-chain and intermediate-chain metabolites before the final formation of the catabolic end-products which are short-chain metabolites known as carboxy-ethyl-hydroxy-chromanols (CEHC). α-tocopherol will be transformed for example in α-CEHC (Fig. 33). In phase II, these metabolites can be then conjugated, sulfated, or glucuronided. All metabolites can be found in feces, whereas only short-chain metabolites will be found in urines (EFSA NDA Panel 2015c; Galli et al. 2017; Mustacich et al. 2010; Schmölz 2016). As previously raised, the degradation of α-tocopherol is less subject to the catabolic activity of tocopherol-ω-hydroxylase than other tocopherols and tocotrienols thanks to α-TTP. α-tocopherol bound to α-TTP is not catabolized by tocopherol-ω-hydroxylase, which has thus a stronger activity towards other tocochromanols. α-tocopherol will be thus preferentially distributed in tissues, while the other tocochromanols will be predominantly catalyzed in the liver (EFSA NDA Panel 2015c).

Sulfate and glucuronide conjugates will be found in urines and feces, but feces remain the main route of elimination of vitamin E. Some recent in vitro and in vivo studies underlined the regulatory potential of vitamin E metabolites, in particular

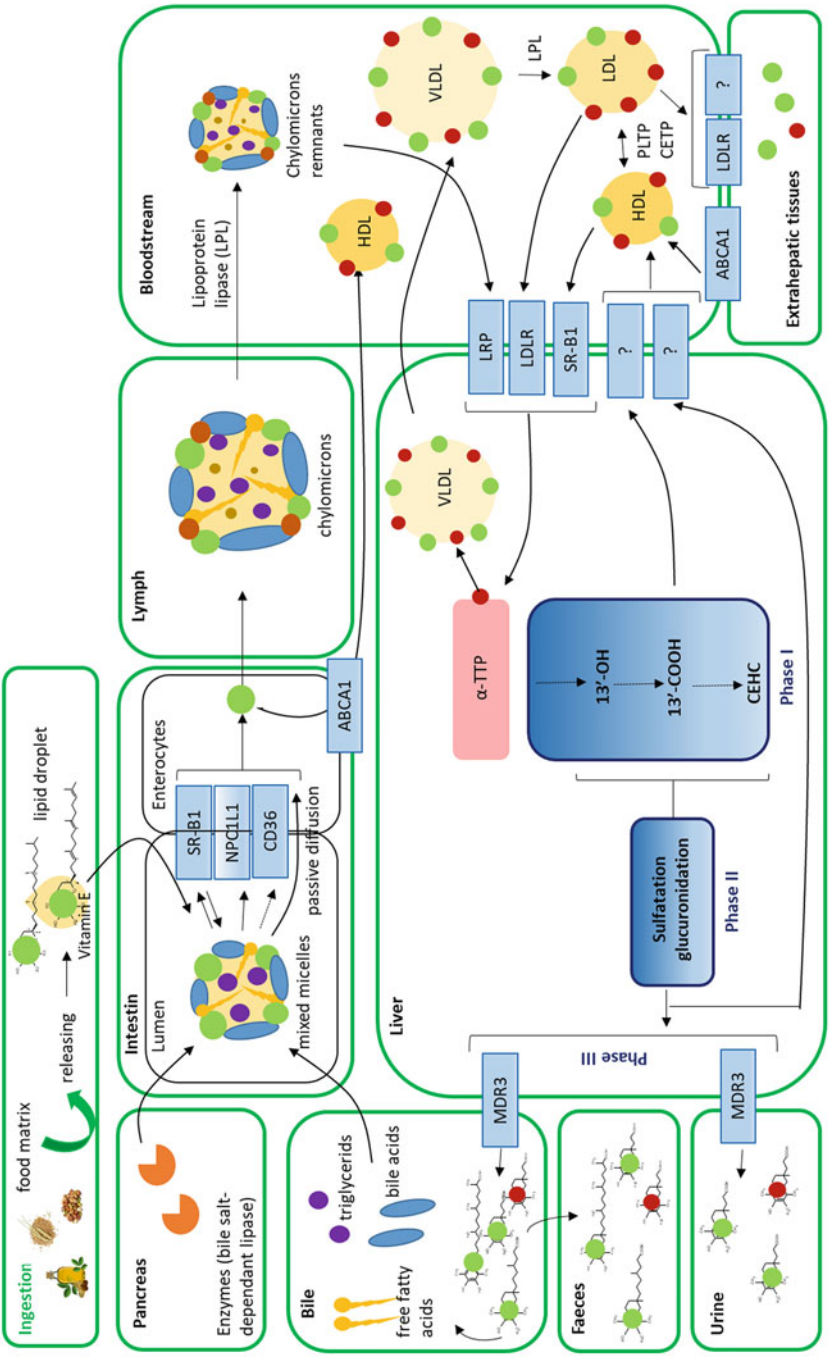

Fig. 32 (continued)

long-chain metabolites from γ-tocopherol and tocotrienols, in inflammatory processes (Birringer and Lorkowski 2019; Jiang 2014; Schmölz 2016). α-tocopherol is secreted into breast milk at about 4 mg/day during the first 6 months of exclusive breastfeeding (EFSA NDA Panel 2015c).

26.5.3 Bioactivities

26.5.3.1 General Role

Vitamin E as a Chain-Breaking Antioxidant

Vitamin E mainly operates as a chain-breaking antioxidant and thus prevents the propagation of free-radical reactions. It is especially implicated in lipid peroxidation, which consists of an oxidative degradation of lipids. Vitamin E is a peroxyl radical scavenger and particularly protects polyunsaturated fatty acids (PUFAq) within membrane phospholipids and plasma lipoproteins. Indeed, lipid peroxyl radicals formed react 1000 times faster with α-tocopherol than PUFAs. The antioxidant mechanism follows the mechanism already described in the first part "Bioactive molecules" (Fig. 30). α-tocopherol radicals and lipid hydroperoxide are thus formed after scavenging of lipid peroxyl radicals by α-tocopherol. α-tocopherol radicals formed may react with another radical to provide steady compounds, attack lipids, or react with an aqueous reducing agent such as ascorbate, selenium, or ubiquinol. This last reaction allows to continuously restore the antioxidant activity of vitamin E. By protecting PUFAs within membranes, α-tocopherol conserves membrane integrity and stability and has a significant role in the stability of erythrocytes and the protection of nervous tissues from oxidative stress. Vitamin E thus prevents

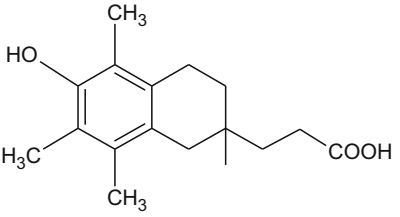

Fig. 33 α-CEHC, a major metabolite of α-tocopherol in the liver

Fig. 32 Absorption, distribution, and metabolism of vitamin E. Adapted from (Galli et al. 2017; Reboul 2019b; Schmölz 2016). ABCA1, ATP-binding cassette transporter; α-TTP, α-tocopherol transfer protein; CETP, cholesteryl ester transfer protein; 13'-COOH, 13'-carboxychromanol; HDL, high density lipoproteins; NPC1L1, Niemann-Pick C1-like intracellular cholesterol Transporter 1; 13'-OH, 13'-hydroxychromanol; PLTP, phospholipid transfer protein; SR-B1: Scavenger Receptor Class B Type 1; LDL, low density lipoproteins; LDLR, LDL receptor; LRP, LDL receptor-related proteins; VLDL, very low density lipoproteins.

hemolytic anemia and neurological symptoms occurring in patients deficient in vitamin E (EFSA NDA Panel 2015c; Institute of Medicine (US) Panel on Dietary Antioxidants and Related Compounds 2000; Traber and Stevens 2011).

Vitamin E as a Modulator of Signal Transduction and Gene Expression

A number of studies using different cell model systems underlined that vitamin E has also non-antioxidant properties. Indeed, the eight naturally occurring forms of vitamin E affect cell signaling and gene expression. Their potential of modulation is not equivalent, despite an equal capacity to chemically scavenge free radicals. Therefore, the differences observed in signaling effects for each natural vitamin E analogue would not be due only to a general antioxidant action, but could be explained by their differences in bioavailability and mostly by differential binding to enzymes, receptors, transcription factors, and membrane microdomains (Azzi 2018, Zingg 2015, 2019). *RRR*-α-tocopherol has notably the ability to modulate the functional activities of several enzymes directly implicated in cell signal transduction, leading to modifications of cellular behavior such as adhesion, apoptosis, autophagocytosis, differentiation, gene expression, immunity, inflammation, metastasis, migration, proliferation, secretion, senescence, and survival. Vitamin E affects the activity of specific enzymes such as protein kinases and phosphatases, lipid kinases and phosphatases, lipid metabolic enzymes, and enzymes involved in cAMP metabolism (Table 13). The cellular effects described are in general inhibitory and vitamin E may act by different mechanisms including direct binding to these enzymes, modulation of their redox regulation, and modification of their level

Table 13 Modulation of enzymatic activity of specific enzymes involved in signal transduction by vitamin E, according to (Zingg 2015)

Enzyme class	Enzymes modulated by vitamin E
Protein kinases	Protein kinase C (PKC)
	Protein kinase B (PKB/Akt)
	Protein tyrosine kinases (PTKs)
Protein phosphatases	Protein phosphatase 2A (PP2A)
	Pleckstrin homology domain leucine-rich repeat protein phosphatase, isoform 1 (PHLPP1)
	Protein tyrosine phosphatase (PTP)
Lipid kinases	Diacylglycerol kinase (DAGK)
	Phosphatidylinositol-3-kinase alpha (PI3Kα)
	Phosphatidylinositol-3-kinase gamma (PI3Kγ)
Lipid phosphatases	5′- and 3′-Inositol phosphatases (SHIP)
Lipid metabolic enzymes	5-, 12-, 15-lipoxygenases (5-, 12-, 15-LOX)
	Cyclooxygenase-2 (COX-2)
	Phospholipase A2 (PLA2)
Enzymes involved in cAMP metabolism	Adenylyl cyclase
	Phosphodiesterase

expression. *RRR*-α-tocopherol has in particular a central role in the modulation of protein kinase C (PKC) activity through several mechanisms. This negative regulation is the cause of inhibition of cell proliferation of different cell types including brain cells, cancer cell lines, fibroblasts, vascular smooth muscle cells, macrophages, mesangial cells, monocytes, macrophages, and neutrophils. The modulation of PKC activity by *RRR*-α-tocopherol is linked to pathophysiological situations among others inflammation, diabetic vascular complications and platelet aggregation (Azzi 2018; Brigelius-Flohé and Traber 1999; Cachia et al. 1998; Pédeboscq et al. 2012; Schneider 2005; Tasinato et al. 1995; Zingg 2015).

Vitamin E is also able to regulate the expression of genes involved in cellular signaling. The regulatory effect of vitamin E on many transcription factors often goes through an indirect mechanism, such as the modulation of signal transduction enzymes implicated in the regulation of their activity. However, in some cases, vitamin E is able to directly interact with the transcription factor and activate it. It is the case for pregnane X receptor transcription factor and for the estrogen receptor beta. The regulation of gene expression may lead up to the activation of additional signaling cascades as a secondary response (Table 14) (Zingg 2007, 2015).

The regulation of signal transduction by vitamin E can be also influenced by other mechanisms such as direct binding of vitamin E to transport proteins involved in signal transduction, modulation of membrane-protein interaction and protein translocation to the plasma membrane, modulation of plasma membrane properties, modulation of cell surface exposition of membrane receptors, modulation of transport and conversion of lipids to signaling mediators, conversion of vitamin E to active metabolites and lipid mediators, and conversion of cytochrome c into a peroxidase by α-tocopheryl phosphate (Zingg 2015, 2019). The modulation of CD36 scavenger receptor/fatty acids transporter by vitamin E may in particular influence many cellular signaling pathways relevant for physiological and pathophysiological cellular functions (Zingg 2019).

Table 14 Modulation of transcription factors by vitamin E, according to (Zingg 2015).

Transcription factor	Effect of vitamin E
Peroxisome proliferator-activated receptor gamma (PPARγ)	Upregulation of expression and increase of activity by indirect mechanisms
Nuclear factor erythroid-derived 2-like 2 (NRF2)	Upregulation of expression by indirect mechanisms
Nuclear factor kappa B (NFκB)	Inhibition of activation by indirect mechanisms
RAR-related orphan receptor alpha (RORα)	Downregulated with vitamin E deficiency, indirect mechanisms
Hypoxia-inducible factor 1 alpha (Hif1α)	Inhibition of activation by indirect mechanisms
Estrogen receptor beta (ERβ)	Direct binding of tocopherols and increase of activity
Pregnane X receptor (PXR)	Direct binding of tocopherols and increase of activity

Vitamin E as an Anti-inflammatory Agent

α-tocopherol is also known to have anti-inflammatory effects both in vitro and in vivo. At high doses, it decreased the release of some pro-inflammatory cytokines and decreases adhesion of monocytes to endothelium (Singh and Jialal 2004).

Despite these new findings, European Food Safety Authority (EFSA) authorized for the moment a unique health claim for food and food supplements containing at least 1.8 mg of vitamin E per 100 g, based on the cause–and-effect relationship between dietary intake of vitamin E and some biological functions: "vitamin E contributes to the protection of cell constituents from oxidative damage" (EFSA NDA Panel 2010e).

26.5.3.2 Animal Studies

There are of course numerous in vivo studies reporting the biological activities of vitamin E. The first study recognizing the essential role of vitamin E in fertility and fetal development in rats dates from 1922 (Evans and Bishop 1922). Vitamin E, by its antioxidant function, could protect the fetus during the period when it is most vulnerable by oxidative stress (Schneider 2005). However, this role has not been clearly established in humans. The role of vitamin E as a peroxyl radical scavenger and inhibitor lipid peroxidation was clearly highlighted experimentally in rats intoxicated with carbon tetrachloride (Corongiu et al. 1986; Niki 2014).

Some animal models were developed such as α-TTP knock-out mice (α-TTP -/- mice) for which the α-TTP has been made inactive by gene mutations (Azzi 2018). These mice were used to study the link between vitamin E deficiency and diseases in which oxidative stress play a role, such as atherosclerosis or neurodegenerative disorders. In order to consider the impact of vitamin E deficiency on the severity of atherosclerosis, these mice were crossed with apoE −/− mice (Schneider 2005; Terasawa et al. 2000; Ulatowski et al. 2014; Yokota et al. 2001). However, a lack of in vivo evidence of the necessary recycling of vitamin E and a lack of evidence of antioxidant damage in animal models in vitamin E deficiency are enquiring. In these models, no compensatory induction of the endogenous antioxidant system was observed. Moreover, despite a large number of significant clinical trials, few studies have shown a link between vitamin E and beneficial effects against oxidative stress based diseases (Azzi 2018).

26.5.4 Benefits (Human Studies)

Vitamin E deficiency is relatively rare and symptoms were not reported in individuals without any specific disease or with low intake of vitamin E in diet. Symptoms were mostly observed in population with familial isolated α-tocopherol deficiency (primary α-tocopherol deficiency) with mutations of genes coding for α-TTP or in patients unable to absorb correctly the vitamin due to different pathologies (secondary α-tocopherol deficiency) such as abetalipoproteinemia, cholestatic liver diseases, severe malnutrition, malabsorption, and cystic fibrosis. In these cases, serum α-tocopherol concentrations are low, in particular in patients with primary α-

tocopherol deficiency, in whom concentrations can go below 2.3 μmol/L. Clinical manifestations of vitamin E deficiency in humans can be characterized by hemolytic anemia, impairment of immune responses and mainly neurological symptoms such as ataxia, peripheral neuropathy with degeneration of large-caliber axons in sensory neurons, myopathy, and pigmented retinopathy. Adequate intake of vitamin E seems to be important for normal development in infants and young children (EFSA NDA Panel 2015c; Guggenheim et al. 1982; Institute of Medicine (US) Panel on Dietary Antioxidants and Related Compounds 2000; Nakagawa et al. 1984; Sokol et al. 1985; Traber and Stevens 2011).

Dietary reference values of vitamin E are mainly based on observed intakes. Previously, the Scientific Committee for Food used the generic term, vitamin E, for both tocopherols and tocotrienols. The content of vitamin E had been presented in α-tocopherol equivalents (α-TEs) (Scientific Committee for Food 1993). In the more recent report, based on available evidence and in line with other instances, EFSA Panel considers vitamin E as α-tocopherol only, including the naturally occurring form (*RRR*-α-tocopherol) and the other three synthetic 2R-stereosisomer forms (*RSR*-, *RRS*- and *RSS*-). Adequate intakes (AIs) were determined for children and adults on the basis of observed intakes of α-tocopherol and α-tocopherol equivalents in healthy populations with no apparent α-tocopherol deficiency in the EU. For infants (7–11 months), AIs are provided on the basis of assessed intakes in fully breast-fed infants followed by an extrapolation (Table 15). The Panel estimated that Average Requirements (ARs) and Populations Reference Intakes (PRIs) for vitamin E (as α-tocopherol) cannot be derived for adults, infants, and children (EFSA NDA Panel 2015c)

The Recommended Dietary Allowance (RDA) was estimated to be 15 mg/day (35 μmol/day) of α-tocopherol for both men and women in the USA and Canada.

Table 15 Dietary reference values for α-tocopherol from EFSA, expressed in mg/day (EFSA NDA Panel 2015c)

	Adequate intakes (mg/day)	
Population	Male	Female
Infants		
0–6 months	-	
7–11 months	5	5
Children		
1–3 years	6	6
4–6 years	9	9
7–10 years	9	9
11–14 years	13	11
Adolescents		
15–17 years	13	11
Adults*		
18–39 years	13	11
Pregnancy		11
Breastfeeding		11

Like EFSA Panel, in order to establish the human requirement for vitamin E, the Institute of Medicine (US) Panel only considers vitamin E as the naturally occurring form (*RRR*-) and the other three synthetic 2*R*-stereoisomer forms (*RSR*-, *RRS*-, and *RSS*-) of α-tocopherol. Other naturally occurring forms of vitamin E (β-, γ-, and δ-tocopherols and the tocotrienols) are not considered because, although absorbed, they are poorly recognized by the α-tocopherol transfer protein (α-TTP) and thus more metabolized in the liver (Institute of Medicine (US) Panel on Dietary Antioxidants and Related Compounds 2000).

As we mentioned previously, despite a large number of significant clinical trials conducted with vitamin E supplementation, few studies have shown a link between α-tocopherol intake and beneficial effects against oxidative stress based diseases. This observation can be explained by the fact that vitamin E does not only act as an antioxidant and that the diseases considered in the various studies are multicausal and are not linked solely to oxidative stress. Overall, large randomized clinical trials and some meta-analysis rather underlined a lack of efficacy of vitamin E supplementation in different categories of population to prevent atherosclerosis and cardiovascular disease (Bleys et al. 2006; Lee et al. 2005; Lonn et al. 2005; Ueda and Yasunari 2006), cancer (Graham et al. 1992; Kirsh et al. 2006; Klein et al. 2011; Lee et al. 2005; Leng et al. 2019; Lonn et al. 2005; Lotan et al. 2012; Wu et al. 2002), Alzheimer disease (Farina et al. 2017; Isaac et al. 2008; Kryscio et al. 2017; O'Brien et al. 2017; Rutjes et al. 2018), and age-related macular degeneration (Age-Related Eye Disease Study Research Group 2001; Evans and Lawrenson 2017; Taylor et al. 2002). Long-duration vitamin E supplementation could, however, reduce risk of death from bladder and kidney cancer, but well-designed cohort studies and randomized clinical trials are needed to confirm this observation (Jacobs 2002; Lin et al. 2019; Shen et al. 2015; Wang et al. 2014). Moreover, as already evoked for vitamin C, an increasing fruit and vegetable intake, source of vitamin E, not antioxidant supplement use, could globally reduce the risk of chronic diseases such as total cancer and prevent premature deaths. Optimal intakes for chronic diseases prevention could be about 800 g/day for fruits and vegetables, 225 g/day for whole grains and 15–20 g/day for nuts (Aune 2019; Aune et al. 2018). Vitamin E supplementation at 200 mg/day, to avoid adverse effects, could prevent aging-associated reductions in immune function in elderly human subjects (De la Fuente et al. 2008; Meydani et al. 1997; Pae and Wu 2017; Wu and Meydani 2014). Some studies underlined that vitamin E supplementation could be associated with improvement of immune functions and reduced risk of acquiring upper respiratory infections in some categories of elderly subjects (Hemilä et al. 2004, 2006; Hemila and Kaprio 2011; Meydani et al. 2004). However, these results are controversial (Graat et al. 2002) and could be explained by differences in study design and genetic differences in particular polymorphism (Pae and Wu 2017). The most convincing clinical studies concern the benefices of a vitamin E supplementation in adult patients with non-alcoholic fatty liver disease (NAFLD) and non-alcoholic steatohepatitis (NASH). In adults, vitamin E significantly improved liver function and provides biochemical and histological improvements. However, these positive effects are not observed in pediatric patients and in patients with type 2 diabetes (Amanullah et al. 2019; Anushiravani et al. 2019; Bril et al. 2019; Cankurtaran et al. 2006; Ji et al. 2014;

Pacana and Sanyal 2012; Said and Akhter 2017; Sanyal et al. 2010; Sato et al. 2015; Tsou and Wu 2019). α-tocopherol showed anti-inflammatory effects and it could be interesting in combination with other antioxidants to prevent inflammation-related diseases. Supplementation with α-tocopherol reduce serum C-reactive protein (CRP) levels in patients with cardiovascular diseases (CVD) and having associated risk factors for CVD such as smoking and diabetes. Further studies are needed to confirm this effect in humans (Murphy et al. 2004; Saboori et al. 2015; Schwab et al. 2015; Singh & Jialal 2004).

26.5.5 Applications in Food

Vitamin E is present in several food categories, including animal-based products such as butter, eggs, and fatty fish. However, it is mainly provided by plant species, with the highest contents in oilseeds, nuts and wheat germ. The richest source of vitamin E is wheat germ oil with 144.03 mg/100 g. Table 16 sums up major plant food sources of vitamin E, according to the EFSA Food Composition database (https://www.efsa.europa.eu/en/data/food-composition), selected on the ground of established regulatory thresholds for any food to be considered a source of vitamin E (>1.8 mg/100 g) or rich in vitamin E (>3.6 mg/100 g). The most abundant tocopherol forms found in food are α-tocopherol and γ-tocopherol. Vegetable oils vary in their content of different tocopherol forms. For example, wheat germ and sunflower oil are good sources of α-tocopherol, whereas soybean oil is rich in γ-tocopherol and wheat germ oil is rich in β-tocopherol (EFSA NDA Panel 2015c).

Overall, food preparation procedures have only minor effects on tocopherols and tocotrienols. Cooking and baking have the greatest impact on the loss of tocochromanols (Piironen et al. 1987). Unlike other antioxidant vitamins and some unsaturated fatty acids degraded due to oxidation, fried foods are often a good source of vitamin E (Fillion and Henry 1998). In a study conducted on immature seeds of five cultivars of common bean, the most abundant form of tocopherol found in fresh seeds was γ-form (about 90% of the total), followed by the α- and δ-forms. β-form was not present. The cultivar and the variety, as well as the method of preservation, had no impact on both tocopherol retention and vitamin E activity. Cooking process led to 13–28% decrease in total tocopherols and a 17–31% reduction of vitamin E activity (Słupski and Lisiewska 2013). In the framework of a study conducted on sorghum flours, all processing with dry heat increased the vitamin E content and its retention, unlike wet heat processing (Cardoso et al. 2014). α-tocopherol and γ-tocopherol are also the major tocopherol forms in peanut oil. Oven roasting increases gradually the tocopherol contents in roasted peanut oil (Juhaimi et al. 2018).

26.5.6 Safety: Toxicity and Side Effects

The Panel on Dietary Antioxidants and Related Compounds in the USA and Canada determined a Tolerable Upper Intake Level (UL) for adults at 1000 mg/day (2,325 μmol/day or 1500 UI/day) of any form of supplemental α-tocopherol. This

Table 16 Vitamin E content of plant products, which are at least sources of vitamin E (>1.8 mg/100 g), expressed in α-tocopherol equivalent from vitamin E activities.

Category	Food	Total vitamin E (mg/100 g) (min–max values when available)
Fruit	Avocados	3.23
	Bilberries (European blueberries)	1.87
	Blackberries	2.65
	Blackcurrants juice	1.88
	Dried apricots	3.95
	Dried prunes, raw / process baking / process cooking in water	2.53 / 4.36 / 1.83
	Rose hips and similar	4.14
	Sea buckthorns	3.05
Grains and grain-based products	Cereal bars mixed	4.12
	Cereal bran	2.36
	Corn chips	3.44

UL is based on bleeding, an adverse effect observed in animal models at high doses (Institute of Medicine (US) Panel on Dietary Antioxidants and Related Compounds 2000). The Scientific Committee for Food in Europe in 2003 determined a UL for adults, including pregnant and lactating women, at 300 mg α-tocopherol-equivalents per day, based on the determination of a No Observed Adverse Effect Level

(NOAEL) of 540 mg α-TE/day coming from the study conducted by Meydani and collaborators in 1998. The ULs for children were extrapolated and are ranged from 100 mg α-TE/day for children aged 1–3 years old to 260 mg α-TE/day for adolescents (15–17 years) (EFSA NDA Panel 2015c; Meydani et al. 1998). Discordant clinical trials relate to the link between high doses of vitamin E and the increase in all-cause mortality. A meta-analysis underlined that high-dosage ($\geq$ 400 IU/day) vitamin E supplement may increase all-cause mortality (Miller et al. 2005). However, a more recent meta-analysis showed that supplementation with vitamin E had no effect in all-cause mortality at doses up to 5500 IU/day (Abner et al. 2011). Another meta-analysis based on 18 randomized controlled trials in healthy people showed no effect on all-cause mortality with vitamin E supplementation at a dose 23–800 IU/day (Curtis et al. 2014). Some drug interactions can be observed with aspirin, warfarin, tamoxifen and cyclosporine A in the case of high doses vitamin E supplementation (superior to 300 mg/day). Vitamin E may potentiate anti-blood clotting action if taken concomitantly with aspirin and warfarin. It may reduce blood concentration of tamoxifen and cyclosporine A (Podszun and Frank 2014). Because of its anticoagulant properties, taking vitamin E is not recommended in patients with history of stroke or digestive ulcer. For the same reason, vitamin E intake should be stopped 1 month before any surgery

26.5.7 Marketed Products

As α-tocopherol is fat-soluble, it is usually esterified with acetic acid or succinic acid to form α-tocopherol acetate. Indeed, the esters are more chemically stable. After ingestion, they are de-esterified and absorbed as free α-tocopherol.

According to reference website for healthcare professionals in France, α-tocopherol acetate can be marketed orally in some pharmaceutical specialties at a dose of 500 mg per tablet to treat vitamin E deficiency. α-tocopherol acetate can be also marketed in injectable form. In association with ascorbic acid or rutin, α-tocopherol can be used in the care of capillary weaknesses, hemorrhoids, venolymphatic insufficiency, and vascular retinopathies (VIDAL 2016).

α-tocopherol, in general in the form of α-tocopherol acetate dissolved in vegetable oil, can also be found in food supplements, alone, in combination with other vitamins and minerals, or in combination with antioxidant plant extracts. The proposed doses range from 100 to 1000 IU per tablet. Vitamin E can be synthetic or with natural origin from seed oils. γ-tocopherol and tocotrienols are also available in some food supplements.

26.5.8 Patents

A considerable number of patents have been filed on vitamin E since its isolation and identification. The patents relate in particular to optimization of its synthesis, development of methods of extraction from natural sources, novel therapeutic

applications, development of galenic formulations to improve its solubility and to enhance its antioxidant activity for pharmaceutical, agro-food, or cosmetic applications.

26.5.9 Perspectives

Most of the research was focused on α-tocopherol. Additional studies are required to deepen its bioavailability and its physiological role. In-depth investigations on the role of other tocopherols (β-, δ- and γ-tocopherols), tocotrienols, as well as metabolic products, including short- and long-chain metabolites, could bring pathophysiological and pharmacological discoveries. The intake of high doses of vitamin E remains controversial and it seems better to privilege a diet rich in fruits and vegetables rather a vitamin E supplementation.

26.6 Vitamin K1: Phylloquinone

26.6.1 Bioactive Constituents

Vitamin K is a group of lipophilic compounds having in common the 2-methyl-1,4-naphtoquinone (menadione) moiety, which is substituted by a varying number of isoprenoid groups the first of which bears one double bond. The remaining isoprenoid units may vary in number and bear additional unsaturations if they are of microbial origin. In this case they are named menaquinones or vitamin K2. The plant-derived compound is called vitamin K1 (phylloquinone, phytomenadione) and consists of menadione and a linear diterpenoid mono-unsaturated (phytyl) chain (Fig. 34). Synthetic vitamin K may be simplified to the sole menadione moiety, making it possibly more water-soluble. This form is active but does not occur naturally.

Biosynthesis of phylloquinone in plants was described in *Arabidopsis thaliana* after elucidation of the main vitamin K pathway in cyanobacteria and bacteria (Basset et al. 2017). It is depicted in Fig. 35. It is derived from chorismate via its isomer isochorismate by isochorismate synthase (Garcion et al. 2008). Isochorismate is submitted to a series of three enzymatic reactions of a sole protein, encoded by the *PHYLLO* gene, that is comprised of modules that are homologous to separate bacterial proteins in the synthesis of menaquinones, producing *o*-succinyl benzoate (OSM), in chloroplasts (Gross et al. 2006). Cyclization leading to the naphtalenoid

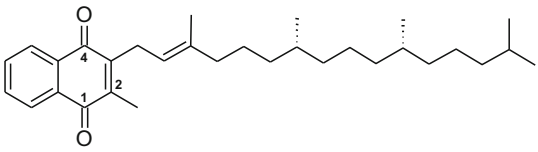

Fig. 34 Chemical structure of phylloquinone

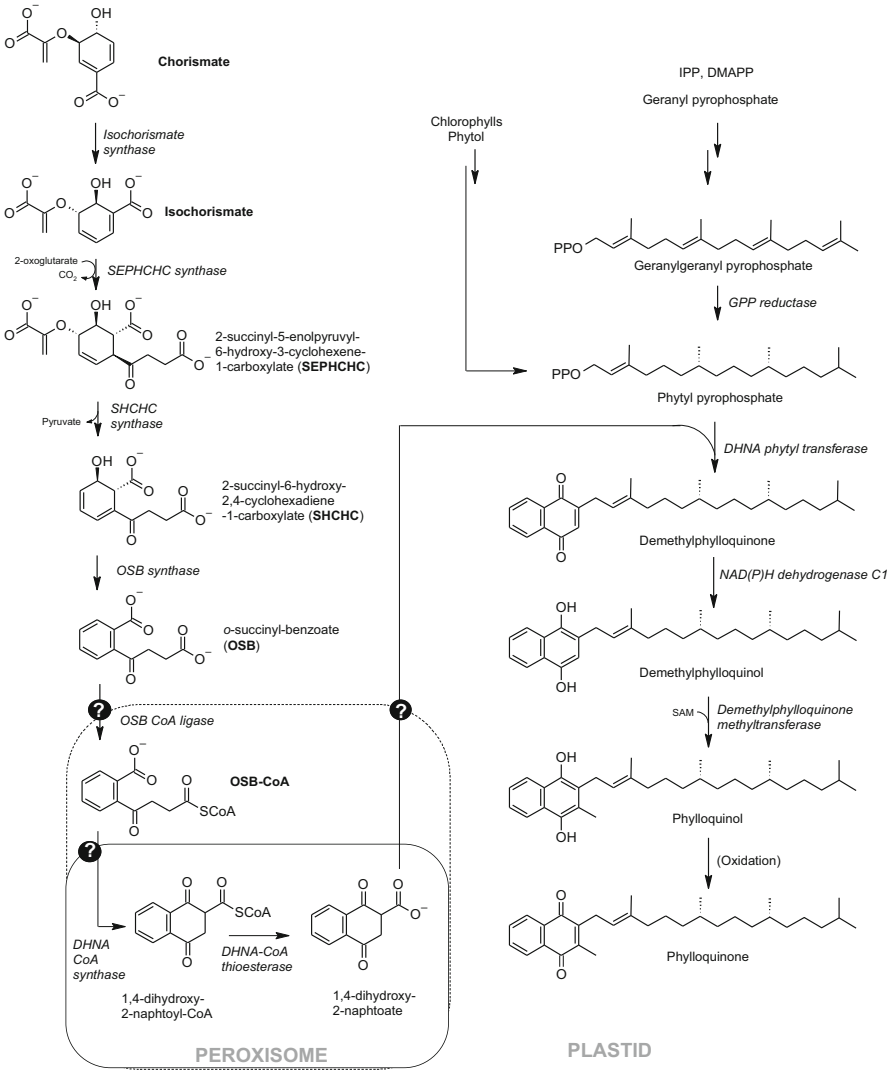

Fig. 35 Biosynthesis of phylloquinone

moiety requires involvement of peroxisomes. OSM activation by coenzyme A may take place also in plastids, but cyclization and subsequent thioester hydrolysis appear to be exclusively peroxisomal. This compartmentalization has been attributed to necessity as the cyanobacterial DHNA thioesterase gene was lost long ago (Reumann 2013). Carrier proteins for transport between cell compartments are not known presently. Attachment of the phytyl chain and decarboxylation lead to demethylphylloquinone (Shimada et al. 2005), which is processed by a methyltransferase, with S-adenosylmethionine as the donor. This last step is

performed on the reduced hydroquinone form of phylloquinone (phylloquinol), enabled by a type II NADPH Dehydrogenase (Fatihi et al. 2015). Because of its high susceptibility to oxidation, phylloquinol is considered to re-oxidize spontaneously to phylloquinone (McCoy et al. 2018).

This biosynthetic pathway exists in prokaryotes (with differences on the phytyl chain leading to menaquinones). Another pathway was described in bacteria (Dairi 2009). This "futalosine" pathway has not been reported in plants to this day.

26.6.2 Bioavailability and Metabolism

26.6.2.1 Bioavailability

Absorption

Humans are not able to synthesize vitamin K which therefore must be provided by the diet via intestinal absorption. Vitamin K1 accounts for about 90% of dietary vitamin K. The absorption of vitamin K1 seems to be relatively similar to that of vitamin E and could implicate the same type of transporters. Like vitamin E, vitamin K1 is released from its food matrix after ingestion and then incorporated into lipid droplets. In the small intestine, phylloquinone is combined by bile salts with other dietary lipids and products of pancreatic lipolysis into mixed micelles which can then reach the intestinal enterocytes (Booth and Suttie 1998; EFSA NDA Panel 2017b; Shearer et al. 1974, 2012; Yamanashi et al. 2017). Like in the case of other lipid-soluble vitamins, it was long assumed that vitamin K was absorbed only by passive diffusion, after dissociation of mixed micelles, through enterocyte apical membrane. But, recent discoveries showed that the absorption of vitamin K is also more complex and could involve the same receptors and transporters as those implicated in the absorption of vitamins A and E, in particular NPC1-like intracellular cholesterol Transporter 1 (NPC1L1), Scavenger Receptor Class B Type 1 (SR-B1), and Cluster of Differentiation 36 (CD36) (Goncalves et al. 2014a, b; Takada et al. 2015; Yamanashi et al. 2017). However, further studies are needed to fully grasp the implication of these different transporters in the absorption of phylloquinone. Absorption of vitamin K1 in healthy adults is very variable and can be ranged from approximately 4% to about 60–64% according to different studies. Indeed, absorption can be impacted by several factors in particular food matrix and fat and fat-soluble micronutrients provided by the diet. Absorption will be increased in presence of butter or oils. Sex and age does not seem to have any effect on absorption of vitamin K, but no data on phylloquinone absorption in infants and children are available. In the state of current knowledge, it is not possible to determine precisely an average absorption of vitamin K from the diet (EFSA NDA Panel 2017b; Jones et al. 2009).

After intestinal absorption, phylloquinone, the predominant form of vitamin K in blood, is mainly incorporated in intestinal epithelial cells into nascent chylomicrons and secreted into the systemic circulation from chylomicrons along the lymphatic pathway. However, even if some complementary studies are required, the ATP-

Binding Cassette Transporter A1 could be probably involved in the secretion of vitamin K into portal blood with intestinal HDL, as for vitamin E (Yamanashi et al. 2017). In blood, no specific carrier protein does not appear to have been identified. The main transporters are triglyceride-rich lipoproteins (TRL), with about 75% to 90% of plasma phylloquinone. The other transporters are chylomicrons remnants and very low-density lipoproteins (VLDL), and to a lesser extent low- and high-density lipoproteins (EFSA NDA Panel 2017b; Erkkilä et al. 2004). Vitamin K1 is rapidly absorbed. Its peak in plasma appears about 4–10 h after ingestion. Depending on studies, the plasma half-life of phylloquinone ranged between 0.22 h and 8.80 h. Vitamin K1 has a rapid removal rate from the circulation (Fig. 36) (EFSA NDA Panel 2017b; Halder et al. 2019).

Among menaquinones (vitamin K2), MK-7 exhibited greatest bioavailability and is rapidly absorbed such as vitamin K1 (Halder et al. 2019).

Distribution

The liver is the main organ that accrues absorbed phylloquinone transported in chylomicrons. Vitamin K1 enters the liver through the endocytosis of chylomicron remnants and involves different apolipoproteins and high-affinity lipopoprotein receptors. ApoE on the surface of chylomicrons is essential for transport and cellular internalization of vitamin K in liver. It facilitates high-affinity binding of lipoproteins to the LDLR (LDL-receptors) and other members of LDLR family such as LRP (LDL receptor-related protein) on the surface of hepatocytes. ApoB-48 is also implicated. Chylomicrons are then taken up by hepatocytes by receptor-mediated endocytosis. The major portion of vitamin K1 is stored in the liver. The rest will join the vitamin K2 and will be exported to other tissues by incorporation in VLDL, mainly bearing surface Apo-E and ApoB-100. In blood, VLDL undergoes dilapidation to form VLDL remnants (IDL) and then LDL (Akbari and Rasouli-Ghahroudi 2018; Shearer et al. 2012). The mean vitamin K1 concentration in the liver ranged from about 3 and 34 ng/g and is lower than the mean vitamin K2 concentration. The mean vitamin K1 percentage in the total content of vitamin K of the human liver is large, ranged from 2.4% to 74%, due to several reasons: conversion of phylloquinone to menadione and then to MK-4 by cellular alkylation, degradation of phylloquinone during tissue handling and storage, variability in phylloquinone intake (EFSA NDA Panel 2017b; Institute of Medicine (U.S.) and Panel on Micronutrients 2001; Shearer et al. 2012). Skeletal muscle contains little phylloquinone, but significant concentrations are found in the heart and some other extrahepatic tissues such as bone. Osteoblasts are also able to internalize vitamin K1 from various lipoproteins fractions, directly from chylomicron remnants or from LDL coming from the catabolism of VLDL previously formed in the liver. ApoE and ApoB-48 on the surface of chylomicrons, as well as ApoB-100 on the surface of LDL, are essential for transport and cellular internalization of vitamin K in bone. ApoB-100 facilitates binding of LDL to the LDLR and APOE and ApoB-48 facilitates binding of chylomicrons remnants to LDL receptor-related protein 1 (LRP1) on the surface of osteoblasts (EFSA NDA Panel 2017b; Shearer et al. 2012). Otherwise, during pregnancy, small quantities of phylloquinone pass through the placental barrier. The

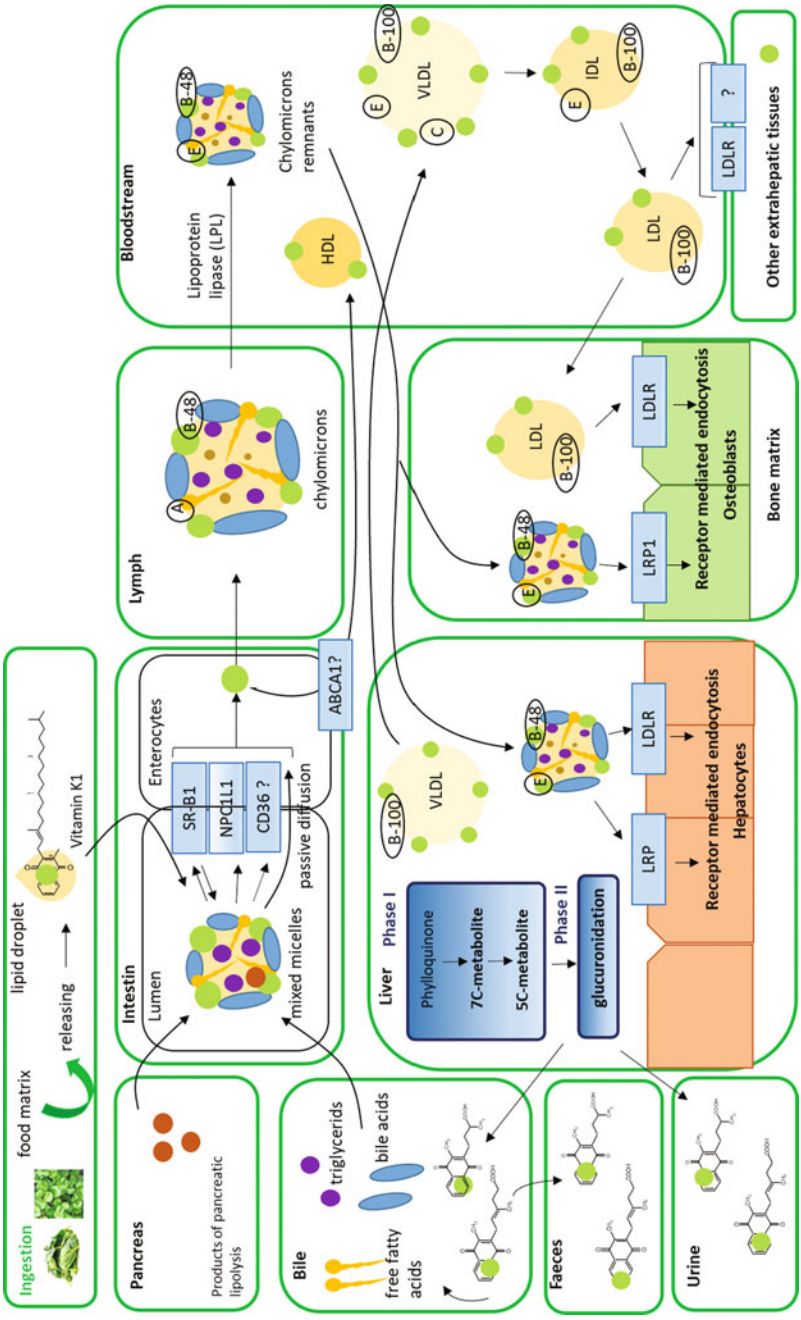

Fig. 36 (continued)

turnover of phylloquinone in the tissue is slower than in plasma with a tissue half-life in the range of 1.8–215 h (Fig. 36) (EFSA NDA Panel 2017b).

26.6.2.2 Metabolism

In the liver, phylloquinone is catabolized according to the same degradative pathway than menaquinones. In phase I, phylloquinone is metabolized by an initial ω-hydroxylation, followed by β-oxidation to provide two major metabolites with shorter side chains: five carbon vitamin K metabolite (5C-metabolite) named 2-methyl-3-(3′,3′-carboxymethylpropyl)-1,4-naphtoquinone and seven carbon vitamin K metabolite (7C-metabolite) named 2-methyl-3-(5′-carboxy-3′-methyl-2′-pentenyl)-1,4-naphtoquinone (Fig. 37). In phase II, these metabolites are conjugated with glucuronic acid and excreted in the bile and the urine. In the case of patients treated with warfarin, the ingestion of a large dose of phylloquinone (400 mg) led to the formation of a third aglycone metabolite in urines, a ten-carbon vitamin K metabolite (10C-metabolite) named 2-methyl-3-(7′-carboxy-3′,7′-dimethyl-2′-heptenyl)-1,4-naphtoquinone (EFSA NDA Panel 2017b; McBurney et al. 1980; Shearer and Newman 2014). Overall, phylloquinone metabolites seem to be eliminated in an equivalent manner in the feces via the bile and in urine. The 5C-metabolite is the main urinary metabolite. However, with a high oral intake of vitamin K (1 mg), non-absorbed phylloquinone and phylloquinone metabolites are eliminated in larger amount in feces (up to 60%) (EFSA NDA Panel 2017b).

26.6.3 Bioactivities

26.6.3.1 General Role (Animal Studies)

All forms of vitamin K have a role of enzymatic co-factor required for γ-carboxylation of glutamate residues, a post-translational modification of proteins. This role relies on vitamin K activation and regeneration following a pattern that is classically known as the "vitamin K cycle" (Fig. 38).

Vitamin K is used in its reduced hydroquinone form by γ-glutamyl carboxylase (GGC) (Berkner et al. 1992) in the endoplasmic reticulum, together with CO_2 and H_2O, a reaction that converts vitamin K hydroquinone into a 2,3-epoxide derivative. GGC is thought to activate vitamin K by turning it into its alkoxide derivative, a stronger base with the capacity to abstract the γ proton, enabling carboxylation at this position, a principle labeled as the "base amplification model" (Dowd et al. 1995).

Fig. 36 Absorption, distribution and metabolism of vitamin K1. Adapted from (Shearer et al. 2012; Yamanashi et al. 2017). A, apolipoprotein A; ABCA1, ATP-binding cassette transporter; B-48, apolipoprotein B48; B-100, apolipoprotein B100; E, apolipoprotein E; αHDL, high density lipoproteins; NPC1L1, Niemann-Pick C1-like intracellular cholesterol Transporter 1; SR-B1: Scavenger Receptor Class B Type 1; IDL, intermediate density lipoproteins; LDL, low density lipoproteins; LDLR, LDL receptor; LRP, LDL receptor-related proteins; LRP1, LDL receptor-related protein 1; VLDL, very low density lipoproteins.

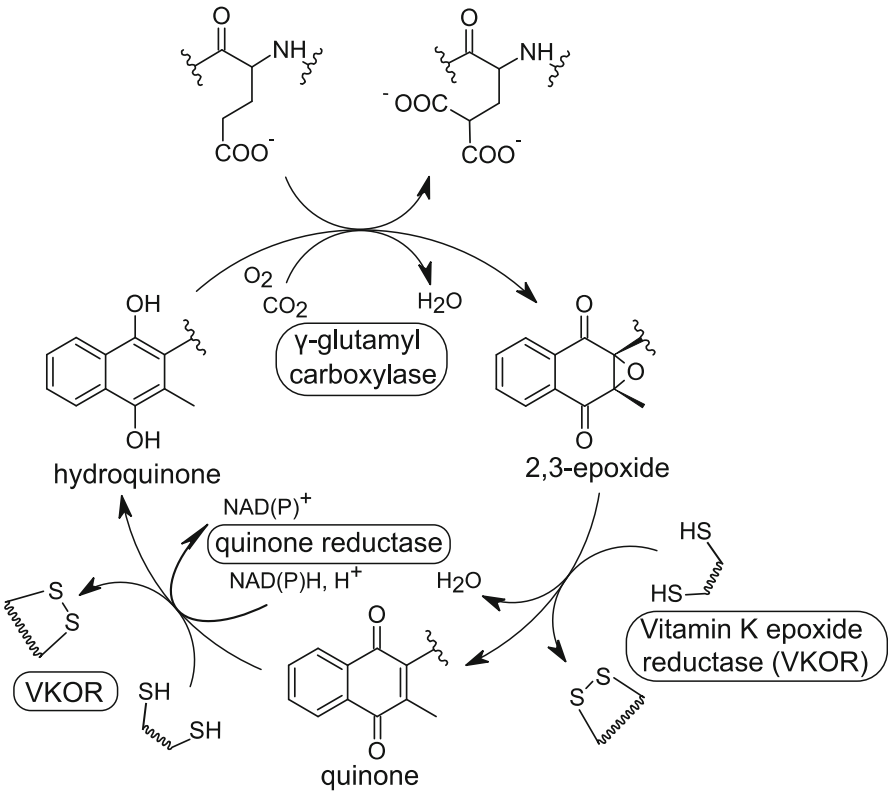

Fig. 38 Vitamin K cycle

The deprotonation of vitamin K hydroquinone was first attributed to a cysteine residue (Furie et al. 1999); more recently, the critical weak alkaline grouping was shown to be the side-chain amine in Lys218 (Rishavy et al. 2006) (Fig. 39).

Vitamin K epoxide reductase (VKOR), an enzyme that uses thiol groups as the reducing agent (Silverman and Nandi 1988), operates the opening of the epoxide and

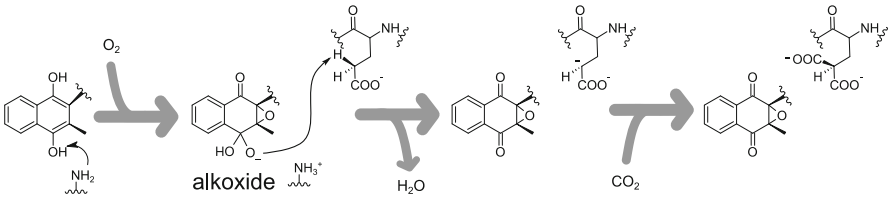

Fig. 39 Proposed mechanism of γ-glutamyl carboxylation by GGC (Furie et al. 1999; Rishavy et al. 2006)

conversion to the quinone derivative. VKOR exists as paralogs VKORC1 and VKORC1L1 that both contribute to vitamin K regeneration (Lacombe and Ferron 2018).

The reduction into the hydroquinone form can be performed by VKOR as well (Gardill and Suttie 1990), following a mechanism that can be reasonably thought to be similar to that of epoxide reduction, as depicted by Preusch and Smalley (1990) (Fig. 40). Nevertheless, additional vitamin K reductase activities have been detected (Ingram et al. 2013). Two FAD-associated quinone reductases were considered: NQO1 (NAD(P)H quinone reductase 1 = DT-diaphorase), which is upregulated in some cancers and known to be responsible for mitomycin C activating bioreduction uses NADH or NADPH as reductant; and NQO2 (NRH quinone oxidoreductase 2), which has only been characterized by its ability to use dihydronicotinamide riboside (NRH), a non-physiological compound (Megarity et al. 2014). NQO1 was found to have a moderate effect on vitamin K hydroquinone production in mice (Ingram et al. 2013) and shown to be more active on synthetic vitamin K3 than on natural K1 or K2. NQO2 may enhance menadione toxicity by operating only one electron reduction to produce a semiquinone that reoxidizes readily to the quinone form. Its effective role for natural vitamin K reduction is not established either (Gong et al. 2008). Nevertheless, a NAD(P)H-dependent vitamin K reductase different from NQO1 is thought to exist, at least in mice (Ingram et al. 2013).

Proteins affected by glutamyl γ-carboxylation are involved in blood coagulation, bone metabolism, and vascular biology. Of course, hypocoagulation, the most obvious trouble linked to vitamin k deficiency in chick experimental restricted diets was also the first identified and led to the identification of this *Koagulationsvitamin* in 1929 by Danish researcher Henrik Dam (carpenter 2003b), who received the Nobel Prize in Physiology and Medicine in 1943 (Dam 1946). As bleeding induced by sweet clover consumption in cattle was the starting point for the identification of dicoumarol as a vitamin K antagonist and the development of therapeutic agents such as warfarin, abnormalities in bovine blood samples were a key material for identification of vitamin K mechanism of action (Nelsestuen and Suttie 1972; Stenflo et al. 1974) as well as of proteins that required it for their maturation, for example, prothrombin (Ganrot and Nilehn 1968).

The role of vitamin K in bone was also primarily discovered in chick bone microsomes (Lian and Friedman 1978).

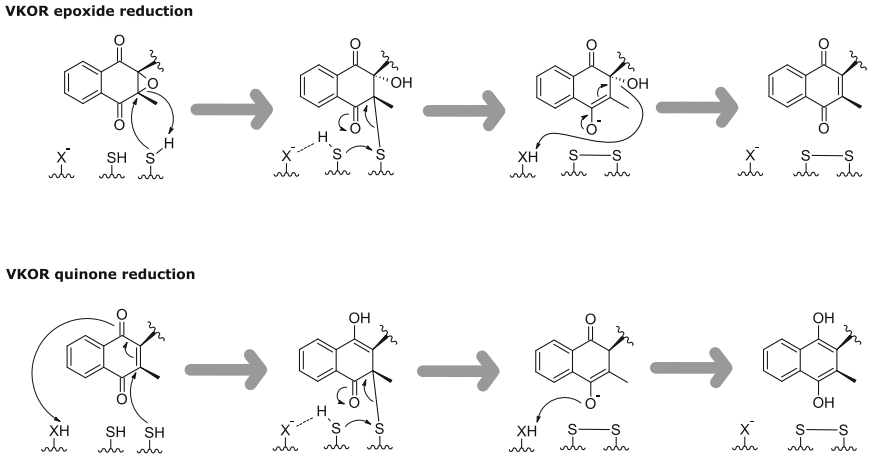

Fig. 40 Proposed mechanisms for VKOR reduction of vitamin K epoxide (up) and quinone (down), adapted from Preusch and Smalley (1990).

26.6.4 Benefits (Human Studies)

A variety of proteins require vitamin K for their maturation. Most of them to this date are coagulation factors: Factors II (prothrombin), VII, IX, X, proteins C, S, Z and Gas6 (Wallin et al. 2008). So-called Gla domains are located in the N-terminal region of these proteins and can only be γ-carboxylated as propeptides: a signal peptide is required for processing and is later hydrolyzed by furin for secretion of the mature molecule. This is exemplified by the sequence of factor VII/VIIa which requires γ-carboxylation among other post-translational modifications, as depicted in Fig. 41. γ-carboxylation enables Ca^{2+} chelation and interaction with phospholipids at the site of injury, making in most cases their activation possible (Furie and Furie 1992).

In Europe, EFSA NDA Panel recognized that "Vitamin K contributes to normal blood clotting," but stated that no effect may be observed for prolonged deliberately restricted diet in humans (EFSA NDA Panel 2009e).

Apart from hemostasis, the most studied vitamin K-dependent proteins are involved in bone metabolism:

- Osteocalcin was the first to be discovered and the identification its γ-carboxylated nature preceded that of vitamin K metabolism in the bone (Price et al. 1976). Osteocalcin is a biomarker of osteoblastic activity and contributes to the regulation of bone mineralization but does not raise bone mass (Diegel et al. 2020; Moriishi et al. 2020). It has been postulated that its binding to calcium in bone may be a mode of modulating the hormonal effects of its decarboxylated form on energy metabolism (Lee et al. 2007) and stress (Meyer Berger et al. 2019) but this was not confirmed outside the research team that formulated this theory (Manolagas 2020).

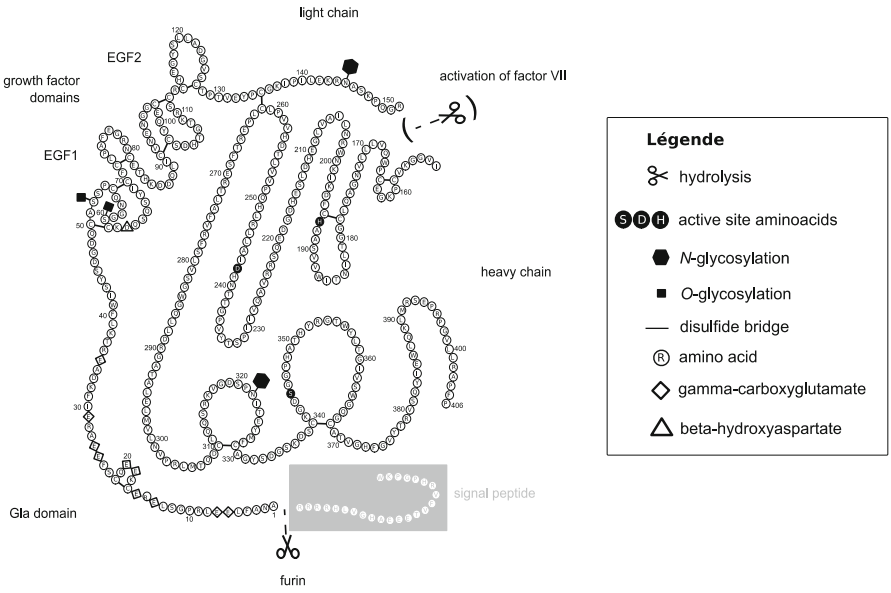

Fig. 41 Sequence of factor VIIa, with Gla domain and signal peptide shown (Hennebelle 2020)

- Matrix Gla-protein (MGP) is an inhibitor of tissue calcifications that is secreted by chondrocytes among other cell types (Cancela et al. 2014).

Other proteins possibly involved in bone metabolism requiring vitamin K activation were identified: growth arrest-specific 6 protein (Gas6), Gla-rich protein (GRP), and periostin (De Caterina et al. 2020).

Low vitamin K status has been correlated with lower bone mineral density. Vitamin K supplementation led to mixed results, with favorable outcome predominantly in Japanese populations (Bügel 2008; EFSA NDA Panel 2009e). Negative effect of vitamin K antagonists has remained controversial for a long time, but comparison with direct oral anticoagulants seems to support it, and thus, the protective role of vitamin K on bones (De Caterina et al. 2020).

In Europe, the health claim "Vitamin K contributes to the maintenance of normal bones" has been authorized (EFSA NDA Panel 2009e).

The incomplete knowledge of numerous vitamin K-dependent proteins and their possible implication in blood vessel calcification and cell proliferation has led to investigations on the possible benefit of vitamin K supplementation in a broader spectrum of diseases. As regards cardiovascular disease, higher vitamin K consumption may be correlated with a lower risk of coronary heart disease (Chen et al. 2019a). Positive findings regarding the risk of various cardiovascular events were obtained using desphospho-uncarboxylated matrix γ-carboxyglutamate protein (dp-ucMGP) as a biomarker, but its value for the estimation of vitamin K status is uncertain, all the more because circulating osteocalcin level did not provide such

Table 17 Dietary reference values of vitamin K from EFSA (based on phylloquinone only), expressed in µg/day (EFSA NDA Panel 2017b).

Infants

correlation. Moreover, low circulating phylloquinone levels were associated with an increased risk of all-cause mortality, but not of cardiovascular disease (Shea et al. 2020). Previous studies regarding cardiovascular health and vitamin K status were reviewed by EFSA NDA Panel (2017b).

A possible interest of vitamin K supplementation has been suggested in cystic fibrosis, as malabsorption of this vitamin is possible. It is not clear at present whether supplementation provides benefits (Jagannath et al. 2020).

Adequate intakes (AIs) for children and adults were determined by European Food Safety Authority. Due to a lack of evidence on intake, absorption, biological role, and content in the body and organs of menaquinones, AIs were determined only for phylloquinone. 1 µg/kg body weight per day was established for all age and sex population groups (Table 17).

Vitamin K deficiency is rare in Humans. Some possible causes are:

- Reduced formation of gut microflora menaquinones, for instance during prolonged antibiotic therapy (Liu et al. 2019), particularly when dietary supply cannot replace it, because of restricted diet (Itagaki and Hagino 2019) or in neonates (Aziz and Patil 2015).
- Reduced intake in the context of vomiting, possibly observed in hyperemesis gravidarum (Baba et al. 2016).
- Decreased absorption because of reduced intestinal capacity, which may be observed in bariatric surgery. Bleeding disorders are suggestive of vitamin K deficiency in the general context of lipid-soluble deficiency; persistent diarrhea may hinder dietary vitamin K absorption and curative antibiotic use may aggravate it (Elalfy et al. 2018).
- Drug therapy or intoxication by vitamin K antagonists such as warfarin.

26.6.5 Applications in Food

Phylloquinone, present in all photosynthetic plant species, is the major source of vitamin K in the human diet. The richest sources of vitamin K1 are dark green leafy vegetables (spinaches, lettuces, purslanes, watercresses) and cabbages (broccoli, Brussel sprouts, kales). Phylloquinone can be also found in some legumes and herbs. For example, thyme contains high level of vitamin K. Table 18 sums up major plant food sources of vitamin K1, according to the EFSA Food Composition database (https://www.efsa.europa.eu/en/data/food-composition), selected on the ground of established regulatory thresholds for any food

Table 18 Phylloquinone content of plant products which are at least sources of vitamin K1

Category	Food	Total vitamin K (μg/100 g)

	Teal leaves and stalks, fermented	262.00

to be considered a source of vitamin K (>11 μg/100 g) or rich in vitamin K (>22 μg/100 g). Menaquinones (vitamin K2), not described in this chapter, are found in animal products such as liver products, meat, cheese, and eggs (EFSA NDA Panel 2017b).

No particular trend was noted as regards seasonal variation of phylloquinone in vegetables. The cooking process does not affect phylloquinone and may even significantly enhance available amount by disruption of cell walls and release from chloroplasts (Damon et al. 2005).

Some vegetable oils provide significant phylloquinone amounts, for example, soy (362 μg/100 g), olive (60.2 μg/100 g), colza (71.3 μg/100 g) and cottonseed (24.3 μg/100 g) oils (ANSES 2017; Peterson et al. 2002).

26.6.6 Safety: Toxicity and Side Effects

There has been no report of any negative effect of supranutritional doses of any form of vitamin K in animals or humans. Studies were mostly performed with phylloquinone (EFSA SCF and NDA Panel 2006). Increased intakes of all forms of vitamin K counter the action of vitamin K antagonists, thus reducing their benefit in cardiovascular disease. Thus their consumption should be controlled or meal composition should be as regular as possible in such cases.

26.6.7 Marketed Products

Vitamin K1 (often labeled as phytomenadione) is used as a pharmaceutical ingredient, for supplementation in cases of deficiency cited above. Its origin seems to be synthetic as it may contain menadione, which is not a natural precursor of phylloquinone (see Fig. 35). The product may contain up to 15% of the (Z) isomer according to the European Pharmacopoeia (2020).

Phylloquinone and menaquinones (in particular MK-6 and MK-7) are added in some foods and food supplements (EFSA NDA Panel 2017b).

26.6.8 Patents

Patents have been dedicated to the preparation of synthetic phytomenadione (CN104744230A), and specially preparation of the pure (*E*) isomer (WO2016038626A1, EP2868658A1). Its cosmetic use has also been considered, as an energizing ingredient (US20070243146A1).

26.6.9 Perspectives

Vitamin K1 has been the most studied vitamer of vitamin K, because of its abundance in the diet and greater simplicity. In recent years, vitamin K2 has raised great interest because of possible better bioavailability and efficiency (EFSA NDA Panel 2017b), but also probably because it may be produced biotechnologically, owing to its microbial origin. Such production is feasible with phylloquinone (Tarento et al. 2018, 2019) making it a competitive candidate for vitamin K formulation, as interest for effects not related to coagulation disorders seems to grow.

Acknowledgments This work was supported by European Union, French State, and the Region of Hauts-de-France (CPER/FEDER Alibiotech).

EFSA NDA Panel (2009a) Scientific Opinion on the substantiation of health claims related to vitamin A and cell differentiation (ID 14), function of the immune system (ID 14), maintenance of skin and mucous membranes (ID 15, 17), maintenance of vision (ID 16), maintenance of bone (ID 13, 17), maintenance of teeth (ID 13, 17), maintenance of hair (ID 17), maintenance of nails (ID 17), metabolism of iron (ID 206), and protection of DNA, proteins and lipids from oxidative damage (ID 209) pursuant to Article 13(1) of Regulation (EC) No 1924/2006. EFSA J 7:1221

EFSA NDA Panel (2009b) Scientific Opinion on substantiation of health claims related to thiamine and energy-yielding metabolism (ID 21, 24, 28), cardiac function (ID 20), function of the nervous system (ID 22, 27), maintenance of bone (ID 25), maintenance of teeth (ID 25), maintenance of hair (ID 25), maintenance of nails (ID 25), maintenance of skin (ID 25) pursuant to Article 13(1) of Regulation (EC) No 1924/2006. EFSA J 7:1222

EFSA NDA Panel (2009c) Scientific Opinion on the substantiation of health claims related to folate and blood formation (ID 79), homocysteine metabolism (ID 80), energyyielding metabolism (ID 90), function of the immune system (ID 91), function of blood vessels (ID 94, 175, 192), cell division (ID 193), and maternal tissue growth during pregnancy (ID 2882) pursuant to Article 13 (1) of Regulation (EC) No 1924/2006. EFSA J 7:1213

EFSA NDA Panel (2009d) Scientific Opinion on the substantiation of health claims related to vitamin C and protection of DNA, proteins and lipids from oxidative damage (ID 129, 138, 143, 148), antioxidant function of lutein (ID 146), maintenance of vision (ID 141, 142), collagen formation (ID 130, 131, 136, 137, 149), function of the nervous system (ID 133), function of the immune system (ID 134), function of the immune system during and after extreme physical exercise (ID 144), non-haem iron absorption (ID 132, 147), energy-yielding metabolism (ID 135), and relief in case of irritation in the upper respiratory tract (ID 1714, 1715) pursuant to Article 13(1) of Regulation (EC) No 1924/2006. EFSA J 7:1226

EFSA NDA Panel (2009e) Scientific Opinion on the substantiation of health claims related to vitamin K and maintenance of bone (ID 123, 127, 128, and 2879), blood coagulation (ID 124 and 126), and function of the heart and blood vessels (ID 124, 125 and 2880) pursuant to Article 13(1) of Regulation (EC) No 1924/2006. EFSA J 7:1228

EFSA NDA Panel (2010a) Scientific Opinion on the substantiation of health claims related to vitamin A and cell differentiation (ID 14), function of the immune system (ID 14), maintenance of skin and mucous membranes (ID 15, 17), maintenance of vision (ID 16), maintenance of bone (ID 13, 17), maintenance of teeth (ID 13, 17), maintenance of hair (ID 17), maintenance of nails (ID 17), metabolism of iron (ID 206), and protection of DNA, proteins and lipids from oxidative damage (ID 209) pursuant to Article 13(1) of Regulation (EC) No 1924/2006. EFSA J 8:1754

EFSA NDA Panel (2010b) Scientific Opinion on the substantiation of health claims related to thiamin and reduction of tiredness and fatigue (ID 23) and contribution to normal psychological functions (ID 205) pursuant to Article 13(1) of Regulation (EC) No 1924/2006. EFSA J 8:1755

EFSA NDA Panel (2010c) Scientific Opinion on the substantiation of health claims related to folate and contribution to normal psychological functions (ID 81, 85, 86, 88), maintenance of normal vision (ID 83, 87), reduction of tiredness and fatigue (ID 84), cell division (ID 195, 2881) and contribution to normal amino acid synthesis (ID 195, 2881) pursuant to Article 13(1) of Regulation (EC) No 1924/2006. EFSA J 8:1760

EFSA NDA Panel (2010d) Scientific Opinion on the substantiation of health claims related to vitamin C and reduction of tiredness and fatigue (ID 139, 2622), contribution to normal psychological functions (ID 140), regeneration of the reduced form of vitamin E (ID 202), contribution to normal energy-yielding metabolism (ID 2334, 3196), maintenance of the normal function of the immune system (ID 4321) and protection of DNA, proteins and lipids from oxidative damage (ID 3331) pursuant to Article 13(1) of Regulation (EC) No 1924/2006. EFSA J 8:1815

EFSA NDA Panel (2010e) Scientific Opinion on the substantiation of health claims related to vitamin E and protection of DNA, proteins and lipids from oxidative damage (ID 160, 162, 1947), maintenance of the normal function of the immune system (ID 161, 163), maintenance of normal bone (ID 164), maintenance of normal teeth (ID 164), maintenance of normal hair (ID

164), maintenance of normal skin (ID 164), maintenance of normal nails (ID 164), maintenance of normal cardiac function (ID 166), maintenance of normal vision by protection of the lens of the eye (ID 167), contribution to normal cognitive function (ID 182, 183), regeneration of the reduced form of vitamin C (ID 203), maintenance of normal blood circulation (ID 216) and maintenance of normal a scalp (ID 2873) pursuant to Article 13(1) of Regulation (EC) No 1924/2006. EFSA J 8:1816

EFSA NDA Panel (2011) Scientific Opinion on the substantiation of health claims related to beta-carotene and protection of DNA, proteins and lipids from oxidative damage (ID 19, 197, 1262, 1460), protection of the skin from UV-induced (including photo-oxidative) damage (ID 178, 197, 1263, 1461, 1968, 2320) and maintenance of the normal function of the immune system (ID 200, 1462) pursuant to Article 13(1) of Regulation (EC) No 1924/2006. EFSA J 9:2021

EFSA NDA Panel (2013a) Scientific Opinion on the substantiation of a health claim related to increasing maternal folate status by supplemental folate intake and reduced risk of neural tube defects pursuant to Article 14 of Regulation (EC) No 1924/2006. EFSA J 11:3328

Abstract

Curcumin is the major bioactive constituent of turmeric (*Curcuma longa* L., Zingiberaceae) rhizome. Turmeric has been used as spice and dye but also in the traditional Chinese and Indian medicine for the treatment of respiratory ailments, wounds, gastrointestinal complaints, hepatic disorders, and cardiovascular disease. Numerous studies reported curcumin as an important pleiotropic agent, with anti-inflammatory, wound healing, antioxidant, hypoglycemic, cardioprotective, neuroprotective, hepatoprotective, antimicrobial, chemopreventive, and anticancer activities. These effects have been demonstrated both in vitro and in experimental animal models, thus paving the way for various clinical trials. The latter investigated different curcumin-based formulations, including highly bioavailable formulations showing their efficacy in central nervous system, cardiovascular, gastrointestinal, liver, and metabolic diseases. Benefits in certain malignant diseases were also reported. Curcumin is marketed worldwide as dietary supplement and herbal medicine, as cosmetic product, or as food additive. Curcumin possesses a good safety profile. Chemical features of curcumin, bioactivity and mechanisms of activity, safety profile, patents, and marketed products are summarized in this chapter. As literature on the topic of curcumin has known an exponential growth, reports cited in this chapter should be considered as illustrative rather than comprehensive.

Keywords

Curcumin · *Curcuma longa* · Turmeric · Bioavailability · Anti-inflammatory · Neuroprotective · Chemopreventive · Curcumin formulations

27.1 Introduction

Curcumin represents the major bioactive constituent-derived turmeric (*Curcuma longa* L., Zingiberaceae) rhizome, accounting from 0.58% to 3.14% of its dry weight (Aggarwal et al. 2007). Turmeric has a long record of use as spice and dye; also, it has been used as a traditional Chinese and Indian medicine since immemorial times for the treatment of cough and respiratory ailments, wounds of different etiologies, gastrointestinal complaints, hepatic disorders, and cardiovascular disease. In combination with coriander, cumin, fenugreek and chili peppers, turmeric forms the curry powder, a dietary spice used worldwide (Sarker and Nahar 2007; Esatbeyoglu et al. 2012).

The revival of natural and complementary therapies in Western medicine has drawn the attention of the scientific community to this remedy. Extensive research over the five last decades has shown that curcumin is an important pleiotropic agent, with anti-inflammatory, wound healing, antioxidant, hypoglycemic,

cardioprotective, neuroprotective, hepatoprotective, antimicrobial, chemopreventive, and anticancer activities (Prasad et al. 2014; Kunnumakkara et al. 2017).

These effects have been demonstrated both in vitro, in cultured cells, and in experimental animal models, thus paving the way for various clinical trials. Studies documenting the chemical features of curcumin, its bioactivity and mechanisms of action, safety profile, patents, and marketed products are summarized in this chapter. As literature on the topic of curcumin has known an exponential growth, reports cited in this chapter should be considered as illustrative rather than comprehensive.

Due to its numerous properties, curcumin is being marketed worldwide, either as dietary supplement and herbal medicine, cosmetic products, or as food additive. Curcumin possesses a good safety profile. This was also confirmed by Food and Drug Administration (FDA), who classified curcumin as *generally recognized as safe* (GRAS) by approving the commercialization of a curcuminoid preparation containing curcumin 75–81%, bisdemethoxycurcumin 2.2–6.5%, and demethoxycurcumin 15–22% (Mahran et al. 2017). More, European Food Safety Authority (EFSA) reports an allowable daily intake value for curcumin of 0–3 mg/kg body weight (b.w.) (EFSA 2014).

27.2 Chemical Structure

In the early nineteenth century, curcumin was isolated as a yellow powder from the dried rhizome of *Curcuma longa*. Chemically, curcumin belongs to the class of diarylheptanoids, being a *bis*-α,β-unsaturated β-diketone. It is also known as diferuloylmethane or 1,7-bis-(4-hydroxy-3-methoxyphenyl)-1,6-heptadiene-3,5-dione. The molecular formula of curcumin is $C_{21}H_{20}O_6$, and it has a molecular weight of 368.39 g/mol^{-1} (Anand et al. 2007).

Chemically, curcumin is an unstable molecule, being sensitive to alkaline pH, oxygen, and irradiation with ultraviolet and visible light. Curcumin presents a specific keto-enol tautomerism (Fig. 1), whose equilibrium is dependent upon the pH value and polarity of the solvent. The ketone form is metabolically targeted for reduction and conjugation: curcumin is more susceptible to degradation and reduction at the diketo moiety, and conjugation is mediated by the hydroxyl groups (Priyadarsini 2014; Stanić 2017).

Curcumin is an unstable molecule, being degraded mostly via an autoxidative process to bicyclopentadione (Fig. 2) as major product and vanillin and ferulic acid in a lesser extent (Gordon et al. 2015). Interestingly, bicyclopentadione is also formed by catalytic oxygenation through cyclooxygenases and lipoxygenases, thus being not only a degradation product but also a metabolite (Schneider et al. 2015).

27.3 Bioavailability and Metabolism

Curcumin bioavailability and metabolism have been investigated in numerous animal and human studies. After oral administration, curcumin undergoes limited absorption in the small intestine, followed by metabolization in the intestine and

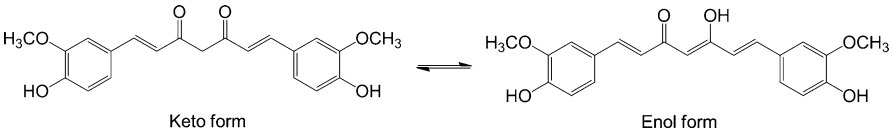

Fig. 1 Keto-enol tautomerism of curcumin

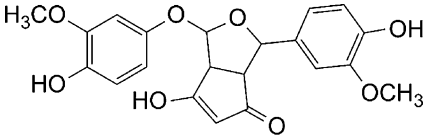
Fig. 2 Bicyclopentadione



liver, and rapid elimination through feces and in a lesser extent through urine (Esatbeyoglu et al. 2012). The low uptake of orally administered curcumin was confirmed in animal models, when oral bioavailability of the polyphenol was found to be lower than 1% (Asai and Miyazawa 2000; Yang et al. 2007).

Human studies also indicate a low absorption of curcumin in the gastrointestinal tract, as after oral administration only minute amounts of curcumin reach peripheral blood. In a clinical study enrolling 15 patients with advanced colorectal cancer which were administered oral doses of 36 up to 180 mg, no detectable plasma levels of curcumin were determined (Sharma et al. 2001). Even after ingestion of high doses of curcumin, up to 8 g, within 1 h after administration, curcumin yielded peak serum concentrations of only 0.5–2 μM (Cheng et al. 2001).

Curcumin is highly metabolized in the intestine and liver, and only small amounts are detectable in other organs. After intraperitoneal administration of curcumin (0.1 g/kg) to mice, 2.25 μg/mL were sampled in the plasma after 15 min. Further, in 1 h after administration, the detected levels of curcumin in the intestine, spleen, liver, and kidneys were 177.04, 26.06, 26.90, and 7.51 mg/g, respectively, and only trace amounts (0.41 mg/g) were observed in the brain (Pan et al. 1999). In another study which assessed curcumin uptake and distribution in animals, Marczylo et al. (2007) found even lower levels of the polyphenol. Oral administration of curcumin (340 mg/kg) in rats gave the following results: plasma (16.1 ng/mL), urine (2.0 ng/mL), intestinal mucosa (1.4 mg/g), liver (3671.8 ng/g), kidney (206.8 ng/g), and heart (807.6 ng/g) (Marczylo et al. 2007). Therefore, species differences, dosage, and sampling of curcumin highly influence its uptake and distribution which are essential for the biological function.

Curcumin undergoes extensive phase I and phase II biotransformation in the intestinal cells and liver (Fig. 3).

Alcohol dehydrogenases present in enterocytes and hepatocytes reduce curcumin to dihydrocurcumin (DHC), tetrahydrocurcumin (THC), hexahydrocurcumin (HHC), and octahydrocurcumin (OHC). These phase I metabolites are found in free and conjugated forms (mostly as glucuronides) (Pan et al. 1999; Ireson et al. 2002). Ireson et al. (2002) investigated curcumin metabolism in human and rat intestinal tissue and in the corresponding hepatic fractions. Once more, species

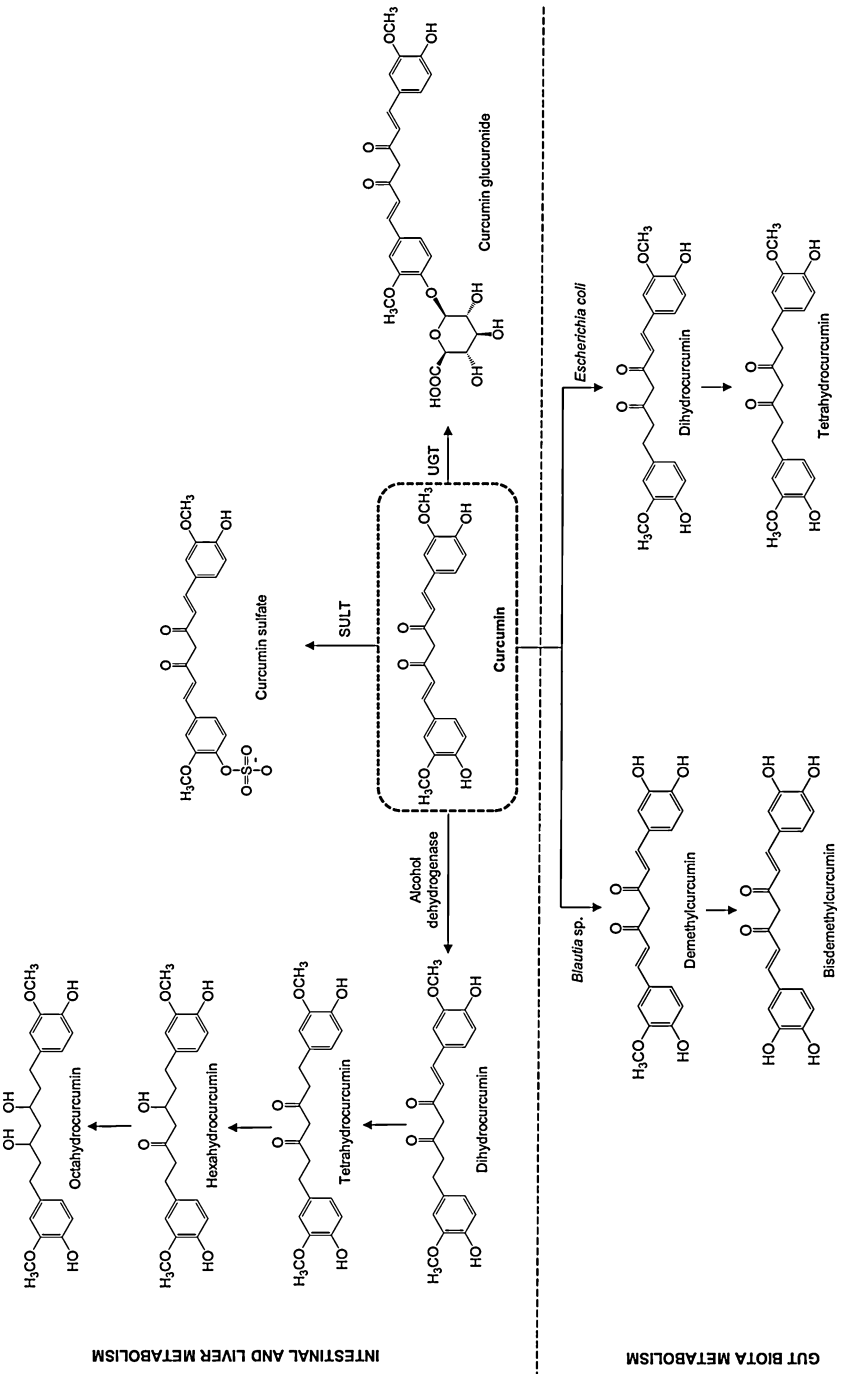


Fig. 3 Major metabolic pathway of curcumin

differences markedly influenced curcumin metabolism. They concluded that the curcumin-reducing ability to HHC in human intestinal and liver tissue cytosol is significantly higher compared to the corresponding rat tissues (by factors of 18 and 5, respectively) (Ireson et al. 2002). More, THC was curcumin major metabolite in the intestinal mucosa, liver, plasma, and urine of rats. In contrast, THC was not detectable in human subcellular fractions (Pan et al. 1999; Marczylo et al. 2007).

Phase II metabolism of curcumin occurs in the intestinal and hepatic cytosol and endoplasmic reticulum microsomes and involves its conjugation with glucuronic acid and sulfate (Ireson et al. 2001, 2002; Garcea et al. 2004; Hoehle et al. 2007). Curcumin is sulfated by sulfotransferases (SULTs), mostly SULT1A1 and SULT1A3 (Ireson et al. 2002). Curcumin sulfation occurs in the cytosol of enterocytes and hepatocytes, and the concentration of sulfated curcumin in the human intestine is threefold higher than in the liver (Ireson et al. 2002).

Glucuronidation of curcumin is catalyzed by uridine 5′-diphospho-glucuronyltransferases (UGTs) in the intestinal and hepatic microsomes (Ireson et al. 2001, 2002). In rats, oral administration of curcumin (500 mg/kg b.w.) led to curcumin glucuronide and curcumin sulfate as major metabolites, alongside HHC, OHC, and HHC glucuronide which were present in small amounts (Ireson et al. 2001). In humans, oral administration of curcumin gives glucuronide and sulfate conjugates as main metabolites, summing almost 100% (Sharma et al. 2004). More, plasma levels of curcumin glucuronides are almost twofold higher than those of sulfate conjugates (Vareed et al. 2008). These results are consistent with the ones from clinical trials conducted by Sharma et al. (2004) and Kunati et al. (2018). Moreover, curcumin and its phase I metabolites can be conjugated by phase II xenobiotic-metabolizing enzymes to monoglucuronides, monosulfates, and mixed glucuronide/sulfates (Garcea et al. 2005).

Excretion of curcumin is mainly done in urine as glucuronide and sulfate conjugates (Asai and Miyazawa 2000; Sharma et al. 2004). After oral administration in humans, curcumin was not detected or was found in minute quantities in feces or urine (Sharma et al. 2001; Schiborr et al. 2014). Thus, curcumin levels sampled on the 8th day from patients consuming 3.6 g of curcumin/day were in the nanomolar range (25–116 nmol/g dried feces) (Sharma et al. 2004).

Curcumin bioactive metabolites are likely to be formed at trace levels in biological samples; therefore their detection and identification represent a real conundrum.

Similarly to other dietary polyphenols, curcumin undergoes an alternative metabolism by intestinal microbiota (Hassaninasab et al. 2011; Lou et al. 2015; Burapan et al. 2017). Studies on curcumin-converting microorganisms were undertaken to unravel the fate of ingested curcumin once it reaches the colon, which presents a unique population of indigenous bacteria.

Escherichia coli is one of the most active curcumin-metabolizing microorganisms isolated from human feces. Thus, curcumin is metabolized by a NADPH-dependent reductase in a two-step reduction pathway (curcumin → DHC → THC) (Fig. 3) (Hassaninasab et al. 2011). *Blautia* sp. MRG-PMF1 is also involved in the gut metabolism of curcumin and produces its demethylation to demethylcurcumin and

bisdemethylcurcumin (Fig. 3) (Burapan et al. 2017). In order to have a representative range of gut bacteria, Lou et al. (2015) used in their study feces sampled from a single male human. After incubation, there were identified novel metabolites derived from curcumin by demethoxylation, reduction, hydroxylation, methylation, and acetylation processes.

To summarize, curcumin is a hydrophobic polyphenol, practically insoluble in water. It presents a reduced intestinal absorption and limited tissue distribution, followed by a rapid metabolism. This translates into a short half-life and explains the low systemic bioavailability of curcumin. Therefore, the bioactivation hypothesis could explain the polypharmacology of curcumin.

In order to overcome the limitations of curcumin's low bioavailability, several pharmacokinetic strategies have been developed. Thus, association of curcumin with bioenhancers such as piperine, quercetin, genistein, eugenol, epigallocatechin gallate, and resveratrol was found to inhibit curcumin metabolism via modulation of phase II enzymes, with a consequent increase in its bioavailability and efficacy. As an illustrating example, piperine, the major alkaloid found in *Piper nigrum*, increased by 20-fold the bioavailability of curcumin, as proven in animal and human studies (Mahran et al. 2017; Shoba et al. 1998).

In addition, synthesis of curcumin analogs and development of modified drug-delivery systems, including liposomal, nanoparticulated, and phospholipid complex formulations of curcumin, has proven increased effectiveness when compared to simple curcumin, as assessed in numerous animal models and clinical studies. Moreover, recent formulations of curcumin have been reported with 100-fold higher bioavailability than curcumin itself, when studied in clinical trials. Thus, modern technologies find their application in the resolution of curcumin's low bioavailability (Khan et al. 2019; Prasad et al. 2014; Marczylo et al. 2007).

27.4 Bioactivities (Animal Aspects)

Numerous animal studies have shown that curcumin possesses various pharmacological effects including antitumor, anti-inflammatory, antioxidant, antidiabetic, hypolipidemic, hepatoprotective, cardioprotective, wound healing, nephroprotective, and neuroprotective effects (Aggarwal et al. 2007; Gupta et al. 2012; Akbik et al. 2014; Kunnumakkara et al. 2017). Scientific literature on assessment of curcumin bioactivity abounds in animal studies; therefore experimental reports cited in the following sections should be considered as illustrative rather than comprehensive.

27.4.1 Anticancer Effects

The chemopreventive, chemosensitizing, and chemotherapeutic properties of curcumin have been investigated in different animal (mostly rodent) models. Curcumin has been found to be effective in many phases of cancer development,

to suppress malignant transformation, beginning, development and invasion of tumor, angiogenesis, and metastasis (Anand et al. 2007).

Chemopreventive efficacy of curcumin for colon cancer has been shown in different rodent models, alongside other cancers located at gastrointestinal level such as esophageal, stomach, liver, and oral cancer. Curcumin also showed chemopreventive effects in animal models of extraintestinal cancers, including the breast, lung, kidney, bladder, blood, and skin (Aggarwal et al. 2007; Hatcher et al. 2008; Epstein et al. 2010).

Heterotransplantation of human cancer cells (xenograft models) into immunodeficient rodents was frequently used for preclinical screen of curcumin as a novel chemotherapeutic agent. Curcumin showed antitumor efficacy against human melanoma cell xenografts when administered intraperitoneally (25 mg/kg b.w.), with an increase in median survival time of 45.7% compared to untreated group (Odot et al. 2004). The authors concluded that the inhibitory effects were mostly due to the antiangiogenic properties of curcumin. More, the combination treatment of curcumin associated with immunization of soluble proteins from supernatants of human melanoma cells was studied. This therapy proved to be more effective, with consequent delay of tumor growth and enhancement of the immune response, that translated into a significantly increase in median survival time of 82.8% (Odot et al. 2004).

When given orally (2% in the diet for 6 weeks) curcumin inhibited cell proliferation and angiogenesis and induced apoptosis in a xenograft nude mice model of prostate cancer (Dorai et al. 2001). Also, curcumin reduced by 50% the volume of xenografts compared to controls in a prostate cancer model, after oral administration of 5 mg/day, 5 days per week for 4 weeks. Analysis of the tumors revealed that curcumin downregulated the expression of murine double minute 2, a major ubiquitin E3 ligase of tumor suppressor p53. More, curcumin enhanced the antitumor effects of gemcitabine and radiation (Li et al. 2007).

Curcumin administered orally (1 g/kg b.w.) in combination with gemcitabine (25 mg/kg b.w.) proved antitumor effects in an orthotopic nude mice model of pancreatic cancer. Curcumin acted as a chemosensitizing agent and potentiated the antitumor effects of gemcitabine by suppressing proliferation (with decrease of tumors volume), angiogenesis, nuclear factor kappa-light-chain-enhancer of activated B cells (NF-κB), and NF-κB-regulated gene products [cyclin D1, c-myc, Bcl-2, Bcl-xL, cellular inhibitor of apoptosis protein-1, cyclooxygenase-2 (COX-2), matrix metalloproteinase (MMP), and vascular endothelial growth factor] (Kunnumakkara et al. 2007).

Curcumin acted as chemosensitizer in combination with other chemotherapeutic drugs such as paclitaxel and docetaxel in xenograft models, showing potential in preventing breast cancer metastasis to the lung and inhibiting tumor growth and angiogenesis in ovarian cancer, respectively (Epstein et al. 2010).

Curcumin and its phase I metabolite THC were evaluated for their chemotherapeutic efficacy in a rodent colon cancer model. THC was found to be more active than its parent compound in inhibiting aberrant crypt foci (ACF) development and cell proliferation in colons of mice exposed to 1,2-dimethylhydrazine dihydrochloride (number

of ACF/mouse was 46.6 ± 17.7 vs. 53.3 ± 10.2) (Kim et al. 1998). In contrast, THC was less active than curcumin in a 12-O-tetradecanoylphorbol-13-acetate (TPA)-initiated mouse skin carcinogenesis model, as it inhibited in a less extent than its progenitor the TPA-induced ornithine decarboxylase activity and tumor promotion (Huang et al. 1995).

More, curcumin and another phase I metabolite HHC were proven to possess anticarcinogenic effects in a dimethylhydrazine-induced rat colon cancer model. HHC reduced the number of ACF in rat colon more effectively than curcumin (1086.80 ± 53.47 vs. 1284.20 ± 25.47), activity mediated by downregulation of COX-2 mRNA expression and induction of apoptosis in epithelial cells of focal crypts. More, both curcumin and HHC acted as chemosensitizers in conjunction with 5-fluorouracil. The synergistic effect of HHC in combination with 5-fluorouracil was superior to that of its progenitor with the chemotherapeutic agent (number of ACF was 665.80 ± 16.64 vs. 880.20 ± 13.67) (Srimuangwong et al. 2012).

Curcumin and its phase II metabolite, curcumin sulfate, have been investigated regarding their antitumor effects. Curcumin sulfate was less active than curcumin in inhibiting prostaglandin E_2 activity in an animal model indicating higher efficacy of curcumin in comparison with its bioactive metabolite (Ireson et al. 2001).

27.4.2 Antidiabetic Effects

Curcumin has also been shown to improve the symptoms associated with diabetes. The ability of curcumin in improving glycemic status [blood glucose, glucose tolerance, and glycosylated hemoglobin (HbA1c)], insulin sensitivity, and normalization of lipid profile was assessed in various animal models.

The most used animals in studying the effect of curcumin are rodents (rat and mouse). Various diabetic rodent models were employed to investigate the effect of curcumin on glycemia. In alloxan, streptozotocin (STZ), and STZ-nicotinamide-induced diabetes rat models, oral administration of various dosages of curcumin (from 60 to 300 mg/kg b.w.) for a period of time of 2 weeks up to 8 weeks resulted in a significant reduction in levels of glucose, hemoglobin (Hb), and HbA1C in blood and prevented body weight loss (Zhang et al. 2013).

El-Moselhy et al. (2011) investigated the effect of curcumin on the progression of insulin resistance and type 2 diabetes mellitus (T2DM) induced by a high-fat diet in rats. Oral administration of curcumin (80 mg/kg b.w.) as pretreatment for 60 days and treatment for 15 days showed an antihyperglycemic effect and improved insulin sensitivity. These results were attributed at least in part to curcumin anti-inflammatory properties as evident by attenuating tumor necrosis factor (TNF)-α levels and to its anti-lipolytic effect as evident by lowering plasma-free fatty acids. Curcumin effects were comparable to those of peroxisome proliferator-activated receptor (PPAR)-γ agonist rosiglitazone, a known antidiabetic drug, which indicated that the mechanism of activity of these compounds might be similar (El-Moselhy et al. 2011).

Curcumin reduced inflammation and oxidative stress in the muscle of fructose-fed rats by avoiding the degradation of the inhibitor of kappa B (IkB)-α and decreasing the oxidative stress-sensitive kinases [extracellular signal-regulated kinases (ERK) 1/2 and p38]; consequently, it prevented the activation of the NF-kB pathway and the subsequent production of pro-inflammatory cytokines such as TNF-α and C-reactive protein (Maithilikarpagaselvi et al. 2016).

Curcumin was shown to interfere with glucose metabolism via phosphatidylinositol 3-kinase/protein kinase B/glycogen synthase kinase 3b (PI3K/Akt/GSK-3b) pathway, whose malfunctioning is associated with the development of metabolic disorders (Bustanji et al. 2009; Yu et al. 2012, 2016). Inhibition in a dose-dependent manner of GSK-3b which phosphorylates glycogen synthase by curcumin translated into an increased glycogen synthesis in the liver of fasting mice. Thus, curcumin enhances glucose disposal via increasing the rate of glycogen synthesis in the liver (Bustanji et al. 2009). Similar beneficial effects were observed in another T2DM rodent model. Curcumin treatment (oral doses of 100 or 200 mg/kg b.w./day for 16 weeks) inhibited phosphorylation of Akt and GSK-3b. GSK-3b is a critical downstream element of Akt whose activity can be inhibited by Akt-mediated phosphorylation. As a result, curcumin reduced glucose blood levels and myocardial dysfunction and other parameters such as fibrosis, oxidative stress, inflammation, and apoptosis in animals heart (Yu et al. 2012, 2016).

Murugan and Pari (2007) evaluated the hypoglycemic and antioxidant activities of curcumin and its phase I metabolite THC in a T2DM rat model. Oral dosing of 80 mg/kg b.w. for 45 days led to a significant reduction in blood glucose levels and HbA1c, alongside with a significant increase in plasma insulin levels and activities of erythrocyte antioxidants [superoxide dismutase (SOD), catalase (CAT), glutathione peroxidase (GPx), glutathione S-transferase (GST), reduced glutathione (GSH)]; also, a significant decrease in thiobarbituric acid reactive substances and hydroperoxide formation in the liver and kidney were noticed. THC was found to be more potent than its parent compound curcumin (Murugan and Pari 2007).

27.4.3 Anti-inflammatory Effects

Several studies in various rodent disease models provide strong preclinical evidence for the benefit of curcumin as anti-inflammatory agent.

Curcumin was shown to attenuate colitis in a dinitrobenzene sulfonic acid (DNB)-induced murine model of colitis. Curcumin added to mice diet at a concentration of 0.25%, 5 days prior the DNB instillation, was able to attenuate experimental colitis through a mechanism correlated with the inhibition of the NF-κB activation and reduction in the activity of p38 group of mitogen-activated protein kinases (MAPK), which are involved in the production of pro-inflammatory cytokines and chemokines (Salh et al. 2003).

In a study investigating the protective effect of curcumin (50 mg/kg b.w. in gavage, daily for 10 days) against trinitrobenzene sulfonic acid-induced colitis in

mice, curcumin pretreatment was associated with significant decreases in diarrhea and in disruption of the colonic architecture. Administration of curcumin in similar doses after colitis inducement for 8 more days significantly reduced the degree of both neutrophil infiltration and lipid peroxidation and decreased serine protease activity. Curcumin also reduced the levels of nitric oxide (NO) and suppressed the NF-kB activation in colonic mucosa (Ukil et al. 2003).

Curcumin exerted significant anti-inflammatory effects against colon inflammation in a mouse model of human inflammatory bowel disease. By using a combined transcriptomics and proteomics approach, the mechanism of curcumin activity against inflammation was unraveled and included the decrease of immune response and increase of xenobiotic metabolism, with resolution of inflammation via decreased neutrophil migration and increased barrier remodeling (Cooney et al. 2016).

The effect of curcumin in combination with a subtherapeutic dose of methotrexate was investigated in an induced arthritis rat model. Intraperitoneal administration of methotrexate (1 mg/kg b.w.) along with low and high dose of curcumin (30 mg/kg b.w. and 100 mg/kg b.w.) for 5 weeks exerted a synergistic anti-inflammatory effect, by significantly reducing the volume of paw edema associated with arthritis. More, curcumin minimized the toxicity of methotrexate, by reduction in hepatocellular injury as assessed by lowering the serum levels of glutamic oxaloacetic transaminase, serum glutamic pyruvic transaminase, alkaline phosphatase, and bilirubin (Banji et al. 2011).

Jeengar et al. (2016) investigated the anti-arthritic properties of a combination consisting of curcumin and emu (*Dromaius novaehollandiae*) oil. Emu oil increased the permeation of lipophilic curcumin through the skin, with a marked decrease in pro-inflammatory mediators levels such as interleukin (IL)-1β, TNF-α, and IL-6 (Jeengar et al. 2016).

The efficacy of a topically applied curcumin-loaded oleic acid-based polymeric bandage was assessed in a wound rat model. The treatment targeted the NF-κB pathway; curcumin downregulated the expression of various kinases involved in the NF-κB pathway and upregulated the expression of the IkB-α, which led to less activation of the NF-κB gene and reduced inflammation (Mohanty et al. 2012).

The anti-inflammatory activity of curcumin and its phase I metabolite THC was investigated by carrageenan-induced rat paw edema assay and cotton pellet granuloma formation test. At low doses, THC was more effective than its progenitor in suppressing inflammation; however, at higher doses, this effect was only partially reversed. THC completely lacked activity in the cotton pellet granuloma formation test (Mukhopadhyay et al. 1982).

27.4.4 Wound Healing Effects

There is evidence supporting the wound healing efficacy of curcumin, as assessed by animal studies. It seems that the wound healing capacity of curcumin is attributed mainly to its anti-inflammatory, anti-infectious, and antioxidant effects.

Curcumin also enhances wound healing by stimulation of tissue remodeling, granulation tissue formation, and collagen deposition. More, even topical use of curcumin promotes epithelial regeneration and increases fibroblast proliferation and vascular density (Akbik et al. 2014).

The in vivo effects of curcumin on wound healing were examined in rats and guinea pigs by Sidhu et al. (1998). Thus, curcumin was administered in doses of 40 mg/kg b.w. for 6 up to 11 days, either orally to guinea pigs or injected intraperitoneally to rats. Punch wounds in curcumin-treated animals closed faster compared to untreated animals. More, curcumin enhanced epithelial regeneration and collagen deposition and increased vascular density of dermis and migration of myofibroblasts, fibroblasts, and macrophages in the wound bed. Moreover, immunohistochemical studies revealed that curcumin increased the levels of transforming growth factor (TGF)-β1, thus demonstrating that the polyphenolic compound acts by modulating the TGF-β1 activity, known as a wound healing promoter (Sidhu et al. 1998).

Mani et al. (2002) investigated the effect of curcumin-dexamethasone combination treatment by topical application in a punch wound rat model. Curcumin significantly enhanced wound healing independently of dexamethasone as compared to controls. Its mechanism of activity was based on enhancement of TGF-β1 expression and increase of inducible nitric oxide synthase (*i*NOS) levels (Mani et al. 2002). It has been shown that increased NO production promotes wound healing by enhancing inflammation (Akbik et al. 2014), fact supported by another animal study conducted by Jagetia and Rajanikant (2012) which also concluded that an increase in NO was partially responsible for the improvement in wound healing by curcumin treatment.

Literature reports suggest that topical application of curcumin has been shown to cause a significant reduction in the expression of antioxidant enzymes in the wound tissue, as curcumin reduces oxidation through nonenzymatic mechanisms (Akbik et al. 2014).

Formulation of curcumin in a collagen matrix was investigated for its topical wound healing in a rat model. Curcumin slightly raised CAT activity but determined a significant decrease of SOD level in treated group compared to control. This decrease in SOD was attributed to antioxidant activities of curcumin, which nonenzymatically reduces superoxide radicals and consequently decreases oxidative stress and antioxidant enzymes level (Gopinath et al. 2004). Similarly, Mohanty et al. (2012) also reported downregulation of SOD, CAT, and GPx expression in a rat model, following the treatment of excised wounds with a curcumin polymeric formulation. This was also due to the reactive oxygen species (ROS) scavenging ability of curcumin, which reduces activation of antioxidant enzymes.

27.4.5 Neuroprotective Effects

Mounting evidence indicates curcumin efficacy in various animal models of neurological disorders. Several studies in rodents have proved the neuroprotective

effects of curcumin in neurodegenerative disorders, especially Alzheimer's and Parkinson's diseases.

Agarwal et al. (2011) investigated the effect of orally administered curcumin (acute administration of 50, 100, and 200 mg/kg b.w. doses) in a model of pentylenetetrazole-induced kindling in mice. Curcumin suppressed dose-dependently the progression of kindling in mice, by reducing the levels of malondialdehyde (MDA) and glutathione in kindled animals. Therefore, curcumin acted as an antiepileptic agent, controlling both development of seizures and oxidative stress during epilepsy (Agarwal et al. 2011). Similar effects were demonstrated in other two models of seizures induced in rats by pentylenetetrazole and kainic acid. Pretreatment with curcumin led to less severe seizures and less cognitive impairment in rats compared to control group (Gupta et al. 2012).

The neuroprotective efficacy of curcumin given intraperitoneally post-ischemia (300 mg/kg b.w., after 4 h of clot implant) was assessed in a rat thromboembolic stroke model. Curcumin treatment selectively inhibited the generation of cytotoxicity factors such ROS, NO, and peroxynitrite in neuronal-rich cell population. Also, it significantly reduced brain infarct volume and edema volume. Sensory motor function, namely, locomotor activity and motor coordination, were improved by curcumin, as assessed by neurobehavioral testing (Dohare et al. 2008).

Garcia-Alloza et al. (2007) demonstrated that curcumin treatment for 7 days (tail vein injections in doses of 7.5 mg/day) reduced plaque formation and β-amyloid accumulation in a mouse model of Alzheimer's disease. Systemic treatment with curcumin cleared and also reduced existing plaques, suggesting a potent disaggregation effect. Curcumin also led to a limited but significant reversal of structural changes in dystrophic dendrites, including abnormal curvature and dystrophy size. The authors concluded that curcumin crosses the blood-brain barrier and reverses existing amyloid pathology and associated neurotoxicity (Garcia-Alloza et al. 2007). More, dietary curcumin also attenuated oxidative injury, microgliosis, synaptophysin loss, spatial memory deficits, postsynaptic loss, and β-amyloid deposits produced by intracerebral ventricular infusion of β-amyloid in rats (Frautschy et al. 2001). These results confirmed the capacity of curcumin in reducing amyloid levels and plaque burden in experimental animal models, thus proving the putative clinical efficacy against Alzheimer's disease (Gupta et al. 2012; Amalraj et al. 2016; Sarker and Franks 2018).

Neuroprotective effects of curcumin were investigated in a 6-hydroxydopamine-treated rat model of Parkinson's disease. Rats pretreated with curcumin (50 mg/kg b.w./day by gavage, for 4 days) showed clear protection of dopamine in the striatum due to attenuation of dopaminergic neurons loss and restoration of dopamine striatal concentration. Curcumin neuroprotective effects were related to its antioxidant activity and ability to penetrate into the brain (Zbarsky et al. 2005). Several studies evaluated the protective effect of curcumin in the 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP)-induced mouse model of Parkinson's disease. Curcumin was shown to substantially improve behavioral deficits and enhance neuron survival in the substantia nigra; the polyphenol significantly reversed the MPTP-induced

depletion of dopamine and its metabolite, 3,4-dihydroxyphenylacetic acid via inhibition of monoamine oxidase (MAO-B) activity (Rajeswari and Sabesan 2008).

Curcumin has shown protective effects in other animal models of neurological disorders such as diabetic encephalopathy, encephalomyelitis, intracerebral hemorrhage, spinal cord injury, cerebral malaria, convulsions, and brain ischemia (Amalraj et al. 2016).

27.4.6 Cardioprotective Effects

Animal studies have provided evidence suggesting protective effects of curcumin against diverse cardiovascular pathological states leading toward heart failure.

Liu et al. (2017) investigated the protective effect of curcumin on heart function in an ischemia reperfusion injury model. Curcumin pretreatment (10, 20, or 30 mg/kg b.w./day, for 20 days) before coronary artery ligature (60 min), followed by reperfusion, showed significant reductions in oxidative stress, infarct size, and inhibition of myocardium apoptosis by decreasing the expression of apoptotic genes in rats (Liu et al. 2017). Similarly, curcumin pretreatment (200 mg/kg b.w. per day orally for 10 days) proved cardioprotective activity in another ischemia reperfusion injury model by activating signaling pathways which reduce mitochondrial damage. Curcumin improved postischemic cardiac function, decreased myocardial infarct size, and decreased myocardial apoptotic index and several biochemical parameters, including the upregulation of the antiapoptotic proteins and the downregulation of the pro-apoptotic proteins. More, curcumin acted by preserving mitochondrial redox potential, with significant elevation of mitochondrial SOD activity, and by decreasing the formation of mitochondrial hydrogen peroxide and MDA (Yang et al. 2013).

In the study carried out by Abo-Salem et al. (2014), curcumin showed protective effects in diabetes-induced cardiac injury in rats. Orally administered curcumin (200 mg/kg b.w./day, for 6 weeks) markedly decreased serum high-density lipoprotein cholesterol and increased cardiac antioxidant enzymes (CAT, SOD, and GST). The authors attributed these effects to curcumin to its hypolipidemic, free radical scavenging, and anti-inflammatory activities (Abo-Salem et al. 2014).

Xiao et al. (2016) investigated the role of curcumin and its mechanism of action on interstitial fibrosis after myocardial infarction (MI) in mice. Curcumin pretreatment (100 mg/kg b.w./day orally for 7 days) significantly attenuated collagen deposition and inhibited the cardiac fibroblasts proliferation and migration. In addition, curcumin inhibited MMP-induced extracellular matrix degradation and disallowed the downregulation of sirtuin 1 (SIRT1) after MI. The study provided evidence for the protective role of curcumin against myocardial fibrosis, which was partially mediated by SIRT1 activation (Xiao et al. 2016).

Curcumin exerted protective effects in an atherosclerosis mice model. Administration of curcumin (oral dose of 0.3 mg/per day/per mouse) combined with a high-fat diet decreased the lesion formation by approx. 20% (Olszanecki et al. 2005).

Curcumin has also been shown to improve cardiac function via upregulating the expression of sarcoplasmic reticulum Ca^{2+}-ATPase in a rabbit model (Zhang et al. 2013).

Nakmareong et al. (2011) investigated whether curcumin and its phase I metabolite, THC, could prevent vascular dysfunction and inhibit development of hypertension in N^{ω}-nitro-L-arginine methyl ester-treated rats. Dietary curcumin and THC (50 and 100 mg/kg/b.w./day for 3 weeks) significantly suppressed blood pressure elevation, decreased vascular resistance, and restored vascular responsiveness, without affecting these parameters in normotensive rats. These effects were mostly due to induction of endothelial nitric oxide synthase (*e*NOS) protein expression in the aortic tissue and increase of GSH blood levels, corroborated with a decrease in oxidative stress. The antihypertensive and some antioxidant effects of THC were more potent than those of curcumin (Nakmareong et al. 2011).

27.4.7 Anti-obesity Effects

Animal studies showed improved lipid profiles following curcumin treatment (Gupta et al. 2012; Rivera-Mancía et al. 2018).

Curcumin potential to prevent obesity was investigated in a mouse model. Supplementation of the high-fat diet with 500 mg/kg b.w. curcumin for 12 weeks reduced body weight gain, adiposity, and suppressed angiogenesis in adipose tissue. Curcumin reduced expression of vascular endothelial growth factor (VEGF) and VEGF receptor 2, important factors in angiogenesis progression. Also, it reduced peroxisome proliferator-activated receptor c and CCAAT/enhancer-binding protein-α, key transcription factors in adipogenesis and lipogenesis (Ejaz et al. 2009).

In animals fed a high-fat diet, dietary curcumin has been shown to decrease serum cholesterol levels, by modulation of enzymes involved in cholesterol uptake and transport in the intestine (acyl-CoA:cholesterol acyltransferase) and transformation of cholesterol into bile acid (cholesterol 7-hydroxylase) (Kim and Clifton 2018).

Curcumin treatment (80 mg/kg b.w./day by oral gavage) for 12 weeks ameliorated high-fat diet (HFD)-induced body weight gain and fat accumulation in liver and adipose tissues and improved serum lipid levels and insulin sensitivity in HFD-induced obese mice. Curcumin regulated the expression of sterol regulatory element-binding proteins (SREBPs) in the liver and adipose tissue, genes which are involved in biosynthesis of cholesterol, fatty acids, and triglycerides (Ding et al. 2016).

Antioxidant effects of curcumin significantly contribute to its anti-obesity activity, as assessed in rabbits models. Administration of curcumin was found to reduce the contents of lipid and thiobarbituric acid reactive substances and to enhance GPx and CAT activities in the liver of purely cholesterol-fed rabbits (Gupta et al. 2012).

Curcumin improved the lipid profile in animals with hyperlipidemia, metabolic syndrome and diabetes, with a decrease in plasma triglycerides and non-high-density

lipoprotein-cholesterol, and an increase in high-density lipoprotein (HDL)-cholesterol levels (Rivera-Mancía et al. 2018).

Curcumin was also shown to inhibit leptin activity in several animal models. It is known that leptin inhibits the appetite and contributes to insulin sensitivity. However, in the context of coexistent obesity/hyperleptinemia/diabetes mellitus, leptin resistance may occur, leading to overfeeding, fat accumulation, and alteration of lipid and glucose metabolism (Rivera-Mancía et al. 2018).

27.4.8 Hepatoprotective Effects

Curcumin exerts protective effects in liver diseases, as assessed in various animal studies. Liver damage can be induced by numerous agents, with progression of liver injury, nonalcoholic steatohepatitis, nonalcoholic liver disease, liver fibrosis, and cirrhosis. The beneficial effects of curcumin in liver diseases can be due to its anti-inflammatory, antioxidant, and antifibrogenic properties. Curcumin acts as a free radical scavenger of ROS mostly via its phenolic, diketone, central methylenic, and methoxy groups (Khan et al. 2019; Farzaei et al. 2018).

Oral supplementation with curcumin 18 mg/day for 30 days alleviated non-alcoholic steatohepatitis (NASH) in rabbits. Curcumin decreased aminotransferases activity and increased the mitochondrial antioxidants. More, curcumin also reduced mitochondrial ROS, improved mitochondrial function, and suppressed the activation of NF-kB pathways, including inhibition of TNF-α production and release. Contrarily, similar doses of vitamin E were unable to reduce NASH. Thus, curcumin exerted hepatoprotective effects through a mechanism involving antioxidant, anti-inflammatory, and mitochondrial-protective activities (Ramirez-Tortosa et al. 2009). In agreement with this study, several other animal models with experimental-induced steatohepatitis showed that the hepatoprotective effects of curcumin are related with downregulation of NF-κB transcription factor, an improvement of hepatic fibrosis also in alcoholic liver injuries, an increase of animal survival rates, and a reduction of oxidative damage (Khan et al. 2019; Pulido-Moran et al. 2016).

The efficacy of curcumin in a lipopolysaccharide (LPS)/D-galactosamine-induced acute liver injury (ALI) in rats was studied by Xie et al. (2017). Curcumin pretreatment (orally given by gavage in doses of 30, 60, and 120 mg/kg b.w. for 3 days prior ALI inducement) attenuated hepatic pathological damage, reduced serum levels of alanine transaminase (ALT) and aspartate transaminase (AST), and reduced MDA content in experimental ALI rats. These effects relied on improvement of inflammation and liver pathology. Higher dosages of curcumin inhibited NF-kB activation and reduced serum and liver levels of inflammatory cytokine TNF-α and upregulated the expression of nuclear factor erythroid 2-related factor 2 (Nrf2) and Nrf2-dependent antioxidant defense genes causing cellular resistance to oxidative stress (Xie et al. 2017).

In CCl_4-induced hepatic damage, curcumin (200 mg/kg b.w./day) administered intragastrically to rats for 3 days decreased aminotransferases (ALT and AST) level, suppressed lipid peroxidation, reduced MDA levels, and improved the level of serum reduced and oxidized glutathione (GSH and GSSG) ratio. Curcumin also showed protective effects against decreased SOD and GPx activities, with a recovery of redox balance and an increase of GSH level. Based on these findings, the authors suggested that hepatoprotective effects of curcumin are mostly due to its antioxidant activity; in addition, curcumin might play a role in restoring the liver redox capacity, as represented by GSH/GSSG cycling capacity (Lee et al. 2017).

27.4.9 Nephroprotective Effects

The nephroprotective potential of curcumin, based mostly on its anti-inflammatory, antiproliferative, and antioxidant activities, was reported by several studies which employed animal models. Curcumin exerts positive effects in terms of cardiovascular and nephron protection, thus alleviating inflammation and oxidative stress, which contribute to the increased morbidity and cardiovascular mortality associated with chronic kidney disease (CKD) (de Almeida Alvarenga et al. 2018; Rauf et al. 2018).

Curcumin has shown nephroprotection in a five-sixths nephrectomy (5/6NX)-induced renal damage rats model. Curcumin pretreatment (60 mg/kg/day by oral administration 7 days before 5/6 NX) decreased blood urea nitrogen, plasma creatinine, and renal vascular resistance and increased glomerular filtration rate and renal blood flow. Curcumin-pretreated group showed a higher concentration of endogenous antioxidants such as lipoic acid, ubiquinone, plasmalogen, glutathione, melatonin in the rats kidney, and mitochondria. Also, curcumin pretreatment decreased alterations in mitochondrial dynamics, bioenergetics, and oxidative stress in nephrectomized rats, suggesting that curcumin might contribute to preservation of renal function (Aparicio-Trejo et al. 2017).

Ali et al. (2017) reported nephroprotective efficacy of curcumin in an adenine-induced CKD rats model. Thus, daily gavage of curcumin at doses of 37.5, 75, and 150 mg/kg b.w. for 35 days were associated with alleviation of elevations in blood pressure, urinary albumin/creatinine ratio, plasma urea, and creatinine. Inflammatory markers such as IL-1β, IL-6, and TNF-α, alongside morphological damage and histopathological markers of inflammation, fibrosis, and apoptosis, were significantly reduced by curcumin at higher dosage. These results were accompanied by an increased expression of Nrf2, as well as the activity of its direct target glutathione reductase (GR) and of an indirect target, the GSH level (Ali et al. 2017).

Curcumin reversed glomerular hemodynamic alterations and structural damage induced by oxidative stress in 5/6NX rats. Administration by oral gavage of 60 and

120 mg/kg b.w. curcumin doses, 7 days before and 60 days after 5/6NX, were able to attenuate proteinuria and to reverse renal structure such as interstitial fibrosis, fibrotic glomeruli, tubular atrophy, and mesangial expansion. In addition, curcumin was able to decrease hemodynamic changes such as glomerular hypertension and hyperfiltration. More, curcumin enhanced translocation of Nrf2, with attenuation of oxidative stress and preservation of the activity of several antioxidant enzymes such as CAT, GPx, GR, and GST (Tapia et al. 2013).

In several animal studies, curcumin and theracurmin, a novel formulation of curcumin with enhanced bioavailability, were reported to have protective effects against cardiovascular disease, commonly associated with chronic kidney disease (CKD). Both attenuated oxidative stress-related events such as cardiac remodeling, mitochondrial dysfunction, and cell death (de Almeida Alvarenga et al. 2018).

27.4.10 Prevention of Respiratory Disorders

The effects of curcumin in prevention of respiratory disease are based on modulation of inflammatory pathways and prevention of oxidative damage, by decreasing inflammatory cells accumulation and cytokines overproduction and increasing ROS scavengers activity (Pulido-Moran et al. 2016).

Curcumin was evaluated for its ability to suppress pulmonary injuries induced by bleomycin and amiodarone in models of induced pulmonary fibrosis in rats. Oral administration of curcumin as pretreatment and treatment during the period of fibrosis inducement played a protective role against the development of pulmonary fibrosis by blocking the release of TNF-α and cytotoxic free radicals. Thus, curcumin acted as an antioxidant, anti-inflammatory, and antifibrotic agent, by interfering with the influx of inflammatory cells, by suppressing the activation of alveolar macrophages and subsequent release of toxic mediators, and by preventing excess collagen accumulation in lungs (Punithavathi et al. 2000, 2003).

Similar protective effects for curcumin were reported by Venkatesan (2000) and Venkatesan and Chandrakasan (1995). The authors showed the beneficial effects of curcumin against cyclophosphamide and paraquat-induced pulmonary fibrosis in rats. Oral administration of curcumin (300 mg/kg b.w. for 10 days) reduced the level of leukocytes and inflammatory mediators and increased lung antioxidant defenses. More, curcumin reduced the toxicity and mortality associated with cyclophosphamide and paraquat administration in rats (Venkatesan 2000; Venkatesan and Chandrakasan 1995).

27.5 Benefits (Human Studies)

Numerous clinical studies evaluated the health benefits of curcumin administered as pure compound, mixture of curcuminoids, or highly bioavailable formulations. Most of these studies highlighted a promising therapeutic potential in oxidative stress and inflammation-related disorders.

27.5.1 Curcumin in Malignant Diseases

27.5.1.1 Curcumin in Colorectal Cancer

A non-randomized, open-label clinical trial investigated the prevention potential of oral curcumin in colorectal neoplasia. The trial (phase IIA clinical trial) enrolled 44 smokers with an increased risk of colorectal adenomas (8 or more aberrant crypt focci detected by colonoscopy). Micronized curcumin (4 g daily for 30 days) reduced by 40% the number of aberrant crypt focci. Lower doses (2 g daily for 30 days) were not effective (Carroll et al. 2011). Two human studies investigated the effects of oral curcumin administered as Curcumin C3 Complex (500 mg of curcuminoids (450 mg of curcumin, 40 mg of demetoxycurcumin (DMC), 10 mg of bisdemetoxycurcumin (BDMC))/capsule) in colorectal cancer patients. In a phase I dose-escalation study, 15 patients with advanced colorectal cancer refractory to standard chemotherapies received daily doses of 0.45–3.6 g of curcumin (1, 2, 4, or 8 capsules) for up to 4 months. The daily dose of 3.6 g curcumin induced significant reductions in inducible prostaglandin E2 production in blood samples (62% and 57% on days 1 and 29 of treatment, respectively) suggesting potential benefits in the prevention or treatment of cancers with other location than the gastrointestinal tract (Sharma et al. 2004). On the other hand, Garcea et al. (2005) found that only 7-day administration of the same daily dose of curcumin (3.6 g administered as Curcumin C3 Complex) reduced the level of the oxidative DNA adduct 3-(2-deoxy-β-di-erythro-pentafuranosyl)-pyr[1,2-α]-purin-10(3*H*)one (M_1G), biomarker of colorectal carcinogenesis, in malignant colorectal tissue in 12 colorectal cancer patients. A curcumin preparation (18 mg of curcumin and 2 mg of DMC suspended in 200 mg turmeric essential oils) was investigated in 15 patients with advanced colorectal cancer refractory to standard chemotherapies (dose-escalation pilot study). The preparation was administered in doses of 0.44–2.2 g containing 36–180 mg of curcumin for up to 4 months. Surprisingly, after 29-day administration of a daily dose of 0.44 g (equivalent to 36 mg curcumin), a decrease by 59% in lymphocytic glutathione S-transferase activity (marker of resistance to chemotherapy) was observed, whereas no downregulation in enzyme activity was detected at higher doses (Sharma et al. 2001). Another study investigated the impact of a combination treatment (480 mg of curcumin and 20 mg of quercetin, oral administration, three times daily) in five familial adenomatous polyposis patients who had previously undergone colectomy. After 6-month therapy, both number and size of polyps were significantly reduced (by 60.4% and 50.9%, respectively) (Cruz-Correa et al. 2006). Several years later, Cruz-Correa et al. (2018) reported the lack of efficacy of pure curcumin (1.5 g twice per day, orally, 12 weeks) in 44 patients with familial adenomatous polyposis (no difference in the mean number or size of lower intestinal tract adenomas between curcumin and placebo groups). However, curcumin potential to prevent and/or treat colorectal cancer is supported by its accumulation and persistence in colorectal mucosa. Administration of Curcumin C3 Complex to colorectal cancer patients (2.35 g/day for 14 days before biopsy or tumor resection) resulted in prolonged colonic tissue levels of curcuminoids (mean mucosal level of curcumin: 48.4 μg/g with persistence of up to 40 h after administration) (Irving et al. 2013). The positive effects of oral

curcumin in colorectal tumor tissue have been clinically proved. A double-blind randomized controlled study enrolling 126 colorectal cancer patients reported increase in the expression of pro-apoptotic and tumor suppressor proteins (Bax and p53, respectively) in tumor tissue after 10–30-day administration of 360 mg of curcumin thrice daily. These effects were accompanied by an increase in apoptotic tumor cells and decrease in serum TNF-α (Mantzorou et al. 2018; Salehi et al. 2019).

27.5.1.2 Curcumin in Pancreatic Cancer

A non-randomized, open-label, phase II trial designed by Dhillon et al. (2008) assessed the efficacy of curcumin in advanced pancreatic cancer. Curcumin was given in a mixture with DMC and BDMC (900, 80, and 20 mg, respectively). Twenty-five patients took oral curcuminoid mixture (8 g daily) until disease progression, with restaging every 2 months. The 2-month therapy downregulated the expression of NF-kB, COX-2, and phosphorylated signal transducer and activator of transcription 3 (pSTAT3) in peripheral blood mononuclear cells; NF-kB, COX-2, and pSTAT3 play key roles in tumorigenesis. It is worthy to mention that one patient had stable disease for more than 18 months, whereas another one showed a marked but brief tumor regression (73%) with significant increased levels of IL-6, IL-8, and IL-10 and IL-1 receptor antagonists (4–35-fold). This increase in cytokine levels was attributed to their release from tumor cells due to cell shrinkage. Other trials investigated the activity of the antimetabolite gemcitabine in combination with oral curcumin in pancreatic cancer. An open-labeled phase II study assessed the effectiveness of gemcitabine (1 g/m^2 intravenously weekly for 3 of 4 weeks) in combination with curcumin in 17 patients with advanced pancreatic cancer; curcumin was administered as mixture of curcuminoids (500 mg of curcuminoids, 450 mg of curcumin, 40 mg of DMC, 10 mg of BDMC) at a dose of 8 g/daily. The levels of CA 19–9 tumor marker were measured every 8 weeks; important reductions were detected in three patients (from 90,830, 714, and 214 to 63,130, 96, and 42, respectively) (Epelbaum et al. 2010). Clinical benefit response (CBR), based on changes in pain, Karnofsky performance status and weight (Bernhard et al. 2014), was achieved in four of the ten symptomatic patients (Epelbaum et al. 2010). The phase I/II study designed by Kanai et al. (2011) evaluated the effects of co-administration of curcumin in 21 gemcitabine-resistant pancreatic cancer patients receiving gemcitabine/S-1 combination therapy (19 patients) or gemcitabine (two patients). S-1 is an oral anticancer drug consisting of tegafur, gimeracil, and oteracil (molar ratio 1:0.4:1) (Kobayakawa and Kojima 2011). Curcumin-based complementary therapy (8 g of curcuminoid mixture/day with 900 mg of curcumin, 80 mg of DMC, and 20 mg of BDMC/g of mixture) proved to be safe and feasible. The median survival time was 161 days, and 1-year survival rate was 19%, whereas the median survival time in non-responders to gemcitabine was only 10 weeks (Kanai et al. 2011). Beneficial effects were also found for the combination of Theracurmin, a highly bioavailable curcumin formulation with standard gemcitabine-based chemotherapy in patients with pancreatic (14) and biliary tract (2) cancers who did not respond to gemcitabine. Administration of Theracurmin

(equivalent to 200 and 400 mg of curcumin daily) improved the fatigue- and functioning-associated quality-of-life scores. The median survival time was 4.4 months in patients with pancreatic cancer with three patients surviving for more than 3 months (Kanai 2014).

27.5.1.3 Curcumin in Prostate Cancer

Hejazi et al. (2016) assessed the efficacy of curcumin supplementation in 40 prostate cancer patients during radiotherapy in a double-blinded, randomized, placebo-controlled study. Twenty patients treated with radiotherapy for prostate cancer received curcumin as Biocurcumin (BCM95) (347 mg of curcumin, 84 mg of DMC, 9 mg of BDMC, and 38 mg of turmeric essential oil/capsule) in a dose of 3 g daily 1 week before initiation until completion of radiotherapy (daily fractions of 2 Gy for 5 days/week to achieve a dose of 74 Gy). Curcumin supplementation enhanced plasma total antioxidant capacity (12.8 vs. 10.6 U/mL in placebo group) and reduced superoxide dismutase activity (189.4 vs. 215.2 U/L in placebo group), but it had no effect on prostate-specific antigen (PSA) levels. Both oxidative stress-related markers and PAS levels were determined 3 months after radiotherapy completion. Curcumin-based combination therapy proved to be efficient in prostate cancer patients. A non-randomized, open-label, pilot phase II study was performed to evaluate the efficacy of docetaxel/prednisone in combination with curcumin in 30 patients with chemotherapy-naive metastatic castration-resistant prostate cancer. Within the first three treatment cycles, curcumin (6 g/day for seven consecutive days in each cycle starting 4 days before docetaxel administration till the second day following administration) caused significant reductions in PSA levels (more than 80% in two-thirds of patients) (Mahammedi et al. 2016). Ide et al. (2010) carried out a randomized, double-blind trial enrolling 85 patients without prostatic intraepithelial neoplasia or cancer but having elevated PSA levels. Six-month administration of a combination of curcumin (100 mg/day) and soy isoflavones (40 mg/day) led to a significant decrease in PSA level (from 18.8 to 10.2 ng/mL) in patients having initial PSA $\geq$ 10 ng/mL. Curcumin in combination with soy isoflavones does appear to be beneficial in patients with elevated PSA levels.

27.5.1.4 Curcumin in Breast Cancer

The open-label, phase I trial carried out by Bayet-Robert et al. (2010) on 14 metastatic breast cancer patients showed promising results for curcumin in combination with a standard dose of docetaxel. Curcumin, formulated as 500 mg capsules (450 mg curcumin/capsule), was orally given for seven consecutive days in each cycle starting 4 days before docetaxel administration till the second day afterward, in escalating doses from 0.5 till 8 g/day. In eight patients receiving the combination therapy, marked reductions in levels of carcinoembryonic antigen (CEA) tumor marker and vascular endothelial growth factor (VEGF) were detected after the third cycle of treatment. The reduction of the latter (by 30% at the third cycle and 21% at the sixth cycle) suggests an antiangiogenic effect of the combination. In a randomized, double-blind, placebo-controlled clinical trial, oral curcumin was found to attenuate radiation dermatitis in patients diagnosed with noninflammatory

breast cancer or carcinoma in situ. Thirty patients receiving radiotherapy without concurrent chemotherapy took 2 g of Curcumin C3 Complex (~390 mg of curcumin, 75 mg of DMC, 12.5 mg of BDMC in 500 mg capsule) thrice a day during radiotherapy. Curcumin reduced the severity of radiation dermatitis and presence of moist desquamation but not the redness (Ryan et al. 2013).

27.5.1.5 Curcumin in Head and Neck Squamous Cell Carcinoma

In patients with head and neck cancer, chewing two curcumin caplets (1 g curcumin) for 5 min reduced IkB kinase β (IKKβ) kinase activity in the salivary cells; the enzyme is involved in NF-kB activation and consequently in tumor growth. Curcumin also downregulated the expression of several pro-inflammatory salivary cytokines such as IL-10, IL-12p70, IL-2, γ interferon (IFN-γ), granulocyte-macrophage colony-stimulating factor (GM-CSF), and TNF-α (Kim et al. 2011).

27.5.1.6 Curcumin in Multiple Myeloma

A phase I/II study investigated the effects of 12-week administration of curcumin alone (2, 4, 6, 8, or 12 g/day in two doses) or in combination with bioperine (10 mg in two doses) in 29 multiple myeloma patients. Curcumin induced significant reductions in the activation of NF-kB and STAT3 but also in the expression of COX-2 in patients peripheral blood mononuclear cells (Salehi et al. 2019). Monoclonal gammopathy of undetermined significance (MGUS) is a plasma cell dyscrasia accompanied by paraproteinemia which can progress to multiple myeloma. In a single-blind, crossover pilot study, enrolling 26 patients with MGUS, curcuminoid mixture (900 mg of curcumin, 80 mg of DMC, and 20 mg of BDMC/tablet, 4 g daily, 12 months) reduced the paraprotein level (12–30% reduction) and urinary N-telopeptide of type I collagen (> 25% reduction), marker of osteolysis (Golombick et al. 2009). Golombick et al. (2012) designed a more complex study, a randomized, double-blind, placebo-controlled, crossover study (6 months) followed by an open-label extension study (3 months) to assess the potential of curcumin to slow down the progression of MGUS and smoldering multiple myeloma (SMM) to multiple myeloma; the study enrolled 36 patients (19 MGUS and 17 SMM). Curcumin was given as curcuminoid mixture: 4 g (3.6 g of curcumin, 0.32 g of DMC, 0.08 g of BDMC) and 8 g daily in the crossover and open-label extension studies, respectively. In both MGUS and SMM patients, 4 and 8 g therapy caused significant reductions in several markers for disease diagnosis and monitoring such as the free light chain ratio (rFLC) (35 and 36% reduction, respectively), difference between involved and uninvolved light chains (dFLC) (9 and 11% reduction, respectively), and involved free light chain (iFLC) (8 and 10% reduction, respectively). Curcumin also decreased the urinary deoxypyridinoline (u-DPYD), a marker of bone resorption (9–14% reduction), random urinary protein, and total serum protein (Golombick et al. 2012). Curcumin appears to slow down the progression of MGUS and SMM to multiple myeloma.

27.5.2 Curcumin in Central Nervous System Disorders

27.5.2.1 Curcumin in Alzheimer's Disease

Recent human trials showed that long-term administration of bioavailable curcumin leads to significant improvements in memory and attention. In a 18-month double-blind, placebo-controlled trial, 21 middle-aged and older non-demented adults received 90 mg of bioavailable curcumin (Theracurmin®) twice daily. Bioavailable curcumin improved memory and attention as revealed by Buschke Selective Reminding Test (SRT), Brief Visual Memory Test-Revised (BVMT-R), and Trail Making Test Part A. The same study investigated amyloid and tau proteins accumulation in brain regions by 2-(1-{6-[(2-[F-18]fluoroethyl)(methyl)amino]-2-naphthyl}ethylidene)malononitrile positron emission tomography (FDDNP-PET) and found reduced deposits in subjects receiving bioavailable curcumin. The benefits of bioavailable curcumin, namely, improvements in memory and attention, seemed to be associated with the decrease in amyloid plaques and tau tangles deposits in the brain (Small et al. 2008). Benefits on cognitive function and mood were also proven for a bioavailable solid lipid curcumin formulation (Longvida®) in a daily dose of 400 mg (corresponding to 80 mg of curcumin). In a randomized, double-blind, placebo-controlled, phase III/IV trial including healthy aged adults, curcumin formulation improved sustained attention and working memory tasks (1 and 3 h after a single dose), mood and working memory (after 4 weeks), and alertness and contentedness (1 and 3 h after single dose following chronic treatment) (Cox et al. 2015; Salehi et al. 2019). Hishikawa et al. (2012) reported three cases of 79-, 83-, and 84-year-old patients with progressive dementia or short-term memory loss who took 764 mg of turmeric powder (corresponding to 100 mg of curcumin) daily for 12 weeks with significant decrease in the acuity of irritability, agitation, anxiety, and apathy. In a randomized, double-blind, placebo-controlled trial enrolling 34 Alzheimer's disease patients, once daily administration of curcumin (4 or 1 g) in combination with a standardized *Ginkgo biloba* leaf extract (120 mg) for 6 months caused an increase in amyloid-β 40 (Aβ40) which is a proteolytic product from the amyloid precursor protein (APP), biomarker of Alzheimer's disease. The outcome of the study suggests that curcumin might break down APP or amyloid-β deposits to Aβ40 which is further released into circulation (Baum et al. 2008; Salehi et al. 2019). Other human trials found no health benefits for Curcumin C3 Complex® and Biocurcumax™, bioavailable curcumin formulation, in Alzheimer's disease patients and healthy older adults, respectively (Salehi et al. 2019).

27.5.2.2 Curcumin in Depression

Lopresti et al. (2014) investigated the potential antidepressant effects of oral curcumin in a randomized, double-blind, placebo-controlled study on 56 patients suffering from major depressive disorder. Curcumin was used as BCM-95® (500 mg capsule containing 88% mixture of curcumin, DMC, and BDMC and 7% essential oil from turmeric rhizomes) at 1 g/day for 8 weeks. Clear benefits of curcumin

supplementation were evident after 4 weeks of treatment: several mood-related symptoms were improved according to the Inventory of Depressive Symptomatology self-rated version (IDS-SR_{30}), questionnaire containing 30 items measuring depressive symptoms. Greater efficacy was observed in patients with atypical depression. In a further randomized, double-blind, placebo-controlled clinical study, Lopresti et al. (2015) examined the effects of curcumin supplementation on several biomarkers associated with antidepressant activity. Fifty patients diagnosed with major depressive disorder received curcumin (BCM-95®, 1 g/day, 8 weeks) or placebo. After 8-week curcumin supplementation, urinary thromboxane B2, substance P and cortisol, and baseline plasma endothelin-1 and leptin were elevated, the latter two being associated with significant reductions in IDS-SR_{30} score. Another study on 108 patients showed that curcumin supplementation has a significant influence on inflammatory biomarkers in major depressive disorder. Curcumin was used as curcuminoid mixture (70% curcumin, 20% DMC, 10% BDMC) at a daily dose of 1 g for 6 weeks. Curcumin supplementation had antidepressant effects (reduction of 17-item Hamilton Depression Rating Scale and Montgomery-Asberg Depression Rating Scale scores.). In addition, it reduced salivary cortisol, IL-1β, and TNF-α plasma levels and enhanced brain-derived neurotrophic factor (BDNF) plasma level (Yu et al. 2015; Salehi et al. 2019). There are two clinical trials on the combined effects of curcuminoids and piperine. Esmaily et al. (2015) investigated the efficacy of the combination on depression and anxiety in obese individuals. Thirty obese subjects received the combination (1 g C3 Complex® and 5 mg Biopiperine® daily) or placebo for 30 days. The combination reduced anxiety (reduction in Beck Anxiety Inventory (BAI) mean score) but not depression (no influence on Beck Depression Inventory (BDI) score). Another study was conducted in patients with major depressive disorder and investigated the efficacy of the combination of curcuminoids and piperine as adjuvant to standard antidepressant therapy. A hundred eleven patients received either standard antidepressant therapy plus combination of curcuminoids and piperine (1 g C3 Complex® and 5 mg Bioperine® daily) or standard antidepressant therapy for a period of 6 weeks. Patients receiving curcuminoid-based adjunctive therapy showed a greater reduction in anxiety and depression symptoms (evaluation by Hospital Anxiety and Depression Scale, HADS and Beck Depression Inventory II, BDI-II) (Panahi et al. 2015). Other two clinical trials proved the efficacy of curcumin as adjunctive therapy in depression. Forty patients with a first episode of depression were treated with curcumin (500 mg/day) and antidepressants or placebo and antidepressants for 5 weeks. The ones receiving curcumin showed a more rapid relief of depressive symptoms (evaluation by Clinical Global Impression-Severity Scale, Hamilton Depression Rating Scale, and Montgomery-Asberg Depression Rating Scale) (Bergman et al. 2013; Salehi et al. 2019). Another clinical trial investigated the effects of fluoxetine (20 mg/day) and curcumin (1 g/day), individually and in combination with 60 patients with major depressive disorder (6-week trial). According to Hamilton Depression Rating Scale, 17-item version (HAM-D17), combination of fluoxetine and curcumin was more efficient than fluoxetine or curcumin alone (77.8%, 64.7%, and 62.5% responders in combination, fluoxetine and curcumin groups, respectively) (Sanmukhani et al. 2014).

27.5.3 Curcumin in Cardiovascular System Disorders

Clinical trials assessing the cardioprotective effects of oral curcumin in healthy individuals reported contradictory outcomes. A trial involving ten healthy volunteers found that 7-day administration of a daily dose of 500 mg curcumin decreased serum lipid peroxides (by 33%) and total cholesterol (by 11.63%) while increasing HDL cholesterol (by 29%) (Salehi et al. 2019). On the other hand, a randomized, double-blind trial enrolling 36 healthy volunteers reported no effects on serum lipid profile for 6-month administration of higher daily doses of curcumin (1 and 4 g) (Baum et al. 2007; Salehi et al. 2019). Longvida® Optimized Curcumin, a bioavailable solid lipid curcumin formulation, demonstrated cardioprotective efficacy in healthy middle-aged people. After 4 weeks, a daily dose of 400 mg (80 mg curcumin) affected several markers relevant for cardiovascular health, namely, lowered plasma triglycerides and soluble intercellular adhesion molecule (sICAM), salivary amylase and increased plasma catalase, myeloperoxidase (no increase in C-reactive protein), and nitric oxide and salivary radical scavenging activity. In addition, plasma amyloid-β protein and alanine aminotransferase were found to be reduced (DiSilvestro et al. 2012). Alwi et al. (2008) designed an interventional study, a randomized, double-blind, controlled trial to evaluate the effects of curcumin in patients with acute coronary syndrome. Fifteen patient groups received low, moderate, or high doses of curcumin (15, 30, and 60 mg thrice daily, respectively) or placebo. After 2 months, an increase in HDL cholesterol and a reduction in total cholesterol and LDL cholesterol were detected in low-dose curcumin group. Surprisingly, moderate and high doses of curcumin were less efficient in ameliorating lipid profile. In a similar randomized double-blind, crossover trial, curcumin supplementation (1 g C3 Complex® and 10 mg Bioperine®/day) increased serum Zn/Cu and reduced Cu/Zn in obese patients, both effects supporting a cardioprotective potential (Mohajer et al. 2014).

27.5.4 Curcumin in Arthritis

Several clinical trials have proved the efficacy of curcumin in osteoarthritis and rheumatoid arthritis. In a pilot randomized double-blind, placebo-controlled, parallel-group trial, 40 patients with mild-to-moderate knee osteoarthritis received either a combination of curcuminoids and bioperine (500 mg C3 Complex® and 5 mg Bioperine® thrice daily) or placebo for 6 weeks. Important reductions in Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC), visual analogue scale (VAS), and Lequesne's pain functional index (LPFI) scores were observed in curcuminoid group. It is worthy to mention that curcuminoids significantly improved the pain and physical function scores (Panahi et al. 2015). Meriva®, a curcumin-phosphatidylcholine phytosome complex, showed clinical efficacy in patients with osteoarthritis. Administration of Meriva® (1 g corresponding to 200 mg curcumin daily, 3 or 8 months) decreased the WOMAC score by more than 50%, improved the Karnofsky Performance Scale Index, and increased the walking distance in the treadmill test. In addition, Meriva® significantly

reduced inflammation biomarkers such as IL-1β, IL-6, soluble vascular cell adhesion molecule 1 (sVCAM-1), soluble CD40 ligand (sCD40L), erythrocyte sedimentation rate (ESR), and C-reactive protein (Belcaro et al. 2010). A double-blind prospective randomized controlled trial evaluated the efficacy of curcumin as adjuvant therapy for diclofenac in patients with primary knee osteoarthritis. Patients (44) received either diclofenac (75 mg/day) with placebo or diclofenac (75 mg/day) with curcumin (1 g/day) for 3 months. The combination of curcumin with diclofenac proved to be more effective in pain reduction and improvement in function in daily life in comparison with diclofenac alone (according to Knee Injury and Osteoarthritis Outcome Score (KOOS), respectively) but with no significant difference between the two groups (Pinsornsak and Niempoog 2012).

A short-term (2 weeks) double-blind, crossover study enrolling 18 patients with rheumatoid arthritis compared the benefits of curcumin (1200 mg daily) with those of phenylbutazone (300 mg daily). The effects of curcumin, particularly with respect to the improvement in morning stiffness, walking time, and joint swelling, were comparable to those of phenylbutazone (Deodhar et al. 1980). Another clinical study (randomized, single-blinded, pilot study) compared the effectiveness of diclofenac sodium, curcumin (used as BCM-95®), and their combination in patients with active rheumatoid arthritis. Three groups of 15 patients each took diclofenac sodium (50 mg daily), curcumin (500 mg daily), or their combination for 8 weeks. Curcumin induced the most significant improvements in disease activity score (DAS) 28 and American College of Rheumatology (ACR) scores. Besides, curcumin induced the highest reduction in C-reactive protein levels (Chandran and Goel 2012). Curcumin proved to be efficient in postoperative inflammation too. Forty-six patients who underwent surgical repair of inguinal hernia and/or hydrocele took curcumin (400 mg), phenylbutazone (100 mg), or placebo thrice daily for 6 days. Curcumin demonstrated similar efficacy with phenylbutazone in reducing the intensity score (TIS) for spermatic cord edema and tenderness and operative site pain and tenderness (84.2% vs. 86% decrease) (Gupta et al. 2013; Salehi et al. 2019). Curcumin supplementation attenuated inflammation in patients with metabolic syndrome and type 2 diabetes mellitus. A randomized, double-blind, placebo-controlled trial evaluated the effects of curcuminoid (Curcumin C3 Complex®)-piperine (Bioperine®) combination (500 and 5 mg, respectively, twice daily for 8 weeks) on oxidative and inflammatory status in patients with metabolic syndrome. Administration of curcuminoid-piperine combination was associated with an increase in superoxide dismutase (SOD) activity and a reduction in serum malondialdehyde and C-reactive protein (Panahi et al. 2015a).

Kertia et al. (2012) investigated the effects of a curcuminoid mixture isolated from *Curcuma domestica* Val. rhizomes, on COX-2 level in synovial fluid of osteoarthritis patients. The study (prospective, randomized open-blinded end-point (PROBE) study) enrolled 80 knee osteoarthritis patients and demonstrated no significant difference in suppressing COX-2 secretion by synovial fluid monocytes between curcuminoid (30 mg thrice daily) and diclofenac sodium (25 mg thrice daily) after 4-week treatment (decreasing score of COX-2 secretion: 0.70 ± 0.51 in curcuminoid group and 0.67 ± 0.45 in diclofenac group).

27.5.5 Curcumin in Type 2 Diabetes Mellitus

In 14 healthy subjects, turmeric powder (6 g, single dose), taken together with a standard 75 g oral glucose tolerance test, increased postprandial serum insulin levels without affecting plasma glucose levels or glycemic index (crossover trial) (Wickenberg et al. 2010). Curcumin was found to prevent the development of type 2 diabetes mellitus in prediabetic patients. In a randomized, double-blind, placebo-controlled clinical trial, 240 prediabetic patients were assigned to either receive curcuminoid extract (75–85% total curcuminoids, 1.5 g daily or placebo). After 9 months, 16.4% of prediabetic patients in placebo group were diagnosed with type 2 diabetes, whereas no prediabetic patient receiving curcuminoid extract developed the disease. Moreover, curcuminoid extract improved the function of β cells, as revealed by higher HOMA-β and lower C-peptide levels in curcuminoid-treated group. In addition, curcuminoid intervention decreased HOMA-IR and increased adiponectin level (Chuengsamarn et al. 2012). Srinivasan was the first to investigate the benefits of turmeric powder in diabetes. He reported that 5 g of turmeric powder decreased blood glucose in one type 2 diabetes mellitus patient (Salehi et al. 2019). Na et al. (2013) performed a 12-week double-blind, placebo-controlled trial on curcumin glucose-lowering effects in type 2 diabetes. One hundred overweight/obese type 2 diabetes mellitus patients were randomly assigned to receive curcuminoid extract (36.06% curcumin, 18.85% DMC, 42.58% BDMC) at a dose of 300 mg daily or placebo for 3 months. Curcuminoid extract significantly decreased fasting blood glucose, HOMA-IR, serum total free fatty acids, and triglycerides and increased lipoprotein lipase activity. Curcumin proved to be efficient as adjuvant therapy in type 2 diabetes mellitus. Co-administration of glyburide, a permeability glycoprotein (P-gp) substrate, with curcumin, a P-gp inhibitor, showed clinical benefits in patients with type 2 diabetes mellitus and hyperlipidemia. In an open-label, randomized, controlled trial enrolling eight type 2 diabetic patients on glyburide therapy (5 mg daily), 10-day co-administration of curcumin (475 mg daily) enhanced the bioavailability of glyburide (significant increase in Area Under first Movement Curre, AUMC) with a consequent decrease in glucose, LDL, VLDL, and triglyceride levels and increase in HDL level (Neerati et al. 2014). Maithili Karpaga Selvi et al. (2015) investigated the effects of co-administration of turmeric powder in type 2 diabetic patients receiving metformin treatment. In brief, 30 patients received metformin treatment (500 mg twice daily), while other 30 patients took metformin (500 mg twice daily) and turmeric powder (2 g equivalent to 46 mg curcumin, daily). In metformin-treated patients, turmeric supplementation decreased fasting glucose, glycated hemoglobin A1c (HbA1c), lipid peroxidation, LDL cholesterol, non-HDL cholesterol, LDL/HDL ratio, and high-sensitivity C-reactive protein and enhanced total antioxidant status. Rahimi et al. (2016) reported the results of a 3-month randomized, double-blind, placebo-controlled clinical trial evaluating the effects of nano-curcumin on HbA1c, fast blood glucose, and lipid profile in type 2 diabetic patients. Seventy type 2 diabetic patients took nano-curcumin (80 mg curcumin in the form of nano-micelle daily) or placebo. Nano-curcumin decreased HbA1c, fasting blood glucose, triglycerides, and body mass index.

27.5.6 Curcumin in Obesity

Other trials evaluated the effects of curcuminoids in combination with bioperine on markers associated with cardiovascular risk in obesity. In a randomized, double-blind trial with a 2-arm 2-period crossover design, 30 obese patients received either a daily dose of 1 g of curcuminoids (500 mg C3 Complex® and 5 mg Bioperine®) or placebo for 30 days. After a 2-week washout period, the patients were crossed over to alternate treatment for other 30 days. At the end of each treatment period, pro-oxidant-antioxidant balance and antibody titers to markers of oxidative stress such as heat shock protein 27 (Hsp27) and oxidized LDL (oxLDL) were evaluated. Curcumin supplementation resulted in a significant decrease in pro-oxidant-antioxidant balance; no influence on antibody titers to Hsp27 and oxLDL was observed (Sahebkar et al. 2013). Surprisingly, 4-week supplementation with turmeric powder at culinary levels (2.8 g daily corresponding to approx. 112 mg curcumin) did not improve oxidative stress (F2-isoprostanes, oxLDL), inflammation (C-reactive protein, IL-1β, IL-6, IL-8, IL-10, IL-12p70, TNF-α, IFN-γ), and global metabolic parameters in 62 overweight/obese females with systemic inflammation (randomized, double-blind, placebo-controlled, cross-over study) (Nieman et al. 2012). Ganjali et al. (2014) conducted a randomized, double-blind, crossover trial to investigate the effects of curcumin on serum cytokines in obese subjects. Thirty obese individuals were given curcumin as C3 complex (500 mg) plus bioperine (5 mg) or placebo twice daily for 4 weeks. Curcumin significantly reduced the serum levels of IL-1β, IL-4, and vascular endothelial growth factor (VEGF). Di Pierro et al. (2015) investigated the effects of a bioavailable curcumin formulation (curcumin-phospholipid phytosome) on the weight and omental adipose tissue in overweight individuals with metabolic syndrome. The phytosomal formulation of curcumin consisted of a turmeric extract (95% curcumin) complexed with sunflower phospholipids (20% phosphatidylserine). Twenty-two subjects received phytosomal formulation of curcumin in combination with piperine (800 and 8 mg twice daily), while other 22 subjects received pure phosphatidylserine. After 1 month, the phytosomal formulation of curcumin enhanced weight loss from 1.88% to 4.91%, body fat reduction from 0.70% to 8.43%, waistline reduction from 2.36% to 4.14%, hip circumference reduction from 0.74% to 2.51%, and body mass index reduction from 2.10% to 6.43%. Phosphatidylserine showed no statistical significant effects, most probably due to low dose and/or short administration time.

27.5.7 Curcumin in Gastrointestinal Disorders

27.5.7.1 Curcumin in Peptic Ulcer

Two clinical trials found beneficial effects of turmeric powder in peptic ulcer. Ulcer reduction was reported in 60 ulcer patients after 6–12-week administration of 1 g turmeric powder daily (Salehi et al. 2019). Higher doses of turmeric powder (3 g daily) produced total ulcer remission in 12, 18, and 19 of 25 patients diagnosed

with gastric and duodenal ulcers after 4, 8, and 12 weeks of treatment, respectively. In 20 patients with erosions, gastritis, and dyspepsia, 3 g of turmeric powder daily reduced abdominal pain and discomfort after 1–2 weeks (Prucksunand et al. 2001).

27.5.7.2 Curcumin in *Helicobacter Pylori* Infection

Curcumin alone (700 mg turmeric tablet containing 40 mg curcumin, thrice daily, 4 weeks) showed limited anti-*Helicobacter pylori* activity in comparison with omeprazole-based triple regimen (20 mg omeprazole, 1 g amoxicillin, and 800 mg metronidazole, twice daily for 1 week); the eradication rate in curcumin treatment group was only 5.9% in comparison with 78.9% in omeprazole-amoxicillin-metronidazole treatment group (Koosirirat et al. 2010). A curcumin-based non-antibiotic therapy demonstrated positive therapeutic effects with respect to dyspepsia and gastric inflammation in patients with *Helicobacter pylori* infection. Twenty-five *Helicobacter pylori*-positive patients with functional dyspepsia received curcumin (30 mg) combined with lactoferrin (100 mg), N-acetylcysteine (600 mg), and pantoprazole (20 mg) twice daily for 7 days. Lactoferrin, N-acetylcysteine, and pantoprazole have been reported to possess anti-*Helicobacter pylori* effects. Lactoferrin exerts both bacteriostatic (binding and sequestration of iron that are essential for bacterial growth) and bactericidal (damage of the outer membrane of gram-negative bacteria) effects. N-acetylcysteine, a well-known mucolytic agent, decreases the thickness of the gastric mucus layer thus impairing the growth of *Helicobacter pylori* and improving the mucosal penetration of the other components in the combination. Pantoprazole, a proton-pump inhibitor, creates a hostile environment for *Helicobacter pylori.* Two months after treatment has ended, *Helicobacter pylori* infection was eradicated in 3 of 25 patients; the severity of dyspeptic symptoms (epigastric pain, postprandial fullness, bloating, belching, nausea) and the levels of serum pepsinogen I and II were significantly decreased in all patients (Di Mario et al. 2007).

27.5.7.3 Curcumin in Inflammatory Bowel Disease

Holt et al. (2005) investigated the effects of curcumin in ulcerative proctitis and Crohn's disease in an open-label pilot study. Five patients with ulcerative proctitis or proctosigmoiditis were treated with 550 mg of curcumin twice daily for 1 month followed by 550 mg thrice daily for another month. The authors reported a decrease in indices of inflammation (erythrocyte sedimentation rate, C-reactive protein) to normal levels. In the same study, five Crohn's disease patients were treated with 360 mg of curcumin thrice daily for one month followed by 360 mg of curcumin four times daily for other two months. The treatment reduced the Crohn's Disease Activity Index (CDAI), erythrocyte sedimentation rate, and C-reactive protein levels. Co-administration of curcumin improved the efficacy of medication used to treat ulcerative colitis. Hanai et al. (2006) performed a randomized, multi-center, double-blind, placebo-controlled trial to investigate the effect of curcumin as adjunctive therapy in quiescent ulcerative colitis. Eighty-nine patients were assigned to receive curcumin (1 g twice daily) or placebo in combination with sulfasalazine or mesalamine for 6 months. Curcumin reduced recurrence rate, clinical

activity index (CAI), and endoscopic index (EI) (Salehi et al. 2019). Another multicenter, randomized, double-blind, placebo-controlled trial, designed by Lang et al. (2015), enrolled 50 patients with active mild-to-moderate ulcerative colitis treated with mesalamine. Patients did not respond to maximal mesalamine oral (4 g/day) and local (1 g in 4 g enema or 1 g suppository/day) therapy administered for 2 weeks. Curcumin (3 g/day) or placebo was added to patients receiving mesalamine. After 1 month, significant clinical and endoscopic remissions were detected in curcumin group (53.8% clinical remission, 65.3% clinical response, 38% endoscopic remission vs. 0% clinical remission, 12.5% clinical response, and 0% endoscopic emission in placebo group, respectively).

27.5.8 Curcumin in Liver Disorders

Rahmani et al. (2016) investigated the effects of curcumin on liver fat content and biochemical and anthropometric indices in patients with nonalcoholic fatty liver disease. Eighty patients were enrolled in a randomized, double-blind, placebo-controlled study and received amorphous dispersion of curcumin formulation (500 mg daily equivalent to 70 mg of curcumin) or placebo for 8 weeks. It was found that curcumin administration significantly reduced liver fat content, serum levels of total cholesterol, LDL, triglycerides, aspartate aminotransferase, alanine aminotransferase, fasting blood sugar, glycated hemoglobin, and also body mass index. Echogenicity of the liver, as revealed by ultrasonography, was improved in 78.9% of patients in curcumin group but only in 27.5% of patients in placebo group. In addition, liver fat content showed no increase in curcumin group but increased in 17.5% of patients in placebo group. Panahi et al. (2017) reported the efficacy of Meriva® in nonalcoholic fatty liver disease. A hundred and two patients were randomly assigned to receive Meriva® (500 mg twice daily) or placebo for 8 weeks. Meriva® reduced body mass index, waist circumference, aspartate aminotransferase, and alanine aminotransferase levels. Ultrasonography showed improvement in liver echogenicity in 75% patients in Meriva® group and only 4.7% patients in placebo group. The study of Kim et al. (2013) reported hepatoprotective effects for fermented turmeric. Fermentation of crushed turmeric was carried out in the presence of *Aspergillus oryzae* (2%) at 25 °C for 36 h followed by drying and standardization to 0.79 mg curcumin per 1 g powder. A randomized, double-blind, placebo-controlled trial enrolled 60 subjects with mild-to-moderate elevated alanine aminotransferase levels (40–200 IU/L). The subjects took either fermented turmeric powder (3 g daily) or placebo. After 12 weeks, serum alanine aminotransferase and aspartate aminotransferase levels were significantly reduced in subjects receiving fermented turmeric powder.

27.5.9 Curcumin in Gall Bladder Disorders

Curcumin showed cholekinetic effects in healthy individuals. Two studies (randomized, double-blind, placebo-controlled, crossover and randomized, single-blind, III

phase, crossover studies) investigated the effects of different doses of curcumin (20, 40, or 80 mg, single dose) on gall-bladder contraction at different intervals (0.5, 1, 1.5, and 2 h) after administration. The 40 mg dosage was found to induce 50% contraction of gall bladder at 2 h after administration (Salehi et al. 2019). With respect to biliary dyskinesia, the effects of curcumin alone have not been investigated yet. Only a combination preparation containing dried extracts of greater celandine (*Chelidonium majus* L.) and turmeric was found to cause a faster reduction in dumpy and colicky pain in patients with biliary dyskinesia after 1-week treatment (Salehi et al. 2019).

27.5.10 Curcumin in Pancreatitis

Curcumin in combination with piperine has been reported to be efficient in pancreatitis. Twenty patients with tropical pancreatitis were randomized to receive curcumin (500 mg/day) with piperine (5 mg/day) or placebo. After 6 weeks, significant reduction in erythrocyte malonyldialdehyde and increase in erythrocyte glutathione (both markers of oxidative stress) were detected in group treated with curcumin and piperine (Durgaprasad et al. 2005; Salehi et al. 2019).

27.6 Application in Food (Including Correctly Cooking Foods Rich in Curcumin)

Curcumin (E 100) is authorized as food additive (food color) in the European Union with maximum permitted levels (MPLs) of 50–500 mg/kg in foods and at *quantum satis* in some food categories (EFSA 2014). As main component of turmeric powder which is widely used as food flavoring, coloring, and preservative agent, curcumin is an ingredient of many dishes worldwide. Heat treatment is known to affect the chemical integrity and consequently the health benefits of many food ingredients (vitamins, proteins, lipids, carbohydrates) (Suresh et al. 2009). Therefore, the impact of different types of cooking on the stability and bioactivity of curcumin is of high interest. The instability of curcumin during heating can be mainly attributed to its diketone moiety which is very susceptible to hydrolysis. In addition to hydrolysis into smaller compounds, conjugated double-bond shift and polymerization might also occur during heat treatment (domestic cooking) (Suresh et al. 2009).

Different cooking methods affect the bioactivity of curcumin. For example, heating was found to increase the water solubility and bioactivity of curcumin. Heating curcumin in water (1 or 5 mg curcumin/mL water at 90 °C with further heating for 10 min in a boiling water bath) increased solubility 12-fold without affecting its stability (Kurien et al. 2007). Moreover, heat-solubilized curcumin showed antioxidant activity (80% reduction in 4-hydroxynonenal-mediated oxidation of proteins) (Kurien et al. 2007) and immunomodulating effects (43–52% reduction in antibody-antigen interaction) (Kurien et al. 2010). On the other hand, heating curcumin in aqueous solution (40 μM) for 11 and 15 min at 95 °C caused

curcumin degradation (67 and 82%, respectively) with changes in antioxidant activity such as decrease in 2,2-diphenyl-1-picrylhydrazyl (DPPH) radical and increase in 2,2′-azinobis(3-ethylbenzothiazoline-6-sulfonic acid) (ABTS) radical cation scavenging effects at 11 min, increase in nitrite scavenging effect at 15 min, and increase in 2,2′-azobis(2-amidinopropane) dihydrochloride (AAPH) radical scavenging effects at 10 and 15 min heating. Microwave heating was found to cause time and radiation power-dependent degradation and changes in antioxidant activity of aqueous curcumin. Exposure to microwave radiation at 500 W for 5 min degraded almost 70% of curcumin. However, the microwave heating at 500 W for 5 min caused more pronounced enhancements (46–100%) in ABTS, nitrite, and AAPH radicals scavenging activity in comparison with regular heating (Jung et al. 2016). Ten min heat treatment in a pressure cooker (15 psi) decomposed curcumin into smaller compounds such as vanillin, vanillic, and ferulic acids (Suresh et al. 2009). Typical Indian cooking (heating spices, including turmeric in hot oil) also enhances the health benefits of curcumin. In order to mimic the effects of traditional cooking, curcumin was pyrolyzed with coconut fat or olive oil (5 mg curcumin and 50 mg fat were pyrolyzed at 250 °C for 20 min). The process generated more hydrophilic products and isoforms (DMC, iso-DMC, BDMC, iso-BDMC, iso-curcumin) but also diketene curcumin (1,5-bis (4-hydroxy-5-methoxyphenyl)-1,4-pentadiene-3-one), previously reported as a synthetic curcumin analogue; the latter showed higher stability and higher anti-tumor activity (induction of apoptosis and G2 arrest in B78H1 melanoma cells) than curcumin (Dahmke et al. 2014).

To conclude, domestic cooking affects curcumin structure, but structure modification is not always accompanied by a reduction in bioactivity; traditional Indian cooking, microwave heating, and even regular heating enhanced different biological effects (antioxidant, antitumor) of curcumin.

27.7 Safety: Toxicity and Side Effects

Curcumin possesses a good safety profile. The US Food and Drug Administration (FDA) has approved curcumin as *generally recognized as safe* (GRAS) (Gupta et al. 2013). The Joint United Nations and World Health Organization Expert Committee on Food Additives (JECFA) and European Food Safety Authority (EFSA) reported that the allowable daily intake (ADI) value of curcumin is 0–3 mg/kg body weight (Hewlings and Kalman 2017).

Curcumin proved to be safe and well tolerated even at high doses. Escalating single doses of C^3 Complex™ (75% curcumin, 23% DMC, 2% BDMC) from 0.5 to 12 g showed an excellent tolerance in healthy volunteers with minimal adverse events (diarrhea, headache, rash, yellow stool) in 30% of subjects (Lao et al. 2006). Long-term high-dose curcumin administration was also well tolerated. In a 3-month phase I clinical trial in patients with high-risk or premalignant lesions, oral curcumin showed no toxicity in humans in doses up to 8 g/day (Cheng et al. 2001). Most of clinical studies reported no significant

toxicity for curcumin or curcumin-based preparations. Only few studies indicated adverse effects for high doses of curcumin. The most frequently reported side effects were gastrointestinal events (abdominal pain, reflux, flatulence, diarrhea, nausea) (Gupta et al. 2013; Fadus et al. 2017). The highest patient compliance was found for daily doses of 2–4 g, most side effects occurring at daily doses higher than 4 g (Fadus et al. 2017). A good tolerability was also found for highly bioavailable curcumin Theracurmin (180 mg curcumin/day for 8 weeks in patients with knee osteoarthritis) (Nakagawa et al. 2014).

27.8 Marketed Products

Curcumin is widely marketed as capsules, tablets, energy drinks, ointments, and cosmetics (Gupta et al. 2013). The most common conventional but also bioavailable curcumin-based formulations (registered and unregistered trademarks) are listed in Table 1; for the latter, the relative bioavailabilities compared to conventional

Table 1 Conventional and bioavailable curcumin-based formulations

Product	Description	Relative bioavailability compared to conventional curcumin
Biocurcumax™ (BCM®)	Turmeric powder and turmeric essential oil (45% ar-turmerone)	6.9
Cavacurmin®	γ-cyclodextrin-based formulation (approx. 15% total curcuminoids)	85
Curcumin C3 Complex®	Curcuminoids (450 mg of curcumin, 40 mg of DMC, 10 mg of BDMC)	–
Curcumin C3 Complex® + Bioperine	Curcuminoids and bioperine	20
CurcuWin®	Water-soluble formulation containing 20–28% turmeric extract	136.3
CurQfen™	Formulation containing 40% curcumin and fenugreek soluble dietary fibers	15.8
LongVida®	Solid lipid curcumin particle-based formulation (20–30% curcumin)	100
Meriva®	Curcumin-phosphatidylcholine phytosome complex (18–20% curcuminoids)	48
MicroActive curcumin	Micronized formulation (25% curcuminoids)	9.7
Micronized curcumin	Micronized powder (25% curcumin powder)	9
NovaSol®	Liquid micelles containing 7% curcumin powder (equiv. to 6% curcumin)	185
Theracurmin®	Colloidal-nanoparticle-based formulation containing 10% curcumin and 2% other curcuminoids	15.9

(unformulated) curcumin are also given (Jamwal 2018; Sharma et al. 2004). The safety and efficacy of most of them have been evaluated in clinical studies as previously described in Sects. 5 and 7.

Curcumin has a low oral bioavailability, and therefore numerous approaches have been developed to overcome this limitation. Reduction in particle size of curcumin by micronization improved dissolution and hence absorption. Co-administration with bioavailability enhancers such as piperine (alkaloid in black pepper) increased curcumin bioavailability 20-fold. Piperine is a potent inhibitor of P-glycoprotein (P-gp), a transporter that limits the absorption of curcumin by effluxing it back into the intestinal lumen. Additionally, piperine inhibits UGTs, enzymes involved in the phase II metabolism of curcumin thus enhancing the circulating level of free curcumin (Jamwal 2018). Turmeric essential oil also acts as a bioavailability enhancer. One of its constituents, α-turmerone, was reported to significantly inhibit P-gp (Yue et al. 2012). Curcumin aqueous solubility and absorption were improved via inclusion complexes with cyclodextrins. A better stability and diffusion rate across the phospholipid bilayer of cell membranes was achieved by phytosomal formulation of curcumin (complexation of curcumin with phosphatidylcholine). The use of soluble dietary fibers, such as the ones from fenugreek, protected curcumin against degradation and provided a prolonged release with enhanced absorption. Other formulations (water-soluble formulation with 63–75% polyvinylpyrrolidone as hydrophilic carrier, micelles with 93% Tween 80 as surfactant, solid lipid particles prepared with soy lecithin, docosahexaenoic acid, stearic acid, and vitamin C) increased curcumin bioavailability over 100-fold compared to conventional curcumin (Jamwal 2018).

27.9 Patents

Numerous patents have been developed related to strategies to enhance the bioavailability of curcumin and its use against different diseases; recent ones are listed in Table 2.

27.10 Perspectives

Curcumin is undoubtedly a phytochemical with a huge therapeutic potential and good safety profile. Its low oral bioavailability considerably limits its use in health promotion, disease prevention, and treatment. Therefore, as many clinical trials showed, administration of highly bioavailable curcumin-based formulations is a prerequisite for beneficial effects in humans. Development of formulations that enhance curcumin absorption rate and stability and provide a sustained or targeted delivery of curcumin are effective strategies to improve therapeutic efficacy of curcumin and open new perspectives for its clinical valorization.

Table 2 Patents related to curcumin

Patent	Title	Ref.
US9861677B2	Composition to enhance the bioavailability of curcumin	Antony (2018)
US10004687B2	Liposomal curcumin for treatment of diseases	Kurzrock et al. (2018)
WO2016013026A1	Curcumin-sophorolipid complex	Singh et al. (2016)
WO2016167732A1	Development of curcumin and piperine-loaded double-layered biopolymer-based nano delivery systems by using electrospray/coating method	Sezgin (2016)
WO2016140904A1	Method to solubilize curcuminoids in water	Majeed and Nagabhushanam (2016)
WO2016113762A1	Modified cyclodextrin coated magnetite nanoparticles for targeted delivery of hydrophobic drugs	Joy and Naduvilidam (2016)
US20160101066A1	Fibrin wafer/disk as a biological carrier for sustained delivery of curcumin	Krishnan and Sreedharam (2016)
WO2015081319A2	Activity enhancing curcumin compositions and methods of use	Banerjee et al. (2015)
WO2015025263A1	A novel composition of curcumin with enhanced bioavailability	Gopi (2015)
US9192644B2	Bioavailable curcuminoid formulations for treating Alzheimer's disease and other age-related disorders	Frautschy and Cole (2015)
US9170257B2	Method and system for measuring the pharmacokinetics of liposomal curcumin and its metabolite tetrahydrocurcumin	Helson (2015)
WO2014036534A1	Curcumin-ER, a liposomal PLGA sustained release nano-curcumin for minimizing QT prolongation for cancer therapy	Ranjan et al. (2014)
WO2014145851A1	Product and method for improving bioavailability of therapeutic compounds	Petersen et al. (2014)
WO2014068597A2	Formulation of curcumin with enhanced bioavailability of curcumin and method of preparation and treatment thereof	Kuriakose (2014)
WO2012125830A2	Curcumin combination with anti-type 2 diabetic drugs for prevention and treatment of disease sequelae, drug-related adverse reactions, and improved glycemic control	Helson (2012)
WO2011101859A1	A novel water-soluble curcumin-loaded nanoparticulate system for cancer therapy	Sanjeeb and Chandana (2011)
US7968115B2	Liposomal curcumin for treatment of cancer	Kurzrock et al. (2011)
US20110257126A1	Water-soluble curcumin compositions for use in anticancer and anti-inflammatory therapy	Neven et al. (2011)
WO2008131059A2	Intranasally administering curcumin in a bolus of helium gas to treat Alzheimer's disease	Dimauro (2008)
WO2007143635A1	Method to prepare pure curcumin	Kim (2007)

Abstract

Isothiocyanate is an enzymatic hydrolysate of glucosinolates that are abundant in Brassicaceae or Cruciferae crops such as broccoli, radish, and cabbage. In addition to application in food products, isothiocyanates can effectively prevent DNA damage and cancer caused by various carcinogens in the diet including polycyclic aromatic hydrocarbons, heterocyclic amines, and nitrosamines. Moreover, isothiocyanates have antioxidant, anti-inflammatory, and antibacterial properties. In this chapter, the source, bioavailability, metabolism, bioactivity, toxicity, and application of isothiocyanates will be summarized. In addition, recent developments in isothiocyanate applications and future research needs will be discussed, to serve as a reference for industries, scientists, and consumers.

Isothiocyanate · Metabolism · Bioactivity · Application · Safety · Product

28.1 Introduction of Isothiocyanates

28.1.1 Source of Isothiocyanates

Isothiocyanate is a class of small molecular compounds with the structure of –N=C=S and abundant in Brassicaceae or Cruciferae vegetables (Table 1). These compounds are formed in a bioconversion progress with glucosinolates as the substrate and catalyzed with β-thioglucosidase (EC 3.2.1.147) (also known as myrosinase). In addition, isothiocyanate can be artificially synthesized when used as food additive or essential oil.

Common Brassicaceae or Cruciferae vegetables that contain glucosinolates include *Arabidopsis thaliana*, broccoli, cabbage, white radish, kale, mustard, and radish.

28.1.2 Classification of Isothiocyanates

The classification of isothiocyanates depends on the types of their substrates – glucosinolates that have three different types according to their structure: aliphatic, terpenoids, and aromatic compounds. Isothiocyanates produced after enzymatic conversion are also divided into aliphatic, terpenoids, and aromatic groups. Common classifications are as follows: allyl isothiocyanate, benzyl isothiocyanate, phenethyl isothiocyanate, indole-3-carbinol, sulforaphane, iberin, sulforaphene, and erucin (Table 2). They exhibit different chemical structures; allyl isothiocyanate is an aliphatic compound, whereas both benzyl isothiocyanate and phenethyl isothiocyanate are aromatic and contain a benzene ring. Structural differences lead to differences in lipophilicity and hydrophilicity. Moreover, they have different potentials for inhibiting microorganisms, anti-oxidation, and anticancer activities.

Table 1 List of glucosinolates found in different Brassica vegetables

Structure of R-group	Semisystematic names of R-groups	Trivial names	*Brassica* spp. (+ present; −absent)				
			Cabbage	Brussels sprouts	Cauliflower	Broccoli	Chinese cabbage
$CH_2 = CH–CH_2–$	Allyl	Sinigrin	+	+	+	+	−
$CH_2 = CH–CH_2–CH_2–$	But-3-enyl	Gluconapin	+	+	+	+	+
$CH_2 = CH–CH_2–CH_2–CH_2–$	Pent-4-enyl	Glucobrassicanapin	−	−	+	+	+
$CH_2 = CH–CH–CH_2–$	(2R)-2-Hydroxybut-3-enyl	Progoitrin	+	+	+	+	+
$CH_3–S–CHOH–CH_2–CH_2–$	3-Methylthiopropyl	Glucoibervirin	+	−	+	−	−
$CH_3–S–CH_2–CH_2–CH_2–CH_2–$	4-Methylthiobutyl	Glucoerucin	+	+	+	+	−
$CH_3–SO–CH_2–CH_2–CH_2–$	3-Methylsulphinylpropyl	Glucoiberin	+	+	+	+	−

Indolyl ITC				
Indole-3-carbinol	1H-Indol-3-yl-methanol	$C_8H_6N–CH_2OH$	147	All vegetables

28.2 Bioavailability and Metabolism

The bioavailability and metabolism of isothiocyanates are closely related to glucosinolates. Cruciferous plants contain both glucosinolates and myrosinase, and when the tissue is destructed (e.g., masticate), glucosinolates are hydrolyzed to form isothiocyanates. Glucosinolate is decomposed by the plant myrosinase in the small intestine or by the bacterial myrosinase in the colon. Metabolites of isothiocyanates can be detected in human urine 2–3 h after the consumption of cruciferous plant. Studies show that a small portion of the intact glucosinolates can be absorbed and excreted intact, although the absorption mechanism is unclear (passive diffusion or facilitated transport, Fig. 1) (Sã¸Rensen et al. 2016). Understanding the bioavailability, transport, and metabolism of isothiocyanates is fundamental to understanding their mechanisms of protective functions.

28.2.1 Metabolic Pathway

The human body mainly ingests isothiocyanate by eating glucosinolate-containing cruciferous vegetables. Glucosinolate is a secondary metabolite of cruciferous plants

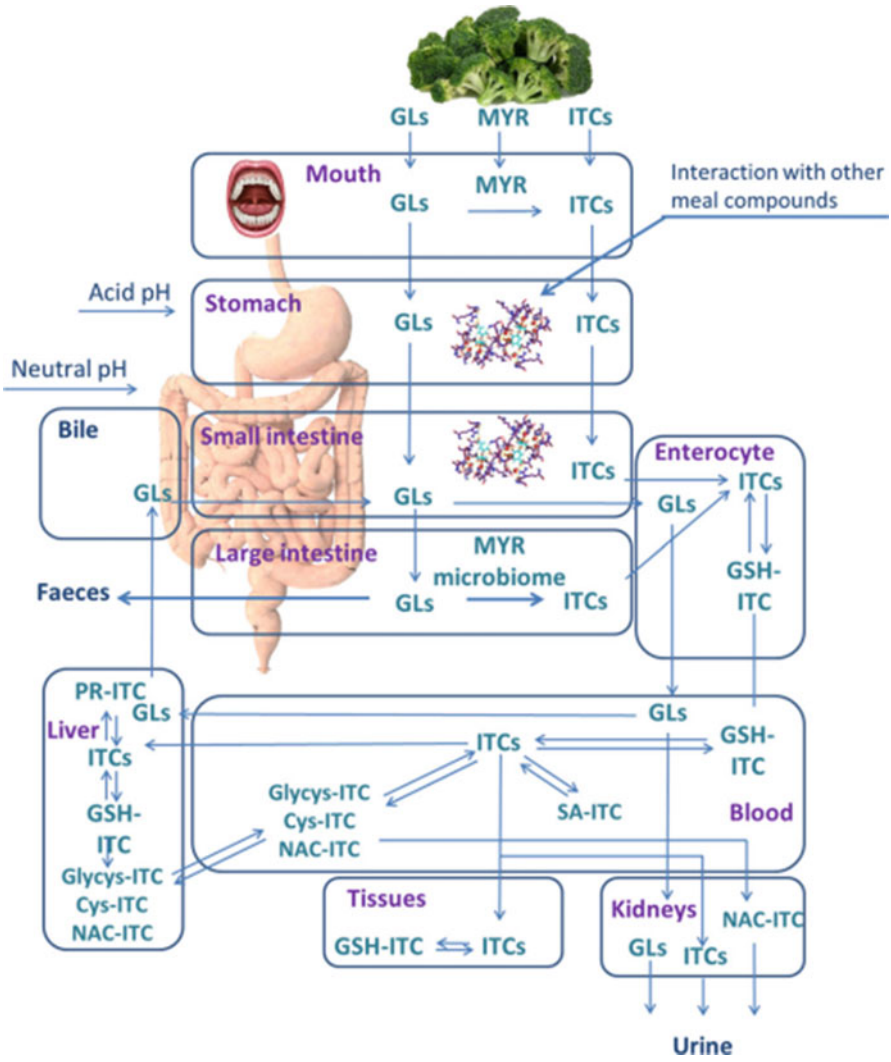

Fig. 1 Overview of the metabolic fates of glucosinolates (GLs) and isothiocyanates (ITCs)

located in the vacuole of plants. When plant tissue is subjected to external damage such as chewing, glucosinolates in the vacuole (as shown in Fig. 2) undergo enzymatic reaction catalyzed by cytoplasm myrosinase to produce flavor substances with a hot and spicy odor. The main three major flavors include isothiocyanates, thiocyanates, and nitriles, as shown in Figure 3. The stomach and intestinal bacteria in the human body also contain myrosinase that can degrade glucosinolates as well (Tian et al. 2018).

Isothiocyanate is a substrate for glutathione transferase. The enzyme-catalyzed nucleophilic attack of the sulfhydryl group of glutathione on the central carbon of the

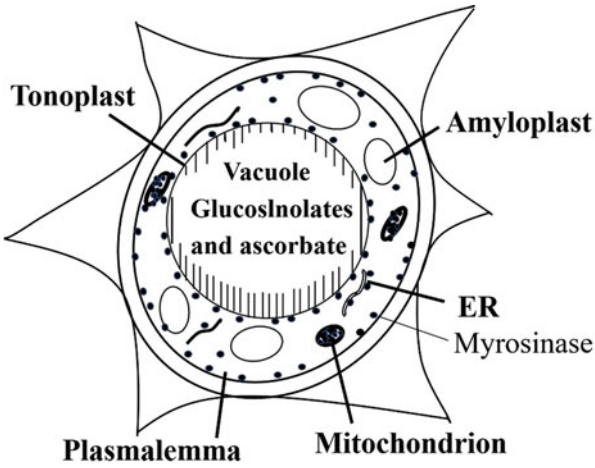

Fig. 2 A model for compartmentation of myrosinase and glucosinolates

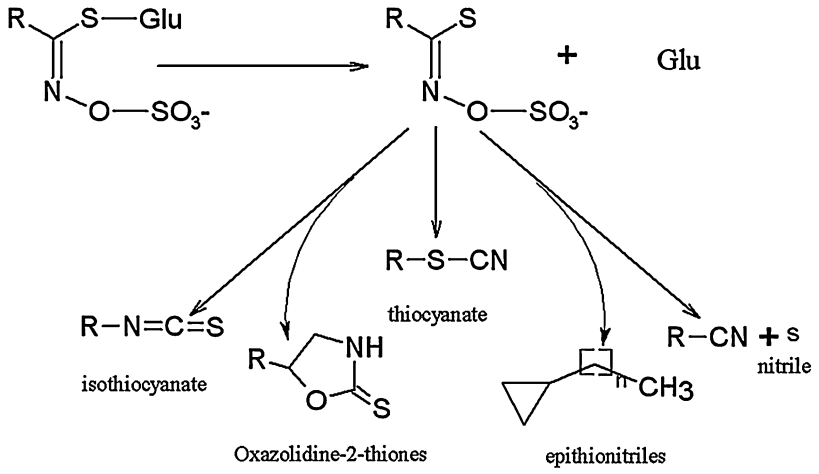

Fig. 3 Summary of metabolic pathways for glucosinolate degradation

isothiocyanate group results in the formation of glutathione dithiocarbamates that are modified by a sequence of enzymatic reactions, leading ultimately to the formation of *N*-acetylcysteine dithiocarbamates (also known as mercapturic acids). This progress is usually discharged in the urine.

Oral or intestinal formed isothiocyanate is primarily metabolized by the thiol uric acid pathway. Enzymatic initiation upon initial conjugation with glutathione to produce dithiocarbamic acid, such as *N*-acetylcysteine-, cysteine-, and cysteinyl glycine-isothiocyanate conjugates (Ye et al. 2002).

28.2.2 Bioavailability

Bioavailability of isothiocyanates can be assessed by measuring metabolites in blood and urine. Allyl isothiocyanate absorption in the intestine is fast and complete. Allyl isothiocyanate is mainly excreted in the urine in rats and mice. In one study, urinary excretion of radiolabeled allyl isothiocyanate was up to 80% of total dose in rats and mice (within 72 h), and the amount of allyl isothiocyanate excreted by feces was approximately 3–12% (for rats) and 4–9% (for mice) of the total dose after oral administration (Ioannou et al. 1984). In addition to renal excretion, allyl isothiocyanate can be excreted through breathing, and a small amount of allyl isothiocyanate-derived radioactive carbon dioxide is detected in animal exhalation.

Like allyl isothiocyanate, urine seems to be the main route of excretion for benzyl isothiocyanate. Within 72 h, exhaled excretion was minimal (0.4%), followed by feces (5.6%), and most was urine (92%); less than 0.5% remained in the carcasses, which is much less than that reported for allyl isothiocyanate in rats. The isothiocyanate metabolized by the enterohepatic circulation is negligible because it accounts for only 4%.

After oral administration in male rats, phenethyl isothiocyanate was rapidly absorbed into the blood. The cumulative excretion in urine and feces within 48 h was 7% and 47%, respectively, of which about 15% was excreted with feces; 14% was exhaled as carbon dioxide, and 0.007% was exhaled as an alcohol soluble organic compound.

28.2.3 Factors Affecting the Bioavailability and Metabolism of Isothiocyanates

28.2.3.1 Vegetable Types and Varieties

The bioavailability of isothiocyanate is directly proportional to the amount of glucosamine hydrolyzed, and the more glucosinolate content is ingested, the greater the corresponding isothiocyanate content. There are significant differences in the content of glucosinolates in different cruciferous vegetables (broccoli, Brussels sprouts, cabbage, broccoli, kale) (Yen and Wei 2010). He et al. studied the traditional Chinese cruciferous Brassica vegetables and found that the difference was also great (He et al. 2005). The total amount of glucosinolate in the cabbage was the greatest, and the amount of bok choy (green vegetables) consumed in the south part of China was the lowest.

28.2.3.2 Oral Phase: Mastication

When chewing vegetables begins, the myrosinase activates and induces the hydrolyzation of glucosin. During chewing, the vegetable tissue is crushed and ground to mix the released compound with the saliva in the food mass. The formation of isothiocyanate during chewing depends on the chewing strength; the

concentrations of glucosinolates, myrosinase, and all factors could affect the velocity of reaction.

28.2.3.3 pH

pH can affect the degradation of glucosinolates. The results showed that the initial content of glucosinolates decreased to 88–97% at pH range of 3.6–9.1, while the retention rate decreased when the pH was less than 3.6, leaving only 60% at pH 1.5 (Jing et al. 2012). The pH values of the human stomach and intestine are 2 and 7.8, respectively, and it was reported that the glucosinolates in cauliflower were reduced to 69% in the stomach. Then they were reduced by 12% in the intestines. However, the myrosinase of the plant itself has been denatured under acidic conditions in the stomach, but glucosinolates can be decomposed by microorganisms in the intestine (Sã¸Rensen et al. 2016). Little is known about the stability of the isothiocyanates during digestion.

28.2.3.4 Microbes

Microorganisms in the intestine can degrade glucosinolates from cruciferous vegetables to produce isothiocyanates. It is generally believed that glucosinolates reach the large intestine before they are decomposed (Elfoul et al. 2001). Glucosides cannot be degraded by alpha-amylase and pepsinase in the upper intestine nor by intestinal trypsin in vitro (Lai et al. 2010). In contrast, glucosinolates can be hydrolyzed by intestinal microbial communities. At the same time, intestinal microflora is the main source of myrosinase in vivo. For instance, Llanos et al. (1995) screened three strains that could degrade the glucosinolate by measuring the decomposition of allyl glucosinolates by 42 lactic acid bacteria. *Lactobacillus agilis* had the strongest decomposition ability and mainly produced lactic acid and allyl isothiocyanate.

28.3 Bioactivities of Isothiocyanates

Isothiocyanates may prevent DNA damage and cancer caused by several dietary carcinogens (Barnett et al. 2015). The mechanism may be that isothiocyanates can detoxify and accelerate the excretion of carcinogens by inhibiting the activity of phase I reductase and inducing the production of phase II enzymes. In addition, isothiocyanates can also prevent diseases. Evidence has shown that isothiocyanates bring to bear their activity through a variety of unique but interrelated signaling pathways, including those involved into detoxification, inflammation, and epigenetic regulation. The effects of isothiocyanates on these pathways are mainly regulating cellular antioxidant systems, enzyme induction or inhibition, and selective gene expression, interferencing with cell cycle and signaling pathways and effects on tumor microenvironment, and inducting of apoptosis or autophagy (Nakamura and Miyoshi 2010). These activities will be demonstrated with examples in the following paragraphs (Fig. 4).

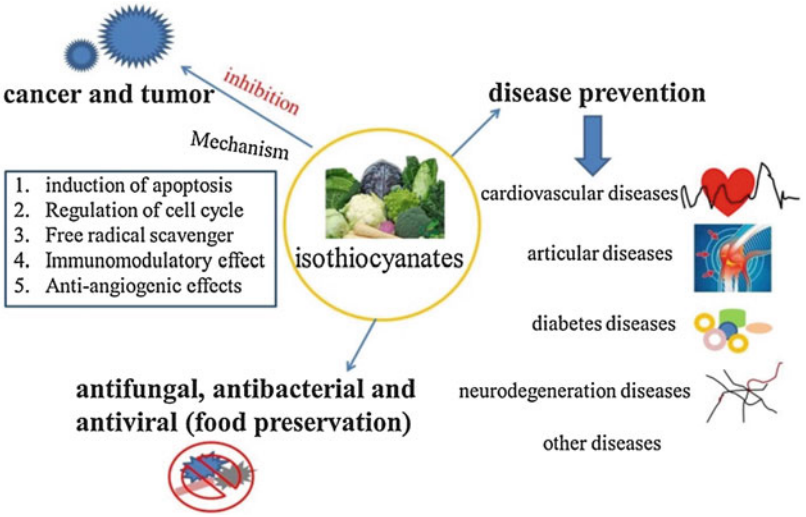

Fig. 4 Bioactive activities of isothiocyanates

28.3.1 Inhibition of Cancer and Tumor Activity

Epidemiological studies showed that the consumption of cruciferous vegetables (including broccoli) could reduce the risk of inducing certain cancers. Isothiocyanate is the most important anticancer and antitumor active ingredients in this vegetable and has certain preventive ability against cancer (Latté et al. 2011; Herr et al. 2010). It has been reported that the per capita intake of glucosinolate in Canada is estimated to be about 16 mg/day. The corresponding intakes in the UK and Japan are estimated to be 30 mg/day and 112 mg/day, respectively. The American population is much smaller. The intake of the Chinese population has not been known. Sepkovic et al. provided isothiocyanates (6–7 mg/kg) to young healthy people every day in 1994 (Sepkovic et al. 1994). The trial lasted for 3 months. The results showed that oral isothiocyanate intake was well tolerated and no adverse reaction was observed in people. The dose can be greater than 1000 mg/kg (fw). Also, it was a strong inducer of cytochrome P4501A isoenzymes and a chemical carcinogen inhibitor in some animal models (Shiizaki et al. 2017).

28.3.1.1 Induction of Apoptosis

Apoptosis, also known as programmed cell death, has been identified as one of the strategies to address cancer cell growth. Isothiocyanates can directly induce apoptosis through mitochondrial release of cytochrome and activation of apoptotic protease activator 1, caspase-9, and adenosine triphosphate. It has been found that the stimulatory effect of isothiocyanates is the proteolytic cleavage of polymerase and the appearance of caspase activity followed by induction of apoptosis in cervical cancer and PC-3 prostate cancer cells.

Phenethyl isothiocyanate modulates different mitochondrial proteins such as B-cell lymphoma-2, Bid, and Bax leading to the release of cytochrome C in the cytoplasm, which is the intrinsic mechanism of apoptosis. Allyl isothiocyanate is considered to be an effective method because of the high bioavailability in urine after ingestion. It caused cell cycle arrest, then it increased apoptotic rate, and lower concentrations of allyl isothiocyanate can induce genotoxicity in mutant cells of the TP53 gene. In addition, the apoptotic effect of sulforaphane is mediated by regulation of acetylated histones and subsequent upregulation of p21 and Bax proteins (Sávio et al. 2014). Studies have reported that isothiocyanate-induced apoptosis is inhibited by inhibition of proteasome activity and tumor suppressor p53 is significantly accumulated in multiple myeloma cells, independent of reactive oxygen species production. These results suggest that isothiocyanates may initiate apoptosis through several pathways. In addition, there is evidence that the cytotoxic effects of isothiocyanates may selectively target cancer rather than normal cell types.

There are some testimonies suggested that phenethyl isothiocyanate, benzyl isothiocyanate, and phenyl isothiocyanate inhibited lung tumorigenesis and O^6-methylguanine formation (DNA-adduct formation in the 4-(methylnitrosamino)-1-(3-pyridyl)-1-butanone-induced tumors) in the DNA of lung cells from A/J mice which were treated with 4-(methylnitrosamino)-1-(3-pyridyl)-1-butanone (Morse et al. 1991; Morse et al. 1989) In recent years, sulforaphane and phenethyl isothiocyanate have significant effects on proliferation and apoptosis of human lung adenocarcinoma cell line LLTE-A2, which caused G(2)/M arrest in a time and dose-dependent manner($p < 0.05$). On the other hand, it increased apoptotic cell fraction ($P < 0.05$) to prevent (Liang and Lai 2008). Besides, phenylhexyl isothiocyanate has also been found to prevent cancer by blocking the initiation of carcinogen-induced tumors in rodents (Nishikawa et al. 2010).

28.3.1.2 Regulation of Cell Cycle

Numerous studies have shown that isothiocyanates can interfere with the cell cycle progression of cancer cells and the effects of isothiocyanates on cell growth and cell cycle progression in HeLa cells by flow cytometry. Cell accumulation at the G2/M phase interface was observed 16 h after treatment with 10 mM allyl isothiocyanate, 2.5 mM benzyl isothiocyanate, or 2.5 mM phenethyl isothiocyanate, the concentration of which inhibited cell growth by 41–79% of control. These results indicate that isothiocyanates delay the cell cycle progression of HeLa cells, leading to inhibition of cell growth (Hasegawa et al. 1993).

Isothiocyanates have been reported to regulate the expressions of protein kinases (cyclin and cyclin-dependent kinases) involved in cell cycle progression. Isothiocyanates mediated the suspension of drug-resistant cells in G1 and G2/M phase in a dose and time-dependent manner. Isothiocyanates mediated G2/M phase inhibition of cell cycle which has been studied in PC-3 cells by downregulating the accumulation of Cdk1, cell division cycle 25C, and Tyr-15 phosphorylation (inactive) Cdk1. The antiproliferative effect of isothiocyanates was also investigated in colorectal adenocarcinoma cells by upregulating phosphorylation of p21 and enhanced checkpoint kinase 2, followed by sustained G2/M arrest. The results

showed that cell which was exposed to benzyl isothiocyanate leads to inhibition of G2/M progression and upregulation of G2/M cell cycle arrest regulatory genes (including p21). The essential point is the regulation of cell cycle progression. In the G2/M phase, a prerequisite for the apoptosis induced by benzyl isothiocyanate is mediated by p38 mitogen-activated protein kinase.

Furthermore, it has been suggested that transcriptional regulation of 14-3-3σ, Cdc25C, and GADD45 by p21 and p53 mediates cell cycle arrest. Inducing cell cycle arrest is considered a promising chemopreventive strategy.

28.3.1.3 Free Radical Scavenger

Oxidative stress is defined as the imbalance between the levels of reactive oxygen species produced and the ability of biological systems to eliminate or to quench the active intermediates formed (Sita et al. 2016), which is the basis of the pathogenesis of various diseases. Isothiocyanates are a class of phytochemicals with good cancer prevention potential and its double-edged swords that regulate cellular oxidative stress (Zhang et al. 2005). Exposure of cells to isothiocyanates could increase their ability to resist oxidative damage. During the process of 12-O-tetradecanoylphorbol-13-acetate-induced oxidative rupture of HeLa 60 cells, benzyl isothiocyanate and other isothiocyanates were potent inhibitors for a large number of superoxide anions, and the mechanism of biologically active antioxidant activity of benzyl isothiocyanate was mainly implemented by the Keap1/NF-E2-related factor 2/antioxidant response element approach. Gülçin found in in vitro antioxidant experiments that broccoli isothiocyanates extract had strong free radical scavenging ability, which was similar to the antioxidant capacity of ascorbic acid, but the temperature and storage stability of isothiocyanates extract were better than that of ascorbic acid (Gülçin et al. 2004).

In addition, isothiocyanates regulate different phase II enzymes. Phase I enzymes (cytochrome P450 enzymes) generally increase the reactivity of fat-soluble compounds and produce some reactive molecules that may be more toxic than the parent molecule. Phase II enzymes (glutathione-S-transferase, aldehyde reductase, S-methyltransferase, *N*-acetyltransferase, etc.) increase water solubility and promote excretion of these metabolites from the body. Therefore, inhibition of phase I and induction of phase II enzymes are essential for protecting cells from DNA damage from carcinogens and reactive oxygen species (Vig et al. 2009). For example, phenethyl isothiocyanate partially induces the expression of phase II enzymes mediated by antioxidant response elements via c-Jun N-terminal kinase-1 and nuclear factor erythrocyte-2-related factor 2 (Keum et al. 2003). Allyl isothiocyanate, benzyl isothiocyanate, and 6-(methylsulfinyl)hexyl isothiocyanate have the ability to induce phase II and antioxidant enzymes via the nuclear factor erythrocyte-2-related factor 2-dependent signal transduction pathway (Mizuno et al. 2011). As a result, activation of the nuclear factor erythrocyte-2-related factor 2 pathway by isothiocyanates confers protection against carcinogens and has emerged as a promising strategy for cancer prevention. Currently, epidemiological evidence supports the role of cruciferous vegetables against lung, colorectal, breast, prostate c, and pancreatic cancers (Herr 2010).

In addition, isothiocyanate can increase the antioxidant capacity of animal cells by inducing the activity of phase II enzymes or by increasing the level of glutathione. Benzyl isothiocyanate induces expression of GST isoenzyme to mediate intracellular reactive oxygen intermediate in a short time (1 h), which is sufficient to increase glutathione S-transferase activity. Allyl isothiocyanate and phenyl isothiocyanate inhibit tumor-specific angiogenesis by significantly reducing the production of nitric oxide and tumor necrosis factor-α (Thejass and Kuttan 2007).

28.3.1.4 Immunomodulatory Effect

The tumor microenvironment is some resemblance to inflammatory lesions and plays a very important role in the process of carcinogenesis. Inflammation encourages cancer cells to grow in a bimodal manner. Some studies have shown that phenethyl isothiocyanate can directly regulate the inflammatory process. Phenethyl isothiocyanate has been shown to inhibit chemically induced inflammatory responses in mice. Mechanistic studies have shown that inflammatory mediators such as nitric oxide, tumor necrosis factor-α, and interleukin-10 are inhibited in the LPS-stimulated macrophages and macrophage migration inhibitory factor can be inhibited by covalent modification of phenethyl isothiocyanate.

A few reports also linked immunomodulatory effects to the anticancer activity of phenethyl isothiocyanate. For example, phenethyl isothiocyanate has been shown to protect mouse liver and lung from changes caused by cigarette smoke. Bioinformatic analysis of phenethyl isothiocyanate-treated animal tumors revealed regulation of genes involved in the inflammation and extracellular matrix pathways. In conclusion, these findings indicate that anti-inflammatory effects contribute to the anticancer effects of phenethyl isothiocyanate (Gupta et al. 2014).

Other studies have found that allyl isothiocyanate exhibits potent anti-inflammatory activity in macrophages cultured in vitro but has little anti-inflammatory activity in mice in vivo. The anti-inflammatory effects of allyl isothiocyanate were accompanied by an increase in the nuclear translocation of nuclear factor erythrocyte-2-related factor 2 and increased the mRNA and protein levels of the nuclear factor erythrocyte-2-related factor 2 target gene heme oxygenase 1 (Wagner et al. 2012).

Unlike allyl isothiocyanate, the anti-inflammatory properties of sulforaphane have been well-documented. Tumor necrosis factor-mediated NF-κB activation in THP1 human monocytes were inhibited by sulforaphane. In *H. pylori*-infected mice, sulforaphane treatment resulted in a reduction in symptoms of gastritis (Wagner et al. 2012). Also, Brandenburg et al. reported through the results of their researches showed the anti-inflammatory potential of sulforaphane in the brain. An established model of neuroinflammation was used in the assay based on stimulation of microglia with endotoxin lipopolysaccharides to determine the effect of sulforaphane on lipopolysaccharides-induced microglia expression of certain cytokines.

28.3.1.5 Anti-angiogenic Effects

In addition to their effects on carcinogen metabolism and cancer cell proliferation, isothiocyanate has been shown to effectively interfere with angiogenesis in vitro and in vivo. In vitro studies, allyl isothiocyanate showed anti-angiogenic and pro-

apoptotic effects, inhibited the growth of ascites tumors and angiogenesis, which may play a potential role in the potential chemoprevention and chemotherapeutic activity of isothiocyanate (Cavell et al. 2011).

28.3.2 Disease Prevention

There has been increasing interest in the field of chemoprevention using natural remedies in recent years. Organic isothiocyanates, mainly allyl isothiocyanate, benzyl isothiocyanate, phenylethyl isothiocyanate, sulforaphane, erucic acid, and phenylhexyl isothiocyanate, are widely studied chemopreventive agents. The isothiocyanates present in many dietary cruciferous vegetables have been shown to have preventive and therapeutic activity against several chronic human degenerative diseases, including cancer, cardiovascular diseases, neurodegeneration, and diabetes. There is also growing evidence that isothiocyanates can inhibit cardiovascular diseases and neurodegenerative diseases. The chemical preventive activity of isothiocyanate has traditionally been attributed to its ability to alter the metabolism of carcinogens. During the first stage of metabolism, the polarity of the toxin increases due to reduction, oxidation, or hydrolysis reactions. If the polarity is strong enough, the metabolites produced will be expelled.

28.3.2.1 Prevention of Cardiovascular Diseases

Cardiovascular diseases like myocardial ischemia-reperfusion injury, atherosclerosis, and coronary heart disease are among the leading causes of death in the world. There are some well-known cardiovascular risk factors, such as hypertension, hypercholesterolemia, smoking, obesity, diabetes, and ageing. Oxidative stress is related to all these known cardiovascular risk factors and the process of forming atherosclerotic plaques. These observations emphasize that oxidative stress is the contact between cardiovascular risk factors and vascular disease and therefore is the goal of cardiovascular prevention.

Sulforaphane has been shown to increase in cell viability and decrease in DNA fragmentation of neonatal cardiomyocytes which might be interceded by multiple antioxidant proteins expression and reactive oxygen species production. Also, the activity of antioxidants and phase II enzymes was induced by sulforaphane in rat aortic smooth muscle cells and in mitochondria of aortic smooth muscle cells which is isolated like catalase, superoxide dismutase, glutathione peroxidase, glutathione reductase, glutathione S-transferase, quinone oxidoreductase-1, and glutathione in vivo (Leoncini et al. 2011). Studies on isolated rat hearts have shown that the protective influence of sulforaphane on cardiac ischemia-reperfusion injury can be attributed to the inhibition of the increase left ventricular end-diastolic pressure after ischemia. Sulforaphane also improved pressure coronary blood flow in the development of left ventricle after ischemia and reduced lactate dehydrogenase levels during reperfusion.

Isothiocyanates have the cardioprotective activity against ischemia/reperfusion injury and were confirmed in an in vivo model. To prove it, the isolated hearts were

subjected to ischemia/reperfusion injury after rats were fed broccoli for 30 days (Mukherjee et al. 2009). Broccoli improved post-ischemic ventricular function while decreased myocardial infarct size and cardiomyocyte apoptosis. Bahadoran et al. (Bahadoran et al. 2012) demonstrated that supplementation with 10 g/day broccoli sprouts had beneficial effects on the most typical diabetic dyslipidemia and lipid-related parameters in type 2 diabetic patients for 4 weeks. Overall, isothiocyanates in vivo and clinical studies of cardiovascular disease protection provide hopeful results.

28.3.2.2 Prevention of Articular Diseases

Chondrocyte death is very important in cartilage degradation and progression of joint diseases involving osteoarthritis and rheumatoid arthritis. Recently, it has been showed that treatment of osteoarthritis chondrocytes with sulforaphane decreased the production of various matrix metalloproteinases and the reduction of Jun N-terminal kinase activation by the pro-inflammatory cytokines interleukin-1 and tumor necrosis factor-α. In chondrocyte lines, sulforaphane also enhanced quinone oxidoreductase-1 activity and glutathione levels. Treatment of grown human chondrocyte monolayer cultures with sulforaphane reduced cell death which was induced and reduced caspase activity which is effector and initiator by tumor necrosis factor-α plus cycloheximide. In addition, in the in vitro and in vivo models of osteoarthritis, sulforaphane prevented cartilage destruction in cells (Davidson et al. 2017).

28.3.2.3 Diabetes Prevention

Type 1 diabetes characterized by destruction of β-cells and lack of b-cell mass during inflammatory isletitis which is a T-cell-driven autoimmune disease. Sulforaphane treats a rat pancreatic β-cell line which prevented interleukin-1b and interferon-gamma-induced b-cell damage. The effect of the activation of the nuclear factor erythrocyte-2-related factor 2 pathway was mediated. The results of the recovery of normal insulin secretion response of glucose in cytokine-treated rat islets and the developmental blockade of type 1 diabetes which in streptozotocin-treated mice were confirmed (Song et al. 2008). Other studies have found that severe inflammation of the animals is treated with cyclophosphamide alone and dark-colored urinary bladders are normalized in morphological analysis by allyl isothiocyanate or phenyl isothiocyanate treatment (Manesh and Kuttan 2005; Zhu et al. 2008). Sulforaphane improved kidney performance and minimized pathological changes in the glomerulus and improved motor nerve conduction velocity, blood flow, and pain behavior in a mouse model of streptozotocin-induced diabetes (Zheng et al. 2011). These findings have promoted the potential use of isothiocyanates in alleviating metabolic disorders and prevent kidney damage and diabetes-related pain (Ye et al. 2002).

28.3.2.4 Protective Effects Against Neurodegeneration

The reason for slow development of neurodegenerative diseases such as Parkinson's disease and Alzheimer's disease, amyotrophic lateral sclerosis, and multiple sclerosis slowly developing is that oxidative stress and neuroinflammation are actively

involved in neuronal death. Reactive oxygen species can directly oxidize and damage macromolecules like DNA, proteins, and lipids, culminating in neurodegeneration at the end (Calabrese et al. 2007).

Isothiocyanates show neuroprotective activity or neurodegeneration in vitro or in vivo models, respectively. They can directly scavenge free radicals or indirectly increase endogenous cellular antioxidant to defenses by activating the nuclear factor erythrocyte-2-related factor 2 transcription factor pathway (Giacoppo et al. 2015). These preventive effects may be primarily due to their unique ability to activate the nuclear factor erythrocyte-2-related factor 2/antioxidant response element pathway. An alternative mechanism of action for neuroprotection is regulation of the signal transduction cascade or its effect on gene expression. Therefore, isothiocyanates could prevent and treat neurodegenerative diseases that were thought as a promising source of alternative medicine.

Sulforaphane protects primary cortical neurons from damage induced by dopamine oxidation products, which are capable of forming adducts with cellular thiols. Therefore, isothiocyanates could prevent and treat neurodegenerative diseases which would be seen as a promising source of alternative medicine (Spencer et al. 2010).

28.3.2.5 Prevention of Other Diseases

Continued exposure to cigarette smoke or contamination can interfere with the lung cleansing, and macrophages drive a powerful innate immune defense system, which leads to chronic obstructive pulmonary disease. In patients and mouse models of the disease, sulforaphane adjusted this pathway and increased the ability of lung macrophages to sequester and inactivate *Haemophilus influenzae* and *Pseudomonas aeruginosa*, both of which exacerbate chronic obstructive pulmonary disease (Fimognari et al. 2012).

Steatosis is the result of abnormal liver function and whose character is the accumulation of triglycerides in hepatocytes. In addition, sulforaphane can increase the levels of quinone oxidoreductase-1 and heme oxygenase-1 mRNA. Sulforaphane can reduce LXRα-induced hepatic lipogenesis, which may represent the result of nuclear factor erythrocyte-2-related factor 2 activation, because quinone oxidoreductase-1 and heme oxygenase-1 are transcribed from the Nrf2 target gene (Kay et al. 2011).

Sulforaphane has a protective effect on cyclosporin-induced gingival fibrosis and the phototoxic effects induced by UVB irradiation. In addition, sulforaphane can increase the expression level of quinone oxidoreductase-1 and heme oxygenase-1 mRNA.

The ultraviolet light of the sun is strong carcinogen that can strengthen inflammation, burn the skin, and cause skin cancer. Activation of nuclear factor erythrocyte-2-related factor 2 by sulforaphane protects body to alleviate UVB-induced inflammation and sunburn responses.

A recent study showed that sulforaphane can be used in conditions that require immunosuppression, involving autoimmune diseases and transplant diseases. The genetic basis of these pathologies involves the role of interleukin-2 and related T-cell activations. Sulforaphane obviously inhibited T-cell proliferation of primary human

T lymphocyte cultures activated by anti-CD3 and anti-CD28. At the same time, sulforaphane also reduced the production of interleukin-2, suggesting its role in proliferation inhibition.

28.3.3 Antifungal, Antibacterial, and Antiviral Inhibiting Effects

Isothiocyanates exhibit biological activity against a variety of pathogens which from food, including viruses (Mochida and Ogawa 2010), fungi (Smolinska and Horbowicz 1999), bacteria (Miran et al. 2010). It was studied the toxic effects of aliphatic isothiocyanate and aromatic isothiocyanate on growth parameters of different fungi, such as sclerotia viability, sclerotia growth and germination of *Sclerotinia sclerotiorum*. The result showed that allyl, methyl, and benzyl isothiocyanates were the most fungicidal of the tested compounds under the experimental conditions. Troncoso-Rojas et al. (2005) tested the effect of benzyl isothiocyanate on the growth of *Alternaria alternata*. The results of in vitro experiments showed that the minimum inhibitory concentration of benzyl isothiocyanate is 0.1 mg/mL, which indicated that benzyl isothiocyanate could control black spot disease in tomato fruit and had no adverse effects on postharvest quality of tomato. Kim and Lee (Kim and Lee 2010) tested the inhibitory effects of phenyl isothiocyanate and its derivatives on intestinal bacteria growth. The results showed that phenyl isothiocyanate (mg/disk) strongly inhibited the growth of *C. difficile* and *Clostridium perfringens* and moderately inhibited the growth of *E. coli* at a dose of 6.0 mg/day.

The length of the isothiocyanate hydrocarbon chain and the size of the molecule, whether it has a double bond thiol group and a thiol group, affect their antimicrobial activity. The side chains of isothiocyanate are derived from different amino acids, and these differences confer different biological properties (Sotelo et al. 2015). Isothiocyanates containing sulfonium groups are the most effective growth inhibitors for oral pathogens, followed by aromatic isothiocyanates (containing benzene rings) and aliphatic isothiocyanates. The presence of double bond in the chemical structure of the isothiocyanates appears to increase antimicrobial activity. For example, the sulfonyl group (CH_3–SO–CH=CH–CH_2–CH_2–) is structurally similar to sulforaphane (CH_3–SO–CH_2–CH_2–CH_2–CH_2–) but has a double bond, which has lower antibacterial activity against *Candida albicans*. Isothiocyanates containing thiol (-S-) or sulfinyl (-SO-) groups have different antimicrobial activities compared to other isothiocyanates. Glucosinolate (CH_3–S–CH_2–CH_2–CH_2–CH_2–) is structurally similar to sulforaphane (CH_3–SO–CH_2–CH_2–CH_2–CH_2–) (having a sulfinyl group) but has a thiol group and exhibits higher antimicrobial activity against *Streptococcus mutans*, *Staphylococcus aureus*, and *Candida albicans*. Antimicrobial activity also depends on the length of the hydrocarbon chain. Short-chain benzyl isothiocyanate (C_6H_5–CH_2–) has a stronger antimicrobial potential than phenylethyl isothiocyanate (C_6H_5–CH_2–CH_2–) against *Candida albicans*, *Streptococcus mutans*, *L. casei*, and *Staphylococcus aureus* (Li et al. 2013).

28.4 Application and Processing Effects of Isothiocyanates in Food

Isothiocyanates are used in foods and seasonings such as mustard oil, mustard sauce, green mustard, kimchi, and sauce because of their typical pungent and spicy taste. Isothiocyanates also have a bacteriostatic effect and can be used for preservation of foods. In addition, their anticancer and anticancer properties can make them be used as functional ingredients of health foods. Pure isothiocyanates added to foods are generally chemically synthesized rather than directly extracted from vegetables. It is worth noting that the amount of isothiocyanates in the food are affected by the cooking way.

28.4.1 Application of Isothiocyanates in Food

28.4.1.1 Food Flavor Compounds

Isothiocyanates have a spicy pungent odor and are the main volatile components in mustard and horseradish sauce, usually used in salads and seafood. As early as 1959, allyl isothiocyanate was used as a food additive. Currently, there are 19 isothiocyanate-based fragrance compounds approved by the Flavor and Extract Manufacturers Association in the United States (Kong et al. 2011). There are 15 isothiocyanate-based fragrances in the list of synthetic fragrances for foods permitted in GB 2760-2014 (Standards for the Use of Food Additives). The characteristics and sources of these natural spices are shown in Table 3.

As a food flavor, the study of the physical and chemical properties of isothiocyanate is of great significance. Isothiocyanates can chemically react with water molecules and hydroxides in neutral and alkaline solutions. Citric acid sugar esters and salad oils can increase the stability of isothiocyanates in some degree. The degradation rate at 37 °C is significantly higher than 0 °C. Therefore, isothiocyanates should be stored in a low temperature and acidic environment. Since isothiocyanates can pass through some food packaging materials such as polyethylene and polypropylene, corrosion-resistant packaging materials should be selected to reduce loss of food flavor and contamination to other foods during storage of isothiocyanate-containing products.

28.4.1.2 Food Preservative

Isothiocyanates have a broad spectrum of antibacterial properties and can be used as a food preservative in food preservation and packaging. Studies have shown that at the concentration of 0.04 mol/L, benzyl isothiocyanate, 3-methylthiopropyl isothiocyanate, phenylpropyl isothiocyanate, butyl isothiocyanate, and 4-pentenyl isothiocyanate have significant inhibition on the growth of *Vibrio parahaemolyticus* and *Salmonella*. At the same time, benzyl isothiocyanate has a good inhibitory effect on two Gram-positive pathogens, such as *Staphylococcus aureus* and *Listeria monocytogenes* (Wang et al. 2017). The inhibitory effects of the same concentration of allyl isothiocyanate on the growth of different microorganisms were as follows,

Table 3 Structural formula, aroma characteristics, and natural presence of currently used isothiocyanate perfumes

Name	FEMA number	GB 2760 Number code	Aroma characteristics (Burdock and Burdock 2002)	Natural sources (Caboni et al. 2013; Afsharypuor and Suleimany 2002; Radonić et al. 2010; Afsharypuor and Sepehrnejad 2006)
Methyl isothiocyanate	4426	–	Pungent smell like mustard and horseradish	Garlic, wasabi, wine
Ethyl isothiocyanate	4420	–	Pungent smell like mustard and garlic	Wasabi, mustard
Isopropyl isothiocyanate	4425	S1090	Pungent mustard-like smell	Mustard, capers fruit, cabbage, wasabi
Allyl isothiocyanate	2034	S0762	Mustard-like strong spicy smell	Onions, cabbage, horseradish, Milk, cauliflower, Brussels sprouts, wasabi, and cruciferous plants' seeds
Butyl isothiocyanate	4082	–	Wasabi, horseradish, mustard-like spikes	Mustard, wasabi, broccoli, capers fruits
Sec-butyl isothiocyanate	4419	S1085	Green incense	Mustard, radish, wasabi
Isobutyl isothiocyanate	4424	S1086	Green incense	Cabbage, garlic, capers fruit
3-Butenyl isothiocyanate	4418	S1079	Strong irritating odor, strong osmotic	Cabbage, milk, cauliflower, mustard, horseradish, wasabi
Amyl isothiocyanate	4417	S1089	Spiked green incense	Radish, kale seeds
Isoamyl isothiocyanate	4423	S1091	Spiked green incense	Radish seeds, kale seeds
Hexyl isothiocyanate	4422	–	Spiked green incense	Radish, horseradish
5-Hexenyl isothiocyanate	4421	S1081	Strong irritating scent	Radish, horseradish, wasabi
3-(Methylthio) propyl isothiocyanate	3312	S0899	Radish, horseradish, sulfur, and mud-like smell	Cabbage, cauliflower, horseradish, mustard head
4-(Methylthio) butyl isothiocyanate	4414	–	Cabbage, radish-like aroma	Cabbage, Brussels sprouts, broccoli
5-(Methylthio) pentyl isothiocyanate	4416	S1088	Radish-like aroma	Radish, horseradish

(continued)

Table 3 (continued)

Name	FEMA number	GB 2760 Number code	Aroma characteristics (Burdock and Burdock 2002)	Natural sources (Caboni et al. 2013; Afsharypuor and Suleimany 2002; Radonić et al. 2010; Afsharypuor and Sepehrnejad 2006)
6-(Methylthio) hexyl isothiocyanate	4415	S1087	Radish-like aroma	Horseradish
Benzyl isothiocyanate	4428	S0893	Mild watercress, drug, horseradish, and oily-like flavor	Celery, lone, nasturtium
Phenylethyl isothiocyanate	4014	S1321	Radish, gooseberry, green incense, and sulfur-like smell	Cabbage, cauliflower, broccoli, mustard, wasabi, radish, mushroom, turnip, watercress, spinach

Paecilomyces variabilis > *Saccharomyces cerevisiae* > *Escherichia coli* > *Bacillus subtilis*, and the inhibition rate increased with the increase of allyl isothiocyanate concentration. The antibacterial effect of allyl isothiocyanate fluctuates very little in a pH range from 4.5 to 7.0. The inhibition rate of allyl isothiocyanate is higher than that of potassium sorbate, sodium benzoate, sodium propionate, nisin, and sodium hydrogen sulfite. Under the premise of the same anti-corrosion effect, the addition of allyl isothiocyanate can reduce the sterilization degree of the cabbage. When 0.01% allyl isothiocyanate is used together with potassium sorbate, the dosage of potassium sorbate can be reduced by about 0.05% in "Chongcai" (Niu et al. 2005).

The strong pungent odor of allyl isothiocyanate limits its application to food industry and has not been widely used for the postharvest preservation of fruits and vegetables. It was found that microcapsule technology could overcome the shortcomings of allyl isothiocyanate to reduce its irritating odor and volatility, thereby prolonging the antibacterial time and the shelf life of food. Wu et al. (2015) used gelatin and gum arabic as wall materials and allyl isothiocyanate as core material to make microcapsules, which could effectively control the release of allyl isothiocyanate and reduce the irritating odor to significantly prolong storage time and maintain quality of tomato. Allyl isothiocyanate microcapsules were able to significantly prolong the shelf life of kimchi (Ko et al. 2012). Piercey et al. (2012) found that β-cyclodextrin-allyl isothiocyanate microcapsules could significantly inhibited aerobic bacteria and *Listeria* in fresh onion slices and promoted the preservation of onions.

In addition to the application in microcapsule technology, isothiocyanates can also form molecularly imprinted polymers, which together with chitosan to form a new active antimicrobial packaging material for beef preservation. Compared to low-density polyethylene packaging film, the active allyl isothiocyanate – molecularly imprinted polymers film – can significantly delay muscle degradation (Huang et al. 2018).

28.4.1.3 Functional Food Ingredients

Epidemiological studies reported that cruciferous vegetables can effectively prevent cancer. Long-term consumption of Brassica vegetables can significantly reduce the risk of various cancers such as stomach cancer, prostate cancer, and melanoma (Fahey et al. 2012) and reduce the incidence of lung cancer caused by smoking and air pollution (Tang et al. 2010). This is primarily due to the anticancer property of isothiocyanates (Musk et al. 1995).

The literature showed that 150 g of fresh broccoli may contain 56–112 g of sulforaphane with anticancer and cardiovascular protection. However, pre-treatment will cause most of the loss. For high-risk groups of this type of disease, the daily intake of broccoli does not achieve good preventive effects. The consumption and frequency of consumption are related to its anticancer and anticancer effects. Sulforaphane is an effective immune-enhancing ingredient in broccoli. The daily intake of 34 mg of glucosinolate per body (50 kg) can effectively enhance immunity. The British Food Research Institute believes that eating broccoli two to three times a week may enhance human health. It is recommended to consume about 300 g of broccoli each time. If you choose to eat every day, the daily intake is 70–80 g.

Commercially available sulforaphane capsules extract sulforaphane glucosinolate from broccoli seeds, each containing 30 mg of sulforaphane glucosinolate, which is hydrolyzed to sulforaphane in the body and functions as 20 times broccoli. As a nutritional supplement, sulforaphane capsules are not a substitute for medicines.

28.4.2 Effects of Processing Methods on Isothiocyanates

Isothiocyanates usually have good biological activity, but the properties are very unstable. For example, sulforaphane (1-isothiocyanate-4-methanesulfonylbutane) in broccoli is sensitive to temperature, while it's not sensitive to light (Li et al. 2007). The conversion of glucosinolates to isothiocyanates is influenced by many factors including heating, so cooking of mustard and broccoli may result in loss of sulforaphane (Alvarez-Jubete et al. 2014).

Different cooking methods differed in the loss of isothiocyanates. Kapusta-Duch et al. (2016) studied the changes of glucosinolates concentrations and their degradation products of three vegetables (rutabaga, green cauliflower, and purple cauliflower) during the cooking process. It was found that the total glucosinolates content in three plants decreased by 6.6%, 68.9%, and 69.2%, respectively. The cooking process resulted in an 11.0% reduction of isothiocyanates contents in green cauliflower and 42.4% reduction in purple cauliflower whereas 329.4% increase in rutabaga.

Isothiocyanates can be obtained from thioglucoside hydrolyzed by endogenous glucosidase in broccoli (isothiocyanates). However, during the cooking process, the kale is easily deactivated, so the concentration of isothiocyanates is reduced after cooking. Wu et al. (2018) compared the content of isothiocyanates in raw broccoli, directly fried with broccoli, hydrolyzed, and fried with broccoli. The results showed that the total isothiocyanate, sulforaphane content were the highest in the raw

broccoli group, and were the lowest in the directly fried with broccoli group. The content and activity of isothiocyanates were not significant difference between hydrolyzed and fried with broccoli group and control group. In addition to cooking methods, the type of vegetable oil used in cooking also affects the content of isothiocyanates in broccoli. Moreno et al. (2010) studied the effects of five different edible vegetable oils on total glucosinolates. The results showed that the use of extra virgin olive oil, soybean oil, peanut oil, or safflower oil didn't reduce the concentrations of total glucosinolates in broccoli. Because high temperature heating, oxygen, and salt can accelerate the destruction of isothiocyanates, vegetables should be heated at a low temperature for a short period of time to reduce the oxygen action and protect the isothiocyanates in vegetables as much as possible.

28.5 Safety: Toxicity and Side Effects

Although isothiocyanates are health beneficial components, overdose intake is toxic to humans and animals. Allyl isothiocyanate and derivatives are moderately toxic and are listed as restricted imported materials in many countries. For instance, a small amount of isothiocyanates inhalation can cause bronchial inflammation such as vomiting and coughing. When exposed to a long-term direct contact, it may cause impaired eczema. If the intake concentration is high enough, it may lead to vascular central and respiratory center paralysis and stimulate the digestive organs to cause gastroenteritis and can cause thyroid hypertrophy (Musk et al. 1995).

28.5.1 Acute Toxicity of Isothiocyanates

Related studies have shown that acute oral toxicity of 95% allyl isothiocyanate in Sprague-Dawley rats is moderate poisoning (LD_{50} male and female rats 271 mg/kg) and acute dermal toxicity is low toxic(LD_{50} male and female rats greater than 2000 mg/kg). Acute oral toxicity of 20% allyl isothiocyanate in Sprague-Dawley rats is low toxicity (LD_{50} male and female rats 1470 mg/kg), and acute dermal toxicity to Sprague-Dawley rats is low toxicity (LD_{50} male and female rats greater than 2000 mg/kg) (Wu 2010).

28.5.2 Chronic Toxicity of Isothiocyanates

Long-term exposure to isothiocyanates can also lead to chronic toxicity. Some structures of side-chain groups of isothiocyanates have β-thiol glucosinolates which are unstable with enzymatic hydrolysis of isothiocyanates and are automatically cyclized in polar solutions. Allyl isothiocyanate is generally considered to be a typical goiters factor to make goiter in animals (Borek et al. 1995). The mechanism of toxicity is that it competes with iodine, which reduces the absorption of iodine and causes swelling of the thyroid gland. 5-Hexenyl isothiocyanate is the primary flavor

component of wasabi. Akagi et al. (2018) performed a subchronic toxicity study on 5-hexenyl isothiocyanate at a daily dose of 0, 3, 12, and 48 mg/kg body weight for 6 weeks of male and female rats for 13 weeks; 5-hexenyl isothiocyanate-targeted organs were identified as the bladder, heart, and liver. Heart weight increased in male 48 mg/kg body weight group and female over 12 mg/kg body weight group. Male and female 12 mg/kg body weight group had bladder hyperplasia, and female 48 mg/kg body weight showed nodular hyperplasia. Male and female rats had no adverse reactions in 3 mg/kg body weight group.

28.5.3 Genotoxic Effects of Isothiocyanates

Numerous studies have shown that high doses of isothiocyanate are genotoxic, leading to sister chromosome exchange and chromosomal aberrations, DNA damage, and carcinogenesis in mammalian cells. Kassie and Knasmüller (2000) confirmed the genotoxicity of allyl isothiocyanate and phenyl isothiocyanate by *E. coli*, *Salmonella* TA100/TA98, and human Hep G2 cell experiments. At high doses of 90–270 mg/kg, allyl isothiocyanate showed moderate genotoxicity in mouse tissues, while phenyl isothiocyanate had no significant toxic effect in all mouse tissues. Bovine serum albumin and human saliva were found to significantly reduce the genotoxicity of isothiocyanates.

Murata et al. (2000) found that high concentrations of allyl isothiocyanate, phenyl isothiocyanate, and benzyl isothiocyanate (2.5–10 mol/L) could cause DNA damage and product 8-oxodG (marker of DNA oxidative damage) in the presence of Cu^{2+}. Laser imaging densitometry tests confirmed that the point mutation was located at the 273 ACG codon of the P53 tumor suppressor gene. Sequence changes at this site would result in the loss of normal biological activity of P53. However, in the absence of Cu^{2+}, isothiocyanates did not cause DNA damage. In human myeloid leukemia HL-60 cells, allyl isothiocyanate could induce the production of 8-oxodG.

28.6 Marketed Products of Isothiocyanates

With the improvement of people's consumption level and the emphasis on food safety, research and development of high-efficiency, nontoxic, residue-free pest control measures and food preservation methods have received widespread attention. In 1937, Walker reported the rapeseed of the genus cruciferous, together with the degradation products of isothiocyanate like sulfur mustard. Antibacterial activity and broad-spectrum fungicides, including allyl isothiocyanate and allyl isothiocyanate are the main product solutions active against many plant pathogenic fungi, bacteria, worms, and viruses. Some human pathogenic bacteria such as *Escherichia coli* bacteria, *Pseudomonas aeruginosa*, *Vibrio parahaemolyticus*, *Helicobacter pylori*, and so on are also biologically active. Isothiocyanate can effectively control pathogens and reduce the decay of fruits, vegetables, and meat during storage. However, since it is highly irritating and difficult to store directly, it is made into an allyl isothiocyanate microcapsule, which is convenient to use. According to the selection

conditions of the microcapsules, the encapsulation efficiency of the microcapsules can reach more than 90%, which can effectively control the release of allyl isothiocyanate and reduce the irritation. The results showed that the tomato microcapsules had a longer preservation time and the tomato sensory quality was better. Meat preservation has always been a serious problem, especially in terms of fresh meat preservation. The isothiocyanate microcapsules can reduce the loss rate of the gravy, delay the increase of the pH value and reduce the redness, and better maintain the original taste and elasticity of the gravy.

In daily life, isothiocyanates are widely used as a food additive with their unique spicy flavor. For example, allyl isothiocyanate is considered to be the main active ingredient of horseradish and is often used for seasoning of cold dishes, raw seafood, and the like. In addition to being used as a seasoning, allyl isothiocyanate is widely used as a food preservative. Adding 0.0001% allyl isothiocyanate in juice, the quality of the juice is still in very high standard even after 1 year of storage in the store. Therefore, more and more researchers examined the antibacterial effect of allyl isothiocyanate and tried to apply it to food packaging.

In addition to its antibacterial action, isothiocyanate also has an antiseptic effect, such as antiseptic effect on chitosan smears during storage of aquatic products. The film-forming ability of the raw material is prepared by the composite coating process of the antibacterial activity of the carp. The results show that the allyl isothiocyanate chitosan composite coating is better than the allyl isothiocyanate chitosan coating and the control group. The allyl isothiocyanate chitosan composite coating can effectively inhibit the bacterial colony. At the same time, it can slow down the fluctuation of alkaline nitrogen, fat oxidation, and pH value and control the fish, so as to maintain the sensory quality of squid, prolong the freshness of squid, and improve the eating quality of squid.

Isothiocyanate is an important sulfur-containing and nitrogen-containing aromatic compound and an important intermediate in organic synthesis. Some of them were rated as safe as spices. Currently, the American Food Flavors and Extracts Manufacturers Association generally recognizes 19 isothiocyanate flavors as safe, while China GB 2760-2014 allows the use of 15 isothiocyanate flavor compounds.

Of course, isothiocyanates can also be processed into related products. The mustard bud-lyophilized powder was used as raw material, and the wet granulation process was used to affect the content of isothiocyanate granules. 75% food grade soft wood was used, and the highest content was dried at 55 °C for 60 min after isothiocyanate. The best chewable tablets were determined by orthogonal test: 30% mustard seedling powder, 20% xylitol, 0.4% citric acid, 15% maltodextrin, 0.5% magnesium stearate, and 34.1% milk powder. The quality index of chewable tablets reached the national standard, and the isothiocyanates content reached 0.25 g/100 g DW.

28.7 Patents of Isothiocyanates

Isothiocyanates are interesting and important in food; therefore innovations in processing and applying are continually emerging. We introduce here recent patents in relevant area.

28.7.1 Flavoring Agents

1. The invention relates to a vegetable seasoning powder rich in isothiocyanate and a production method thereof (Guo et al. 2016)

The vegetable flavoring powder rich in isothiocyanate contains the mature vegetable powder of cruciferous plants and its sprout powder, in which the weight ratio of the mature vegetable powder of cruciferous plants and its sprout powder is 1:1.5 and the content of isothiocyanate in the said vegetable flavoring powder is 800–2500 mg/100 g dry weight. Vegetable flavoring rich in isothiocyanate is made from cruciferous vegetables or their sprouts through selection, cleaning, heat treatment, freezing, enzymatic hydrolysis, drying, and ultra-fine grinding. Spicing with compound salt, monosodium glutamate, garlic powder, ginger powder, green onion powder, onion powder, chili powder, star anise powder, pepper powder, sterilization, packaging, prepared. The production process of the invention is simple, the formulation is reasonable and scientific, and it can be industrialized. The content of isothiocyanate in the product is 800–2500 mg/100 g dry weight.

28.7.2 Antistaling Agent

1. A method for prolonging the shelf life of meat by using aromatic extract (Fan et al. 2019)
   The method of prolonging meat shelf life with aromatic extract is simple and effective. It can safely and reliably extend the shelf life of fresh pork to 30 days and effectively achieve the preservation effect and has the advantages of green environmental protection, low power consumption, energy saving, and no secondary pollution.
   The method includes the following:

① Extract and concentrate isothiocyanate and w-hydroxyl isothiocyanate from mustard into a paste, which is used as an aromatic extract agent.
② Place the meat class of aromatic extract agent in a storage box.
③ Refrigerate box placed at 0 °C~ 8 °C freezer.

2. Mustard essential oil preservative and its application in fruit and vegetable preservation (Guan et al. 2008)
   The main active ingredient of wasabi essential oil preservative is wasabi essential oil containing more than 99% allyl isothiocyanate. The solid sustained-release tablets are composed of wasabi essential oil (5% ~ 10%), -cyclodextrin (80% ~ 85%), and stearic acid (5% ~ 10%). This antistaling agent can slowly release the mustard oil, combined with fruits and vegetables plastic film packaging, applicable to apple, pear, grape, jujube, citrus, mango, cherry, banana, potato, onion, garlic, and other fruits and vegetables preservation, suitable effective inhibition of

pathogenic microorganisms in the postharvest process of fruits and vegetables, prolong the preservation time and the distance of the market circulation.

3. The invention relates to a highly effective externally controlled preservative and a preparation method thereof (Li et al. 2007)
   The invention provides an effective externally controlled preservative, which is composed of 30% ~ 50% silica, 49.995% ~ 68% edible alcohol, and 0.005% ~ 2% allyl isothiocyanate by mass percentage. It can be widely used in the storage of food, medicine, reagents, tobacco and leather, when applied to food storage, paper film packaging bag shape and moisture permeability, small flake form placed in food packaging, make fresh drug slow release in the form of gases, evaporate into the internal space, in the fresh food forms around a certain concentration of gas phase protection layer, effectively restrain and kill several kinds of fungi and bacteria, and other corruption. At the same time, it can improve the osmotic pressure in packaging and lower food water activity, thereby effectively achieving preservation purposes.
4. Antibacterial deoxygenation dual-effect food preservative and its preparation method (Liang et al. 2008)
   The antibacterial and deoxidizing dual-effect food preservation agent is composed of a combination of the deoxidizer component and the antibacterial component, with the deoxidizer component accounting for 60–90% and the antibacterial component accounting for 10–40%. The antibacterial component includes the adsorption carrier and the antibacterial solution. The adsorption carriers include food starch, silica, vermiculite, diatomite, zeolite, bentonite, fiber, etc. The bacteriostatic solution is edible alcohol, propylene glycol or the mixture of them. Antibacterial and synergistic agents include allyl isothiocyanate, allicin, cinnamaldehyde, cinnamic acid, carvol, eugenol, thymol, and citral. It has the function of double protection of oxygen absorption and bactericidal and bacteriostatic.
5. Isothiocyanate preservative and its application (Koster et al. 2004)
   Mustard oil containing isothiocyanates has been publicly shown to have antibacterial and antifungal effects in oral therapy and in some foods. Isothiocyanate compounds in mustard oil are active agents providing antimicrobial effects. Derived from white mustard or yellow mustard, the oil also provides antibacterial and antifungal beneficial effects. However, white mustard oil is known to be a viscous oil, so it is difficult for the oil to be dispersed uniformly into solid food products or on the surface of solid food products. In addition, isothiocyanate compounds are effective antimicrobials at relatively low doses. As a result, it is difficult to distribute such a low quantity uniformly to a solid food substrate or to the surface of a solid food product. In addition, the main ingredient in white mustard oil is a moisture-sensitive compound that begins to degrade, or hydrolyze, within hours of being exposed to water. In general, the mustard processing industry mainly uses white mustard powder, while essential oils are largely ignored. In fact, in order to take advantage of white mustard powder, which has no “heat” sensitivity, the ground mustard powder has to go through a heat deactivation step. Myrosinase is deliberately catalyzed so that the essential oil

does not form when the powder is mixed with moist food products such as meat and sausage.

28.7.3 Annexing Agent

1. The invention relates to a soft yellow mustard paste which is easy to spread and a preparation method thereof (Zhang et al. 2019)
   The mustard seeds were crushed at low temperature to protect the myrosinase activity and avoid enzyme inactivation caused by high temperature, so that the glucosinolates in mustard seeds could fully generate allyl isothiocyanate, thus reducing the generation of other bitter substances. Adding appropriate amount of soybean protein can improve the stability of allyl isothiocyanate hydrolyzed from wasabi powder and make the main flavor substance isothiocyanate less volatile. The hydrolysis of allyl isothiocyanate was inhibited, and the flavor of wasabi was prolonged. The inclusion of cyclodextrin in allyl isothiocyanate makes the product taste mellow and soft, without pungent irritation, and increases the acceptability of the product. Intermittent ultrasonic emulsification homogenization makes mustard sauce more uniform and better applicability, and flexible sterilization is adopted in the later stage to better retain the flavor of the product. The products are prepared by activation, preliminary crushing, ultra-fine crushing, heating and dissolution, stirring, hair preparation, ingredients, phacoemulsification, and sterilization.
2. Complexes for immobilizing isothiocyanate natural precursors in cyclodextrins, preparation, and use (Roselli et al. 2004)
   The product of isothiocyanate embedded in cyclodextrin has antibacterial and bactericidal properties. The organic isothiocyanates are stable as inclusion compounds in cyclodextrin, allowing them to dissolve in aqueous media and controlling their release. The antimicrobial, bactericidal, and/or fungicidal composition of this compound can be used in the food and food processing fields. Their physical properties make them simple for use in food and food processing applications, and thus the dosage of the preservation process can be controlled without compromising the sensory properties of the food to be preserved.

28.7.4 Other Patents

1. Application of isothiocyanates in the preparation of herbicides for the control of weeds in fields and lawns (Lin et al. 2010)
   The application of a group of isothiocyanate compounds in the preparation of agricultural herbicides for the control of weeds in farmland and lawn is provided, which can be used as single agent or compound agent and can be made into soluble liquid agent, water emulsion, oil agent, emulsion, or other dosage forms.
2. Application of isothiocyanates in promoting hair growth (Cheng et al. 2009)

Natural and synthetic isothiocyanate compounds or their derivatives and metabolites have broad clinical application and market development prospect in promoting hair growth, especially in the treatment and prevention of hair loss.

28.8 Perspectives

The isothiocyanate is mainly hydrolyzed by glucosinolates in the family Brassicaceae and Brassica. There are many types; common are benzyl isothiocyanate, allyl isothiocyanate, indole-3-carbinol, phenethyl isothiocyanate, sulforaphane, sulforaphene, iberin, and erucin. Their structures are different and their functions are different in all aspects. The absorption of isothiocyanates in the human body also depends on the degree of hydrolysis of the glucosinolates. The type of vegetables, the chewing of the mouth, the pH of the environment, and the action of microorganisms all affect the hydrolysis of glucosinolates. The bioavailability of isothiocyanates can be understood by measuring metabolites in blood and urine. These are the basis for studying the mechanisms of their human protection effects.

Isothiocyanates possess a lot of biological activity, which can effectively inhibit cancer tumors and treat diseases and antibacterial. At present, the research mainly focuses on anticancer, and it can exert its activity by inducing various signal transductions such as apoptosis, thereby enhancing the human immune system. Consumption of isothiocyanate has great benefits for human health, and it can also play a good role in food preservation. Whose activities of antibacterial and antiviral have a good application in controlling food diseases, which is also an important direction for the development of isothiocyanates in the food industry in the future.

With the development of extraction and analysis technology, more and more isothiocyanate compounds will be identified from food, and their application in the food field and even in the medical field will be expanded. Isothiocyanates currently used in the food industry are mainly concentrated food flavors compounds. The unique spicy pungent odors of isothiocyanates make mustard oil, mustard sauce, kimchi, sauce, and other foods and condiments be more attractive and popular. Secondly, the antibacterial properties of isothiocyanates also make them apply to food preservation. At the same time, some physiological activities of isothiocyanates such as antitumor and anti-oxidation can be used as components of functional foods and can positively promote people's health. However, isothiocyanates are affected by the cooking method and time during cooking. High temperature and long-term heating can accelerate the destruction of isothiocyanates. Thus, cooking should be carried out in the shortest possible time to minimize the loss of isothiocyanate.

Although isothiocyanates have a variety of physiological functions and are beneficial to a human body within a certain range, pure isothiocyanates have acute toxicity, chronic toxicity, and genotoxicity. Excessive intake of isothiocyanate can cause poisoning in humans or animals. Under normal circumstances, the daily intake of isothiocyanates from cruciferous vegetables such as broccoli and broccoli is not enough to cause high doses of poisoning. Although there is a certain amount of isothiocyanates in the seasonings such as mustard sauce, mustard oil, and kimchi, the

seasoning is originally used as an auxiliary seasoning for food, and the daily intake is small. It's not easy to cause food poisoning.

In general, this chapter provides an overview of the classification, bioavailability, metabolism, functional activity, application in food, and patented products of isothiocyanates. What is the next major development in the study of isothiocyanates?

Many extrinsic and intrinsic factors can influence the final uptake, formation, bioaccessibility and bioavailability of isothiocyanate. A great deal of efforts has been made to grow Brassica vegetables containing much greater levels of glucosinolates contents in order to understand the effects of industrial processing on the glucosinolate-myrosinase system, to optimize these processes, to indicate the bioaccessibility and bioavailability of isothiocyanate, and to study the beneficial therapeutic effects of isothiocyanates in vitro and in vivo. However, still many factors and mechanisms need to be researched in further study. Factors that affect the bioaccessibility/bioavailability of glucosinolates and isothiocyanates such as meal composition are not yet clear, and more studies should be performed to elucidate how the final isothiocyanate absorption can be enhanced during consumption of a meal.

People pursue a higher quality of life including food and clothing. In order to improve food quality, researchers have been trying to constantly promote the development of science and technology. Isothiocyanates have been shown to reduce the risk of cancer; therefore they will be studied intensively. Isothiocyanate has the potential to prevent the complexities associated with cancer. Cruciferous vegetables are considered to be one of the significant sources of glucosinolates availability required for isothiocyanate formation. Recently the public and scientific community focuses on the beneficial properties of isothiocyanate. This has caused a demand of functional foods and dietary supplements rich in isothiocyanate concentrations in the United States and Europe health food markets. The health effects of isothiocyanates are promising, but there are specific limitations and challenges. Further research is needed to determine in depth the biological activities of various glucosinolates in order to determine their advantages and disadvantages.

Polysaccharides in Food

29

Junqiao Wang, Junyi Yin, and Shao-Ping Nie

Contents

Abstract

The polysaccharide is widely found in various food sources, including mushrooms, seaweeds, cereal grains, etc. The structure of polysaccharide is usually complicated, so a combination of chemical methods, instrumental technologies, and biological methods are always applied simultaneously in order to fully understand the primary structure. It is widely accepted that they have many bioactivities, such as immunomodulatory activity, anticancer activity, antioxidant activity, antidiabetic activity, renal protective and liver protective function, and so on. In this chapter, an overview of the latest developments in isolation,

Polysaccharide · Isolation · Purification · Structure · Bioactivities

29.1 The Definition and Research History of Polysaccharides

Polysaccharides are widely distributed in food resources like plants, animals, and mushrooms, and they are one kind of major and essential bio-macromolecules in living organisms together with proteins and polynucleotides. The monomeric units, known as monosaccharide unit, of polysaccharide are mutually jointed by various types of linkages. Polysaccharides are condensation polymers where the glycosidic linkage formed from the glycosyl moiety and a hydroxyl group of the adjacent sugar unit. Most of them exhibited as linear or branched chains with exception of cyclic polysaccharides named cycloamyloses. Based on the number of monosaccharide presented, polysaccharides can be divided into two class, homopolysaccharides and heteropolysaccharides. Researches on the chemistry of simple sugars began in the late nineteenth century by Fischer (1893). The ring structure was determined in 1920–1940 by Haworth and his colleagues (Haworth 1925, 1928; Haworth and Hirst 1930). Since then, more and more scientists were interested in the studies of sugar chemistry. Currently, starch, cellulose, chitin, and other polysaccharides have been engaged in extensive researches and characterized by classical chemical methods. In 1988, Dr. Dwek from University of Oxford published a review titled "Glycobiology" (Rademacher et al. 1988), which was very important in the sugar research history. In recent years, the study of polysaccharide emphasized on their utilization in the intestine and the beneficial impact on colon health. More and more reports in Nature and Science announced the functionality of polysaccharides. Furthermore, due to the rapid development of technologies, it is more accurate and convenient to characterize the chemical structure of polysaccharides. The extensive use of NMR and MS technologies made it possible to analyze polysaccharides with complex structure properties.

29.2 Isolation and Purification of Polysaccharides

Polysaccharide usually exists in the cell wall of food sources. Hot water extraction is the most popular approach for polysaccharide due to a safety and environment friendly compatibility. In order to accelerate the dissolution of polysaccharide from cell walls, high-temperature, ultrasonic, microwave, enzyme hydrolysis is frequently utilized. Acidic and diluted alkali solutions are also commonly used to extract

polysaccharides in the basic rule of breaking cell walls from outer to inner layer. Generally, the traditional procedures for polysaccharide extraction are conducted as follows:

1. Firstly, powder of food materials are defatted by organic solvents in order to eliminate part of low molecular substance, such as pigments and lipids that may be co-extracted by water.
2. Then, the dried defatted materials are extracted using hot water, acidic solution, and diluted alkali solution. Furthermore, some assistant methods are used to improve the extraction process.
3. Afterward, the extract solutions are deproteinized by Sevag method to remove the free protein, and in some cases, protease or proteinase would be added to polysaccharide solutions to remove both the free and covalently linked proteins. After dialyzing against water to remove small molecular compounds, the deproteinized solution is precipitated by alcohol to obtain a crude polysaccharide.

Purification process is conducted for preparing pure polysaccharides using a combination of techniques, such as fractionation by ethanol precipitation, ultrafiltration, freeze-thawing method, and different column chromatography methods. The most common chromatography methods are ion-exchange chromatography and gel filtration chromatography, based on the separation principle of ion strength properties and molecular size differences, respectively.

29.3 Chemical Structure of Bioactive Polysaccharides

The structure of polysaccharide is usually complicated, and determination of its structure requires a combination of chemical methods and instrumental technologies, in addition to biological method. To understand the primary structure, the information of monosaccharide composition, molecular weight, glycosidic linkages and sequences, ring size, anomeric configuration, and substitution (if appropriate) is essential. The polysaccharides extracted from food materials are generally purified prior to structural characterization. Therefore, the first step for analyzing a polysaccharide is determination of its molecular weight distribution and purity. And the second step is identification of monosaccharide composition that reflected the availability of purification procedure and unveiling structural information to a certain extent. The detailed principles, advantages and disadvantages, and precautions of methods for polysaccharide characterization have been comprehensively described in several reviews (Nie et al. 2018b; Xie and Nie 2010; Xie et al. 2017; Yang and Zhang 2009; Yin et al. 2018). Especially, a comprehensive utilization of "partial degradation-methylation-NMR" strategy was put forward by Yin, Xie, and Nie, for characterizing the fine structure of polysaccharides with complex structure (Yin et al. 2018).

29.3.1 Bioactive Polysaccharide from Edible Mushrooms

29.3.1.1 Glucan

Mushroom is a kind of fungi that is popular for its special flavor and nutrition. In many Asian countries, like China, Japan, and Korea, mushrooms such as Lingzhi (*Ganoderma lucidum*), maitake (*Grifola frondosa*), and Shiitake (*Lentinus edodes*) have been harvested, cultivated, and consumed for hundreds of years, being valued as edible/medicinal sources. These mushrooms represent an unlimited resource of polysaccharides with a distinctive antitumor and immunomodulating activity. Both naturally collected and artificially cultivated fruiting bodies of mushrooms are contained bioactive polysaccharides. The fungal walls are mainly composed of structural polysaccharide. Polysaccharides extracted from mushroom are regarded as one of the primary bioactive constituents and are beneficial to human health. The most common polysaccharides contained in edible mushroom are α-, β-, or mixed glucans. Among them, β-D-glucan with a (1→3)-linked main chain substituted at O-6 is a typical structure observed in various mushrooms, such as lentinan from *Lentinus edodes*, schizophyllan from *Schizophyllum commune*, grifolan from *Grifola frondosa*, and scleroglucan from *Sclerotium sclerotia*. Besides, Linear (1→3)-β-D-glucan or (1→3)-β-D-glucan with some different branch chains, such as (1→2)-, (1→3)-, (1→4)-, and (1→6)-linked Glc*p*, was commonly observed in mushrooms. Such kind of chemical structures has been proved to be responsible for some biological properties, for example, antitumor, immunomodulatory, and antioxidant activities. A glycogen-like structure, α-D-glucan with main chain of (1→4)-linked Glc*p*, was also found in some mushroom polysaccharides, such as *Agaricus bisporus* (Smiderle et al. 2010), *Coprinus comatus* (Li et al. 2013), and *Cordyceps sinensis* (Wang et al. 2017b, c). Additionally, polysaccharide with (1→6)-β-D-Glc*p* backbone was reported in mushrooms of *Calocybe indica* (Mandal et al. 2010), *Entoloma lividoalbum* (Maity et al. 2014), *Pleurotus citrinopileatus* (Liu et al. 2012), and *Russula albonigra* (Nandi et al. 2014), of which mostly by alkali extraction. The differences observed among these D-glucans are the types and degree of branching, which usually depends on the sources, extraction solvent, or isolation procedures.

29.3.1.2 Heteromannan

Heteromannans are another kind of polysaccharides found in mushrooms, especially in ascomycetes (Leal et al. 2010; Ruthes et al. 2016). They consist part of the cell wall structure of mushrooms and can also be attached to proteins forming the cell wall matrix (Ruthes et al. 2016). Generally, the heteromannans are extracted by diluted alkali solution (NaOH or KOH). Their solubility in water enables separation from other water-insoluble polysaccharides through dialysis, and the solubility in 50% ethanol improves the purity. The heteromannan displayed fairly similar structure, always an α-(1→6)-linked mannan core constitutes the main chain, more or less substituted by α-Man*p* and/or β-Gal*f* containing side chains. The molecular weight of these polysaccharides ranged from 15 to 100 kDa (Leal et al. 2010).

29.3.1.3 Heterogalactan

In addition to glucan and heteromannan, heterogalactans have been characterized in mushroom, especially in *Basidiomycetes*. In most cases, this polysaccharide showed a (1→6)-α-Gal*p* backbone with O-2 substitution and can also be partially *O*-methylated with 3-*O*-Me-α-D-Gal*p* residues presented at the main chain (Ruthes et al. 2016).

29.3.2 Functional Polysaccharide from Seaweed

Marine macroalgae (seaweeds) are commonly consumed in daily diet, especially in Asian. They can be classified into brown algae (phaeophyta), green algae (chlorophyta), and red algae (rhodophyta) based on the chemical composition (Gupta and Abu-Ghannam 2011). Seaweeds contain unique, hydrocolloid polysaccharides such as alginate and carrageen that have been applied in many food industries. Importantly, they are also rich sources of naturally sulfated polysaccharides, which possessed a number of biological activities, such as antiviral, anticoagulant, immunomodulatory, etc. (Wijesekara et al. 2011; Wijesinghe and Jeon 2012). The major sulfate polysaccharides identified in marine algae were fucoidan and laminarans from brown algae, ulvan from green algae, as well as carrageenan from red algae.

29.3.2.1 Fucoidan

Fucoidan is a type of natural sulfated polysaccharide mainly distributed in the cell wall matrix of brown seaweeds, like *Fucales*, *Laminariales*, *Chordariales*, *Dictyotales*, *Dictyosiphonales*, *Ectocarpales*, and *Scytosiphonales* (Gupta and Abu-Ghannam 2011). It is a branched polymer containing substantial amount of L-fucose and sulfate ester groups. Actually, this kind of sulfated polysaccharide has been characteristically identified in all brown algae so far and seems not in green algae, red algae, as well as in freshwater algae. The structure of fucoidan differs among seaweed species and was predominantly composed of (1→3)-α-L-fucose main chain or alternating (1→3)-α-L-fucose and (1→4)-α-L-fucose, (1→2)-α-L-fucose sometimes presented in the backbone. Sulfate groups usually occupied in C-2 and/or C-3 and C-4 position of fucose. Specifically, it is worth noting that fucoidan is not a pure fucan sulfate but a heteropolymer containing fucose, galactose, xylose, mannose, or glucuronic acid.

29.3.2.2 Laminarin

Laminarin, found in *Laminaria* and *Saccharina* species, is low molecular weight polysaccharide and bioactive constituent in brown algae. As a food reserve in brown algae, the content of laminarin is up to 35% of dry weight (Kadam et al. 2015). It contains 20–25 glucose monomers constituted (1→3)-β-D-Glc*p* main chain and certain (1→6)-β-D-Glc*p* branching. There are two types of laminarin chains differ in the reducing end. One is end with a mannitol residue, and the other is end with

a glucose residue. The molecular weight of laminarin is approximately 5 kDa dependent on the degree of polymerization.

29.3.2.3 Ulvan

Ulvan is the major water-soluble polymer found in green seaweed of two major genera, Ulva and *Enteromorpha* sp., accounting for around 8–29% of the dry weight (Lahaye and Robic 2007). The extraction is generally conducted by water solutions containing a divalent cation chelator at about 80–90 °C and accumulated by alcohol or quaternary ammonium salt precipitation (Lahaye and Robic 2007). As reviewed by Lahaye and Robic (2007), ulvan structure shows great complexity and variability, and determination of the sugar sequence is a major challenge. Sulfate, rhamnose, xylose, iduronic, and glucuronic acids are the main components of Ulvan. Specifically, the major repeating disaccharide unit is ulvanobiouronic acid 3-sulfate type containing either glucuronic acid or iduronic acid (Jiao and Yu 2011).

29.3.2.4 Carrageenans and Agarans

For red seaweed, the sulfated polysaccharides are primary galactans called agarans and carrageenans. The two galactans differs in stereochemistry, of which with 4-linked α-galactose of L-series termed as agarans and those of D-series termed as carrageneens. Especially, carrageneens are widely used as food additives at present. The repeating disaccharide units of carrageneens are composed of alternating 3-linked β-D-Gal*p* and 4-linked α-Gal*p* or 3,6- anhydro-α-Gal*p*, as showed in Fig. 1.

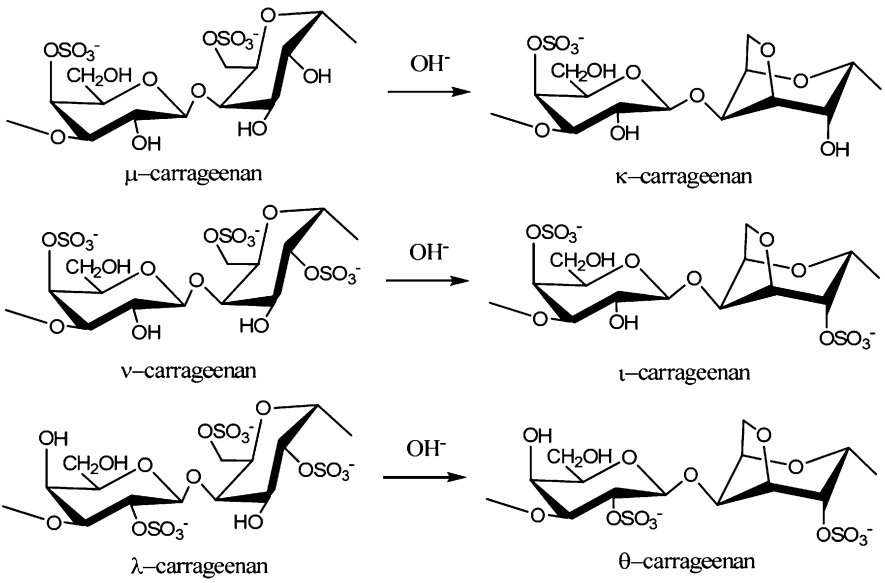

Fig. 1 The repeating disaccharide units of different types of carrageenan and their transformation by treatment with alkali (Jiao and Yu 2011), https://doi.org/10.3390/md9020196

29.3.3 Bioactive Polysaccharide from Cereal Grains

Cereal grains, such as rice, wheat, barley, oat, rye, maize, and sorghum, are staple foods for the majority of population all around world, especially for the Western diets. The bioactive polysaccharides in cereals, mainly referring to the non-starch polysaccharide derived from cell walls, account for approximately 3–8% of the grain (Bader Ul Ain et al. 2018), and it considered as an excellent source of soluble and insoluble dietary fiber.

29.3.3.1 Arabinoxylan and (1→3) (1→4)-β-Glucan

The noncellulosic polysaccharides presented in cereals are predominantly arabinoxylans, β-glucans, pectins, and arabinogalactans. Among them, arabinoxylans and mix linked (1→3) (1→4)-β-glucans are predominant cell wall structural components and bioactive polysaccharides. The cell walls of barley and oats contained generally higher levels of β-glucan, whereas rye and wheat cell walls were abundant in arabinoxylans (Bader Ul Ain et al. 2018; Cui and Wang 2009; Muralikrishna and Subba 2007). Both of them have been characterized extensively due to their promising functional properties. The structure of cereal β-glucan is a typical linear homopolysaccharide, and over 90% of them was made up of two or three consecutive (1→4)-linked Glc*p* separated by a single (1→3)-linked Glc*p*, forming as two building blocks, a trisaccharide or tetrasaccharide unit. For arabinoxylans, it is composed of a linear xylan backbone with β-(1→4)-linkage, a ferulic acid moiety, and an α-L-Ara*f* substitution along the backbone. The Ara*f* residues are attached to the backbone at C-3 and/or C-2 position. While the majority of Ara*f* substitutions are monomeric, a small proportion of Ara*f* were found as short oligosaccharide side chains with (1→2)-, (1→3)-, and (1→5)-linked Ara*f* residues. In addition, xylose and galactose are reported existed in the reducing end in some cases. Uronic acid, galactose, glucose, and acetyl groups were substituted at O-2 and/or O-3 of the xylan chain in much lower amount (Shuangyue et al. 2015). This suggested that the general structural characteristic of arabinoxylan varies significantly among cereal sources and cultivars.

29.3.3.2 Fructans

Fructans, also called polyfructosyl sucroses, consist mainly or exclusively of fructose and contain no or one glucose (Lewis 1993). They have many different types of structures, ranging from three up to a few hundred monomer unit and could be classified based on the types of fructose-fructosyl linkages, β-(2→1)-D-Fru*f* or β-(2→6)-D-Fru*f*, as well as their core molecule. Inulin was the common known inulin-type fructans, which had a linear chain of almost exclusively β-(2→1)-D-Fru*f* residues. Fructans of levan-type were mainly consisted of linear β-(2→6)-D-Fru*f* units. Gramminan-type fructan was built up of both β-(2→1)-D-Fru*f* and β-(2→6)-D-Fru*f* linkage. Neo-inulin and neo-levan-type fructans were composed of 6G-kestotriose and have predominantly β-(2→1)-D-Fru*f* and β-(2→6)-D-Fru*f*, respectively. The structure of these five fructan types could be clearly overviewed by Fig 2. As reviewed by Verspreet et al., rye contained the highest levels of fructan among

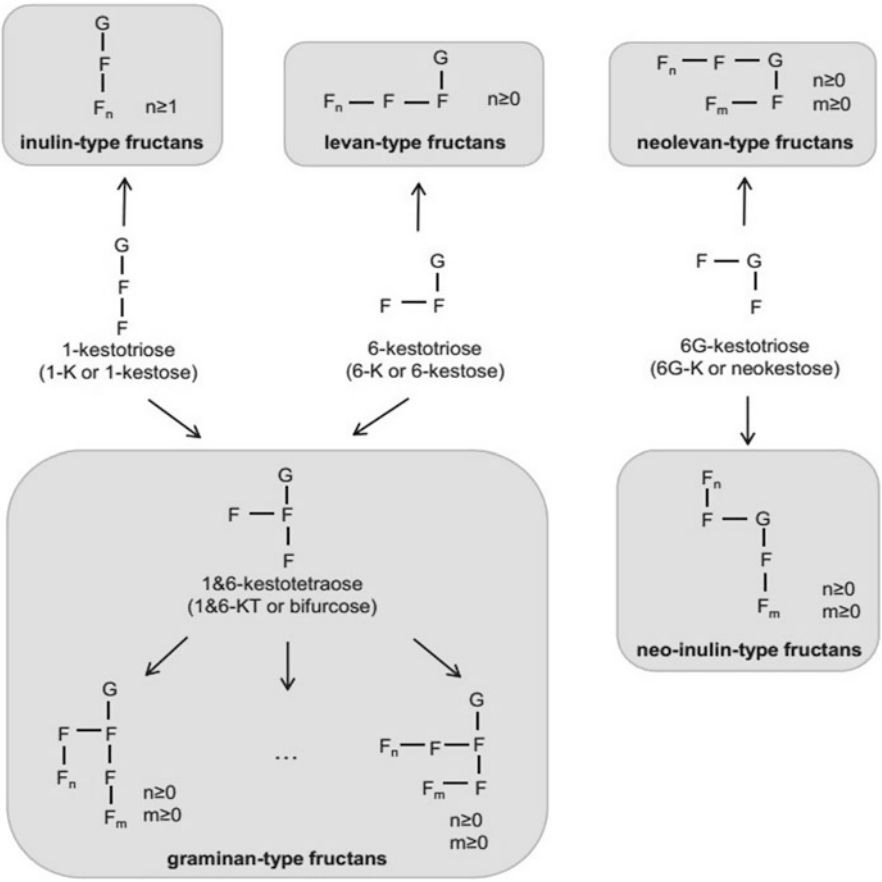

Fig. 2 Overview of the five different fructan types. G and F represent glucose a fructose unit, respectively. Vertical and horizontal lines between two fructose units depict β(2,1)-linkages and β(2,6)-linkages, respectively (Verspreet et al. 2015), reprinted with permission from Elsevier

cereal grains, of which concentrations ranged from 3.6% to 6.6% of dry weight (Verspreet et al. 2015). Cereal grain fructans comprise a complex mixture of mostly branched structures. These fructans had a profound positive effect on colon health.

29.3.4 Bioactive Polysaccharide from Vegetables and Fruits

Food polysaccharides are proved to have certain beneficial effects on the diet and human health, such as immunomodulatory, antitumor, anti-inflammatory, antibacterial, hypoglycemic, and anticancer activities. Fruits and vegetables play a crucial part in human diet and daily life. They are abundant in soluble and insoluble dietary fiber, such as hemicelluloses and pectins. Traditionally, dietary fiber was

defined as "plant polysaccharides (including cellulose, hemicelluloses, gums, oligosaccharides, and pectin) and lignin which are resistant to hydrolysis by digestive enzymes" by AOAC International and AACC International in the 1970s (Prosky et al. 1985). Recently, a more comprehensive description of dietary fiber by Codex was defined as "carbohydrate polymers with ≥10 (or 3, depending on the jurisdiction) monomeric units that are resistant to enzymatic hydrolysis during human small intestinal digestion" (Codex 2015).

On the other hand, fructans, another kind of dietary fiber, were also naturally presented in some vegetables and flowers, like taproot of chicory, tubers of dahlia, bulbs of tulip, and onion (Ritsema and Smeekens 2003). Fructans are also a kind of reserve carbohydrate in some edible plants. Due to the similarity structures of fructans in cereal grains, it will not list separately in this part.

29.3.4.1 Pectin

Plant acidic polysaccharides, particularly pectic polysaccharides, are widely distributed in the primary cell walls of roots, stems, leaves, fruits, etc. of all land plants. Pectic polysaccharides have a complex structure composed of up to 17 monosaccharides with more than 20 different linkages (Ndeh et al. 2017; Voragen et al. 2009). But to some extent, it shares common features, particularly the presence of galacturonic acid in the backbone giving these polysaccharides anionic properties. Besides, it also comprises a few neutral polysaccharide chains such as arabinans and arabinogalactans that always interconnecting the anionic moieties. Generally, the major pectic polysaccharides are recognized as homogalacturonan (HG), rhamnogalacturonan-I (RG-1), and rhamnogalacturonan-II (RG-II). HG was composed of linear α-D-(1→4)-Gal*A* residues with some of C-6 carboxyl groups methyl-esterified, while RG-I was made up of alternating disaccharide repeating unit of →4)-α-D-Gal*A*-(1→2)-α-L-Rha(1→ with various glycan chains attaching to the backbone (mainly arabinose and galactose) (Koubala et al. 2014; Mohnen 2008; Willats et al. 2006). RG-II, a relative minor component of cell wall, is considered to be the most structurally complex polysaccharide with about 12 different monosaccharide residues interconnected by more than 20 types of glycosidic linkages. It consisted of a homogalacturonan backbone comprising seven to nine →4)-α-D-Gal*A*-(1→ residues, and some of them was methyl-esterified in addition to a highly branched side chains which vary with the source of fruits and vegetables. Different pectin fractions were extracted from cell wall materials of fruits and vegetables using water, sodium carbonate (Na_2CO_3), and chelate agent like 1,2-cyclohexanediaminetetra-acetic acid (CDTA). Specifically, CDTA and Na_2CO_3 were employed to extract pectin that was ionically or covalently bound to the cell wall materials (Lara et al. 2004; Posé et al. 2012; Redgwell et al. 1992; Selvendran 1985). CDTA-mediated extraction released pectin from the cell wall by complexing calcium, which was mainly distributed in the middle lamella containing a relatively high content of galacturonic acid. Na_2CO_3 extraction was able to release the neutral sugar-rich pectin from the primary cell wall by breaking ester linkages.

29.3.4.2 Xyloglucan

Xyloglucan is a matrix polysaccharide that is also presented in the cell walls of most land plants, and the best characterized xyloglucans are from tamarind seeds (Popper et al. 2011). Xyloglucan possessed a linear backbone of (1→4)-β-D-glucan, in this sense identical with cellulose. The backbone is composed of a cellotetraose with the first three glucose, counting from the nonreducing end, carrying an α-D-xylose residue on position 6 and the fourth glucose residue unsubstituted. Some of the xylose residues carry additional sugars, especially D-galactose and L-fucose.

29.3.4.3 Glucomannan

Glucomannan is widely distributed in conifers, the corms of *Amorphophallus* konjac and dicotyledons like *Dendrobium*, Aloe, in addition to the microorganisms or fungal cell walls. They are neutral polysaccharides acting as a source of soluble dietary fiber with a particular feature of high viscosity. They are constructed from mannose as the primary residues and galactose containing side chains. In most cases, these polysaccharides present a β-(1→4)-linked backbone containing Man*p* and Glc*p* residues, with some acetyl substituent. For example, konjac glucomannan is composed of β-D-(1→4)-Man*p* and β-D-(1→4)-Glc*p* with reported ratio of 1.6:1 or 1.4:1(Zhang et al. 2014). There are acetyl groups attaching randomly to C-6 position of approximately 1 per 19 sugar residues and some side chains linking to Man*p* residues by joint C-3. On the other hand, *O*-acetylated glucomannan isolated from *Dendrobium huoshanense* and *Dendrobium officinal* was found to substitute at O-2 and O-3 position of β-D-Man*p*, as shown in Fig. 3 (Xing et al. 2014, 2015). Polysaccharides from leaf skin of aloe vera were identified as *O*-acetyl-β-(1→4)-glucomannans, with the acetyl groups attaching to O-2, O-3, and/or O-6 positions (Shi et al. 2018a, b). The degree of acetylation and the ratio of mannose and glucose depend on the raw materials, affecting the properties of the polymer.

29.3.4.4 Galactomannan

As the name suggested, the polysaccharide is composed of two kinds of monosaccharides with mannose as the major component and galactose as the minor one. Unlike galactomannans found in the mushrooms, plant galactomannans are water-soluble β-(1→4)-linked D-mannan with side chains of single α-(1→6)-linked D-Gal*p* residue. The number of galactose units in plant galactomannans is commonly less than that the mannose units. They are mainly found in tara, guar, locust bean or carob seeds, etc. This kind of polysaccharide is functionalized as storage non-starch carbohydrate reserved in endosperm walls and vacuoles of seeds and vacuoles in

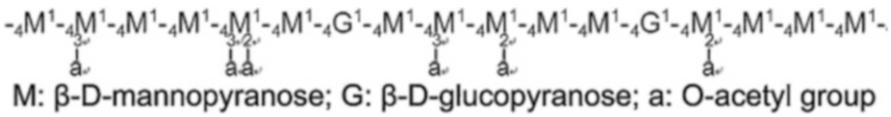

Fig. 3 Chemical structure of Dendronan from *Dendrobium officinale* (Xing et al. 2015), reprinted with permission from Elsevier

vegetative tissues (Meier and Reid 1982). The promising rheological properties of the plant galactomannans, such as thickening and additive effects, made them employ in diverse industrial and food applications.

29.4 Bioactivities (Animal Aspects)

It is widely accepted that naturally derived polysaccharides have many bioactivities, such as antitumor activity, immunomodulatory activity, gastrointestinal benefit activity, liver protection activity, hypoglycemic function, hypolipidemic function, antivirus activity, and so on. The unique structural features and biological properties of polysaccharides can be utilized successfully in various pharmacological, nutraceutical, and functional applications. Therefore, some of the bioactive polysaccharides have been made into clinical drugs or medicines for the treatment of certain diseases. One advantage for the clinical application of polysaccharides is that these carbohydrates are noncytotoxic to body cells.

29.4.1 Immunomodulatory Effect

The bioactive polysaccharides could interact with the immune systems directly or indirectly, triggering diverse cellular and molecular events and leading to the activation of immune function. The reported immunostimulatory polysaccharide included glucans, mannans, pectics, galactans, fucoidans, arabinoxylans, arabinogalactan, and other bioactive polysaccharides from plants, edible fungi, and algae. The β-(1→3)-glucans with triple helical conformation regarded as crucial structural characteristics for immunostimulating activity. For example, (1→3)-β-D-glucans that had β-D-Glc*p* units attaching by (1→6) linkages as single unit branches systemically enhanced the immune system (Bohn and BeMiller 1995). A highly branched β-glucan from the spores of *Ganoderma lucidum* significantly promoted dinitrochlorobenzene-induced delayed-type ear swelling in mice (Wang et al. 2017d). The backbone of immunostimulatory mannans mainly consists of (1→4)-D-Man*p*, especially from aloe vera, showing immuno-pharmacological and therapeutic properties. Huang et al. pointed out that β-(1→4)-D-Man*p* and *O*-acetyl structure might be responsible for the immunomodulatory activity of polysaccharide from *Dendrobium officinale* (Huang et al. 2015).

The immunomodulatory effect of food polysaccharides on cyclophosphamide (Cy or CTX) induced immunosuppressed mice was extensively studied. Food polysaccharides were intraperitoneally (in some cases) or orally administrated (in most cases) to mice after intraperitoneally injection of Cy to induce a chemotherapeutic injury. Recoveries of spleen and thymus indexes, activation of macrophage phagocytosis and NK cells, enhancement of splenocyte proliferation (cell-mediated immunity), in addition to an increased cytokine production, and serum hemolysin (humoral immunity) were observed after administrated with polysaccharides (Chen et al. 2016; Fei et al. 2016; Gong et al. 2015; Huang et al. 2015; Liu et al. 2017a;

Yang et al. 2017; Yuan-Yuan et al. 2014; Zhang et al. 2017c; Zheng et al. 2017; Zou et al. 2018). The immunoglobulin levels, like immunoglobulin (Ig) G, IgM, and IgA, in mice serum were also significantly increased (Hao and Zhao 2016; Zheng et al. 2017). Polysaccharides were also reported to ameliorate CTX-induced immunosuppression through reducing the apoptosis and oxidative damage (Li et al. 2017c). The intake of litchi pulp polysaccharides improved intestinal mucosal immune function via stimulating mesenteric lymph node cells proliferation and secretion of serum IgA (Fei et al. 2016). A macromolecular polysaccharide from *Grifola frondosa* could effectively reverse the downregulation of mRNA levels of cytokines of splenocyte in mice, in addition to increase the levels of lactate dehydrogenase (LDH) and acid phosphatase (ACP) in the spleen, as well as IL-2, IL-6, IL-1β, and IFN-γ mRNA expressions in splenocyte (Xiao-Lei et al. 2015).

Food polysaccharides might activate the intracellular signaling cascades in immune systems mediated primarily by specific pattern recognition receptors (PRRs) in the cell membrane, such as scavenger receptors (SRs) and toll-like receptors (TLRs). Activated PRRs could further enhance adaptive immune responses through the promotion cytokine productions that strengthened the cellular and humoral immune responses. Zhou et al. demonstrated that *Astragalus* polysaccharides might modulate immunity through activation of TLR-mediated MyD88-dependent signaling pathway (Zhou et al. 2017).

The improvement of immune dysfunction by polysaccharides was demonstrated to be mediated by intestinal mucosal immunity. Sheng et al. found that polysaccharide from *Hericium erinaceus* upregulated the production of secretory immunoglobulin A (sIgA) and activated the MAPK and AKT cellular signaling pathways in the intestine (Sheng et al. 2017). Yu et al. also demonstrated *Ganoderma atrum* polysaccharide (PSG-1) increased levels of phosphorylation of MAPKs and Akt, in addition to NF-κB expression in peritoneal macrophage. Ca^{2+} concentration and PKC activity of spleen lymphocytes, as well as cAMP level and PKA activity in PSG-1 groups, dramatically increased as compared with that of the model group (Yu et al. 2015). As was known, it was difficult for polysaccharides to be digested and absorbed in the intestine directly. Therefore, in recent years, many studies preferred to investigate the impact of polysaccharides on intestinal microbiota and interaction between polysaccharide-induced microbiome alteration and host immune system using approaches like multi-omics. Polysaccharide showed a prominently improvement in the intestinal immunity indexes in mice. Tang et al. found that polysaccharides from purple sweet potatoes modulated the intestinal bacteria of increasing SCFA-producing *Lachnospiraceae* and *Oscillospira* and reducing *Alcaligenaceae* and *Sutterella* (Tang et al. 2018). Zhang et al. determined a dynamic profile of mouse gut microbiome response to the intake of longan polysaccharide and thus constructed a correlation network by polysaccharide, bacterial species, microbial metabolic pathways, SCFAs, and the immune index that was better illustrate the causality (Zhang et al. 2017a). The protective effect of fungal polysaccharides from *Cordyceps sinensis* (CSP) and *Ganoderma atrum* (PSG), as well as their combinations on colon immune dysfunction induced by Cy, was studied, respectively, by Fan et al. Result showed that CSP significantly promoted microbial-derived butyrate to

improve histone h3 acetylation mediating regulatory T (Treg)-cell-specific Foxp3, as well as significantly restored Cy-induced elevation of IL-17 and IL-21. On the other hand, PSG significantly downregulated MyD88, in addition to increased IL-10 and TGF-β3. The combination of two polysaccharides balanced the disequilibrium of cytokines secretion and Foxp3/RORγt ratio-related Treg/T-helper 17 (Th17) balance, as well as downregulated the TLR-mediated inflammatory signaling pathway and promoted secretory immunoglobulin A (sIgA) secretion to suppress colonic inflammation (Fan et al. 2018). In summary, it is believed that polysaccharide-derived alterations in intestinal microbiota and microbial-associated inflammatory signals might be involved in the polysaccharide immunomodulatory activities.

29.4.2 Anticancer Effect

Polysaccharides from plants and mushrooms have potent anticancer activities (Zong et al. 2012). Unlike the tradition anticancer chemotherapy drugs, polysaccharides are nontoxic with small or no side effects. They provided therapeutic benefit in tumor-bearing mice. The antitumor polysaccharide varied from glucan, mannan, and hemicelluloses to heteroglycan. Among them, mushroom polysaccharides have been used in clinical anticancer therapy in some countries, particularly β-D-glucans (Zhang et al. 2007). In 1967, Chihara et al. reported that the polysaccharides from *Lentinus edodes*, lentinan and the β-(1→4),(1→6) linked glucan, showed a prominent inhibitory effect on the tumors growth in Sarcoma 180-bearing mice (Chihara et al. 1969, 1970). Since then, the antitumor activity of polysaccharide has aroused attention worldwide, much focusing on discovering novel antitumor adjuvant resources. Particularly, it has been proved that polysaccharides with structural characteristics of β-(1→3)-linkage in the main chain of glucan with β-(1→6)-branching points were effective in antitumor ability (Wasser 2002). In addition, β-(1→3)-glucans with triple helical conformation are regarded as a key structural feature of bioactivities. The tertiary structure of lentinan was lost when denatured with DMSO, urea, or sodium hydroxide, without changes of its primary structure. However, it was interesting to observe a lowered tumor inhibitory ability by progressive denaturation treatment (Maeda et al. 1988).

In addition to the well-known antitumor β-(1→3)-glucans, a wide range of biological glucans with other structures have been described. Masuda et al. revealed that maitake α-glucan, a highly branched α-(1→6)-branched α-(1→4)-glucan, significantly inhibited tumor growth and improved survival rate of colon-26 carcinoma- and B16 melanoma-bearing mice. The oral administration of this polysaccharide directly activated macrophages and dendritic cells in Peyer's patches and induced Th1/CTL immune response so as to inhibit the tumor growth (Masuda et al. 2017). Polysaccharide from fruit bodies of *Auricularia auricula-judae* (AAG) with a main chain of β-(1→4)-glucan and side chains of β-(1→6)-D-Glc*p* showed a significant inhibitory effect on tumor growth in a dose-dependent manner with no cytotoxicity. Furthermore, AAG-induced apoptosis in S-180 tumor cells by upregulating Bax and downregulating Bcl-2 (Ma et al. 2010).

For other food source, derived polysaccharides were also documented as an active anticancer agent. For example, a RG-II-type polysaccharide extracted from green tea inhibited tumor metastasis, and the effect was related to activation of macrophages and NK cells (Park et al. 2017). The *Ganoderma atrum* polysaccharide (PSG-1) predominantly suppressed the tumor growth in tumor-bearing mice through mitochondria-mediated apoptotic pathways, cAMP/PKA signaling pathway, and PKC pathway (Li et al. 2011b). PSG-1 enhanced immunity, and antitumor effects might be related to their potential in promoting the production of TNF-α in tumor-bearing mice. The proposed signaling mechanism might be as follows: PSG-1 acted on the TLR4 receptors on macrophages, signaled through the p38 MAPK pathway, and then activated NF-κB that initiated the release of TNF-α (Li et al. 2011a; Qiang et al. 2015; Zhang et al. 2013). Ginseng leaves polysaccharide inhibited tumor metastasis via macrophage and NK cell activation (Shin et al. 2017). Intake of *Dendrobium candidum* polysaccharides significantly reduced the tumor weight and increased the levels of serum cytokines (IL-2 and TNF-α) in S180-bearing mice than that of without polysaccharide treatments (Jin et al. 2010). Luo and Fan proposed that the antitumor properties of *Dendrobium denneanum* polysaccharides were attributed to their excellent immune-enhancing and antioxidant activities (Fan and Luo 2011). Long et al. demonstrated an obvious immunoregulatory effect of *Polygonatum sibiricum* polysaccharides on tumor-bearing mice via TLR4-MAPK/NF-κB signaling pathways (Long et al. 2018). A sulfated polysaccharide extracted from *Undaria pinnatifida* showed a strong anticancer effect by 7, 12-dimethylbenz [a]anthracene (DMBA)-induced breast cancer rat model, which might be attributed to immunomodulatory ability and regulating abnormal sex hormone levels (Han et al. 2016). Liu et al. investigated the antitumor effect of tea polysaccharides on colitis-associated cancer in azoxymethane/dextran sulfate sodium (AOM/DSS) mice model. Results showed that tea polysaccharides inhibited the activation of STAT3 and the levels of downstream protein expression such as MMP2, cyclin-DI, surviving, and VEGF. Confirmed by the in vitro noncontact co-cultured cell system, tea polysaccharides were demonstrated to inhibited colitis-associated colorectal cancer via suppressing interleukin-6/signal transducer and activator of transcription (STAT)-3 signaling pathway (Liu et al. 2018). A water extracted polysaccharide from *Lentinus edodes* exerted direct antitumor effects by inducing of cell apoptosis via both reactive oxygen species (ROS)-mediated and TNF-α-mediated pathways (Wang et al. 2017a).

Besides, food polysaccharide combination with chemotherapeutics is regarded as a promising method for cancer therapy strategy. With the combination treatment of polysaccharides, an enhanced efficiency of CTX and relieved side effects caused by chemotherapy was documented (Li et al. 2011a; Zong et al. 2018).

On the other hand, microbial dysbiosis has been found in tumor genesis. Li et al. evidenced that the tumor-suppressive activity of *Ganoderma lucidum* polysaccharides was not only attributed to the activation of macrophages but also the modulatory effect of gut microbiota (Li et al. 2018a). As the most abundant metabolites of polysaccharides, SCFAs were considered to reflect the alteration of the composition of gut microbiota. SCFAs, especially butyrate, arising in the large bowel during

polysaccharide fermentation by bacterial were considered to take a vital part in its antitumor function in the colon. Three proposed aspects of polysaccharides reduced the risk of cancer were ameliorating leaky gut, avoiding hypernutrition, and reinforcing immune balance, as indicated by Liu et al (2019a).

Presently, several polysaccharides and polysaccharide conjugates (polysaccharide-protein and polysaccharide-peptide complexes), such as lentinan, schizophyllan, krestin, and grifolan, have been commercialized in clinical therapy of patients with anticancer therapy (Zhang et al. 2007). The antitumor effect of polysaccharides and the possible mechanisms have been studied extensively and reviewed (Chen and Huang 2018; Liu et al. 2015b, 2019a; Meng et al. 2016; Reshetnikov and Tan 2001; Zhang et al. 2007; Zong et al. 2012).

Based on the previous literatures, the proposed antitumor mechanisms were summarized as follows: (1) inhibition of the oncogenesis and prevention of tumor metastasis, (2) induction of apoptosis of tumor cells, (3) enhancement of host immune system, (4) improvement of oxidative stress, and (5) modulation of gut microbiome composition.

29.4.3 Antioxidant Effect

Oxidative stress arises either from excessive production of free radical species, a reduction of endogenous antioxidant defense capacity, or both. Lipid peroxidation is a destructive process in which oxidants react with lipids in cell membranes, leading to the damage of cell. The antioxidant enzymes play a key role in in vivo antioxidant system. Previous studies had demonstrated that the antioxidant enzymes could defense against the formation of ROS and transform active oxygen molecules into nontoxic compounds so as to reduce the oxidative stress. Specifically, superoxide dismutase (SOD), total anti-oxidizing capability (T-AOC), and glutathione peroxidase (GSH-Px) have been commonly chosen to be biomarkers in evaluation of oxidative stress. Among them, SOD is a kind of natural cellular antioxidant enzyme to scavenge free radicals and maintain cell metabolic balance. The prevention of GSH-Px against oxidative stress, on the other hand, is reduction of hydrogen peroxide and lipid peroxides into water and molecular oxygen. In the case of T-AOC, this parameter reflects the capacity of nonenzymatic antioxidant defense system (Mansour 2000). As for the lipid peroxidation, malondialdehyde (MDA) and lipid peroxidase (LPO) is generally regarded as sensitive indicator for evaluation of antioxidant abilities against oxidative stress as well (Liqin et al. 2015). Polysaccharide could obviously increase the levels of antioxidant enzymes and alleviate oxidative stress and lipid peroxidation in serum and organs (heart, liver, brain, renal, intestine, etc.). For example, the polysaccharides from plants and mushrooms, like *Ligusticum chuanxiong* (Chao et al. 2017), *Arctium lappa* (Liu et al. 2014), *Hericium erinaceus* (Han et al. 2013), *Lepista sordida* (Zhong et al. 2013), *Agaricus bisporus* (Li et al. 2018), Radix *Cyathulae officinalis* Kuan (Han et al. 2015), litchi pulp (Fei et al. 2016), aloe vera gel (Gaurav et al. 2014), *Dendrobium officinale* (Huang et al. 2015), oat β-glucan (Błaszczyk et al. 2015), and others, had a

beneficial effect on antioxidant enzymes of SOD, CAT, GSH-Px, and T-AOC and reduced MDA and LPO levels. An upregulated mRNA expression levels of antioxidant enzymes, including Cu, Zn-SOD, Mn-SOD, CAT, glutathione peroxidase 1 (GPx), thioredoxin 1, and thioredoxin 2 in organs including the liver, heart, and brain, were observed after oral administration of *Chuanminshenviolaceum* polysaccharides (Jing et al. 2017). Besides, Zhong et al. demonstrated that *Ganoderma lucidum* polysaccharide increased the expression of manganese superoxide dismutase (Mn-SOD), an important cellular antioxidant enzyme. They also found that polysaccharide inhibited the translocation and expression of p47phox, a core regulatory subunit of NADPH oxidase, indicating the antioxidant function of polysaccharide might be partially attributed to alleviate the NADPH oxidase-related ROS production pathway (Zhong et al. 2015). Jiang et al. pointed out that the improvement of oxidative stress by *Coptis chinensis* polysaccharide was closely related to JNK/IRS1/PI3K pathway (Jiang et al. 2015).

On the other hand, accumulation of ROS would activate mitochondrial and ER stress, triggering abnormalities, such as apoptosis and necrosis. *Ganoderma lucidum* polysaccharide reduced the ratio of Bax/Bcl-2 and inhibited the release of cytochrome c, in addition to reduce the expression of ER stress biomarkers including 78 kDa glucose-regulated protein (GRP78), CCAAT/enhancer-binding protein (C/EBP)-homologous protein (CHOP), and caspase-12 and inhibit the activation of JNK. These findings indicated *Ganoderma lucidum* polysaccharide inhibited the oxidative stress-induced apoptosis by a mitochondria-dependent pathway and alleviating ER stress (Zhong et al. 2015).

29.4.4 Antidiabetic Effect

Diabetes mellitus (DM) is a worldwide concern and obviously influences the quality of human life. It is an impaired carbohydrate, fat, and protein metabolic syndrome induced by insufficient insulin secretion or decreased tissue sensitivity to insulin. Generally, there are two types of DM, type 1 DM (T1DM) and type 2 DM (T2DM), withT2DM as the dominant which accounting for around 90% of DM (Skyler and Oddo 2002). For T2DM, insulin resistance (IR) and pancreatic β-cell dysfunction are the major causes, and an individual was diagnosed T2DM with the fasting blood glucose (FBG) $\geq$7.0 mmol/L (126 mg/dL) or 2 h oral glucose tolerance test of $\geq$11.1 mmol/L (200 mg/dL) (Würsch and Pi-Sunyer 1997). The effect of dietary polysaccharides on glucose control was mainly achieved by altering its small intestinal transit time (SBTT), preventing the carbohydrate from digestive enzyme suppression, and restraining these enzymes (Qin et al. 2012). Xiao et al. identified that the main antidiabetic polysaccharide fraction in *Ganoderma lucidum* polysaccharides was a low molecular weight β-heteropolysaccharide of 15.9 kDa. Its mechanism was probably associated with the downregulation of the hepatic glucose-regulated enzyme through AMPK activation and improvement of insulin resistance, as well as a decrease in epididymal fat/body weight ratio (Xiao et al. 2017). Wang et al. found that *Angelica sinensis* polysaccharide improved insulin

resistance via regulating the related metabolic enzymes and activating the PI3K/Akt pathway (Wang et al. 2016b). Likewise, Li et al. observed that PI3K/Akt pathway acted as the hypoglycemic mechanism of tea polysaccharides in T2DM mice model (Li et al. 2015).

Consumption of polysaccharides may add to the satiety and reduce hunger attributed to their huge volume and relative low energy density, in addition to affect the secretion of intestinal hormones or peptides. In addition, polysaccharide-rich foods can also enhance the satiety through long-term chewing, which will affect the amount and velocity of food intake. Meanwhile, they can promote the production of saliva and gastric acid through enhancing gastric distension (Trompette et al. 2014).

Diabetic animals feeding with the polysaccharide intervention could increase levels of gut *Firmicutes* and decrease levels of *Bacteroidetes* and alleviated diabetes. A recent report in gut provided the evidence of a high molecular weight polysaccharide (>300 kDa) from *Hirsutella sinensis* prevented diet-induced obesity and type 2 diabetes by modulating the composition of gut microbiota, of which selectively promoted the growth of gut bacterium *Parabacteroides goldsteinii*. Further oral treatment of obese mice with live *Parabacteroides goldsteinii* prevented body weight gain, improved intestinal integrity, and reduced inflammation and insulin resistance. These results proved that *Hirsutella sinensis* polysaccharide and *Parabacteroides goldsteinii* acted as novel prebiotics and probiotics that may be applied to obesity and type 2 diabetes (Wu et al. 2019).

On the other hand, polysaccharides from various edible sources, such as *Plantago asiatica* L. seeds, *Cyclocarya paliurus* leaves, *Ganoderma atrum*, *Dendrobium officinale*, fermented *Momordica charantia* L., *Astragalus membranaceus*, and others, have been confirmed to improve production of SCFAs, which were beneficial to the diabetics (Gao et al. 2018; Liu et al. 2019b; Nie et al. 2019; Zhu et al. 2016a). For example, butyrate prevented and inhibited colon carcinogenesis, protected against oxidative stress of mucosal, decreased inflammation, and enhanced the colonic defense barrier in diabetes (Wu and Wu 2012). The regulation of blood glucose concentrations may involve several positive effects exerted by SCFA production of polysaccharide occurring at different levels: (1) inhibition of the inflammatory state that decreased insulin resistance, (2) upregulation of GLP-1 secretion that stimulates insulin release, and (3) enhancement of β-cell function that results from improvement of glucose homeostasis.

Additionally, it was common to know that T2DM caused a complex metabolic problems and endocrine disorder. Specifically, a metabolomic approach was conducted to investigate the effect of polysaccharide on metabolites in type 2 diabetic rats. Zhu et al. investigated the effect of *Ganoderma atrum* polysaccharide on serum metabolites using ultra-performance liquid chromatography quadrupole time-of-flight mass spectrometry (UPLC-Q-TOF/MS) and identified eight potential biomarkers (methionine, dTMP, D-tryptophan, 5-hydroxy-indoleacetaldehyde, glycocholic acid, biliverdin IX, malate, and taurocholic acid). In addition, biological pathways and processes, including metabolism of carbohydrates, fatty acid biosynthesis, glycolysis and gluconeogenesis, and metabolism of lipids and lipoproteins,

are significantly changed by PSG-1 treatment (Zhu et al. 2016b). Nie et al. investigated the molecular mechanisms of arabinoxylan at the point view of urine metabolomics by UPLC-Triple-TOF/MS. Results suggested that TCA cycle, tryptophan metabolism, lipid and ketone body's metabolism, taurine and hypotaurine metabolism, lysine metabolism, and BCAA metabolism were significantly improved by arabinoxylan treatment. Besides, arabinoxylan may exert prebiotic effect by upregulating serotonin and melatonin biosynthesis and spermine biosynthesis pathway, as well as decreasing choline level (Nie et al. 2018a).

The possible mechanisms by which the polysaccharides were involved in the development of diabetes included energy metabolism, inflammation, innate immune system, and bowel function of the intestinal barrier in microbiota. Based on gastrointestinal process, polysaccharides could alleviate DM through the mechanisms of action of gastrointestinal viscosity, gastrointestinal satiety, large intestinal fermentation, and gastrointestinal anti-inflammation (Hu et al. 2018).

29.4.5 Renal Protective Effect

The biological effects of polysaccharides have been investigated previously in some animal models of kidney diseases, such as diabetic nephropathy; 5/6 nephrectomy; chemical-induced renal damages, like adenine, cadmium, and potassium bromated (KBrO3); and other renal injury models. Mechanisms of renal prevent or protective actions have been demonstrated for some polysaccharides. The effects were primarily related to anti-inflammation, anti-oxidation, immune-regulation, anti-fibrosis, and improvement of metabolic disturbance effects.

29.4.5.1 Diabetic Nephropathy

A glucan-rich polysaccharide from *Pleurotus sajor-caju* (Fr.) Singer improved the glucose tolerance, attenuated hyperglycemia, and hyperinsulinemia in diabetes mice with a high-fat diet through upregulating the adiponectin and GLUT-4 gene expressions, in addition to downregulating the expression inflammatory factor (Kanagasabapathy et al. 2012). The renoprotective function of *Ophiopogon japonicus* polysaccharide was related to reduction of hyperglycemia, which attenuated serum albumin concentration as well as downregulated TGF-β1expression and connective tissue growth factor (CTGF) in diabetic glomeruli (Wang et al. 2015b). *Inonotus obliquus* polysaccharide could restore the integrity of glomerular capsules and increase the amount of glomerular mesangial cells in glucolipotoxicity-induced renal fibrosis (Chou et al. 2016). *Lycium barbarum* polysaccharides improved the renal function and alleviated the inflammatory response in the kidneys of diabetic rabbits. It was worth noting that the prevention effect of polysaccharides on renal function was better than that of treatment effect (Zhao et al. 2016).

29.4.5.2 Chronic Renal Failure (CRF)

CRF is a progressive renal injury disease, and the incidence is rising markedly in recent years. Chinese chive polysaccharides were able to improve the kidney

functions in adenine-induced CRF, and the effect might be associated with its antioxidant, anti-inflammatory, and anti-fibrosis abilities (Li et al. 2018b). Wang et al. investigated fucoidan derivatives on chronic kidney disease in rats and revealed that substituted functional groups and molecular weight took a crucial part in protecting the kidney. The mechanisms were related to an alleviation of renal tubules, interstitium, and mesangial areas mediated by replacing electronegative content of the glomerular cells and inhibition of cell proliferation, in addition to their antioxidant activity (Wang et al. 2012). A purified *Laminaria japonica* polysaccharide significantly inhibited the progression of vascular calcification that was associated with preventing osteoblastic differentiation of vascular smooth muscle cells in adenine-induced CRF mice (Li et al. 2018c).

On the other hand, CRF is also associated with the systemic effects of malnutrition and muscle wasting. *Astragalus* polysaccharides were reported to ameliorate muscle mass and protein metabolism. The levels of serum pro-inflammatory factors and oxidative index (MDA and SOD) were restored by the polysaccharide treatment. The potential mechanism of muscle wasting was involved in protein anabolism (Akt/mTOR), ubiquitin-proteasome pathway, and autophagy signaling pathways (Geng et al. 2017; Lu et al. 2016).

29.4.5.3 Acute Kidney Injury (AKI)

Acute renal damage is increasing prevalent with a severe morbidity and mortality. Acute kidney failure is associated with KBrO3 or glycerol or ischemia reperfusion injury. Polysaccharides were showed to have a protective effect against AKI. A low molecular weight fucoidan ameliorated ischemia reperfusion injury caused AKI via inhibiting the activation of MAPK pathways, especially JNK/p38-MAPK (Chen et al. 2013). A low molecular weight sulfated polysaccharide fraction extracted from *Laminaria japonica* had a protective effect on glycerol-induced AKI, and the fraction contained higher amounts of fucose, and sulfate showed a better kidney protective activity (Li et al. 2017d). Comet assay, a method to evaluation of DNA damage/repair and genotoxicity testing, was conducted to investigate the DNA damage in the kidney. Results clearly showed that pretreatment of *Lycium barbarum* polysaccharides reduced the extent of KBrO3-induced DNA damage (Li et al. 2017).

29.4.5.4 Other Renal Injury Rat Models

Shen et al. reported that *Potentilla anserina* polysaccharide remarkably improved redox homeostasis in Cd-induced mice. It attenuated the mitochondria dysfunction, degeneration, and fibrosis of the kidney and exhibited anti-apoptosis activity via regulating both mitochondria-mediated intrinsic apoptotic pathway and the death receptor-initiated extrinsic pathway (Shen et al. 2017). Chiu et al. revealed that pretreatment of *Cordyceps sobolifera* polysaccharide improved LPS-induced kidney abnormalities and protected against LPS-triggered oxidative stress and inflammatory response (Chiu et al. 2014).

29.4.6 Liver Protective Effect

29.4.6.1 Acute Liver Injury Models

Acute liver damage is hepatic disorder caused by acute severe injuries induced by toxin chemicals, viral infection, metabolic disorder, and ischemic injury, leading to the functional loss of liver cells within 1–4 weeks. For evaluation of the injury of the liver, the activities of hepatic biomarker enzymes, such as alanine aminotransferase (ALT), aspartate aminotransferase (AST), alkaline phosphatase (ALP), and lactate dehydrogenase (LDH), in serum were considered as the indicators. Various literatures had revealed that polysaccharide could effectively lower the CCl_4-caused increases of serum ALT, AST, ALP, and LDH activities and hepatic MDA level and antagonize the decreases in antioxidant SOD and GSH activities caused by CCl_4. Polysaccharides from various dietary sources, such as apple (Yang et al. 2013), soybean (Sun et al. 2018), tea (Sun et al. 2013; Wang et al. 2014a), *Lycium barbarum* (Gan et al. 2018; Xiao et al. 2012), *Astragalus* (Hamid et al. 2017), *Rhodiola rosea* (Xu et al. 2018), and *Oudemansiella radicata* (Liu et al. 2017b), markedly attenuated liver injury through their anti-inflammatory and antioxidant actions. Xiao et al. revealed that *Lycium barbarum* polysaccharide promoted liver regeneration after CCl_4 treatment and attenuated hepatic inflammation through downregulation of pro-inflammatory mediators and chemokines. In addition, the protective activity was partly through the downregulation of NF-κB activity (Xiao et al. 2012). Recently, Gan et al. pointed out that *Lycium barbarum* polysaccharide alleviated CCl4-induced oxidative injury and inflammatory response and improved the liver fibrosis might be via inhibiting TLRs/NF-kB pathway (Gan et al. 2018).

Selenium (Se) is a very important trace element, and its combination with polysaccharide was reported to enhance the bioactivity of polysaccharide. Hamid et al. found that selenizing *Astragalus* polysaccharides showed obviously protective effects against CCl_4-induced liver injury and fibrosis was more preferable to both *Astragalus* polysaccharides and sodium selenite given alone. The protective effect was via inhibiting hepatic oxidative stress, inflammatory response, and fibrogenesis and inducing cell apoptosis (Hamid et al. 2017). Likewise, Gao et al. found selenylation modification of Chinese angelica polysaccharide significantly enhanced antioxidative and hepatoprotective function, and the mechanisms were suppressing the MAPK pathway (Gao et al. 2017). Besides, Se-containing tea polysaccharide could ameliorate the high fructose-induced insulin resistance and hepatic oxidative injury (Ren et al. 2015).

Besides, other chronic liver injury mice models were also conducted to investigate the protective effect of polysaccharide. *Angelica sinensis* polysaccharide markedly alleviated acetaminophen (APAP)-induced acute liver injury via amelioration of lipid peroxidation and oxidative stress, in addition to the inhibition of hepatic apoptosis (Cao et al. 2018). This polysaccharide could also attenuate concanavalin A (Con A)-induced liver failure through caspase-3-dependent apoptosis by caspase-8 and JNK-mediated pathway and inhibiting the activation of IL-6/STAT3 and NF-κB signaling pathways (Wang et al. 2016c). Polysaccharides from *Sophorae tonkinensis* Radix significantly attenuated APAP-induced hepatic

oxidative damage through inhibiting ROS generation and increasing the levels of antioxidant enzymes in the liver (Cai et al. 2018). A beneficial effect of sea buckthorn berries polysaccharide on LPS/d-GalN-induced acute liver failure was reported to be accompanied by a downregulation expression of TLR4, inhibition activation of ERK, JNK and p-38 MAPK, and NF-κB, indicating a suppression of TLR4-NF-κB signaling pathway involved (Liu et al. 2015a). Polysaccharide from stem of *Codonopsis pilosula* played a vital role in the protection against ischemia/reperfusion (I/R)-induced renal injury, and its renoprotective effect was probably mediated by inhibiting the release of pro-inflammatory cytokine (TNF-α) (Li et al. 2012).

29.4.6.2 Chronic Liver Diseases

Alcoholic liver disease (ALD) and nonalcoholic fatty liver disease (NAFLD) are two kinds of the most common precursors of chronic liver disease. NAFLD is a hepatic manifestation of the metabolic syndrome that is associated with obesity, type 2 diabetes, and atherosclerosis. Schisandra polysaccharide significantly reduced the liver index and ameliorated lipid accumulation and fatty degeneration of hepatocytes in NAFLD mice. The effects may be mediated to a downregulation of LXRα/SREBP-1c/FAS/ACC and SREBP-2/HMGCR pathways in the liver (Wang et al. 2016a). ALD is a prevalent global health issue as the liver is the major organ responsible for the metabolism of alcohol and alcohol consumption is common in daily life. Many dietary polysaccharides had been evidenced to have a protective or preventive effect against alcohol-induced liver damage. Maca polysaccharide also dramatically increased the SOD, GSH-Px, and GST levels in alcohol mice and lightened inflammation induced by alcohol (Zhang et al. 2017b). *Triticum aestivum* sprout-derived polysaccharide significantly inhibited ethanol-induced cytochrome P450 2E1 (CYP2E1) activation and upregulated the expressions of nuclear factor erythroid 2-related factor 2 (Nrf2) and hemeoxygenase-1, in addition to downregulated NADPH oxidase genes in mice. Furthermore, the upregulation of Nrf2 was mediated by PI3K/Akt pathway. Similarly, this polysaccharide attenuated hepatic injury by modulation of caspase-3 and apoptosis-associated mitochondrial proteins as observed in other models (Nepali et al. 2017).

The metabolic disorder improved by polysaccharides and underlying metabolic pathways involved had been studied. Metabolomic approach was employed to analyze the alterations in metabolic profiles of serum and the liver. Wang et al. investigated the metabolism pathways of *Dendrobium huoshanense* polysaccharide on alleviating ethanol-induced liver injury using UHPLC/LTQ Orbitrap XL MS. Results reveled that *Dendrobium huoshanense* polysaccharide ameliorated the altered metabolic levels particularly involved in phosphocholine and L-Proline (Wang et al. 2015a). Hepatic proteomic analysis performed by two-dimensional difference gel electrophoresis coupled with MALDI-TOF/TOF-MS revealed that cystathionine β-synthase (Cbs) and D-lactate dehydrogenase (Ldhd) were two key proteins in the *Dendrobium huoshanense* polysaccharide intervention. They might help in preventing the abnormal hepatic methionine metabolism pathway and

decreasing the level of hepatic methylglyoxal generated from disordered metabolic pathways (Wang et al. 2014b).

Abstract

Dietary fibers have become increasingly popular in recent years with various applications in the food and pharmaceutical industry industries. Dietary fibers are plant-based foods which are incompletely digested by digestive enzymes. The water-soluble fibers are prebiotics, which are fermented in the colon and have a beneficial role for gut microbiota. The insoluble fibers are not affected by digestive systems and provide bulking. Fiber intake has various benefits: it reduces appetite, lowers variance in blood sugar levels, reduces the risk of cardiovascular disease, lowers the risk of diabetes, balances intestinal pH, alleviates constipation, and facilitates regular defecation.

Keywords

Dietary fibers · Polysaccharides · Oligosaccharides · Inulin · Pectin

30.1 Introduction

Codex Committee on Nutrition and Foods for Special Dietary Uses agreed on a definition of dietary fiber (DF) in 2009 (Codex Alimentarius 2009). According to the definition, dietary fibers are the carbohydrate polymers consisting of ten or more monomeric units that are not digested in human small intestine. Dietary fibers can be:

- Naturally occurring carbohydrate polymers found in food.
- Carbohydrate polymers that are isolated from raw food material using some treatments (physical, enzymatical, chemical). These have health benefits which have been demonstrated by scientific evidence.
- Carbohydrate polymers that are synthetic and have health benefits which have been demonstrated by scientific evidence.

Even though the Codex Alimentarius definition of dietary fibers mentioned that they have ten or more monomeric units, there are some definitions considering carbohydrates having 3–9 monomeric units (oligosaccharides) can also be dietary fiber. European Union (EU) defines dietary fibers as "carbohydrate polymers consisting of three or more monomeric units, that are not digested/absorbed in the small intestine" (European Commission 2008). According to definition of American Association of Cereal Chemists International (AACCI 2011), "dietary fibers are the edible parts of plants (poly- and oligosaccharides, lignin, etc) that are resistant to

digestion/absorption in the small intestine, but can be completely or partially fermented in the colon." Health Canada (2012) also reported that dietary fibers consist of carbohydrates with three or more monomeric units.

Dietary fibers include primarily non-starch polysaccharides that are plant cell walls components such as cellulose, hemicelluloses, and pectins. They also include some other polysaccharides of plant or algal (gums and mucilages) and oligosaccharides (inulin) (Mudgil and Barak 2013). Resistant starches, fructo- and galacto-oligosaccharides, and modified celluloses are analogous carbohydrates that are considered as dietary fibers. Some synthetic carbohydrates such as polydextrose are also included in dietary fiber (Borderías et al. 2005).

In recent years, dietary fibers have received much attention because of their beneficial health effects such as reducing cholesterol, diabetes, and coronary heart disease, improvements in large bowel function, and reduction of postprandial blood glucose and insulin levels (Mudgil and Barak 2013). The physiological effects of dietary fibers are related to their physicochemical properties such as solubility, water-holding capacity, viscosity, etc. (Guillon and Champ 2000). Dietary fibers are divided into two categories based on solubility: soluble and insoluble fibers. Insoluble dietary fibers are mainly cell wall of plants such as cellulose, lignin, and hemicelluloses. On the other hand, soluble fibers are non-cellulosic polysaccharides such as pectin, gum, mucilage, β-glucan, etc. (Dai and Chau 2017). Insoluble fibers are responsible for the increase in fecal bulk and decrease in the intestinal transit time. Soluble fibers form gels and increase the viscosity of the contents of the gastrointestinal tract causing delayed gastric emptying. They are also are associated with reduction in glycemic response and plasma cholesterol (Mudgil and Barak 2013).

30.2 Bioactive Constituents

Cellulose, hemicelluloses, inulin, dextrin, oligosaccharides, resistant starch, pectin, β-glucan, glucomannan, guar gum, psyllium, and methylcellulose are the main examples of dietary fibers. Lignin and minor compounds such as waxes, cutin, saponins, polyphenols, phytates, and phytosterols can be extracted with poly- and oligosaccharides during fiber analysis procedures (Table 1). However, these compounds, except lignin, are not considered as dietary fiber (Mudgil and Barak 2013).

30.2.1 Cellulose

Cellulose is an insoluble fiber found naturally in nuts, whole wheat and grains, bran, seeds, edible brown rice, etc. It is the major cell wall component in plants and the most abundant polysaccharide found in nature. It is an unbranched linear polysaccharide with 10,000 glucose unit per molecule linked with β,1-4 glycosidic bonds. Cellulose is an insoluble fiber and resistant to digestive enzymes. However, 50% of cellulose can be fermented by gut microflora in the colon, and short-chain fatty acids

Table 1 Functional properties and main sources of dietary fibers, according to Bozzetto et al. (2018) and McRorie (2015)

Fibers	Functional properties			Main sources
	Viscosity	Solubility	Fermentation	
Bran	Low	Low	Low	Whole grain
Cellulose				Vegetables
Hemicellulose				Vegetables
Lignin				Seeds
Inulin	Low	High	High	Roots and tubers
Dextrin				Chemically altered wheat and corn starch
Oligosaccharides				Fruits, vegetables, legumes, grains
Resistant starch				Type I, whole grain; Type II, high-amylose maize starch, raw potato, and banana; Type III, cooked and cooled starchy foods; Type IV, chemically modified starches; Type V, amylose-lipid complex
Pectin	High	High	High	Fruits, vegetables, legumes
β-Glucan				Oat and barley
Glucomannan				Tuberous roots of the konjac plant
Guar gum				Leguminous seed plants (guar, locust bean), seaweed extracts (carrageenan, alginates), microbial gums (xanthan, gellan)
Psyllium	High	High	Low	Husks of ripe seeds from *Plantago ovata*
Methylcellulose				Food additive

can be produced (Mudgil and Barak 2013). Due to its water-binding capacity, cellulose causes an increase in fecal bulk (Dai and Chau 2017).

30.2.2 Hemicellulose

Hemicelluloses are the second most abundant polysaccharides after cellulose. Similar to cellulose, hemicelluloses are also one of the cell wall components. They are not chemically homogeneous like cellulose and include both linear and branched molecules consisting of different types of pentoses, hexoses, and uronic acids. These monosaccharides can be xylose, rhamnose, arabinose, glucose, mannose, galactose, and some uronic acids (4-*O*-methylglucuronic, D-glucuronic, and D-galacturonic acids). Hemicelluloses have lower molecular weight compared to cellulose (Hu et al. 2009). Hemicelluloses increase the hydration of the stool causing a promotion of bowel movements. Hemicelluloses prevent cholesterol absorption by binding cholesterol in the gut (Mudgil et al. 2012). Similar to cellulose,

hemicelluloses can be also digested by gut bacteria, and as a result short-chain fatty acids can be used as fuel by colon cells (Mudgil and Barak 2013). Hemicelluloses can be extracted by solubilization in aqueous alkali after removing the water-soluble and pectic polysaccharides.

30.2.3 Lignin

Lignin is not a polysaccharide but is considered as a dietary fiber. It is found in woody part of the foods and in outer layers of cereal grains as chemically bound to hemicelluloses in the plant cell wall.

30.2.4 Gums and Mucilages

Gums and mucilages are types of dietary fibers that are not found in plant cell wall, but produced in specialized secretory plant cells (Dhingra et al. 2012). They are highly branched polysaccharides and are used in foods as gelling, thickening, stabilizing, and emulsifying agents (Mudgil and Barak 2013). Gums are known as pathological products of plants formed after injury or as a result of unfavorable conditions (i.e., drought) by the breakdown of cell walls (extracellular). However, mucilages are normal products of plant metabolism and formed intracellularly (within the cell). Gum arabic, guar gum, locust bean gum, agar, carrageenan, and alginates can be given as examples of gums. Psyllium is an example of mucilages. They both have effect on reducing glucose and insulin levels and cholesterol (Mudgil et al. 2012).

30.2.5 β-Glucans

β-Glucans are the major component of the cell wall material in oats and barley grains and also present in wheat in small quantities. *They* are consisting of D-glucose monomers linked by β-glycosidic bonds. The macromolecular structure of β-glucan depends on the source. The simplest β-glucan is found among prokaryotes and eukaryotes, and it is linear and unbranched (β-(1,3)-D-glucan) (El Khoury et al. 2012). Branched structures consist of β-(1,3)- or β-(1,4)-glucan backbone with (1,2)- or (1,6)-linked branches (Barsanti et al. 2011). β-Glucans are water-soluble fibers and can form gel-like network in the upper gastrointestinal tract. The cholesterol lowering ability of β-glucans is considered to be related to their gelling capacity (Mudgil and Barak 2013).

30.2.6 Pectins

Pectins are the polysaccharides found in plant cell walls and outer skin and skin of fruits and vegetables. The main constituent of pectin is galacturonic acid. They

are soluble in hot water and can form gels upon cooling; therefore they are used as a thickening agent in foods. Similar to β-glucans, the gelling property of pectins is responsible for cholesterol lowering ability (Mudgil and Barak 2013).

30.2.7 Resistant Starch

Digestible starches can be hydrolyzed by digestive enzymes to give glucose to be absorbed (Nugent 2005); however, a fraction of starch cannot be digested in the body and defined as resistant starch (RS). European Food-Linked Agro-Industrial Research-Concerted Action on Resistant Starch (EURESTA) defined RS as the "total amount of starch and the products of starch degradation that resists digestion in the small intestine of healthy individuals" (Öztürk and Köksel 2014). RS can be classified into five groups (Okumus et al. 2018): RS1, starches which are physically inaccessible to digestion as they are entrapped within whole or partly milled grains; RS2, native starch granules that are found in raw potatoes, green bananas, and high-amylose corn starch; RS3, retrograded starches found in cooked-cooled potato, in bread, and in corn flakes; RS4, chemically modified starches to obtain resistance to enzyme digestion; and RS5, amylose-lipid complexes that are resistant to enzymatic digestion. Resistant starches have physiological functions similar to those of dietary fibers. They are insoluble fibers; however, they act as soluble fibers. There are several studies investigating that RS can reduce the risk of diabetes, obesity, and high cholesterol. Fermentation of resistant starches results in formation of short-chain fatty acid that has inhibition effect on the development of colonic cancer cells (Haralampu 2000; Huth et al. 2000; Öztürk and Köksel 2014; Wollowski et al. 2001).

30.2.8 Nondigestible Oligosaccharides

Nondigestible oligosaccharides with 3–10 monomeric units are found in fruits, vegetables, and cereals. They can also be synthesized from mono-, di-, and polysaccharides by chemical and enzymatic processes. Fructooligosaccharides, gluco-oligosaccharides, and inulin are examples of nondigestible oligosaccharides. They can be fermented in the large intestine by beneficial bacteria causing the formation of short-chain fatty acids which are beneficial for colon health (Jian et al. 2013).

30.2.9 Synthetic Carbohydrate Compounds

Synthetically prepared methylcellulose, hydroxy-propylmethylcellulose, polydextrose, and resistant dextrins are also considered as dietary fibers as they are also nondigestible. Unlike cellulose methylcellulose and hydroxy-propylmethylcellulose are soluble fibers but hardly fermented in the large intestine (Mudgil and Barak 2013).

Polydextrose and resistant dextrins can be partially fermented in the colon and have bulking ability (Craig et al. 2000; DeVries 2003).

30.3 Bioactivities (Animal Aspects)

30.3.1 Anticancer Activity

Environmental aspects such as diet and physical activity and genetic deviation are the two main factors effecting the colon cancer formation (Zeng et al. 2014). Several animal studies have suggested that there is a relationship between high dietary fiber intake and low prevalence of colon cancer (Caderni et al. 2001; Cho et al. 2012; Clarke et al. 2008; Conlon et al. 2012; Kameue et al. 2004; Le Leu et al. 2007). Most of these benefits can be associated with short-chain fatty acid production during the fermentation of dietary fibers in the colon. These short-chain fatty acids are the energy source of colonocytes and prevent tumor growth. The major short-chain fatty acids are acetic acid, propionic acid, and butyric acid. Among these fatty acids, butyric acid is the critical one in maintaining colon health (Macfarlane and Macfarlane 2011). The preventative effect of dietary fibers may be attributed to the reduced contact time of carcinogens within the intestinal lumen and to the production of the metabolites produced during the metabolism of fibers in the body (Zeng et al. 2014).

30.3.2 Antidiabetic Activity

Dietary fibers have been associated with improved postprandial glucose and insulin responses. There are many studies investigating the reduction of postprandial glucose responses after fiber-rich meal consumption (Fotschki et al. 2014; Grover et al. 2011; Utrilla-Coello et al. 2013). The postprandial glucose reducing effect of soluble fibers is due to the gel forming ability of soluble fibers (Cassidy et al. 2018). On the other hand, consumption of insoluble fibers reduces the risk of type 2 diabetes (Mudgil and Barak 2013).

30.3.3 Antihypercholesterolemic Effect

Bile acids are the end products of cholesterol catabolism and are synthesized from cholesterol in the liver. After their function they are reabsorbed and returned to the liver (Chiang 2013; Dawson et al. 2009). Dietary fibers have been reported to bind bile salts in the duodenum, and this results in the synthesis of additional bile salts from cholesterol which lowers blood cholesterol. The decrease in the blood cholesterol was also observed in several animal studies (Agyekum and Nyachoti 2017; Bennani-Kabchi et al. 2000; Gallaher et al. 2000; Moharib and El-Batran 2008; Terpstra et al. 2000).

30.4 Bioavailability and Metabolism

Epidemiological data suggest that populations subsisting on high-fiber diets are free of the diseases of Western civilization, among them are coronary heart disease and cancers. Underlying mechanisms of action are worth investigating regarding protective effects on the cardiovascular system, and bioactive components in fibers should be isolated and identified (Tang et al. 2017). Studies in animals and humans show that each type of fiber has specific effects, i.e., in man bran has no effect on serum lipids, but pectin lowers cholesterol levels. In animals fed atherogenic diets, alfalfa and pectin exert some protection, while cellulose does not. Kritchevsky considers that in order to understand the effects of different dietary fibers, it is necessary to assess the mechanism(s) of action of each chemical component of a given fiber (Kritchevsky and Story 1978).

Among fiber isolates, gelling and mucilaginous fibers, like pectins and guar gum, lower circulating lipids in humans and increase excretion of bile acids resulting from the fecal metabolism of cholesterol. These fiber components influence luminal solubility of lipids and the lymphatic absorption of cholesterol and triglycerides. The direct effects on lipid absorption could explain the hypolipidemic actions and secondary long-term consequence on hepatic and peripheral lipoprotein metabolism (Vahouny 1982).

β-glucans are linear unbranched polysaccharides found in natural sources, especially mushrooms. They act as dietary fibers in the digestive tract. Their structure enables interaction with innate immunity receptors. There are two forms of β-glucans, insoluble and soluble, which are able to interact in the bowel with lipids and biliary salts and determine reduction of cholesterol levels (Sima et al. 2018). Barley-derived β-glucans are viscous dietary fibers, which delay gastric emptying and cause gastric distension, release appetite-related hormones, and slow glycemic responses (Aoe et al. 2014). Yeast-derived beta-glucans have an immunomodulatory function by stimulating type 2T helper cells, which mitigate type 1T helper cells. Through this modulation results a balance between the two lymphoid systems and a decrease of the intestinal inflammatory process. β-Glucans can also stimulate phagocytosis, which protects against inflammation, sepsis, and infections (Schwartz and Hadar 2014).

Based on observing robust positive effects of whole grain intake in 11 major prospective studies, Lillioja et al. provide compelling evidence that increasing whole grain intake is an important public health issue. They consider that whole grain intake is often equated with fiber intake, regarded as inert material, while the most highly concentrated source of nutrients in cereals is aleurone, a live plant tissue that binds magnesium, zinc, and ferulic acid, responsible for health effects. They also describe three separate benefits attributable to whole grain fibers: the stool bulking effect, regulating the access by microbial digestive enzymes; the creation of gels by cell wall polysaccharides, especially pectins and β-glucan; and the fermentation of polysaccharides to volatile fatty acids with huge direct health benefits (Lillioja et al. 2013). In the past decades, resistant starches (RS) have also been used for their health benefits. They stay undigested in the small intestine but undergo fermentation

in the large intestine. RS restrict gluconeogenesis and enhance glycogenesis, maintaining glucose and lipid homeostasis and thus improving pancreatic function (Meenu and Xu 2018).

Fardet et al. comment on the synergy that occurs when more nutrients affect different pathways of the same disease process or when their effects are summed. Summed effects could occur between natural chemicals in whole grains which include selenium, manganese, zinc, iron, magnesium, tocotrienols, B vitamins, carotenoids, anthocyanins, choline, and fermentable polysaccharides. Both combined and individual effects must be understood (Fardet 2019).

Development of atherosclerosis has been linked to infections. Certain microbial ecosystems residing in the human body that contribute to metabolic and cardiovascular diseases have been identified. Microbiota affects atherogenesis by three pathways: local or distant infections causing harmful inflammatory responses with consecutive plaque rupture; metabolism of cholesterol and lipids by gut microbiota affecting the development of atherosclerotic plaques; and diet-specific components metabolized by gut microbiota (Jonsson and Backhed 2017). However, other authors have a different point of view. The study of Bindels et al. demonstrated that metabolic benefits exerted by dietary RS occur independently of the microbiota, especially improvements in insulin levels, and could involve alterations in the bile acid cycle and also adipose tissue immune modulation (Bindels et al. 2017). Mannan oligosaccharides (MOS) proved very effective at reducing hyperlipidemia and inflammation. The effect of dietary MOS on atherosclerosis development was studied by Hoving et al. in hyperlipidemic ApoE∗3-Leiden.CETP (E3L.CETP) mice, a well-known model for human-like lipoprotein metabolism. MOS may improve inflammation via interaction and modification of gut microbiota, the authors suggest. They found that MOS modulated the gut microbiota composition and activity associated with increased fecal BA excretion, which could explain lowered plasma total cholesterol levels and stopping of atherosclerosis progression (Hoving et al. 2018).

Dysbiotic gut ecosystems increase production of endogenous ethanol, disrupting the integrity of the intestinal barrier with increased accumulation of hepatic fat and production of inflammatory markers (Poeta et al. 2017). Gut-derived lipopolysaccharides contribute to increased hepatic oxidative stress and inflammation, fibrosis, and insulin resistance, with further alteration of intestinal barrier integrity. These dysfunctionalities of the gut-liver axis determine the phenotype of fatty liver (Saez-Lara et al. 2016).

Myoinositol, a member of the vitamin B complex, stimulates contractility of the gastrointestinal tract and has a key role in cell membrane potential maintenance, intracellular signaling, and calcium concentration control (Ciacci et al. 2011).

Soluble fibers, like pectin, resistant starches, gums, and inulin are fermented by colonic microbiota, producing short-chain fatty acids (acetate, propionate, and butyrate). Short-chain fatty acids regulate appetite by their anorexigenic effect, slowing gastrointestinal motility and controlling nutrient absorption. They modulate the release of appetite-related hormones (cholecystokinin, ghrelin, glucagon-like peptide 1, and peptide YY) (El Khoury et al. 2012).

30.5 Benefits (Human Studies)

30.5.1 Cardiovascular Disease

Cardiovascular disease (CVD) is a heavy social burden in many countries, being a category of chronic noncommunicable diseases that cause high mortality (Chan et al. 2013). Hypertension, dyslipidemia, obesity, and type 2 diabetes mellitus are the main components of cardiovascular risk (Kones and Rumana 2014). The "Western" diet, low in fiber and high in fats, sugars, and animal proteins, is the main factor that contributes to inflammation and metabolic syndrome. The most important strategy to treat atherosclerosis is lifestyle change, knowing the beneficial properties of various nutrients. In recent years, epidemiological and clinical studies have focused on the central role of diet plays in the prevention of atherosclerosis (Torres et al. 2015).

The cardioprotective effects of fibers are multiple, from anti-oxidation and anti-inflammation to attenuation of myocardial damage, modulation of enzyme activities, and regulation of blood pressure, glucose, and lipid profiles (Tang et al. 2017). These effects usually occur with the synergistic intervention of bioactive components like vitamins, minerals, and phytochemicals from vegetables. Soybeans, onions, sesame, tomatoes, celery, lettuce, and asparagus have great potential in cardiovascular prevention (Tang et al. 2017). Green leafy vegetables have been shown to significantly reduce the incidence of CVDs in a recent meta-analysis (Pollock 2016). In another study, different varieties of carrots demonstrated antithrombotic activities (Yamamoto et al. 2008). Broccoli, through sulforaphane present in this vegetable, has been found to protect the myocardium from ischemic reperfusion injury (Mukherjee et al. 2010).

Dietary fibers are characterized by physiochemical complexity of their individual components, and experimental, clinical, and epidemiological evidences confirm the role of these components in modifying cardiovascular risk factors.

An extensive meta-analysis of 15 cohort prospective studies included a large general population with low CVD risk (n = 1,409,014) and demonstrated that dietary fiber consumed increased amounts leads to reduced risk of mortality from CVD (Kim and Je 2014).

30.5.1.1 Dyslipidemia

Hypercholesterolemia is an important risk factor of cardiovascular disease, together with hypertension and diabetes. The search for new methods of preventing dyslipidemia is ongoing, and current therapies induce different side effects. Statins are the most common drugs administered for hypercholesterolemia, but statin-associated muscle pain lowers adherence to therapy. Soluble fiber, alone or in combination with plant sterols and stanols, red yeast rice, bergamot, berberine, or artichoke, might be considered as an alternative therapy, still in need of evidence for long-term safety and efficacy. It is considered that these nutraceuticals exert significant lipid-lowering activity and have pleiotropic actions like improvement of

endothelial dysfunction and arterial stiffness, together with anti-inflammatory and antioxidative properties (Banach et al. 2018).

It is a known fact that water-soluble dietary fiber significantly decreases serum cholesterol levels and may contribute to prevention of arterial thrombotic disease. Epidemiological studies have shown that vegetable consumption is inversely correlated to cardiovascular risk.

Wheat bran does not alter significantly lipoprotein distributions or serum lipids in humans. In contrast, dietary fibers from fruits and vegetables determine stronger responses, i.e., pectin, a viscous fiber decreases progression of IMT thickening (Wu et al. 2003).

CHD and stroke as evolution of atherosclerosis related to hyperlipidemia, hyperinsulinemia, and hypertension are strongly related to diet. In the study of Veldman et al., 20 male hyperlipidemic volunteers two randomized in groups received a pectin supplement (15 g/day) or placebo (15 g/day) for 4 weeks. Pectin supplementation caused significant decreases in total cholesterol, LDL, apolipoprotein A and B, and lipoprotein(a). In the plasma of the pectin-supplemented group, the development of more permeable fibrin networks believed to be less atherogenic was detected. It is believed that pectin modified network characteristics by a combination of its effects on the metabolism of fibrin, confirming the therapeutic effects of dietary intervention. This study also showed that fibrin network architecture is independent of plasma fibrinogen levels, contradicting what was previously thought (Veldman et al. 1997).

In order to determine the efficacy of Anticholest, an apple-pectin-guar soft drink in reducing elevated cholesterol levels, 33 participants (aged from 8 to 73 years) were divided into 3 groups receiving dosages of 1 cup every second day or of 1 cup or 2 cups a day. Anticholest significantly reduced TC, LDL-c, and TC/HDL-c, increasing HDL-c in a dose-dependent manner ($p < 0.01$). A significant decrease was also detected in TGL ($p < 0.05$). Anticholest appears to be an appropriate treatment for patients with increased cardiovascular risk, and the lack of side effects and its easy administration as viscous drink are essential for long-term compliance and management of chronic progressive conditions like atherosclerosis (Pirich et al. 1992).

Oats are a rich source of β-glucan, a viscous, soluble fiber known for its cholesterol-lowering properties. A meta-analysis of randomized controlled trials investigated the effect of diets enriched with oat β-glucan compared with controlled diets on LDL cholesterol, non-HDL cholesterol, and apoB. Data were pooled using the generic inverse-variance method with random effects models. Pooled analyses showed that the median dose of 3.5 g/d oat β-glucan significantly lowered LDL cholesterol (−0.19; 95% CI −0.23, −0.14 mmol/l, $p < 0.00001$), non-HDL cholesterol (−0.20; 95% CI −0.26, −0.15 mmol/l, $p < 0.00001$), and apoB (−0.03; 95% CI −0.05, −0.02 g/l, $P < 0.0001$) compared to control. Ho et al. consider that inclusion of oat-containing foods may be a strategy for achieving lipid targets in CVD prevention (Ho et al. 2016). The molecular weight (MW) of β-glucan contributes to viscosity, and individual genotype influences the cholesterol-lowering efficacy of β-glucan. In the study of Wang et al., HMW β-glucan rather than LMW

β-glucan reduced circulating TC in mildly hypercholesterolemic adults. Individuals carrying the CYP7A1SNP rs3808607-G allele were more responsive to the cholesterol-lowering effect of β-glucan with HMW (Wang et al. 2016).

The results of a study with bael leaf extract reported by Asghar et al. demonstrated its protective role in hypercholesterolemia. Bael leaf contains crude fiber (8.1 g% in the infant plant, 11.0 g% in the mature, and 9.5 g% in the ripen plant). Supplementation with crude extract decreased total cholesterol, triglycerides, LDL, and HDL in the study patients compared to control (Asghar et al. 2018).

Studies evaluating the effect of beans on cholesterol have focused on soybeans and other beans, peas, and seeds commonly consumed in Western countries. A meta-analysis of randomized controlled trials evaluating the effects of non-soy beans on blood lipids was conducted by Bazzano et al. From 140 relevant studies, 10 randomized clinical trials comparing a non-soy bean diet to control, with a duration of at least 3 weeks, were selected, representing a total of 268 participants. The decrease in total cholesterol in the intervention groups compared to control was −11.8 mg/dL (95% CI, −16.1 to −7.5) and of LDL −8.0 mg/dL (95% CI, −11.4 to −4.6). HDL cholesterol did not change significantly. The selected studies included participants with high, borderline high, and normal cholesterol levels who were not on cholesterol-lowering drugs. Total baseline cholesterol ranged from 199 to 294.6 mg/d. The majority of participants in the supplementation groups was represented by men and achieved lower total cholesterol and LDL levels than women. This meta-analysis represents the strongest evidence to date that consumption of non-soy beans lowers serum total and LDL cholesterol, contributing to decrease CVD risk (Bazzano et al. 2011).

Although current dietary guidelines recommend the consumption of three cups of dried beans per week, present consumption is much lower. Guenther et al. consider that consumption of starchy vegetables, mainly white potatoes, is much higher than recommended. They suggest dietary modification strategies with an increase in bean consumption targeted at CVD risk factor reduction (Guenther et al. 2010).

A total of 22,915 participants from the EPIC Norfolk study were included in a cross-sectional analysis which proved that mean fiber intake of 18.5 g/day lowers triglycerides and serum cholesterol levels (Wu et al. 2007).

30.5.1.2 Hypertension

In recent years, new bioactive components of foods have emerged to also control blood pressure levels, besides influencing other risk factors. Several studies suggest that beta-glucan, the soluble fiber from oat grains which contributes to reduction in plasma cholesterol, may also improve glycemia, insulin resistance, and weight loss. Although far fewer than the lipid studies, small trials with dietary fiber supplementation in hypertensive and pre-hypertensive subjects have shown that fiber intake decreases arterial blood pressure. This effect was first confirmed in research on hypertensive rats (Aleixandre and Miguel 2016).

A total of 18,433 subjects aged 18 years or older were included in an analysis aimed to explore the connection between dietary fiber intake and the risk of hypertension. Hypertension values were considered ≥130 mmHg systolic blood

pressure (SBP) and ≥ 80 mmHg diastolic blood pressure (DBP) according to the 2017 American College of Cardiology/American Heart Association Blood Pressure Guidelines. Recall interviews were used to obtain dietary fiber data from the National Health and Nutrition Examination Survey 2007–2014, and logistic regression models were applied to assess associations between consumption of cereal, vegetable, fruit fiber, and hypertension. Total fiber intake was associated in a nonlinear trend with the risk of hypertension, while the relation between cereal and vegetable fiber intakes with hypertension risk was linear. Fruit fiber consumption was not associated with a decreased risk of hypertension in US adults. The study concluded that the risk of hypertension gradually decreased as total dietary fiber intake increased up to 0.35 g/kg/day and that consumption of fiber-rich foods is advisable to prevent and control hypertension (Sun et al. 2018).

Another cross-sectional study on 111 T1DM patients with diabetes duration 18 +/− 9 years demonstrated that increased dietary fiber intake contributes to lower BP levels. BMI was 24.8 +/− 3.85 kg/m^2 and HbA1c 9.0 +/− 2.0%. Patients were randomized into two groups according to the American Diabetes Association (ADA) recommendations for fiber intake: < 14 g fiber/1000 kcal and >/= 14 g/1000 kcal. Increased daily mean total fiber intake of 19.8 ± 7.2 g/day (5.8 ± 2.4 g from soluble and 14.0 ± 5.3 g from insoluble fiber) determined significant decreases of BP levels. Furthermore, the authors reported an association between fiber type and BP. Dietary fibers originating from pulses (beans, lentils, peas) and fruit (banana, orange, grape, apple, papaya, pineapple, mango, and peach) were associated with the most significant decreases of BP, suggesting that fiber intake may favorably affect vasodilatation and oxidative stress. The authors consider that additional studies are needed to explain the mechanisms implied in the beneficial effects of fiber intake on BP levels (Beretta et al. 2018).

Lillioja et al. provide recommendations about whole grain consumption, consecutive to a meta-analysis of 11 major prospective studies from the United States that examined the effect of whole grain intake on the development of T2DM, CHD, and hypertension. Disease incidence was correlated to whole grain intake (grams/day). The risk of T2DM, CHD, and hypertension was significantly lower with higher whole grain cereal intakes. The authors consider that in order to maintain health, 40 g or more whole grains should be consumed daily, equivalent to a bowl of whole grain breakfast cereal. They also point at aleurone in bran, a critical grain component overlooked in favor of indigestible fiber. In millers' bran live aleurone cells are present in a concentration of 50% and store minerals, protein, and ferulic acid, a powerful antioxidant. Deficits of magnesium, zinc, and ferulic acid are involved in the development of chronic disease. Dieticians and physicians should be more concerned about the possible mechanisms by which aleurone exerts its effects on health, and also consumers should scan more carefully package labels on whole grain content. This change of attitude could generate enormous public health benefits (Lillioja et al. 2013).

A 6-month, open-label clinical trial enrolled 141 consecutive hypertensive and overweight patients, randomized to oral ingestion of either psyllium powder or guar gum 3.5 gr t.i.d., taken 20 min before the two main meals or to standard diet.

Ingestion of each fiber significantly improved BMI, fast plasma glucose and insulin, HbA1c, LDL-C, and apoB. Improvements in plasma TG concentration, SBP, and DBP were only exerted by the psyllium supplementation, compared to guar gum supplementation or standard diet (Cicero et al. 2007).

Data from the French ENNS 2006–2007 Nutrition and Health Survey that included 18–74-year-old participants demonstrated that dietary fiber and whole grains reduce systolic blood pressure (Vernay et al. 2012).

A cross-sectional study from the INTERnational study cohort on MAcro/micro-nutrients and blood Pressure (INTERMAP) made on 2195 US participants aged 40–59 years investigated the correlation between BP and total soluble and insoluble fiber intake. Aljuraiban et al. showed that an intake of total fibers of 6.8 g/ 1000 kcal lowers systolic blood pressure with 1.69 mmHg and an insoluble fiber intake of 4.6 g/ 1000 kcal with 1.81 mmHg (Aljuraiban et al. 2015).

Another large prospective study was made on 28,926 US health professional middle-aged and older women and revealed that consumption of 1–2 and 2–4 servings/day of whole grains lowers the risk of hypertension (Wang et al. 2007).

30.5.1.3 Diabetes

Type 2 diabetes (T2DM) has reached epidemic proportions in the United States and Western countries. Recent evidence suggests that prebiotics can modulate the gut microbiome, an important link in regulating lipid metabolism, blood glucose, and insulin sensitivity. Prebiotics are potential therapeutic strategies for prediabetes and T2DM (Alfa et al. 2018).

In a cross-sectional study on 4,399 Japanese type 2 diabetic patients, Fuji et al. demonstrated that increased dietary fiber intake was associated with better glycemic control and better CV risk reduction. Dietary fiber intake was determined using a brief self-administered diet history questionnaire. Improvements were observed in various parameters including insulin sensitivity and micro-inflammation, metabolic syndrome, blood pressure, and CKD. Furthermore, dietary fiber intake lowered the prevalence of albuminuria and improved estimated glomerular filtration rate after multivariate adjustments including protein intake (Fujii et al. 2013).

Another cross-sectional study of Ahola et al. found that dietary fiber was associated with lower mean blood glucose concentrations in patients with T1DM. Glycemic values were even lower when protein was replaced with other macronutrients and when fat substituted carbohydrate, after adjustments for fiber intake (Ahola et al. 2018).

Numerous human studies involving resistant starches have shown a decrease in postprandial blood glucose and insulin levels (Lattimer and Haub 2010). In a critical review on antidiabetic and anti-obesity effects of dietary resistant starch, Meenu and Xu concluded that resistant starches have many health benefits that are different from digestible starches. Numerous food products were fortified with RS to increase its dietary intake and exhibited positive impact on human health (Meenu and Xu 2018).

The STARCH trial was the first metabolic phenotyping that studied the effect of resistant starch on diabetes risk factors. It included 63 overweight or obese

participants (BMI $\geq$ 27 kg/m^2, weight $\leq$ 143 kg), with ages between 35 and 75 years with confirmed prediabetes. They were randomized to consume either 45 g/day of RS (RS = amylose) or amylopectin (control) for 12 weeks. The effect of RS on inflammatory markers and insulin sensitivity was evaluated. Energy expenditure, appetite, food intake, substrate oxidation, colonic microbial composition, fecal and plasma levels of short-chain fatty acids, and gut permeability were secondary outcomes. Dietary resistant starch (RS) improved gastrointestinal tract function, inflammatory markers, and insulin sensitivity significantly compared to amylopectin, lowering the risk for diabetes (Marlatt et al. 2018).

In patients with glucose intolerance or newly diagnosed T2DM, 4 weeks of dietary treatment with fortified rice containing RS improved endothelial function and reduced postprandial glucose and oxidative stress compared with control (Kwak et al. 2012).

Another study examined the effect of resistant starch on blood glucose, insulin levels, dyslipidemia, and humoral immune responses in healthy overweight subjects (over 120% ideal body weight) fed either 24 g/d RS or regular corn starch (CS) for 21 days. No significant changes in weights or other physical parameters occurred following intakes. However, there were significant decreases of total cholesterol (p <0.05), LDL cholesterol (p <0.05), and fasting serum glucose concentrations (p <0.05) in subjects supplemented RS. RS supplement also increased serum immunoglobulin G (IgG) concentrations. Insulin levels were unaffected. The supplementation was considered palatable with minimal bowel discomfort (Park et al. 2004).

Dainty et al. propose a dietary strategy for T2DM risk reduction by means of a diet with high-amylose maize resistant starch bagels that improves fasting insulin sensitivity in adults at increased risk of T2D (Dainty et al. 2016).

In a crossover overnight study made by Sandberg et al., 21 healthy subjects were given 4 rye-based evening test meals. The test meals consisted of whole grain rye flour bread (RFB) or whole grain rye flour and rye kernels bread (RFB/RKB) in a 1:1 ratio, with or without added resistant starch (+RS). White wheat flour bread (WWB) was used as reference meal. The RFB/RKB + RS combination positively influenced biomarkers of glucose by significantly decreasing postprandial glucose and insulin response (p <0.05). It also increased the serum PYY gut hormone on the following morning. RFB and RFB/RKB improved subjective appetite ratings. Alone or combined with rye kernels, RFB increased the sensation of satiety and lowered perceived hunger sensations at 11–14.5 h after intake (Sandberg et al. 2017).

In women with diabetes, whole grain and bran intakes were associated with reduced all-cause and CVD-specific mortality (He et al. 2010). Consumption of whole grain breakfast cereal and bran was significantly associated with a lower incidence of ischemic stroke (Consumption 2018).

Arabinoxylan (AX) is a hemicellulose synthesized by glycosyltransferases (membrane enzymes): arabinoxylan synthase, transferase, and feruloyl transferase (substitutes ferulate into arabinose residues) (Mitchell et al. 2007). AX is abundant in cereal endosperm cell walls of rye and wheat, followed by oats, barley, maize, and rice. Arabinoxylans display functional properties including viscosity enhancement,

gel formation, emulsion or foam stabilizations, water absorption, fat replacement, and prebiotic activity. As constituents of dietary fiber, arabinoxylans also have nutritional and health-promoting benefits.

Arabinoxylan may help manage diabetes, according to a small study published in the *European Journal of Clinical Nutrition* in 2004. Fifteen patients with T2DM supplemented their diets with arabinoxylan-enriched bread and muffins or with bread and muffins made with white wheat flour for 5 weeks. The arabinoxylan-enriched bread group showed significant improvement in blood sugar control. Arabinoxylan may also help regulate blood sugar in people without diabetes, as a small study published in the *American Journal of Clinical Nutrition* suggests. After consuming a breakfast containing arabinoxylan-enriched bread, 14 healthy participants were found to have significantly lower blood sugar compared to consumption of normal bread.

30.5.2 Gastrointestinal Disease

30.5.2.1 Regulation of Microbiota

The human intestinal tract is populated with a great variety of bacteria, the microbial ecosystem (gut microbiota) with an essential role in maintaining functionality and homeostasis. Western diet rich in processed and fiber-poor foods and the use of antibiotics alter the composition of gut microbiota and lead to dysbiosis (Wypych and Marsland 2017). Dysbiosis is associated with gastrointestinal disease, allergy, T2DM, and intestinal inflammation (Hiippala et al. 2018). The gut microbiota is populated with *Bifidobacterium*, *Bacteroides*, *Proteobacteria*, *Firmicutes*, *Acinetobacter*, and *Clostridium*. The composition of microbiota can vary depending on clinical conditions like inflammatory bowel disease and nonalcoholic fatty liver disease (Takahiro et al. 2017). The role of gut microbiota in these diseases occurs through proinflammatory signaling and via direct hepatotoxicity of bacterial products (Parnell et al. 2012).

Different studies have shown a strong correlation between gut microbiota composition and dietary patterns. For example, the gut microbiota of people who consume a high-fiber diet is dominated by *Bacteroidetes* (Takahiro et al. 2017; El Khoury et al. 2012). Dietary fiber can modulate composition and metabolic function of human microbiota. Dietary patterns have a strong impact in bacterial diversity and production of microbial-derived fecal fermentative end products. Cross-sectional studies in human populations revealed that fiber-rich diet is associated with increased gastrointestinal microbial community diversity. In Europe the consumption of dietary fiber is on average 16–29 g/day and in the United States 12–18 g/day. A consumption of 10 g/day dietary fiber can increase the abundance of *Bifidobacterium* and *Lactobacillus* species in gastrointestinal microbiota and stimulates changes in *Bacteroidetes* and *Firmicutes* bacterial species (Holscher 2017).

In a study comparing 15 healthy European children consuming a high-protein and animal fat diet with 14 healthy African children on a high-fiber diet, de Filippo et al.

detected differences in the fecal microbiota. In European children, the microbiota was dominated by *Firmicutes*, and in Africans it was dominated by *Bacteroidetes* (De Filippo et al. 2010).

A cross-sectional study on 28 healthy Japanese women also revealed a relationship between dietary patterns and the fecal microbiota. The fecal microbiota was analyzed by the terminal restriction fragment length polymorphism (T-RFLP) method. T-RFLP pattern analysis divided the subject in two clusters: cluster A (abundance of *Bacteroidetes* and *Clostridium*) and cluster B (abundance of *Bifidobacterium* and *Lactobacillales*). Cluster A included 12 subjects with low-protein diet, and cluster B group included 16 subjects with fiber-rich diet, especially mushrooms rich in prebiotics like inulin, β-glucan, and fructooligosaccharides. These prebiotics increased the number of beneficial bacteria, like *Bifidobacterium* and *Lactobacillales*. Bifidobacteria have an important role in intestinal health and a healthy gut microbiota (Takahiro et al. 2017).

In a recent study on 28 subjects, Eslamparast et al. demonstrated that prebiotic fibers have beneficial effects in the composition and activity of gut microbiome. Prebiotics stimulate bacterial production of short-chain fatty acids, reduce the luminal pH, inhibit the growth of pathogens, and improve glucose and lipid metabolism (Eslamparast et al. 2017).

30.5.2.2 Nonalcoholic Fatty Liver Disease

Nonalcoholic fatty liver disease (NAFLD), the most common cause of chronic liver disease, is considered the hepatic manifestation of the metabolic syndrome (Shen et al. 2017).

In a single-center double-blind, placebo-controlled, parallel-group study on 30 participants with NAFLD, the efficacy of prebiotic supplementation in reducing liver fat and hepatic injury was demonstrated. The patients were randomized to a 16 g/day prebiotic-supplemented group and an isocaloric placebo group for 24 weeks. The liver enzymes (ALT, AST), TNF-α, and total cholesterol were reduced in the group with prebiotic supplementation demonstrating improvement of liver injury. The authors consider that prebiotics can modify the gut barrier integrity and endotoxin translocation, as well as increase *Bifidobacterium* with beneficial role in NAFLD (Lambert et al. 2015).

A study on 32 patients with NAFLD for 6 months evaluated the association between fiber intake and zonulin (ZO) concentration as marker of intestinal permeability. During the study the dietary fibers were increased from 19 g/day to 29 g/day: soluble fiber (6.69 ± 3.21 g per day) and insoluble fiber (17.44 ± 7.11 g per day). This study demonstrated a significant improvement of liver injury markers serum aspartate aminotransferase (AST), alanine aminotransferase (ALT), and gamma-glutamyltransferase (GGTP), decrease of ZO concentration, and improvement in hepatic steatosis (Krawczyk et al. 2018).

A recent study demonstrated that a higher insoluble fruit fiber consumption (≥7.5 g/day) was associated with improved liver health and improvements in fatty liver parameters. The authors speculate that the production of short-chain fatty acids

from fermented fibers ensures the preservation of the intestinal barrier and has a protective and nourishing role for colonocytes (Cantero et al. 2017).

Another study on 31 subjects demonstrated that a Mediterranean diet associated with monounsaturated fatty acids and prebiotics reduced hepatic fat and improved insulin sensitivity even without weight loss in NAFLD patients (Abenavoli et al. 2014).

30.5.2.3 Inflammatory Bowel Disease

Inflammatory bowel diseases represent disorders of the gastrointestinal tract characterized by immune activation and consequently chronic relapsing inflammation that include Crohn's disease and ulcerative colitis.

A recent study demonstrated the effectiveness of a mixture of digestive enzymes, beta-glucan, and inositol in inflammatory bowel disease. The study included 43 participants randomized in 2 groups: group A ($n = 23$) with conventional treatment (topical and systemic mesalamine) plus one tablet after lunch and dinner of a mixture of digestive enzymes, beta-glucan, and inositol for 4 consecutive weeks and group B ($n = 20$) which was given only conventional treatment. The mixture contributed to improved quality of life and reduced abdominal pain, bloating, and flatulence in patients with inflammatory bowel disease, improving their overall clinical condition. β-Glucan had a prebiotic effect and reduced the level of pro-inflammatory cytokines (IL10, IL12, and TNF-alpha). The authors demonstrated that inositol reestablished intestinal motility and improved gastrointestinal symptoms, also restoring intracellular calcium levels (Spagnuolo et al. 2017).

30.5.2.4 Colonic Cancer

Lifestyle (physical inactivity) and dietary patterns (poor diet) play a significant role in the development of colorectal cancer. It is the third most commonly diagnosed cancer in men and the second most commonly diagnosed in women worldwide. The symptoms of colorectal cancer are bloody stools, fatigue, and bowel movement changes (constipation, diarrhea, or narrowing of the stool). The risk of colorectal cancer is significantly increased by inadequate fiber intake and inflammatory bowel diseases, such as Crohn's disease and ulcerative colitis (Emilsson et al. 2017). Dietary patterns are useful for the investigation of chronic disease development. The term dietary pattern refers to several techniques of defining total diet quality (Brown and Fung 2013). Current dietary recommendations to prevent colorectal cancer include eating a variety of vegetables, fruits, and whole grains rich in fiber while limiting consumption of processed foods and less red and processed meats (Perera et al. 2012). Recent studies demonstrate that diets high in fiber can be preventive against colorectal cancer, as every 10 g of fiber consumed daily reduces risk by 10% (Aune et al. 2011).

A recent randomized controlled trial entitled BENEFIT (**B**eans/**B**ran **E**nriching **N**utritional **E**ating **F**or **I**ntestinal health **T**rial) determined the feasibility of increasing dietary fiber intake in colorectal cancer survivors and examined serum inflammatory biomarkers. There were 29 participants who successfully completed the 4-week pilot dietary intervention trial, consuming 35 g/day navy bean powder or

30 g/day rice bran that allowed them to meet the 5% dietary intake level shown to inhibit colon tumor formation. This pilot study established that a fiber-rich diet in colorectal cancer survivors has a chemopreventive effect, maintains a healthy gut through decreased oro-fecal transit time, produces short-chain fatty acids that reduce gut inflammation, and promotes apoptosis (Borresen et al. 2016).

Rice bran is rich in dietary fibers, γ-oryzanol, tocotrienols, β-sitosterol, and essential vitamin E complex. Rice bran extracts have been reported to contain biologically active compounds with chemopreventive, anti-inflammatory, antioxidant, antimutagenic, and anticarcinogenic properties. In human colorectal cancer, they inhibit cell proliferation and angiogenesis, induce apoptosis, and stimulate the immune system. A recent study demonstrated that purple rice bran oil has a chemopreventive role in colorectal cancer, significantly suppressing inflammation and decreasing the production of interleukin-1β (IL-1β), IL-6, tumor necrosis factor-α (TNF-α), and leukotriene B4 (LTB4) (Sirithunyalug et al. 2018).

The immunomodulating effects of arabinoxylan bran MGN-3 were examined by Ghoneum in 32 cancer patients with various malignancies including colon cancer, with depressed NK cell activity after conventional cancer treatment. Treatment with MGN-3 for 2 weeks led to a significant tenfold increase in NK cell activity, increase in NK cell binding capacity, and granularity and improvement in tumor-associated antigens and in T and B cell proliferation in vivo in a selected number of patients (Ghoneum and Gollapudi 2003).

30.5.3 Obesity and Weight Reduction

The prevalence of obesity is increased in developed and developing countries throughout the world. Obesity is associated with an increased risk of diseases, like cardiovascular disease, hypertension, dyslipidemia, and different forms of cancer. Weight loss has lots of health benefits, for example, it improves insulin sensitivity and decreases adipose tissue inflammation (Strączkowski et al. 2018). The consumption of products rich in β-glucan is associated with weight reduction, because they can reduce energy intake and are able to modulate appetite. β-Glucans have the ability to form highly viscous solutions and have the property of fermentability, which brings health benefits and contributes to weight reduction. It was demonstrated that diets rich in fibers have a positive contribution to long-term weight management, reduce LDL cholesterol, and improve glycemic control (El Khoury et al. 2012).

The soluble dietary fiber glucomannan, with a strong water-holding capacity, reduced energy intake, increased satiety, and produced a significant reduction of weight at a dose of 1.24 g daily in a study on 1076 subjects with an energy-restricted diet. The duration of the study was 5 weeks (Birketvedt et al. 2005).

In a critical review, it was concluded that soluble fibers with viscosity-producing properties, such as guar gum, pectin, psyllium, and β-glucan, are more strongly associated with reduced hunger and/or appetite perceptions than low-fiber diets (Dikeman and Fahey 2006).

In a large European study with a 6.5 year follow-up, consumption of 10 g/day total dietary fiber was associated with significant weight reduction and waist circumference reduction (Du et al. 2010).

In a recent review, Bozzetto et al. revealed the beneficial effects of dietary fiber on blood glucose metabolism, LDL cholesterol, blood pressure, and plasma triglycerides (Bozzetto et al. 2018).

30.6 Applications in Foods

In recent years various fiber ingredients have been added to formulated foods to increase fiber intake. A healthy dietary pattern includes whole foods rich in fibers from vegetables, whole grains, fruits, nuts, and seeds, in order to achieve the daily recommended amount for dietary fiber and also fulfil the needs for other important nutrients. Adding fiber to food can provide an alternative way to reach recommended intake levels. Functional fibers derived from wheat, corn, and rice have been commonly accepted in various food applications, both for their health attributes and technical functionalities. A recent trend in food industry explores the utilization of novel or uncommon sources of dietary fiber from processing of fruits, vegetables, and seeds. Dietary fiber extracts and isolates are obtained from different sources based on certain preparation methods and have various physicochemical properties, leading to many applications in food product development. From a functionality perspective, any fiber can play a number of roles. For example, citrus fiber may be used as bulking agent in reduced-sugar products, to improve texture, to manage moisture, and to add color, and as natural antioxidant (Viuda-Martos et al. 2010b).

Dietary fibers display a plethora of activities when they are incorporated in food systems, due to their water-binding capacity, gel-forming ability, and fat mimetic properties. Fibers contribute to improvement of texture, sensory characteristics, and shelf life of foods through antisticking, anticlumping, texturizing, and thickening effects (Yangilar 2013). For example, in bakery products, fibers prolong freshness; in bread they can modify softness, loaf volume, and firmness. In meat products they improve texture, fat binding, cooking yield, and water binding (Yangilar 2013).

Drinks and beverages containing soluble fibers (pectins, fractions of grains, and multifruits, polidextrose, ß-glucans, cellulose beetroot fiber) are the most used. Added soluble fibers increase their viscosity and stability (Yangilar 2013). Bakery products and breakfast cereals are enriched with dietary fibers derived from fruits because of their nutritional quality, strong antioxidant capacity, high amounts of total and soluble fiber, less caloric content, and greater grade of fermentability and water retention. In dairy products the most used fiber is inulin, which reduces syneresis in yoghurt and fermented milk products and improves palatability in cheeses and ice creams. Pectins are used for elaboration of marmalades and jams, because they stabilize the final product. In low-calorie products, sugar is substituted by inulin and oligofructose.

Recently, enzymatic treatments have been reported to alter fiber qualities and increase their solubility and functional properties. Mrabet et al. used Viscozyme® L

for the first time in 2016 to convert insoluble fiber in dates to soluble fiber, leading to a functional ingredient with increased antioxidant activity and higher concentrations of prebiotic oligosaccharides (Mrabet et al. 2016). In 2017 Wen et al. studied the effects of enzymatic treatment in combination with micronization on structural and functional properties of rice bran, resulting a fine fiber powder with increased soluble-to-insoluble fiber ratio, reduced water and oil holding capacity, increased swelling capacity, and improved absorption capacity for cholesterol and sodium taurocholate (Wen et al. 2017).

30.7 Safety: Toxicity and Side Effects

Although a recommended dietary allowance, or RDA, has not been set for fiber because of insufficient evidence, the Food and Nutrition Board has set an Adequate Intake for the nutrient. It is the amount that should satisfy the needs of most healthy individuals within a specified age range. While fiber has a number of health benefits for the body, eating too much can lead to uncomfortable side effects and potentially serious complications.

Even though fiber has numerous benefits, too much of it can be harmful. Since fiber is not actually digested by the body, the digestive tract has a more difficult task moving it, which may cause cramping, bloating, gas, and abdominal discomfort. Not drinking enough water to help move the bulk leads to constipation. If the constipation isn't resolved, it can lead to an intestinal blockage, the most dangerous side effect associated with excessive fiber intake. An intestinal blockage can lead to nutrient malabsorption and a dangerous accumulation of toxins in the body.

The 2009 Codex Alimentarius Commission definition of dietary fibers dividing them into three categories introduced items obtained from food raw material and synthetic carbohydrate polymers (Codex Alimentarius Commission 2010). These have to provide physiological effects comparable to natural fibers occurring in foods. The Codex recommends consumption of 14 g fiber/1000 kcal, for both genders at all age groups. Although no tolerable upper intake level has been set for dietary fiber, it is recommended that women eat 25 g of fiber a day and men 38 g per day. Above 70 g could lead to negative effects, leading to reductions in the absorption of some minerals. It is not clear yet if this could create mineral deficiencies.

Psyllium seed is not recommended to patients with fecal impaction and undiagnosed abdominal pain or other symptoms, a sudden change in bowel habit longer than 2 weeks, nausea, vomiting, rectal bleeding, and constipation. It is also not to be used by patients with diseases of the esophagus and cardia, ileus, or megacolon. Psyllium seed is not to be used by patients with known hypersensitivity to psyllium or any of the other constituents of the product.

Green bananas are rich in resistant starches, which can increase the risk of constipation. In underripe bananas starch constitutes 80–90% of the carbohydrate content, which as the banana ripens changes into free sugars (Hermansen et al. 1992). They also contain high doses of tannic acid which has an inhibitory effect on

the digestive tract and gastrointestinal motility and obstructs secretion of gastrointestinal fluids (Samanta et al. 2004).

Safety data on long-term or regular use of arabinoxylan are currently lacking. However, since arabinoxylan may lower blood sugar levels, there's some concern that using arabinoxylan in combination with diabetes medications may have harmful effects.

Supplements created as combinations of fiber and herbs are not always tested for safety and might also be unregulated. They may contain doses that differ from the labeled amount for each herb, or they may be contaminated with heavy metals. The safety of such supplements in children, pregnant women, nursing mothers, and patients on different medications is not known, and unexpected herb-drug interactions might occur.

30.8 Marketed Products

Food developers face technical challenges during formulation design of new products, as single formulations cannot easily achieve the high level of recommended daily intake of dietary fiber. The impact of dietary fiber materials can be unpredictable for sensory properties and product quality. Another problem can be the massive production using automated assembly lines which can affect integrity, palatability of fiber-fortified foods, and bioavailability (Table 2).

Table 2 The properties of dietary fiber: material science-oriented physicochemical properties, nutrition-oriented physiological effects, and food application-oriented technological functionalities (Kendall et al. 2010; Rastall 2010; Viuda-Martos 2010b; Brownlee 2011)

Physicochemical properties (material physics/chemistry)	Physiological effects (biomedical and nutritional area)	Technological functionality (food product development)
Solubility	Changes in intestinal function	Water binding/holding capacity
Viscosity	Reduction of cholesterolemia	Fat/oil binding and retention capacity
Density and bulk volume	Modification of the glycemic response	Viscosity and rheological property
Surface area characteristics and porosity	Laxation Satiety	Gel-forming capacity and swelling
Particle size	Fermentation in the colon	Fermentative capacity
Cation exchange capability	Reduction of nutrient availability	Metal ion-chelating capacity
Chemical reactivity/interaction with other organic molecules including fat/oil, protein, vitamins, antioxidants	Enhanced health benefit through synergistic effects with other active ingredients	Texturizing capacity – thickening, bulking, texture modification Flavor modification Control of sugar crystallization

Table 3 Trends of dietary fiber utilization in novel food product development (van der Kamp et al. 2010)

Approaches	Food applications
Use of fiber-rich raw materials containing intrinsic and intact fiber for conventional food production	Bread, breakfast cereals, pasta and noodles, bakery goods, extruded snacks
Addition of isolated, purified fiber in nontraditional DF carriers for enrichment or fortification	Meat, fishery, and dairy products including fermented beverages
Utilization of processing waste stream or by-product rich in fiber for formulation improvement	Restructured meat and fishery products, bread, extruded snacks

The food industry incorporates dietary fibers into a wide variety of foods, such as pasta, breads, baked products, breakfast cereals, yogurts, vegetable milk, and fermented beverage (Table 3). The acceptable level of fiber incorporation to bakery and pasta formulations is limited to 5%, while the addition above 10% yields some unfavorable alterations to product quality characteristics such as color and texture and determines loss of cooking and sensory properties (Li and Komarek 2017).

Adding fibers to foods from a variety of sources promotes positive health benefits and has been successful in reducing nutrient deficiencies. According to current regulations, a food item can carry the claim of "more or added fiber" when it contains at least 2.5 g of fiber or more per serving than the reference food. A "good source of fiber" claim can be made when the food contains 2.5 to 4.9 g of fiber, and a "high fiber" claim can be made when a food item contains 5 g or more fiber per serving (Hazen 2012).

Dietary fibers are used in various formulations like flours, premixes for breads and baked products, breakfast cereals, pasta, fortified milk, fortified yogurts, fortified beverages, fortified juices, granola and cereal bars, and fortified plant-based milk and yogurts.

Dietary fiber supplements are also marketed in various forms like pills, capsules, powders, and gels. Dietary fiber supplements can contain one or more dietary ingredients, minerals, vitamins, or herbs.

Pure psyllium powder, a one-ingredient supplement that supports satiety and offers digestive benefits delivers the large amount of 4.5 g of fiber per teaspoon, which immediately begins to gel once mixed with water. Another product is an orange-flavored powder that looks like fruit punch mix smoothie once added with water, being surprisingly tasty. Psyllium powder capsules are designed without side effects like gas and bloating, being made of calcium polycarbophil to help regulate bowel movements and eliminate diarrhea and constipation. Two capsules should be taken with eight glasses of fluid. Another sugar- and gluten-free supplement contains 6 g of psyllium fiber and is recommended up to three times per day.

A vegan gluten- and dairy-free formula contains 9 g of fiber, 9 g of protein, and 1 g of sugar sweetened with stevia. It is made from 15 raw organic superfoods, including sprouted seeds and legumes, grains, probiotics, and omega-3 fatty acids, in 120-calorie servings.

Fibersol® is a line of fiber ingredients developed for homemade baking products for health-conscious consumers with many functional benefits, like replacing calories from sugar and fat and increasing satiety.

Inulin is an excellent dietary fiber with significant health-promoting benefits. It is used in many applications, including bakery, cereals and cereal bars, dairy, infant nutrition, beverages, confectionery, ice cream, and healthcare nutrition. Inulin can be used as sugar, as a texturizer, and as fat replacer. In infant formulas it improves the intestinal microflora of babies and small children, mimicking the prebiotic effect of mother's milk. Inulin's application in confectionery highlights its sugar-replacement properties, resulting in low-calorie products. Optionally inulin can be used in a high-quality, sugar-free chocolate or "low-fat," "low-sugar," or "low-calorie" ice creams, sorbets, or frozen desserts with good texture and taste. Inulin can enrich the fiber content of soups, sauces, and seasonings. Noodles are a popular food, particularly in Asia, and inulin supplementation provides an excellent opportunity to promote a healthier lifestyle by increasing the intake of dietary fiber and helping control body weight.

Glucomannan, a water-soluble super fiber supplement derived from the elephant yam, has shown promise as an effective weight-loss supplement. It will absorb 50 times its own weight in water, so when taken before a meal with a glass of water, it creates a full feeling in the stomach.

30.9 Patents

At present, dietary fibers have various applications and patents in food development.

The patent of Aldritt et al. refers to an effervescent formula that included water-soluble dietary fiber for laxative effects, which also decreased cholesterol; increased the absorption of vitamins and minerals, especially dietary calcium; and promoted the growth of beneficial bifidobacteria in the lower gut. The composition included at least 2.5 g dietary fiber, 50–1250 mg sorbitol, 5–500 mg sodium benzoate, and 5–500 mg polyethylene glycol. The effervescent formulation had lots of benefits: can be a useful dosage form for delivering active agents, can be dissolved rapidly, was easier to swallow, and could be packaged in controlled quantities (Aldritt et al. 2006).

Another patent created a low molecular weight dietary fiber material, obtained by using enzymes which hydrolyzed any starch into small molecules and only partially hydrolyzed β-glucan molecules. The advantages of this dietary fiber material with β-glucan were low molecular weight with excellent physicochemical, physiological, and sensory properties and a particular polydispersity, low viscosity, and high stability in water. This dietary fiber material had neutral palatability and could be used in baked goods, bars, ice cream, yogurt, beverages, or other foods without affecting the sensory attributes of the food. The modified β-glucan with an average molecular weight ranging from 50 to 1000 kDa had a therapeutic role in regulation of glycemic response, reduction of cholesterol, enhancing the growth of bifidobacteria

and immune activity, and lowering the risk of cardiovascular and intestinal diseases (Milan and Peal 2013).

A patent created as dietary fiber gel filling reduced the caloric and fat content of prepared sandwiches with minimal effect on texture and taste. This dietary fiber gel filling replaced a portion of fat of prepared sandwiches by the content of β-glucan from yeast, soluble fibers derived from flax seed, vegetable, and fruit fiber sources. The concentration range for β-glucan was from 5% to 15% of the composition. The advantage of the present invention was a higher fiber alternative to traditional prepared sandwich type foods that reduced caloric and fat content. This dietary fiber gel can be used not only for sandwiches but also for tacos, crepes, pies, pancakes, and wraps (Evans et al. 2014).

An invention of a formulation of soluble, functional fiber ideal for addition to liquid foods and nutritional formulas included fructooligosaccharides (FOS) and partially hydrolyzed guar gum (PHGG). PHGG is entirely fermented in the colon and increases the production of butyrate that plays an important role in the regulation of cell differentiation, proliferation, and apoptosis in the intestine. PHGG 21 g/ day is considered a prebiotic and increases the concentration of the beneficial bacterial strains lactobacilli and bifidobacteria. Fifteen grams per day PHGG reduces constipation. FOS are short-chain fructose polymers with prebiotic activity that also stimulate the growth of lactobacilli and bifidobacteria. FOS 4 g/day suppresses growth of pathogenic bacteria and enhances a positive immune response. This patent provides a dietary fiber formulation with great prebiotic potential (Ca and Street 2008).

The process of making a flour composition with resistant starch for increased total dietary fiber was the reason behind several other patents. These fortified flours have numerous beneficial effects: reduced caloric value, reduced glycemic response, controlled glucose regulation, impacted satiety, sustained energy release, improved athletic performance, and mental concentration and memory. High-amylose flours are processed with a short hydrothermal treatment to increase total dietary fiber content. The native source can be corn, tapioca, rice, wheat, sweet potato, oat, amaranth, pea, sorghum, and barley. The high-amylose flours contain 27% amylose for wheat or rice and 40% amylose for other sources. These flours can be used for breakfast or expanded cereals, breads, cakes, muffins, pastry, pasta, snacks, fried and coated foods, yogurts, cheeses, sour creams, and beverages (Evans et al. 2014).

The invention of a pouch with pores was intended to deliver the daily recommended soluble fiber intake, having one portion placed into the mouth to release the quantity of soluble dietary fibers desired. The pouch can contain flavorants, sweeteners, minerals, vitamins, energizing agents, and antimicrobial agents (Schleef et al. 2008).

30.10 Future Perspectives

The simplified definition of dietary fiber as a carbohydrate that resists digestion and absorption and that may or not undergo microbial fermentation in the large intestine is essential for correlating consumption levels and health benefits. Dietary fibers

have many different constituents, of particular interest being inulin, β-glucan, pectin, bran, arabinoxylan, and resistant starches, which all play an important role in human health. Although further research is needed to better understand particular health claims and mechanisms involved, current research is oriented toward all these constituents.

An inverse relationship has been reported between fiber consumption and the risk for coronary heart disease and various types of cancer. The FDA has launched the claim that increased intake of dietary fiber can reduce the incidence of coronary heart diseases and cancer and although not yet adopted, dietary fiber is suggested to have a role in obesity and diabetes. The mechanisms supporting these claims are still unclear; some data are contradictory, but the majority of studies agree with the fact that the lower energy density of dietary fiber could decrease the gross energy of a food.

Much of the recent literature has been focusing at the ability of different dietary fiber types to affect certain physiological systems, especially trying to understand the influences on fermentation patterns of the intestinal microbiome. The prebiotic function of fibers is intensely studied using new DNA sequencing procedures that will permit to completely characterize the bacterial populations involved in the future. Butyrate as product of fermentation regulates gene transcription acting as a histone deacetylase inhibitor, which influences cell proliferation, differentiation, and apoptosis of colonocytes. The goal of these studies will be to determine individual differences and risk to develop diseases and consequently personalize dietary modifications that improve human health.

In a recent review on evidence base of BioBran/MGN-3 arabinoxylan compound as a complementary therapy for conventional cancer treatment, Soo Liang Ooi et al. examine the current evidence from 32 preclinical studies, clinical case reports, and small clinical trials that confirm the upregulating of the patient's immune system, especially by boosting NK cell activity. MGN-3 is considered safe with no adverse event reported. The combination of MGN-3 with new biological targeting treatments may open future perspectives in tumor therapy. The authors consider that additional pharmacokinetic studies and well-designed RCTs to strengthen the evidence for clinical application are needed (Ooi et al. 2018).

The main interest for further studies in specific areas of dietary fiber research includes the components of fibers such as β-glucan, arabinoxylan, and resistant starches.

Oligosaccharides in Food

31

Chao Zhao

Contents

Abstract

Oligosaccharides are small molecular carbohydrates comprising of 3–10 monosaccharides. They have shown beneficial effects on immune system and gut health, such as anti-allergic, anti-inflammatory, antidiabetic, anticancer, antiaging, and anti-obesity activities. Functional oligosaccharides are commonly found in plants, algae, bacteria, and higher fungi. Milk is perfect for human

health improvement. The biological functions of milk oligosaccharides, especially human milk oligosaccharides, are known to have considerable health benefits for humans, such as the growth promotion to the beneficial intestinal flora and the resistance to the infections of bacteria and virus. Oligosaccharides synthesis is becoming increasingly important to pharmaceutical industry, in which chemoenzymatic syntheses are considered as effective ways. The functional oligosaccharides have been widely applied in various branches such as pharmacological supplements and food ingredients. This chapter gives a brief summary about the chemical characteristics, the potential health benefits, the application in foods, and marketed products of the functional oligosaccharides.

Keywords

Oligosaccharides · Bioactive · Gut health · Human milk oligosaccharides · Application

31.1 Introduction

Before the 1960s, sugars were just generally regarded as the chemical energy and structural substances. With the development of molecular biology, medicine sciences and other disciplines in recent years, people gradually realized that carbohydrates perform numerous roles in living organisms except for the storage of energy (e.g., starch and glycogen) and as structural components. Saccharides and their derivatives include many other important biomolecules that play key roles in the immune system, fertilization, preventing pathogenesis, blood clotting, and development. According to the IUPAC-IUBMB Joint Commission on Biochemical Nomenclature, naturally occurring carbohydrates that consist of 3–10 monosaccharide units, linear or branched, connected by α- and/or β-glycosidic linkages, are defined as oligosaccharides (Zhao et al. 2017). Plants and algae are the richest sources of functional oligosaccharides (Zhao et al. 2017). Recently, much attention has been paid by consumers on natural bioactive compounds to be used as functional ingredients in nutraceuticals. Functional oligosaccharides are intermediate between monosaccharide and polysaccharides and are well known as prebiotics, due to they benefit the host by selectively stimulating beneficial bacteria in the intestine, especially *Bifidobacterium* species (Xu et al. 2009). Compared with ordinary oligosaccharides, functional oligosaccharides are zero or low calorie and have more unique physiological functions, such as promoting *Bifidobacterium* proliferation, improving the body's immunity, preventing dental caries and constipation, and inhibiting tumor, etc. Moreover, functional oligosaccharides have a positive effect on different well-being aspects of the host, such as immune modulation, intestinal health, gastric microbial function, calcium absorption, and bone mineral density, particularly among adolescents (Kumar et al. 2016). The types of oligosaccharides, known as

research focus, are marine oligosaccharides, fructo-oligosaccharides (FOS), chitosan-oligosaccharides (COS), human milk oligosaccharides (HMOs), galacto-oligosaccharides (GOS), etc. The FOS existed in fruits and vegetables such as onions and bananas are difficult to be eliminated and absorbed by human body. However, it can be easily used by *Bifidobacterium* as a bioactive factor for proliferation. Marine oligosaccharides which mainly contained agar oligosaccharides and carrageenan have huge development potential and have attracted broad attention in drug discovery (Yang et al. 2019; Zhao et al. 2015, 2018). Marine algae are rich in sulfated polysaccharides (SPs) such as carrageenans in red algae, fucoidins in brown algae, and ulvans in green algae (Ngo and Kim 2013) and considered as valuable sources of structurally diverse bioactive compounds. COS as a biocompatible compound is derived from the hydrolysis and the deacetylation of chitin, which is one polymer of N-acetyl-D-glucosamine and abundantly found in the exoskeleton of arthropods including crabs and shrimps (Mattaveewong et al. 2016). The concentration of HMOs in mature human milk is 10–15 g/L, which is 100- to 1000-fold higher than that in bovine milk, and its content often exceeds the total amount of protein in human milk (Zhao et al. 2017). GOS was produced in the course of lactose hydrolysis and due to the transgalactosydic reaction by the enzyme β-galactosidase produced (Fischer and Kleinschmidt 2018). GOS can reach the large intestine and fermented by the gut microbiota, and it also can exert various health benefits for the host by improving the growth of probiotic bacteria (Panesar et al. 2018). Functional oligosaccharides were found widely in plants, algae, bacteria, and higher fungi. They have become the research hotspots because of which cannot be digested in the gastrointestinal tract (Pan et al. 2018a). Oligosaccharides have large amounts of important biological activities, application, and development in health food engineering. And functional oligosaccharides continue to stimulate great interest and have potential future value. So, the different uses of oligosaccharides have been studied in structural chemistry, molecular biology, medicine, and food science fields.

31.2 Bioactive Constituents

Oligosaccharides exhibit a high degree of diversity in structure. In contrast to polysaccharides, the structure of oligosaccharides has been well analyzed. This numerous structure diversities lead to highly specialized and selective interactions that play key roles in their activities. In general, oligosaccharides are usually composed of five different monosaccharides: glucose, galactose, *N*-acetylglucosamine, fucose, and sialic acid (Morozov et al. 2018). The known functional oligosaccharides have included arabino-oligosaccharides, arabinogalacto-oligosaccharides, arabinoxylo-oligosaccharides, galacturono-oligosaccharides, rhamnogalacturonoligosaccharides, and HMOs (Table 1). These natural oligosaccharides can improve the balance and activity of the intestinal microflora and greatly prevent the gastrointestinal infections (Fig. 1). Oligosaccharide chains (glycans) are linked to lipids or to compatible amino acid side chains

Table 1 Natural functional oligosaccharides and their glycosidic linkages

Types	Monosaccharides	Number of monosaccharides	Bonds indicative of functions
Arabino-oligosaccharides	Arabinose	2–8	α-1,5
Arabinogalacto-oligosaccharides	Arabinose, galactose	2–9	β-1,4
Arabinoxylo-oligosaccharides	Xylose, arabinose	5–10	α-1,2, α-1,3, β-1,4
Clycosylsucrose	Glucose, fructose	3	α-1,2, β-1,4
Cyclodextrins (CDs)	D-glucopyranose	6 (α-CD), 7 (β-CD), 8 (γ-CD)	α-1,4
Fructo-oligosaccharides	Sucrose, fructose	2–5	β-1,2
Galacto-oligosaccharides	Galactose	2–5	β-1,2, α-1,4
Galacturono-oligosaccharides	Galactosamine	2–9	α-1,4
Gentio-oligosaccharides	Glucose	2–10	β-1,6
Glucose-oligosaccharides	Glucose	2–10	α-1,2, β-1,3, β-1,6
Human milk oligosaccharides	Glucose, galactose, GlcNAc	2–8	α-1,2, α-1,3, α-1,4, α-2,3, β-2,6, β-1,3, β-1,4
Isomalto-oligosaccharides	Glucose	2–5	α-1,4
Lactosucrose	Galactose, fructose	2–3	β-1,4
Lactulose	Galactose, fructose	2	β-1,4
Malto-oligosaccharides	Mannitose, glucose	2–10	α-1,2, α-1,4
Palatinose	Glucose, fructose	2	β-1,6
Raffinose	Galactose, fructose, glucose	3	β-1,2, α-1,4
Rhamnogalacturonoligosaccharides	Rhamnose, galactose	4–8	α-1,2, α-1,4, β-1,4
Soybean oligosaccharides	Fructose, galactose, glucose	2–4	α-1,6
Stachyose	Galactose, fructose, glucose	4	α-1,4
Xylo-oligosaccharides	Xylose	2–7	α-1,4

in proteins by *N*- or *O*-glycosidic bonds (Fig. 1). *N*-linked glycosylation almost always involves oligosaccharide attachment to asparagine via β-linkage to the amine nitrogen of the side chain (Angelyn and Barbara 2011). And then, oligosaccharides that participate in *O*-linked glycosylation are attached to threonine or serine on the hydroxyl group of the side chain (Madson 2016). Modification of the glycosylation has enriched the biological activities of oligosaccharides.

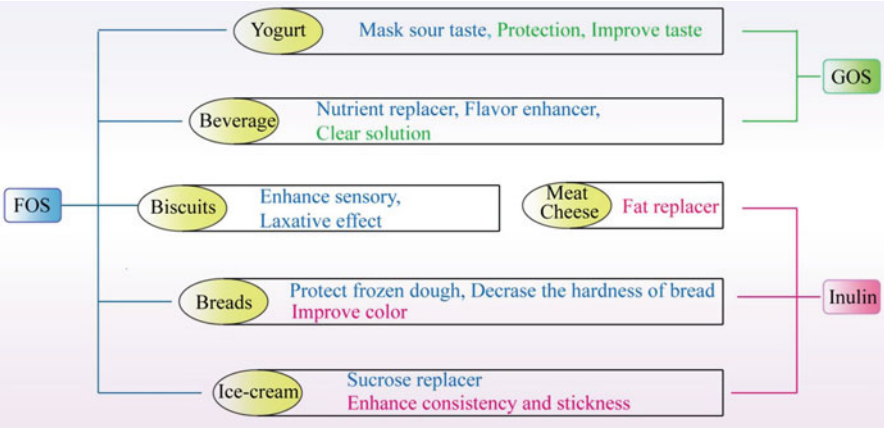

Fig. 1 The effects of GOS, FOS, and inulin on food

31.3 Bioactivities

31.3.1 Anti-allergic Activity

Allergic diseases are one of the public health problems over the world. It is estimated that about one-third of the general population and one-fifth of the population in western countries were troubled in allergic diseases. In essence, allergy is caused by an exaggerated adaptive immune response to harmless environmental substances, such as animal dander, house dust mites, foods, pollen, insects, and chemical agents (Ngo and Kim 2013). Many researchers have made a series of experiments against allergy. Maternal dietary supplemented with specific nondigestible oligosaccharides during pregnancy in mice led to reduce allergic asthma symptoms in the offspring (Hogenkamp et al. 2015). Further experiment showed that the dietary intervented with nondigestible oligosaccharides and partial hydrolyzed whey protein prevented the onset of food allergic symptoms in mice (van Esch et al. 2017). In recent years, COS with low molecular weight has been proven to exhibit protective effect against ovalbumin-induced lung inflammation in a mouse model of asthma. Oral administration of low-molecular-weight COS (LM-COS) (16 mg/kg body weight/day) has resulted in a significant reduction in both mRNA and protein levels of interleukin (IL)-4, IL-5, IL-13, as well as tumor necrosis factor (TNF)-α in the lung tissue and bronchoalveolar lavage fluid (BALF). Moreover, compared with the ovalbumin-sensitized/ovalbumin-challenged asthma control group, the protein levels of IL-4, IL-13, and TNF-α in BALF were decreased by 5.8-, 3.0-, and 9.9-fold, respectively. These results suggested that the oral administration of low-molecular-weight COS was effective in alleviating the allergic inflammation in vivo. And it could be an excellent source for the development of a potent therapeutic agent against mast cell-mediated allergic inflammatory responses and airway inflammation in allergic

inflammatory diseases, including asthma (Chung et al. 2012). *Eucheuma cottonii* sulfated oligosaccharide (ESO) that shows anti-food allergy activity in RBL-2H3 cells and BALB/c mouse model in vivo possesses preventive and therapeutic potential in allergic disease (Xu et al. 2017). ESO has decreased the levels of mast cell protease-1 and histamine, as well as inhibited the level of specific immunoglobulin (Ig) E up by 77.7%. The productions of IL-4 and IL-13 were seriously diminished by ESO that could also upregulate Treg cells by 22.2–97.1%. ESO has reduced the allergy response in mice by decreasing basophil degranulation, upregulating Treg cells via Forkhead box protein 3 (Foxp3), and releasing IL-10.

31.3.2 Anti-inflammatory Activity

Inflammation is a natural protective response of innate immune system to tissue injury or damaging external stimuli such as pathogens, allergens, infections, irritants, and ultraviolet light irradiation (Du et al. 2018). Inflammation involves a series of physiological responses against exogenous pathogens. Once infection is detected by the immune system, inflammatory signaling cascades recruit innate immune cells to the affected tissue sites. Immune cells, including macrophages, natural killer cells, and dendritic cells, use inflammatory signaling cascades to eliminate foreign substances such as viruses and bacteria (Chen and Nunez 2010). The immune system cells eliminate the pathogens by phagocytosis and production of cytokines and chemokines which play the vital roles in maintaining immune homeostasis. However, recent studies suggest that excess or chronic inflammation is associated with diseases such as inflammatory bowel disease, diabetes, cardiovascular disease, and neurodegenerative disease (Glass et al. 2010; Pearson et al. 2003); thus the regulation of excess and chronic inflammation is important for health. It is notable that chronic low-grade systemic inflammation can be induced by dietary factors like high-fat and high-sugar diets. Systemic inflammation subsequently affects local inflammatory responses and tissue-specific insulin resistance, which contributes to the progression of obesity, diabetes, and cancer. The incidence and progression of inflammation-related diseases can be prevented or delayed by lifestyle modifications, such as dietary intervention (Kang et al. 2016). In particular, the change of living habit and diet is an important factor for mitigating excess inflammation (Wu and Schauss 2012). Functional oligosaccharides can provide an effective way to prevent inflammation.

Sucrose-derived oligosaccharide is capable of regulating blood glucose and has great potential as an anti-inflammatory component in foods (Kang et al. 2016). The konjac oligosaccharide has markedly attenuated the inflammatory response to 2,4,6-trinitrobenzene sulfonic acid-induced experimental acute colitis (Liu et al. 2016). Comparing with its precursor, lactulose, oligosaccharides derived from lactulose have been characterized with slower fermentation by microbiota in the colon and showed beneficial effects in trinitrobenzene sulfonic acid-induced colitis rat. This kind of oligosaccharides would be able to reach the distal colon without great alterations. These properties could be of great interest in the treatment of

inflammatory bowel disease, because distal areas of the large intestine are typically affected in ulcerative colitis and involved very frequently in patients with Crohn's disease (Algieri et al. 2014). Oral administration of α-galacto-oligosaccharide (α-GOSg) and raffinose family oligosaccharides (RFOs) has significant protective effects against dextran sulfate sodium (DSS)-induced colitis. The beneficial effects of α-GOSg and RFOs were associated with the suppression of cyclooxygenase (cox-2) expression and possibly the other nuclear factor-kappa B (NF-κB)-related pro-inflammatory genes (Dai et al. 2018). Moreover, agaro-oligosaccharides (AGO) were found to be able to treat colitis through inducing the expression of heme oxygenase-1 in intestinal colonic mucosa. Also, increased colonic damage and myeloperoxidase activity after TNBS treatment was inhibited by AGO that can suppress the expression of tumor necrosis factor-α (TNF-α) induced by TNBS (Higashimura et al. 2013). D-galactose (DG) treatment mimicked the lung pro-inflammatory status as shown in the NA mice. FOS attenuated the DG-induced lung pro-inflammatory status and downregulated JNK/Jun pathway in the lung, which could be contributed to the probiotic and metabolic effects and metabolic products of FOS in the large intestine (Yeh et al. 2014).

The anti-inflammatory activities of HMOs and COS were reported. COS can inhibit inflammation and dyslipidemia in epididymal adipose tissue of diabetic mice (Zheng et al. 2018d). Synbiotics *Bifidobacterium infantis* and milk oligosaccharides (MO) are effective in reversing cancer-prone nonalcoholic steatohepatitis in western diet (WD)-fed FXR knockout mouse model (Jena et al. 2018). *B. infantis* and MO inhibited hepatic inflammation and reduced hepatic fat and liver injury, as well as normalize dysregulated bile acid synthesis and are useful to prevent NASH in WD-fed farnesoid x receptor knockout mice (Jena et al. 2018). Supplementation of infant formula with HMOs may be an important step toward improving the bioactivity of commercially available infant formula and promoting gut maturation and protection when mother's own milk is not available or insufficient (Rasmussen et al. 2017). The intestinal anti-inflammatory effect of goat milk oligosaccharides (OS) was assessed in trinitrobenzene sulfonic acid-induced colitis rat. Treatments fed with OS decreased in the anorexia and body weight loss, increased the trefoil factor 3 levels, reduced the bowel wall thickening and longitudinal extension of necrotic lesions, and downregulated the colonic expressions of interleukin 1β, inducible nitric oxide synthase, cyclooxygenase 2, and mucin 3. Thus, goat milk oligosaccharides have anti-inflammatory effects in rats with experimental colitis and may be useful in the management of inflammatory bowel disease (Daddaoua et al. 2006). HMOs also uniquely suit to provide optimal nutrition and immune protection to infants. Mice fed on 2′-fucosyllactose (2'-FL), one of the short-chain oligosaccharides associated with HMOs, have significantly increased vaccine-specific delayed-type hypersensitivity (DTH) responses accompanied by increased serum levels of vaccine-specific immunoglobulin (Ig) G1 and IgG2a in a dose-dependent manner. And increased activation marker (CD27) expression on splenic B lymphocytes was detected in 2'-FL-treated mice. Further, proliferation of vaccine-specific $CD4^+$ and $CD8^+$ T-cells, as well as interferon-γ production after ex vivo

restimulation, was significantly increased in spleen cells of mice receiving 2'-FL, which were in line with changes detected within dendritic cell populations (Xiao et al. 2018). COS also had some preventative effects such as alleviating atherosclerosis and enhancing the immune system. Treatment with COS can decrease the accumulation of lipid and significantly restore atherosclerosis in Apo E−/− mice and make a contribution to atherosclerosis prevention or treatment for elders in functional food (Zheng et al. 2018a). The murine model of the genital tract infected by *Chlamydia trachomatis* (Ct) was built to demonstrate the immune protective effects of chitosan oligosaccharides (COS) on mouse. Ten-day COS treatment increased the serum IgG antibody and IL-11 levels and spleen and thymus indexes, as well as reduced the positive infection rate and inclusion body formation with Ct, suggesting that COS can induce immune protection on the Ct-infected mouse genital tract and might be regarded as an alternative drug for the treatment of genital tract infection (Qian and Chen 2018). Alginate oligosaccharide (AO) administrated to the mouse model of ovalbumin-induced asthma showed that AO effectively decreased inflammatory cell numbers, eosinophil count, and IgE levels in BALF, and it dose-dependently inhibited asthmatic histopathological changes in the lung. AO can be a promising asthma treatment for its modulation of T-helper type 1 and type 2 cytokines (Bang et al. 2015). Zhang et al. have reported that COS treatment for 11 weeks upregulated the ratio of osteoprotegerin (OPG)/receptor activator of NF-κB ligand (RANKL) and downregulated the RANKL/RANK, thus improving the cartilage damage (both extent and grade) in OA male SD rats. COS may be used as a unique biological agent to prevent and treat osteoarthritis, and this effect is associated with modulation of the expression of osteoprotegerin and receptor activator of NF-κB ligand (Zhang et al. 2017). COS exposure led to a dose-dependent attenuation of LPS-induced secretion of TNF-α and IL-6 in the incubation medium. In addition, the corresponding reductions in TNF-alpha and IL-6 at the mRNA level indicated that exposure to these cytokines reduced the expression of these cytokines (Yoon et al. 2007). COS mitigates the glycerol-induced (acute renal failure) inflammatory response, improves renal function, and has the antioxidant effects in the kidney (Yoon et al. 2008; Fernandes et al. 2010). The anti-inflammatory effects of COS directly depend on their physical and chemical properties. The antioxidant and anti-inflammatory effects of enzyme synthesis depend on their degree of polymerization, while lower polymerization shows greater biological activity (Liang et al. 2016). Because it was observed to inhibit the expression of inflammatory genes caused by lipopolysaccharides (LPS), this was associated with reduced NF-κB (nuclear factor kappa-light-chain-enhancer of activated B cells). Therefore, COS can weaken the vascular endothelial inflammatory response induced by LPS (Li et al. 2014). Low-molecular-weight COS shows protective effect via inhibiting lung inflammation in ovalbumin-induced allergic asthma mice. The oral administration of LM-COS can effectively alleviate the allergic inflammation in vivo and be a good source material for development of a potent therapeutic agent against mast cell-mediated allergic inflammatory responses and airway inflammation in allergic inflammatory diseases, including asthma (Chung et al.

2012). COS supplement not only attenuate organ dysfunction but also improve survival rate in LPS injection-induced sepsis mice (Qiao et al. 2011).

AC oligosaccharides (ACOS) show better inhibitory effects on LPS-induced mRNA expression of pro-inflammatory cytokines including IL-6, IL-8, IL-1, TNF, and MCP-1 in macrophage cells and suppressed the inflammation in lung tissues of C57BL/6 mice (Zheng et al. 2018c). The suppressive effect of ACOS on inflammation may be an effective approach to prevent inflammation-related diseases. The anti-inflammatory effects of a mixture of glucosamine and chitooligosaccharides (GC), produced by bi-enzyme single-step hydrolysis, are represented by the relievation of knee joint swelling and partial remission of typical OA symptoms in osteoarthritis (OA) mice. This study showed that GC had strong anti-inflammatory effects and potential as a therapeutic agent against OA and other inflammatory diseases (Li et al. 2018a).

31.3.3 Antidiabetic Activity

From International Diabetes Federation, type 2 diabetes used to be called non-insulin-dependent diabetes or adult-onset diabetes and accounts for at least 90% of all cases of diabetes. It is characterized by insulin resistance and relative insulin deficiency, either or both of which may be present at the time diabetes is diagnosed. The diagnosis of type 2 diabetes can occur at any age. Type 2 diabetes may remain undetected for many years, and the diagnosis is often made when a complication appears or a routine blood or urine glucose test is done. It is often, but not always, associated with overweight or obesity, which can cause insulin resistance and lead to high blood glucose levels. People with type 2 diabetes can initially manage their condition through exercise and diet. Contributing to the edible safety and pharmacological activity, prebiotics play a critical role in preventing diabetes mellitus and obesity. Prebiotics are usually nondigestible carbohydrates and can selectively promote the growth of beneficial bacteria. Some studies show that type 2 diabetes and obesity are related to the dietary fiber intake. The dietary fiber can control the release of glucose into the blood with time and is conducive to the management of diabetes mellitus and obesity (Bennett et al. 2006). Functional oligosaccharides are considered as the important source of dietary fibers (de Alcantara et al. 2006), which can modulate satiety, glucose or lipid metabolism, and hypertension. The functional oligosaccharides have been discovered to reduce postprandial blood glucose and insulin responses and improve the overall blood glucose and lipid concentrations. The arabinoxylan oligosaccharides can prevent type 2 diabetes by reducing postprandial blood glucose levels as well as increasing insulin sensitivity and postprandial ghrelin secretion (Xu et al. 2009). FOS was reported to promote the growth of beneficial bacteria such as *Bifidobacterium*, *Lactobacillus*, and *Bacteroides*. Besides, it's benefit to diabetic individuals (Zheng et al. 2018b). Research on antidiabetic activity of oligosaccharides has received wide attention. A partially purified oligosaccharide from Rehmanniae Radix was shown for the first time to be an active principle of prepared Rehmanniae Radix that improved glucose intolerance in type 2

diabetic mice (Chiu et al. 2018). COS improve the disturbance in glucose metabolism and reverse the dysbiosis of gut microbiota in diabetic mice (Zheng et al. 2018b). Mannan-oligosaccharide (MOS) supplementation on C57BL/6 J mice fed a high-fat diet (HFD) results in attenuated high-fat diet-induced metabolic syndrome, including slower body weight gain, lowered serum lipids, and reduced insulin resistance (Wang et al. 2018b). MOS also modulate the overall structure of the gut microbiome, which is highly correlated with metabolic syndrome parameters (Wang et al. 2018a). *Ophiopogon japonicus* oligosaccharide (OJOS) treated to *db/db* diabetic mice for 8 weeks could effectively lower the body weights, blood glucose levels, and the AUCs during oral glucose tolerance test and inhibit the changes of 24 h urinary albumin excretion and 24 h urine protein amounts, glycosylated serum protein, total cholesterol, triglyceride, HDL-C and low-density lipoprotein cholesterol, and urea nitrogen and creatinine levels in serum, suggesting that OJOS shows significant hypoglycemic and protective effects in *db/db* mice (Wu et al. 2017). To study the anti-obesity and antidiabetic effects of neoagarooligosaccharides (NAOs), mice were fed with HFD + NAOs (0.5%, w/w) (HFD-0.5 group) for 64 days, which showed significant reduction of 36% for body weight gain and 37% for food efficiency ratios without abnormal clinical signs compared to the HFD group. Fat accumulation in the HFD-0.5 group was recovered nearly to the levels found in the normal diet group. NAOs also significantly decrease the size (area) of adipocytes and tissue weight gain in the perirenal and epididymal adipose tissues. After NAOs were absorbed by mice fed with HFD, the increased concentrations of total cholesterol, triglyceride, and free fatty acid in serum were also effectively ameliorated to the levels found in serum of the mice fed with normal diet. Also, insulin resistance and glucose intolerance in mice with HFD were distinctly improved, and adiponectin concentration in the blood was notably enhanced after NAO administration. Intake of NAOs can effectively suppress obesity by inducing production of adiponectin in the HFD-induced obese mice (Hong et al. 2017).

Low-molecular-weight chitosan oligosaccharide (GO2KA1) remarkably inhibited sucrase in all three parts of the intestine, while glucoamylase activity was decreased only in the middle and lower part. Sucrase, as a digestive enzyme secreted in the small intestine, catalyzes the hydrolysis of sucrose to its subunits fructose and glucose. The sucrase-isomaltase (SI) complex expression on mRNA level was evaluated; GO2KA1 had minimal inhibitory effect on the upper part and more pronounced inhibitory effect on the middle part, while the highest inhibition was observed on the lower part. Long-term GO2KA1 supplementation in mice shows significant blood glucose and HbA1c reduction, confirming the previous in vitro observations that GO2KA1 has inhibitory effect on carbohydrate hydrolysis enzymes, namely, sucrase or maltase (Kim et al. 2014).

31.3.4 Anticancer Activity

Cancer is one of worst nightmares for human, increasing with changing lifestyle, nutrition, etc. According to the report, cancer belongs to the large group of complex,

devastating diseases that entail uncontrolled cell growth with the potential to invade or affect any part of the body. Death due to cancer worldwide is projected to rise with an estimated 12 million deaths in 2030. Around 25 million persons are living with cancer around the world (Foster and Fenlon 2011). Therefore, cancer is a painful existence for the public. The formation of cancer cells in human body can be directly induced by free radicals. Multiple natural anticancer drugs like chemopreventive agents have gained positive effects on cancer treatment (Gurib-Fakim 2006). Oligosaccharides as a nature resource can be used indirectly to reduce cancer formation in human body. Recently, numerous studies reported that oligosaccharides have antiproliferative activity in cancer cell lines in vitro, as well as inhibitory activity against tumors growing in mice. Ginseng oligosaccharides can reliably inhibit the growth of mouse transplantable H22 cells and improve the weight of immune organs of tumor-bearing mice (Jiao et al. 2014). The antitumor and immunoregulatory effects of water-soluble ginseng oligosaccharides (WGOS) were further evaluated in hepatoma-22 (H22)-bearing mice, which demonstrated that treatment with WGOS inhibited tumor growth in vivo and significantly increased relative spleen and thymus weight, serum tumor necrosis factor-α level, spleen lymphocyte proliferation, natural killer cell activity, phagocytic function, and nitric oxide production secreted by macrophage in H22-bearing mice (Jiao et al. 2014). Chen et al. (2011) found that the Lewis X oligosaccharides-heparanase complex could be regarded as an ideal vaccine and represented a novel way for the therapeutical strategy of tumor. Agaro-oligosaccharide (AGO) feeding resulted in tumor appearance delay and tumor number decrease in the two-stage mouse skin carcinogenesis model. And prostaglandin E2 (PGE2) production was suppressed by AGO intake in 12-*O*-tetradecanoylphorbol-13-acetate-induced ear edema model. AGOs are expected to prevent tumor promotion by inhibiting PGE2 elevation in chronic inflammation site (Enoki et al. 2012). Carrageenan, extracted from marine red algae, has been largely applied as nutrient supplements and biochemical reagents and in medicine. The sulfonated and non-sulfonated carrageenan oligosaccharides were assayed for the antitumor activity in sarcoma 180 tumor in mouse. After 15 days of transplantation, the weight of tumor in mice increased to 1.248 g. When the mice were provided with anticancer drug cyclophosphane by intramuscular injection, the weight of tumor decreased to 0.184 g, and the rate of tumor inhibition came to 85.3%. For the non-sulfonated (sulfur content 1.0 per disaccharide unit) and light-sulfonated (sulfur content 2.1) oligosaccharides, the weights of tumor decreased to 0.442 g and 0.272 g, and the rates of tumor inhibition reached 64.6% and 78.2%, respectively, in the dose of 100 mg kg^{-1} (Mou et al. 2003; Yeh et al. 2014). Water-soluble oligosaccharides were extracted from the fruiting bodies with water and then used to examine the anticancer activitis in mice. Gray oligosaccharide (LDGO-A) has potential to be the compounds of natural antitumor by which the tumor inhibitory rate can reach to 40.02% and the tissues arrange more regular and firmer in histology of immune organs (Ding et al. 2015). Mice treated with chitosan (5 mg/kg/day) in combination with *Agaricus blazei* Murill (246 mg/kg/day) for 6 weeks have reduced levels of glutamic oxaloacetic transaminase (GOT) and vascular endothelial growth factor (VEGF) (Yeh et al.

2015). And, N-acetyl-d-glucosamine oligomer (NACOS) and glucosamine oligomer (GO) have significant effect on suppressing tumor growth and lead to tumor tissue apoptosis apparent in a tumor (colon 26)-bearing mouse model, which can be candidates as antitumor functional foods (Masuda et al. 2014).

Recently, many researchers have reported that the hydrolyzed products of chitosan N-acetyl-d-glucosamine oligomers (chitin oligosaccharide; NACOS) and D-glucosamine oligomers (chitosan oligosaccharides; COS) possess numerous biology activities (Azuma et al. 2015) and the chemopreventive effect of COS in colon cancer cells (Nam et al. 2007). The treatment effects were evaluated measuring the activities of enzymes quinone reductase (QR), ornithine decarboxylase (ODC), glutathione S-transferase (GST), and glutathione (GSH) in human colorectal adenocarcinoma cell line ht-29 (cox-2). COS had a chemical effect on colon cancer by increasing QR and GST activities and GSH levels, as well as by inhibiting ODC activity and cox-2 expression (Azuma et al. 2015). COS was reported to slow down the growth of tumors in mice (Zhai et al. 2018). COS may also be beneficial in suppressing colorectal cancer development, and a progressive disease can be detected early by colonoscopy (Mattaveewong et al. 2016). COS also have bioadhesive characteristic (Tokumitsu et al. 2000). Good adhesion was found in epithelial tissue and mucous coats on the tissue surface. The positive charges of the COS can alter the ion environment of the cell membrane, which is important to maintain cell integrity and many of the functions necessary for cell growth (Zou et al. 2016). A negative charge on the surface of a tumor cell can independently trigger its signal transmission. As a result, malignant biological behaviors such as invasion and metastasis occur. COS are the only natural polysaccharides that have a cationic charge. Therefore, the electrostatic effect is proposed to help absorb the COS on the cell membrane of tumor cells and change the charge properties, thus changing the permeability of tumor cells. Conversely, the mutual repulsion between the COS and normal cells has the same positive charge resulting in selective targets for tumor cells other than normal cells (Huang et al. 2006). Matrix metalloproteinase-9 (MMP-9) is vital components in cancer invasion and metastasis. The upregulated expression of MMP-9 leads to the release of vascular endothelial growth factor (VEGF) and formation of angiogenesis. COS can suppress tumor angiogenesis by inhibiting the expression of MMP-9, which consequently suppresses the expression of VEGF (Xu et al. 2012). It was suggested that tumor cells were not killed directly by COS but indirectly related to the immune stimulation effect of COS. This increases the production of lymphocytes, induces lymphocytic cytokines, and promotes the proliferation of lysocytic lymphocytes, thus producing antitumor effect (Tokoro et al. 1988).

31.3.5 Antiaging Activity

The function of COS in skin has attracted increasing attention in recent years for its skin-permeable and moisturizing abilities. COS can markedly suppress the UVB-induced increase in mRNA and protein expression of matrix

metalloproteinases-1 (MMP-1) and matrix metalloproteinases-3 (MMP-3) in skin fibroblasts. Hence, the deeper mechanism of antiaging is explored by researchers. The experiment of anti-photoaging activity gradually came into research's view. Topical application of COS contributed to the prevention of ultraviolet-induced skin dryness, epidermal hyperplasia, and wrinkle formation in mouse skin manifested by increasing activities of antioxidative enzymes and suppressing the production of pro-inflammatory cytokines, which presumably worked in concert to inhibit the excessive degradation of collagen (Kong et al. 2018a). COS also has a protective effect against D-gal-induced damages of subacute aging in mice mainly by promoting the serum IgG and IgM levels, preventing the atrophy of mice thymus and spleen, as well as increasing the activities of pivotal antioxidant enzymes in mice liver and kidney, revealing that the mechanism might be closely associated with its beneficial modulation of oxidative and immune system (Kong et al. 2018b).

31.3.6 Anti-obesity Activity

Obesity is one of the most important public health problems, with more than 2.6 million people dying each year from obesity and its related complications. More than 1.7 billion adults worldwide have excess weight among which 312 million are obese (Ejtahed et al. 2018). With the social and economic development, everyone's pace of life has changed a lot compared to the past, especially in the diet. Unhealthy eating patterns can cause a range of diseases. Recent research has shown that the gut microbiome is a new factor in obesity and related metabolic risk in humans (Blandino et al. 2016). Excess calories, mainly stored in fat pads, cause the systemic deregulations. Continuous supply of these calories may further get stored to the non-adipose tissues in the form of fat and called as ectopic fats that further promote insulin resistance and nonalcoholic fatty liver. Adipose tissue hypertrophy/hyperplasia recruits macrophages and releases inflammatory cytokines leading to low-grade systemic inflammation (Singh et al. 2017, 2018). Fucosylated chondroitin sulfate oligosaccharides from *Isostichopus badionotus* regulate lipid disorder in C57BL/6 mice fed a high-fat diet (Li et al. 2018b). COS injection lead to reduce the dietary intake, body weight, and glucose and lipid levels, which may act as a potent downregulator for expression levels of obesity-related genes in *ob/ob* mice. *Rehmannia glutinosa* oligosaccharides exhibited strong protective effects against high l-carnitine-induced liver injury in mice (Li et al. 2016). COS also reduce plasma total cholesterol (TC), aortic lipid deposition, and body weight representing a clear function in regulating blood lipids (Muanprasat and Chatsudthipong 2017). Cyclodextrins (CDs) has same function as well. CDs are cyclic oligosaccharides that have been generated from starch by enzymatic cleavage of the amylose helix, of which the three most studied species consist of six, seven, or eight glucopyranose units called α-CDs, β-CDs, and γ-CDs, respectively (Davis and Brewster 2004). In particular, the β-CDs are able to interact with cell membranes and are known to extract cholesterol and other lipids from the membranes (Irie et al. 1992; Ohtani et al. 1989), and CDs can extract cholesterol from the plasma membrane, and then, cholesterol from the

intracellular compartments moves to the plasma membrane to replace the lost cholesterol. Also, CDs can enter the cell via endocytosis and directly bind and export cholesterol from the endolysosomal compartments (late endosomes and lysosomes), and CDs, either at the plasma membrane or after endocytosis, can induce cellular signaling pathways that promote intracellular cholesterol (Szente et al. 2018). Bovine milk oligosaccharides and *Bifidobacterium longum* subsp. *infantis* jointly restore diet-induced obesity intestinal microbiota and barrier function defects in mice (Boudry et al. 2017). And isomalto-oligosaccharides, green tea extract, and their combination exerted beneficial effect against high-fat diet-induced negative metabolic (gut and adipose tissue) and nonalcoholic steatohepatitis phenotype primarily by preventing dysbacteriosis and resultant endotoxemia (Singh et al. 2017, 2018). Chitosan oligosaccharide capsules (COSCs) possess anti-obesity effect via activating the JAK2-STAT3 signaling pathway to alleviate leptin resistance and suppressing adipogenesis to reduce lipid accumulation on rats suffering from obesity induced by a high-fat diet (Pan et al. 2018b). Fatty acid synthesis and blood triglyceride content were effectively reduced after galacto-oligosaccharides (GOS) feeding which may improve lipid metabolism in mice (Cheng et al. 2018). Additionally, NACOS can improve glucose metabolic disorder and suppress mRNA expression of the protein regulators related to lipogenesis, gluconeogenesis, adipocyte differentiation, and inflammation in adipose tissues, as well as inhibit the destruction of the gut barrier in HFD-treated mice (Zheng et al. 2018b). One study investigates the anti-obese effects of glucosamine (GLC) and COS on high-fat diet-induced obese rats. The result demonstrates that GLC and COS improve dyslipidemia and prevent body weight gains by inhibiting the adipocyte differentiation in HFD-fed rats (Huang et al. 2015).

31.3.7 Promoting Digestion Function and Gut Health

The intestinal microflora plays an important role in the metabolism of endogenous and exogenous substances in the diet and is thought to participate in beneficial and deleterious effects on human health. Fermentability and viscosity are the two main characteristics of dietary fibers affecting energy intake weight gain, fat accumulation, and the lipid profile (Hadri et al. 2015; Kristensen and Jensen 2011). At present, fermentable fibers such as FOS have a potent short-term inhibitory effect on food intake and promote a decrease of body weight. These effects of fermentable fibers are thought to be related to their modulation of gut microbiota and to the production of short-chain fatty acids (SCFAs) which act as indirect regulators. Functional oligosaccharides can promote the increase of short-chain fatty acids. According to the studies, constipation can be affected by the composition of the microbiome and its metabolic activity (Liebregts et al. 2007). Fructo- and galacto-oligosaccharides are known to stimulate the growth of *Bifidobacterium* and *Lactobacillus* and also inhibit potentially pathogenic bacteria, enterobacteria, *Clostridium difficile*, and *Salmonella* (Xu et al. 2009). Besides, short-chain fatty acids produced by *Bifidobacterium* can stimulate intestinal peristalsis and improve fecal humidity

through osmotic pressure, thus playing a role in the treatment of intestinal diseases (Fernández-Bañares 2006). It can improve the absorption of water and electrolytes in the small intestine, thereby leading to a reduction in the incidence of diarrhea and its duration. Short-chain fatty acids are an important source of energy for enterocytes and are key signaling molecules for the maintenance of gut health. In the case of newborns, the gastrointestinal tract is a vital part of their immune system. The intestinal epithelium constitutes a functional barrier that prevents pathogenic invasion of the host through the gut microbiome and provides the active components of the lymphocyte lineage that modulate the immune response (Lewis et al. 2017). The immature intestinal tract of neonates has excessive expression of inflammatory genes and insufficient expression of genes regulated by congenital signal feedback. This can lead to an exaggerated immune response leading to excessive inflammation. Breast feeding can substantially alter the neonatal intestinal immunity (Newburg and He 2015). Studies show that the human milk oligosaccharides can indirectly increase the production of short-chain fatty acids, and these augmented levels are mediated by *Bifidobacterium* species. SCFAs can interact with the receptors GPR41 and GPR43, increasing the intestinal secretion of polypeptide YY and glucagon-like peptide 1 (GLP-1), respectively (Canfora et al. 2015).

FOS supplementation results in the enlargement of the cecum and increased cecal acidification. FOS also effectively boosts the apparent absorption rate of calcium, magnesium, and iron, as well as restores the phytic acid-impaired magnesium and iron apparent absorption rates, additionally significantly increasing hepatic zinc levels and femoral magnesium levels (Wang et al. 2010). Dietary supplementation of 2 g/kg COS can increase the growth performance of weaning pigs by increasing dry matter and nitrogen digestibility and modulating the frequency of diarrhea (Zhou et al. 2012). It has been reported that the inhibitory effect of dietary fiber on food intake can be lost over time and that FOS gum limits fat storage (Hadri et al. 2015). NAOS can be effectively resistant to enzymes of the upper gastrointestinal tract, which remained intact after 24 h incubation with different amylolytic enzymes. NAOS remarkably stimulated the growth of *Bifidobacterium* and *Lactobacillus* in Man-Rogosa-Sharp (MRS) medium, anaerobically, and significantly increased the numbers of *Lactobacillus* and *Bifidobacterium* ($p < 0.05$) in fresh feces or cecal content while reducing putrefactive microorganisms in vivo. Mice fed with 2.5% (w/v) NAOS for 7 days had larger increases in colonic beneficial bacteria population than those fed with even 5% (w/v) FOS for 14 days. NAOS may be a great prebiotic for host (Hu et al. 2006). Co-supplementation of cranberry extract (CRX) and isomalto-oligosaccharides (IMOs) significantly improved cecal SCFA contents, gut beneficial bacterial quantity, gut histology, and related changes (colon mucin production, gut permeability) as compared to individual agents in HFD-fed mice. It also prevented HFD-induced systemic and tissue inflammation, glucose intolerance, and systemic obesity-associated metabolic changes in the adipose tissue and liver. The combination of CRX and IMOs appeared more effective in the prevention of HFD-induced gut derangements (Singh et al. 2017, 2018). The low-molecular-weight chitosan may have a therapeutic effect on osteolytic diseases for its inhibition effect on skull bone damage in LPS-induced mice (Guo et al. 2018). The mixture of

oligosaccharides and other substance has tremendous potential. A novel prebiotic blend (PB) composed of FOS, GOS, inulin, and anthocyanins can effectively prevent the development of irritable bowel syndrome (IBS) by attenuating the inflammatory response both in Caco-2 cells and the post-infectious IBS model. And pretreatment of PB in mice effectively reduces the severity of the IBS symptoms and modulates the gut microbiota in the PI-IBS model. This provides biological plausibility to the usefulness of this prebiotic product as a preventive measure for gastrointestinal dysbiosis and dysfunction (Chen et al. 2017). Another study shows the combination of IMOs with cinnamaldehyde presents untoward effects on the resident gut microbiota and associated metabolic outcomes in HFD-fed mice (Singh et al. 2017, 2018).

Human milk oligosaccharides (HMOs) consist of free oligosaccharides and have high structural diversity and represent the third largest group of bioactive molecules in human milk (Kulinich and Liu 2016). The vast majority of HMOs contain a lactose, polylactosamine, or lacto-*N*-biose core. Galactose, glucose, fucose, *N*-acetylglucosamine, and the sialic acid derivative, *N*-acetyl-neuraminic acids, are the five monosaccharide building blocks that can constitute HMOs (Kobata 2010). All HMOs carry lactose (Galβ1-4Glc) at the reducing end, which can be elongated in a beta-1,3 or beta-1,6 linkage by two different disaccharides, either type 1 carbohydrate structures (containing Galβ1-3GlcNAc units) or type 2 structures (containing Galβ1-4GlcNAc units) (Zhao et al. 2017). Because humans lack the enzymes (sialidases or fucosidases) to break down HMOs, these compounds reach the colon intact where they are digested by bacteria within the intestinal microbiota (Plaza-Diaz et al. 2018). HMOs are considered as prebiotics to promote the growth of a favorable microbiota. HMOs can induce increased levels of *Bifidobacterium* in the colonic flora of breast-fed infants, accompanied by a great reduction in pathogenic potential bacteria by the bifidogenic activity of HMOs (Moon et al. 2016; Thomson et al. 2018). HMOs have a great influence on the composition of intestinal flora. Therefore, we can selectively use some *Bifidobacterium* to produce beneficial effects on the human body (Zhao et al. 2016).

31.3.8 Protective Liver Function

Alcohol abuse is one of most important health issues, as it causes 3.8% of all deaths (Rehm et al. 2009). The alcohol excessive consumption is also a major cause of liver disease as it could trigger serious liver injuries and result in liver fibrosis and cirrhosis. According to the reports of US National Institute on Alcohol Abuse and Alcoholism, alcohol-induced liver disease accounts for up to 48% of cirrhosis-related deaths in the United States and is the leading cause of death from liver injury-related deaths in other countries (Gao and Bataller 2011). In addition, although the acetaminophen (*N*-acetyl-*p*-aminophenol, APAP) as an antipyretic and analgesic drug is safe when taken at prescribed doses, an overdose can induce severe hepatotoxicity in both humans and experimental animals (Thomas 1993). APAP is primarily metabolized in the liver by phase II conjugating enzymes, mainly UDP-glucuronosyltransferase (UGT) and sulfatase, to generate the nontoxic

metabolites APAP-glucuronate and APAP-sulfate (Thomas 1993). *N*-acetyl-*p*-benzoquinone (NAPQI) as the cytochrome P450-mediated metabolic APAP metabolites can cause liver damage, whose toxicity binds to cell macromolecules such as proteins, lipids, and DNA (James et al. 2003). NAPQI also reacts with glutathione (GSH), causing cell GSH failure and producing reactive oxygen species (ROS) in the liver. In the case of APAP overdose, the induction of hepatic antioxidant enzyme activity, such as NADPH quinone oxidase 1 (NQO1) and heme-1 (ho-1), may be an adaptive response to counteract the imbalance of antioxidant homeostasis in the liver, thereby reducing ROS formation and limiting the progression of hepatotoxicity (Aleksunes et al. 2006). Natural products that decrease cytochrome P450 enzyme activity (Mutlib et al. 2006) and increase antioxidant enzyme activity or GSH levels may attenuate APAP-induced liver toxicity (Acharya and Lau-Cam 2010). In vitro and in vivo studies have shown that COS can alter drug-metabolizing enzyme (DME) and antioxidant system. COS has been shown to increase the activity of the second-stage detoxification enzymes such as NQO1 and glutathione S-transferase (GST) enzyme (Nam et al. 2007) and to induce intracellular GSH level (Mendis et al. 2007). At the same time, COS has been demonstrated to have hepatoprotective activity against chemically induced liver injury (Chen et al. 2005).

31.3.9 Calcium Absorption Promotion

Calcium is an essential nutrient in bone hydroxyapatite, and an adequate dietary intake of calcium during childhood and adolescence is important for mineralization of the skeleton and achievement of genetically programmed peak bone mass (Sanwalka et al. 2012). Low-calcium intake in adolescent girls is associated with an increased risk of bone fractures later in life (Abrams et al. 2004). Therefore, optimal calcium intake is very important during adolescence. Most of calcium absorption occurs in the small intestine. However, if the insoluble, unabsorbed calcium coming from the small intestine is maintained in an ionic form, about 5–10% could occur in the colon (Younes et al. 1996). Nondigestible FOS is not hydrolyzed enzymatically in the small intestine but is fermented by resident microbiota in the colon, producing SCFAs that lower intraluminal pH and thereby may increase mineral solubility (Cummings and Macfarlane 2002). In addition, the low pH modifies the colonic microbiota and increases proliferation and activity of beneficial flora, such as *Lactobacillus* species (Macfarlane et al. 2006). However, even a proper diet does not guarantee a proper calcium balance. In addition to quantity, its absorption is a key factor in determining the biological availability for bone development and maintenance. In some cases, poor calcium balance may be due to intestinal malabsorption due to infection, inflammation, or pathology. Some people in the calcium-deficient population have chronic bowel diseases, including celiac disease (Krupa-Kozak et al. 2017). Inulin, a polydisperse carbohydrate material consisting mainly of beta (2–1)fructosyl-fructose links, is an example of prebiotic naturally occurring in tubers, bulbs, and tuberous roots of several edible fruits and vegetables (Drabinska et al. 2016). Inulin and other inulin consumption

also lead to the production of SCFAs. On the other hand, they stimulate the growth and/or activity of selected symbiotic bacteria, including health-promoting *Bifidobacterium* and *Lactobacillus* (Rossi et al. 2005). Moreover, inulin and oligofructose are not hydrolyzed by the human digestive enzymes nor absorbed in the upper part of the intestinal tract (Ellegard et al. 1997). Following ingestion of a few grams per day of inulin or oligofructose, the composition of the fecal flora of human volunteers is significantly modified: *Bifidobacterium* becomes the dominant genus, and potentially harmful species such as clostridia are decreased (Roberfroid et al. 1998). In human trial, scientist has validated a stable isotope technique to determine the true intestinal calcium absorption allowing to distinguish the exogenous calcium and endogenous calcium, thus measuring true calcium absorption. These measurements were based on the amount of calcium isotopes in urine after 24 h of collection. There was no significant difference in mineral uptake among healthy young adults supplied with a 15-gram/day placebo, inulin, or oligofructose, respectively, in this study. If the large intestine is the major place in which fructans enhance calcium absorption, a 24-h period of urine collection may be too short however to detect the effect. This experiment at least confirmed that fructans have no adverse effects on calcium absorption (Franck 2006). In the basis of these results, researcher performed a similar study but this time with a group of male adolescents and collected urine sample about 36 h instead of 24 h. Adolescents were chosen because it is thought that the mineral absorption rate is highest during adolescence. Twelve volunteers consumed 15 g/day of either oligofructose or a placebo (sucrose) for 1 week. A significant increase (+26%; $p < 0.05$) in the fractional calcium absorption from 47.8% (placebo) to 60.1% (oligofructose) was observed upon ingestion of oligofructose. This evidence indicates that oligofructose may help to maximize the peak bone mass in adolescents (Franck 2006).

31.4 Application in Foods

The current trend shows the demand for the functional foods has increased vigorously. Among this category, the functional oligosaccharides are beneficial ingredients implied in productive process. What's more, the oligosaccharides derived from plant, animals, and microbial sources were widely used in daily food, beverages, bakery products, processed fruits/vegetables, confectionary, infant formulas, and meat industry. With the extensive use of functional oligosaccharides, the annual production of oligosaccharides has been increased annually. There were about 20 kinds of oligosaccharides that were put into quantity production. Japan and Europe were the leading manufacturing market to produce oligosaccharide. Both of them have produced the oligosaccharides on a mass-factory scale 35 years ago, especially the production of fructo-oligosaccharide (Panesar et al. 2018). Besides, Europe in 2015 had accounted for the biggest market in the production of oligosaccharide which was added to infant formula. According to the data showed in related literature, the market value of prebiotics reached $1.17 billion in 2015, which indicated that the oligosaccharide contained within prebiotic would bring high

profits. And with the increasing demand for prebiotic, the market profits would be substantial (McDougall 2011). In 2011, the demand for functional oligosaccharide around the world reached up to 1.35 million tons. In 2010, the demand mass of isomalto-oligosaccharide (10,000 tons) was the most in China, the demand quantity of fructo-oligosaccharide (80,000 tons) was second, while the gross product in China was only 12,0000 tons which couldn't satisfy the numerous requirement of the society.

Nowadays, along with the alteration of people's diet concept, the public focused not only on tastes of food but also on the function of food. Meanwhile, the fructo-oligosaccharide (FOS) could serve as the flavoring agent and nutrient supplements in food. The sweetness of fructo-oligosaccharide is 0.4–0.6 times sweeter than sucrose, so it is used as full-fat ice cream at 10% and 30% sucrose replacement levels with minor effect on the apparent viscosity and pseudoplasticity (Soukoulis et al. 2010). Yogurt is well populated in Mediterranean, Asia, and Central Europe market, but the sour taste of yogurt can be produced by *Streptococcus thermophiles* and other acid-forming bacteria in the process of production. The addition of FOS can mask the sour taste to enhance acceptability of products (Irvine and Hekmat 2011). What's more, it plays a vital role in fermentation time and viability of the probiotic strain during storage (Singla and Chakkaravarthi 2017). The laxative effect and sensory of biscuits added with FOS was enhanced. In the meat industry, FOS was used to improve technological parameters. Especially, addition of short-chain FOS not only has no effect on weight loss and water activity but also reduced the energy with 92 kcal/100 g (Bali et al. 2015). Huet et al. (2016) had found that partly fermented infant milk formulae containing short-chain GOS and long-chain FOS were well-tolerated and had no side effect on the growth of healthy infants. The fructo-oligosaccharides were also used in fruit juice and act as fortification to improve the quality of product (Renuka et al. 2009). What's more, the addition of FOS in frozen dough improved the baking quality even after frozen storage for up to 8 weeks. The added FOS alleviated deterioration of frozen dough and thus resulted in increases in proof volume and loaf volume of bread and decrease in hardness of bread crumb. Thus it can be used in bakery food to improve edible quality (Park et al. 2016). With the extensive use of FOS, the market value of FOS is a considerable figure. FOS was firstly researched and developed by Meiji Japan, which is one of the leading manufacturers. In 2007, the FOS sales volume in Japan was 3,000 tons and kept a 12.8% market share of functional oligosaccharides. And Japan sales accounted for 24.72% of the global market share. China had a late starting for the exploitation of FOS, but the productivity ranked top among the world with the productive mass for 15,000 tons.

Due to the nondigestible and low-cariogenic feature of galacto-oligosaccharide, it was applied in beverage, infant milk formula, functional food, and baked goods (Czermak et al. 2004). The addition of GOS to yogurt can produce smoother texture and not break down this prebiotic in the gut. GOS is also applied in beverage because it can clear solutions and sustain high processing temperatures during machining process. Its low glycemic index makes it appropriate for patients suffering diabetes or cardiovascular disease (Sangwan et al. 2011). Besides, GOS can selectively

stimulate the growth of probiotic in the gut which can be exploited by pharmaceutical (Torres et al. 2010). Japan was the first country to put the galacto-oligosaccharide (GOS) into commercial process with the sales figure $200 million, and the sales in world reached up to $1,000 million in 2004. Further, the yearly output of GOS in the worldwide market was 94.1 kilotons and is expected to increase to 175.7 kilotons by 2020. Moreover, the demand of GOS in China market also increased annually (Panesar et al. 2018).

Inulin is a common prebiotic, which was firstly extracted from the tuber of inula in 1804, and was added in bakery products to encapsulate starch granules, thus lowering their digestion rate. In addition, inulin can improve the color of white bread through Maillard reaction (Poinot et al. 2010). With the increasing demand for calorie-controlled and healthier food, various food industries were forced to derive few alternative safe sweeteners for consumption. The use of inulin as a fat replacer in ice cream with levels of 9% results in enhanced consistency and stickiness (Akbari et al. 2016). To exploit a palatable and nutritive meat product, inulin is supplemented in minced meats as fat replacer with reduced fat content, and the color, texture, and flavor are similar to the meats without inulin (Rodriguez Furlan et al. 2014). Calories from the fermented sausage were significantly reduced on 10% inulin addition. The short-chain inulin which contains various kinds of saccharides was widely used for the production of inulin oligosaccharides (IOS). Inulin and resistant starch could be used to take the place of 7.2% of fat in imitation Mozzarella cheese (Bi et al. 2015). At present, there is only three commercial manufacturing companies (Orafti, Warcoing, and Sensus) producing inulin. The Beneo Orafti Co., which is the member of Sudzucker group, lies in Belgium and is also the biggest inulin manufacturing enterprise around the world. The annual output of inulin is up to 400,000 tons with the annual yield for approximately $0.7 billion. Orafti also uses inulin as raw material to produce IOS and FOS. Warcoing Co. is also located in Belgium, which was the first company to produce inulin. The output of inulin comes up to 100,000 tons with a market segment of 50%. Sensus Co. is the subsidiary company of Cosun Group, which is seated in the Netherlands. The annual sales revenue is up to $1.26 billion. Above all, Europe occupies the majority of inulin market. Besides, the Innova Market Insights data show that inulin has the highest market share of 22% in dietary fiber-containing food and beverage in 2017. And the compound annual growth rate (CAGR) of inulin industry is estimated to reach 9.1% from 2015 to 2022. The global market size is expected to total $2.37 billion. The application and effect of FOS, GOS, and inulin is present in Fig. 1.

A mixture of FOS, GOS, and inulin is also a common ingredient applied in food (Fig. 2). For example, the mixture of FOS and inulin has been incorporated in edible coatings of apples to enhance the nutritional benefits and shelf life of freshly cut apple by reducing the water loss and selectively controlling gas permeability (Rößle et al. 2010). Besides, the use of FOS/inulin (50:50) can enhance the acceptability of *Lactobacillus acidophilus* and *Bifidobacterium animalis* contained in petit-suisse cheese and increase the content of linoleic acid in cheese (Rodrigues et al. 2012; Cardarelli et al. 2008). The addition of inulin and FOS improves the appearance and mouthfeel of orange cake with brown color and chewiness (Volpini-Rapina et al. 2012).

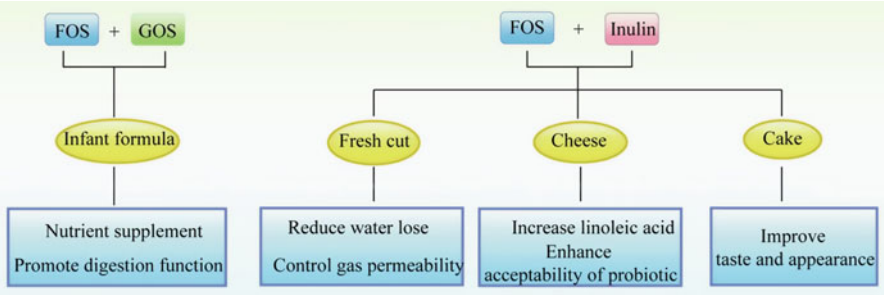

Fig. 2 The application of the mixture containing GOS, FOS, and inulin
