Preface

Phytochemicals are non-nutritive compounds that have properties to protect health, preventing diseases. They are not essential nutrients, which means that the body does not need them to sustain life. It's well known that plants produce these chemicals to protect themselves, but recent studies have shown that they can protect people from disease too. There are many thousands of known phytochemicals. Some known phytochemicals are lycopene in tomatoes, isoflavones in soybeans, and flavonoids in fruits.

Phytochemicals have existed as long as plants have, but we only know of their existence for about a hundred years. Medicinal plants are used traditionally all over the world. Knowledge of traditional medicine may have developed over the centuries by trial and error. The Chinese have the oldest medical system. Over 5,000 years ago, Chinese medicine was based on the influence of yin and yang and the five ingredients. The first mentions of herbal medicine come from 2800 BC when the Chinese Emperor Shennong wrote the words "The Great Native Herbal." Hippocrates (460–377 B.C.E.) and Aristotle (384–322 B.C.E.) brought herbs from India and Egypt to Europe. The Greek physician Dioscorides wrote "De Materia Medica" in the first century C.E.

In the nineteenth and twentieth centuries, the main goal of scientists was to discover active ingredients with medicinal or insecticidal properties. Results of such efforts were the discovery of salicylic acid, morphine, and pyrethroids. In the 1980s, many laboratories began identifying phytochemicals in plants that could be used as drugs. Many of the phytochemicals discovered appear to prevent or help against cancer, heart disease, and stroke. At the same time, other scientists were conducting epidemiological studies to determine the relationship between the consumption of certain phytochemicals and human health. Most studies show that a diet rich in plants reduces the incidence of cancer and heart disease.

Currently, most new drugs are not found in plants, but they are newly synthesized products. Recently, we have taken a new interest in the discovery of phytochemicals. What regains attention is the fact that many chemicals have not yet been discovered. New, state-of-the-art laboratory technology facilitates the discovery and identification of new phytochemicals.

The *Handbook of Dietary Phytochemicals* summarizes the latest advances in the chemistry, biological activity, nutrition, and function of dietary phytochemistry, as

well as the latest advances in the health and function of phytochemical-rich foods. It consists of 44 chapters that discuss the different chemical types of phytochemicals in our diet and food as well as present data collected from animal or human experiments that are directly related to human health. Each chapter covers chemistry, epidemiological studies, bioavailability, function, and safety of biological activity (animal experimentation) in humans and products on the market. In addition, over 200 figures make it easier to understand the main findings in each area. This book will become a valuable tool for researchers in food science and nutrition.

Full Professor of Nutrition and Food Science Dr. Jesus Simal-Gandara
University of Vigo (Spain)

About the Editors

Jianbo Xiao
Faculty of Food Science and Technology
University of Vigo
Vigo, Spain

Prof. Jianbo Xiao is at present a professor in the Faculty of Food Science and Technology, University of Vigo, Spain. He obtained his Ph.D. in nutritional science from Okayama Prefectural University, Japan (2009). Prof. Xiao worked as a postdoc supported by the AvH Foundation at the University of Würzbug, Germany (2013–2015). Then, he worked as an assistant professor at the University of Macau from 2015 to 2020. His research focuses on dietary polyphenols. He has accepted and published more than 300 peer-reviewed papers in journals such as *Nature Reviews Drug Discovery*, *Biotechnology Advances*, *Medicinal Research Reviews*, *Trends in Food Science & Technology*, *Critical Reviews in Food Science and Nutrition*, *Food Chemistry*, *Molecular Nutrition and Food Research*, and so on (Google scholar citation:11000, H-index=56). Prof. Xiao was selected as 2016, 2017, 2019, and 2020 Clarivate Analytics Highly Cited Researcher (HCR) in agricultural science, and he is currently "the editor in chief of *Food Frontiers* (Wiley), special content editor of *Food Chemistry* and associate editor of *Journal of Berry Research, Frontiers in Pharmacology* and *Phytomedicine Plus*, and the editorial board member of *Trends in Food Science & Technology , Critical Reviews in Food Science and Nutrition, Journal of Nutritional Biochemistry, Food and Chemical Toxicology, Phytomedicine, Industrial Crops and Products, Environmental Toxicology and Pharmacology, Current*

Drug Metabolism, Food Science and Human Wellness, and so on." He was chairman of the 2015 International Symposium on Phytochemicals in Medicine and Food (ISPMF2015, Shanghai) organized by the Phytochemical Society of Europe, and its second edition (2-ISPMF, Fuzhou, 2017), third edition (3-ISPMF, Kunming, 2018), and fourth edition (4-ISPMF, Xi'an, 2020).

Satyajit D. Sarker
Liverpool John Moores University
Liverpool, UK

Prof. Satyajit D. Sarker is Professor of Pharmacy and the Director of School of Pharmacy and Biomolecular Sciences, Liverpool John Moores University (LJMU), Liverpool, UK. He is the Founding Head of the Centre for Natural Products Discovery at LJMU. He obtained his B.Pharm. (Hons.) and M.Pharm. (postgraduate) degrees from the University of Dhaka and his Ph.D. in Phytochemistry from the University of Strathclyde, Glasgow, UK. Prof. Sarker is a world-renowned natural products researcher, whose research falls in the area of pharmaceutical and natural products chemistry and rational drug design (medicinal chemistry), and focuses on anticancer, analgesic, anti-inflammatory, antioxidant, antimalarial, and antimicrobial properties, and cancer chemopreventive and wound-healing potential of purified compounds from higher plants as well as novel synthetic organic molecules.

Prof. Sarker is one of the most cited phytochemists and has over 630 publications with more than 18,800 citations, an h-index of 61, and an i10 index of 401 (Google Scholar). He has been the Editor-in-Chief of *Phytochemical Analysis* since 2010, has been part of the Editorial Advisory Board of more than 40 journals, and regularly reviews articles for more than 80 international journals. He coauthored the popular textbook, *Chemistry for Pharmacy Students*, published by Wiley & Sons in 2007, and subsequently, this book was translated in Indonesian, Japanese, Greek, and Portuguese languages; the second edition of this book was published in 2019. He is also the coauthor of the only book on steroid dimers, published by the same publisher in 2012. He coedited both the second and third editions of the book, *Natural Products Isolation*, published by Humana Press

Springer-Verlag, respectively, in 2005 and 2012. His novel contribution in the field of phytochemistry is the book *Computational Phytochemistry*, published by Elsevier in 2018, and his latest book is *Medicinal Natural Products: A Disease-Focused Approach*, published by Elsevier in 2020.

D. H. C. Yoshinori Asakawa
Institute of Pharmacognosy
Tokushima Bunri University
Tokushima, Japan

Prof. Dr. D.H.C. Yoshinori Asakawa first studied biology at the Tokushima University, then went to graduate school at Hiroshima University in 1964 and studied organic chemistry, and obtained his PhD degree there and was appointed as a research assistant. Then, Prof. Asakawa went to the Université Louis Pasteur, France, as a postdoctoral fellow, where he worked for 2 years (1972–1974) with Prof. Guy Ourisson, one of the most original natural product chemists worldwide. In 1976 he moved to Tokushima Bunri University as an associate professor, and was promoted to full professor in 1981. Prof. Asakawa served as dean twice, and since 1986, he is director of the Institute of Pharmacology.

Prof. Asakawa is the former editor of *Phytomedicine and Spectroscopy,* and serves on the editorial boards of the *Journal of Natural Products, Phytochemistry*, *Phytochemistry Letters*, *Planta Medica*, Current Chemistry and Biology, *Fitoterapia*, *Flavour and Fragrance Journal*, *Natural Product Research*, *Natural Product Communications, Arkivoc and Malaysian Journal of Sciences*, among others. He is the president of the Phytochemical Society of Asia (PSA) and of Chemistry of Terpenes, Essential Oils, and Aromatics (TEAC) and permanent committee member of ISEO.

His research interests are the isolation and structure elucidation of bioactive secondary metabolites of bryophytes, pteridophytes, and inedible mushrooms; medicinal and aromatic plants and insects and their bioassay; biotransformation of secondary metabolites by fungi and mammals; total synthesis of natural products; chemical reaction of organic per-acids; and chemical phylogeny of spore-forming plants. Prof. Asakawa has published, up to now, 700 original papers, 14 reviews,

and 40 books. His three books on the "chemical constituents in bryophytes," appeared in "Progress in the Chemistry of Organic Natural Products Vol. 42 (1982), 65 (1995) and 95 (2013)" (Springer Verlag), are the "bibles" for bryophyte researchers, biochemists, phytochemists, and others.

For his outstanding research, he was awarded the Hedwig Medal by the International Association of Bryologists; the International Prize of Phytochemistry; Jack Cannon Gold Medal; International Symposium of Essential Oils Award; Gusi International Peace Prize; Gerald Blunden Award; Japanese Society of Pharmacognosy Prize; Gold Medal and Doctor Honoris Causa from Lublin Medical University, Poland; Polish Ambassador of Pharmacy and Fellow of The National Society of Ethnopharmacology, India; and the honorary membership of Turkish Academy of Science.

Since 1978, he was invited as the opening, plenary and invited lecturers from 52 countries and he invited 57 post docs and 30 students from various countries into his laboratory and organized International symposia for 8 times in his University as the chairperson.

J. Xiao et al. (eds.), *Handbook of Dietary Phytochemicals*,
https://doi.org/10.1007/978-981-15-4148-3_2

Abstract

Phytonutrients can be defined as phytochemicals that are present in phyto-foods and have some nutritional value, especially in relation to maintenance of human health and prevention of diseases. Their regular and adequate intake may offer protection from major chronic diseases, including cardiovascular and neurodegenerative diseases, and cancer. Phyto-foods like apples, blueberries, broccoli, cabbage, carrots, cherries, soybeans, tomatoes, and walnuts contain phytonutrients of various chemical classes. There are over 25,000 phytonutrients from different phytochemical classes, e.g., anthocyanins, carotenoids, coumarins, flavonoids, diarylalkanoids, lignans, phenolic acids, polyphenols, sterols, and terpenes, which have been found in plant foods. This chapter introduces various types of phytonutrients and their health benefits and leads to various relevant chapters incorporated in this book.

Keywords

Phytonutrients · Phytochemicals · Secondary metabolites · Phyto-food · bioactivity

1.1 Introduction

Simply, phytonutrients are phytochemicals that are present in plant-based food (also known as phyto-food) and have some nutritional value, especially in relation to maintenance of human health and prevention of human ailments. They are not necessarily essential compounds like vitamins and minerals that are found in plants, but they are usually plant secondary metabolites that help proper functioning of human body. There are over 25,000 phytonutrients discovered from plant foods, and they belong to several classes of phytochemicals, e.g., anthocyanins, carotenoids, coumarins, flavonoids, diarylalkanoids, lignans, phenolic acids, polyphenols, sterols, and terpenes. In addition to various fruits and vegetables consumed by humans, other plant-based food items, e.g., whole grains, nuts, beans and tea, also possess significant amounts of phytonutrients. The beneficial effects of these phytonutrients most often stem from their inherent antioxidative properties and may offer cancer chemoprevention, enhance cardiovascular health, and contribute to management of diabetes (Krzyzanowska et al. 2010; Probst et al. 2017; Bansal et al. 2018). Although most phytonutrients do not work like drugs to treat diseases, epidemiological evidence suggests that phytonutrients intake can be linked to a number of positive health outcomes including reduced risk for chronic diseases (Probst et al. 2017). While the book, *Handbook of Dietary Phytochemicals*, comprises more than 40 chapters covering various classes of dietary phytochemicals mainly in the context of their beneficial role to human health, this chapter is aimed to briefly introduce various aspects of phytonutrients or dietary phytochemicals, highlighting their major sources, chemical classes, and major health benefits.

1.2 Major Dietary Sources of Phytonutrients

The major sources of dietary phytonutrients are mainly fruits and vegetables, but whole grains, nuts, beans, and tea, which are present in our regular diets, can be good sources of phytonutrients. Plants producing edible fruits, vegetables, and spices that contain significant amounts of phytonutrients belong to a number of families. The families, Apiaceae (*alt.* Umbelliferae), Cruciferae, Cucurbitaceae, Fabaceae (*alt.* Leguminosae), Rosaceae, and Rutaceae, are just six examples of such plant families. Some examples of common sources of phytonutrients are presented in Table 1.

Table 1 Examples of some phytonutrients and their main sources

Phytonutrients	Sources		
	Common name	Botanical name	Family
Anthocyanins	Aubergine	*Solanum melongena* L.	Solanaceae
	Blackcurrant	*Ribes nigrum* L.	Grossulariaceae
	Blackberries	*Vaccinium* Sect. *cyanococcus* Rydb.	Ericaceae
	Blueberries	*Vaccinium* Sect. *cyanococcus* Rydb.	
	Cranberries	*Vaccinium* Subg. *oxycoccus* L.	
	Red cabbage	A cultivar of *Brassica oleraceae* L.	Brassicaceae
Carotenoids	Carrots	*Daucus carota* L.	Apiaceae
	Pumpkin	*Cucurbita pepo* L.	Cucurbitaceae
	Tomatoes	*Solanum lycopersicum* L.	Solanaceae

	Pistachios	*Pistacia vera* L.	Anacardiaceae
	Strawberries	*Fragaria* x *ananassa* Duchesne	Rosaceae

Dietary sources of phytonutrients are described in more details in all subsequent *chapters* dealing with various chemical classes of phytonutrients, e.g., anthocyanins, coumarins, diarylalkanoids, flavonoids, phenylpropane derivatives, and so on.

1.3 Major Classes of Dietary Phytonutrients and Their Health Benefits

Phytonutrients found in human diets are essential plant secondary metabolites, and they belong to various phytochemical classes. This section will present an overview only on the major phytochemical classes, e.g., anthocyanins, carotenoids, coumarins, diarylalkanoids, flavonoids and isoflavonoids, lignans and neolignans, phenolic acids, polyphenols (tannins), sterols and terpenoids, and their health benefits.

1.3.1 Anthocyanins

Anthocyanins are naturally occurring water-soluble pigments, which are present in many edible fruits and vegetables, and they constitute a major group of phytonutrients (Khoo et al. 2017). Well over 600 natural anthocyanins have been reported to date, all coming from six anthocyanidin aglycones derived from the flavylium backbone (**1**) (Fig. 1) with different glycosylations and acylations. Sometimes anthocyanins are considered as flavonoids, but unlike other flavonoids, anthocyanins have a positive charge on the oxygen atom of the C ring of a basic flavonoid structure.

Depending on their pH, the anthocyanin pigments can be red, purple, blue, or black. These compounds are fairly unstable, and the integrity of their structure depends on pH, light, and temperature. The *Vaccinium* species like blueberry (*Vaccinium* Sect. *cyanococcus*), cranberry (*Vaccinium* Subg. *oxycoccus*), bilberry (*V. myrtillus*), and other berries like black and red raspberry (*Rubus occidentalis*) and blackberry (*Rubus ursinus*); other fruits, e.g., blackcurrant (*Ribes nigrum*) and cherry (*Prunus avium*); and vegetables like aubergine peel (*Solanum melongena*), red cabbage (*Brassica oleraceae*), radish (*Raphanus raphanistrum* subsp. *sativus*), beetroots (*Beta vulgaris*), and colored sweet potato (*Ipomoea batatas*) are the major phyto-foods that contain high levels of anthocyanins. One of the most common anthocyanins is cyanidin (**2**) (Fig. 1). Most of the health benefits associated with anthocyanins are because of their strong antioxidant property and their effects against oxidative stress (Khoo et al. 2017; Putta et al. 2017). These phytonutrients are good for maintaining cardiovascular health, lowering cholesterol level, enhancing glucose metabolism, controlling obesity, and preventing cancers, especially breast cancer (Yousuf et al. 2016; Li et al. 2017). Anthocyanins have also been shown to possess antidiabetic, anti-inflammatory, and neuroprotective properties. Further details on this group of phytonutrients have been furnished in the *chapter* dedicated to dietary anthocyanins in this book.

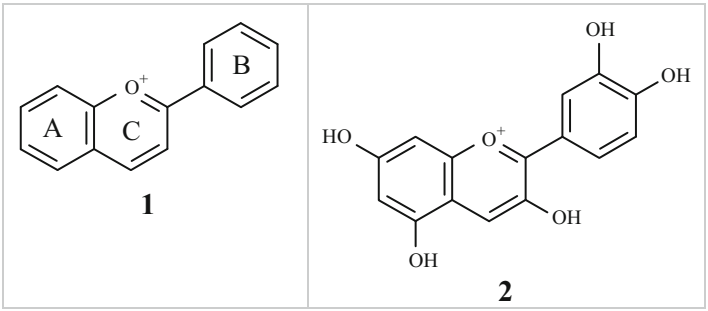

Fig. 1 The general structure of anthocyanins (**1**) and the structure of cyanidin (**2**)

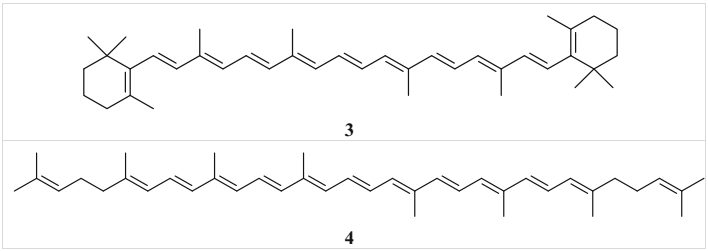

Fig. 2 Structures of β-carotene (**3**) and lycopene (**4**)

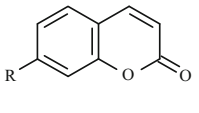
1.3.2 Carotenoids

Carotenoids are actually naturally occurring colored terpenoids, called tetraterpenoids (Fig. 2). They are yellow, orange, and red pigments produced by various plants, algae, bacteria, and fungi (Sarker and Nahar 2007a). For example, the orange color pigment found in carrots is known as β-carotene (**3**), and the red color found in tomatoes is lycopene (**4**) (Fig. 2). There are more than 700 carotenoids identified to date, about 40 of them are present in human diets. They are present extensively in various edible plants, e.g., carrots (*Daucus carota*), pumpkins (*Cucurbita pepo*), corn (*Zea mays*), and tomatoes (*Solanum lycopersicum*), and are another important group of phytonutrients with significant health benefits.

These phytonutrients possess high levels of antioxidant property, and thus the dietary carotenoids provide health benefits in decreasing the risk of various diseases, particularly cancers and cardiovascular and eye diseases (Johnson 2002; Krinsky and Johnson 2005; Saini et al. 2015; Eggersdorfer and Wyss 2018).

1.3.3 Coumarins

Coumarins are the largest class of 1-benzopyran derivatives ubiquitously distributed in the plant kingdom (Sarker and Nahar 2017), and there are about



Coumarins	R
Coumarin (**5**)	H
Umbelliferone (**6**)	OH

Fig. 3 Structures of coumarin (**5**) and 7-hydroxycoumarin (umbelliferone, **6**)

4000 naturally occurring coumarins identified to date. They also constitute one of the major groups of phytonutrients found in plant-based food items. Coumarin (**5**) (2*H*-1-benzopyran-2-one) (Fig. 3), the first member of the coumarin class, is a fragrant colorless compound, which was isolated from the tonka bean (*Dipteryx odorata*, family: Fabaceae) in 1820. The simplest member of natural coumarins is 7-hydroxycoumarin or umbelliferone (**6**), which is also the starting material for the biosynthesis of other more complex coumarins (Fig. 3). Plants from the families Apiaceae, Asteraceae, and Rutaceae are major sources of naturally occurring coumarins (Sarker and Nahar 2007a). Some commonly consumed coumarin-containing phyto-foods include apricots (*Prunus armeniaca*), carrots (*Daucus carota*), celery (*Apium graveolens*), cherries (*Prunus avium*), citrus fruits (*Citrus spp.*), parsnip (*Pastinaca sativa*), and strawberries (*Fragaria* × *ananassa*), as well as spices like aniseed (*Pimpinella anisum*), caraway (*Carum carvi*), cinnamon (*Cassia cinnamon*), coriander (*Coriandrum sativum*), dill (*Anethum graveolens*), and fennel (*Foeniculum vulgare*). Natural coumarins can be classified into simple, simple prenylated, simple geranylated, furano, pyrano, sesquiterpenyl, and oligomeric coumarins (Sarker and Nahar 2007a, 2017).

Dietary coumarins offer various medicinal values, which are based predominantly on their antimicrobial, antiviral, anti-inflammatory, antidiabetic, antioxidant, and various enzyme-inhibitory activities. In addition to their therapeutic properties, the aromatic properties of coumarins, especially in spices, are exploited extensively in culinary, cosmetic, and tobacco industries. In this book, a whole chapter has been dedicated on coumarins as dietary phytochemicals covering various aspects of this important group of phytonutrients.

1.3.4 Diarylalkanoids

Diarylalkanoids are compounds, where there are two aryl groups (benzene rings) connected by an alkyl chain (Atta-ur-Rahman 2002). The best-known example of this group of compounds occurring in phyto-foods is curcumin (**7**) (Fig. 4), which is a diarylheptanoid that occurs in the spice/food color called turmeric obtained from the rhizomes of *Curcuma longa* (Sarker and Nahar 2007b; Hewlings and Kalman 2017). Another popular example is resveratrol (**8**) (Fig. 4), which is

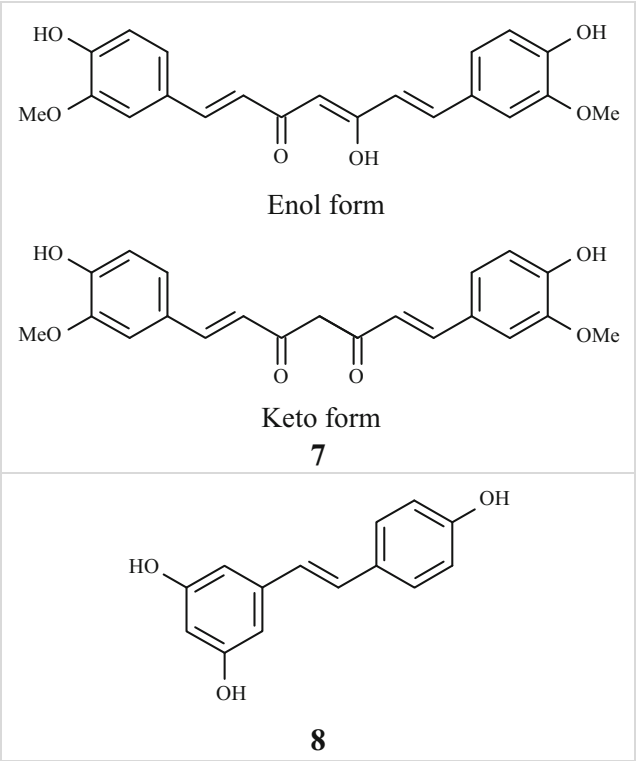


Fig. 4 The structures of curcumin (**7**) and resveratrol (**8**)

actually a diarylethanoid, and found in high quantities in red grapes (*Vitis vinifera*) (Salehi et al. 2018).

Both curcumin (**7**) and resveratrol (**8**) are well-known natural antioxidants and have been linked to a plethora of health benefits, including management of arthritis, inflammation, protection against cancer, heart diseases, and diabetes (Hewlings and Kalman 2017; Salehi et al. 2018).

1.3.5 Flavonoids and Isoflavonoids

Flavonoids are the derivatives of 1,3-diphenylpropane, and they constitute a large group of phytonutrients, which are widespread in various fruits, vegetables, and edible flowers (Sarker and Nahar 2007a). Most flavonoids are yellow pigments and contribute to the color of the flowers and fruits where they usually occur as *O*- or *C*-glycosides. While quercetin (**9**) is the most common flavonoid found in phyto-foods, rutin (**10**) and hesperidin (**11**) are the most prevalent of all flavonoid glycosides found in fruits and vegetables (Fig. 5). There are well over 2,000 glycosides of the flavones and flavonols classes reported in the literature

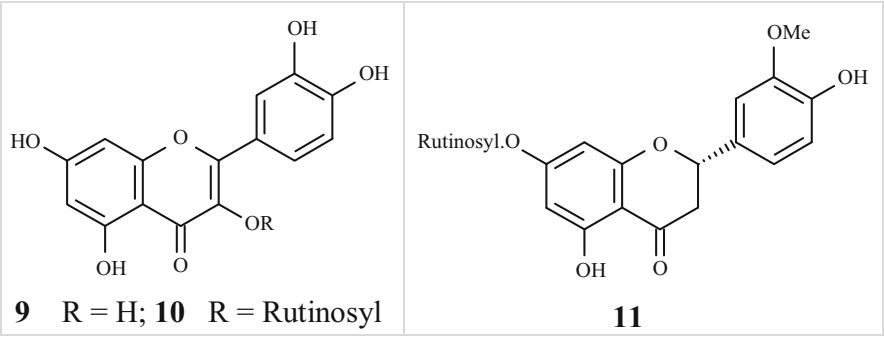

Fig. 5 The structures of quercetin (**9**), rutin (**10**), and hesperidin (**11**)

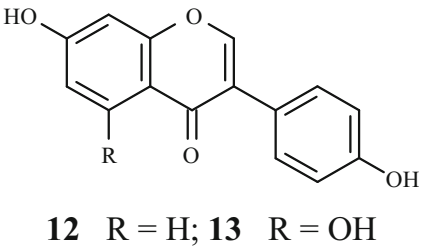
Fig. 6 The structures of daidzein (**12**) and genistein (**13**)



(Sarker and Nahar 2007a). The major dietary sources of flavonoids include tea (*Camellia sinensis*), citrus fruits (*Citrus* species, e.g., *Citrus sinensis*), apples (*Malus pumila*), and legumes (from the Fabaceae family) (Yao et al. 2004).

Most flavonoids are potent antioxidants, because of their high propensity to electron transfer, ferrous ions chelating activity, and direct scavenging of reactive oxygen species. Several flavonoids possess anticancer, antiaging, anti-inflammatory, antihepatotoxic (hepatoprotective), antitumor, antimicrobial, antithrombotic, and antiviral properties (Yao et al. 2004; Sarker and Nahar 2007a). The antioxidant properties of flavonoids present in fresh fruits and vegetables usually contribute to their preventative effect against cancer and heart diseases.

When the 2-phenyl side chain of flavonoid isomerises to the 3-position, it gives rise of a new class of bioactive compounds called isoflavones, e.g., daidzein (**12**) and genistein (**13**) (Fig. 6) (Sarker and Nahar 2007a), which are part of the human diets world over, particularly in Far East Asian countries, where the traditional cuisine is usually rich in soy products that contain high amounts of isoflavonoids.

Dietary legumes (species from the family Fabaceae *alt*. Leguminosae), including soybeans (*Glycine max*), chickpeas (*Cicer arietinum*), fava beans (*Vicia fava*), pistachios (*Pistacia vera*), peanuts (*Arachis hypogaea*), and other fruits and nuts, are rich sources of isoflavonoids (Bastamante-Rangel et al. 2018). Soybeans are the richest source of isoflavones and contain large amounts of daidzein (**12**) and genistein (**13**). Soy foods and ingredients contain varying concentrations of isoflavones. Isoflavones offer several human health benefits, which are predominantly

because of their high antioxidant property. Dietary isoflavones prevents the development of specific menopause symptoms and offer protection against several chronic diseases, including cardiovascular diseases, osteoporosis, neurological impairments, and hormone-dependent cancers. There are *chapters* in this book, dedicated to different types of dietary flavonoids and isoflavonoids, which present details on outcomes from various clinical trials, and in vivo animal studies.

1.3.6 Lignans and Neolignans

Lignans, e.g., matairesinol (**14**), are another important group of phytonutrients present in our diets. They are a group of phenolic compounds, biosynthesized from the conjugation of two phenylpropane units, e.g., coniferyl alcohol (Sarker and Nahar 2007a), linking two units in different positions except direct linking of two phenyl moieties (Fig. 7). On the other hand, neolignans, e.g., magnolol (**15**), are formed from two units of phenylpropenes linking directly through two phenyl groups (Fig. 7).

Lignans and neolignans are widely distributed in the plant kingdom and particularly found in high concentrations in the plants from the families, e.g., Asteraceae, Berberidaceae, Magnoliaceae, Pinaceae, Piperacae, Phytolaccacae, and Rutaceae (Sarker and Nahar 2007a). Among the phyto-foods, flax seeds (*Linum usitatissimum*) and sesame seeds (*Sesamum indicum*) contain the highest amounts of lignans, e.g., hydroxyresinol, lariciresinol, matairesinol (**14**), pinoresinol, secolariciresinol, sesamin, and syringaresinol (Teponno et al. 2016; Rodriguez-Garcia et al. 2019). Other dietary sources of lignans include cereals like barley (*Hordeum vulgare*), oat (*Avena sativa*), and wheat (*Triticum aestivum*), soybeans, cruciferous vegetables, and some fruits, particularly apricots (*Prunus armeniaca*) and strawberries.

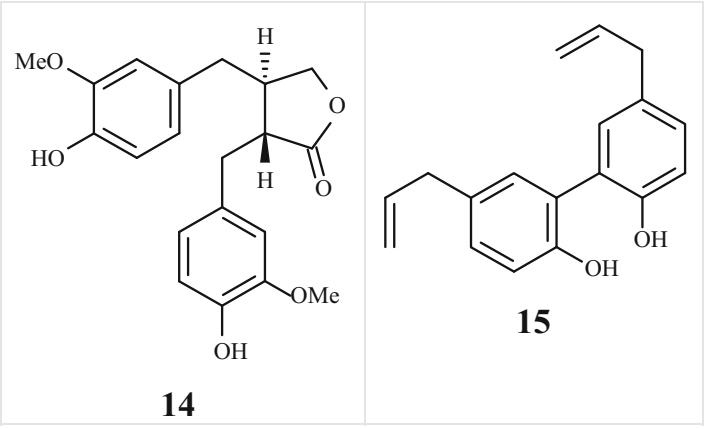


Fig. 7 The structures of the lignan, matairesinol (**14**), and the neolignan, magnolol (**15**)

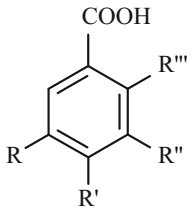
Lignans and neolignans have anticancer, antiasthma, antihypertensive, anti--inflammation, antimicrobial, antioxidant, cardioprotective, hepatoprotective, hypocholesterolemic, insecticidal, and pro-estrogenic properties (Peterson et al. 2010; Rodriguez-Garcia et al. 2019).

1.3.7 Phenolic Acids

Organic acids with phenol functionalities are usually termed as phenolic acids, and several of these compounds occur abundantly and widely in the plant kingdom. Many phyto-foods, such as fruits, vegetables, spices, nuts, and grains, possess high amounts of these compounds (Robbins 2003; Sarker and Nahar 2007a). Phenolic acids can be subdivided into two subgroups: simple benzoic acid derivatives, e.g., benzoic acid (**16**), gallic acid (**17**), salicylic acid (**18**), and vanillic acid (**19**) (Fig. 8), and cinnamic acid derivatives, which are in fact phenylpropene derivatives, e.g., caffeic acid (**20**), cinnamic acid (**21**), coumaric acid (**22**), and ferulic acid (**23**) (Fig. 9) (Natella et al. 1999; Del Olmo et al. 2017).

Phenolic acids constitute a large class of phytonutrients and offer significant beneficial effects on human health and well-being, particularly offering protective effects against various chronic diseases, e.g., coronary heart disease, stroke, and cancers (Del Olmo et al. 2017). Many dietary benzoic and cinnamic acid derivatives, particularly those with phenolic hydroxyl group(s), are well-known antioxidants and have several health benefits due to their strong free radical-scavenging properties (Sova 2012).

Dietary phenolic acids possess antidiabetic, anticancer, anti-inflammatory, antioxidant, and antitumor properties as well as various levels of antimicrobial properties (Natella et al. 1999; Sova 2012; Adisakwattana 2017). In this book, there are several *chapters* dealing with various aspects of different phenolic acids.



Compounds	R	R’	R’’	R’’’
16	H	H	H	H
17	OH	OH	OH	H
18	H	H	H	OH
19	OMe	OH	H	H

Compounds	R	R’
20	OH	OH
21	H	H
22	H	OH
23	OMe	OH

Fig. 9 The structures of cinnamic acid derivatives: caffeic acid (**20**), cinnamic acid (**21**), coumaric acid (**22**), and ferulic acid (**23**)

1.3.8 Polyphenols (Tannins)

Polyphenols are naturally occurring compounds with multiple phenolic moieties (Sarker and Nahar 2007a) and distributed ubiquitously in the plant kingdom. Although this large group of phytonutrients tends to cover a variety of phenolic compounds, this section only refers to tannins, which are water-soluble heterogeneous group of polyphenols with high molecular weights ranging from 500 to 3000 Daltons (Chung et al. 1998; Smeriglio et al. 2017), found in phyto-foods, especially in fruits, e.g., apples, blackberries, dates (*Phoenix dactylifera*), grapes, mangoes (*Mangifera indica*), raspberries, strawberries; vegetables, e.g., rhubarbs (*Rheum* × *hybridum*) and squash (*Cucurbita* species); and tea (*Camellia sinensis*) (Smeriglio et al. 2017). Tannins are usually polymeric complex forms of phenolic acids, e.g., hydroxybenzoic, gallic acid (**17**), and ellagic acid (**24**), as well as phloroglucinol (**25**) and anthocyanins (Fig. 10).

Tannins can be classified into two major classes: hydrolyzable tannins and condensed tannins (or non-hydrolyzable tannins or proanthocyanidins). Hydrolyzable tannins could be further divided into gallotannins, which yield sugar and gallic acid on hydrolysis, and ellagitannins, which on hydrolysis do not produce only sugar and gallic acid, but also ellagic acid (**24**) ((Smeriglio et al. 2017).

Tannins are often present in unripe fruits but disappear during ripening. They provide plants with protection against microbial attacks. They offer beneficial effects on metabolic disorders and prevent the onset of several oxidative stress-related diseases (Smeriglio et al. 2017). They are useful in the treatment of diabetes, diarrhea, bleeding gum, and skin injuries. Tannins are strong antioxidants, and they possess anthelmintic, anticancer, antidiabetic, anti-*Helicobacter pylori*, anti-inflammatory, antimicrobial, anti-nutritional, antioxidant, anti-ulcer, antiviral, cardioprotective, and immune-regulating activities (Sarker and Nahar 2007a; Serrano et al. 2009; Kumari and Jain 2012; Smeriglio et al. 2017).

1.3.9 Sterols

Phytosterols are a group of naturally occurring 3-hydroxysteroids, widely distributed in the plant kingdom, and many phyto-foods are rich in phytosterols, e.g.,

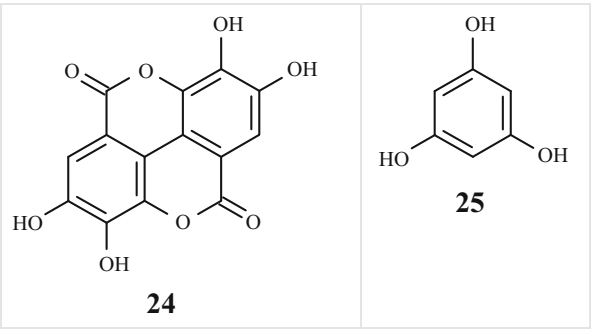

Fig. 10 The structures of ellagic acid (**24**) and phloroglucinol (**25**)

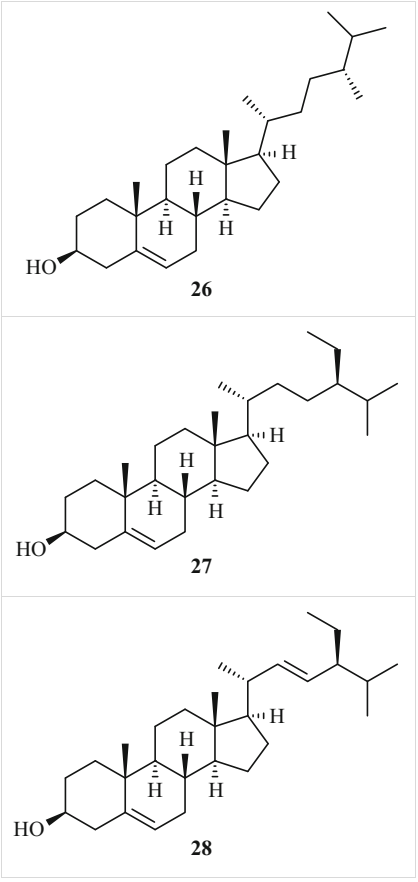

Fig. 11 The structures of major dietary phytosterols: campesterol (**26**), β-sitosterol (**27**), and stigmasterol (**28**)

campesterol (**26**) (sources: banana, coffee, cucumber, grapefruits, lemon grass, onion, oat, pepper, pomegranate, potato, and rapeseeds), β-sitosterol (widely distributed; main sources: vegetable oils, nuts, and avocados) (**27**), and stigmasterol (main sources: vegetable oils, legumes, nuts, and seeds) (**28**) (Fig. 11) (Sarker and Nahar 2007a; Ogbe et al. 2015).

Phytosterols are structurally similar to cholesterol. When phytosterols are consumed, they can compete with cholesterol for intestinal absorption, resulting in significant reduction in blood cholesterol levels (cholesterol lowering property) in humans (Recette et al. 2010).

In addition, phytosterols possess anti-inflammatory, anti-osteoarthritis, anticancer (against breast, colon, prostate, rectal, and stomach cancers), and immunity-stimulating properties and provide protection against cardiovascular diseases (Trawtwein and Demonty 2007). Phytosterols are also effective in the management of obesity as they can induce weight loss.

1.3.10 Terpenoids

Terpenoids form one of the largest and most diverse groups of phytonutrients. They are found in fruits, vegetables, nuts, and spices (Sarker and Nahar 2007a). To date, there are over 55,000 individual terpenoids reported in the literature. Terpenoids are also known as isoprenoids and derived from a combination of two or more isoprene units (a five-carbon unit, chemically known as 2-methyl-1,3-butadiene).

Terpenoids can be divided into subclasses: monoterpenes (two isoprene units, 10 carbon atoms), sesquiterpenes (3 isoprene units, 15 carbon atoms), diterpenes (4 isoprene units, 20 carbon atoms), triterpenes (6 isoprene units, 30 carbon atoms), tetraterpenes (8 isoprene units, 40 carbon atoms), and polymeric terpenoids (several isoprene units, more than 40 carbon atoms). Some examples of dietary sources of various types of terpenoids are presented in Table 2.

Monoterpenes found in phyto-foods are important as flavoring agents in pharmaceutical, confectionary, and perfume products and possess appetite-enhancing, anti-inflammatory, anti-itching, and bactericidal properties. Many terpenoids from phyto-food have various medicinal values, e.g., anticancer, antidiabetic, and antidiarrheal

Table 2 Examples of some terpenoids phytonutrients and their main sources

Terpenoids	Type	Source	Botanical name	Family
Carvacrol	Monoterpene	Thyme	*Thymus vulgaris*	Lamiaceae
(+)-Limonene		Lemon	*Citrus limon*	Rutaceae
β-Caryophyllene	Sesquiterpene	Cinnamon	*Cinnamomum zeylanicum*	Lauraceae
Curzerenone		Turmeric	*Curcuma longa*	Zingiberaceae
Trans-β-Farnesene		Sweet potato	*Ipomoea batatas*	Convolvulaceae
Retinol	Diterpene	Carrot	*Daucus carota*	Apiaceae
Trans-retinoid acid		Mango	*Mangifera indica*	Anacardiaceae
Cucurbitacin E	Triterpene	Bitter gourd	*Momordica charantia*	Cucurbitaceae
Lupeol		Figs	*Ficus carica*	Moraceae
Capsanthin	Tetraterpene	Capsicum	*Capsicum annum*	Solanaceae

applications, and they are beneficial to human health and well-being (Rabi and Gupta 2008; Khan et al. 2018). It has also been suggested that daily intake of phyto-foods, containing terpenoids, might be useful for the management for obesity-induced metabolic disorders, such as type 2 diabetes, hyperlipidemia, insulin resistance, and cardiovascular diseases (Goto et al. 2010). Some of the subsequent *chapters* will deal with dietary terpenoids of various classes.

1.4 Conclusion

As more and more clinical trials and detailed mechanistic studies have now been carried out to establish the potential health benefits as well as safety margins of different types of phytonutrients present in our diets, the importance of phyto-foods in our diets has become more apparent. Phytonutrients are in no way any replacements for conventional drugs, but evidence suggests that they can certainly contribute to prevention of various chronic and severe illnesses and maintenance regime of our health and well-being through properly planned diets.

Abstract

Nowadays, the society looks with increasing interest in the diet, which is no longer simply a means by which to take the necessary nutrients but has become a means by which it is possible to preserve the health state. German philosopher Ludwig Feuerbach once said: "We are what we eat." This statement is even truer today because of the hectic life, people often tend to eat frugal, fast, and often very fat and unhealthy meals. Today, there is a very high attention both from the social point of view and by the scientific community to the so-called functional foods. These foods, which contain several bioactive compounds, exert innumerable biological properties and therefore can help to preserve the health state. In addition, the use of nutraceuticals has taken the upper hand, unfortunately, often also to the detriment of functional foods, which unlike the former still remain foods and, as such, with a certainly better efficacy-safety profile. The term nutraceutical, indeed, does not refer to a food but rather to a formulation containing one or more compounds isolated from plant extracts or one or more titrated plant extracts. Moreover, some formulations (capsules, tablets, powders, etc.) are rarely studied before being commercialized, and their effectiveness remains rather doubtful in light of a very lax regulation in many countries worldwide.

"Let food be thy medicine and medicine be thy food." Hippocrates (400 BC).

2.1 Introduction

Most bioactive food constituents are derived from fruits and vegetables that are rich in minerals and phytochemicals, such as vitamins, carotenoids, phenolic acids, flavonoids, and proanthocyanidins. These substances play an important role as dietary antioxidants, improving cellular defenses, and contributing to counteract the oxidative stress related to aging, as well as to a variety of chronic and degenerative diseases. However, the bioavailability of phytochemical antioxidants can vary according to several factors, such as plant cultivar, growth conditions, harvesting time, and food processing. Moreover, the specific chemical and biological properties of each phytochemical have an impact on absorption and metabolism, thus giving

rise to different effects on the oxidative stress of cellular or tissue compartments (Institute of Medicine of the National Academies 2000; Carlsen et al. 2010). The last release of the USDA National Nutrient Database for Standard Reference (US Department of Agriculture, USDA 2018) has incorporated the vast majority of foods that can be used to develop nutrient values, listed in the Food and Nutrient Database for Dietary Studies (FNDDS). Many studies have been focused on the antioxidant power of most commonly consumed plant-derived foods, showing that very large differences can be found in their antioxidant power, with very high values found for spices, herbs, berries, fruits, nuts, chocolate, and vegetables (Carlsen et al. 2010). Wu et al. (2004) reported highest antioxidant value for cranberries, blueberries, and blackberries among fruits and for beans, artichokes, and russet potatoes among vegetables. Moreover, nuts (pecans, walnuts, and hazelnuts) and spices (ground cloves, ground cinnamon, and oregano) have also been reported as good sources of antioxidants.

This chapter will focus in particular on selected foods that represent the keystone of the Mediterranean diet, antioxidant diet for excellence characterized by a high consumption of plant-based foods, as well as on foods and their isolated bioactive compounds that have become part of our diet as such (functional foods) or as enriched foods, food supplements, nutraceuticals, etc. In particular, it talks about plant foods and their products well-known for nutritional and traditional medical applications, such as olive oil, grapes and wine, edible berries, pomegranate, Brassicaceae, nuts, herbs, and spices (Fig. 1). All these products can be included among the so-called functional foods, used for well-being and able to prevent the onset of chronic diseases, promoting longevity (Motohashi et al. 2017).

The society, indeed, looks with increasing interest to the adoption of a healthier lifestyle and consequently to a diet that cannot only adequately nourish the body but also provide it with all the resources necessary to prevent the onset of oxidative stress-related diseases, today always more diffused.

2.2 Bioactive Constituents

The term “phytochemicals” refers to a plethora of plant-derived compounds that can be divided in two large groups: nutrient and non-nutrient compounds. Carbohydrates, lipids, and proteins as well as some non-essential nutrients such as vitamins and minerals belong to the first group. Secondary metabolites such as alkaloids, terpenes, organic acids, as well as phenols, organosulfurs, iridoids, steroids, saponins, and so on, whose importance is mostly of ecological nature, as they are used as defense mechanisms against predators (herbivorous animals, pathogens, etc.), for interspecific competition or to facilitate reproductive processes (Gul et al. 2016), belong to the second group. In contrast to primary metabolites, these products are not ubiquitous in the living organism and are not expressed continuously; indeed, their concentration and profiles are affected by

Fig. 1 Functional foods well-known for nutritional and traditional medical applications

genotype and pedo-climatic conditions (Smeriglio et al. 2016, 2017, 2018a, b). Today, several databases reporting phytochemical content of foods such as US Department of Agriculture (USDA), Phenol-Explorer, and European Food Information Resource (EuroFIR) are available and freely consultable (www.usda.gov; http://phenol-explorer.eu/; www.eurofir.org).

However, what emerges from the recent literature is the great interest in secondary metabolites and in particular toward polyphenols, compounds that are increasingly studied both in vitro and in vivo, with a wide range of health properties (Fig. 2), often directly related to the particular polyphenol class investigated (Costa et al. 2017). Beyond some ubiquitous polyphenol classes, there are some food-specific, which contribute to conferring specific health properties.

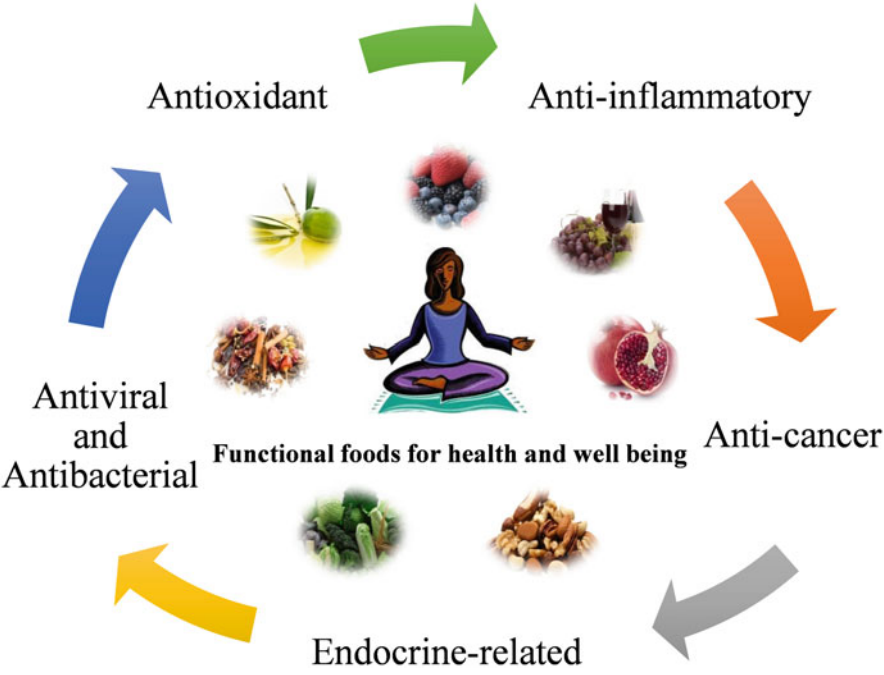

Fig. 2 Health properties of functional foods and their isolated bioactive compounds

The main polyphenol classes, as well as the chemical structure of most representative compounds identified in most antioxidant functional foods selected, were reported in Table 1 (Serreli and Deiana 2018; Nile and Park 2014; Giovinazzo and Grieco 2015; Wu and Tian 2017; Bolling et al. 2011; Raiola et al. 2017; Guldiken et al. 2018).

2.3 Bioavailability and Metabolism

The study of the pharmacokinetics of polyphenols is fundamental for understanding and evaluating the beneficial properties of these compounds; indeed, to explain their biological activities, polyphenols must be bioavailable, and the dietary abundant ones are not necessarily those that have the best bioavailability profile (D'Archivio et al. 2010).

External, food and host organism-related factors affecting the bioavailability of dietary polyphenols in humans. Among the first ones, environmental conditions (i.e., sun exposure, rainfall, degree of ripeness, different type of culture, fruit yield, and so on) and food availability are the main ones. Moreover, several factors are directly related to the food matrix including presence of positive or negative effectors of absorption (i.e., fats, fibers, and proteins), interaction with other polyphenols with

Table 1 Polyphenol compounds in selected functional foods

Functional foods	Main polyphenol classes	Chemical structure of most representative compounds
Extra virgin olive oil 	Secoiridoids, phenylethanoids, phenolic acids, flavonoids, hydroxy-isocromans, lignans	 3,4-DHPEA-EDA
Edible berries 	Anthocyanins, flavonols, catechins, phenolic acids, tannins, stilbenes, lignans	 Cyanidin
Grapes and wine 	Flavonols, flavan-3-ols, anthocyanins, dihydroflavonols, proanthocyanidins, hydroxybenzoic acids, hydroxycinnamates, stilbenoids	 Catechin
Pomegranate 	Ellagitannins, gallotannins, flavonoids, lignans, triterpenoids, phytosterols	 Punicalagin
Nuts 	Flavonoids, phenolic acids, gallotannins, lignans, ellagitannins, stilbenes	 Epicatechin

(continued)

Table 1 (continued)

Functional foods	Main polyphenol classes	Chemical structure of most representative compounds
Brassicaceae 	Glucosinolates, phenolic acids, and flavonoids	 Glucoraphanin
Spices 	Phenolic acids, terpenes, flavonoids, phenylpropanoids	 Rosmarinic acid

similar chemical structure, as well as food concentration and amount introduced. In addition, food processing methods (i.e., thermal treatments, homogenization, lyophilization, cooking methods, and storage) can influence a lot the polyphenols bioavailabily. Finally, other important factors to take into account are related to the host, such as intestinal (i.e., enzyme activity, intestinal transit time, and microbiota) as well as systemic variability (i.e., gender and age, genetics, diseases, and not less important particular physiological conditions) (D'Archivio et al. 2010).

2.3.1 Extra Virgin Olive Oil

Extra virgin olive oil (EVOO) is one of the most investigated foods for its polyphenol profile and pharmacokinetic characteristics. A significant, although very variable, absorption (~40–95%) of the main polyphenols, hydroxytyrosol (HT) and tyrosol (Tyr) (Rodriguez-Morato et al. 2016), as well as other minor compounds such as hydroxycinnamic and hydroxybenzoic acid derivatives (Feliciano et al. 2016; Zhao and Moghadasian 2008) and flavonoids (Ma et al. 2017, 2018), has already been demonstrated. The dietary intake of EVOO polyphenols, in the context of a balanced diet, has been estimated at around 9 mg, of which free HT and Tyr represent at least 1 mg; the remaining part is mainly composed of elenolic esters, oleuropein and ligstroside aglycones (De la Torre 2008; Trombetta et al. 2017). Several in vivo studies have shown how HT and Tyr are absorbed and exert their biological effects in a dose-dependent manner, even at lower doses than the traditional daily dietary intake of Mediterranean countries (Serreli and Deiana 2018). Moreover, about 98% of these polyphenols were found in the plasma and urinary compartment mainly in glucuronidated and sulfated forms (Serreli and Deiana 2018). After ingestion, the EVOO polyphenols may be partially modified in the

gastric environment. The most affected ones are the secoiridoid aglycones. They are normally subjected to a time-dependent hydrolysis in the acid gastric environment, leading to a significant increase in the free HT and Tyr amount already after 30 minutes, while the glycosylated secoiridoids reach the small intestine unmodified (Serreli and Deiana 2018). However, under physiological pH and transit gastric time conditions, some molecules reach the small intestine unmodified. Being particularly concentrated in the intestinal lumen, they might exert a significant local action modulating the oxidative status as well as the inflammation and immune response (Deiana et al. 2018). Following the ingestion of EVOO, the HT and Tyr levels increase rapidly reaching a maximum plasma and urinary concentration after about 1 and 2 hours, respectively, demonstrating how the small intestine is the main absorption site (Serreli and Deiana 2018). The mechanism has not been fully clarified, although it has been demonstrated, by in vitro Caco-2 transwell model that HT transport occurs via a bidirectional passive diffusion (D'Antuono et al. 2016). Moreover, it has been suggested that the different physicochemical properties of EVOO polyphenols may play a pivotal role in the absorption rate; HT and Tyr have the highest bioavailability, followed by verbascoside and luteolin (D'Antuono et al. 2016). However, beyond this aspect, it has been shown that the bioavailability of these compounds in the ingested forms is poor due to intensive metabolism, which occurs at different levels (Rodriguez-Morato et al. 2016; Lopez de las Hazas et al. 2016).

Once absorbed, HT and Tyr are widely distributed throughout the body with a marked organotropism for the skeletal muscle, kidney, liver, lungs, and heart (Serreli and Deiana 2018). A recent study by Peyrol et al. (2018) highlighted the key role of bilitranslocase in the internalization of HT and its glucuronide metabolite in endothelial cells. Furthermore, it has been shown that HT and its metabolites, HT sulfate and HT acetate sulfate (Lopez de las Hazas et al. 2016), as well as Tyr (Angeloni et al. 2017), are able to overcome the blood-brain barrier.

In the liver, the EVOO polyphenols are subjected to an important first-pass metabolism, leading mainly to three types of conjugation, methylation, glucuronidation, and sulfation, by catechol-O-methyltransferase (COMT), uridine-50-diphosphate glucuronosyltransferase (UDPGT), and sulfotransferase (SULT) (Serreli and Deiana 2018).

The sulfated and glucuronidated HT and Tyr are in fact the main metabolites found in human plasma and urine, as well as at the level of the intestinal epithelium, where it is known that they represent the main phase II pathways of the xenobiotic metabolism (Rodriguez-Morato et al. 2016). Another important HT metabolic pathway leads to the homovanillic alcohol formation by COMT (De la Torre et al. 2017). However, it is necessary to underline that HT, homovanillic alcohol, and its derivative homovanillic acid are also endogenously formed by the oxidative metabolism of dopamine, and therefore low concentrations of these metabolites can always be found in biological matrices (Rodriguez-Morato et al. 2016). Glucuronidated metabolites have also been observed for minor components such as luteolin, pinoresinol, and ferulic acid (Silva et al. 2018).

2.3.2 Edible Berries

The chemistry of berry phenols directly influences, other than biological effects, their bioavailability and metabolism. The main structural features of berry phenols regard (1) oxidation degree and hydroxylation patterns, (ii) ability to exist as stereoisomers, (iii) glycosylation, and (iv) polymerization degree (Smeriglio et al. 2016). The main polyphenol classes found in edible berries are anthocyanins, flavonols, flavanols, proanthocyanidins, ellagitannins, and phenolic acids; however, the most representative one is certainly anthocyanins. These phytochemicals belong to the flavonoid class widely distributed in fruits and vegetables and especially abundant in berries with red, blue, or purple pigments (Nile and Park 2014).

Recent studies indicate that anthocyanins are rapidly absorbed in the stomach by bilitranslocase as well as by the small intestine, in particular at jejunum level, appearing in blood circulation and urine as unmodified, methylated, glucuronide, and/or sulfate conjugated (Passamonti et al. 2003). They appear in the bloodstream within few minutes and reach the maximum plasma concentration after 15–180 min, depending on their chemical features and food matrix (Smeriglio et al. 2016).

Anthocyanins show a marked organotropism for jejunum followed by the stomach, kidney, liver, and brain. Indeed, it has been demonstrated that they can readily cross the blood-brain as well as the blood-retinal barrier. Although their availability to target tissues appears limited, it is consistent to explain their health effects (Smeriglio et al. 2016).

Unlike anthocyanidins, which passively diffuse across the mucosal epithelium, anthocyanins, being highly water-soluble molecules, if not enzymatically hydrolyzed in the small intestine, needed specific carriers to cross the intestine barrier such as sodium-glucose co-transporters (SGLTs) or glucose transporters (GLUTs). However, it has been shown that anthocyanins cross the intestinal barrier preferentially as unmodified molecules (Kamiloglu et al. 2017).

Intestinal microflora rapidly hydrolyze them to the aglycone form, and their bioavailability strictly depends on the sugar moiety; indeed glucose leads to a higher bioavailability than galactose or arabinose (Nile and Park 2014). Derived highly unstable compounds spontaneously degraded into several monomeric phenolic acids and aldehydes such as protocatechuic acid and phloroglucinol aldehyde, which however, contribute to the health effects exerted by native molecules (Smeriglio et al. 2016).

Once in circulation, the metabolites can be subjected to phase II liver metabolism by drug detoxification enzymes such as COMT, SULT1, and UDPGT (Nile and Park 2014).

Many in vivo studies showed that after consumption of a dietary amount of edible berries, no detectable quantities of native anthocyanins or their metabolites were found in plasma, while they were found in the urine in quantities $<0.1\%$ of ingested doses, suggesting poor intestinal absorption (Smeriglio et al. 2016). Several in vivo studies suggest that the food matrix can affect the pharmacokinetics of anthocyanins. From this point of view, phytic acid, contained mainly in the hulls of nuts, seeds, and grain, increases the bioavailability of anthocyanins reducing gastrointestinal

mobility and slowing the passage of anthocyanins through the stomach, duodenum, and jejunum favoring their absorption (Smeriglio et al. 2016).

Another important aspect, which influences anthocyanin bioavailability, is the individual variations in the xenobiotic metabolism due to human polymorphisms, which affects the main enzymes involved in the biotransformation of these bioactive compounds (Smeriglio et al. 2016).

2.3.3 Grape and Wine

Flavonoids and stilbenoids are the representative polyphenol classes in the grape berry skins and consequently in the wine. However, during winemaking, just a small part shifted to the wine, and the final yield strongly depends on the contact rate and grape variety (Giovinazzo and Grieco 2015). In addition to technological factors, which govern the winemaking procedures, several microbiological, chemical, and physical factors contribute to modify the phenol's structure and concentration during the fermentation, fining, and storage of wine (Giovinazzo and Grieco 2015).

Polyphenols are synthetized by grapevine during normal development in response to abiotic and biotic stressors (Degu et al. 2016). Harvest time plays a pivotal role to confer the typical phenol profile to the berries, and the concentration of the different polyphenol classes may change after in relation to postharvest handling protocols (Giovinazzo and Grieco 2015).

Two main polyphenol families can be distinguished in grapevine: flavonoids and non-flavonoids. Flavonoids class includes flavonols, both glycosides and aglycones, flavanols, anthocyanins, dihydroflavonols, and proanthocyanidins (Amor et al. 2018), while the non-flavonoid class includes hydroxybenzoic and hydroxycinnamic acids as well as stilbenoids (Amor et al. 2018).

Unlike what is believed, the predominant polyphenol class in grapevine is that of flavanols with catechin, epicatechin, and proanthocyanidins as the most abundant compounds. They accumulate in the seeds and skin of the grape berries representing the 13–30% of the total phenolic content (Giovinazzo and Grieco 2015). Flavonols are the second most abundant flavonoids, whose profile strongly depends on grapevine varieties. They are present as glycosides in grape skin and as aglycones in wine and juice because, during processing and storage, acid hydrolysis occurs (Giovinazzo and Grieco 2015). Kaempferol, quercetin, and isorhamnetin are the most abundant flavonols in both red and white grapes, whereas myricetin and its derivatives are present only in red grapevine varieties (Giovinazzo and Grieco 2015). Furthermore, recently, acetylated and p-coumaroylated derivatives of isorhamnetin, laricitrin, and syringetin have been identified for the first time in grape skins and wines (Favre et al. 2018).

Anthocyanins can be detected only in red grape varieties, and their biosynthesis is closely related with berry development. Each grape species and variety has a different anthocyanin pattern. They accumulate mainly in the berry skin, although in some cultivars they may accumulate also in the berry flesh (Giovinazzo and Grieco 2015). Anthocyanins and proanthocyanidins are among the most important

compounds in red wine quality because they influence color, bitterness, astringency, and chemical stability to oxidation, the main features of this beverage (Giovinazzo and Grieco 2015).

Stilbenoids are certainly another well-known polyphenol class of grape and wine stilbenoids. Among these, cis−/trans-resveratrol is undoubtedly the leader followed by resveratrol-3-*O*-glucoside (piceid), piceatannol, and viniferins (Giovinazzo and Grieco 2015).

With the exception of anthocyanins, whose absorption and metabolism were reported in Sect. 3.2, most polyphenols cannot be absorbed intact after consumption and have to be modified by the intestinal enzymes or by the colonic microflora. The degree of modification they undergo as well as their bioavailability depends essentially on their chemical structure. The main absorption occurs in the small intestine, where the glycosides are hydrolyzed, while the other polyphenols arrive unchanged in the colon, where they are subjected to extensive structural modifications by colonic microflora, leading to the production of specific active metabolites, i.e., flavonoid aglycones and phenolic acids, which exert biological activities ascribed to the parent molecules. From this point of view, the inter-individual variability plays a pivotal role in producing these active metabolites (Giovinazzo and Grieco 2015).

Once absorbed, polyphenols undergo further structural modifications due to conjugation processes, which mainly include methylation, sulfation, and glucuronidation, which could affect their bioavailability and, consequently, their biological activity (Giovinazzo and Grieco 2015). The polyphenol class which shows the most concerns, from this point of view, is that of stilbenoids.

Indeed, despite various in vitro and in vivo biological activities that have been attributed to stilbenoids, many concerns remain about the translation of results to humans (Dvorakova and Landa 2017). Resveratrol and other resveratrol-like stilbenoids are characterized by a very low bioavailability and extensive metabolism. When administered orally, only about 1–2% of the resveratrol dose can be found in plasma; furthermore, its half-life is 8–14 min due to its rapid metabolism, which occurs predominantly by phase II and, to a lesser extent, by phase I enzymes (Dvorakova and Landa 2017). The first metabolism leads to the corresponding mono-glucuronides or mono-sulfates, while the second one to piceatannol. The most abundant resveratrol metabolites are trans-resveratrol-3-*O*-glucuronide and trans-resveratrol-3-*O*-sulfate, although, depending on the dose administered, the metabolism can shift predominantly toward sulfation. Moreover, the human microbiota metabolizes resveratrol into dihydroresveratrol. Regarding other stilbenoids, informations about metabolism are rather limited (Dvorakova and Landa 2017).

2.3.4 Pomegranate

Numerous polyphenol classes have been identified in pomegranate (Table 1). However, hydrolyzable tannins (HTs) are the main and, among others, the most investigated in this functional food. They can be grouped into ellagitannins (ETs) and gallotannins (GTs) based on the different phenolic acids that are esterified with a

polyol residue (mainly D-glucose). ETs are widespread in nature and can be found in several plant families, while GTs are less common. Pomegranate fruit is rich in ETs. Among them, punicalagin isomers constitute up to 85% (w/w) of total tannins extracted from pomegranate fruit peel (Wu and Tian 2017), although it is also a rich source of ellagic acid and its methylated and glycosidic derivatives (Smeriglio et al. 2017).

On the contrary to simple phenols, whose pharmacokinetics have been extensively investigated by several animal and human studies (Velderrain-Rodríguez et al. 2014), the results about tannin metabolic fate are still scarce and controversial. Furthermore, unlike proanthocyanidins (condensed tannins), few studies on the bioavailability of HTs are currently available.

Recently, Nuñez-Sánchez et al. (2014) investigated the absorption of the main pomegranate juice polyphenols after oral administration. They detected low plasma concentrations of ellagic acid after 0.5–3 h, while no parent compounds (ETs) were detected. This behavior can be ascribed probably to the low water solubility of ellagic acid as well as to its ability to chelate calcium and magnesium ions at intestinal level, leading to nonabsorbable complex (Smeriglio et al. 2017). The main ellagic acid derivatives have been found in the human plasma and urine (Nuñez-Sánchez et al. 2014).

Tannins, because of their complex structure, cannot be absorbed at the gastric level and are partially bioavailable for absorption in the gut tract, particularly in the small intestine for HTs. Furthermore, the gut absorption is strictly related to their polymerization degree (Smeriglio et al. 2017).

Several in vitro studies showed that ETs are stable in the gastric environment, in the presence of gastric and pancreatic enzymes as well as in the presence of bile salts. The best conditions for hydrolysis of ETs are at neutral-alkaline pH (pH 7.1–8.4), typical of the duodenum and the small intestine environment (Smeriglio et al. 2017). During the remaining phases of digestion, the human microbiota metabolizes ETs and ellagic acid to dibenzopyranone metabolites, namely, urolithin A and B. These metabolites are absorbed by the gut in which they undergo glucuronidation. Furthermore, because urolithin A undergoes hydroxylation by cytochrome P450, it may have an improved ability to glucuronidate and enhance the excretion of specific metabolites (Smeriglio et al. 2017).

However, a clinical trial performed on human volunteers fed with a single dose of ellagitannin-rich diet demonstrated, once again, a large inter-individual variability in the pomegranate metabolite profile (Espín et al. 2013).

2.3.5 Tree Nuts

The phytochemical profile of tree nuts varies considerably by nut type, genotype, pre- and postharvest conditions, as well as storage conditions. However, flavonoids are the most abundant polyphenol class with flavan-3-ols, which are the main subclass, followed by flavonols and anthocyanins (Bolling et al. 2011).

Recently, the total phenol value of nine tree nuts was reviewed. This value range from 197 to 1602 mg gallic acid equivalent/100 g with walnuts and pecans, which are the top two, followed by pistachios, hazelnuts, almonds, Brazil nuts, cashews, macadamias, and pine nuts (Bolling et al. 2011). Flavonoids are predominantly present in the food matrix in glycosylated form, which may be partially hydrolyzed by lactase-phlorizin hydrolase (LPH) in the epithelium or in the lumen of the small intestine. In this way, most lipophilic aglycones may enter the epithelial cells by passive diffusion. Alternatively, glycosides can be directly transported in the epithelium via epithelial glucose transporters; subsequently they are hydrolyzed by intracellular β-glycosidase. Unlike dietary nutrients, large amounts of ingested flavonoids are unabsorbed in the proximal intestine and reach the colon where they undergo microbiota-mediated hydrolysis and fermentation (Cassidy and Minihane 2017).

Within the epithelium, flavonoids undergo phase I metabolism with the resultant metabolites transported to the liver via the portal vein. Reached the liver, they undergo further phase I (oxidation or methylation) and phase II metabolisms (glucuronidation, sulfation, or methylation) that result in more polar bioactive compounds that are mainly glucuronidated. The first one occurs by several cytochrome P450 isoforms, in which cytochromes 1A1, 1A2, 1B1, 3A4, and 2C9 are those mainly involved in the flavonoid metabolism, while in the second one, UGTs, sulfotransferases, and COMTs are involved. The latter play a pivotal role in the flavan-3-ol subclass metabolism because they are involved in the *O*-methylation of catecholic flavonoids including catechins, epicatechins, and epigallocatechins (Cassidy and Minihane 2017).

The elimination of flavonoids occurs via urine and bile excretion by which they enter into enterohepatic recycling (Cassidy and Minihane 2017). However, several transporter proteins such as P-glycoprotein are also involved in the flavonoid efflux through the membrane into the portal bloodstream, facilitating absorption, or came back into the intestinal lumen, reducing bioavailability (Cassidy and Minihane 2017).

Recently, another important aspect was highlighted regarding nut polyphenol bioaccessibility: the food matrix effect (Mandalari et al. 2016). The rate and extent of polyphenols released in the gastrointestinal tract, after gastric digestion and gastric plus duodenal digestion, from natural and blanched almond skin (NS and BS, respectively) extract simply diluted in water and milk and incorporated into bakery products, were investigated. Results showed that phenolic acids were the most bioaccessible polyphenols. When diluted in water, NS statistically increased the release of flavan-3-ols and flavonols, whereas bakery products better BS polyphenols. The samples diluted in milk showed the lowest polyphenol recovery and free total phenols content as well as the lowest antioxidant activity, probably due to an interaction between polyphenols and milk proteins, which decreases the bioaccessibility of almond polyphenols. These results could explain the difference observed between polyphenol bioavailability and almond consumption as tale or as part of more complex food matrix (Mandalari et al. 2016).

2.3.6 Brassicaceae Vegetables

Plants belonging to the Brassicaceae family are characterized by a typical polyphenol class, the glucosinolates. These bioactive compounds, relatively stable in the plant cell, contain a thiohydroximate-*O*-sulfonate group linked to glucose and about 200 different alkyl, aralkyl, or indolyl side chains (Barba et al. 2016). When the plant tissue is subjected to cutting, chopping, or mixing, a β-thioglucosidase called myrosinase, normally stored separately, is released, leading to glucosinolate hydrolysis (Oliviero et al. 2018). Glucose and an unstable aglycone, the thiohydroximate-*O*-sulfonate, are the reaction intermediates. They spontaneously reorganize themselves by releasing sulfate ion and several metabolites strictly related to the nature of the side chain of the parent compound and the physicochemical conditions of the medium. For example, acid pH and ferrous iron-rich environment leads to the formation of nitrile derivatives, while neutral pH favors the formation of isothiocyanates (ITCs). ITCs are too unstable compounds, and they easily split into thiocyanate ion and indole-3-carbinol (Capuano et al. 2017).

Normally, dietary intake of Brassicaceae vegetables occurs after cooking, and the breakdown products of glucosinolates is responsible for the typical aroma that is released. Cooking tends to denaturate myrosinase, and this event is strictly dependent on cooking methods used such as boiling, steaming, or microwaving and cooking time. Enzymatic inactivation makes that glucosinolates reach the colon unmodified where they are metabolized by the intestinal microbiota, leading to break down of molecules, which are absorbed and/or excreted.

However, several in vitro and in vivo studies investigated the absorption and metabolic fate of uncooked Brassicaceae vegetables showing as intact glucosinolates could be partially absorbed in the stomach. The unabsorbed part transits through the gastrointestinal tract and as a result of gastric and gastric plus duodenal digestion, which promotes plant myrosinase release, reaches the small intestine where they are hydrolyzed, leading to break down of products, which may be easily absorbed. The remaining non-hydrolyzed glucosinolates reach the colon where they could be hydrolyzed by bacterial myrosinase, leading to break down of molecules, which are absorbed and/or excreted. The presence of bacterial myrosinase activity was corroborated by several studies, which observed the ITC formation in the human feces post-incubation of pure glucosinolates or Brassicaceae vegetable juices in which the enzyme was inactivated by heating (Barba et al. 2016; Capuano et al. 2017; Oliviero et al. 2018).

Since the formation of several breakdown products by intestinal microbiota is very likely, up to date, this aspect is still under investigation, and in humans, only urinary excretion of conjugated metabolites of ITCs, following the consumption of Brassicaceae cooked vegetables, was observed. However, several in vitro investigations showed that secondary degradation of ITCs can lead to the formation of amines, and *Bifidobacterium* strains are able to metabolize glucosinolates to nitriles, which in turn can be converted by other microorganisms into ammonia and organic acids (Barba et al. 2016).

Nevertheless, as seen with other polyphenol classes, the diversity of the enzymatic pattern is associated with the generation of a wider range of metabolites than those so far identified (Oliviero et al. 2018).

Animal studies with radiolabeled ITCs showed a rapid absorption with a peak plasma concentration observed 3 h after ingestion. Absorbed ITCs are then conjugated to glutathione in the liver and excreted in the urine as mercapturic acid (12–80% of the ingested dose), while secondary excretion routes are in the form of CO_2 in the expired air or as unknown metabolites in feces. In humans, the mercapturic acid metabolic pathway is the predominant one, with a good statistical correlation between mercapturic acid excretion and amount of ITCs consumed, so much so that it is considered a biomarker of ITC intake (Oliviero et al. 2018). However, the ITC bioavailability in humans strictly depends on the respective contributions of plant myrosinase and intestinal microbiota in the hydrolysis of glucosinolates, with an increased bioavailability after ingestion of raw Brassicaceae vegetables. Indeed, urine excretion of mercapturic acid after consumption of raw Brassicaceae vegetables, which occurs after 8 h of ingestion, accounts for 17–88% of the ingested dose of glucosinolates and depends on several factors such as molecule type, plant matrix (cabbage, watercress, broccoli, etc.), and human enzymatic pattern. When the vegetables are cooked, this rate does not exceed 20%, and the peak of mercapturic acid in urine occurs only after 12 h of ingestion (Barba et al. 2016).

Glucosinolate metabolites undergo enterohepatic circulation. ITCs showed a pronounced organotropism for the intestinal mucosa, liver, kidneys, bladder, lungs, and spleen, while the body disposition of other glucosinolate breakdown products is still poorly understood. Similar to ITCs, nitriles and epithionitriles could be metabolized and excreted in the urine as mercapturic acid, whereas oxazolidine-2-thione and thiocyanate ion are directly excreted unchanged (Barba et al. 2016; Capuano et al. 2017; Oliviero et al. 2018).

2.3.7 Spices

Besides their use as flavoring, coloring agents, and preservatives, herbs and spices possess several health properties ascribed mainly to the presence of different phytochemicals of which polyphenols represent the class most investigated. Among them, phenolic acids are certainly the predominant ones (Guldiken et al. 2018). However, to understand better their health effects, it is essential to establish the bioavailability of their bioactive constituents.

Phenolic acids, such as hydroxycinnamic and hydroxybenzoic acids, are a class of ubiquitous polyphenols in the plant kingdom. They are present in plant tissues as complexes with lignin and carbohydrates and proteins with which they are able to establish hydrogen bonds by hydroxyl groups in the aromatic ring and ester linkages, respectively. These phenolic complexes are able to resist to gastric and duodenal digestion reaching the colon where they undergo metabolization by microbiota.

Hydroxycinnamic acids are the most diffused and herbs and spices are the richest sources (Mosele et al. 2015).

Caffeic, ferulic, coumaric, as well as chlorogenic and rosmarinic acids (esters of caffeic acid) are the main compounds included in this group. In vitro experiments of simulated microbial metabolism showed that chlorogenic acid undergoes ester hydrolysis, leading to quinic acid and then to hippuric acid and caffeic acid formation, which in turn can be dehydroxylated to coumaric acid and then degraded to hydroxylated phenylpropionic acids or directly dehydrogenated to dihydroxylated phenylpropionic acids. Anyway, mono- and di-dihydroxylated phenylpropionic acids are the main metabolites detected (Mosele et al. 2015). This metabolic pathway was corroborated by detection in vivo of m-coumaric and hippuric acids, after chlorogenic acid administration (Mosele et al. 2015). Rosmarinic acid, being too an ester of caffeic acid, shares the same metabolic pathway with chlorogenic acid once hydrolyzed to caffeic acid.

Ferulic acid, another common hydroxycinnamic acid, has a common metabolic pathway of the previous ones because it can give, by simple dehydrogenation, dihydroferulic acid, which in turn can form, by demethylation, dihydroxyphenylpropionic acid and alternatively, by dehydrogenation followed by α-oxidation, can give vanillic acid (Mosele et al. 2015). However, different profiles of metabolites were observed between in vitro and in vivo studies. This is due both to a large human inter-variability, related to a specific microbiota composition, and to hepatic and renal metabolism, whose metabolites undergo before urine excretion (Mosele et al. 2015).

Hippuric acid was the common phenolic metabolite detected in plasma and urine after the intake of different phenolic acids. Hippuric acid, other than derived by microbial transformation of the quinic acid moiety, as described above, can be derived by the hepatic metabolism of benzoic acids. Nevertheless, the concentration of hippuric acid in urine decreased considerably after the antibiotic treatment and in the urine of ileostomy patients, suggesting an important contribution by the gut microbiota (Mosele et al. 2015). In light of these results, the intestinal absorption of dietary phenolic acids into systemic circulation is poor, although they can exert their activity at the intestinal level (Opara and Chohan 2014; Guldiken et al. 2018).

From this point of view, several in vitro studies on Caco-2 cell transwell model have been very useful to understand the intestinal absorption of phenolic acids from culinary herbs, although they must be correctly interpreted. Indeed, often it happens to compare studies, which use the same experimental model, but starting from samples of very different nature. In particular, the critical points are the starting material (herbs and spices or pure compounds) and amount of starting material, in particular if consistent with a dietary intake and if the starting material was applied as tale or after cooking and/or digestion. In light of these critical points, indeed, very different results can be achieved (Opara and Chohan 2014). However, critically evaluating various in vitro and in vivo studies carried out to date, it can only confirm that phenolic acids have a very low bioavailability and that they carry out most of their effects at the intestinal epithelium level, although the mechanisms have not been still clarified. Furthermore, instability during food processing, distribution, and

storage, as well as the food matrix composition are other key factors which limit the potential health benefits of phenolic acids. Different studies showed interactions between phenolic acids and food matrices, such as milk, olive oil, or sugar, suggesting that variations in phenolic acid absorption also occur due to interactions between polyphenols and other food components, such as proteins, which destabilize these compounds, decreasing their bioaccessibility and subsequently their bioavailability (Nunes et al. 2017).

2.4 Bioactivities and Benefits

The biological properties and health effects of the above functional foods have been widely reviewed. Other than their traditional use, many in vitro and in vivo (animal and human) studies performed suggest that their intake may prevent the onset of several chronic diseases (Rigacci and Stefani 2016; Nile and Park 2014; Giovinazzo and Grieco 2015; Wu and Tian 2017; de Souza et al. 2017; Raiola et al. 2017; Guldiken et al. 2018; Smeriglio et al. 2018a). The recognized biological activities have been ascribed predominantly to the polyphenol classes discussed in Sect. 3, although synergistic effects could not be excluded, so much so that often the food as it is, or its raw extract, shows a greater activity than their bioactive isolated compounds.

In addition to their well-documented free radical scavenging and antioxidant activity, these functional foods seem to exert several bioactivities such as antibacterial, antiviral, anticarcinogenic, anti-inflammatory, and endocrine-related activities (Fig. 2).

2.4.1 Extra Virgin Olive Oil

Cultivation of olive tree (Fig. 1e) and olive production date back to about 7000 years ago, while nutritional and medicinal properties of olive oil have been known since the ancient times (Hashmi et al. 2015). EVOO is the most important component of the Mediterranean diet, being its health effects mainly due to a high content in monounsaturated fatty acids and to the presence of phenolic compounds. EVOO nutraceutical properties, as well as biological properties of its minor unsaponifiable fraction components (vitamin E, carotenoids, and phenolic compounds), have been investigated by in vitro and in vivo studies, revealing a protective role in oxidative stress-related diseases (Sabatini et al. 2018; Yubero-Serrano et al. 2019).

The bioavailability of EVOO polyphenol metabolites is often higher than that reached by the ingested parent compounds; therefore, these metabolites are likely to contribute significantly to the health effect correlated to the regular consumption of EVOO. However, although in the last decade several studies have been carried out in order to evaluate the potential health benefits of EVOO phenol metabolites, the data available are still poor. In vitro studies showed that EVOO phenol metabolites are able to exert significant antioxidant and free radical scavenging activity by

modulating several molecular pathways. They perform their activity mainly at the cardiovascular and gastrointestinal level ameliorating physiological condition and preventing exacerbation of inflammation and oxidative stress, sometimes even with greater efficiency than native compounds (Serreli and Deiana 2018).

Different parts of *O. europaea* L. have been widely used in traditional medicine for a wide range of ailments, either alone or in combination with other herbs (Hashmi et al. 2015) showing a broad spectrum of health-promoting properties such as antioxidant, anti-inflammatory, anti-allergic, anti-atherogenic, antithrombotic, and antimutagenic effects (Abdelhalim et al. 2017; Gorzynik-Debicka et al. 2018). In Mediterranean folk medicine, *O. europaea* was also used as a common remedy for gout, for bacterial infections such as gingivitis and otitis, and for icterus, cough, and hair loss as well as febrifuge (Hashmi et al. 2015). Furthermore, it was used also as liver depurative and hypotensive (Cornara et al. 2014).

Traditionally, for its emollient properties and its affinity with the skin, EVOO was also used as a vehicle for drugs or medicinal plants with topical application, whose active ingredients were characterized by lipophilic properties (Leporatti and Ghedira 2009). Lately, this aspect has aroused the interest of researchers, and some studies have been made on the use of nutraceutical oral and topical preparations of hydroxytyrosol and vitamin E conveyed in EVOO. The first important result is the greater bioavailability found for hydroxytyrosol, which, until then, had been always conveyed in water thanks to its amphiphilic properties. The second one is that the presence of other polyphenols naturally present in EVOO seems to synergize the action of hydroxytyrosol and vitamin E, expressing interesting health effects on in vitro cell-based model of skin inflammation (Smeriglio et al. 2019a) as well as on healthy patients predisposed to the onset of oxidative stress-related metabolic diseases (Colica et al. 2017) and even more on patients affected by nonalcoholic fatty liver disease (Nobili et al. 2019).

2.4.2 Edible Berries

Common edible berries include strawberries (genus *Fragaria*), raspberries (Fig. 1a), and blackberries (genus *Rubus*) belonging to the Rosaceae family, blueberries (*Vaccinium myrtillus* L.) and cranberry (*V. macrocarpon* Ait.) belonging to the Ericaceae family, and red currants (*Ribes rubrum* L.) and black currants (*R. nigrum* L.) belonging to the Grossulariaceae family. These small fruits are important commercial food due to their delicious taste and flavor and their healthy properties. Berries are appreciated worldwide both fresh and as transformation products such as juices, jams, tea, desserts, jellies, and bakery products (Monforte et al. 2018). They are mainly rich in phenolic compounds (phenolic acids, flavonoids) and ascorbic acid, both with high antioxidant properties (Skrovankova et al. 2015). Blue, purple, and red colors of berries are due to the presence of anthocyanins, which show a wide variety of health-promoting properties for human health, such as antioxidant, anti-inflammatory, and anti-carcinogenic effects, thereby reducing the incidence of chronic and degenerative diseases (Smeriglio et al. 2016). Many different berries are used worldwide for

nutritional purposes, but also in folk medicine. Recently, the folk medicinal use of different *Rubus* species was reviewed (Sultana 2018). Tea made from the leaves of *R. idaeus* L. was reported as an efficient remedy for wounds, diarrhea, and colic pain or as a uterine relaxant. In addition, the author also refers the use of leaves from other berries, such as blackberry, as an anti-inflammatory agent and raspberry as antibacterial, anti-inflammatory, diaphoretic, diuretic, and choleretic agent (Sultana 2018). A review concerning the ethnobotanical uses of the genus *Vaccinium* (Abreu et al. 2014) has reported many ethnomedical and food uses in 36 *Vaccinium* species, mainly from North America, Asia, and Europe. These medicinal remedies are mainly referred to digestive, genitourinary, and endocrine/metabolic systems, with *V. vitis-idaea* L., *V. myrtillus* L., *V. macrocarpon* Aiton, and *V. uliginosum* L. being the most cited species. A recent study on the ethnobotany of Patagonia (Chamorro et al. 2019) has reported the medicinal use of other berries, described in the Mapuche medical system, e.g., *Berberis microphylla* G.Forst. (Berberidaceae), *Ribes magellanicum* Poir. (Grossulariaceae), and *Luma apiculata* (DC.) Burret (Chilean myrtle, Myrtaceae). Several in vitro and in vivo studies showed that extracts of several cultivars of blackberries, black and red currants, blueberries, and black and red raspberries showed a remarkably scavenging activity toward chemically generated superoxide radicals; they are therefore useful in fighting aging and related diseases. Behavioral studies in rodents showed an attenuation of brain aging after ingestion of strawberries, blueberries, or blackberries. Moreover, berry polyphenols reduce the risk of cardiovascular disease and type 2 diabetes (Nile and Park 2014).

There is a wide literature about anticancer effects of berry polyphenols. Furthermore, several berry-isolated compounds were found to possess antimutagenic activity; among them, the most investigated are ellagitannins and in particular ellagic acid (Nile and Park 2014).

On the contrary, proanthocyanidins, and in particular the A-type of cranberry, may enhance both in vitro and in vivo urinary bacterial anti-adhesion activities. Among the berries, cranberries, cloudberries, red raspberries, strawberries, and bilberries possess clear antimicrobial effects against human pathogens, inhibiting the growth primarily of gram-negative bacteria without any effect on gram-positive bacteria. Berry polyphenols also have vasoprotective and anti-inflammatory activity; indeed several berry anthocyanin-rich extracts are available as food supplement to treat microcirculation disease and to maintain normal vascular permeability. Recently, some in vitro studies have also found black raspberry extracts to be effective in reducing vascular endothelial growth factor expression, a promoter of angiogenesis, which is a critical step for tumor progression and metastasis (Nile and Park 2014).

2.4.3 Grape and Wine

Vitis vinifera L. is a perennial woody vine (Fig. 1c) native to the Mediterranean region, Central Europe, and southwestern Asia. Grape and red wines have been recognized and consumed worldwide for over 2,000 years. One of the earliest

sources that document grape uses is the preparation of wine depicted on the walls of the Theban 18th dynasty tomb chapel of Nakht. The beneficial health effects of wine have been linked to the "French paradox," i.e., the lower incidence of coronary heart disease in the Bordeaux area in France, with respect to northern European countries, despite a similar diet rich in saturated fats. This fact has been related to the traditional consumption in the French region of red wine rich in flavonoids. The latter, indeed, is known for having potent antioxidants with cardioprotective, anti-inflammatory, anticancer, and antimicrobial properties (Georgiev et al. 2014). However, it is good to underline that different grape cultivars show typical flavonoid patterns and have different health-promoting effects on the human body. Giovinazzo and Grieco (2015) have reviewed, recently, the major health effects of grape and wine, ascribing their main biological properties not only to flavonoids but also to the stilbenoid content and in particular to *trans*-resveratrol. Moreover, another important polyphenol class is that of proanthocyanidins, which showed 50 times greater antioxidant activity than vitamin C and 20 times greater antioxidant activity than vitamin E.

The antioxidant properties of grape compounds reduce the risk of atherosclerosis; play a key role in the prevention of heart disease, diabetic neuropathy, and Alzheimer's disease; and exert an immune-modulatory effect. Anthocyanin and *trans*-resveratrol seem able to prevent the onset of cardiovascular diseases and age-related disorders correlated with metabolic syndrome. In addition, the positive effects described in mice subjected to a high-fat diet and supplemented with *trans*-resveratrol open up new approaches for treating also obesity-related disorders. Increased consumption of grapes has also been associated with a reduced risk of cancer. This observation well correlates with the flavonol and *trans*-resveratrol intake (Giovinazzo and Grieco 2015). Another polyphenol, which attracted much attention, was the flavan-3-ol epicatechin, contained in red wine in concentrations higher than other flavonoids. Moreover, winemaking by-products, such as red grape pomace and grape seeds, are also suitable raw materials to obtain antioxidant and anti-inflammatory dietary supplements due to their phytochemical contents such as gallic acid, catechin, and epicatechin, which show an immune-modulatory role in inflammatory conditions (Giovinazzo and Grieco 2015). The polyphenol amount in grape seeds is approximately 60–70%, and in the United States, many commercial preparations of grape seed extract (GSE) with up to 95% procyanidins are marketed as dietary supplement, being appreciated for their powerful protective properties against free radicals and oxidative stress (Smeriglio et al. 2018). Different parts of *V. vinifera* (mainly fruits) have been used also to prepare remedies of traditional medicine (Bombardelli and Morazzonni 1995), e.g., the use of leaves in infusion as hemostatic and for treatment of diarrhea, hepatitis, and stomachaches (Mansour et al. 2013).

2.4.4 Pomegranate

Initially named *Malum punicum*, meaning the apple of Carthage, this specie was then called by Linnaeus *Punica granatum* (Fig. 1g). The common name of the species comes from the Latin words *pomum*, apple, and *granatum*, seeded. The plant has

been cultivated and used for several millennia throughout the Middle East, Southern Asia, and Mediterranean region, while nowadays it is extensively cultivated in Southeast Asia and China. Various cultivars are appreciated for their taste, and "Wonderful" is the most famous commercial variety worldwide. Fruit seeds are consumed fresh, used as spice, and utilized for different culinary purposes. They contain dietary fibers, vitamins, and healthy substances, such as punicalagins and punicic acid, responsible for most of the plant's biological properties. The juice is rich in anthocyanins, in particular pelargonidin glycosides, and other polyphenol classes including ellagitannins (Khan et al. 2017), although the last ones are particularly abundant in the peel and inner membranes of pomegranate. Phenolic acids are present in both fruit and juice, showing significant antioxidant activity and healthy properties (Wu and Tian 2017), recognizing pomegranate as one of the new superfoods.

Many studies and reviews on the pharmacological properties of pomegranate have shown the therapeutic utility of various parts of this plant. The most popular use of pomegranate worldwide is as a vermifugal agent so much so that this fruit is already mentioned in the Eber's papyrus (1550 BCE), testifying that ancient Egyptians used the root extracts of pomegranate in removing intestinal tapeworms (Arun and Singh 2012).

In folk medicine, different parts of the plant have been used, including its flowers, leaves, bark, roots, fruit peel, and juice. In particular, the fruit shows strong astringent effects due to an abundant content of tannins, and therefore, its decoction has been indicated for treating stomach disorders and dysentery. Moreover, the flower infusion has been used to treat diarrhea and infections that cause vaginal discharge. Together with pomegranate peel, the flower infusion has been used to relieve inflammation of the pancreas, while the fruit juice can heal gallbladder diseases. Fresh or dried root barks, or ethanol extracts thereof, have been widely used to remove intestinal parasites. Finally, pomegranate has been used in folk medicine for its antibacterial, anti-inflammatory, antispasmodic, diuretic, carminative, sudorific, galactogogue, and emmenagogue properties (Shaygannia et al. 2016).

Recent studies show that extracts of all parts of the fruit have therapeutic properties and can be useful for a range of diseases, such as diabetes, male infertility, cardiovascular disorders, cancer, and Alzheimer's disease (Sreekumar et al. 2014).

For example, quercetin and ellagic acid, both present in pomegranate, show together a higher inhibitory effect against cancer cell growth. Pomegranate extract has also antiestrogenic effect in the mammary gland, without any adverse effects on cardiovascular and skeletal system; it could be considered a selective estrogen receptor modulator, and further studies are necessary to test its efficacy on estrogen-dependent breast cancers (Sreekumar et al. 2014).

2.4.5 Tree Nuts

Tree nuts are important food sources since prehistoric times, providing beneficial effects to human health due to the presence of protein, fibers, unsaturated fatty acids, minerals (magnesium, potassium, and copper), vitamins (vitamin E, vitamin B6,

folic acid, and niacin), phytosterols, and polyphenols, such as catechins and resveratrol (Vadivel et al. 2012). Several tree nuts, such as walnuts, pecans, almonds (Fig. 1d), and chestnuts, are among the dietary plants with the highest content in antioxidants. Even though limited, the current evidence indicate that tree nut phytochemicals are bioaccessible and bioavailable in humans. Their consumption is associated with a wide range of biological activities including antioxidant, anti-inflammatory, antiproliferative, antiviral, chemopreventive, and hypocholesterolemic actions, decreasing the onset of chronic degenerative diseases (Bolling et al. 2011). In addition, nut intake can be associated with healthy body weight maintenance, because nut fat content consists mainly of unsaturated fats, which able to induce energy expenditure by thermogenesis (Vadivel et al. 2012). Traditional Mediterranean nuts include almonds, hazelnuts, walnuts, pine nuts, and pistachios. Among these, walnuts (*Juglans regia* L.) are most commonly found in our diet and contain different compounds with antioxidant and anti-inflammatory bioactivity. These phytochemicals are responsible for a wide range of health-promoting effects, including lowering of cholesterol, increasing the ratio of high-density lipoprotein cholesterol to total cholesterol, and improving arterial function (Fatima et al. 2018). For these reasons, tree nuts showed promising results on cardiovascular diseases, both in prevention and in the treatment of related diseases. On the contrary, studies, which correlate the tree nut consumption with a decrease of incidence of cancer or metabolic disorders, are still scarce. Another aspect to underline is the allergenic potential of nuts, especially among children. However, the roasted tree nuts are certainly more digestible and less allergenic than natural ones. Consumption of tree nuts, despite being high-energy foods, does not increase weight gain, but it gives satiety and increases thermogenesis as long as a small quantity is consumed within a balanced diet (de Souza et al. 2017).

2.4.6 Brassicaceae

The Brassicaceae family is a vast complex of plant species including different domesticated entities (Fig. 1b). The latter belongs mainly to the genus *Brassica*, but species of the genera *Crambe*, *Eruca*, *Diplotaxis*, *Raphanus*, and *Sinapis* are also included. Domesticated Brassicaceae are among the most important plant foods. They are cultivated as vegetable crop to produce fresh or conserved food, but several ones are also exploited for oilseeds, yielding edible oils (Mcvetty and Duncan 2016). The consumption of Brassicaceae can produce beneficial effects to human health due to the presence of different bioactive compounds. More specifically, the antioxidant activity derives from the presence of well-known bioactive agents in fresh vegetables such as vitamins C and E, carotenoids, and antioxidant enzymes such as catalase, superoxide dismutase, and peroxidase. In addition, Brassicaceae are also rich in flavonoids, coumarins, terpenes, and sulfur-containing compounds such as glucosinolates and S-methylcysteine sulfoxide (Raiola et al. 2017). These compounds have been shown to reduce oxidative stress, especially by inducing detoxification enzymes, and in addition to stimulate the immune system and to reduce the

incidence of cancer (Herr and Büchler 2010). Health-promoting effects of Brassicaceae have been attributed mainly to glucosinolates and in particular to their hydrolyzation products isothiocyanates. Glucosinolates are typical of pungent Brassicaceae such as horseradish, mustard, and cabbage. Isothiocyanates have attracted much interest from a medical point of view due to their anti-inflammatory and anticancer potentials. Several in vitro and in vivo studies suggest a chemopreventive activity of these bioactive compounds through the redox-sensitive transcription factor Nrf2. Furthermore, studies in cultured cells, on animal models, and in humans support the anti-inflammatory effect of *Brassica*-derived phytochemicals. However, the molecular mechanisms by which these bioactive compounds exert their health-promoting properties are still scarce and controversial. Recent findings suggest the involvement of epigenetic mechanisms, being the isothiocyanates able to inhibit histone deacetylase transferases and DNA methyltransferases in cultured cells, but further studies are necessary to corroborate this assumption (Wagner et al. 2013).

The ancient use of Brassicaceae, not only as food but also for medicinal purposes, is confirmed by the mention of *rhaphanos*, or *krambē*, as a remedy against drunkenness and subsequent headache. These news date back to Theophrastus (fourth century B.C.E.), while Dioscorides also cited the plant in his famous book *De Materia Medica* written about the year 65 C.E. (Maggioni et al. 2018).

Recently, different folk medicinal uses of Brassicaceae have been reported, especially concerning the seeds of *Brassica nigra* (L.) W.D.J. Koch, a species cultivated worldwide. The seeds are employed in the treatment of rheumatism and joint pains, indurations of the liver and spleen, and throat tumors and as laxative. Seeds are also appreciated for their antioxidant and antimicrobial activities (Obi et al. 2009). Recently, the leaves of *B. nigra* have been shown to possess therapeutic value too, including hepatic and nephroprotective effects (Rajamurugan et al. 2012).

Due to its antioxidant and anti-inflammatory properties (Rokayya et al. 2014), *Brassica oleracea* L. (cabbage) has been widely used as a traditional remedy for gastrointestinal disorders such as gastritis, peptic and duodenal ulcers, and irritable bowel syndrome. In addition, recent studies have shown that the cabbage can be also used for the treatment of skin inflammation (Lee et al. 2018).

2.4.7 Spices

Spices are different parts of a plant generally used in diet for their aromatic properties but characterized by a low nutritional value. However, these aromatic species contain different phytochemicals, mainly phenolic acids and flavonoids, with powerful antioxidant activity that may still be an important contributor to the antioxidant intake of human diet. A positive correlation was found between total phenol content and antioxidant activity of spices (Guldiken et al. 2018). Such compounds have been selected, through plant evolution, as protection against plant cell oxidative damage (Paur et al. 2011).

A recent study on the antioxidant properties of 425 spices and herbs from 59 different manufacturers or countries showed that clove, in the form of dried sample, had the highest mean antioxidant value, followed by peppermint, allspice, cinnamon, oregano, thyme, sage, rosemary (Fig. 1f), saffron, and estragon. Moreover, fresh samples often showed lower values in comparison with dried material, as confirmed by data obtained for oregano, rosemary, thyme, basil, chives, dill, and parsley (Guldiken et al. 2018). This kind of evidence seems related to the drying process, which preserves most of the phytochemicals intact in the dried products, which, based on the same weight, shows therefore a greater antioxidant activity. Some authors showed that among commercially available spices, the highest antioxidant capacity was found for clove, oregano, and thyme, probably due to the presence of rosmarinic acid in thyme and oregano, eugenol in clove and allspice, and gallic acid in clove. The properties of these compounds could be related to the inhibition of NF-κB transcription factor, involved in immune and inflammatory responses (Paur et al. 2011).

From ancient times, spices were used as food and to prevent and treat chronic health problems, but also as coloring agents, preservatives, and food additives. Different ethnobotanical studies documented the use of spices in traditional medical systems in different countries. Herbs and spices are common to the traditional Mediterranean diet and are widely used in China and India, where the history of spices is more than 7500 years old. The most common spices reported different therapeutic activities, such as purgative, laxative, expectorant, carminative, and diuretic and showed that spices can have synergistic actions with holistic effects on human health (Sachan et al. 2018).

2.5 Application in Food

Bioavailability of phytochemicals, other than influenced by external factors, physicochemical features of bioactive compounds, and host-related factors, is strongly influenced by several food-related factors. The food matrix and food processing are the main key factors involved.

It is well-known that the best way to take a food is to eat it raw (uncooked) to keep all its native nutritional and health properties. However, sometimes this is not feasible or otherwise not preferable.

Thermal treatment affects the content and, consequently, the amount of the bioavailable phenolic compounds. However, it does not influence always negatively the bioavailability of bioactive molecules. Indeed, often, heat treatment leads to the formation of metabolites that show a greater activity compared to native molecules; therefore, sometimes the final biological properties of the food are not affected or, sometimes, may be enhanced, as was observed after thermal treatment of several spices. On the contrary, when the health effects of a given food are ascribable only, or largely, to the native molecules, the cooking, or in any case the food processing in general, significantly affects its biological properties. An example is the EVOO, in which the concentration of hydroxytyrosol, elenolic acid, and oleuropein aglycone

as well as its derivatives decreases fast enough after thermal treatment (D'Archivio et al. 2010). However, not all cooking methods are the same, because the temperatures used differ, in some cases, substantially. Generally, boiling and frying determined a higher loss of total phenols than steaming, although for each vegetable, a preferential cooking method could be selected to preserve or improve its nutritional properties. The steam-cooked broccoli, for example, results in an increase of the polyphenol content and consequently in its antioxidant activity. Another aspect which affects the polyphenol content is the storage of not only fresh fruits and vegetables but also of processed foods such as juices, frozen foods, wine, and so on. After cold storage, broccoli, for example, lost about 75% of its caffeoyl-quinic derivatives and 40–50% of its sinapic acid and feruloyl derivatives (Raiola et al. 2017). In the same manner, an important decrease of phenolic acids was observed in frozen red raspberries. Regarding storage, the light, for some foods in particular, plays a pivotal role; an example is the EVOO. Exposed to light, EVOO lost about 45% of its total phenol content in 4 months. On the contrary, if stored adequately in closed bottles in the dark, the antioxidant activity of EVOO remains unchanged until 8 months. This does not mean that its polyphenol profile does not change but that the hydrolysis of the more complex polyphenols leads to an increase in simpler polyphenol concentration such as hydroxytyrosol and tyrosol, preserving the food's total antioxidant capacity (D'Archivio et al. 2010; Smeriglio et al. 2019b).

Technological processes, such as chopping, milling, and homogenization, could increase the bioavailability of polyphenols by the alteration of the food matrix. It is well-known, indeed, that a direct interaction between polyphenols and some food components, such as proteins, carbohydrates, fiber, and fat, exist, although, sometimes, with controversial results and strictly dependent on the polyphenol class investigated (D'Archivio et al. 2010; Mandalari et al. 2016). Generally, dietary fiber slows the gastric transit, increasing the absorption of the polyphenols, while the fats sometimes sequester the related molecules decreasing their absorption. However, there are exceptions and one of these is the EVOO. Hydroxytyrosol and tyrosol showed an increased bioavailability when administered conveyed in EVOO compared to an aqueous solution, despite their amphiphilic nature (Colica et al. 2017; Nobili et al. 2019).

Another factor affecting the polyphenol bioavailability is the interaction with other compounds. It has been reported that intermolecular bonds between transport protein such as serum albumin and quercetin metabolites can occur, slowing the metabolite elimination. Similarly, epigallocatechin-3-*O*-gallate possesses a high affinity for blood proteins, and this could increase its plasma half-life (D'Archivio et al. 2010).

2.6 Safety: Toxicity and Side Effects

Discussing about food and risk-benefit profile is almost a foregone conclusion if we exclude everything outside the food per se, such as pesticides and heavy metals, and anything else that comes from human intervention and environmental factors. This is

because substantially, it concerns something that has been assumed for decades by humans without showing any undesired effects and because, as seen previously, they contain several bioactive molecules but with low concentrations and often poor bioavailability. However, it is important to make a distinction between foods and food-isolated compounds, which generally can be found in dietary supplements. Food supplements, in fact, contain high amounts of one or more bioactive molecules, which contribute to overall dietary intake, and the potential risks associated with a high daily intake have not been, up to date, deeply investigated. In particular, the most worrisome aspects concern the increased bioavailability of these bioactive compounds that can determine side effects due to potential pharmacokinetic interactions with both endogenous molecules and with other xenobiotic such as drugs (Smeriglio et al. 2017).

Furthermore, other than phytochemicals which showed a wide range and less specific health properties, there are others with a specific activity that can represent a serious risk for human health if not taken in the correct doses and under certain conditions. Among them, those which attracted the most attention lately are the isoflavones. They are able to interfere with the endocrine system causing positive or negative biological effects on organism, its progeny, or subpopulations. Therefore, the main concern regards the potential adverse effects of isoflavones on human health reproduction. Animal and human studies showed, indeed, side effects on female and male reproductive systems upon in utero exposure to isoflavones, in particular to genistein. However, the European Food Safety Authority (EFSA) concluded, based on actual evidences, that in postmenopausal women, isoflavones do not adversely affect the breast, thyroid, and uterus (Smeriglio et al. 2018b).

Another aspect, which is of particular concern, is the maternal ingestion of polyphenol-rich foods as well as dietary supplements, especially during the third trimester of pregnancy. A direct correlation was highlighted between polyphenol-rich diet and fetal ductal constriction, with statistically significant differences between fetuses exposed to high-polyphenol diet and low-polyphenol diet. In particular, the first group showed an increase of ductal velocities, pulsatility index, and right ventricle dimension than those exposed to minimal amounts of these substances. The molecular mechanisms involved have not been fully elucidated. In light of these observations, however, the intake during late pregnancy is not recommended (Hahn et al. 2017).

Nevertheless, also among foods, there is one, which draws particular attention.

Tree nuts have become an important part of human diet worldwide, thanks to several in vitro, animal, and human studies which highlight their ability to control weight and their high-diet values. However, despite the widely accepted health benefits, they are one of the eight foods, such as wheat, milk, egg, soy, fish, and shellfish, responsible for 90% of IgE-mediated allergic reactions in the world. Moreover, it has been observed that, even though the proportion of younger children suffering from tree nut allergies is lower compared to other big eight food allergies, the allergic reactions to tree nuts are more dangerous than other ones, causing most frequent cases of fatalities (Vanga and Raghavan 2017).

Finally, another category of foods most investigated from the safety point of view is spices.

Paracelsus said: "the dose makes the poison"; thus, depending on the dose of exposure, the potential health benefits of spice phytochemicals may become toxic effects including carcinogenic, neurotoxic, genotoxic, teratogenic, cytotoxic, nephrotoxic, hepatotoxic, and gastrointestinal side effects. Among spices, those that are of particular concern are red chili and some commonly used spices such as cinnamon, nutmeg, black pepper, and basil (Guldiken et al. 2018).

A clinical study showed that high chili pepper consumption increases, in a dose-dependent manner, the risk of aerodigestive track cancers of different ethnic-cultural groups, with a strong correlation between the consumption of capsaicin pepper and stomach cancer (Guldiken et al. 2018).

The risk associated instead to commonly spices is strictly correlated to their safrole content. This molecule is able to interfere with DNA, leading to the formation of adducts, and is well-known as a weak hepatocarcinogen. Other spices such as red pepper, fennel, cardamom, dark pepper, cumin, and coriander may activate acid secretion and exert harmful effects on the gastric mucosa.

Furthermore, several adverse effects on human health were observed following co-administration of spices and drugs (Guldiken et al. 2018).

In conclusion, not everything that is natural can be considered safe, and dose-related side or toxic effects should be considered and evaluated. Furthermore, further studies on the potential adverse events that might be associated with high intake of food-isolated bioactive constituents are needed.

2.7 Marketed Products

Today, there is a great availability of nutraceutical formulation such as tablets, powders, capsules, and so on, containing food bioactive compounds. The basic research supports the biological properties ascribed to them, but the health effects on humans are sometimes scarce or controversial. This is due, mainly, to the poor availability of clinical trials and to the difficulty to translate in vitro and animal studies to humans. The main issues are bioavailability, metabolism, dose/response ratio, and side effects of these food bioactive compounds or nutraceutical formulations. Furthermore, in some countries, in which the regulations on nutraceuticals are quite lax, other aspects such as phytochemical characterization, extract standardization and stability of pure compounds, and food extracts and formulation as tale are rather lacking, making sure that there are substantial differences between a product and another product with the same bioactive compounds and between lots of the same product. Apart from these latter ones, which are easily resolvable problems, simply by applying good laboratory practices and conceiving a product seriously from the qualitative point of view, the most problematic aspect remains the bioavailability of many bioactive compounds.

Several technological strategies are to date available to preserve the bioactive compounds by degradation during processing and to improve their bioavailability

and consequently their health effects. The most common procedure, already used for a long time for drugs, is to encapsulate the bioactive compounds in a coating material, which can release its contents at a controlled rate and under specific conditions.

This represents a great challenge, especially for molecules such as polyphenols characterized by insufficient gastric permanence, low intestinal absorption and/or solubility, gastrointestinal tract degradation (i.e., pH, enzymes) and/or interaction (presence of other nutrients, food matrix), as well as chemical instability under industrial processing conditions and storage (i.e., temperature, light, oxygen). The nutraceutical use of these compounds, therefore, requires an adequate formulation that guarantees the native characteristics of the bioactive compounds up to the time of consumption and that allows the active ingredients to reach the target site in order to exert their biological activity.

Several microencapsulation techniques of bioactive compounds are available nowadays, being very widespread in the food and cosmetic industry. They can be mainly divided into physical, physicochemical, chemical, and other stabilization methods. Among these, the most used are the spray-drying, freeze-drying, coacervation, molecular liposome inclusion, co-crystallization, nanoencapsulation, yeast encapsulation, and emulsion (Smeriglio et al. 2014).

2.8 Patents

Several patents are today available about food polyphenols, many of which concern extraction methods, enriched foods, cosmetic formulations, and recently, many nutraceutical formulations.

Remaining consistent with what was the guideline of this chapter, Table 2 shows the international patents related to selected functional foods (extra virgin olive oil, edible berries, grapes and wine, pomegranate, nuts, Brassicaceae, and spices).

In addition to the international patents listed in Table 2, it is worth pointing out that there are also patents in which the foods treated in this chapter are used as a vehicle to convey synthetic active ingredients or plant extract-isolated bioactive compounds. Italian national patent for utility model N°202 017 000 075 448 and Italian national patent for industrial invention N°102 016 000 007 757 are two examples being related to gastric-resistant food/pharmaceutical capsule for the containment and administration of hydroxytyrosol conveyed in EVOO.

2.9 Perspectives

Despite the high number of in vitro and in vivo studies about polyphenols and health properties, the available clinical studies are scarce, controversial, and sometimes with conflicting results because different formulations, dosages, and treatment

Table 2 Patents released in the last 20 years about functional foods selected, based on innovative extraction procedures, formulations, and preservations of active ingredients. (Source: https://worldwide.espacenet.com (only the first 500 results are displayed). Last accessed: March 1, 2019)

Functional food	Patent name	Classification	Application number
Extra virgin olive oil	A novel composition obtainable from extra virgin olive oil and methods of preparation thereof;	International	GB20170009211 20170322
	Reactor for increasing the quantity of polyphenols and/or the turbidity stability of extra-virgin olive oil, system and method using said reactor	International	EP20140731366 20140508
	Method of extracting phenolic fractions of extra virgin olive oil	International	US201214002920 20120302
	Method for the preparation of herbs-enriched extra virgin olive oil-based products	International	GR20110100490 20110812
	Soft capsule for directly drinking extra-virgin olive oil	International	JP20050116225 20050317
	Dietary extra-virgin olive oil with omega-3 fatty acids and relevant production technique	International	WO2003IT00391 20030624
	Process to acquire extra virgin olive oil enriched with vitamin E	International	ES20000000744 20000327
	Process to acquire extra virgin olive oil enriched with vitamins	International	ES20000000743 20000327
Edible berries	Preserving miracle fruit berries	International	US201615227389 20160803
	Sustained-release preservative and preservation method for berries	International	CN201710573890 20170714
	Method for vacuum drying of fruits and berries	International	RU20160132597 20160808
	Method for organic manufacture and increase in duration of garden strawberry berries storage	International	RU20160111906 20160329
	Processing technology of quick-frozen grape berries	International	CN20151449787 20150728
	Composition of formulation for inner beauty using berries extract as a major ingredient and method thereof	International	KR20150000471 20150105
	Extraction Tool for Stemming Soft Fruit and Berries	International	US201414267044 20140501
	Antioxidant compound jelly with natural berries rich in anthocyanin special for astronauts and preparation method of antioxidant jelly	International	CN20151065873 20150207

(continued)

Table 2 (continued)

Functional food	Patent name	Classification	Application number
Edible berries	Special compressed food prepared by taking berries as raw materials and used for supplementing vitamins to astronauts and processing method of special compressed food	International	CN201410761293 20141213
	Method and device for producing a functional product of berries made into puree with crushed seeds and skins of the berries and the product made by this method	International	EP20150712444 20150218
	Morus berries and avoiding glucose peaks	International	CN20118075610 20111201
	Goji berries extract production method	International	RU20110140748 20111010
	Methods of wild berries fermented powder tablet and wild berries fermented powder tablet manufactured the methods	International	KR20110050626 20110527
	Method for nonwaste low-temperature processing of fruit and berries for preserves	International	RU20090138771 20091020
	Natural antioxidative feed additive based on elements from berries	International	EP20090764174 20091029
	Method of preserving fruits and berries	International	RU20070130948 20070813
Grapes and wine	Improved and more gentle process for extracting useful substances from grapes, grape must extracted therefrom and wine produced therefrom, as well as device for carrying out electroporation	International	ZA20060006882 20060817
	A method of handling harvested grapes and converting same to wine without exposure to oxidizing air	International	ZA19730007718 19731002
Pomegranate	Use of a vegetal formulation containing pomegranate seed oil as an immune system enhancer due to its antioxidant function	International	WO2018TR50157 20180410
	Use of a vegetal formulation containing pomegranate seed oil as an assistive agent in reduction of blood lipids known as triglyceride	International	WO2018TR50158 20180410
	Composition for improving skin condition comprising pomegranate concentrate as active ingredient	International	KR20180153788 20181203
	Pomegranate hand cream and preparation method thereof	International	CN201810646859 20180621
	Skin whitening pomegranate extract and preparation method thereof	International	CN201810603225 20180612

(continued)

Table 2 (continued)

Functional food	Patent name	Classification	Application number
Pomegranate	Pomegranate peel antioxidant additive and preparation method thereof	International	CN20161195941 20161202
	Pomegranate extract for relieving of menopausal symptoms containing a high content of ellagic acid	International	KR20180042898 20180412
	Whitening and moisturizing mask containing pomegranate essence and preparation method of mask	International	CN201711439770 20171227
	Hydrogel sour pomegranate powder skin care product as well as preparation method and application thereof	International	CN201711214270 20171128
	Pomegranate fresh fruit preservation method	International	CN201711030441 20171027
	Preparation method of health-preserving pomegranate tea	International	CN201710848497 20170919
	Method for producing pill for relieving menopausal symptoms containing pomegranate	International	KR20160036782 20160328
	Health care pomegranate tea	International	CN201611017478 20161119
	Red pomegranate anti-allergy anti-inflammatory whitening shower gel and preparation method thereof	International	CN201710104678 20170224
	Preparation method of functional pomegranate ice wine	International	CN201611091452 20161201
	Pomegranate skin extract for treating fatty liver	International	US201415109723 20140109
	Preparation method of pomegranate peel antioxidant substance	International	CN201610367488 20160530
	Application of pomegranate and sour pomegranate medicine composition to preparation of drug for treating hyperlipidaemia	International	CN201610130896 20160308
	Anti-aging natural pomegranate skin-care product and preparation method thereof	International	CN201610189191 20160330
	Pomegranate seed soft capsule	International	CN20151910165 20151210
Nuts	Nuts with added healthy function and method for manufacturing the same	International	KR20180130290 20181029
	Nut-based beverage made with unroasted nuts	International	MX20170014851 20160516
	Nuts with added healthy function and method for manufacturing the same	International	KR20160156225 20161123

Spices	Extraction of essential oils from spices using the microwave technique for the manufacture of biofungicides	International	MX20140007045 20140612
	Essential oil extract of natural spices, encapsulated, oily dispersed and its preparation method	International	PL20110397664 20111230
	Method for improving the aroma of sterilized leaf spices, especially marjoram and thyme	International	PL20090390034 20091223
	Method for improving extraction rate of total flavonoid in spices by using radiation technique	International	CN20101510872 20101018

durations are used, most of them include subjects coming from different populations, sex, age, body mass index, and other features. This approach risks to flattening the observed results that are already sufficiently weakened by the small sample size and by the huge number of bacterial strains/plant extracts or isolated compounds investigated alone or in combination. Basic research suggests a direct correlation between the consumption of polyphenol-rich foods and foods low in fatty acids, such as fruits and vegetables, and the decreased onset of various oxidative stress-related diseases such as cardiovascular and inflammatory diseases, diabetes, and cancer. However, in vitro and in vivo results are not always movable to humans due to the large inter--individual pharmacokinetic variability; hence, it is important to carry out well-designed clinical trials. Therefore, what emerges from the literature currently available is the lack of studies, which investigate in depth the pharmacokinetics of these compounds. In fact, before carrying out a clinical study, a rational formulation of the molecules of interest should be taken into account, which guarantees best bioavailability and consequently health effects.

Dietary Flavonols and O-Glycosides

3

Senem Kamiloglu, Merve Tomas, and Esra Capanoglu

Contents

Abstract

Flavonols are the most widespread subgroup of the flavonoids. Quercetin, kaempferol, myricetin, and isorhamnetin are the major dietary flavonol aglycones, which most commonly occur as *O*-glycosides in dietary sources including fruits, vegetables, tea, and wine. The role of flavonols and *O*-glycosides

in human nutrition has gained increased interest due to their associated health beneficial effects for a number of chronic diseases, including cardiovascular diseases, diabetes, and cancer. However, the potential bioactivity of flavonols and *O*-glycosides will depend on their bioavailability. Following digestion, flavonol glycosides are cleaved to their aglycones, which may be metabolized in the enterocytes and further in the liver, forming glucuronidated, sulfated, and/or methylated metabolites, or they may be passively permeate the intestinal epithelial barrier. Flavonols that reach the colon may be degraded by the colonic microbiota to different metabolites, which may also contribute to the observed biological effects. In this chapter, the recent findings on the bioavailability, metabolism, bioactivity, and benefits of dietary flavonols and *O*-glycosides are highlighted. In addition, the recent information on food applications, safety issues, marketed products, and patents are also presented.

Keywords

Quercetin · Kaempferol · Myricetin · Isorhamnetin · Bioavailability · Metabolism · Cardiovascular diseases · Diabetes · Cancer · Toxicity

3.1 Introduction

Flavonols belong to a large group of compounds collectively known as flavonoids, which are a subgroup of an even larger group of compounds known as polyphenols. They are the most widespread subgroup of the flavonoids, being dispersed throughout the plant kingdom with the exceptions of algae and fungi (Crozier et al. 2009). Flavonols not attached to sugar moieties are referred as the aglycone form, whereas flavonols with sugar moieties are called flavonol glycosides. The major dietary flavonol aglycones are quercetin (3,5,7,3′,4′-pentahydroxyflavone), kaempferol (3,5,7,4′-tetrahydroxyflavone), myricetin (3,5,7,3′,4′,5′-hexahydroxyflavone), and isorhamnetin (3,5,7,4′-tetrahydroxy-3′-methoxyflavone), which most commonly occur as *O*-glycosides. Fruits, vegetables, and beverages are important dietary sources of these flavonol *O*-glycosides. In particular, berries, onion, and *Brassica* vegetables including cabbage, kale and broccoli, buckwheat, tea, and red wine are among the well-known sources of quercetin and kaempferol aglycones and *O*-glycosides (Table 1). Apples also contain quercetin glycosides including quercetin 3-*O*-galactoside, quercetin 3-*O*-glucoside, quercetin 3-*O*-rhamnoside, quercetin 3-*O*-arabinoside, and quercetin 3-*O*-xyloside. However, as apple flavonols are almost exclusively present in the peel of the fruit (Jakobek and Barron 2016), the flavonol content of whole fruit is low (5.73 mg/100 g fresh weight) compared to berries (www.phenol-explorer.eu) (Table 1).

Dietary intake of flavonols varies between countries. In the Netherlands, the average intake of flavonols was reported to be approximately 23 mg/day, of which quercetin contributed 16 mg/day, kaempferol 3.9 mg/day, and myricetin 1.4 mg/day. Tea was the major source in this population (48% of total intake), followed by onions (29%) and apples (7%) (Hollman and Arts 2000). The same foods and beverages are

The data presented in this table is extracted from Phenol-Explorer database (www.phenol-explorer.eu)

also the most predominant dietary sources of flavonols in Denmark and the USA. However, eating habits and cultural differences may significantly influence the dietary source of flavonols. For example, while green tea is the superior source of flavonols in Japan, berries are reported to be the most important dietary sources in Finland. Variations of dietary sources also can be observed among different regions within the same country. For instance, in Italy, red wine is known to be the most significant source of dietary flavonols. On the other hand, in the northern villages of Italy, the major sources of flavonols are reported to be fruits and vegetables (Aherne and O'Brien 2002). In addition to the above, the methods of culinary preparation also have a marked impact on the flavonol content of foods and hence their intake. For example, peeling of fruits and vegetables can eliminate a significant portion of flavonols because these compounds are often present in higher concentrations in the outer parts than in the inner parts, as in case of apples. Moreover, many fresh fruits and vegetables are subjected to a form of processing, e.g., cooking, before consumption, which may also significantly affect the flavonol content. Accordingly, it has been demonstrated that the quercetin content of onions and tomatoes reduced by 75–80% after boiling for 15 min, 65% after cooking in a microwave oven, and 30% after frying (Briones-Labarca et al. 2011).

In 1936, Szent-Györgyi found that quercetin 3-*O*-rutinoside, also known as rutin, had vitamin properties and termed this flavonol as "vitamin P." At that time, dietary

flavonols are believed to have a poor bioavailability, and therefore nutritional scientists excluded vitamin P from the category of vitamins. In 1970s, quercetin and other plant flavonols are assumed to be potential carcinogens as these compounds were found to possess mutagenic activity (Terao 2009). On the other hand, a great number of recent scientific studies based on in vivo experiments reported the benefits of flavonol consumption with respect to cardiovascular diseases, diabetes, inflammation, viral infections, enhanced physical strength, and cancer prevention (Ahmad et al. 2015; Gormaz et al. 2015; Chen et al. 2016a; Kashyap et al. 2016; Bazzucchi et al. 2019). However, the potential bioactivity of flavonols and *O*-glycosides will depend on their bioavailability. Following digestion, flavonol glycosides are cleaved to their aglycones, which may be metabolized in the enterocytes and further in the liver, forming glucuronidated, sulfated, and/or methylated metabolites, or they may passively permeate the intestinal epithelial barrier (Day et al. 2001). Furthermore, flavonols that reach the colon may be degraded by the colonic microbiota to different phenolic acids, e.g., phenylacetic acid and protocatechuic acid (Serra et al. 2012), which may also contribute to the observed biological effects.

Considering the above, in this chapter, bioactive constituents, bioavailability, metabolism, bioactivity, and benefits of dietary flavonols and *O*-glycosides are highlighted. In addition, the recent information on food applications, safety issues, marketed products, and patents are also presented.

3.2 Bioactive Constituents

Flavonols are formed from the combination of derivatives synthesized from phenylalanine via the shikimic acid pathway and acetic acid. The initial step of flavonol biosynthesis includes the formation of amino acid phenylalanine from phenylpyruvate. Then, by the action of phenylalanine ammonia-lyase (PAL) enzyme, phenylalanine is transformed to *trans*-cinnamic acid, which is hydrolyzed to *p*-coumaric acid (C9). The C9 acids condense with three malonyl-CoA molecules (C2) by chalcone synthase (CHS) to form chalcones (C15) (Aherne and O'Brien 2002; Survay et al. 2011). The C15 chalcones are then isomerized into (2*S*)-flavanones by chalcone isomerase (CHI). (2*R*, 3*R*)-*trans*-dihydroflavonols are subsequently formed from (2*S*)-flavanones by flavanone 3β-hydroxylase (FHT). Lastly, flavonol synthase (FLS), 2-oxoglutarate-dependent dioxygenase, catalyzes the desaturation of dihydroflavonols to flavonols (Leonard et al. 2006).

The structure of the flavonols is based on the flavonoid nucleus, which consists of three phenolic rings referred to as the A, B, and C rings. The benzene ring A is condensed with a six-member ring C, which carries a phenyl benzene ring B as a substituent in the 2-position. The term *4-oxo-flavonoids* is often used to describe the structure of flavonols (Aherne and O'Brien 2002), which can be distinguished from other flavonoids with the presence of (i) a double bond at the 2–3-position, (ii) a carbonyl group at the 4-position, and (iii) a hydroxyl group at the 3-position of C ring (Fig. 1). Azaleatin, fisetin, galangin, gossypetin, kaempferide, kaempferol,

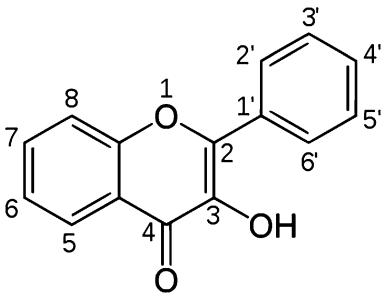

Fig. 1 Chemical structure of flavonols

isorhamnetin, morin, myricetin, natsudaidain, pachypodol, quercetin, rhamnazin, and rhamnetin are the common flavonol aglycones, which structurally differ from each other by variations in the number and position of hydroxyl and methyl groups (Table 2).

In nature, the majority of flavonols are present as *O*-glycosides. Glycosylation occurs frequently at the 3-position of the C ring, but substitutions can also take place at the 5-, 7-, 4′-, 3′-, and 5′-carbons (Crozier et al. 2009). The glycosidic sugars are generally glucose; however other carbohydrate substitutions including arabinose, galactose, rutinose, lignin, rhamnose, and xylose are also present (Aherne and O'Brien 2002). There are several flavonol glycosides, comprising mono-, di-, and tri-glycosides based upon quercetin, kaempferol, azaleatin, kaempferide, myricetin, and rhamnetin, and various permutations of glucose, galactose, rhamnose, arabinose, and rutinose. Some examples of flavonol glycosides and their glycosylation positions are given in Table 3; however it is noteworthy to mention that there are numerous flavonol conjugates, with 179 different glycosides of quercetin alone (Hollman and Arts 2000). The classification of the structures requires the knowledge of the nature of α or β aglycon sugar bonds as well as the optical configuration of the involved sugar (dextro or levo). As a rule, D-configured sugars, i.e., glucose, galactose, xylose, and glucuronic acid, form β bonds, while the α bonds are made of L-sugars such as arabinose and rhamnose. For example, this arrangement can be observed in the composition of apple flavonols, which are composed of quercetin glycosides, including α-L-arabinoside, β-D-galactoside, β-D-glucoside, α-L-rhamnoside, and β-D-xyloside (Escarpa and Gonzalez 2001).

3.3 Bioavailability and Metabolism

Several factors affect the bioavailability of a compound, including degradation by gut microflora and enzymes, decomposition in the gut lumen, and first pass metabolism by the liver. In addition, the physicochemical properties of the compound will also influence its bioavailability, consisting molecular weight, partition coefficient, and pKa (Choudhury et al. 1999). The absorption of dietary aglycones and *O*-glycosides has been the subject of many studies, and most of them have been related with quercetin and its glycosides.

Table 2 Flavonols and their hydroxylation and methylation positions

Flavonol	IUPAC name	5	6	7	8	2′	3′	4′	5′	6′
Azaleatin	2-(3,4-dihydroxyphenyl)-3,7-Dihydroxy-5-methoxychromen-4-one	OCH_3	H	OH	H	H	H	OH	OH	H

The bound sugar moiety is also known to influence the bioavailability of flavonoids. For instance, Morand et al. (2000) examined the effect of the type/nature of the sugar on the absorption of glycosides. They found that quercetin 3-glucose (33.2 μM) absorbed in the small intestine and was better absorbed than quercetin (11.7 μM) itself. In contrast, glycosides containing a rhamnose moiety could not be absorbed in the small intestine. These researchers suggested that the 3-O-glucosylation improves the absorption of quercetin in the small intestine.

In another study, Manach et al. (1995) studied the bioavailability and the plasma transport of flavonols in rats fed with quercetin or rutin diets. They also investigated the flavonol concentrations in plasma, ileal and cecal contents, and feces. They suggested that the rate of elimination of quercetin metabolites was relatively low and

high plasma concentrations can be easily maintained with a regular supply of flavonoids in the diet. In contrast, Gugler et al. (1975) showed that quercetin was poorly absorbed (1%) across the gastrointestinal tract in a human trial. However, they observed that recovery in feces after the oral dose was 53% degraded by microorganisms in the gut.

Choudhury et al. (1999) investigated the absorption and excretion of the aglycone quercetin and compared with its 3-glucoside (isoquercitrin) and 3-rhamnoglucoside (rutin) in the rat. They reported that isoquercitrin (0.48% of administered dose) orally absorbed was bioavailable. On the other hand, their results revealed that neither unchanged rutin, quercetin, nor the conjugated metabolites in the form of glucuronide or sulfate were detected in the urine after oral dosing. They also found that all the flavonoids studied produced low total urinary recoveries after intravenous administration, 9.2% for quercetin-3-rhamnoglucoside, 6.7% for the 3-glucoside, and 2.4% for the aglycone, indicating that extensive metabolism to low molecular weight compounds or excretion via other routes may be occurring. The differences in the metabolism of each compound could be linked to their physicochemical properties. Quercetin is the most lipophilic compound enabling its entry by passive diffusion into the liver. Very little unchanged quercetin and a greater number of metabolites and their conjugates were observed in the urine. However, rutin (less lipophilic compound) would not be distributed into the liver as readily. This lead to a greater proportion of unchanged compound and fewer metabolites being detected in the urine (Choudhury et al. 1999). Erlund et al. (2001) showed that quercetin-3-rutinoside was more bioavailable in women compared to men, and plasma levels were the highest in women using oral contraceptives. This could be related to interindividual variation in the gastrointestinal microflora or absorption or biotransformation mechanisms which affect the bioavailability. Another study conducted by Hollman et al. (1999) reported that the peak concentration of quercetin (C_{max}) in plasma was 20 times higher and reached T_{max} more than 10 times faster after the intake of glucoside ($C_{max} = 3.5$ μM; $T_{max} < 0.5$ h) than the rutinoside ($C_{max} = 0.18$ μM; $T_{max} = 6.0$ h). They also suggested that quercetin glucoside is actively absorbed from the small intestine, whereas quercetin rutinoside is absorbed from the colon after deglycosylation. Reinboth et al. (2010) investigated the bioavailability of quercetin in dogs, administering oral doses of 30 mmol/kg b.w. of the aglycone, isoquercitrin, or rutin, equivalent to 10 mg quercetin/kg b.w. They have reported that quercetin and isoquercitrin were mainly absorbed in the small intestine with isoquercitrin being one and a half times more bioavailable than quercetin. Dang et al. (2014) indicated that the bioavailability of myricetin was found to be 9.62% and 9.74% at two oral doses (50 mg/kg and 100 mg/kg, respectively), showing that it was poorly absorbed after oral administration.

In general, the first part of metabolism consists of tissues including the small intestine, liver, and kidneys, whereas the second part of the metabolism occurs in the colon. Studies on humans have clearly shown that metabolism in human body is vital to determine which ones are better absorbed and which ones cause formation of bioactive metabolites. Sugar moieties, such as quercetin-3-glucoside, are cleaved from the phenolic backbone in the small intestine and absorbed here through the

ingestion of flavonoids. Moreover, enzymes play an important role in the absorption. For instance, lactase phlorizin hydrolase (at enterocyte membrane) or β-glucosidase (cytosolic, for polar glycosides) hydrolyze glycosylated flavonoids and then aglycones enter epithelial cells by passive diffusion. On the other hand, some flavonoids linked to a rhamnose moiety must reach the colon and hydrolyzed by the colon microbiota (Marín et al. 2015). When the aglycon or the new bioactive metabolites formed are absorbed at small intestine, they go through some degree of phase II metabolism at enterocyte level, such as glucuronidation, methylation, and sulfation (Hollman 2004; Marín et al. 2015). Afterward, these products enter the bloodstream by the portal vein, reaching the liver. If a flavonoid glycoside is not absorbed in the small intestine, it can be metabolized by the colonic microflora into its aglycone in the large intestine (Xiao 2017). It is also worth emphasizing that tissue distribution can help predict a variety of events related to the efficacy. Xu et al. (2014), for example, reported that the highest level of kaempferide was observed in heart, whereas tamarixetin was observed in the lung of rats when their distribution in different tissues (heart, liver, lung, spleen, kidney, prostate, and brain) was investigated.

3.4 Bioactivities

Dietary flavonols and *O*-glycosides have many important biological activities, including antioxidant, anti-inflammatory, antiangiogenic, hypolipidemic, neuroprotective, and anticancer effects (Table 4). All these studies significantly indicated that dietary flavonols and *O*-glycosides may help treating some critical health problems.

Epilepsy is a common neurological disorder in which brain activity becomes abnormal, causing unpredictable seizures. Das et al. (2017), after investigating the effects of fisetin in traumatic epilepsy in rats for its antiepileptic activity, reported that fisetin pretreatment was found to inhibit the development of iron-induced electrical seizure and significantly decrease the corresponding multiple unit activity in the cortex and in the hippocampus. Moreover, it significantly reduced the production of malondialdehyde suggesting the antilipidperoxidative action of fisetin. Another worldwide health problem is food allergy for which present medications have many side effects and do not stop the progression of hypersensitivity reactions. Elkholy et al. (2019) showed that fisetin exerted potent immunomodulatory and anti-inflammatory activities, thus abled them to alleviate OVA-induced food allergy in mice. This alleviation could be due to their capability to rebuild the normal T-helper 1/T-helper 2 cytokine balance and AT1 blockade activity. In addition, Kim et al. (2014b) reported that administration of spiraeoside to mice suppressed the passive cutaneous anaphylaxis reaction. Thus, they supposed that spiraeoside can be utilized as an anti-allergic agent.

Even though there are many researches on acute lung injury and acute respiratory distress syndrome, the mortality rate as a result of these diseases still remains high. In the study of Feng et al. (2016), fisetin was injected (1, 2, and 4 mg/kg, i.v.) 30 min

Table 4 Recent animal studies on chronic disease

Components	Chronic disease	Animal model	Key outcomes	References
Fisetin	Epilepsy	Wistar rats	Antiepileptic action of fisetin in iron-induced model of epileptic rats by inhibiting oxidative stress	Das et al. (2017)
	Food allergy	BALB/c mice	Fisetin alleviated food allergy and shows potent anti-inflammatory and immunomodulatory effects	Elkholy et al. (2019)
	Acute lung injury	Sprague-Dawley rats	Fisetin may regulate the inflammatory process in lipopolysaccharide-induced acute lung injury	Feng et al. (2016)
	Ischemic heart disease	Wistar rats	Fisetin attenuates isoproterenol-induced cardiac ischemic injury	Garg et al. 2019
	Neurotoxicity	Pregnant Wistar rats	Fisetin reduced the toxic effects of MeHg in the developing rat brain	Jacob and Thangarajan (2017)
	Depression	ICR mice Ahi1$^{loxp/loxp}$ mice	Fisetin provided antidepressant effects	Wang et al. (2017)
	Acute pancreatitis	C57BL/6mice	Fisetin reduced pancreatitis and pancreatitis-associated lung injury	Jo et al. (2014)
	Atopic dermatitis	NC/Nga mice	Fisetin exhibited as a potential therapeutic for atopic dermatitis	Kim et al. (2014)
	Alcohol-induced acute liver	C57BL/6 mice	Fisetin at 5 and 10 mg/kg can attenuate the adverse effects of alcohol in liver tissues	Koneru et al. (2016)
	Glaucoma	DBA/2 J mouse	Fisetin was able to promote the visual functions of DBA/2 J mice	Li et al. (2019)
	Cardiac hypertrophy	SHR and control Wistar Kyoto rats	Fisetin inhibited cardiac hypertrophy in hypertension rats	Lin et al. (2019)
	Hyperglycemia	Wistar rats	Fisetin ameliorated hyperglycemia in diabetic rats	Althunibat et al. (2019)
	Aging	Wistar rats	Fisetin could be considered as an antiaging compound	Singh et al. 2019
Galangin	Hypertrophic scar	BALB/c mice	Galangin was a novel anti-hypertrophic scar compound	Zhang et al. (2016)

Components	Chronic disease	Animal model	Key outcomes	References
Spiraeoside	Type I allergy	Balb/c mice	Spiraeoside prevented mast cell activation and allergic responses	Kim et al. (2014)
Troxerutin	Hepatic gluconeogenesis	ICR mice	Troxerutin markedly reduced high-fat diet-induced enhancement of hepatic gluconeogenesis	Zhang et al. (2017)
	Liver cancer	Wistar rats	Troxerutin exerted a significant therapeutic effect against liver cancer by modulating liver function enzymes, xenobiotic enzymes	Thomas et al. (2017)
Icariin	Parkinson's disease	C57BL/6 mice	Icariin showed neuroprotective effect on dopaminergic neurons in Parkinson's disease mice	Chen et al. (2017)
	Bone infection	Rabbits	Icariin exhibited osteoplastic properties on osteoblasts and enhanced bone repair	Zhang et al. (2017)
	Depression	Sprague-Dawley rats	Icariin showed protective effects against corticosterone-induced depression and metabolic dysfunction	Gong et al. (2016)
	Ischemic stroke	Sprague-Dawley rats	Icariin exhibited neuroprotective effect on ischemic stroke in rats	Xiong et al. (2016)
	Acute kidney injury	C57BL/6 N mice	Icariin protected against kidney injury	Xie et al. (2018)

before lipopolysaccharide (LPS) administration (5 mg/kg, i.v.) in rats. They demonstrated that fisetin effectively reduced the inflammatory cytokine release and total protein in bronchoalveolar lavage fluids and the lung wet/dry ratios. Fisetin, moreover, inhibited LPS-induced increases of neutrophils and macrophage infiltration and attenuated myeloperoxidase activity in lung tissues. Additionally, the protective effect of fisetin in acute lung injury may be due to its ability to inhibit the expression Toll-like receptor 4 and the activation of nuclear factor-κB (NF-κB) in lung tissues. In addition, Jo et al. (2014) showed that pre- and posttreatment with fisetin attenuated the severity of cerulein-induced pancreatitis and pancreatitis-associated lung injury, inhibiting the activation of NF-κB and c-Jun NH_2-terminal kinase. Atopic dermatitis (AD) is a chronically relapsing and pruritic inflammatory skin disease. Kim et al. (2014a) investigated whether fisetin relieves AD-like clinical symptoms induced by repeated dinitrofluorobenzene treatment in NC/Nga mice. They reported

that fisetin significantly inhibited infiltration of inflammatory cells and suppressed the expressions of various inflammatory mediators. Furthermore, fisetin also inhibited phosphorylation of NF-κB p65, which associated with inflammation. Recent researches on alcohol consumption indicated that production of reactive oxygen species (ROS) and improvement of lipid peroxidation are the prime causes in the initiation of acute liver injury. Furthermore, the involvement of matrix metalloproteinases (MMPs) plays role in the pathogenesis of alcoholic liver diseases. Koneru et al. (2016), for instance, investigated the protective effect of fisetin on the liver from binge alcohol-induced toxicity and to explore the underlying mechanisms of inhibition of MMP and oxidative stress. They demonstrated that pretreatment with fisetin (5 and 10 mg/kg) ameliorated the alcohol-induced alterations in liver function, antioxidant defense, histological changes, mitochondrial respiratory enzymes, and MMP activities.

Coronary microvascular disease is another type of ischemic heart disease in its severest form, i.e., myocardial infarction, which continues to be a major cause of morbidity and mortality all throughout the world. Garg et al. (2019) reported via an in vivo study that flavonols like fisetin had a cardioprotective effects in the heart at doses of 10 and 20 mg/kg via suppression of oxidative stress-mediated apoptosis and inflammation and suppressed the receptor for advanced glycation end products (RAGE)/NF-κB. Methyl mercury (MeHg) is a neurotoxin causing irreversible cognitive damage in offspring of gestationally exposed mothers. Accordingly, Jacob and Thangarajan (2017) evaluated the effect of gestational intake of fisetin on MeHg neurotoxicity in F1 generation rats. They reported that intake of fisetin during pregnancy in rats ameliorated in utero MeHg exposure induced neurotoxicity outcomes in postnatal weaning F1 generation rats. Same group further investigated the mechanism behind the mitigating action of fisetin against prenatal MeHg exposure-induced neurotoxicity. They concluded that fisetin regulates the expression of regulatory genes and proteins involved in plasticity and synaptic transmission and decreases MeHg neurotoxicity in the developing rat brain (Jacob and Sumathi 2019). Fisetin has been reported to play an important role in depression, causing a series of physiological abnormalities including decreased tropomyosin receptor kinase B (TrkB) phosphorylation. Wang et al. (2017) indicated that fisetin increased phosphorylated TrkB level without altering total TrkB. Gong et al. (2016) also carried out studies on antidepressant-like effect and the possible mechanisms of icariin in a rat model of corticosterone-induced depression. They observed that icariin remarkably increased sucrose intake and hippocampal brain-derived neurotrophic factor levels and decreased the immobility time in forced swim test in corticosterone-induced depressive rats. Icariin pretreatments reversed the pathological process of corticosterone-induced depression via regulation of the disturbed metabolic pathways.

Glaucoma is another common chronic neurodegenerative disease, which could cause visual loss, especially in aged people. Li et al. (2019) carried out studies on whether fisetin is able to mitigate glaucoma. They reported that fisetin is able to promote the visual functions of DBA/2 J mice by inhibiting NF-κB activation. In addition, they found that both mRNA levels and secretory of tumor necrosis

factor alpha (TNFα), interleukin (IL-1β), and IL-6 were dramatically decreased in fisetin-treated DBA/2 J mice compared to untreated mice. In a recent study, Lin et al. (2019) investigated the effect of fisetin extenuates hypertension-associated cardiac hypertrophy in spontaneously hypertension rats. They showed that fisetin inhibits cardiac hypertrophy by effectively suppressing calcineurin-NFATC3, hypertrophic marker, in SHR hearts. In a recent study, Althunibat et al. (2019) observed that fisetin prevented cardiomyopathy via restoration of hyperglycemia and attenuation of oxidative stress, inflammation, and apoptosis in the diabetic heart. In another recent study, Shi et al. (2018b) found that the underlying mechanisms of fisetin could be attributable to suppression of NF-κB and activation of the nuclear factor erythroid 2-related factor 2 pathway. In parallel with these studies, Jayachandran et al. (2019) investigated the effects of streptozotocin (STZ) on Nrf2, NF-kB, and AMPK pathway and how the isoquercetin treatment at a molecular level overcame the burden of diabetes mellitus. They showed that isoquercetin prevented the oxidative stress and regulation of the expression of Nrf2 pathway-associated proteins and genes.

Aging is the time-related deterioration, characterized by different molecular hallmarks at the cellular and organismal level. More recently, Singh et al. (2019) observed that fisetin suppressed the aging-induced elevation in levels of reactive oxygen species, eryptosis, lipid peroxidation, and protein oxidation, whereas it significantly increases the levels of antioxidants and activates plasma membrane redox system. Based on these findings, the authors proposed that fisetin-rich diet might be a potential antiaging intervention strategy.

Hypertrophic scar is a complex fibroproliferative disorder, causing pain, burning, and itching. Zhang et al. (2016) revealed that galangin effectively extenuated hypertrophic scar formation, suppressing proliferation and inhibiting activin receptor-like kinase 5/Smad2/3 signaling, thus suggesting that galangin is as a potential agent for the treatment of hypertrophic scar or other fibroproliferative disorders.

Osteoporosis is a bone disease, causing loss in bone mass, micro-architectural deterioration of bone tissue, and predisposition to fracture. Accordingly, Chen et al. (2018) concluded that hyperoside was effective in preventing osteoporosis, inhibiting the TNF-receptor-associated factor 6, mediating receptor activator of nuclear factor-κB ligand (RANKL)/RANK/NF-κB signaling pathway and elevating the osteoprotegerin/RANKL ratio. Another study conducted by Zou et al. (2017) demonstrated that hyperoside has hepatoprotective action upon CCl_4-induced chronic liver fibrosis in mice, improving the expression of Nrf2 in nucleus, decreasing the MDA content and GOT/GPT/serum monoamine oxidase activity, and increasing the anti-oxidase (GSH-Px/SOD/CAT) activity toward the formation of trichloromethyl radicals.

Ischemic stroke, leading cause of death, is characterized by an obstruction within a blood vessel supplying blood to the brain. Dai et al. (2018) investigated the effect of isoquercetin on ischemia/reperfusion (I/R) brain injury. They found that isoquercetin has a neuroprotective effect against I/R injury in vivo, mediated by extenuating both oxidative stress and neuronal apoptosis via Nrf2-mediated

inhibition of the NOX4/ROS/NF-κB pathway. Similarly, Zhou et al. (2015) found that kaempferol provided cardioprotection via antioxidant activity and inhibition of phospho-GSK-3β activity in rats with I/R. Moreover, Wu et al. (2016) observed that administration of myricetin mitigated brain injury and neurological deficits via improvement of mitochondrial function and activation of Nrf2 pathway. In addition, Xiong et al. (2016) showed that icariin has neuroprotective effect on ischemic stroke in rats, inhibiting inflammatory responses mediated by NF-κB and peroxisome proliferator-activated receptors (PPARα and PPARγ).

Acetaminophen (APAP) causes serious liver damage. Recently, many researches have been performed in mice for their ability to prevent APAP-induced liver injury. Xie et al. (2016) reported that isoquercitrin pretreatments effectively extenuated APAP-induced hepatic oxidative stress via inhibition NF-κB and MAPK pathways and amelioration of iNOS, TNF-α, IL-1β, and IL-6 production. Accordingly, Domitrović et al. (2015) reached similar results; they reported that myricitrin ameliorated toxic liver damage by several mechanisms, increasing glutathione, cytochrome P450 2E1 level, proliferating cell nuclear antigen expression in regenerating liver tissue and reducing hepatic lipid peroxidation, cyclooxygenase-2, and tumor necrosis factor-alpha overexpression and inflammation in the liver, and inhibiting hepatic expression of transforming growth factor-beta1, alpha-smooth muscle actin, and liver fibrosis. Another study conducted by Ma et al. (2015a) demonstrated that quercetin prevented the CCl_4-induced inflammation via modulation of the TLR2/TLR4 and MAPK/NF-κB signaling pathway.

Schizophrenia is a chronic and severe mental disorder. Ben-Azu et al. (2018) examined the possible mechanisms involved in the antipsychotic-like activity of morin in ketamine model of schizophrenia and observed that morin may demonstrate antipsychotic-like therapeutic effect via modulation of oxidative/nitrergic, cholinergic actions and neuroprotection.

Rheumatoid arthritis is a chronic inflammatory disease. Haleagrahara et al. (2017) showed that quercetin reduced the severity of arthritic inflammation disease in animals, decreasing levels of TNF-α, IL-1β, IL-17, and MCP-1.

Zhang et al. (2017) showed that troxerutin effectively decreased high-fat diet-induced enhancement of hepatic gluconeogenesis via its inhibitory effects on endoplasmic reticulum stress-mediated nucleotide oligomerization domain activation and consequent inflammation.

Parkinson's disease is a neurodegenerative disorder, which is related to the dysfunctions of nigrostriatal dopaminergic systems. Chen et al. (2017) examined the neuroprotective effects of icariin on dopaminergic neurons and the possible mechanisms of Parkinson's disease. They reported that icariin has neuroprotective effect on dopaminergic neurons in Parkinson's disease mice model. The potential mechanisms might be related to PI3K/Akt and MEK/ERK pathways.

Acute kidney injury is a complication of sepsis and increases mortality. Xie et al. (2018) research group indicated that icariin ameliorated cecal ligation and perforation-induced mortality and acute kidney injury, inhibiting renal oxidant damage, inflammatory responses, apoptosis, and vascular permeability.

3.5 Benefits

Studies on humans have clearly shown that drug treatment for diseases often causes severe side effects. Therefore, natural compounds, dietary flavonols and *O*-glycosides, exert a significant therapeutic effect against inflammatory, cancer, and diabetes. However, the protective effects of flavonols and *O*-glycosides on human studies are limited, whereas human cell studies are more common (Table 5).

Osteoarthritis is a common disorder, causing pain and stiffness. Moreover, inflammatory cytokines, IL-1β, induce the production of other inflammatory mediators such as NO and PGE2. Ma et al. (2015b) after investigating the anti-inflammatory effects and mechanisms of astragalin on IL-1β-stimulated human osteoarthritis chondrocytes reported that astragalin inhibited IL-1β-induced NO and PGE2 production by activating PPAR-γ, which subsequently inhibited IL-1β-induced NF-κB and MAPK activation in chondrocytes.

Colorectal cancer is the second leading cause of cancer death in women and the third for men. Chemotherapy, which is the most widely used treatment for cancer, may induce a wide range of adverse effects in patients. Recently, Farsad-Naeimi et al. (2018) investigated the effects of fisetin supplementation on inflammatory and metastatic factors in colorectal cancer patients. They demonstrated that fisetin supplementation markedly attenuated the plasma levels of interleukin (IL)-8 and high-sensitivity C-reactive protein. Therefore, fisetin supplementation can ameliorate the inflammatory status in colorectal cancer patients. In another study, Youns and Hegazy (2017) showed that fisetin inhibited cellular proliferation and viability of hepatic (HepG-2, IC50: 3.2 μM), colorectal (Caco-2, IC50: 16.4 μM), and pancreatic (Suit-2, IC50:8.1 μM) cancer cell lines mediated through activation of CDKN1A, SEMA3E, GADD45B, and GADD45A and downregulation of TOP2A, KIF20A, CCNB2, and CCNB1 genes. Moreover, Wang and Huang (2018) suggested that fisetin effectively inhibited cell proliferation and migration and induced apoptosis in NSCLCs. Huang et al. (2015) showed that galangin and myricetin inhibit angiogenesis induced by ovarian cancer cell lines, inhibiting secretion of vascular endothelial growth factor by the Akt/p70S6K/ hypoxia-inducible factor-1α (HIF-1α) pathway. Another study conducted by Zou and Xu (2018) investigated the effects of galangin on the suppression of retinoblastoma. They observed that galangin suppressed the growth of retinoblastoma tumor through inactivating protein kinase B and promoting Caspase-3 pathway. Thyroid cancer is a thyroid malignant tumor causing enlarged lymph node and pain in the anterior region of the neck. More recently, Fang et al. (2019) demonstrated that icariin showed antitumor effect via downregulating miR-625-3p. Moreover, icariin blocked phosphoinositide 3-kinase/protein kinase B and mitogen-activated protein extracellular signal-regulated kinase kinase/extracellular signal-regulated kinase signaling pathways. Another study found that icariin inhibits both inducible and constitutive signal transducer and activator of transcription 3 activation, making suppressor of tumor cell survival, angiogenesis, and proliferation (Jung et al. 2018). Cisplatin is a valuable chemotherapy agent in clinical studies. However, adverse side effects notably nephrotoxicity limit the use of cisplatin which seriously limits

Table 5 Recent human/cell studies on chronic disease

Components	Chronic disease	Human/cell model	Key outcomes	References
Astragalin	Osteoarthritis	25 patients (age, 57)	Astragalin inhibited IL-1β-induced inflammatory mediators NO and PGE2 production in chondrocytes	Ma et al. (2015b)
Fisetin	Colorectal cancer	37 colorectal cancer patients (100 mg fisetin ($n = 18$) or placebo ($n = 19$) for 7 consecutive weeks)	Fisetin could improve the inflammatory status in colorectal cancer patients	Farsad-Naeimi et al. (2018)
	Hepatic, colorectal, and pancreatic cancer	Hepatic (HepG-2), colorectal (Caco-2) and pancreatic (Suit-2) cancer cell lines	Fisetin inhibited cellular proliferation and viability of hepatic, colorectal, and pancreatic cancer cell lines	Youns and Hegazy (2017)
	Lung cancer	A549 human NSCLC cell line	Fisetin inhibited the growth of A549 cells in a dose- and time-dependent manner	Wang and Huang (2018)
	Chronic obstructive pulmonary disease	NCI-H292 (CRL-1848) and HEK293T (CRL-3216)	Fisetin is a good therapeutic drug candidate for the treatment of inflammatory lung diseases	Lee et al. (2018)
Galangin	Ovarian cancer	A2780/CP70 and OVCAR-3	Galangin inhibited angiogenesis induced by ovarian cancer cell lines	Huang et al. (2015)
	Osteosarcoma	MG-63 and U2-OS	Galangin attenuated osteosarcoma cell proliferation	Liu et al. (2017)
	Laryngeal cancer	TU212 and M4e	Galangin suppressed laryngeal cancer cell proliferation, migration, and invasion, inactivating PI3K/AKT and p38 signaling pathways	Wang and Tang (2017)
	Kidney cancer	A498 cells	Galangin inhibited the proliferation of the kidney cancer A498 cells via inhibition of the PI3K/AKT/mTOR signaling pathway	Zhu et al. (2018)

Icariin	Bipolar disorder Alcohol use disorder	Ten participants with bipolar I or bipolar II disorders	Icariin may reduce depressive symptoms and decrease alcohol consumption	Xiao et al. (2016)
	Cisplatin-induced cytotoxicity	HEK-293 cell	Icariin exerted protective effect on cisplatin-induced cytotoxicity	Zhou et al. (2019)
	Thyroid cancer	SW579 and TPC1 cells	Icariin showed antitumor effect on thyroid cancer	Fang et al. (2019)
	Myeloma	MMcell and U266	Icariin exhibited as a signal transducer and activator of transcription 3 blocker in myeloma therapy	Jung et al. (2018)
Isoquercitrin	Bladder cancer	5637 and T24 cells	Isoquercitrin inhibits the progression of human bladder cancer	Chen et al. (2016b)
Isorhamnetin	Colon cancer	HT-29 and $Caco_2$	Isorhamnetin glycosides induced a higher percentage of apoptosis in HT-29 than in $Caco_2$, whereas isorhamnetin was more apoptotic in $Caco_2$	Antunes-Ricardo et al. (2014)
Kaempferide	Cervical cancer	HeLa (cervical), MDA-MB-231 (breast), HCT 116 (colon), and HL60 (leukemia)	Kaempferide induced apoptosis in cervical cancer cells	Nath et al. (2015)
Kaempferol	Atherosclerosis	HUVECs	Kaempferol alleviated ox-LDL-induced cell apoptosis	Che et al. (2017)

(continued)

Table 5 (continued)

Components	Chronic disease	Human/cell model	Key outcomes	References
	Human cancer	Human breast carcinoma (MCF-7) cells, human stomach carcinoma (SGC-7901) cells, human cervical carcinoma (Hela) cells, and human lung carcinoma (A549) cells	Kaempferol showed antiproliferative activity on a panel of human cancer cell lines	Liao et al. (2016)
Morin	Kidney injury	HK-2 cells	Morin acted as an ER stress inhibitor	Mo et al. (2019)
Myricetin	Colon cancer	HCT-15	Myricetin treatment reduced cell proliferation and induced apoptotic death of HCT-15 human colon cancer cells via BAX/BCL2-dependent pathway	Kim et al. (2014)
Quercetin	Blood pressure	Meta-analysis of randomized controlled trials ($n = 587$)	Quercetin significantly reduced blood pressure	Serban et al. (2016)
Quercitrin	Periodontal disease	hGF, hMSC	Quercitrin increased both soft and hard tissue regeneration of the periodontium	Gómez-Florit et al. (2015)
Rhamnazin	Inflammation	RAW264.7 cell	Rhamnazin was protective against LPS-induced cytotoxicity in macrophage cells	Kim (2016)
Robinin	Ox-LDL and inflammatory stress	Peripheral blood mononuclear cells were isolated from healthy human volunteers	Robinin ameliorates oxLDL-induced inflammatory insult through TLR4/NF-κB pathway	Janeesh et al. (2014)
Troxerutin	Acute cerebral infarction	Acute cerebral infarction patients ($n = 456$)	Troxerutin could improve neurological defects and promote functional recovery	Liang et al. (2017)

its clinical application. Zhou et al. (2019) investigated the protective effect and possible mechanism of icariin on cisplatin-induced nephrotoxicity on HEK-293 cells. They observed that icariin prevented cisplatin-induced HEK-293 cell injury via regulating NF-κB and PI3K/Akt signaling pathways. Chen et al. (2016b) reported that isoquercitrin inhibited bladder cancer via regulation of the PI3K/Akt and PKC signaling pathways. Antunes-Ricardo et al. (2014) showed that isorhamnetin glycosides showed cytotoxic effect against colon cancer cells, but their activity was affected by glycosylation. Nath et al. (2015), furthermore, demonstrated that kaempferide induced apoptosis in cervical cancer cells through activation of the caspase cascade.

Chronic obstructive pulmonary disease is another chronic inflammatory lung disease and is predicted to be the third leading cause of death worldwide by 2030. Lee et al. (2018) suggested that fisetin is a good drug candidate for improving the lung function of patients with chronic obstructive pulmonary disease, suppressing the TNF-α/NF-κB signaling pathway. Liu et al. (2017) observed that galangin extenuated osteosarcoma cells proliferation via selective activation of the transforming growth factor (TGF)-β1/Smad2/3 signaling pathway. Bipolar disorder is a common and severe psychiatric illness. Xiao et al. (2016) after investigating the effects of icariin on comorbid bipolar and alcohol use disorder in humans reported that icariin may decrease depressive symptoms and reduce alcohol consumption in persons with bipolar disorder and alcohol use. Atherosclerosis is a common disease in which plaque builds up inside your arteries. In addition, endothelial cells, macrophages, and smooth muscle cells have been demonstrated as the main cell types participating in atherosclerosis (Che et al. 2017). Che et al. (2017) observed that kaempferol abated ox-LDL-induced cell apoptosis by upregulation of autophagy via inhibiting PI3K/Akt/mTOR pathway in human endothelial cells. Endoplasmic reticulum (ER) stress may cause various kidney diseases. In a recent study, Mo et al. (2019) found that morin acted as an antioxidant and ameliorated ER-induced cytotoxicity in HK-2 cells. Rhamnazin was protective against LPS-induced cytotoxicity in macrophage cells via modulation of reactive oxygen species/reactive nitrogen species (Kim 2016). In short, dietary flavonols and *O*-glycosides are good candidates to prevent chronic diseases due to their pharmacological properties.

3.6 Application in Food

Food processing often causes losses in bioactive compounds, due to oxidation, enzymatic action, removal of skin or seeds, and leaching into water or oil that is then discarded (Rickman et al. 2007). On the other hand, the concentration of simpler derivatives may increase upon the breakdown of larger molecules. In the literature, there are several reports on the changes of contents of the flavonols, in particular quercetin, rutin, and kaempferol, due to different processing methods (Dos Reis et al. 2015; Nayak et al. 2015; Kamiloglu et al. 2016). A systematic review (Rothwell et al. 2015) collected extensive data and expressed the results as retention

factors (RFs), fold changes in flavonol content due to processing. According to this study, kaempferol and quercetin monoglycosides from broccoli were lost significantly as a result of boiling and frying (RF < 0.3); however steaming caused milder loss (RF $= 0.64$). Steaming also resulted in fewer losses of quercetin derivatives from carrot compared to boiling (RF $= 0.89$ and 0.37, respectively). On the other hand, similar losses of quercetin derivatives from onion were observed upon blanching, boiling, frying, and microwaving (RF $= 0.42$–0.54). Blanched and steamed cabbage and cauliflower contained increased amount of free quercetin; however free quercetin often represents only a small amount of all quercetin derivatives. Although different cooking methods caused a variation in the loss of rutin content in peeled potatoes (RF $= 0.39$–0.54), rutin content in carrots was affected similarly by boiling and steaming. On the contrary, almost all rutin was lost in cauliflower upon boiling, whereas steaming induced no significant change (RF $= 0.08$ and 0.76, respectively) (Rothwell et al. 2015).

In addition to food processing effect, interaction of flavonols with other components in the diet is also critical. Both macroconstituents, i.e., carbohydrates, lipids, and proteins, and microconstituents, i.e., minerals and vitamins, most often occur in foods in combination in a food matrix and are consumed together, which has an impact on the bioavailability of flavonols (Singh and Gallier 2014). Accordingly, a study carried out with rats (Matsumoto et al. 2007) reported that difructose anhydride III, i.e., an indigestible saccharide, promotes the absorption of αG-rutin, a soluble flavonol glycoside. The mechanism behind this observation may be the inhibition of αG-rutin conversion to rutin, a hardly absorbable compound due to its insolubility, by difructose anhydride III (Matsumoto et al. 2007). Another study assessing the effect of pectin on plasma quercetin levels and the fecal flora in mice supplemented with rutin found that the plasma quercetin and isorhamnetin concentrations were significantly higher in the pectin-rutin diet group compared to cellulose-rutin diet group. The authors suggested that pectin might increase the bioavailability of quercetin from rutin by changing the metabolic activity of the intestinal flora and/or the physiological function of the gut. Another explanation is that soluble fiber, e.g., pectin, could increase the gastrointestinal transit time, improving the absorption of flavonols (Tamura et al. 2007). In the study of Azuma et al. (2002), the effects of lipids and emulsifiers on the absorption of orally administered quercetin were investigated in rats. Co-administration of lipids such as lecithin and soybean oil or emulsifiers including sucrose fatty acid ester, polyglycerol fatty acid ester, and sodium taurocholate with quercetin had statistically no significant effects on absorption of quercetin, whereas, the combination of lipids and emulsifiers significantly enhanced the absorption of quercetin (Azuma et al. 2002). The same research group (Azuma et al. 2003) also examined the effects of co-ingestion of quercetin glucosides from onion with different sources of lipids including soybean oil, fish oil, beef tallow, and lecithin. The diet containing soybean oil significantly enhanced the accumulation of quercetin metabolites in plasma of rats. Fish oil and beef tallow also increased the plasma concentration to a similar extent to that with soybean oil, whereas lecithin was the most effective among all the lipids. Moreover, emulsifiers also showed an enhancing effect on the accumulation

of quercetin metabolites (Azuma et al. 2003). Later, another research group (Lesser et al. 2004) investigated the influence of dietary fat on oral bioavailability of quercetin in pigs. Quercetin was administered either as aglycone or as quercetin 3-*O*-glucoside in test meals differing in fat content (3, 17, or 32%). The results revealed that regardless of the chemical form applied, quercetin bioavailability was higher in the 17% fat diet compared to the 3% fat diet ($p < 0.05$) and no additional effect on bioavailability was observed when the flavonols were administered with diets containing 32% fat (Lesser et al. 2004). Same group further investigated the influence of fatty acid pattern of dietary fats on the oral bioavailability of quercetin, which was enhanced after intake of medium-chain and long-chain triacylglycerols, compared to the standard diet (Lesser et al. 2006). In a more recent in vivo study (Guo et al. 2013), overweight men and postmenopausal women ingested quercetin with a fat-free, low-fat, or high-fat diet. During high-fat diet, plasma quercetin maximum concentration and area under curve increased, compared to fat-free diet. Isorhamnetin and tamarixetin, the methylated metabolites of quercetin, were also increased during high-fat diet. The authors reported that it is likely that dietary lipids enhanced the micellarization of quercetin in the small intestine, which favored its solubility and absorption (Guo et al. 2013). In another study, healthy volunteers consumed supplements containing quercetin and kaempferol glycosides together with black tea, black tea with milk, green tea, and water. The addition of milk to black tea did not affect the plasma concentration of quercetin or kaempferol, and hence flavonols from tea were absorbed, and their bioavailability was not affected by the addition of milk (Hollman et al. 2001). Moreover, in the study of Ferri et al. (2015), effect of co-administration of α-tocopherol with quercetin and rutin is evaluated using a rat model. The concentrations of flavanols in plasma and brain indicated that α-tocopherol was able to promote quercetin and rutin transport. The authors indicated that the potential mechanism of enhanced transport of quercetin, rutin, and their putative metabolites might be due to the P-glycoprotein action and/or impairment of the phosphorylation/dephosphorylation mechanism, which controls the in-/outflux of metabolites across the blood-brain barrier (Ferri et al. 2015).

Besides the macro- and micronutrients given above, presence of other flavonoids can also affect the bioavailability of flavonols. For instance, Silberberg et al. (2005) performed a study on rats adapted to diets containing quercetin, or (+)-catechin, or both. When quercetin and (+)-catechin were fed together, their respective plasma concentration significantly decreased, whereas the urinary and hepatic concentrations were only reduced in case of quercetin. On the other hand, co-administration of quercetin and (+)-catechin had no effect on the formation of their metabolites, i.e., glucurono- and sulfo-conjugates (Silberberg et al. 2005). Similarly, Orrego-Lagarón et al. (2016) studied the simultaneous administration of naringenin and quercetin, which are common constituents of tomatoes and other fruits and vegetables, using an in situ model of intestinal perfusion in mice. The results showed that when naringenin and quercetin are administered together, the permeability coefficient values were decreased, whereas the levels of phase II metabolites were increased (Orrego-Lagarón et al. 2016).

3.7 Safety: Toxicity and Side Effects

Majority of studies on safety of flavonols are performed with quercetin. Several scientific bodies and national authorities declared information about the safety and recommended doses of quercetin. International Agency for Research on Cancer, the specialized cancer research agency of World Health Organization (WHO), declared that quercetin is not classifiable as to its carcinogenicity to humans. The Food and Drug Administration (FDA), the federal agency of the US Department of Health and Human Services, also approved quercetin as Generally Recognized As Safe (GRAS) under the intended conditions of use (Ożarowski et al. 2018). The average daily intake of quercetin was estimated as 200 mg and of approximately 460 mg for high consumers. Similarly, in Italy, based on a regulation, the amount of quercetin aglycone in dietary supplements is restricted to 200 mg per day. On the other hand, in Canada, 1200 mg quercetin was defined as the daily limit. However, in case of daily administration of 40–1200 mg quercetin, it has to be separated into two or three doses and consumed together with the meal. Furthermore, for uses over 12 weeks or during pregnancy and breastfeeding, the consumer should consult to a healthcare practitioner (Andres et al. 2018).

Several clinical trials showed that oral intake of quercetin in humans rarely results in adverse effects. Yet, no adverse incidences were reported in human intervention studies, in which volunteers were given quercetin at daily doses of 500 mg for 4–8 weeks (Javadi et al. 2014; Shi and Williamson 2016), 730 mg for 4 weeks (Edwards et al. 2007), or 1000 mg for 5 days, for at least 2 weeks or for 12 weeks (Ganio et al. 2010; Rezvan et al. 2017). On the other hand, in a study conducted with chronic pelvic pain syndrome patients for 1 month, one individual experienced headaches after taking a 1000 mg daily doses of quercetin for a few days. In addition, another patient complained about mild tingling sensation after each quercetin dose (Shoskes et al. 1999). In another study, in which the patients suffering from chronic hepatitis C were treated with daily doses of 250–5000 mg quercetin for 4 weeks, some patients developed mild stomach discomfort when quercetin was taken without a meal (Lu et al. 2016). Information on the safety of quercetin based on clinical trials is limited as there is no data considering long-term treatments ($>$12 weeks) with high dose of quercetin ($\geq$1000 mg per day) (Andres et al. 2018).

Animal studies showed that under certain conditions, quercetin might cause some implications including organ toxicity, cancer, and effects on endocrine system. According to chronic toxicity studies carried out with rats, consumption of approximately 1900–2100 mg quercetin per kg body weight per day resulted in reduced body weight, elevated organ weight (including liver and kidney), increased incidence of hyperplastic polyposis syndrome, presence of calcium oxalate crystals in urine, and existence of yellow-brown pigmentation in the stomach and small intestine (Ito et al. 1989; Dunnick and Hailey 1992; Program 1992). Furthermore, studies using different carcinogens showed that in rodents treated with 150–3400 mg quercetin per kg body weight per day, tumor development was observed in kidney (Zhu and Liehr 1994), colon (Pereira et al. 1996), pancreas (Barotto et al. 1998; Valentich et al. 2006), duodenum (Matsukawa et al. 2002), and mammary glands

(Singh et al. 2010). The possible mechanism behind the carcinogenic effect of quercetin was explained by the inhibition of catechol-*O*-methyltransferase enzyme resulting in increased formation of 4-hydroxyestradiol, which is a carcinogenic metabolite, as well as decreased formation of anti-carcinogenic metabolite 2-methoxyestradiol (Zhu and Liehr 1994; Singh et al. 2010). In addition, in male rats administration of 50–150 mg quercetin per kg body weight per day for 10 days increased the testosterone concentrations in the serum (Ma et al. 2004). In another study, Abd-Ellah et al. (2016) also demonstrated increased serum testosterone levels in male rats fed with 90 mg quercetin per kg body weight per day for 16 days. However, as some other studies conducted for longer periods did not report any effect of quercetin on serum testosterone levels in male rats, it is assumed that this increase in testosterone concentrations in the serum might be considered as a temporary effect of quercetin (Andres et al. 2018).

In addition to the above, both human and animal studies demonstrated that quercetin may interact with drugs and hence modulate their bioavailability. In humans, single or multiple administration of 300–1500 mg quercetin per day decreased the bioavailability of midazolam (sedative) (Duan et al. 2012; Nguyen et al. 2015) and talinolol (antihypertensive drug) (Wang et al. 2013; Nguyen et al. 2014), whereas enhanced bioavailability of cyclosporine (immunosuppressant drug) (Choi et al. 2004), fexofenadine (antihistamine drug) (Kim et al. 2009), and pravastatin (cholesterol-lowering drug) (Wu et al. 2012) was observed. Similarly, in some studies with rats, rabbits, and pigs, animals were fed with 0.6–100 mg quercetin per kg body weight per day for several days, and as a result, the bioavailabilities of many drugs including irinotecan, etoposide, tamoxifen, paclitaxel, doxorubicin (anticancer drugs), digoxin (heart failure drug), verapamil, diltiazem (hypertension, angina pectoris, and heart arrhythmia drugs), valsartan (antihypertensive drug), ranolazine (angina pectoris drug), and paracetamol were enhanced (Ożarowski et al. 2018). On the other hand, the bioavailability of simvastatin (cholesterol-lowering drug) and cyclosporine was reduced when taken together with quercetin (Hsiu et al. 2002; Cermak et al. 2009; Yu et al. 2011). Increased bioavailability of drugs may cause enhanced effectiveness of the drug; however it may also give rise to the potential side effects. In case of a possibility of an increased side effect, the dosage of drug should be adjusted (Andres et al. 2018).

Besides quercetin, kaempferol is also reported to possess some adverse effects including mutagenic and genotoxic effects (Galati and O'Brien 2004; Elgorashi et al. 2008). In addition, it has been reported that the consumption of kaempferol reduces the bioavailability of iron and/or folic acid and hence may cause some undesirable effects in iron and/or folic acid deficient patients (Lemos et al. 2007; Chen and Chen 2013). On the other hand, despite numerous in vitro studies on carcinogenic effects of kaempferol, there are no data from in vivo studies evidencing this effect (Devi et al. 2015). Similarly, for another flavonol, myricetin and its glycoside myricitrin, acute studies in mice did not provide evidence of genotoxicity, supporting the opinion of WHO's expert committee on food additives (JECFA) that myricitrin poses no safety concern for humans when consumed at current estimated dietary exposures (Hobbs et al. 2015).

3.8 Marketed Products

Nowadays, flavonol supplements, in particular quercetin supplements, are widely available in markets for affordable prices. The labels of these marketed products contain some health claims including support of immune and skin health, anti-inflammatory responses, cardiovascular and cholesterol health, and reduction of symptoms of arthritis. Additionally, these marketed products may help fight against allergies and pain; support circulation, mood, and energy levels; and help protect the kidneys, brain, and liver. The scientific studies related to these health claims of flavonols are given in detail in the previous sections. In some marketed products, flavonols are combined with other compounds to increase their low bioavailability. For example, there are a few quercetin supplements enhanced with 20–50% bromelain, which is an enzyme derived from the stems of pineapples. Although quercetin supplements enhanced with bromelain may provide increased absorption of quercetin, these products may not be suitable for those with pineapple allergies. In another product, quercetin is combined with vitamin C to ease the gastrointestinal discomfort that the consumed may experience and also to increase the antioxidant activity. Many of the products available on the market contain 500 mg of flavonol on average; however products with less or more amount of flavonols are also available.

3.9 Patents

In recent years, numerous patents have been published as a result of inventions related to applications of flavonols, in particular quercetin and its *O*-glycosides. These patents include methods of extraction of flavonols from natural sources (Zhang 2016; Cao et al. 2018; Shi et al. 2018a), production of nanocapsules (Wang et al. 2015; Krolevets 2016; Zhang et al. 2019), and prevention and treatment of various diseases including immune diseases (Park et al. 2017), liver disease (Kim et al. 2018), breast cancer (Lee 2018), and many others.

In Table 6, some recent US patents on health promoting effects of flavonols are presented. Mbikay et al. (2015) claimed that a therapeutically effective amount of quercetin-3-*O*-β-D-glucoside and, optionally, a therapeutically effective amount of a statin reduce the plasma cholesterol levels of patients. In another study, it has been suggested that quercetin combined with one or more of vitamin B3, vitamin C, and folic acid can be used to treat cancer together with a chemotherapy agent (Lines 2015). Same researcher also used a similar formulation, i.e., quercetin, vitamin B, vitamin C, and *Bauhinia forficata* extract, to treat metabolic syndrome and diabetes (Lines 2016). Moreover, a composition containing quercetin or isoquercetin, one or more of vitamin B3, vitamin C, and a folate, has been used to treat Zika virus infection. This formulation may also prevent microcephaly and treat and prevent infections of other *Flaviviridae* viruses (Lines 2017). Similarly, Bakar (2016) also claimed that quercetin, or analogues, or derivatives thereof have antiviral activity for prophylaxis or treatment of flavivirus infection or a disease resulting therefrom in humans or animals. The antiviral activity included the inhibition of virus attachment

Table 6 Recent US patents on health promoting effects of flavonols

Patent no	Date	Inventors (country)	Title	Major claims
US 2015/0190369 A1	Jul. 9, 2015	Mbikay et al. (Canada)	Quercetin-3-glucoside and uses thereof	Quercetin-3-*O*-β-D-glucoside (Q3G) increases the amount of cell surface low-density lipoprotein receptor (LDLR) on a cell and reduces the amount of functional protein convertase subtilisin/kexin type 9 (PCSK9) secreted by the cell Plasma cholesterol levels are reduced in patients treated with a therapeutically effective amount of Q3G and, optionally, a therapeutically effective amount of a statin
US 2015/0283112 A1	Oct. 8, 2015	Kim et al. (Korea)	Composition comprising myricetin as active ingredient for enhancing exercise performance or fatigue recovery	Myricetin or a pharmaceutically available salt thereof increases exercise capacity and enhances physical strength. Energy efficiency is increased by improving the function of mitochondria The composition comprising myricetin as active ingredient prevents aging and recovers from fatigue The composition also has an anti-obesity effect by increasing energy consumption
US 2015/0366838 A1	Dec. 24, 2015	Lines (Switzerland)	Method for treating cancer with a combination of quercetin and a chemotherapy agent	Combination of a chemotherapy agent and a composition that includes quercetin, one or more of vitamin B3, vitamin C, and folic acid may be used to treat cancer
US 2016/0000749 A1	Jan. 7, 2016	Bakar (Malaysia)	Method of inhibiting or treating a dengue virus infection with quercetin	Quercetin, or analogues, or derivatives thereof have antiviral activity for prophylaxis or treatment of *flavivirus* infection (that may comprise dengue virus types 1, 2, 3, and 4) or a disease resulting therefrom in humans or animals. The antiviral activity includes the inhibition of virus attachment to host cells and inhibition of intracellular virus replication

Table 6 (continued)

Patent no	Date	Inventors (country)	Title	Major claims
				enhance drugs concentrations in the brain tissues and effectively enhance the efficacy of drugs without increasing the plasma concentration
US 2017/0216246 A1	Aug. 3, 2017	Lines (Switzerland)	Method for treating Zika virus infection with quercetin-containing compositions	Composition containing quercetin or isoquercetin, one or more of vitamin B3, vitamin C, and a folate may be used to treat Zika virus infection. Composition may also prevent microcephaly and treat and prevent infections of other *Flaviviridae* viruses

to host cells and inhibition of intracellular virus replication. According to Otsuka et al. (2017), quercetin glycosides have inhibitory activity on the expression of myostatin involved in muscle atrophy. Likewise, another flavonol, myricetin or a pharmaceutically available salt thereof, has been shown to increase the exercise capacity and to enhance the physical strength. Increase in energy efficiency was due to the improved function of mitochondria. Myricetin is also claimed to prevent aging and recover from fatigue and has an anti-obesity effect by increasing energy consumption (Kim et al. 2015). In another study, nanosomal preparation of the complex formed with quercetin and 2-hydroxypropyl-beta-cyclodextrin was used in the treatment of cerebral pathological conditions in adults and newborns. The preparation was effective in protecting cerebral function in experimental Parkinson's disease models and in newborn pigs subject to hypoxia (Dajas et al. 2016). Similarly, kaempferide, rutin, troxerutin, myricetin, and hydroxy derivatives thereof, in particular their glycoside, ester, and ether derivatives, can promote the drug molecules that have therapeutic or healthcare effect, such as ginsenoside, stilbene glucoside, resveratrol, levodopa, edaravone, vinpocetine, nicergoline, citicoline, and oxiracetam, to enter brain tissues, to dramatically enhance drugs concentrations in the brain tissues and effectively enhance the efficacy of drugs without increasing the plasma concentration (Bei and Guo 2017). In addition to the above, administration of a composition containing isorhamnetin-3-*O*-β-D-glucoside to a subject in need thereof alleviates the radiation injury (Lai and Lai 2017).

3.10 Perspectives

In addition to the research already performed in the literature, new strategies need to be addressed to gain additional information. Below, a number of important points are highlighted as to how, in the future, one might approach to this topic differently, in order to maximize the knowledge gained from this chapter.

- Recently, the role of interindividual variability on the impact of flavonols on bioefficacy attracted great attention. So far, studies investigating this effect could not correlate the observed bioactivity with the bioavailability due to lack of data (Menezes et al. 2017). Hence, future studies, which include the parent compound and known metabolites, together with details of the individuals, i.e., age, gender, genotype, composition of gut microbiota, diet, lifestyle, and health status, are needed to address the effect of interindividual variation on bioavailability of flavonols and *O*-glycosides (Almeida et al. 2018).
- Encapsulation technology can be used to enhance the bioavailability of flavonols or to achieve controlled release of these compounds during digestion. Spray drying, coacervation, liposome entrapment, inclusion complexation, cocrystallization, nanoencapsulation, freeze-drying, yeast encapsulation, and nanoemulsion are some of the current technologies that are used to encapsulate bioactive compounds (Fang and Bhandari 2010). Although there are several reports in the literature that studied the encapsulation of flavonols (Hao et al. 2017; Azzi et al. 2018), the effect of this processing technique on the human body is not fully established yet. Therefore, further research on this topic is necessary.
- One of the factors affecting the bioavailability of flavonols is their interaction with other components in the diet. Co-digestion of flavonols with other macro- and microconstituents in foods will affect their bioavailability. In general, while indigestible carbohydrates, e.g., dietary fiber, proteins, and minerals, are likely to cause unfavorable effects on flavonol bioavailability, digestible carbohydrates, lipids, vitamins, and some other micronutrients, e.g., other flavonoids, alkaloids, and carotenoids, may enhance the bioavailability of flavonols. Interaction between flavonols and food matrix is a complex phenomenon that should be further investigated to provide maximum beneficial health effects to the consumers.
- Scientific information on the safety evaluation of flavonols from clinical trials is limited due to lack of relevant safety data, especially considering high-dose flavonol treatments for longer terms. Therefore, in future human intervention studies, it is important to investigate the safety and possible side effects of flavonols considering long-term treatments with high dose of flavonols (e.g., for quercetin >12 weeks and ≥ 1000 mg per day).

3.11 Conclusions

The focus of this chapter was the bioactive constituents, bioavailability, metabolism, bioactivity, benefits, food applications, safety issues, marketed products, and patents of dietary flavonols and *O*-glycosides. Flavonols, e.g., quercetin, kaempferol, myricetin, and isorhamnetin, most commonly occur as *O*-glycosides in dietary sources. In the human body, flavonol glycosides are cleaved to their aglycones and further metabolized to their glucuronidated, sulfated, and methylated conjugates. Moreover, compounds that reach the colon may be degraded by the colonic

microbiota to different metabolites, which may also contribute to the health beneficial effects of flavonol consumption with respect to cardiovascular diseases, diabetes, inflammation, viral infections, enhanced physical strength, and cancer prevention. Dietary intake of flavonols may be affected by the food processing, which often results in significant losses. Although rare adverse effects of flavonol consumption are reported, majority of the clinical trials and animal studies indicated that flavonol consumption is safe under the intended conditions of use.

Contents

Abstract

Epidemiological studies have long indicated a possible role for dietary flavonoids, notably flavones and flavonols, in the prevention of a range of degenerative diseases, e.g., cancer, diabetes, cardiovascular diseases, and neurological disorders like Parkinson's and Alzheimer's disease. The flavonoids are a large and variable group of compounds, comprising thousands of different structures. The bulk of the dietary flavonoids occur as glycosides.

The effect of flavonoid aglycones and their corresponding glycosides on cell metabolism and etiology of degenerative diseases has been a topic of interest for a number of decades. In contrast, the role of the metabolic products of dietary flavonoid that reach all parts of the human body through systemic circulation, has received much less attention.

Studies on animal and human metabolism have shown that the amount of flavone and flavonol glycosides which is absorbed intact is negligible; the bulk is absorbed only after deglycosylation. Thus, dietary glycosides are not likely to

play a direct role in chemoprevention. However, the sugar groups on glycosides can greatly affect the bioavailability of flavones and flavonols. Flavonoids linked with indigestible sugars are not absorbed in the small intestine but are transported through the digestive tract to be degraded by gut bacteria in the large intestine.

The compounds that directly play a role in the prevention of degenerative diseases are most likely not dietary flavones themselves but rather their metabolites and conjugation products.

Chemoprevention · Glucuronides; Methylated flavones · Quercetin

4.1 Introduction

Natural flavonoids, and their glycosides, are among the most abundantly available secondary metabolites in the human diet and, for several decades, now have been consistently linked with the prevention of a range of degenerative diseases (Imran et al. 2018; Smeriglio et al. 2016; Zhang and Tsao 2016). Though, any specific mechanisms of action for this group of phytochemicals are still a matter of debate (Khan et al. 2016).

The total amount of different naturally occurring flavonoids is estimated to be 10,000 (Dixon and Pasinetti 2010). Thousands of flavonoids that have been identified plants are discussed in a series of six triannual reviews of the flavonoid literature (Harborne and Williams 1995, 1998, 2001; Williams and Grayer 2004; Veitch and Grayer 2007, 2011). Initially, the main focus of attention was on anthocyanins – the intensely colored red to blue pigments of the flowering plants – and their potential role in plant ecology. In the last few decades, scientific interest shifted towards flavones and flavonols, due their possible beneficial effects as dietary components in the prevention of human cancer and other degenerative diseases. The presence of the more lipophilic flavonoids is regularly reported in extracts of dried powdered plant material, i.e., underground or aerial parts or even whole plants. Unfortunately, the precise location of lipophilic flavonoids in plants in many cases has remained unreported. Notably, the more highly O- and C-methylated and isoprenylated flavones and flavonols can be expected to reside in specific glands or trichomes on the surface of leaves, stems, or flowers rather than be evenly distributed throughout the tissues. In analysis of plant material, it would be good practice if surface flavonoids are removed by dipping the undamaged tissue in acetone, chloroform, or dichloromethane, after which the remaining polar flavonoids can be extracted with hot aqueous methanol thus providing two data sets for that tissue (Harborne and Williams 2001).

The formation of flavonoids in plants involves several biosynthetic pathways (Fig. 1). The aromatic B-ring is formed in the shikimate-phenylpropanoids pathway. The other aromatic ring (A) is formed via the polyketide pathway through C2 chain elongation of coumarate with malonyl-CoA as the condensing unit, initially resulting in the formation of the naringenin chalcone. The enzyme chalcone isomerase (EC

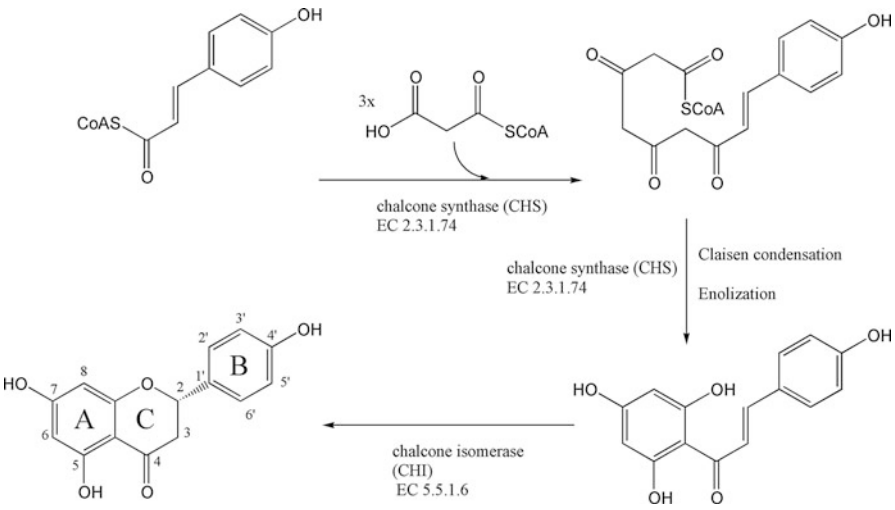

Fig. 1 Biosynthesis of flavonoids

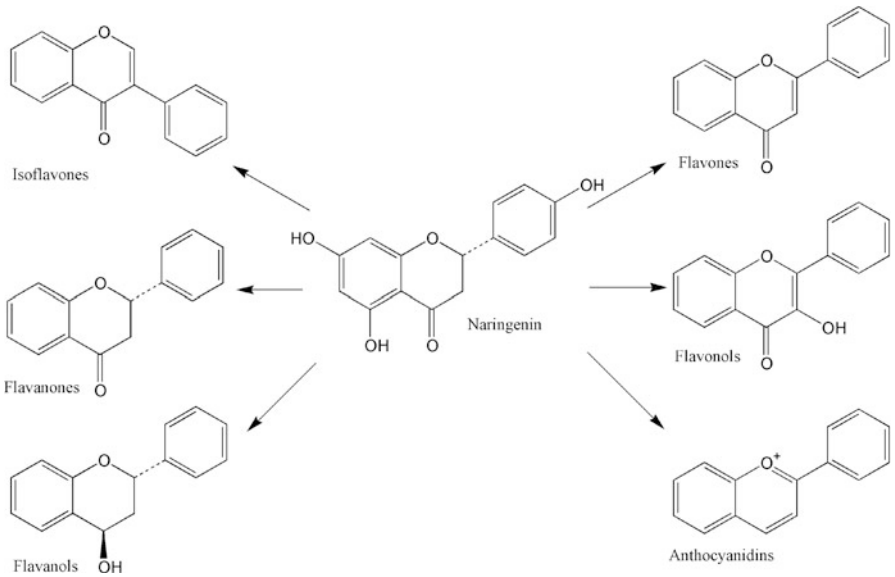

Fig. 2 Different classes of flavonoids with naringenin as common precursor

5.5.1.6), which is ubiquitously present in the plant kingdom, then catalyzes stereo-specific cyclization to form naringenin (Saito et al. 2013). The latter flavanone is the common precursor of all flavonoid types (Fig. 2). The sequence of events in the biosynthesis leading to naringenin explains why the most common substitution pattern in flavonoids involves *O*-substitutions at C-5, C-7, and C-4′. The wide

variety of structures is caused by further substitution patterns on the flavonoid skeleton. Predominant among these are examples characterized by simple patterns of *O*-substitution (OH, OMe) and prenylation (Veitch and Grayer 2007). Notably, *O*-methylation and prenylation result in compounds that are highly lipophilic (Harborne and Williams 1995, 1998). Advanced prenylation links the flavones with the terpenoid biosynthetic pathway and can result in a wide variety of structures, ranging from simple prenyl flavones to ring-closed furano, pyrano, chromano,

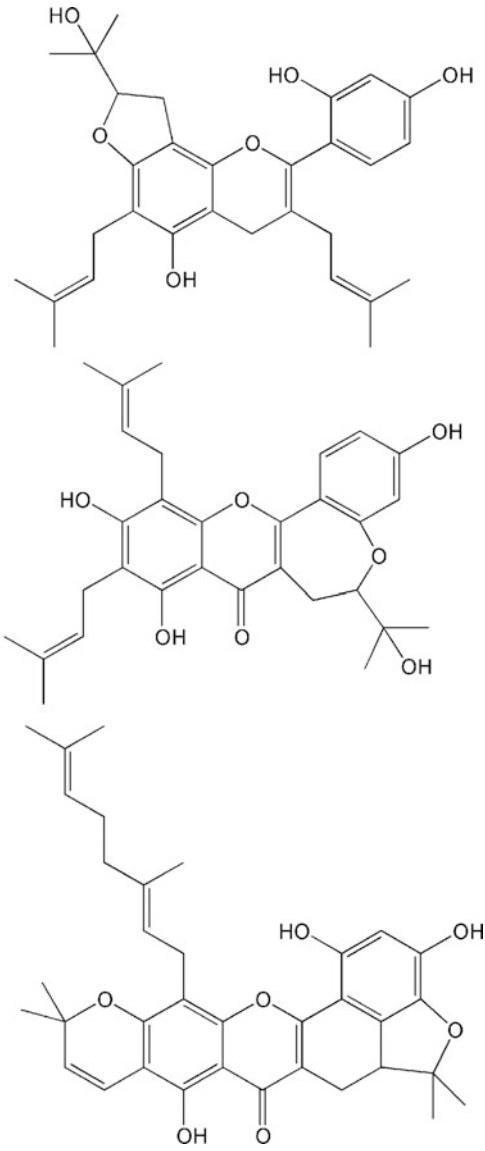

Fig. 3 Examples of highly prenylated flavonoids. (After Harborne and Williams 2001)

and methylenedioxy derivatives (Harborne and Williams 2001) in which the flavonoid core may be difficult to spot (Fig. 3).

A further cause for variation in the flavonoids is the formation of glycosides. The bulk of flavonoids in plants exist in glycosidic form, either as *O*-glycosides or, more rarely, as *C*-glycosides. The *O*-glycosides of flavones and flavonols, and the *C*-glycosides of flavones form the most numerous groups of glycosylated flavonoids (Veitch and Grayer 2011). The most common sites for *O*-glycosylation are C-7 on the flavones, and C-7 and C-3 on the flavonols; 5-*O*-glycosylation of flavones and flavonols is comparatively rare in nature (Harborne and Williams 1995). The sites for *C*-glycosylation on flavones are either C-6 or C8, and several di-*C*-glycosides have been reported (Jay et al. 2006; Xiao et al. 2016). A wide variety of sugars can be involved in glycosylation. Typically, sugars are all in the pyranose form and sugar linkages are β- for glucose, galactose, xylose and α- for rhamnose (Harborne and Williams 1998). Acylation of the sugars is common, with acetic acid as the most frequent acyl substituent, though other acids, e.g., malonic, p-coumaric, or caffeic acid, have been reported as acylating groups (Veitch and Grayer 2007, 2011). As a general rule, glycosylation makes the relatively lipohilic flavones and flavonols more water-soluble so that they are not necessarily restricted to glands or trichomes on the surface of leaves, stems, or flowers but may be more evenly distributed in plant tissue. Acylation converts water-soluble flavonoid glycosides back again into lipophilic substances and may be seen as a means to regulate distribution of this group of compounds within the plant tissues. The exact role of flavones and flavonols for the plant is still a matter of speculation, though it is generally assumed that they protect plant tissue against the damaging effects of UV-B radiation or accumulation of oxygen radicals which is part of the plant's defense system against fungal attack. Ionizing radiation and radical oxygen species have been considered a major cause of damage to macromolecules not only in plants but in humans too. The possibility that dietary flavones and flavonols may protect against this damage was proposed almost four decades ago (Ames 1983) and has been considered time and again. However, clinical trials so far have only provided weak correlations (Del Bo et al. 2019; Grosso et al. 2017; Jin et al. 2012; Ried et al. 2017; Suen et al. 2016; Tang et al. 2016).

4.2 Screening for Biological Activity

Papers that discuss the properties of flavonoids commonly start with a list of biological activities that are ascribed to this compound group. This is remarkable since neither the Food and Drug Administration (FDA) nor the European Food Safety Authority (EFSA) have recognized any dietary flavonoid as a drug, i.e., a product intended for use in the diagnosis, cure, mitigation, treatment, or prevention of disease (EFSA 2010; FDA 2017). However, a number of herbal products rich in flavonoids are listed in community herbal monographs and have received formal marketing authorization based on traditional medicinal uses of the herbs (European Parliament, Council of the European Union 2004).

Most of the biological activities ascribed to flavonoids are based on preclinical studies. The last few decades have seen remarkable developments in molecular biology, bioanalytical techniques, and handling of large data sets, and these developments have significantly altered the way preclinical studies are viewed.

The large anticancer drug discovery programs of the 1960s and 1970s were all based on phenotypic screening, i.e., assays to find compounds that improve a disease phenotype. Initial primary screening involved mice in vivo bearing transplantable leukemia cell lines L1210 or later replaced by panel of tumor xenografts in nude mice (DeVita and Chu 2008). These in vivo assays resulted in the development of a range of plant-derived anticancer drugs that are still in clinical use today, e.g., vincristine and vinblastine from *Catharanthus roseus* (syn. *Vinca rosea*), podophyllotoxin derivatives etoposide and teniposide from *Sinopodophyllum hexandrum* (syn. *Podophyllum emodi, Podophyllum hexandrum*), combretastatin A-4 from *Combretum caffrum*, taxanes (paclitaxel, docetaxel, cabazitaxel) from *Taxus* species, and campthothecins (topotecan, irinotecan) from *Camptotheca acuminata*. In the 1990s, cell culture systems became more sophisticated and the screening system was changed to a panel of 60 human cancer cell lines grown in vitro. The latter in vitro cell viability screening assay is still considered a form of phenotypic screening; the assay was used to determine cytotoxicity of compounds without initial concern about specific targets or mechanisms of action. However, the NCI-60 screen allowed identification of differential cytotoxicity fingerprints which may be used to assign compounds to specific mechanistic classes or even identify novel mechanistic classes (Boyd and Paull 1995).

Around the turn of the millennium, developments in molecular biology, notably the expansion of OMICS (genomics, transcriptomics, proteomics) and PCR-based, heralded the shift to functional screening as the primary tool in drug discovery. A better understanding of the molecular basis of cancer, but also of metabolic disorders like diabetes or neurodegenerative diseases like Parkinson's and Alzheimer disease, made the development of therapies targeted at specific proteins or transcription factors that play a key role in degenerative diseases an achievable and logical approach. The increasing amount of information genome databases, combined with improved PCR-based methods for gene isolation and cloning, allowed the production of substantial amounts of recombinant proteins that became available for detailed studies of protein-ligand interactions. This in turn opened the field of bioinformatics, where interactions of virtual model proteins with novel ligands is studied by docking experiments in silico. The discovery and subsequent development of a range of small-molecule kinase inhibitors is probably the best example of what can be achieved with a target-based approach to drug screening (Zhang et al. 2009).

Target-based screening proved particularly successful for identifying therapeutic biologics (e.g., enzymes, antibodies, peptides, vaccines) that function by interfering with a molecular activity and whose mechanism of action is dependent on a specific protein target. However, many of the small-molecule novel drug entities that may have looked promising in the initial functional screening assays did not do well in later clinical trials. Of the drugs that were approved by the FDA in the decade ranging from 1999 to 2008, an era in which the major focus was on target-based

approaches, the contribution of phenotypic screening to the discovery of first-in-class small-molecule drugs exceeded that of target-based approaches (Swinney and Anthony 2011).

Current screening of synthetic and natural product libraries for novel therapeutic small molecules usually applies a mixed approach, known as mechanism-informed phenotypic screening (Moffat et al. 2014; Coussens et al. 2017). The phenotypic screen is considered more physiologically relevant and less artificial than pure target-based assays because intact cells and native cellular environment are used (Zheng et al. 2013). Cells grown in a monolayer on plastic have remained the bedrock of cancer drug discovery assays, although three-dimensional growth of non-adherent cells is regarded as a more representative model. In addition, many disease models have been developed and applied to phenotypic compound screening, e.g., strains of *Caenorhabditis elegans*, zebrafish, *Xenopus laevis*, and *Drosophila melanogaster*. Then, rather than simply determining the effect of drugs on cell survival, molecular events such as gene expression and protein phosphorylation are monitored. Also, assays can be used that link complex cell signalling networks to transcriptional activation and expression of reporter genes (e.g., coding for luciferase or green fluorescent protein).

Many of the defined drug targets are single components in extended cell signalling networks, and their inhibition does not necessarily result in an altered phenotype. What was often ignored in pure target-based screening is that within cell signalling, a redundancy is common, and compensatory and feedback mechanisms can undo the effect of a drug (Moffat et al. 2014). In addition, the drugs often target part of the canonical pathways, defined in the Kyoto Encyclopedia of Genes and Genomes (http://www.genome.jp/kegg/). Less information is available on non-canonical pathways that may operate in aberrant cells that lay at the basis of many degenerative diseases. Regulation of cell metabolism occurs at many levels, e.g., too often mRNA expression is seen as a shorthand for protein activity whereas comparative OMIC studies have shown that transcriptomics or RNA-sequence data does not always correspond to proteomic data. In the same vein, when posttranslational processes can make that, there may be no correspondence between proteomics and actual protein/enzyme activity (Amoedo et al. 2017). The latest addition to the OMICS cluster is metabolomics, which allows identification of differences of metabolic profiles between different cell types of tissues. The method has been applied to identify novel targets tumors, but the absence of comprehensive metabolomics repositories still poses a limitation to what can be a powerful tool to monitor the rerouting of metabolic pathways in diseases processes (Goveia et al. 2016). Another limitation of metabolomics may be the limited spatial resolution, as cell metabolites can diffuse within tissues and even the entire organism, making it difficult to pinpoint any changes to specific cell types (Amoedo et al. 2017).

All the screening assay mentioned above have been applied to flavonoids, partly because these compounds are so ubiquitously present in a wide variety of medicinal herbs and in fruits and vegetables that are consistently linked with good health and prevention of degenerative diseases. In silico target-based screening, often followed up with in vitro inhibition assays, has indicated that many flavonoids can potentially

inhibit kinases (Hou and Kumamoto 2010; Zhao et al. 2019), androgen receptors (Singh et al. 2017), and ABCG2 multidrug transporters (Boumendjel et al. 2011), or can trigger anti-inflammatory pathways (Alfa and Arroo 2019).

4.3 Structure–Activity Relationship (SAR)

Series of screenings of flavonoids for biological activity has resulted in the identification of pharmacophores, though what exactly defines a flavonoid pharmacophore, i.e., the features necessary to ensure interactions with a specific biological target (Wermuth et al. 1998), depends on the type of screening.

When considering flavonoid-induced inhibition of multidrug resistance-associated protein (MRP) or of the breast cancer resistance protein (BCRP, part of the ABCG2 protein family), both energy-dependent drug-efflux pumps which normally export steroid molecules, the presence of the 4-carbonyl, the 5-hydroxyl group, the 3-hydroxyl group, and the 2–3 double bonds are required for the activity (Boumendjel et al. 2002; Scotti et al. 2012; Fang et al. 2019). Docking studies suggested that the hydrophobic B-ring would bind to the steroid-binding region whereas the 3-hydroxyl in combination with the 4-carbonyl mimics the adenine in ATP (Boumendjel et al. 2002).

Looking for cytotoxic effects against breast cancer cell lines or inhibitors of aromatase, the C-4 keto group of flavonoids was considered essential, the 7-hydroxyl enhanced the activity, and flavones show greater activities than flavanones, i.e., 2–3 double bond increases the efficacy. Glycosylation of flavones removed their activity (Manthey and Guthrie 2002; Li et al. 2007).

Considering antioxidant capacity and anticancer activity, the important features are 4′-hydroxyl group is essential, a second hydroxyl group in the B-ring resulting in a catechol substitution pattern enhances the activity, and a 3-hydroxyl group on the C-ring increases the antioxidant activity. Again, comparing flavanones and flavones showed that the 2–3 double bond conjugated to the 4-carbonyl group in ring C is essential (Pannala et al. 2001; Scotti et al. 2012).

Combined in vitro enzyme assays and in silico docking studies, assessing the interaction of flavones with glycogen synthase kinase-3β (GSK-3β), indicated that hydroxyl groups that form hydrogen bonding with the amino acid residues in the enzyme contribute to provide stability, while sugar conjugations at C-3 or C-7 are less suitable in providing stability (Johnson et al. 2011). Similar experiments, assessing the interaction between flavones and glyoxalase I (GLO I), a key enzyme in pathways leading to the detoxification of methylglyoxal, found that a plane configuration of *cis* C-4 ketone and C-5 hydroxy was essential, as this configuration mimics an enediolate intermediate that forms in the detoxification pathway of methylglyoxal. Hydroxy groups at the B-ring of flavones enhanced the inhibitory activity of the flavonoid compounds, whereas C-3 or C-7 glucuronic acid conjugates were found to be very poor inhibitors. In this model, the double bond between C-2 and C-3 did not significantly affect inhibitory effects (Takasawa et al. 2008).

The radical scavenging effects luteolin and its glycosides cymaroside (7-O-β-D-glucoside), cesioside (7-O-β-D-primeveroside), isoorientin (6-C-β-D-glucoside), and stereolensin (6-O-β-D-glucoside) were assayed, and their inhibition of pro-inflammatory pathways was tested in rat leukocytes. The presence of catechol substitution pattern on the B-ring and a 5-OH substitution of the A-ring were considered to significantly contribute to the anti-inflammatory and antioxidant activities of the flavone. Glycosyl substitutions at C-6 or C-7 did not affect the radical scavenging properties but slightly diminished the inhibitory effect on induction of pro-inflammatory pathways (Odontuya et al. 2005).

Overall, mechanism-informed phenotypic screening of flavonoids has provided the rough contours of a flavonoid pharmacophore with anti-inflammatory and potential cancer preventive properties (Fig. 4). The presence of a C-2,3 double bond and hydroxyl groups at C-5 and C-4′ are crucial for the cytostatic effects. Additional hydroxyls on the B-ring resulting in two hydroxy substituents *ortho* to each other tend to enhance the activity, whereas a methoxy group in the 3′-position on B-ring lowers the antiproliferative activity. Flavones tend to be more potent that flavonols (having a hydroxyl at C-3), but C-6 hydroxyl groups significantly decrease the cytotoxic activity (Plochmann et al. 2007; Menezes et al. 2016). A structural feature common in flavonols, i.e., 3-hydroxyl and 4-carbonyl groups, mimics the adenine 6-amino and 1-nitrogen groups, respectively in ATP, and thus allows interference with energy-dependent transporter proteins (Conseil et al. 1998; Barron et al. 2002).

Glycosylation, notably at C-3, generally diminishes the cytotoxic activity, whereas the formation of methylethers or prenylation, i.e., modifications that make the flavones more lipophilic, tend to increase the activity (Walle 2007; Menezes et al. 2016).

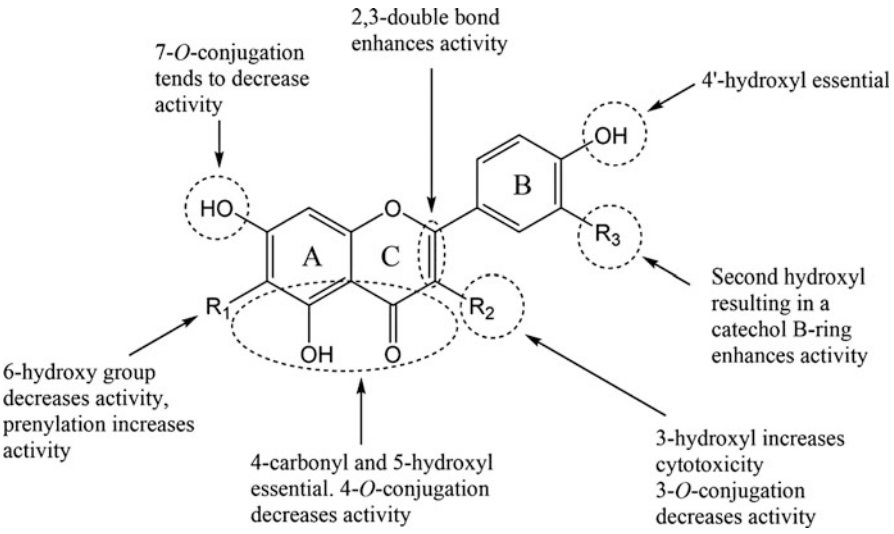

Fig. 4 Generalized flavone pharmacophore

4.4 In Vitro Activities

Generally, in vitro assays have shown that *O*-glycosylation reduces the bioactivity of flavones regarding prevention of degenerative diseases, e.g., antioxidant activity, antidiabetic activity, anti-inflammation activity, anticancer activity, anticoagulant activity, antiplatelet activity, aldehyde oxidase inhibition, and immunomodulatory activity. Though, some other types of bioactivity may be enhanced by *O*-glycosylation of flavones (Xiao 2017). However, the in vitro effects of dietary flavones and their glycosides are of limited practical use if we wish to understand the role of these compounds in the prevention of degenerative diseases. If we look at these compounds as drugs with a particular pharmacophore, what is important is that they can interact with their specific biological target (Wermuth et al. 1998). In other words, the flavones have to reach sufficiently high concentrations to elicit a therapeutic response. In in vitro assays, bioactivity is commonly expressed in IC_{50} for inhibition of physiological processes or EC_{50} for drugs that activate a process. Both IC_{50} and EC_{50} are measures of concentration, expressed in molar units. The concentration of flavones and flavone conjugates (glucuronides, sulfates) in human systemic circulation is less than 1 μmol/L (Hostetler et al. 2017). Thus, if any in vitro flavone bioactivity is reported with a value, expressed as IC_{50} or EC_{50}, of more than 1 μmol/L, then this compound is not likely to ever elicit a therapeutic response in vivo. Consequently, these compounds should be labelled as having "weak activity"; compounds with IC_{50} or EC_{50} values higher than 10 μM should be labelled as "inactive."

If we want to assess the health-enhancing role of dietary flavones and their glycosides, only in vitro bioactivity experiments are not sufficient. We need to assess the pharmacokinetics of the compounds and study their absorption, distribution, metabolism, and excretion (ADME).

The ADME properties determine the concentration of bioactive compounds in systemic circulation and also how long an effective concentration is maintained after a meal.

4.5 ADME Properties

Many detailed ADME studies focus specifically on quercetin and its glycosides, due to their abundant availability. Dietary quercetin occurs almost exclusively as β-glycosides, where the aglycone can be bound to a variety of sugars depending on the food source, e.g., apples are rich in galactosides, rhamnosides, and arabinosides, whereas in onions, glucosides are the main glycosidic form. The sugar moiety was shown to be an important determinant of the bioavailability of quercetin from foods (Arts et al. 2004). This may seem odd since studies in vitro using a Caco-2 model of intestinal absorption and in situ using a rat intestinal perfusion model have shown that quercetin is not absorbed as a glycoside, but mainly in its free aglycone form via passive diffusion in the small intestine (Guo and Bruno 2015). Lactase-phlorizin hydrolase (LPH), a mammalian β-glycosidase present in the brush border membrane

of the small intestine, is the main determinant of quercetin bioavailability. Absorption of quercetin glucosides is higher than that of the aglycone (Cermak et al. 2003), because the glucosides are more water-soluble than free quercetin and thus diffuse more easily through the intestinal tract to reach the brush border membrane where they then can be hydrolyzed and subsequently absorbed (Guo and Bruno 2015). However, this is true only for *gluco*sides; LPH efficiently hydrolyses quercetin-3-*O*-β-glucosides and 4′-*O*-β-glucosides, but not other glycosides like quercetin-3-*O*-β-galactoside, quercetin-3-*O*-β-rhamnoside, and quercetin-3-*O*-α-arabinopyranoside (Arts et al. 2004). The latter glycosides are not absorbed in the small intestine but pass into the large intestine where they are degraded by intestinal microflora. The initial degradation step is deglycosylation, mediated by gut microbiota-derived β-glucosidases, that generates quercetin aglycone some of which in turn can be absorbed from the large intestine through passive diffusion. The latter absorption step is much less efficient than that in the small intestine, due to the differences in surface area available for absorption in both organs. Flavone-*C*-glycosides are not hydrolyzed by LPH, and they too reach the large intestine unaltered where they are deglycosylated by gut microflora (Zhang et al. 2007; Xiao et al. 2016). Deglycosylation is only the first step in the degradation of flavones and flavonols by human gut microflora; the aglycone is further degraded.

The exact way that flavones and flavonols are degraded in the large intestine depends for a large part on the combination of the bacterial species that make up the microbiome in this organ. The microfloral profile differs from person to person and is shaped by genetic factors and environmental factors such as diet, lifestyle, geography, infection, and medication. For any one individual, the composition of the gut microbiome tends to be stable over time (Sen and Orešič 2019). Based on human intestinal bacterial species so far identified that are involved in the conversion of flavonoids, a general degradation pathway can be sketched out (Braune and Blaut 2016). The bacterial degradation of flavonol and flavone aglycones starts with the reduction of the C2-C3 double bond yielding the corresponding flavanonols and flavanones (Schoefer et al. 2003). The next step is C-ring fission, resulting in the formation of chalcones. The next steps differ as a result of the 3-hydroxyl group in flavonols, which is absent in flavones. The flavonol forms a chalcone intermediate that can undergo keto-enol tautomerism and is eventually converted into an aurone; the hydrolytic opening of the five-membered ring of the aurone results in the formation of phenylacetic acid derivative and phloroglucinol. The fission of the heterocyclic ring of flavones leads directly to a chalcone structure, which is reduced to the dihydrochalcone, and then hydrolyzed to form a phenylpropionic acid derivative and phloroglucinol. The phloroglucinols are further degraded into short-chain fatty acids (Brune and Schink 1992) (Fig. 5).

Very little, if any, of the flavone and flavonol glycosides that are present in the human diet reaches systemic circulation. Indeed, in vitro studies with rat jejunal tissue have shown that some quercetin-3-*O*-glucoside can be absorbed as a glycoside through sodium-dependent glucose transporter 1 (SGLT1) (Wolffram et al. 2002; Day et al. 2003), but at the same time, multidrug resistance protein (MRP2, aka ABCC2) actively transports 4′-*O*-glucoside and 3-*O*-glucoside out of the brush

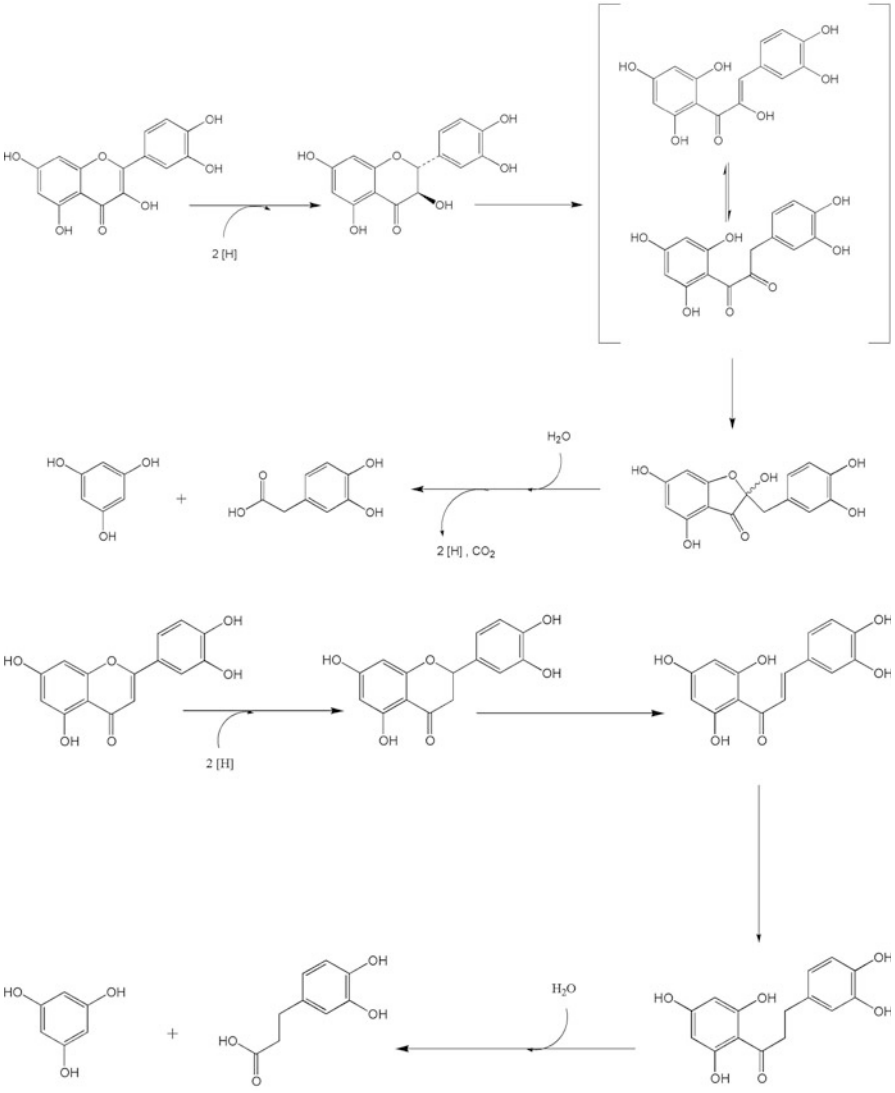

Fig. 5 Generalized scheme of bacterial degradation of flavonols (**a**) and flavones (**b**). (After Braune and Blaut 2016)

border cells and back into the lumen of the small intestine (Walgren et al. 2000; Luo et al. 2015), together with other flavone conjugates (O'Leary et al. 2003).

Flavonols and flavones that enter into the circulatory system are rapidly conjugated to form glucuronides, sulfates, or mixed sulfo-glucuronide conjugates; these reactions are catalyzed by human β-glucuronidases and sulfotransferases (Day et al. 2001; O'Leary et al. 2003; recently reviewed by Williamson et al. 2018; Wang et al. 2017). Quercetin is also a substrate for human catechol-*O*-

methyltransferase, resulting in the formation of 3′-methylquercetin (isorhamnetin) and 4′-methylquercetin (tamarixetin) (Cermak et al. 2003; O'Leary et al. 2003). These methylated derivatives can also be further converted into glucuronides and sulfates.

Considering that dietary flavone- and flavonol-glycosides do not enter into human systemic circulation, and that flavones and flavonols circulate in plasma not as aglycones, but predominantly as conjugated metabolites, it is the latter conjugates that ought to be the focus studies on the biological activity of flavonols in humans (Day et al. 2001; Spencer et al. 2004).

4.6 Further Screening for Biological Activity

It has been argued for decades that, if we wish to understand the role of dietary flavonoids, the transformations these compounds undergo during digestion and cellular metabolism should be analyzed, and the bioactivities of both unmetabolized parent compounds and their putative metabolites should be evaluated. However, literature on in vitro studies addressing this issue has remained scarce (Aragonès et al. 2017). Though many metabolites of flavones and flavonols have been identified, the challenge remains to get sufficient amounts of well-characterized purified material to perform bioactivity studies. Synthetic methods have been developed to obtain flavonol glucuronides and sulfates, compounds that are of interest as the main human plasma metabolites (Needs and Kroon 2006; Zhang et al. 2012).

Cell viability assays showed that quercetin, and its metabolites quercetin-3′-sulfate, quercetin-3-glucuronide, isorhamnetin, and isorhamnetin-3-glucuronide inhibit the growth of human breast cancer MCF-7 cells in a dose-dependent manner. Although the concentrations that were tested in the in vitro assay (25–100 μM) were at least an order of magnitude higher than would ever be found in vivo, neither of the metabolites affected cell viability of nonmalignant mammary epithelial cell line H184B5F5 M10 at doses up to 100 μM (Wu et al. 2018a, b). Luteolin-3′-*O*-, 4′-*O*-, and 7-*O*-glucuronides reduced the expression of inflammatory genes in lipopolysaccharide-treated RAW264.7 cells, a commonly used model for inflammation studies (Kure et al. 2016). In both studies, in vitro the aglycone showed stronger inhibitory activity than the conjugated metabolites, though since the concentration of these aglycones in vivo is almost negligible, it is the conjugated compounds that should be considered as the active pharmaceutical ingredients. Quercetin and its sulfated and methylated metabolites quercetin-3′-*O*-sulphate, isorhamnetin, and tamarixetin were all shown to inhibit the activity of xanthone oxidase, an enzyme that plays a key role in purine catabolism. The IC_{50} values found were less than 1 μM, which makes this type of activity a feasible option in vivo, e.g., for the treatment of gout (hyperuricemia). The metabolites quercetin-3-*O*-glucunoride and isorhamnetin-3-*O*-glucuronide did not inhibit xanthine oxidase (Mohos et al. 2019).

Some recent studies focused on the biological activity of the degradation products of flavonoids that are produced in the large intestine and then absorbed (Hanske et al. 2013). Using in vitro kinase assays, the flavonol degradation product

2,4,6-trihydroxybenzoic acid was demonstrated to inhibit CDKs 1, 2, and 4 in a dose-dependent manner. No such activity was found for 3,4,5-trihydroxybenzoic acid or phloroglucinol. Docking studies, in silico, identified putative key amino acids involved in these interactions. Again, the concentrations used in the in vitro bioassays (50 μM–1000 μM) were much higher than can ever be expected in an in vivo system (Sankaranarayanan et al. 2019). Colonic quercetin metabolites 4-methylcatechol, 3-(3,4-dihydroxyphenyl)propionic acid, 3,4-dihydroxybenzoic acid, 3,4-dihydroxyphenylacetic acid, homovanillic acid, and phloroglucinol were poor inhibitors of xanthine oxidase (Mohos et al. 2019). However, pyrogallol, a breakdown product of more dietary flavonoids, strongly inhibited xanthine oxidase activity ($IC_{50} = 1.8$ μM); this is relevant since sulfate conjugates of pyrogallol can reach plasma concentration higher than 10 μM (Pimpão et al. 2015).

It is often argued that, if we wish to understand the role of dietary flavonoids in the maintenance of health or in the prevention of degenerative diseases, the compounds need to be tested in vivo. Epidemiological studies and human intervention studies keep hinting at the potential of dietary flavonoids to prevent degenerative diseases (Potì et al. 2019; Rodríguez-García et al. 2019). Some stronger evidence comes from animal studies, e.g., dietary quercetin has been shown to affect gene expression and function of epididymal adipose tissue in Western diet-induced obese mice, and to ameliorate the effects of diet-induced metabolic syndrome (Kobori et al. 2016). However, epidemiological studies, human intervention studies, and in vivo animal studies only provide limited insight into the mechanism of chemoprevention. To fully elucidate the internal workings of the chemoprevention process, a reductionist methodology and in vitro mammalian and human cell cultures will remain an important tool for the foreseeable future. Whether dietary flavone and flavonol glycosides directly affect cell metabolism in vitro is a question of limited practical interest, because glycosides never reach the target cells in vivo. Glycosides do affect the bioavailability of dietary flavones and flavonols in vivo, but if we wish to understand how chemoprevention works, in vitro tests should best concentrate on the ways that flavone and flavonol metabolites and their conjugates affect cell metabolism.

Abstract

Flavonoids are one of the most widely occurring secondary plant constituents and are rich in vegetable and fruit diets as well as beverages of plant origin. In flavonoid glycosides, the sugars can either be linked to the aglycone via an ether bond (*O*-glycosides) or via a C–C- bond resulting in flavonoid C-glycosides. Their occurrence in food plants, their role in bioactivity of food, and their catabolism are covered in this chapter. The major class of C-glycosylflavonoids in food plants is represented by flavones, in addition dihydrochalcones and C-glycosylisoflavones can be found. Citrus fruits can be considered as a major source of C-glycosylflavones, whereas in most cases relatively low amounts have been found in cereals. A rich source of C-glycosylated dihydrochalcones are tomatoes, as well as rooibos and honeybush herbal teas, and the most common C-glycosylisoflavone puerarin is mainly consumed via kudzu roots. Due to their higher chemical stability in terms of hydrolysis during cooking and also after ingestion, they can be considered as a specific group within flavonoids. Their metabolic fate is clearly different from *O*-glycosidic flavonoids with absorption of intact glycosides, followed by phase II metabolization. However, also deglycosylation by gut microbiota and degradation of aglycones to compounds like (hydroxy)phenylpropionic acids have been recognized. Only limited data on the actual daily intake of C-glycosylflavonoids including information on content in fresh and processed food are available.

Keywords

C-Glycosylflavonoids · Flavonoid C-glycosides · Citrus fruit flavonoids · Cereal flavonoids · Flavonoid metabolisms · Flavonoid bioactivities · Flavones · Dihydrochalcones · Isoflavonoids

Abbreviations

ABTS	2,2′-azinobis-(3-ethylbenzthiazoline-6-sulfonic acid) diammonium salt
CGF	C-glycosylflavonoids
CGT	C-glycosyltransferase
COX	Cyclooxygenase
CYP	Cytochrome P450 enzymes
DPPH	2,2-diphenyl-1-picrylhydrazyl
ESI	Electrospray ionization
IC_{50}	Half maximal inhibitory concentration
IL	Interleukin
MCF	Human breast cancer cell line
MIC	Minimal inhibitory concentration

mRNA	Messenger RNA
OGF	*O*-glycosylflavonoids
PGE-2	Prostaglandin E2
P-gp	P-glycoprotein
PXR	Pregnane-X- receptor
RAW	Mouse macrophage cell line
TE	Trolox equivalents
TNF-α	Tumor necrosis factor α
Vero	African green monkey kidney cells

5.1 Introduction

Flavonoids are one of the most widely occurring secondary plant constituents and are rich in vegetable and fruit diets as well as beverages of plant origin. In plant food, flavonoids mostly occur as glycosides, i.e., bound to one or more monosaccharide moieties. Major structural diversity of flavonoids arises from hydroxylation, methoxylation, and glycosidation. The sugars can be attached to the aglycone via an ether bond (*O*-glycosides) or being directly linked to the aglycone via a C–C bond resulting in flavonoid C-glycosides (C-glycosylflavonoids, CGF). This type of glycosidation results in distinct features compared to *O*-glycosides concerning their resistance to hydrolysis. Hence, C-glycosylflavonoids represent a specific group of plant phenolics which is often underestimated. Their occurrence in food plants, their role in bioactivity of food, and their catabolism will be covered in this chapter.

5.2 Bioactive Constituents

5.2.1 Chemistry of Flavonoids with Emphasis on C-Glycosylflavonoids

Chemically, their basic structure can be designated as 2-phenylbenzopyrane which is deriving major flavonoid classes, i.e., flavones, flavonols, flavanones, flavanols (which are related to proanthocyanidins), chalcones including dihydrochalcones and α- and β-OH-dihydrochalcones, and anthocyanidins. Migration of the aromatic ring from C-2 to C-3 position of the basic skeleton leads to isoflavonoids. The nomenclature of flavonoid classes follows the oxidation pattern of the C-ring. Figure 1 illustrates the nomenclature of flavonoids and shows the basic structures of most important plant flavonoid classes.

In C-glycosylflavonoids, glucose is the predominant sugar moiety, although also xylose, arabinose, rhamnose, galactose, and apiose were identified as glycosidic moieties. Additionally, C-glycosylflavonoids can be acylated with acetyl, p-coumaroyl, sinapoyl, feruloyl, and/or vanilloyl residues. By far the majority of C-glycosylflavonoids in plant derived food can be found among flavones, more

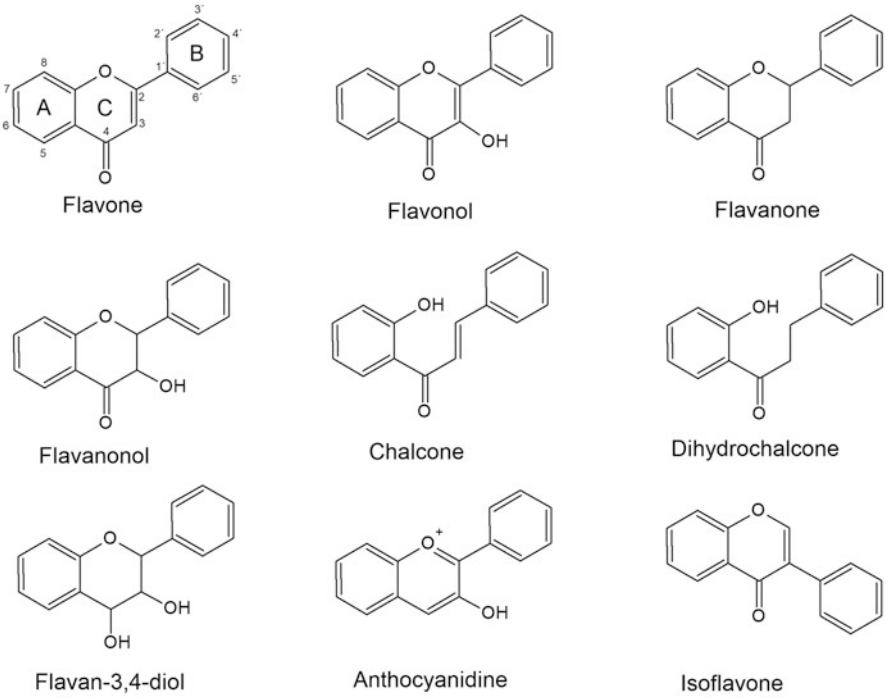

Fig. 1 Major flavonoid classes and common numbering of flavonoids

rarely in flavanols, flavonols, flavanones, dihydrochalcones, isoflavones, and isoflavanones. In C-glycosylflavones, glycosylation can occur either as mono-C-glycosylflavones (positions C-6- or C-8-), di-C-glycosylflavones (positions C-6,8-, 3,6-, 3,8-), as mixed C-/*O*-glycosides, as well as acylated glycosides, resulting in a remarkable complexity of C-glycosyl patterns. In addition, the interconversion of 6-C- and 8-C-glycosylflavones via Wessely-Moser rearrangement which can already occur during boiling has to be considered (Courts and Williamson 2015).

5.2.1.1 Analysis of C-Glycosylflavonoids

Analysis of CGF in food sources is above all accomplished by HPLC coupled to photodiode array detection and mass spectrometry usually applying electrospray ionization (ESI). The C-glycosidic linkage obviously has higher stability in mass spectrometric fragmentation processes leading in the first step not to the aglycone as in case of *O*-glycosylflavonoids by cleavage of the hemi-acetal C–O bonds, but to fragmentation of the sugar moiety when medium fragmentation energy is applied.

Intraglycosidic cleavages (Fig. 2) and losses of water can be observed. For instance, as outlined by Vukics and Guttman (2009), in product ion spectra of protonated vitexin mainly losses of 1–3 water molecules as well as $^{0,2}X^{+}$, $^{0,2}X^{+}-H_2O$, $^{0,4}X^{+}-2\ H_2O$, and $^{2,3}X^{+}-2\ H_2O$ fragments could be found, whereas in negative ion mode $^{0,2}X^{-}$ was the major fragment.

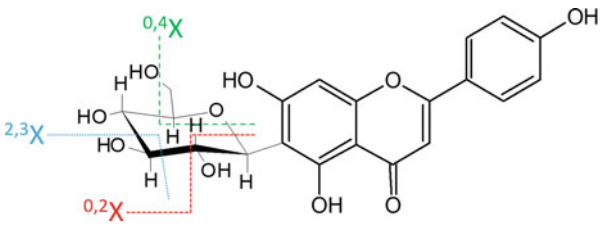

Fig. 2 Most frequently occurring intraglycosidic cleavages observed in mass spectral analysis of C-glycosyl flavones. ^{a,b}X: a, b indicate the broken sugar bonds; X indicates fragments where the charge is kept on the aglycone

Significant simultaneous losses of −90 and −120 mass units in case of hexoses and −60 and −90 u in case of pentoses can be used by applying neutral loss scans to detect CGF in complex food matrix. Also, in case of di-C-glycosyl flavones with different monosaccharides attached to the aglycone LC-ESI-MS with stepwise fragmentation will help in identification. Further, it has been shown that due to hydrogen bonding in case of a 6,8-di-C-glycosylflavone, the loss of a fragment −60 u if the pentose is attached at position C-6 is higher compared to a pentose attached to position C-8. However, it has to be considered that relative abundances of fragments depend on type of instrumentation and sound conclusions can only be drawn when spectra of C-6- and C-8-pentosylglycosides can be compared under identical instrumental settings (Waridel et al. 2001; Ferreres et al. 2003; Vukics and Guttman 2009).

5.2.1.2 Biosynthesis of C-Glycosylflavones

The biosynthetic pathway of C-glucosylflavones in cereals has been studied in detail by Brazier-Hicks et al. (2009). The flavanone precursor is converted to a 2-hydroxyflavanone and its corresponding open-chain form. A C-glucosyltransferase (CGT) forms 2-hydroxyflavanone C-glucosides by attaching a glucose moiety either at position C-6 or C-8. Through dehydration the flavone-6-C-glucoside and flavone-8-C-glucoside is finally formed, respectively. Most of the CGF identified so far in plants are members of the UGT708 subfamily which are able to C-glycosylate 2,4,6-trihydroxyacetophenone-like structures (e.g., 2-hydroxyflavanones). In a number of food plants, such CGF were found, such as rize, maize, buckwheat, citrus fruits, kudzu, and soy bean. However, also direct formation of 6-C-glycosylflavones or isoflavones by CGTs belonging to different UGT (UDP glycosyltransferase) subfamilies, i.e., UGT84 and UGT71, has been described for gentian (*Gentiana triflora*), kudzu and wasabi (*Eutrema japonicum*) (Mashima et al. 2019).

5.2.2 Food Sources of C-Glycosyl Flavonoids

A condensed summary of C-glycosylflavonoids detected in plant food sources can be depicted from Table 1. The most common structures of CGF in food are presented in Table 2 and Fig. 3.

Table 1 Food sources of C-glycosylflavonoids

Food source	Plant	Flavonoid class	C-Glycosylflavonoids	References
Fruits and seeds				
Cereals				
Wheat	*Triticum sps.*	C-Glycosylflavones	Apigenin-6-C-, 8-C-, 6,8-di-C-glycosides (including acylated derivatives)	(Courts and Williamson 2015; Wijaya and Mares 2012)
Barley	*Hordeum vulgare*	C-Glycosylflavones	Apigenin-6,8-di-C-glycosides	(Courts and Williamson 2015; Xiao et al. 2016)
Oat	*Avena sativa*	C-Glycosylflavones	Luteolin-6-C-, and 6,8-di-C-glycosides	(Popovici and Weissenboeck 1976)
Rye	*Secale cereale*	C-Glycosylflavones	Apigenin-6,8-di-C-glycosides	(Courts and Williamson 2015)
Spelt	*Triticum aestivum* subsp. *spelta*	C-Glycosylflavones	Apigenin-6,8-di-C-glycosides	(Hostetler et al. 2017)
Buckwheat	*Fagopyrum esculentum*	C-Glycosylflavones	Apigenin- and luteolin-6- and 8-C-glycosides	(Brazier-Hicks et al. 2009; Courts and Williamson 2015; Hostetler et al. 2017)
Rice plant	*Oryza sativa*	C-Glycosylflavones	Apigenin-6-C- and 6,8-di-C-glycosides, chrysoeriol-6-C-glycosides (including acylated derivatives), luteolin-6,8-di-C-glycosides	(Courts and Williamson 2015; Xiao et al. 2016; Hostetler et al. 2017)
Rice fruit	*Oryza sativa*	C-Glycosylflavones	Apigenin- and luteolin-6,8-di-C-glycosides	(Pereira-Caro et al. 2013; Hostetler et al. 2017)
Maize	*Zea mays*	C-Glycosylflavones	Maysin; maysin analogues; derhamnosyl-maysin	(Elliger et al. 1980; Xiao et al. 2016)
Millet	*Sorghum bicolor*	C-Glycosylflavones	Apigenin-6-C-and 8-C-glycosides; luteolin-8-C-glycosides	(Courts and Williamson 2015)
Pearl millet	*Pennisetum glaucum (syn. Pennisetum americanum)*	C-Glycosylflavones	Apigenin- and luteolin-8-C-glycosides	(Boncompagni et al. 2018; Courts and Williamson 2015)

Citrus fruits				
Bergamot	*Citrus bergamia*	C-Glycosylflavones	Apigenin-6,8-di-C-glucoside, diosmetin-6,8-di-C-glucoside	(Caristi et al. 2005; Abad-Garcia et al. 2012)
Grapefruits	*Citrus paradisi*	C-Glycosylflavones	Apigenin-6-C- and 6,8-di-C-glycosides	(Abad-Garcia et al. 2012; Wang et al. 2017)
Kumquats	*Fortunella japonica*	C-Glycosylflavones, C-glycosyl-dihydrochalcones	Acacetin-6-C- and 8-C-glycosides, apigenin-8-C-neohesperidoside, phloretin-3′,5′-di-C-glucoside	(Lou et al. 2016; Xiao et al. 2016)
Lemons	*Citrus limon*	C-Glycosylflavones	Apigenin-6-C- and 6,8-di-C-glycosides, chrysoeriol-6,8-di-C-glycosides, diosmetin-6-C-, 8-C- and 6,8-di-C-glycosides	(Abad-Garcia et al. 2012; Courts and Williamson 2015; Wang et al. 2017)
Limes	*Citrus aurantiifolia*	C-Glycosylflavones	Diosmetin-6-C- and 6,8-di-C-glucoside	(Caristi et al. 2005; Courts and Williamson 2015)
Mandarins, tangerines	*Citrus reticulata*	C-Glycosylflavones	Apigenin-6,8-di-C-glucoside, diosmetin-6,8-di-C-glucoside	(Hostetler et al. 2017)
Oranges (sweet oranges, blood oranges)	*Citrus sinensis*	C-Glycosylflavones	Apigenin-6-C-,8-C- and 6,8-di-C-glycosides, chrysoeriol-8-C-glucoside, chrysoeriol-6,8-di-C-glucoside (stellarin-2), diosmetin-6,8-di-C-glucoside	(Caristi et al. 2005; Abad-Garcia et al. 2012; Courts and Williamson 2015; Barreca et al. 2016; Hostetler et al. 2017; Wang et al. 2017)
Oranges (sour oranges)	*Citrus aurantium*	C-Glycosylflavones	Apigenin- and luteolin-6,8-di-C-glucoside (lucenin-2, vicenin-2), diosmetin-6,8-di-C-glucoside	(Barreca et al. 2010)
Pummelo	*Citrus grandis*	C-Glycosylflavones	Apigenin 6-C- and 6,8-di-C-glycosides (including acylated derivatives), diosmetin-6.C- and 6,8-di-C-glycosides, luteolin-6,8-di-C-glucoside	(Abad-Garcia et al. 2012; Zhang et al. 2014; Wang et al. 2017)
Tangelo	*Citrus reticulata X C. paradisi*	C-Glycosylflavones	Apigenin- and luteolin-6,8-di-C-glucoside	(Barreca et al. 2013)

(continued)

Cucumber	*Cucumis sativus*	C-Glycosylflavones	Apigenin- and luteolin-6-C- and 8-C-glycosides, cucumerin A, B (phytoalexins)	(McNally et al. 2003)
Carob seed germ flour	*Ceratonia siliqua*	C-Glycosylflavones	Apigenin 6-C-, 8-C- and 6,8-di-C-glycosides (including acylated derivatives)	(Picariello et al. 2017)
Carambola fruit	*Averrhoa carambola*	C-Glycosyl-dihydrochalcones; C-glycosylflavones	Apigenin-6-C-glycosides (carambolaflavones)	(Wang et al. 2018)
Fenugreek (seed germs)	*Trigonella foenum-graecum*	C-Glycosylflavones	Apigenin- and luteolin-6-C-, 8-C- and 6,8-di-C-glycosides	(Xiao et al. 2016)

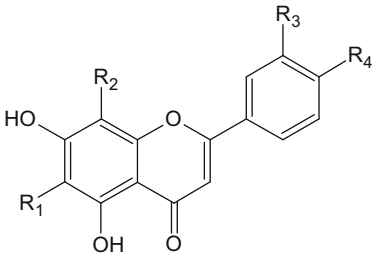
Mesquite (South American algarrobo)	*Prosopis spp.*	C-Glycosylflavones	Apigenin-6,8-di-C-glycosides (including feruloylate derivatives)	(Picariello et al. 2017)
Quince (seeds)	*Cydonia oblonga*	C-Glycosylflavones	Apigenin-, chrysoeriol- and luteolin-6-C-, 8-C- and 6,8-di-C-glycosides	(Ferreres et al. 2003)
Cocoa (processed)	*Theobroma cacao*	C-Glycosylflavan-3-ols	Catechin- and epicatechin-C-glycosides	(Stark and Hofmann 2006; Courts and Williamson 2015)
Figs (skin)	*Ficus carica*	C-Glycosylflavones	Luteolin-6,8-di-C-glycoside	(Vallejo et al. 2012)
Leaves and stems				
Bamboo shoots (leaves)	*Different species*	C-Glycosylflavones	Apigenin-C-glycosides, luteolin-8-C-glycosides	(Zhang et al. 2007)
Beet root and leaves	*Beta vulgaris*	C-Glycosylflavones	Apigenin-8-C-glycosides	(Courts and Williamson 2015; Ninfali et al. 2017)
Honeybush herbal tea	*Cyclopia sps.*	C-Glycosylflavones, C-glycosyldiydrochalcones	Phloretin-3′,5′-di-C-glucoside, vicenin-2, 3-hydroxyphloretin-3′,5′-di-C-hexoside	(Schulze et al. 2015)
Lemongrass leaves	*Cymbopogon citratus*	C-Glycosylflavones	Apigenin-6-C-, 8-C- and 6.8-di-C-glycosides, luteolin-6-C-, 8-C- and 6.8-di-C-glycosides	(Figueirinha et al. 2008)
Lotus (different plant parts)	*Nelumbo nucifera*	C-Glycosylflavones	Apigenin- and luteolin-6-C- and 8-C-glycosides; especially rich in Lotus plumules (all other parts contain less CGFs)	(Li et al. 2014)
Palm products (palm leaves etc.)	*Different species*	C-Glycosylflavones	Apigenin-6- and 8-C-glycosides, luteolin-6-C- and 8-C-glycosides	(Williams et al. 1973)
Pigeon pea	*Cajanus cajan*	C-Glycosylflavones	Apigenin-8-C-glycosides, luteolin-8-C-glycosides	(Nix et al. 2015)

(continued)

Table 1 (continued)

Food source	Plant	Flavonoid class	C-Glycosylflavonoids	References
Rooibos herbal tea	*Aspalathus sp.*	C-Glycosyl-dihydrochalcones, C-glycosylflavanones, C-glycosylflavones	Aspalathin, nothofagin, eriodictyol-C-glycosides, apigenin- and luteolin-6-C- and 8-C-glucosides	(Courts and Williamson 2015; Hostetler et al. 2017)
Sugar cane	*Saccharum officinarum*	C-Glycosylflavones	Apigenin-6-C-, 8-C- and 6,8-di-C-glycosides, luteolin-8-C-glycosides, 4′,5′-dimethyl-luteolin-8-C-glycoside	(Courts and Williamson 2015)
Taro (leaves)	*Colocasia esculenta*	C-Glycosylflavones	Apigenin-, chrysoeriol-, diosmetin-, luteolin-6-C-, 8-C-, 6,8-di-C-glycosides	(Ferreres et al. 2012)
Tea (green, oolong, white, black)	*Camellia sinensis*	C-Glycosylflavones	Apigenin C-glycosides, luteolin C-glycosides	(Hostetler et al. 2017)
Rhubarb	*Rheum sp.*	C-Glycosylflavones	Apigenin-6-C- and 6,8-diC-glycosides	(Courts and Williamson 2015)
Roots				
Beet root and leaves	*Beta vulgaris*	C-Glycosylflavones	Apigenin-8-C-glycosides	(Courts and Williamson 2015; Ninfali et al. 2017)
Kudzu	*Pueraria montana*	C-Glycosylisoflavones	Daidzein 8-C-glucoside (puerarin), 3′-OH-puerarin, 3′-OMe-puerarin, 5-OH-puerarin	(Wu et al. 2011)

Table 2 Structures of most common C-glycosylflavones and aglycones



Compound	R_1 (C-6)	R_2 (C-8)	R_3 (C-3′)	R_4 (C-4′)
Apigenin	H	H	H	OH
Luteolin	H	H	OH	OH
Chrysoeriol	H	H	OCH_3	OH
Diosmetin	H	H	OH	OCH_3
Vitexin	H	β-D-gluc	H	OH
Isovitexin	β-D-gluc	H	H	OH
Orientin	H	β-D-gluc	OH	OH
Isoorientin	β-D-gluc	H	OH	OH
Vicenin-2	β-D-gluc	β-D-gluc	H	OH
Lucenin-2	β-D-gluc	β-D-gluc	OH	OH
Schaftoside	α-L-ara(p)	β-D-gluc	H	OH
Isoschaftoside	β-D-gluc	α-L-ara(p)	H	OH

β-D-gluc = C-β-D-glucosyl-; α-L-ara(p) = C-α-L-arabinopyranosyl-

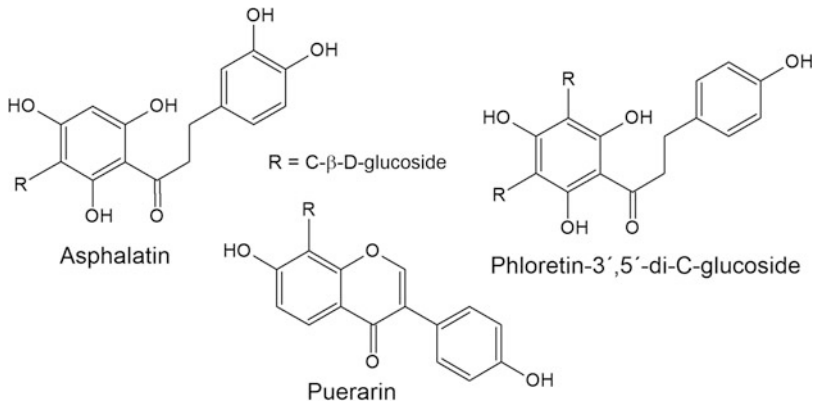


Fig. 3 C-Glycosylflavonoids other than flavones: asphalatin and phloretin-3′,5′-di-C-glucoside as examples of C-glycosyldihydrochalcones, puerarin representing a C-glycosylisoflavone

As shown in Table 1, by for the majority of CGF in food plants are present as C-glycosylflavones, followed by C-glycosyldihydrochalcones, main food resources of this type of compounds are tomatoes (phloretin-3′, 5′-di-C-glucoside) and rooibos tea (aspalathin, nothofagin). Fermentation (heating and/or sundrying) of rooibos tea forms C-glycosylflavanones (eriodictyol glycosides), and further oxidation leads to

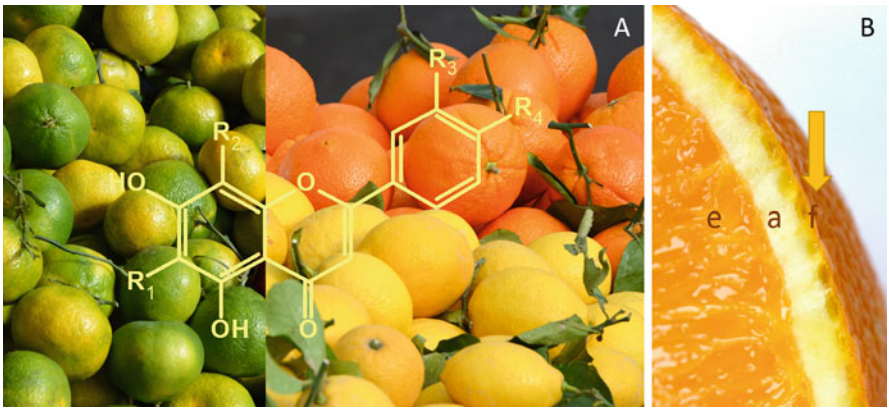

Fig. 4 (**A**) Citrus fruits like oranges, lemons, and mandarins are a major food source of C-glycosyl flavones. (**B**) C-Glycosylflavones can mainly be found in the outer flavedo layer (f) whereas lower amounts are present in the albedo layer (a) and endocarp (e)

C-glycosylflavones. Similar as in rooibos tea, C-glycosylflavan-3-ols in cocoa seeds are resulting from the fermentation process (Courts and Williamson 2015).

In order to evaluate the relevance of CGF as compounds in food and their possible impact on human health, of course their amounts in the diet have to be known. However, data concerning quantities, especially in processed food, are scarce. The following data refer to reported quantities summarized by Hostetler et al. (2017). Citrus fruits represent a major source of C-glycosylflavones (Fig. 4), with total quantities of 1.6–9.2 mg/100 g fresh weight (corresponding to 6–23 mg per serving) in orange juice, 8.6–15.4 mg/100 g fresh weight in fruit juices of bergamot, 2.9–3.5 mg/100 g in mandarin juice, and 6.7–7.6 mg/100 g fresh weight in lemon juice. Investigations of commercials juices of pink grapefruit (*C. paradisi*) and oranges (*C. sinensis*) showed quantities of vicenin-2 (apigenin-6,8-di-C-glucoside) of 29.3–45.3 mg/L (Bucar, unpublished data). Investigations of accumulation patterns of C-glycosylflavones in various tissues and *Citrus* species revealed the highest proportions in the flavedo layer (colored outer layer of the pericarp) and significantly less in the albedo layer (inner whiteish layer of the pericarp), segment membranes, and fruit juice (Wang et al. 2017), see also Fig. 4.

In a wheat grain-based meal, the estimated amount of C-glycosylflavones is relatively low ranging between <1–5 mg per serving (28 g dry grain). Our own exploratory analysis of apigenin-6,8-di-C-glycosides in spelt (*Triticum aestivum* subsp. *spelta*) pointed towards preferable intake of wholemeal flour (66 mg/kg) compared to plain flour (32 mg/kg), and amounts in wheat (*Triticum aestivum*) semolina were comparably low (6 mg/kg) (Bucar, unpublished results). According to Hostetler et al. (2017), this is also true for different types of rice (amounts of apigenin and luteolin-C-glycosides below <1 mg per serving (28 g) and dehulled, roasted, as well as whole buckwheat (<1 mg per serving). Similar low amounts are reported for legumes like field peas (*Pisum sativum*), i.e., <1–1 mg per 28 g serving, and chick peas (<1 mg per serving). However, unexpectedly high amounts of vitexin (apigenin-8-C-glucoside) equivalents were detected in flour of millet seeds with

77–275 mg/100 g (Courts and Williamson 2015), however determined by a spectrophotometric method without further confirmation after chromatographic separation. A study of Boncompagni et al. (2018) on grains of 96 pearl millet lines from a panel of inbred lines covering a large genetic diversity revealed also highly divers quantities of C-glycosylflavones. Ranges of 0 to 283.4, 272.7, and 261.1 mg/kg (mean values of 71.9, 28.1, and 40.0) were found for glucosylvitexin, orientin, and vitexin, respectively. Extremely high amounts of different apigenin-C-glycosides were reported for carob seed germ flour summing up to more than 8.3 g/kg in total (Picariello et al. 2017).

Although high quantities of apigenin- and luteolin-C-glycosides (up to 246.6 mg/100 g dry weight) have been found in different processed teas (green, black, oolong teas of *Camelia sinensis*), in the final infusion only <1–4 mg per serving (corresponding to 2 g dry material) can be expected. Flavonoids and phenolics in tea are covered in more detail in ▶ Chaps. 18, "Tea Catechins" (Daglia and Baldi), and ▶ 40, "Procyanidins in Food" (Sieniawska et al.).

Tomatoes and infusions of rooibos herbal tea (*Aspalathus linearis*) are the main food source of C-glycosyldihydrochalcones (Courts and Williamson 2015). In investigated tomato cultivars, phloretin-3′,5′-di-C-glucoside contributed by 5–14% to the total flavonoid content which varied from 4 to 26 mg per 100 g fresh weight. Further relevant sources of this C-glycosyldihydrochalcone are the fruit peels of mature kumquats (*Fortunella japonica*) showing highly remarkable 1.35 g per 100 g dry weight (Lou et al. 2016), as well as honeybush herbal tea (*Cyclopia spp.*) with 0.77–13.3 mg/L hot water infusion (Schulze et al. 2015).

In rooibos (leaves and stems), a significant difference in unprocessed and fermented herbs can be observed. Whereas unfermented freeze-dried rooibos tea contains about 1.5 g aspalathin and 0.43 g nothofagin per 100 g, due to oxidative ring cyclisation to eriodictyol-C-glycosides, the amount of both dihydrochalcones declines to 102 mg and 35 mg per 100 g, respectively, in fermented rooibos tea. In addition, the C-glycosylflavones luteolin-6-C-glucoside (isoorientin) and luteolin-8-C-glucoside (orientin) have been extracted to aqueous infusions of fermented rooibos tea at quantities of 100 and 80 mg per 100 g, whereas the corresponding apigenin glucosides were only present in lower amounts of 33 and 27 mg per 100 g, respectively (Courts and Williamson 2015; Hostetler et al. 2017).

As most prominent source of C-glycosylisoflavonoids (mainly puerarin), kudzu (Japanese arrowroot, *Pueraria montana var. lobata*) has to be mentioned. According to Wu et al. (2011), its dried roots contained 1.97% of puerarin, whereas other puerarin derivatives were present only in low quantities (0.024–0.16%). Structures of most common flavone C-glycosides are shown in Table 2, and C-glycosylflavonoids other than flavones are presented in Fig. 3.

5.3 Bioavailability

CGF have a higher stability compared to their *O*-glycosylflavonoids (OGF) in regard to their hydrolysis rate. Human studies reveal that flavonoid C-monoglycosides (such as vitexin, isovitexin, orientin, isoorientin, and puerarin, for structures see

Table 2 and Fig. 3) are only absorbed to a minor extent. Metabolism of CGF differs mainly from that of *O*-glycosylated flavonoids which are hydrolyzed easier by acid and enzymes compared to CGF. Therefore, CGF are not affected to the extent as seen for OGF by hepatic and gastrointestinal hydrolysis obvious due to the appearance of intact CGF in urine. No mammalian enzymes which are capable of cleaving the C-glycosidic linkage are known; therefore, resident bacteria in the human colon are the only metabolism step experienced by CGF. With a bamboo extract (containing vitexin, isovitexin, orientin, isoorientin) administered to rats, it was found that these CGF are poorly absorbed from the gastrointestinal tract and are therefore passed to colon which were then excreted by feces within 24 h. After examination of rats after 12 h of administration, no CGF were found in liver and brain. Microbial degradation gave rise to metabolites like phloroglucinol, hydrocaffeic, and phloretic acid. In contrast, C-multiglycosides of flavonoids are absorbed from the small intestine in unmodified nature and distributed to the liver. From there, CGF are either infiltrated into the system circulation and distributed to various tissues or directed to urinary excretion (Xiao et al. 2016). Hence, deglycosylation does not seem to be essential for CGF absorption (Courts and Williamson 2015).

Bioactivity of such phenolic compounds is strongly dependent on the release rate from the matrix (bioaccessibility), alterations during the passage of gastrointestinal tract, and the principal metabolism in vivo. Bioaccessibilty of dietary flavonoids is again dependent on many factors such as matrix, filling of stomach, liquid consumption during eating, pH value of gastrointestinal tract, peristalsis, and blood and lymph flow. On the other hand, it is dependent on the nature of the flavonoid – nature and scale of glycosidation, type of sugar, and how it is linked to the aglycone. The interaction of flavonoids and proteins is feasible after what they are less likely to be ready for digestion. The main reactions going on in the liver include methylation, sulfatation, and glucuronidation (Czubinski et al. 2019).

Glycosides can be seen as prodrugs enhancing the solubility of their aglycones. Only a small extent of flavonoid glycosides is absorbed in the small intestine – the majority is transported to the large intestine and there deglycosylated by colonic bacteria takes place. Once they are absorbed, they are metabolized by phase II enzymes and then conveyed into the liver. Hydroxylation, reduction, or methylation take place to release the aglycones which in turn get further metabolized (sulfated/glucuronidated) to the typical flavonoid metabolites (with improved solubility and molecular weight) which circulate in the body.

Especially the enzymes of UDP-glucuronosyltransferases 1 and 2 family are responsible for the glucuronidation of flavonoids. Local release of aglycones from glucuronidated species has been observed in inflammatory cells, such as macrophages which release lysosomal enzymes, including β-glucuronidase, which can lead to deconjugation in the tissues and uptake of aglycones by the cells to a much higher rate compared to the glucuronide conjugates. The in situ deconjugation has been pointed as an absolute requirement to the flavonoid bioactivity by delivering the free aglycone to the tissues, which is the final effector (Xiao et al. 2016; Xiao 2017) (Fig. 4).

More than 400 bacterial species can habitat a human body and therefore the metabolization rate differs from one person to another. Little is known for the

deglycosidation processes for CGF although some bacterial strains were reported to be involved in the cleavage of C-glycosides; among them are strains from *Enterococcaceae*, *Lachnospiraceae*, and *Streptococcaceae*. The specific strain responsible for the cleavage of C-coupled sugar is noted in the sections below assigned to the affected compound. It is further reported that most bacteria able to cleave the C-linkage are also able to act on *O*-glycosides. Bacteria could be responsible for one step in the metabolization or can perform the whole cascade to degradation products (Braune and Blaut 2016). Degradation of isoorientin by human intestinal bacteria was studied by Hattori et al. (1998).

The binding of ingested compounds to serum albumin is an important factor how pursuing distribution, excretion, and metabolism is carried out in human body. Serum albumin is known for its function as carrier and storage place for various compounds of endogenous and exogenous nature (such as fatty and amino acids, steroid hormones, and drugs) and therefore is of critical importance for bioavailability and duration of drug action. A study conducted by Cao et al. examined the affinity of various flavonoids to human serum albumin by using high performance affinity chromatography. For this reason, 63 structurally different flavonoids were tested for their human serum albumin binding affinity among others 4 CGF. Apigenin-6-C-glycoside, puerarin, vitexin, and vitexin-2″-rhamnoside were tested with protein binding rates of 59.6%, 30.6%, 47.7%, and 19.1%, respectively. When drugs are bound to proteins, reversible complexes are formed from which drugs cannot diffuse through plasma membranes and no metabolization is possible. On the other hand, drugs can diffuse from these reversible complexes when drug plasma concentration is low and can therefore maintain an equilibrium. In this study, various substitution on the flavonoid basic structure was performed which allow interpretation of structural relationships. Glycosylation of flavonoids leads to a decrease of protein binding rate by 30–50%. This effect was mediated by steric hindrance and the higher polarity due to glycosylation. Compounds are bound to human serum albumin by a hydrophobic pocket which in turn is decreased by a lower lipophilicity. A high protein binding rate stands for a longer half-life and a slow elimination into plasma of these drugs (Cao et al. 2019).

5.3.1 Vitexin and Isovitexin

Vitexin was found to be deglycosylated to its aglycone apigenin by a bacterium found in human feces, *Lachnospiraceae* CG19-1 (Courts and Williamson 2015), whereas isovitexin was also deglycosylated by *Eubacterium cellulosolvens* to apigenin and 3-(4-hydroxyphenyl)propionic acid (Xiao et al. 2016) (see Fig. 5). The excretion ways of vitexin were studied with the substance vitexin-4″-*O*-glucoside by Cai et al. For this reason, mice were given 30 mg/kg vitexin-4″-*O*-glycoside either orally or intravenously and samples were collected at certain time points. In an oral dosing experiment after 24 h, original substance was recovered from urine with 17.9% and in feces with 6.3%. Intravenous administration led to a recovery rate of 4.7% (urine) and 0.8% (feces). These low recovery rates showed that vitexin-4″-*O*-glucoside have to be metabolized also by other means. The authors conclude that this glycoside has entered

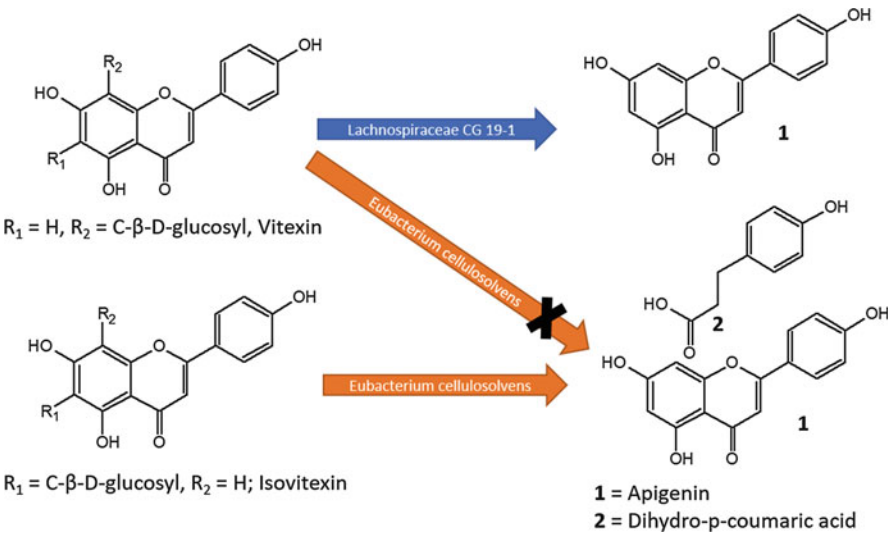

Fig. 5 Deglycosylation of vitexin and isovitexin by selected gut bacteria. Whereas Lachnospiraceae strain CG 19-1 deglycosilated vitexin to apigenin (Braune and Blaut 2016), *Eubacterium cellulosolvens* degraded only isovitexin to apigenin and dihydro-p-coumaric acid, but not vitexin (Xiao et al. 2016)

enterohepatic recirculation (elimination from the bile to the intestine and simultaneously reabsorption into the blood flow) and was then eliminated. More than four-fold higher elimination was detected after oral administration, whereas plasma concentrations were higher after i.v. administration. It can be concluded the renal way is the major excretion way of vitexin-4″-*O*-glucoside from mice (Cai et al. 2013).

A further experiment was performed with vitexin-2″-*O*-xyloside in order to gain insight into the bioavailability of CGF. The compound was administered (8.15 μmol) directly in the caecum of rats and blood samples were taken at various time points. The CGF gave rise to two peaks in the blood – on the one hand the unchanged vitexin-2″-*O*-xyloside and, on the other hand a vitexin glucuronide. This glucuronide was detectable as early as 30 s after administration. Unmetabolized drug enters enterohepatic recirculation and therefore gets reabsorbed in the intestine partly in conjugated form. The caecum was observed, showing a retarded amount of vitexin-2″-*O*-xyloside of around 25% and no conjugates were detected – therefore metabolization products by gut bacteria or enterocytes are thought to be immediately released into the blood (Xiao et al. 2016).

5.3.2 Schaftoside, Isoschaftoside, Vicenin-2

With a human gastrointestinal model, the metabolization of schaftoside and isoschaftoside was shown resulting in the information that these CGF are stable through their passage of gastrointestinal dialyze model. The same data were obtained for

vicenin-2 and vitexin. During this model, only *O*-glycosidic linkages of vitexin-*O*-glycosides were broken by colon bacteria. A search was started for specific degradation products of vitexin, but it can be considered as stable due to the fact that no metabolites (such as 3-(4-hydroxyphenyl) propionic acid) occurred over time. Data regarding active absorption and enzymatic influence is missing in this model (van Dooren et al. 2018). In an in vivo model using rats it was shown that schaftoside, isoschaftoside, and vicenin-2 were rapidly absorbed into the blood circulation. The plasma curves led to the conclusion that there are possibly two absorption sites in the intestine. The distribution of these three CGF was mainly in the kidneys followed by liver, lungs, heart, and spleen (for vicenin-2 and isoschaftoside) (Xiong et al. 2015).

Lupin seeds (*Lupinus angustifolius*) are widely used in nutrition. Isolation gave rise to the free aglycone apigenin and three CGF could be isolated from this plant whereas apigenin 6,8-di-*C*-glucoside (vicenin-2) and apigenin 7-*O*-apiosyl-6,8-di-*C*-glucoside as the two main CGF. It was found that these CGF are able to bind to proteins and during digestion can be released if these proteins are broken down. When digesting these seeds in an in vitro model, the total phenolic content decreased by 57% (at stomach level) and an additional 5% when measured at small intestine level. No qualitative change in CGF composition was found after digesting the seeds, but quantitative changes were found (a lesser amount was documented). In other *Lupinus* species a change was found in the CGF composition after digestion. In *L. luteus* no hexoside of apigenin feruloyl-7-apiosyl-6,8-di-C-glucoside was detectable and in *L. albus* no aglycone apigenin was found post digestion. In case of *L. luteus* new *O*-glycosides appear in after digestion measurements. On the example of *L. angustifolius*, it was demonstrated that 83% of apigenin 7-*O*-apiosyl-6,8-di-*C*-glucoside were released at stomach digestion and additionally 9% at intestine level. Very similar results were obtained for apigenin 6,8-di-*C*-glucoside with 86% in stomach and + 7% in the intestine. These results show that CGF are bioaccessible in a high extent. An additional experiment of protein digestion was conducted and showed that 54% of lupin protein was digested during the in vitro model. The higher the total phenolic content, the lower was the protein digestion rate. The decrease could be explained by complex formation or the inhibitory potential of phenolic compounds on proteolytic enzymes (Czubinski et al. 2019).

5.3.3 Orientin and Isoorientin

Isoorientin was found to be deglycosylated by a bacterium found in human feces, *Lachnospiraceae* CG19-1 (Courts and Williamson 2015). In a study using human intestinal bacteria, isoorientin was metabolized to phloroglucinol, luteolin, (+)-eriodictyol, 6-C-glucosyleriodictyol, and 3,4-dihydroxyphenylpropionic acid. This metabolic deglycosylation were also reported to happen together with orientin in sheep and cows mediated by *Eubacterium cellulosolvens* (Xiao et al. 2016). Orientin and isoorientin were metabolized to luteolin by *Lachnospiraceae* CG19-1 and for isoorientin a further bacterial deglycosylation way was described with *Eubacterium cellulosolvens* (Braune and Blaut 2016).

When CGF are not absorbed in the upper intestinal tract, they get degraded by intestinal bacteria to breakdown products. In this context, isoorientin is metabolized to (±)-eriodictyol-6-C-β-glucoside which in turn is reduced to luteolin and (±)-eriodictyol. The latter substance is further degraded to phloroglucin, 3-(3,4-dihydroxyphenyl)-propionic acid and 3-(3-hydroxyphenyl)-propionic acid (Webster and Wood 2016). A newly found human bacterial strain *Enterococcus* sp. 45 (affiliated with *Enterococcus casseliflavus*) was able to cleave orientin to luteolin. Furthermore, it was noted that these bacteria are able to acetylate and deoxygenate orientin. These effects were carried out by several other bacterial strains too. Furthermore, the original substance orientin could be detected (Xu et al. 2014).

5.3.4 Puerarin (Daidzein-8-C-Glucoside)

A specific bacterial *strain PUE* (affiliated with *Dorea longicatena*, *Lachnospiraceae*) was able to cleave puerarin to daidzein. This strain is regularly found in human gut microbiota. This reaction was also reported for *Lachnospiraceae* CG19-1, *Lactococcus* sp. MRG-IFC-1, and *Enterococcus* sp. MRG-IFC-1 (Braune and Blaut 2016). Furthermore, human microbiota is not only able to metabolize puerarin to daidzein and glucose but also to (3S)-equol (Xiao et al. 2016).

The CGF puerarin was found to have a 138-times lower binding rate to human serum albumin compared to the corresponding aglycone. In contrast, the binding to bovine hemoglobin was found to be 2.45 times higher compared to daidzein. And in the case of plasma proteins of type II diabetes, the CGF and the aglycone had similar affinities. When looking at the pharmacokinetics, a 7-*O*-glucoside of puerarin showed a higher plasma concentration and was longer detectable in the blood as puerarin itself (Xiao 2017).

5.3.5 Aspalathin

This is the best examined CGF so far in human and porcine studies. In these studies, methylated metabolites of aspalathin were found after oral administration. No intact aspalathin was found in the plasma of human and pig. However, in urine this substance was detected showing limitation of plasma extraction methods (eventually binding to serum albumin) and therefore, surveillance of plasma concentrations of CGF is challenging due to insensitive methods. In a bioavailability study with aspalathin, there were glucuronide and sulfate conjugates found in vivo. Furthermore, it was shown that the catechol-*O*-methyl-transferase takes action in this metabolic process by methylating the catechol moiety of aspalathin giving rise to a 3-*O*-methylaspalathin which was then detected in urinary samples. With Caco-2 cells, the passive transport by diffusion of aspalathin into the intestinal epithelium was demonstrated. During this transport, aspalathin was not deglycosylated. The uptake into enterocytes occurred only in a small manner probably by the

nonselective transport of *O*-glycosides by enterocyte glucose carrier proteins (such as SGLT-1). Aspalathin has only a poor bioavailability (Courts and Williamson 2015).

After administration of fermented and unfermented rooibos tea (*Aspalathus linearis*) to human, volunteers' urine and blood samples were collected over 24 h and evaluated. The main metabolite found after fermented tea consumption was eriodicytol-*O*-sulfate and *O*-methyl-aspalathin-*O*-glucuronide in case of unfermented tea. Further metabolites found in both teas include aspalathin-*O*-sulfate, *O*-methyl-asphalathin-sulfate, and aspalathin-*O*-glucuronides. The authors suggest the absorption of eriodicytol-*O*-sulfate in the large intestine due to the excretion via urine after 5–12 h, whereas most aspalathin metabolites were found in urine within 5 h (uptake from small intestine). No metabolites in plasma were found throughout this study (Xiao et al. 2016).

5.4 Bioactivities

In food plants, as in ethnomedically applied plants, a plethora of compounds can be responsible for the observed effects, it is not clearly possible to distinct whether a plant is solely active due to the high CGF content. Therefore, here only plants are linked to an activity which are especially rich in CGF. Betimes, only in vitro data are available.

5.4.1 Antidiabetic Activity

Due to the stable C-glycoside linkage, it is thought that this substance group is able to modulate the blood glucose level. In an in vitro experiment, model pancreatic β-cells (RIN-5F cells) were incubated with and without aspalathin (100 μM). Within 3 h, it was found that insulin secretion has risen by 30% along with no increase of cytotoxicity. The potential of this substance is thwarted by its poor bioavailability. In another study using L6 rat myotubes aspalathin was able to increase glucose uptake by 24% when used in 1 μM and by 64% in 10 μm concentration. Isovitexin was able to show in vivo an insulin secretion increase by 58% after 1 h. With this, also the glycogen values were upregulated (27%) in the muscles of these rats (Courts and Williamson 2015).

The leaves of *Microctis paniculata*, a common ingredient in Chinese herbal teas, were studied for their CGF content. Two substances, vitexin and isovitexin, were isolated from these leaves and tested for their activity to inhibit α-glucosidase. As both compounds are also frequently found in food plants, the results of this study should be presented here. The methanolic extract was able to inhibit α-glucosidase with a half maximal inhibitory concentration (IC_{50}) of 61.3 μg/ml in a concentration-dependent manner. For vitexin (see Fig. 6) and isovitexin, an IC_{50} concentration of 96.9 μg/ml (244.0 μM) and 115.1 μg/ml (266.2 μM) was obtained in the α-glucosidase assay (positive control: acarbose with 1007 μM). Therefore, the two CGF are

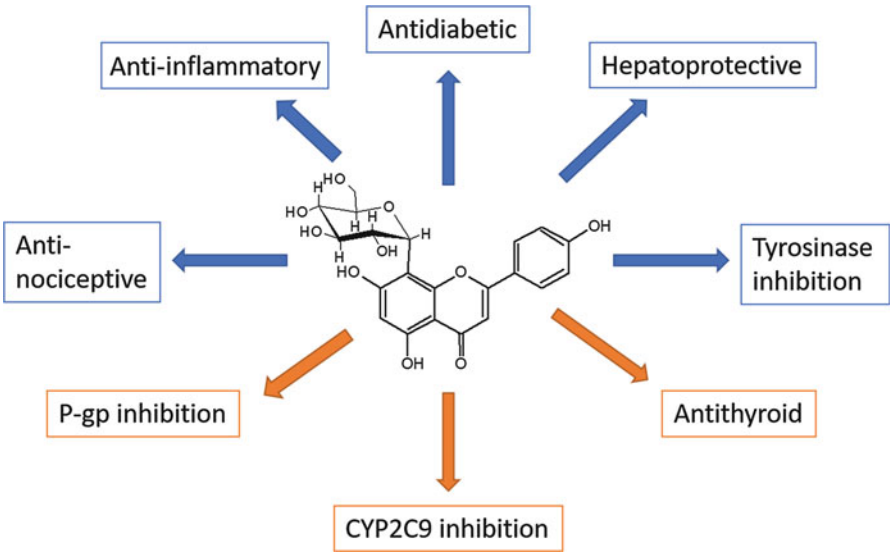

Fig. 6 Biological activities of vitexin. Activities which could cause undesired interactions with other compounds or lead to adverse effects are indicated in orange

emphasized as possible antidiabetes drug candidates (Xiao et al. 2016). The same two substances were tested in the α-glucosidase assay by another working group according to Xiao et al. (2016). They reported an in vitro IC_{50} of 4.1 μg/ml for vitexin and 6.7 μg/ml for isovitexin, which are both lower than that of acarbose. Both CGF were isolated from *Ficus deltoidea*. In addition, an in vivo experiment using normoglycemic mice and diabetic rats induced by streptozotocin was performed. Both CGF were found to lower the postprandial glucose level when measured at 30 min. Vitexin when orally administered at 1 mg/kg to normoglycemic mice significantly reduced the blood glucose level by 24.7%, and at higher concentrations of 3 mg/kg and 15 mg/kg the reduction was further enhanced to 26.5% and 31.3%, respectively. After 1 h, the glucose level returned to normal in normoglycemic mice. All three doses were equivalent to acarbose (3 mg/kg), the positive control. Extrapolation of 1 mg/kg in mice leads to an equivalent dosage of 0.08 mg/kg in humans. Isovitexin was able to lower the postprandial glucose level in normoglycemic mice at 60 min when used at 3 mg/kg and 15 mg/kg, whereas 1 mg/kg isovitexin was comparable with acarbose. In diabetic-induced rats higher concentrations of corresponding CGF were employed. The peak of postprandial glucose level in these rats was found to be at 60 min with an additional increase of 20.8%. The highest reduction (19.7%) in diabetic rats was achieved with 200 mg/kg vitexin and 100 mg/kg isovitexin, respectively. An already significant result was obtained with 50 mg/kg vitexin (human equivalent dose of 8.1 mg/kg) and 20 mg/kg isovitexin (human equivalent dose of 3.3 mg/kg). Similar effects were obtained with 5 mg/kg acarbose. Furthermore, the toxicity of oral administration of 2 g/kg vitexin and

isovitexin was measured with no signs of toxicity (mortality and weight change) after 24 h and 14 days. The dried leaves of *F. deltoidea* only contain 0.34% vitexin and 0.13% isovitexin; therefore, an infusion can only be active in patients with mild diabetes (Xiao et al. 2016). The formation of advanced glycation endproducts (AGE) is feared as a driving force in diabetic pathogenicity. It is associated with cataract, neuro-, nephro-, and retinopathy in diabetic patients. A hydroethanolic extract of mung beans (*Vigna radiata*) was found to be a potential inhibitor of this AGE product formation. 80.4% inhibition was achieved with a concentration of 500 ppm in the bovine serum albumin glucose test. In the subsequent analysis, it was found that mung beans are rich in phenolic compounds – especially vitexin and isovitexin. These two CGF were tested in the same test model at a concentration of 100 μM and were found to be slightly lower inhibitory active than rutin, an already known excellent AGE inhibitor. Researchers believe that the anti-glycation activity can be attributed to the free radical scavenging ability of these CGF (Xiao et al. 2016). Sprouts are part of a modern diet; therefore, it was documented in an experiment that fenugreek (*Trigonella foenum graecum*) and barley sprouts (*Hordeum vulgare*) could be of potential use in diabetes management. Both sprout juices were able to reduce the fasting blood glucose level compared to untreated diabetic rats. An additional effect on the lipid profile of rats was observed, whereas barley sprout juice performed best, nearly improving the lipid profile of diabetic rats to normal status (total cholesterol – 27.9%, triglycerides – 16,9 and LDL – 51.4% compared to untreated diabetic rats). Both juices were also able to reduce lipid peroxidation and oxidative stress measured by malondialdehyde levels and catalase activity (Mohamed et al. 2019). The leaves of *Centaurea alexanderina* were extracted with methanol and then screened for their constituents resulting in three reported CGF: vicenin-2, vitexin, and isovitexin, all of them can also be found in citrus fruits. With this extract and oral glucose tolerance test with normoglycemic rats was conducted. The dose of 600 mg/kg extract was able to lower the blood glucose levels by 9.4 and 10.5% when tested after 1 and 2 h, respectively. These results were just over the reference substance glibenclamide. In diabetic rats, the treatment with the extract over 30 days led to a significant decrease of blood glucose levels by 3.8% for 600 mg/kg, whereas the maximum was reached after 60 days with 4.9% (Kubacey et al. 2012).

5.4.2 Anticancer Activity

Citrus CGF were found to alter key enzymes responsible for cell activation and receptor binding and simultaneously be of low toxicity tested in animals (Xiao et al. 2016). In an experiment using isoorientin, it was documented that this CGF was able to increase apoptosis and autophagy and inhibit proliferation in human hepatoblastoma cancer cells. The induction of apoptosis was mediated by mitochondrial dysfunction, the inhibition of signals which trigger apoptosis and autophagy (such as p53 and NFκB) and also Fas-pathway was activated. Isoorientin was tested against human liver cells and no toxicity was found for this CGF using

concentrations up to 80 μM (Xiao et al. 2016). P-glycoprotein (p-gp) is a membrane protein known for its efflux capacity and therefore of importance in the resistance development of cancer cells to anticancer treatment. 75 flavonoids were screened for their ability to inhibit p-gp amongst others also three CGF: orientin, puerarin, and vitexin (see Fig. 6). In a first step it was found that all three CGF were of nontoxic nature when tested in 100 μM against MDR1-MDCKII cells. Vitexin was the best CGF to inhibit p-gp with 34.3%, followed by orientin with 20.8% and puerarin with 18.5% respectively (Bai et al. 2019). Furthermore, it was shown with esophageal cancer cells (EC-109) that orientin and vitexin were able to induce apoptosis and therefore inhibit cell growth. The oncogene expression of p53 was significantly increased after 48 h incubation in a concentration-dependent manner (up to 80 μM), whereas the effect of orientin was found to be stronger (An et al. 2015). An extract rich in vitexin and isovitexin (and chlorogenic acid) from *Trigonella foenum graecum* was tested active against human breast cancer cell line (MCF-7) and African green monkey kidney (Vero) cells with an IC_{50} of 2.5 μg/ml for each strain (Kadaikunnan et al. 2015). A mixture of CGF (vitexin, isovitexin, and orientin) was detected in a CO_2 extract of the leaves of *Cajanus cajan*. This extract was tested against three cell lines in order to evaluate the cytotoxicity: mouse macrophage cell line RAW 264.7 (68.9 μg/ml), Vero (62.5 μg/ml), and baby hamster kidney-21 cells (64.1 μg/ml). For the MCF-7 an IC_{50} value of 55.7 μg/ml was determined (Zu et al. 2010).

5.4.3 Antioxidant Activity

In general, CGF show higher antidiabetic and antioxidant activity as their equivalent O-glycosides and aglycones. CGF, mainly vitexin (see Fig. 6) and orientin, isolated from pigeon pea leaves (*Cajanus cajan*) were found to be active in DPPH (2,2-diphenyl-1-picrylhydrazyl) radical scavenging experiment and was therefore successfully tested as stabilizer for blueberry juice (Xiao et al. 2016). From *Ficus deltoidea*, a traditional Malaysian tea, 16 CGF were extracted, whereas vicenin-2 (apigenin-6,8-*C*-diglucoside) was found to contribute with 9.1% antioxidative activity to the over-all effect of this tea. Other CGF do not elicit a notable antioxidant effect (Xiao et al. 2016). CGF of cayenne pepper (*Capsicum annuum*), widely used as spice, were found to act as antioxidant by superoxide radical scavenging and further were a strong inhibitor of xanthine oxidase. From these fruits, luteolin-6-*C*-glucoside, luteolin-6,8-*C*-diglucoside, and apigenin-6-*C*-glucoside-8-*C*-arabinoside were extracted. Luteolin-6-*C*-glucoside revealed the strongest antiradical-activity when tested in nonenzymatic β-nicotinamide adenine dinucleotide/phenazine methyl sulfate assay with an IC_{50} of 207.8 μM. In the xanthine oxidase test, apigenin-6-*C*-glucoside-8-*C*-arabinoside was able to elicit the strongest response with IC_{50} of 51.4 μM. In a DPPH model, only luteolin derivatives were active, whereas the apigenin derivatives were found to have no impact which can be traced back to the missing 3,4-dihydroxy group in the B-ring (Materska 2015). Barreca et al. found the juice of sour

oranges (*Citrus aurantium*) rich in CGF like lucenin-2, lucenin-2 4′-methyl ether, and vicenin-2 and was able to show a high antioxidative power mediated by reducing free radicals of DPPH by 48% and ABTS (2,2′-azinobis-(3-ethylbenzthiazoline-6-sulfonic acid) diammonium salt) by 75%. The authors conclude that lucenin-2 is the most important CGF in consideration of total antioxidant effect due to the catechol moiety which confers stabilization to formed radicals (Barreca et al. 2010). The same working group screened various *Citrus* varieties in order to gain insight into the CGF content distribution. In this study, it was detected that the main CGF of lemon and citron (*Citrus limon* and *Citrus medica*) was lucenin-2 4'-*O*-methyl ether. In case of orange (*C. aurantium*), clementine (*C. deliciosa*), and tangerine (*C. reticulata*), vicenin-2 was found as the most abundant substance. Kumquats (*C. japonica*) showed a totally different profile with phloretin-3′,5′-di-C-glucoside as main component. The flavonoids of one juice were extracted and tested for their ability to quench free radicals. The overall flavonoid fraction was able to reduce DPPH radicals by 50% and ABTS radicals by 80%. It was found out that the fraction containing lucenin-2 and vicenin-2 was co-responsible for this excellent antioxidant effect by bearing free and highly active phenolic hydroxyl groups and the essential double bond in the pyrone C-ring (Barreca et al. 2014). The seeds of lotus (*Nelumbo nucifera*) are used in China to cook soup and are used as herbal tea. An ethanolic fraction was successfully tested as antioxidant against DPPH radicals (1476.2 μM TE (trolox equivalents)/g) and ABTS (2974.0 μM TE/g) and exerted also an anti-inflammatory activity (see below) (Chen et al. 2019). Finger millet (*Eleusine coracana*) is considered as staple in developing countries and was found to include some CGF, in particular five apigenin derivates. Variations of this grain were tested for its ability to reduce radicals of DPPH in a range of 14.2–21.5 μM TE/g and ABTS from 19.0 to 26.8 μM TE/g. No declaration of CGF to a specific antioxidant activity was drawn (Xiang et al. 2019). Another food ingredient, mung beans (*Vigna radiata*) were found to possess antioxidant activity. The best result in the DPPH radical scavenging capacity assay was found to be 16.79 μmol TE/g when extracted with acetone-water. Further antioxidant assays were performed: ferric reducing ability of plasma assay (20.43 μmol TE/g), hydroxyl radical scavenging capacity (95.59 μmol TE/g), and oxygen radical absorbance capability with 184.14 μmol TE/g. Therefore, mung beans can be considered as natural antioxidant and furthermore anti-inflammatory activities were observed by this working group. A correlation was found between antioxidant activity and the anti-inflammatory activities (Xiao et al. 2016). From the seeds and sprouts of fenugreek (*Trigonella foenum graecum*), a popular spice used worldwide two well-known CGF were isolated, namely, vitexin and isovitexin. The antioxidant power of the ethanolic extract of the seeds was found to be 41.23 μg/ml (IC_{50}) in the nitric oxide radical inhibition assay. In the β-carotene assay, 50% inhibition was achieved with an extract concentration of 22.75 μg/ml. With this assay it can be shown that the compounds found in the extract are able to reduce the by-products of lipid peroxidation. Various antioxidative assays were conducted: Further results (anticancer and antibacterial effects) were obtained for fenugreek and can be found in the respective section of this chapter (Kadaikunnan et al. 2015).

5.4.4 Hepatoprotective Activity

Isoschaftoside was found to be present in green tea leaves. In an animal testing model, 0.1% of isoschaftoside was given to rats as a dietary supplementation and no change in growth and food intake was measured. It was found that the liver injury induced by D-galactosamine was partly reversed by this CGF due to a suppression of increase of plasma alanine aminotransferase and asparatate aminotransferase (Xiao et al. 2016). The leaves of beetroots (*Beta vulgaris*) host two flavonoids which are *O*-substituted C-glycosides – namely, vitexin-7-*O*-β-D-glucopyranoside and vitexin-2″-*O*-β-D-glucopyranoside. Rat liver cells were injured with carbon tetrachloride and the hepatoprotective effect of these two CGF was measured by looking at the release rate of glutamic pyruvic transaminase. The first CGF was found to be active at 65.8% and the latter one with 56.1% when tested at a concentration of 100 μM. This effect was comparable with silibinin, a substance known for its hepatoprotective activity. It was further noticed that vitexin has an inhibitory activity on cell death in hepatocytes induced by tumor necrosis factor α (TNF-α) (Xiao et al. 2016).

5.4.5 Anti-inflammatory Activity

The abovementioned fraction of lotus (see Sect. 4.7) was further tested against RAW 264.7 cells in a concentration of 12.5–50 μg/ml and was able to significantly reduce the production of NO radicals which are part in the development of inflammation. Furthermore, the flavonoids of lotus were able to reduce the production of pro-inflammatory cytokines such as interleukin (IL)-1β, IL-6, prostaglandin E2 (PGE-2), and TNF-α. Using affinity ultrafiltration LC/MS, the authors were able to identify potential cyclooxygenase (COX)-2 ligands. In the subclass of CGF vitexin was found to be the most promising COX-2 ligand (Chen et al. 2019). The working group of Kwon et al. determined the influence of glycosidation of flavonoids on nitric oxide production after lipopolysaccharide stimulation in BV2 microglial cells. It was found that most CGF were able to reduce the amount of NO produced. In relation to our topic, kaempferol-6-C-glucoside (present in lotus, figs and citrus juice) and luteolin-8-C-glucoside were still able to significantly inhibit the LPS-induced NO production. Especially the C-glycosidation in 6 and 8 position proved as superior (Xiao et al. 2016). A further aspect in inflammation is the vascular dysfunction. For this it was studied that orientin (and to a smaller extent also isoorientin) was able to inhibit the barrier disruption mediated by LPS and further blocked the leukocyte migration which leads to vascular permeability. These findings were also confirmed in an in vivo model with mice verifying the enhanced barrier integrity and reduced migration by a reduction of LPS-induced mortality. By various tests it was found out that orientin and isoorientin are able to inhibit MAPK and NFκB pathways. This study was able to draw structure-activity relationships: the glucoside position 8 (orientin) seems to be superior regarding the anti-inflammatory activity compared to the glucoside in position 6 as can be found in isoorientin. Vitexin and

isovitexin were also tested in this setting but did not elicit a positive effect due to the missing OH-group in position 3 (Xiao et al. 2016). In a study exploring the anti-inflammatory effect of the leaves of lemongrass (*Cymbopogon citratus*), a new luteolin-C,*O*-glycoside was described as cassiaoccidentalin B, and was found together with isoorientin in this plant. The glycosides were found to be less cytotoxic (up to 100 μM) compared to the aglycon luteolin. The CGF were found to possess no anti-inflammatory activity due to the decrease of activity by C-glycosylation. The effect on the activity of O-glycosides was less pronounced. It is also noted by the authors that macrophages release enzymes such as β-glucuronidase which are able to catalyze the deconjugation of flavonoids in the peripheral tissues of inflammation (Xiao et al. 2016). Various mungbean samples (*Vigna radiata*) were evaluated for their anti-inflammatory potential. For this, the production of various inflammatory markers was evaluated, namely, IL-1β, IL-6, and COX-2 in RAW 264.7 mouse macrophages. In the case of IL-1β, half of the samples of mung beans were able to inhibit the LPS-induced messenger RNA(mRNA) expression, whereas the highest inhibition ranged at 60%. A similar picture emerged when looking at the expression levels of IL-6. For COX-2, all samples were able to significantly inhibit the expression. The expression levels of IL-1β and IL-6 correlated with the anti-oxidant activity also reported from this study (see Sect. 4.7). Pure CGF vitexin and isovitexin and a physiological mixture of both as found in the beans were tested for their capacity to inhibit cytokine expression. It was shown that vitexin is of great importance for inhibiting the mRNA expression of COX-2, for both other cytokines no effect was shown and therefore other pure compounds such as phenolic acids are responsible for this phenomenon. Furthermore, no synergistic effect was achieved by the combination of both CGF (Xiao et al. 2016). A QSAR study performed with CGF and their corresponding anti-inflammatory activity showed various correlations. In general, C-glycosylation was preferable to O-glycosylation and the anti-inflammatory activity is increased by a glycosylation of ring A. In return, the activity is reduced by methoxylation of the hydroxyl groups in the flavone and the higher the polarity of C-2″-moiety is (Xiao et al. 2016), see Fig. 6.

An ethanolic extract of two varieties of muskmelon (*Cucumis melo*) was found to possess in vivo anti-inflammatory activities. By an UPLC-MS/MS setup among other flavones and flavonols, CGF such as isovitexin and isovitexin-2″-*O*-rhamnoside were found. Animals were orally pretreated with 25 and 50 mg/kg ethanolic extracts of peels and pulps of *Cucumis melo* var. *cantalupensis* and *Cucumis melo* var. *reticulatus* and inflammation was induced with carrageenan in the hind paw. All extracts were able to significantly inhibit the formation of edema after 3 h. The best result was obtained with the pulp of *Cucumis melo* var. *reticulatus* (50 mg/kg) reaching an inhibition of 69.41%. After this time point, the results of edema volume reduction were comparable with indomethacin for the pulp of *Cucumis melo* var. *reticulatus* (50 mg/kg) and the pulp of *Cucumis melo* var. *cantalupensis* (25 and 50 mg/kg). The extracts were also found be able to reduce pro-inflammatory cytokines like IL-1β, IL-6, PGE-2, and TNF-α in various extents (Ezzat et al. 2019). Another study conducted by Borghiet al. focused on the effect of the pure compound vitexin. Various assays were performed to evaluate the anti-

inflammatory and antinociceptive (for further details see section below) mechanisms of vitexin. In the carrageenan assay, this CGF was able to reduce the production of pro-inflammatory cytokines (IL-1β, IL-6, IL-33, and TNF-α) and in the same time to induce IL-10 which is known as anti-inflammatory marker. Therefore, it can be concluded that vitexin is able to reduce inflammatory pain (Borghi et al. 2013). An extract rich in vicenin-2, schaftoside and isoschaftoside was administered to rats in a carrageenan paw swelling model in a concentration of 25–100 mg/kg. This treatment with the extract significantly reduced the nonspecific inflammation, whereas the highest swelling was maintained after 4 h. In the highest concentration (100 mg/kg), the extract was superior compared to the well-known anti-inflammatory drug aspirin, which was used as control substance (Xiong et al. 2015).

5.4.6 Antimicrobial/Antiprotozoal Activity

From the seeds and sprouts of fenugreek (*Trigonella foenum graecum*), a popular spice used worldwide, two well-known CGF were isolated, namely, vitexin and isovitexin. Gram-positive bacteria were susceptible for this extract and showed good activity whereas gram-negative bacteria were of low activity. Highest inhibition zones were achieved by the highest concentration tested (1000 μg of extract). Therefore, especially *Bacillus subtilis*, *Klebsiella pneumoniae*, and *Staphylococcus aureus* were susceptible to the fenugreek extract. In a smaller extent, the extract was also active against *Salmonella typhi* and *Escherichia coli*. Furthermore, various fungi were tested and it appeared that *Candida albicans*, *Penicillium notatum*, and *Aspergillus flavus* were vulnerable by these extracts (Kadaikunnan et al. 2015). Various flavonoids were tested against *Trypanosoma* and *Leishmania* strains. Vitexin was only moderately active against *T. brucei rhodesiense* with an IC_{50} of 55.7 μg/ml, whereas the aglycone apigenin was active against all three tested strains with lower IC_{50} values (Xiao 2017). In the leaves of the Brazilian plant *Serjania erecta*, two CGF were identified – vitexin and isovitexin. An ethanolic extract was produced and tested against various bacterial strains. For subsequent bacterial strains (minimal inhibitory concentration (MIC)) values of $\leq$15 μg/ml were detected: *Pseudomonas aeruginosa* (performed the best with MIC of 5 μg/ml), *Escherichia coli*, *Saccharomyces cerevisiae*, and *Staphylococcus aureus*. No activity was found for *Mycobacterium tuberculosis* (MIC of 128 μg/ml) (Cardoso et al. 2013). The leaves of *Centaurea alexanderina* were extracted with methanol and then screened for their constituents resulting in three reported CGF: vicenin-2, vitexin, and isovitexin. Various extracts of this plant were screened against a variety of bacterial strains, whereas only *Pseudomonas aeruginosa* was susceptible against the methanolic extract with an inhibition zone of 40 mm (Kubacey et al. 2012). An extract from *Carissa opaca,* which was found to be rich in vitexin, isovitexin, and orientin, was tested against various bacterial strains. *Bacillus subtilis*, *Enterobacter aerogenes*, *Klebsiella pneumoniae*, *Pseudomonas aeruginosa*, *Salmonella typhi*, and *Staphylococcus aureus* were susceptible to a varying extent with a MIC of $\leq$5 mg/ml. No breakdown of components to a distinct activity was done in this study.

Furthermore, the inhibition of various fungi, i.e., *Aspergillus flavus*, *A. fumigatus*, and *A. niger* was successfully tested for this extract (Sahreen et al. 2013). Another extract with the same compounds, namely, a mixture of vitexin, isovitexin, and orientin, was detected in an ethanolic and a CO_2 extract of the leaves of *Cajanus cajan*. The CO_2 extract (MIC $\leq$2.5 mg/ml) showed much lower MIC values compared to the ethanolic extract. Bacterial strains such as *Bacillus subtilis*, *Escherichia coli*, *Proteus vulgaris*, *Pseudomonas aeruginosa*, *Staphylococcus aureus*, and *Staphylococcus epidermidis* were found to be vulnerable by this plant extract. Fungi species such as *Aspergillus niger* and *Candida albicans* were also susceptible. The CO_2 extract showed a higher activity against gram-positive bacteria than gram-negative bacteria. With *S. aureus* a time-kill assay was conducted with the CO_2 extract in order to evaluate the death rate in relation to drug and time. For this, a concentration of the respective MIC value and ½ MIC was tested over 4 h. Bacterial cells were able to survive the ½ MIC concentration, but with MIC concentration (39 μg/ml) cells were dead within these 4 h. An in vivo experiment with mice was conducted where animals were infected with *S. aureus* and either administered penicillin or the CO_2 extract (30 or 60 mg/kg intragastrically). After 4 weeks the mice were sacrificed and liver and spleen weights were significantly higher as in the control group. This could be traced back to the inflammation going on in these organs. Other organs were in the same range as the control group. It is mentionable that the group which received the CO_2 extract had reduced inflammation rates, even at the low dose. Therefore, it can be concluded that this extract works in vivo and no direct damage is originating from the extract (Zu et al. 2010).

5.4.7 Antinociceptive Activity

Urtica circularis, a herb cultivated in Argentina, is added to food due to its high content of minerals and vitamins. An ethanolic extract was produced from the aerial parts and a HPLC measurement showed the presence of mainly vicenin-2 but also a small amount of vitexin in the extract. In an experiment where pain was induced by formalin and the licking time of mice was observed, the extract was administered intraperitoneally at 30 mg/kg and 100 mg/kg doses and an additional 500 mg/kg by oral route. The licking time, checked between 15 and 30 min after exposure, was markedly reduced by 78.5%, 91.0% and 88.5% respectively. For this, an ED_{50} of 15.8 mg/kg was calculated. When active in the late phase, substances are attributed to act as antinociceptives by peripheral mechanisms (no involvement of the opioid system). By testing the extract in combination with atropine, an involvement of the cholinergic system could be documented. The writhing test, where pain was induced by acetic acid, was also performed and prior testing the mice were administered i.p. with 10–300 mg/kg *Urtica* extract. The extract dose-dependently inhibited the writhing of mice, whereas the maximum of 80.6% inhibition was achieved with the 300 mg/kg dose surpassing the effect of 10 mg/kg indomethacin i.p. (ED_{50}: 72.2 mg/kg). The 500 mg/kg p.o. dose inhibited the writhing by 48.4%. The experiments showed that the combination of *Urtica* extracts in not effective

concentrations (50 and 100 mg/kg p.o.) with indomethacin (3 mg/kg p.o., also no effect) gave rise to a promising antinociceptive effect. Furthermore, pure compounds found in the extract were tested as control. 10 mg/kg i.p. of vitexin and vicenin-2 were administered and resulted in an inhibition of 91% (again superior compared to indomethacin 10 mg/kg) and 41%, respectively. In contrast, apigenin did not elicit any effect. As gastrointestinal side effects often occur with antinociceptive drugs, the effect of the extract was observed on the stomach were only mice administered with 300 mg/kg and indomethacin 10 mg/kg were tested positive for lesions in the stomach (extract: 71% vs. indomethacin: 100%). When administered with 100 mg/kg *Urtica* extract, no difference was observed to control group which were fed only with water. Furthermore, the acute toxicity of the *Urtica circularis* extract was tested in oral concentrations up to 3000 mg/kg and no signs of toxicity were observed (Gorzalczany et al. 2011). This effect of vitexin was confirmed by another working group. Mice were pretreated with 0.3–10 mg/kg of vitexin i.p. and 30 min afterwards writhing was induced by acetic acid which led to a dose-dependent inhibition of writhing score. Another assay with phenyl-p-benzoquinone was performed where also the writhing was inhibited by vitexin. For this reason, a participation of nociceptive mechanisms which are attributed in both assays such as prostanoids, IL-33, and endothelin-1, is feasible (Borghi et al. 2013). The leaves of *Centaurea alexanderina* were extracted with methanol and then screened for their constituents resulting in three reported CGF: vicenin-2, vitexin, and isovitexin. Writhing was induced with acetic acid and mice were pretreated with doses of 300 and 600 mg/kg leaves extract. These doses significantly reduced the writhing by 35% and 49%, respectively, whereas aspirin (100 mg/kg) as reference compound reached 72%. An additional experiment where a nociceptive irritation was induced by formalin was conducted. Especially the second pain phase involving inflammation was significantly reduced by 47% (300 mg/kg) and 58% (600 mg/kg), respectively. Aspirin again inhibited paw licking by 71%. In the tail flick test, only the higher concentration of 600 mg/kg extract was able to inhibit the mechanism significantly. In the hot plate test, the extract was able in both concentrations to delay the thermal irritation but was less pronounced as with tramadol as positive control substance. One last test was performed inducing edema with carrageenan. 600 mg/kg of extract was able to protect 41% of the edema production after 4 h and was therefore significant. As positive control indomethacin was used in this experiment showing a protection of 48%. An inhibition of the prostaglandin production is discussed as the analgesic effect of this plant. With all these five tests, it can be concluded that *C. alexanderina* is able to peripherally (writhing and paw licking) and centrally (tail flick and hot plate) inhibit the emergence of pain (Kubacey et al. 2012).

5.4.8 Various

Vitexin and isovitexin, isolated from mung beans (*Vigna radiata*), were tested for their ability to inhibit tyrosinase (see Fig. 6). Tyrosinase is an essential enzyme in the melanin synthesis and therefore applicable in cosmetic industry for

hyperpigmentation and as whitening agent. In an in vitro assay vitexin and isovitexin were found to inhibit tyrosinase with an IC_{50} of 6.3 and 5.6 mg/ml, respectively (Xiao 2017). The sprouts of buckwheat (*Fagopyrum esculentum*) showed promising results in an in vivo study against stress in mice. The sprouts of this grain are rich in rutin, orientin, isoorientin, vitexin, and isovitexin. Mice were intragastrically given a 100 mg/kg buckwheat sprout solution and then exposed to stress (limited food and immobilization). The control group (no buckwheat in the solution) showed elevated corticosterone, glucose blood level, hyperlipidemic and thiobarbituric acid reactive substance values. The last substance is assayed in order to gain insight into the oxidative damage effect of stress. All these factors were downregulated by buckwheat flavonoids and therefore are a promising candidate for antistress treatment. Furthermore, plasma concentrations were determined for each CGF in buckwheat sprouts and it was found that 2 h after oral administration all CGF were intact (Xiao 2017). Isovitexin and vitexin were isolated from various plants of Argentina and tested for their ability to reduce oxidative stress (ROS) which was induced by gentamicin. Both CGF were able to inhibit the reactive oxygen species production in mononuclear leucocytes with 22.4% and 34.3% when 10 μM of the flavonoid was administered. In an additional experiment, IC_{50} values of ROS production were determined resulting values for isovitexin and vitexin of 75.36 and 22.7 μM, respectively. As reference substance vitamin C was tested and lead to an IC_{50} of 1.06 μM. The actual antistress experiment was only conducted with luteolin which was able to show a significant decrease of ROS compared to the control group. Luteolin was also able to reduce lipid peroxidation in this context. Furthermore, it was able to enhance the susceptibility of *Escherichia coli* and *Staphylococcus aureus* in combination with gentamicin (Bustos et al. 2018).

5.5 Benefits (Human Studies)

Increasing interest in flavonoids lead to an increasing number of research studies which step-by-step shed light on the metabolism and activities of this class of substances. Since not all flavonoids from one class behave in the same way in the body the clarification and testing of various flavonoids of one class are needed. Due to the fact that in vivo studies with humans are very limited, general conclusions are difficult to make. Especially the family of C-glycosylated flavonoids need a lot more attention. From the literature, it can be concluded that C-glycosylation is beneficial for the antioxidant and antidiabetic activity. In general, flavonoid glycosides are able to create higher plasma levels than their corresponding aglycones. The influence of the attached sugar has to be investigated very carefully in order to predict absorption and metabolism in vivo (Xiao 2017).

The bioactivities of CGF can be seen in subchapter 4 which presents some promising effects such as antidiabetic and anti-inflammatory action. However, until the application in humans against diabetes is feasible, a lot more research has to be done.

In plant derived food, CGF do not occur as singular phenolic compounds, but are embedded in a complex mixture including also other types of flavonoids except CGF.

There are some human studies of dietary flavonoids which have been comprehensively reviewed by Crozier et al. (2010) and Del Rio et al. (2013). Unfortunately, no CGF were specifically examined in these studies. Some data is available for CGF which only show the metabolization of CGF by intestinal bacteria. They are able to cleave the sugar moiety and release the pure aglycone. For instance, it was found that the *Lachnospiraceae* CG19-1 strain is able to metabolize the CGF vitexin to its aglycone apigenin. Also, the binding affinities of flavonoids to human serum albumin are documented in literature. For the bioactivity, human cell lines were utilized but no in vivo data for humans is available until now for CGF.

One aspect in literature has to be taken into account when dietary flavonoids are administered for boosting health. It is reported that flavonoids could be substrates for p-gp which leads to an efflux of these compounds back into the lumen of the gut. Therefore, no effect is exhibited by these administered flavonoids. Another aspect is the importance of p-gp in cancer chemotherapy. Overexpression of p-gp plays an important role in the development of cancer cell resistance. The working group around Di Pietro et al. tested various flavonoids as potential efflux pump inhibitors against various efflux transporters. The in silico predicted binding affinity for vitexin was so low that no further experiments were determined. But in the overall experiment it was shown that glycosylation of flavonoids is detrimental for the binding affinity to efflux transporters (Di Pietro et al. 2002).

5.6 Application in Food

Data on alterations of CGF in plant derived food during processing are quite limited. In rooibos (leaves and stems) a significant difference in unprocessed and fermented herbs can be observed. Fermentation leads to a severe loss of aspalathin which undergoes oxidative cyclisation to the corresponding flavanone C-glycosides. Further oxidation results in flavone C-glycosides (Courts and Williamson 2015; Hostetler et al. 2017). Oxidation is also a prerequisite in processed cocoa seeds to form C-glycosylated flavan-3-ols nonenzymatically. This process leads to a less bitter product as the puckering astringent taste of epicatechin and catechin is converted to a smooth astringent sensation without exhibiting a bitter taste (Stark and Hofmann 2006; Courts and Williamson 2015). High temperature applied for sterilization and preparation of food products indicate a high probability of such nonenzymatically generated C-glycosides, which could be present in the human diet. Furthermore, undergoing a Wessely-Moser rearrangement isomerization concerning C-6 or C-8 position of bound monosaccharides under cooking conditions could take place (Courts and Williamson 2015). For kudzu roots extracts, containing significant amounts of the isoflavonoid C-glycoside puerarin, cooking in beef patties did not lead to a relevant loss of puerarin content, indicating stability of this isoflavonoid C-glycoside during cooking (Kumari et al. 2015). Of course, as with water soluble glycosides cooking will leach out these compounds from the food material, however,

generally a higher stability compared to their O-glycosidic counterparts can be expected.

5.7 Safety: Toxicity and Side Effects

Studies on antinutritional effects have been performed for pearl millet (*Pennisetum glaucum*) (Gaitan et al. 1995; Boncompagni et al. 2018). Aside from the most relevant antinutrient compound, phytate, CGF were reported to have unwanted goitrogenic effects. The compounds in question are vitexin, glucosyl vitexin, and glucosyl orientin. Epidemiologic studies indicate that endemic goiter in rural areas of Africa and Asia might be related to a diet based on pearl millet as staple food (Boncompagni et al. 2018). In vivo antithyroid activity by purified vitexin could be shown in rats at 80 μM test concentration, 20 μM was not active (Gaitan et al. 1995), supporting this assumption.

In a study of Fantoukh et al. (2019), the influence of a methanolic extract of unfermented rooibos tea and selected chemicals of this plant material including the C-glycosyldihydrochalcones aspalathin and nothofagin as well as the C-glycosylflavones vitexin, isovitexin, isoorientin, and the C-glycosylflavanone eriodictyol-6-C-glucoside on interaction with cytochrome P450 enzymes (CYP), pregnane-X-receptor (PXR) and p-gp were investigated. Whereas the results obtained with the methanolic extract are only of limited relevance for infusions made for food purposes, the activities of pure compounds could give some indications of potential interactions with simultaneously taken pharmaceutical drugs or other food phytochemicals. Most prominent inhibitory effects were found for isovitexin on CYP3A4 (IC_{50} 3.4 μM) and for vitexin on CYP2C9 (IC_{50} 8.0 μM). Aspalathin and nothofagin exhibited only a moderate activation of PXR, associated with an increased mRNA expression of CYP3A4 and CYP1A2.

5.8 Marketed Products

There are no food products on the market specifically due to CGF content. Compared to food products made from plain flour, higher contents of CGF can be found in corresponding food products prepared from whole meal flour (Bucar, unpublished data; Hirawan and Beta 2011). However, these products are generally richer in plant phenolics. Rooibos herbal teas might serve as an example which focuses on a CGF (aspalathin) as active ingredient (Courts and Williamson 2015; Hostetler et al. 2017).

5.9 Patents

One Chinese patent describes the preparation of a C-glycosylflavones extract and a preparation method thereof, among others bamboo leaves are mentioned as source as well as blueberry without defined species (CN 103159750 A 20130619). Several

patents have been filed for rooibos and aspalathin, i.e., an antidiabetic extract from rooibos (US 8877717 B2 20141104), an aspalathin-like dihydrochalcone, extracts from unfermented rooibos and the treatment of the central nervous system (EP 2053050 A1 20090429), an antidiabetic extract of rooibos (WO 2008110551 A1 20080918), related to that a product which contains aspalathin and acts as a pancreatic β cell insulin secretion and tissue glucose promoting agent (JP 2008214274 A 20080918), an anticancer agent containing aspalathin (JP 2007197409 A 20070809), and a rooibos extract with increased aspalathin content (WO 2006081989 A1 20060810). Numerous patents have been filed for puerarin containing plant materials, and this is true also for vitexin and vitexin containing materials. To mention a few, a process to extract passion fruit skin for a phenolic rich extract contain CGF like vitexin and orientin was described (BR 102016030133 A2 20180717), similarly taro bean leaves (CN 107281258 A 20171024) as well as common buckwheat husk (CN 105859701 A 20160817) or peeled mung bean (KR 2009045964 A 20090511) can serve as source for CGF.

5.10 Perspectives

The major class of C-glycosylflavonoids in food plants is represented by flavones, in addition dihydrochalcones and some selected examples from C-glycosylisoflavones can be found. Citrus fruits can be considered as a major source of C-glycosylflavones, whereas relatively low amounts have been found in cereals with exception of millet seeds and carob seed germ flour. A rich source of C-glycosylated dihydrochalcones are tomatoes, as well as rooibos and honeybush herbal teas, and the most common C-glycosylisoflavone puerarin is mainly consumed via kudzu roots.

Due to their higher chemical stability in terms of hydrolysis during cooking and also after ingestion, they can be considered as a specific group within flavonoids. Their metabolic fate is clearly different from O-glycosidic flavonoids with absorption of intact glycosides, followed by phase II metabolization. However, also deglycosylation by gut microbiota and degradation of aglycones to compounds like (hydroxy) phenylpropionic acids have been recognized. The catabolic potential of gut microbiota for C-glycosylflavonoids seems to be still underestimated with insufficient data on microbial community – catabolic activity correlations. It can also be recognized that only limited data on the actual daily intake of C-glycosylflavonoids including information on content in fresh and processed food are available. This is also important for considering the appropriate doses for in vitro and in vivo studies which have shown a wide range of bioactivities of C-glycosylflavonoids.

Abstract

Biflavonoids and oligomeric flavonoids are the representatives of flavonoids from the diet, which can be classified into several subclasses according to the essential chemical structures. Proanthocyanidin and biflavonoid are two types of representative compounds that are widely distributed in various foods. Although the previous studies have verified that the increase of the polymerization degree of these molecules usually lowered the *in vivo* bioavailability, the *in vivo* metabolism of these compounds still remained indeterminate. Some of the most commonly reported *in vitro* activities of biflavonoids and oligomeric flavonoids were summarized subsequently. And the applications of biflavonoids and oligomeric flavonoids in several processed foods were elucidated because the chemical change during the processing of these compounds can affect the taste and color of the foods. Moreover, the effect on the prevention and relief of some chronic diseases, as well as the uncertain side effects and toxicity of the commercial products being popular on the market, were summarized and analyzed. In addition, the effects of biflavonoids and oligomeric flavonoids on public health, the patents that related to the extract and preparation method, and prospectives and recommendations of their applications were proposed.

Diet · Biflavonoids · Oligomeric flavonoids · Proanthocyanidin · Bioavailability · Metabolism · Bioactivities

6.1 Introduction

Biflavonoids and oligomeric flavonoids are kinds of fascinating molecules that are a major class of flavonoids ingested from food. And they are always found in the great consumption of food, such as apple, grape, berry, cereal, beans, etc. Moreover, the eye-catching color and unpredictable astringency of red wine, black tea, and juice are inseparable from these molecules. Most importantly, these compounds have been proved to be beneficial to our health (Bhagwat and Haytowitz 2015; Ou and Gu 2014). These special characteristics of biflavonoids and oligomeric flavonoids inspire us to investigate them and develop new products to benefit human beings.

The concepts of biflavonoid and oligomeric flavonoid are easily confused with that of flavonoid, polyphenol, and tannin, because these compounds are overloppingly defined owing to their similar chemical structures, bioactivities, and distribution in food. In fact, their phytochemicals are essentially different. It is also difficult for nonprofessionals to distinguish the names of the chemicals and

structures of flavonoid monomers, dimers, and polymers. In this chapter, a precise definition of biflavonoid and oligomeric flavonoid was put forward. Correspondingly, these natural compounds were classified according to their chemical structures and distribution in food.

It has been proved that the *in vivo* absorption and metabolism of the dietary phytochemical are closely related to their health promotion effects and possible potential side effects. Therefore, the bioavailability of these molecules after being ingested, the metabolic processes in the human body, and the interaction of these molecules with gut microflora are systematically investigated and summarized. Moreover, some excellent biological activities, such as the antioxidant activity, antiproliferative activity toward cancer cells, anti-inflammatory, antimicrobial activity, and lipase inhibitory activity of biflavonoids and oligomeric flavonoids, are introduced. Several recognized benefits of these compounds are discussed subsequently, including cardiovascular protection, losing weight, and prevention of neurodegenerative diseases.

The chemical changes of these molecules during food processing dramatically affect the color, aroma, and flavor of foods. Thus, biflavonoids and oligomeric flavonoids were also introduced as color, aroma, and/or flavor modifiers in tea, red wine, juice, cocoa, etc. Although the benefit of biflavonoids and oligomeric flavonoids outweighs their risk, the toxicity and side effects of these dietary phytochemicals should be considered. The biosafety of biflavonoids and oligomeric flavonoids in food is the foundation of the marketed products. Moreover, the patents within two decades that related to these compounds, the framework of biflavonoids and oligomeric flavonoids in extraction technology, and the functional application were presented. In the end, the future outlook and development directions of biflavonoids and oligomeric flavonoids in the field of food were respectively described and recommended.

6.2 Bioactive Constituents

Biflavonoids and oligomeric flavonoids in food have gained wide attention of researchers over decades due to their health promotion effects and fascinated flavors. Biflavonoid and oligomeric flavonoid are plant secondary metabolites and they both belong to flavonoid polymer. As a subgroup of the flavonoid family, they also have the C_6—C_3—C_6 basic skeleton in their monomers. Strictly, oligomeric flavonoid contains flavonoid dimer, trimer, and polymer with limited degrees of polymerization. Since the special chemical structure and bioactivity of some flavonoid dimers have been reported, flavonoid dimer is generally called biflavonoid as an individual concept distinguishing from oligomeric flavonoid. Biflavonoid and oligomeric flavonoid are a class of functional components which exist in foods and beverages. These compound can be classified into several major categories base on their chemical structure of their flavonoid monomer, for example, proanthocyanidin, which is formed by the polymerization of flavone-3-ol monomer, and biflavonoid, which are flavone or flavanone dimers (also called biflavone). Moreover, these

molecules can be changed during food processing and storage, and some new biflavonoids and oligomeric flavonoids are also generated (Tanaka et al. 2010).

As mass consumption beverages, tea, red wine, and cocoa are all rich in proanthocyanidin. Apple and its processing products are the most important source of dietary proanthocyanidin. This compound is also abundant in many berries, beans, grain, chickpeas, nuts, and cinnamon, serving as dietary proanthocyanidin (Bhagwat and Haytowitz 2015; Bittner et al. 2013; Hammerstone et al. 2000; Santos-Buelga and Scalbert 2000). Some species of *Garcinia*, a class of fruits cultivated in the tropics, are also favored by consumers because of its abundant biflavonoid. *Ginkgo biloba* is also a very famous edible plant with massive biflavonoids. Moreover, biflavonoids and oligomeric flavonoids have also been found in some functional foods and herbs (Gontijo et al. 2017; Latief et al. 2015; Lu et al. 2004; Nkengfack et al. 2002; Yan et al. 2017).

6.2.1 Proanthocyanidin

Proanthocyanidin is the largest class of flavonoid polymer and found in various foods, representing a major class of flavonoids ingested from the diets (Neilson et al. 2016; Ou and Gu 2014). Chemically, proanthocyanidin is a polymer formed by the condensation of flavan-3-ol. And the basic units usually are catechins and epicatechins. Proanthocyanidins can depolymerize to anthocyanidins under oxidative conditions, and their chemical structures depend upon the polymerization number, linkage ways, and substitution pattern of the basic units. There are three subgroups of proanthocyanidins, i.e., procyanidin, prodelphinidin, and propelargonidin (Fig. 1). Two types of linkage ways are named as type A and type B of the interflavanoid bonds in proanthocyanidin. A-type linkage has a less common feature in proanthocyanidins with C—C and C—O—C interflavanoid bonds, while B-type linkage is most common with the C—C bonds only (Fig. 1). Oligomeric proanthocyanidins strictly refer to dimer and trimer polymerizations of basic units. But there is also a denotation that proanthocyanidin with a degree of polymerization less than 10 is called oligomer. The A-type and B-type linkages simultaneously occurr in one molecular, and the gallic acid ester or glycoside substitute usually appears in the oligomeric structure. Some proanthocyanidins, never contain sugar residues, are called condensed tannins (Bhagwat and Haytowitz 2015; Hümmer and Schreier 2008; Smith 2000).

As one of the most famous class of flavonoid polymers, proanthocyanidins are essential functional components that naturally occurr in polyphenolic compounds, being widely available in fruits, berries, nuts, beans, grains, and bark. Meanwhile, they are determinants of flavor and astringency in teas, wines, and fruit juices. The US Department of Agriculture (USDA) and European Food Information Resource (EuroFIR) periodically report the proanthocyanidin content in some functional foods (www.usda.gov; www.eurofir.org). The main proanthocyanidins in some selected functional foods were listed in Table 1.

A

Subgroup	monomer	Subsitution pattern			
		R_1	R_2	R_3	R_4
Procyanidin	Catechin	OH	H	H	OH
	Epicatechin	OH	H	OH	H
Prodelphinidin	Gallocatechin	OH	OH	H	OH
	Epigallocatechin	OH	OH	OH	H
Propelargonidin	Afzelechin	H	H	H	OH
	Epiafzelchin	H	H	OH	H

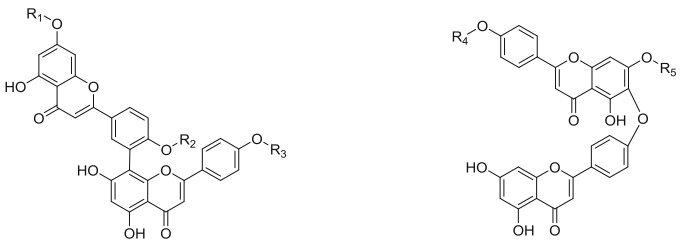
6.2.2 Biflavonoid

Biflavonoid is a class of flavonoid dimer that is differing from proanthocyanidins, which is primarily formed by flavone or flavanone constitutional units. And the units could be interconnected by C—C or C—O—C interflavanoid bonds, involving A-, B-, or C-rings of the monomer. And more than one interflavanoid bond of the monomer is connected with biflavonoids. Normally, the chemical discrimination between flavone, flavanone, and flavonol monomer is necessary. However, the interflavanoid bond of biflavonoid occurs in the C-ring of the monomer and trimers constituted by flavone or flavanone, occasionally leading to a very difficult distinguishment between biflavone and biflavanone. The most common substituents of biflavonoid molecules are glycoside and methoxy (Fig. 2) (Gontijo et al. 2017).

As a functional component, biflavonoid is only found in several common foods, such as *Garcinia*, *G. biloba*, and onion (Gontijo et al. 2017; Ly et al. 2005; Mohamed 2008). *Garcinia* is a genus of flowering plant in the family Clusiaceae native to Asia, America, Australia, tropical and southern Africa, and Polynesia. And there are nearly 400 acknowledged species all over the world. Most of them are recognized and used locally, only a few are well known globally. *G. mangostana* (also called purple mangosteen) and *G. madruno* are the most famous species of *Garcinia*.

Table 1 Procyanidins in some selected functional foods

Names	Chemical structure	Source of foods
Procyanidin A1	Epicatechin-(2β→7,4β→8)-catechin	Areca nut, buckwheat, cranberry, litchi, mulberry, peanut, tea
Procyanidin A2	Epicatechin-(2β→7,4β→8)-epicatechin	Apple, avocado, bilberry, cranberry, cocoa, grape, black soybean, litchi, peanut, red chicory, saskatoon berry, tea
Procyanidin B1	Epicatechin-(4β→8)-catechin	Apple, almond, beans, blueberry, bilberry, cocoa, grape, kiwifruit, olive, pear, pistachio, strawberry, tea
Procyanidin B2	Epicatechin-(4β→8)-epicatechin	Apple, almond, blueberry, bilberry, cocoa, grape, hawthorn berry, kiwifruit, pear
Procyanidin B3	Catechin-(4α→8)-catechin	Almond, beans, bilberry, buckwheat, grape, kiwifruit, peanut, strawberry
Procyanidin B4	Catechin-(4α→8)-epicatechin	Apple, grape
Procyanidin B5	Epicatechin-(4β→6)-epicatechin	Apple, almond, black soybean, buckwheat, cocoa
Procyanidin B6	Catechin-(4α→6)-catechin	Beans, hazelnut, pecan nut, walnut
Procyanidin B7	Catechin-(4α→6)-epicatechin	Almond, beans, grape, peanut
Procyanidin C1	Epicatechin-(4β→8)-epicatechin-(4β→8)-epicatechin	Apple, almond, black soybean, cinnamon, grape, hawthorn berry
Procyanidin C2	Catechin-(4α→8)-catechin-(4α→8)-catechin	Beans, buckwheat, hazelnut, grape, strawberry



Amentoflavone: R1 = H, R2 = H, R3 = H.
Isoginkgetin: R1 = H, R2 = CH_3, R3 = CH_3.

Isocryptomerin: R4 = H, R5 = CH_3.
Cryptomerin A: R4 = CH_3, R5 = H

Fig. 2 Chemical structure of biflavonoids

The white and fragrant botanically endocarps are edible, and the exocarp of purple mangosteen is used as a spice. More than 30 kinds of biflavonoid have been identified from *Garcinia*. Many of the species are locally used as traditional medicine. Some representative biflavonoids were isolated from *Garcinia* plants, such as amentoflavone and GB series. The first biflavonoid, ginkgetin, is isolated from *G.*

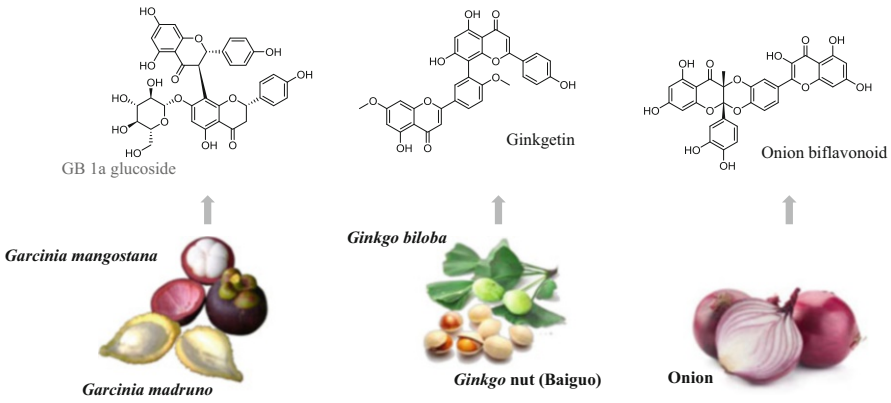


Fig. 3 Representative biflavonoids in *Garcinia*, *Ginkgo biloba*, and onion, respectively

biloba. Being the only living species in the division of Ginkgophyta, the fruit (nut) of *G. biloba* is edible, and the leaves can be processed into medical oral liquids. Many people believed that the proper utilization of *Ginkgo* nut and leaves is good for the health. Moreover, other famous biflavonoids like isoginkgetin and sciadopytisin also can be found in *G. biloba*. As an important flavonoid source of vegetables, onions are cultivated and used all around the world. It has been proved that some biflavonoids can be isolated and identified from outer layers of the onion and some bioactivities of the onion biflavonoids have been also investigated (Fig. 3). In addition to the above three edible plants, biflavonoids have also been found in some other plants with medicinal or health functions, such as *Semecarpus anacardium*, *Sorbus domestica*, *Coreopsis tinctorial*, and so on (Murthy 1986; Termentzi et al. 2009; Yan et al. 2017).

6.2.3 Other Natural Biflavonoid

Other flavonoid monomers, such as chalcone, dihydrochalcone, xanthone, aurone and isoflavone, can also naturally form polymers, especially dimers. But these compounds are very rare in diets. Most of them are found in medicinal plants, and few are identified in some special foods. For instance, humulusol (a kind of chalcone dimer), which was found in *Humulus lupulus*, can be used as an important flavoring agent for beer (Yu et al. 2014). Previous studies have showed that some species of *Garcinia* contain xanthone dimers, but most of them have been found in the bark, and just seven xanthone dimers have been isolated from exocarp of *G. mangostana* (Liu et al. 2016). As for isoflavone dimer, it has been found in *Tadehagi triquetrum* which is a traditional herb that can be cooked with foods (Xiang et al. 2005). Beyond that, there exists a kind of special biflavonoid that two flavonoid monomers co-exist in one molecule without a direct link. For example, the biginkgoside series have been found in *G. biloba* leaves, and their basic chemical structure is that two

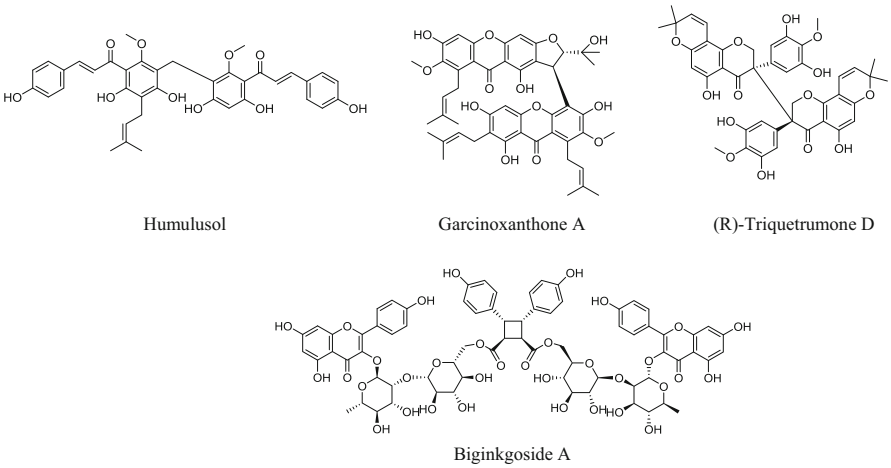

Fig. 4 Representative chalcone dimer, humulusol, xanthone dimer, garcinoxanthone A, isoflavone dimer, (R)-triquetrumone D, as well as a special biflavonoid, biginkgoside A

flavonoid glycoside moieties respectively connect to a cyclobutanedicarboxylic acid fragment (Fig. 4) (Ma et al. 2016).

6.2.4 Biflavonoids and Oligomeric Flavonoids Produced During Food Processing

During food processing and storage, some flavonoids with active chemical properties are often polymerized. Meanwhile, the original flavonoid polymers in food also undergo some reactions to generate new molecules or change the degree of polymerization. The above changes always occur in tea, wine, juice, and cocoa.

Oxidation is the most common reaction involved in the production of new biflavonoids or oligomeric flavonoids. On one hand, the oxidation can build the new interflavanoid at the cost of two flavonoid monomers. On the other hand, it modifies the chemical structure of the monomer molecules. For example, theaflavin and theasinensin are the representative oxidative biflavonoids in tea. They are all generated by the enzymatic oxidation of epigallocatechin (EGC), epicatechin (EC), epigallocatechin gallate (EGCG), and epicatechin gallate (ECG). Dehydrodicatechin is the first reported biflavonoid produced by oxidation in tea, which is generated by catechin dimers and trimers. EGC and its quinone can condense to dehydrotheasinensin or proepitheaflagallin. The same condensation is also occurred in GC. Moreover, the secondary oligomeric flavonoids can also produce more complex flavonoid polymers, such as bistheaflavins, dehydrotheaflavin, and theanaphthoquinone.

There are also other small-molecule compounds that would be part of the flavonoid condensation. Aldehydes are always linked to oligomeric flavonoids

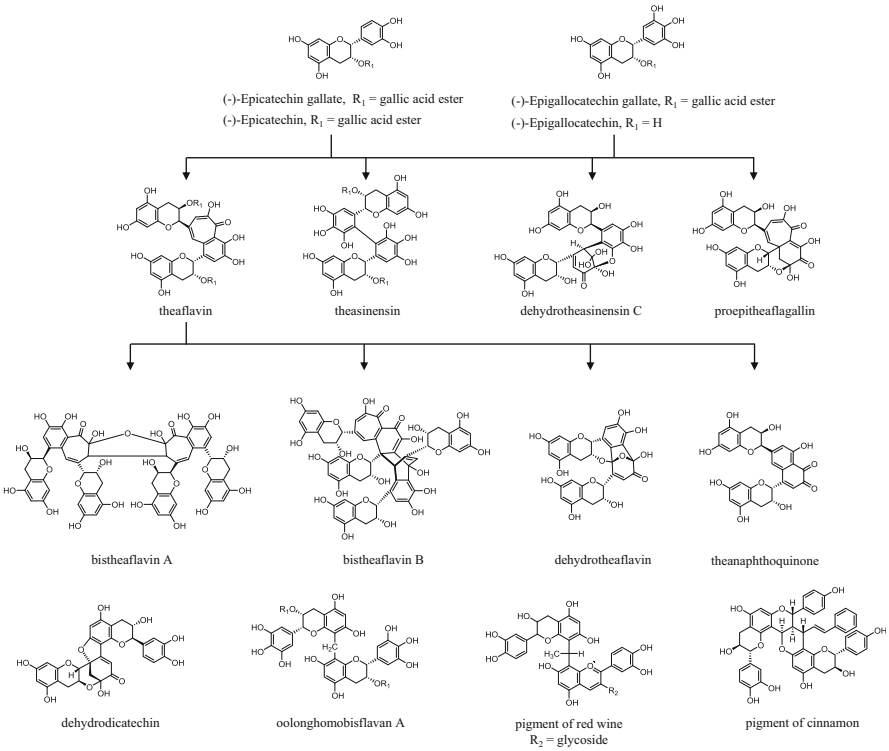

Fig. 5 Representative secondary oligomeric. Theaflavin, theasinensin, dehydrotheasinensin C, and proepitheaflagallin are produced by the oxidative condensation of epicatechin, epicatechin gallate, epigallocatechin, and epigallocatechin. Two bistheaflavins, dehydrotheaflavin and theanaphthoquinone, are produced by the oxidative condensation of theaflavin. Dehydrodicatechin is oxidized from catechin dimers and trimers. Oolonghomobisflavan A and pigment of red wine are two classes of biflavonoids connected by aldehyde. Pigment of cinnamon is procyanidin-cinnamaldehyde conjugate

during the storage of wine and the processing of tea. Oligomeric proanthocyanidin of persimmon fruits can be connected by acetaldehyde and results in insolubly condensed tannins with a high degree of polymerization. The reaction causes the astringency of the persimmon to decrease. Cinnamaldehyde also can be reacted with procyanidin to generate a dimeric product which is a reddish-brown pigment in cinnamon bark. Furthermore, the changes of the polymerization degree of procyanidin always occur in processing of juice (Fig. 5) (Alcalde-Eon et al. 2006; Tanaka et al. 2010).

Biflavonoid and oligomeric flavonoids are a large class of naturally functional components with widely distributed and diverse structures. Predictably, more and more biflavonoid and oligomeric flavonoid molecules will appear on our tables along with the development of food science and natural product chemistry.

6.3 Bioavailability and Metabolism

The metabolism and pharmacokinetics of biflavonoids and oligomeric flavonoids in foods are significantly helpful to understand the effects of these compounds on human. Bioavailability refers to the proportion of biflavonoids and oligomeric flavonoids that can be absorbed by the whole body. The bioavailability and metabolism of flavonoids are affected by many factors, including individual differences (i.e., sex, age, genotype, gut microbiota), as well as growing environment (i.e., region, climate, temperature), processing (i.e., baking, frying), storage and matrix (i.e., water, fiber) of food, etc.

In order to study the bioavailability and metabolism of biflavonoids and oligomeric flavonoids in human bodies, molecular biological and biochemical techniques are always utilized. Recently, metabolomics based on nuclear magnetic resonance (NMR), gas chromatography-mass spectrometry (GC-MS), and liquid chromatography-mass spectrometry (LC-MS) have become an effective tool to analyze flavonoid metabolites, which helps us understand more about the flavonoid metabolism *in vivo* (Yonekura-Sakakibara et al. 2019). To understand the absorption and metabolism of biflavonoids and oligomeric flavonoids in foods, it is necessary to study various metabolites of biflavonoids and oligomeric flavonoids *in vivo* and identify the physiologically active ingredients. Herein, the recent progress of the bioavailability and metabolism of dietary biflavonoids and oligomeric flavonoids was summarized.

6.3.1 Proanthocyanidin

Proanthocyanidin is one of the most abundant biflavonoids and oligomeric flavonoids in fruits and vegetables. The bioavailability of proanthocyanidins is closely related to the degree of polymerization and molecular weight. Generally, the absorption ratios of proanthocyanidins are negatively related to the degree of polymerization and molecular weight (Ou and Gu 2014), and the absorption ratio of monomers may be 100-fold higher than that of dimers (Choy and Waterhouse 2014). Some monomers and dimers can be directly absorbed by the small intestine and found in plasma. Trimer and tetramer of proanthocyanidins are absorbed lower than dimers. If the degree of polymerization is higher than four, the large proanthocyanidins molecule may be unabsorbable due to the gut barrier (Ou and Gu 2014). Also, the absorption sites of proanthocyanidins are varied with the molecule weight and structure (Tao et al. 2019). The monomers are mainly absorbed by the proximal gut, while the oligomers and polymers have to be fermented by the gut microflora, and the fermentation metabolites are absorbed by the gastrointestinal tract (Tao et al. 2019). Moreover, the state of proanthocyanidins may affect the absorption, and only the soluble state of proanthocyanidins can be absorbed by enterocyte surface (Ou and Gu 2014).

Most of the dietary proanthocyanidins are oligomeric and polymeric; therefore the bioavailability of proanthocyanidins is relatively low. GC-MS and high-

performance LC-MS are used to evaluate the levels of proanthocyanidins *in vivo*. Results showed that after drinking red wine for 1.4 h, the level of catechin within the volunteer bodies could reach to 76.7 nmol/L (Bell et al. 2000). After ingesting 387.58 μmol of epicatechin for 48 h, 9.55 μmol of epicatechin appeared in urine (Castello et al. 2018). Without the enzymolysis of deconjugating enzymes, EGCG was absorbed in a ratio of 0.32% in human plasma and 0.012% in fasted rats (Gan et al. 2018; Nakagawa and Miyazawa 1997; Tao et al. 2019). The digestion and absorption of proanthocyanidins *in vivo* can be divided into two parts. The first part happens in an acidic condition of the stomach, and the second part is in gut. Proanthocyanidins first digested in the oral cavity and stomach. α-Amylase and gastric fluid help the depolymerization of proanthocyanidins, and then depolymerized proanthocyanidins reach to the gut. Only a small part of proanthocyanidins can be directly absorbed by the proximal intestine. Besides, glucuronidation of proanthocyanidins happens at small intestine catalyzing by uridine 5′-diphosphate glucuronosyltransferases. Over 90% proanthocyanidins will reach the colon, where these proanthocyanidins will be fermented by gut microflora and metabolized by intestinal enzymes before absorption. More than 30 kinds of metabolites and metabolite derivatives have been identified as the products of the interaction between proanthocyanidins and gut microflora, including phenylvalerolactones and phenolic acids. These small metabolites can be absorbed by the gut (Choy and Waterhouse 2014; Smeriglio et al. 2017; Tao et al. 2019).

After absorption in the gut, proanthocyanidin metabolites will further be transported into the liver for further metabolism. Typically, these metabolic processes include sulfated, glucuronidated, methylated conjugates, etc. Sulfation and methylation are catalyzed by sulfotransferases and catechol-*O*-methyltransferase, respectively. After liver metabolism, these metabolites can be secreted back to gut by bile (Choy and Waterhouse 2014). Moreover, these new metabolites can be found in different organs, blood, and urine (Ou and Gu 2014). Only small amounts of monomer and dimer proanthocyanidins are detected in the blood. Methylated and glucuronidated metabolites seem to be the majority part of proanthocyanidin metabolites in the blood (Smeriglio et al. 2017). Moreover, if the degree of polymerization is less than three, these proanthocyanidins can pass the blood-brain barrier and may affect the nervous system (Tao et al. 2019).

However, the transporters of proanthocyanidins have not been identified in the gut yet. Proanthocyanidins are mainly absorbed by passive diffusion (Ou and Gu 2014). Therefore, although proanthocyanidins are very abundant in food, they are absorbed at a relatively low ratio. It is considered that long-term and low-dose uptake of proanthocyanidins may be beneficial for the gut absorption (Tao et al. 2019).

In addition, the interactions between proanthocyanidins and gut microflora are very important for bioavailability and metabolism of proanthocyanidins. Compared with their parent metabolites, many gut microflora-fermented metabolites exhibited higher activities and healthier benefits. Many studies have proved that proanthocyanidins can change the compositions and metabolic activities of gut microflora (Liu et al. 2017). Cranberry proanthocyanidins are reported to increase the proportion of health-benefit bacteria, *Akkermansia muciniphila*, in gut microflora

(Anhe et al. 2015). Also, other proanthocyanidins from grape seeds are reported to decrease Firmicutes/Bacteroidetes ratio to promote health level (Zhang et al. 2018). Through metabolomics methods, 2-(3,4-dihydroxyphenyl) acetic acid and 5-(3,4-dihydroxyphenyl)-γ-valerolactone are found as the major product metabolites of procyanidin dimers digested by human gut microflora. Other product metabolites, e.g., 1-(3′,4′-dihydroxyphenyl)-3-(2″,4″,6″-trihydroxyphenyl) propan-2-ol, phenylvaleric acids, 3-hydroxyphenylpropionic acid, monohydroxylated phenylvalerolactone, 3-hydroxyphenylacetic acid, and 4-hydroxyphenylacetic acid are also detected (Appeldoorn et al. 2009). Until now, the proanthocyanidin-gut microflora interaction and bioactive composition of proanthocyanidin metabolites still remain largely unknown. And more studies should be conducted to clarify the issues. Figure 6 summarized the proanthocyanidin dimer B1 metabolic pathway by gut microflora. Proanthocyanidins are firstly catabolized to cleave the interflavanoid bond and the C-ring. The A-ring oxidation, dehydroxylation, and β-oxidation are followed, and then proanthocyanidins are finally converted to small metabolites (Tao et al. 2019).

Proanthocyanidins also help to improve the metabolism of human and moderate balancing of hormones (Pascual-Serrano et al. 2017). Since proanthocyanidins have the ability to antioxidant and maintain the redox balance *in vivo*, they can inhibit lipid peroxidation and the activity of lipoxygenases (Smeriglio et al. 2017). In a recent study, rats fed of high-protein diets transport the undigested proteins to the colon and increase the concentrations of branched-chain fatty acids, ammonia, and hydrogen sulfide. While after feeding with proanthocyanidin-rich extract from avocado peel, the concentration of hydrogen sulfide is decreased, and the concentration of indole is increased. Moreover, the polyphenol extract from avocado peel can also counteract high-protein diets with changing gut microflora (Cires et al. 2019). Therefore, food proanthocyanidins also have some beneficial effects on endogenous metabolism, which is closely related to the effects of proanthocyanidins on diabetes, obesity, metabolic disorders, and cancers.

6.3.2 Other Biflavonoids and Oligomeric Flavonoids

Compared to proanthocyanidins, the bioavailability and metabolism of other biflavonoids and oligomeric flavonoids are less studied. It has been reported that the intraperitoneal administration of biflavonoids has better bioavailability than oral administration. The oral bioavailability is considered very low (Kim et al. 2008). Although the bioavailability and metabolism of biflavonoids are still unknown, they may undergo hydrolysis with the products of monomers, being metabolized as the same rules as monomers (Tabares-Guevara et al. 2017). Usually, oligomeric flavonoids can be hydrolyzed to monomers and dimers by gastric acid in the stomach (Kumar and Pandey 2013).

Biflavonoids can antioxidize and modify the metabolism of mice. There are three possible active ingredients of biflavonoids *in vivo*. The first ones are the biflavonoid and conjugated biflavonoids. The second is biflavonoid-derived monoflavonoids at

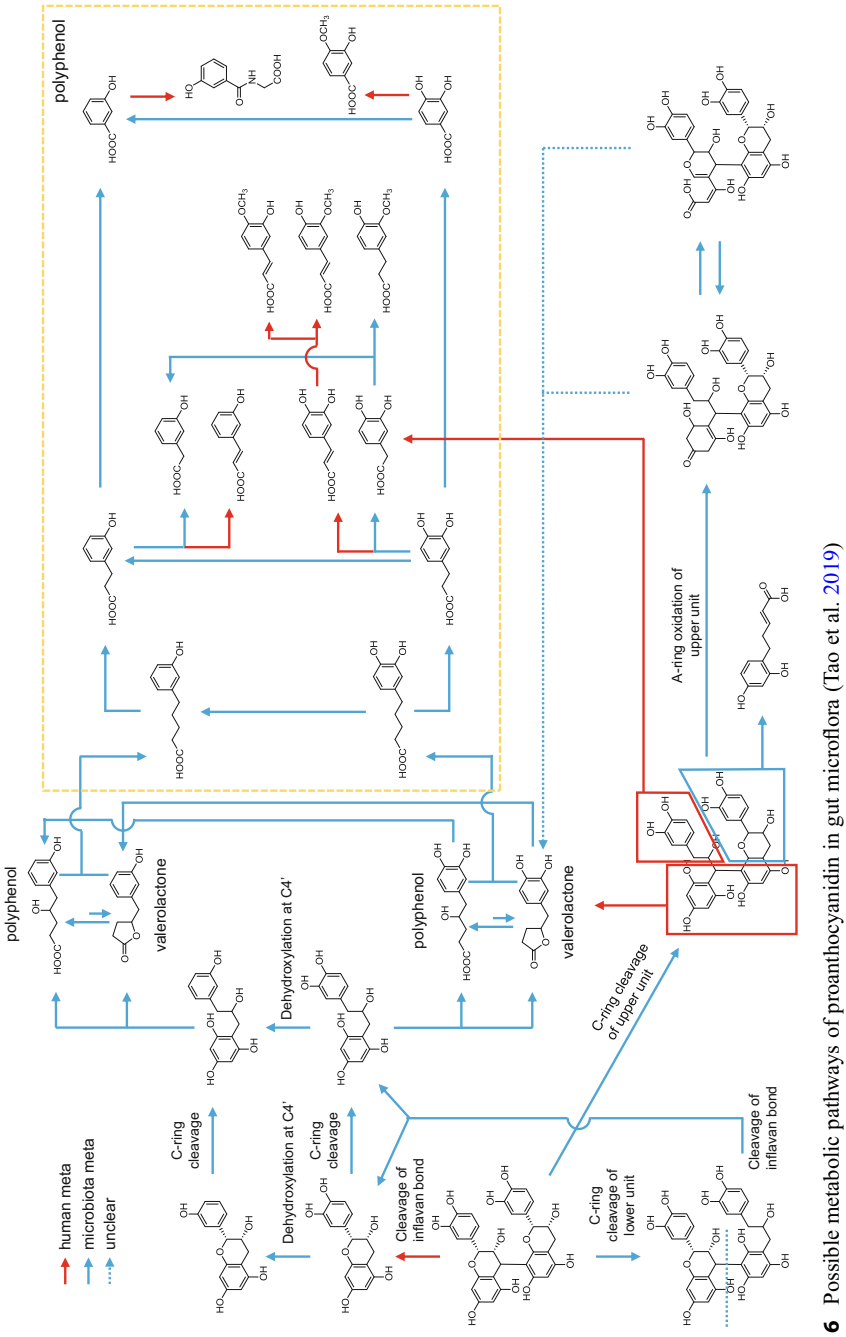

Fig. 6 Possible metabolic pathways of proanthocyanidin in gut microflora (Tao et al. 2019)

the forms of conjugation or unconjugation. The third possibilities are the microbial-derived catabolic products with conjugated and unconjugated forms (Tabares-Guevara et al. 2017).

Recently, chromatography-MS-based analysis techniques have been developed to study the metabolism and pharmacokinetics of biflavonoids and oligomeric flavonoids. Isoginkgetin, a natural biflavonoid proteasome inhibitor, has been successfully detected by LC-MS/MS-based method in rat plasma (Zhao et al. 2019a). LC-MS/MS-based method was also used to detect total oligomeric flavonoid fraction (Kandikattu et al. 2015). Besides, the pharmacokinetic of amentoflavone, a biflavonoid discovered in many plants, has also been investigated. Oral gavage and intravenous and intraperitoneal injection of amentoflavone were used to administrate rats, respectively. Conjugated metabolites of amentoflavone were detected in rat blood circulation system, and the results showed that much lower bioavailability of amentoflavone was found in oral gavage than the intraperitoneal injection (Yu et al. 2017). Chrysocauloflavone I, an uncommon biflavonoid, was performed in a pharmacokinetic experiment, and the results indicated after intravenous injection of chrysocauloflavone I in rats, it could be detected in all tissues, and the half-life of chrysocauloflavone I *in vivo* was about 85 min (Yang et al. 2016). Moreover, the total oligomeric flavonoids in *Cyperus rotundus* were found to restore the activity of glutamine synthetase, with catalyzing glutamate to glutamine (Sunil et al. 2011).

6.4 Bioactivities

Numerous studies have demonstrated that either crude or purified biflavonoids or oligomeric flavonoids, particularly from grape seed, cocoa, and tea, possess various excellent bioactivities, such as the antioxidant, antiproliferative, anti-inflammatory, and antimicrobial activities.

6.4.1 Antioxidant Activity

The antioxidant characteristics of extracts from grape seed, grape pomace, tea, and cocoa have been widely studied, including scavenging of free radicals, inhibition of lipid oxidation, reduction in hydroperoxide formation, and so on (Charradi et al. 2013). Grape seed extracts and cocoa by-products have shown high free radical scavenging activity via their high content of procyanidins (Cos et al. 2004; Lamuela-Raventós et al. 2005). There is a good coincidence between the degree of polymerization and the scavenging activity of procyanidin. Polymerization degree up to trimers will increase the free radical scavenging activity, while further polymerization will decrease this activity.

Procyanidins are often categorized as *in vivo* antioxidants since they have multi-hydroxyl groups in chemical structures, they can be preferentially oxidized. Procyanidins support the direct antioxidant abilities to balance both the steady-state concentration (production and metabolism) of cell oxidants and the occurrence of

oxidant-mediated events. Further, certain procyanidins can generate benefits in some pathological situations associated with high oxidant production, such as hypertension and cardiovascular disease, obesity, diabetes, etc. (Fraga and Oteiza 2011).

Proanthocyanidins extracted from grape seeds can provide more significant protection than vitamins C and E and β-carotene when similar doses are used, with lowering free radicals and free radical-induced lipid peroxidation and DNA damage in liver and brain tissues (Bagchi et al. 1997). *In vitro* studies have demonstrated that proanthocyanidins from grape seeds exhibit potent scavenger capacity for superoxide and hydroxyl radicals and can greatly inhibit the oxidation of low density lipoprotein (LDL) and lipid-containing membranes induced by metal ions or the other radical generators (Mazur et al. 1999). Furthermore, proanthocyanidins significantly improved the total antioxidative capacity of superoxide dismutase (SOD), glutathione (GSH), glutathione peroxidase (GPx) and catalase (CAT) and reduced the malondialdehyde (MDA) levels compared with the oxidative damage mice model group through a meta-analysis (Smeriglio et al. 2017).

Amentoflavone can inhibit the production of superoxide anion and total reactive oxygen species (ROS) in phorbol 12-myristate 13-acetate-stimulated human neutrophils. It can also alleviate the oxidant hemolysis and lipid peroxidation in human erythrocytes induced by 2, 2′-azobis hydrochlorides. In addition, amentoflavone has been observed to suppress the production of nitric oxide (NO), prostaglandin E-2 (PGE-2), and the nuclear translocation of c-Fos, which is related to anti-inflammation (Yu et al. 2017). Another biflavonoid complex from *Garcinia kola*, named kolaviron, has stronger inhibition to H_2O_2 than the standard antioxidants, e.g., butylated hydroxyanisole and β-carotene, has the similar inhibition as α-tocopherol, and significantly scavenges superoxide generated by phenazine methosulfate NADH. Furthermore, kolaviron scavenges hydroxyl radicals via the significant inhibition of the oxidation of deoxyribose. In animal models, kolaviron reduces the background levels of protein oxidation marker in plasma, malondialdehyde in the membrane, and oxidative damage to DNA in the nucleus and mitochondria (Farombi and Owoeye 2011).

6.4.2 Antiproliferative Activity of Cancer Cells

The potential roles of proanthocyanidins and procyanidin in chemoprevention by dietary cranberry, grape seeds, and cocoa are gradually being emerged. As reported, the antiproliferative activity of proanthocyanidin-rich extracts from berries in multicancer cell lines (including oral cancer cell lines, e.g., KB and CAL-27; prostate cancer cell lines, e.g., RWPE-1, RWpe-2, and 22Rv1; lung cancer cells, e.g., HT-29 and A549; melanoma cells, e.g., A375 and Hs294T; colon cancer lines, e.g., HCT-116, and SW-620; breast cancer lines, e.g., MCF-7 and MDA-MB-435) has been elucidated (Neto 2007). Grape seed extracts have also exhibited antitumor properties to human colorectal carcinoma, head and neck squamous cell carcinoma, and prostate cancer cells (Baliga and Katiyar 2006). The treatment of human colonic cancer cells with procyanidin-enriched cocoa powder extracts reduced 70% of

cellular growth. In most studies, tea extracts were often used to treat rats or mice via oral administration (Santos-Buelga and Scalbert 2000).

On the base of studies on the working mechanisms of proanthocyanidins, various targeting molecules being potentially useful for the prevention or treatment of cancers have been identified. For instance, nuclear factor kappa-B (NF-κB) and its target proteins, mitogen-activated protein kinase (MAPK) signaling pathway, the P13K/Akt pathway, mitochondrial pathway, Wnt/β-catenin signaling channel, cell apoptosis, cytokines and matrix metalloproteinases, and cell cycle progression have discovered to involve in the antiproliferative functions of proanthocyanidins.

The anticancer properties of proanthocyanidins have also been illustrated by *in vivo* studies with animal models. Dietary feeding of grape seed proanthocyanidins inhibits UVB-induced photocarcinogenesis in SKH-1 hairless mice in terms of tumor incidence, multiplicity, and growth/size. It has been convinced that the protection from UVB-induced immunosuppression afforded by dietary grape seed proanthocyanidins may be associated with the protection from UVB-induced photocarcinogenesis. The treatment of grape seed proanthocyanidins inhibited tumor growth induced by subcutaneous inoculation of viable 4T1 murine mammary cancer cells in immunocompetent Balb/c mice with the extension of survival period. Dietary supplementation with grape seed proanthocyanidins was found to either inhibit the incidence of dimethylbenzanthracene-induced mammary tumor in Sprague-Dawley (SD) rats or inhibit azoxymethane-induced distal colon-crypt foci rats. Furthermore, adding grape seed proanthocyanidins to the diet of mice can significantly inhibit the growth of melanoma xenografts in nude mice (Nandakumar et al. 2008). Studies have shown that grape seed proanthocyanidins can inhibit the growth of A375 and Hs294T melanoma cells, which is related to the reduction of β-catenin melanoma cells.

Furthermore, several biflavonoids isolated from *Lonicera japonica* showed *in vitro* cytotoxic properties and proliferation inhibition against cell lines of colon, lung, kidney, ovary, and breast cancer (Gontijo et al. 2017). Ginkgetin is cytotoxic to human ovarian adenocarcinoma (OVCAR)-3 cells but enhances the proliferation of normal skin fibroblasts of human beings. Amentoflavone exerted obvious cytotoxic effects on cervical adenocarcinoma (HeLa) cells and MCF-7 cells (Kim et al. 2008). Some studies indicated that amentoflavone could inhibit the expression of fatty acid synthase (FASN) in human breast carcinoma SKBR3 cells containing epidermal growth factor receptor 2 (HER2). This inhibition decreased the translocation of sterol regulatory element-binding protein 1 (SREBP-1) in SKBR3 cells. In another experiment, amentoflavone was observed to increase the cleavage activity of caspase-3, to suppress SKBR3 cell activity, without affecting normal cell growth of FASN-none-expressed NIH-3T3 cells. Amentoflavone also could significantly inhibit solid tumor development that was induced by B16F-10 melanoma in C57BL/6 mice (Yu et al. 2017).

6.4.3 Anti-inflammatory

The biflavonoids, including amentoflavone, bilobetin, and ginkgetin, showed anti-allergic function. The other kinds of biflavonoids of ochnaflavone, ginkgetin, and isoginkgetin are generally reversible inhibitors of lymphocyte proliferation, e.g., T cell and B cell.

Amentoflavone showed potent anti-inflammatory activity *in vitro* and *in vivo*. Amentoflavone inhibited the increase of interleukin-1β (IL-1β), IL-6, tumor necrosis factor-alpha (TNF-α), and PGE 2 induced by phytohaemagglutinin in human peripheral blood mononuclear cells. Amentoflavone was also observed to suppress the production of NO, PEG-2, and the nuclear translocation of c-Fos, a subunit of activator protein (AP)-1. Amentoflavone possessed the anti-inflammatory activity of indomethacin or prednisolone against several animal models of acute inflammation, as well as the potent analgesic activity against acetic acid-induced writhings in mice (Kim et al. 2008).

Ginkgetin has inhibition effect of phospholipase A and it also can suppress pro-inflammatory genes in animal models of skin chronic inflammation. Ginkgetin was confirmed with inhibitory activity against adjuvant-induced arthritis with no severe side effects, such as the reducement of thymus and spleen weights. The *Garcinia* biflavonoids isolated from the leaves of *G. garderiana*, GB1 and GB2, showed *in vivo* anti-inflammatory activity against CGN-induced edema. Besides, amentoflavone, ginkgetin, and sciadopytisin showed anti-inflammatory activity against croton oil-induced ear edema (Gontijo et al. 2017; Loggia et al. 1996).

One anti-inflammatory mechanism of biflavonoids is that these compounds can affect the transcription proinflammatory molecules and biflavonoids were also can suppress the expression of the inducible nitric oxide synthase and COX-2 (Lee et al. 2006). The anti-inflammation activity of proanthocyanidins derived from grape seed was intensively studied. It was found the proanthocyanidins protected endotoxin-stimulated macrophages (RAW 264.7) from the overproduction of inflammatory mediators of NO, the production of PGE-1, and the expression of NO synthase. It was demonstrated that grape seed proanthocyanidin restrained the inflammatory response of activated neutrophil, thus preventing neutrophil adhesion and activation. *In vivo* studies have shown that high-fat diet (HFD) rats supplemented with grape seed procyanidins could attenuate the inflammatory markers in the liver, white adipose tissue, and circulation system, which were associated with the inhibition of the proinflammatory molecules C-reaction protein, IL-6 and TNF-α, and the enhancement of the anti-inflammatory cytokine adiponectin (Nowshehri et al. 2015).

6.4.4 Anti-obesity Activity

After treated with grape seed procyanidin extract, a significant decrease in body weight gain and the weight of white adipose tissue in HFD hamsters occurred. In

mice fed with HFD, supplements consisting of either cocoa flavanol extract or a flavanol fraction enriched with monomeric, oligomeric, or polymeric procyanidins prevented weight gain, increase of fat mass, impairment of glucose tolerance, and insulin resistance. A proanthocyanidin-rich fraction of *Cassia nomame* fruits was effective in preventing and ameliorating obesity.

Proanthocyanidins had inhibitory effects on digestive enzymes, such as lipase, α-amylase, and trypsin. Lipase-inhibiting effects had been shown by five biflavonoids from fruits of *Cassia nomame*. Procyanidin substantially inhibited pancreatic lipase activity and reduced triglyceride absorption. Furthermore, the inhibitory effects increase with the polymerization degree. Proanthocyanidin also showed inhibition effects of amylase and smaller oligosaccharide-digesting enzymes. The inhibition efficacy of proanthocyanidin extracted from some foods was in the order as follows: cranberry > grape > cocoa for α-amylase and grape > cranberry > cocoa for glucoamylase. The larger and the more complex the tannins are, the more effective inhibition of enzymes occurs. Proanthocyanidins isolated from *Manilkara zapota* (chiku) were also shown inhibition reaction of α-amylase and α-glucosidase. These *in vitro* results are supported by oral glucose tolerance tests in animals and by a limited number of human intervention studies. Two proanthocyanidin fractions from seed shell with different degree of polymerization both effectively suppressed the elevation of blood glucose from oral starch. Proanthocyanidins, furthermore, represented the inhibition activity on pancreatic proteases *in vitro* experiments.

Proanthocyanidins inhibit obesity through energy storage regulation including adipose hyperplasia and hypertrophy, glucose metabolism, and lipid metabolism. There were controversial results for the benefit from inhibition of adipogenesis by proanthocyanidins *in vitro* and *in vivo*. Proanthocyanidins have been demonstrated that increase glucose uptake in hepatocytes, adipocytes, and myotubes *in vitro*. Moreover, *in vivo* studies have proved that proanthocyanidins upregulated the expression of glucose transporter proteins-4 (GLUT-4) in adipose tissue and muscle and modulate GLUT-4 translocation to the plasma membrane. Animals' studies have shown a hypolipidemic effect of proanthocyanidins that also improved lipid homeostasis by increasing the reverse transport of cholesterol to the liver and its elimination via bile acids. Chronic treatment with grape seed procyanidin also reduced the hepatic steatosis induced by an HFD (Josepa Salvado et al. 2015).

6.4.5 Antimicrobial Activity

Flavonoids are small molecular secondary metabolites synthesized by plants with various biological activities. Their chemical, physical, and biochemical properties make them capable for the interaction of plants with other organisms like animals, microorganisms and other plants and also for their various reactions to environmental stresses (Mierziak et al. 2014). A biflavonoid class of flavonoids isolated from the plant of *Selaginella tamariscina* has antibacterial effects and combination effects of amentoflavone and conventional antibiotics (Hwang et al. 2013). The extracts from *Guazuma ulmifolia* Lam., mainly proanthocyanidins dimer B, have shown potential

as antimicrobial and antiprotozoal agents against a great number of diseases (Pereira et al. 2019). The antibacterial activity of proanthocyanidins originates from grape seed extracts (GSE) and has been investigated against different species and strains of Campylobacter (Silván et al. 2013). Moreover, a study has evaluated the potential antimicrobial use of GSE to inhibit the growth of *Alicyclobacillus acidoterrestris* cells and spores in apple juice during storage at 37 °C (Molva and Baysal 2015). Some naturally occurring and synthetic biflavonoids also show antibacterial, antifungal, and antiviral activities.

Amentoflavone was found having antifungal activity against several pathogenic fungal strains, including *Candida albicans*, *Saccharomyces cerevisiae*, and *Trichosporon beigelii*. In *Candida albicans*, it could stimulate the intracellular trehalose accumulation and disrupt the dimorphic transition, which meant a stress response to the component (Jung et al. 2006). Further research on its antifungal mechanism of *Candida albicans* suggested that this active phytochemical arrested cell cycles during the S-phase and inhibited cell proliferation and division. The anti-candida activity was proved to be related to apoptotic cell death, which may be associated with the mitochondrial dysfunction. Additionally, hydroxyl radicals induced by amentoflavone may play a significant role in apoptosis (Hwang et al. 2012).

6.5 Benefits

Dietary biflavonoids and oligomeric flavonoids have many health benefits. It is reported that the health benefits of biflavonoids and oligomeric flavonoids include reducing body weight, hypoglycemia, vasodilation, anti-inflammatory, antioxidation, antibacterial, neuroprotection, improving gut microflora, and so on. Because these are prominent benefits of biflavonoids and oligomeric flavonoids, they have been made into functional foods. In this part, we will systematically summarize the benefits of biflavonoids and oligomeric flavonoids in treatments of obesity, diabetes mellitus, neurological diseases, cancer, and cardiovascular disease (CVD).

6.5.1 Obesity and Diabetes Mellitus

Obesity and diabetes mellitus are globally enormous public health problems. In 2017, it was estimated that there were up to 425 million adults with diabetes (IDF Diabetes Atlas), and 650 million obese individuals in the world. Rises in prevalence of obesity coincide with the prevalence of type 2 diabetes mellitus which accounts for 90% of the total number of diabetic patients in almost all developed countries. Both are important causes of death and disability worldwide. People are more inclined to prevent, control, and alleviate these diseases through daily diet than medication (Bhupathiraju and Hu 2016).

Significant evidence suggests that proanthocyanidin-rich diets have the potentiality to protect against obesity and diabetes mellitus. Chronic procyanidin-rich apple

polyphenol administration significantly improved impaired glucose tolerance in high-normal and borderline subjects (Shoji et al. 2017). Improvements in insulin sensitivity and lower fasting blood glucose were observed in randomized controlled clinical trials that evaluated the therapeutic potential of cinnamon in healthy persons and type 2 diabetes patients (Yang and Chan 2017) and improved also significantly in overweight and obese adults consuming high-procyanidin cocoa for 12 weeks (Katz et al. 2011). And many clinical trials support the premise that cocoa can improve glycemic outcomes in healthy and overweight adults (Strat et al. 2016). Daily intake of chokeberry juice with rich procyanidin over a period of 3 months was effective in lowering fasting glucose levels in patients with non-insulin-dependent diabetes in a human intervention study (Kulling and Rawel 2008). Consumption of tea was inversely associated with the incidence of type 2 diabetes in a European population (Yang and Chan 2017). Grape seed extract significantly improved markers of inflammation and glycaemia and an oxidative stress marker obese type 2 diabetic subjects in a double-blinded randomized crossover trial (Kar et al. 2009).

Compared to the numerous clinical reports, the mechanism of these compounds' effect in the human body is not very clear. But there are some proposed mechanisms which were systematically analyzed. Procyanidins could lower hepatic glucose production by activating AMP-activated protein kinase (AMPK) and/or insulin-signaling pathways as well as involved in protecting pancreatic β cells from oxidative stress and promote insulin secretion and β-cell survival (Yang and Chan 2017). Procyanidins are also an inhibitor of the enzymes responsible for starch digestion, including α-amylase and α-glucosidase, which may respond to the suppression of the postprandial blood glucose (Kato 2019). Furthermore, some studies show that procyanidin modulates adipocyte processes such as lipolysis, lipid and glycogen synthesis, glucose uptake, and differentiation (Pinent et al. 2006). Proanthocyanidins have the ability to reduce body weight and fat storage *in vivo*. Firstly, proanthocyanidins can decrease the absorption of glucose and lipids by inhibiting the amylase and intestinal lipase (Blade et al. 2016). Proanthocyanidins can also decrease the absorption of bile acids and cholesterol (Tamura et al. 2013). Decreased absorption and digestion of dietary fat can alleviate hyperlipidemia. Secondly, proanthocyanidins can activate GLP-1/DPP4 (Gonzalez-Abuin et al. 2015) and regulate gastrointestinal tract-brain signals (Josepa Salvado et al. 2015). Thirdly, after absorption, proanthocyanidins will reach the adipose tissues, muscle, and liver, where proanthocyanidins can moderate gene and protein expression of lipid genes. Typically, proanthocyanidins inhibit lipogenesis as well as promote lipolysis, fatty acid oxidation, and mitochondrial biogenesis. It is reported that grape seed procyanidin extracts can reduce isoproterenol-stimulated lipolysis of 3T3-L1 cells (Moreno et al. 2003). Grape seed procyanidin extracts can also inhibit cholesterol esterase (Adisakwattana et al. 2010) and pancreatic α-amylase (Goncalves et al. 2011). Finally, proanthocyanidins can activate AMPK signaling pathway in the adipose tissues, muscle, and liver. Activated AMPK promotes thermogenesis, energy expenditure, and fatty acid oxidation and inhibits lipogenesis. However, some other studies find proanthocyanidins cannot reduce body weight (Casanova et al. 2014). Therefore, the anti-obesity effect of proanthocyanidins may rely on

dosage, administration duration, individual difference, and so on (Blade et al. 2016; Nie and Stürzenbaum 2019).

6.5.2 Neuroprotection

Neurodegenerative diseases which are the disturbance of cerebral redox homeostasis are incurable and debilitating conditions that are characterized by slowly progressive losses of neurons. Two neurodegenerative diseases, Alzheimer's disease (AD) and Parkinson's disease (PD), are the most prevalent. There are 46.8 million AD patients (in 2015) and 6.1 million PD individuals (in 2016) worldwide (Van Bulck et al. 2019). The intake of biflavonoids and oligomeric flavonoids as a class polyphenol which is easily obtained from natural foods was noticed to have a role in relieving and preventing the diseases (Del Rio et al. 2013). Long-term fruit juice with a high concentration of polyphenols consumption can provide protection against Alzheimer's disease (Dai et al. 2006). Procyanidin-rich grape juice consumption significantly enhanced the cognitive function relative to placebo-controlled elderly in a randomized control trial with 12 weeks. Grape juice supplementation with 12 weeks could improve the spatial memory and driving performance of middle-aged working mothers (Zhao et al. 2019b). Consumption cocoa flavanols based on proanthocyanidins have considerable benefits to cognitive function associated with healthy volunteers (Scholey et al. 2010). EGb® as a commercial *G. biloba* extract can significantly improve cognitive performance and social functioning regardless of patients with mild and severe Alzheimer's disease (Le Bars et al. 2002). The speed of response to the spatial working memory and immediate recognition tasks improved after supplementation with Enzogenol® which is a supplement of *Pinus radiata* bark extract (Pipingas et al. 2008). Intake of a commercial supplement Pycnogenol® from French maritime pine could improve spatial working memory of elderly individuals during a 3-month treatment period (Ryan et al. 2008).

Several published works have shown that these compounds can attenuate some pathophysiologic states such as oxidative stress, inflammation, neuron apoptosis, and the aggregation of Aβ peptide and Tau proteins (the pathological hallmarks of AD), but little is known of the molecular mechanism of these biological processes. Existing studies show that cAMP response element binding (CREB) has been identified to be essential in memory formation and consolidation. Silent information regulator 1 (SIRT1) as a potent therapeutic target for the prevention and treatment of AD could potentially modify the initiation and progression of AD by affecting multiple aspects of cortical and hippocampal neuron functions. And SIRT1 may regulate CREB activity via deacetylation in different tissues or organs. Procyanidins and its metabolites *in vivo* might involve in the phosphorylation of CREB against cognitive and memory impairment, then resulting in an upregulated expression of various genes which associate with the learning and memory. Moreover, procyanidin may be able to stimulate SIRT1-mediated signaling pathway to enhance the neural plasticity, improve cognitive function, and attenuate neurotoxicity caused by Aβ and Tau during AD (Zhao et al. 2019b). In addition, the biflavonoids from *G. biloba* can

significantly improve the coordinated motor ability of Parkinson's disease, via significantly inhibiting the expression of tyrosine hydroxylase in the substantia nigra and the activity of superoxide dismutase in the striatum (Kudolo et al. 2005). Although there has no report shows that procyanidins can reverse or cure neurodegenerative diseases, their neuroprotection capabilities could reduce the risk of the diseases and ameliorate relevant clinical symptoms as well as pathological features, consequently preventing and slowing down its progress.

6.5.3 Cancer

The global death toll due to cancers increased by 17.0%, to 8.8 million between 2005 and 2015 (Wang et al. 2016). It is an appealing proposal to increase the intake of polyphenols in the daily diet to prevent and treat cancer as well as relieve symptoms caused by cancer. Proanthocyanidins which are the most abundant classes of dietary polyphenols were reported to prevent cancer (Neilson et al. 2016).

Procyanidin dietary intake has been shown strongly inverse associations with colorectal cancer risk, based on data that examined six main classes of flavonoids and the risk of colorectal cancer from a national perspective case-control study in Scotland (Theodoratou et al. 2007). More than 50% reduction in the surface area of breast induration was recorded in 29.5% patients who were treated with the grape seed proanthocyanidin extract (IH636®) in 12-month double-blind, placebo-controlled, randomized phase II trial (Brooker et al. 2006). Seresis®, an oral supplement combination containing proanthocyanidins, was considered to have pharmacological prevention of skin cancer caused by UV (Greul et al. 2002). Increased tea consumption was associated with decreased numbers of breast cancer biomarkers. Green tea drinking reduces oxidative DNA damage, lipid peroxidation, and free radical generation in smokers and decreases in oxidative stress in nonsmokers. These indicators are beneficial for reducing cancer incidence (Dufresne and Farnworth 2001). Total flavonoids of diet, especially proanthocyanidins, showed suggestive protective associations with high-grade prostate cancer among men who were followed from 2 years after returning the 1999 survey. Of course, the association of higher dietary flavonoid intake with several healthier lifestyle factors cannot be overlooked (Wang et al. 2014). There is weak support for the protective effects of cocoa and chocolate against cancer risk and overall mortality based on limited epidemiologic evidence. But the data lack food frequency questionnaires that assess the intake of cocoa products (Maskarinec 2009).

The anticancer effects of proanthocyanidins own to their ability of antioxidation, anti-inflammatory, and targeting signaling pathway. ROS has been reported in many cancers. It is reported the grape seed proanthocyanidins have higher free radical scavenging capacity than vitamins C and E and can protect DNA from free radical damage (Bagchi et al. 2014). Grape seed proanthocyanidins can clear ROS to decrease the growth of colon cancer (Rauf et al. 2019). NF-κB signaling pathway is related to inflammatory, and activated NF-κB signaling pathway can promote cancer progression. Proanthocyanidins are reported to inhibit NF-κB signaling pathway as well as its targets in skin cancer cells (Meeran and Katiyar 2008).

Besides, cancer stem cells play very important roles in the development of cancers. Oligomeric proanthocyanidins are found to target the cancer stem-like cells of colorectal cancer and downregulate the markers of cancer stem cells. Also, oligomeric proanthocyanidins can inhibit Hippo signaling pathway (Toden et al. 2018). Although the intake of proanthocyanidins does not cure cancer, it is worthwhile to improve the diet without much cost in exchange for small prevention cancer benefits.

6.5.4 Cardiovascular Disease

The leading cause of noncommunicable disease death was CVD. There were 17.9 million died due to CVD in 2015 (Wang et al. 2016). Proanthocyanidins have been used in the treatment of CVD. The anti-CVD effects of proanthocyanidins mainly rely on its ability of antioxidation and anti-inflammatory. Reactive oxygen species (ROS) refer to unstable oxygen-containing chemical species. ROS can result in tissue injury and play a very important role in the development of CVD (Panth et al. 2016). Proanthocyanidins are naturally abundant antioxidant reagents. They can protect the body against oxidative stress. Moreover, the effects of the antioxidation of proanthocyanidins are related to their chain lengths. Long-chain proanthocyanidins have increased antioxidation activity than short-chain proanthocyanidins (Blade et al. 2016). Red wine contains abundant proanthocyanidins. It has been proved that moderate drinking of red wine can decrease the risk of coronary heart disease (Renaud and de Lorgeril 1992). Proanthocyanidins can significantly decrease the ROS such as hydroxyl and superoxide radicals *in vitro*. Blueberry supplementation to high-fat and cholesterol-feeding animals can help lowering blood pressure and relieving endothelial dysfunction (Rodriguez-Mateos et al. 2013). Anti-inflammatory effects of proanthocyanidins also contribute to their effects in treating CVD. Proanthocyanidins can change the expressions of inflammatory factors as well as target both MAPK and NF-κB signaling pathways (Mantena and Katiyar 2006). Arachidonic acid pathway is related to inflammatory reactions. Proanthocyanidins can modulate arachidonic acid pathway-related enzymes (Kruger et al. 2014; Blade et al. 2016).

Other biflavonoids and oligomeric flavonoids also have some effects of treating CVD. Kolaviron is a kind of biflavonoid extract which forms the seeds of *Garcinia kola*. It has cardioprotective effects. Kolaviron can inhibit lipopolysaccharide-induced inflammatory in vascular smooth muscle cells (Oyagbemi et al. 2016). Isoginkgetin and ginkgetin can inhibit NF-κB signaling pathways and have an ability to anti-inflammatory (Zhou et al. 2011).

6.6 Application in Food

Biflavonoids and oligomeric flavonoids are widely distributed in processed foods, such as tea, red wine, apples, and cocoa. These compounds can affect the color, aroma, and flavor of foods, especially contributing to less sweetness, more astringency, and bitterness. And the chemical change of natural biflavonoids and

oligomeric flavonoids during the food processing or storage will significantly affect the quality and nutrition of the foods. Therefore the changes of biflavonoids and oligomeric flavonoids become research focus.

During processing, the content, polymerization degree, and molecular structure of biflavonoid and oligomeric flavonoids are changing, which is a complicated process. Some changes in biflavonoids and oligomeric flavonoids are essential for the formation of products, such as tea producing and fermentation of red wine, while others need to be avoided, such as the aggregation and browning occurred in fruit juice. Nowadays, the food industry is facing challenges of preserving the highest possible quality of natural food products obtained after processing. On the base of well understanding the changes and applications of oligomeric flavonoids, especially proanthocyanidins, in food processing, better and more efficient actions for retaining these nutriment compounds that are sensitive to temperature or pressure can be obtained.

6.6.1 Tea

Fresh tea leaves are rich in flavonoids, especially flavan-3-ol and its dimer and trimer. In order to process them into different products, tea leaves should go through many processing steps including withering, rolling, fermentation, post-fermentation, drying, roasting, etc. Catechins and proanthocyanidins in tea leaves are sensitive to enzymatic and nonenzymatic oxidation. Processing techniques take advantages of changes in these compounds to create the unique flavor and quality of tea.

Tea polyphenols including catechin, epicatechin, epigallocatechin gallate, and epicatechin gallate mainly exist in the chloroplast and vacuole, while the oxidation-polymerase enzyme mainly exists in the cytoplasm. High intensity of mechanical actions leads to the deformation of tea cells and rupture of the outer membrane of chloroplast, causing catechin substrate to contact and react with oxidase. This process facilitates the formation of catechin polymers in tea cells, such as proanthocyanidin dimers and theaflavins (Chen et al. 2020). Subsequently, polyphenol oxidase activity is passivated rapidly by high temperature to prevent the enzymatic oxidation of tea polyphenols in fixation step.

Preparations of black tea and brick tea both require a fermentation process. By fermentation, the enzymatic browning and oxidation of tea polyphenols give the tea a dark red color. In this period, the oxidation of flavan-3-ols by polyphenols oxidase produces series of benzotropolone compounds, including theaflavin and its gallate derivatives as well as theasinensins. Meanwhile, the catechin monomer contents are decreased correspondingly. The oxidation products of catechins play a decisive role in the color, aroma, and quality of black tea. In addition, theaflavins could only be detected when black tea was heated up to 80 °C, resulting from the degradation of thermosensitive intermediates (Tanaka et al. 2010). In oolong tea, the highest content of total proanthocyanidins was in fresh tea buds before processing, and then decreased by about 20% after fermentation and roughly 15% after drying. During semi-fermentation, some catechins may be oxidized and polymerized to form

theaflavins (Dou et al. 2007). Thearubigins is the deep oxidation products of catechin and tea polyphenols, accounting for 20% of the total solid content of black tea. Besides, the degradation products of theaflavins, namely, epitheaflavic acids, play an important role in the formation of thearubigins. Different from thearubigins, theabrownin is a pigment of brick tea formed in the post-fermentation, and the chemical structure is still unclear. The tea processing technologies make full use of the oxidation, browning, and degradation of biflavonoid and oligomeric flavonoids, and the resulting complex products are further contributed to the color, flavor, and quality of the tea.

6.6.2 Red Wine

Proanthocyanidins, as typical bitter substances in red wine, can effectively stabilize anthocyanins, increase the complexity of wine flavor and affect the clarity and stability of the wine. Generally, wines made from matured grapes contain a higher proportion of proanthocyanidins than that made from immatured grapes, as the content and polymerization degree of proanthocyanidins increase with grapes ripening. In addition, proanthocyanidins are found mainly in grape skins, seeds and marginally in grape flesh, whereas the mean degree of polymerization of proanthocyanidins in seeds is lower than that in flesh. To some extent, molecular size of proanthocyanidin and it's monomer composition, have considerable influences on the perception of convergence. Greater degree of polymerization and percentage of galloylation of proanthocyanidins usually cause more astringent of wine (Gil et al. 2012).

Postharvest dehydration has been shown to significantly improve the leaching and release of proanthocyanidins in the subsequent process. Besides, postharvest dehydration reduces the water content and protects the flavonoid ingredients by slowing down the oxidation rate of these compounds (Segade et al. 2016). Through dehydration, the seeds show a significant increase in proanthocyanidin concentration and a decrease in degree polymerization, while the amount and the mean polymerization degree of proanthocyanidins in skins are both decreased (Moreno et al. 2008). During grape maceration, proanthocyanidins are dissolved from grape skins and seeds. The concentration of proanthocyanidins in wine tends to increase with the extension of maceration time, but the degree of polymerization decreases (Busse-Valverde et al. 2012). The proanthocyanidin content of grapes pretreated with cold maceration is significantly increased after pressing, by promoting the release of proanthocyanidin in grape seeds. The use of maceration enzyme can also further increase the proanthocyanidins released from grape skins and seeds (Busse-Valverde et al. 2012).

The levels of flavan-3-ol, catechin, and epicatechin decline in micro-oxidized wines. Radicals and quinones formed during the oxidation process can be polymerized to form larger proanthocyanidins, reacting with anthocyanins to form new pigments or precipitate. Thus, the decreases of flavanols and oligomeric proanthocyanidins are most likely due to the formation of new pigments (Carrascon

et al. 2015). The concentration of SO_2 may affect the method of forming new tannins and polymerized pigment compounds that proanthocyanidins combine with other polyphenols, including anthocyanins. With a low concentration of SO_2 in wine, the monomer anthocyanins and flavan-3-ol are also significantly reduced, while tannins and non-bleached pigments are increased. When treated with high SO_2, these changes in wine are largely suppressed. During aging, proanthocyanidins react with anthocyanins, causing the decrease of free anthocyanins rapidly and increase of polymerized anthocyanins. Therefore, the color of wine gradually changes from the initial purplish red to brick red. Especially during the aging process in oak barrels, the concentration of proanthocyanidins descends, but the degree of polymerization increased, on account of the formation of some polymer precipitation by the combination of high polymer and micro-oxidation. Therefore, with the increase of proanthocyanidins' polymerization degree and precipitation, the convergence of red wine becomes moderate (del Carmen Llaudy et al. 2006).

To ensure the clarity and bright color of wine properties and stability of shelf life, fermented wine will go through the clarification processes. Conventionally, the application of clarifiers, such as egg whites (Martínez-Lapuente et al. 2017) and plant proteins (Granato et al. 2014) as well as some clarification techniques, like filtration and centrifugation, can improve the wine's clarity. Some flavonoids and polysaccharides in wine will be adsorbed by the membrane materials. In addition, removal of grape seeds results in 40% lower of proanthocyanidin level in wine, compared to that made from whole grapes. This demonstrates the nutritional superiority of fermentation by the whole berry. Other techniques, such as maceration enzymes treatment or cold extraction, preferably enhance the color and improve the content of seeds proanthocyanidins in the wine (Bautista-Ortín et al. 2014). During the whole fermentation process, proanthocyanidins also play a strong antioxidant role in effectively avoiding the oxidation of anthocyanins and leading the favorable change of wine color.

6.6.3 Juice

Many fruits (berry, apple, peach, hawthorn, etc.) with abundant proanthocyanidins are always processed into juice products in order to facilitate transportation and consumption. The processing needs to go through blanching, squeezing, enzymatic hydrolysis, extrusion, concentration, clarification, pasteurization, storage, and other series of steps. These steps can affect the content of proanthocyanidin and its polymerization degree.

Blanching is necessary to protect the color of fruits and inactivate the enzyme activities. It also helps to change the permeability of the cell membrane so that the nutrients can be dissolved out more easily. After blanching, proanthocyanidins are stable in chokeberry juice (Wilkes et al. 2013); oligomeric proanthocyanidins of juice increases in cranberries (White et al. 2011).

The most significant loss of proanthocyanidins is caused by squeezing and the removal of skins and seeds. After squeezing, proanthocyanidins are mostly retained

in pomace, and the extraction amount is between 20% and 40%. Release of proanthocyanidins during crushing could be further improved by preheating or enzymatic hydrolysis of mash (Toydemir et al. 2012). Comparing with several squeezing technologies, the content of procyanidin B2 in juice is the lowest by the rack-and-frame press and is the highest by belt press. However, juice processed by belt press has the worst sensory quality, characterized by less sweetness, more acidity, more bitterness, and more astringent (Heinmaa et al. 2017).

Enzymatic hydrolysis could improve the content of proanthocyanidins in juice. Using pectinase to treat chokeberry in 95 °C for 3 min before the mash press, the concentration of proanthocyanidins is raised by 11% (Wilkes et al. 2013). As for apple juice, the proanthocyanidin content is increased by pectinase treatment. Nevertheless, the treatment is adverse for the stability of cloudy juice, reducing the viscosity of the product by the high hydrolysis of pectin (Oszmiański and Wojdyło 2007).

Some heat treatments, like concentration and extrusion, are not conducive to the retention of proanthocyanidins. Extruded grape seeds and pomace contain 120% and 80% of proanthocyanidins respectively than those in materials without extrusion (Khanal et al. 2009). The concentration of proanthocyanidins in blueberry and grape residue can be also significantly reduced by heating. When heating around 60 °C, the concentration of proanthocyanidins decreases. However, heating for 3 days at a low temperature might be harmless, while heating for more than 8 h at a high temperature resulted in a significant loss of proanthocyanidins (Khanal et al. 2009). For example, the monomers, dimers, trimers, tetramers, pentamers, hexamers and heptamers in peaches were reduced by 11%, 9%, 12%, 6%, 5%, 30% and 30% respectively during the heat treatment. After 3 months of aging, monomer, dimer, trimer, and tetramer levels in canned peach dropped by 10%, 16%, 45%, and 80%, respectively (Hong et al. 2004).

Chitosan and gelatine treatments, used in clarification of apple juices, both can cause the decline of proanthocyanidins content and polymerization (Oszmiański and Wojdyło 2007). A similar phenomenon was observed in blueberry juice treated with 10 $g \cdot L^{-1}$ cyclodextrin that can be used as a protective agent for phenolic compounds, especially proanthocyanidins, in fruit juice (Kelanne et al. 2019). In different blueberry products, there were only 19% and 23% proanthocyanidins retained in unclarified and clarified juices and 41% in dense mixtures. Monomer and dimer retained more than the high polymers in all products after processing (Brownmiller et al. 2009). Conlusively, clarification will result in the reduced content of proanthocyanidins and retain more oligomeric proanthocyanidins in fruit juice.

The proportion of the low molecular weight of polymeric pigments in pasteurized juice is higher than that in aged juice, and the trend of high molecular weight is opposite. Proanthocyanidins with anthocyanins would form polymers, usually referred to as polymeric pigments, during the processing. A larger scale of polymerization will also occur during long-term storage, after which the degree of polymerization of proanthocyanidins was finally determined to range from 1 to 8 in chokeberry (Howard et al. 2012). Pasteurization was proved to have no evident

effect on proanthocyanidins in grape juice (Genova et al. 2016) and cranberry juice (White et al. 2011). In peach pieces, proanthocyanidin B1 changed slightly from 14.7 μg·g^{-1} to 15.8 μg/g after pasteurization (Oliveira et al. 2012), in contrast to highbush blueberries juice (Skrede et al. 2000). Considering the possible relationship with pre-cold extraction, the phenolic compounds like proanthocyanidins of fruit juices are not usually changed by the application of pasteurization and even increased. Sometimes the rise of temperature may promote the release of flavonoid compounds. For example, proanthocyanidins in chokeberry juice were increased by 17% after pasteurization (Wilkes et al. 2013).

The concentration and degree of polymerization of proanthocyanidins will change during the storage period. More monomer and flavan-3-ol dimers were observed after 30 °C storage. The possible reason for such changes can be ascribed to the depolymerization of proanthocyanidins and the conversion to basic units (Wojdyło et al. 2014). Meanwhile, the polymeric proanthocyanidins probably combine with some macromolecules such as polysaccharides and proteins in juice and then form precipitation, which leads to a decrease in the determination of the polymeric proanthocyanidin content. The high polymers found in the sedimentation demonstrate that the higher the polymerization degree of proanthocyanidins, the easier the polymerization occurred. Proanthocyanidin compounds of hawthorn fruit and beverage were stable at 4 °C and relatively unstable at 23 °C and 40 °C. Procyanidin B2 was significantly degraded by 50% and 30%, respectively in fruits and beverages after 6 months of storage at 23 °C, and almost completely degraded after 6 months at 40 °C (Chang et al. 2006). Pre-treatment before storage is beneficial for the quality of fruit products during the storage period. For instance, adding L-ascorbic acid had a protective effect on proanthocyanidins because of the competition for the substrate of the polyphenol oxidase (Kolniak-Ostek et al. 2013).

Although high levels of proanthocyanidins may represent more nutritional and functional benefits, they are not conducive to sensory evaluation, which may be not very acceptable to consumers. Some sensory properties (color, bitterness, and astringency) of juice can be controlled by modulating the squeezing conditions. The pressure, speed, and environment of pressing will affect the content of proanthocyanidins. The rising temperature during pressing results in the transition of bitter or astringent proanthocyanidins, and the paste can be oxidized to reduce bitterness and astringency. Meanwhile, filling with inert gas or isolating air during the period will have a protective effect on proanthocyanidins.

6.6.4 Cocoa

Raw cocoa beans contain procyanidin A2 (9–13 mg/kg) and procyanidin B2 (340–650 mg/kg). After fermentation, procyanidin A2 in cocoa beans is partially degraded and epimerized, whereas a second epimer emerges after roasting (De Taeye et al. 2017). The stability of monomer and dimer proanthocyanidins in cocoa beans is dependent on pH value. When pH $>$ 6, epicatechin, catechin, procyanidin B2, and procyanidin B5 become unstable and then degrade almost completely within a few

hours. Whereas at pH 5.0, they are relatively stable. Additionally, ascorbic acid has been found to promote the stability of monomer and dimer of proanthocyanidins in cocoa, which is not dependent on the decrease in pH but as an antioxidant agent (Zhu et al. 2003).

6.6.5 Other Food Productions

Proanthocyanidins are found to exist in cinnamon. When cinnamon is peeled from the branches, the surface of cinnamon wood immediately changes from white to reddish-brown, due to the reaction of proanthocyanidins with aldehydes catalyzed by enzymes (Tanaka et al. 2010). *Coffea arabica* leaves, a substitute for the traditional tea, contain procyanidins B and C as well. Being dried at different temperatures, the content of procyanidin B in these leaves increases with the rising temperature and reaches the highest content at 50 °C (57.79 mg/g). Additionally, young leaves have higher level of proanthocyanidins than older leaves, indicating that the content of proanthocyanidins in leaves is closely related to the maturity of leaves (Ngamsuk et al. 2019). Some biflavonoids abundant in *Semecarpus anacardium*, *G. cambogia*, and *G. gingko* has not been reported relevant changes in the application of food. In a word, the changes of biflavonoid and oligomeric flavonoid, represented by proanthocyanidins, in food processing and application are complex and attractive.

6.7 Safety: Toxicity and Side Effects

There are few studies on the toxicity and side effects linked with proanthocyanidins. The prevalent view is that the procyanidins are beneficial natural plant constituents with low risk of side effects or drug interactions. They have an excellent safety profile, without obvious side effects, toxicity, either drug interactions. Human safety and toxicity studies for proanthocyanidins are limited.

Side effects of proanthocyanidins are rare, but when they do occur, they are limited to occasional allergic reactions and mild digestive distress (Schulz et al. 2001). One study unexpectedly found that a combination of proanthocyanidins and vitamin C might slightly increase blood pressure in people with high blood pressure. Neither treatment alone had this effect (Ward et al. 2005). These results may become a statistical fluke, but nonetheless people with hypertension should be careful when they simultaneously consume vitamin C and proanthocyanidins. One study, though, has found that Pycnogenol (pine bark extract) may help improve kidney function in people with metabolic syndrome who take high blood pressure medicine (Stuard et al. 2010). The maximum safe dosages for young children, pregnant or nursing women, or those with severe liver or kidney diseases have not been established. Additionally, proanthocyanidins may have some anticoagulant properties when taken in high doses and therefore should be used only under medical supervision by individuals on blood-thinner drugs, such as warfarin

(Coumadin), heparin, clopidogrel (Plavix), ticlopidine (Ticlid), pentoxifylline (Trental), or aspirin. Meanwhile, some interactions we should know include high doses of proanthocyanidins that might cause a risk of excessive bleeding, if you are taking warfarin (Coumadin), heparin, clopidogrel (Plavix), ticlopidine (Ticlid), pentoxifylline (Trental), or aspirin.

The supplement with compounds like pine bark extract that contains proanthocyanidins is believed to be safe in almost all cases. However, there are few groups who should not supplement with procyanidins. They include gestating or nursing women, people with bleeding disorders, anyone scheduled for surgery in the near future, individuals with systemic diseases like lupus and multiple sclerosis, and others according to their doctors' recommendations. Thus, in order to be sure that you are not at risk for any possible side effects of procyanidin supplementation, it is best to talk about it first with the personal doctor.

6.8 Marketed Products

The pursuit of health and long life is the eternal wish of the people, which brings a huge consumption of natural products with health-promoting effects. Based on the profits from the researches and propagation of firms, many biflavonoid and oligomeric flavonoid products are widely accepted by consumers. However, due to the high production costs, pure biflavonoids and oligomeric flavonoids are rarely used in commercial products, whereas the products with guaranteed healthy functions and content of bioactive components are mostly popular in the market.

Many extracts with biflavonoids and oligomeric flavonoids from various plants are marketed openly, and oral products are the most familiar form. For instance, apple, berry, grape seed, tea, and cinnamon are used to make the proanthocyanidin-rich health products. It makes consumer intake the functional molecules without special eating of these foods. Furthermore, a kind of pine barks extracts with a commercial name of Pycnogenol, which is not from foods but can also be used as an oral supplement. Meanwhile, the products are carefully designed for different target people, such as children, elderly people, and middle-aged persons who are classified and sold separately. There are also some proanthocyanidin extracts, especially from apple, used as cosmetics and conditioners.

In addition to the proanthocyanidins, products which contain biflavonoids are also a class of health supplements with wide acceptance. The extracts from *G. Cambogia* and *G. kola* can be easily purchased on the market as a kind of product for losing weight. For example, a beverage made from the leaves of *G. biloba* has been used as traditional Chinese medicine. *G. biloba* nuts (also called Baiguo), also a kind of vegetable in food, are used as a popular snack in China and Japan. In addition to direct consumption, the powder and extract of the leaves and the extracts of the fruits are also a health supplement on the market.

Essentially, the good-selling products with biflavonoids and oligomeric flavonoids, due to the health promotion of these molecules, can partly meet the health

demand of contemporary people. It can be expected that there may be more new biflavonoid and oligomeric flavonoid products on the market in the near future.

6.9 Patents

In recent years, many patents on proanthocyanidin and biflavonoids have been published, ranging from the preparation, purification, and modification methods and the identification of biological functions to their applications in food, medicine, cosmetics, and other industries. Some patents have described the extraction of proanthocyanidin and biflavonoids from flavonoid-rich plants, such as *Garcinia*, palm infructescence, black wattle bark, *Selaginella tamariscina*, *Daphniphyllum oldhami*, *Stellera chamaejasme* vegetal, Chinese arborvitae twig and leaf, ginkgo leaves, and so on. Some patents have proved many biological functions of proanthocyanidin and biflavonoids, e.g., scavenging free radicals, improving sleep, antivirus, antitumor, anticancer, antiallergic, and anti-inflammatory activities. Proanthocyanidin and biflavonoids are widely used in the pharmaceutical industry, and some compositions have been proved helpful to many disease and disorders, including gastric ulcer, a mineralocorticoid receptor-related disease, inflammation, diarrhea, oropharyngeal bacterial colonization, glucose and lipid metabolism disorder, atherosclerosis, asthma, gout, renal lithiasis, acne, frostbite, obesity, hypercholesterolemia, and so on. Several patent applications have proposed some novel methods for the preparation of proanthocyanidin and biflavonoids with known biological activities. Proanthocyanidin and biflavonoids are also used in the food industry, such as drinks, teas, wines, yoghourt, functional foods, healthcare foods, and food supplement.

Table 2 has listed the relevant international patents published by various countries over last decades about proanthocyanidin and biflavonoids, and these patents are classified by the contents (preparation, purification, modification, or application of active compositions).

6.10 Perspectives and Recommendations

The concern and enthusiasm for biflavonoids and oligomeric flavonoids from food have never decreased in the past decades, either in research areas or public health. However, proanthocyanidins are the most focused one, and other compounds were overlooked. In fact, there are many ancient traditional foods and new healthy food with unexplored biflavonoids and oligomeric flavonoids into the modern human life step by step. The bioactivity, function, benefits, and potential health risk of these molecules are all required to be carefully investigated. Some products that contain flavonoid polymers with uncertain activity and toxicity have already been promoted to the market. The public health benefits and unknown risks of these foods or supplements all need continued attention. Apart from the benefits of biflavonoids and oligomeric flavonoids, the bitterness, astringency, and intestinal stimulation

Table 2 International patents published in the last 20 years about proanthocyanidin and biflavonoids, based on preparation, purification, modification, and application of active compositions. Source: https://worldwide.espacenet.com. Last accessed: Nov 29, 2019

Oligomeric flavonoids		Patent name	Application number
Proanthocyanidin	Preparation, purification, and modification	Preparation method and applications of palm infructescence proanthocyanidins	CN201910132127A20190222
		Method for producing low polymerization degree proanthocyanidin and proanthocyanidin having low polymerization degree produced by said method	JP2012076002W 20121005

toward people ranging from all ages should be considered. The taste preference of people varies with ages, which may affect the total intake amount of these compounds from diets.

Although there are considerable studies on the *in vivo* metabolism and bioavailability of biflavonoids and oligomeric flavonoids, with hypothesizing that these compounds are frequent intake from daily diets, it is believed that the research should be further expanded, especially in terms of the relationship between metabolic processes and health promotion. In addition, the low bioavailability of these phytochemicals does not mean low biological activity *in vivo*. Interaction between flavonoid polymers and gut microbiota is one possible way to achieve active functions *in vivo*. Thus, the effect of these molecules, especially oligomeric flavonoids, on the gut microbiota needs to be clarified. Besides, the investigation on hypoglycemic, hypolipidemic, anti-inflammatory activity should also be continued, especially *in vivo* researches.

Abstract

Soy and its bioactive compounds, isoflavones, have become a hot issue in the last 20 years. Increased breeding of the plant has created a strong market in many countries. Nevertheless, the cross-consumption of foreign products is not safe for certain ethnic groups and requires risk assessment evaluation because of ethnic differences among populations that induce, for certain compounds, different end points in humans. For example, in Asians and white people, the intake of these compounds can have different bioactive effects. Chemically, isoflavones are isoflavonoids, a subgroup of polyphenolic compounds that have affinity for estrogen receptors and can act as endocrine disruptors in white people. Isoflavones from soy can also be found as constituents of astragalus roots, adzuki beans, chaste, green peas, chickpeas, lupins, kudzu, and red clover, among other plants. An extract named okara also contains isoflavones in variable concentrations and is a by-product of the production of soy preparations, such as tofu and soybean beverages. The main isoflavones isolated from soy are the malonyl glycosides of genistein, daidzein, and glycitein; these aglycones appear only in very low levels. All of these compounds undergo enterohepatic metabolism and are detoxicated by cytochrome P450 (CYP) 1A2 and 3A4, which imply an important potential to induce drug–herb interactions with concomitant intake. Recent research on bioactivity/toxicity of isoflavones has provided a perspective for potential health improvement, but sometimes these results are hard to compare in different ethnic groups. Correct evaluation of each extract in animal and clinical trials is the key to understanding the end points in order to assess safety. This chapter discusses, in detail, the future challenges for isoflavone-derived products, especially in the Western market.

Keywords

7.1 Introduction (Sources and History)

Historically, the soybean (*Glycine max* (L.) Merr.) originally came from China as a basic food ingredient in traditional Asian cuisine, which has been used for thousands of years. The data show that probably the soybean started to be used around 5000 BC (Lee et al. 2011), but the history of the soybean has been informed mainly by historical documents indicating that the soybean was domesticated in East Asia in association with the Zhou dynasty (approximately 2500 years ago) in China. Since 2003, archeological research has brought to light more broad information suggesting that North China was, indeed, the region where the soybean was domesticated. Soybeans have been found at many archeological sites in China, Korea, and Japan. However, the details are still poorly understood. At the beginning of the Mumun period (around 3500 years ago), intensive agriculture was established –

including adzuki beans, soybeans, rice, wheat (*Triticum* cf. *aestivum*), and barley (*Hordeum vulgare*) (Zhao 2010) – and this has continued until the present era. Evidence of the cultivation of crops such as foxtail millet, broomcorn millet, canola (rapeseed (*Brassica rapa*)), and possibly hemp (*Cannabis sativa*) has also been found in the Middle Neolithic Dawenkou culture, which existed in Shandong province in around 4300–2600 BC (Lee et al. 2007). The cultivation of most of these crops appears to have been maintained over the centuries until now.

Soybeans have continued to be consumed over the centuries, but from the outset the populations of these regions learned how to prepare soybean products to avoid the toxicity of isoflavones. The processing of soybeans includes various steps that help to clean the crude material from them. Traditional foodstuffs were traditionally prepared after prolonged simmering, several rinses, and cooking steps in water. These procedures remove isoflavones from the soybean foodstuff. This indicates that the historical exposure to isoflavones was probably low in Asia (Barnes 2010). However, some amounts of these compounds remain in the product – for example, in protein extracts, where there is still a small amount of isoflavones (Fernandez-Lopez et al. 2016). A database of isoflavone content in unprocessed and processed soy products is available from the US Department of Agriculture (USDA) (Bhagwat and Haytowitz 2015).

Soybeans did not reach the Americas and Europe until the eighteenth century; the earliest records of their presence there date back to 1765 in Savannah (Georgia, USA), 1739 in Paris, and 1790 in London (at Kew Gardens). It is only in the last century that the human intake of soy and soy-derived products has increased in these Western countries, with industrialized processing that started in the 1940s (Barnes 2010, with references; Fernandez-Lopez et al. 2016). Nowadays, these products are mainly used for surrogate food production as a protein source solution for vegetarians because of their high protein content and usefulness in the production of different products such as meat analogues. Despite that, doubts remain regarding the effects of these foods in ethnic groups other than Asians and "the potential effects on health, such as the effectiveness on cardiovascular risk reduction or, conversely, on the possible disruption of thyroid function and sexual hormones" (Rizzo and Baroni 2018). This is mainly because isoflavones have a molecular structure that mimics endogenous estrogens, raising doubts about the safety of their use because they can act as estrogen disruptors. The difficulty in the evaluation of their bioactivity is also due to the fact that they are selective estrogen receptor (ER) modulators (Messina 2014). Nowadays, there is more and more information indicating that they are the most prevalent and potent xenoestrogens present in human food (Omoruyi et al. 2013).

This chapter describes a critical multidisciplinary review conducted mostly on the last 10 years of publications, including identification of key literature in this field. Between 2009 and 2013, the author of this chapter contributed, as an expert, to a European Food Safety Authority (EFSA) Scientific Cooperation (ESCO) report titled *Hazard Identification of the Use of Dietary Isoflavones and Isolated Isoflavones from Soy or Red Clover in Food and Food Supplements*, a short public

version of which was made available in 2012. This item was analyzed as a gray literature search, but the confidentiality of the data was maintained. This chapter discusses the knowledge and research developed in this scientific area, including findings from recent reviews in the field, and provides a critical evaluation of the state of the art.

A nonsystematic literature search of Medline and Embase (http://www.ncbi.nlm.nih.gov/pubmed; http://www.embase.com) was performed using the following subject headings/keywords or Medical Subject Heading (MeSH) terms where available. The search was systematized through the following three sets. The first set (a) included soy and soy products; the second set (b) focused mainly on constituents of soy from the phytochemical point of view and nutritional issues; and the third set (c) retrieved information about bioactivity and health purposes in animals and humans:

(a) "Soy" and "soy foods," "soybeans" or "soy beans" or "*Glycine max*" or "soy products"
(b) "Soy protein" or "soy milk" or "traditional soy foods"; "vegetarian" and "soy"; "protein quality" and "isoflavones"; "soy" and "phytochemicals" and "nutrients" or "bioactive compounds"
(c) "Soy" and "isoflavones" and "animal"; "soy" and "cancer" or "soy" and "thyroid" or "soy" and "sex hormones" or "health benefits" or "chronic diseases"

The search was extended to the references within.

The data were summarized, and animal and human information is given here to facilitate critical assessment of the published literature. Part of the hazard identification focuses on the market for isoflavone-rich products, including soy infant formulas, and the data collected should be analyzed in the light of ethnic differences. In this review, we discuss worldwide consumption of soy isoflavones in terms of nutrient composition and bioactive compounds in soy and soy foods. Furthermore, we discuss current evidence of their possible effects on human health and safety. These arguments are relevant to Western countries with growing soy consumption, especially by vegetarians.

7.2 Bioactive Constituents

Isoflavones are polyphenolic compounds from a subfamily named flavonoids. In the majority of flavonoids, the chemical structure includes a phenyl group on the benzopyran ring in position 2, but in the isoflavonoids, this group is in C3 relative to the oxygen in the ring (see Fig. 1). These compounds are also included in the category of phytoestrogens because they mimic the estrogen molecule and have affinity for estrogen receptors (Bennetau-Pelissero 2013), as is explained later in this chapter.

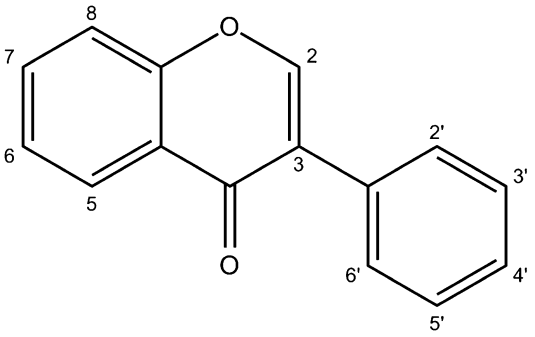

Fig. 1 Basic isoflavone structure. PubChem compound ID (CID): 72304 (3-phenyl-4H-chromen-4-one) (from https://pubchem.ncbi.nlm.nih.gov/compound/Isoflavone)

Chemically, the isoflavone nucleus is a 3-phenylchromen-4-one according to the International Union of Pure and Applied Chemistry (IUPAC) nomenclature; in other systems of nomenclature it is known as 3-phenyl-4H-chromen-4-one, 3-phenyl-4H-1-benzopyran-4-one, or 4H-1-benzopyran-4-one, 3-phenyl-, among other names. The molecular formula (MF) is $C_{15}H_{10}O_2$ and the molecular weight (MW) is 222.243 g/mol.

Seeds from the Leguminosae (Fabaceae) species *Glycine max* (L.) Merr., with the common name of "soybeans," are included in a list of species of possible concern because of their content of compounds such as agglutinin (an *N*-acetylgalactosamine-specific lectin), a proteinase inhibitor, and other toxic proteins (BFR 2007; Patisaul 2017).

A similar concern pertains to isoflavones, of which soybeans have an average content of 1–2 mg/g (Campos et al. 2006; http://www.drugbank.ca/drugs/DB12007).

The structures found are mostly malonyl-glycosylated derivatives of genistein (IUPAC name: 5,7-dihydroxy-3-(4-hydroxyphenyl)chromen-4-one; MF: $C_{15}H_{10}O_5$; MW: 270.24 g/mol), daidzein (IUPAC name: 7-hydroxy-3-(4-hydroxyphenyl) chromen-4-one; MF: $C_{15}H_{10}O_4$; MW: 254.241 g/mol), and glycitein (IUPAC name: 7-hydroxy-3-(4-hydroxyphenyl)-6-methoxychromen-4-one; MF: $C_{16}H_{12}O_5$; MW: 284.267 g/mol), which account for an average of 70–50%, 40–20%, and less than 10% of the isoflavones, respectively (Campos et al. 2006). The total isoflavones in soy can also be expressed as glycosides and malonyl glycosides of the main aglycones – for instance, 67–516 μg/g daidzin, 91–1079 μg/g genistin, 12–177 μg/g glycitin, 217–768 μg/g malonyldaidzin, 43–158 μg/g malonylglycitin, 64–2446 malonylgenistin, and 4.3–265 μg/g genistein (http://www.drugbank.ca/drugs/DB12007).

The isoflavone genistein is one of the most active and studied isoflavones and was originally isolated by Perkin and Newbury in 1899 from dyer's broom (*Genista tinctoria*) (Perkin and Newbury 1899). It is the isoflavone most widely represented among many cultivars of *Glycine max*, as discussed previously, and recent studies on it have been mainly related to soy intake.

The extracts found in dietary supplements and in many subproducts in food or supplements have the main isoflavones, conjugated to sugars, cited above; they exist

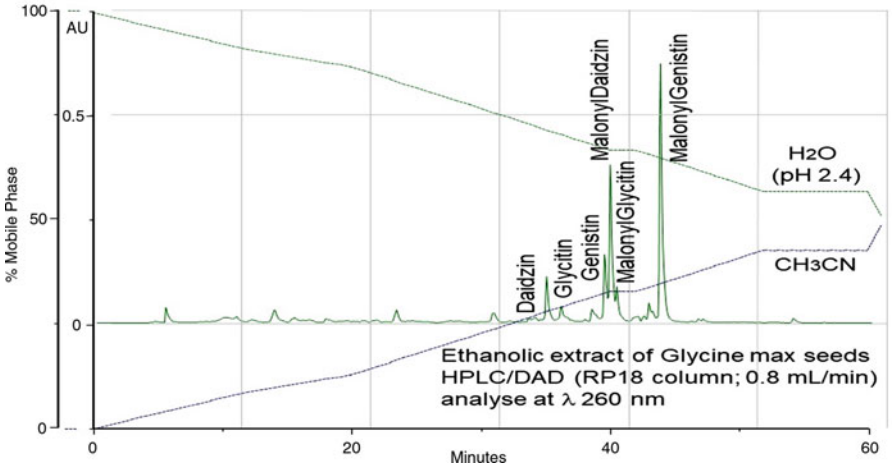

Fig. 2 Relative concentrations of the main isoflavones in an extract of *Glycine max* seeds analyzed by high-performance liquid chromatography with diode array detection (HPLC/DAD) using an RP18 column at 25 °C; the eluent mixture was water (acidified to pH 2.4 ± 0.1 with *o*-phosphoric acid)–acetonitrile gradient with a flow rate of 0.8 ml/min (full information is available in Campos et al. 2007). The chromatogram was acquired at λ 260 nm. Daidzin retention time (RT) 34.8 min, glycitin RT 36 min, genistin RT 39.3 min, malonyldaidzin RT 39.7 min, malonylglycitin RT 40.2 min, and malonylgenistin RT 43.6 min. The sample seeds were graciously provided by the seed bank at the Botanical Garden, University of Coimbra, Portugal

as both simple and complex β-D-glycosides, and in different proportions, which result in a diversity of potential estrogenic effects (Moreno-Franco et al. 2011; Campos and Costa 2012). These are discussed below.

Using high-performance liquid chromatography with diode array detection (HPLC/DAD), analysis of hydroalcoholic extracts is possible to see the main isoflavones in different seed cultivars – for instance, the chromatograms shown in Fig. 2. The most concentrated isoflavones found are the malonyl forms of daidzein, glycitein, and genistein. The last one is the major compound in the extract as malonyl glucoside genistein. Glycosidic forms are also present, as shown in Fig. 2, and are the first shown on the left side of the chromatogram because they have more polar structures.

As shown in Fig. 3, it is possible to analyze the variation in the concentrations of the main isoflavones in extracts of seeds from cultivars of *Glycine max* with similar profiles, using HPLC/DAD with an RP18 column at 25 °C. These samples were prepared with the same relationship between the weight of the sample and the solvent. The HPLC/DAD profiles of these compounds are very similar; however, the concentration of isoflavones is different, with the cultivar Kuro Maru Daizu representing a more concentrated example. More data can be consulted in Campos et al. (2007).

The respective ultraviolet spectra of the various isoflavones from soy, identified in the chromatograms, are shown in Fig. 4.

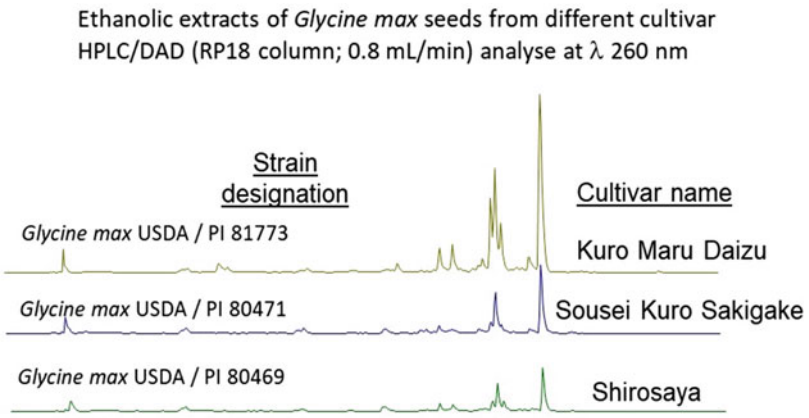

Fig. 3 Relative concentrations of the main isoflavones in extracts of seeds from some cultivars of *Glycine max* with the same profile, analyzed by high-performance liquid chromatography with diode array detection (HPLC/DAD) using an RP18 column at 25 °C. The samples were prepared with the same relationship between the weights of the sample and the solvent. The samples were generously provided by the Germplasm Bank at the US Department of Agriculture (USDA) (freely distributed by the US National Plant Germplasm System (NPGS) for educational, agricultural research, or breeding purposes). None of the seeds used in this study had any form of intellectual property rights protection (data published for the first time). Full information on the samples is provided in Table 2 of Campos et al. (2007)

7.3 Bioavailability and Metabolism (Bioactivity, Nutritional Values, and Functional Aspects)

Following the ingestion of soy foods/beverages/extracts rich in isoflavones, these compounds undergo enterohepatic metabolism. First, they are absorbed in the intestine and further metabolized mainly as glucuronide forms in the liver, then they enter the blood transport system, mainly linked to glycoproteins. Briefly, following ingestion, isoflavone glycosides or their respective aglycones undergo conjugation and give rise to the corresponding metabolites in the plasma once the glycosidic moiety has been hydrolyzed (Setchell et al. 2009; Chandrasekharan and Aglin 2013). The main metabolites are 7-*O*- and 4′-*O*-glucuronides, with small quantities of sulfate esters. A longer transit time for consumed isoflavones glycosides in the large intestine may increase bacterial metabolism of them, which can be crucial, for instance, for the production of certain metabolites such as equol (Zubik and Meydani 2003; EFSA 2012; Liu et al. 2016).

The importance of the microflora in the metabolism of isoflavones was first observed in the 1980s, when studies on germ-free animals showed that formation of equol was dependent on the gut microflora and that antibiotic administration obliterated the conversion into equol (Setchell and Cole 2006; Zhou et al. 2008).

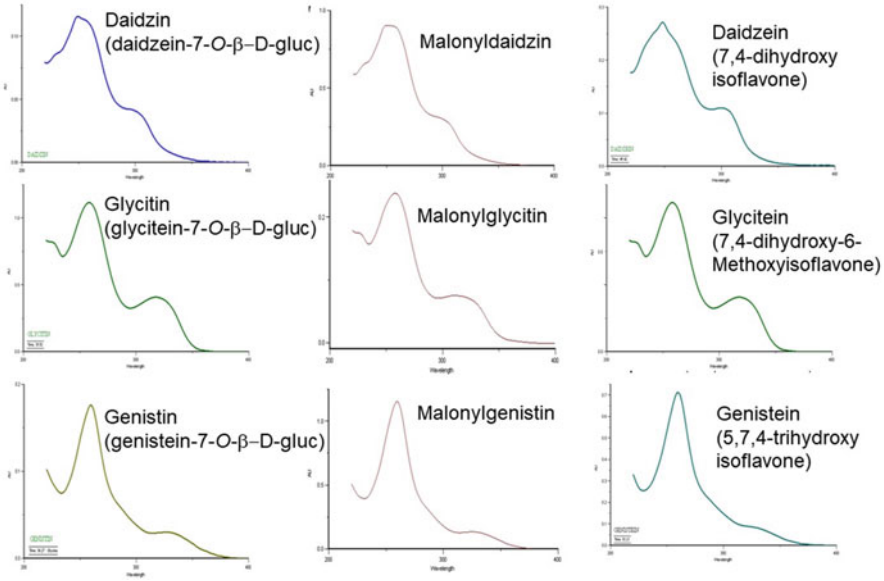

Fig. 4 Soy isoflavones (glycosides, malonyl glycosides, and their respective aglycones). The spectral data were collected between 220 and 400 nm (the spectral zone of the phenolic acids and flavonoids in this study). Daidzin λ_{max} 248.7, 259 (sh), 302 (sh) nm; glycitin λ_{max} 258.7, 320 (sh) nm; genistin λ_{max} 259.7, 328.4 (sh) nm; malonyldaidzin λ_{max} 249–258, 302 (sh) nm; malonylglycitin λ_{max} 258.3, 313.8 (sh) nm; and malonylgenistin λ_{max} 259.4, 330 (sh) nm. λ_{max} maximum wavelength, *sh* shoulder

S-(−)equol (7-hydroxy-3(4′-hydroxyphenyl)chroman) is a metabolite of the soy isoflavone daidzein (the aglycone of the glycoside daizin), which has higher bioavailability and greater affinity for estrogen receptor-β than daidzein itself. Not all of the population is able to produce *S*-(−)equol, and the ability is linked to certain gut microbes (Virk-Baker et al. 2014). Some authors have described an association between a lower risk of breast pathology and *S*-(−)equol production in Asian women, but data on Western people are still scarce.

Other minor metabolites resulting from the oxidative phase I of daidzein and genistein are mainly 6-hydroxy-, 8-hydroxy-, and 3′-hydroxy-daidzein, as well as 6-hydroxy- and 3′-hydroxy-genistein (EFSA 2015). Chandrasekharan and Aglin (2013) did a review that can be consulted for more detail of the metabolization of isoflavones.

Briefly, the metabolization of isoflavones is enterohepatic, and detoxication is achieved mainly via cytochrome P450 (CYP) 1A2, although there is also passage via CYP2E1, 3A4, and 2C8 but to a lesser extent. The metabolization of estrogen follows a similar pathway. Genistein act as an inhibitor of the isoenzymes CYP1A2, 2C9, and 3A4. When genistein intake occurs concomitantly with intake of drugs that need these isoenzymes, potential drug interactions can occur, changing the therapeutic outcomes. However, if they will be consumed concurrently with

prodrugs that need these isoenzymes for biotransformation to their active forms, this process will not occur; therefore, the desired therapeutic effect will not occur or could be decreased. Therapy with anastrozole or tamoxifen for breast cancer can be affected by concomitant intake of these isoflavones.

These molecules, especially genistein, can have an affinity for β- and α-estrogen receptors (ERβ and ERα) of around 43% and 1%, respectively, giving a theoretical efficacy relative to estradiol (TERE) close to half of the activity of estrogen itself (Campos and Matos 2010). In white people this can induce an important increase in estrogenic activity (Ko 2014).

Another important matter is the relationship between the dose and the effect, which can be paradoxical. With regard to low doses, some authors have referred to results that showed induction of cancer cell proliferation in comparison with medium doses, which could present the potential to induce the negative feedback of estrogen production with aromatase inhibition. Doubts about safe use, especially at high doses, are also a big concern in Western countries (Ko 2014), and good assessments of potential toxicity are needed.

It is important to keep in mind that the food matrix and dose affect the absorption and metabolism of isoflavones in general and could change the end points of evaluations. In humans, the glucuronidated forms of isoflavones are detected in plasma and urine, achieve maximal plasma concentrations within 4–8 h, and are then eliminated from the body through the bile and kidneys, with a mean terminal elimination half-life of approximately 6–8 h (Chandrasekharan and Aglin 2013).

To ensure the reproducibility of clinical trials, the major important factors should be evaluated beforehand. First of all, the chemical composition of the extract is crucial, which means that all of the compounds need to be identified and quantified (Campos and Costa 2012). Host characteristics such as the metabolizer phenotype – which could be also linked to ethnicity, age, and the genotype – are also very important (Chandrasekharan and Aglin 2013).

Relevant data are now starting to become available to the scientific community and show these major differences and approaches that should be considered, but for the population in general, this information is not widespread.

Regarding all of these questions, deep reflection on the subject is needed. Nowadays, it is recognized that soybeans are an important source of protein used worldwide for various purposes including raising cattle and the majority of the animals needed for human consumption, such as chickens and pigs (Graham and Vance 2003), fish in aquaculture (Król et al. 2016; Casu et al. 2017), and even shrimps (Conklin 2003). Nonetheless, soy isoflavones that remain in the protein fraction are devoid of a nutritional characteristic *tout court*. Despite all of the research carried out aimed at establishing the nutritional value of isoflavones, they cannot be considered to have that function. They are not structural constituents like proteins, functional like lipids, or energetic like carbohydrates. As micronutrients, these structures are not fundamental for metabolic functions as vitamins or minerals. Even the antioxidant function attributed to them has not been shown to have a clear function in humans. As nutrients, at least for white people, their impact is ultimately negligible.

Despite all of the controversy referred to above, their ability to bind to estrogen receptors and mimic estrogen has been studied with the aim of replacing hormone

therapy, especially in postmenopausal women. As has been further described, in some circumstances they could be of benefit but also could result in risk, depending on the health status of the person and even depending on their ethnicity (Campos and Costa 2012). Postmenopausal women are an easy target in the marketing of these products, and great caution is needed to avoid side effects and chronic toxicity.

Therefore, consideration should be given to their consumption, especially because so far, no benefit of isoflavones has been proved in white women despite all the research already carried out. According to the EFSA's 2012 report, the EFSA Panel on Dietetic Products, Nutrition and Allergies concluded (in page 6) "*that the evidence provided was insufficient to establish a cause and effect relationship between soy isoflavones and maintenance of bone mineral density and reduction of vasomotor symptoms associated with menopaus*e." The US National Center for Complementary and Integrative Health (NCCIH; formerly known as the US National Center for Complementary and Alternative Medicine (NCCAM)) has also referenced this situation, saying "Current evidence indicates that it's safe for women who have had breast cancer or who are at risk for breast cancer to eat soy foods. However, it's uncertain whether soy isoflavone supplements are safe for these women" (NCCIH 2020).

Chen et al. (2019) did a review where they concluded that "In order to minimize study heterogeneity in future research, we urge standardization of the many variables involved in isoflavone trials, … Isoflavone aglycone content should be consistent across trials for better communication, prediction of therapeutic activity, and ensure reproducibility. In addition, outcome measures and study duration should be standardized, along with the metabolic profiles of participants." The same was claimed by Campos and Matos in 2010, when they purpose the determination of the Theoretical Efficacy Related to Estradiol (TERE) to assess previous data that predict the bioactivity of isoflavones through this model as a way to obtain a reproducible clinic trials.

Much research has been carried out in the last 30 years to gather enough data to appropriately assess the potential of soy isoflavones in cholesterol reduction, prevention of atherosclerosis and cardiovascular disease (CVD), chemotherapy, anti-inflammatory applications, and antioxidant activity, for instance. The interpretation of the data regarding the health potential of soy isoflavones must be done with great care. Even more important are the clinical trials (discussed later in the text) investigating isoflavones as potential treatments for atrophy and postmenopausal symptoms that are ongoing; these will either validate the previous findings or not, in order to allow safe use of these compounds.

7.4 Bioactivities (Animal Experiments/Animal Aspects)

Our literature search on animal experiments was mainly approached using the keywords "soy" and "isoflavones" and "animal." In the last 10 years, 225 papers were indexed in PubMed and 163 in the Web of Science, but only 81 and 73 of these, respectively, offered free full-text access. Of those, the sort order was changed to

"best match" and the first three papers were two from 2017 and one from 2013, which we describe below in more detail. All of the others are summarized in the text.

In the Web of Science, the main areas of publication were Nutrition Dietetics (117), Food Science Technology (55), Oncology (45), Biochemistry Molecular Biology (38), and Toxicology (30). The documents had a prevalence of articles (296) and reviews (83). The years of major publications in the field were 2007–2011.

Before discussing and presenting the animal experiments, it is important to undertake careful consideration of some of the experiments described below. For instance, we must not lose sight of the fact that isoflavones as plant ingredients can be considered antinutritional factors (ANFs).

Independent of the potential benefits, the assessment of the risk should bear in mind the following conclusions from Król et al. (2016): "Our results indicate that gut transcriptomic profiling provides a useful tool for testing the applicability of alternative protein sources for aquaculture feeds and designing diets with reduced impact of ANFs on fish health. Ultimately, understanding diet–gut interactions and intestinal homeostasis in farmed fish is important to maximize performance and to ensure that aquaculture continues to be a sustainable source of food for a growing world population." This issue was discussed with regard to fish, but it can also be studied in other animals, and similar data should be provided. The same question involves animals that we eat, but laboratory ones are used in experiments carried out with the intention of understanding the impact of these bioactive compounds. Laboratory animals are frequently fed with products containing soy protein and isoflavones. This is very important because these compounds have effects on the metabolism of these animals and may bias the interpretation of the results.

Below are summaries of animal experiments involving soy isoflavones and hormone-dependent tumors (HDTs). However, metabolism differs between humans and animals; therefore, the outcomes of animal studies may not be applicable to humans.

Kijkuokool et al. (2006) designed a study to determine the effects of genistein on *N*-nitroso-*N*-methylurea-induced tumorigenesis in adult female Sprague Dawley rats that were 30 days of age, with a bodyweight of 120–140 g. They verified median latency periods (to tumor growth) of 59.5 and 51 days for the vehicle and genistein, respectively. Genistein dosing was associated with increases in the cross-sectional tumor area, tumor multiplicity, metastases, and malignancy; serum 17β-estradiol levels were significantly higher in genistein-treated animals than in vehicle-tread controls during the first 2 months of treatment (the time when most of the rats developed tumors). The authors concluded that "supplementation of genistein at a dosage comparable to the isoflavone consumption in humans did not affect the reproductive system but resulted in enhancement of NMU [*N*-nitroso-*N*-methylurea]-induced tumorigenesis in adult female rats. Thus, the supplementation of soy isoflavone in premenopausal women may potentially potentiate the risk of breast cancer."

Breast and prostate cancers are prevalent HDT under close screening and study in WHO. All data that can be evaluated for prevention or for assistance with treatment

is important, but the extrapolation from animal data is not so accurate. For this reason, the major discussion in this chapter focuses on human trials.

With the increase in life expectancy, relief of peri- and postmenopausal symptoms in women is also a hot issue.

From the data analyzed, we emphasize the evaluation of two soy intervention trials by Maskarinec et al. (2017), who found little evidence of a difference in the response to soy foods between Asian women and non-Asian women.

In a study carried out in Mexico, Rodríguez-Landa et al. (2017) hypothesized that it might be possible to use the estrogenic activity of genistein to ameliorate anxiety in women undergoing surgical menopause, and so they investigated anxiolytic-like effects. The comparison was done with identical doses of genistein and 17β-estradiol (0.045, 0.09, and 0.18 mg/kg/7 days) in a surgical menopause model in rats, which did the elevated plus maze and locomotor activity tests 12 weeks after ovariectomy. The animals were adult female Wistar rats, weighing 200–250 g. The results were dose dependent. To support the extrapolation of the results to humans, the authors claimed that "these effects appear to be related to the activation of estrogen receptor-β (ERβ). Genistein has a structural conformation that is similar to 17β-estradiol, which allows it to be recognized by ERβ" (Rodrígues-Landa et al. 2017). Genistein does have affinity for ERβ (around 43.9% relative to estrogen itself) but also can be bound to ERα (around 0.86%) (Fokialakis et al. 2004). The input of these two links will contribute to the result when a correlation is done with estradiol that is able to bind 100% to both receptors (Campos and Matos 2010). The results indicate that genistein produces anxiolytic-like effects in ovariectomized rats, which highlights its potential therapeutic application.

However, in our point of view, this is not the only reason, as genistein has a configuration similar to a flavone type that is able to be a γ-aminobutyric acid (GABA)-A ($GABA_A$) ligand with antidepressant-like activity in the central nervous system. The same activity is also attributed to other flavonoids (Coleta et al. 2008) that are able to bind as benzodiazepine-like molecules to $GABA_A$ benzodiazepine receptors.

The data that are cited below are not directly related to animal experiments that could be the basis for human trials; the more relevant information is for humans that consume animals feed with diets including isoflavones, as is discussed at the end of this section.

To evaluate the effect of dietary genistein on the molecular mechanism of fatty liver syndrome (FLS), Lv et al. (2018) fed a high-energy, low-choline diet to hens, to establish an FLS model, in China. This pathology in hens is characterized by a large amount of fat deposited in the hepatocytes, resulting in a fatty liver, liver hemorrhage, and obesity. It can significantly decrease egg production and induce sudden death, resulting in major economic losses for the poultry industry.

The interest in the study cited above is the correlation of the results between the low and high doses of genistein utilized by the authors. In the experiment, hens treated for 64 days with 40 mg of genistein per kilogram had significantly increased transcriptional levels of gonadotropin-releasing hormone (GnRH) in the hypothalamus, while the same hormone was downregulated in hens fed 400 mg of genistein

per kilogram. These effects on GnRH explain the difference in the reproductive performance of laying hens with FLS and the negative effects of high-dose genistein, which could also be due to inhibition of tyrosine protein kinases and related effects. The authors noted that other studies on rodents also indicated that the effects of the genistein dose on production performance varied with sex, age, and endogenous hormone levels. They also showed that a low dose of genistein improved serum levels of estrogen, while a high dose had no significant effect. These data are important for animal studies in general.

Similar data have been reported by other authors. The optimum dietary dosage range for soy protein that contains isoflavones still needs to be clarified because many brands of laboratory animal feed contain this compounds, as was mentioned earlier.

According to the WHO Global Health Observatory (GHO), "ischemic heart disease, stroke, chronic obstructive lung disease and lower respiratory infections have remained the top killers during the past decade. Chronic diseases cause increasing numbers of deaths worldwide. Diabetes caused 1.6 million (2.8%) deaths in 2015, up from 1.0 million (1.8%) deaths in 2000. Deaths due to dementias more than doubled between 2000 and 2015, making it the 7th leading cause of global deaths in 2015. Injuries continue to kill 5 million people each year. Road traffic injuries claimed about 3700 lives each day in 2015, about three-quarters of whom were men and boys."

As noted above, dementia is an increasing menace to health in the twenty-first century, probably with more patients in high-income countries, and much research is being carried in this field. Flavonoids, including genistein, are even being screened as a possible treatment for Huntington's disease (Pierzynowska et al. 2018). Although dementia is a complicated disease with no cure, hypotheses regarding use of these substances to alleviate some of the symptoms are promising. Therefore, the results presented in this report merely provide a basis for the use of genistein in further studies.

7.5 Benefits (Function in Humans/Human Studies)

Since Axelson et al. (1982) first published the finding of equol in human urine, various publications regarding isoflavones, from different sources, including the same team (Setchell et al. 1984; Setchell and Cassidy 1999), have speculated about the importance of phytoestrogens in hormone-dependent diseases. Notwithstanding this and all of the recent findings about the therapeutic potential of isoflavones, when work on phytoestrogens first started to be published and equol was found in the urine of sheep in Australia, this was associated with infertility of the sheep (Bennetts et al. 1946). In fact, soybeans have become one of the more widely consumed foods that contain isoflavones, although these compounds are in fact widespread in nature in many other plants, as was noted earlier. Other sources of soy dietary isoflavones include soy-rich foods such as tofu, miso, and soy milk, as well as soy-based ingredients – for instance, soy protein concentrate and isolate, soy

flour, and a range of isoflavone-rich supplements. Within Europe, dietary intakes of isoflavones has generally been very low (<5 mg per day), but between 2002 and 2012 an increase in that intake has been verified, together with its impact of estrogen-like activity in some genetic groups, such as white people. This could be dangerous, given the potential of estrogenic-like activity and hypothyroidism (Campos and Costa 2012). The same situation should probably be evaluated in other ethnic groups such as African Americans because in the USA the intake of soy and soy-derived products is too high and the relevant data are too scarce.

Setchell and Cassidy (1999) and Setchell et al. (2002) described dietary isoflavones as having relevance to human health because of their biological effects; however, at that time, ethnic differences or the possibility of inducing side effects or even chronic toxicity were not evaluated.

From data collected in a Japanese population, it has been possible to draw interesting conclusions intrinsic to this target population (Ueshima 2007). The fact that this population consumes soy and has little propensity for HDTs may have a direct relation, given the low plasma concentration of the hormones involved. These results have become known as the "Japanese paradox" and have induced people around the world to consume soy and soy derivatives rich in isoflavones such as genistein, daidzein, and glycitein, and their respective glycosidic forms (genistin, daidzin, and glycitin) (Nakamura and Ueshima 2014). A large number of studies have attempted to demonstrate that soy consumption decreases the risk of developing several chronic diseases (in particular, CVD, cancer, and osteoporosis) and relieves climacteric symptoms, but the estrogen impact is not well understood yet, and a huge difficulty remains when data are compared, given the often controversial end points of the studies. In Campos and Matos (2010) and in Campos and Costa (2012), a theoretical calculation was suggested for application to the different isoflavones under study in a way to achieve accuracy of the results.

Up until now, however, the majority of the benefits have not been proved safe. The difficulty is to get a good correlation comparing the ethnicities under study and quantification of the various isoflavones in the products that are involved; all of this can give different outputs for benefits and risks (Campos and Matos 2010).

From the data collected and analyzed in this review, we summarize below the main topics that are discussed: CVD, HDTs, breast and prostate cancer, peri- and postmenopause, thyroid outcomes, and recent studies proposing isoflavones in Huntington's disease and sleep disturbance.

It is evident that the end points have been mostly the same throughout the chronology, and evaluation of secondary or side effects has been scarce. Five publications evaluated breast outcomes (breast density, epithelial proliferation, and mammographic abnormalities), ten publications evaluated uterine outcomes (endometrial thickness), and four publications evaluated thyroid outcomes (circulating thyroid hormones). Only one study reported adverse events. Statistical differences between isoflavone and placebo groups in the outcomes mentioned below were not reported.

Recently, Namasi et al. (2018) did a systematic review of cohort studies on the association between consumption of soy products and mortality from all causes,

CVD, and cancer. This aimed to clarify the association of soy intake with total and cause-specific mortality. Briefly, from the data that were analyzed, the authors verified no significant association between a high intake of soy products and all-cause, CVD, and cancer mortality. However, what was highlighted was the need for further studies to clarify the association between soy product intake and the risk of mortality. Summarized information and conclusions are given in the following sections.

7.5.1 Cardiovascular Disease

Cardiovascular diseases are defined by the WHO as "disorders of the heart and blood vessels and include coronary heart disease, cerebrovascular disease, rheumatic heart disease and other conditions." Every year, 17.9 million people die from CVD, accounting for 31% of global deaths.

The Global Burden of Diseases, Injuries, and Risk Factors updated snapshot of the state of CVD over the last 25 years reaffirms that it continues to be a significant public health concern worldwide despite impressive advances in the technical capacity for preventing and treating CVD. The main risk factors (hypertension, dyslipidemia, and diabetes) have become a collective concern for higher- and middle-income countries (Basu et al. 2019).

Data from the WHO point to 1.1 billion adults having raised blood pressure, which is detrimental to good heart health, despite the availability of drugs that can be used to control this disorder.

Isoflavones, like most flavonoids, are capable of inducing vasodilation and lowering blood pressure via this pathway.

Taku et al. (2010) published data from a systematic review and meta-analysis of randomized placebo-controlled trials (14 trials totaling 789 participants), where they presented the effects of soy isoflavone extracts on blood pressure in adult humans. The mean daily ingestion of soy isoflavones (as aglycone equivalents) was 25–375 mg for 2–24 weeks. The most significant result showed a decrease in systolic blood pressure (SBP) by 1.92 mmHg (95% confidence interval −3.45 to −0.39, $P = 0.01$) in comparison with the placebo (heterogeneity $P = 0.39$, fixed-effects model), but no dose–response relationship was observed. These data were collected from adults with normal blood pressure and prehypertension. This suggests a greater effect in studies lasting longer than 3 months, in Western populations, at lower doses, and in studies with a lower risk of bias. The authors also verified from the data collected that soy isoflavones did not affect diastolic blood pressure (DBP).

Jackson et al. (2011) also showed that isoflavones can contribute to hypertension control by inducing vasodilation. They can improve brachial artery flow because of the interaction with the estrogen-response element of genes related to endothelial nitric oxide synthase, increasing endogenous nitric oxide production and thus inducing vasodilatation.

Carmignani et al. (2014) aimed to verify the effect of a soy dietary supplement and a low dose of hormone therapy on the main cardiovascular health biomarkers in

a 16-week, double-blind, randomized, placebo-controlled trial. (The trial was registered at the Brazilian Clinical Trials Registry (Registro Brasileiro de Ensaios Clínicos), study number RBR-76mm75.) The study included 60 participants recruited from two menopause outpatient clinics at the Women's Integrated Health Care Center at the University of Campinas (UNICAMP) in Campinas (São Paulo) and at the Leonor Mendes de Barros Maternity Hospital in São Paulo (Carmignani et al. 2014). The main goal was to assess the effect of soy dietary isoflavone supplementation on clinical biomarkers of cardiovascular health and serum changes in the lipid profile and fasting glucose levels. The isoflavone intervention consisted of 20 g per portion of a food powder containing 12 g of soy protein and 45 mg of total isoflavones (26.5 mg aglycones), to be mixed with 200 mL of any beverage. The soy intervention contained approximately 8 mg of total daidzein, 15 mg of total genistein, and 3.5 mg of total glycitein.

If the theoretical efficacy (TE) and the TERE were calculated as proposed by Campos and Matos (2010), in accordance with the formula cited above (for the three isoflavones daidzein, genistein, and glycitein), as is exemplified in Table 1, the understanding of the outcomes for the results obtained by Carmignani et al. (2014) would be more clear. As is shown in Table 1, the estrogen-like impact of mixing these isoflavones has a TERE of 1/15, corresponding to 14.85% of estradiol activity, which is very low. Probably, this is under the therapeutic value needed to achieve a good outcome. The values used for estrogen affinity among the estrogen receptors in this calculation came from Fokialakis et al. (2004). If the researchers had had this information before the clinical trial, the prevision for the outcomes (estrogen affinity for both receptors) would have been more effective.

In fact, from data collected in the clinical trial, the authors concluded that "the use of dietary soy supplement did not show any significant favorable effect on cardiovascular health biomarkers compared with hormone therapy." The study was performed in Brazil with no ethnic information given, but, in general, its results are in line with the low 1/15 activity if the TERE is calculated as above.

Table 1 Theoretical calculation of the efficacy of the two mixes of isoflavones described in the essay cited by Carmihnani et al (2014), using the estrogen receptor (ER) affinity–binding values for compounds including daidzein and genistein

		Receptor type	
	Intake (mg/day)	ERα	ERβ
Daidzein	8	0.00248	0.0016
Genistein	15	0.129	6.585
Glycitein*	3.5	Very low/irrelevant	
Total	26.5	0.13148	6.5866
TE	6.71808	(= 0.13148 + 6.5866)	
TERE	1/15 of the theoretical activity of estradiol (14.85% of estradiol activity)		

TE theoretical efficacy, *TERE* theoretical efficacy relative to estradiol
*very now bioactivity which is irrelevant for the total.

In Japan, Nakamura and Ueshima (2014) evaluated the Japanese paradox in correlation with cholesterol levels and coronary stroke. One of the studies they analyzed was performed by Shimazu et al. (2007), who prospectively assessed the association between dietary patterns and CVD mortality in 40,547 Japanese men and women aged 40–79 years without a history of diabetes, stroke, acute myocardial infarction, or cancer at the baseline in 1994. After adjustment for potential confounders, the Japanese dietary pattern score was associated with a lower risk of CVD mortality despite the fact that the Japanese dietary pattern appeared to be related to higher sodium intake and a high prevalence of potential hypertension. Soybeans were one of the relevant foods, among others, and no correlation was established between these parameters.

Ramdath et al. (2017), from Canada, reviewed evidence on the cardiovascular benefits of nonprotein soy components in relation to known CVD risk factors such as hypertension, hyperglycemia, inflammation, and obesity beyond cholesterol lowering. Although the evidence suggested that nonprotein soy constituents improved markers of cardiovascular health, further careful studies are required to confirm these effects.

7.5.2 Hormone-Dependent Tumors: Breast and Prostate Cancer

Cancer is the second leading cause of death globally and was responsible for an estimated 9.6 million deaths in 2018. Globally, about one in six deaths is due to cancer, with approximately 70% of these deaths occurring in low- and middle-income countries. Dietary risks such as low fruit and vegetable intake contribute to one third of deaths from cancer. That is why much research is focused on foods and their respective bioactive molecules that can help to prevent and/or treat such disease.

Among the most common cancers worldwide that cause death, breast cancer (2.09 million cases) and prostate cancer (1.28 million cases) are in the top five, being first equal with lung cancer (2.09 million cases), followed by colorectal cancer (1.80 million cases), skin cancer (nonmelanoma cancer) (1.04 million cases), and stomach cancer (1.03 million cases) (Bray et al. 2018).

The etiology of these cancers is diverse and sometimes controversial, as is the case for breast and prostate cancers, which are the most hormone-dependent tumors, with estrogen and androgen being the key drivers for both. In the USA, for example, breast cancer rates are extremely high overall, largely because of the high incidence of estrogen receptor–positive cancers among older women. Although the causes of HDTs are more broad, implementation of existing evidence-based prevention strategies could be a way to prevent them and, in certain circumstances, to help treat them.

Some years ago, the data indicated that the low rate of prostate cancer in Asians could well be associated with soy intake (Cook et al. 1999). Yan and Spitznagel (2009) systematically reviewed 15 epidemiological publications on soy consumption and nine studies on isoflavones in association with prostate cancer risk in a

multiethnic population. They found a good correlation, suggesting that consumption of soy foods is associated with a reduction in prostate cancer risk in men. However, the majority of the epidemiological studies on consumption of fermented soy foods in association with prostate cancer risk in men were from a Japanese population.

A more recent study using Status in Surveillance, Epidemiology, and End Results (SEER) data suggested that the quality of race data in cancer registries is excellent for white people, black people, and Asians/Pacific Islanders, and it is substantial for Hispanics and American Indians/Alaska Natives, but considerable underreporting has been shown for other ethnicities (Máire et al. 2016). Thus, reported differences in rates among racial and ethnic populations should be interpreted with caution. Information in Máire et al. (2016) is also reporting of prognostic measures that may influence treatment, such as the relationships between a 21-gene prognostic signature for breast cancer and the frequency of chemotherapy treatment, and the intensity of follow-up for low-risk prostate adenocarcinomas managed with "watchful waiting."

Soy isoflavones are among the more controversial molecules involved in the research being discussed. They have been suggested to be protective against cancer (genistein, for instance, can act as an aromatase or 17β-hydroxysteroid dehydrogenase inhibitor, decreasing estrogen and testosterone, respectively) or may act as proliferation inducers for estrogen-like activity. Moreover, they can modulate the activities of key enzymes in the biosynthesis and metabolism of steroid hormones, acting as agonists or antagonists at estrogen receptors, pregnane X receptors, and constitutive androstane receptors (Cassetta et al. 2017).

Evidence was reported by Shu et al. (2009) suggesting a possible benefit in survivors of breast cancer related to soy consumption. This analysis was carried out on data from 5042 Asian women in China in the Shanghai Breast Cancer Survival Study; therefore, its results cannot be extrapolated to white women, Africans, or African Americans, for instance. In addition, the data were only observational, and the consumption of soy-based foods (which, incidentally, has been practiced by this population for generations) was assessed only through the use of questionnaires, which also included other foods such as meat, fish, and vegetables. This study included many other favorable variables, which also contributed significantly to the "outcomes" – for example, additional treatments with tamoxifen, vitamin supplements, consumption of "tea" (supposedly from *Camellia sinensis*, although this was not specified), and physical activity. In addition to all of this, the authors also mentioned other types of food, such as crucifers, as important contributors to the final outcome. The authors attributed the survival of women with breast cancer in the study to all of these factors, not just the consumption of soy or soy-related products (Shu et al. 2009).

To further clarify this issue and other similar situations, a meta-analysis was conducted by Dong and Qin (2011) from the Department of Nutrition and Food Hygiene at the University of Soochow in China. They concluded that the intake of soy isoflavones may be associated with a reduced risk of breast cancer in Asian populations but not in the West.

Regarding the absence of relevant data on low doses of genistein and possible enhancement of the proliferation of HDTs, Steinberg et al. (2011) conducted a clinical trial that clearly demonstrated that a dose of 10–15 mg/daily brought no benefit for healthy postmenopausal women. As for the "risk," one case of breast cancer and one case of endometrial cancer were verified in the study. Despite the fact that these cancers can occur in this age group, the authors reported that in fact isoflavones may have contributed to these events. This is one of the most problematic situations, since the amount of genistein that binds to ERα is low in this case but may be enough to cause prestimulation of tumor cells, as has been reported in several studies. The authors further suggested that there is a possible small risk to healthy women after menopause. The evaluation was performed with around 80–100 mg of isoflavones, which seems to be a high dose, but the amount of the more active isoflavone, genistein, was minimal (10 and 15 mg in the two groups under study). Daidzein just might have had some relevance but only if the women were "equol producers," which was not the case with any of them (this feature is more common in Asian populations). The impact on the thyroid was small but visible, although the doses were low with respect to preparations currently on the market, since the investigators just wanted to mimic a vegetarian diet with the inclusion of soy.

In a previous study where the exposure to isoflavones was greater than in the work cited above, Unfer et al. (2004) evaluated a similar group of women for 5 years. In this study the amount of genistein (the more active isoflavone), as an example, corresponded to 67.5 mg/day. The authors noted that there was an increased risk of endometrial hyperplasia, which had also been reported elsewhere (Hu et al. 2003).

The importance of evaluating the respective doses of those bioactive compounds is crucial for assessment of the effects of different levels in women and to compare clinical trials with each other. According to the TERE calculation proposed by us some years ago (Campos and Matos 2010), the result would be 29.63% affinity for ERβ and 0.585 for ERα, given 30.3% activity, which relative to estradiol would be a little below 1/3. This already represents considerable estrogenic activity.

In their meta-analysis, Chen et al. (2014) noted that isoflavone intake had a possible effect in reducing the risk of HDTs in women of ethnicities associated with Asian countries, but there was no evidence to suggest that the same consumption could be similarly effective in women of other ethnicities from Western countries.

Consistently reported risk factors for prostate cancer are age, race/ethnicity, and family history, and the risk increases rapidly among older men. It is the most commonly diagnosed cancer among men in the Western world, and African American men have the highest rates in the USA (WHO data).

If prostate cancer treatment is started early, the prognosis is good, but the treatment often leads to side effects such as urinary and erectile dysfunction. Therefore, an alternative strategy is very important because in certain cases, androgen deprivation therapy, as the standard of care, fails.

The enzyme 5α-reductase, which converts testosterone into dihydrotestosterone, has been involved in breast and prostate cancers. Therefore, breast carcinomas that

are positive for 5α-reductase type 1 may partly maintain some androgen regulatory mechanisms (Li et al. 2009) and be partly associated with the proliferation effect of progesterone in breast cancer cells.

The relevance here is that one of the anticancer mechanisms proposed for genistein is linked with inhibition of 5α-reductase activity in prostate tissue. Nevertheless, even in this case, the results are controversial (Lou et al. 2005). Only limited data from intervention studies in human are available, and the results are still unreliable.

The steroid 5α-reductase type 2 (SRD5a2), which is very important in androgen metabolism, has two polymorphisms in its gene (*SRD5A2*) – V89L (rs523349) and A49T (rs9282858) – which have been studied for associations with prostate cancer risk, with conflicting results. To provide a more precise estimation of these two polymorphisms and prostate cancer risk, Li et al. (2013) performed a meta-analysis using all published case–control studies of prostate cancer published since January 1995. However, prostate cancer is a biologically heterogeneous disease with variable molecular alterations, and the results were not conclusive.

Yan and Spitznagel (2009) reported that the inverse association between soy consumption and prostate cancer risk found in epidemiological studies was supported by animal studies. The data were related to dietary soy protein and soy phytochemical extracts as the main sources of compounds that inhibited experimentally induced prostate tumorigenesis. However, one study also showed that soy protein increased prostate tumor growth in an androgen-independent model. Genistein, as has already been noted, is the isoflavone that is more implicated in prostate cancer prevention and even as a possible treatment on the basis of its inhibition of tumor development in animals and proliferation of prostate cancer cells in cultures.

Zhang et al. (2016), from China, did a review with a critical discussion of some issues correlated with the protective effect of isoflavones against the development of prostate cancer. As their main conclusion, they stated that "Isoflavones play a protective role against the development of prostate cancer. However, careful consideration should be given when isoflavones are used in the prevention and treatment of prostate cancer." Briefly, the authors did not find data supporting an important role for isoflavones in prostate-specific antigen level reductions in cancer patients or healthy men. As was discussed previously in this text, the effect of isoflavones on sex hormone levels and on the risk of this cancer could be determined by equol-converting bacteria in the intestine, but this is directly correlated with specific polymorphic variations and the concentrations of isoflavones. Another important point, which has already been discussed here, is that the intake of various types of phytoestrogens with lower concentrations in the daily diet may produce synergistic effects against prostate cancer. Moreover, prostate tissue may concentrate isoflavones to potentially anticarcinogenic levels. In addition, it should be noted that isoflavones may act as agonists in prostate cancer.

The discussion is wide ranging because in some randomized, controlled trials on the role of isoflavones in men with prostate cancer, the results have been inconsistent as to whether isoflavones can lead to cancer progression.

7.5.3 Perimenopause and Postmenopause

The impact of soy isoflavones differs depending on ethnicity, and in Europe, different groups have studied this issue to do a risk assessment of the increased intake of such compounds by the white population.

In 2015, an external scientific report titled *Preparatory Work to Support the Risk Assessment for Peri- and Postmenopausal Women Taking Food Supplements Containing Isolated Isoflavones* was published. The authors (Tijhuis et al. 2015) issued the following disclaimer: "This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority." The text stated that "food supplements targeted at peri- and postmenopausal women typically provide a daily dose of isoflavones in the range of 35–150 mg/day." In addition, it was emphasized that "the background exposure from the diet in the general European population was estimated to be lower than 1 mg/day, whereas in consumers of soy-based foods it could be higher." The panel concluded that "it was not possible to derive a single health-based guidance value for the different preparations in post-menopausal women. However the doses used in the intervention studies and their duration could serve as guidance for the intake of food supplements." From the data collected, the authors mentioned the following, among their main conclusions: (a) "isoflavones may interact with the synthesis of thyroid hormone"; (b) "the human data did not support the hypothesis of an increased risk of breast cancer from observational studies nor of an effect on mammographic density nor on proliferation marker Ki-67 expression in interventional studies"; (c) "no effect was found on endometrial thickness and histopathological changes in the uterus up to 30 months of supplementation with 150 mg/day of soy isoflavones"; and (d) after 60 months, some nonmalignant histopathological changes were reported. Most of these four points need to be clarified to assure a safe mode for isoflavone intake by white population.

One of the most problematic symptoms in postmenopausal women is hot flashes, which have been reported in approximately 70–80% of US women of menopausal and perimenopausal age, in comparison with approximately 10–20% of Asian women. It has been estimated that the average estimated blood concentration of the soy isoflavone genistein is approximately 25 ng/mL in Asian women but only 2 ng/mL in US women. From the review and meta-analysis by Li et al. (2015), it was concluded that soy isoflavones show slight and slow effects in attenuating menopausal hot flashes in comparison with estradiol. The authors measured the efficacy of soy isoflavones and conducted a systemic literature search to build a time–effect model for placebo and soy isoflavones in treating menopausal hot flashes. In this model, it was hypothesized that the placebo and soy isoflavone effects would vary with time and reach a plateau. Therefore, the effect profiles for placebo and soy isoflavones were described with a sigmoid maximum effect (E_{max}) model, with time considered as an independent variable. From the data analyzed under these

parameters, the authors achieved a time course for the reduction of hot flashes after administration of the placebo and soy isoflavones. The data that were collected showed a maximal percentage change (in terms of reduction of hot flashes) with soy isoflavones of 25.2% after elimination of the placebo effect, amounting to 57% of the maximum effects of estradiol (estradiol E_{max} 44.9%). However, they also found that a time interval of 13.4 weeks was needed for soy isoflavones to achieve half of their maximal effects, which was much longer than the interval for estradiol, which was only 3.09 weeks. Similarly, treatment intervals of 12 weeks are too short for soy isoflavones, which require at least 48 weeks to achieve 80% of their maximum effects. These data are relevant to understanding the problem and optimizing the design of possible clinical trials. In Table 1, details are provided about the concentration of the different isoflavones included in the placebo-controlled trials under analysis. A further study should be done using the determination of the TE and TERE proposed by Campos and Matos (2010) to complete the approach started by Li et al. (2014).

7.5.4 Thyroid Function

An increase in the risk of hypothyroidism in peri- or postmenopausal white women is a very important aspect and should be discussed with respect to the consumption of soy and products containing isoflavones. The results reported by Sathyapalan et al. (2011) have proved to be interesting because these authors evaluated the effects of soy isoflavones in white women with "subclinical hypothyroidism." This clinical situation is widespread, particularly in women with a large number of anti-thyroperoxidase antibodies, which are often found as biomarkers in the development of Hashimoto's thyroiditis. During its progression, this leads to destruction of the thyroid and requires lifelong replacement therapy with levothyroxine, which is one of the five most widely consumed drugs worldwide, precisely because of the high prevalence of this disease in women. In a randomized, double-blind study, it was estimated that the risk of hypothyroidism was three times higher with isoflavone intake from 30 g of soy protein, containing 16 mg of total isoflavones, corresponding to 8.64 mg of genistein, 5.6 mg of daidzein, and 1.92 mg of glycitein. What was more alarming in this study was that it gave support to the existing concerns about the consumption of isoflavones in the short and long terms, resulting in inadequate synthesis of hormone due to thyroid inhibition of thyroperoxidase, together with increased urinary excretion and fecal bile displacement of T4 from transthyretin. The persons involved in this study had very good iodine supplementation, which was indicated by elevated urinary excretion of iodine; this is not the case for most of the world's population. This excretion of iodine was not changed by isoflavone intake. In this study, genistein levels, which is the one that has shown more inhibition among isoflavones, to peroxidase thyroxine are in very low dose (8.64 mg) in comparison with what is found in extracts available on the market (Campos and Costa 2012), but this is a dose that can probably be found in dairy products.

Thus, a comparison of this impact is complex to evaluate, and the risk may be higher that we suppose. Anyway, clinicians should be aware of this relevant information to ensure better diagnosis of this pathology.

7.5.5 Sleep Status

Good sleep is crucial for good health. Since estrogen modulates sleep duration and quality, Cui et al. (2015) hypothesized that isoflavones would have a beneficial effect on sleep status in a way similar to estrogen. They conducted a cross-sectional study to examine the relationship between daily isoflavone intake and sleep status in Japanese subjects. To explore this idea, they studied 1076 Japanese adults aged 20–78 years, and they assessed the daily isoflavone intake by means of a brief self-administered diet history questionnaire. Sleep was evaluated using a self-reported questionnaire too. From the data obtained, the authors concluded that "higher daily isoflavone intake was positively associated with optimal sleep duration and quality in a Japanese population. This finding suggests that daily isoflavone intake may have a potentially beneficial effect on sleep status."

7.6 Epidemiological Studies

Bennetts et al. (1946), who were trying to identify the cause of a specific sheep-breeding problem in Western Australia, discovered phytoestrogens, as mentioned above. They implicated equol, a metabolite of daidzin that is an isoflavone existing in subterranean clover pastures, as the toxic molecule. Almost four decades later, equol was identified in human urine and related to soy intake in Asian diets. Further, it was found to be implicated in possible prevention of HDTs, CVD, and osteoporosis. Much research has now been published, but with conflicting data. In a short letter to the editor of the *American Journal of Clinical Nutrition*, Messina (1995) presented his point of view, stating that the isoflavone intake by Japanese was overestimated. He explained that Setchell and Cassidy (1999) estimated a Japanese daily per capita isoflavone intake of 150–200 mg, whereas his estimate was much lower. The outcomes discussed in these publications would therefore be different. This is one of various examples in the literature on this issue.

At that time, the world was focused on the "French paradox" based on data collected in a French population, which suggested that ingestion of antioxidants, mainly from red wine and alcohol itself, could be a panacea for cancer prevention and CVD. According to data from the world's largest study of heart disease, conducted by the WHO in 21 countries and including 10 million men and women, the French heart disease statistics appeared to have been underestimated and the French paradox overestimated. The French rate of heart disease was actually similar to those of the Italians, Spanish, and Germans (mainly those in Southern Germany) but still lower than those of many other countries (Campos and Costa 2012).

Other researchers looking in a different way for similar phenomena performed epidemiological studies in Asian populations in the 1990s that revealed a possible relationship between ingestion of soy, prevention of HDTs, and a lower incidence of climacteric symptoms in postmenopausal women.

These results, known as the Japanese paradox (based on data collected in a Japanese population), induced Western people to consume soy and soy derivatives rich in isoflavones such as genistein, daidzein, and glycitein, and their respective glycosidic forms (genistin, daidzin, and glycitin). A large number of studies have attempted to demonstrate that soy consumption decreases the risk of developing several chronic diseases – in particular, cancer, osteoporosis, and CVD – and relieves climacteric symptoms. At this stage, however, the majority of these postulated benefits should be considered with caution, as has been demonstrated in this text.

The two epidemiological studies described above were mainly focused on prevention of CVD and cancer, using phenolic compounds as the targets for this bioactivity. The first one, regarding the French paradox, was flawed and disregarded an important side effect – cirrhosis – in people with an increased intake of wine over a period of decades. With regard to the Japanese paradox, the scientific community has started to gather sufficient data to suggest that this concept needs to be assessed with caution to prevent a future failure mainly associated with the estrogen-like effect (Campos and Costa 2012).

So far, even 30 years later, with epidemiological studies suggesting that breast cancer rates are low in populations that consume soy, the following statement from Strauss et al. (1998) remains valid: "Epidemiological studies suggest that diets rich in phytoestrogens (plant estrogens), particularly soy and unrefined grain products, may be associated with low risk of breast and prostate cancer. It has also been proposed that dietary phytoestrogens could play a role in the prevention of other estrogen-related conditions, namely cardiovascular disease, menopausal symptoms and post-menopausal osteoporosis. However, there is no direct evidence for the beneficial effects of phytoestrogens in humans. All information is based on consumption of phytoestrogen-rich diets, and the causal relationship and the mechanisms of phytoestrogen action in humans still remain to be demonstrated. In addition, the possible adverse effects of phytoestrogens have not been evaluated. It is plausible that phytoestrogens, as any exogenous hormonally active agent, might also cause adverse effects in the endocrine system, i.e. act as endocrine disrupters."

The major problem in these meta-analytical approaches correlating dietary patterns in population studies is that they cannot be reproduced in other study populations. Consequently, nutritional studies using factor analysis have reported quite different patterns, even when dietary patterns have been successfully linked to disease protection. The converse is also true in these evaluations when a good correlation can be established between feeding behavior and specific estimates regarding relative risks or mortality. The studies are consequently not reproducible nor comparable. These scenarios of unreproducibility limit the significance of the a posteriori pattern analysis approach in epidemiological research (Nakamura and Ueshima 2014).

7.6.1 Evaluation and Management of Dietary Isoflavones in Different Ethnic Populations

Genetic differences between people from different ethnic groups should be evaluated carefully when the goal of the epidemiological study is to provide guidelines to improve the consumption of a product to avoid/prevent a disease. For example, African and white women are genetically different from Asians, as well as from other ethnic groups, as has been discussed. Genetic variants are closely linked to metabolism, via CYP, and the various isoforms that constitute it, with a direct bearing on the specific diets, typical of each ethnic group, that influence existing polymorphisms. The existence of these metabolic changes influences the activity of these isoenzymes even when they are exposed to the same substrate in the same metabolic process.

Isoflavone content is not restricted to soybeans; isoflavones can also be found in other foods such as adzuki beans, alfalfa, green peas, chickpeas, lentils, lupins, and peanuts, among others, as has been discussed above (Ko 2014). Soybeans are used in various traditional cuisine dishes all over the world; the amounts of isoflavones found nowadays in some products should be assessed to ensure that some diseases associated with estrogen disruption and/or thyroid dysfunction are not being caused by the increase and subliminal amounts of these compounds in Western diets.

With the increased use by Western populations of Asian medicinal plants – among which are some that contain isoflavones, such as *Astragalus* and *Angelica* roots, *Cimicifuga*, and kudzu – the impact in different ethnic populations should be assessed to evaluate the risks as soon as possible. Many of these issues are being discussed on the basis of the relevance of the research developed in the field; however, the broader end points of these bioeffects remain unclear (Wuttke et al. 2007; EFSA 2012; Campos and Costa 2012; Ko 2018).

As a simple example, in the case of soy isoflavones, estrogen and genistein have a similar metabolic pathway involving CYP1A2. In different ethnic groups, there are polymorphisms in that isoenzyme (Testa and Krämer 2008), and the cross-effect of the joint metabolism of these substances should be evaluated carefully. The polymorphic variation in this isoform is mainly due to genetic factors (39–72%). Asians, for instance, have several polymorphisms in *CYP1A2* that affect efficacy and toxicity in the metabolism of various drugs and catalytic activation of carcinogenic heterocyclic amines. This isoform can be induced by tobacco smoke and can be inhibited by grapefruit juice or by genistein itself. Caffeine metabolism occurs via the same route. Although there are different polymorphic forms, in white people there is a predominance of isoform *CYP1A2*1F*, which has been associated with increased levels of carcinogen formation and thus tumor induction.

From our point of view, these data should be integrated into the selection of patients for randomized clinical trials. Genetic information about the patients involved is crucial for full understanding of the data collected and the results obtained.

It is important to note that these genetic modifications in different ethnic groups are also linked to age and gender. In women, they are connected to the age at which

menopause arises and symptoms related to low estrogen that occur during this period of women's lives.

In Campos and Costa (2012), data were correlated with regard to the genes involved in the metabolism of steroid hormones and their association with hormonal levels and symptoms related to menopause. Briefly, the populations involved in some of the studies were African Americans and European Americans. The genotypes evaluated were catechol-*O*-methyltransferase (*COMT*); *CYP1A2*, *CYP1B1*, *CYP3A4*, and *CYP1A1*; and CYP19 sulfotransferase (*SULT1A1*) and *SULT1E1*; the related hormone levels were also evaluated. The results showed that European American women with the *SULT1E1* variant had low levels of dehydroepiandrosterone sulfate and lower levels of estradiol sulfate dehydroepiandrosterone and testosterone than women without this variant allele. Also, in this group, *SULT1A1*3* was associated with symptoms related to hot flashes and depression. In African American women, the *CYP1B1*3* genotype was associated with hot flashes and *CYP1B1*4* was found to be associated with depressive symptoms. Changes in *CYP1A2* genotypes were associated with hot flashes in postmenopausal women. The fact that Asians have different CYP polymorphisms may cause different effects in this period of life with respect to climacteric symptoms. Thus, the approach for preventive treatment of the symptoms associated with this situation should be adapted to women's ethnicity to be more beneficial and avoid risk where possible. The discussion of the points noted above cannot be separated with regard to isoflavone supplements or food products, because the risk associated with their intake by white people remains the same.

CYP isoforms are important in the metabolism of endogenous hormones and can cause changes in their quantity and essentially in the type of metabolites produced, but those are still poorly studied. Polymorphic changes are due primarily to the foods that individual ethnic groups have been exposed to for generations, their environment, and their way of life. Over the centuries, Caucasians have not been exposed to soy and/or isoflavone-rich foods, unlike Asians, and in Europe the isoflavones from various plants have been considered antinutrients and not recommended even for animal consumption.

For white people, caution should be exercised especially when these products are advertised as having beneficial health impacts for them, once isoflavones and/or all the products that contain those bioactive compounds, because for this ethnic group the risk assement was not did over a sustained period, that allows to say that they are safe.

Virk-Baker et al. (2014) designed a study to evaluate the relationship of the prevalence of breast cancer, ductal hyperplasia, and overall breast pathology with the capacity to be an *S*-(−)equol producer, as compared with nonproducer postmenopausal women undergoing a breast biopsy. A cross-sectional study design was used to evaluate the impact of supplementation of the participants' usual diets with one soy bar per day for three consecutive days. The results showed that the threshold value of −1.60 used for defining *S*-(−)equol status in the population under analysis was comparable to the ratio of −1.75 previously published by Setchell and Cole (2006). This study was the first to test the *S*-(−)equol-producing status of African

American women with a relatively large sample size ($n = 51$). Of the African American participants, 13.72% (7 out of 51) were *S*-(−)equol producers as compared with 19.56% of white Americans (18 out of 92), but the difference was not statistically significant. Briefly, the authors observed no "associations between *S*-(−) equol producing status and breast pathology, hyperplasia, or breast cancer. Based on our results of null associations, we rejected our hypothesis of lower prevalence of ductal hyperplasia, breast cancer, or overall breast pathology among *S*-(−)equol producers as compared to non-producers" (Virk-Baker et al. 2014).

The lower prevalence observed among African American women in the study described above was similar to results published by Hedlund et al. (2005) regarding white men who were long-term low-soy consumers.

Further studies are needed to confirm the observed lower prevalence of the *S*-(−) equol phenotype among postmenopausal African American women in order to further understand the dietary or lifestyle factors responsible for the observed lower prevalence in this group. To be more precise, the data that point to a protective effect in prevention of breast cancer associated with consumption of isoflavones (usually from soybean) and to *S*-(−)equol-producing status imply continuous consumption and not only a short-term consumption.

The Indian Menopause Society has projected that by the year 2025, there will be 103 million menopausal women in India, and data on the relief of symptoms are still scarce. At the gynecology outpatient department of a teaching hospital in Northern India, Ahsan and Mallick (2017) did a questionnaire-based, observational, non-randomized, prospective, open-labeled pilot study over a period of 1 year (October 2012–2013). The study involved 29 perimenopausal women and 21 postmenopausal women. The baseline was determined by a previous determination of the Menopause Rating Scale (MRS) on a specific questionnaire. Both groups started treatment with 100 mg of soy isoflavone per day for 12 weeks. The MRS response of the perimenopausal women showed a mean total score of 19.55% and a somatic subscale score of 27.7%. Among the postmenopausal women under evaluation, 12.62% showed improvement in their mean total scores, 14.54% in somatic subscale scores, and 26.79% in psychological subscale scores. These were improvements but possibly had little significance, from our point of view. However, through analysis of individual symptoms it was observed that the maximum improvement (40%) was seen in symptoms of hot flashes of mild to moderate degree in both perimenopausal and postmenopausal women. Severe to very severe hot flashes were seen only among perimenopausal women, which improved by 36.11% after treatment. Those are more relevant effects, but no identification or partial quantification of the various isoflavones in the supplement given to these women was performed. It is probable that this trial could not be reproduced.

7.6.2 Clinical Trials

In our search for "soy" and "isoflavones" we activated the following filters: "clinical trial," "free full text," "published in the last 5 years," and "humans." The same was

done with the clinical trials documented in the literature. Selected data are explained below.

In Italy, Bitto et al. (2010) performed a randomized, double-blind, placebo-controlled trial of therapy with 54 mg/day of genistein in 389 postmenopausal women with osteopenia for 24 months. A subcohort (138 patients) continued this therapy for an additional year. The trial was performed in Italy, but no details of the ethnicity of the subjects was mentioned. From the results, the investigators verified that the administration of the therapy for 3 years did not affect serum thyroid hormones or autoantibodies at the dose under evaluation. They also verified that in this clinical trial, the genistein aglycone positively regulated bone metabolism without harmful estrogenic activity. In fact, these results were theoretically expected, since, if we did a calculation of the TE, the affinity of genistein for ERα would be 1.044% and that for ERβ would be 23.709%, with a TERE calculation of about 1/4 relative to estrogen itself (Campos and Matos 2010). The main advantage was affinity for bones, which was due to the predominance in the affinity of genistein for ERβ. Nevertheless, the low affinity for ERα in this study corresponded to an affinity of 1.044%, which was considered nonestrogenic.

In China, Liu et al. (2012) evaluated the effect of dietary soy isoflavones on blood pressure with data collected from four selected trials. The duration of the intervention varied from 1 to 12 months. The sample sizes varied from 18 to 302 subjects, with an average age ranging from 48.5 to 66.7 years. The ingested soy protein ranged from 20 to 50 g/day and the isoflavone dosage from 65 to 153 mg/day. Briefly, no data on the ethnic groups included in the studies was mentioned. Additional subgroup analyses did not find any significant effects of gender, the duration of the intervention, or the doses of isoflavones or soy protein on SBP or DBP in response to soy isoflavone intake, but this intake did lead to a larger reduction in blood pressure in younger hypertensive subjects than in normotensive subjects.

In a meta-analysis of 11 trials, Liu et al. (2012) demonstrated that soy isoflavone intake resulted in mean decreases of 2.5 mmHg for SBP and 1.5 mmHg for DBP in comparison with placebo. Once again, they highlighted that the obvious heterogeneity detected among the 11 trials could primarily be ascribed to the blood pressure status of the subjects in the studies, and that the findings must be interpreted with caution in view of the limited statistical power.

More three clinical trials from the last 14 years are available, and the main conclusions are presented below.

In 2005, the Johns Hopkins University Clinical Trials Unit in the USA did a phase 4 clinical trial to evaluate the effects of an isoflavone-containing soy supplement called Revival (although there was no mention of the dose) on memory/cognition, quality of life, and hot flashes in men with prostate cancer undergoing testosterone suppression therapy (ClinicalTrials.gov study identifier: NCT00245518). The study sample consisted of 39 men aged 21 years or older with prostate cancer and hypogonadism for at least 3 months. The participants were given either a placebo or Revival once daily for 14 weeks. Blood was drawn to check their cholesterol levels and liver, kidney, thyroid, and prostate health. Urine was collected to check on bone markers. The patients completed questionnaires to test

their memory, attention span, and vocabulary. The hypothesis to be confirmed was that "treating men who have prostate cancer with daily Revival will result in at least a 50% reduction in hot flashes compared to placebo. Possible benefits may include increase in memory, decrease in hot flashes, and a general increase in quality of life." The results obtained were only from 33 participants who completed the study with no report of adverse events and were similar in some of the items except for hot flashes and sexual behavior. Full details can be obtained at https://clinicaltrials.gov/show/NCT00245518.

In 2017, Silva et al. published data from a prospective, randomized, double-blind trial in 30 postmenopausal women who were evaluated in the gynecology department at the Federal University of São Paulo (UNIFESP), Brazil. This was a phase 2 clinical trial to evaluate "postmenopausal facial skin after estradiol and genistein topical treatment." The aim of this trial was "to compare the effects of estradiol or genistein treatment on the hyaluronic acid concentration on the postmenopausal facial skin." The study subjects were postmenopausal women aged 45–55 years who met the study inclusion criteria of being 2–5 years postmenopause with a follicle-stimulating hormone (FSH) level >40 mU/mL, an estrogen level <20 pg/mL, and a body mass index <30 kg/m^2. They were divided into two groups: one treated with 17β-estradiol gel 0.01% ($n = 15$), and the other treated with genistein gel 4% (isoflavone; $n = 15$). The length of treatment was 24 consecutive weeks. Pre-auricular skin biopsies were performed on each patient before and after the treatment for evaluation of hyaluronic acid in the tissue. The materials were processed using immunohistochemical and biochemical methods (https://clinicaltrials.gov/show/NCT01553773). The study was completed, and the data showed an increase in the amounts of both type I and type III facial collagen by the end of both treatments. However, the outcomes of the estrogen-treated group were superior to those of the genistein-treated group, with statistical significance of $P < 0.001$. The authors concluded that "treatment with topical estrogen is superior to genistein, but both have positive impacts on facial skin collagen. Nevertheless, it is still unclear whether prolonged use of genistein and other topical phytoestrogens could produce systemic effects and further research is needed to clarify this question" (Silva et al. 2017). Caution is needed in the interpretation of this conclusion, in view of the fact that the incidence of skin cancers is increasing.

Menopause induces estrogen loss, which leads to increased bone loss. Sathyapalan et al. (2017) did a relevant study to help reduce osteoporosis postmenopause. Since soy isoflavones can act as selective estrogen receptor modulators, their role in bone turnover should be evaluated. The primary outcome was an assessment of changes in plasma bone turnover markers. The secondary outcomes were assessments of changes in cardiovascular risk markers, including insulin resistance, blood pressure, and the lipid profile. The trial was performed as a double-blind, randomized, parallel study in which 200 women were randomized within 2 years after the onset of menopause to receive 15 g of soy protein with 66 mg of isoflavone, or 15 g of soy protein alone, daily for 6 months. The type of isoflavone was not identified. From the results, the authors observed significant reductions in fasting glucose, insulin, and SBP, but there were no significant changes in the fasting lipid profile

or DBP with either preparation used in the study. There was a significant increase in thyroid-stimulating hormone (TSH) and a reduction in free thyroxine ($P < 0.01$). Even with a possible beneficial effect on bone health and an improvement in cardiovascular risk markers, the significant increase in TSH and the reduction in free thyroxine following soy supplementation indicated a detrimental effect on thyroid function. This is very important, as side effects should be addressed and caution is needed in the recommendation of these products, because sometimes the benefits are overestimated.

7.7 Safety: Toxicity and Side Effects

Most of the issues associated with safety, toxicity, and side effects have already been identified and discussed throughout this text. In this section, some other details are briefly discussed.

7.7.1 Infant Nutrition

Concerns have been raised over potential risks of soy protein formulas for infant nutrition – in particular, because of their isoflavone content. The authorities or pediatric societies in Australia, Canada, France, Ireland, New Zealand, Switzerland, and the UK have advised health professionals and caregivers that because of the limited availability of data, the use of soy protein formulas in infants should be restricted to specific cases. Following the publication of these guidelines, in 2006 the European Society for Paediatric Gastroenterology Hepatology and Nutrition (ESPGRAN) Committee on Nutrition summarized the available information on the composition and use of soy protein formulas as substitutes for breastfeeding and cows' milk protein formulas. The main concerns were safety and adequacy for the growth and development of infants. The committee evaluated soy as a source of protein that could be inferior to cows' milk, with lower digestibility and bioavailability, as well as having a lower content of methionine, which is the main product used in infant formulas for this purpose. They noted no nutritional advantage over cows' milk and discussed high concentrations of phytate, aluminum, and isoflavones, which could have untoward effects. Another important statement noted that there was no evidence supporting the use of soy protein formulas for the prevention or management of infantile colic, regurgitation, or prolonged crying (Agostoni et al. 2006). The conclusion emphasized that manufacturers should aim to reduce the concentrations of trypsin inhibitors, lectins, goitrogenic substances, phytate, aluminum, and phytoestrogens in soy protein formulas, but no specific information about isoflavones was provided.

Testa et al. (2018) did a review of studies published from January 1980 to June 2017 and made a statement about the use of soy-based formulas (SFs) in infant nutrition. They mentioned the belief that the use of SFs during infancy can reduce the risk of the development of several diseases later in life, but they did not find

definitive data that could substantiate these claims. With regard to risks, they noted the potentially toxic role of the phytoestrogens (isoflavones) contained in these products and pointed out that in vitro animal studies had yielded conflicting results and "raised suspicions that SF could have potentially negative effects on sexual development and reproductive function, neurobehavioral development, immune function, and thyroid function" (Testa et al. 2018). From their analysis of the literature, they concluded that "the impact of modern SFs on human development seems to suggest that their use is not associated with relevant abnormalities. Only children with congenital hypothyroidism need adequate monitoring of thyroid function." However, ethnic differences were not evaluated.

7.7.2 The Thyroid

For case reports in a PubMed search using the keywords "soy" and "isoflavones" with the filters "case reports," "free full text," "published in the last 10 years," and "humans" activated, only one item was found, but it is very relevant.

Nakamura et al. (2017) (from the Department of Internal Medicine at Saiyu Soka Hospital in Matsubara, Japan) reported a case involving soy isoflavones that induced hypothyroidism in a patient with chronic lymphocytic thyroiditis. Although the majority of the research data might lead one to suppose that the Asian population in general tolerates soybeans well, these authors emphasized that consuming health drinks that include soy isoflavone extracts can lead to severe hypothyroidism.

In various countries in North and South America, many people have thyroid pathologies such as hypothyroidism, and some other patients have potentially chronic lymphocytic thyroiditis. The causes are far from being identified, but some exogenous foods influence the thyroid. If foods interfere with the production of thyroid hormone, they can cause serious hypothyroidism, as could be the case with isoflavones from soy. This situation should be assessed very carefully now that food with soy is widespread all over the world.

Bitto et al. (2010) published data from 3 years of a study in 389 postmenopausal women taking 54 mg/day of genistein. The results showed that serum thyroid hormones and autoantibodies were not significantly influenced by the treatment. Despite this evidence, the safety of isoflavones still warrants further investigation, especially in ethnicities other than Asians.

7.8 Marketed Products

There is a compilation of the isoflavone content of foods provided by a study funded by the USDA and the US Army, which can be obtained from the website http://www.nal.usda.gov/fnic/foodcomp/Data/isoflav/isoflav.html (Project PHYTOHEALTH, grant agreement ID: QLK1-CT-2002-02453, 2003–2006).

The data presented in Campos and Costa (2012) show a wide range of isoflavone levels that different products in the market may provide to the consumer in

some European countries. Even when isoflavone extracts from soy are recommended as therapeutics in some over-the-counter (OTC) tablet preparations, the profile of the relative concentrations of the different constituents is not consistent across all brands (Campos et al. 2006). It is relevant to mention that the majority of soy suppliers breed a wide range of soy cultivars, and despite we showed in Figs. 2 and 3 similar HLPC profiles for isoflavones extracts, other cultivars present different relative concentrations of the main compounds that imply an unpredictable estrogen-like impact, as is explained above.

In the review published by Rizzo and Barini (2018), important data were given about the total grams of intake of soy protein or soy isoflavone and the relative variability of soy foods. They also included information about this intake in many countries around the world.

In recent decades, a new generation of soy products has come onto the market (e.g., yogurts, cheeses, soy milk drinks, and infant formulas) and commonly consumed food products now incorporate soy flour (e.g., bakery products) and protein isolates (e.g., meat products and soy meatless products such as soy burgers). In the last 15 years, the development of nutritional supplements rich in isoflavones has targeted the niche market of menopausal women. The EFSA (2012) report emphasized that "On the basis of the data presented, the Panel concludes that the evidence provided is insufficient to establish a cause and effect relationship between the consumption of soy isoflavones and maintenance of bone mineral density, and between the consumption of soy isoflavones and reduction of vasomotor symptoms associated with menopause" and that "On the basis of the dietary intake estimates, for the high dietary intake adult and infant consumer, particularly where there may be indications of (congenital) hypothyroidism, large data gaps regarding critical windows of development, and timing of exposure remain outstanding and need to be addressed before any conclusive assessment on safety can be made."

7.9 Perspective/Conclusions

Even with such important data from many studies in different countries, the conclusions should be interpreted with caution. Observational studies among Asian populations have consistently found that the intake of isoflavone-containing whole soy and traditional soy-based foods can be related to a lower incidence of chronic disease or cancer. In contrast, studies performed in Western populations have frequently included controversial end points and failed to consistently demonstrate health benefits. Probably the main problem is the kind of products involved in the studies, as various combinations of soy and isoflavones are involved and no estrogenic-like activity of them has been evaluated in a way to give comparable results. Until now, the epidemiological and migratory evidence for the role of soy isoflavones in health prevention and promotion has been somewhat unclear because the ethnic groups under evaluation have not been specified in the equation. Current and ongoing clinical trials with soy may help us to further understand its role in breast and prostate cancer prevention, peri- and postmenopausal relief of specific

symptoms, and safe use in relation to the thyroid. Further studies in infant and adult humans are needed to address factors related to the observed effects of soy isoflavones in the global market, but the health impacts are diverse, depending on various factors (ethnicity, age, gender, etc.), and the risks associated with some of them could be pernicious.

8.1 Introduction

Plant foods represent a very rich source of bioactive compounds, among which are polyphenols. According to their chemical structures, polyphenols can be classified into phenolic acids, flavonoids, lignans, and stilbenes. The polyphenols that mainly characterize the human diet, representing about two-thirds and one-third of the total daily intake of these phytochemicals, are phenolic acids and flavonoids (Ovaskainen et al. 2008).

Several studies have reported an inverse relationship between flavonoids-rich foods and some degenerative diseases (Ma et al. 2018; Spagnuolo et al. 2015). According to their structures, dietary flavonoids are classified into six main groups, namely, anthocyanidins, flavanols, flavanones, flavones, flavonols, and isoflavones. Whereas some of these classes of flavonoids are distributed in a wide range of plant foods, others, such as flavanones, are found only in particular foods. In fact, this class of flavonoids is present almost exclusively in *Citrus* species. To a lesser extent, they are found also in some plants including tomatoes and mint. In *Citrus* fruits, flavanones account for approximately 95% of the total flavonoids (Peterson et al. 2006a, b). Flavanones occur mainly in flavedo, albedo, and segment membranes.

A total flavanones content in the range of 35–147 mg/100 g was found in *C. sinensis* (orange) (Peterson et al. 2006b). Naringin and narirutin were quantified in *C. paradise*. A content in the range of 44–106 mg/100 g was demonstrated (Peterson et al. 2006b). However, because generally in the preparation of juices, the albedo and membranous parts are discarded, flavanone levels in *Citrus* juices are lower. Indeed, levels of naringenin in the range of 17–76 mg/100 mL were found in the juice of *C. paradisi* (Ross et al. 2000) and levels of hesperidin and narirutin in the range 13–77 mg/100 mg were found in the juice of *C. sinensis* (Tomas-Barberan and Clifford 2000).

In Europe, *C. sinensis* represents the major source of *Citrus* flavanones (Zamora-Ros et al. 2010). Flavanones are present in all cultivars. However, red cultivars showed a higher number of flavanones (Grosso et al. 2013). *Citrus* fruits are largely consumed as fresh or as juices or are canned. Moreover, uses in cosmetic and pharmaceutical industries are reported. *Citrus* fruits have been used in traditional medicinal medicines of several countries including China, Korea, and Japan. In particular, Chinese Pharmacopoeia reports six *Citrus* species, namely, *C. aurantium* L., *C. medica* L., *C. sinensis* Osbeck, *C. reticulata* Blanco, and *C. wilsonii* Tanaka (Lv et al. 2015) to treat skin

inflammation, indigestion, cough, ringworm infections, muscle pain, and to lower blood pressure. Both in vitro works and evidences from epidemiological, clinical, and preclinical studies described the healthy promoting properties of *Citrus* species and flavanones (Kang et al. 2016; Loizzo et al. 2012, 2016; Rendeiro et al. 2016; Tundis et al. 2012; Zaidun et al. 2018; Zhou et al. 2018). The purpose of this chapter is to compile data related to the bioactivities of *Citrus* flavanones, their bioavailability and metabolism, application in foods, marketed products, potential toxicity and side effects, and critically analyze the future perspectives.

8.2 Bioactive Constituents of *Citrus* Species

In the *Citrus* genus, different types of flavonoids have been identified: flavanones, flavones, flavonols, and – uniquely to blood oranges – anthocyanins. The flavonoids contained in greater quantities in *Citrus* fruits are flavanones, representing approximately 95% of the total (Peterson et al. 2006b). This subclass of polyphenols is the intermediate structure for the biosynthesis of a wide range of flavonoids found throughout the plant kingdom. In the vegetal tissues, flavanones result from the condensation of two precursors: three molecules of malonyl-CoA with one molecule of *p*-coumaroyl-CoA by chalcone synthase (CHS), forming the 2′,4′,6′,4-tetrahydroxychalcone or naringenin chalcone (Fig. 1) (Forkmann and Heller 1999).

Eventually, chalcone isomerizes into (2S)-flavanone (5,7,4′-trihydroxyflavanone), otherwise known as naringenin. This reaction can occur spontaneously, due the instability of the chalcone structure or stereospecifically by chalcone–flavanone isomerase (CHI), which plays a significant role in the cyclization reaction of chalcones to form all flavonoid classes (Forkmann and Heller 1999; Aoki et al. 2000). The main *Citrus* flavanones aglycones are naringenin (5,7,4′-trihydroxyflavanone), hesperetin (4′-methoxy-3′,5,7-trihydroxyflavanone), eriodictyol (5,7,3′,4′-tetrahydroxyflavanone), and isosakuranetin (4′-methoxy-5,7-dihydroxyflavanone) (Fig. 2).

In *Citrus* fruits, these four compounds are generally glycosylated at position 7 by either the disaccharide neohesperidose or rutinose (Fig. 3) producing four neohesperidose glycosides, namely, naringin, neoeriocitrin, neohesperidin, and poncirin, and four rutinose glycosides, namely, didymin, eriocitrin, hesperidin, and narirutin (Peterson et al. 2006b).

Neohesperidosides derivatives have a bitter taste, while rutinosides derivatives have no taste. Surprisingly, chemical hydrogenation of neohesperidin in alkaline solution produces the semisynthetic neohesperidin dihydrocalcone, a potent artificial sweetener (Kinghorn et al. 2010).

8.3 Bioavailability and Metabolism of Flavanones

To exert their beneficial properties, polyphenols should be released during digestion and absorbed (Parada and Aguilera 2007). Several works investigated how much of polyphenols can be absorbed after ingestion. Nevertheless, the poor bioavailability of these molecules have been highlighted.

Generally, the bioavailability of polyphenols is dependent on different factors including bioaccessibility, transport, and metabolism (Bouayed et al. 2012). Most studies that analyzed the bioavailability of *Citrus* flavanones involved hesperetin, naringenin, and their glycosides. After intake, flavanone glycosides are hydrolyzed in the small intestine and colon.

Subsequently, during the passage across small intestine and liver, aglycones are converted into their respective metabolites such as glucuronides, sulfoglucuronides, and sulfates, which are distributed at the various cell sites. A considerable quantity can be found in urine (Matsumoto et al. 2004). The deglycosylation of naringenin-7-*O*-β-D-glucoside happens early in the small intestine.

Naringenin-7-*O*-β-D-rhamnoglucosides occur in the colon (Choudhury et al. 1999). Indeed, Felgines et al. (2000) showed the presence of naringenin conjugates within 3 h in the plasma of rats fed with naringenin or its 7-*O*-β-D-glucoside. No naringenin metabolites neither naringenin-7-*O*-β-D-rhamnoglucoside were found. However, in the same work, similar naringenin concentrations after 10 h of ingestion were found regardless of the diet. This evidence demonstrated the delayed intestinal absorption of naringenin rhamnoglucosides.

Naringenin and its glucuronides were found in plasma and brain of rats 10 min after administration of a concentration of 20 mg/kg (Peng et al. 1998). Higher concentrations of naringin were detected in the bile and liver (Tsai 2002). Manach et al. (2003) confirmed that in humans, both naringin and hesperidin are absorbed in the distal part of the intestine, and once deglycosylated, during their transfer from the luminal side of the gut to the portal vein, aglycones are sulfated and/or glucuronated by uridine diphosphate (UDP)-glucuronosyltransferase and sulfotransferase.

Erlund et al. (2001) evaluated the concentration in human plasma of naringenin and hesperetin aglycones after ingestion of grapefruit or orange juice (8 ml/kg body weight). A range of 0.6–6.0 mmol/l with a peak concentration of 6.0 mmol/l for naringenin (from grapefruit juice) and 2.2 mmol/l for hesperetin (from orange juice) was found. A considerable distribution to tissues for both flavanones was suggested (Erlund et al. 2001). Successively, the ingestion of 135 mg of both hesperetin and naringenin under fasting conditions in 6 volunteers resulted in their appearance as metabolites in blood plasma 20 min later. Peak plasma concentration of 2.7 and 7.4 mmol/l for hesperetin and naringenin was reached 4.0 and 3.5 h after ingestion, respectively (Kanaze et al. 2007).

After ingestion of 1 l of orange juice (characterized by a content of 444 mg of hesperidin and 96.4 mg of narirutin), analysis over 24 h led to C(max) values at 1.28 and 0.20 mmol/L for hesperetin and naringenin (after deconjugation), respectively. The levels in urine of flavanones, expressed as percentage of their intake, amounted to 7.9% and 6.4% for naringenin and hesperetin, respectively. The dose not considerably affected the urinary excretion of flavanones (Manach et al. 2003). Generally, naringenin is more bioavailable than hesperetin as resulted by both plasma and urine analyses (Gardana et al. 2007; Kanaze et al. 2007).

The study of Cao et al. (2010) aimed to explain the different efficacy of two Zhi Zhu Wan (ZZW) varieties on the basis on the results of pharmacokinetics of hesperetin and naringenin. ZZW is a Chinese formulation that contains *Atractylodes Rhizome* and *Fructus Citrus Immaturus*, which derived from *C. aurantium* and *C. sinensis*. Although the immature *C. aurantium* and *C. sinensis* fruits showed many common constituents, there are significant differences in their quantity and in the presence of other characteristics compounds (Liu et al. 2008; Wang et al. 2008). These chemical differences reflect the different clinical uses. After oral

administration of *C. aurantium*, both naringenin and hesperetin were detected in plasma and demonstrated similar pharmacokinetic parameters. After oral administration of *C. aurantium*, both hesperetin and naringenin were detected in plasma and showed comparable pharmacokinetic parameters. After oral administration of *C. sinensis*, only hesperetin was detected. Moreover, it was found that the pharmacokinetic properties for hesperetin in *C. sinensis* was different from hesperetin in *C. aurantium*, and it was slowly eliminated. Based on all these results, it can be concluded that hesperetin can be considered the effective compound for both ZZW varieties.

The main plasma and urinary metabolites of aglycones are obtained by glucuronidation and sulfation pathways. Glucuronide metabolites dominate with a percentage of about 87%. However, the importance of the other metabolites should not be neglected (Manach et al. 2003). Hesperetin-7-*O*-β-D-glucuronide, hesperetin-3′-*O*-β-D-glucuronide, hesperetin sulfoglucuronide, and hesperetin diglucuronide are the main metabolites of hesperetin (Matsumoto et al. 2004; Mullen et al. 2008). Naringenin-7-*O*-β-D-glucuronide, naringenin-4′-*O*-β-D-glucuronide, naringenin-4′-*O*-sulfate-7-*O*-β-D-glucuronide, naringenin-4′,7-*O*-disulfate, and naringenin-4′-*O*-β-D-glucuronide-7-*O*-sulfate are the most abundant metabolites of naringenin (Brett et al. 2009; Tripoli et al. 2007).

A good determinant of flavanones intestinal absorption is their ability to permeate of epithelial cells. The faster absorption of aglycones in comparison to glycosides was demonstrated in humans by Miyake et al. (2006) that investigated the mechanism of absorption of eriocitrin and eriodictyol.

The transport of flavonoids across the cell membranes in general imply the presence of ATP-binding cassette (ABC) transporters, present in the enterocytes apical or basolateral membrane, and allow the excretion back into the intestinal lumen or uptake into the blood, respectively. Intestinal ABC transporters related to the flavonoids include breast cancer resistance protein (BCRP), P-glycoprotein, and multidrug resistance proteins. Kobayashi and Konishi (2008) confirmed that the aglycone hesperetin was better absorbed across Caco-2 cell monolayers in comparison to its glycoside hesperidin. The absorption occurs through transcellular passive diffusion and a proton-coupled active transport (Kobayashi et al. 2008). In the same year, Brand et al. (2008) revealed that hesperetin-7-*O*-β-D-glucuronide and hesperetin-7-*O*-sulfate are mainly transported to the apical side in Caco-2 monolayers. Instead, it was demonstrated that hesperetin aglycone is able to permeate the basolateral side of the monolayers of Caco-2 cell line. The results from this work showed that BCRP-mediated transport could be one of the key steps that could limit the bioavailability of hesperetin (Brand et al. 2008). Successively, Brand et al. (2010) analyzed the differences in metabolism and transport, and the activity of separated hesperetin enantiomers in in vitro models by using (i) human intestinal fractions that contain UDP-glucuronosyl transferases or sulfotransferases, (ii) Caco-2 cell monolayers, and (iii) mouse Hepa-1c1c7 cells transfected with human EpRE-controlled luciferase.

These results showed relatively small differences in the metabolism, transport, and activity between (S)- and (R)-hesperetin. This is important for the consideration

that experiments that are performed with commercially available racemic hesperetin may adequately reflect what can be expected for the naturally occurring (S)-hesperetin.

Taking onto account that the bioavailability of healthy compounds may be influenced by the food matrix in which they are to be found, the bioavailability and metabolism of *C. sinensis* juice flavanones, namely, naringenin-7-*O*-rutinoside and hesperetin-7-*O*-rutinoside, and the impact of the ingestion of the juice with a yogurt were studied (Mullen et al. 2008). Human plasma and urine were collected over a 24 h after the consumption of juice (250 mL) with and without of yogurt (150 mL). Juice contains 168 and 12 μmol of hesperetin-7-*O*-rutinoside and naringenin-7-*O*-rutinoside, respectively, paracetamol (1 g) and lactulose (5 g). It was demonstrated that the investigated dairy food matrix may delay the intestinal absorption of both naringenin-7-*O*-rutinoside and hesperetin-7-*O*-rutinoside with no impact on their bioavailability. The role of the dietary matrix (yogurt) on the bioavailability of flavanones was studied in a successive work in which it was demonstrated that the quantity of flavanone metabolites excreted in urine after 24 h of *C. sinensis* juice consumption has reduced about 7 times when the orange juice is ingested with yoghurt (Roowi et al. 2009). Probably, this reduction is due to the alteration of flavanones metabolism by the action of the microflora in the large intestine.

Flavanones demonstrated to be resistant to oxidative reactions, while their isomerization into chalcones was observed mainly for the orange juice. The processing of pasteurization for 30 s at 95 °C, freezing, and concentration of juice showed no effect on the in vitro flavanones bioaccessibility (Gil-Izquierdo et al. 2002). Chalcones were found in higher quantities in industrially pressed juice in comparison to the manually pressed juice.

Spigoni et al. (2017) recently investigated the bioavailability in humans of different metabolites of *Citrus bergamia* (bergamot) phenolics (including flavanones) after juice intake. In particular, the potential use of bergamot in the system of lipotoxicity-induced myeloid angiogenic cells (MACs) impairment was analyzed. MACs play a crucial role in endothelial functionality and repairing processes. However, the lipotoxic effects of some compounds, such as palmitic acid and stearic acid, may decrease these activities. After consumption of bergamot juice, the circulating flavanone metabolites in plasma and urine were assessed. Twelve flavanone phase II conjugates were identified and quantified. Then, the effects at physiological concentrations of hesperetin-7-*O*-glucuronide, naringenin-7-*O*-glucuronide, hesperetin-3′-*O*-glucuronide, and naringenin-4′-*O*-glucuronide were investigated on gene expression of apoptosis and inflammation markers in MACs after exposition to stearic acid. Hesperetin-7-*O*-glucuronide and naringenin-4′-*O*-glucuronide demonstrated to be able to mitigate stearate-induced inflammation in MACs.

Previously, Aschoff et al. (2016) analyzed the bioavailability and the colonic catabolism of flavanones from orange juice by using a dose 2.4-fold higher in comparison to the flavanones from fruits. This choice is due to the consideration that the juice contains flavanones at lower concentrations as compared to the fruits. In this randomized two-way cross-over project, twelve healthy subjects are invited to

consume a meal including either pasteurized juice or fresh fruits, providing 751 and 1774 μmol as total *Citrus* flavanones content, respectively.

Naringenin, deglucuronidated and desulfated hesperetin, and four catabolites, namely, hippuric acid, 4-hydroxyhippuric acid, 3-(3′-hydroxy-4′-methoxyphenyl) propionic acid, and 3-(3′-hydroxyphenyl)hydracrylic acid, were quantitated in 24-h urine.

The urinary excretion of hesperetin as well as postprandial catabolites excretion showed nonsignificant differences after consumption of both orange juice and fruits. In conclusion, the excretion of flavanones after ingestion of orange fruits did not differ from that succeeding at juice consumption, although the use of a 2.4-fold higher dose. Probably, this is due to a saturation of absorption or flavanones entrapment in the matrix of the fruit that is rich in fibers.

At the end of this paragraph, some general considerations are necessary. Numerous studies show marked individual differences in the bioavailability of this class of compounds, due to both molecular factors, including the activity and/or synthesis of enzymes responsible of the biotransformation and transporters, and physiological factors, including gastric motility, body composition, and body weight. Variations have been described for biotransformation enzymes and secretory transporters associated with flavonoids, including uridine diphosphate glucuronosyltransferases, CYP3A4, and P-glycoprotein (Dai et al. 2001; Fisher et al. 2000; Hall et al. 1999; Lown et al. 1995; van der Kolk et al. 2000). Determinant for the bioavailability of flavonoids are also the composition and activity of the gastrointestinal microflora.

8.4 Bioactivities of *Citrus* Flavanones: *Animal Experiments*

Flavanones extracted from *Citrus* fruits are involved in many essential physiological functions: as an antioxidant, anti-inflammatory, and antitumor activity (Table 1). They are able to counteract the endogenous and exogenous biological stimuli. They can also reduce cholesterol and triglyceride levels in experimental animals (Jeon et al. 2007; Habauzit et al. 2011; Horcajada et al. 2008).

Citrus flavanones also possess antioxidant activities, although these activities are poorer in respect to many other polyphenols (Jeon et al. 2002). Their anti-inflammatory, antitumor, anti-atherogenic properties cannot be explained solely based on their antioxidant properties. Investigations of their mechanism of action suggested that they can act as free radical scavengers and, also, modulate cellular signalling processes or may themselves serve as signalling molecules.

Several animal studies have been published during the past few years (Acquaviva and Iauk 2010; Nijveldt et al. 2001; Ross and Kasum 2012). A lot of attention has been paid to the anticarcinogenic properties of flavanones. In particular, hesperidin has been shown to inhibit mammary, urinary bladder, and colon carcinogenesis in laboratory animals (So et al. 1996; Yang et al. 1997; Tanaka et al. 1997; Miyagi et al. 2000).

Flavanones may act with different mechanisms of action, such as inhibiting carcinogen activation, stimulating carcinogen detoxification, scavenging free radical species, controlling cell cycles, inhibiting cell proliferation, inducing cellular apoptosis, and inhibiting angiogenesis, metastasis, and growth factors activity.

Nandakumar and Balasubramanian (2011) have investigated the antigenotoxic activity of hesperidin and have demonstrated that the daily administration of this compounds (30 mg/kg BW) for 45 days prevented 7,12-dimethylbenz(α)anthracene (DMBA)-induced experimental breast cancer formation. Probably this effect is due to the regulation of both phase I and phase II metabolizing enzymes and due to its strong antioxidant activity.

In addition, in vivo studies have shown that naringenin could suppress the early stage of colon cancer by attenuating inducible nitric oxide synthase (iNOS) and cyclooxygenase 2 (COX-2) levels in carcinogen-injected rats (Leonardi et al. 2010). It is known that inducible iNOS is another enzyme that plays a pivotal role in mediating inflammation. Therefore, the anti-inflammatory effect of flavanones may be due both to their antioxidant activity and to their effect on enzymes involved in the inflammatory cascade.

It was demonstrated that phenolic compounds present in the juice of blood oranges might prevent lipid peroxidation and the formation of atherosclerotic plaques (Acquaviva and Iauk 2010; Sorrenti et al. 2004). Hesperidin and naringenin also act on lipid metabolism; in fact, they are able to regulate the apolipoprotein B secretion by HepG2 cells, probably through the inhibition of cholesterol ester synthesis, and to inhibit 3-hydroxy-3-methylglutaryl-coenzyme A reductase and acyl coenzyme A cholesterol O-acyltransferase in rats (Lee et al. 1999a, b).

Moreover, a decrease in serum LDL and hepatic cholesterol levels was observed in rabbits fed with a cholesterol-rich diet and supplemented with orange juice (Kurowska et al. 2000).

An increase in high-density lipoprotein levels has been shown in hypercholesterolemic patients who consumed orange juice (Erlund 2004). Other biological activities attributed to naringenin and hesperidin include antidiabetic properties.

It is known that peroxisome proliferator-activated receptor gamma (PPARγ) plays a critical role in peripheral glucose homeostasis and in modulating insulin sensitivity. PPARγ induces glucose uptake by directly or indirectly increasing the transcription of genes encoding proteins such as GLUT4. The partial antagonism, exerted by flavanones, may be useful in improving insulin sensitivity (Vinayagam and Xu 2015). Recently, it was demonstrated that a 4-week diet-based administration of hesperidin (10 g/kg), in streptozotocin (STZ)-induced diabetic type 1 rats, induced a decrease of blood glucose compared to nondiabetic rats. In addition, hesperidin did not influence both bone metabolism and body weight in diabetic rats. Moreover, the antidiabetic effect of hesperidin may be due to its ability to inhibit pancreatic damage, thanks to its antioxidant activity, increasing insulin secretion and consequently decreasing glucose levels, and altering glycogen contents in the diabetic tissues by the improvement of glycolytic and gluconeogenetic enzymes (Akiyama et al. 2010). In addition, several studies showed that also naringenin possesses an insulin-mimetic effect; naringenin, in fact, is able to decrease blood glucose levels in healthy male Wistar rats (Vinayagam and Xu 2015). In particular, the oral administration of naringenin (25 mg/kg bw) for 45 days exerts a significant inhibition of intestinal α-glucosidase activity in diabetic rats induced by streptozotocin (STZ). This effect delays the absorption of carbohydrates with a consequent significant decrease in postprandial glycemic levels. Moreover, naringenin treatment, in diabetic rats, improved GLUT-4 and induced 5′ adenosine monophosphate-activated protein kinase (AMPK) activation, that increases glucose tolerance and insulin sensitivity, while at the same time decreasing TNF-α expression and ALT, AST levels in the serum, preventing STZ-induced liver damage in rats (Priscilla et al. 2014, 2015).

Scientific research has shown that flavanones can provide benefits in the prevention and treatment of metabolic diseases due to their antioxidant activity and their ability to modulate the expression of some proteins involved in hyperglycemia and hyperlipidemia.

It is reported that flavanones possess neuroprotective effects against various types of insult associated with neurodegenerative diseases, including Parkinson and Alzheimer diseases.

The neuroprotective activity of the *Citrus* flavanones may be due to their capacity to cross the blood-brain barrier and to arrest free radical-induced oxidative damage, which is known to play a pivotal role in many degenerative diseases. Antunes et al. (2014) have demonstrated that hesperidin mitigated both the increased levels of ROS and the activity of glutathione reductase induced by 6-hydroxydopamine.

Moreover, their neuroprotective action is mediated by the interaction with specific intracellular targets that are implicated in several signalling pathways important for maintaining the cellular homeostasis. Naringin is able to counteract the degeneration of the nigrostriatal dopaminergic (DA) projection by increasing the level of glia-derived neurotrophic factor (GDNF) in nigral DA neurons, with a concomitant activation of mammalian target of rapamycin complex 1 (mTORC1) (Leem et al. 2014). Moreover, naringin exerts its anti-inflammatory activity in CNS mitigating the increase of TNF-α induced by 1-methyl-4-phenylpyridinium (MPP+) in microglia (Leem et al. 2014).

Li et al. (2015) demonstrated that the pre-treatment with hesperidin (100 mg/kg body weight) for 10 days recovered deficits in non-cognitive nesting capability and social interaction and attenuated Aβ deposition, plaque-associated amyloid precursor protein (APP) expression, and microglial activation and TGF-β1 immuno-reactivity in both cerebral cortex and hippocampus of transgenic APP/PS1 APP/PS1 mice. Certainly further clinical studies must be performed to validate the neuroprotective activities of the flavanones.

8.5 Benefits (Human Studies)

Citrus flavanones have shown many interesting effects in vivo and in vitro models, including antioxidant properties, cholesterol and triglycerides reduction, cell proliferation and angiogenesis inhibition, estrogenic activity, nitric oxide (NO) level modulation, and decrease of lymphocyte immobilization and platelet aggregation (Bellocco et al. 2009; Barreca et al. 2009; Codoner-Franch and Valls-Belles 2010). Instead, their effectiveness in humans remains controversial because of both the intersubject variability in flavanones pharmacokinetics and the chemical transformation carried out by gut microbiota that in turn influences their absorption and biological activity as well.

Citrus healthy properties are mostly related to their antioxidant capacity. However, in healthy subjects, *Citrus* flavanones do not have significant antioxidant effects, suggesting that their antioxidant potency is negligible in normal conditions (Testai and Calderone 2017). Conversely, they can improve endogenous antioxidant

defense in non-healthy individuals, allowing a reduced risk of certain chronic diseases and the prevention of some cardiovascular disorders as well as certain kinds of cancer (Tomás-Navarro et al. 2014).

Rangel-Huerta et al. (2017) demonstrated that the consumption of an orange juice with a high content of flavanones improves oxidative stress and inflammatory biomarkers by decreasing the serum levels of hydroxyoctadecadienoic acid (9-HODE+13-HODE) and dihydroxyoctadecanoic acid (12,13-DiHOME and 9,10-DiHOME), as well as increasing the levels of 12-hydroxyeicosatetraenoic acid (12-HETE) compared to normal flavanones juice in 30 subjects from the BIONAOS study (Biomarkers In Overweight And Obese Adults).

Moreover, *Citrus* flavanones also have anti-inflammatory properties, mainly hesperetin, naringenin, and their glycosylated derivatives (Barreca et al. 2017). These molecules are capable of regulating cellular inflammation process, due to their antioxidant properties, but also by interacting with key enzymes (such as protein kinase, phosphodiesterase, lipoxygenase, cyclooxygenase, and phospholipase), inhibiting arachidonic synthesis, downregulating of NFkB activation and consequently of pro-inflammatory cytokines (TNF-a, IL-6, and IL-1), chemokines, COX-2, and iNOS (Tomás-Navarro et al. 2014; Bodduluru et al. 2016). Results of in vivo research and clinical trials support their use as compounds readily available at a low cost without any side effects or intolerance.

8.5.1 Cardiovascular Disease and *Citrus* Flavanones

Cardiovascular diseases (CVD), including myocardial infarction, coronary heart disease, strokes, cardiomyopathy, and other heart disease, are one of the leading causes of morbidity and mortality in worldwide. Epidemiological, clinical, and preclinical studies have deeply analyzed the relationship between *Citrus* flavanone intake and the risk of cardiovascular disease (Hollman et al. 2010; Testai and Calderone 2017). Their results suggest that *Citrus* flavanones prevent cardiovascular disease positively influencing some cardio-metabolic parameters (He et al. 2006; He et al. 2007; Gan et al. 2015) that are the main risk factors of CVD, such as hypertension, dyslipidemia, overweight, and hyperglycemia.

A number of sources suggest the cardioprotective activity of hesperidin and its aglycone form, hesperetin in particular (Barreca et al. 2017). A prospective study carried out on approximately 10,000 Finnish men and women reveals a 20% reduction in cerebrovascular diseases in those who consumed the highest levels of flavanones (4.7–26.8 mg aglycone/day) (Knekt et al. 2002).

A significant inverse correlation between flavanone consumption and cerebral ischemia has been found in women who consume high levels of flavanones (>63 mg/day) *versus* low levels (<13.7 mg/day) (Cassidy et al. 2012). Moreover, a systematic review and meta-analysis of prospective cohort studies reported that flavonoids intake, especially of flavanones, was associated with a decreased risk of cardiovascular disease ($p = 0.002$) (Wang et al. 2014).

Many clinical trials have focused their attention on modulation of CDVs risk factor by *Citrus*.

A meta-analysis of three randomized clinical trials, including 233 patients, demonstrated a correlation between grapefruit intake and a reduction in systolic blood pressure and waist circumference in overweight and obese adults (Onakpoya et al. 2017). In general, these effects of flavanones on hypertension, particularly naringenin and hesperetin, are due to improvement of vasodilation and endothelial function (Salehi et al. 2019) through endothelial production of NO and activation of voltage-operated calcium channels and potassium currents (Liu et al. 2014).

Metabolic syndrome, characterized by altered glucose metabolism, elevated blood pressure, dyslipidemia, and obesity is one of the main cardiovascular risk factor. A cohort clinical trial performed on 10,000 Polish subjects reveals that habitual consumption of flavonoids, among which flavanones, reduces the incidence of metabolic syndrome (Grosso et al. 2017).

Rizza et al. (2011) carried out a clinical trial of 3 weeks on 28 subjects with metabolic syndrome demonstrating that hesperidin (500 mg/day) reduces E-selectin expression, cholesterol, and ApoB level and induces enhancement of NO levels.

Intake of 300 mL of fruit juice (containing 95% of *Citrus* flavonoids) produces no variations of glucidic parameters but improvement of lipidic panel, with decrease in the cholesterol, LDL-C and C-reactive peptide levels, in subjects with metabolic syndrome ($n = 33$) compared with healthy subjects ($n = 20$) in a clinical trial of 4 or 6 months (Mulero et al. 2012).

High level of lipoprotein and cholesterol in plasma as well as hyperinsulinemia and hyperlipidemia led to development of atherosclerosis with the plaque formation in arteries, which is a gateway for cardiovascular diseases. Among flavanones, naringenin is the most effective to decrease triglycerides and LDL-C and inhibit glucose uptake as well. On the contrary, it promotes the improvement of high-density lipoprotein (HDL-C) level and antioxidant defenses, decreasing atherosclerosis-related genes expression (Orhan et al. 2015). These effects can be due to molecular structures characterized by the presence of a hydroxyl mevalonate moiety resembling that of statins, a drug able to inhibit cholesterol biosynthesis (Barreca et al. 2017).

Clinical evidences show that 400 mg/day of naringenin administrated for 2 months causes a reduction of the LDL-C, cholesterol and ApoB levels and an increase in HDL-C levels and detoxifying enzyme only in hypercholesterolemic subjects ($n = 30$) (Jung et al. 2003).

In addition, bergamot fruit shows anti-cholesterolemic properties both in animal and human studies (Cappello et al. 2016; Constans et al. 2015). A *C. bergamia* extract (Bergavit® containing 150 mg of flavonoids with 16% neoeriocitrin, 47% neohesperidin and 37% naringin) reduced cholesterol levels and improved lipidic and lipoproteic panel in mild hypercholesterolemic patients ($n = 88$) (Toth et al. 2016).

The results from clinical trial are controversial. In fact, Morand et al. (2011) observed no difference in fasting glucose, insulinemia, total cholesterol, LDL cholesterol, HDL cholesterol, and triglycerides in 24 overweight subjects after

drinking juice contained 292 mg of hesperidin and 47.5 mg of narirutin for 4 weeks. This flavanone combination, instead, reduced pressure parameter (4 mmHg), ameliorated postprandial microvascular reactivity, and some biomarkers of oxidative stress. Similar results have been obtained with a combination of naringin and hesperidin (500 mg plus 800 mg) in a randomized controlled study that saw 4 weeks of treatment involving moderately hypercholesterolemic patients. These findings, according to some authors, could be related to the difference in individual pharmacokinetic parameters.

Several clinical trials have demonstrated the positive effect of *Citrus* flavonoids in the reduction of cardiovascular risk factors. Although some of the mechanisms responsible for the beneficial effects of *Citrus* flavanones on the cardiovascular system are unclear, the nutraceutical value of these fruits in cardiovascular disease therapy should be considered as valid approach.

8.5.2 Diabetes and *Citrus* Flavanones

Type 2 diabetes mellitus (T2DM) represents a worldwide health problem and is a chronic, progressive disease characterized by elevated blood glucose levels and insulin resistance.

Chronic hyperglycemia causes complications, such as cardiovascular disease, diabetic retinopathy, renal dysfunction, and leg ulcers (Marathe et al. 2017). A healthier diet plays a key role in the T2DM prevention as suggested by various epidemiological studies (Schwingshackl et al. 2017). Nutraceutical products from plants have been reported to reduce hyperglycemia and lipid disorders in individuals with T2DM or with a predisposition to T2DM (Kaleem and Ahmad 2018).

Among *Citrus* flavanones, naringin and naringenin have been shown to control diabetes and its related complications in animal and cell studies by improving glucose tolerance and insulin sensitivity but also reducing plasma and/or hepatic cholesterol and triglyceride levels (Assini et al. 2013; Sharma et al. 2015).

A nutraceutical product rich in *Citrus* flavanones, limonoids, and tocotrienols (Diabetinol®) showed a significantly reduced peak hyperglycemic response, TC, and LDL-C levels and decreased HbA1c levels after 3 months supplementation in subjects with mild impaired fasting glucose (Judy et al. 2010). Similarly results have been achieved in subjects with greater severity of impaired fasting glucose ($\leq$15.4 mmol/L) in a 24-week, randomized, double-blind, placebo-controlled, parallel study carried out by Evans (Evans et al. 2015).

Ethanol extracts of *C. junos* (yuja) peel (YE) contain naringin, hesperidin, rutin, quercetin, and tangeretin, showing antidiabetic properties in animal models (Kim et al. 2013), and have been assayed by individuals with impaired fasting glucose (IFG) in an 8-week, randomized, double-blinded, crossover, placebo-controlled clinical trial. The authors reported that YE significantly reduced fasting plasma glucose levels, fasting plasma insulin, postprandial glucose, and c-peptide and homeostatic model assessment-insulin resistance compared to the placebo group (Hwang et al. 2015).

A body of evidence suggests that oxidative stress is a main mechanism in pathogenesis of diabetes. Bonina et al. (2002) evaluated some serum oxidative stress biomarkers in T2DM patients ($n = 33$) who took ROC supplement (50 mg/d, orally) for 2 months. They observed an oxidative stress improvement characterized by high levels of free thiol groups and reduced concentration of serum free radical. In addition, the glycemic profile remained stable in all subjects for the whole period, and the total antioxidant status was unmodified by ROC administration.

Despite the numerous preclinical studies demonstrated the useful of *Citrus* flavanones in diabetes, further human studies focused on dosage, bioavailability, efficacy, and safety are required.

8.5.3 Cancer and *Citrus* Flavanones

A growing amount of literature data evidences that the risk of cancer can be reduced with a diet rich in vegetables and fruits (Boffetta et al. 2010). Some epidemiological studies reported that *Citrus* fruit consumption is protective against a variety of human cancers. *Citrus* fruit exerts this chemopreventive action through the protection of DNA from injury and the inhibition of the early phase of carcinogenesis by promotion of xenobiotic detoxification process.

A recent review of Italian and Swiss case-control studies (10,000 cases of 14 different cancers and about 17,000 controls) has shown that the high consumption of *Citrus* fruit is associated with a reduced risk of cancers of the digestive tract and larynx (Turati et al. 2015). Previously the analysis data from a series of case-control studies regarding *Citrus* fruits intake and risk of several types of cancer has found that the ORs for the highest versus lowest category of *Citrus* fruit consumption varied from 0.42 to 0.82 for esophageal, oral cavity, pharyngeal, laryngeal, stomach, and colorectal cancer. Instead, the authors have found no consistent association with breast, endometrial, ovarian, prostate, and renal cell cancer. This observed protective effect against cancers of digestive and upper respiratory tract is linked to the content on flavanones, vitamin C, and other compounds with antioxidant, antimutagenic, and antiproliferative properties contented in *Citrus* fruit (Foschi et al. 2010). In addition, the meta-analysis done by Bae and Kim confirm the association between intake of *Citrus* fruit and gastric cancer risk evidencing a 13% reduction of gastric cancer. In particular, the authors reported that 100 g of *Citrus* fruit intake per day inhibits cardia gastric cancer by 40% (Bae and Kim 2016). *Citrus* flavanones such as naringin, hesperidin, and 20-hydroxyflavanone (2HF) also have antitumor activities. They inhibit tumor growth and promote cancer cell apoptosis through cell cycle arrest and caspase-activation induced by either death receptors or mitochondrial pathways, as demonstrated by both in vitro and in vivo studies. All these studies show the potential anticancer activity of *Citrus* flavanones even if presently no clinical studies support these findings and the current intake of *Citrus* fruits is insufficient to induce apoptosis of cancer cells in humans.

8.5.4 Neurodegenerative Disease and *Citrus* Flavanones

Neurodegenerative disorders including Alzheimer's, Parkinson's, amyotrophic lateral sclerosis, and Huntington's disease are debilitating, incurable diseases that are becoming increasingly prevalent (Wyss-Coray 2016). Much attention is paid to dietary supplementation for maintaining cognitive function in old age and delaying the onset of neurodegenerative diseases. Epidemiologic studies reveals that higher intakes of flavonoids over 10–15 year are associated with a reduced rate of cognitive decline in old age (Kesse-Guyot et al. 2012; Letenneur et al. 2007).

Most of the human studies focused on flavanols and anthocyanins (Krikorian et al. 2012), while few researches have been performed with flavanones, even though they are the main components of the most commonly consumed juices and also are easily absorbed and cross the blood-brain barrier (Manach et al. 2005). A cross-sectional epidemiologic survey of 1091 men and women born in 1936 reported a positive association between flavanone consumption and crystallized intelligence (Butchart et al. 2011). Kean et al. (2015) carried out a controlled, placebo-matched, crossover, randomized, double-blind human-intervention trial on healthy older adults ($n = 37$) that drunk daily a flavanone-rich orange juice (305 mg) for 8 weeks. They reported an improvement of global cognitive function compared to low-flavanone control, while no difference in mood and blood pressure was observed. These findings underlined that constant daily flavonoid intake provides cognitive benefits not only to adults with mild cognitive impairment or neurodegenerative disease but also to healthy older adults. Up to date, no human studies provide data to support possible mechanisms that underlie positive cognitive effects of flavanones. Future research should be conducted to clarify the potential role of flavanone-based dietary supplementation to maintain and increase cognitive function in healthy young adults and mitigate cognitive impairment in older adults with neurodegenerative disease.

8.6 Application in Food

Many *Citrus* fruits, including particularly orange, clementine, tangerine, and grapefruit, are eaten fresh, unlike more acidic fruits such as limes and lemons that are generally not eaten fresh. In fact, generally, lemonade or limeade are beverages that are prepared by diluting derived juices and by adding sugar. *Citrus* juices and rinds are used in different drinks. The colorful peel of some *Citrus* fruits is used in cooking as a flavoring.

Although the consumption of *Citrus* fruits is reported since ancient times, *Citrus* processing was not possible until the development of both thermal and concentration processes. Since then, the *Citrus* industry has quickly developed, becoming soon prominent among food industries. Now, the *Citrus* industry is the second largest fruits processing industry, after the grape industry that principally produces wine. Approximately 30% of *Citrus* fruits is processed to obtain juice.

The variation of *Citrus* flavanones content in beverages and foods is dependent on different factors including *Citrus* species and cultivar, growth conditions, fruits' ripeness, postharvest processing, cooking process, and storage conditions.

Cooking processes, including boiling, baking, frying or microwave, are responsible of numerous changes in physical characteristics and chemical composition of food matrix (Zhang and Hamauzu 2004). Ismail et al. (2004) found that thermal treatment decreased the total phenolic content in food matrix. Previously, Gil-Izquierdo et al. (2002) analyzed some processes used for the production of orange juice at industrial scale, namely, mild and standard pasteurization, concentration, freezing, and squeezing. Moreover, commercial squeezing was compared with domestic squeezing in order to evaluate the influences of these processes on orange juice composition. Taking into consideration flavanones, mild and standard pasteurization processes did not influence the flavanones content. A slight decrease of flavanones content in the soluble fraction was proved. Only didymin decreased with a percentage of 52%.

The freezing process produced a considerable decrease of flavanones content in the soluble fraction. Comparing commercially and domestically squeezed orange juice, commercial squeezing gives a major content of flavanones than domestic squeezing. In agreement with this study, Moura and de Sylos (2009) analyzed samples of tangor murcott and orange juice (a mixture of Valencia and Pera varieties) and evidenced that pasteurization and concentration processes of juice did not affect significantly the amount of flavones hesperidin and narirutin.

The flavanone hesperetin is used as food enhancer and sweetener in a wide variety of dessert and alcoholic beverage (Ley et al. 2005).

Naringin is listed in Commission Decision 1999/217/EC establishing a register of flavoring substances in application of Regulation EC 2232/96, allowing its use in food without restriction. It has been subsequently evaluated by EFSA Scientific Panel on Food Contact Materials, Enzymes, Flavourings and Processing Aids (CEF) in the Flavouring Group Evaluation 32 (EFSA 2011) with an interim finding that it is considered safe for use in food but that more data on human intake is desirable. A further possible application of naringenin in food matrix regards the inhibition of genotoxic compounds produced at 100–180 °C in particular acrylamide, which is dangerous for human health (Cheng et al. 2009). More than 30 years ago, Horowitz and Gentili (1971) reported that the peels of oranges and lemons contained a number of compounds, which could be converted into sweeteners.

8.7 Safety: Toxicity and Side Effects

Numerous studies demonstrated as *Citrus* flavanones are safe and well tolerated. Among these, particularly naringenin and hesperidin are investigated.

EFSA Scientific Panel on Food Contact Materials, Enzymes, Flavourings and Processing Aids (CEF) has assessed naringin in 2010 as a food flavoring. Data from chronic oral feeding studies in rats showed that naringenin up to 5 mg/kg complete feed is safe with an appreciable margin of safety.

Based on mammalian studies, only transient amounts of naringin and its metabolites residues in animal tissues are to be expected. This would represent an unimportant contribution to human exposure. Therefore, the use of the flavanone in animal's nutrition is evaluated safe for the consumer. However, the EFSA's panel on additives and products or substances used in animal feed (FEEDAP) could not conclude on the safety and efficacy of the product when delivered in water for drinking because related data are not available (EFSA 2011).

Li et al. (2014) investigated the potential chronic toxicity in Sprague-Dawley (SD) rats of naringin by oral gavage for 6 months followed by a recovery period of 1 month at doses of 0, 50, 250, and 1250 mg/kg. During both these periods, no mortality and/or toxicologically substantial variations in hematology, biochemical analyses, organ weights, ophthalmology, serum sex hormone, and histopathological and macroscopic examinations were reported. A slight, reversible, and non-pathological hair loss was observed during the treatment. However, it was not considered to be of toxicological importance. Overall, the obtained results demonstrated that the levels with no adverse effects of naringin, when orally administered in rats for 6 months, are greater than 1250 mg/kg/day.

Several animal and human studies have been reported that hesperidin is safe and well tolerated (Meyer 1994). The hesperidin safety was demonstrated on patients with rheumatoid arthritis administered 3 g of glucosyl hesperidin (G-Hsd) every morning for a 3-month treatment (Kometani et al. 2008). In another work, 94 menopausal women had a daily intake of 0.9 g of hesperidin with 0.3 g of hesperidin methyl chalcone and 1.2 g of vitamin C for 1 month (Smith 1964).

One of the most popular formulation containing hesperidin is Daflon 500 mg. This formulation has been analyzed in animals and humans trials (Meyer 1994). In animal studies, the safety of Daflon 500 mg is demonstrated by (i) a LD_{50} (lethal dose 50) of 3 g/kg, that is, 180 times the daily therapeutic dose, and (ii) by the absence of toxic effects after repeated oral dosing for 13 and 26 weeks, using a dose that represents 35 times the daily dosage in the rat and primate, respectively. The passage into breast milk and the transplacental passage are negligible. Clinical trials have collected more than 2850 patients treated with Daflon 500 mg at the dosage of 2 tablets/day for the period 6 weeks–1 year and satisfied the international scientific requirements. Side effects are essentially of a gastrointestinal or autonomic nature. Hemodynamic parameters as well as laboratory parameters were uninfluenced even by prolonged treatment for 1 year. Satisfactory clinical acceptability already confirmed in the short term was equally found in long-term treatment.

In animal studies, the concomitant administration of hesperidin with β-adrenergic blocking agents, calcium channel blockers, or statins significantly changed the maximal plasma concentration and the absorption of these drugs (Cho et al. 2009; Piao and Choi 2008; Uesawa and Mohri 2008).

In the study of Cho et al. (2009) the effects of hesperidin on the bioavailability and pharmacokinetic parameters of diltiazem and its desacetyldiltiazem (its main active metabolite) in rats, were investigated. Diltiazem (15 mg/kg) was orally administered in the presence or absence of hesperidin (1, 5 or 15 mg/kg), administered 30 min before the calcium channel blocker. Compared with the control group,

hesperidin (at doses of 5 or 15 mg/kg but not at 1 mg/kg) considerably modified the pharmacokinetics of diltiazem. Hesperidin (15 mg/kg) significantly increased the C (max) of desacetyldiltiazem but not significantly modified the desacetyldiltiazem metabolite-parent *ratio*. In conclusion, data from this work demonstrated the ability of hesperidin to enhance in rats the bioavailability of diltiazem probably by increasing its absorption and by reducing its first-pass metabolism in the intestine and in the liver via inhibition of cytochrome P450 3A or P-glycoprotein.

8.8 Marketed Products

Greater attention to health and social changes has led to the growth of the natural products market not only in the pharmaceutical and nutraceutical sectors but also in the food sector in Europe and in United States. This growth trend has been facilitated by the updated Novel Food legislation that makes easier for exporters to introduce new products. Sustainability in terms of reutilization of plant and food by-products is still a strong trend, demanded by companies as well as consumers (https://www.cbi.eu/market-information/natural-ingredients-health-products/trends/).

Citrus fruits represent a rich source of nutrition and vitamins and are important additions to any diet lacking in this components. *Citrus* are one of the key products in both food and beverage. Due its high nutritional value, *Citrus*-derived compounds could be used in innovative health functional food and beverage. Among *Citrus* flavanones, hesperetin, naringenin, eriodictyol, isosakuranetin, and their glycoside are the main abundant compounds. The *Citrus* flavanones are marketed individually or in the form of a mix, as nutraceuticals, since they act synergistically with the vitamin C to neutralize free radicals and counteract oxidative stress. The biological activities of *Citrus* flavanones are thought to be particularly beneficial for capillary strength, probably due an action on collagen (Kawaguchi et al. 2006). For this reason, these supplements are used in treatment of venous diseases such as chronic venous insufficiency, varicose veins, spider veins, and hemorrhoids (Mastantuono et al. 2015).

Moreover, hesperidin and naringenin are natural aromatase inhibitors. This activity is linked to a reduction in estrogen circulation that inhibited platelet aggregation and positively affect blood-clotting mechanisms which reduces the risk of cardiovascular disease. Bioflavonoids from *Citrus* possess also powerful anti-inflammatory properties (Benavente-García et al. 1997).

Recently, a researcher demonstrated the effect of naringenin on metabolic syndrome and obesity (Alam et al. 2014). Consequently, food supplements based on these bioactive compounds have been developed for this specific indication. Although the optimum daily doses of *Citrus* flavanones have not been determined, the label of nutraceutical products recommend 2000–6000 mg of these compounds for adults each day. This dose take into account the low toxicity of flavanones and the rare occurrence of side effects following their intake (Panche et al. 2016).

In food industry, hesperetin was used to fortified foods. A recent study proposed the nano-incapsulation of this flavanone in nanostructure lipid carriers coated with

different biopolymers such as alginate, chitosan, and low methoxypectin. Physico-chemical and sensorial analysis evidenced that developed nanoparticles could be applied for milk fortification to mask flavanone bitterness, inhibit color change, and enhance its solubility (Fathi and Varshosaz 2013). Further studies are necessary to identify other possible applications in food and nutraceutical industries.

8.9 Patents

The available information on patents was collected from some databases such as Espacenet (European Patent Office), Google Patents, and SciFinder. The research focuses on *Citrus* flavanones alone or as active ingredient in formulations used for the treatment of several pathological conditions. The search was performed in January 2019. The used keywords were: *Citrus* flavanones, naringenin, hesperetin, hesperidin, didymin, eriodictyol, neoeriocitrin, neohesperidin, poncirin, didymin, eriocitrin, and narirutin. A very high number of patents was found. For this reason, the research was limited to the last year (2018). After the removal of duplicated patents, the documents found were processed individually in an attempt to classify them based on the date and purpose for which they were registered (Table 2). Most of the patents found for the year 2018 do not concern single flavanones but are related to extracts or to mixtures of compounds (including flavanones) or to formulations in which are present flavanones.

Most of the patents have been designed and registered with the purpose of creating new products and formulations with specific biological activities. In particular, products with anti-inflammatory, and neuroprotective activity, products useful for the prevention and/or treatment of dermatitis, and skin damage caused by radiation and for repelling mosquitoes were prepared. Instead, fewer patents are present with regard to extraction and identification techniques. Among these, the patent CN108490094A reported the method for the determination of 22 flavonoids and phenolic acids in *Citrus* fruits.

8.10 Future Perspectives

Being *Citrus* flavanones daily present in the diet, their impact on human health is of relevance.

Extensive studies were carried out in order to investigate their ability to promote health and to provide protection against chronic diseases with high social impact including cardiovascular diseases, diabetes, and obesity. Among these compounds, particularly hesperetin, hesperidin, naringenin, naringin, and eriodictyol are mainly investigated.

In this chapter, we summarized and analyzed data related to the bioactivity of *Citrus* flavanones, their bioavailability and metabolism, their application in foods, marketed products, and safety.

Table 2 Patents overview of *Citrus* flavanones in 2018

Title	Date	Patent no.	Application no.	Use
Co-crystal of isoniazid and naringenin and preparation method of co-crystal	2018-09-28	CN 108586332A	CN 201810359523	Improvement of naringenin solubility and isoniazid activity
Application of naringenin and derivatives in the prevention and treatment of Alzheimer's disease	2018-11-13	CN 108785301A	CN 2018-11042921	Neuroprotective
Application of naringenin and naringin in tumor radiotherapy	2015-09-30	CN 104940932A	CN 2015-10404716	Tumor radiotherapy
Flavonoids pharmaceutical compositions and preparations and applications	2018-10-26	CN 108704037A	CN 2018-10626248	Prevention and treatment of dermatitis and skin damage caused by radiation
Mosquito repellent liquid	2018-04-21	CN108391665A	CN 201810363142	Repelling mosquitoes
Antibacterial coating and preparation method of green	2018-09-21	CN108559343A	CN 201810445336	Antimicrobial
Method for the determination of 22 *Citrus* fruit flavonoids and phenolic acids species	2018-09-04	CN108490094A	CN 201810274708	Compounds determination
Naringin microsphere silk fibroin/ hydroxyapatite composite scaffold and preparation method	2018-06-15	CN108159502A	CN 201810184370	Application to bone defect areas of different shapes
Application of naringin to preparation of medicine for treating and delaying intervertebral disc degeneration	2018-07-13	CN108272812A	CN 201810122205	Treating and delaying intervertebral disc degeneration
Such compositions and their use in the preparation of anti-inflammatory drugs	2018-09-04	CN108478549A	CN 201810497584	Anti-inflammatory

The available data from animal models and clinical trials together with epidemiological studies suggest that this class of phytochemicals may beneficially affect both aetiology and physiopathology of several diseases. However, despite the ever-increasing number of studies on this flavonoids class, their health effects are still unknown or partially known. This is due to various reasons: (a) often interpretation of results from performed studies is problematic, because several different mechanisms and pathways may be involved; (b) serum biomarkers together with data from dietary intake could be used when studying the biological properties of *Citrus* flavanones; (c) clinical studies that investigate both high and low doses of *Citrus* flavanones are warranted; (d) bioavailability of each compound of a mix should be monitored, because marked interindividual variation could confound results; and (e) information about daily intake and bioavailability needs to be more fully developed.

Abstract

Chalcones are plant-derived polyphenolic compounds commonly found in edible plants such as tomatoes, apples, licorice, and fingerroot. The molecular structure of two aromatic rings connected by three carbons with conjugated carbonyl group and double bond results in the yellow or orange color of chalcones. The compound is biosynthetically available through chalcone synthase pathway and structurally related to flavanone and anthraquinone. A wide range of biological activities were found to be associated with natural chalcones from food and these activities havebeen proven to be contributed by the keto-ethylenic group in the main structure of chalcones. The biological activities reported include antioxidant, antimicrobial, anticancer, anti-inflammatory, antihypertensive, antidiabetic, anti-obesity, anti-neuroprotective, and hepatoprotective effects. Moreover, these chalcones have excellent profile in terms of food safety by showing non-toxicity against normal cells through a number of animal and human clinical studies. The overall beneficial effects of chalcones revealed that these compounds are highly nutritious and safe to be consumed, as well as highly potential lead compounds to be further developed into alternative drugs to treat various diseases.

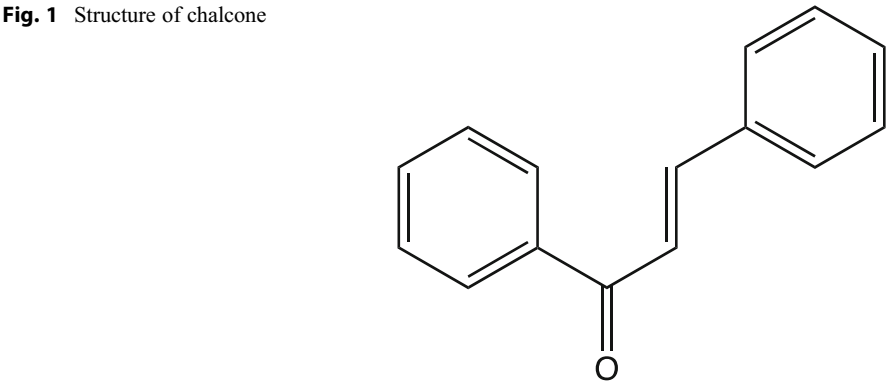
Keywords

3-Diphenyl-2-propen-1-one · Naringenin chalcone · Phloretin · Phloridzin · Isoliquiritigenin · Licochalcone · Cardamonin · Panduratin A

9.1 Introduction

Chalcone is a naturally derived compound present abundantly in edible plants, including vegetables, fruits, spices, and teas. It is widely distributed in various parts of the plant, including roots, rhizomes, leaves, and seeds. Examples of food sources that contain plenty of chalcones are tomato, apple, licorice, fingerroot, kava, wax jambu, and ashitaba leaves. These compounds are usually present as yellow or orange pigments in plants due to conjugated bonds in their structures. The word "chalcone" was first introduced by Kostanecki and Tambor in 1899 based on their discovery of mono-oxychalcone (Kostanecki and Tambor 1899). Chalcones are prominent secondary metabolites and serve as important precursors in the biosynthesis pathway of flavone-based compounds such as flavonoid and anthraquinone. As shown in Fig. 1, it has a unique core chemical structure, which is made up of two aromatic rings connected by a three-carbon linker consisting of α, β-unsaturated carbonyl group (–C=O–CH=CH–). As such, it possesses conjugated double bonds and delocalized π-electron system in the two rings and has a systematic IUPAC name of 3-diphenyl-2-propen-1-one. Chalcone has the tendency to exist in either *cis*- or *trans*-configuration due to the presence of double bond in the structure and is nearly planar in shape. The structure of chalcone as described gives rise to several alternative names such as benzylidene acetophenone, benzyl acetophenone, and *β*-phenylacrylophenone.

Fig. 1 Structure of chalcone



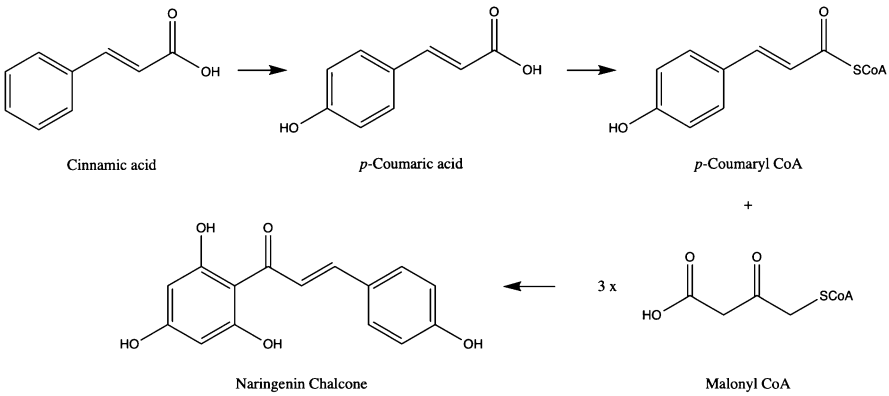


Fig. 2 Chalcone synthase reaction

The interesting scaffold of chalcones in terms of its core chemical structure has attracted numerous researchers worldwide to study on their derivatives and biological activities. Natural chalcones were produced through biosynthesis pathway of chalcone synthase, as presented in Fig. 2. Briefly, the biosynthesis reaction involves the condensation between a coenzyme A (CoA)-ester (starter substrate) of cinnamic acid or its derivatives such as coumaric acid or ferulic acid and three units of malonyl-CoA (extender substrate) by decarboxylation reaction. The product formed is a linear polyketide chain, which is further cyclized through intramolecular Claisen condensation and aromatization to give naringenin chalcone (Dao et al. 2011b; Jez et al. 2001). Naturally derived chalcones usually have hydroxylated aromatics rings. Common plants found to produce chalcones are *Acacia* (Hudson and Lewis 1983), *Angelica* (Kozawa et al. 1978; Baba et al. 1990; Nakata et al. 1999), *Carthamus* (Obara and Onodera 1979), *Myrica* (Mathiesen et al. 1996), *Coreopsis* (Geissman 1941; Kim et al. 2019), *Cryptocarya* (Fujioka et al. 2010), and *Desmos* (Nakagawa-

Goto et al. 2005). On the other hand, chalcones can be synthesized in chemistry laboratory through a general reaction of Claisen-Schmidt condensation, where aromatic aldehyde is condensed with either aliphatic or aromatic ketone in the presence of acid or base (Patil et al. 2009).

Both natural and synthetic chalcones have shown excellent biological properties with low toxicity profile. The presence of the keto-ethylenic group is believed to be the main contributor of these biological activities, with some studies confirmed that the removal of this group diminishes their activities. The keto-ethylenic group furnishes conjugation effect between the carbonyl group (–C=O) with its neighboring double bond (–C=C). Resonance occurs due to the side-by-side location of both functional groups and results in the free movement of electrons around these atoms. Consequently, resonance reduces the reactivity of the double bonds (–C=C) toward electrophilic additions but activates its ability for nucleophilic addition and thus the keto-ethylenic group is prone to nucleophilic attack. The mentioned reaction does not occur in the double bond (–C=C) that is located adjacent to other electron withdrawing groups such as amine (–CN), carboxylate ($–COO^-$), nitro ($–NO_2$), ester (–COOR), and ether (–COR) groups (Mayr et al. 2003; Yuvaraj et al. 2016). Hence, the keto-ethylenic group in chalcones is easily cyclized into biological active heterocyclic compounds through Claisen addition (1,2 addition) or Michael addition (1,4 addition), depending on the strength of the nucleophile and reaction conditions. For example, chalcones can be developed into pyrazoline, oxazoline, thiazine, oxazine, and pyrimidine (Hayat et al. 2010; Ingarsal et al. 2007; Selvam et al. 2013; Reddy and Reddy 2010; Kanagarajan et al. 2010).

A diverse biological activity has been found to associate with chalcone and its derivatives. The biological activities that have been reported are antioxidant (Wei et al. 2005; Dinkova-Kostova et al. 1998; Vogel et al. 2008), anticancer (Mendes et al. 2008; Modzelewska et al. 2006; Reddy et al. 2008; Sharma et al. 2010), anti-inflammatory (Zhang et al. 2014b), antihypertensive (Liu et al. 1992), neuroprotective (Han and Zhao 2010), antimicrobial (Nielsen et al. 2004; Boeck et al. 2005), anti-HIV (Wu et al. 2003), antitubercular (Lin et al. 2002), antimalarial (Li et al. 1995; Geyer et al. 2009; Mishra et al. 2008), anti-leishmanial (Kayser and Kiderlen 2001; Nielsen et al. 1995), anti-hyperglycemic (Enoki et al. 2007; Damazio et al. 2010), anti-tyrosinase (Khatib et al. 2005; Jun et al. 2007), anti-obesity (Horiba et al. 2010; Hassan et al. 2007), and vasorelaxant (Dong et al. 2010) activities. Furthermore, many studies have shown that both natural and synthetic chalcones show non-toxicity to normal cells (Utsintong et al. 2013; Sahu et al. 2012). The excellent pharmacological profile of chalcones revealed its potential to be developed as lead compounds for various diseases. In this chapter, the chalcones from food source will be the main focus. The most common chalcones found in edible plants are licochalcones (Furusawa et al. 2009), butein (Hudson and Lewis 1983; Geissman 1941), phloretin and its glucosidephloridzin (Lin et al. 2016; Mark and Larry 1993), and naringenin chalcones (Verhoeyen et al. 2002).

9.2 Bioactive Constituents (with Chemical Structures)

9.2.1 Tomato

Tomatoes (*Solanum lycopersicum*) are a common source of chalcones, especially naringenin chalcone (**1**) and its conjugates. It is a popular vegetable that is highly consumed worldwide and found to contain various polyphenols with health benefits. Flavanones, dihydroxy-cinnamates, and chalcones, together with their glycosides, are the main classes of polyphenolic compounds identified in tomatoes. Thus, tomato has been recognized as an important source of dietary flavonoids and chalcones, similar to prunes and citrus (Ross and Kasum 2002). A number of previous studies indicated that regular consumption of this vegetable is able to reduce the prevalence of cardiovascular diseases (Pandey et al. 1995; Silaste et al. 2007), diabetes (Lazarus et al. 2004), and cancer (Grieb et al. 2009; Zhang et al. 2009a), as well as improve perennial allergic rhinitis (Yoshimura et al. 2007; Iwamura et al. 2010). One of the predominant bioactive compounds present in tomatoes is naringenin chalcone (**1**), besides common flavonoids, such as rutin, naringenin, kaempferol, and quercetin. Other chalcones and its conjugates that were found in tomatoes are eriodictyol chalcone (**2**) (Iijima et al. 2008; Gómez-Romero et al. 2010) and dihydroxychalcones (Vallverdú-Queralt et al. 2011; Slimestad et al. 2008). These chalcones are produced almost exclusively in the skin or peel of the tomatoes with negligible quantity in other parts of the fruit (Slimestad et al. 2008). The accumulation of chalcones in tomatoes occurs with the onset of ripening, achieving maximum levels at the turning stage and followed by a rapid decrease during ripening. In other words, chalcones are not detectable in green peel, but its concentration increased steeply when turning into red tomatoes (Muir et al. 2001; Bovy et al. 2002). However, common processing methods of tomatoes in to ketchup usually transform this compound into naringenin, hypothesizing the degradation is correlated to temperature (Krause and Galensa 1992; Slimestad and Verheul 2005).

Naringenin chalcone (**1**) appears to be a major bioactive chalcone in tomatoes. It is regulated in a tissue-specific and development-dependent manner (Krause and Galensa 1992; Verhoeyen et al. 2002). This yellow pigment is formed simultaneously with the color turning of the fruit and accumulated in the cuticle of the tomato skin throughout fruit ripening (Verhoeyen et al. 2002; Ballester et al. 2010). The accumulation level of naringenin chalcone (**1**) at the colour turning stage is found to be approximately tenfold higher than that of rutin (quercetin 3-O-rutinoside), which is another major flavonoid present in tomato (Muir et al. 2001). Various studies have been conducted to investigate the bioactivities and health benefits of tomatoes in relation to this compound. The biological activities reported include antiallergic (Gafner et al. 2013; Yamamoto et al. 2004), anti-inflammatory (Hirai et al. 2007) and anti-obesity (Horiba et al. 2010; Hassan et al. 2007). The interesting biological profile of this chalcone has led to the exploitation of research studies on the chemical structure modifications to produce naringenin chalcone derivatives. One of the examples of derivative is tetracarboxymethyl-naringenin-

chalcone that showed inhibition toward the cathelicidin-induced inflammatory reaction in the chronic skin disease rosacea (Gafner et al. 2013).

For the antiallergic activity, naringenin chalcone (**1**) isolated from tomatoes showed inhibitory effects on histamine release. Interestingly, this chalcone showed the strongest inhibitory effects among the polyphenols present in the extract of tomato skin or peel. The inhibitory effects were not exhibited by flavonoid compounds, such as rutin, quercetin, and kaempferol (Yamamoto et al. 2004). In addition, this constituent is able to suppress airway inflammation in allergic asthma by inhibiting the Th2 cytokine production from CD4 T cells of the spleen. On the other hand, the anti-inflammatory activities of **1** have been proven in macrphage model by inhibiting the production of pro-inflammatory mediators such as tumor necrosis factor (TNF)-α, monocyte chemoattractant protein (MCP)-1, and nitric oxide (NO) in dose-dependent manner (Hirai et al. 2007). Naringenin chalcones (**1**) are also able to improve the adipocyte functions related to metabolic processes revealing its potential as an anti-obesity agent (Hassan et al. 2007; Kunimasa et al. 2009). The effect has been further confirmed in a study reporting on the exertion of insulin-sensitizing properties by activating an adiponectin-related pathway, enhancement on activity of peroxisome proliferator-activated receptor γ, and upregulation of the gene associated with mitochondrial energy metabolism by this constituent (Horiba et al. 2010).

A number of naringenin chalcone (**1**) and eriodictyol chalcone (**2**) conjugates were detected in tomatoes (Fig. 3). Similarly, these conjugates accumulated mainly in the peel of this health benefiting vegetable. Conversely, chalcone conjugates were found in the fruit of tomatoes. The common conjugate moieties seen to be associated with these chalcones are hexoses (*hex*). The conjugate moieties identified in eriodictyol chalcone (**2**) were also found to be present in naringenin chalcone (**1**). Interestingly, naringenin chalcone (**1**) has been reported to have a wider variety of conjugate moieties, including deoxyhexose, pentose, and malonylated hexose, and some unidentified moieties (Iijima et al. 2008; Mintz-Oron et al. 2008; Moco et al. 2006). Similar modification patterns in conjugation of eriodictyol chalcone (**2**) and naringenin chalcone (**1**) imply that these constituents share the same set of enzymes in their modification pathways. The biological activities of chalcone aglycone and its conjugates are very likely to be different from each other based on previous studies on the constituents with conjugates (Iijima et al. 2008; Nguyen et al. 2004; Yao et al. 2006).

The dihydroxychalcones found in tomatoes are phloretin-3′,5′-di-*C*-glucoside (**3**) and dihydroxy-dimethoxychalcone-*C*-diglucoside (**4**) with the structures presented in Fig. 3. Phloretin-3′,5′-di-*C*-glucoside (**3**) is the first *C*-glycoside, as well as first dihydrochalcone, identified in tomatoes. The presence of constituent **4** was reported only in tomato juices and ketchup but not in fresh tomatoes. The production of **4** is possibly due to the technological preparation processes of tomatoes such as dehydration and stabilization (Gahler et al. 2003; Galicia-Cabrera 2007; Vallverdú-Queralt et al. 2011). Once again, studies showed that the industrial processes of tomatoes into food products did play an important role in terms of preserving the nutritional constituents. Dihydrochalcones have been proven to show significant

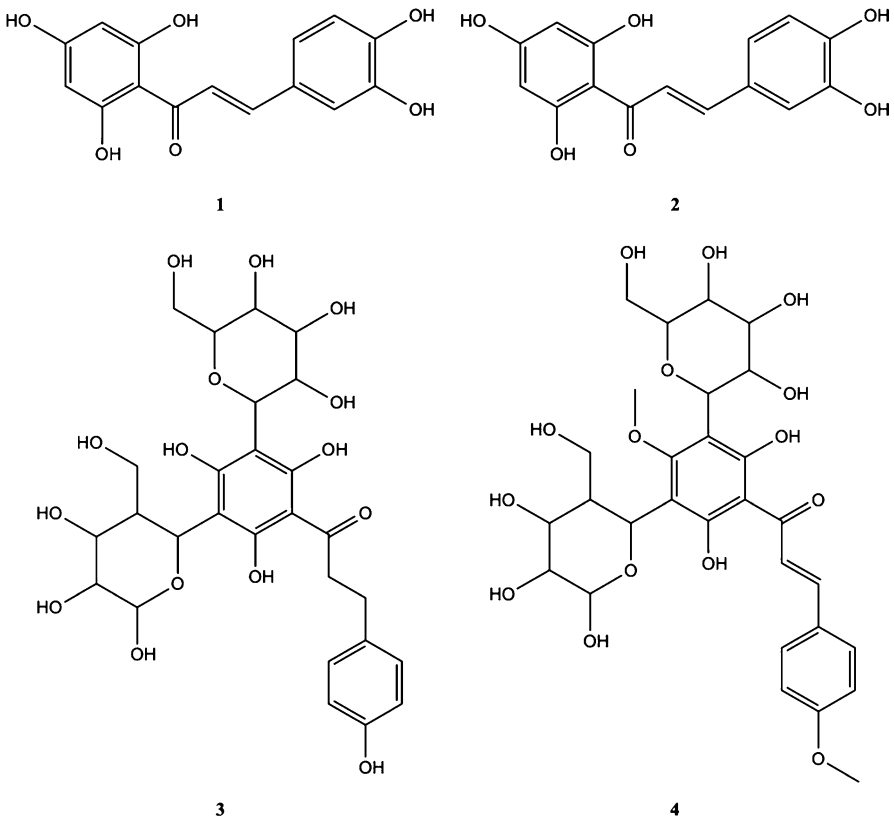

Fig. 3 Structure of naringenin chalcone (**1**), eriodictyol chalcone (**2**), phloretin-3′,5′-di-*C*-glucoside (**3**), and dihydroxy-dimethoxychalcone-*C*-diglycoside (**4**)

antioxidant activities in radical scavenging and lipid peroxidation suppression activities (Dziedzic et al. 1985; Nakamura et al. 2003). These constituents are widely applied in the food industry as food additives due to their stability, colorless property, safe consumption, and easy producibility by catalytic hydrogenation from flavanones and glucosides (Borrego et al. 1995).

9.2.2 Apple

Apple is a rich source of polyphenols such as flavonoids, hydroxycinnamates, anthocyanins, and dihydrochalcones (Ramirez-Ambrosi et al. 2013). Numerous studies have reported the polyphenols produced by apple are good antioxidants and have preventive effects against cardiovascular diseases and cancers (Sun and

Liu 2008; Yoon and Liu 2007; Reagan-Shaw et al. 2010; Sesso et al. 2003). Among the polyphenols, dihydrochalcones are the dominant constituents that accumulate in the root barks, shoots, leaves, and fruits of apples. For the fruits, dihydrochalcones build up in the tissues of apples, including skin, pulp, and specifically core and seeds that are usually discarded when the apples are consumed freshly. Thus, the overall intake of these chalcones has been claimed to be greater for apple-derived products such as juice, cider, and pomace since whole apple fruit is processed. Furthermore, fruit bruising will result in browning and 20–40% reduction on the amount of dihydrochalcones (Tomás-Barberán and Clifford 2000). Dihydroxychalcone is considered somewhat distinctive in plants since this chalcone is only traceable in approximately thirty plant families.

The main dihydrochalcone present is phloretin (**5**) and its conjugate phloridzin or phlorizin (**6**), which comprises up to 90% of the soluble polyphenols found in the leaves of the apple tree (Gosch et al. 2010b). Phloridzin (**6**) is also known as phloretin-2′-β-D-glucopyranoside, a glucoside of phloretin (**5**), as presented in Fig. 4. The amount of phloridzin (**6**) in apples varies greatly depending on the cultivar (Burda et al. 1998; Amiot et al. 1992; McRae et al. 1990). This white to yellow crystalline solid is sweet in taste and found in strawberries as well. However, both constituents **5** and **6** do not accumulate in the plant species closely related to apple such as pear and cherry, even though these species show strong similarities of flavonoid genes (Fischer et al. 2007; Williams 1964; Andreotti et al. 2006). Thus, these differences have been utilized for juice authenticity control (Schieber et al. 2001) and chemotaxonomic differentiation (Challice 1981). These constituents have wide applications in many industries such as natural sweetener, longevity extending products and food additives in food and beverages, cosmetics, and pharmaceuticals (Ehrenkranz 2006; Aratsu et al. 2003).

The biosynthesis pathway of phloridzin (**6**) has been claimed to be involved in the reduction reaction of *p*-coumaroyl CoA to dihydro-*p*-coumaroyl CoA and subsequently converted into phloretin (**5**) by the action of chalcone synthase pathway. The reaction is followed by the glycosylation of phloretin (**5**) (Jugde et al. 2008; Gosch et al. 2009, 2010a). The other dihydrochalcones that have been found in apples and its derived products are phloretin 2′-*O*-xylosylglucoside (**7**) and 3-hydroxyphloridzin (**8**) (Lu and Foo 1997; Burda et al. 1998) (Fig. 4). The human health beneficial effects of dihydrochalcones, especially phloretin (**5**) and phloridzin (**6**), have been exploited in the last decade with a number of patents being filed for treatment of neurological disorders and diabetes (Diamandis et al. 2008; Ehrenkranz 2006; Aratsu et al. 2003). These constituents have shown various biological activities such as antioxidant (Bors et al. 1990; Calliste et al. 2001; Rezk et al. 2002), antimicrobial (Vikram et al. 2010), anti-inflammatory (Lee et al. 2011), anticancers (Yang et al. 2001; Lin et al. 2016), and inhibition of cardiovascular disease (Stangl et al. 2005).

Phloretin (**5**) showed potent antioxidant activities in many bioassays, including lipid peroxidation inhibition, peroxynitrite scavenging, 1,1-diphenyl-2-picrylhydrazyl radical scavenging, and hydroxyl radical scavenging (Bors et al. 1990; Calliste et al. 2001; Rezk et al. 2002). The antioxidant activities of phloridzin (**6**) are much weaker

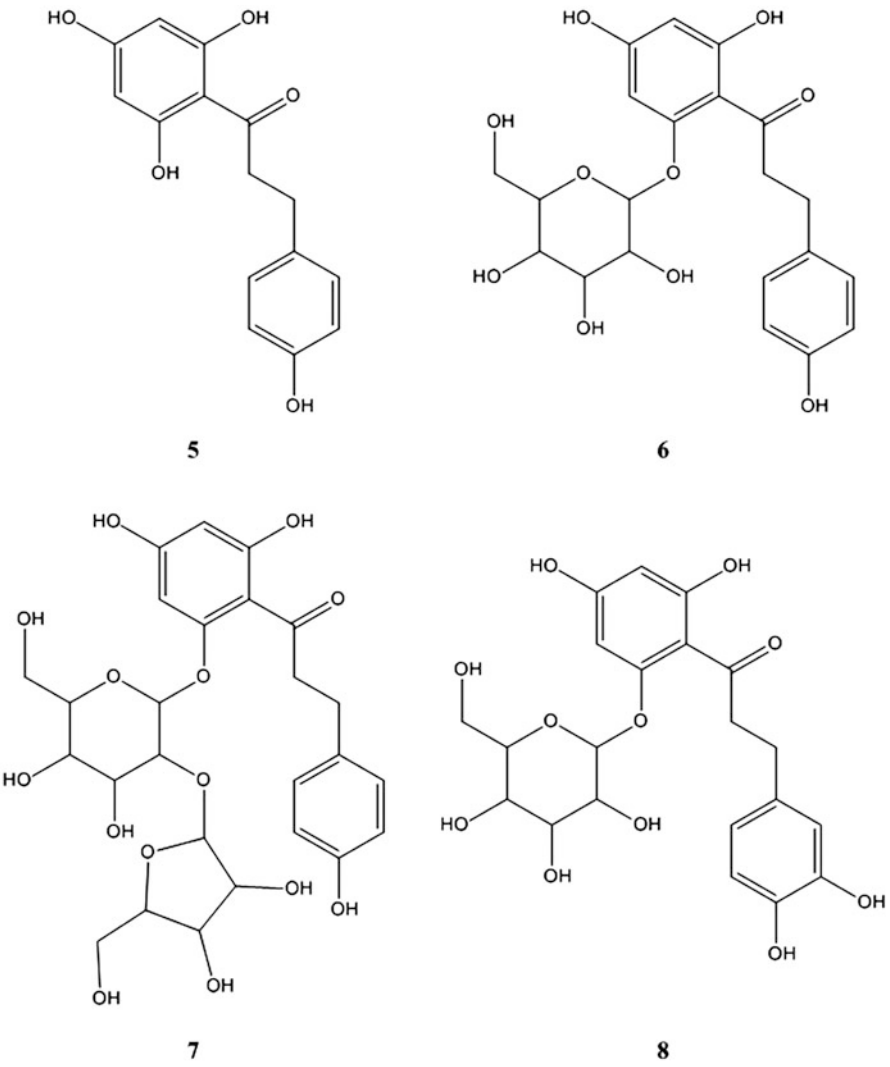

Fig. 4 Structures of phloretin (**5**), phloridzin (**6**), phloretin 2′-*O*-xylosylglucoside (**7**), and 3-hydroxyphloridzin (**8**)

if compared to **5**, indicating that hydroxyl group (-OH) of **5** being replaced by the glucose unit as seen in **6** is important in the contribution of activities (Rezk et al. 2002). Many studies have been done on the antitumor effects of phloretin (**5**), and most of them showed that this constituent has significant inhibitory effects on colon, bladder, liver, lung, and breast cancer cells (Delphi and Sepehri 2016; Schiavano et al. 2015; Wu et al. 2009; Yang et al. 2009; Nelson and Falk 1993; Ma et al. 2016). These studies demonstrated that **5** is a specific inhibitor of GLUT2, which will be expressed in a higher level in tumor tissues than normal cells, revealing its potential

to be used in cancer therapy. Besides, it also showed antitumor growth effects in breast cancer cells and metastasis mechanisms by inhibiting cell growth and arresting the cell cycle in breast cancer cells in a p53 mutant-dependent manner, as well as decreasing the migratory activities of the cells (Wu et al. 2018).

Phloretin (**5**) has shown to give positive effects toward inflammatory bowel diseases (IBD). In addition, it is able to downregulate the mRNA levels of many pro-inflammatory cytokines such as NF-κB, TNF-α, interleukin-8, CXCL3, and CXCL10 in human colon epithelial cells (Jung et al. 2009). The outcome is further proven by another study on the suppression of TNF-α-induced inflammatory response in human colonic epithelial cells and amelioration of colon inflammation in animal model (Lee et al. 2011). The study also showed that constituent **5** is a nontoxic inhibitor of *E. coli* O157:H7 biofilms formation, revealing its potential to be used as a lead compound in treating IBD. Phloridzin (**6**) has also been proven to be a potential food additiive or dietary auxiliary agent for patients with ulcerative colitis, which is one type of the IBD, by improving the symptoms of acute colitis and protecting the intestinal brush border (Lu et al. 2018). It is also found to possess antipyretic (Gosch et al. 2010a), antidiabetic (Ehrenkranz 2006), and melanogenic stimulatory (Jung et al. 2009) properties.

9.2.3 Licorice

Licorice or liquorice plant is one type of legumes, which is rich in bioactive chalcones. It belongs to the family of Leguminosae where the representative species are *Glycyrrhiza* sp., such as *G. glabra*, *G. inflata*, and *G. uralensis* (Yang et al. 2017). Licorice is commonly used as a food ingredient due to its sweet flavors. Thus, this plant is widely used in the preparation of pharmaceutical products such as hematinic pills and expectorant in cough to mask the bitter taste of other remedies (Fenwick et al. 1990). The examples of licorice-containing products in the food industry are snacks, candies, beverages, as well as dietary supplements. It is also used by tobacco companies as a flavoring and moistening agent (Omar et al. 2012). Besides, the roots of licorice are commonly used as prescribed herbs in Chinese traditional medicines for a variety of ailments such as gastric ulcers, bronchitis, fevers, and sore throats (Isbrucker and Burdock 2006; Furusawa et al. 2009). It has been widely used as traditional medicine in the countries of Asia and Europe, including China, Japan, and the United Kingdom. It is commonly called as Gan Cao in China. Commercially, licorice exists in two principal forms, which are licorice root and licorice extract (Isbrucker and Burdock 2006).

Extensive studies on this plant revealed the existence of a high abundance of flavonoids. The principal metabolites of licorice roots are triterpene saponins, as well as flavanones and chalcones with a variety of conjugates (Isbrucker and Burdock 2006; Simmler et al. 2013). Glycyrrhizin is a triterpene saponin that is present in a significant amount in roots of licorice. It is 30–50 times sweeter than sucrose and has been widely used as an acceptable alternative sweetener by food producers and consumers (Omar et al. 2012; Yang et al. 2017). Furthermore, this compound has

been reported to be responsible for various pharmacological effects such as anti-inflammatory, antiviral, anticancer, and hepatoprotective properties (Ashfaq et al. 2011). On the other hand, the glucosides of flavanone (liquiritigenin) and 2′-hydroxychalcone (isoliquiritigenin) (**9**) and its isomer are also present as the main constituents in licorice (Nomura et al. 2002; Zhang and Ye 2009). These isomers are chemically interchangeable, and the interconversion occurs as a function of time and temperature, subsequently affecting the glycosylation of both constituents (Simmler et al. 2013). Interestingly, the glycosides of these compounds are claimed to be important in contributing the biological activities as either prodrugs or bio-equivalent agents of the corresponding aglycones, which are flavanone and isoliquiritigenin (**9**) (Kamei et al. 2005; Asl and Hosseinzadeh 2008).

Isoliquiritigenin (**9**), as shown in Fig. 5 has beneficial effects in the inhibition of NLRP3 inflammasome activation, which is an important factor in inflammatory diseases such as type 2 diabetes (Simmler et al. 2013; Honda et al. 2014). The treatment with this chalcone caused a reduction in high-fat-diet-induced obesity, hypercholesteremia, insulin resistance, blood glucose lowering, and anti-hyperglycemia effects (Honda et al. 2014; Gaur et al. 2014). Anticancer studies on compound **9** reported its promising capability in chemoprevention such as the ability to inhibit ErbB3 signaling and PI3K/Akt pathway in DU145 prostate cancer cells and regulate cell proliferation (Jung et al. 2006). Furthermore, the anti-invasive effect of isoliquiritigenin (**9**) was elucidated on MCF-7 breast cancer cells through a reduction in the secretion of vascular endothelial growth factors (VEGF), as well as inhibition of PI3K and NF-κB signaling pathways (Wang et al. 2013). The modulation of breast cancer cell proliferation through apoptotic induction by this chalcone was proven, and it increased PTEN expression to inhibit aberrant Akt signaling through modulation of the miR-374a/PTEN/Akt axis (Peng et al. 2017). Additionally, isoliquiritigenin (**9**) displayed potent antioxidant effects by reducing cardiac reactive oxygen species (ROS) levels in ischemic injury through the activation of AMPK and ERK signaling pathways (Chin et al. 2007; Zhang et al. 2013).

Licochalcones are the major chalcones present in the licorice plant, and the examples are licochalcone A (**10**), licochalcone B (**11**), licochalcone C (**12**), licochalcone D (**13**), and licochalcone E (**14**) with their structures presented in Fig. 5. These chalcones, especially licochalcone A (**10**), were found to possess various biological activities, including anti-inflammatory (Furusawa et al. 2009; Yang et al. 2017), anti-leishmanial, antibacterial, (Zhai et al. 1995; Tsukiyama et al. 2002), anticancer (Nabekura et al. 2015), antidiabetic (Park et al. 2012; Lee et al. 2018), and antiviral (Dao et al. 2011a) activities. Licochalcone A (**10**) exhibited inflammatory suppression activities by inhibiting a range of inflammatory cytokines such as TNF-α, IL-1β, and IL-6. It has been proven capable of suppressing the iNOS gene expression and NF-κB signaling pathway, which leads to inflammatory response (Kwon et al. 2008; Furusawa et al. 2009). Moreover, this chalcone is able to inhibit Th2 cytokines IL-4, IL-5, and IL-23 and hypersecretion of mucus by goblet cells in the airway and subsequently resolve inflammation (Chu et al. 2013).

For antitumor activities, licochalcone A (**10**) induced apoptosis in PC-3 prostate cancer cells and suppressed cell cycle regulators such as cyclin B1 and cdc2 in G2

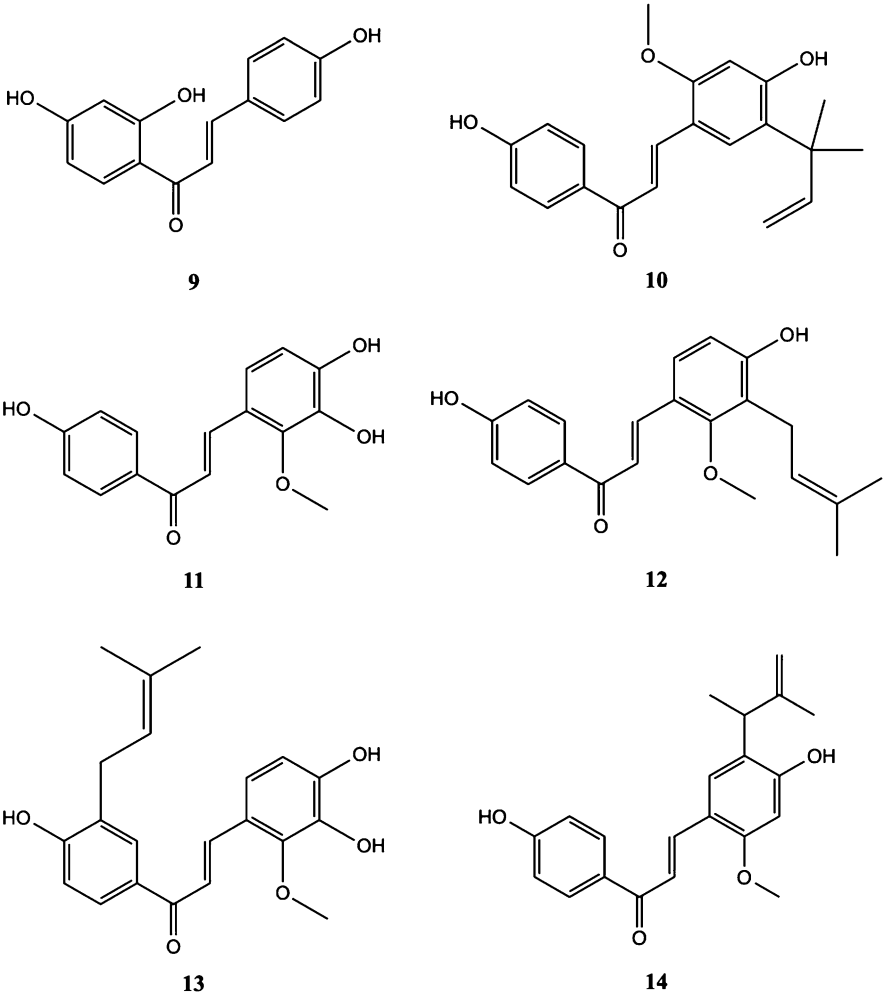

Fig. 5 Structures of isoliquiritigenin (**9**), licochalcone A (**10**), licochalcone B (**11**), licochalcone C (**12**), licochalcone D (**13**), and licochalcone E (**14**)

and late G1 phase of PC-3 prostate cancer cells (Fu et al. 2014). This chalcone also showed inhibitory activities in cell proliferation and apoptosis in DU145 cells (Park et al. 2014). Furthermore, the specific apoptosis induction in glioma stem cells by mitochondrial dysfunction but not in normal somatic and neural stem cells of this chalcone reveals its promising potential as an anticancer agent (Kuramoto et al. 2017). Further study on animal model showed that oral administration of licochalcone A (**10**) gave antitumor effect in a colitis-associated colon cancer model (Kim et al. 2010). On the other hand, compound **10** has been reported to possess antifungal activity against *Candida albicans* and significantly inhibited the

formation of biofilm, highlighting its potential as an antifungal agent for oral candidiasis (Messier and Grenier 2011; Seleem et al. 2016).

Licochalcone A (**10**) was also found to have the ability to enhance the anti-plasmodial activity of arteminisin, which is a well-known antimalarial drug. This study was done to counter the problem of antimalarial drug resistance by applying lichochalcone A (**10**) in the artemisinin-based combination therapies (ACTs), as well as the shortage of artemisinin. Thus, the interactions of arteminsinin and compound **10** were evaluated against synchronized erythrocytic stages of chloroquine-sensitive 3D7 and chloroquine-resistant RKL 303 strains of *P. falciparum*. Interestingly, this combination exhibited synergistic anti-plasmodial activity on these strains. Artemisinin was found to interfere with the hemozoin formation by the parasite but not the chalcone. Both compounds also did not show reduction in sorbitol-induced hemolysis, suggesting that these compounds did not inhibit the new permeation pathways (Mishra et al. 2009).

Licochalcones A–D (**10**–**13**), which are also known as retrochalcones, showed excellent antibacterial profile, especially lichochalcone A (**10**) and licochalcone C (**12**). Compounds **10** and **12** carry a prenyl side chain in their structure that makes the structures highly hydrophobic and able to penetrate the cell membrane, thus resulting in a strong effect in the inhibition of bacterial respiration in whole cells and NADH oxidase in the bacterial membranes (Haraguchi et al. 1998). On the other hand, licochalcone E (**14**) has been getting more attention with the studies focused on its anti-inflammatory properties through downregulation of NF-κB, revealing its potential in the treatment of chronic contact dermatitis (Cho et al. 2010). In addition, this chalcone exhibited antidiabetic properties through an increase in PPARγ expression that results in an increase in adipocyte differentiation and acts as a resolution of hyperglycemia and hyperlipidemia in diabetic patients (Park et al. 2012). Interestingly, licochalcone E (**14**) exhibited antimicrobial activity against *Staphylococcus aureus* strains and reduced the production of α-toxins, even in the methicillin-resistant strain, MRSA (Zhou et al. 2012).

9.2.4 Fingerroot

The tropical plant fingerroot (*Boesenbergia rotunda*) is also known as Chinese keys or Chinese ginger. Fingerroot belongs to the ginger family, Zingiberaceae, and is used as a flavoring agent or eaten as a vegetable. It is commonly used as a spice in Asian cuisine, particularly Thai dishes, and known as Krachai in Thailand (Trakoontivakorn et al. 2001). Rhizomes and leaves of species from this family are commonly associated with antioxidant properties and have also been used in traditional medicine (Chan et al. 2008). The popularity and wide applications of fingerroot have gained the interests of researchers and resulted in extensive studies reporting on various pharmacological activities such as antiallergic, antibacterial, anticancer, and anti-inflammatory properties (Kiat et al. 2006; Ongwisespaiboon and Jiraungkoorskul 2017). These activities were claimed to be contributed by chalcones and flavonoids present in the plant.

The bioactive chalcones found in fingerroot are boesenbergin A (**15**), pinocembrine chalcone (**16**), cardamonin (**17**), pinostrobin chalcone (**18**), panduratin A (**19**), and 4-hydroxypanduratin A (**20**) (Fig. 6). Each of these chalcones contributes to different pharmacological effects and concentrates in different ratios in

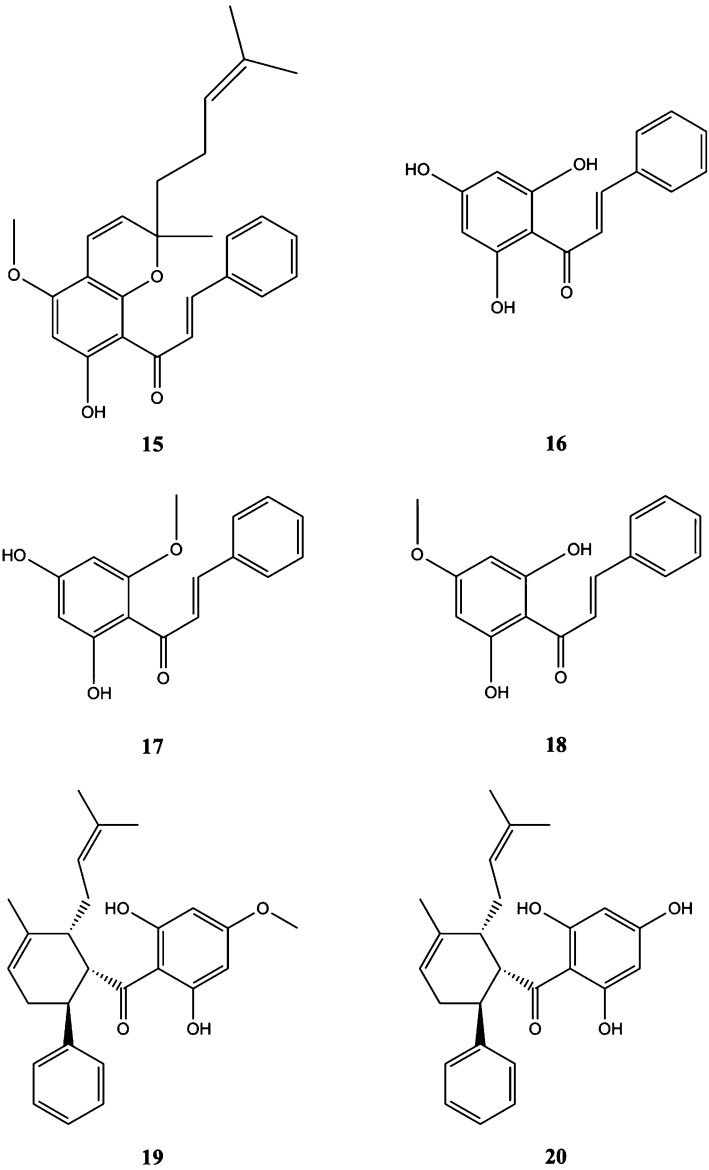

Fig. 6 Structures of boesenbergin A (**15**), pinocembrine chalcone (**16**), cardamonin (**17**), pinostrobin chalcone (**18**), panduratin A (**19**), and 4-hydroxypanduratin A (**20**)

various parts of the plant (Trakoontivakorn et al. 2001; Isa et al. 2012; Tan et al. 2015; Woo et al. 2015; Ongwisespaiboon and Jiraungkoorskul 2017). Fingerroot plant has been used traditionally for its aphrodisiac properties, and the effects were found to be associated with boesenbergin A chalcones (**15**), pinostrobin chalcone (**18**), and panduratin A (**19**) (Ongwisespaiboon and Jiraungkoorskul 2017). Besides, the antibacterial effect of the fingerroot was attributed to chalcones, pinocembrin chalcone (**16**), pinostrobin chalcone (**18**), and panduratin A (**19**). Compound **16** was found to act against *Staphylococcus aureus*, *Helicobacter pylori*, and *Salmonella typhimurium* (Bremner and Meyer 1998; Trakoontivakorn et al. 2001).

Panduratin A (**19**) and its derivative 4-hydroxypanduratin A (**20**) that contains a cyclohexene moiety are found in relatively high concentrations in fingerroot (Trakoontivakorn et al. 2001). Several biological activities have been reported on these chalcones, including anti-inflammatory, antioxidant, antibacterial, and anti-obesity properties (Kim et al. 2013; Woo et al. 2015). Compounds **19** and **20** demonstrated anticancer effects on breast (MCF-7), colon (HT-29), lung (A549), and prostate (PC3 and DU145) cancer cells through inhibition of cell proliferation and induction of apoptosis. Moreover, these chalcones are also associated with anti-inflammatory effects through inhibition of COX-2 enzymes (Kirana et al. 2007; Isa et al. 2012). The improvement of skin barrier function and modulation of Th1, Th2, and Treg-related immune responses were observed after treatment with panduratin A (**19**). The potential of panduratin A (**19**) as a skin nutraceutical, owing to its ability to enhance skin hydration and barrier function, was further confirmed by the modulation of cornified envelope formation and filament aggregating protein processing (Woo et al. 2015). Besides, this chalcone is a highly potential natural anti-biofilm agent that can be used to eliminate oral bacterial colonization during early dental plaque formation, attributed to its potent anti-biofilm properties against *Streptococcus mutans*, *Streptococcus sanguis*, and *Actinomyces viscosus* (Yanti et al. 2009).

Boesenbergin A (**15**) was found to possess anti-inflammatory and antioxidant properties (Isa et al. 2012). Similar to panduratin A (**19**), this compound exhibited cytotoxicity against several cancer cell types such as MCF-7, HT-29, and A549 cancer cells (Isa et al. 2012). However, in contrast to panduratin A (**19**), boesenbergin A (**15**) showed high toxicity against normal liver cells, WRL-68. It is hypothesized to be linked to higher metabolism of **15** in the cells, suggesting its potential side effects despite its anticancer activity (Isa et al. 2012). Another chalcone cardamonin (**17**) has gained a lot of attention in recent years due to its anticancer, antipyretic, and protease inhibitory activities (Tan et al. 2015). The selective inhibition of drug-resistant breast cancer stem cells and chemoprotective activity of **15** were reported. Besides, its anti-inflammatory effects were demonstrated on monocytes and macrophages through inhibition of nitric oxide (NO) release, as well as COX-2 and iNOS expression (Hatziieremia et al. 2006; Israf et al. 2007). This compound has also been reported to demonstrate inhibitory effect against HIV-1 protease (Cheenpracha et al. 2006; Kiat et al. 2006).

The HIV-1 protease inhibition activities were also exhibited by other chalcones present in fingerroot, pinostrobin chalcone (**18**), panduratin A (**19**), and hydroxypanduratin A (**20**) (Tewtrakul et al. 2003; Cheenpracha et al. 2006). Studies

revealed that cardamonin (**17**) and pinostrobin exhibited noncompetitive inhibition toward dengue 2 virus NS3 protease, while competitive inhibition was shown by panduratin A (**19**) and 4-hydroxypanduratin A (**20**) (Kiat et al. 2006). In addition, compound **17** showed apoptotic induction and inhibition of fibrosarcoma growth, further highlighting the medicinal role of fingerroot for its anticancer benefits (Nurrachma et al. 2018). Cardamonin (**17**) also exhibited hepatoprotective effects against ischemia reperfusion injury in rats model by elevation of NO/eNOS and reduction of iNOS. Treatment with cardamonin (**17**) could be a promising strategy to improve functional and structural abnormalities of the liver in patients (Atef et al. 2017).

9.3 Bioavailability and Metabolism

One of the factors that are involved in the bioavailability and metabolism of food phenolic compounds is the absorption of compounds that have sugar or organic acid and ester linked substitutions in their structures. This specific feature allows the compounds to be degraded by the esterase enzymes produced in the colon and unabling them to be reabsorbed into the upper part of the gastrointestinal tract (Scalbert and Williamson 2000; Olthof et al. 2001; Rechner et al. 2001; Adam et al. 2002; Rondini et al. 2002). In addition, the number and type of sugar unit present in the phenolic compounds also play important roles in their absorption. Sugar units such as glucose, galactose, or xylose that are attached to the phenolic compounds are able to be absorbed through the small intestine by the cytosolic β-glucosidase or lactase phlorizin hydrolase but not rhamnose due to its degradation by the enzymes of rhamnosidase. For example, dihydroxychalcones are absorbed in the small intestine of rats followed by conjugation reaction; thus their glycosides could be recovered intact in plasma (Crespy et al. 2001a, b; Glöck et al. 2001).

The metabolism of dietary phenolic compounds is done by deconjugation and reconjugation processes, whether the compounds are hydrolyzed into aglycones and conjugated by methylation, sulphation, and/or glucuronidation. Similar to pharmaceutical agents, food phenolic compounds can act as substrates for both phase I and II metabolic enzymes. The most common example of phase I enzyme is cytochrome P450, while phase II enzyme is sulfotransferases or 5′-diphosphoglucuronyl transferases (UGTs). Phase I metabolism is very likely to produce metabolites with enhanced pharmacological activities or toxicity. Conversely, phase II conjugation reactions might result in metabolites with reduced activities and have higher chances to be excreted. As mentioned previously, chalcones, which are obtained from food sources, have been widely studied for their pharmacological activities. However, the studies on the bioavailability and metabolism of these metabolites are limited.

The oral bioavailability of the well-known chalcone naringenin chalcone (**1**) from tomatoes was studied using the rat model, and this chalcone was found to be metabolized extensively by glucuronidases. Three major metabolites, naringenin chalcone-2′-O-β-D-glucuronide, naringenin-7-O-β-D-glucuronide, and naringenin-4′-O-β-D-glucuronide, were detected in urine, while only one of these metabolites

which is naringenin chalcone-2′-O-β-D-glucuronide was found in plasma after 1 h of administration of **1**. This metabolite was then found to inhibit histamine production, suggesting its contribution to antiallergic activities of naringenin chalcones (**1**) (Yoshimura et al. 2009). However, some studies indicated that the metabolites might be deconjugated during inflammation and contribute to its aglycone bioactivity (Kawai et al. 2008). Thus, the antiallergic activity might be contributed by naringenin chalcone (**1**) instead of its metabolite; study on the active form of metabolites in the inflammatory site is highly recommended.

Phloretin (**5**), a dihydroxychalcone present exclusively in apples, and its glycoside product phloridzin (**6**) were studied for their bioavailability and metabolism because these constituents were commonly consumed. Phloridzin (**6**) was found to be hydrolyzed to its aglycone, phloretin (**5**) and glucose by lactase-phloridzin hydrolase (LPH) in the brush border of small intestine in the hamster (Malathi and Crane 1969). A detailed study of the bioavailability of phloretin (**5**) further showed that approximately half of the doses were excreted in urine within 2 days after phloridzin (**6**) was administered in the rats. Trace amount of **5** was still detected, but most of the metabolites were degraded products. Examples of metabolites are phloroglucinol and phloretic acid, together with their related metabolites produced through dehydrogenation, β-oxidation, and glycine conjugation processes. The results were further confirmed that phloretin (**5**) was hydrolyzed to phloretic acid and phloroglucinol by the cecal microflora in rats, which were discovered in urine and feces (Monge et al. 1984). Interestingly, phloretin (**5**) was also detected in urine, suggesting that it was absorbed before metabolism.

A confirmation study with high-dose feed of phloretin (**5**) and phloridzin (**6**) in rats was conducted. These chalcones showed different absorption rate with phloretin (**5**) appeared to be absorbed more rapidly in plasma than phloridzin (**6**). However, both chalcones were absorbed rapidly in the intestine with no trace in plasma at 24 h, indicating an efficient excretion in urine (Crespy et al. 2001b). Moreover, another study was done by administering phloridzin (**6**) into rats by intravenous (IV) cannula at a concentration of 5μM. The results demonstrated that the uptake of glucose by active glucose transporter SGLT1 in the small intestine was inhibited and subsequently impaired the resorption of glucose in kidney and resulted in glucosuria. This study indicated that phloridzin (**6**) is diabetogenic, but this is a misinterpretation due to lack of the evidence on the effects in the pancreas (Rodriguez et al. 1982). The matrix effect of apples on bioavailability of these dihydroxychalcones is highly recommended to have a better insight in the consumption of these constituents as in apples.

Licorice is an important ingredient in traditional medicine and commonly used as a dietary supplement. Thus, the bioavailability and metabolism of this plant, together with its phytoconstituent chalcones, are well studied. One of the studies has been conducted to evaluate the metabolism of three common licorice species, *G. glabra*, *G. uralensis*, and *G. inflata*, in addition to fourteen compounds, including chalcones which were isolated from these plants. This study was conducted by measuring the inhibitory effect of nine cytochrome P450 enzymes using UHPLC-MS/MS cocktail assay. All three licorice species were found to inhibit several drug-metabolizing

cytochrome P450 enzymes at varying degree and showed unique profile of phytoconstituents with potential drug interactions. The unique enzyme interactions profile of licorice species implied the importance of disclosure of botanical species identity and methods of preparation and extraction for the production of dietary supplements. Isoliquiritigenin (**9**) and licochalcone A (**10**) exhibited inhibition of more than 50% at a concentration of 10 μM against CYP2C8 and CYP2C9 genes. Licochalcone A (**10**), which is specific to *G. inflata*, was also a moderate inhibitor of CYP2C19 and CYP3A4 (testosterone) and a weak inhibitor of CYP1A2 (Li et al. 2017).

Isoliquiritigenin (**9**) is found to have poor bioavailability due to its extremely low water solubility. Its oral bioavailability in rats is less than 50%, which greatly diminishes its pharmacological effects (Zhang et al. 2009b, 2013, Qiao et al. 2014). This chalcone is found to conjugate rapidly in the liver and form monoglucuronides by UGT1A1 and UGT1A9 where isoliquiritigenin 4′-*O*-glucuronide is the major conjugate present (Guo et al. 2008). Studies have shown that it is absorbed rapidly and also underwent quick elimination after intravenous and oral administration in mice. The high distribution of isoliquiritigenin (**9**) in the heart, lung, kidney, and liver was observed, indicating that it has good curative effects on these organs. Furthermore, the main route of excretion of this constituent is predicted to be in the kidney where it is detected in high concentration (Qiao et al. 2014). Its high polarity results in its inability to cross the blood-brain barrier (Hua et al. 2010; Li et al. 2008). The diverse pharmacological activities of isoliquiritigenin (**9**) have attracted researchers to study on the enhancement of its absorption characteristics by using nanostructured lipid carrier, which is widely used as an oral delivery carrier for drugs with poor water solubility (Zhang et al. 2014a).

Another chalcone from licorice plant, licochalcone A (**10**) was well studied for its metabolism effects by using human liver microsomes and human hepatocytes in both in vitro and in vivo models. Five oxygenated phase I metabolites were produced by the human liver microsomes, including three major mono-oxygenated metabolites and two minor di-oxygenated metabolites. On the other hand, nine phase II monoglucuronides of licochalcone A (**10**) and phase I metabolites were produced during the incubation with human hepatocytes. One sulphate conjugate and one glutathione conjugate of this chalcone were also formed from human hepatocytes. Furthermore, the enzymes responsible for metabolic biotransformation of licochalcone A (**10**) were identified. The major metabolism of this compound has been predicted to be the phase II conjugation reactions (Huang et al. 2017), even though phase I metabolites are more potent than **10** in terms of pharmacological and toxicity effects. Furthermore, a study was conducted to develop a HPLC method to enable the separation of these chalcones and three of its glucuronic acid conjugates for simultaneous quantification in urine and plasma after intraperitoneal administration of a single dose of licochalcone A (**10**) in rat. The method was found to be selective, reliable, and sensitive and validated according to good laboratory practice (GLP) guidelines (Nadelmann et al. 1997).

The metabolism of cardamonin (**17**), a chalcone present in fingerroot, was studied by using seven major types of P450 enzymes in human and animal liver microsomal

incubation system. The human livers were obtained from autopsy samples (n = 5 Chinese males, 27–48 years old) from Dalian Medical University, China, while the livers of cattle, sheep, and pig were obtained from animals in abattoirs; meanwhile mouse, rat, guinea pig, and dog livers were obtained from the experimental animal center of Shanghai University of Traditional Chinese Medicine, China. HPLC coupled with ion trap MS was utilized for the identification of metabolites. Selective inhibitors were used in this study to inhibit the hydroxylation of this chalcone in order to identify the isozymes involved in the metabolism, and the results showed the isoenzymes are CYP1A2 and CYP2E1. In addition, the outcomes of this study on the species difference on the metabolism of cardamonin (**17**) showed that the guinea pig possesses the metabolic capacity that is the most similar to that of humans and could be used for further pharmacokinetic studies (He et al. 2009). Another chalcone from fingerroot, panduratin A (**19**) was examined for its metabolism effects on activation (phosphorylation) of AMPK and deactivation (phosphorylation) of its substrate acetyl-CoA carboxylase (ACC) in liver (Hep-G2) and muscle (L6 muscle) metabolic cells. The treatment of chalcone increased the activation of p-AMPK and resulted in fat production reduction and energy consumption increment. The treatment also enhanced deactivation of p-ACC, which plays an important role in fat production. The overall results confirmed that panduratin A (**19**) showed anti-obesity effect by facilitating energy metabolism in liver cells (US8653143B2).

9.4 Bioactivities (Animal Aspects)

Biological activities of food or dietary products and its bioactive constituents are widely studied in animal models, which is an in vivo test where the effects are evaluated by using living organisms or cells. The importance of in vivo studies is highly justifiable with the false-positive or misleading results from the in vitro assays, especially in the industry of pharmaceutical and functional foods. Pharmacokinetic aspects are necessary to be taken into account to ensure that the bioactive constituents are delivered to the site of action, as well as the metabolism reactions that are likely to degrade these constituents throughout the journey to the active sites. Thus, the animal model testing is crucial and widely used to further confirm the biological activities obtained from the in vitro models. This section will focus on the in vivo bioactivities of chalcones from the food source.

Naringenin chalcone (**1**) was investigated for its antiallergic activities in the in vivo model due to its abundancy in tomatoes, which are claimed to improve perennial allergic rhinitis. This chalcone was orally administered into mice with airway inflammation, and the results showed that it suppressed the asthmatic symptoms significantly. It worked by inhibiting Th2 cytokine production from CD4 T cells, and mucus hypersecretion was also found to be reduced (Iwamura et al. 2010). In contrast, long-term and high-dose consumption of tomato extract through oral administration did not give any positive effects (Yamakoshi et al. 2004), revealing that naringenin chalcone (**1**) is suggested to be taken as supplement for patients with allergic airway inflammation.

Licochalones, which are present abundantly in licorice plant, are also well-known for their significant anti-inflammatory activities, especially as treatment for allergic airway inflammation. Licochalcone A (**10**) was evaluated for this bioactivity by using an in vivo study on a non-infectious mouse model of asthma. This chalcone was proven to inhibit the production of Th2 cytokines, including IL-4, IL-5, and IL-13 in the bronchoalveolar lavage fluid, and result in a decrease in OVA-specific IgE and IgG of mice serum. It also showed strong inhibition against the OVA-induced eosinophilia in lung tissue and hypersecretion of mucus by goblet cells in the airway, subsequently resolving inflammation (Chu et al. 2013). Similar to naringenin chalcone (**1**), licochalcone A (**10**) is potential to be developed into drugs for allergic airway inflammation because of its ability to delay the progression of inflammation effectively. Also, the anti-inflammatory activities of licochalcone A (**10**) on the inhibition of NO production and PGE_2, as well as the expression of iNOS, COX-2, IL-1β, and IL-6 in LPS-induced RAW264.7 cells, are further confirmed in the animal model. This chalcone is able to suppress the BALB/c mice from LPS-induced endotoxin shock, deducing the ability of **10** in inhibiting the production of inflammatory mediators (Kwon et al. 2008).

Licochalcone A (**10**) also showed antitumor effect in the colon by inhibiting carcinogenesis and metastasis in mouse models. The oral administration of **10** significantly reduced tumor formation in the colon and cell proliferation with expression of cell nuclear antigen, β-catenin, COX-2, and iNOS. It is also found to suppress the level of pro-inflammatory cytokines and chemokines. More interestingly, the survival rate of the mouse is increased by inhibition of liver metastasis and expression of matrix metalloproteinase-9 in the liver. The outcomes suggested that licochalcone A (**10**) is a potential anticancer agent toward colorectal cancer (Kim et al. 2010). Licochalcone B (**11**) also showed antitumor activities both in vitro and in vivo in the tumor model, besides exhibiting positive in vitro effects in the proliferation of malignant bladder cancer cells T24 and EJ. The murine MB49 bladder carcinoma in C57BL/6 mice was used as an in vivo model in this study. Licochalcone B (**11**), which was administered by intratumoral injection every 2 days, showed inhibition in tumor growth at the concentration of 160 μM. The in vivo antiapoptotic effects of **11** were examined, and the results showed microscopic sign of apoptosis. Furthermore, no toxicity was detected in mice serum glutamic oxaloacetic transaminase (GOT) and glutamic pyruvic transaminase (GPT) at 160 μM licochalcone B (**11**) concentration (Yuan et al. 2014).

In addition, the consumption of licochalcone A (**10**) was also claimed to be able to relieve obesity. In the high-fat diet-induced obesity mouse model, this constituent induces the browning of the subcutaneous adipocytes and successively expresses the key brown adipocyte-specific markers. The finding indicates that **10** plays a role in increasing the thermogenesis, fat oxidation, and lipolysis, besides lipogenesis reduction (Lee et al. 2018). On the other hand, licochalcone A (**10**) exhibited potent in vitro and in vivo activities against *Toxoplasma gondii*, a protozoa which causes toxoplasmosis that possesses serious public health problems. The in vivo evaluation was conducted by using mouse infection model, and the results showed that **10** inhibited the proliferation of *T. gondii* with low toxicity to the HFF host cells. The

survival rate of the infected mice is significantly increased after the administration of chalcone, suggesting that **10** is a promising agent in the treatment of toxoplasmosis (Si et al. 2018).

Isoliquiritigenin (**9**) is another major chalcone from licorice plant that possesses anti-inflammatory effects. A study performed by using mouse model showed that this chalcone showed potent inhibitory effects toward the production of NLRP3 inflammasome-induced IL-1β and activation caspase-1 from hepatic steatosis, white adipose tissue, hypercholesterolemia, adipose tissue inflammation, obesity, and insulin resistance, reflecting its anti-inflammatory activities. The effects shown are even stronger than parthenolide, which is a well-known inhibitor, revealing its potential to be a drug target for the treatment of inflammatory diseases (Honda et al. 2014). This finding was then confirmed by a study on the antidiabetic effect of isoliquiritigenin (**9**), which revealed a blood glucose-lowering and anti-hyperglycemia effect on mice (Gaur et al. 2014). This constituent was also found to inhibit mouse S180 tumors by suppressing GSK-3β, subsequently inducing NF-κB pathway-related protein expressions. TNF-α expression was then increased in NK cells and induced autophagy in S180 tumor cells (Ren et al. 2018). Furthermore, isoliquiritigenin (**9**) was evaluated for its aromatase inhibitor in recombinant protein and MCF-7 cells transfected with CYP19 (MCF-7aro) for the potential to be used as chemoprotective agent against breast cancer for postmenopausal women. Compound **9** was administered as diet for ovariectomized athymic mice transplanted with MCF-7aro cells, and the results showed that it is able to inhibit the aromatase (Ye et al. 2009).

Another chalcone from licorice, licochalone C (**12**) exhibited an important biological cardioprotective function through a range of activities. The study was conducted by using rats which were anesthetized and treated with heparin to prevent coagulation, followed by heart removal for the bioassay. The pretreatment with licochalcone C (**12**) showed significant improvement in the recovery of left ventricular developed pressure (LVDP) and its maximum up/down rate ($\pm$ dp/dt_{max}). The increased levels of superoxide dismutase (SOD) and glutathione/glutathione disulphide (GSH/GSSG) ratio indicates the relieve of oxidative stress. Moreover, this chalcone is able to decrease the terminal deoxynucleotidyl transferase dUTP nick end labelling (TUNEL)-positive cell ratio and morphological changes, revealing its antiapoptotic activities. Licochalcone C (**12**) also exhibited anti-inflammatory effects by relieving the mitochondrial injury and decreasing the levels of creatine kinase (CK), lactate dehydrogenase (LDH), malondialdehyde (MDA), and tumor necrosis factor-alpha (TNF-α). The overall outcomes of this study suggest that **12** is a potential therapeutic agent to prevent myocardial ischemia/reperfusion injury (Zhou et al. 2015).

Phloretin (**5**) from apples has been evaluated for antitumor activities on colon, bladder, liver, lung, and breast cancer cells. Its significant antitumor activities were supported by in vivo studies. This chalcone showed inhibition of cell proliferation and arrested cell cycle in human breast cancer cell line MDA-MB-231 in a p53 mutant-dependent manner, besides decreasing the migratory activities of the cells. The in vivo study was done by using BALB/c nude mice bearing MDA-MB-231

tumor xenografts, at which a decrease of *N*-cadherin and vimentin and an increase in p53, p21, and E-cadherin were detected in the tumor (Wu et al. 2018). For inflammation, phloretin (**5**) was shown to suppress inflammatory bowel diseases by inhibiting many pro-inflammatory cytokines in human epithelial cells, besides suppressing TNF-α-induced inflammatory response in human colonic epithelial cells. This animal study was conducted by using trinitrobenzenesulfonic acid (TNBS)-induced rat model, and treatment showed that phloretin (**5**) ameliorated colon inflammation and body weight loss significantly, revealing its potential to be a therapeutic agent for inflammatory bowel diseases (Lee et al. 2011).

Another chalcone from apple, phloridzin (**6**) is a natural food additive that is a competitive inhibitor of sodium glycogen transporter 1 (SGLT1). This causes diarrhea due to the disruption of intestinal brush border resulting from the suppression effect of SGLT1, which is known as a typical symptom of ulcerative colitis (UC). However, an in vivo study showed that constituent **5** could be a dietary supplement of UC by its ability to improve the symptoms of acute colitis, besides protecting the intestinal brush border through promoting the expressions of SGLT1 and series of proteins (Lu et al. 2018). Another study on the hepaprotective effects of phloridzin (**6**) against methotrexate (MTX)-induced hepatotoxicity in terms of histopathological variables, biochemical parameters, and molecular estimation was performed. The rats were administered with MTX to develop liver toxicity and pre-treated with **6**. The outcomes showed that the chalcone significantly reduced hepatic injury through significant relief in oxidative stress, inflammation, and apoptosis in hepatic tissues. The promising results suggest that this chalcone from apple is worthy of further studies in clinical trials for prevention and early treatment of MTX-induced hepatoxicity (Khalifa et al. 2017).

Cardamonin (**17**), a bioactive chalcone present in fingerroot, showed excellent protective effects on liver ischemia reperfusion injury. The study was conducted with the use of a rat model that has been induced using the weight hanging method where the hepatic portal vein, artery, and bile duct have been occluded. Treatment with **17** significantly increased the NO/eNOS expression in ischemia reperfusion injury and decreased the iNOS expression. Thus, it is able to improve functional and structural abnormalities of the liver through relief of oxidative stress and inflammation (Atef et al. 2017). Another study was also found to report the anti-inflammatory effect of cardamonin (**17**) but focused on the intestinal inflammation and mechanism potential in dextran sulphate sodium (DSS)-induced colitis with the use of an animal model. This chalcone was proven to ameliorate mouse body weight, diarrhea, spleen swelling, colon shortening, and histological damage. These effects were observed due to the ability of **17** in reducing the activity of myeloperoxidase and production of NO, TNF-α, and IL-6 in the colon, as well as suppressing TLR4 expression and inactivation of NF-κB and MAPK pathways. The outcomes of this study showed that cardamonin (**17**) is highly potential to be effective in the treatment of human inflammatory bowel disease (IBD) or related complications (Ren et al. 2015).

Cardamonin (**17**) was also proven to show chemoprotective activities in colorectal cancer. The study evaluated this chalcone for its therapeutic effect in the colorectal cancer mouse model which was induced by azoxymethane (AOM).

Cardamonin (**17**) was administered orally at a dose of 10 mg/kg body weight for 16 weeks and showed positive effects against the tumor. The chalcone showed inhibition toward tumor growth, as well as expression of cell cycle arrest and apoptosis in human colorectal cancer cell lines (James et al. 2017). Furthermore, the treatment of cardamonin (**17**) in delayed cerebral vasospasms (DCVS) after subarachnoid haemorrhage (SAH) was evaluated using rat model through internal carotid artery puncture method. The administration of **17** was done through daily intraperitoneal injections at a dose of 7.5 mg/kg body weight. The results showed that the chalcone tends to relieve cerebral vasospasms after SAH and the effects are deduced to be contributed by the inhibitory ability of c-Myc expression and apoptosis, in addition to the expression of α-SMA. Cardamonin (**17**) was also found to inhibit Akt signal transduction pathway by decreasing protein kinase C. The overall results indicate that **17** has the potential to be used to prevent DCVS after SAH (Ma et al. 2018). Interestingly, cardamonin (**17**) also showed a positive effect in the peripheral and central antinociceptive activities using chemical and thermal models of nociception through the involvement of TRPV1, glutamate, and opioid receptors. The administration of **17** by both oral and intraperitoneal routes at doses up to 10 mg/kg body weight gave significant inhibition in abdominal writhing responses that were induced by acetic acid. The results also confirmed that the chalcone exhibited significant analgesic activity in formalin-, capsaicin-, and glutamate-induced paw licking tests but did not give any toxicity effects (Chung et al. 2018).

9.5 Benefits (Human Studies)

Tomatoes have been claimed to possess antiallergic effects and thus led to the interest of researchers to study its effect in the human body. A randomized, double-blind, placebo-controlled human clinical study was carried out on tomato extracts with regard to its histamine release inhibition effect. The extracts were prepared from a seed and skin mixture by using 60% ethyl alcohol at 60 °C for 2 h and confirmed to contain 0.2% of naringenin chalcone (**1**). For the subjects, 33 adults with perennial allergic rhinitis (PAR) comprising of 14 men and 19 women in the age range of 18–56 years were enrolled in this study. The oral administration of tomato extracts was carried out in the form of tablet for 8 weeks with a dose of 360 mg per day. PAR patients did not have any serious adverse effects throughout the study, indicating that the dose given is safe. The outcome of the study demonstrated that the tomato extract is able to improve the nasal symptoms, particularly sneezing, relieving rhinorrhea and nasal obstruction, even though no significant change in the nasal signs was observed by physician. Thus, tomato extracts with naringenin chalcone (**1**) may have therapeutic efficacy in allergic rhinitis (Yoshimura et al. 2007). The results are in good agreement with the in vitro studies on both tomato extracts and naringenin chalcone (**1**) that showed positive effects in antiallergic activities (Kojima et al. 2000).

Apple peel is rich of chalcones, particularly phloretin (**5**) and phloridzin (**6**). A human clinical study was done to evaluate the inhibitory effects of a variety of

botanical extracts on intestinal diacylglyceride acyltransferase 1 (DGAT1) enzyme, including apple peel extract. The enzyme inhibition is associated with attenuation of postprandial hypertriglyceridemia in overweight and obese humans. Four botanical extracts that showed good activities with a primary cell-free DGAT1 enzyme assay were selected to be further studied in a parallel, double-blind, placebo-controlled clinical trial. Apple peel extract which contains 5% of phloridzin (**6**) was selected as one of the extracts. Ninety healthy, overweight, and obese subjects were administered with 2 g of extracts for 7 days, and their serum triglyceride (TG) levels were measured before and after consuming high-fat meal. The results showed that the apple peel extract did not show a significant reduction in TG level, even though it showed relatively good inhibition in the in vitro assay. Instead, whole grape extract was the only extract found to have potential to inhibit DGAT1 enzyme without intolerable side effects (Velliquette et al. 2015).

For licochalcone A (**10**), human clinical studies are mainly focused on the topical formulation for skin diseases. A double-blind, randomized, vehicle-controlled human clinical study was carried out to evaluate skin tolerability and efficacy of moisturizer containing licochalcone A **(10)**, l-carnitine, and 1,2-decanediol (active formulation) for acne treatment. One hundred and twenty Asian subjects were recruited for a 8-week study and subjects were given adapalene gel and the combination of active formulation and adapalene gel for the comparison effects on the severity of acne, skin bio-engineering measurements and skin tolerability. The results showed that the active formulation demonstrated significant relief in inflammatory lesions and total lesions at the end of the study without flare-up, as well as less skin irritation when compared to other groups. Thus, the moisturizer containing the licochalcone A (**10**), *l*-carnitine, and 1,2-decanediol is able to prevent cutaneous irritation and further enhance patients' adherence to acne medications (Chularojanamontri et al. 2016). Furthermore, another human clinical study was reported to focus on anti-irritative efficacy of a cosmetic formulation containing licochalcone A (**10**). The chalcone exhibited significant reduction in erythema in post-shaving skin irritation model, as well as UV-induced erythema formation, suggesting the therapeutic skin care benefits of licochalcone A (**10**) on sensitive or irritated skin (Kolbe et al. 2006).

A variety of products which contain fingerroot extracts are available in the market. The consumption safety of the extract was evaluated in human clinical studies, and no adverse effects were reported for these products. A human clinical study on the photoaging properties of *Boesenbergia pandurata* has been conducted by measuring skin hydration, gloss, wrinkling, and elasticity. The study was carried out with the use of a double-blind method on the ethanol extract of the fingerroot plant, which contains 8% of panduratin A (**19**). The outcomes of this clinical study by using 92 subjects showed that consumption of the extract powder in tablet form showed significant enhancement in skin hydration and gloss, as well as reduced wrinkling after 12 weeks. The tablet is made up of sodium caseinate (63 mg), dextrin (87 mg), and extract (150 mg). In terms of skin elasticity, no significant difference was observed. More importantly, no adverse symptoms were observed throughout the study period. Thus, the extract of fingerroot that contains the bioactive chalcone

has potential to be used as nutraceutical or nutri-cosmetic material for human skin (Kim et al. 2017).

9.6 Application in Food

9.6.1 Tomato

The tomato is a common food known to have health benefits due to its cholesterol-free and low-fat properties. Moreover, it is highly nutritious with the presence of vitamins, carotenoids, and phenolic compounds such as flavonols and chalcones, together with their conjugates. The consumption of tomatoes is growing extensively, as well as the demand for tomato-based products. Common examples of the products are ketchups, tomato juices, and tomato paste, which are used as food ingredients. The processes of these products include washing, dehydration, hydration, cooking, cleaning, and packaging. The in vivo bioavailability of phenolic compounds, especially flavonols and chalcones, in these products plays an important role in their accessibility and extractability from food (Bugianesi et al. 2004; Simonetti et al. 2005). Thus, studies have been done on the phenolic fingerprint for tomato-based products.

The presence of the types of phenolic compounds is greatly depending on the varieties of tomatoes and cultivation conditions, including light, temperature, fertilization and irrigation (Slimestad and Verheul 2005). Naringenin chalcone (**1**), a major chalcone found in tomatoes, is easily degraded to its isomeric flavone, naringenin (**21**) during the processes of making tomato-based products from the fresh tomatoes. Both of these structures were presented in Fig. 7. The degradation is due to the spontaneous cyclization of chalcone during the entire process (Krause and Galensa 1992; Capanoglu et al. 2008). Tomato paste is a common tomato-based product, and its industry processes involve fresh tomatoes chopped in a "breaker" unit and heating of the pulp after the seed and skin are removed, followed by the evaporation process to remove the moisture and finally pasteurization for packaging as shown in Fig. 8 (Capanoglu et al. 2008). The physiological and biochemical processes which occur during these processes are important to maintain or improve the nutritional value of tomato pastes, in terms of phenolic compounds which are chalcones that we referred to in this case. Naringenin chalcones (**1**), which are functional ingredients in the food industry (Peschel et al. 2006), undergo degradation into its isomeric flavone, naringenin, upon the production of paste. Studies showed that the "breaking" process is the most critical due to the significant increase in the amount of chalcones but with a sudden drop after pulping with the removal of seed and skin (Capanoglu et al. 2008). Thus, the recovery of chalcones from the seed and skin of tomatoes is suggested to be done firstly by extraction and return these chalcones into the paste in order to enhance the health benefits of the tomato paste.

Other tomato-based products such as ketchup and tomato juice are considered ambient stable products. The technological process to produce ketchup involves mixing the pasteurized tomato paste with sugar, salt, vinegar, spices, and

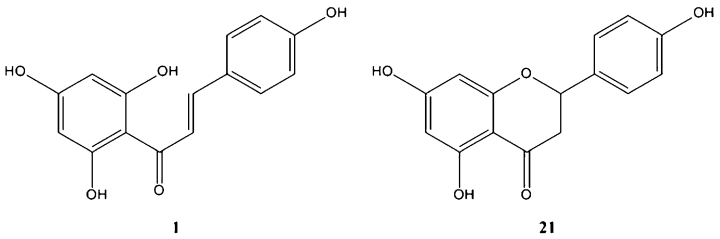

Fig. 7 Structures of naringenin chalcone (**1**) and naringenin (**21**)

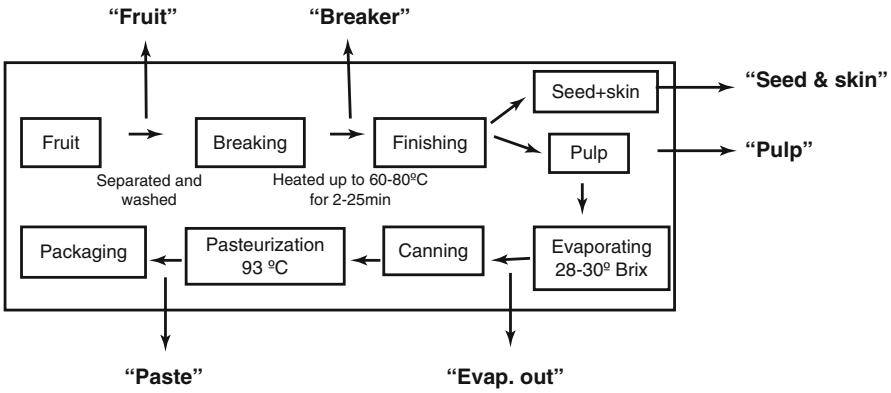

Fig. 8 Industry processes of tomato-based products (Capanoglu et al. 2008)

preservatives, followed by pasteurization at 96 °C for 4–6 min and packaging. The tomato juice is obtained by extraction and concentration and formulated with the addition of extra virgin olive oil, citrus, and salt. It is then pasteurized at 80 °C for 20 min and bottled. Phloretin-*C*-diglycoside (**3**) and dihydroxy-dimethoxychalcone-*C*-diglycoside (**4**) were detected in ketchup and tomato juices with only the former constituent (**3**) found to be present in fresh tomato previously (Vallverdú-Queralt et al. 2011). The production of **4** is deduced to be the happened during the industrial processes where technological practices are utilized such as dehydrations and stabilization (Gahler et al. 2003; Galicia-Cabrera 2007). The main challenge in the production of these products is to maintain the consistency of the physicochemical parameters by choosing the right variety of tomatoes and their ingredients.

9.6.2 Apple

Cider is a popular drink which is an alcoholic beverage made from fermented apple juice. Apple cider is easy to make, and its primary contents are water, ethanol, sugars, organic acids, and phenolic and aromatic compounds. The most important content of cider is the phenolic compounds due their major contribution toward the

organoleptic characteristics such as flavor, color, bitterness, and astringency (Alonso-Salces et al. 2006). The composition of organic acids used in the fermentation process is another important indicator for the quality of cider. In addition, amino acid content is a crucial factor in the fermentation process because they are the nutrients for the yeast. Thus, changes in phenolic compounds and organic acid and/or amino acid content are important when monitoring the fermentation process and assessing quality control of the final product. As mentioned, apple is a rich source of anthocyanins, dihydrochalcones, and flavonols, as well as hydroxycinnamates. On top of these metabolites, tyrosol is formed from tyrosine by yeasts. Metabolites profiling studies were conducted during fermentation process for the production of cider to monitor the changes on metabolites, and as the comparison profile with fresh apple and apple juice.

A higher amount of chalcones are usually detected in the cores and seeds of the apples; thus these constituents are being discarded if fresh apples are consumed. Conversely, apple products such as juices and ciders are produced by using whole fruit, indicating that the intake of chalcones will be higher if these products were consumed instead of fresh fruits (Tomás-Barberán and Clifford 2000). Studies showed that the amount of phloridzin (**6**) in apples varies greatly depending on the cultivar with an amount ranging from 5 to 10 mg/kg present in most of the cultivars. For the examples of apples with bigger range of amount, Kemerrien (French) cider apples contain 169 mg/kg of phloridzin (**6**), English cultivars contain 190 mg/kg, while Verde Doncella contains less than 0.1 mg/kg (Burda et al. 1998; Amiot et al. 1992; McRae et al. 1990). The difference in the amount of **6** in the apple results in different amount of **6** extracted when these cultivars are processed into juice or cider.

Apple pomace has the highest amount of phloridzin (**6**) if compared to the flesh and skin of the apple. Other chalcones, phloretin 2′-*O*-xylosylglucoside (**7**) and 3-hydroxyphloridzin (**8**) with a higher polarity than **6**, were detected in the pomace (Lu and Foo 1997; Burda et al. 1998). These chalcones are another major constituent in apple and used as marker compounds for apple-based products previously (Spanos and Wrolstad 1992; Lea and Arnold 1978). Besides, two derivatives of phloretin (**5**) were detected as the minor constituents and deduced to be the di-glycosides of phloretin (**5**) due to their medium polarity properties (Chinnici et al. 2004). Studies showed that apple pomace has a high level of polyphenols, including chalcones that are valuable in the food industry.

In addition, the total content of dihydrochalcones in the commercial apple juice, regardless of clear or cloudy in appearance, is speculated to be 5–10 times higher than that of domestic juice obtained from extractors (Versari et al. 1997). This is because the whole fruit that is used in the industrial process undergo thermal treatment which in turn inactivates the enzymes that degrade the dihydrochalcones. The pasteurization process which involves heating at 105 °C for 45 min led to a higher rate of degradation of phloretin conjugates if compared to sterilization which is conducted at 120 °C for 20 s. Pasteurization, which involves a higher temperature, will inactivate the oxidative enzymes. On the other hand, filtration process in the clarification of apple juice will decrease the amount of dihydrochalcones such as phloridzin (**6**), even more significant if the filtration time is prolonged due to the

retention on the filters. Commercial pectinases, which are usually used in apple juice clarification, were found to decrease the content of dihydrochalcone intensely by approximately 90% (Mangas et al. 1997). Furthermore, the content of phloretin conjugates present in the apple juice degraded drastically associated with the processes involving enzymatic treatment, indicating its high specificity toward pectinases (Di Lecce et al. 2013).

9.6.3 Licorice

There are approximately 20 known species of licorice (*Glycyrrhiza*), and half of them are used as pharmaceutical ingredients in herbal remedies by many countries around the world. This plant is usually used in herbal medicines as dry raw slices, roasted slices, or slices baked with honey. Different ways to use the licorice will definitely lead to different chemical composition in the plant, including chalcones. Studies have shown that raw licorice possesses higher anti-inflammatory activities than roasted licorice. Some studies have been done to examine the roasted licorice root under a different condition, in the form of solvent extracts. The major constituents of licorice are glycyrrhizin and a pair of isomers, liquiritigenin (**22**) and isoliquiritigenin (**9**) with the structures shown in Fig. 9. The isomers are biosynthetically related and interchangeable. The conversion can occur in a function of time and temperature to reach an equilibrium of 9:1 proportion. The isomerization of isoliquiritigenin (**9**) to liquiritigenin (**22**) was very likely to occur during the processes of licorice, from drying to storage and finally preparation of a boiling alcoholic extract (Simmler et al. 2013). These constituents are claimed to be coexisting in licorice plants. One of the studies which was conducted by extracting roasted licorice root with 95% ethanol showed that the amount of isoliquiritigenin (**9**) detected is lower than both the dry roasted and honey roasted licorice root ethanolic extracts refluxed at 200 °C and 250 °C for 30 min. Among the extracts, the highest amount of **9** was detected in the honey roasted extract refluxed at 250 °C (Sung and Li 2004).

Licochalcone A (**10**) and licochalcone C (**12**) were found to be useful as food preservatives due to their excellent antibacterial activities, suggesting their potential use in the food industry to prevent food spoilage and act against pathogenic bacteria. These chalcones are active against bacterial strains of *Bacillus cereus*, *Bacillus subtilis*, and *Clostridium sporogenes* (Haraguchi et al. 1998; Tsukiyama et al.

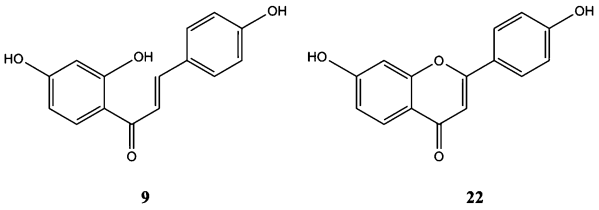

Fig. 9 Structures of isoliquiritigenin (**9**) and liquiritigenin (**22**)

2002), attributed to the prenyl side chain that increases the hydrophobicity of the whole molecules and in turn allows them to penetrate into the cell membrane and act against the bacteria. Licochalcone A (**10**), which presents as the major constituent in many licorice plants, showed positive effects against Gram-positive bacteria such as *Enterococcus* spp., *Lactobacillus* spp., *Leuconostoc* spp., *Staphylococcus* spp., *Streptococcus* spp., and especially *Bacillus* spp. with MIC values of as low as 2–3 μg/mL. Its antibacterial activities are stronger than isoliquiritigenin (**9**). Interestingly, this chalcone is highly resistant to a variety of condition, including temperature of up to 121 °C for 15 min, pH 5.0–7.0, 3% (wt/vol), NaCl (salt), and 20 μg/mL of protease digestion (Tsukiyama et al. 2002). Compound **10** was also found to completely inhibit the outgrowth of *B. subtilis* spores. The outcomes prove that licochalcone A (**10**) is a highly potential compound to be developed as antibacterial agent or preservative in the food industry, particularly soup and fermented foods that contain high level of salt and protease, respectively.

9.6.4 Fingerroot

Fingerroot, which is rich of chalcones, has been widely used in culinary as spices or herbs, especially in local Thai food. The foods are usually served raw or cooked by different methods such as frying, boiling, and grilling. Examples of food include curry and soup, which is a combination of herbs and vegetables with fingerroot as one of the common herbs. Due to the high number of herbs used in culinary, Thai food are considered as health beneficial food. The health benefits of certain cooked food were studied and proven to exhibit antioxidant and anti-mutagenic activities (Nakahara and Trakoontivakorn 1999; Nakahara et al. 2002). Interestingly, one of these studies showed that thermal sterilization that requires high heating temperature has enhanced both the mentioned activities, suggesting that heat treatment is important in improving the beneficial effects of certain food (Tangkanakul et al. 2011).

The antimicrobial and antifungal properties of fingerroot suggest that this herb could be used as food preservative or food packaging, apart from being a natural antioxidant. Natural food preservative from plant extracts is always in high demand due to the increasing number of food poisoning cases and illness resulting from artificial food preservatives (Shan et al. 2007). The crude extracts of fingerroot were found to exhibit good antibacterial activities, especially against antibiotic-resistant strains. These activities were suggested to be contributed by a combination of mechanism of actions due to the presence of different constituents, including cell wall degradation, cytoplasmic membrane and membrane proteins deconstruction, intracellular content leakage, and cytoplasm coagulation (Khan et al. 2009; Burt 2004).

The choices of extraction method of fingerroot should be taken into serious consideration in order to make sure that the important constituents, including chalcones, will not be degraded after the extraction process. Studies have shown that ultrasound-assisted extraction (UAE) caused a drop in the antimicrobial activity of the extract (Thongson et al. 2004), even though it is widely applied in the food

industry due to its significant improve in the extraction yield, shorter extraction time, and lower amount of organic solvent used if compared to conventional extraction methods (Dolatowski et al. 2007; Vilkhu et al. 2008). However, the temperature control in UAE to achieve mild extraction condition may result in an enhanced amount of the constituents, especially chalcones which contribute to the bioactivities of the extracts. Furthermore, solvent selection is a crucial decision to extract the constituents in the highest amount, besides considering the safety and environmental issues. Ethanol is the solvent that has been recommended and widely used in herbal medicine manufacturers due to safety issues and ethanol extracts are usually showing excellent anti-microbial activities against both Gram positive and Gram negatives bacterial strains (Yi and Wetzstein 2011).

4-Hydroxypanduratin (**20**), which is present in fingerroot, was found to possess a variety of biological activities such as antioxidative, anti-mutagenic, antivirus, and antibacterial activities (Trakoontivakorn et al. 2001; Shindo et al. 2006; Cheenpracha et al. 2006). For antibacterial activities, it is found to be strongly bioactive against many foodborne pathogens including *Bacillus cereus*, *Bacillus subtilis*, *Escherichia coli*, *Listeria monocytogenes*, *Proteus mirabilis*, *Vibrio parahaemolyticus*, *Salmonella typhi*, *Klebsiella pneumoniae*, and *Staphylococcus aureus* (Marliyana et al. 2015, 2017). Similar to the chalcones from licorice plants, 4-hydroxypanduratin (**20**) has high potential to be used as a natural food preservative.

9.7 Safety: Toxicity and Side Effects

Food sources rich in chalcones are apples, tomatoes, licorice, and fingerroot. These foods are common and consumed in raw or processed forms and used as food ingredients, food additives, and nutritional supplements. Hence, it is crucial to examine the toxicity and/or side effects of these food. Fresh food samples and extracts, together with their major constituents, particularly chalcones, are usually evaluated. Safety evaluations of the food and drugs for human consumption can be carried out by animal models to examine their toxicity and predict their safe doses for humans. The toxicity effects examined in the animals include hematological, gastrointestinal, and cardiovascular adverse effects (Olson et al. 2000).

9.7.1 Apple

Apple extracts are known to have strong antioxidant effects and other physiological functions. The safety tests of the consumption of the extracts were carried out on some of the market products of apple polyphenols, including phloretin (**5**) and phloridzin (**6**) with their conjugates. One of the findings on the polyphenol extracted from unripen apples revealed that the product is safe to be consumed at an average dietary dosage level, even though it was found to possess mutagenic effect at a dose of 120-fold higher than the estimated average dose. The unripen apple extract does not show any significant hematological, clinical, chemical, hispathological, and

urinary effect at high dosage through acute and sub-chronic oral toxicity tests (Shoji et al. 2004; Fujiwara et al. 2013). Another apple polyphenol extract obtained from matured apple fruits was examined for its genotoxicity. Phloridzin (**6**) is detected as one of the polyphenols in the extract. The results confirmed that the extract does not show any genotoxicity at a 100-fold safety margin through hepatocytes unscheduled DNA synthesis (UDS) and bone marrow micronucleus and comet assay in intestinal cells, thus suggesting that the daily intake is acceptable (Lina et al. 2012).

Conversely, studies showed that the consumption of fruits is associated with cardiovascular and other chronic diseases, even though the effect is not significant. One of the studies was done to examine the protective effects of the fresh apple extracts on human umbilical vein endothelial cells (HUVEC), which were exposed to cytotoxic glycated protein (GFBS)/iron ($FeCl_3$) chelate. The findings showed that the extracts have cells recovery ability, suggesting its protective effect in the patient with diabetic angiopathy (Nishigaki et al. 2010). Furthermore, the apple peel extracts were proven to possess protective effect against cardiac toxicity that is induced by arsenic trioxide (ATO), which is an effective drug for the treatment of acute promyelocytic leukemia (APL). The protective effect of the peel was proposed to be attributed to its well-known antioxidant properties. Thus, the peel has the potential to be used as a nutraceutical for cancer patients on ATO therapy. Dihydrochalcones, particularly phloretin (**5**) and phloridzin (**6**) are the main ingredients of the peel that contributed to these protective effects during the intake of the apple peels (Vineetha et al. 2014).

9.7.2 Tomato

Similar to apple, tomatoes were proven scientifically to be beneficial in the prevention and therapy of toxicity induced by pharmaceutical drugs. For examples, a study showed that tomato paste possessed in vivo protective effect against the damage resulted by acetaminophen and amiodarone. The protective effects shown were against oxidative stress, tissue damage, and biochemical indices against acetaminophen-induced acute hepatotoxicity, as well as lower effect against amiodarone-induced lung toxicity and little effect against cyclosporine A-induced nephrotoxicity (Jamshidzadeh et al. 2008). Nevertheless, a human clinical trial study showed that the subjects who consumed the apple peel extract at a dose of 360 mg per day for 8 weeks did not show any adverse effect throughout the study, and no significant deviation was observed in the results of urinalysis, blood, and biochemistry of the subjects. The results indicated that the apple peel extract, which contains 0.2% of naringenin chalcone (**1**), is safe for consumption (Yoshimura et al. 2007).

However, some studies showed that the consumption of tomato and/or its products may cause harmful effects. The common harmful effects are allergies, gastroesophageal reflux disease (GERD) or heartburn, kidney problems, irritable bowel syndrome (IBS), lycopenodermia, urinary problems, body aches, arthritis, and migraine. For allergies, consumption of raw tomatoes may cause allergies with different symptoms such as sneezing, itchy throat, face swelling, and dermatitis, as

well as lead to extremely severe anaphylaxis in children or individuals who are susceptible to allergies (Chow and Sediva 2013; Zukiewicz-Sobczak et al. 2013; Gann et al. 1999). The allergy responses differ based on the composition of compounds present in tomatoes. The identified allergens are β-fructofuranosidase, profilin, superoxide dismutase, pectinesterase, polygalacturonase, cyclophilin, lipid transfer proteins, Lyc e 2, and Lyc e 3 (Sandra et al. 2003; Westphal et al. 2004; Foetisch et al. 2001; Kondo et al. 2001; Asero et al. 2000; Quynh et al. 2006; Welter 2014) and none of these allergens belong to chalcone. Thus, there is no evidence that chalcones from tomatoes will give these allergic responses. Furthermore, patients with GERD were found to have higher consumption frequency and amount of tomato and tomato juice (Jarosz and Taraszewska 2014; Wang et al. 2004). The effects were claimed to be attributed to organic acids and citric and malic acids but not chalcones (Priyadharsini and Muthukumar 2016).

Even though some research outcomes have shown that regular consumption of tomatoes may have protection effect against kidney problems, the US Department of Health and Human Services advices the reduced intake of tomatoes for patients with kidney problems due to its high potassium content and the presence of oxalate that will result in hyperkalemia and formation of kidney stone (Massey et al. 1993; Siener et al. 2016; Dogukan et al. 2011; Phillips and Polzin 1998). An excessive intake of lycopene, as a result of high tomato consumption, can lead to lycopenodermia, a condition which involves discoloration of the skin. Glycoalkaloids has been claimed to contribute to gastrointestinal tract disorders and arteritis pain as a result of consumption of green tomatoes. Moreover, urinary problems such as urinary incontinence and cystitis and undesired bladder symptoms are associated with consumption of tomato and its products (Townsend et al. 2013; Friedlander et al. 2012). These negative effects were not related to chalcones present in tomatoes.

9.7.3 Licorice

Licorice is claimed as a valuable medicinal plant and widely used as traditional medicine in many countries. Due to its pharmacological activities, this plant has been reported to possess many side effects. The adverse effects are observed after the continuous consumption of significant amount of licorice (up to 100 g/day) for several years. One of the common side effects found with long-term ingestion of licorice is blood pressure elevation, which is also known as hypertension. The side effect was found to be closely related to the signaling pathway of renin-angiotensin-aldosterone system. The phytoconstituents of licorice induce aldosterone action in the kidneys while binding to mineralocorticoid receptors, resulting in hyper-mineralocorticoid syndrome. In addition, hypokalemia (low potassium level) and hypernatremia (high sodium level) are commonly found as side effects that lead to edema subsequently. These side effects may result in a more severe condition that induces myopathy. The onset and level of severity of these side effects greatly depend on the dosage level and duration of licorice ingestion, as well as individual susceptibility

(Zadeh et al. 2013). For example, subjects with delayed gastrointestinal transit time are prone to these side effects due to enterohepatic cycling and reabsorption of the metabolites of licorice.

Another side effect of licorice plants is ocular side effects with some transient visual loss cases reported due to the consumption of licorice. The visual symptoms reported were similar to that of ocular migraine but without headache. The side effect was found to be associated with vasospasm of the brain and retinal or optic nerve blood vessels. Clinical studies showed that the ocular side effects occured when consumption of licorice is high. Thus, intake of this plant should be in caution, especially for those who have migraine headache, to prevent level-up effects (Jun and Zhengang 1988; Walker et al. 1992, 1994).

Licochalone A (**10**), which is a major constituent of licorice, was studied for its toxicity effect with the animal models. The chalcone showed nontoxicity up to 2000 mg/kg body weight through oral administration in the anti-inflammatory and antitumor tests of licorice plants and licochalcone A (**10**) (Kim et al. 2010). Moreover, the administration of licochalcone A (**10**) at 1 mg/kg body weight through oral gavage technique in mice did not detect any induction of nephrotoxicity, hepatotoxicity, and oxidative stress. This study was done to investigate its inhibitory effect toward solid tumors in CT-26 cell-inoculated mice. In addition, the administration of **10** prior to cisplatin treatment resulted in a preventive effect on the cisplatin-mediated increased level of serum nitric oxide (NO) and tissue lipid peroxidation, subsequently recovering the depleted reduced glutathione levels in the tissues. Thus, licochalcone A (**10**) is beneficial in reducing the side effects of cisplatin therapy in cancer patients, instead of contributing to the toxicity or side effects (Lee et al. 2008). Moreover, compound **10** showed low toxicity against the human foreskin fibroblast (HFF) host cells through MTT [3-(4,5-dimethylthiazol-2-yl)-2,5-di-phenyltetrazolium bromide] test besides the evaluation of the antiproliferative effects toward *Toxoplasma gondii*, which results in toxoplasmosis (Si et al. 2018).

9.7.4 Fingerroot

The acute toxicity of the fingerroot extract was studied in conjunction with its wound healing activities in animal model. The outcome of the study showed that oral administration of the extract up to a dose of 5 g/kg body weight is safe and no drug-related toxicity was detected. Clinical observations, as well as the data collected from hematology and hispathology showed no significant difference with the control data (Mahmood et al. 2010). The flavanones, which have the closest structures with chalcones, from fingerroot extracts were examined for their toxicity and mutagenicity in the rats. Pinocembrin (**23**) and pinostrobin (**24**), as shown in Fig. 10, were administered orally at the dose of 500 mg/kg body weight, and no death was observed. The weights of the body and vital organs, as well as blood biochemistry values obtained for flavanone treated rats, were comparable with the control. Moreover, mutagenicity test indicated that no micronucleus formation or mitotic index was encountered with dose up to 100 mg/kg, suggesting non-mutagenic

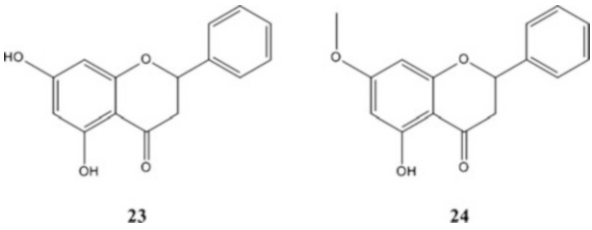

Fig. 10 Structures of pinocembrin (**23**) and pinostrobin (**24**)

properties of the two compounds (Charoensin et al. 2010). Similarly, one of the market products of the fingerroot extract powder reported no mutagenicity or genotoxicity, and acute oral toxicity showed that the LD_{50} value is greater than 2,000 mg/kg body weight in male and female rats.

Similar to other chalcones present in the food, panduratin A (**19**) possessed hepaprotective effect instead of toxicity effect. An animal study was conducted with this chalcone, which was isolated from the rhizomes of *Boesenbergia rotunda*. The compound was administered for 8 weeks by oral gavage at several dosage levels up to 50 mg/kg body weight into rats with liver damage induced by intraperitoneal injection of thioacetamide. Acute toxicity was assessed, and a safe dose of up to 250 mg/kg body weight was confirmed. The study revealed that **19** could reduce platelet-derived growth factor (PDGF) and transforming growth factor (TGF-β1), as well as hepatic metalloproteinase enzyme (MMP-2) and its inhibitor extracellular matrix protein (TIMP-1), suggesting that panduratin A (**19**) is a potential compound to protect the liver from the progression of cirrhosis (Salama et al. 2018).

A study has been done on the structure-toxicity relationship of the eighteen chalcones, including cardamonin (**17**) and pinostrobin chalcone (**18**) which are present in fingerroot plants. Multiple cell-based assays were conducted in the study to evaluate different aspects of toxicity such as cell proliferation, mitochondrial health, cell cycle, and other cellular features by using a human hepatic stellate cell line. The outcome of the chalcone structure-based toxicity model is presented in Fig. 11. The study revealed the active structural element and moieties that are deduced to contribute to the toxicity in the cells. Pinostrobin chalcone (**18**) which has a hydroxyl group at position R1 (refer to Fig. 11) did not show any toxicity effect, while the substitution effect in the rings showed that substitution at ring A gave a higher impact than that of ring B. The study is claimed to be important to understand the molecular mechanism of pharmacological effects, as well as side effect (Zenger et al. 2015).

9.8 Marketed Products

A variety of apple products can be found in the market, including the polyphenol extracts. The current market of apple polyphenol is small, but it is growing significantly due to market demand on global health and nutrition. The products from

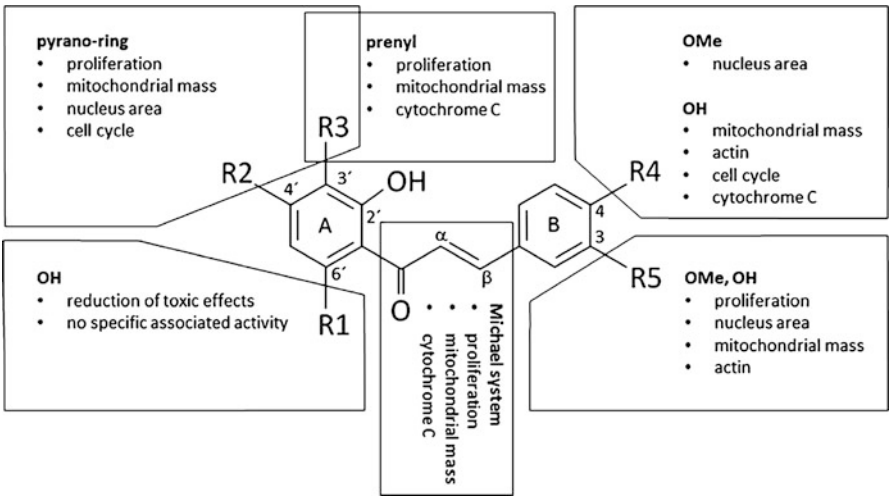

Fig. 11 Significant structure-toxicity relationships of distinct substitutions at chalcone (Zenger et al. 2015)

apple polyphenol extract differ in composition, depending on the type and maturity of the apples used. These products are claimed to be high in various physiological activities, especially antioxidant activities. The examples of the products are Applephenon® and Evesse™. Applephenon® is a patented product with polyphenols extracted from wild and unripe apples produced in Central Asia. The consumption safety of this product was supported with scientific data, and it is safe to be consumed at average dietary level (Shoji et al. 2004). Its antioxidant activities were confirmed by oxygen radical absorbance capacity (ORAC) value which is extremely high in comparison to other polyphenol products. Chalcone is one of the polyphenol compounds present in the extract.

On the other hand, Evesse™ is a product of apple polyphenols extracted from the apples. The whole fresh apples are de-waxed by ethanol and then combined with freeze-dried apple granules and hot water. After that, the enzymes are added for denaturation purpose in order to yield sugar-rich syrup while the residual carbohydrate polymers are degraded with enzymes to remove sugar. Evesse™ is precipitated with food grade ethanol and consists high amount of polyphenol with phloridzin (**6**) at a concentration lower than 5%. This product is available in powder and granules and is tasteless and odorless, allowing easy formulation in the food industry. The market of the product is focused in the USA and Europe in terms of foods and beverages, even though it was initially targeted as a supplement. Safety evaluation test on Evesse™ EPC showed that it has an adverse effect in in vivo studies of unscheduled DNA synthesis (UDS) test in hepatocytes, bone marrow micronucleus test, and comet assay in intestinal cells. Nevertheless, this product showed a positive effect in both in vitro bacterial reverse mutation and mouse lymphoma tests (Lina et al. 2012).

Licorice is widely found as one of the active ingredients in food products, dietary supplements, and traditional medicine products. It has been proven to be active toward a wide range of ailments (Omar et al. 2012). Commercially, licorice exists in two principal forms which are root and extract (Isbrucker and Burdock 2006). Some of the examples of products containing licorice in the market are bronchial wellness tea, cleanse and detox tea, throat spray, energy vitality drink, fresh breath spray, and digestive tea. This plant contains a number of chalones, which are bioactive phytocomponents responsible for the claimed health benefits.

Fingerroot products in the market come in essential oil, powder, and dried sliced forms. Among the products, essential oil is widely seen and known for its warm and camphorous aroma. One of the examples is Pandoradiet™ with panduratin A (**19**) as a marker compound. The content of compound **19** should not be less than 3.52%. The product has been claimed to have high water solubility and stability toward heat and low pH, resulting in various types of food application such as drink, capsule, and tablet. The products of fingerroot have been claimed to have therapeutic effects which include healthy digestive system support and calming effects.

9.9 Patents

9.9.1 Apple

A number of patents related to apple and its chalcones, phloretin (**5**) and phloridzin (**6**), are available. Some of these inventions are focused on the purification of chalcones from apples. One of the inventions disclosed the method to obtain the highly pure phloridzin (**6**) from apple tree branches. The method involves the pretreatment steps of raw material, extraction using CO_2-enzyme supercritical method and purification with centrifugal partition chromatography (CN105777822A). The method was claimed to be safe and highly effective with simplified preparation processes, in addition to shorter purification time and higher yield. Another invention focused on the purification of **6** from apple root bark. This invention (CN102643315B) filed the a series of purification methods include the extraction of raw materials by pulverization, filtration of extracts using acid water, precipitation by centrifuging the supernatant and recrystallization using purified water to obtain pure phloridzin (**6**). The inventors claimed that the method is applicable in industry scale due to its simplicity, low cost, and low polluting effect. For apple pomace, a patent (CN103214530B) was found on the purification for phloridzin (**6**). The steps include crude extraction using ethanol in a range of ratio values in thermostatic water bath, adsorption purification with microporous resin by pH adjustment, and elution of pure phloridzin (**6**) with pH-adjusted ethanol.

The applications of phloridzin (**6**) in food, cosmeceutical, and nutraceutical industries are widely recorded as well. One of the patents found is regarding the best composition of phloretin (**5**) or phloridzin (**6**) to be used the food products, food additives, supplements, animal feeds and pharmaceutical preparations for their beneficial effects (DE10053496A1). The concentration of compounds **5** and **6** in the

food products is preferred to be in the range of 1–100 μM for better absorption characteristics in the small intestine. Another invention was found on the application of phloridzin (**6**) in terms of the preparation of a hepatic or healthcare food. This invention (CN101683351B) provides a pharmaceutical composition of **6** in a general formula that gives a pure natural preparation which is safe and reliable with low toxicity and no adverse effect. The medicament can be used in the form of tea which has a delicious taste and possesses protective effect against hepatic injury, as well as treating acute alcoholism by improving intoxication such as headache, dizziness, and hypodynamia. Besides, the process of obtaining the phenolic fraction of fruits from the Rosaceae family which is rich in phloretin (**5**) and phloridzin (**6**) were filed in a patent (US7427418B2). These phenolic fractions are claimed to be beneficial to be used as the cosmectical and dietary or nutraceutical agents. The cosmetic product is made up of an antioxidant composition of a phenolic fraction, which consists of more than 20% by weight of polyphenols with at least 10% of phloridzin (**6**).

9.9.2 Tomato

Tomato products are usually present in processed form preserved in bottles and cans. Examples are tomato juice, puree, ketchup, chutney, and pickles, and these products are ready to serve, which are highly savored by consumers. A patent (US3549384A) has been filed on the preparation method of tomato products, specifically to prepare an improved tomato ketchup from fresh whole tomatoes. This invention suggested that the conventional method of tomato ketchup manufacture results in loss of flavor and higher tendency of tomato ketchup separation during storage. Thus, the method to improve the production of tomato ketchup was reported. The method includes breaking the tomatoes into particulate solids and heating the surface within seconds to a temperature that is able to inactivate the pectinase enzyme, subsequently heating the ketchup mixture completely to break down the enzyme in order to minimize enzyme activities. Besides, another patent (US2858226A) was filed for the dehydration process of tomato juice to obtain the solid dried products, which are highly nutritious. A previously used puff-drying technique is not guaranteed with good results because the juice concentration does not expand properly during hydration, thus results in failure of dehydration and impossibility of rehydrate. Therefore, this invention was focused on the dehydration process where the products obtained are in free-flowing crystalline granular particles that will not coalesce and gum even exposed to the air for a long period of time. More importantly, the desired characteristics of the products have been retained where the flavor and nutritional value of the products are similar to the freshly prepared juice. An old patent (US2092729A) concerning the preparation of tomato juice beverage was filed to obtain the juice with adequate vitamin content. Briefly, the method includes the submerging of fresh tomato in a hot pool with sterilizing temperature to obtain pulp and juice, followed by extracting the pool of juice and entrapped pulp, supplemented by the condensate available from the additionally heat-treated pulp and entrapped juice.

Naringenin chalcone (**1**), which is present in tomatoes, has been found to possess a wide range of biological activities. Thus, there are a few patents filed for this chalcone on its pharmacological effects. One of which is focused on the production of tomatoes which are rich in naringenin chalcone (**1**) and have excellent taste. This invention (JP2011078334A) reported that genetic recombination method which was previously used to increase the content of **1** in the mature phase of tomatoes possesses adverse effects in human body. In this report, the tomatoes are produced by breeding selection without using genetic recombination techniques and have high content of **1** in fully ripe stage (>10 mg). The antiallergic activities of this chalcone was also filed in an invention. This invention (JP2002080352A) is focused on naringenin chalcone (**1**) as an active ingredient in an antiallergic agent. This antiallergic agent is able to prevent or treat allergic diseases, including anti-inflammatory disease, atopic dermatitis, allergic rhinitis, allergic asthma, and pollinosis, which involves the inhibition of the histamine and leukotriene release. Furthermore, another invention was filed to relate cosmetic and dermatological composition of carboxymethyl (CM) naringenin chalcone for the treatment of senile pruritus, psoriasis, chronic urticaria, and atopic dermatitis in topical form. This invention (FR3065372A1) reported several advantages of the application of naringenin chalcone (**1**), including its ability to inhibit cytokine thymic stromal lymphopoietin (TSLP), in turn relieving the itchy sensation associated with atopic dermatitis and subsequently reducing the scratching behavior of patients that causes deterioration of the skin barrier. The importance of this chalcone then led to another patent filed relating to its stability. This invention (JP2003221356A) provides the stabilizing method of **1**, which involves the use of γ-cyclodextrin. The addition of cyclodextrin to the naringenin chalcone (**1**) aqueous solution with constant stirring increases their physical contact and in turn stabilizing the chalcone.

9.9.3 Licorice

There are a number of patents filed on the extraction method of licochalcones. One of the patents is focused on the extraction of licochalonce A (**10**) by thermal processing. The invention (KR100645994B1) described the method to obtain baked licorice by heating the plant at a temperature ranging from 100 °C to 250 °C for 80 to 120 min The licorice extraction method by using a mixture of hexane and ethanol as a solvent with ultrasound instrument was also reported. The yield of the licochalcone A (**10**) can be increased by adjusting the processing time and temperature of the extraction with the solvent allowed in food processing. Another purification method of the same chalcone was filed in another patent (CN105859538B). The method involves the reflux method of crushed *Glycyrrhiza* spp. with solvent, together with purification method of licochalcone A (**10**) and recrystallization method. This method was claimed to be simple and results in shorter production time and higher yield.

Licochalcone A (**10**) is a pharmacologically active compound that gains great interest of researchers. A patent was filed on its application to prepare anticancer

medicines or healthcare products. The invention (CN103768042A) revealed that this chalcone has inhibitory effects on cell proliferation of various tumors such as breast, lung, stomach, and pancreatic cancer and melanoma. Thus, licochalcone A (**10**) is applicable as an anticancer drug or healthcare product preparations for clinical treatment or auxiliary treatment of correlated tumors. Furthermore, an invention (DE10356187A1) recorded that licochalcone A (**10**) could be used as part of the active ingredient as cosmeceutical or dermatological products in combination of phytosterols and aqueous extract from *Glycyrrhizae inflatae*. The invention relates to cosmeceutical or dermatological preparations comprising of active ingredients, particularly toward sensitive and aging skin. According to the invention, it is advantageous to have licochalcone in the form of an aqueous extract with the mixture of licochalonce A (**10**), water, and one or more polyoyls. Another patent was also filed for the active substance with incorporation of licochalcone A (**10**) and phenoxyethanol, relating to a cosmetic and pharmaceutical preparation. This invention (US8969418B2) reported an active substance comprised of licochalcone A (**10**), phenoxyphenol, and glycerine with 0.01–20.00% by weight of active ingredients, and the preparations showed better activity against dyschromia, inflammatory skin conditions, reddening, skin aging, skin dryness, and sensitive skin.

9.9.4 Fingerroot

Some patents related to fingerroot and its chalcones were found. One of the patents was filed on the use of extract of *Boesenbergia pandurata* and its chalcones, panduratin derivatives. The patent (US8653143B2) relates the composition of panduratin derivatives or the extract of *Boesenbergia pandurata* as the active ingredient for the prevention and treatment of a metabolic disease, including obesity, diabetes, hyperlipidemia, and hypercholesterolemia. It also focused on the safety application as the active ingredients in the mentioned diseases besides evaluating their effects on weight and body fat loss, lipid accumulation inhibition and anti-diabetes.

Panduratin A (**19**), a chalcone in fingerroot, is a biological active compound with a few patents filed for its pharmacological usage. An invention (KR100973221B1) was found to relate the novel use of chalcone as antimicrobial and anti-acne agent. The chalcone was claimed to show excellent inhibitory activities against the growth of skin microorganisms, including *Staphylococcus* spp., and can be used to treat acne effectively. Moreover, panduratin A (**19**) was filed for an invention on its anti-atopic dermatitis properties by suppressing pruritus. Atopic dermatitis was characterized by dry skin, erythema, keratinization, and epidermal thickness and wounds. In addition, the same chalcone was reported for its novel use in enhancing muscle growth and exercise performance capability, as well as fighting fatigue according to an invention (EP2572710B1). This patent has assured the safety of the use of panduratin A (**19**), which was isolated from the rhizome of dry *Boesenbergia pandurata* by using distilled water, ethanol, and subcritical water or supercritical carbon dioxide from the oil obtained by pressing the plant. This natural chalcone was proven to enhance

the expression of intramuscular PPAR-δ protein, thus promoting muscle enhancement besides recovering from fatigue and improving the ability of exercise.

9.10 Perspectives

Chalcones are a common class of compounds found to be present in edible plants including tomatoes, apples, licorice, and fingerroot. Its molecular structure of two aromatic rings connected by three carbons with conjugated carbonyl group and double bond gives way for the yellow or orange color of these compounds. The compound is biosynthetically available through chalcone synthase pathway and structurally closely related to flavanone and anthraquinone. A wide range of biological activities are associated with the natural chalcones from food, attributing to the keto-ethylenic group in the structure. The biological activities reported include antioxidant, antimicrobial, anticancer, anti-inflammatory, antihypertensive, neuroprotective, and hepatoprotective effects. Moreover, these chalcones have excellent profile in terms of food safety by showing nontoxicity against normal cells through a number of animal and human clinical studies. The overall beneficial effects of chalcones revealed that these compounds are highly nutritious and safe to be consumed, as well as highly potential lead compounds to be further developed into alternative drugs to treat various diseases.

Abstract

Xanthones, polyphenolic compounds, are one of the most important classes in natural products, as they exhibit variety of pharmacological and health benefits, i.e., anti-obesity, antidiabetic, antioxidant, anti-Alzheimer, anti-inflammatory, and anticancer. Xanthones can be found in higher plants that are used as food sources, for example, *Garcinia mangostana* L. (the queen of fruits, mangosteen), a tropical fruit with reddish-purple pericarp that *ca*. 80% of it consists of xanthones. α-, β-, and γ-Mangostin are the major xanthones present

in mangosteen that exhibit potential pharmacological activities. Mangosteen is used as popular food in beverages and in other health products. Also, it is traditionally used as a remedy in treating wounds, inflammation, and bacterial infections. Here in in this chapter, we draw the attention to xanthone compounds present in mangosteen showing their bioactivity and benefits on health, biosynthesis, drug discovery, registered patents, and physicochemical property space.

10.1 Introduction

Xanthones are natural polyphenols with the basic molecular formula $C_{13}H_8O_2$ that are commonly found in lichens, fungi, and higher plants (Vieira and Kijjoa 2005). Xanthones have been reported from three main families and seven major genera of higher plants: Anacardiaceae (*Mangifera*), Gentianaceae (*Gentiana* and *Swertia*), and Guttiferae (*Calophyllum*, *Garcinia*, *Platonia*, and *Hypericum*). Since their initial discovery, they have been found in several natural sources aside from *planta* (El-Seedi et al. 2009). For example, new xanthones have been isolated from *Aspergillus versicolor*, the deep-sea-derived fungus (Wang et al. 2016a); from *Talaromyces islandicus*, an endophytic fungus obtained from freshly collected marine red alga *Laurencia okamurai* (Li et al. 2016); and from *Kielmeyera variabilis* from the Clusiaceae family (Coqueiro et al. 2016). Xanthones have basic tricyclic skeleton that encompasses two benzenoid and one pyranoid rings (Fig. 1) (Gales and Damas 2005).

10.2 Xanthones Biosynthesis

Xanthone biosynthesis has been examined at the transcriptional, protein, and metabolite levels based on in situ mRNA hybridization, indirect immunofluorescence detection, and mass spectrometry analyses, respectively. The xanthone carbon skeleton is biosynthesized by the action of the enzyme benzophenone synthase (BPS). Both the BPS transcripts and proteins are localized in the innermost endodermal cell layers of the root cortex and the outermost exodermis, respectively. Xanthone metabolites have been reported to be found in the same tissues (Tocci et al. 2018). In *Hypericum perforatum*, the starting substrates for xanthones biosynthesis are acetyl-CoA, isobutyryl-CoA, 4-coumaroyl-CoA, and benzoyl-CoA. The latter is used by BPS, the key enzyme in xanthone biosynthesis (Beerhues 2011); BPS cDNAs have been reported to be cloned from both *Hypericum* and *Garcinia* genera (Nualkaew et al. 2012). *H. androsaemum* BPS was converted to phenylpyrone synthase, a new polyketide synthase (PKS) variant, by a point mutation in the active site cavity (Klundt et al. 2009). The important reactions in xanthone biosynthesis are shown in (Fig. 2) (El-Awaad et al. 2016). The two trihydroxyxanthone products are likely the precursors of all plant xanthones (El-Seedi et al. 2010).

The biosynthesis of neobraclactones A–C, three unmatched xanthones from *Garcinia bracteata*, has been suggested to involve hydration of the double bond

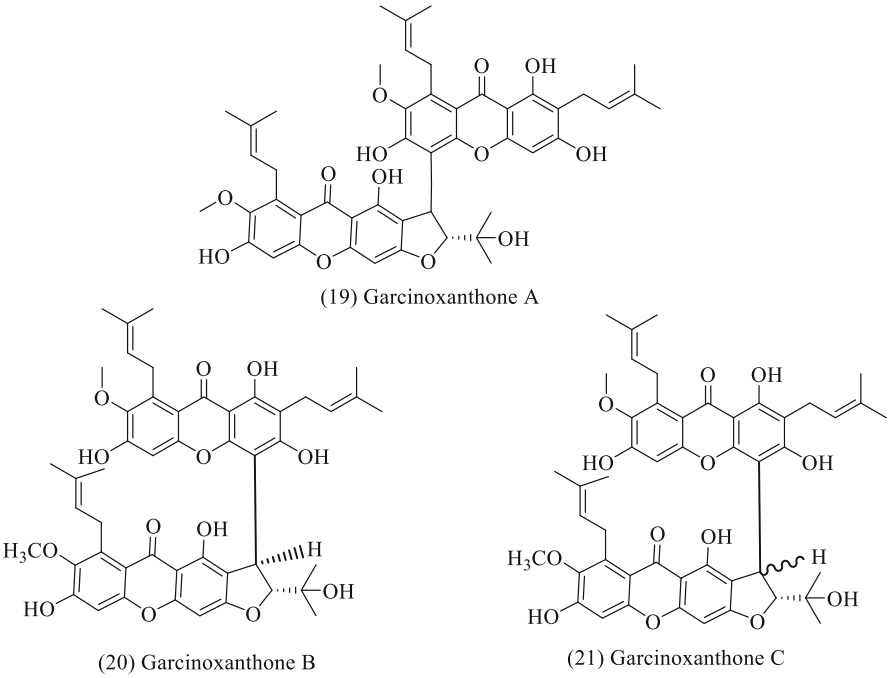

Fig. 1 Xanthone bioactive compounds

between C-8 and C-8a of xanthone 4 to afford intermediate A, followed by a Baeyer–Villiger oxidation-like reaction to generate intermediate B. After that, a nucleophilic attack of the lactone carbonyl of B by 8-OH produce the five-membered γ-lactone unit. After subsequent dehydration and oxidation of the prenyl group, neobractatin (4) is converted into neobraclactones A and B (1–2); then, compound 3 can be generated via cyclization of the 1,1-dimethylallyl group with the ortho-hydroxyl group at C-3, as shown in (Fig. 3) (Niu et al. 2017).

10.3 Biological Activities and Pharmacological Assays of Natural Xanthones

Naturally-occurring xanthones have been reported to have diverse biological activities (Fig. 4). In this section, the biological activities of xanthones are deeply described with an emphasis on their potential utility as therapeutic agents (El-Seedi et al. 2010).

10.4 Mangosteen Containing Xanthones

Garcinia mangostana Linn. commonly called "Queen of fruits and Food of Gods". Mangosteen is a well-known tropical Asian delicious fruit mainly in Indonesia, Malaysia, and Thailand (Fig. 5) (Astuti et al. 2013; Shan et al. 2011).

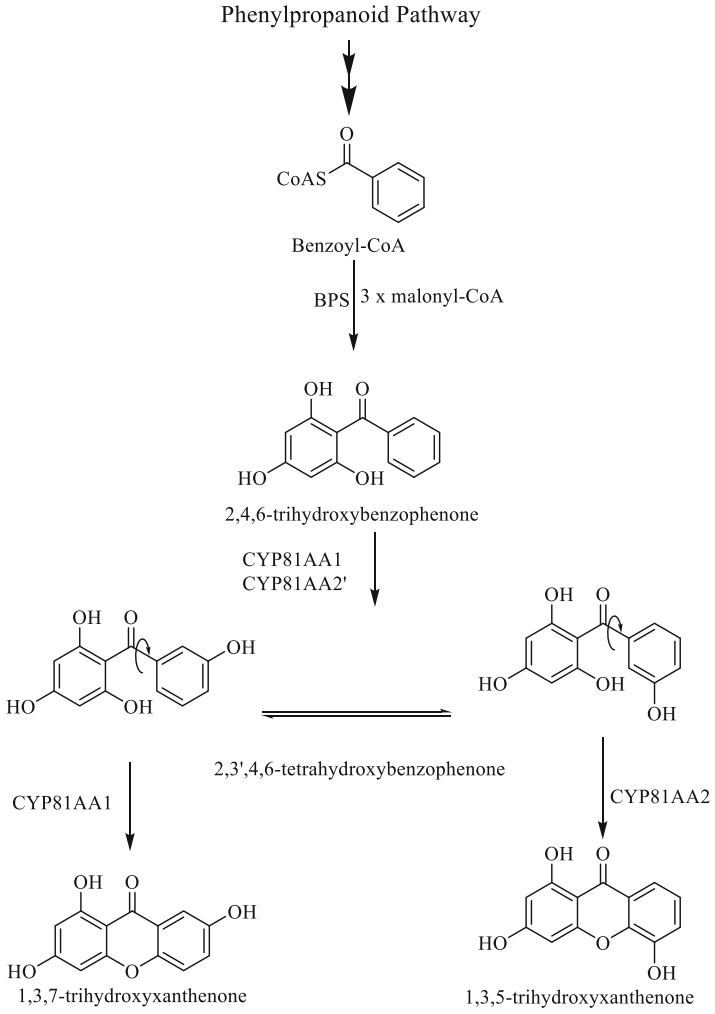

Fig. 2 Xanthone biosynthesis. The crucial enzymes are benzophenone synthase (BPS) that forms the carbon skeleton and cytochrome P450 (CYP81AA(1-2)) that catalyses both 3′-hydroxylation and regiospecific *C–O* phenol coupling

G. mangostana fruits are enriched by xanthones, terpenes, anthocyanins, phenols, tannins, and vitamins (Sarawut Jindarat 2014; Shan et al. 2011). Mangosteen derived xanthones, viz., *α*- and *β*-mangostin predominantly found in roots, barks, edible fruits, and seeds. Mangosteen has been traditionally used for treatment of common cold, diarrhea, cystitis, dysentery, rash, skin infections, and gastrointestinal ailments. Xanthones from mangosteen have been reported as antioxidant, antibacterial especially for *Mycobacterium tuberculosis* and anticancer (Sarawut Jindarat 2014). A previous recent study (Sukma et al. 2011) found new xanthone named γ-mangostin **(3)** in peels of the fruits having anti-inflammatory action besides α **(1)-** and *β* **(2)-**mangostins. The anticancer activity was correlated to xanthones class being natural

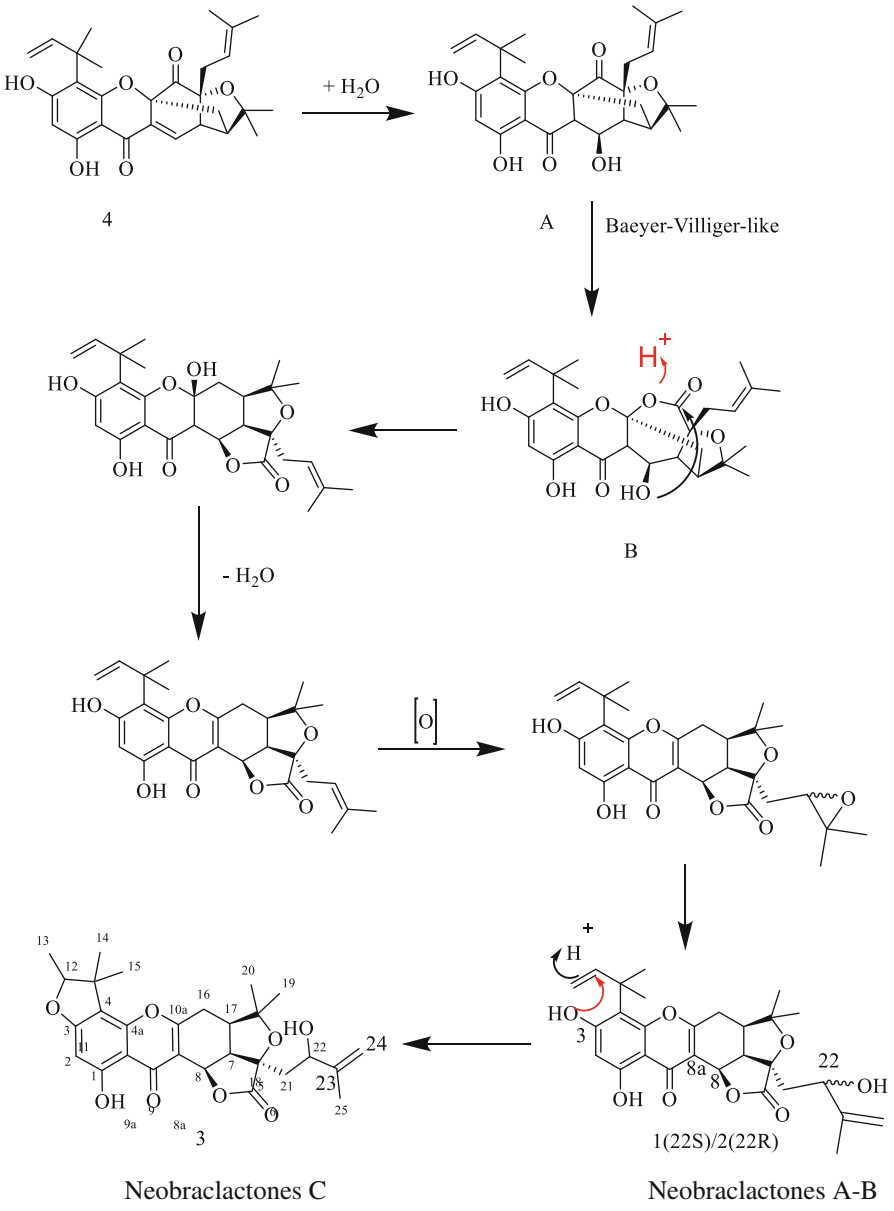

Fig. 3 Plausible biosynthetic pathways of neobraclactones A–C

chemopreventive agent at different stages of carcinogenesis (Shan et al. 2011). Mangosteen nowadays becomes widely known dietary supplement for its effective health benefits. Different mangosteen food supplements are available in the markets in form of juice or capsules under the trade names of XanGo® (XanGo LLC, Orem, UT) or Mangoxan (Pure Fruit Technologies, American Fork, UT).

10.5 Health Benefits of Mangosteen Fruits Xanthones

10.5.1 Anti-obesity Activity

Obesity is widely recognized as a major public burden caused by an imbalance between energy intake and energy consumption. Obesity leads to severe pathological diseases such as hyperlipidaemia and atherosclerosis (Cooke and Bloom 2006). More than 12 xanthones were isolated from *G. mangostana* L. and evaluated for their inhibitory activities against porcine pancreatic lipase (Chae et al. 2016). These xanthones were shown to suppress the lipid absorption in the small intestine via delaying the hydrolysis of dietary lipid-derived triacylglycerol into glycerol and fatty acids. Furthermore, α-mangostin **(1)** from *G. mangostana* is an effective noncompetitive inhibitor of pancreatic lipase with an IC_{50} value of 5 μM. Additionally, β-mangostin **(2)**, γ-mangostin **(3)**, isomangostin **(4)**, gartanin **(5)**, garcinone D **(6)**, 9-hydroxycalabaxanthone **(9)**, smeathxanthone A **(10)**, tovophyllin A **(11)**, mangostanin **(12)**, and 1,7-dihydroxy-3-methoxy-2-(isoprenyl) xanthen-9-one **(13)** showed moderate activity relative to orlistat as a positive control as in (Fig. 6).

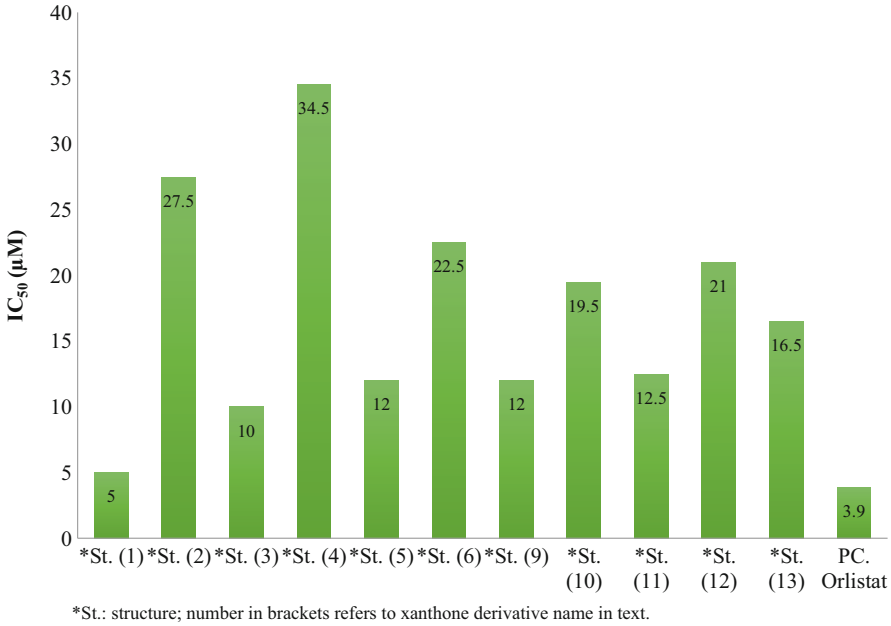

Fig. 6 Pancreatic lipase inhibition assay of *G. mangostana* isolated xanthones L.in comparison to positive control orlistat. (∗St.: structure; number in brackets refers to xanthone derivative name in text)

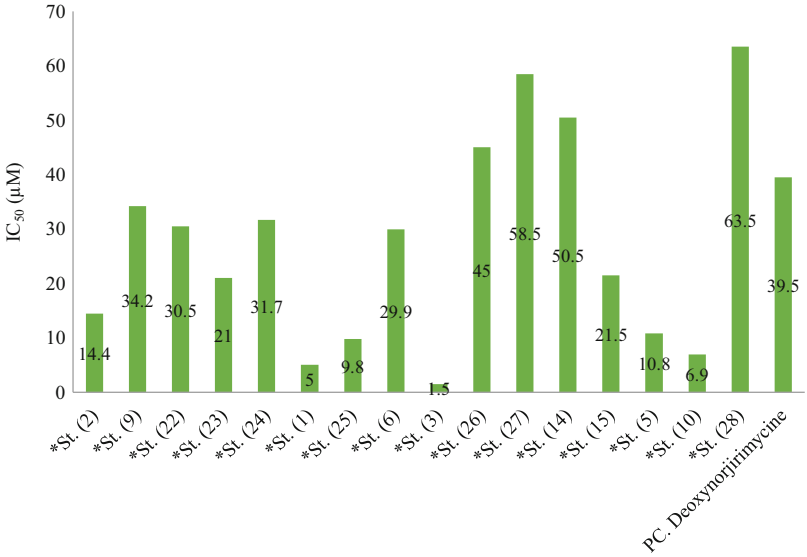
10.5.2 Antidiabetic Activity

Xanthones are the most abundant class of secondary metabolites in *G. mangostana* L., and the ethanol extract of *G. mangostana* L. showed potent α-glucosidase inhibitory activity with $IC_{50} = 3.2$ µg/ml. α-Glucosidase, a glucosidase found in the small intestine, breaks down starch and disaccharides into glucose (Santos et al. 2018). α-Glucosidase inhibitors are used for the treatment of type 2 diabetes by decreasing the absorption of carbohydrates in the intestine, resulting in a slower and lower increase in blood glucose (Kim et al. 2005). α-Glucosidase inhibition by sixteen xanthones isolated from *G. mangostana* was evaluated. In vitro and in vivo α-glucosidase inhibitory assays for 16 xanthones revealed that mangosteen is a rich source of potent α-glucosidase inhibitors. The most potent of the tested compounds is γ-mangostin **(3)**, which is a substantial improvement over the traditional glycosidase inhibitor deoxynorijirimycin. α-Mangostin **(1)** and the ethanol extract of mangosteen were shown to be effective anti-hyperglycaemic agents in several studies (Ryu et al. 2011). It was observed that better inhibition as free hydroxyl groups exist on A and B xanthone ring, suggestive that the number of free hydroxyl groups influenced the inhibition potency. The alkyl substituent was a more crucial factor for the inhibition. Geranylated xanthone like smeathxanthone A **(10)** is seven times more effective than prenyl xanthone 1,5,8-trihydroxy-3-methoxy-2-(isoprenyl) xanthone **(14)**.



*St.: structure; number in brackets refers to xanthone derivatives name in text.

Fig. 7 α-glucosidase inhibition assay of *G. mangostana* isolated xanthones L.in comparison to positive control deoxnorjirimycin (Ryu et al. 2011). (∗St.: structure; number in brackets refers to xanthone derivatives name in text)

Furthermore, a comparison of prenyl and prenyl hydrate substitution established that prenylation gave more effective inhibitory activity in comparison to the positive drug control, deoxynojirimycin IC_{50} (39.5 ± 0.5 μM), as shown in (Fig. 7).

10.5.3 Antioxidant and Anti-Alzheimer Activities

Redox homeostasis is maintained in all biological systems as an intracellular equilibrium. Excessive oxidative stress can lead to severe damage in DNA and alteration of endogenous macromolecules such as proteins and lipids. Xanthones have been described as effective antioxidants, as they are capable of decreasing the cellular ROS levels. The antioxidant activity of xanthones can be useful for treatment of cardiovascular and neurodegenerative diseases, inflammation, atherosclerosis, and cancer. Phyu and Tangpong studied the effect of xanthones from *G. mangostana* and its antioxidant activity which allowed protection of the brain and nervous system from lead poisoning (Phyu and Tangpong 2014). They concluded that xanthones from *G. mangostana* showed potent effect on Pb-induced acetylcholinesterase (AChE) dysfunction and memory loss, and oxidative stress inhibition. It was found that xanthones are comparable to vitamin E in decreasing the symptoms of lead poisoning and because xanthone is water soluble rather than vitamin E posing xanthones as of better tolerance and bioavailability. α-Mangostin **(1)**,

8-deoxygartanin **(15)**, gartanin **(5)**, garciniafuran **(16)**, garcinone C **(7)**, garcinone D **(6)**, and γ-mangostin **(3)** were isolated by Wang and coworkers (Wang et al. 2016b), showed potent inhibition of self-induced β-amyloid (Ab) aggregation and also β-site amyloid precursor protein-cleaving enzyme 1, and acted as potential antioxidants and biometal chelators. α-Mangostin, γ-mangostin, gartanin, and garcinone C showed stronger antioxidant activity to DPPH free radical than the standard Trolox and ROS species, and strong neuroprotective effects against glutamate-induced HT22 cell death, also gartanin, garcinone C, and γ-mangostin were able to penetrate the blood–brain barrier (BBB). Due to these various pharmacological activities of xanthones and their lyophilic nature, they could have used as promising agents for treating Alzheimer's disease (Wang et al. 2016b) (Table 1).

10.5.4 Anticancer Activity

Cancer in general is a term applied of malignant diseases involving irregular cell growth causing tumor formation with the possibility to invade or extend to other parts of the body (Aboul-Enein et al. 2012). According to WHO, cancer is one of the deadliest diseases with a high mortality rate globally; 1.69 million deaths from lung cancer, 788,000 deaths from liver cancer, 774,000 deaths from colorectal cancer, 754,000 deaths from stomach cancer, and 571,000 deaths from breast cancer occur each year, making the development and discovery of new, patentable anticancer drugs with higher efficacies a pressing need (Roleira et al. 2018). As a green method and since the discovery of penicillin from *Penicillium notatum* fungus, compounds purified from natural sources have provided a wealth of bioactive molecules (Davison and Bewley 2018); plants, as a source of natural compounds, have provided medicinal science with many lead compounds and drug molecules, especially anticancer agents (Khazir et al. 2014) i.e., epipodophyllotoxin, vinca alkaloids (vinblastine and vincristine) from *Catharanthus roseus* and camptothecin quinolone, as well as the famous anticancer drug Taxol (*Taxus brevifolia*) (Sharma et al. 2017). Due to the increasing interest in functional foods to treat ailments and improve health, scientists have directed their attention toward *G. mangostana* as a source of polyphenolic compounds such as xanthones that can be used to prevent and treat cancer (Mohamed et al. 2017; Rasheed et al. 2018). Mangostanaxanthone IV **(17)**, *β*-mangostin **(2)**, garcinone E **(8)**, and α-mangostin **(1)** from *G. mangostana* exhibited significant antiproliferative and cytotoxic activities via the induction of apoptosis and necrosis in both HepG2 (human hepatocellular carcinoma), HCT116 (colorectal adenocarcinoma), and MCF-7 (human breast adenocarcinoma) cells, as shown in (Table 2) (Mohamed et al. 2017).

In a previous study, among 14 tested compounds from *G. mangostana*; 7-*O*-demethyl mangostanin **(18)** showed significant cytotoxic activity against seven cancer cell lines, CNE-1, CNE-2 (human malignant glioma cell), A549, H460 (lung cancer cell line), PC-3 (prostate cancer cell line), SGC-7901 (gastric cancer cell line), and U87 (human malignant glioma cell), and it was better than the positive control hirsutanol A as shown in (Fig. 8) (Yang et al. 2017).

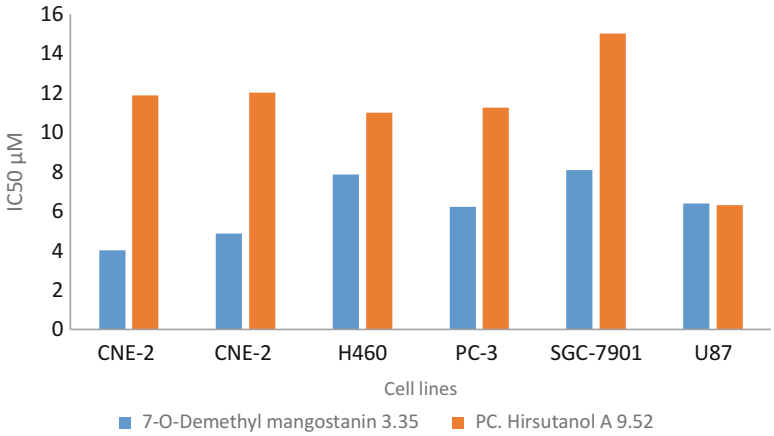

Fig. 8 Cytotoxic effect of 7-*O*-demethyl mangostanin (18) against positive control hirsutanol A using MTT assay (Yang et al. 2017)

As reported, xanthones isolated and purified from *G. mangostana* exhibited variety of biological activities using different bioassays (Chin and Kinghorn 2008). Antioxidant activity using the authentic and morpholinosyndnonimine (SIN-1)-derived peroxynitrite assays on 14 isolated xanthones from *G. mangostana* were evaluated, followed by evaluation of α-mangostin **(1)** specially for its worthy potency on SIN-1 derived peroxynitrite test (IC_{50} <0.49 μM), using mouse mammary organ culture (MMOC) assay, and was found to exhibit inhibition of 7,12 dimethylbenz[α] anthracene-induced preneoplastic alveolar lesions in the MMOC assay, exhibiting an IC_{50} = 2.4 μM of 1.0 μg/ml (Jung et al. 2006; Kinghorn et al. 2011). Also, γ-mangostin **(3)** was found to exhibit potent antiproliferative activity lower than the clinical chemotherapeutic agent carmustine, against human malignant glioblastomas (MGs), using U87 MG and GBM 8401 assays. The IC_{50} values of γ-mangostin were 74.14 ± 2.93 and 64.67 ± 2.42 μM to that of the control drug, carmustine (BCNU), whose IC_{50} values were 632.1 and 346.6 μM in U87 MG and GBM 8401 cells (Chang et al. 2010). The major xanthones in edible mangosteen fruit, α- and γ-mangostin,

Table 3 Dimeric xanthones (garcinoxanthones A–C) showed potent inhibition of LPS-induced NO production in RAW246.7 cells compared to indomethacin

Naturally occurring xanthone	Inhibitory effect on LPS-induced NO production in RAW264.7 cell line: IC_{50} (μM)
Garcinoxanthone A **(19)**	$IC_{50} > 20$
Garcinoxanthone B **(20)**	11.3 ± 1.7
Garcinoxanthone C **(21)**	18.0 ± 1.8
Indomethacin	3.9 ± 0.3

exhibited valuable dietary source as they have multi-activity on different bioassays relevant to cancer chemoprevention (Mohamed et al. 2017), antimalarial (Riscoe et al. 2005), and so on. So further in vivo bioassays investigations for xanthones in *G. mangostana* is required to reach applications in drug discovery (Kinghorn et al. 2011).

10.5.5 Anti-inflammatory Activity

Inflammation is a protective response of the body against infection, and it is usually associated with effects such as swelling, pain, increased vascular permeability, protein denaturation, and membrane alteration (Chahar et al. 2012). Pro-inflammatory cytokines, i.e., IL-1β, IL-6, and TNF-α, and inflammatory mediators, including ROS, NO, and PGE2, from nitric oxide synthase (NOS) and COX-2 pathways are produced by pro-inflammatory cells called macrophages; NO is used as a defence response by many pathogens, but its overproduction may cause chronic inflammation (Ee et al. 2011). Xanthones show a variety of activities against NO production.

Liu and co-workers isolated three dimeric xanthones, garcinoxanthones A–C **(19-21)**, and four monomeric xanthones, garcinoxanthones D–G, from *G. mangostana* pericarps (Table 3) (Liu et al. 2016). These rare dimeric xanthones showed potent inhibition of LPS-induced NO production in RAW246.7 cells compared to indomethacin. The significant activities of the dimeric compounds have led to such new classes of xanthones being studied both in vitro and in vivo for utilization in healthy foods and pharmaceutical applications.

10.6 Xanthone Drug Discovery and Improvement

Highly oxygenated xanthones can additionally play an important role in drug discovery and natural products chemistry serving as a key intermediate for the synthesis or derivatization to produce other important classes of drugs (Sahin et al. 2009). Studies on the reactivity of xanthones and their application as key intermediates in the synthesis of highly functionalized structures have mostly focused on the reactivity of its carbonyl group (Kang and Fang 1997; Sousa and Pinto 2005) and to lesser extent, the ether function. Moreover, xanthone nucleus was found to be

involved in the synthesis of fused naphthalenes as well as isoquinolines (Sousa and Pinto 2005). Examples on xanthone utilization as starting material for the synthesis of complex other natural products include mycotoxins, i.e., diversonol, blennolide C4, and hemisecalonic acids (Ohnemueller et al. 2007). With regards to xanthones derivatization to improve its pharmacokinetic properties and its bioavailability considering its relatively low polarity, several approaches have also been reported mostly targeting the reduction of its particle size, nano-formulation, or addition of surfactants. Most of the reports on improvement of xanthone pharmacokinetics have focused on either α-mangostin **(1)** or mangiferin. Functionalized gold nanoparticles of magniferin (a xanthone derivative isolated from *Mangifera indica* leaves) were attempted as drug delivery method and found non-toxic to normal breast cell line (MCF-10A) (Patra et al. 2018). Self-assembled phospholipidic nano-mixed miceller system (SPNMS) of mangiferin functionalized with co-delivery of vitamin E was also found to improve the bioavailability and ultimate biopharmaceutical performance of magniferin in rats for an enhancement of its anticancer effect (Khurana et al. 2018). Similarly, *in vivo* application of α-mangostin is limited due to its hydrophobic nature, poor aqueous solubility, and stability and thus low bioavailability affecting its accumulation in the target organs. Nanoencapsulation of α-mangostin into the core of poly(ethylene glycol)–poly(l-lactide) (PEG–PLA) nanoparticles improved its bioavailability in both the brain and liver, reduced Aβ deposition, attenuated neuroinflammatory responses, ameliorated neurologic changes and suggesting that nanotechnology can improve xanthones therapeutic efficacy, particularly in management of Alzheimer's disease (Yao et al. 2016). Other drug applications of nanoparticles encapsulation of α-mangostin include its application as an oral drug delivery system for the chemoprevention or treatment of colon and prostate cancers (Qiu et al. 2016). α-Mangostin self-microemulsion was evaluated as a drug loading system to improve its pharmacokinetic performance and to enhance its serum bioavailability and moreover its distribution in lymphatic organs (Xu et al. 2017). In terms of sustaining α-mangostin local release for acne treatment, nanoparticles of α-mangostin prepared using ethyl cellulose-methyl cellulose polymer were also found successful to sustain its release into synthetic sebum (Pan-In et al. 2015). A soft capsule, with vegetable oil as the dispersion matrix, was prepared to improve the bioavailability of α-mangostin and was found effective to improve its bioavailability and its tissue distribution i.e., small intestine, ovaries, stomach, and bone (Zhao et al. 2016). Inclusion of other xanthones in such nano-formulations has yet to be applied to improve its efficacy and or biodistribution.

10.7 Mangosteen Registered Patents

Multiple patents have been earned by different pharmaceutical companies regarding preparation, extraction and pharmacological activities correlated to xanthones particular mangostins constituents. Inventors of Mangoxan® registered a patency for nutraceutical composition of Mangosteen fruit pulps and pericarp combination. The inventors correlated the main health benefits of mangosteen fruits due to the presence

of main active ingredient xanthones (Garrity et al. 2004). Another patency was registered for preparation of nutraceuticals enriched with mangostins from *G. mangostana* due to its potent antioxidant and anti-inflammatory actions (Gokaraju et al. 2014). A patent was registered for novel extraction procedures of mangostin xanthones rich extracts (Moffett and Shah 2006). Another one for novel production of γ-mangostin xanthones from *G. mangostana* fruits have been registered since previously proven antioxidant activity (Gokaraju et al. 2013).

10.8 Physiochemical Property Space

Recent trends have shown a potential in analyzing a group of compounds based on their physicochemical properties. The tricyclic skeleton is a central core structure in xanthones and unifies these compounds chemically. Hence, an introduction of more properties should provide more useful analytical tools that help in exploring this particular group of compounds. The added value is not only in providing a new aspect to investigate a possible correlation but also to predict a possible pharmacological action that could provide a new feature in such compounds. Many correlations can be established for a certain group of compounds taking the advantage of several properties that can be included. Xanthones are no exception. In this section we used web-based principle components analysis, namely, Chemical Global Positioning System of Natural Products (ChemGPS-NP) (Larsson et al. 2007). The ChemGPS-NP provides a wide range of molecular descriptors describing physical–chemical properties of the investigated compounds. Molecular and physicochemical properties incorporated chemically intuitive descriptors, described in detail by Larsson and co-authors. These descriptors include molecular weight; sum of atomic van der Waals volumes (scaled on C atom); sum of atomic Sanderson electronegativities (scaled on C atom); sum of atomic polarizabilites (scaled on C atom); mean atomic van der Waals volume (scaled on C atom); mean atomic Sanderson electronegativity (scaled on C atom); number of atoms; number of non-hydrogen atoms; number of bonds; number of non-hydrogen bonds; number of multiple bonds; aromatic ratio; number of rings; number of rotatable bonds; notable bond fraction; number of double bonds; number of aromatic bonds; number of carbon atoms; number of nitrogen atoms; number of oxygen; number of halogens; number of benzene-like rings; number of aromatic carbon atoms (sp2) n amid; number of amides; number of aliphatic hydroxyls; number of aromatic hydroxyls; number of donor atoms for hydrogen bonds (N and O); number of acceptor atoms for hydrogen bonds (N, O, and F); unsaturation index; hydrophilic factor; Ghose–Crippen molar refractivity; topological polar surface area using N and O; topological polar surface area using N, O, S, and P; Ghose–Crippen octanol/water partition coefficient; and Lipinski Alert Index (drug-like index). The selected ChemGPS-NP descriptors were calculated for all sets of compounds using the software dragonX by Talete srl. (http://www.talete.mi.it). Compounds were submitted on the basis of their structure information as simplified molecular input line entry specification (SMILES; http://www.daylight.com/smiles/) and initially verified as described by Rosén and coworkers

(Rosén et al. 2009) as to omit salts, hydration, and stereochemical and ionic information. Principal component and PCA score prediction were calculated employing the software SIMCA-P+, with the training set ChemGPS-NP. Prior to PCA determination, all data were centered and scaled to unit variance. Navigation through the chemical property space formed by the first three principle components shows obvious deviation with garcinoxanthone C as they distance themselves from the group of xanthones in this chapter (Fig. 9).

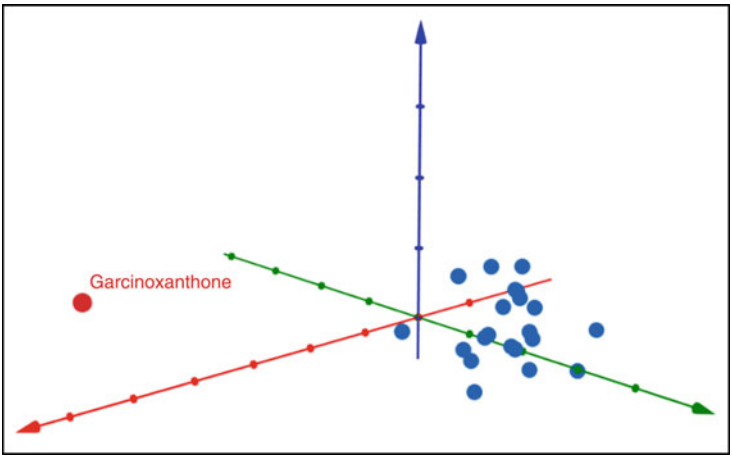

Fig. 9 The remarkable deviation of garcinoxanthone from the rest of the xanthones in the chemical property space where PC1(x=red), PC2(y=green) and PC3(z=blue)

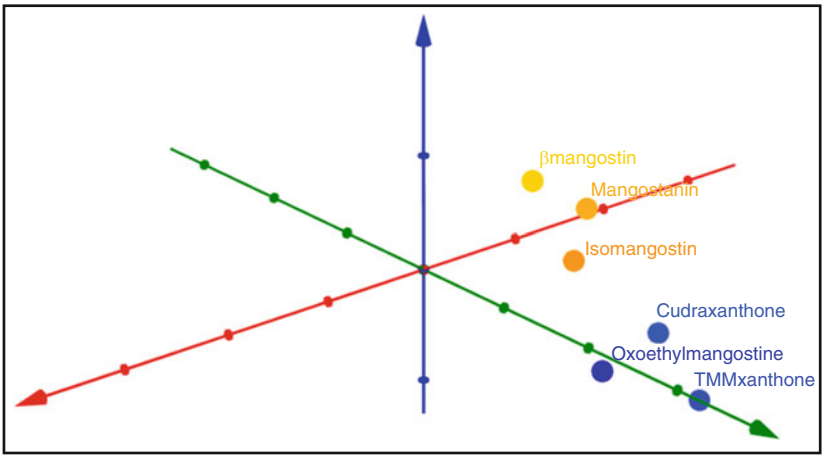

Fig. 10 Anti-obesity and antidiabetics, activity spaces within the chemical property space of xanthones. The fading shade grade shows decrease in activities while the intense shade shows the higher

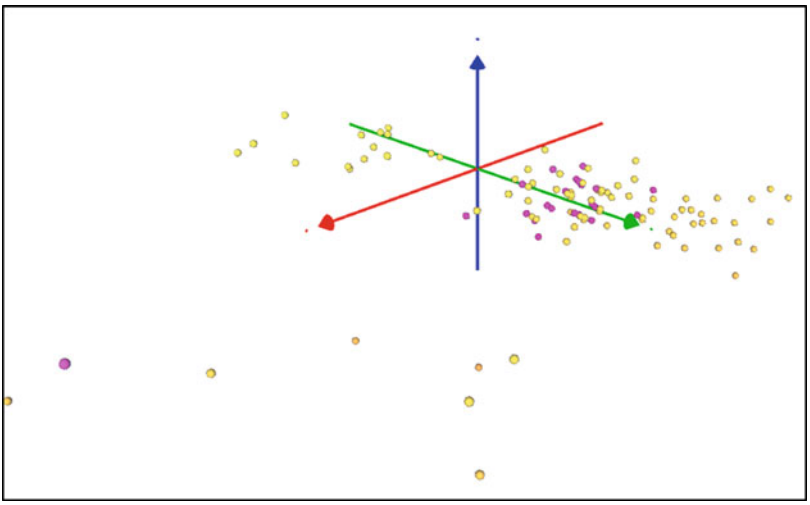

Fig. 11 Activity space determined with bioactive xanthones (anti-obesity and antidiabetics) in pink as compared with the yellow spheres of xanthones in general

The target correlation was established between anti-obesity and antidiabetics, as presented by plotting highest activities of the main compounds. Two distinct spaces were identified referring to unique activity spaces (Fig. 10). Such correlation can be advantageous to predict similar activities for compounds that close or in subspace.

In the Fig. 11 we are able to determine the "activity space" by plotting the active compounds and defining that enclosed space. The activity space can further predict type and extent of activity of any xanthone compounds by simple comparison by two simple questions, firstly, "Does the compound belong to the activity space or not?" and secondly "How far is the compound location from the central of activity space?" – i.e. the further is the distance, the lower could be the activity. The activity space studied here belongs to the anti-obesity and antidiabetics.

Abstract

Prenylflavonoids, which are also often referred to as prenylated flavonoids, are one of the classes of naturally occurring flavonoids that are widely distributed in plants. They possess at least one prenyl group on the flavonoid skeleton and have various reported bioactivities. Several prenylated flavonoids have been reported from edible plant species, such as *H. lupulus*, *G. glabra*, *M. alba*, *A. heterophyllus*, *G. max*, etc., and their efficacy for promoting human health has been discussed by mainly investigating their bioactivities. This chapter summarizes the bioactivities, bioavailabilities, and metabolism of the prenylated flavonoids from *H. lupulus*, *G. glabra*, *M. alba*, *A. heterophyllus*, and *G. max*, as well as their safety, application in foods, and some restrictions.

11.1 Introduction

Prenylated flavonoids are one of the classes of flavonoids produced by plants and are widely distributed in the Leguminosae, Moraceae, Euphorbiaceae, Guttiferae, and Umbelliferae plant families (Sasaki et al. 2011). They are also often called prenylflavonoids and possess at least one prenyl group, constituted by a dimethylallyl (3-methylbut-2-en-1yl) unit with five carbons on the flavonoid skeleton. In general, *C*-prenylation occurs on the flavonoid skeleton, and *O*-prenylation has also been reported (Barron and Ibrahim 1996; Yang et al. 2015). In the prenylated flavonoids, the prenyl group is also often cyclized to form a pyran ring with the flavonoid skeleton.

Flavonoids are not only a biologically important family of compounds for plant defense but also pharmaceutically important natural products with various properties, including antitumoral, antiviral, anti-inflammatory, antibacterial, antifungal, anti-osteoporotic, antithrombogenic, antiatherosclerotic, and other activities (Agrawal 2011). In most cases, the prenylation(s) of the flavonoids improve their biological activity (Mukai 2018). An example is the *C*-prenylation of the methylflavonoids isolated from the roots of *Desmodium caudatum*: The *C*-prenylation of the methylflavonoids enhanced the antifungal activities against *Trichophyton* sp. by fourfold over that of the flavonoids without a prenyl group, due to the enhanced binding affinity to biological membranes and improved interaction with target proteins by the increased lipophilicity (Sasaki et al. 2012).

Several prenylated flavonoids have been reported from edible plant species, namely, *H. lupulus*, *G. glabra*, *M. alba*, *A. heterophyllus*, and *G. max*. Their impact on human health has been discussed on the basis of the bioactivities of the phytochemicals found in these plants. Among them, *H. lupulus* (Hop) (Fig. 1A) is a flowering plant belonging to the Cannabaceae family and is native in Europe, Southwestern Asia, and North America. It goes without saying that the female cone fruits of *H. lupulus* have been utilized to produce beers. The addition of hops to beverages, especially beer, is largely to impart the distinctive bitter taste and

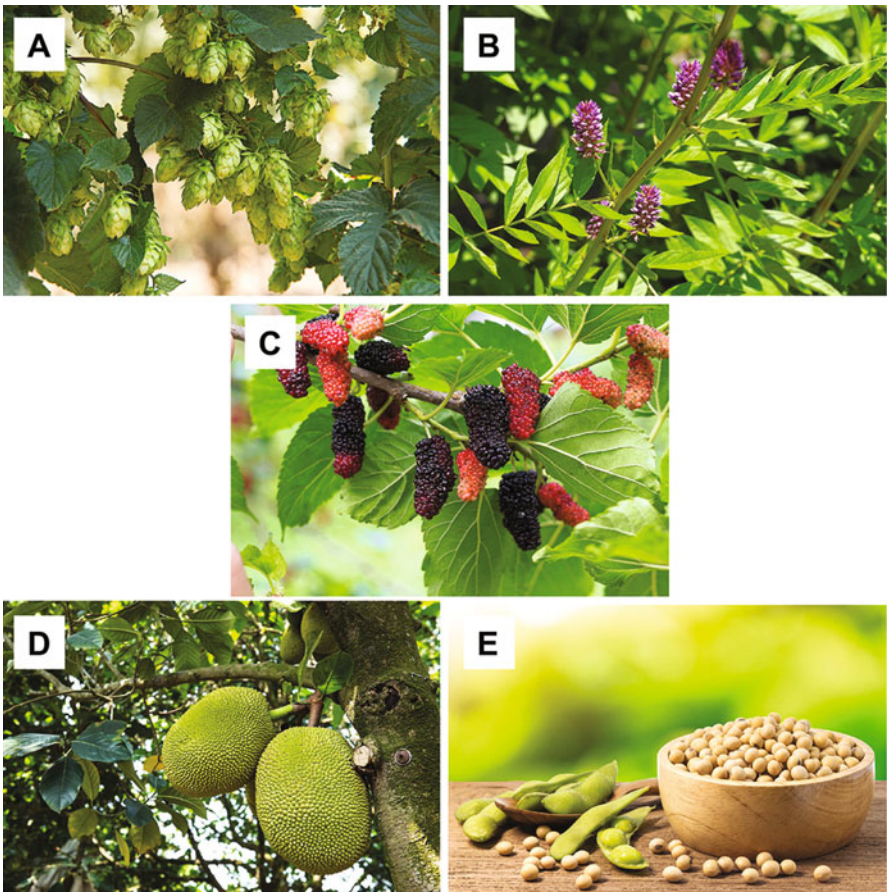

Fig. 1 Photos of edible plant species containing prenylated flavonoids. (**A**) Hop (*H. lupulus*), (**B**) licorice (*G. glabra*), (**C**) white mulberry (*M. alba*), (**D**), jackfruit (*A. heterophyllus*), (**E**) soybean (*G. max*)

aroma, to precipitate certain nitrogenous constituents of the wort, to act as filter aid in the hop back, to confer antibacterial properties to beer, and to assist in the stabilization of the wort (Almaguer et al. 2014). In addition, *H. lupulus* has been traditionally utilized to relieve excitability and restlessness associated with headache, to improve appetite and digestion, and to relieve toothache, earache, and neuralgia (Barnes et al. 2007; Grieve 1971), as well as to remedy sleeplessness and nervousness (Blumenthal and Busse 1998; Zanoli and Zavatti 2008). Further applications of hops for diuretic, antispasmodic, aphrodisiac, sedative, anti-inflammatory, antirheumatic, and anti-pneumonia purposes have also been reported (Zanoli and Zavatti 2008; Bown 2001; Blumenthal and Busse 1998; Weiss 1988; Duke 1985).

G. glabra (licorice) (Fig. 1B) belongs to the family Leguminosae and is native to Southern Europe and parts of Asia. The *G. glabra* root is widely utilized in the food industry as a flavoring agent and confectionary. The first recognized medicinal use of

licorice has been traced back to ancient Assyrian, Egyptian, Chinese, and Indian cultures (Fiore et al. 2005). Licorice is used in traditional medicine for the treatment of some diseases, such as those involving the genital-urinary, gastrointestinal, respiratory, and cardiovascular systems, as well as skin and eye sicknesses (Fiore et al. 2005). Barnes et al. also reported the usage of licorice as an expectorant, demulcent, antispasmodic, anti-inflammatory, and laxative (Barnes et al. 2007). Furthermore, licorice reportedly plays critical roles in the treatments of dyspepsia, and gastric and duodenal ulcers, as well as in the prevention of toxin accumulation in the liver, the reduction of allergic reactions, and the recovery from fatigue and debilitation (Xiaoying et al. 2017). In addition, licorice reportedly possesses efficacy for the treatments of chronic gastritis, peptic ulcer, colic, and primary adrenocortical insufficiency, as well as the accumulation of phlegm associated with coughs and bronchial catarrh (Barnes et al. 2007; Xiaoying et al. 2017).

M. alba (white mulberry) (Fig. 1C) is a moderately fast-growing deciduous shrub or tree growing up to 20–35 m that belongs to the Moraceae family. *M. alba* is commonly found in Korea and China, as well as in warm temperate and subtropical zones of Europe, Asia, and America, and is mainly cultivated in Southeast and East Asian and Middle Eastern countries (Muller 2001). *M. alba* has a wide range of usages and is especially valued for its edible fruits and medicinal properties. Its sweet-tasting fruits are consumed in the raw, fresh, or dried form and are utilized for beverage production, while the foliage is fed to silkworms in the silk-making industry (Ercisli 2004). The fruits of this plant are commonly converted to syrup and used as a honey alternative in Central, Northeast, and Southeast Anatolia (Ercisli 2004). The fruits are also fermented to produce beer, jams, and jellies, while the root extract is used for the treatment of inflammation, diabetes, high blood pressure, and AIDS (Srivastava et al. 2006). Powder from *M. alba* leaves is used in Chinese traditional medicine for treating obese diabetic and hypertensive patients. The leaves are also used in Indian cuisine, such as curry, *saag*, *pakoda*, *paratha*, and *dhokla* (Srivastava et al. 2006; Yen et al. 1996).

A. heterophyllus (jackfruit) (Fig. 1D) also belongs to the same family as white mulberry and is indigenous to South and Southeast Asia. The jackfruit tree reportedly originated in either the rain forests of the Western Ghats in Southwestern India or Malaysia. This plant was progressively introduced to other countries and is currently cultivated in Asia, Australia, the Caribbean region, and America (Azad et al. 2007; Baliga et al. 2011). This plant species has many dietary and medicinal uses. The seeds and young fruits are used as vegetable curries and pickles, while the fresh fruits are consumed in the raw form and in fruit salads. Furthermore, the ripened fruits are converted to syrup, whereas the pulps are consumed as the dried material, or incorporated into juice, biscuits, leather, toffee, and flavors for beverages and ice cream (Azad et al. 2007; Prakash et al. 2009). In India, jackfruits are popular foods and are ranked third in annual production, after banana and mango. In Bangladesh, it is an extremely important tree, and the fruits are widely consumed (Baliga et al. 2011). Most of the parts of the jackfruit tree reportedly possess medicinal properties and have been utilized in the preparation of various old holistic ("whole-body") Indian folk healing systems, Ayurvedic and Yunani medicines

(Saxena et al. 2009). Ripe jackfruits are used to prevent the excessive formation of bile, to develop fresh phlegm, to strengthen the body, and to increase virility. Seed and bark extracts are utilized to aid digestion and for the treatment of diarrhea and dysentery.

G. max (soybean) (Fig. 1E) is the plant that provides soybeans for making soy-based foods (Chen et al. 2012). *G. max* belongs to the Fabaceae family and is native to Southeastern Asia. Its dietary value has been recognized in Asian countries for more than 5,000 years. It is claimed that, in China, the Chou dynasty developed several fermentation methods to make soybeans in different dietary forms, such as tempeh, miso, and tamari soy sauce, before the discovery of tofu in the second century (Badole and Bodhankar 2013). Soybean was introduced to the USA between 1765 and 1800 (Badole and Bodhankar 2013; Brachfeld and Choate 2007) and to Europe in the 1700s (Badole and Bodhankar 2013). One of the important roles of soybean was its implementation in crop rotation as a nitrogen fixator, to restore nitrogen-depleted soil. Several traditional medicine applications of soybean and its constituents include osteoporosis prevention (Wong et al. 2009), bone mineral density restoration in menopausal women (Wong et al. 2009), anti-inflammation (Liao et al. 2009), cancer prevention (Zou and Chang 2011; Sakamoto et al. 2010), and as an antioxidant (Dixit et al. 2012; Takahashi et al. 2005). Other parts of this plant also have been utilized in treatments for various diseases in traditional medicine (Baliga et al. 2011).

This chapter mainly highlights the bioactivities, bioavailabilities, and metabolism of prenylated flavonoids in *H. lupulus*, *G. glabra*, *M. alba*, *A. heterophyllus*, and *G. max*, as well as their safety, application in foods, and some restrictions. Their marketed products, as well as patents, will also be discussed in this chapter.

11.2 Bioactive Dietary Prenylated Flavonoids

Several dietary prenylated flavonoids with good pharmacological activities have been isolated from *H. lupulus*, *G. glabra*, *M. alba*, *A. heterophyllus*, and *G. max*. Xanthohumol (**1**) and desmethylxanthohumol (**2**) are examples of bioactive *C*-prenylated chalcones with a 3,3-dimethylallyl moiety at C-5′, isolated from *H. lupulus* (Stevens et al. 1997; Stevens and Page 2004; Zanoli and Zavatti 2008) (Fig. 2). Two flavanone types of prenylated flavonoids with a 3,3-dimethylallyl moiety at C-8, isoxanthohumol (**3**) and 8-prenylnaringenin (**4**), were also isolated from this plant (Stevens et al. 1997; Stevens and Page 2004; Zanoli and Zavatti 2008). In addition to the prenylated chalcones and flavanones, phytochemical investigations of *H. lupulus* reportedly indicated the presence of 6-prenylnaringenin (**5**), with a 3,3-dimethylallyl moiety at C-6 of the flavanone backbone structure (Stevens et al. 1997; Stevens and Page 2004; Zanoli and Zavatti 2008).

A phytochemical investigation of *G. glabra* revealed that this plant contains licoflavone A (**6**), which is the flavone type of **5** (Xiaoying et al. 2017) (Fig. 3). Furthermore, licochalcone A (**7**) with a 1,1-dimethylally moiety at C-5′ and

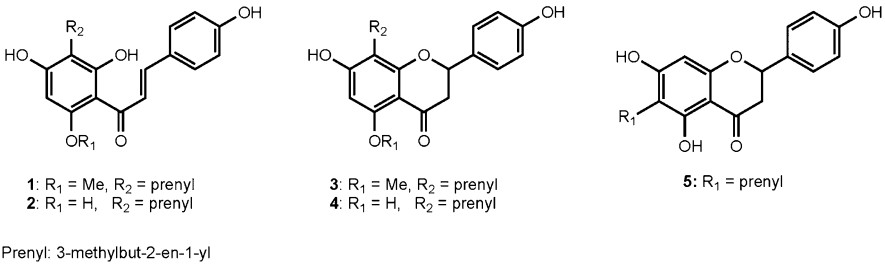

Fig. 2 Examples of bioactive dietary prenylated flavonoids (**1**–**5**) of *H. lupulus*

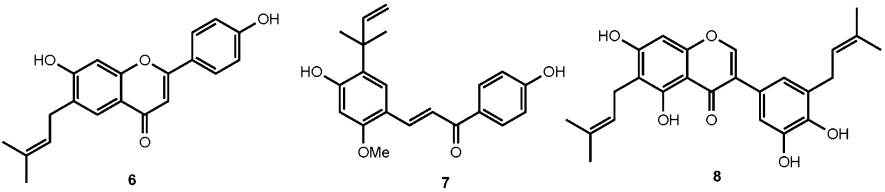

Fig. 3 Examples of bioactive dietary prenylated flavonoids (**6**–**8**) of *G. glabra*

isoangustone A (**8**) with two 3,3-dimethylallyl moieties at C-6 and C-5′ of the isoflavone skeleton have also been isolated from *G. glabra* (Xiaoying et al. 2017).

Flavone types of prenylated flavonoids, such as 3′-geranyl-3-prenyl-2′,4′,5,7-tetrahydroxyflavone (**9**), 3′,8-diprenyl-4′,5,7-trihydroxyflavone (**10**), cyclomulberrin (**11**), sanggenons J (**12**) and K (**13**), cyclomorusin (**14**), morusin (**15**), atalantoflavone (**16**), and kuwanon G (**17**), have been isolated from *M. alba* (Butt et al. 2008; Dat et al. 2010) (Fig. 4). The prenyl moiety of most of the prenylated flavones is cyclized to form the pyran ring, as observed in the structures of **11**–**16**, and this is one of the characteristic structural features of the isolates from *M. alba*. The *C*-geranylated flavone possessing a geranyl moiety consisting of two dimethylallyl units, as in **9**, was also isolated from this plant.

As in the case of *M. alba*, prenylated and/or prenyl moiety-cyclized flavone types of prenylated flavonoids, such as albanin A (**18**), cudraflavones B (**19**) and C (**20**), artocarpin (**21**), norartocarpin (**22**), artocarpetin A (**23**), kuwanon C (**24**), and brosimone I (**25**), have been isolated from *A. heterophyllus*, together with **4** (Baliga et al. 2011; Ko et al. 1998; Lin et al. 1996) (Fig. 5). Furthermore, phytochemical investigations have revealed that jackfruit is a rich source of highly prenylated flavones, such as artonins A (**26**) and B (**27**), cycloheterophyllin (**28**), cycloheterophyllin diacetate (**29**), and cycloheterophyllin peracetate (**30**) (Baliga et al. 2011; Ko et al. 1998; Lin et al. 1996), in which at least two dimethylallyl moieties have been cyclized with the flavone skeleton to form the pyran rings.

In contrast to *H. lupulus*, *G. glabra*, *M. alba*, and *A. heterophyllus*, 6α-hydroxypterocarpan types of prenylated isoflavonoids, such as glyceollins I–III (**31**–**33**), glyceofuran (**34**), and glyceollins IV–VI (**35**–**37**), were isolated from *G. max* as phytoalexins (Bamji and Corbitt 2017; Keen et al. 1989; Nwachukwu et al. 2013;

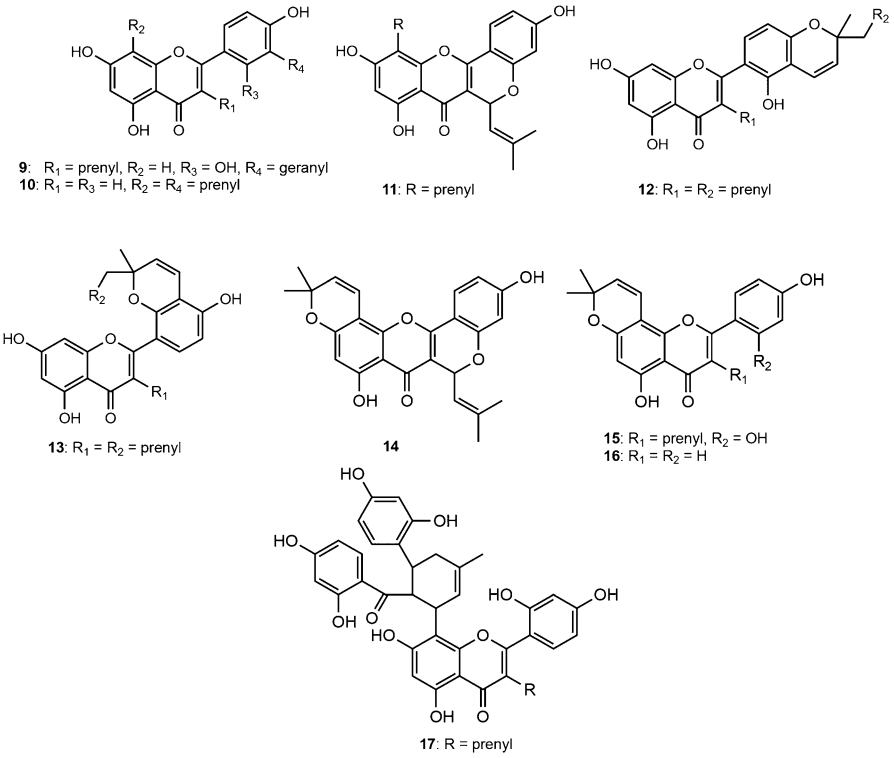

Fig. 4 Examples of bioactive dietary prenylated flavonoids (**9**–**17**) of *M. alba*

Simons et al. 2011) (Fig. 6). These are prenylated isoflavonoids with a dimethylallyl moiety at C-6 or C-8; however, most of the dimethylallyl moieties of the prenylated isoflavones from soybean have been cyclized to form pyran or furan rings.

11.3 Bioavailability and Metabolism

Dietary prenylated flavonoids possess numerous biological activities. The continuous and long-term intake of dietary prenylated flavonoids could lead to potential side effects, as alterations of their chemical structures due to our bodily metabolism lead to changes in their bioavailability, which can cause aberrant accumulation in the tissues of some organs. In general, the prenylations of flavonoids have been recognized as an important biodefense system in plants, since those modifications often enhance the bioactivities of the flavonoids over those of the non-prenylated forms and/or add new ones to the flavonoids. Recent investigations of the effects of the prenylation of flavonoids have proposed that the modification(s), which increase their lipophilicity, contribute to alterations of their bioavailability by improving the

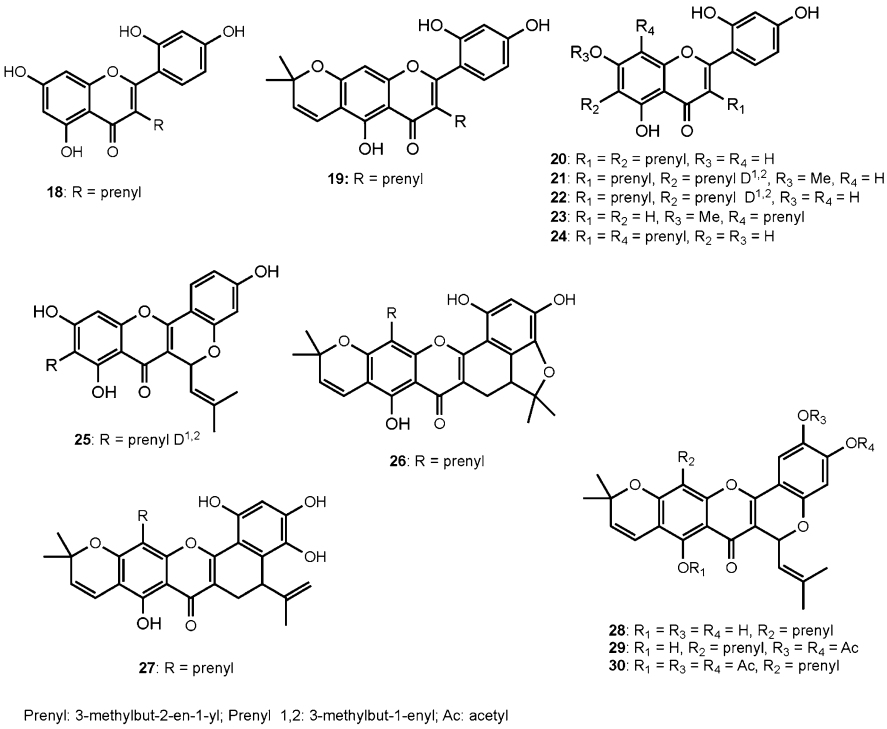

Fig. 5 Examples of bioactive dietary prenylated flavonoids (**18**–**30**) of *A. heterophyllus*

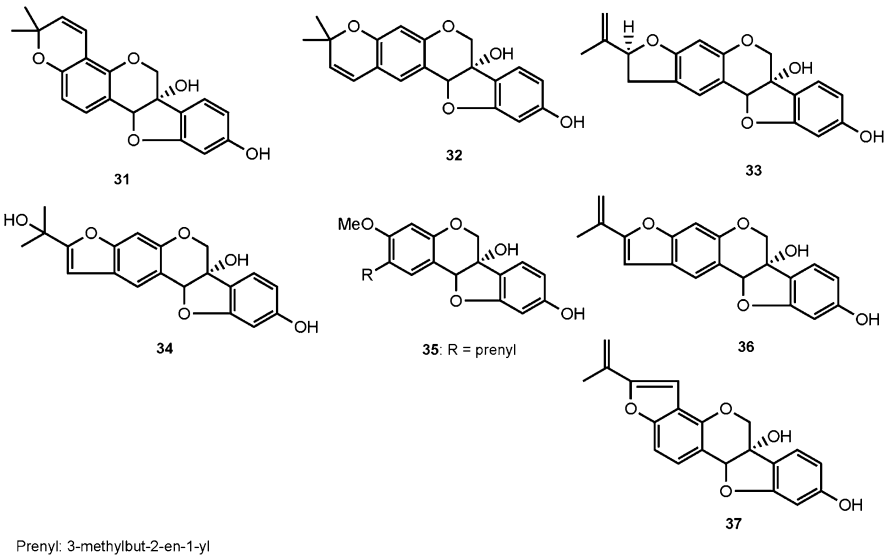

Fig. 6 Examples of bioactive dietary prenylated flavonoids (**31**–**37**) of *G. max*

absorption by tissues and/or interactions with target proteins, although further investigations will be required to understand the detailed mechanism (Mukai 2018; Terao and Mukai 2014). To be truly effective, diet-based prenylated flavonoids should be easily absorbed and metabolized. Considering the importance of these criteria, investigations have been conducted on the metabolism of dietary prenylated flavonoids from *H. lupulus*, *G. glabra*, and *G. max*.

One of the most extensively investigated diet-based prenylated flavonoids is xanthohumol (**1**), a well-known constituent of *H. lupulus*. In 2010, Hanske et al. reported the impact of human intestinal bacteria on the bioavailability of **1**, by comparing germ-free (GF) and human microbiota-associated (HMA) rats (Hanske et al. 2010). This study demonstrated that **1**, its conjugates, and isoxanthohumol (**3**) conjugates were present in the blood samples of GF and HMA rats, while **1** was found only in the blood of HMA rats. Furthermore, Hanske et al. revealed that the colonization of the rats' guts by human intestinal bacteria had no effect on the overall recovery of the applied **1** dose. However, in this study, the excretion of **1** and **3** conjugates was lower in HMA rats, and thus the study also suggested their hydrolysis by human intestinal microbiota. 8-Prenylnaringenin (**4**) was also formed by the bacterial *O*-demethylation of **3**, exclusively in HMA rats. It was recommended that, for the evaluation of the in vivo effects of **1**, the microbial impact on its metabolism in the gut should be considered (Hanske et al. 2010).

The beneficial effects on markers of metabolic syndrome in old Zucker fa/fa rats, in a rodent model of obesity, have also been reported for xanthohumol (**1**), based on a study of the in vitro phase II metabolism of **1**, using nine human recombinant UDP glucuronosyltransferases (UGT) and five sulfotransferases (SULT) (Legette et al. 2013). HPLC-DAD and HPLC-MS analyses demonstrated that **1** was significantly glucuronidated by UGT 1A8, 1A9, and 1A10. Furthermore, the study also revealed that UGT 1A1, 1A7, and 2B7 were the more important UGTs and that SULT 1A1∗2, 1A2, and 1E1 were the most active SULT forms in the sulfation reaction, while UGT 1A3, 1A4, and 1A6, as well as SULT 1A3 and 2A1, were less important UGTs for the conjugation of **1** (Ruefer et al. 2005). An in vitro investigation of the metabolism of **1** and isoxanthohumol (**3**) in human liver microsomes indicated that the hydroxylation of the prenyl methyl groups of **1** and **3** was the principal route in the oxidative process, to afford either the *cis* or *trans* hydroxylated metabolites of **1** and the *trans* isomer of **3** (Figs. 7 and 8). The investigation also revealed that the epoxidation of the double bond on the prenyl groups of both **1** and **3** led to the formation of cyclized metabolites by intramolecular reactions with the neighboring hydroxyl group (Nikolic et al. 2005). This study also showed that 8-prenylnaringenin (**4**), a potent phytoestrogen, was obtained as a demethylation product of **3**, while the similar demethylation reaction was not observed for **1**. Knowing that the cyclization of **1** to **3** could occur by acid catalysis in the stomach, **1** might contribute to the in vivo levels of the estrogenic **4**, resulting from the consumption of hops (Nikolic et al. 2005)

Very little information about the bioavailability and metabolism is available for the *G. glabra* prenylated flavonoids. Nonetheless, LC/SRM-MS analyses of rats orally administered a licorice water decoction, at 0.9 g crude drug/kg, detected the

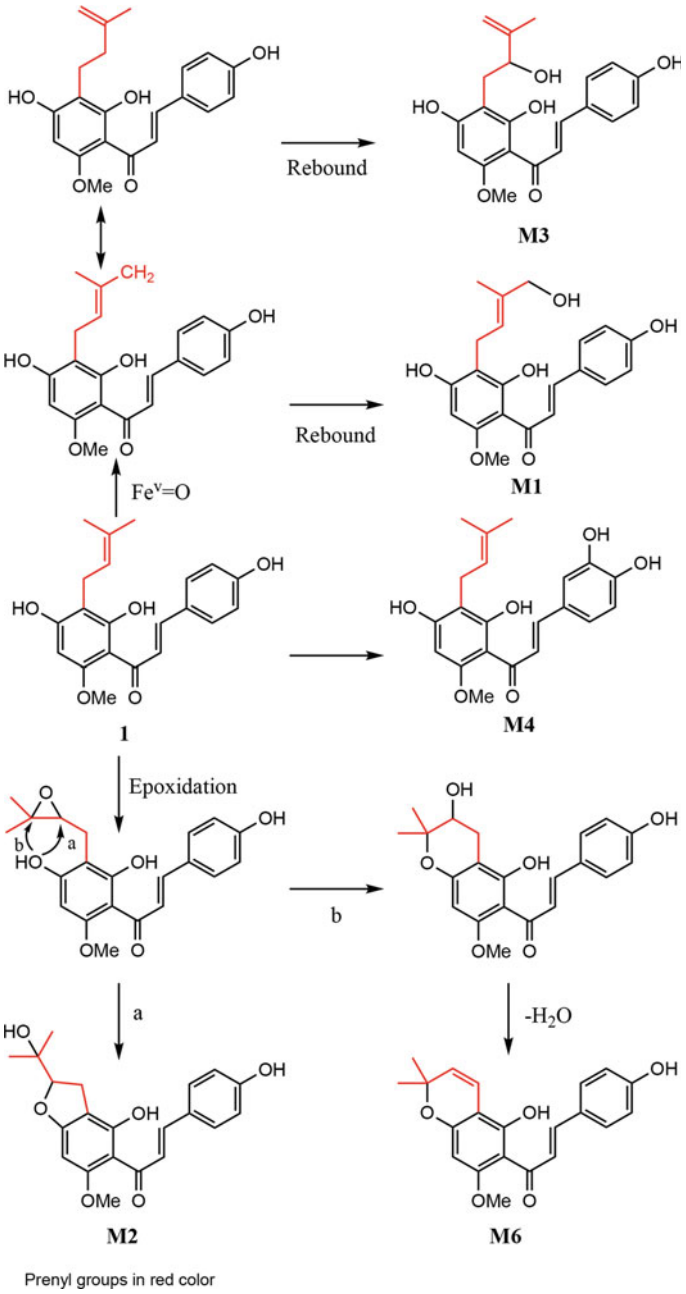

Fig. 7 Metabolic pathways of **1** catalyzed by human liver microsomes. M1 is formed by hydrogen abstraction followed by oxygen rebound. The metabolites of **3**, M7, M8, M10 and M11, are formed via analogous mechanisms (See Fig. 8). Epoxidation of the double bond leads to the formation of cyclized products by intramolecular attack of the hydroxyl group

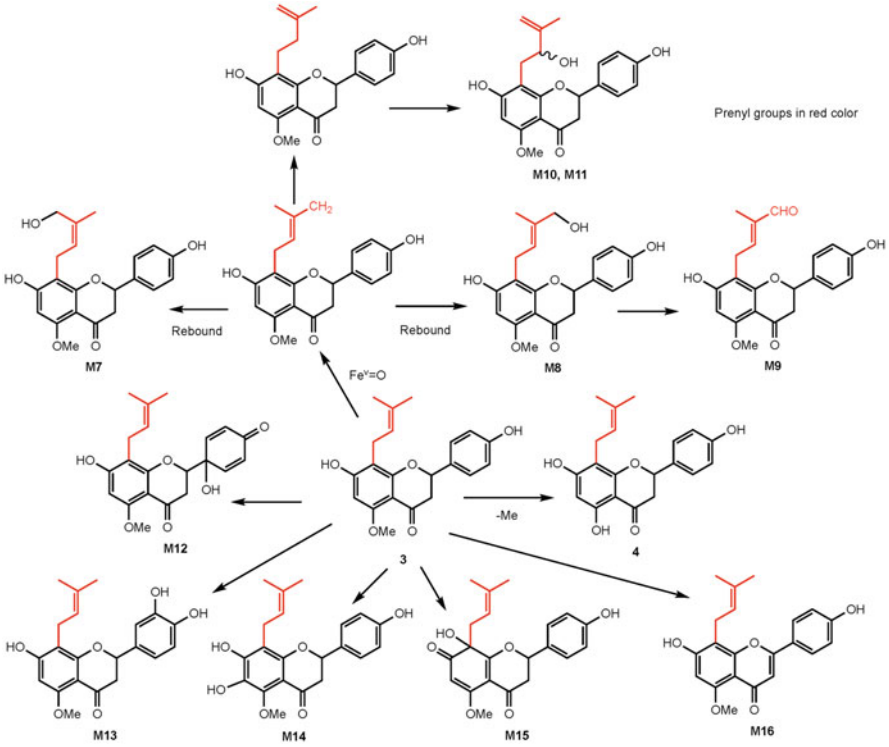

Fig. 8 Metabolic pathways of **3** catalyzed by human liver microsomes. Metabolites originate through the transformation of either the prenyl group or the flavanone skeleton. The metabolism of **3** is similar to that of **4**, except for the formation of M14 and M15. The demethylation reaction is biologically significant, since it converts the weakly estrogenic **3** into the potent phytoestrogen **4**

presence of licoisoflavone A-*O*-GluA and licoisoflavone B-*O*-GluA, together with monoglucuronide and diglucuronide conjugates of licoisoflavones A and B, in their blood, urine, and feces (Xiang et al. 2011). Isoangustone A (**8**) was also found to be metabolized in a similar manner as licoisoflavones A and B (Xiang et al. 2011). Glabridin, one of the major prenylated isoflavones in licorice, was also detected by LC–MS^n in an extract from human plasma obtained by solid-phase extraction (Aoki et al. 2005).

During an investigation of the estrogen-modulating effects of glyceollin-enriched soy protein in a postmenopausal primate model, the bioavailability of dietary glyceollins I–III (**31**–**33**) was reported in the serum (Wood et al. 2006). Interestingly, the bioavailability of single-dose prenylated flavonoids was lower than that of the parent flavonoids, despite the higher uptake into the epithelial cells of the digestive tract. This observation has been explained to be due to the restriction of the efflux from epithelial cells to the blood circulation by the prenyl groups, thus generating an insufficient increase in the plasma concentration (Terao and Mukai 2014).

Prenylation also reportedly accelerates the accumulation of quercetin and naringenin in liver and muscle tissues, respectively, after long-term feeding. In these cases, the prenyl groups would restrict the efflux from hepatocytes to the blood and enterohepatic circulations, by decreasing the excretion of prenylated flavonoids from the blood circulation and the efficient uptake by tissues. These investigations suggested that in cases of long-term supplementation, the hepatotoxicity as well as other deleterious and beneficial effects should be considered to avoid high accumulation in some tissues (Mukai et al. 2012; Terao and Mukai 2014).

The effect of prenylation on the physiological functions of dietary flavonoids was clarified by comparing the efficacy of 8-prenylnaringenin (**4**) with that of naringenin in the prevention of disuse muscle atrophy, in a model of denervation in mice (Mukai et al. 2012). The consumption of **4**, without the presence of naringenin, prevented the loss of weight in the gastrocnemius muscle, with tenfold higher potency than that of naringenin, suggesting that the prenylation generated novel functions for **4**.

Currently, there are no reports on the bioavailability and metabolism of prenylated flavonoids from *M. alba* and *A. heterophyllus*. Considering the importance of the bioavailability and metabolism of dietary prenylated flavonoids, in-depth studies should also be performed on the prenylated flavonoids from *M. alba* and *A. heterophyllus*, to provide further insights into the beneficial nutritional values of dietary prenylated flavonoids.

11.4 Bioactivities of Dietary Prenylated Flavonoids

Due to the presence of prenylated flavonoids in many food sources, their biological activities have been intensely investigated, and antioxidant, estrogenic, anticancer, anti-inflammatory, antibacterial, antivirus, and antiphospholipase phosphorylation activities have been described (Mukai 2018; Yang et al. 2015). However, these investigations have mainly been performed in vitro. Considering the relevance of in vivo studies of the dietary aspects of prenylated flavonoids, this chapter focuses on only the in vivo bioactivities of prenylated flavonoids, as well as extracts that are rich in prenylated flavonoids.

11.4.1 Extracts Rich in Prenylated Flavonoids

11.4.1.1 Menopausal Alleviation and Other Activities of Hop Extracts Rich in Prenylated Flavonoids

The efficacy of the hop has been investigated by orally administering hop extract and chemically standardized hop extracts with xanthohumol (**1**), isoxanthohumol (**3**), 8-prenylnaringenin (**4**), and 6-prenylnaringenin (**5**) to female Wistar rats, at a dose of 60 mg/kg body weight/day for 8 weeks (Keiler et al. 2017). This study indicated that the hop extracts significantly decreased the number of osteoclasts in the tibial metaphysis and prevented the reduction of the trabecular thickness from

estradiol depletion, without showing either proliferative or uterotrophic effects on the endometrium. Nevertheless, an unexpectedly high serum level of **4** relative to those of the other major marker compounds was also observed.

A xanthohumol (**1**)-rich (*c*. 18%) hop extract reportedly reduced obesity occurrence in rats on a high-fat diet (Yui et al. 2014). In this study, lower liver weights, as well as triacylglycerol levels, in the plasma and liver were also observed. These observations probably occurred from the modulation of hepatic fatty acid synthesis and the secretion of adiponectin induced by the dietary **1**-rich hop extract. The inhibition of intestinal triacylglycerol absorption by the dietary **1**-rich hop extracts also points to the reduction of triacylglycerol levels in the plasma and liver.

11.4.2 Main Bioactive Compounds

11.4.2.1 Antidiabetic Activity

The effect of the xanthohumol (**1**)-enriched stout beer consumption on the hepatic glucolipid metabolism imbalance seen in type 1 diabetes was investigated with five groups of Wistar rats, streptozotocin-induced diabetic rats given untreated drinking water and drinking treated with 5% ethanol, stout beer, and stout beer supplemented with 10 mg of **1**/L, in addition to healthy rats' untreated drinking water as a control (Lima-Fontes et al. 2017). This investigation revealed that **1** reduced hepatic fibrosis, reversed hepatic glucose transporter expression as well as glycogen content, and modulated the lipid metabolism in type 1 diabetic rats. However, **1** probably interfered with the insulin signaling pathway, as its consumption targeted the metabolic changes induced by diabetes. Further investigation of the effects of xanthohumol (**1**) and **4** on liver and skeletal muscle lipids and glycolytic metabolism in a type 2 diabetes mellitus mice model also revealed that the consumption of **1** and **4** protected against the development of type 2 diabetes mellitus metabolic-related complications and had beneficial effects by reducing obesity, preventing insulin resistance, and modulating lipid and glucose metabolic pathways (Costa et al. 2017). This showed a potential dietary approach for avoiding common metabolic illnesses, such as type 2 diabetes mellitus.

The antidiabetic action of fermented soybeans containing glyceollins I–III (**31**–**33**) in type 2 diabetic animals was investigated, by comparing the effects in diabetic mice induced by intraperitoneal injections of streptozotocin at a dose of 20 mg/kg/body weight, with those treated with no soybeans (control), 10% unfermented soybeans, and 10% fermented soybeans containing glyceollins (Park et al. 2012). Park et al. thus provided insight into not only the improvement of glucose homeostasis but also the partial enhancement of hepatic insulin sensitivity in type 2 diabetic mice by fermented soybeans containing glyceollins. In addition, the oral administration of **31**–**33** at a dose of 30 or 90 mg/kg to prediabetic rats revealed that **31**–**33** significantly decreased the blood glucose excursion and were absorbed in plasma cells 4 h after oral administration. The glucose uptake, basally stimulating insulin, was increased 1.5-fold in 3 T3-L1 adipocytes by 5 μM of **31**–**33** in a dose-responsive manner, while the glucose uptake was potentially improved (Boué et al.

2012). These findings suggested the potential benefits of glyceollins as an intervention in prediabetic conditions, as well as a treatment for type 1 and type 2 diabetes, by increasing both the insulin-mediated and insulin-independent glucose uptake by adipocytes.

11.4.2.2 Anticancer Activity

Some studies have reported the in vivo anticancer activities of xanthohumol (**1**), the most abundant prenylated chalcone in *H. lupulus* (Jiang et al. 2018). A previous investigation indicated that the central necrosis within tumor tissues, the focal proliferation areas, the reduction in inflammatory cell number, the decrease in the microvessel density, and the increase in the percentage of apoptotic cells were caused by the oral administration of **1** to nude mice inoculated with MCF7 cells (Monteiro et al. 2008). Vene et al. also reported that **1** delayed tumor progression and inhibited the growth of poorly differentiated prostate carcinoma, in transgenic adenocarcinoma of the mouse prostate (TRAMP) transgenic mice in vivo (Vene et al. 2012), while Jiang et al. reported that **1** suppressed pancreatic cancer growth in xenograft mouse models, by investigating both the tumor weight and volume in nude mice with subcutaneously implanted PANC-1 cells, followed by the administration of **1** at a dose of 25 mg/kg/day per mouse (Jiang et al. 2015). Interestingly, **1** has also been found to significantly increase animal life span by delaying the insurgence of neurological disorders due to leukemic cell dissemination, which was investigated by administering 50 mg/mouse (5 days/week) of **1** to mice by an intraperitoneal route (Benelli et al. 2012). Furthermore, Dokduang et al. suggested that **1** inhibits STAT3 activation both in vivo and in vitro, due to the suppression of the Akt-NFκB signaling pathway, and may be considered as a possible therapeutic agent against cholangiocarcinoma (Dokduang et al. 2016), because the oral administration of 50 μM of **1** in drinking water to nude mice inoculated with cholangiocarcinoma inhibited tumor growth. In addition, the suppression of triple-negative breast tumor growth in vivo by glyceollins I–III (**31**–**33**) was determined by evaluating the tumor growth in immunocompromised female nude mice with fat pads injected with either MDA-MB-231 or MDA-MB-468 cells mixed with a reduced growth factor Matrigel, followed by a treatment with glyceollins at a dose of 50 mg/kg/day (Rhodes et al. 2012).

A study of the effect of glyceollins I–III (**31**–**33**) on the growth of estrogen-dependent MCF-7 breast cancer and BG-1 ovarian cancer cells implanted in ovariectomized athymic mice revealed that **31**–**33** inhibit the estradiol-stimulated tumor growth of MCF-7 and BG-1 cells in these mice by −53.4% and − 73.1%, respectively. Thus, Salvo et al. suggested that **31**–**33** are useful antiestrogenic agents in the prevention or treatment of breast and ovarian carcinomas (Salvo et al. 2006).

11.4.2.3 Other Activities

In addition to the antidiabetic and anticancer effects, Ferk et al. reported that xanthohumol (**1**) might prevent heterocyclic mutagenesis inducing preneoplastic lesions and DNA damage in the liver and colon (Ferk et al. 2010). Furthermore, the effect of **1** on the prevention of acute hepatic injury induced by carbon

tetrachloride (CCl_4) was suggested by the facts that pretreatment of rats with **1** significantly decreased the liver weight in CCl_4-intoxicated rats, by normalizing the increased values of plasma lactate dehydrogenase, glutamate oxaloacetate transaminase, and glutamate pyruvate transaminase activities, and reduced the incidence of histopathological alterations produced by CCl_4. In addition, **1** is reportedly a good inhibitor of lipid peroxidation and protects antioxidant enzymes from the degradation induced by CCl_4 intoxication (Pinto et al. 2012).

The potential anti-inflammatory effect of glyceollins I–III (**31**–**33**) has been proposed, based on their significant reduction of 12-*O*-tetradecanoylphorbol-13-acetate-induced skin inflammation in an animal model (Kim et al. 2011). The allergic airway inflammation in a murine model of asthma was reportedly attenuated by licochalcone A (**7**) at a dose of 50 mg/kg, while **7** also prevented the increase of T-helper type 2 cytokines, including interleukin (IL)-4, IL-5, and IL-13, and decreased the serum levels of ovalbumin-specific immunoglobulin IgE and IgG (Chu et al. 2013).

Cycloheterophyllin (**28**) and artonins A (**26**) and B (**27**) from *A. heterophyllus* reportedly possess antioxidant activities, by inhibiting iron-induced lipid peroxidation in a rat brain homogenate (Ko et al. 1998). The potent inhibition of arachidonic acid-induced platelet aggregation by **28** was also reported (Lin et al. 1996).

The most potent phytoestrogen, 8-prenylnaringenin (**4**), protected from ovariectomy-induced bone loss and had minimal trophic effects (dose independent) on the uterus and endometrium with a tenfold lower stimulatory effect than 17β-estradiol, in adult ovariectomized rats as an animal model that mimics hormone-dependent osteoporosis in menopausal women (Hümpel et al. 2005). This showed that **4** may be an alternative new candidate for the treatment of peri- and postmenopausal symptoms. In addition, **4** has been administered orally, to assess its effects on ovariectomy and long-term treatment on pituitary and liver functions in rats, at doses of 6.8 and 68.4 mg/kg body weight, and compared to treatments with 17β-estradiol benzoate (E2B) at 0.17 and 0.7 mg/kg body weight (Böttner et al. 2008). As a result, the high dose of **4** reduced the body weight gain and raised LDL levels caused by the ovariectomy effect and elicited an increase in the uterine wet weight, while the serum GH levels and IGF-1 concentrations were, respectively, increased and decreased, with an attenuation of the total cholesterol augmentation owing to the ovariectomy induction. Bowe et al. reported that the tail skin temperature was significantly reduced within 2 days of daily subcutaneous administrations of **4** at the dose of 400 μg/kg, using a rat model of menopausal hot flushes (Bowe et al. 2006). Furthermore, they also revealed that the subcutaneous co-administration of either **4** or 17β-estradiol with the estrogen receptor (ER) antagonist, ICI 182,780 (200 μg/kg), which is thought not to cross the blood-brain barrier, totally blocked the effects of **4** or 17β-estradiol on the tail skin temperature. The increased tail skin temperature in ovariectomized rats was significantly inverted by the ERα- and ERβ-specific agonists, 4,4′,4″-(4-propyl-[1H]-pyrazole-1,3,5-triyl)trisphenol and 2,3-bis (4-hydroxyphenyl)-propionitrile, at doses of 100 and 60 μg/kg, respectively. Thus, Bowe et al. proposed that estrogens and phytoestrogens regulate the vasomotor by controlling the peripheral mechanisms related to both ERα and ERβ. On a related

note, ovariectomized rats fed with soy-free chow containing **4** for 3 months were reported to possess increased uterine weights and histologic estrogen-induced features, at a dose of 68.42 mg/kg body weight (Rimoldi et al. 2006).

11.5 Benefits

11.5.1 Diabetes

Dietary prenylated flavonoids and the extracts from their sources are used as food supplements with some beneficial effects for humans. Nevertheless, as far as we are aware, no human studies have been reported regarding the benefits of dietary prenylated flavonoids on diabetes.

11.5.2 Symptoms of Menopause in Women

The beneficial effects of the standardized hop extracts and the prenylated flavonoid, 8-prenylnaringenin (**4**), in women's menopause symptoms have been clinically investigated, and **4** reportedly possessed positive effects in postmenopausal women and could be used as an alternative to the conventional hormone replacement therapy treatment regimens (Rad et al. 2006). A study on the benefits of hop extracts on menopause symptoms attributed this property to **4** (Minecka et al. 2017). However, further studies are needed to determine the clinically effective dose of **4**.

11.6 Application in Foods

To the best of our knowledge, no specific preparation method of food rich in prenylated flavonoids has been reported so far. However, we would be obliged to comment that the food processing and products from soybean are one such example (Chen et al. 2012). Soybean processing is divided into two categories, non-fermented and fermented soyfoods. The non-fermented soyfoods include fresh soybeans, dehydrated soybeans, soy sprouts, whole fat and defatted soybeans, soy flour, and soymilk and its products, such as tofu, okara, and yuba. Fermented soyfoods are miso, natto, soy sauces, tempeh, and fermented tofu (Chen et al. 2012).

11.7 Safety: Toxicity and Side Effects

Safety for consumption has always been a primary concern for health regulators worldwide. Hence, as with any other food sources, the safety of dietary prenylated flavonoids for consumption and the side effects they may pose have also been investigated (Štulíková et al. 2018). Although the five plants discussed in this

chapter are edible, some toxicities and side effects of their chemical components have been reported.

An investigation of the effect of 8-prenylnaringenin (**4**) on the uterine wet weight of ovariectomized rats is one of the examples for the possible high risk in human applications (Keiler et al. 2015). In this study, Keiler et al. demonstrated that the subcutaneous administration of **4** to ovariectomized rats at 15 mg/kg of body weight for 3 days led to a significant increase in the uterine wet weight, as well as proliferation of the vaginal epithelium. In addition, although **4** was reported to prevent and treat hormone-dependent osteoporosis, this compound has also been found to be at least tenfold less stimulating than 17β-estradiol in the uterus of the animal model (Hümpel et al. 2005). A daily dose of 100 mg/kg body weight, with doses up to 1,000 mg/kg body weight, administered to female Sprague Dawley (SD) rats resulted in weak hepatotoxicity in the test subjects. However, there were no significant effects on the reproduction of SD rats and the development of two generations of SD rat offspring (Hussong et al. 2005).

In contrast, Keiler et al. reported that the hop extracts do not show any unwanted side effects in the mammary gland, based on the results obtained from an 8-week administration of this extract to rats (Keiler et al. 2017). Furthermore, a human study was performed with menopausal women to determine the safety and pharmacokinetics, using oral administration of hop extracts that are rich in xanthohumol (**1**), isoxanthohumol (**3**), 8-prenylnaringenin (**4**), and 6-prenylnaringenin (**5**) (van Breemen et al. 2014). Although the long half-lives of the estrogenic and pro-estrogenic effects of these prenylated flavonoids were found, no acute toxicity was reported. In addition, a recent review has also documented the safety of **1**, on the basis of experiments performed with human lung fibroblast cells (MRC-5), primary human hepatocytes, human skin fibroblasts, and oligodendroglia-derived cells (OLN-93) (Jiang et al. 2018). Furthermore, Vanhoecke et al. reported that the daily administration of 23 mg/kg body of **1** for 4 weeks to mice had no observable toxicity and side effects in the bone marrow, liver, exocrine pancreas, kidneys, muscles, thyroid, and ovaries (Vanhoecke et al. 2005). However, it should be noted that the in vivo studies were performed with normal animals to evaluate the safety and effectiveness. Hence, further investigations are required for the evaluation of the toxicity of **1** to normal organs in tumor-bearing mice (Jiang et al. 2018).

Although the safety of dietary prenylated flavonoids for consumption is a primary concern, that of the prenylated flavonoids found in *G. glabra*, *M. alba*, *A. heterophyllus*, and *G. max* has not yet been reported. The inadequate information on the dietary prenylated flavonoids provided thus far highlights the requirement of further investigations to prove their safety for consumption.

11.8 Marketed Products

H. lupulus, *G. glabra*, *M. alba*, *A. heterophyllus*, and *G. max* are marketed as processed food. *M. alba* and *A. heterophyllus* are also marketed in their raw or dried forms as fruits.

Beer contains many prenylated flavonoids from *H. lupulus*, such as xanthohumol (**1**) and desmethylxanthohumol (**2**) and their derivatives, isoxanthohumol (**3**), 8-prenylnaringenin (**4**), and 6-prenylnaringenin (**5**) (Venturelli et al. 2016). The high and increasing consumption of beer in almost all countries around the world is due to its availability in markets and affordability to almost all people, dependent on local regulations. Beer is therefore considered as the main marketed product with hops that is rich in prenylated flavonoids (**1**–**5**).

The use of *G. glabra* as food is mainly about its utilization as a natural flavoring agent, as listed by the Council of Europe. This means that licorice could only be added to food in small quantities as a flavor, and consequently, the active principles related to its prenylated flavonoids (**6**–**8**) content should be minimal (Barnes et al. 2007).

The applications of *M. alba* in food were also reported, and the fruits are generally eaten fresh or dried and marketed in a syrup form as an alternative to honey products (Ercisli 2004).

Some dietary applications of *A. heterophyllus*, one of the sources of prenylated flavonoids (**5**, **18**–**30**), have been reported so far. The raw fruits are marketed in the forms of vegetable curries and pickles, while the ripe fruits are processed into ice creams, beverages, jam, halwa, and jelly. The seeds are also available in the market in canned, brined, and tomato sauce forms (Baliga et al. 2011).

As marketed *G. max* products, we have fresh soybeans, dehydrated soybeans, soy sprouts, whole fat and defatted soybeans, soy flour, and soymilk and its products such as tofu, okara, and yuba, miso, natto, soy sauces, and tempeh. Some of these soyfoods are consumed daily by Westerners, and the most abundant in the USA are tofu, soymilk, miso, and soy sauce. Some soyfoods have also been locally adopted in America, with marketed names such as tofu ice cream, tofu hot dogs, veggie burgers, soy flour pancakes, soymilk yogurt, and soymilk cheese (Chen et al. 2012). Soybeans subjected to some extrinsic factors, such as fermentation with fungi, UV irradiation, and physical injury, produced prenylated flavonoids called glyceollins with multifunctional health-promoting properties (Nwachukwu et al. 2013). Some of these conditions applied during the preparation processes of certain soyfoods listed above have been extensively reviewed (Chen et al. 2012) and could be considered as a significant contribution in the production of soy diets rich in glyceollins (**31**–**37**).

11.9 Patents

Some findings related to plant foods with prenylated flavonoids are protected by patents. A patent was granted on the hop extract for its use in the preparation of a medication with estrogenic properties (WO2002085393A1 2002). Another patent protects the production of novel hop extracts with increased contents of prenylated chalcones and flavones. It is related to a method for producing pharmaceutical preparations of hop extracts and their use in the prophylaxis and therapy of conditions caused by estrogen deficiency or dysregulation of sex hormone metabolism (WO2003014287A1 2003). Thus far, no patent has been registered for the prenylated flavonoids found in *G. glabra*, *M. alba*, *A. heterophyllus*, and *G. max*.

11.10 Perspectives

Regarding edible plants, there are fewer reports on prenylated flavonoids, as compared to their non-prenylated counterparts. This translates into fewer investigations performed on the benefits and health risks posed by dietary prenylated flavonoids. Considering the boost to the biological activity imparted by the prenyl moiety to non-prenylated flavonoids, both the beneficial and detrimental effects of prenylated flavonoids could be amplified when consumed. Moreover, the dietary aspect also presents the bioavailability and metabolism conundrums of prenylated flavonoids that have yet to be fully clarified. Taken together, the current knowledge of dietary prenylated flavonoids is inadequate. Hence, increased efforts to investigate the benefits and health risks posed by prenylated flavonoids are necessary.

Abstract

Anthocyanins are a group of water-soluble pigments in the colorful plant world, which can be used as additives in food. Anthocyanins have a basic structure of flavonoid, which have shown outstanding antioxidative effects. The daily intake of anthocyanins is abundant, and they are inversely correlated with various kinds of chronic diseases, according to the epidemiological study. Anthocyanins have anti-inflammatory effects, could regulate lipid metabolism, ameliorate insulin resistance, and improve cholesterol efflux in foam cells, which can prevent and alleviate chronic diseases such as cardiovascular diseases, diabetes mellitus, neurosis, visual degradation, cancer, and so on. However, the bioavailability of anthocyanins was proved low, which may restrict the bioactivity of anthocyanins. Some of the studies reported that the metabolites of anthocyanins could be the active compounds to prevent diseases. The commercialized products of anthocyanins are emerging in the market these years, but their development is not enough, thereby calling for more careful and systematic studies.

12.1 Introduction

The plants in nature are colorful and beautiful, which are mainly related to pigments with a wide range of properties in plants. For example, chlorophyll, carotene, and lutein can make plants green, orange, and yellow. Generally, plant pigments are classified into water-soluble pigments and fat-soluble pigments. The fat-soluble pigments are mainly chlorophyll, crocin, and lycopene. Among the natural pigments, anthocyanins are the largest water-soluble group, which is widely distributed (Fig. 1).

A long time ago, people began to notice that plant juice could color clothes and food. During the Renaissance, Nehemiah Grew studied the juice of vegetable organs

Fig. 1 Anthocyanins in plant food

and proposed the concept of "red pigment," which made vegetables colorful. In 1810, *Goethe Farbenlehre* made a record of the red substance of the plant in detail. Later, with the invention of the microscope, people could observe the distribution of this "red pigment" in specific cell layers of plant organs. Since nobody had any knowledge of chemistry at that time, the colorful cell sap was considered as a class of pigments. Then, in 1835, Marquart created "anthocyanin" to name the blue pigments of cornflowers. The term anthocyanin is derived from the Greek words anthos (flower) and kyanos (blue).

From the end of the nineteenth century to the early twentieth century, researchers discussed the physiological and biochemical effects of anthocyanins in plants and proposed the theory of photoprotective function of anthocyanins. In 1891, Wheldale first identified the presence of glycosyl groups in anthocyanins. In 1905, Molish first obtained anthocyanin compounds. Then Willstatter and his co-workers laid the foundation of the chemistry of these pigments. They found that anthocyanins are glycosides of anthocyanidins, the latter being polyhydroxy and methoxy derivatives of a basic structure, 2-phenyl-benzopyrylium. In the meantime, they proposed a possible way of anthocyanins synthetization in plants. They extracted anthocyanin salts by methyl alcoholic hydrogen chloride, acetic acid, or other similar solvents and precipitated a crude, often syrupy, product with ether (Blank 1947). In 1918, Parkin printed a report to show the results of a survey of 400 species of plants. He found that anthocyanins existed in the cytoplasm. But the study ignored distributions in specific cell layers and did not list the species surveyed. Subsequently, Gertz and Wheldale conducted a larger-scale survey. They analyzed the relationship between

anthocyanin content and plant species and recorded the plant species with higher expression levels of anthocyanin.

In recent years, with the advent of high-performance liquid chromatography (HPLC), the synthesis process of anthocyanins has been basically clarified. The synthesis of anthocyanins in cells is mainly concentrated in the cytoplasm around the vacuoles, via the phenylpropionic acid synthesis pathway and the flavonoid biosynthesis pathway. Later, people have studied how anthocyanins are produced in plants. The pathway of synthesis of anthocyanins is similar to other flavonoids, mainly concentrated in the cytoplasm around the vacuole, through the phenylpropionic acid synthesis pathway and the flavonoid biosynthesis pathway. There are three processes from phenylalanine to anthocyanin. The first step is the process from phenylalanine to coumarin-coenzyme A. The second step is the process from coumarin-coenzyme A to dihydroflavonol. The third step is synthesis of various anthocyanins.

Anthocyanins are widely distributed in the cytosol of flowers, fruits, stems, leaves, and root organs of angiosperms and distributed in 27 families and 72 genera. Anthocyanins are basically derived from five types of plants:fruits, vegetables, beans, cereals, and nuts. Specific content is shown in the table below (Table 1).

These figures indicates that anthocyanins are vital components of the diet of human. In recent years, people paid more attention to the biological and medicinal properties of anthocyanins. Numerous studies have demonstrated that anthocyanins have many properties useful for the health of human such as antioxidant, anti-obesity, anti-inflammatory, anti-atherogenic and anti-aggregation, antitumor, and so on. In addition, some reports have shown that supplementation of anthocyanin mixtures reduced inflammatory markers in hypercholesterol subjects rather than individual anthocyanins. All in all, it is worthwhile to explore more properties of anthocyanins.

12.2 Bioactive Constituents

Anthocyanins are natural compounds that vest color to vegetables, fruits, and other plants. They belong to a wide distribution of phenolic compounds, collectively known as flavonoids. Anthocyanins and their derivatives have various molecular structures, and they exhibit different chemical and biological effects.

12.2.1 The Main Structures of Anthocyanidins and Anthocyanins

Anthocyanidins have a 3, 5, 7-trihydroxyl-2-phenylbenzo-pyran cation structure (Fig. 2), and it is composed of an aromatic ring A bonded to an oxygen-containing heterocyclic ring C, which is also bonded by a carbon-carbon bond to a third aromatic ring B. In general, anthocyanins can undergo four types of substitution reactions such as hydroxylation, glycosylation, methylation, and acylation. The anthocyanidins are

Table 1 Anthocyanin varieties and their contents in selected common fruits, vegetables, beverages, and wines

Crop species		Anthocyanins	Content(mg/100 g FW)
Fruits	Apple peel	Cy-3-gal, Cy-3-ara,Cy-3-glu, Cy-3-xyl	10~2160
	Elderberry	Cy-3-glu, Cy-3-sam, Cy-3-sam-5-glu, Cy-3-diglu	200~1560
	Chokeberry	Cy-3-gal, Cy-3-ara	506~1000
	Garnetberry	Cy-3-glu, Dp-3-glu, Cy-3-rut, Dp-3-rut	80~810
	Grape	Cy-3-glu, Dp-3-glu, Pn-3-glu, Pt-3-glu, Mv-3-glu, Mv-3-glu-acetate	33~751
	Bilberry	Dp-3-gal, Dp-3-ara, Dp-3-glu, Pt-3-glu, Mv-3-glu	300~600
	Vaccinium oxycoccos	Dp-3-gal, Cy-3-gal, Mv-3-gal	300~500
	Blueberry	Mv-3-gal, Dp-3-gal, Dp-3-ara, Pt-3-gal, Pt-3-ara, Mv-3-ara	60~480
	Cherry	Cy-3-glu, Cy-3-rut	4~450
	Black raspberry	Cy-3-rut, Cy-3-xyl-rut, Cy-3-glu, Cy-3-sam	76~428
	Hawthorn	Cy-3-glu, Cy-3-ara, Cy-3-gal	11~407
	Cranberry	Cy-3-gal, Cy-3-glu, Cy-3-ara, Pn-3-ara, Pn-3-gal	20~360
	Huckleberry	Cy-3-gal, Cy-3-glu, Cy-3-ara, Dp-3-gul, Dp-3ara, Mv-3-glu	180~330
	Blackcurrant	Cy-3-(2^G-xylosylrutinoside), Cy-3-sam, Cy-3-glu, Cy-3-rut	250
	Blackberry	Cy-3-glu, Cy-3-rut	90~250
	Red raspberry	Cy-3-sop, Cy-3-glu, Cy-3-rut, Cy-3-glu-rut	10~116
	Strawberry	Pg-3-glu, Cy-3-glu,	12~36
	Olive	Cy-3-rut, Cy-3-glu, Cy-3-caffeylrutionside, Cy-3-(2^G-xylosylrutinoside)	42~228(dry weight)
	Pear	Cy-3-glu, Cy-3-ara	5~10(peel)
	Fig(peel)	Cy-3-rut, Cy-3-glu	3.2~9.7
	Fig(flesh)	Cy-3-rut, Cy-3-glu	0.15~1.5
	Mulberry	Cy-3-glu, Cy-3-rut	180~s185
Vegetables	Eggplant	Dp-3-gul, Dp-3-diglu-5-gul, Dp-3-diglu-caffeic acid, Dp-3-rut	750
	Purple cabbage	Cy-3-sop-5-glu acylated with p-coumaric, ferulic, or sinapyl acids, Cy-3-sop-5-glu	25~203.26
	Carrot	Pg-3-diglu-5-gul acylated with p-coumaric, ferulic, or caffeic acids	11~60
	Potato(red)	3-caffeylferulylsophoroside-5-glu of Cy and Pn	15~45
	Onion	Cy-3-glu, Cy-3-lam	5~25
	Cauliflower	Cy-3-sop-5-glu acylated with p-coumaric or ferulic acids	4.21

Table 1 (continued)

Crop species		Anthocyanins	Content(mg/100 g FW)
Legumes and grains	Purple corn	Cy-3-glu, Cy-3-glaPg-3-glu, Pn-3-glu, Cy-3-(6′ malonylglucoside)	1779
	Rice	Cy-3-glu, Pn-3-glu	10~493
	Wheat	Cy-3-glu	0.5~16
	Black bean	Dp-3-glu, Cy-3-glu, Dp-3-glu, Pt-3-glu	
Juice	Grenadine juice	Cy-3-glu, Cy-3,5-diglu, Dp-3-glu, Dp-3,5-diglu, Pn-3-glu, Pn-3,5-diglu	600~765
	Orange juice	Cy-3-glu, Dp-3-glu	200 mg/100 mL
Fruit wine	Red wine	Cy-3-glu, Dp-3-glu, Pn-3-glu, Pt-3-glu, Mv-3-glu	9~40

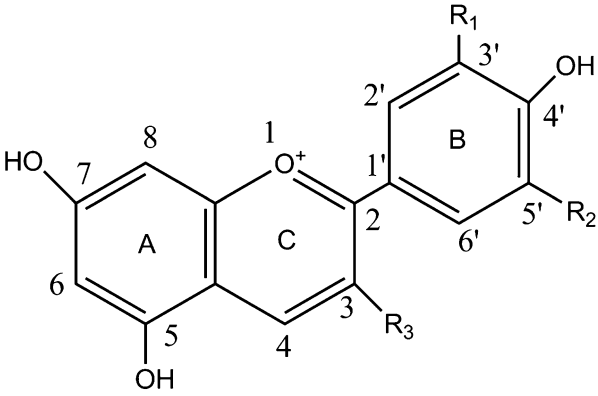

Fig. 2 Structures of the six main anthocyanidins in nature. Pg, $R_1 = H$, $R_2 = H$; Cy, $R_1 = OH$, $R_2 = H$; Dp, $R_1 = OH$, $R_2 = OH$; Pn, $R_1 = OCH_3$, $R_2 = H$; Pt, $R_1 = OCH_3$, $R_2 = OH$; Mv, $R_1 = OCH_3$, $R_2 = OCH_3$. R_3 = O-Glc

the basic structure of the anthocyanins. When the anthocyanidins are combined with sugar moiety in the form of their glycoside, they are called as anthocyanins. Up to now there are reports of more than 600 different anthocyanins and 23 anthocyanidins. However, only six of them are the most common, cyanidin (Cy), delphinidin (Dp), malvidin (Mv), pelargonidin (Pg), peonidin (Pn), and petunidin (Pt).

12.2.2 The Color of the Anthocyanins

Anthocyanins are the most important pigments in vascular plants; they are harmless and easily incorporated into aqueous media, making them useful as natural water-soluble colorants. They confer a wide variety of colors, touching practically all visible spectra, from orange and red through purple and bluish hue. Moreover, the color of red wine was originally associated with the presence of an group of anthocyanins. Color differences between anthocyanins are largely determined by

the pH, structure, the presence of co-pigments, etc., and the mechanism by which anthocyanins exhibit different colors is described below.

12.2.2.1 Anthocyanin Color at Different pH

The color of anthocyanins depends on the pH of the solution. This is because of the molecular structure of anthocyanins having an ionic property. At a lower pH solution (pH $<$ 3), anthocyanins appear to be red, and violet at pH 7–8; at a very high pH (pH $>$ 11), it is blue in color (Figs. 3 and 4).

12.2.2.2 Anthocyanin Color at Different Molecular Chemical Structures

Glycosylation

Anthocyanidin glycosylation generally reduces the maximum wavelength absorption of the anthocyanins with respect to their anthocyanidins, produces hypsochromic effect, and confers the bluish hue of the anthocyanins. Glycosylation sites and glycosylic numbers are important reasons for the anthocyanin hue and intensity.

The glycosylation site is closely related not only to the hues of the anthocyanins but also to the color intensity. On the one hand, the glycosylation site affects the hues of the anthocyanins. The more A-ring was glycosylated, the deeper the bluish hue of the corresponding anthocyanins. On the other hand, glycosylation at the specific sites of the anthocyanidins distinctly affects the color intensity of the anthocyanins. Glycosylations at C_3 site can produce the most intense colors of the anthocyanins. Additional 5-glycosylation decreased the hue angles of the anthocyanins and brings about a slight shift to red-purple for the anthocyanins.

The glycosyl number appears to mainly affect the hues of the anthocyanins, and the hue of anthocyanin may also be related to glycosyl type. The blue hues of the anthocyanins were deepening with the increasing number of the glycosyls attaching at the A-ring. Increasing the number of glucose units caused more yellow color for the anthocyanins. C_3 glycosylation with a di- or tri-saccharide reduced the hue angle of the anthocyanin slightly.

Hydroxylation

The anthocyanins A- and B-ring C_3, C_5, C_7 positions and C-ring $C_{3'}$, $C_{4'}$, $C_{5'}$ positions can be different degrees of hydroxylation. The hydroxylation of different parts of anthocyanins has an inconsistent effect on the color. The increase of the number of hydroxyl groups in the B-ring causes shifts the maximum absorption wavelength (λ vismax) of the anthocyanin visible region to the short-wave direction, i.e., produces hypsochromic effect and the bluish hue is enhanced. The hydroxyl group at the C-position of the C-ring causes the anthocyanins to exhibit different colors, most of the anthocyanins hydroxylated at the C_3 position are red, and the C_3 deoxyanthocyanin is yellow. Anthocyanins with hydroxyl groups at the C_4 position are mostly yellow.

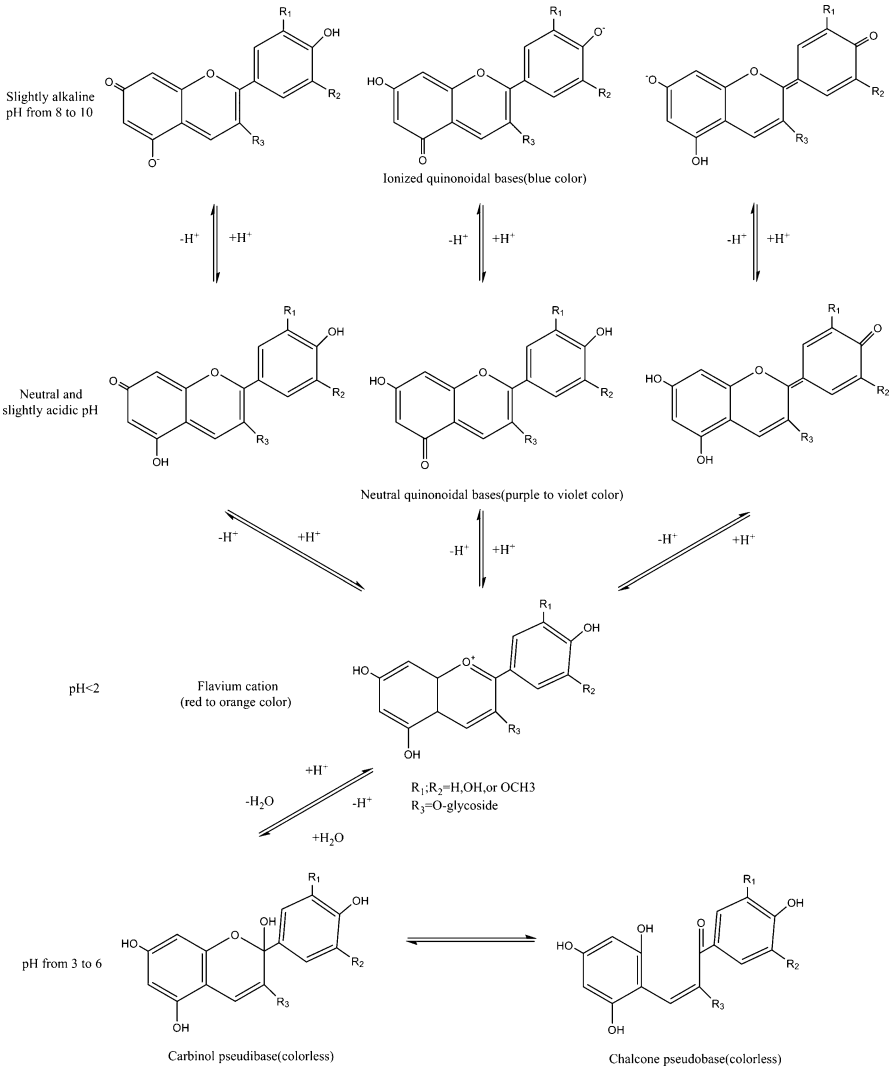

Fig. 3 Scheme of the pH-dependent structural interconversion between dominant forms of monoglycosylated anthocyanins in aqueous phase

Acylation

The acylation of anthocyanins occurs on their substituted glycosyl group and organic acids, aromatic acids, and fatty acids. Acylation produces hypsochromic effect, and the bluish hue is enhanced. However, the aliphatic series acylation of anthocyanins makes it almost no color change.

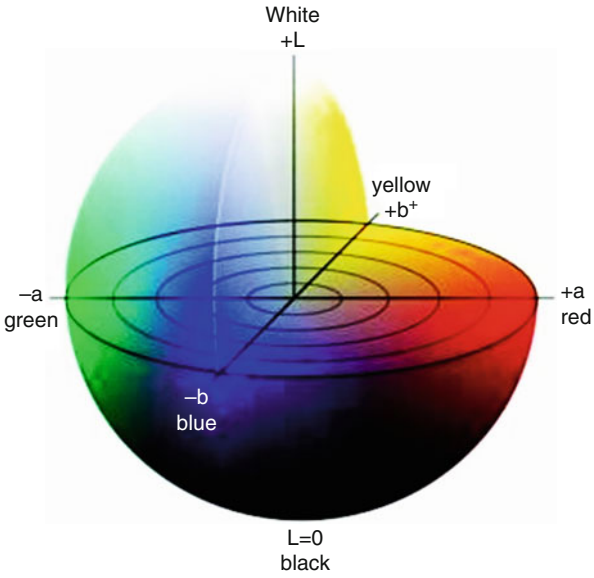

Fig. 4 The color schematic of anthocyanins (Gordillo et al. 2012)

Methoxylation

Methoxylation of anthocyanins generally occurs at the $C_{3'}$ and $C_{5'}$ positions and leads to anthocyanin yellowing, but B-ring methylation causes the anthocyanin λ vismax to move toward long waves, and the red hue is enhanced.

Co-pigmentation Effect

Co-pigmentation is a phenomenon in which pigments and other colorless organic compounds or metallic ions form molecular or complex associations, resulting in a change or an increment in the color intensity. Co-pigments are usually colorless, but when mixed with an anthocyanic solution, an interaction is carried out producing a hyperchromic effect and a bathochromic shift in the absorption spectra (UV-Vis region). The co-pigments can be flavonoids, alkaloids, amino acids, organic acids, nucleotides, polysaccharides, metals, or another anthocyanin (Castañeda-Ovando et al. 2009).

Metallic Ion Interaction

Various colors in the flower were originally explained by the formation of chelates between the metals and the flavylium salts. Anthocyanins and anthocyanidins having o-di-hydroxyl groups in the B-ring (Dp, Cy, Pt) can form metal-anthocyanin complexes. The complexation between anthocyanins and some metals such as Al, Cu, Fe, and Mg or Sn and Mo causes them to appear blue color.

12.2.3 Antioxidant Activity

The antioxidant activity of anthocyanins is largely dependent on their basic structure, such as the position and number of hydroxyl groups around the pyrone ring, the presence of acyl groups, the position and degree of methoxyl groups, and the number of sugar residues and their position. When the number of OH groups is increased, the antioxidant activity of anthocyanins is greater. The ring orientation determines the ability of anthocyanin molecule to donate hydrogen atom from a hydroxyl group to free radical. In addition, due to the positive charge of anthocyanins, the number and arrangement of aromatic hydroxyl groups, the degree of structural conjugation, and the electron-donating and electron-withdrawing substituents present in the ring structure, leading to anthocyanins, are effective donors of hydrogen. These compounds can easily provide protons to highly reactive free radicals to prevent further formation of free radicals. Among several anthocyanidins, Dp followed by Cy and Pg has been found to be the most effective in scavenging superoxide anion, whereas Pg was the most powerful against the hydroxyl radical. Regardless of the sugar attached, potency of anthocyanins toward the superoxide radical and peroxynitrite radical scavenging was in the following order: Dp > Pt > Mv ≈ Cy > Pn > Pg (Liobikas et al. 2016).

Anthocyanins can also prevent oxidation of ascorbic acid caused by metal ions through chelation of metal ions and form ascorbic (co-pigment)-metal-anthocyanin complex (Kong et al. 2003). The role of the anthocyanins can be explained by several antioxidant mechanisms, including hydrogen donation, metal chelation, and protein binding.

12.2.4 Anthocyanin Derivatives

Anthocyanin derivatives have been found in wines and beverages, or certain special types of plants, which are natural derivatives of a series of anthocyanins formed by anthocyanins during fermentation and aging, or biosynthesized in plants. Anthocyanin derivatives have high stability and exhibit different colors. Therefore, the research on anthocyanin derivatives has received more and more attention in recent years. This section mainly introduces different types of anthocyanin derivatives.

12.2.4.1 Flavanols Attached to Anthocyanin

At present, there are few studies on the direct addition of anthocyanins to flavanols to form anthocyanin derivatives. According to the reaction route, derivatives formed by direct coupling of anthocyanins and flavanols can be broadly classified into two types: A-F (anthocyanin-flavanol) or F-A (flavanol-anthocyanin) derivatives. The A-F compound is an electrophilic substitution reaction between the C_4 position of the anthocyanin cation and the C_8 or C_6 position of the flavanol to form a colorless flavene. In the formation of F-A compounds, the proanthocyanidin forms a carbocation as a nucleophile agent under acid hydrolysis. On the other hand,

cleavage of the interflavanic linkage of a flavanol oligomer provides a carbocation F^+ that reacts at C_4 position with the C_8 or C_6 of the anthocyanin, producing a colorless compound F-AOH, while F-AOH via dehydration to form the pigment in flavylium to form F-A^+ (Fig. 5).

In addition, anthocyanins can also be linked to phenolic substances via alkyl groups to form derivatives, which are generally formed by the reaction of anthocyanins, phenolic substances (such as flavanols), and small molecule aldehydes (such as acetaldehyde, propionaldehyde, etc.). In the early stages of winemaking, derivatives formed by the alkylation of anthocyanidin and flavanol play an important role in the color of the wine. The formation mechanism of the anthocyanin-alkyl-flavanol compound is under acidic conditions, small molecule aldehydes are protonated to form respective carbocations (R-HC^+OH). Then the carbocation is added to the nucleophilic site (generally at the C_8 position) of the flavanols. The formed protonated adduct that's formed then dehydrates to form a new carbocation, which is nucleophilic attack by anthocyanins to form the final anthocyanidin-alkyl-flavanol derivative.

12.2.4.2 Pyranoanthocyanins Derivatives

Pyranoanthocyanins is a series of stable anthocyanin derivatives formed during the fermentation and aging process of wine. The basic structure of pyranoanthocyanins is based on the structure of the proanthocyanins, and a cycloaddition reaction is formed between the C_4 position of the anthocyanins and the hydroxyl group at the C_5 position to form another fourth pyran ring. The pyranoanthocyanins are first discovered in wine, and a series of stable anthocyanin derivatives formed during fermentation and aging constitute different families of pyranoanthocyanins. The structure of the typical pyranoanthocyanins compounds family is shown in Fig. 6. Several typical pyranoanthocyanins families are described below.

Phenol-pyranoanthocyanins is the reaction product of grape malvidin and vinylphenol, which may be produced by cycloaddition of 4-vinylphenol, which is formed by the action of cinnamic acid decarboxylase, with anthocyanin C_4 and C_5 positions (Fig. 7).

Pyruvic acid and acetaldehyde are two common products produced by yeast metabolism during wine fermentation. These two substances interact with free anthocyanins to form a new class of pyranose pigments, vitisins, which produce a significant hypsochromically shifted.

Vitisin A is formed by cyclization of the enol structure of pyruvic acid and the C_4 and C_5 positions of dimethylcetoin-3-*O*-glucoside in an acidic environment. It is the main anthocyanin in port wine aged for 1 year.

Compared with vitisin A, vitisin B is the simplest structure of pyranoanthocyanins currently isolated from red wine, mainly produced by cyclization of acetaldehyde and malvidin (Fig. 8). Its maximum absorption wavelength is around 490 nm, showing a distinct orange-yellow characteristic in the visible spectrum.

Methyl pyranoanthocyanins is a methyl group attached to the C_{10} position of the fourth pyran ring newly formed by anthocyanins. The formation of methyl

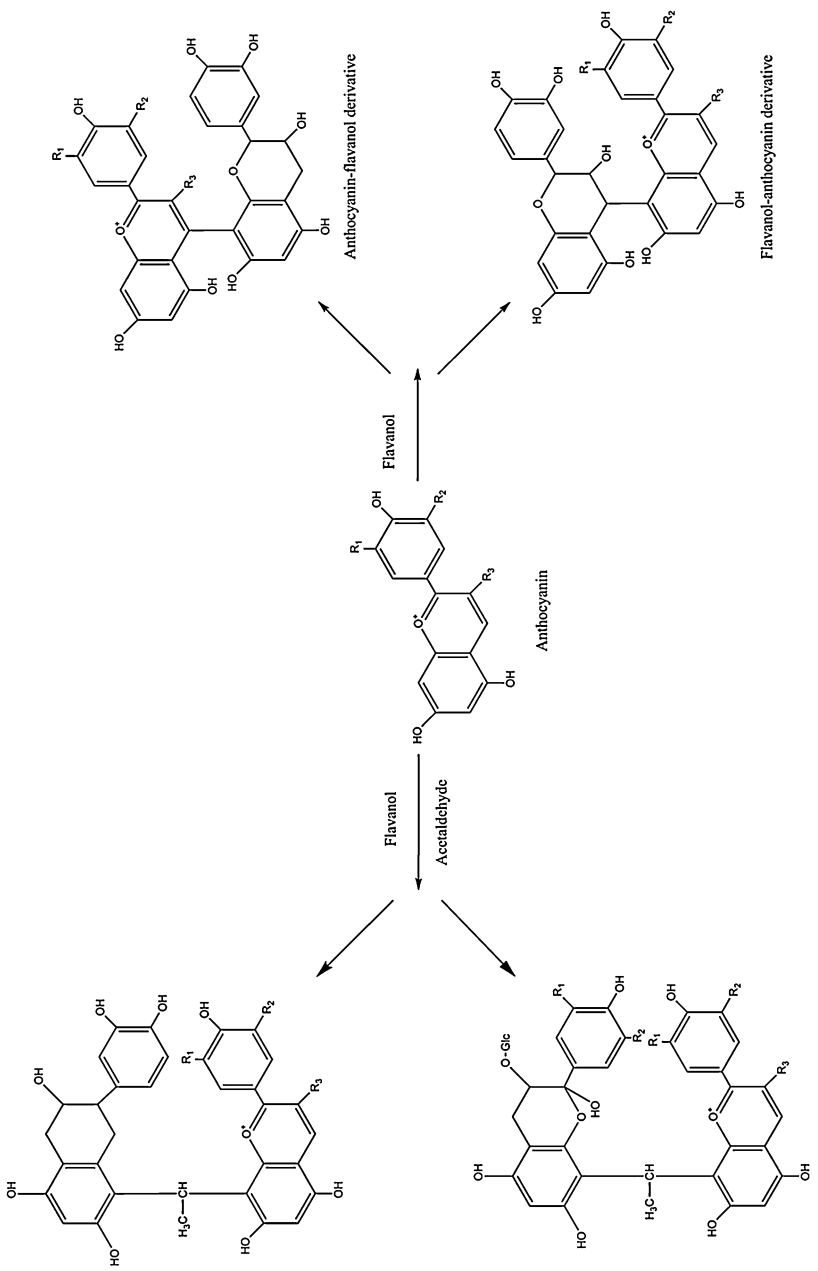

Fig. 5 Formation pathway of flavanols attached to anthocyanin

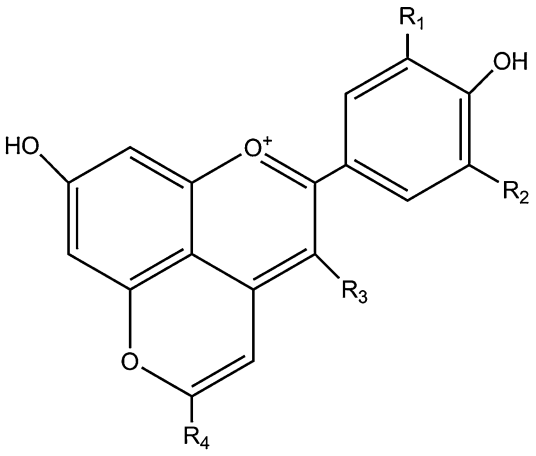

Fig. 6 The structures of pyranoanthocyanins

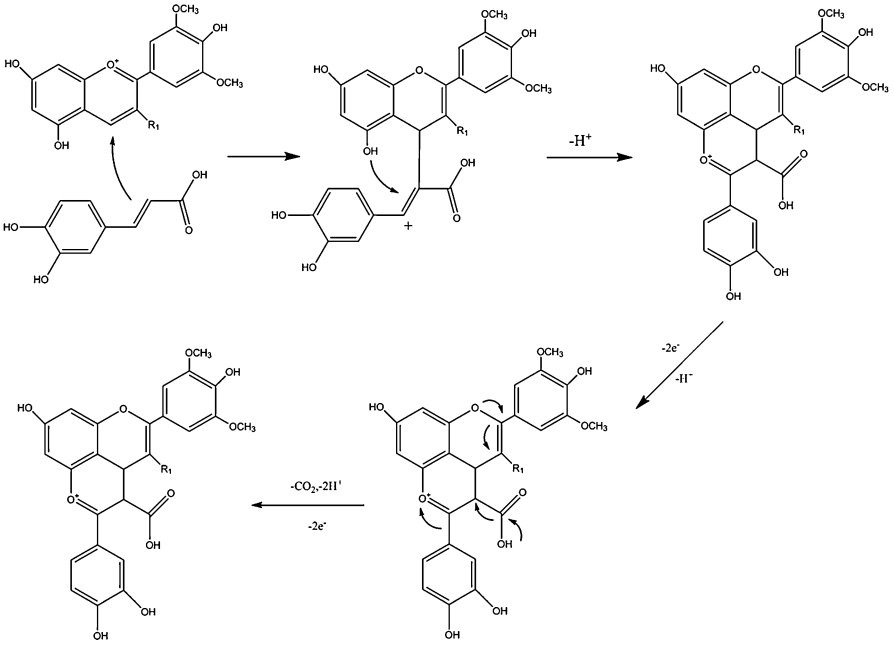

Fig. 7 Formation pathway of phenol-pyranoanthocyanins

pyranoanthocyanins in wine is derived from free anthocyanins and acetyl acetic acid reaction. Its synthetic pathway is similar to the production of vitisin A (Fig. 9). Compared with free anthocyanins, the maximum visible absorption wavelength of methyl pyranoanthocyanins is hypsochromically shifted, showing a distinct orange-yellow color in solution, and has high color stability.

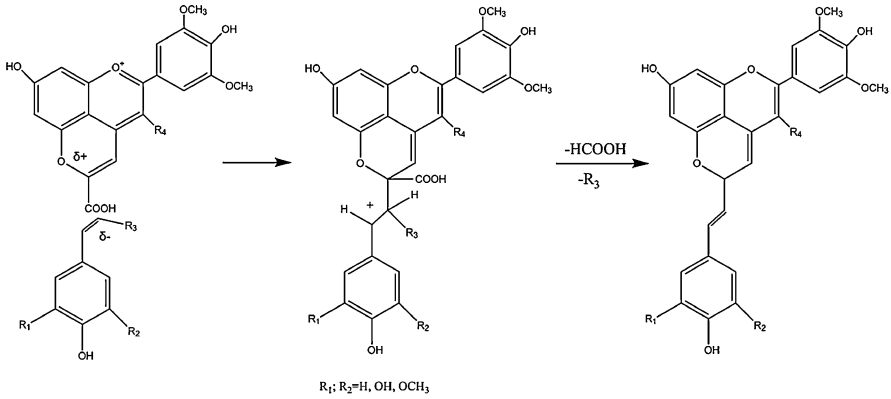

Fig. 8 Formation pathway of vitisin A

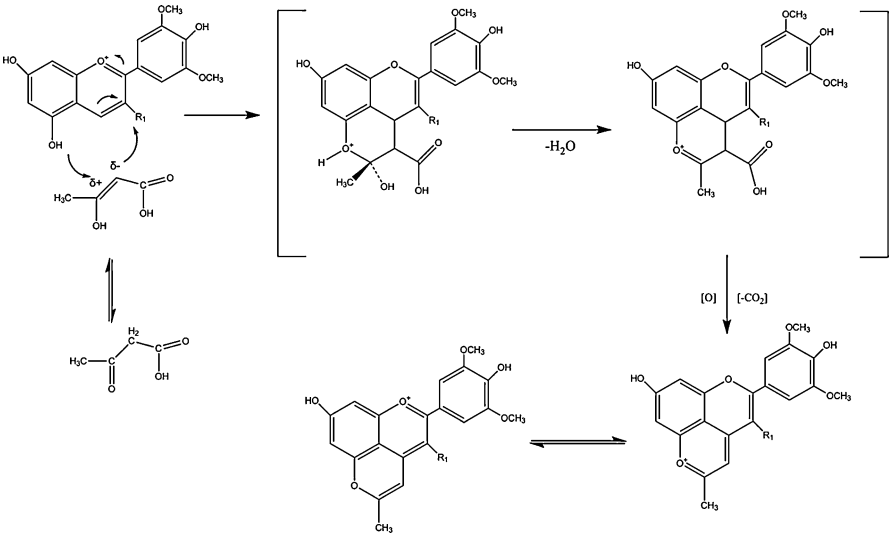

Fig. 9 Formation pathway of methyl pyranoanthocyanins

Pyranoanthocyanin-flavanols is another family of pyranoanthocyanins found in wine. The formation of pyranoanthocyanin-flavanols derivatives in wine is derived from the cycloaddition of anthocyanins and vinylflavanol; while the vinylflavanol may be derived from the cleavage of the flavanol-alkyl-flavanol polymer in the wine. Vinylflavano may also come from the intermediates that formed when flavanols and acetaldehyde are addition and dehydration reaction (Fig. 10).

The first generation of pyranoanthocyanins, such as phenol-pyranoanthocyanins, vitisin-type pyranoanthocyanins, methyl pyranoanthocyanins, and pyranoanthocyanin-flavanols, is formed by the reaction of anthocyanins and small molecule derivatives during the fermentation of fruit wine, while the first generation of pyranoanthocyanins

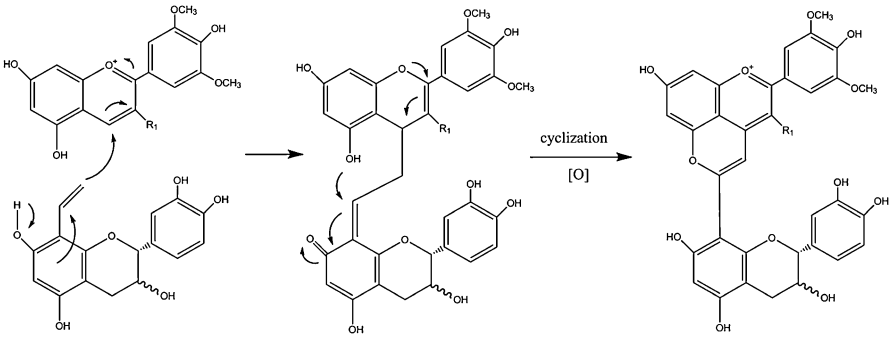

Fig. 10 Formation pathway of vinylflavanol-pyranoanthocyanins

will continue to react with small molecules to form more complex derivatives in the later stages of aging. These complex derivatives are called second-generation pyranoanthocyanin derivatives, such as portisin-type pyranoanthocyanins, pyranoanthocyanin methine dimers, and oxovitisins.

12.2.5 Anthocyanin Degradation

Different factors may affect the degradation pathway and mechanism of anthocyanins, which may affect their final products. Through the structural identification of the final product and intermediate products, it is speculated that the current possible degradation pathways for anthocyanins are mainly divided into three types. The first is that anthocyanin undergoes water addition to form methanol pseudobase glycosides and then the ring opening of C–O bonds generates chalcone glycosides and finally degrades into coumarin derivative. The second is that the anthocyanin is hydrolyzed to form a pseudobase glycoside, and further the ring open at the C–O bond to form a chalcone glycoside, which further hydrolyzes the glycosidic bond to form chalcone, and finally degrades to benzoic acid. The third is that the first hydrolysis removes glucose to form an aglycone, further producing a more unstable intermediate α-diketone, and the α-diketone finally forms an aldehyde and a benzoic acid derivative.

12.2.5.1 Thermal Degradation

The thermal degradation pathway of anthocyanins was first proposed by Markakis in 1957. He speculated that the first step in the degradation of anthocyanins in aqueous solution was the ring-opening reaction of anthocyanins and the formation of chalcone. Initial degradation step is hydrolysis of sugar moiety and aglycone formation, which forms cyclic adducts. In addition, anthocyanin would decompose upon heating into a chalcone structure, the latter being further transformed into a coumarin glucoside derivative with a loss of the B-ring (Patras et al. 2010). According to the severity and nature of heating, thermal degradation of anthocyanins

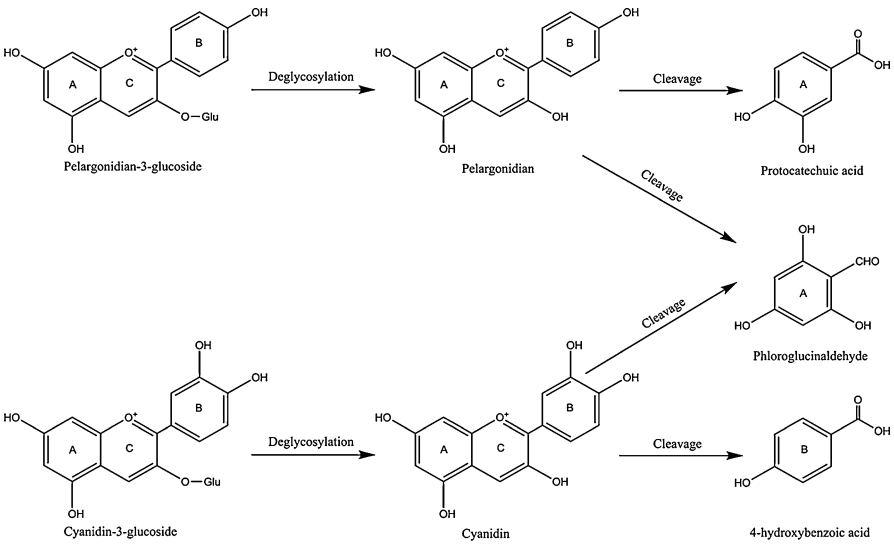

Fig. 11 Possible thermal degradation mechanism of two common anthocyanins (Patras et al. 2010)

can result in a variety of species. Figure 11 shows the degradation of anthocyanins and formation of various intermediate compounds.

12.2.5.2 Oxidative Degradation

Anthocyanins have different oxidative degradation pathways under acidic and neutral conditions. In an acidic solution of pH 1–3, H_2O_2 nucleophilic attack on the C_2 position of anthocyanins, and covalent bond cleavage between C_2 and C_3 forms benzoylphenyl acetate, the ester is easily hydrolyzed under alkaline conditions to form phenolic acids such as benzoic acid and 2,4,6-trihydroxyphenylacetic acid (Fig. 12). In a neutral solution of pH 6–7, heating causes the malvidin-3,5-diglucoside to be converted to oxime base and the oxime base to form the coumarin derivative 3,5-di-(*O*-*β*-D-glucosyl)-7-hydroxycoumarin (R_3 = *O*-glucose).

12.2.5.3 Enzymatic Degradation

Caffeic acid quinone is an oxidation product of caffeic acid, which plays an important role in the degradation of anthocyanins by polyphenol oxidase. The polyphenol oxidase degradation pathway of anthocyanins is as below: catechol is firstly oxidized by oxygen and polyphenol oxidase to form phenylhydrazine structure, and then anthocyanins are further oxidized by benzoquinone into colorless compounds. The mechanism is shown in Fig. 13.

12.2.5.4 Photodegradation

The final product of light-induced anthocyanin degradation is identical to the final product of thermal degradation; however the degradation pathways of the two are

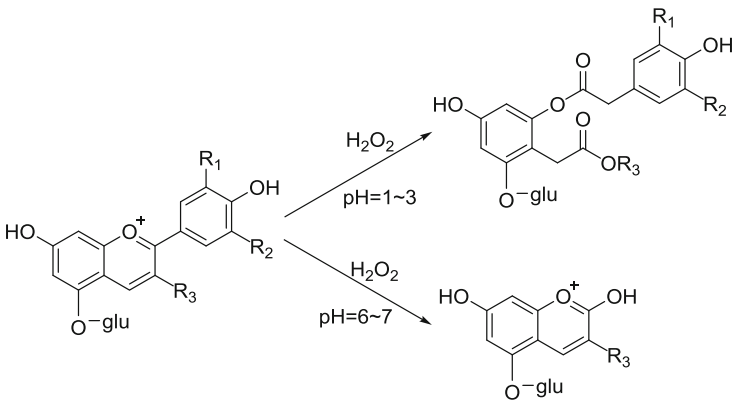

Fig. 12 Degradation mechanism of anthocyanins by hydrogen peroxide oxidation

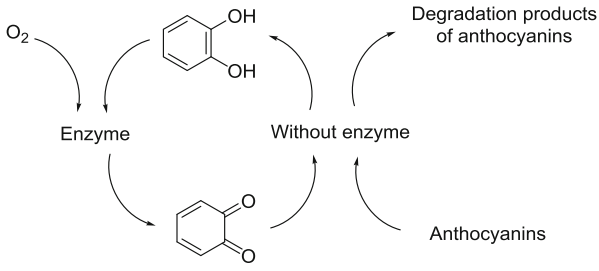

Fig. 13 Degradation mechanism of anthocyanins by polyphenol oxidases

different. The possible pathway of light-induced degradation of anthocyanins is anthocyanins are first degraded to form intermediates of C_4 hydroxyl groups, the intermediate products are hydrolyzed and opened at the C_2 position, and finally chalcone is formed and is rapidly degraded into benzoic acid and 2, 4, 6-trihydroxybenzaldehyde and other products (Fig. 14).

12.2.5.5 Pulsed Electric Field Degradation

The absorption of cyanidin-3-glucoside (Cy-3-glu) increased at 333 nm after pulsed electric field (PEF) treatment, which indicated that a chalcone compound was formed, furthermore the products 3,4-dihydroxybenzoic acid and 2,4,6-trihydroxybenzoic acid were detected. The degradation of cyanidin-3-glucoside by PEF is related to the following possible pathway: cyanidin-3-glucose first undergoes water addition reaction to form pseudobase glucoside, further opening of C–O bond to form a chalcone glycoside, the substance undergoes hydrolysis of glycosidic bonds to form chalcone, which is finally degraded to 3,4-dihydroxybenzoic acid and 2,4,6-trihydroxybenzoic acid (Fig. 15).

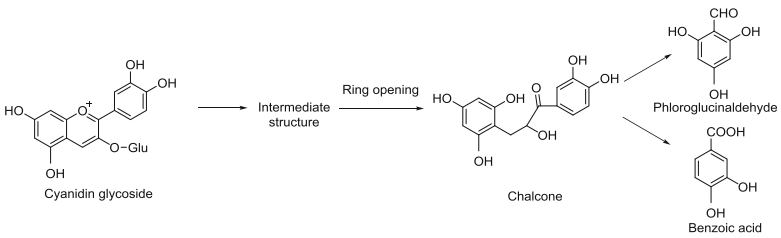

Fig. 14 Degradation mechanism of anthocyanins by light-induced degradation

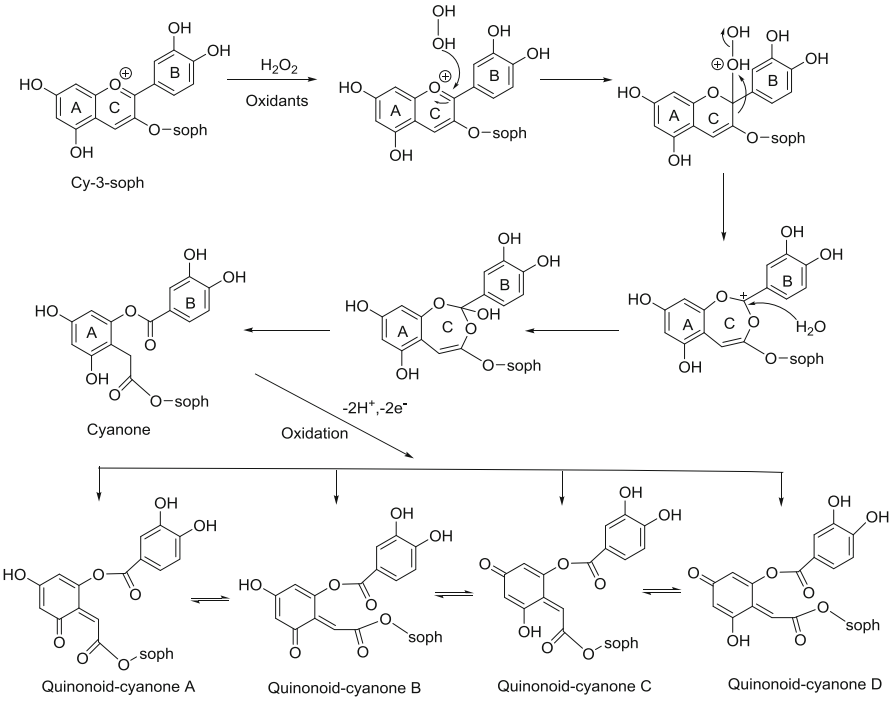

Fig. 15 One of the hypothetical schemes of Cy-3-soph degradation at pH 1.5 exposed to pulsed electric field (Sun et al. 2011)

12.3 Epidemiological Study

The anthocyanins are essential components of the human diet. They play an important role in human health as antioxidant, anti-obesity, and anti-inflammatory agent. As a result, it is crucial to associate anthocyanins intake with health effects. Due to the difference about the area of residence, seasonality, and gender, the intake of

Table 2 Dietary intake of anthocyanin/anthocyanidin from some countries

Country	Anthocyanin(mg/d)
Denmark, Odense	3–50
Finland, Helsinki	7–83
Sweden	3–35
UK	4–49
Portugal, Coimbra	34–108
Belgium, Ghent	3–33
Germany	1–63
The Netherlands, Amsterdam	3–41
Poland	3–43
Spain	29–71
Greece	37–61
France	2–61
Norway	3–43
Italy	6–93
America	2–1040
China, Guangzhou	2–69

dietary anthocyanins varies greatly among different populations. Anthocyanin intake was assessed in many epidemiological studies and clinical trial studies. Wu collected information about anthocyanins intake among different countries. Americans may consume anthocyanins ranging from 12.5 mg/d to 1040 mg/d (Wu et al. 2006). In Europe, particularly in Amsterdam, Netherlands, the dietary intake of anthocyanidins ranged from 2.8 mg/d to 25.2 mg/d. In China, anthocyanidin intake from various food ranging from 27.6 mg/d to 43.1 mg/d. Table 2 below shows the approximate intake of anthocyanins in some countries. Cyanidin-3-*O*-glucoside is used as a reference.

Bioactive compounds in foods have been gaining interest, and it is reported that botanical compounds play a protective role in reducing the risk of chronic metabolic diseases. Chronic diseases such as cancer, cardiovascular diseases (CVDs), diabetes mellitus (DM), obesity, and neurodegenerative diseases (NDGDs) are characterized by slow progression and long duration, leading to mortality and accounting for more than 60% of death in the world. As a result, more and more people are studying the properties of various ingredients of botanical compounds. Recent studies have established that regular consumption of anthocyanins could reduce risk for chronic diseases. Several cross-sectional researches confirmed a negative correlation between anthocyanin intake and incidence rate of obesity and T2DM. In a cross-sectional study of 1898 females aged 18–75 from the UK, higher intake of anthocyanins was associated with significantly lower central systolic blood pressure, pulse wave velocity, and mean arterial pressure. The ability of aortic stiffness is assessed by pulse wave velocity which is relatively well-fixed to predict the cardiovascular events (Jennings et al. 2012). In a population-based cohort study of 10,054 men and women in Finland, it was found that higher consumption of apples and berries, foods rich in

anthocyanins, was associated with a lower risk for T2DM (type 2 diabetes mellitus). Epidemiological studies also indicate that purified anthocyanin supplementation could reduce fasting blood glucose and increased serum adiponectin concentrations in patients with T2DM (Liu et al. 2014).

It is indicated that anthocyanins have many properties that play important roles in the health promotion of human such as antioxidant, anti-obesity, anti-inflammatory, anti-atherogenic and anti-aggregation, and anticancer properties, inhibiting lipid peroxidation and platelet aggregation, preventing diabetes, and so on.

12.4 Metabolism and Bioavailability

A growing number of studies have shown that anthocyanins have a number of health benefits and disease prevention effects. However, as anthocyanins are water-soluble polyphenols with strong polarity and relatively high molecular weight, they cannot actively pass through the blood vessel and are not very clear about the forms and incentives of their biological activity. This section will start with the current research to illustrate the characteristics of anthocyanins in terms of bioavailability.

We all know that anthocyanins have antioxidant, anti-inflammatory, antitumor, and other biological activities in the organism, and the absorption and metabolism of anthocyanins in the body are related to whether they can exert their biological activities well in the body. Due to the richness of anthocyanins and the complexity of digestion, so far, researches have focused on the absorption and metabolism of single anthocyanins or the overall absorption of foods containing anthocyanins. The mechanism of anthocyanin absorption and metabolism has not been fully understood.

12.4.1 The Absorption of Anthocyanins

In short, after eating an anthocyanin-rich fruit, the maximum plasma concentration can be reached within 0.5–2 h, and the maximum plasma level of total anthocyanins is in the range of 1–100 nmol/L. In animal studies, the systemic bioavailability of anthocyanins is estimated to be 0.26–1.8%. The absorbed anthocyanins are cleared from the circulation rapidly. This has led to a widespread belief that the absorption efficiency of anthocyanins is low. However, how does anthocyanin digest and absorb in the human body?

After oral administration, anthocyanins are digested and absorbed mainly in the stomach and intestines. A portion of the anthocyanins can be absorbed into the gastrointestinal wall in intact form, followed by extensive first-pass metabolism, and eventually into the systemic circulation as a metabolite. The remaining large amount of anthocyanins can enter the intestinal tract and be absorbed by the small intestine or catalyzed by intestinal microbes in the large intestine to form metabolites (Fang 2014).

12.4.1.1 The Translocation of Anthocyanins

In the mouth. There are few studies on the degradation of oral anthocyanins. The only studies have shown that anthocyanins can be taken up by oral epithelial cells in the oral cavity, and the rate of absorption is closely related to the structure of anthocyanins. In a study by Kom Kamonpatana, 12 healthy individuals evaluated the stability of anthocyanins, mucus binding, and uptake of epithelial cells after retaining red or strawberry juice in the mouth for 5 min (Kamonpatana et al. 2014). The experimental results indicate that the anthocyanin structure affects the stability and uptake of buccal cells. In the mouth, digestion of saliva exposes anthocyanins from the food matrix in preparation for absorption of the gastrointestinal tract.

In the stomach. Gastric absorption is an important event with respect to the large and rapid appearance of anthocyanins in systemic circulation. Gastric contents have a pH ranging between approximately pH 1.5 and 4 because of the influx of natural gastric secretions, including HCl and stomach enzymes. Anthocyanins can be stabilized by the low pH environment of the stomach and exist in a variety of ionic forms. However, in vivo bioavailability experiments have fully demonstrated that anthocyanins can be absorbed by the stomach wall in prototype form, and the absorption rate is faster. In general, after oral administration of anthocyanins, anthocyanins can be detected in plasma after 15–60 min, which is mainly absorbed through the stomach wall and then enters the blood (Talavéra et al. 2003). Under the action of gastric acid, the anthocyanins in the food are completely dissolved and released, and most of the anthocyanins can bind to the bilirubin translocation enzyme to promote their passage through the gastric mucosa. Therefore, its absorption speed is faster. Subsequently, anthocyanins absorbed from the stomach enter the blood and other tissues.

The small intestine. Depending on the size and composition of the meal, the food is discharged from the stomach into the small intestine within a few hours. In the intestine, lactate hydrolase hydrolyzes glycosides to form more hydrophobic anthocyanins that can passively diffuse into intestinal cells (Kay 2006). A variety of different transport mechanisms have also been proposed in this section, including sodium-dependent glucose cotransporters and other glucose-related transporters (GLUTs) or entero-biliary transposases. Once passed through the intestinal cell wall, anthocyanins may be modified by xenobiotic metabolism in the intestinal cells. The extent to which anthocyanins are affected by the first stage of metabolism is unclear.

Inside the small intestine, the relative proportion of anthocyanin forms (glycosides or aglycone, conjugated or unconjugated, and flavylium, chalcone, or hemiketals) during the first passage through the intestine at any time, and its location is impossible to predict. The proportion of phenolic acids derived from anthocyanin increases with increasing distal passage through the GIT. Enterohepatic recycling of anthocyanin adds to this complex pool of anthocyanin-derived metabolites. It can be expected that the pool of anthocyanins is increasingly more catabolized over time, and the pool of phenolic acids is increasing.

The large intestine. Like the small intestine, the large intestine constitutes a very large surface area for anthocyanin absorption. However, it has been suggested that

regions of the large and small intestine are not equivalent in their anthocyanin absorptive capacity, and, specifically, the anthocyanins are not well absorbed from the colon. It is assumed that both large and small intestinal walls can participate in the enterohepatic recycling of anthocyanin. This enterohepatic recycling appears to be extensively based on the long residence time and diverse profile of urinary anthocyanin metabolites detected by LC-MS-MRM.

The absorption diagram of anthocyanins is as follows (Fig. 16):

Anthocyanins can be absorbed intact despite having different molecular sizes and types of sugar or acylated groups attached. Many factors can affect the rate and extent of anthocyanin absorption, such as the glycone, sugar moiety, and acylated groups. The extent of absorption may be decreased for the complex anthocyanins. Digestion and absorption of anthocyanin mainly depend on the gastrointestinal tract. Therefore, it is obvious that gastrointestinal diseases such as atrophic gastritis and peptic ulcer can reduce the secretion of digestive fluid, change the pH of the intestinal tract correspondingly, and reduce the absorption utilization rate of many nutrients, which also has a certain impact on the absorption of anthocyanin. As we all know, as the age increases, many functions of the body will decline. All tissues and organs generally show a decline in function during aging. From the perspective of the digestive system, the gastrointestinal mucosa becomes thinner with age, the gastrointestinal glands and villi gradually shrink, the muscle fibers shrink, and the elasticity decreases. Studies have shown that different levels of tension and age in animals can affect the absorption and utilization of cyanidin. With the increase of age, the absorption rate of anthocyanins will also decrease accordingly, and age is also one of the influencing factors of anthocyanin absorption. Meanwhile, anthocyanins belong to the broad-based flavonoids, and their absorption is affected by the chemical substances of the same kind. Isoquercetin (quercetin 3-*O*-glucoside)

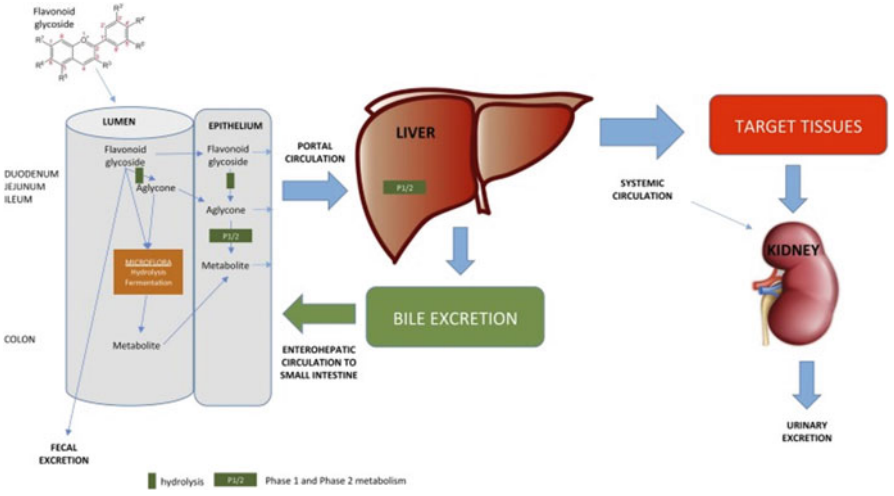

Fig. 16 Absorption of anthocyanins

has a similar chemical structure with cyclamine 3-*O*-glucoside. Studies have found that the transport and absorption of isoquercetin are affected by a protein called sodium-glucose-linked transporter in the epithelial mucosa. At the same time, this sodium-glucose-linked transporter can be inhibited by glucose and rhizoside. Therefore, anthocyanin absorption may be inhibited when foods have high glycemic index or when there are large amounts of structural analogues.

12.4.2 Anthocyanin Metabolites in Human Body

Anthocyanins are mainly absorbed in the stomach and intestines. In different organs, the molecular structure of anthocyanins changes due to environmental changes. For example, in the stomach, the pH is low and anthocyanins are present in the form of flavylium cation. However, in the intestinal tract, the pH is close to neutral, and the stability of anthocyanins is reduced, and anthocyanins are converted to colorless chalcone. Anthocyanins enter the circulatory system through the liver after being absorbed in the gastrointestinal tract. Some anthocyanins are metabolized in the liver and kidney by methylation and glucuronidation. For example, cyanidin-3-*O*-glucoside can be converted into paeonidin-3-*O*-glucoside and petunia-3-*O*-glucoside. In the eyes, cerebral cortex, and cerebellum, it is mainly present as an anthocyanin prototype.

12.4.2.1 Process of Anthocyanin Metabolism

The metabolism of anthocyanins runs through the entire digestive tract but is mainly carried out in the small intestine. Previous studies have shown that initial metabolism occurs when anthocyanins enter the mouth. For example, saliva can enhance the bioavailability of some flavonoid nitrous oxides with catechol structure (Peri et al. 2005).

In the stomach, anthocyanin maintains a 2-phenylbenzopyran structure due to the very low pH (1–2) and strong acidity of the gastric juice. In contrast to the stomach, the pH in the intestine is near neutral, the stability of anthocyanins is reduced, and anthocyanins of different structures coexist. Moreover, the intestinal flora, especially the flora of the colon, further modifies the structure of anthocyanins. Anthocyanins are unstable under neutral pH conditions, and their aglycones are cleaved by carbocyclic rings and eventually decomposed into corresponding phenolic acids and aldehydes. Studies have shown that under the action of bifidobacterium and lactobacillus, malvac-3-glucoside can be converted into lilac acid. Cyanthrin-3-glucoside was transformed into m-phenolic and protocatechuic acids. The above describes anthocyanins which are not absorbed by the stomach and small intestine and are largely modified into phenolic acids in the colon. However, the specific intestinal environment of the small intestine modified by anthocyanins is difficult to determine.

In contrast, some transformation occurs when anthocyanin is injected intravenously into the bloodstream. For example, cyanidin-3-glucoside can be converted to

peonidin-3-glucoside and delphinidin-3-glucoside, both of which continue to be converted to petunia-3-glucoside and finally to mallow-3-glucoside.

12.4.2.2 Anthocyanin Metabolites

The conversion reaction of anthocyanins in vivo mainly includes methylation, acetylation, glycoside hydrolysis, and glucuronic acid-binding reaction. The current research is not particularly clear about how these changes occur in anthocyanins. However, most studies have shown that there are protoplast anthocyanins, anthocyanin conjugates, and some phenolic acids in the blood and in some organs, of which phenolic acid is the common metabolite. And the metabolites of cyanidin-3-*O*-glucoside are shown in Fig. 17.

12.4.2.3 Factors Affecting Anthocyanin Metabolism

Different intake pathways have an important effect on the metabolism of anthocyanins. Oral intake of anthocyanins is partially metabolized by the gastrointestinal mucosa and enters the circulatory system through the liver. Some of the anthocyanins are metabolized by methylation and glucuronidation, and some metabolites enter the intestinal tract through bile; while intravenous anthocyanins are not after the liver metabolizes, it will reach various organs through blood circulation.

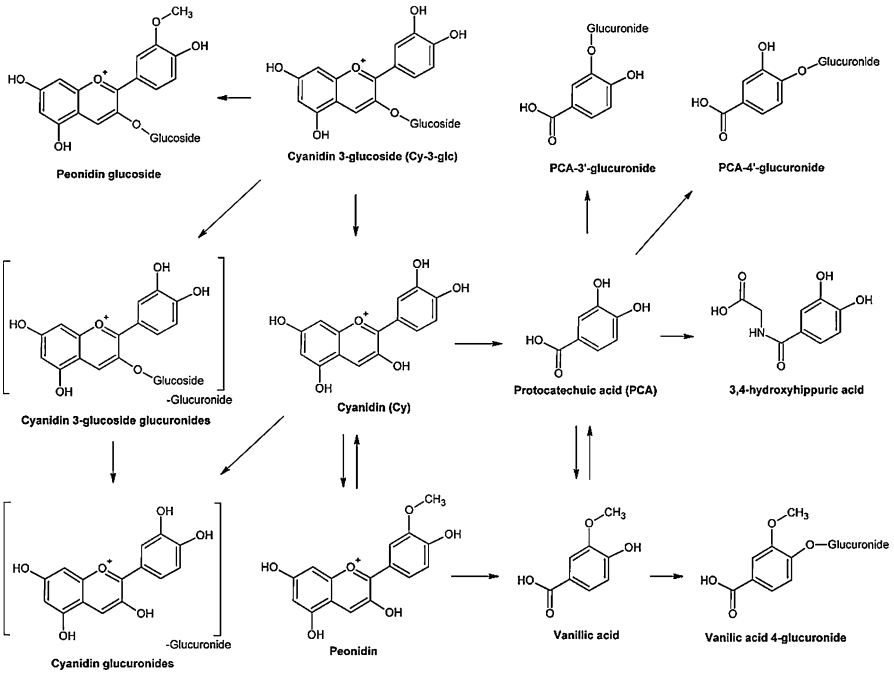

Fig. 17 Metabolites of cyanidin-3-*O*-glucoside

The amount and type of anthocyanins ingested are different, and the structure of anthocyanins modified by the intestinal flora in the intestinal tract is different, so the amount of phenolic acids produced by anthocyanins after being metabolized by intestinal microbes may also vary. The aging process is associated with reduced hepatic perfusion and morphology including reduced hepatocyte density, which has been suggested to reduce the phase I and phase II metabolism of xenobiotics and therefore potentially flavonoid metabolism.

Studies have shown that intestinal microbes deglycosinate compounds, but microorganisms can also undergo a range of other transformations, including oxidation, demethylation, and catabolism to smaller fragments, including small phenolic acids and aromatic catabolites. A wide range of microbial-derived metabolites specifically identified for anthocyanins support strong interactions between flavonoids and microbiome. Since the gut microbes of different genus act on different kinds of anthocyanins, the type and quantity of gut microbes affect this process.

12.4.3 Bioavailability of Anthocyanins

In recent years, human studies on the bioavailability of anthocyanins have also increased rapidly. Studies have shown that anthocyanins enter the blood in the form of glycosides, whether in human or animal models, and are excreted from the urine. After ingesting a certain amount of blackcurrant (including C3G 3.57 mg/kg body weight), blackcurrant proanthocyanidin can be measured in human plasma and urine. The concentration in plasma is 0.12 nmol/L, and the anthocyanin excreted in urine is estimated to be 0.11% of the intake.

In addition, these experiments have also shown that anthocyanins have extremely low bioavailability and that anthocyanins are rapidly degraded and excreted in the human body. The bioavailability of anthocyanins in red wine (2 cups/day) was 218 mg/300 mL, and after 12 h the urine content was 5% of the intake (Bitsch et al. 2004). Bub et al. studied the uptake and utilization of the main anthocyanins in red wine and red grape juice, namely, malvidin-3-*O*-glucoside. Ingested red wine (containing 68 mg malvidin-3-*O*-glucoside/500 mL) or red grape juice (containing 117 mg malvidin-3-*O*-glucoside/500 mL) can be quickly measured in plasma and urine (Bub et al. 2001). The maximum concentration and appearance time in plasma were red wine 1.4 nmol/L, 20 min, and red grape juice 2.8 nmol/L, 180 min. The amount of anthocyanin in red wine and red grape juice in urine was 0.03% of intake.

The bioavailability of anthocyanins was the subject of several excellent reviews. In contrast to the accumulating evidence supporting their health effects, the plasma concentrations of anthocyanins were found to be low. The percentage of intact anthocyanins excreted in urine was found to be $<0.1\%$ in human studies. In animal studies, absolute bioavailabilities of anthocyanins were found to be only 0.26–1.8% when intravenous administrations were used for comparisons (Table 3).

Table 3 Absorption and metabolism of anthocyanins in humans

Materials	Anthocyanin dose (total intake)	C_{max}	T_{max} (h)	Urinary excretion (%)
Blackcurrant	236 mg	0.120 umol/L	1.25–1.75	0.11(8 h)
Red wine (500 mL)	68 mg (Mv-3-glue)	0.0014 umol/L	0.8	0.02(6 h)
Dealcoholized red wine	56 mg (Mv-3-glue)	0.0017 umol/L	1.5	0.02(6 h)
Blueberry powder (100 g)	1.2 g	0.029 umol/L	4	0.003–0.012
Elderberry extract (12 g)	720 mg	0.097 umol/L	1.2	0.06(24 h)
Red wine (400 mL)	180 mg	43 ng/mL	1.5	0.23(7 h)
Red grape juice (400 mL)	284 mg	100 ng/mL	0.5	0.18(7 h)
Blackcurrant juice	1.24 g 0.72 g 0.75 g	53 ng/mL 16 ng/mL 32 ng/mL	0.75 0.75 1.5	0.07(4 h) 0.05(4 h) 0.05(4 h)
Chokeberry extract(7.1 g)	721 mg	0.096 umol/L	2.8	0.15(24 h)

C_{max}, maximal plasma concentration; T_{max}, time to reach C_{max}; urinary excretion (%), % of intake; Mv-3-glu, malvidin-3-glucoside

In summary, the bioavailability of anthocyanins has the following characteristics:

1. The bioavailability of anthocyanins is low, and the ratio of excretion in urine to oral bioassay is generally less than 0.1%.
2. Anthocyanin was absorbed rapidly, and the maximum concentration can be measured in the plasma for 15–60 min and completely eliminated within 6–8 h. This phenomenon indicates that anthocyanins are mainly absorbed through the stomach.
3. Anthocyanins are absorbed by the intact anthocyanin prototype, circulated in the circulation system, and finally discharged through the urine.

12.5 The Bioactivities of Anthocyanins

Anthocyanins have antioxidant and anti-inflammatory properties, regulate lipid metabolism, improve insulin resistance, and fight tumors.

12.5.1 The Antioxidant Activity of Anthocyanins

Reactive oxygen species (ROS) is an ion, atom, or molecular group with a single unpaired electron. Free radicals in animals are mainly oxygen free radicals,

accounting for about 95% of the total amount of free radicals. ROS include oxyanion radicals ($O_2-\cdot$), hydrogen peroxide molecules (H_2O_2), hydroxyl radicals ($OH\cdot$), hydroperoxy groups ($HO_2-\cdot$), and the like. Anthocyanins exert antioxidant capacity by directly scavenging free radicals and indirectly scavenging ROS. Oxygen anion radicals, hydroxyl radicals, and various lipid peroxidation radicals can initiate lipid peroxidation. The phenolic hydroxyl group on the molecular structure of anthocyanins has reducibility, and can release electrons by self-oxidation, directly removing various free radicals, thereby achieving the purpose of inhibiting oxidation.

Anthocyanins can reduce the level of oxidation by increasing the activity of intracellular superoxide dismutase and glutathione transferase. In addition, it can inhibit the activity of oxidases such as phospholipase and lipoxygenase which induce intracellular oxidation. When ROS accumulation in the body is excessive, Nrf-2 binds to the target gene, promotes the production of antioxidant enzymes and other antioxidants, and improves the body's antioxidant capacity. When the oxidative stress is too severe, the body's immune regulation system centered on NF-κB, AP-1, and MAPK participates in the reaction and regulates the reaction. In case of inflammation and hypoxia, the dynamic balance of the production and elimination of ROS in the body is broken, resulting in oxidative stress. When oxidative damaged DNA and protein accumulation exceed the limits of cellular repair and detoxification mechanisms, a series of diseases occur. Anthocyanins can directly enter cells to scavenge free radicals, increase the activity of antioxidant enzymes, and inhibit lipid peroxidation.

12.5.2 Anti-inflammatory

Anthocyanins have significant anti-inflammatory effects. Anthocyanins can regulate cell activation, inhibit the production of cytokines, inhibit the migration of inflammatory cells, and inhibit transcription factors to impede inflammatory factors including tumor necrosis factor-α (TNF-α), interleukin (IL)-1β, IL-6, and transforming growth factor-β (TGF-β), IL-8, and IL-l0. Anthocyanins can also bind to the receptors of inflammatory factors and reduce their effects.

Interestingly, anthocyanins exert anti-inflammatory effects in vivo through the following three pathways: anthocyanins have a regulatory effect on MAPK and NF-κB inflammatory signaling pathways, the regulation of anthocyanins on the inflammatory signaling pathway in CD40-CD40L, and the regulation of anthocyanins on nuclear receptor signaling pathway (Vendrame and Klimiszacas 2015). Anthocyanins inhibit the release of inflammatory factors or mediators by affecting the three pathways above.

12.5.3 Regulation of Lipid Metabolism

Long-term intake of high-fat diets easily leads to excess free radicals in the body, pulmonary lipid metabolism disorder, excessive accumulation of fat, and other

phenomena. It regulates the expression of certain adipocytokines, enzymes, and genes that control fat metabolism, inhibits fat synthesis, and promotes into fat decomposition.

It is a possible mechanism of action of anthocyanins to regulate lipid metabolism and alleviate obesity caused by high-fat diet. The effects of anthocyanins on dyslipidemia are mainly reflected in lowering serum total cholesterol, triglyceride, and low-density lipoprotein-cholesterol levels and increasing levels of high-density lipoprotein-cholesterol and apolipoprotein.

12.5.4 Amelioration of Anthocyanins on Insulin Resistance

Insulin resistance (IR) means that insulin in the body promotes the ability of organs, tissues, and cells to absorb and utilize glucose. In order to maintain relatively normal blood sugar levels, the body must compensate for the secretion of insulin and form hyperinsulinemia. IR refers to the decrease in the efficiency of insulin-promoting glucose uptake and utilization by various reasons, and the compensatory secretion of excess insulin produces hyperinsulinemia to maintain the blood glucose. Insulin resistance easily causes metabolic syndrome and type 2 diabetes.

Interestingly, anthocyanins can use their own phenolic hydroxyl groups to neutralize excess ROS in cells, reduce oxidative stress levels, and prevent free radical damage and secondary insulin resistance; on the other hand, by inhibiting stress activation of stress proteins such as JNK and MAPK in adipocytes to increase tyrosine phosphorylation of IRS-1 after insulin stimulation and GLUT4 from cytoplasm to cell membrane to improve insulin sensitivity in liver and muscle tissue, anthocyanins can also improve the exocrine function of adipose tissue by regulating gene expression of human adipokines, thereby improving insulin resistance status of polar bodies.

12.5.5 Antitumor Effect of Anthocyanins

In the initial stage of tumor, anthocyanins can protect DNA from genetic mutation by anti-oxidation; in the tumor stage, anthocyanins can reduce the expression of inflammatory factors, such as COX and NO by inhibiting the MAPK signaling pathway, and inhibit VEGF. Its expression controls the proliferation of tumor cells; in the development stage of tumors, anthocyanins exert anticancer effects by activating JNK and caspase-3 to promote apoptosis of cancer cells and inhibiting MMP expression to prevent invasion and metastasis of cancer cells.

12.6 Anthocyanin's Benefits in Human

Anthocyanins are glycoside derivatives of anthocyanidin, which belongs to flavonoids. Anthocyanins are found in a wide variety of plant foods such as blueberries, cherries, purple potatoes, and black rice and very easy to obtain. Furthermore,

anthocyanins have various bioactivities such as scavenging free radicals, cancer prevention, inflammatory suppression, inhibiting lipid peroxidation, preventing diabetes, losing weight, and protecting vision, and they can protect cells and animals because of these bioactivities. In addition, human studies also manifest that anthocyanins play an important role in protecting human diseases including metabolic-related diseases and non-metabolic-related diseases.

12.6.1 Protective Effects of Anthocyanin on Cardiovascular Disease

Cardiovascular diseases (CVDs) are manifestations of general vascular disease or systemic vascular disease in the heart. The causes can induce CVDs including atherosclerosis, arteritis, hypertension, hyperlipidemia, leukemia, anemia, thrombocytopenia, and so on. CVDs are a common disease that seriously threatens the health of humans, especially middle-aged and older people over the age of 50. And they are characterized by high prevalence, high disability, and high mortality. According to reports, approximately 85.6 million ($>1/3$) of American adults have CVD, and among them, 43.7 million people are ≥ 60 years old. And people all over the world spend a plenty of money to treat cardiovascular diseases. We should pay attention and focus on the prevention of CVDs. Recently, several large cohort studies, follow-up studies, and cross-sectional studies have shown that anthocyanin intake is negatively correlated with cardiovascular disease incidence.

The studies further confirm that anthocyanins can reduce the incidence and mortality of atherosclerosis, coronary artery disease, hypertension, nonfatal myocardial infarction, and stroke. Total cholesterol and serum triglycerides are routine projects for lipid analysis and represent risk factors for the predisposition of CVD. Anthocyanins could decrease the level of total cholesterol and serum triglycerides. Low-density lipoprotein (LDL) is a lipoprotein particle that carries cholesterol into peripheral tissue cells and can be oxidized to oxidized low-density lipoprotein. Moreover, oxidation of low-density lipoprotein easily causes atherosclerosis. Anthocyanin intake could reduce the level of LDL. LDL cholesterol can deposit in the arterial wall of the blood vessels such as the heart and brain, gradually forming atherosclerotic plaque, blocking the corresponding blood vessels, and finally causing coronary heart disease and stroke. And the LDL cholesterol can be decreased by anthocyanins. Meanwhile, anthocyanin-rich blueberry increases high-density lipoprotein (HDL) cholesterol, thereby preventing the risk of atherosclerosis because HDL can promote the reverse transport of cholesterol and clear cholesterol in peripheral tissues. Anthocyanins could decrease triacylglycerol (TAG) and TAG/HDL cholesterol ratio. Additionally, anthocyanins decreased the serum high-sensitivity C-reactive protein (hsCRP) levels, soluble vascular cell adhesion molecule-1 (sVCAM-1), and plasma interleukin (IL)-1β levels significantly in people with hypercholesterolemia (Zhu et al. 2013).

As previously mentioned, oxidation of low-density lipoproteins easily causes atherosclerosis, suggesting that oxidation reaction plays an important role in atherosclerosis. Malondialdehyde is the end product of lipid peroxidation, which can

exacerbate membrane damage. 8-OHdG is a biomarker of DNA oxidative damage. Anthocyanin supplementation can improve the ferric-reducing ability of plasma (FRAP), total antioxidant capacity (TAC), and oxygen radical absorbance capacity (ORAC) and reduce the production of malondialdehyde, 8-OHdG, and isoprostane. Abnormal glucose metabolism could increase the risk of CVD. Anthocyanins could reduce body mass index (BMI), fasting blood glucose, 2-hour postprandial blood glucose, and glycated hemoglobin. Anthocyanin-rich cranberry juice could reduce serum glucose, thereby decreasing apolipoprotein-B (apo-B) and increasing apolipoprotein-A1 (apoA-1) and paraoxonase-1 (PON-1) activity in type 2 diabetic male patients and decreasing the risk of CVD. Furthermore, anthocyanin intake was inversely proportional to the incidence of hypertension. Blueberry consumption could decrease central systolic blood pressure (cSBP), central diastolic blood pressure, mean arterial pressure (MAP), augmentation index, pulse wave velocity (PWV), brachial-ankle pulse wave velocities, and intima-media thickness, and the increased production of nitric oxide decreases blood pressure and arterial stiffness. Moreover, anthocyanin supplementation could decrease spontaneous and oxidative hemolysis and the number of activated platelets, thereby ameliorating CVD risk.

12.6.2 Protective Effects of Anthocyanin on Type 2 Diabetes Mellitus

Diabetes mellitus (DM) is a group of metabolic disorders caused by defects in insulin secretion and function and characterized by long-term hyperglycemia, accompanied by a series of complications such as diabetic nephropathy, ischemic heart disease, and stroke. As a result, DM and its comorbidities cause huge healthcare burden and high mortality worldwide. Nearly 415 million people had type 2 diabetes mellitus (T2DM) in 2015, and it is expected to rise to 642 million by 2040 (Xu et al. 2018). So we must develop effective interventions and policy recommendations to alleviate these pressing public health issues. The causes of DM include genetic and environmental factors and obesity, resulting from eating too much and engaging in less physical activity, which is the major environmental factor for T2DM. That is, lifestyle and dietary habits are the major factors that determine the development and progression of obesity and T2DM. And T2DM is mainly caused by insufficient insulin secretion and insulin resistance. A lot of evidence indicates that dietary modifications such as fruit and vegetable intake could prevent these chronic degenerative diseases for the presence of many bioactive compounds. Among these bioactive compounds, anthocyanins especially attracted much attention for its wide distribution in plant foods and potent bioactivities. Wedick's team found that higher consumption of anthocyanins has a lower risk of T2DM, and higher intake of anthocyanin-rich foods such as blueberries, apples, and pears has also a lower risk of T2DM.

A meta-analysis of 8 prospective studies of a total of 312,015 participants suggests that anthocyanin intake was inversely associated with T2DM risk (Xu et al. 2018). Basal glycemia and postprandial blood glucose are two important indicators for diabetes diagnosis. Among them, basal glycemia can reflect the

function of islet β-cells and generally represent the secretory function of basal insulin. Postprandial blood glucose represents the blood glucose level after glucose load, and it is the earliest clinical manifestation before the onset of T2DM. Anthocyanin extracts could reduce the augment of postprandial glycemia and basal glycemia in T2DM patients. Insulin is a protein hormone secreted by pancreatic islet β-cells in the pancreas by endogenous or exogenous substances such as glucose, lactose, glucagon, etc., and insulin is the only hormone in the body that lowers blood sugar, and hyperinsulinemia is often a compensatory manifestation of insulin resistance. Anthocyanins could reduce the augment of insulin and dose dependently decrease insulinemia in prediabetic individuals. Insulin resistance refers to the decrease in the efficiency and utilization of insulin-promoting glucose uptake, and the body's compensatory secretion of excess insulin produces hyperinsulinemia to maintain blood sugar stability. Anthocyanin can decrease peripheral insulin resistance due to the decrease of insulin concentration in blood. Insulin sensitivity is the degree of insulin resistance, and most people with type 2 diabetes have reduced insulin sensitivity. Anthocyanins could lower postprandial insulin peaks and improve insulin sensitivity in insulin-resistant patients, and it has the potential to mitigate adiposity in overweight men. Glycated hemoglobin (HbAlc) is a product formed by non-enzymatic glycation of hemoglobin and albumin in red blood cells in the case of hyperglycemia. And HbAlc is an indicator of overall glycemic control in diabetic patients. Anthocyanins could decrease HbAlc serum levels. Hippuric acid is the main nonprotein nitrogen metabolite in urine, and its content reflects the metabolism of the kidney, and the content of hippuric acid in diabetic patients is low. Anthocyanin supplement can increase fasting serum hippuric acid. In brief, the epidemiological research and clinical trials provide tangible proof that increased anthocyanin intake is correlated with a lower incidence of T2DM and suggest that overweight or obese individuals should consider consuming more anthocyanin-rich foods to prevent development and progression of T2DM.

12.6.3 The Neuroprotection Function of Anthocyanin

Neurosis is a group of mental disorders that are mainly manifested as anxiety, depression, fear, coercion, suspected symptoms, or neurasthenia with a very high incidence. The symptoms of neurosis are complex and diverse, and the typical experience is a psychological activity that the patient feels uncontrollable and thinks should be controlled. The neurosis patients are deeply painful and impede mental or social function, but without any verifiable organic sexual pathology basis. Some epidemiologic study shows that anthocyanins can alleviate several neurosis-related diseases such as depression, anxiety, and cognitive function. Depression is one of the most common neuropsychiatric disorders. Epidemiological study of 1572 Italian individuals reveals that anthocyanins are inversely correlated with depression symptoms (Godos et al. 2018). Anxiety disorder is the most common type of neurosis, with anxiety as the main feature. Anthocyanins could improve alertness and decrease

fatigue and have an anxiolytic effect. Furthermore, anthocyanin-rich food consumption could improve cognitive ability, including verbal learning and memory in individuals with cognitive impairment. And anthocyanins could improve immediate spatial memory and driving performance.

Monoamine oxidase (MAO) is a mitochondrial enzyme containing flavin, embedded in neurons and non-neuronal cells, which catalyzes the oxidation of monoamines in a variety of tissues, including the brain. For a long time, elevated MAO activity has been associated with the causes of depression, anxiety, and neurodegenerative diseases. Anthocyanin extracts can improve mood effectively by inhibiting monoamine oxidase-B in healthy young adults (Watson et al. 2015). Insulin-like growth factor-1 (IGF-1) is a neurotrophic factor that plays an important role in neuronal survival and brain function. IGF-1 function is impaired in Parkinson's disease. Cyclic glycine-proline (cGP) is a metabolite of IGF-1 and has neuroprotective effects by improving IGF-1 function. Measuring the level of cGP can better represent the bioavailability of IGF-1. Blackcurrant anthocyanins can ameliorate anxiety and depression by increasing the concentration of cGP to improve the function of IGF-1 in Parkinson's patients. In a summary, anthocyanin supplements can exert neuroprotection function in human through many aspects.

12.6.4 The Protective Effects of Anthocyanins on Visual Functions

Visual function is the ability of the human visual system to perform certain visual tasks. It mainly includes the ability to detect the presence of objects, distinguish the details of an object, perceive the color of an object, and distinguish visual objects from a visual background. However, the visual function is degraded due to improper use of the eye or excessive use of the eye in daily life. Recent human studies have shown that the intake of anthocyanins can improve visual function. Recent increases in the daily workload of video display terminals (VDTs) have led to an increase in various symptoms associated with eye fatigue, including eye pain, dry eye or excessive tearing, and blurred vision, which may impair vision health and vision quality. Many clinical studies have shown a significant association between eye fatigue and psychophysiological eye function, which can be assessed by objective ophthalmic parameters such as critical flicker fusion (CFF). Anthocyanin supplementation could alleviate the reduction of CFF and mitigate the symptoms of eye fatigue, VDT load-induced ocular fatigue sensation, ocular pain, eye heaviness, uncomfortable sensation, and foreign body sensation in VDT workers. Anthocyanin-rich fruits could decrease the dark-adaptation threshold and hasten the recovery of visual acuity after photobleaching. Glaucoma optic neuropathy is considered to be one of the leading causes of irreversible blindness worldwide, and insufficient blood supply to the retina and optic nerve is one of the primary risk factors. Anthocyanin extracts of blackcurrant could increase blood flows at both neuroretinal rim of the optic nerve head and peripapillary retina in normal tension glaucoma (NTG) patients (Ohguro et al. 2008).

12.6.5 Other Properties of Anthocyanins

Anthocyanins not only protect humans from suffering from CVD, T2DM, nerve-related diseases, and visual function degradation but also protect from colitis, liver diseases, cancers, and other diseases. Anthocyanin treatment could reduce fecal calprotectin levels and decrease endoscopic Mayo score and histologic Riley index on ulcerative colitis. Furthermore, clinical trial suggests that anthocyanin-rich bilberry extract can mitigate ulcerative colitis by decreasing the proinflammatory cytokines IFN-γ, tumor necrosis factor-α (TNF-α), monocyte chemotactic protein-1 (MCP-1), and the level of phosphorylated p65-NF-κB and enhanced the levels of Th17-cell-specific cytokine IL-22 and immunoregulatory cytokine IL-10 (Roth et al. 2016). Moreover, anthocyanins could decrease serum levels of hepatic biomarkers including serum γ-glutamyl transferase (GGT), aspartate aminotransferase (AST), and alanine aminotransferase (ALT) levels in healthy adult men with borderline hepatitis. Anthocyanins could significantly reduce plasma alanine aminotransferase, cytokeratin-18, M30 fragment, and myeloperoxidase in nonalcoholic fatty liver disease. Anthocyanin intake was inversely associated with the risk of esophageal cancer and colorectal cancer. These promising intervention results deserve further long-term clinical trials to evaluate the beneficial effects of anthocyanin consumption on colitis, liver diseases, and cancer. In general, anthocyanin supplement protects a wide variety of human diseases.

12.7 Anthocyanins and Disease Prevention

Disease burden is measured by financial cost, mortality, morbidity, or other indicators. To reduce the cost of the society, disease prevention is more meaningful than clinical therapy. Dietary polyphenols exert positive effects in promoting health and preventing a wide range of chronic diseases. According to abundant studies on animals and humans, anthocyanins are a group of splendid polyphenols that have been associated with disease prevention, including cardiovascular diseases, diabetes, neurodegenerative conditions, cancer, and so on. Anthocyanins possess antioxidant, antidiabetic, antihyperlipidemic, anti-inflammatory, anticarcinogenic, neuroprotective, chemotherapeutic, and antiulcer activities.

12.7.1 Anthocyanins Prevent Metabolic Syndrome-Related Diseases

Metabolic syndrome (MetS) is represented by a group of interrelated metabolic disorders, which is accompanied by overweight or central (intra-abdominal) obesity, insulin resistance, cardiovascular diseases, and hepatic steatosis. MetS now affects 30–40% of adults, especially at a high rate in western countries. Anthocyanin-rich foods were reported to reduce the risks of metabolic syndrome-related diseases.

Obesity is presented as excess fat accumulation due to the unbalanced energy uptake and consumption. Commonly obesity is not considered seriously by individuals because of the high frequency and the impalpable injury. However, it is the basis of various metabolic syndrome-related diseases. Anthocyanin extracts have shown to prevent weight gain in mice, which is mainly on the white adipose tissue. Anthocyanin supplement significantly reduced body weight gain and suppressed fat accumulation in mesenteric adipose tissue in a high-fat diet mice model, reduced retroperitoneal adipose tissue, and decreased the adipocyte size of the epididymal fat (Jiang et al. 2018a). Meanwhile, anthocyanin treatment reduced the plasma content of free fatty acids, triglycerides, and cholesterol in obese mice. Chronic, low-grade inflammation is closely associated with obesity, which is also the trigger of many other chronic diseases. Anthocyanins decreased the level of F4/80 and downregulated the expression of TNF-α, IL-6, and nuclear factor kappa B (NF-κB). Adipose tissue is a consequence of excess lipid accumulation but also a cause of metabolic disorders. Adipokines are adipocyte-derived secretory factors which mediate many signaling cascades in target tissues, including insulin sensitivity and other procedures of energy homeostasis. Adipokines such as leptin and resistin are secreted from fat tissues, which mediate energy metabolism and insulin resistance. Serum adiponectin increased and the serum insulin and leptin level deceased by the treatment of anthocyanins, which indicated the improvement of adipokines. Interestingly, despite the abundant sugar, supplementation of the anthocyanin-rich fruit or the fruit juice, they have shown no promotion of body weight, on the contrary reduced the lipid accumulation (Wu et al. 2013).

Anthocyanins reduce the fasting glucose, total cholesterol, triglyceride levels, LDL, and glucose tolerance. Anthocyanins prevent the progression of type 2 diabetes by upregulating glucose transporter 4 (GLUT4) proteins' translocation in the membranes of heart and skeletal muscle tissues, which additionally promote energy usage. Anthocyanins could increase the activation of peroxisome proliferator-activated receptor-gamma (PPAR-γ) in adipose tissue and skeletal muscles, thereby increasing secretion of adiponectin and leptin. Anthocyanins can also activate AMP-activated protein kinase (AMPK) and downregulate retinol-binding protein 4 (RBP4) expression to mediate glucose metabolism. In addition, anthocyanins reduce the apoptosis of pancreatic cells and protect the function of secreting insulin. Anthocyanins also alleviate insulin resistance, upregulate insulin receptor, and sensitize the insulin signaling. Anthocyanins could trap methylglyoxal (MGO) and reduce the carbonyl stress and the formation of advanced glycation end products (AGEs), which is a risk factor of diabetes (Chen et al. 2014).

Nonalcoholic fatty liver disease (NAFLD) is the most prevalent liver disease in the world. Anthocyanins could reduce the high production of alanine aminotransferase (ALT) and aspartate aminotransferase (AST) and the reactive oxygen species (ROS), which indicated less hepatocyte damage. As previously mentioned, anthocyanins could reduce the level of plasma TG, LDL, and glucose, which are also the risk factors of NAFLD. Additionally, it can reduce the level of free fatty acid and

suppress the level of inflammatory cytokines in blood circulation. In the liver, anthocyanins inhibit lipid droplet accumulation in hepatocytes and ameliorate liver steatosis. Anthocyanins could reduce the lipid synthesis by mediating the protein expression of acetyl coenzyme A carboxylase (ACC) activities, sterol regulatory element-binding protein-1 (SREBP-1), fatty acid synthase (FAS), and glycerol-3-phosphate acyltransferase (GPAT). Furthermore, anthocyanins protect the integrity of mitochondrial and promote the lipid oxidation enzyme PPARα, CPT1 protein and gene expression of acylCoA-oxidase.

Accompanied by the injury of hepatocytes, inflammatory cells are infiltrated into the liver tissue from the blood circulation, the resident macrophage Kupffer cells are activated, and inflammatory cytokines as well as chemokines were generated, which will aggravate cell damage and the activation hepatic stellate cells. Supplementation of anthocyanins significantly inhibited inflammatory cell infiltration and secretion of cytokines, which prevented progression of nonalcoholic steatohepatitis (NASH) and liver fibrosis. Anthocyanin-rich extract can enhance the level of PI3K and p-Akt in the liver. Anthocyanins can also target AMPK phosphorylation and autophagy, thus suppressing the activation of hepatic stellate cells.

Heart attack and fibrosis could be consequences of diabetes mellitus. Anthocyanin treatment significantly reduced cardiac hypertrophy and fibrosis and protected the heart. Endothelial cells also produce a wide range of factors that mediate cellular adhesion, smooth muscle cell proliferation, and vessel wall inflammation. Moreover, they act as a semipermeable barrier that controls blood-tissue exchange of fluids, nutrients, and metabolic wastes from the intravascular compartment to the interstitium. Anthocyanins alleviate endothelial dysfunction and apoptosis and attenuate oxidative stress. Anthocyanins could target the phosphorylation levels of AMPK, promote the level of eNOS and the generation of NO, and elevate cyclic GMP (cGMP) in the aorta. Moreover, they can also suppress iNOS level and restrain oxidative damage. Anthocyanins promoted the expression of ATP-binding cassette transporter G1 (ABCG1) and lower cholesterol, mainly 7-ketocholesterol (7-KC). Anthocyanins could also inhibit inflammatory cytokine secretion from endothelial cells. Protecting of endothelium of anthocyanins lead to a much less aortic lesion, and a better function of relax or constrict the vessel. Additionally, compared to aspirin, anthocyanins have less side effects and could be a potential antiplatelet agent that prevents atherosclerosis and other cardiovascular diseases.

12.7.2 Anthocyanins Prevent Neuro-damage

Insulin resistance is related to hyperphosphorylation of microtubule-associated protein tau in the hippocampus, which may cause the development of Alzheimer's disease. Anthocyanin-rich extract reduced the level of inflammation and oxidative

stress, improved insulin sensitivity and learning/memory performance, and prevented tau phosphorylation in the hippocampus. Anthocyanins might regulate FKBP52 (FK506-binding protein 52) and prevent Alzheimer's disease. FKBP52 has been found to inhibit tau protein aggregation. The docking score of anthocyanins for FKBP52 is greater than for FK506 for the FK1 domain. Anthocyanins cause FKBP52 structural variations to be the same as FK506 when the protein and ligand interact. Anthocyanins as legends will make PKBP52 stable, and different anthocyaninshavevariousbindingresults:C3G>Pt3G>Pa3G>D3G>FK506>P3G>M3G (Hung et al. 2014). Anthocyanins could improve hippocampal insulin signaling in amyloid beta-infused rats, thus preventing cognitive dysfunction. In addition, anthocyanin treatment reduced the generation of amyloid protein. Protocatechuic acid as a metabolite of anthocyanins can also attenuate brain mitochondrial dysfunction, thereby preventing oxidative stress.

Vascular dementia is one of the challenging problems of elderly. Oral treatment of mulberry extract for rats suffering from vascular dementia showed enhanced memory and increased densities of the neuron but less apoptosis and oxidative stress. The neuroprotective effect of the extract might also be associated with the increased cholinergic function. LPS has been reported to affect neuronal cells via activation of microglia as well as to directly initiate neuroinflammation. Anthocyanin treatment at a dose of 24 mg/kg/day for 2 weeks prevented ROS production, inhibited neuroinflammation and neurodegeneration, and improved memory functions in LPS-treated mice. Anthocyanins reversed the activation of JNK, prevented neuroinflammation by lowering the levels of inflammatory markers (p-NF-κB, TNF-α, and IL-1β), and reduced neuronal apoptosis by reducing the expression of Bax, cytochrome c, cleaved caspase-3, and cleaved PARP-1 while increasing the level of survival proteins p-Akt, p-GSK3beta, and anti-apoptotic Bcl-2. Anthocyanin treatment increased the levels of memory-related pre- and post-synaptic proteins and improved the hippocampus-dependent memory in the LPS-treated mice. Anthocyanins reduced the level of phospho-c-Jun N-terminal Kinase 1 (p-JNK). Anthocyanin treatment also reduced activated astrocytes and microglia in the cortex of LPS-injected mice, as indicated by reductions in GFAP and Iba-1, respectively.

Parkinson's disease (PD), one of the most common neurodegenerative disorders, is characterized by the loss of dopaminergic neurons in the substantia nigra pars compacta (SNpc) to the striatum (ST) and involves oxidative stress. In cell model, SH-SY5Y cells stressed with 6-hydroxydopamine (6-OHDA), mulberry extract (ME) downregulated ROS and NO generation; mediated Bcl-2 and Bax proteins, mitochondrial membrane depolarization, and caspase-3 activation; and significantly protected the cells from neurotoxicity in a dose-dependent manner. In mesencephalic primary cells stressed with 6-OHDA or 1-methy1-4-phenylpyridinium (MPP^+), pretreatment with ME also protected the dopamine neurons. In the subacute mouse PD model induced by 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP), ME showed a preventative effect against PD-like symptoms (bradykinesia) in the behavioral test and prevented MPTP-induced dopaminergic neuronal damage in an immunocytochemical analysis of the SNpc and ST (Kim et al. 2010).

12.7.3 Anthocyanins Prevent Retinal Damage

Retinal damage is becoming a more and more severe challenge to mankind in all ages. Anthocyanins are reported to inhibit retinal cell apoptosis and photochemical damage in rats. Anthocyanins inhibited the expression of AP-1, upregulated NF-κB and P-IκB, and decreased the level of caspase-1. In human studies, bilberry extract treatment on the eye fatigue induced by acute video display terminal had some favorable effects. Bilberry supplementation induced a reduction in critical flicker fusion (CFF), but the near point accommodation (NPA) was not changed. Ocular fatigue sensation, ocular pain, eye heaviness, uncomfortable sensation, and foreign body sensation were mitigated more in the bilberry group. Thus supplementation improved some of the objective and subjective parameters of eye fatigue induced by VDT loads.

Cataracts have become the leading cause of blindness which is mediated by oxidative stress. Anthocyanins prevented oxidative stress and reduced photoreceptor cells. Anthocyanins with an *N*-trimethyl chitosan (TMC)-coated liposomes transport to a depth of 40 μm in the cornea, where SOD, catalase in lens elevated, and lipid peroxidation prevented.

12.7.4 Anthocyanins Prevent Cancer

The antitumor potential of anthocyanins is reported based on a wide variety of biological activities. However, the more meaningful aspect is the anti-tumorigenesis effect, due to the antioxidant, anti-inflammation, and anti-mutagenesis activities inhibiting proliferation, invasion, angiogenesis, and metastasis.

Diets containing 5% of either black or red raspberries, strawberries, blueberries, noni, and a double dagger ai or wolfberry were used to treat *N*-nitrosomethylbenzylamine-esophagus cancer model. All berry types were about equally effective in inhibiting tumorigenesis in the rat esophagus. They also reduced the levels of the serum cytokines, IL-5 and GRO/KC, and the rat homologue for human IL-8, and this was associated with increased serum antioxidant capacity. Lyophilized black raspberries (BRB) reduced the incidence of esophageal cancer from 100% in model group to 81.5% in the rats treated with BRB ($p < 0.05$). The tumor multiplicity was reduced from 4.73 +/− 0.45 tumors per esophagus in the model group to 1.44 +/− 0.26 in rats treated with intervention with BRB. Using bioassay-directed fractionation, the anthocyanins in BRB were found to be the most active constituents for downregulation of carcinogen-induced NF-κB and AP-1 expression in mouse epidermal cells in vitro. An important study has shown that anthocyanins are the main bioactive component in BRB to prevent cancer growth. Animals were treated for 30 weeks to induce esophageal tumors; anthocyanin treatments (5% whole BRB powder, an anthocyanin-rich fraction, an organic solvent-soluble extract, each contained similar to 3.8 μmol anthocyanins/g diet) were about equally effective in reducing tumorigenesis in the esophagus, indicating that the anthocyanins in BRB have chemopreventive potential. The organic-insoluble (residue)

fraction was also effective, suggesting that components other than berry anthocyanins may be chemopreventive. The hexane and sugar diets were inactive (Wang et al. 2009).

Breast cancer is related to altering of estrogen metabolism. In an animal model, blueberry anthocyanins and black raspberry anthocyanins inhibited 17 beta-estradiol-induced mammary tumor incidence, volume, and multiplicity. In the mammary tissue, anthocyanin extracts inhibited the increase of cytochrome P4501a1 and 17β-HSD7 at different time points (6 weeks, 18 weeks, 24 weeks). In another study, the experimental diet rich in anthocyanins significantly delayed the first tumor appearance by 21 days; reduced estrogen-associated growth of pituitary prolactinomas, circulating prolactin, and estradiol levels; and offset estrogen-associated increases in mammary cell proliferation, estrogen receptor-alpha (ER-alpha), and cyclinD1. miRNAs related to the tumorigenesis that were either overexpressed (miR-182 and miR-375) or underexpressed (miR-127 and miR-206) following estrogen treatment were significantly protected by anthocyanin-rich diet (Aqil et al. 2016).

In an azoxymethane (AOM)-/dextran sodium sulfate (DSS)-induced mice colon cancer model, anthocyanin treatment led to a reduction of carcinogenesis in the colon and lower tumor multiplicity. In the mice model, supplement of purple potato extract reduced the injury caused by azoxymethane in aberrant crypt foci of colons. A less proliferating cell nuclear antigen (PCNA) and a greater apoptotic caspase-3 expression were found in the colon mucosal epithelial cells. Importantly, anthocyanin treatment maintained the balance of gut microbiota by decreasing the pathogenic bacteria and increasing the probiotics. Anthocyanins also caused demethylation of the SFRP2 gene promoter, resulting in increased expression of SFRP2, both at the mRNA and protein levels. Furthermore, the expression levels of DNMT31 and DNMT3B, as well as of p-STAT3, were downregulated by anthocyanins in these animals (Tian et al. 2018). In vitro, anthocyanin-rich extracts from purple potato suppressed human colonic SW480 cancer cell growth by arresting the cell cycle at G1 phase but not cytotoxicity. Anthocyanins can modulate multiple signaling pathways such as NF-κB, Wnt/-catenin, PI3K/AKT/PKB/mTOR, and ERK/MAPK in colon cancer.

It is important to reduce the side effects of chemotherapy. Phytochemicals including anthocyanins are also applied in clinical trials for the protection of the heart and reduction of cardiovascular diseases or cardiotoxicity induced by anticancer drug. Cisplatin can induce hepatotoxicity and oxidative stress. Anthocyanin-rich extract caused a marked reduction in the activities of alanine aminotransferase and aspartate aminotransferase after cisplatin administration.

12.7.5 Anthocyanins Prevent Other Chronic Diseases

Anthocyanins have been proved to prevent some other chronic diseases. Due to the antioxidant and anti-inflammatory ability of anthocyanins, they can suppress

the development of autoimmune arthritis. In a collagen-induced arthritis mice model, black soybean coat extract (mainly C3G) reduced the incidence of arthritis, according to the histological inflammation analysis, cartilage scores, and oxidative stress. Proinflammatory cytokines in the joints were suppressed by anthocyanins, and NF-κB was suppressed. Importantly, Th17 cell number in the spleen was decreased; the differentiation of Th17 from splenocytes and human PBMCs and Th17-associated genes in vitro was suppressed by the treatment of anthocyanins. Motor function is inversely correlated to the age. Osteoclast formation is a crucial action for the loss of bone in animals, especially accompanied by the decreasing of estrogen. Blueberry anthocyanins were proved to reduce bone loss in osteoporosis mice model and suppress osteoclast formation in vitro. Among them, delphinidin is the most efficient anthocyanidins to suppress microphage differentiation to osteoclast and suppressed the activation of NF-κB, c-fos, and Nfatc1 and master transcriptional factors. PCA as a metabolite of anthocyanins also inhibited LPS-induced bone loss in vivo, suppressed RANKL-stimulated expression of c-Fos and nuclear factor of activated T cells c1, and downregulated the level of p-JNK and osteoclastogenesis-related genes including 3-integrin, DC-STAMP, OC-STAMP, Atp6v0d2, CTR, and CtsK. Muscle atrophy is common in elderly. Delphinidin suppressed muscle weight loss through downregulating oxidative stress-related gene expression including Cbl-b, inhibited MuRF1 expression, and promoted miR-23a AND NFATc3 expression.

Anthocyanins are also beneficial for male reproductive ability. Cyanidin-3-*O*-*β*-D-glucopyranoside promoted erectile function in diabetes mellitus rat model. Anthocyanin minimized corporal apoptosis, increased the expression of endothelial eNOS and nNOS, and reduced the level of 8-OHdG. In an andropause animal model with low androgen, anthocyanin treatment increased the activity of SOD in serum and reduced oxidative stress. Anthocyanins reduced the level of apoptotic cells in the prostate. Oxidative stress in the testis is a threat of spermatogenesis. Under hypobaric hypoxia, blueberry extract reduced lipid peroxidation, decreased apoptosis, and increased GR and SOD activities in rat testis. In a chloropropanol-induced injury on male rat reproductive system, cyanidin-3-*O*-*β*-glucoside (C3G) improved the number and motility of the sperms, alleviating seminiferous tubule injury. Interestingly, C3G showed no influence on sexual hormone but increased the androgen receptor expression. Meanwhile, C3G reduced the oxidative stress and number of apoptotic cells and promoted the integrity of the blood-testis barrier in the testis. Additionally, C3G mediated the activation of p-ERK, p-JNK, and p53, which are related to the protection of Sertoli cells and spermatogenesis (Jiang et al. 2018b).

Anthocyanins have shown some potential on the protection of skin damage. In an acute skin photodamage mice model, Nano-C3G could effectively reduce the UVB-induced lipid peroxidation, malondialdehyde, and 8-hydroxy-2′-deoxyguanosine contents; downregulate p53, Bcl-2-associated X (Bax), and caspase-3 and caspase-9 expression; and balance the B-cell lymphoma-2/leukemia-2 ratio. Moreover, Nano-C3G (125, 250, 500 μM) improved the visual appearance, skin moisture, histologic appearance, and apoptotic index (based on

TUNEL staining) under UVB exposure (Liu et al. 2018). In a cell study, when HaCaT cells were exposed to UV radiation in the presence of nanoberries, their viability was maintained. In dermal fibroblasts, treatment with anthocyanins significantly reduced radiation-induced apoptosis and intracellular reactive oxygen species generation at 48 h. Furthermore, high dose of anthocyanins markedly decreased Smad3 mRNA expression and increased Smad7 mRNA expression post-irradiation. In mice, anthocyanin treatment significantly reduced the level of skin injury, epidermal thickness, and collagen deposition after irradiation. Treatment with anthocyanins significantly decreased the number of α-SMA, TGF-β, and Smad-3-positive cells after irradiation.

12.8 The Safety of Anthocyanins

Anthocyanin daily intake is larger; in addition to giving rich colors to nature, anthocyanins contained in plant foods also have a variety of physiological health and disease prevention effects, so they can be used as food additives and medical foods. Then, what is the cytotoxicity of anthocyanins? And what dose of anthocyanin is harmful to cells? In animal experiments, how many doses can cause harm to animals? How many anthocyanins are allowed to be taken in a daily diet, and what is the recommended daily meal amount? This is waiting for us to discuss.

12.8.1 Toxicity of Anthocyanin In Vitro

12.8.1.1 Cytotoxicity and Common Detection Methods

Cytotoxicity is a simple cell-killing event caused by cells or chemicals and does not depend on the cell death mechanism of apoptosis or necrosis. The correlation coefficients commonly used in cytotoxicity experiments are GI_{50} and IC_{50}.The values means concentration that inhibited 50% of the net cell growth.

12.8.1.2 Effects of Different Sources of Anthocyanins on the Activities of Different Cell Lines

The effects induced by the anthocyanin extract on the survival of different cell lines were analyzed in both dose-response and time-course experiments. Compared with cancer cells, anthocyanins have a greater concentration of effects on normal cell viability. The activity of PRSE (polyphenol-rich strawberry extract) was investigated in normal fibroblast cell lines of both murine (NIH-3 T3) and human (WI38) origin, and they are significantly less sensitive to PRSE with respect to cancer cell lines (mean IC_{50} of 3.24 ± 0.14 mg/mL and 1.68 ± 0.77 mg/mL) (Amatori et al. 2016). Lili et al. have studied and evaluated the cytotoxic effects of three different berry extracts on RAW264.7 cells (macrophages) at three different concentrations (100, 150, and 200 mg/mL). The data from MTS assay showed no significant changes in

cell viability, indicating that three berry extracts were not cytotoxic at dosage up to 200 mg/mL (Li et al. 2013). Other research also shows the growth of normal cells is less significantly inhibited by anthocyanin extracts than that of cancer cells. The IC_{50} values of various normal cells are more than twice that of corresponding cancer cells, reflecting the advantage of small side effects of natural products. About cancer cells, the treatment of cells with purified anthocyanin extract or crude extracts from *Hibiscus sabdariffa* calyx at 5–800 μg/mL did not show significant cytotoxic effects on Caco-2, HepG-2, HCT8, and A549 cell lines (Maciel et al. 2018). The *C. cyanus* petals aqueous extract exhibited IC_{50} and GI_{50} (> 900 μg/mL) values for HepG-2, Caco-2, and A549 cell lines, meaning low cytotoxicity. Based on the stress oxidative assay, the extract exhibited prooxidant action (10–100 μg/mL) but did not cause damage or cell death (Escher et al. 2018). Similar results were also described by Amatori et al. for A17 (breast cancer cell line) cells which show higher response to PRSE exposure (IC_{50} of 1.14 ± 0.29 mg/mL). At this stage, there have been few studies on the toxicity test of cells with certain anthocyanins, and more attention has been paid to the protective effect of anthocyanins on cell damage caused by certain harmful elements.

12.8.2 Anthocyanin in Animals

12.8.2.1 Food Safety Toxicology Evaluation

Anthocyanin pigments are required as a natural food colorant to be evaluated for their safety. Food safety toxicology evaluation has four stages:

First stage: acute toxicity test, LD_{50}, combined with acute toxicity, maximum tolerated dose method
Second stage: genotoxicity test, traditional teratogenic test, and 30d feeding test
Third stage: subchronic toxicity test-90d feeding experiment, reproduction test, and metabolic test
Fourth stage: chronic toxicity test (including carcinogenic test)

The table presented some common sources of anthocyanin toxicology safety data (Table 4).

Among them, grape skin extract-grape skin anthocyanin can be safely used in food and is a coloring agent according to GRAS (Generally Recognized as Safe). In addition to being used as a coloring agent, anthocyanins extracted from blueberries can also be used as an antioxidant nutrient supplement. The products on the market are tablet products, each containing 50 mg of anthocyanin. In general, common anthocyanins from different substances have different effects on animal toxicity tests. The daily intake of anthocyanins in the US diet is estimated to be between 180 and 215 mg (blueberry anthocyanin). Therefore, the intake of most anthocyanins between these measurements will not cause harm to the human body.

Table 4 Toxicological tests of anthocyanins from different sources

Anthocyanin source	LD_{50}	Micronucleus test	Sperm deformity test	Toxicity grading standard	Remarks
Purple corn	>21.50 g/(kg·bw) rat oral	–	No teratogenic effect	Safe	
Grape skin	15 g/(kg·bw)(male rat oral) 10.8 g/(kg·bw) (female mice oral)	–	No teratogenic effect	Safe	ADI:0–2.5 mg/kg(JECFA2006; ADI value first mentioned in 1982
Black bean	19 g/(kg·bw)(mice oral)	No teratogenic effect			
Blackcurrant	10 g/(kg·bw) (rat, mice oral)	–	–		In the USA, the recommended intake is 180–215 mg/day
Roselle	9260 mg/(kg·bw) (mice oral)				
Myrica		–	No teratogenic effect		
Cowberry	>25 g/(kg bw) (mice oral)	–	No teratogenic effect		Weak accumulation

Note: negative; ADI, daily allowable intake of people

12.8.3 Population Investigation

Cell and animal experiments by anthocyanins indicate that anthocyanins are safe in a certain concentration range and have certain anti-inflammatory, anti-oxidation, and anticancer effects. Based on the species differences between experimental animals and humans, scientists have been working in recent years to extrapolate research findings from experimental animals outside the body. In daily life, most of the dark fruits and vegetables we eat contain different amounts of anthocyanins. This benefit requires us to further discuss anthocyanins through human clinical trials. Wilhelmina's Crowd experiment, subjects daily intake 250 mL of wild blueberry juice (containing 216 mg (448 μmol cyanidin 3-glucoside equivalents)) for a period of 36 days. The results has shown that the excretion content of anthocyanins was basically unchanged within 7 days, and the anthocyanin content in the long-term body circulation is gradually reduced (Kalt et al. 2017).

The emotional and cognitive changes of young people after adding purple grape juice were studied (the content of anthocyanin in purple grape juice was 136.6 mg per 200 mL), which showed that people's cognition, memory, and concentration improved in a certain period of time (Haskellramsay et al. 2017). In one population, the utilization rate of different anthocyanins in the bilberry extract was studied in the intestine. The cranberry extract contained 15 different kinds of anthocyanins, and each person ingested 10 g of untreated onetime. About 1.3 ± 0.9 μmol of anthocyanins and 20.3 ± 5.2 μmol of degradation products were excreted via urine in healthy volunteers ($N = 5$) (Mueller et al. 2018; Mueller et al. 2017). Myoungsook conducted an experiment in which 32 people received 2.5 g of black bean extract every person per day (anthocyanin content, 12.58 mg/g; cyanidin-3-glucoside, 68.3%) for 8 weeks. The treatment has shown a strong improvement in plasma lipid profiles, which is related to the reduction of abdominal fat (Lee et al. 2016). Therefore, further confirmation of anthocyanins as food additives can be added by human studies.

To date, anthocyanin toxicity has not been found under ordinary dietary conditions in humans. In short, the anthocyanins ingested in the daily diet will not cause damage to the human body. According to the current anthocyanin population intervention test results, no adverse reactions will occur if the anthocyanin intake level reaches 320 mg/d.

12.9 Development and Utilization of Anthocyanins

Anthocyanins are a natural, environmentally friendly food source pigment, which are abundant and nontoxic and provided specific nutritional and health value and pharmacological effects. It has tremendous potential for application and development in food, functional foods, medical and health, cosmetics, chemical production, and so on. The extraction process is a key link in the production and use of anthocyanins. Currently, the main extraction methods of anthocyanins prevailingly include organic solvent extraction, water extraction, supercritical fluid extraction, ultrasonic-assisted extraction, microbial fermentation extraction, enzymatic extraction, microwave assisted extraction, liquid static high pressure-assisted extraction, subcritical water extraction, pressurized solvent extraction, dual aqueous phase extraction, and high-voltage pulsed electric field-assisted extraction.

Different purities of anthocyanin extracts can be applied to products in different fields. For example, anthocyanin crude extracts can be mainly used as food additives, raw materials for food, and functional foods and for medical purposes. The high purity monomer of anthocyanin is principally used as a standard in scientific research, due to its high cost. At present, the relatively mature fields of development and utilization concerning anthocyanin extracts are food additives, deep processing of anthocyanin-rich products, and dietary supplement or functional foods.

12.9.1 Pigments Used as Additives

As one of the indispensable additives in the food industry, pigments play an important role in improving the sensory quality. Pigments can be classified into artificial synthetic pigments and natural pigments according to their sources. Synthetic pigments include amaranth, carmine, sunset yellow and so on. Natural pigment is the term that refers to an edible pigment which is derived from plants, fruits, animals, and microorganisms, such as anthocyanins and carotenoids. Natural pigments from animal and plant tissues, are safe and nontoxic and have no side effects. Meanwhile, a myriad of pigment, which has biological activities and nutritional strengthening effects, can show attractive colors and provide a pleasant feeling by adding to foods. However, synthetic pigments are mostly from coal tar fuels. The chemical structures of synthetic pigments are azo compounds, which can form β-naphthylamine and α-amino-1-1 naphthol in the process of metabolism. Compared to natural pigments, synthetic pigments possess certain potential carcinogenicity, have a limited scope of application. They are popularly applied in soft drinks and confectioneries. Nevertheless, it is prohibited in meats, infant foods, and biscuits. The principal pathways of toxically synthetic pigments are (1) the toxicity of chemical substances injures human health; (2) the hazardous substance can be generated through metabolic process; and (3) it is contaminated by heavy metals such as arsenic, lead, or other toxic and harmful compounds in the process of synthesis. Therefore, the development and utilization of natural pigments is an inevitable trend. Furthermore, its application prospects are broad.

Anthocyanins are natural pigments derived from plant-based raw materials, which are vital substitutes for synthetic pigments, due to the good water solubility. It can be used as additives in the food industry. The Joint FAO/WHO Expert Committee on Food Additives (JECFA) uses toxicological data to evaluate the safety of anthocyanins as food additives. Ultimately, it is determined that anthocyanins have "minimal toxicity" or are "practically nontoxic" and can be included in the natural pigment food additive (Table 5). Currently, anthocyanins are mainly used in $pH < 4.5$. Anthocyanin extracts have been approved by the Chinese Ministry of Health for use, such as for beverages, jams, candies, dairy, and ice cream (Table 6). Anthocyanin extracts as food additives are not need to be certified, which are utilized in beverages, dairy, cakes, and so on, according to FDA standard (Table 7). Anthocyanin extracts are widely used in European Union countries and in Japan. And EU has summarized the levels of usage of anthocyanins (E 163) as food additive in the five population groups (Table 8).

12.9.2 Deep Processing of Anthocyanin-Rich Products

Anthocyanins from purple cabbage, purple potato, blueberry, black rice peanuts, etc. going through deep processing have splendid development prospects.

Recently, anthocyanin-rich berry products have been widely developed and utilized and also are very popular and have a vast market at home and abroad. Anthocyanins

Table 5 General standard for food additives (grape skin extract as anthocyanin)

Food category	Max level (mg/kg)
Flavored fluid milk drinks	100
Cream analogues	150
Milk and cream powder analogues	150
Dairy-based desserts (e.g., pudding, fruit, or flavored yogurt)	200
Fat-based desserts excluding dairy-based dessert products of food category	200
Edible ices, including sherbet and sorbet	100
Canned or bottled (pasteurized) fruit	1500
Jams, jellies, marmalades	500
Fruit-based spreads (e.g., chutney) excluding products of food category	500
Fruit preparations, including pulp, purees, fruit toppings, and coconut milk	500
Fruit-based desserts, including fruit-flavored water-based desserts	500
Fermented fruit products	500
Fruit fillings for pastries	500
Vegetables (including mushrooms and fungi, roots and tubers, pulses and legumes, and aloe vera) and seaweeds in vinegar, oil, brine, or soybean sauce	100
Vegetable (including mushrooms and fungi, roots and tubers, pulses and legumes, and aloe vera), seaweed, and nut and seed purees and spreads (e.g., peanut butter)	100
Vegetable (including mushrooms and fungi, roots and tubers, pulses and legumes, and aloe vera), seaweed, and nut and seed pulps and preparations (e.g., vegetable desserts and sauces, candied vegetables) other than food category	100
Fermented vegetable (including mushrooms and fungi, roots and tubers, pulses and legumes, and aloe vera) and seaweed products, excluding fermented soybean products of food categories	100
Cocoa-based spreads, including fillings	200
Cocoa and chocolate products	200
Imitation chocolate, chocolate substitute products	200
Soft candy	1700
Chewing gum	500
Decorations (e.g., for fine bakery wares), toppings (non-fruit), and sweet sauces	500
Cereal and starch based desserts (e.g., rice pudding, tapioca pudding)	200
Crackers, excluding sweet crackers	200
Bread-type products, including bread stuffing and bread crumbs	200
Egg-based desserts (e.g., custard)	200
Mustards	200
Soups and broths	500
Emulsified sauces and dips (e.g., mayonnaise, salad dressing, onion dip)	300
Non-emulsified sauces (e.g., ketchup, cheese sauce, cream sauce, brown gravy)	300
Mixes for sauces and gravies	300
Dietetic foods intended for special medical purposes	250
Dietetic formulae for slimming purposes and weight reduction	250
Dietetic foods	250

(continued)

Table 5 (continued)

Food category	Max level (mg/kg)
Food supplements	500
Water-based flavored drinks, including "sport," "energy," or "electrolyte" drinks and particulated drinks	300
Cider and perry	300
Wines (other than grape)	300
Distilled spirituous beverages containing more than 15% alcohol	300
Aromatized alcoholic beverages (e.g., beer, wine and spirituous cooler-type beverages, low-alcoholic refreshers)	300
Snacks – potato, cereal, flour, or starch based (from roots and tubers, pulses, and legumes)	500
Processed nuts, including coated nuts and nut mixtures(with, e.g., dried fruit)	300

Table 6 Natural anthocyanin approved in China

Source	Recommended range	Maximum (g/kg)
Black bean red	Sweets, pastries, fruit and vegetable juice, flavor drinks, and assembled wine	0.8
Blackcurrant red	Cakes, soda drinks, and wine	According to production requirement
Red rice red	Modified milk, cold drinks, sweets, and wine	According to production requirement
Sweetberry honeysuckie red	Cold drinks, sweets, pastries, flavored drinks, and wine	3.0
Fall kwai red	Sweets, cakes, jelly, soda drinks	0.25
Roselle red	Sweets, fruit and vegetable juice, flavor drinks, and assembled wine	According to production requirement
Grape red skin	Cold drinks, jam, pastries, soda drinks, flavored drinks and assembled wine	1.0
Mulberry red	Fruit cakes, sweets, jellies, flavored drinks, and wine	5.0
Cowberry red	Cold drinks, fruit and vegetable juices, and flavor drinks	According to production requirement

are a vital series of phenolic compounds in grape and wine. They are prevailingly distributed in the vacuoles of 3–4 layers of cells of grapes. If whole grapes are adopted for fermentation, anthocyanins can infiltrate the fermentation broth during the process to obtain wine. According to statistics, the yield of wine in the global market reaches up to 24.67 billion L, and wine accounts for above 80%. The new wine contains abundant anthocyanins, predominantly anthocyanin 3-*O*-glucoside and delphinidin 3-*O*-glucoside. As researches put it, it is universally acknowledged that anthocyanins

Table 7 Source and the recommended range of anthocyanins approved by FDA in USA

Source	Recommended range
Ipomoea hederacea	Sweet wine
Brassica oleracea	Ice cream, yogurt, sweet milk
Hibiscus sabdariffa	soft drink, sweets
Vaccinium oxycoccos	Fruit pulp, sour and spicy pulp, jelly, fruit wine, solid drink, powder containing sour sweet
Clitorea tematea	Cocktail, solid drink premix, rice flour cake with sweet gum, or solid food
Grewia asiatica	Drink
Rubus idaeus	Fruit juice

Table 8 Summary of anticipated exposure to anthocyanins (E 163) from its use as food additive using maximum reported use levels in five population groups (mg/kg bw/day)

	Toddlers (12–35 months)	Children (3–9 years)	Adolescents (10–17 years)	Adults (18–64 years)	The elderly (>65 years)
Mean	1.5–4.0	1.5–4.7	1.0–2.5	0.7–1.9	0.5–1.1
High level	3.2–6.9	2.7–7.8	1.6–3.9	1.1–3.4	0.9–2.3

enjoy paramount effects on skin care and prevention of cardiovascular diseases. In addition, 7% grapes are mainly used for processing juices, jams, and other products, such as grape juice, grape enzymes, and grape jam.

Besides grapes, other anthocyanin-rich berry products have been widely exploited. Other related products of blueberry, cranberry, and others exert a tremendous fascination on consumers, for example, blueberry wine and cranberry wine. In addition to wine, the technology of berry jam development has matured. The sauce and jam of berry invariably manifest promising economic performance. Meanwhile, related products include grains, such as preserved vermicelli and beverage, which are made by purple sweet potato.

12.9.3 Dietary Supplement or Functional Foods

Expecting the basic effects on coloring, much of the research in anthocyanins at home and abroad has examined the favorable biological activities, namely, antioxidation, antiaging, anti-inflammatory, neuroprotective, and promote re-synthesis of erythrosin (Yang et al. 2009). Previous investigations of long-term use of anthocyanin-rich products had emphasized on maintaining vascular health and preventing cardiovascular disease. Anthocyanins are indicative of potential functions in reducing inflammation and protecting the arterial wall from damage. Simultaneously, it is more preferable than vitamins C and E in protecting arteries. Consequently,

Table 9 Anthocyanins used in functional food

Sources	Purity	Functions	States
Blueberry	80 mg/capsules	Improve vision	Norway
Cranberry powder, cowberry extractive, blueberry powder	2 g/100 g	Improve immunity	China
Bilberry powder	5.88 g/100 g	Relieve visual fatigue	China
Cowberry extractive	6.7 g/100 g	Relieve visual fatigue	China
Blueberry extractive	28.88 mg/capsules	Improve vision	USA
Cranberry extractive	18 mg/capsules	Improve immunity, protective urinary system	Germany
Blueberry extractive	12.5 mg/capsules	Anti-oxidation, improve vision	Canada
Bilberry extractive	20 mg/capsules	Relieve fatigue, improve vision	UK
Nordic strawberry extractive	90 mg/capsules	Relieve eye fatigue, improve vision	Japan

anthocyanins, which are called "pigment nutrients," can be extensively used as crucial functional foods and raw material in pharmaceutical.

Presently, there are a multitude of health products produced from anthocyanins worldwide which includes tablets and capsules (Table 9). The functions as principally claimed are relieving visual fatigue and strengthening immunity, anti-oxidation, and so on.

In a word, combining the advantages of superior physiological efficacies, extensive sources, no side-effects and with the support of advanced production technology, the development and utilization of anthocyanin-related products have feasibility in food industry and economy. However, many external factors like pH, metal ions, oxygen, and enzymes can seriously affect the stability of anthocyanins in the food processing and storage. Therefore, the instability exceedingly limits its development and utilization. It is of great significance to discuss the stability and expand its application by physical-chemical and biological means. The main methods include co-pigmentation, molecular modification, microencapsulation, complementary synergy, biotechnology, and so on. Generally, the modification of anthocyanins to make up for deficiency makes its application as natural pigments more extensive. Hence, it is a problem that cannot be ignored for the development and utilization of anthocyanin-rich products.

12.10 Perspective

Anthocyanins as a group of dietary polyphenols are widely applied in the food industry and could provide potential benefits for humans. We systematically introduced the source, chemical activity, bioactivity, and functions of anthocyanins, which show a universal source and a broad development potential.

Also, some of the unclear issues are still calling for further investigation. (1) Appropriate dosage of anthocyanins to be used – in animal studies or clinical studies – is still uncertain (Kim et al. 2013). The recommended anthocyanin intake has not been certainly determined yet, which limited the application of anthocyanins for daily consumption and product development. (2) The structural and functional relationship of anthocyanins is still not well evaluated. Structural issues are quite important for influencing the bioavailability and bioactivity of anthocyanins. Additionally, different anthocyanin-rich foods contain different prominent monomers, and the structural-functional study will impact the value of their development. (3) The direct molecular targets of anthocyanins in cells are still not well illustrated. Although some studies indicated that anthocyanins can directly bind to IL-17, NF-κB as a modulator, it is still a mystery of the molecular targets, as to anthocyanins showed so broad-spectrum effects on many signaling pathways. (4) The anthocyanin-related signal transduction pathways are still needed for further exploration. For instance, autophagy is crucial in adipocyte, hepatocyte, and hepatic stellate cell apoptosis or activation (Zhang et al. 2012); however, anthocyanins mediation on it is merely studied yet. (5) To illustrate the effects of anthocyanins in metabolic syndrome, the comparison studies about anthocyanins and some other well-known drugs or compounds are needed, which is a valuable source of anthocyanin product development. (6) Studies of anthocyanins on other animal models and cells are needed. With no doubt, all the animal or cell models have some limits. The hazard factor exposures in our daily life are much more complex. Thus the studies of disease prevention or therapy need different models to mimic the actual environment. (7) The stability, bioavailability, and effect of anthocyanins in vivo are still controversial problems. Some studies try to enhance the stability and to make nano-encapsulation of anthocyanins, which may have shown better bioavailability and sustain longer time than the unembedding anthocyanins (Bennet et al. 2014). However, some studies proved that its metabolites have better bioactivities. Whether it is better to improve or inhibit the degradation of anthocyanins is still unknown.

All in all, anthocyanins are important in our daily life, and it has a bright future for the application in food additive production and for disease prevention and therapy.

Abstract

Triterpenoids, as a more important and the largest group of phytochemicals, exist in thousands of medicinal plants from which more than 20,000 substances with up to 100 basic skeletons have been isolated, purified, and structurally elucidated. Natural or synthetic triterpenoid compounds have been proven to have superior biological activities against various types of cancers, inflammations, and metabolic syndromes via related signaling pathways with the help of preclinical experiments. However, their inherent systemic toxicity and poor water solubility cause different levels of side effects and low bioavailability; inevitably, they possess several limitations for clinical trials as well as for applications in functional foods, pharmaceuticals, cosmetics domains, and similar fields. Therefore, it is urgent to study the pharmacokinetics profile, metabolic pathways, and mechanism of action and also to improve their bioavailability by combining them with chitosan, cyclodextrin, etc. or reducing the molecular particle size. This chapter summarizes the advanced knowledge about triterpenoids, mainly those stemmed from medicinal plants, in relation to the following aspects: bioactivities whether animal or human, bioavailability, metabolism, safety, side effects, and application in distinct fields especially dietary supplements. Moreover, structural formulas of common basic skeleton and the compounds mentioned in the context, market products, and patents are also discussed.

Triterpenoids · Phytochemicals · Pharmacokinetics · Plant · Clinical · Bioavailability · Dietary

13.1 Introduction

Naturally occurring triterpenoids, also known as triterpenes, form a pivotal part of terpenoids. They are regarded as the largest class of plant secondary metabolites, characterized generally by six isoprene units, i.e., 30 carbon atoms, and classified into mono-, di-, tri-, tetra-, penta-, and hexa-cyclic compounds, among which tetra- and pentacyclic are more popular (Cargnin and Gnoatto 2017). Historically, in 1788 Lowitz first extracted betulin from birch tree bark, although it was named by Mason in 1831. Later, researchers in succession roughly separated the representative triterpenoids such as oleanolic acid, ursolic acid, and glycyrrhetinic acid (GA) in the nineteenth century. In 1887, Vesterberg isolated pure α- and β-amyrin successfully and assigned molecular formula to them (Dev 2018). Subsequently, scholars focused on the structural chemistry of triterpenoids. In fact, before the mid-twentieth century, substantial progress in the field of triterpenoids was not obtained. After Ruzicka (1953) put forward the biogenetic isoprene rule theory and with the development of spectroscopy and extraction technology, separation, purification, and structural elucidation of triterpenoids are no longer a stiff problem. To date, thousands of

scholars have isolated, purified, and structurally elucidated more than 20,000 triterpenoid compounds from a variety of plant species worldwide (Wang et al. 2014).

As bioactive phytochemicals, triterpenoids are widely distributed in multifarious plant species. They contain free acids or aglycones, and are synthesized based on the cytosolic mevalonate reaction pathway similar to that of sterols (Ikeda et al. 2008). Briefly, isopentenyl-diphosphate (IPP) generated from acetyl-coenzyme A (acetyl-CoA) combines with its isomer dimethylallyl pyrophosphate (DMAPP), and then they together convert into farnesyl-diphosphate (FPP) through several reaction steps including acetylation, reduction, and phosphorylation in the presence of related enzymes. Next, using squalene synthase, FPP gets converted into squalene which further transforms into 2,3-oxidosqualene by oxidosqualene cyclases. Finally, cyclization of 2,3-oxidosqualene forms parental heterogeneous scaffolds such as lanosterol, cycloartenol, dammarenediol, α-amyrin, β-amyrin, etc. with modified functional groups or rearranged basic skeletons, leading to structural diversity. To date, more than 100 structures have been distinguished (Mullen et al. 2016). In fact, dating back to ancient time, numerous plants have been widely used for remedial purpose. As early as 1578, Shizhen Li compiled *Compendium of Materia Medica*, recording morphology, flavor, and usage of approximately 1892 medicinals, including triterpenoid-rich plants, such as *Centella asiatica*, *Glycyrrhiza uralensis*, *Alisma orientale*, *Momordica charantia*, *Cimicifuga foetida*, *Ganoderma lucidum*, *Panax ginseng*, and *Poria cocos*, which involved Alismataceae, Apocynaceae, Araliaceae, Betulaceae, Compositae, Cruciferae, Gentianaceae, Labiatae, Leguminosae, Myrtaceae, Oleaceae, Polygalaceae, Ranunculaceae, Rubiaceae, Solanaceae, and more families. Some literatures have introduced novel triterpenoids based on their sources from families to genes.

In-depth research on the synthesis and preclinical or clinical experiments of triterpenoids demonstrates that botanical triterpenoids and their derivatives are effective in the treatment of inflammation, obesity, diabetic mellitus, atherosclerosis, and hyperlipidemia, have tumor-multiplication inhibiting effects, and so on. The corresponding action mechanisms may be related to nuclear factor-kappa B (NFκB), adenosine monophosphate (AMP)-activated protein kinase (AMPK), phosphoinositide 3-kinase (PI3K), peroxisome proliferator-activated receptor alpha (PPARα), mitogen-activated protein kinase (MAPK), signal transducer and activator of transcription 3 (STAT3), and other signaling pathways. So far, there are over 300 new derivatives of triterpenoid acids that have been synthesized at Dartmouth College, USA (Liby et al. 2007). It has been verified that efficacy and bioavailability of 2-cyano-3,12-dioxoolean-1,9-dien-28-oic acid (CDDO) and its homologous compounds are stronger than those of triterpenoid acids. Nevertheless, undesirable physicochemical properties such as low aqueous solubility, poor bioavailability, and low permeability limit therapeutic application and clinical experiment of triterpenoids. The absolute bioavailability of oleanolic acid was only 0.7% for oral doses of 25 and 50 mg kg^{-1} (Gao et al. 2017). Naturally occurring triterpenoids without having prominent bioactivities at low concentration and without enough content to carry out clinical experiments are not suitable candidates for the same.

Consequently, it is indispensable to either synthesize novel compounds by altering chemical groups or reduce the oral drug size to nanometer scale (Wang et al. 2013b).

In view of the curative potency, triterpenoid-rich plants or their major active constituents have been extensively utilized in dietary supplements, medicine, and cosmetics fields. In China, oleanolic acid has been used as over-the-counter drugs for the treatment of chronic or acute hepatitis. Glycyrrhizic acid is used extensively as a sweetener in beverages and chewing tobacco. This chapter introduces updated knowledge of triterpenoids with regard to their chemical structures, bioavailability, metabolism, bioactivities, clinical experiment, application, safety, and patent aspects.

13.2 Bioactive Constituents

According to incomplete statistics, more than 100 distinct triterpenoid scaffolds including squalene, limonoids, cucurbitane, cycloartane, protostane, dammarane, lanostane, fusidane, euphane, friedelane, hopane, lupane, oleanane, gammacerane, ursane, α-amyrin, and β-amyrin compounds in which tetra- and pentacyclic triterpenes make up the majority (Hill and Connolly 2017; Teng et al. 2018) have been recognized.

Tetracyclic triterpenoids consist of cucurbitane, cycloartane, protostane, dammarane, lanostane, fusidane, euphane-type, etc., and they are found in various plants; however, different types have targeted plant sources. Cucurbitane-type largely stems from Cucurbitaceae such as *Siraitia grosvenorii*, *Momordica charantia*, and *Hemsleya amabilis*, for which the main bioactive compounds include cucurbitacins and mogrosides. Structural characterizations of these compounds indicate the presence of a variety of oxygen-containing functional group substitution at different positions (Chen et al. 2005). Cycloartane-types are regarded as the characteristic components of *Cimicifuga* and are widely distributed in various families, for example, Ranunculaceae (*Thalictrum*), Leguminosae (*Astragalus*), Meliaceae (*Trichilia casaretti*), Juncaceae (*Juncus effusus*), and so forth. Lanostane-type triterpenoids contain pachymic acid and ganoderic acid found in *Poria* and *Ganoderma* genera, whereas dammarane-type triterpenoids contain ginsenosides and ganoderiols existing in *Panax* genus. Protostane-type, as a stereoisomer of dammarane-type, is mainly found in *Alisma orientale*. Friedelane, lupane, oleanane, gammacerane, ursane, α-amyrin, β-amyrin, and hopane-type consist of pentacyclic triterpenoids, which are distributed ubiquitously and abundantly. Their active compounds arouse researchers' enormous interest and made them lucubrate in vivo or in vitro trials.

Figure 1 shows the parts of structural formula of bioactive constituents and their skeletons studied herein, concretely, including squalene; cucurbitacin B, cucurbitacin E, and saponin mogroside V (cucurbitane); celastrol and its methylether-pristimerin (friedelane); pachymic acid, eburicoic acid, and ganoderic acid A (lanostane); ganoderiol F (ganoderiol F); nimbolide and limonin (limonoid); β-boswellic acid, 11-keto-β-boswellic acid (KBA), and acetyl-11-

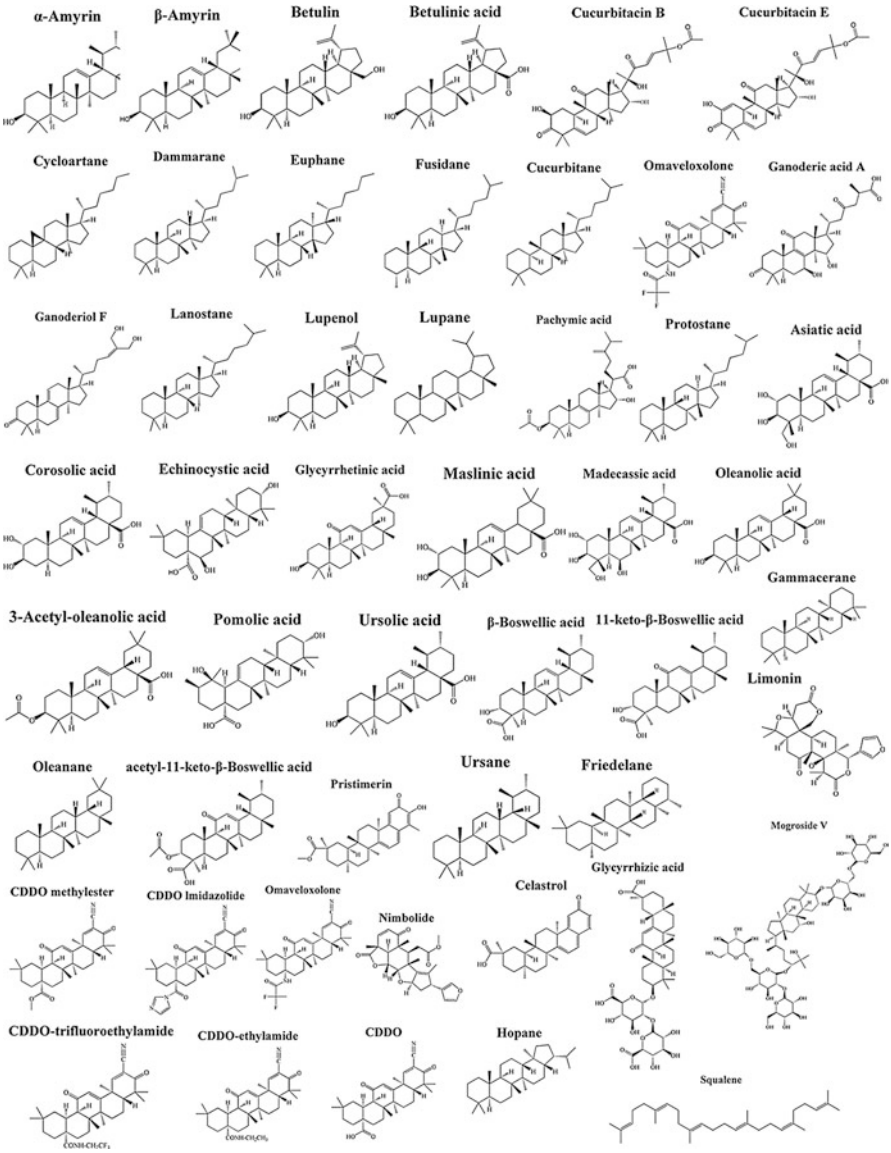

Fig. 1 Parts of structural formula of bioactive constituents described in this chapter

keto-β-boswellic acid (AKBA); lupeol, betulin, and betulinic acid (lupane); oleanolic acid, 3-acetyl-oleanolic acid, CDDO, CDDO-ethyl amide (CDDO-EA), CDDO imidazolide (CDDO-Im), CDDO methyl ester (CDDO-Me), CDDO-trifluoroethyl amide (CDDO-TFEA), omaveloxolone, GA, glycyrrhizic acid, echinocystic acid, and salaspermic acid (oleanane); and corosolic acid, maslinic

acid, ursolic acid, centellosides (asiatic acid and madecassic acid), and pomolic acid (ursane).

13.3 Bioavailability and Metabolism

When a drug enters the body through intravenous, intramuscular, subcutaneous, oral, mucosal, cutaneous, or transdermal route, it undergoes four processes of absorption, distribution, metabolism, and excretion (ADME), which are key physiological properties of pharmacokinetics. Pharmacokinetics is the discipline that involves the study of the efficacy of ADME by measurements, analysis, and prediction of the changes of drug concentrations in human body plasma by using the mathematical principles. In contrast, pharmacodynamics refers to the action mechanisms of drug effects on the organism, and both play a critical role in drug delivery system (Heller et al. 2018). However, various factors such as the physical and chemical properties of the drug, the given dosages and concentration, the route of administration, and the binding ability to plasma proteins affect the actual efficacy of the drug in the body. Rectal administration can avoid several aforementioned influence factors profited from its three transmission routes. Roughly, first, it is directly absorbed into the large circulation by the middle vein, inferior vein, and anal veins of the rectum without passing through the liver so as to avoid the first pass effect; second, the upper rectal vein enters the liver through the portal vein and then participates in the systemic circulation after metabolism; and third, the rectal lymphatic system also absorbs some drugs. The three pathways do not pass through the stomach and small intestine, thus avoiding the effects of acidic and alkaline digestive enzymes on the drug and also reducing the stimulation of the drug to the gastrointestinal tract. Therefore, rectal administration significantly improves the bioavailability of the drug (Van Hoogdalem et al. 1991; Taha et al. 2004). Moreover, Van De Waterbeemd and Gifford (2003) reported that poor ADME properties and target-organ toxicity (together for short ADME/T) are the main reasons for failure of clinical research and commercialization of triterpenoids. According to literature, the budget for developing a candidate drug should exceed $800 million (Yang et al. 2012). During the period from 2000 to 2010, out of 808 drug candidates developed by four major pharmaceutical companies, 356 compounds (44%) failed to progress into clinical studies due to their toxicity. Therefore, it is overwhelming to systematically study the pharmacokinetic and pharmacodynamics behavior of triterpenoids for better facilitating further research.

13.3.1 Bioavailability

The US Food and Drug Administration (FDA) states that bioavailability is the rate and extent to which the therapeutic moiety is absorbed and becomes available to the site of drug action (Holst and Williamson 2008). In other words, bioavailability is the

percentage of drug dose administered by any extravascular route that gets absorbed into the systemic blood circulation (Toutain and Bousquet-Mélou 2004). In general, bioavailability can be categorized into absolute and relative values, whose value contrasted with intravenous administration presumed as 100%, all of them assessed by maximum plasma concentration (C_{max}), the half-life in plasma ($t_{1/2}$), the time required to reach that concentration (t_{max}), the area under concentration-time curve (AUC), and related parameters. The study of medicinal plants has gradually deepened from the physicochemical properties and the level of pharmacological action of drug components to the level of drug bioavailability, which decides therapeutic effects. Factors affecting bioavailability include physicochemical properties (lipophilicity, solubility, and ionization), membrane permeation, presystemic metabolism, and first-pass clearance.

Several intrinsic physical characteristics of triterpenoids affect their bioavailability, which include low water solubility (<1 μg mL^{-1}), poor gastrointestinal absorption, reduced systematic exposure, and extensive metabolic clearance. The aqueous solubility of triterpenoids is generally low, roughly up to 0.02 μg mL^{-1}, e.g., lupeol, oleanolic acid, and betulinic acid. The biopharmaceutical classification system classified common oral solid preparations into four types in consideration of solubility, gastrointestinal permeability, and dissolution. Most triterpenoids or plant extracts belong to the fourth category, that is, low solubility and low permeability. Table 1 summarizes the bioavailability of triterpenoids. Jeong et al. (2007) evaluated the pharmacokinetics of oleanolic acid, indicating that its absolute oral bioavailability in Sprague–Dawley (SD) rats was only 0.7% for oral doses of 25 and 50 mg kg^{-1}. Zhang et al. (2012) studied the pharmacokinetics of celastrol showing that its absolute oral bioavailability in SD rats was 17.06% for oral doses of 1 mg kg^{-1}. Sasaki et al. (2003) investigated the pharmacokinetics of glycyrrhizic acid solution, reporting that its absolute oral bioavailability in SD rats for extravascular doses of 30 mg kg^{-1} was lower (0.25%) for oral administration and higher (20.2%) for nasal administration. Tremendous research efforts have been devoted to improve their bioavailability. At present, researchers mainly concentrate on the following six delivery systems: (1) non-covalent complex with hydrophilic cyclodextrins (CD); (2) nanoparticulate drug delivery; (3) chemical modification, prodrugs; (4) self-nanoemulsifying/microemulsifying drug delivery system (SN/MEDDS); (5) supercritical anti-solvent process; and (6) lipid/phospholipid-based delivery system. Of course, universal methods, for instance, hydrogel and submicron emulsions, do exist. Product launching requires a long process. Fourier-transform infrared spectroscopy, Raman spectroscopy, thermodynamic analysis, differential scanning calorimetry, phase solubility, etc. are employed to determine that the effectiveness of the complex is superior to that of the guest, followed by in vitro experiments, animal experiments, and clinical experiments to verify the activity and safety of the complex.

CDs are a type of cyclic oligosaccharide, which are formed head-to-tail by linking 6–12 D-glucopyranose residues through α-1,4-glycosidic bonds, and most of α-, β-, and γ-CDs severally contain six, seven, and eight units. Taking advantages of their structural characterization results indicating external hydrophilic group with

Table 1 Bioavailability of triterpenoids

Compound	Mode of administration	Experimental model	Biological utilization rate	References
Asiatic acid	Oral (20 mg kg^{-1})	SD rat	16.25%	Yuan et al. (2015)
Celastrol	Oral (1 mg kg^{-1})	SD rat	17.06%	Zhang et al. (2012)

Nimbolide	Oral (50 mg kg^{-1})	SD rat	3.06%	Mahamuni et al. (2018)
Oleanolic acid	Oral (25 and 50 mg kg^{-1})	SD rat	0.7%	Jeong et al. (2007)

hydrophobic cavity inside, CDs were selectively incorporated with triterpenoids. This finally resulted in the formation of non-covalent inclusion complexes, which led to the improvement in the stability, water solubility, and bioavailability of phytoconstituents (Claude et al. 2004). Yang et al. (2011) prepared nimbin wrapped in β-CD or its derivatives to assemble nimbin/β-CD conjugates which acted as potential candidates for healthcare applications by virtue of satisfactory aqueous solubility and high thermal stability. Xiao et al. (2016) used oleanolic, echinocystic, ursolic, and betulinic acid substrates and synthesized a batch of pentacyclic triterpenoids/α-CD complex, which exhibited increased lipophilicity and improved anti-hepatitis C virus (HCV) activity, whose mechanism depended on preventing virus entry at post-binding step. López-Miranda et al. (2018) explored elaborately the complexation behaviors of oleanolic and maslinic acid complexed with α-,β-,γ-, hydroxypropylated (HP)-α-, HP-β-, and HP-γ-CDs by analyzing thermodynamic parameters, complexation constant, complexation efficiency, and solubility under different pH and temperature conditions. This method has been implicated in oleanolic, betulinic, and glycyrrhizic acid, GA, pedunculoside, and boswellic acids (Lima et al. 2016).

Nanoparticulate drug delivery systems include solid lipid nanoparticles, nanosuspension, nanoencapsulations, and nanoemulsion. Sanna et al. (2015)

prepared celastrol-loaded poly(ε-caprolactone) nanoencapsulations (CL-NP) by nanoprecipitation method and studied thermal properties, antiproliferative efficacy, and mechanism of action on prostate cancer cells. The results indicated that CL-NPs showed higher cytotoxicity with inhibitory concentration (IC50) <2 μM. Nanosuspension is a submicron colloidal dispersion prepared with excipient substrates via high-pressure homogenization. The carriers include albumin, chitosan, gelatin, and poly-lactic acid which can shrink particle sizes and expand surface area to prolong drug release time and further improve bioavailability. Li et al. (2011) reported that nanosuspension of oleanolic acid is greater than that of pure oleanolic acid in saturation solubility, dissolution rate, and oral bioavailability (six- to seven fold). Cháirez-Ramírez et al. (2015) developed and evaluated the properties of lupeol nanonutraceuticals. Apparently, a nanoemulsion loaded with betulinic acid can be used as an effective delivery system that improves oral bioavailability by enhancing its absorption, reducing its clearance, and prolonging its duration of action. Zhang et al. (2016) reported the development of 25-OCH_3-PPD nanoemulsion based on phospholipid complexes. The phospholipid complex of 25-OCH_3-PPD was prepared and evaluated in vitro and in vivo. Solubility studies showed that the solubility of the phospholipid complex in water (4.9 times) and *n*-octanol (1.4 times) was higher. In vivo pharmacokinetic results are expected to demonstrate improved oral bioavailability of 25-OCH_3-PPD using nanoemulsions prepared from phospholipid complexes.

Prodrugs, as inactive and bioreversible derivatives of active phytochemistry, undergo an enzymatic and/or chemical *in vivo* reaction to release the active parent drug, which is usually designed for targeting delivery through specific membrane transporters (Huttunen et al. 2011). Zhou et al. (2017) reviewed the application, merit, and demerit of prodrugs strategy in triterpenoids, including esters, amides, glycosides, mutual prodrug, polymers, and several natural prodrugs, no matter which one is capable of improving poor drug-like properties from solubility, half-life, site selectivity, and presystem metabolism. Cao et al. (2012) selected peptide transporter1 to synthesize prodrug of oleanolic acid whose oral bioavailability enhanced by 2.04-fold.

SN/MEDDS can be defined as anhydrous homogenous liquid mixtures composed of oil, surfactant, cosurfactant (or solubilizer), and triterpenoids; which spontaneously come into oil/water (O/W) nanoemulsion/microemulsion with droplet size <200 nm after diluting in water under gentle stirring (Patel and Velikov 2011). Xi et al. (2009) selected Sefsol 218 as oil phase, Cremophor EL and Labrasol as primary surfactants, and Transcutol P as cosurfactant and optimized three SNEDDS-oleanolic acid formulations for which ratio of Sefsol 218/Cremophor EL/Labrasol/Transcutol P was 50:25:25:0/50:20:20:10/50:17.5:17.5:15 (w/w), respectively, based on dissolution, stability, and particle size profiles. The relative bioavailability of SNEDDS-oleanolic acid complex showed a 2.4-fold increase; moreover, an increased mean retention time and dissolution in rat plasma was also observed compared to commercial tablet. Yang et al. (2013) optimized the formulation design of SMEDDS-oleanolic acid in which Cremophor EL, alcohol, and ethyl oleate acquired the ratio 35:15:50 (w/w) and pharmacokinetic profiles indicated 5.07-fold

increase in oral relative bioavailability contrasting with oleanolic acid tablet. Shen et al. (2016) prepared akebia saponin D-phospholipid complex (APC) by solvent-evaporation method and further optimized the new formulation for APC-SNEDDS using glyceryl monooleate (type 40), polyoxyl 35 castor oil, diethylene glycol monoethyl ether, and APC severally as oil, surfactant, cosurfactant, and drug in a ratio of 1:4.5:4.5:1.74. Finally, results showed that the lipophilicity of APC enhanced (11.4-fold) and the oral bioavailability of APC and APC-SNEDDS improved significantly to 183.8% and 431.8%, respectively. Qi et al. (2014) screened the most suitable formulation of liquid celastrol-SMEDDS system including surfactant (OP-10) 60%, co-surfactant (Transcutol P) 15%, and oil phase (ethyl oleate) 25%, through evaluating solubility, self-emulsifying grading, droplet size, and ternary phase diagram parameters, and selected microcrystalline cellulose MCC KG 802 as adsorbent to prepare celastrol-SMEDDS dispersible tablets. Whether liquid celastrol-SMEDDS or its dispersible tablets were used, relative bioavailability was, respectively, 569 ± 7.07% and 558 ± 6.77% and significantly enhanced compared to 0.4% sodium carboxymethylcellulose suspension.

Supercritical anti-solvent process is a micronization technology to make triterpenoid particles reach micronic or nanometric scale. Yang et al. (2012) administered ursolic acid microparticles (100 mg kg^{-1}) in male Wistar rats and found that both the dissolution rate and absorption increased. Sui et al. (2012) prepared micronized glycyrrhizic acid and administered 250 mg kg^{-1} in Wistar male rats to compare the difference of pharmacokinetics. Results showed that the maximum saturation concentration was fivefold higher than that of pure glycyrrhizic acid and the pharmacokinetics properties improved significantly. Of course, other technologies for microparticle preparation including co-melting, dissolution, spray freeze-drying, and solvent evaporation also exist (Tong et al. 2011).

Lipid/phospholipid-based delivery system, for short liposomes/phytosomes, uses lipid or phospholipid as vesicles complexed with active constituents. Further, they together dissolve in non-polar solvents to obtain cell-like structure. Celastrol was dissolved in bits of anhydrous ethanol after being mixed with soy phosphatidylcholine. First, magnetic stirring was carried out for 3 h, and then the solvent was removed by rotary evaporation. The celastrol-phospholipid complex was formed, which was stored in desiccators. The celastrol phytosomes were prepared by brief sonication of the celastrol-phospholipid complex by adding deionized water. Compared to crude celastrol, AUC of celastrol phytosomes exhibited obvious fourfold increase, with fivefold increase in C_{max} (Freag et al. 2018). Boswellic acids were dissolved in bits of dichloromethane after being mixed with soy phosphatidylcholine. First, magnetic stirring was carried out for 2 h, and then the solvent was removed by rotary evaporation. The as-formed boswellic acid–phytosome complex was kept in desiccators. The method improves pharmacokinetics and anti-inflammation activity of boswellic acids (Sharma et al. 2010). Thin film dispersion–sonication method was used to prepare polyvinylpyrrolidone-K30-modified oleanolic acid liposomes. First, oleanolic acid was dissolved in little amount of methylene chloride, then it was mixed with soy lecithin and cholesterol, and then the solvent was removed by rotary evaporation to form film. The liposomes solution was

disrupted and freeze-dried with solution containing sodium deoxycholate, phosphate buffered saline, and 1% polyvinylpyrrolidone-K30, and finally the product was obtained successfully. The relative bioavailability of novel liposomal formulation enhanced by 6.08-fold; moreover, its absorption and stability in gastrointestinal tract increased (Liu et al. 2017b).

13.3.2 Metabolism

After a drug gets distributed ubiquitously in the human body, a series of metabolic reactions occurs under the influence of various enzymes and body fluid environment, resulting in changes in the chemical structure of the drug, and then it displays enhanced water solubility which is in favor of excretion. Owing to the structure of the material and the influence of the efflux protein, the triterpenoids are poorly absorbed in the intestinal tract and have low bioavailability. Triterpenoid is retained in the intestinal flora for a long time, and then little amount is absorbed by the bacterial group after hydrolysis. Nevertheless, owing to the complexity of internal environment and limitation of in vitro research techniques which cannot be extrapolated to the human body, only a few literature reports are available. Table 2 summarizes the metabolic pathways and metabolites of triterpenoid.

Metabolism can be divided into the following three phases: phase I includes hydrolysis, oxidation, and reduction reactions catalyzed by cytochrome P450 (CYP) superfamily; phase II points out at conjugation reaction between active compounds or their metabolites with some substrates; and phase III involves drug transporters placed in gastrointestinal tract, kidney, and epithelial and endothelial cells of the liver etc. and facilitates metabolites transport across blood–brain barrier. The intestinal and hepatic metabolism is called by a joint name presystemic metabolism. Metabolism in the liver is mainly accomplished by liver microsomes. To date, in vitro human liver models include cytosol, S9 fraction, supersomes, microsomes, transgenic cell lines, primary hepatocytes, liver slices, perfused liver, and others. All of them have their own highlights and weaknesses (Brandon et al. 2003).

Kimura et al. (2008) found that the elimination of glycyrrhizic acid from the liver may be one of the factors leading to low oral bioavailability by comparing the AUC of mice administered with the same dose via hepatic portal vein and intravenous injection. They also found that oral administration of glycyrrhizic acid in mice without intestinal flora did not detect GA in plasma. It was thus concluded that most of glycyrrhizic acid was hydrolyzed into GA in the presence of intestinal flora in the small intestine; and GA is a non-ionic molecule with strong liposolubility and it easily enters into the blood circulation through the intestinal wall. Jeong et al. (2007) investigated the absorption and metabolism of oleanolic acid by Caco-2 cell monolayer and liver microsome model. Studies showed that oleanolic acid gets metabolized by a variety of enzymes present in the intestine and liver, in particular CYP isozymes, such as CYP3A. Liao et al. (2005) observed the in vivo process of ursolic acid in rats and found that even though the dosage was high, the concentration of ursolic acid in the blood plasma was very low. It could thus be predicted that

Table 2 Metabolism of triterpenoids

Compound	Types	Metabolite	Metabolic pathways	References
25 (R)-OCH_3-PPD	CYP3A4	25-OH-PPD	Hydroxylation, dehydrogenation, and *O*-demethylation	Zhang et al. (2014a)
Asperosaponin VI	Intestinal flora	Hederagenin	Hydrolysis	Zhang et al. (2014b)
Ganoderiol F	Intestinal flora	Ganodermatriol	Hydrolysis	Zhang et al. (2009)
Ginsenoside Rb_1	Intestinal flora	Rd, Rg3, or F2, Rh2	Hydrolysis	Qian et al. (2006)
Glycyrrhizic acid	Intestinal flora	GA	Hydrolysis	Murata et al. (2010)
Lancemaside A	Intestinal flora	Echinocystic acid	Deglycosylated	Joh et al. (2012)
Mogroside V	Intestinal flora	Mogrol	Deglycosylated	Luo et al. (2016)
Soyasaponin I	Intestinal flora	Soyasaponin B	Hydrolysis	Hu et al. (2004)
Saikosaponin C	Intestinal flora	Prosaikogenin E1, E2, and E3, saikogenin E	Hydrolysis	Yu et al. (1997)

ursolic acid is widely distributed in the tissues and less distributed in the blood stream. Moreover, it may also be attributed to the decrease of bioavailability after metabolism through the intestine or liver. Some experiments showed that the metabolism of ursolic acid in the rat liver microsome incubation system treated with CYP3A inducer dexamethasone was significantly faster than that in the blank control group. After 30 min of metabolism, substitution of ursolic acid in the liver microsome incubation system was significantly different from that in the blank control group ($P < 0.01$). Furthermore, the classical CYP2B inducer phenobarbital and CYP1A inducer β-naphthoflavone were used as probes to pretreat the rats, respectively, and there was no significant difference in metabolic capacity between the two groups ($P > 0.05$), indicating that ursolic acid was mainly mediated by CYP3A in liver microsomes. The obvious homology of CYP3A cDNA sequences in liver and intestine indicates that the metabolism of ursolic acid by intestinal enzyme CYP3A may be one of the reasons for its low oral bioavailability.

Panax ginseng, whose active components include ginsenosides, is used to treat diabetes, insomnia, debility, aging, and sexual inadequacy from ancient century. As one of the popular Chinese herb medicines, its safety is relatively credible; however, they lack scientific theoretical data support. Thus, increasing research efforts should be focused upon to carry out systematic explorations on pharmacokinetics and pharmacodynamics of ginsenosides and their metabolism prior to animal experiments. Akao et al. (1998) compared cumulative contents and feces of germ-free and infected with *Eubacterium* sp. A-44 rats and found that ginsenoside Rb_1 could transform into compound K. Lai et al. (2009) investigated pharmacokinetic profiles

and metabolic pathways of 20(S)-ginsenoside Rh_1. Results showed that its absolute bioavailability was only 1.01%. Moreover, its metabolic pathways include deglycosylation in intestinal bacteria and hydration reaction in gastric; thus, it is reasonable to suspect that presystemic metabolism causes poor bioavailability. At present, more than 20 ginsenosides are deglycosylated by intestinal bacteria to active forms through oral conduction.

Limonin is one of the most representative limonoids, which belong to highly oxygenated C13α-triterpenoids, with intense bitterness and existing in citrus seeds. In fact, limonin was isolated in 1841, and till 1960, its exact structure was determined by the five teams working together. Furthermore, several hundred congeners were separated. Limonin can prevent osteoporosis, intestinal carcinogenesis, hepatocarcinogenesis, hypertension, etc. The in vitro and in vivo trials were carried out to expound the biotransformation and metabolic profile of limonin, i.e., possible metabolites and metabolic pathways. The mixture of limonin and rat's liver microsome incubation and the urine and blood samples were collected at 6, 12, and 24 h of SD rats after administering 80 mg kg^{-1} limonin. The samples were subjected to high-performance liquid chromatography coupled with quadrupole time-of-flight mass spectrometry analysis. Results indicated that five metabolites were identified and formed through reduction and hydrolysis pathways (Liu et al. 2018a).

13.4 Bioactivities

13.4.1 Crude Extractions

Leaves, roots, and stems of plants are utilized for health-promoting purpose from time immemorial including fungi, ferns, monocots, dicots, animals, and marine life. Researchers have isolated and identified large quantity of triterpenoids which were intended to be the major active components for curative effect. To date, oleanolic acid exists in more than 1600 plant species; moreover, ursolic acid is separated from up to 120 plant species. In fact, crude extractions have more potent activities by virtue of collaboration of different compounds. In recent years, crude extracts of triterpenoids have been reported to possess various biological and pharmacological properties such as anti-diabetes, anti-fungal, cytotoxic, liver-protecting, anticancer, chemopreventive, anti-allergic, immunomodulatory, hemolysis, immunostimulatory, and anti-inflammatory activity. Table 3 summarizes the bioactivities (limited to rodents' experiments) of crude extracts from triterpenoid-rich plants.

Momordica charantia (Cucurbitaceae), commonly known as bitter melon, is widely cultivated as a subtropical vegetable crop in Asia and has been used to treat shanghuo, toothache, diabetes mellitus, diarrhea, and furuncle in China. More than 50 triterpenoids have been isolated, among which representative triterpenoids are cucurbitane-type which possess anticancer and antidiabetic activities as verified scientifically (Wang et al. 2017). Pitchakarn et al. (2010) studied the effect of 80% ethanol extracted from leaves of *M. charantia* on prostate cancer in vivo and in vitro. PLS10 cell line was selected to carry out cytotoxicity, growth inhibition,

Table 3 Bioactivities of crude extractions

Plant origin	Diseases	Animal	Dose	Results	References
Antrodia camphorata	Ergogenic and antifatigue	Institute of Cancer Research (ICR) strain mice	50 or 200 mg kg^{-1}	↑Physical fatigue and exercise performance	Huang et al. (2012)

Wedelia chinensis	Prostate cancer	Athymic (nu/nu) nude mice	4 or 40 mg kg^{-1}	↓Androgen receptor	Tsai et al. (2009)

invasion, and migration assays. Moreover, athymic nude mice were given extract solution (0.1% or 1%) for 3 weeks to verify the metastasis assay. Deng et al. (2017) studied the effect of water extraction from fruits of *M. charantia* on liver injury in vivo and in vitro. In the beginning, researchers detected the main components of *M. charantia* extraction which included polysaccharide (27.92 g/100 g), protein (15.8 g/100 g), phenolic (0.04 g/100 g), and total saponin (0.48 g/100 g). 72 male Kunming mice were purchased and randomized into six groups administered with intragastrical *M. charantia* extraction 250, 500, and 750 mg kg^{-1} and vitamin C 250 mg kg^{-1} as positive control, and the rest were normal group and restraint stress model group. After 7 days, all the mice were dissected and their blood sample and liver collected. Furthermore, their pathological structure, biochemical analysis, protein expression, and conventional data were studied. Results displayed that *M. charantia* extraction could protect against liver injury in mice subjected to restraint stress by improving antioxidative capacity and protecting the liver mitochondrion. Han et al. (2018) adopted C2C12 myoblasts and ICR mice to study the insulin sensitivity and action mechanisms of four cucurbitane triterpenoids from *M. charantia* fruits' ethanol extract. Mice were assigned into control, C2 (0.84, 1.86 mg kg^{-1}), and positive control rosiglitazone (1.35 mg kg^{-1}) groups; subsequently, epididymal adipose tissue, quadriceps skeletal muscle, liver, and pancreas were collected to conduct glycogen assay and routine testing. The phenomenon that C2 increased glucose uptake into skeletal muscle via insulin receptor substrate-1 activation showed that cucurbitane triterpenoids can be deemed as insulin sensitizer.

Boswellia serrata belongs to Burseraceae family and is cultivated in far-ranging tropical and sub-subtropical regions. Its resin emits intense fragrance; thus it has been used as the raw ingredient of incense, balm, and myrrh long time ago, and its medicinal value has also been recorded in many ancient books, early dating back to 1500 BC in *Ebers Papyrus*. Furthermore, in Indian Ayurveda, there are descriptions about the treatment of arthritic diseases, Crohn's disease, asthma, and inflammation ailments. In China, it is usually used to repair skin damage such as bruises and infected sores. Modern medicine has confirmed that *B. serrata* gum resin extract possesses anti-inflammation, wound healing, immunomodulatory, anti-arthritic, antimicrobial, and neuroprotective activity, possibly profited from boswellic acids which contain more than 12 different compounds, among which KBA and AKBA acquired significant pharmacological attention. Barakat et al. (2018) explored the protective effect of boswellic acids which was bought directly in the form of *B. serrata* extract tablets (covered 65% boswellic acids) on doxorubicin-induced hepatotoxicity model. 40 Swiss albino mice were allocated into five groups ab libitum in control, model, and treatment groups (125, 250, 500 mg kg^{-1}), and finally blood and liver samples were collected. Treatment groups could decrease serum liver enzyme activities and hepatic malondialdehyde levels, upregulate nuclear factor-erythroid-2-related factor 2 (Nrf2) gene expression, and downregulate cleaved caspase-3 gene expression. Along with histopathological examination and DNA fragmentation analysis, integrated results revealed that boswellic acids are useful for protection against hepatotoxicity via impacting Nrf2/heme oxygenase-1 (HO-1) pathway.

13.4.2 Pure Compounds

Owing to the uncertainty on researching structure-activity relationships and biological mechanism actions of the crude extractions, plus the finite content which cannot even meet the requirement of animal experiment in plants, an increasing number of researchers prefer purchasing pure triterpenoids from biological companies, whereas as a result of expensive price, only oleanolic acid, ursolic acid, betulinic acid, and their derivatives are ubiquitous. Therefore, Table 4 summarizes the progress of bioactivities of pure triterpenoids.

Ischemia-reperfusion injury (IRI) refers to the sudden re-acquisition of blood supply to organs or tissues after a period of ischemia and can be divided into two processes, ischemia and reperfusion, which not only fails to restore the function of organs or tissues but also aggravates functional metabolic disorders and structural irreversible damage, on account of the formation of excess free radicals; activation of neutrophils, Kupffer cell, and platelets; endothelial cell injury; and enhanced vascular permeability, nitric oxide, cytokines, nuclear factor, and apoptosis. In clinical practices, IRI occurs in blood circulation disorders such as traumatic shock, surgery procedures, and organ transplantation and exists in many organs such as the myocardium, brain, liver, lung, and retina; in view of the abovementioned considerations, its mechanism is complex and multifactorial. Apolipoprotein E knockout (ApoE-KO) mice received intragastric betulinic acid 50 mg kg^{-1} day^{-1} for 7 days, which proceeded to transient focal ischemia operation in the middle cerebral artery and made the period of ischemia/reperfusion to 2 h/22 h. Pretreatment with betulinic acid could reduce oxidative stress and nitrosative stress, so it was valid to guard against celebral IRI (Lu et al. 2011). Nrf2+/+ (WT) and Nrf2−/− mice bred from pairs of Nrf2+/− (CD1/ICR) mice were administered with CDDO-Im 30 μmol kg^{-1} before 24 h/3 h or after 24 h ischemia. The effect of CDDO-Im on kidney IRI was evaluated thoroughly by comparing the change of renal function, histology, cell, and protein levels with those of normal groups. Pretreatment of CDDO-Im is helpful for protecting against kidney IRI, to a large degree, depending on the characteristic of Nrf2 activator (Liu et al. 2014). Ding et al. (2014) studied the effect of AKBA on mice suffering from middle cerebral artery occlusion and subsequent reperfusion. All the SD rats were divided in three groups based on treatment involving administration of 20 mg kg^{-1} AKBA by intraperitoneal inject. Treatment using AKBA can shrink the infarct volume, remit neuronal damage, and attenuate oxidative stress. Further, integration of Western blot and transfection tests displayed that AKBA possesses neuroprotection by feat of the activation of Nrf2/HO-1 pathway. Xu et al. (2017) and colleagues assessed the efficacy of asiatic acid on hepatic IRI. Male C56BL/6 mice were administered oral dosage of 30 mg kg^{-1} asiatic acid before 1 h vascular occlusion, which was effective to cut down hepatic histopathological damage, apoptotic signaling, and global inflammatory level. Results indicated that hepatoprotection of asiatic acid was collected with proliferator-activated receptor gamma (PPARγ) and nucleotide-binding oligomerization domain-like receptor (NLR) family pyrin domain-containing 3 (NLRP3). Tong et al. (2018) investigated the effect of celastrol pretreatment (2, 4, and 6 mg kg^{-1}) on myocardial

Oleanolic acid	Cartilage degeneration	db/db mice and C57BL/6J mice	200 mg kg^{-1}	PPARγ	Kang et al. (2017)
Oleanolic acid	Adiposity	C57B6/J mice	50 mg kg^{-1}	Hepatocyte nuclear factor 1b (HNF1b)	Su et al. (2018)
Oleanolic acid	Postmenopausal osteoporosis	C57BL/6 mice	10 mg kg^{-1}	NF-κB	Zhao et al. (2018)
Oleanolic acid	Schizophrenia	ICR mice	3, 10, or 30 mg kg^{-1}	Akt/GSK-3β	Park et al. (2014)
Oleanolic acid	Colitis	C57BL/6J mice	5, 10 mg kg^{-1}	↓Th17 cell differentiation ↑Treg cell differentiation	Kang et al. (2015)
Oleanolic acid	Liver injury	Nrf2-null mice Keap1KD mice	22.5 mg kg^{-1}	Nrf2 activation suppresses Oatp1b2	Lu et al. (2015)
Oleanolic acid	Atherosclerosis	Quails	25, 50, or 100 mg kg^{-1}	↓NADPH oxidase ↑Nrf2 and HO-1	Jiang et al. (2015)
Oleanolic acid	Adipose tissue insulin resistance	SD rats	5 or 25 mg kg^{-1}	Insulin receptor substrate-1/PI3K/Akt	Li et al. (2014b)
Oleanolic acid	Depression	ICR mice	2.5, 5, 10, 20, or 40 mg kg^{-1}	Brain-derived neurotrophic factor (BDNF)-ERK-CREB	Yi et al. (2014)
Oleanolic acid	Allergic asthma	Female BALB/c mice	2 and 20 mg kg^{-1}	↓GATA-3, retinoic acid-related orphan receptor γt (RORγt)	Kim et al. (2014a)

Oleanolic acid	Hepatocellular carcinoma	BALB/c mice	75 or 150 mg kg^{-1}	ERK-p53-mediated cell cycle arrest and mitochondrial-dependent apoptosis	Wang et al. (2013a)
Oleanolic acid	Diabetic nephropathy	OLETF and LETO rats	100 mg kg^{-1}	Endoplasmic reticulum stress reduction	Lee et al. (2015)
Oleanolic acid	Cholestasis	C57BL/6 mice	5, 10, 20 mg kg^{-1}	Nrf2-mediated upregulation of Mrp2, Mrp3, and Mrp4	Chen et al. (2014)
Oleanolic acid	Chronic cyclosporine nephropathy	ICR mice	25 mg kg^{-1}	Nrf2/HO-1	Hong et al. (2014)
Pomolic acid	Renal interstitial fibrosis	BALB/c mice	0.4 mg kg^{-1}	↓Mothers against decapentaplegic homolog 3 (SMAD)-STAT	Park et al. (2018)
Pristimerin	Acute lung injury	Swiss albino mice	0.5 and 1 mg kg^{-1}	Antioxidant, anti-inflammatory, and anti-apoptotic pathways	Shaaban et al. (2018)
Pristimerin	Autoimmune hepatitis	Swiss albino mice	0.4 and 0.8 mg kg^{-1}	Nrf2/HO-1	Elagamy et al. (2018)
Pristimerin	Colon cancer	Female BALB/c mice	1 and 5 ppm	Akt/Forkhead box O3a (FOXO3a)	Park and Kim (2018)
Pristimerin	Rheumatoid arthritis	SD rats	0.4 and 0.8 mg kg^{-1}	Vascular endothelial growth factor receptor 2 (VEGFR2)	Deng et al. (2015)
Squalene	Ulcerative colitis	Female C57BL/6 mice	25 or 125 mg kg^{-1}	MAPK p38 and NF-κB	Sánchezfidalgo et al. (2015)
Ursolic acid	Lipid and glucose metabolism	C57BL/6J mice	50 or 200 mg kg^{-1}	PPAR-α	Jia et al. (2015)
Ursolic acid	Hepatic cirrhosis	C57/BL6 and AMPKα$2^{-/-}$ mice	50 mg kg^{-1}	Liver kinase B1 (LKB1)-AMPK	Yang et al. (2015b)
Ursolic acid	Hepatic inflammation	ICR mice	25 and 50 mg kg^{-1}	MAPK/NF-κB	Ma et al. (2014)
Ursolic acid	Chronic obstructive pulmonary disease	Wistar rats	10, 20, or 40 mg kg^{-1}	↓PERK ↑Nrf2	Lin et al. (2017)

(continued)

Table 4 (continued)

Compound	Disease	Animal model	Dose	Signaling pathway	References
Ursolic acid	Traumatic brain injury	ICR and Nrf2$^{-/-}$ mice	50, 100, or 150 mg kg^{-1}	Nrf2	Ding et al. (2017)
Ursolic acid	Ehrlich ascites carcinoma	Swiss female albino mice	25, 50, and 100 mg kg^{-1}	Mitochondrial-dependent pathway	Saraswati et al. (2013)
Ursolic acid	Non-alcoholic fatty liver disease	SD rats	0.125%, 0.25%, 0.5%	PPAR-α	Li et al. (2014a)
Ursolic acid	Allergic asthma	Female BALB/c mice	2 and 20 mg kg^{-1}	Th2-GATA-3 and IL-17-NF-kB	Kim et al. (2013b)
Ursolic acid	Spinal cord injury	Female C57BL/6J mice	100 and 200 mg kg^{-1}	MAPK, PI3K	Sahu et al. (2018)
Ursolic acid	Cerebral IRI	SD rats	10 and 20 mg kg^{-1}	High mobility group box 1 (HMGB1)/ TLR4/NFκB	Wang et al. (2018b)
Ursolic acid	Abdominal aortic aneurysm	ApoE$^{-/-}$ mice	100 mg kg^{-1}	STAT3, disintegrin, and metalloproteinase 17 (ADAM17)	Zhai et al. (2018)
Ursolic acid	Atherosclerosis	ApoE$^{-/-}$ mice	100 mg kg^{-1}	↓LOX-1 mediated by ROS/NF-κB	Li et al. (2018b)
Ursolic acid	Diabetic nephropathy	SD rats	35 mg kg^{-1}	Antioxidant and anti-inflammatory effects	Xu et al. (2018)
Ursolic acid	Liver fibrosis	SD rats	40 mg kg^{-1}	NOXs/ROS	Gan et al. (2018)

IRI making use of the left anterior descending coronary artery occlusion model of SD rats. Intraperitoneal administration of celastrol can attenuate histopathological changes, reduce myocardial injury, suppress myocardial apoptosis and autophagy, inhibit the oxidative stress and inflammatory response through activating the PI3K/Akt pathway, and suppress high mobility group box 1 protein (HMGB1) expression. Wang et al. (2018a) found that ursolic acid also participated in cerebral IRI via HMGB1/Toll-like receptor 4 (TLR4)/NFκB.

Diabetic nephropathy, a complication due to diabetes mellitus, is the second leading cause of end-stage renal disease and diagnosed by urinary albumin $\geq$30 mg g^{-1} Cr or estimated glomerular filtration rate (eGFR) of $\geq$30 mL/min/1.73 m^2. SD rats were subjected to streptozotocin 35 mg kg^{-1} intraperitoneally, including the model group, positive control group (metformin 150 mg kg^{-1} intragastrical), and treatment group (betulinic acid 20 or 40 mg kg^{-1} intragastrical). After execution, blood and kidney samples were collected; inflammatory cytokines, lipid peroxidation profile, blood glucose, and insulin level were measured; histopathological observation and Western blotting involving putative protein were carried out. Attenuating oxidative stress and inflammatory condition indicated that betulinic acid exhibited protection through the AMPK/NF-κB/Nrf2 signaling pathway (Xie et al. 2016). However, Wang et al. (2016b) thought that betulinic acid ameliorated diabetic nephropathy condition through enhancing the interaction between β-barrestin2 and IκBα and then affected the activation of NFκB. After the type 2 diabetes model was completed and successfully judged by the fasting blood glucose whether or not it is more than 16.7 mmol L^{-1}, the SD rats in the celastrol treatment group received dosage of 100, 200, and 500 μg kg^{-1} to explore its protective effect and its mechanism in diabetic mice. The results demonstrated that celastrol protected against diabetic nephropathy possibly related with TLR4/(myeloid differentiation factor 88) MyD88/NF-κB signaling (Han et al. 2016). Hou et al. (2017) administered 15 mg kg^{-1} glycyrrhizic acid intraperitoneally to db/db or db/dm mice for 8 weeks and illustrated the underlying mechanism related to AMPK/silent information regulator 1 (SIRT1)/PPAR-γ coactivator-1α (PGC-1α) signaling. Lee et al. (2015) studied the therapeutic effect and possible mechanism of oleanolic acid and *N*-acetylcysteine on diabetic nephropathy. When Long-Evans Tokushima Otsuka (LETO) rats were used as control, at the same time, Otsuka Long-Evans Tokushima Fatty (OLETF) rats were used as model, treatment groups were subjected to oleanolic acid or *N*-acetylcysteine for 20 weeks. Both the treated groups exhibited decreased urinary albumin/creatinine and triglyceride levels and increased superoxide dismutase and blood insulin secretion levels, which were mediated by oxidative stress and endoplasmic reticulum stress. The diabetic model induced by injecting streptozotocin 40 mg kg^{-1} intravenously was divided into three groups including model, treatment (ursolic acid 35 mg kg^{-1}), and positive control (telmisartan 12 mg kg^{-1}). At the last day, all SD rats were dissected, and their blood and kidney samples were preserved for the inquisitive purpose. Results showed that ursolic acid played a protective role in diabetic nephropathy due to its own antioxidation and anti-inflammation effects as indicated by Xu et al. (2018).

13.5 Benefits

Plenty of available preclinical evidences show that triterpenoids have multi-functional activities in terms of various malignant tumor and metabolic syndrome via intrinsic and extrinsic pathways. However, the failure rate of new drugs in the early clinical stage is as high as 90%. Even in the third phase, the failure rate is not less than 50%. Moreover, in view of the difference in characteristics of human and animal, the results of pharmacokinetics and pharmacodynamic need to be reassessed. In the early years, researchers made direct use of the extract containing active blended triterpenoids from plants to carry out clinical experiments. Limited contents act as chains for human experiments. In recent years, a batch of novel synthetic triterpenoids sprung up. According to the available data, clinical experiments can be classified into the following three phases: phase I includes the determination of dose-limiting toxicities, toxicity profile, pharmacokinetic analysis, and maximum tolerated dose; phase II is to measure pharmacodynamics relationship under the dose of maximum tolerance and determine appropriate dose; phase III is to observe the long-term safety and tolerability. Some clinical experiments of triterpenoids are summarized in Table 5.

M. charantia, known as bitter melon, is a herb plant used to heal diabetes and colic problem. Cortez-Navarrete et al. (2018) screened 24 eligible patients diagnosed with type 2 diabetes mellitus (T2DM), who were divided into two groups and given *M. charantia* extract (2 g day^{-1}) or placebo for 3 months. Furthermore, a randomized, double-blinded, and placebo-controlled clinical trial was conducted to investigate the therapeutic mechanism. They exhibited significant decrease in glycemic basic parameters such as weight, body mass index, fat percentage, waist circumference, and oral glucose tolerance test; conversely, the indexes about insulin were increased, which indicated that hyperglycemic action was related to insulin secretion instead of insulin sensitivity (Identifier: NCT02397447). Last year, Chung Shan Medical University as sponsor presided over a clinical experiment about exploring the efficacy of Greenyn *M. charantia* extracts on diabetes. Greenyn *M. charantia* extracts contain insulin receptor binding protein. Subjects were orally taking new drug or starch (600 mg day^{-1}) for 3 months, and then the fasting glucose, hemoglobin A1c, glucose tolerance test, and insulin sensitivity were measured; at the same time its safety was also evaluated (Identifier: NCT03151837).

Licorice, known as dried roots and rhizomes of *Glycyrrhiza glabra*, is used as a medicinal plant and cultivated throughout the world. Currently, researchers found that licorice extract possesses cytoprotective, hepaprotective, anti-inflammatory, antioxidant effects which aid in enhancing the activity of glycyrrhizic acid which has aroused interest in functional foods as sweetening additive. Ravanfar et al. (2016) selected 75 acute ischemic stroke (AIS) patients to implement human studies. All of them fell into three groups one placebo and two extract (450 mg day^{-1} and 900 mg day^{-1}) in which glycyrrhizic acid took up 7.85% and was lower than safety limitation (217 mg). The national institute of health stroke scale and modified rankin scale scores confirmed that licorice whole extract was safe, tolerable, and efficient for alleviating the adverse effects caused by AIS (Identifier: NCT02473458).

Table 5 Clinical experiments of triterpenoids

Compound	Model	Dosage	Results	Identifier	References
CDDO	Solid tumor	0.6–38.4 mg/m^2/h	MTD and DLT no determinate	NCT00352040	Speranza et al. (2012)
CDDO-Me	Solid tumor	5–1300 mg day^{-1}	MTD (900 mg day^{-1}), DLT (1300 mg day^{-1})	NCT00529438	Hong et al. (2008, 2012)
CDDO-Me	T2DM/CKD	25 and 75 mg	Kidney function ameliorate	NCT00811889	Pergola et al. (2011)
CDDO-Me	Healthy adults	20, 60, 80 mg	Safe and well tolerated	NCT01461161	Teuscher et al. (2014)
GA	Healthy adults	130 mg	Attenuate vascular smooth muscle vasodilatory function	NCT00759525	Sobieszczyk et al. (2010)
18β-GA	Chronic hemodialysis	500 mg	Lower serum potassium	NCT00384384	Farese et al. (2009)
Licorice extract	Acute ischemic stroke	450/900 mg day^{-1}	Improve neurologic	NCT02473458	Ravanfar et al. (2016)
Loquat extract	Healthy adults	500 mg day^{-1}	No differences in muscle mass, muscle strength, and physical performance	NCT02401113	Cho et al. (2016)
M. charantia extract	T2DM	2 g kg^{-1}	Modify the parameters of insulin secretion	NCT02397447	Cortez-Navarrete et al. (2018)
Omaveloxolone	Solid tumor	2.5 mg day^{-1} (12 cycle/28 days)	Safe and well tolerated	NCT02029729	Creelan et al. (2017)
Ursolic acid	Metabolic syndrome X	150 mg	Increase insulin sensitivity	NCT02337933	Ramírez-Rodríguez et al. (2017)

Sobieszczyk et al. (2010) selected 15 health subjects who received oral dosage of 130 mg once daily for 2 weeks, either GA or placebo, to verify whether decreased 11β-hydroxysteroid dehydrogenase (11β-HSD) activity caused by GA would affect vascular functions. They found that GA treatment significantly reduced serum potassium concentrations and plasma aldosterone concentrations by measuring and analyzing hemodynamic parameters. Thus, GA, as selective inhibitor of 11β-HSD, is effective for attenuating vascular smooth muscle vasodilatory function (Identifier: NCT00759525). Farese et al. (2009) randomly allocated 20 maintenance hemodialysis patients into two groups, who were given 18β-GA or dextrose 500 mg twice a day for 6 months. During the measurement, serum and hematology parameters were assessed. 18β-GA can reduce serum potassium concentration in chronic hemodialysis patients, which may be related to rectal and colonic loss (Identifier: NCT00384384).

Ramírez-Rodríguez et al. (2017) evaluated the effect of ursolic acid in metabolic syndrome X in 24 patients, who received 150 mg ursolic acid or calcined magnesia once a day before breakfast for 12 weeks. Ursolic acid administration can increase insulin sensitivity and modulate conventional index and leads to transient remission of metabolic syndrome. (Identifier: NCT02337933). Loquat extract used as dietary supplement was orally given to 54 sarcopenia patients (500 mg), which contained ursolic acid (50.94 mg), per day for 12 weeks. Cho et al. (2016) concluded that effect of Loquat extract exhibited no difference in muscle strength, muscle mass, and physical performance; however, it significantly influenced the right-handgrip strength of female subjects as indicated by the appendicular skeletal mass, quadriceps muscle power, hand grab power, and short physical performance battery (Identifier: NCT02401113).

In view of the slender efficacy of natural occurring triterpenoids, it is urgent to develop novel triterpenoids. To date, there exist CDDO and its ramification such as CDDO-Me, CDDO-Im, CDDO-EA, all of which belong to patent triterpenoid acids such as oleanolic acid, ursolic acid, and betulinic acid. Animal in vivo studies verified that synthetic triterpenoids almost were Nrf-2 activator, which mediated the anti-inflammation and antioxidative pathway. Many researchers paid significant attention to CDDO-Me. At present, there exist 30 clinical studies reporting registered use of CDDO-Me as drug, including chronic kidney disease (CKD), alprot syndrome, advanced solid tumors, lymphoid, diabetic nephropathy, and T2DM, even health subjects; nevertheless, less than 50% have been completed. Teuscher et al. (2014) assessed the safety, pharmacokinetics, and tolerance power of CDDO-Me with 20, 60, and 80 mg doses under the interference of food intake. It is safe and well tolerated without regard to meal times for healthy volunteers. Pergola et al. (2011) inspected long-term efficacy and dose effects by comparing eGFR with before or after CDDO-Me administration to patients diagnosed with T2DM and CKD. When three different dose groups were administered, i.e., 25, 50, and 75 mg, significant increase in eGFR values was observed through consecutive 52 weeks, indicating CDDO-Me is a promising candidate for treating CKD (Identifier: NCT00811889). Hong et al. (2008) reported the primary results about the pharmacokinetic parameters of CDDO-Me in 34 patients with advanced solid tumors or

lymphoid malignancies. The maximum tolerant dose (MTD) was 900 mg day^{-1}, whereas the dose-limiting toxicity (DLT) was 1,300 mg day^{-1} (Identifier: NCT00529438).

Creelan et al. (2017) selected 11 patients with confirmed melanoma or non-small cell lung cancer (NSCLC) to determine the safety and pharmacokinetics of omaveloxolone. Despite dose-limiting toxicities and maximum tolerated dose deficiency, it was well tolerated and safe in experimental dose (Identifier: NCT02029729). Since 2014, omaveloxolone or RTA 408 has been administered as drug, and 10 projects have been launched out of which seven were completed. The latest one is to assess the effects of food or dosage on omaveloxolone pharmacokinetics. They plan to recruit 32 healthy adult people to conduct three-phase studies by measuring pharmacokinetics parameters especially C_{max} and AUC (Identifier: NCT03664453).

13.6 Application in Food

The World Health Organization pointed out that less than 80% of human beings eat traditional medicines from herb plant extracts or active ingredients to meet their healthcare needs (Craig 1999). Triterpenoid-rich plants have wide varieties and are distributed extensively worldwide. Through the ages, people made use of these plants to prevent common chronic ailments such as fever, cough, hypertension, diabetes, and inflammation. These plants are safe enough to be used as dietary supplements. In view of the abovementioned discussion, mounting attention has been paid in nutraceutical and pharmaceutical applications of triterpenoids in the recent years. Noteworthy, the toxicity of pure compounds needs to be verified by animal and human studies.

Glycyrrhizic acid is mainly obtained from three licorice species, namely, *Glycyrrhiza glabra* L., *Glycyrrhiza uralensis* Fisch., and *Glycyrrhiza inflata* Bat., and it is the most dominant active constituent of licorice root extract in the proportion of 10–25%. Traditionally, licorice was found to be useful for persons with symptoms of peptic ulcers, malaria, abdominal pain, asthma, pharyngitis, insomnia, and infections. Correspondingly, glycyrrhizic acid exhibited antigenotoxic, antitussive, antiviral, anti-inflammatory, and gastroprotective properties. Owing to high-sweetness (170-fold than sucrose), low-calorie, flavor-enhancing, and salt-softening functional food properties, glycyrrhizic acid is applied as sweetening and flavoring agent in tobacco flavors, beverages, cocoa, and confectionery products. Furthermore, glycyrrhizic acid can be applied in beer and ale products in light of good foamability and high sweetness which can neutralize bitter taste. However, glycyrrhizic acid may produce undesirable brownish color and lessen sweetness in acidic solutions (Isbrucker and Burdock 2006). GA is formed by hydrolysis of glycyrrhizic acid by intestinal bacteria by virtue of glucuronidase, and it has strong sweetness (941 times than sucrose); thus it can be used in same fields mentioned above (Hayashi and Sudo 2009).

Siraitia grosvenorii (Swingle) is a familiar fruit named "luo han guo" in China and is used to alleviate sore throats, cough, and minor stomach and intestinal troubles. Its extract can be consumed as a sugar substitute for diabetic patients due to the presence of minimal caloric cucurbitane-type glycosides containing primarily mogroside IV, V, and VI. The extract has been reported to be 300 times sweeter than sucrose. Thus, *S. grosvenorii* extract can be utilized in soft drinks, cereals, and nutritional and energy shakes in the form of sweetener and flavor enhancer (Pawar et al. 2013).

M. charantia is a known vegetable named as bitter melon and has the functions of clearing away heat and detoxification, nourishing and rejuvenating skin, decreasing blood sugar, nourishing the blood and liver, and anti-diabetes, or other related complications. Despite 288 compounds reported in *M. charantia* from different tissue extracts, cucurbitane-type triterpenoids were recognized as potential food supplements to prevent T2DM. To date, *M. charantia* is found in health drink, bitter gourd tea, preserved fruit, candied fruit, and kimchi (Nagarani et al. 2014).

Centella asiatica is the most ubiquitous, among which 50 *Centella* species belong to Apiaceae or Umbelliferae. It is popular in Asian countries as herb medicine to treat insanity, asthma, ulceration, wound healing, headache, body ache, and eczema. Its extract takes effect mainly because of its component, centellosides. In fact, centellosides are a mixture of various triterpenoids including asiatic acid, madecassic acid, asiaticoside, and madecassoside. Similarly, centellosides have memory-enhancing, antidiabetic, neuroprotective, anti-inflammatory, antioxidant, wound healing, and anticancer properties. In view of these properties, *C. asiatica* has been utilized to develop tonic drinks for general health and blood circulation (Hashim 2013).

Oleanolic acid has been isolated from more than 1600 plant species, and a range of benefits has been reported. Oleanolic acid takes up approximately 3% in the leaf of dried *Olea europaea*. Incorporating oleanolic acid into basic products can improve the nutritive value of the patent products, which finally turn into functional foods for healthcare consideration. Guinda et al. (2004) explored the process of prepared supplement oil with oleanolic acid and found that it was better to use solid oleanoic acid in concentration less than 400 ppm; conversely dissolved option can also be used.

Squalene is an acyclic triterpenoid directly related to cholesterol synthesis and exhibits strong antioxidation, antiaging, cardioprotective, and photoprotect capabilities. It has been found in shark liver oil (<40%), amaranth oil (<10%), olive oil (<1%), various oils, and human sebum. Squalene is popular in cosmetics and dietary supplement and also used as an additive in animal feed (Kumar et al. 2017).

It is estimated that ginsenosides are not less than 150 in number and form a large group of triterpenoid saponins isolated from diverse tissues of *Panax* species. According to unique nature of aglycone moieties, protopanaxadiol and protopanaxatriol are the chief bioactive ingredients including Rb1, Rb2, Rb3, Re, Rh1, Rh2, Rh3, Rf, Rg1, Rg2, Rg3, Rg5, and others. Ginsenosides are effective in treating liver diseases, eyesight troubles, and cardiovascular and gastrointestinal problems. Previously, native Brazilians deemed "Brazilian ginseng" to be "for all

things," in consideration of its uses as a tonic, an aphrodisiac, and a remedy for diabetes, ulcers, cancer, and others. In the United States, ginseng is used not only as a dietary supplement but also in a series of products such as milk, tea, crunchy white chocolate, dark chocolate, and candy (Chung et al. 2011).

Western medicine produces toxicity and resistance through long-time administration. Therefore, progressively more attention should be paid to functional foods with nontoxic and health-promoting characteristics, which mediate basic foods and medicines. To date, commercial products mainly involve tea, beverages, olive oil, and confectionery industries. Moreover, dietary supplements make a good measure, which incorporate bioactive triterpenoids as ingredients.

13.7 Safety: Toxicity and Side Effects

The safety of triterpenoids either as extracts or pure compounds is very crucial for the development of clinical experiments and healthcare products. In the duration of several decades, researchers carried out various toxicity tests which were also related to the study of activities, sometimes. Toxicity tests generally cover acute, subacute, chronic, genetic, and other special toxicities. Table 6 summarizes the toxicity of triterpenoids.

Bamboo shavings are dried intermediate species of stems and are used to treat hot cough, biliary sputum, convulsions, diarrhea, feeling upset, insomnia, excessive thirst, stroke, fascination, chest diaphragm inflammation, stomach heat, vomiting, pregnancy resistance, and fetal restlessness. Bamboo shavings extract (BSE) contains polyphenol, flavonoids, and friedelane- or lupane-type triterpenoids. Zhang et al. (2004) handled safety evaluation for acute toxicity and mutagenicity and 30-day feeding test from three aspects. SD rats and Kunming strain mice were administered with 1, 2.15, 4.64, and 10 g kg^{-1} BSE for 14 days, and then the acute toxicity was judged by calculating MTD and observing general status, toxic symptom, and mortality in rats. Mutagenic toxicity was evaluated by carrying out Ames test, mice micronucleus test, and sperm abnormality test using Kunming strain mice. Then, SD male and post-weaning female rats were divided into four groups, and dosages of 0, 0.21, 0.42, and 0.83 g kg^{-1} BSE, respectively, were administered. Further, the changes of the liver, kidneys, spleen, testes, and ovaries were observed by paraffin section, hematoxylin-eosin staining, and photoscope detection. BSE did not show any acute toxicity symptoms, so the MTD of BSE >10 g kg^{-1}. All the results of mutagenicity tests were negative. No obvious toxicity, pathological changes, and adverse effects were exhibited in the 30-day feeding test.

Isbrucker and Burdock (2006) reported the safety profiles of licorice extract including its main bioactive compounds systematically. In simple terms, glycyrrhizic acid was found to be without expressed acute toxicity below 4 g kg^{-1}. Based on the 30-day feeding test, no-observed effect levels were in the range of 15–229 mg kg^{-1}. When the dosage is below 4–5 g kg^{-1}, glycyrrhizic acid leads to mutagenic effects in offspring.

Table 6 Toxicity of triterpenoids

Compound	Model	Toxicity	References
Birch triterpenoid extract	Acute-Swiss mice	No symptoms of mortality or toxicity occurred within 15 days of taking <2 g kg^{-1}	Majeed et al. (2014)
BSE	Acute-SD rats and Kunming strain mice	No symptoms of mortality or toxicity occurred within 14 days of taking <10 g kg^{-1}	Zhang et al. (2004)
BSE	Mutagenicity-Kunming strain mice	All of the results of Ames test, mice micronucleus test, and sperm abnormality test are negative	Zhang et al. (2004)
BSE	30-day feeding test	No difference in hematology, clinical chemistry, and histopathological results	Zhang et al. (2004)
Ganoderma lucidum total triterpenes	Acute-Swiss albino mice	No symptoms of mortality or toxicity occurred within 14 days of taking <5 g kg^{-1}	Smina et al. (2011)
Ganoderma lucidum total triterpenes	Subacute-Swiss albino mice	No changes in parameters of hematological and biochemical within 30 days of giving <0.5 g kg^{-1}	Smina et al. (2011)
Hydroalcoholic solution of triterpenes	Mutagenicity TA98, TA1535, and YG1024	No mutagenicity	Lupi et al. (2009)
Methyl 3-octanoyloxyiminoolean-12-en-28-oate	Acute-Wistar rats and Swiss mice	No symptoms of mortality or toxicity occurred within 14 days of taking 2 g kg^{-1}	Bednarczyk-Cwynar et al. (2012)
Oleanolic/ursolic acid	Acute-BALB/c albino mice	No symptoms of mortality or toxicity occurred within 72 h of taking 2 g kg^{-1}	Resende et al. (2006)

Lupi et al. (2009) isolated hydroalcoholic solution of triterpenes (8.323 mg L^{-1}) from *Boswellia sacra* resin, *Commiphora myrrha* resin, and *Hyssopus decumbens* essential oil by electromagnetic field extraction. S9 was selected as metabolic activator to carry out Ames tests, which showed the absence of mutagenicity in *Salmonella typhimurium* (TA98, TA1535, and YG1024).

Triterpenoid-rich plant extracts have low triterpenoid content, so they are non-toxic when the content is below 1 g kg^{-1}. In contrast, owing to the difference of physical condition in human or the out of range dosage, there are many side effects in clinical experiments, which even led to the termination of studies. Therefore, Table 7 lists some terminated clinical experiments or some exceptions in completed clinical experiments.

GA	Chronic hemodialysis	Diarrhea (minority)	Farese et al. (2009)
GA	Health adults	No adverse effects	Sobieszczyk et al. (2010)
Licorice root	Acute ischemic stroke	No adverse effects	Ravanfar et al. (2016)
M. charantia	T2DM	Headache and dizziness, nausea, vomiting, constipation	Cortez-Navarrete et al. (2018)

Phase 3 occurrence of renal events (BEACON) trial was terminated in the condition of increased mortality related to fluid retention. Chin et al. (2014) provided a hypothesis that CDDO-Me could lead to acute sodium retention and increase blood pressure in patients with T2DM and stage 4 CKD, via modulating endothelin pathway. Given the same clinical phenotype, this mechanism can be extrapolated to the reason why the BEACON experiment failed (Identifier: NCT01549769; NCT01351675).

13.8 Marketed Products

In light of the potential bioactive and well-tolerated characterization of triterpenoids, increasing number of businessmen put their eyes on the development involved in pharmaceutical, food, healthcare products, and other industries. In general, addition of triterpenoids in the form of direct raw materials or as dietary supplements to low nutritional commodities, in order to endow additional value to patent products, results in the increase in the efficiency in the treatment of diabetes, stomach problems, hepatitis, coughing, and other illnesses. Traditional medicinal plants have a long history, and their efficacy and safety can be guaranteed. At the same

time, there have been many studies on the main active ingredients in medicinal plants in the past 100 years. For example, *Ganoderma lucidum* (lingzhi) can prevent bronchitis, hepatitis, hypertension, arthritis, and nephritis (Ye et al. 2018). *Antrodia cinnamomea* (Niuzhangzhi) plays a curative role in abdominal pain, itchy skin, intoxication, diarrhea, and inflammation (Qiao et al. 2015; Huang et al. 2018). *Schisandra chinensis* (Wuweizi) can defend from cough, fatigue, rheumatism, amnesia, contusions, insomnia, and arthritis (Qiu et al. 2018; Szopa et al. 2017). *Glycyrrhiza uralensis* (Gancao) can be utilized for the treatment of asthma, chronic gastritis, bladder infection, and atopic dermatitis (Schmid et al. 2018). *Poria cocos* (Fuling) is effective for insomnia, dysfunction, diarrhea, and urinary problems. In recent years, literature studies reported that abovementioned medicines contain ganoderic acid, eburicoic acid, schinenlactone, glycyrrhizic acid, and pachymic acid, respectively.

For dietary supplements, their functions mainly focus on enhancing immunity, improving hypoxia tolerance, relieving physical fatigue, improving assisted memory, reducing blood fat, regulating blood sugar level, meliorating sleep, and others. In China, there exist more than thousands of nutraceutical health products which are actually a mixture of traditional herbs or their extracts. Their categories are widely found in tea, wine, drinks, oral solution, etc.

For cosmetics, oleanolic acid, ursolic acid, glycyrrhizic acid, ginsenosides, asiaticoside, and others have been registered in China Food and Drug Administration, among which the emblematic one is *Centella* extracts. *C. asiatica* extract can tightly connect the epidermis to the dermis, promote the formation of collagen in the dermis layer, and regenerate fibrin, thereby relaxing the skin, reducing the tension of the skin, and making the skin firm, smooth, and elastic. Moreover, *C. asiatica* extract can repair damaged skin tissue, treat skin ulcers, calm skin, and relieve sensitive symptoms. At present, many international makeup brands use the *C. asiatica* extract in their products as a promotional hotspot. In America, France, Italy, Korea, and China, this extract has been used in mask, water, cream, emulsion, recovery skin-salve, sunscreen emulsion with anti-wrinkle effect, tightening, whitening, freckle, sunscreen, repair, and other functions. In Korea, oleanolic acid and salvianolic acid have been employed in anti-wrinkle or skin-whitening emulsion cosmetics.

In the field of pharmaceuticals, the ancient prescriptions used in all the countries are derived from the mixture of many traditional herbs. With the in-depth study of plant extracts, a large number of pure products have been made into decoctions, tablets, capsules, and granules to assist in the treatment of some diseases. For instance, WS® 1442 isolated from hawthorn leaves with flowers was found to consist of triterpenoids, flavonoids, phenol carboxylic acids, and oligomeric procyanidins. As nutraceuticals, it is used to treat early stages of congestive heart failure in many European countries. In vitro and in vivo tests have shown that it is safe, is well tolerable, and has great potential to treat heart failure and improve exercise capacity (Holubarsch et al. 2008).

Table 8 summarizes the representative marketed products and their indications from triterpenoid-rich plant or synthesis of novel compounds.

Table 8 Marketed products of triterpenoids

Products	Constituent	Indications
Asiaticosides	Centella	Trauma, surgical trauma, burns, keloids, and scleroderma
Asiaticoside ointment	Centella	Wound, ulceration, scorching, adhesion, cicatrix, scleroderma
Compound centella tablet	Centella	Invigorate blood circulation, remove blood stasis, and relieve pain. Used for falls and injuries, limb pain
Compound glycyrrhizin tablets	Glycyrrhizic acid	Chronic liver disease, improving liver function abnormalities, eczema, dermatitis, alopecia areata
Compound glycyrrhizin injection	Glycyrrhizic acid	Chronic liver disease, improving liver function abnormalities, eczema, dermatitis, urticaria
Extractum glycyrrhizae liquidum	Licorice	Bronchitis, pharyngitis, bronchial asthma, chronic adrenal insufficiency
Renshen guipi wan	Ginseng	Deficiency of qi and blood, palpitation, insomnia, lack of energy and diet, and yellow complexion
Renshen jianpi wan	Ginseng	Using for the diet caused by spleen and stomach weakness, wan stuffy and noisy, nausea and vomiting, abdominal pain and loose stools, not thinking about diet, weakness and tiredness.
Renshen yangrong wan	Ginseng	Using for deficiency of heart and spleen, deficiency of qi and blood, thin body and weak spirit, little food and loose stool, weakness after disease.
Renshen zaizao wan	Ginseng	Invigorate qi and blood, dispel wind and phlegm, activate blood circulation
Ganoderma lucidum nanogels	*Ganoderma lucidum*	Frostbite
Sanqi tablets	Panax nonginsheng	Using to dissipate stasis, stop bleeding, reduce swelling and relieve pain
Panax notoginseng hemostatic tablet	Panax nonginsheng	Stasis to stop bleeding, detumescence, pain
Astragalus granule	*Astragalus*	Shortness of breath, palpitation, spontaneous sweating
Astragalus jianwei ointment	*Astragalus*	Stomachache caused by deficiency of the spleen and stomach
Ganoderma capsule	*Ganoderma*	Insomnia, forgetfulness, physical weakness, neurasthenia
Fufang Lingzhi granules	*Ganoderma*	Acute infectious jaundice hepatitis, chronic hepatitis
G. lucidum spore powder capsule	*Ganoderma lucidum*	Deficiency of the heart and spleen, weakness after disease, adjuvant therapy for tumor patients
G. lucidum spores softgel	*Ganoderma*	Boost immunity
Guizhi Fuling capsule	*Poria cocos*	Invigorate blood circulation, remove blood stasis, and eliminate disease
Jingpai yunjiu	*Poria cocos*	Remove chloasma and enhance immunity
Oleanolic acid tablets	Oleanolic acid	Adjuvant therapy for acute and chronic hepatitis

13.9 Patents

Many patents on triterpenoid compounds are available, which can roughly be classified into five categories, namely, extraction of compounds and their separation methods, synthesis of compounds and their synthesis methods, methods for improving the drug properties of compounds, research and development of products, and others. Table 9 lists some patents based on these aspects.

The active ingredients and their contents in different plants vary significantly. The solvent, temperature, ratio, and other process parameters affect the extraction efficiency. Therefore, many patents are related to the process optimization of extracting total triterpenes from plants, such as *Dracocephalum moldavica*, glossy privet fruit, scandent schefflera, *Chaenomeles* fruit, and spina gleditsiae. With the development of technology, people continue to simplify the process or increase yield from organic solvent extraction to subcritical water extraction and then supercritical extraction. These patents on synthesis mainly include a method for making synthetic triterpenoids used in the treatment and prevention of various diseases, such as stimulating bone and cartilage growth and improving chronic/acute kidney/liver disease, neurodegenerative diseases, cardiovascular disease, and various types of cancers. These patents on methods for improving pharmacokinetics properties accord with the aforementioned information in Sect. 3.1 including SMDDS, reducing particle diameter and binding with hydrophilic substances CDs, polygalacturonic acid, and others. These patents on activity study keep pace with the discussion in Sect. 4. These studies are related to either mixtures or semi-pure compounds, and a large number of animal studies were carried out to verify their efficacy in cancer, liver disease, T2DM, CKD, and so on. These patents on research and development of products disclose many formulas about products containing triterpenoids or their plant origin which are widely used in nutraceuticals, pharmaceuticals, cosmetics, and even industrial products.

13.10 Perspectives

Triterpenoids are important natural secondary metabolic products derived from crucial medicinal plants such as *Panax ginseng*, *Glycyrrhiza uralensis*, Radix Bupleuri, etc. Overwhelming evidence has shown that triterpenoids possess anti-inflammation, anti-obesity, antidiabetic, and anticancer efficacy through plurality of common signaling pathway in animal experiments. However, there are several challenges to overcome. First, inferior bioavailability caused by weak hydrophilia and poor gastrointestinal absorption limit the practical application of triterpenoids. Although there are abundant ways to enhance their bioavailability, no method has been found that is propitious to industrial production or successful in clinical trials. Second, their commercialization includes low production levels and cost-effective purification from the complex mixtures present in their natural hosts. Limited production leads to insufficient quantity and purity to carry out further animal and human experiments. Third, with respect to therapeutic mechanism, a lot more

Table 9 Patents on triterpenoids

Category	Main content	References
Extraction of compounds and methods	Separation of high-purity ursolic acid from loquat leaves by subcritical water extraction technology, which can be used as a functional factor in pharmaceuticals, healthcare products, and cosmetics	Chen et al. (2012a)
	The triterpenoids were extracted from apple pomace by organic solvent extraction method. The process was optimized and then made suitable for industrial production. At the same time, the composition analysis and activity study were also carried out. The results showed that the compound mainly contained ursolic acid and oleanolic acid, and it could protect against carbon tetrachloride-induced acute liver injury models and could be used in the development of health supplements	Ren and Zhang (2015)
	Direct separation and purification of triterpenoids and polysaccharides from *Antrodia camphorata* via supercritical fluid technology. This method is simple in process, cost-effective, solvent-free, safe, and environmentally friendly	Chuang et al. (2016)
	Using edible oil and fat as entrainer, supercritical carbon dioxide extraction technology was used to prepare high-efficiency anti-tumor *Ganoderma lucidum* extract, which is rich in variety, high in total content, stable in traits, safe to eat, and can be used in healthcare products	Xu et al. (2015)
Synthetic compounds and methods	Betulin ramifications are useful to inhibit various cancers (e.g., ovarian cancer, breast cancer, colorectal cancer, cervical cancer, and glioblastomas)	Xu et al. (2008)
	New compounds and methods are used to treat neurodegenerative diseases, psychiatric disorders, chronic pain, spinal cord injuries, and other injuries, which overcome current technical limitations	Sporn et al. (2009)
	Certain triterpenoids can treat bone/cartilage diseases via inducing gene expression and differentiation of stem or progenitor cells	Sporn et al. (2014)
	CDDO and its synthetic derivatizations can come into play in treating and preventing renal/kidney disease, endothelial dysfunction, fatty liver disease, insulin resistance, diabetes, and cardiovascular disease	Sporn et al. 2018)
Methods for improving pharmacokinetics properties	The application of the SMDDS to the preparation of the *Ganoderma lucidum* triterpenoid extract can improve the dissolution rate of the drug, so that it can be	Chen et al. (2009)

(continued)

Table 9 (continued)

Category	Main content	References
	rapidly absorbed by the gastrointestinal tract, improve the bioavailability, and completely exert the drug effect in the body	
	Lupane-, oleanane-, and lanostane-type triterpenes isolated from medical natural products were made into supramolecular nanoparticles which could be easily absorbed through the gastrointestinal tract, and then the bioavailability and intestinal permeability advanced significantly	Pabst et al. (2018)
	Oleanolic acid combines with polygalacturonic acid to form nano-sized micelles through esterification reaction. By drug targeted transportation, the bioavailability of oleanolic acid can be enhanced, insulin resistance can be better inhibited, and insulin sensitivity can be improved	Guan and Li (2017)
	The non-crystalline, glassy solid form of CDDO-Me displays an improved bioavailability over the non-hydrous crystalline form	Walling et al. (2009)
Activity study	Cucurbitane tetracyclic triterpenoids mainly include mogroside groups purified by macroporous resin separation and high pressure reversed-phase preparative chromatography. These compounds can inhibit pulmonary fibrosis via reducing accumulation volume of collagen in alveolar epithelial–mesenchymal and inflammation; thus these compounds are promising as a drug or healthcare product for pulmonary fibrosis	Xie et al. (2017)
	According to changes in relevant clinical indexes, it can be judged that celastrol and derivatives can prevent obesity	Mazitschek and Ozcan (2017)
	The triterpenoid compound extracted from the *Poria cocos* peel can reduce the degree of kidney disease, urine protein content, and creatinine and urea nitrogen and plays a therapeutic role in kidney disease	Yan et al. (2017)
	Maslinic acid can alter the mechanism of cell excitability and can aid in the treatment of central nervous system diseases such as depression, Parkinson's, and spinal injuries	Li et al. (2017a)

Research and development of products	Bitter substances (3–9%) from *Ganoderma lucidum* are added to flour to make vermicelli with antiallergy, antiandrogen, and antihypertension effects	Lee (2003)
	A mixture of triterpenoids, polyphenols, and similar compounds is extracted from five plants such as *Centella asiatica* using an ethanol solution, and animal experiments confirmed that the mixture is helpful for improving oral diseases and can be added to toothpaste, mouthwash, and chewing gum preparations	Li (2015)
	The special treatment of broken *Ganoderma lucidum* spore powder can increase the content of its functional active ingredients, help to enhance immunity, prevent radiation damage, and better play its role as a healthcare product	Li et al. (2018a)
	Ganoderma lucidum superfine powder, *Ganoderma lucidum* extract powder, and *Ganoderma lucidum* broken spore powder are blended into new *Ganoderma lucidum* powder in an appropriate ratio, which can increase anti-liver tumor activity	Liu et al. (2017a)

systematic explorations are still needed. Finally, the research lacks extremely in evaluation of pharmacokinetics and pharmacodynamics of triterpenoids.

Abstract

Sesquiterpenes are secondary metabolites that have interesting health-promoting functions, including anti-inflammatory, cardiovascular, gastro-protective, and anticancer properties. The potential of these compounds in human health will be further discussed throughout this chapter, being incorporated as part of a balanced diet and as pharmaceutical agents. Several foods consumed daily are a rich source of these compounds such as fruits, vegetables, algae, edible medicinal plants, and mushrooms. An overview of the bioactive constituents found in these aliments, metabolism routes and bioavailability, benefits for human health, safety upon ingestion, and market products will be described. Moreover, a deep understanding of the chemical constituents and biological activity observed will be detailed (structure-activity relationship studies). On the other hand, some of the peculiar aspects of these compounds (for instance, sesquiterpene lactones) is the bitterness that they confer to foods such as chicory, lettuce, or dandelion. This bitter taste is a direct consequence to their role as antifeedants, and this characteristic might help to ascertain the appropriate daily doses of sesquiterpenes. Little is known about the intake of sesquiterpenes in our diet. This chapter provides an understanding of the role of sesquiterpenes in health and human diet and the importance of increase their comsumption.

Keywords

Sesquiterpenes · Fruits · Vegetables · Algae · Mushrooms · Functional food · Edible medicinal plants

Abbreviation

A-549	Adenocarcinomic human alveolar basal epithelial cells
ATP	Adenosine triphosphate
B16F10	Murine melanoma cell line
BEL-7402	Human hepatoma cell line
BGC-823	Human gastric cancer cell line
COX-1	Cyclooxygenase-1
COX-2	Cyclooxygenase-2
D-GaIN/LPS	Lipopolysaccharide/D-galactosamine
DMAPP	Dimethylallyl diphosphate
EGb	Standardized *Ginkgo biloba* leaf extract
FPP	Farnesyl pyrophosphate
FPS	Farnesyl pyrophosphate synthase
GA3P	Glyceraldehyde 3-phosphate
GABA	γ-Aminobutyric acid
GOT	Glutamate-oxaloacetate aminotransferase
GPT	Glutamate-pyruvate aminotransferase
H_2O	Dihydrogen oxide
HCT-8	Human ileocecal adenocarcinoma cells
HeLa	Human cervical cancer cell line (Henrietta Lacks)
HSV-1	*Herpes simplex* virus type 1
I.929	Mouse fibroblast cell line
IC_{50}	Half maximal inhibitory concentration
ID_{50}	Half infectious doses
iNOS	Inducible nitric oxide synthase
IPP	Isopentenyl diphosphate
LD_{50}	Half lethal dose
LPS	Lipopolysaccharide
MDM2	Mouse double minute 2
MEP	Methylerythritol phosphate
MIC	Minimum inhibitory concentration
MVA	Mevalonic acid
NF-kB	Nuclear factor-kB
NGS	Next-generation sequencing
NLT	Not less than
NMT	Not more than
NO	Nitric oxide
NSAIDs	Nonsteroidal anti-inflammatory drugs
OVCAR-3	Human ovarian carcinoma cell line

PAs	Pyrrolizidine alkaloids
PGE2	Prostaglandin E2
RAW	Monocyte/macrophage-like cells, originating from Abelson leukemia virus transformed cell line derived from BALB/c (albino, laboratory-bred strain) mice
RCR	Respiratory control ratio
RD	Raynaud's disease
SERCA	Sarco-/endoplasmic reticulum calcium
SK-N-SH	Neuroblastoma cell line
SLs	Sesquiterpene lactones
SOD	Superoxide dismutase
TNF-α	Tumor necrosis factor alpha
TPA	Tetradecanoylphorbol-13-acetate
TPS	Terpene synthase
USA	United States of America
UV	Ultraviolet
UVB	Ultraviolet B radiation
W	Watts

14.1 Introduction

14.1.1 Fruits

Fruits constitute an important part of the human diet. Fruits not only provide vitamins and other nutrients needed for life, but they also maintain health and prevent disease, including cardiovascular disease, cancer, diabetes, Alzheimer's disease, cataracts, and age-related deterioration. Given the nutritional benefits, fruit consumption has increased over the years. Although fresh or frozen fruits are more common, processed products account for a high percentage of worldwide production as juices and derivatives like alcoholic beverages (cider, wine, and spirits) and baby food (Liu 2003). A wide variety of phytochemicals can be found in fruits, and these include phenols, flavonoids, saponins, and acetogenins, among others. However, sesquiterpenes represent a significant fraction, especially in essential oils obtained from fruits. The most commonly consumed fruits in the world that are rich in sesquiterpenes are described below (Fig. 1).

14.1.1.1 Apple

A large number of edible apple varieties or *Malus domestica* spp. are cultivated around the world. Direct consumption and fabrication of cider and other derivative foods are the main destinations for apple crops. The composition of apples changes between the different varieties, and there are also small changes in phytochemicals during the maturation and ripening of the fruit. In contrast to other species, storage has additional effects on the chemical composition of apples. The most abundant

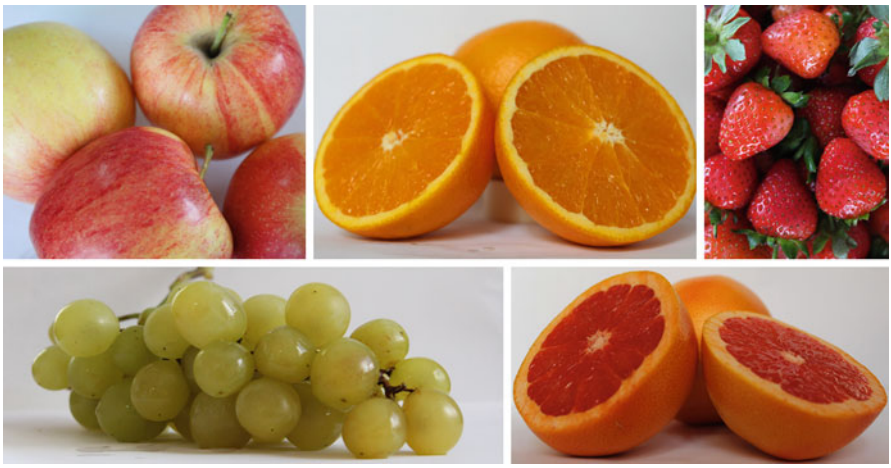

Fig. 1 Fruits that are rich in sesquiterpenes

sesquiterpene in the main varieties of apples is α-farnesene (Fig. 4; Ferreria et al. 2009; Rapparini et al. 2001).

14.1.1.2 Orange

Oranges are the fruit of the *Citrus x sinensis* species, a hybrid between *Citrus maxima* or grapefruit and *Citrus reticulata* or mandarin. Alkaloids, tannins, saponins, phenols, and flavonoids are described as phytochemicals in this fruit (Okwu and Emenike 2006), and several types of bioactivity have been associated with these fruits, e.g., antioxidant and anticancer effects. The most abundant sesquiterpenes found in several varieties of oranges are α-copaene, δ-cadinene, valencene, α-ylangene, β-caryophyllene, and β-elemene. In this chapter the first four compounds will be discussed, whereas β-caryophyllene and β-elemene will be described in the next chapter, although a brief introduction is provided here. β-Caryophyllene is found in grapefruit and grapes, and it is a primary component of spices. It is found in oregano, cinnamon, cloves, and rosemary and in herbs such as hops (common lupulus) or lavender and even in marijuana. On the other hand, β-elemene is an extended sesquiterpene that is found in a wide variety of plants.

14.1.1.3 Strawberry

Strawberries are a characteristic fruit from plants of the genus *Fragaria x ananassa*. A large number of health benefits have been reported for strawberries due to the presence of a wide variety of nutrients and the main phytochemicals, namely, polyphenols. It is worth noting that the sesquiterpenoid nerolidol is found within the characteristic volatile compounds.

14.1.1.4 Grapes

Grapes belong to *Vitis vinifera*, which is an extensively studied species, and they contain several sesquiterpenes, including β-elemene, β-bisabolene, β-caryophyllene, germacrene D, β-farnesene, α-humulene, farnesol, and α-bisabolol. Only farnesol will be discussed in this chapter because the other sesquiterpenes mentioned above are also present in other food types. Accordingly, these other sesquiterpenes will be described in more detail in the next chapter. For example, β-bisabolene is present in wild carrots, spices such as anise and oregano, and some herbs like Roman chamomile. The sesquiterpene α-humulene, also found in cannabis and in other aromatic herbs, is the main component in hops, and it is also found in beer. Moreover, the main component in chamomile is α-bisabolol, which is a widely used sesquiterpene due its protective effect on skin.

14.1.1.5 Grapefruit

The grapefruit, or *Citrus x paradisi*, is appreciated due to its high content in vitamin C, fiber, and lycopene. Moreover, several sesquiterpenes have been described in essential oils of this fruit, including α-copaene, α-humulene, β-caryophyllene, germacrene D, nerolidol, β-cubebene, and nootkatone.

14.1.2 Vegetables

Vegetables constitute a rich source of vitamins, essential minerals, fiber, and phytochemicals, and they are widely recommended for their health-promoting properties. In this work, the different sesquiterpenes found in vegetables will be discussed along with the potential of these compounds and their importance as part of a balanced, healthy diet (Chadwick et al. 2013).

14.1.2.1 *Curcuma zedoaria* (Christm.) Roscoe

Curcuma zedoaria (Zingiberaceae plant), commonly known as zedoary, has been cultivated as a vegetable or spice in South and Southeast Asian countries. The rhizomes of this plant have been widely used in Chinese and Japanese traditional medicine, and they are prescribed for stomachic complaints, as an emmenagogue and for the treatment of "Oketsu" syndrome (blood stasis or stagnant syndrome). This plant constitutes a rich source of sesquiterpenes, and it is worth highlighting carabrane-type (such as curcumenolactones A, B, and C and curcumenone), guaiane-type (4-epicurcumenol and alismoxide), and germacrane-type (glechomanolide and dehydrocurdione) sesquiterpenes, among others (Morikawa 2007).

14.1.2.2 *Cichorium intybus* L.

Chicory (*Cichorium intybus L.*) is an important agricultural crop in Northern Europe, and it is widespread in Europe, North Africa, and parts of Asia. The roots and leaves of this plant have several uses, for instance, the roots are cooked as a vegetable or roasted as a coffee surrogate, and they are an excellent source of inulin and fructose; the leaves are consumed as a vegetable and are used as livestock forage, especially

for ruminants; and the sprouts are consumed raw or as admixtures to salads (Barry 1998; Wang and Cui 2011). In northern France, chicory root is grown especially for use as dried or roasted products and in beverages. Once harvested, the root is sliced and dried to produce an intermediate raw material called green slices. The slices are either ground to obtain flour or roasted and then crushed to give grains. The grains can be marketed directly or extracted with hot water to obtain a concentrated liquid or, after spray-drying, soluble powders. Chicory flour can be used as an ingredient to improve bread, and, when roasted, chicory is used to enhance the aroma, color, or flavor of food. In many countries, such as Italy, chicory is largely cultivated as a green vegetable, but in Western Europe witloof chicory is mainly consumed due to its slightly bitter taste and whitish-yellow color. One of the quality criteria is the bitter taste caused by sesquiterpene lactones (SLs), which are mainly present in the latex (Sessa et al. 2000). The levels of SLs in chicory is strongly dependent of the cultivar and the cultivation conditions, i.e., climate, season, state of growth or nitrogen, and phosphorus availability (Foster et al. 2006; Peters et al. 1997; Peters and Van Amerongen 1996).

14.1.2.3 *Cynara cardunculus* L.

Cardoon (*Cynara cardunculus*) is an herbaceous plant and a member of the Asteraceae family, which is native to the Mediterranean Basin. This family includes the globe artichoke (*Cynara cardunculus* L. var. *scolymus* L.), the cultivated cardoon (*Cynara cardunculus* L. var. *altilis* DC.), and the wild cardoon (*Cynara cardunculus* L. var. *sylvestris* Lamk Fiori) (Rouphael et al. 2016; Scavo et al. 2018). The artichoke crop can last six or more years, with the peak productivity achieved in the third year and more than 60% of the total world production carried out in the Mediterranean area, with Italy and Spain producing 474,000 and 215,000 t per year, respectively (Christaki et al. 2012). In contrast, the cultivation of cardoon is much less important and only has regional significance in the Mediterranean area. The immature inflorescence (or head) of artichoke is consumed due to its high concentration of nutrients and healthy metabolites, which represent 30–40% of the fresh weight, while in the case of cardoon, the young leaves are consumed. The artichoke leaves can also be eaten, and their extracts are sold as dietary products. The main chemicals present in artichoke leaves are phenolics, flavonoids, and sesquiterpenes (Noldin et al. 2003). Aguerin B, grosheimin, cynaropicrin, and 11,13-dihydroxy-8-deoxygrosheimin are the major sesquiterpene lactones isolated from the leaves of cardoon (Rial et al. 2014). Artichoke leaves are frequently used in folk medicine to treat several diseases, including hepatitis, hyperlipidemia, and obesity.

14.1.2.4 *Lactuca sativa* L.

Lettuce (*Lactuca sativa* L.) is a vegetable consumed across the world, and it contains a large amount of beneficial secondary plant metabolites. Spain, Italy, and France produce 35, 21, and 13% tonnage of lettuce production in Europe, respectively. The main types of lettuce produced are criphead, butterhead, looseleaf, and romaine (Barrière et al. 2014). Sesquiterpene lactones impart a bittery taste to lettuce and consumers are able to detect the sweet and bitter compounds in lettuces combined,

with a clear preference for sweeter and less bitter genotypes (and consequently lower sesquiterpene lactone content) (Chadwick et al. 2016). Some of the isolated sesquiterpenes from this species are lactucin, 11β,13-dihydrolactucin, and lactupicrin (Mahmoud et al. 1986). The seeds of lettuce have also been traditionally used in Iran for medicinal purposes, e.g., for the relief of inflammation, gastrodynia, and osteodynia (Sayyah et al. 2004).

14.1.2.5 *Solanum melongena* L.

Aubergine or "eggplant" (*Solanum melongena* L.) is grown in tropical, subtropical, and warm temperate regions for its deep purple or white fruit, which can be up to 30 cm in length and is eaten as a cooked vegetable. Cooked aubergine has a concentration of 2.4 μg/kg of volatiles, and this gives aubergine its characteristic aromatic smell; a monoterpene (car-3-ene) is the main component with an aubergine-like smell (Macleod and De Troconis 1983). One of the major sesquiterpenes reported is aubergenone.

Another vegetable from the Solanaceae family is the tomato. Several sesquiterpenes have been found in their trichomes (Antonious and Kochhar 2003; Falara et al. 2011; Kennedy 2003; Kim et al. 2014; van der Hoeven 2000) although none of these have been reported in the edible mature tomato fruit and they are therefore not covered in this chapter.

14.1.2.6 Cucurbitaceae Family

Pumpkins belong to the Cucurbitaceae family, and they are an edible vegetable found on the American and European continents, as well as in the Caribbean (Gossell-Williams et al. 2006). Three species are representative of this family and are widely cultivated, *Cucurbita maxima*, *Cucurbita pepo*, and *Cucurbita moschata*, with *C. pepo* being the most popular species. In the pumpkin plant, the fruit and the white seeds are the edible part. The pumpkin seed oil contains bioactive compounds such as triterpenoids, sesquiterpenoids, polyphenols, etc. However, sesquiterpenes in pumpkins are rarely mentioned, while other terpenoids are very common (Montesano et al. 2018). The pumpkin seeds yield approximately 50% oil, and they have traditionally been used to treat problems in the prostate gland and irritable bladder (Rajasree et al. 2016).

14.1.2.7 Cyperaceae Family

There are three species of interest regarding nutritional or medicinal value in the Cyperaceae family of monocotyledonous plants: *Cyperus articulatus* L., *Cyperus esculentus* L., and *Cyperus papyrus* L. *C. esculentus* is also known as tigernut or chufa plant, and the tubers are edible and form part of the diet of many people in North Africa and the south of Spain. The essential oils of *Cyperus* plants have diverse interesting biological properties such as analgesic, anti-inflammatory, antipyretic, and antifungal (Hassanein et al. 2014). Some sesquiterpenes have been described for this plant, such as α-cyperone and cyperene, and they will be discussed below.

14.1.3 Algae

For a long time, humans have used algae (or seaweeds) for food and as colorants, fertilizers, medicines, etc. In particular, seaweeds have been consumed as a vegetable since prehistoric times in Eastern Asia, and China is probably the biggest consumer of algae in the world. However, in Western countries, algae are not normally ingested in an unprocessed form. Due to their nutritional value, the interest in algae is still developing. High levels of carbohydrates, minerals, vitamins, and trace elements, such as iodine, have been found in edible algae. Algae have similar or slightly higher levels of fiber than terrestrial foods, and they accumulate a diversity of minerals, which come from their marine surroundings. Furthermore, the lipid content is low and is mainly made up of polyunsaturated fatty acids, numerous antioxidants are present in the shape of vitamins and pigments due to their long exposure to direct sunlight, and the protein content can reach 47% of the dry weight (MacArtain et al. 2008). There are four major algal groups used in food: Chlorophyta (green algae), Phaeophyta (brown algae), Rhodophyta (red algae), and Cyanophyta (blue-green algae) (Bangmei and Abbott 1987). These organisms are a rich source of bioactive secondary metabolites, including sesquiterpenes. These compounds have been described in Chlorophyta, Rhodophyta, and Cyanophyta groups, which will be discussed below. Some of the edible algae species containing sesquiterpenes in each group are listed in the Table 1 (Pallela and Kim 2011; Pereira 2016).

14.1.3.1 Chlorophyta Algae

The characteristic green color of this alga is mainly due to the presence of chlorophylls *a* and *b* in the same ratio as in higher plants. Some *Caulerpa* spp. (Chlorophyta) are edible, and they are consumed in Japan and Indonesia – examples include *C. lentillifera* and *C. racemosa* (aka sea grapes or green caviar). However, other algae might be toxic because of the presence of toxic compounds such as the alkaloid caulerpin (Higa and Kuniyoshi 2000; Nagappan and Vairappan 2014). *Caulerpa peltata* is consumed by natives of the southeast of Iran as a food additive and medicine (Movahhedin et al. 2014). Other green algae, such as *Ulva fasciata* and *U. lactuca*, are food ingredients for soups and salads in India (Chakraborty and Paulraj 2010). Several sesquiterpenes have been isolated from this group, such as caulerpals A and B (from *Caulerpia taxifolia*) (El Gamal 2010) and guai-2-en-10α-ol and guai-2-en-10α-methanol (from *Ulva fasciata*) (Chakraborty et al. 2010).

14.1.3.2 Rhodophyta Algae

Red algae are considered to be the most important source of bioactive secondary metabolites in comparison to the other algal classes. The red color is due to the pigments phycoerythrin and phycocyanin (El Gamal 2010). The genus *Laurencia* (in the Rhodophyta group) comprises red algae including 146 species, which are mainly found in tropical, subtropical, and temperate coastal waters. This fact makes this genus one of the most diverse genera of marine algae. *L. nidifica*, *L. flexilis*, and *L. okamurai* are examples of edible species consumed in countries surrounded by the

Table 1 Edible algae species rich in sesquiterpenes

Algal Group	Species	Common name	Consumer region
Chlorophyta	*Ulva fasciata*	Sea lettuce	Hawaii, Japan, Polynesia
	Ulva lactuca Linnaeus	Sea lettuce	Widespread in Asia, Europe, and Western North America
	Ulva clathrata	Spiky tendrils	USA, China, Japan, Taiwan
	Caulerpa bikinensis W.R. Taylor	–	Polynesia
	Caulerpa lentillifera J. Agardh	Green caviar	Asia, Pakistan, the Philippines, Malaysia
	Caulerpa racemosa var. macrophysa	–	Thailand
	Caulerpa peltata	Big parasol green seaweed	Indonesia, Malaysia, the Philippines, and Tonga
	Caulerpa taxifolia	Lukay-lukay	The Philippines
Rhodophyta	*Laurencia obtusa* (Hudson) J.V. Lamouroux	Rounded brittle fern weed	Indonesia, Thailand, Vietnam, Mediterranean Basin, Hawaii
	Laurencia okamurai	–	Japan
	Laurencia flexilis Setchell	–	China
	Laurencia nidifica J. Agardh	Mustard limu	Hawaii
Cyanophyta	*Arthrospira platensis*	Spirulina	East Africa

Pacific Ocean (Bangmei and Abbott 1987; Harizani et al. 2016; Kim et al. 2008), although several *Laurencia* spp. are commonly consumed as foods or ingredients or for traditional medicine in these countries (Pereira 2016). More than 500 sesquiterpenes have been described for this genus (Harizani et al. 2016).

14.1.3.3 Cyanophyta Algae

Cyanophyta are one of the most primitive forms of photosynthetic prokaryotes. They are also called "blue-green algae," although the term "algae" in modern usage is restricted to eukaryotes. Cyanophyta have been used as food or medicine for centuries, and the first recorded human consumption is from the fourteenth century. It has been reported that the consumption of cyanophyta promotes immunity and prevents inflammatory diseases (Siah Ku et al. 2013). Within this group of algae, spirulina or *Arthrospira platensis* is used for its nutritional value and reported medicinal properties, such as antidiabetic, antihypertensive, and antimicrobial actions. The sesquiterpenes β-caryophyllene and β-selinene have been reported for this species.

14.1.4 Food with Medicinal Properties

Medicinal plants have been used since ancient times to treat several disorders and diseases. Some of these natural medicines have become part of our diet as functional

foods that provide medicinal effects in addition to the nutritive and taste values. Different edible medicinal plants found to date will be discussed in this section, and these contain sesquiterpenes as major compounds.

14.1.4.1 Common and Japanese Butterbur

Common butterbur (*Petasites hybridus* (L.) G. Gaertn., B. Mey. & Scherb) is an herbaceous perennial plant from the Asteraceae family. The extracts from rhizomes and leaves have been used as dietary supplements as they have shown an ability to reduce the occurrence or severity of migraines and provide an effective treatment for hay fever. In traditional medicine such extracts have been used as spasmolytic and anti-inflammatory agents (Avula et al. 2012). Likewise, Japanese butterbur (*Petasites japonicus* Maxim., Compositae family) is a perennial herbaceous plant that is cultivated as a vegetable in Japan. Several sesquiterpene lactones have been isolated from this plant, for instance, fukinone and 2β-hydroxyfukinone. Furthermore, fresh stems from Japanese butterbur are used as a food garnish in Japanese dishes (Yoshikawa et al. 2006). In traditional medicine, well-backed flower bud has been used as an expectorant or in the treatment of asthma. Moreover, juice squeezed from the leaves has been used to treat bee stings (Shimoda et al. 2006).

14.1.4.2 *Ginkgo biloba* L.

Ginkgo biloba (Ginkgoaceae family) has been used in Chinese medicine at least since the fourteenth century for the treatment of asthma, bronchitis, and cardiovascular diseases. The German physician-pharmacist Dr. Willmar Schwabe III introduced this plant into medical practice in the west, with the first standardized *G. biloba* leaf extract used in 1965 for the management of insufficiency states of cerebral and peripheral circulation and neurosensory organs. Currently, this is one of the most widely sold herbal supplements and medicines in the world, and it has become one of the top-selling dietary supplements in the USA (Avula et al. 2015). In China, extracts of *G. biloba* leaves are formulated as tablets and capsules for oral administration and as injections for intravenous administration. The popularity of this supplement stems from it having positive effects as add-on therapies, on memory and on the circulatory system in clinical studies; it improves cognitive function and may be beneficial in patients with Alzheimer's disease (Ahlemeyer and Krieglstein 2003; Janßen et al. 2010). The active components include ginkgolides A, B, C, and J (diterpene lactones), bilobalide (sesquiterpene lactone), and flavonol glycosides. *Ginkgo* extracts are available as tinctures, capsules, tablets, decoction, and a standardized extract, which contains 24–32% flavonoids and 6–12% terpenoids (Zengion and Yarnell 2011).

14.1.4.3 *Chrysanthemum parthenium* (L.) Bernh.

Feverfew plant (*Chrysanthemum parthenium* (L.) Bernh.) is also frequently referred to as *Tanacetum parthenium* (L.) Sch. Bip. This plant is common in gardens and has long been used as a folk remedy in northern Europe for the treatment of various diseases, including arthritis, fever, and migraine. It is consumed by eating fresh feverfew leaves grown domestically or as tablets made from dried powdered feverfew leaves, which is widely available in health food shops in the United Kingdom

(Summer et al. 1992). The main component responsible for the biological activity of feverfew preparations is the sesquiterpene lactone parthenolide. In addition, this plant also contains phenolic compounds that show anti-inflammatory activity. These properties and the good source of bioactive compounds provide an opportunity to develop beverages based on this plant. The optimal conditions for the manufacture of feverfew infusions were studied by Marete et al. (Marete et al. 2011). Parameters such as color stability, stability of phenolic compounds and parthenolide, as well as storage time were studied. This study showed that the most favorable conditions to prepare feverfew infusions are mildly acidic (pH = 4.6) and refrigerated storage maintains stable phenolic and parthenolide contents for approximately 4 months. Moreover, feverfew extracts have also shown inhibition in the generation of prostaglandins from exogenous arachidonic acid in a cell-free system, the secretion of histamine from activated mast cells, and the aggregation and secretion of 5-hydroxytryptamine from platelets (Summer et al. 1992).

14.1.4.4 *Artemisia annua* L., *Artemisia absinthium* L., and *Artemisia herba-alba* Asso.

The genus *Artemisia* (family of Asteraceae) includes more than 500 species. There are several reports in which *Artemisia* plants are described as dietary foods and as traditional herbal medicines for the treatment of diseases such as malaria, hepatitis, cancer, and inflammation (Bourgou et al. 2017). For instance, *Artemisia annua*, known as "qinghao" in traditional Chinese medicine, is used in the treatment of malaria, and *Artemisia herba-alba* – known as "chih" in Tunisia – is an aromatic and medicinal herb commonly used to aromatize tea and in local folk medicine for the treatment of diabetes, coughing, intestinal disturbances, parasitic infection, and neurological diseases. On the other hand, *Artemisia absinthium* L. (also known as wormwood) is an edible vegetable and traditional medicinal food in East Asia. It is a yellow flowering, perennial plant, and it is used for the treatment of several illnesses including chronic bronchitis, asthma, gastroenteritis, and pruritus, and it also has sedative effects (Aberham et al. 2010). The aerial parts are commonly used in gastric herbal preparations, dietary supplements, and alcoholic beverages (as absinthe products) (Abad et al. 2012). Furthermore, some sesquiterpenes from this plant have been reported to provide the characteristic bitterness, for instance, ketopelenolide b (Aberham et al. 2010).

14.1.4.5 *Ambrosia artemisiifolia* L.

Common ragweed (*Ambrosia artemisiifolia* L., Asteraceae) is an annual invasive plant with high allergenic potential that triggers rhinitis, ocular rhinitis, and other symptoms of hay fever (33 million people are sensitized in Europe and 23 million in the USA). However, this plant was used by Native Americans for medicinal purposes. Recently, the herb of *A. artemisiifolia* has gained popularity as a medicinal plant and food. Several products are available on the market, typically as food supplements (dry ragweed powder, alcoholic extract) or as food (puree made of the fresh buds of the plant). Twenty-nine sesquiterpenes have been isolated from *A. artemisiifolia*, and many of them have shown antibacterial, antifungal, antiprotozoal,

anti-inflammatory, cardiovascular, and hepatoprotective effects. The beneficial effects of ingested ragweed include anxiolytic activity, strengthening of the immune system, detoxification of the body, improved erectile function, appetite stimulation, and anticarcinogenic, anti-allergic, and mucolytic effects. However, recent studies have shown that the repeated use of ragweed resulted in toxic effects in rats, and these results question the safety of long-term human consumption of common ragweed (Kiss et al. 2017).

14.1.4.6 *Taraxacum officinale* (L.) Weber ex F. H. Wigg.

The common dandelion (*Taraxacum officinale)* is a plant of the Asteraceae family, and it is used as a food and medical herb due to various health benefits, which include antioxidant, anti-inflammatory, and anticarcinogenic properties. Moreover, dandelion is a completely edible weed that is consumed raw in salads, cooked, roasted (used as a coffee substitute), or as a flavoring, for example, in alcoholic drinks, candies, and cheeses. Different dandelion tissues contain sesquiterpene lactones that are responsible for the bitter taste (Aberham et al. 2010; Esatbeyoglu et al. 2017).

14.1.4.7 *Chrysanthemum indicum* L.

Chrysanthemum indicum L. (Compositae family) is a perennial garden herb used to treat several immune-related disorders, hypertension symptoms, and infectious diseases in Korean and Chinese medicine (Hwang and Kim 2013). The flowers are edible and are also commonly used as tea to cure inflammation, headache, and eye diseases (Morikawa 2007). Several sesquiterpenes have been isolated from the methanolic extract of these flowers, for instance, indicumolides A, B, and C (Feng et al. 2009).

14.1.4.8 *Litsea cubeba* (Lour.) Pers.

Litsea cubeba (Lour.) Pers. (Lauraceae family) can be used as a flavoring or herbal medicine. It is distributed in Southeastern Asia, Southern China, Japan, and Taiwan. Its fruit is known as "Chen-Qie-Zi" in Chinese traditional medicine, and it has been used due to its wide range of biological activities, which include antibacterial, antifungal, antioxidant, anticancer, and anti-inflammatory properties (Si et al. 2012; Wang and Liu 2010). This fruit possess a characteristic flavor that resembles a mixture of pepper, ginger, and citrus. For this reason, the essential oil of its fruit is used as a flavor enhancer in foods, cosmetics, and cigarettes and as a raw material to produce citral. Sesquiterpene hydrocarbons (β-caryophyllene, α-copaene, β-elemene, α-humulene, and δ-cadinene) and oxygenated sesquiterpene (caryophyllene oxide) have been identified in the essential oil (Chen et al. 2016; Yang et al. 2013). Nevertheless, the main compounds that constitute the essential oil are monoterpenes (94–98%). Likewise, this composition depends on geographical and climatic conditions. Moreover, the biological activities described for this essential oil are attributed to synergistic or antagonistic effects of its chemical composition (Si et al. 2012).

14.1.4.9 *Thymus saturejoides* Coss.

Thymus saturejoides Coss. (commonly named in Morocco as "za-itra") is one of the most popular aromatic herbs distributed in the Mediterranean basin. It is a flavoring agent used in herbal tea, and it is appreciated for its tonic and stimulant properties as well as being used for the preservation of a range of food products. Numerous biological properties have been reported for this plant, such as analgesic, anti-inflammatory, antispasmodic, and antioxidant effects (Kasrati et al. 2014).

14.1.4.10 *Warburgia ugandensis* Sprague and *W. stuhlmannii* Engl.

Sesquiterpenes have been described as being responsible for the bitter and hot taste of many plants. For instance, *Warburgia ugandensis* Sprague and *W. stuhlmannii* Engl., which are often used as food spices and medicines, are very hot to human taste and polygodial, warburganal, muzigadial, and ugandensidial (Fig. 2) have been described as being responsible for this taste. These compounds are produced by the plant as antifeedant compounds against larvae of armyworms (Kubo and Ganjian 1981).

14.1.5 Mushrooms

Since ancient times mushrooms have been consumed by humans as part of the normal diet due to the high nutritional value and their attractive taste and aroma. Some researchers have indicated that edible mushrooms are favorably nutritional when compared with meat, egg, and milk as food sources, with a protein content in the range 27–48%, fewer than 60% carbohydrates and low fat content (2–8%) (Wani et al. 2010). Besides, medicinal benefits have been reported for mushrooms in addition to the nutritional value, including antitumor, antiviral, and hypolipidemic effects (Mattila et al. 2000). Despite the beneficial properties of mushrooms, sesquiterpene lactones have only been described in the *Antrodia camphorata* species.

14.1.5.1 *Antrodia camphorata*

Antrodia camphorata – also known as "niuchangchih" or *Antrodia cinnamomea* – is an edible Taiwanese mushroom that grows in the *Cinnamomum kanehirae* tree trunk. This mushroom is widely used as a food dietary supplement for cancer prevention. In the past, *A. camphorata* has been used in traditional medicine to

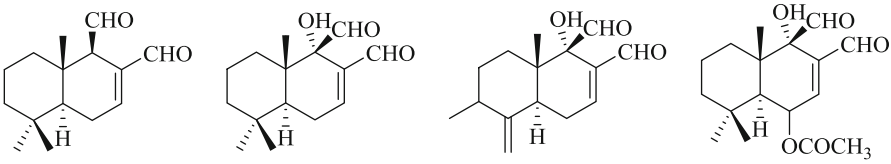

Fig. 2 Sesquiterpenes responsible for the bitter taste of *Warburgia ugandensis* and *W. stuhlmannii* species

treat influenza, headache, and fever, but numerous recent studies have led to the discovery of different applications for this mushroom. Nowadays, extracts of *A. camphorata* are mainly used as functional food due to the many pharmaceutical effects. More than one hundred secondary metabolites have been isolated from this species, and these include the sesquiterpenoid antrocin, which has been shown to be the most active. *A. camphorata* extract has shown many pharmacological activities such as anticancer activity, anti-inflammatory and hepatoprotective properties, and antiviral and immunomodulatory effects, among others (Geethangili and Institute 2006).

14.2 Bioactive Constituents

Sesquiterpenes are colorless lipophilic components, and their biosynthesis involves isoprene units and occurs through farnesyl pyrophosphate found in endoplasmic reticulum. It is well established that in higher plants, two independent pathways, from different compartments, are involved in the biosynthesis of IPP (isopentenyl diphosphate) and DMAPP (dimethylallyl diphosphate). In the cytosol, IPP is derived from the mevalonic acid (MVA) pathway, which begins with the condensation of acetyl-CoA. It is well established that in this cytosolic compartment, the production of sesquiterpenes and triterpenes takes place. Moreover, in plastids IPP is generated in the methylerythritol phosphate (MEP) pathway, and it is assumed that in this compartment, monoterpenes, diterpenes, and triterpenes are produced. Nevertheless, there is evidence that cross talk occurs between the two different biosynthetic pathways (Fig. 3; Yu and Utsumi 2009).

14.2.1 Bioactive Sesquiterpenes with Low Levels of Functionalization (Essential Oils)

Sesquiterpenes with few oxygenated functions in the structure, i.e., farnesenes or bisabolenes (Fig. 4), are normally present in the essential oils and aromas of plants. Many of them are phytoalexins, compounds produced by plants in response to biotic stress or antifeedants (Dai et al. 2015). Sesquiterpenes present in essential oils from different foods are listed in Table 2.

The sesquiterpene α-farnesene is a pale yellow to yellow liquid with a vegetative scent, a taste of green vegetables, and a fruity aftertaste. It is used as a flavoring agent in food and beverages, and it imparts the characteristic odor to green apple. Several studies have demonstrated that essential oils from green apples play an important role in the reproduction and olfactory behaviors of moth females. α-Farnesene – among other components – has been shown to play an important role in the periodicity of reproductive behaviors and olfactory responses (Yan et al. 2003).

Moreover, α-copaene, δ-cadinene, and valencene constitute the major sesquiterpenes found in oranges. The sesquiterpene α-copaene appears in a large variety of plants and spices, such as sweet basil and black pepper, as well as in several citrus

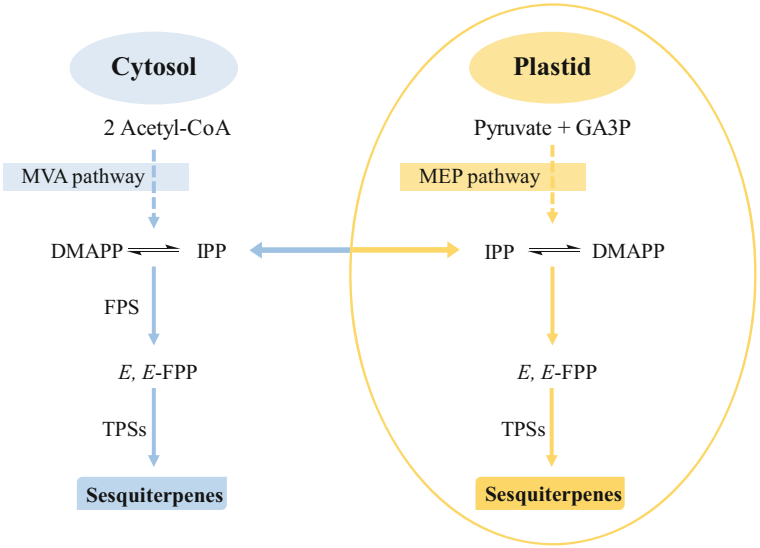

Fig. 3 Intercrossed biosynthetic pathways for sesquiterpenes. (Image adapted from Yu and Utsumi 2009)

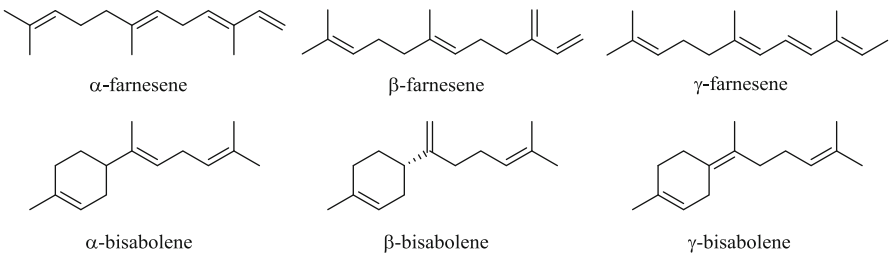

Fig. 4 Several examples of farnesene and bisabolene sesquiterpenes

fruits. The aroma of α-copaene is woody with notes to spicy honey. Essential oils that contain α-copaene have shown diverse biological activities, including antibacterial, antimicrobial, fungicidal, anti-inflammatory (Sádecká et al. 2014), and antitumor (Yang et al. 2017). δ-Cadinene is a bicyclic sesquiterpene that is insoluble in water and is a remarkable intermediate in the biosynthesis of important phytoalexins. This compound brings a sharp aroma to dry wood. It has been reported that *Rhododendron nivale* Hook. essential oils (in which the main component is δ-cadinene) showed in vitro acaricidal activity against adult *Psoroptes cuniculi* in a concentration- and time-dependent manner. In the same way, essential oils from

Xenophyllum poposum induce in vitro antibacterial and antifungal activities (Tracanna et al. 2012). Additionally, in vitro antiproliferative and apoptotic effects on human ovarian tumoral cell line (OVCAR-3) have been described for δ-cadinene (Hui et al. 2015). Finally, valencene is a hydrophobic sesquiterpene with an eremophilane skeleton, and it is found in diverse citrus species, such as mandarin or oranges, and in other aromatic plants like rosemary or common oregano. The odor description suggests sweet and fresh citrus, reminiscent of grapefruit, woody and orange aroma. Significant cytotoxic effects on HeLa cell line and antioxidant activity have been reported for this sesquiterpenoid (Liu et al. 2012).

Nerolidol (in addition to linalool) is the main terpenoid in cultivated strawberry (Aharoni et al. 2005), and it can also be found in grape berry and in wine

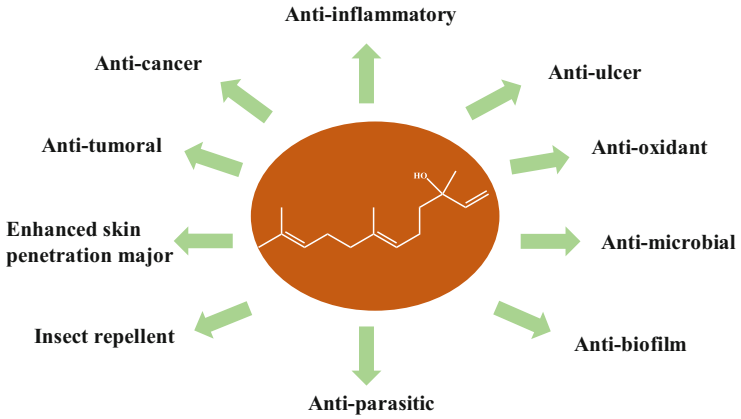

Fig. 5 Biological activities of nerolidol

(Perestrelo et al. 2014). Nerolidol is one of the major compounds present in the essential oils of several plants, e.g., *Cananga odorata* (ylang-ylang) and hemp. In fact, researchers are focused on the biological activities of essential oils that have been isolated from wood, leaves, and other aerial parts of plants and from bulbs and seeds from diverse genera of different families such as *Piperaceae*, *Amaranthaceae*, *Capparaceae*, and *Amaryllidaceae*. Several biological activities have been described, and these are illustrated in Fig. 5. It has been reported that *cis*-nerolidol exhibits weaker activity than its *trans* conformer (Weng-Keong et al. 2016).

Farnesol is a hydrophobic sesquiterpene alcohol that can be ingested from diverse fruits, including grapes (Perestrelo et al. 2014), tomatoes, or peaches (Špicáková et al. 2017) and infusions of chamomile or lavender (Duncan and Archer 2008). Its delicate aroma is reminiscent of lilac, and it is therefore widely used in perfumes. Diverse bioactivities have been described for farnesol, including anti-inflammatory, anti-allergic, antioxidant, chemopreventive, and anticancer properties.

Nootkatone, or (+)-nootkatone, is the most important and expensive sesquiterpene in grapefruit because it provides the characteristic aroma and flavor responsible for the citrus, sweet, and woody nuance. With an eremophilane backbone, nootkatone is also found in Alaska yellow cedar trees or *Cupressus nootkatensis* and in the roots of *Chrysopogon zizanioides* (a bunchgrass native to India), the essential oil of which is known as tranquility oil due to its sedative effects. Moreover, it has been described in Alpiniae Oxyphyllae Fructus, a Chinese plant used in folk medicine to improve memory. Other traditional uses highlight the insecticidal activity of nootkatone. High industrial demand for nootkatone has led to the development of synthetic and biosynthetic routes. In this respect, the biochemical oxidation of valencenes has been described, and the production of nootkatone by modified microorganisms has been reported (Sowden et al. 2005). Additionally, nootkatone has shown considerable antiproliferative effects against two human lung

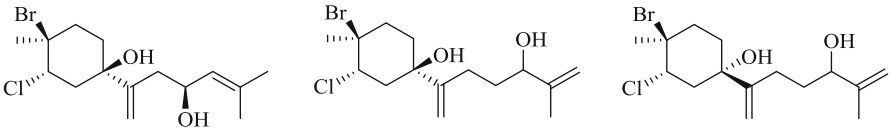

Fig. 6 β-Bisabolenes isolated from *L. scoparia*

adenocarcinoma and human promyelocytic leukemia cell lines (Gliszczynska et al. 2011) and anti-inflammatory activity due to its involvement in the expression of diverse cytokines such as TNF-α, which is associated with Alzheimer's disease (Y. Wang et al. 2018).

Three β-bisabolene-type compounds were isolated from *L. scoparia* (Davyt et al. 2006): (2*S*,3*S*,6*R*,9*S*)-3-Bromo-2-chloro-2,3-dihydro-6,9-dihydroxy-β-bisabolene [(1*R*,3-*S*,4*S*)-4-bromo-3-chloro-1-((*S*)-4-hydroxy-6-methylhepta-1,5-dien-2-yl)-4-methylcyclohexanol], (2*S*∗,3*S*∗,6*R*∗)-3-bromo-2-chloro-2,3-dihydro-6,10-dihydroxy-β-bisabolene[(1*R*∗,3*S*∗,4*S*∗)-4-bromo-3-chloro-1-(5-hydroxy-6-methylhepta-1,6-dien-2-yl)-4-methylcyclohexanol], and (2*S*∗,3*S*∗,6*S*∗)-3-bromo-2-chloro-2,3-dihydro-6,10-dihydroxy-β-bisabolene[(1*S*∗,3*S*∗,4*S*∗)-4-bromo-3-chloro-1-(5-hydroxy-6-methylhepta-1,6-dien-2-yl)-4-methylcyclohexanol] (Fig. 6). The first compound mentioned showed moderate antiparasitic activity against *Nippostrongilus brasiliensis* with an EC_{50} value of 0.11 mM.

14.2.2 Bioactive Sesquiterpenes Containing the α-Methylene-γ-lactone Moiety

The bioactive constituents of several sesquiterpenes contain an α-methylene-γ-lactone moiety in their structure, and this has been designated as being responsible for the activity by reacting through a Michael addition with free sulfhydryl or amino groups in proteins to alkylate them (Ghantous et al. 2010). Such compounds have been described as cytotoxic, antitumor, allergic, antimicrobial, antifeedant, phytotoxic, and insecticidal agents. Sesquiterpene lactones can be classified into several main classes, including germacranolides, eudesmanolides, guaianolides, pseudoguaianolides, heliangolides, and hypocretenolides (Fig. 7; Chaturvedi et al. 2015). For instance, parthenolide is isolated from feverfew (*Tanacetum parthenium*), which has been proposed as a source of bioactives for functional foods (Marete et al. 2011), and it showed anti-inflammatory, antimicrobial, and antitumor activity (Nakshatri et al. 2004; Won et al. 2004). Isoalantolactone, isolated from ragweed, has been reported to possess multiple biological and pharmacological activities including antibacterial, antifungal, anti-inflammatory, and anticancer effects (Fig. 8; Kiss et al. 2017).

Sesquiterpene lactones are also responsible for the bitter taste of many plants, for instance, dandelion tissues contain sesquiterpene lactones such as eudesmanolides, namely, tetrahydroridentin B and taraxacolide-*O*-β-glucopyranoside; guaianolides,

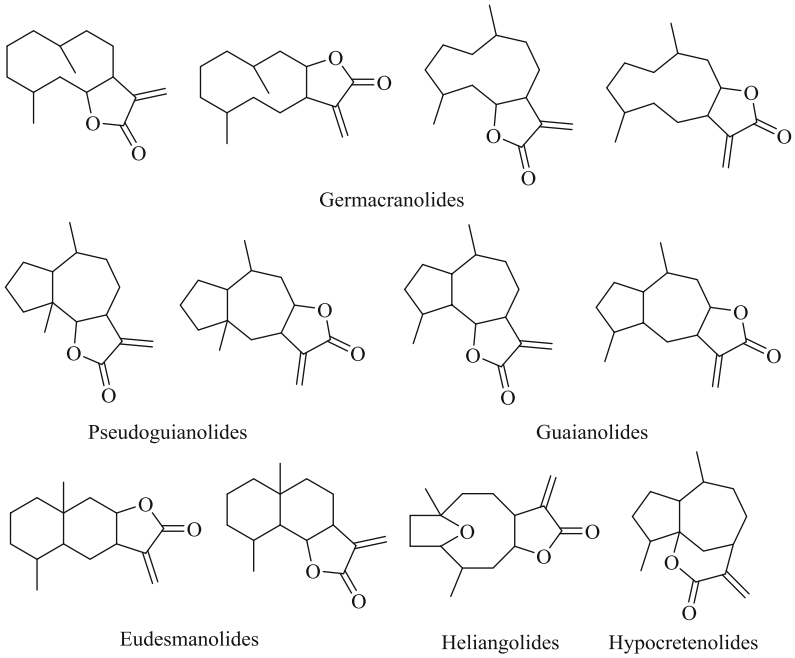

Fig. 7 Classification of sesquiterpene lactones depending on the type of backbone

namely, 11β,13-dihydrolactucin and ixerin D; and esterified germacranolide acids, namely, taraxinic acid β-glucopyranosylester. These compounds have shown a wide range of biological activities, including anti-inflammatory, antimicrobial, hypolipidemic, and antihyperglicemic properties. On the other hand, chicory also contains this particular bitterness due to the presence of lactucin, 8-deoxylactucin, lactucopicrin, and their 11(*S*),13-dihydro derivatives (Fig. 9; Willeman et al. 2014).

Cynaropicrin is the major compound found in *Cynara* species. Besides its anti-inflammatory properties (Mizuno and Usuki 2018), it has also shown phytotoxic activity on two weed species of economic importance, i.e., barnyard grass (*Echinochloa crus-galli* L.) and *Brachiaria* (*Urochloa decumbens* (Stapf) R.D. Webster) (Rial et al. 2014). Root length was the most affected parameter with values of 80% of inhibition achieved at the first two concentrations tested (1000 and 300 μM). Furthermore, the joint action of several sesquiterpenes found in extracts of *Cynara* species has been evaluated using the etiolated wheat coleoptile bioassay. The sesquiterpenes studied were aguerin B, grosheimin, cynaropicrin, and 11,13-dihydroxy-8-desoxygrosheimin (Rial et al. 2016). Synergism, additivity, and antagonism were found depending on the compound and the relative proportions in the mixture. For example, the compound 11,13-dihydroxy-8-deoxygrosheimin showed synergism and additivity with aguerin B at high and low doses, respectively, whereas with grosheimin, it showed additivity at all tested doses, and with cynaropicrin it showed antagonist effects.

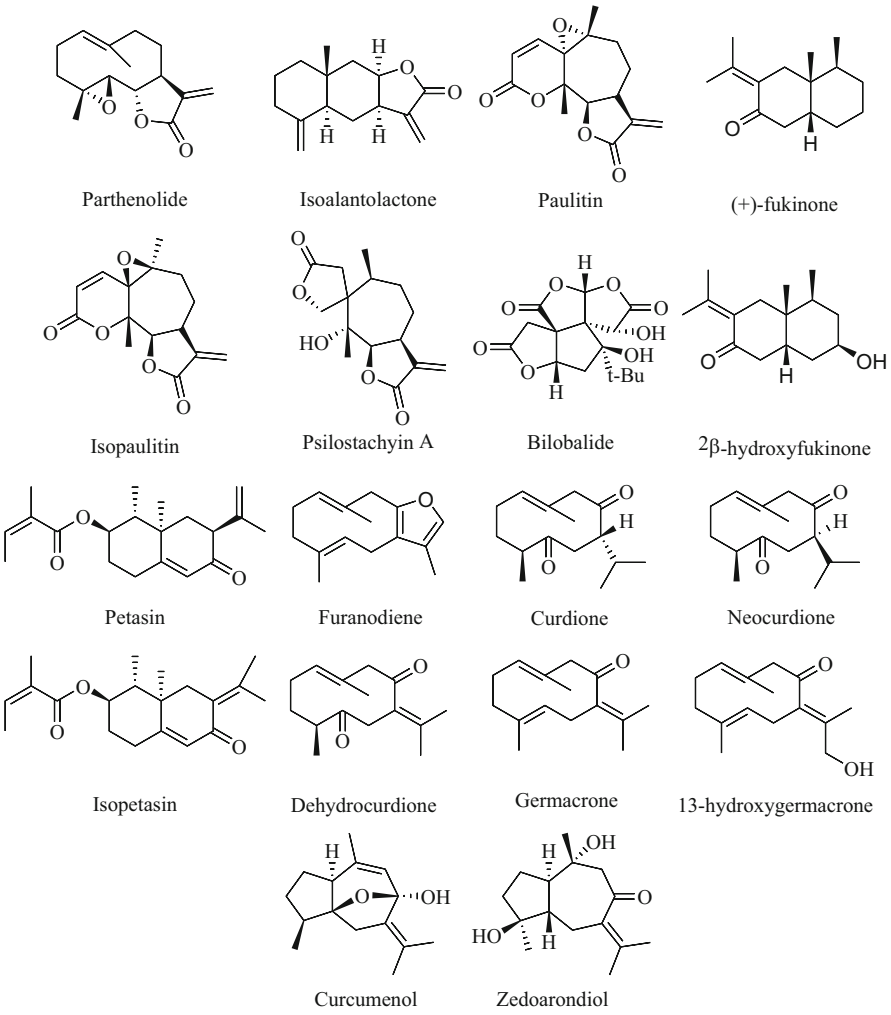

Fig. 8 Bioactive sesquiterpenes from natural sources

14.2.3 Bioactive Sesquiterpenes Containing More than One Lactone Ring

Sesquiterpenes with more than one lactone ring have been identified as bioactive compounds. For instance, paulitin and isopaulitin have shown anticancer activity, and psilostachyin A has shown antileishmanial and antiplasmodial activities (Fig. 8; Kiss et al. 2017).

One of the compounds responsible for the activity of *Ginkgo biloba* is bilobalide. Bilobalide is a sesquiterpene trilactone (Fig. 8) that has shown beneficial effects on cerebral ischemia and neurodegenerative disorders. Several mechanisms of action

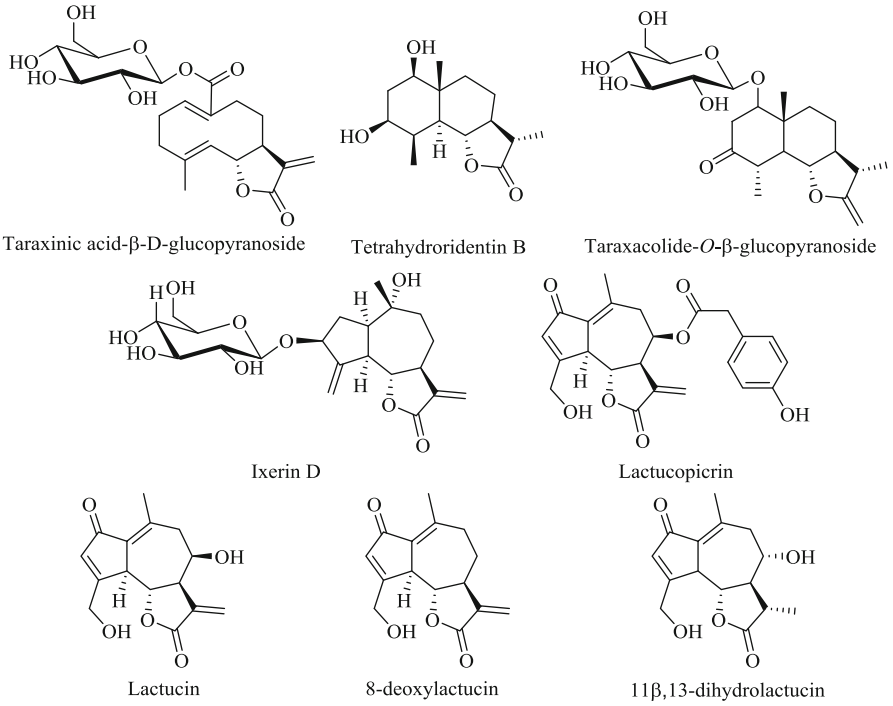

Fig. 9 Sesquiterpenes responsible for the bitter taste in dandelion and chicory

have been described for its neuroprotective properties, including preservation of mitochondrial ATP synthesis and suppression of hypoxia-induced membrane deterioration in the brain, among others (Defeudis 2002).

14.2.4 Bioactive Glycosylated Sesquiterpenes

Glycosylated sesquiterpenes are found, for instance, taraxinic acid or ixerin D has been identified in dandelion (Fig. 10), and such compounds are normally isolated with a glucose molecule, which improves their solubility in water. Moreover, glycosylated sesquiterpene lactones have been identified in chicory and related species, e.g., picriside A, cichorioside B, and crepidiasides A and B (Fig. 10; Peters et al. 1996). These compounds have shown anti-inflammatory properties (Wirngo et al. 2016).

14.2.5 Bioactive Sesquiterpenes Without a Lactone Ring

Sesquiterpenes that do not contain a lactone ring have also proven to be active. For instance, petasin and isopetasin (Fig. 8) are responsible for the activity of butterbur

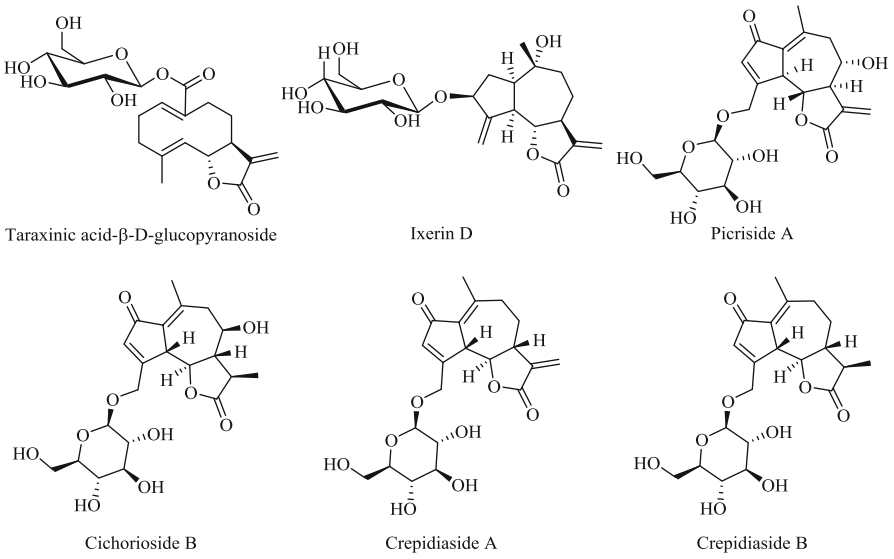

Fig. 10 Glycosylated sesquiterpenes

extract. These compounds are effective in the treatment of migraine headache and hay fever (Schapowal 2002; Sutherland and Sweet 2010). These compounds have also been used as spasmolytic and anti-inflammatory agents. In addition, (+)-fukinone and 2β-hydroxyfukinone (Fig. 8) appear to be involved in the anti-type I allergic mechanism of butterbur extract and have shown inhibitory effects on mast cell degranulation (Shimoda et al. 2006).

Moreover, the sesquiterpenes furanodiene, curdione, neocurdione, dehydrocurdione, germacrone, 13-hydroxygermacrone, curcumenol, and zedoarondiol (Fig. 8) have been described as being responsible for the hepatoprotective effect of *Curcuma zedoaria* extracts (Morikawa et al. 2002).

It is worth highlighting a mixture of five sesquiterpenes produced when aubergine is incubated with spores of *Monilinia fructicola* or other fungi. These compounds are not found when this vegetable is incubated in water (Stoessl et al. 1975). These sesquiterpenes are stress metabolites that may function as a natural defense (Fig. 11).

Additionally, cyperone, cyperene, and patchoulenone from *Cyperus* species are considered to be the main biologically active compounds in its essential oils (Fig. 12).

Bioactive constituents classified within this group have also been found in algae. For instance, caulerpenyne is the major secondary metabolite produced by Chlorophyta *C. taxifolia*, and it is present in other edible *Caulerpa* spp. (Fig. 13). This compound has anticancer, antitumor, and antiproliferative properties (Smit 2004). In particular, this compound is cytotoxic on the neuroblastoma SK-N-SH cell line with a maximum effect after 24 h of treatment with $IC_{50} = 8 \pm 1$ μM. In the

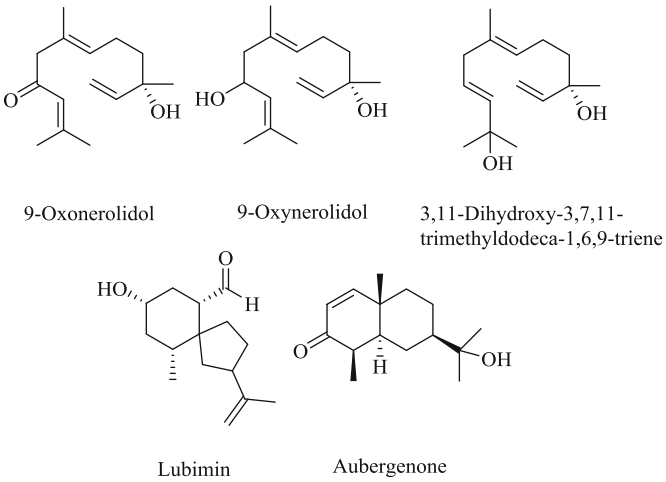

Fig. 11 Stress metabolites produced by aubergine

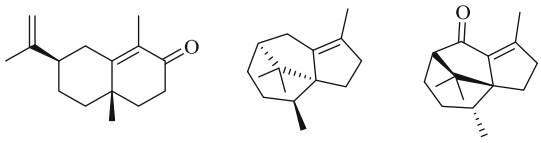
Fig. 12 Biologically active sesquiterpenes from *Cyperus* species



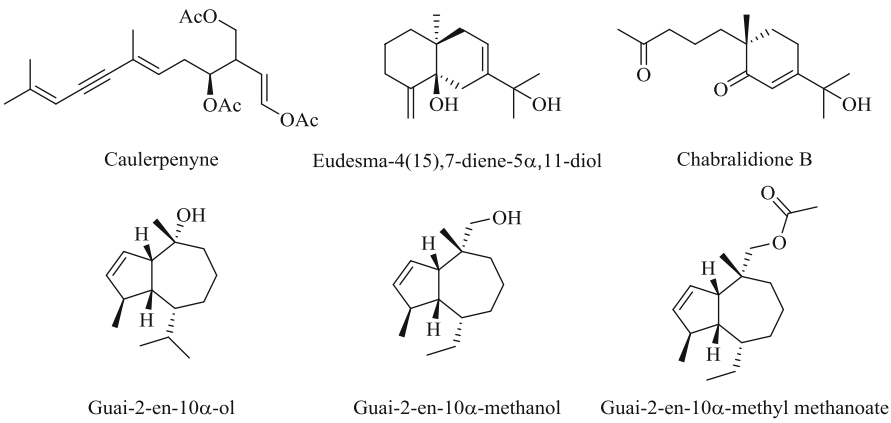


Fig. 13 Bioactive sesquiterpenes found in algae

neuroblastoma cell line at 10 μM and in 2 h, caulerpenyne induced cell death but not mitotic arrest in G_2/M phase. The microtubule network of SK-N-SH cells was also affected by this metabolite, which condensed the microtubules at the cell periphery and made the neurites disappear.

Eudesman-4(15),7-diene-5,11-diol and *seco*-eudesmane chabrolidione B (both from *L. obtusa*) (Fig. 13) have shown significant antifungal activity, with an MIC value of 2.92 μM for both compounds against *Candida albicans* and 2.10 and 4.10 μM for eudesma-4(15),7-diene-5α,11-diol and the *seco*-eudesmane chabrolidione B, respectively, against *C. tropicalis* (Alarif et al. 2016).

In addition, three guaianolides isolated from *U. fasciata* were active against three different *Vibrio* spp. (*V. parahaemolyticus*, *V. harveyi*, and *V. vulnificus*). Among them, guai-2-en-10α-methyl methanoate had the highest activity against *V. parahaemolyticus* and *V. vulnificus* (MIC 25 μg/mL for each), while guai-2-en-10α-ol, with the cycloheptanol moiety, exhibited the lowest activity of the three against *V. parahaemolyticus* and *V. harveyi* (MICs 110 and 160 μg/mL, respectively) (Chakraborty et al. 2010).

14.2.6 Bioactive Sesquiterpenes with a 1,2,4-Trioxane Ring

The Chinese medicinal plant *Artemisia annua* L. (qinghao) is the source of the sesquiterpene lactone artemisinin (also called qinghaosu) and of a large number of natural products, including amorphane and cadinane sesquiterpenes. Artemisinin is an effective antimalarial agent, especially for multidrug resistance and cerebral malaria. The unusual 1,2,4-trioxane ring structure that makes this natural product unique (Fig. 14) is responsible for this activity, and it is the most potent antimalarial available, rapidly killing all asexual stages of *Plasmodium falciparum* (Eckstein-Ludwing et al. 2003). Due to its activity against the malarial parasite, artemisinin has attracted the attention of the World Health Organization (WHO) for use as an antimalarial drug. However, the therapeutic value of this compound is limited by its low solubility in both oil and water and by the low content in *A. annua*, which ranges from 0.01% to 0.8% of the plant dry weight. This fact, together with the appearance of resistance to artemisinin, has led to the development of semisynthetic drugs with improved pharmacological properties such as artemether, arteether, and artesunate (Fig. 14; Brown 2010). Furthermore, *A. annua* is the only commercial source of artemisinin because its chemical synthesis is not commercially feasible and, as a consequence, numerous efforts in metabolic engineering have been made to obtain higher amounts of artemisinin in transgenic plants (Liu et al. 2011). Moreover, the phytotoxicity of artemisinin and two of its biosynthetic precursors (arteannuin B and artemisinic acid) (Fig. 14) has been reported, and they inhibited lettuce seed germination at 33 μM for 24 h. This phytotoxicity was attributed to the peroxide moiety (Duke et al. 1987).

14.2.7 Laurane-Type Carbon Backbone

The genus *Laurencia* (Rhodophyta group) comprises more than 500 different sesquiterpenes (Harizani et al. 2016), and it is one of the most attractive sources of sesquiterpenes among all marine microalgae. The majority of these

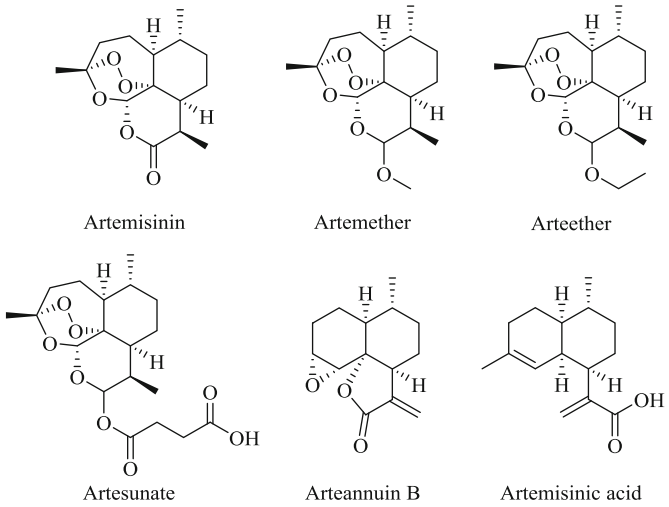

Fig. 14 Semisynthetic drugs with improved pharmacological properties using artemisinin as a lead compound (artemether, arteether, and artesunate) and its biosynthetic precursors (arteannuin B and artemisinic acid)

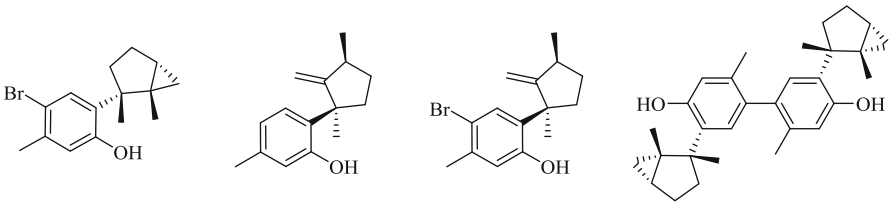
sesquiterpenes are halogenated, with bromine as the most abundant halogen followed by chlorine. Moreover, other algae also produce brominated sesquiterpenes, including *Neomeris annulata* (Chlorophyta group) (Meyer and Paul 1995; Paul et al. 1993), although in the particular case of Chlorophyta, the sesquiterpenes typically lack the extensive halogenation of the Rhodophyta group (Maschek and Baker 2008). Some halogenated metabolites have shown a wide range of biological activities, including antibacterial, antimalarial, antioxidant, and cytotoxic properties. It has been demonstrated that the nature of the halogen in the structure plays a critical role in the bioactivity (Mao and Guo 2010; Shaza 2014).

Sesquiterpenes with a rearranged laurane-type carbon backbone, which are rare in nature, have been reported and include laurinterol, debromoisolaurinterol, isolaurinterol, or laurebiphenyl (Fig. 15; Mao and Guo 2010). *Laurencia* is generally the main producer of this kind of sesquiterpene. These laurane-backbone sesquiterpenes have shown several beneficial properties, including antimicrobial, insecticidal, and anticancer activities (Ishii et al. 2017; Vairappan et al. 2001). Thus, for instance, laurinterol has shown high antimicrobial activity against strains of *Staphylococcus aureus* (complete inhibition after 48 h at 1–5 μg/mL), *Mycobacterium smegmatis* (1–5 μg/mL), and *C. albicans* (10–100 μg/mL) (Sims et al. 1975). Likewise, miscellaneous biological activities have been reported. Laurinterol and debromolaurinterol possess inhibitory activity against Na^+/K^+-ATPase, with IC_{50} values of 0.04 and 0.4 mM, respectively (Okamoto et al. 2001). On the other hand,



Laurinterol Debromoisolaurinterol Isolaurinterol Laurebiphenyl

Fig. 15 Laurane compounds in algae

moderate cytotoxicity has been observed for laurebiphenyl (found in *L. nidifica* and *L. triticha*) (Harizani et al. 2016) against A-549, BGC-823, BEL-7402, HCT-8, and HeLa cell lines. IC_{50} values of 1.68, 1.22, 1.91, 1.77, and 1.61 μg/mL were obtained, respectively (Jie Sun et al. 2005).

14.2.8 Chamigrane Halosesquiterpenoids

Chamigrane-type backbones (spirane sesquiterpenes) are very common in *Laurencia* spp. Some structures worth highlighting include ma'iliohydrin (Francisco and Erickson 2001), elatol (dos Santos et al. 2010), obtusol, isoobtusol (Martin et al. 1989), yicterpenes A and B, nidificene, and nidifidienol (Fig. 16). As mentioned above, the nature of the halogen in the structure is critical for the biological activity. Li and co-workers evaluated yicterpenes A and B for their inhibition of marine zooplankton (*Artemia salina*), phytoplankton (*Heterosigma akashiwo*), and bacteria (*Vibrio ichthyoenteri*, *Proteus mirabilis*, *Enterobacter cloacae*, and *Bacillus cereus*). The results indicated that the chlorinated yicterpene A was slightly more active against *A. salina*, *H. akashiwo*, and *B. cereus* than the brominated yicterpene B. For instance, LC_{50} values of 219.9 and 305.7 μmol/L after 24 h were obtained for yicterpenes A and B, respectively, against *A. salina* (Li et al. 2013). Furthermore, several studies have shown that these sesquiterpenes play important roles in ecological interactions, such as antiherbivore activity and potential defense against infection by microorganisms, as well as antileishmanial, antibacterial, and cytotoxic activities (Vairappan 2003; Francisco and Erickson 2001).

The chamigranes nidificene and nidifidienol from *L. nidifica* are active against the HSV-1 virus (*herpes simplex* virus type 1) with IC_{50} values of 1.5 and 2.4 μg/mL, respectively (Kimura et al. 1999).

Obtusane (from *L. okamurai*, *L. obtusa*, and other *Laurencia* spp.) showed inhibitory effects on nitric oxide (NO) release from lipopolysaccharide (LPS)-activated RAW 264.7 macrophages ($IC_{50} = 44.9$ μM) and had a slight effect on TNF-

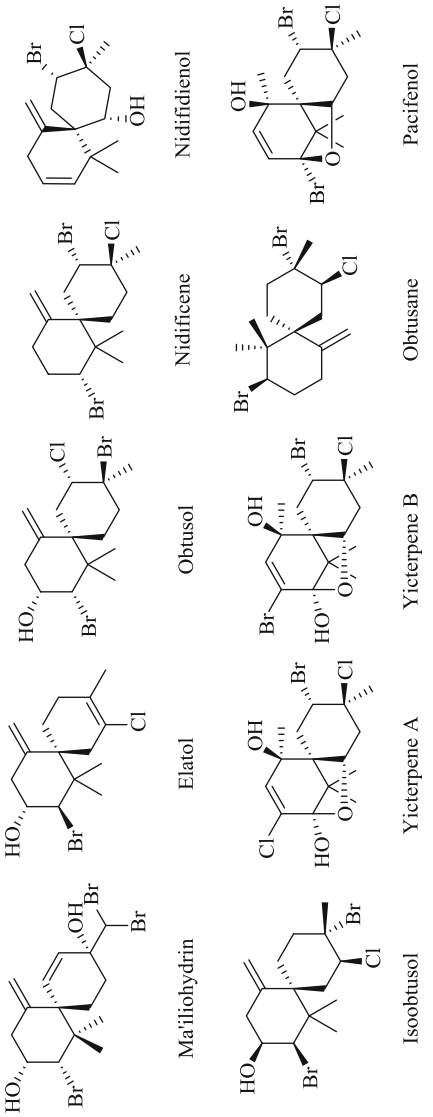


Fig. 16 Chamigrane compounds in algae

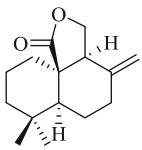
Fig. 17 Structure of antrocin



alpha production ($IC_{50} > 250.9$ μM) (Da Silva Machado et al. 2014). This compound was evaluated for antimycobacterial activity against *Mycobacterium bovis* and exhibited an $IC_{50} = 44.7$ μM. This compound showed moderate toxicity in a bioassay of lactate dehydrogenase release with an $IC_{50} = 197.2$ μM. Moreover, pacifenol, which is found in *L. nidifica* and *L. okamurai*, is an effective inhibitor of the degranulation process in human neutrophils, and it inhibits in vitro eicosanoid release stimulated by ionophores. At 100 μM this compound inhibited LTB_4 and TXB_2 release by 82% and 75%, respectively, compared with the control (Gil et al. 1995).

14.2.9 Drimane-Type Sesquiterpenoid

A wide range of natural compounds can be isolated from *A. camphorata*, with terpenoids being the predominant group but with several other types such as sesquiterpenoid, diterpenoid, benzenoid, and benzoquinone derivatives also found. From the sesquiterpenoids present in *A. camphorate*, it is worth highlighting antrocin (Fig. 17), a drimane-type sesquiterpenoid that has proven to show significant activity against different types of cancer (Chiu et al. 2016; Rao et al. 2011). Moreover, extracts from submerged cultivation mycelium of *A. camphorata* produced an anti-inflammatory effect on the murine macrophages cell line RAW 264.7 through inhibition of the expression of iNOS (inducible nitric oxide synthase) and COX-2 (cyclooxygenase-2) (proteins that are responsible of the production of nitric oxide (NO)) and prostangladins, which are important mediators in the process of inflammation (Hseu et al. 2005).

14.3 Bioavailability and Metabolism

14.3.1 Sesquiterpenes with Low Levels of Functionalization

The sesquiterpene α-copaene, which is present in a wide variety of plants, spices, and several citrus fruits, is considered to be essentially insoluble and is not reactive owing to its chemical structure, for which two stereoisomers are described: ylangene and trans-α-copaene. The theoretical log *P* (3.75, from ALOGPS) value indicates a possible localization in cellular membranes and cytoplasm in cells, and this leads to a possible use of α-copaene as a biomarker (Ahmed et al. 2016).

Likewise, valencene is the biological precursor of nootkatone (Sharon-asa et al. 2003), a remarkable sesquiterpene due to its industrial applicability, as described above (Sowden et al. 2005).

Nerolidol is one of the main components of strawberry essential oils. This farnesene-skeleton sesquiterpene can appear in four isomeric forms due to the double bond at C-6 and an enantiomeric carbon at the C-3 position. Several enzymatic complexes could metabolize xenobiotics by oxidation, reduction, hydrolysis, hydration, conjugation, condensation, or isomerization to increase the polarity and excretion. These isozymes are known as P450 or CYP, and they can mainly be found in the endoplasmic reticulum in liver cells because the liver is the first organ involved in drug metabolism. However, a major effect has been observed on CYP located in the small intestine, probably owing to the higher concentration of nerolidol after oral administration (Lněničková et al. 2017).

In a similar way to nerolidol, the chemical structure of farnesol is derived from farnesene. Two isomeric forms (*cis* and *trans*) exist due to the two double bonds, thus *cis*,*cis*-; *trans*,*trans*-; *cis*,*trans*-; and *trans*,*cis*- forms exist. However, the *trans*,*trans* isomeric form is the only one present in all natural sources of this compound. The calculated physicochemical properties show the membrane permeability of this compound because it does not break Lipinski's rule. Although data are not available regarding human bioavailability for farnesol, in vivo studies revealed nontoxic daily doses of around 50 mg (Ku and Lin 2016). Farnesol is an intermediate compound in the cholesterol metabolic pathway in cells. This compound arises from farnesyl diphosphate and is a direct precursor of squalene (Edwards and Ericsson 1999). Furthermore, it is a competitive inhibitor of mevalonate kinase, an intermediate enzyme in the aforementioned biosynthetic pathway. Thus, mevalonate kinase acts as a regulator in lipid metabolism and differentiation (Hinson et al. 1997).

14.3.2 Sesquiterpenes Containing More than One Lactone Ring

Extracts of *G. biloba* leaves are usually formulated as tablets and capsules for oral administration or as an injection for intravenous administration. In an effort to facilitate our understanding of the link between the administration of *G. biloba* leaf extract and its pharmacological action, and to identify the chemical basis of the extract responsible for its therapeutic effects, Liu et al. (Liu et al. 2018) performed rat-based and cell-based pharmacokinetic studies of Yinxing Tongzhi tablets, a standardized *G. biloba* leaf extract, and Shuxuening, a ginkgo preparation for i.v. administration. Bilobalide, the active sesquiterpene in *Ginkgo* extracts, showed an intermediate rate of membrane permeation, it was not affected by the intestinal efflux transporters, and it was poorly excreted into bile in rats. Bilobalide also showed higher oral bioavailability than ginkgolides A and B (active diterpenes also present in *Ginkgo* extracts). Furthermore, bilobalide showed good in vivo reach and limited binding to tissue, it reached both extracellular and intracellular targets, and it was distributed evenly in various body fluids and tissues. Another important

pharmacokinetic characteristic is the elimination route. In the case of bilobalide, glomerular filtration-based renal excretion is the major elimination route, although other elimination routes may be involved, and these require further investigation. Liu et al. concluded that oral administration of Yinxing Tongzhi tablets provided higher levels of systemic exposure than intravenous administration of Shuxuening due to the advantageous pharmacokinetic properties of bilobalide and the low content of bilobalide in the injected dose.

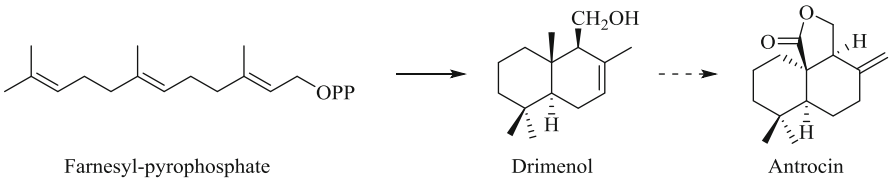
14.3.3 Sesquiterpenes with a 1,2,4-Trioxane Ring

Artemisinin is one of the most active compounds against malarial parasites. However, its low solubility in both oil and water has limited its therapeutic use. Recently, the use of dried leaves of *Artemisia annua* has been proposed as alternative way to supply artemisinin. In a rodent study, dried leaves provided ≈45 times more artemisinin in the serum than that delivered from similar doses of pure artemisinin; they were five times more effective against *Plasmodium chabaudi* and three times more resilient against emerging artemisinin drug resistance. The plant has traditionally been prepared as a tea infusion, but this mode of preparation is not recommended due to the low solubility of artemisinin in water and the low stability of artemisinin at high temperature. Furthermore, the bitter taste of dried leaves and infusions is distasteful for humans. However, this taste could be masked with other foods or by encapsulation (Brown 2010; Ghantous et al. 2010; Kiss et al. 2017).

The bioavailability of artemisinin in this alternative taste masking approach was studied by Desrosiers and Weathers (Desrosiers and Weathers 2016) with artemisinin measured after simulated digestion from dried leaves in four types of capsules in conjunction with protein and protein-based foods: dried milk, casein, bovine serum albumin, peanuts, peanut butter, Plumpy'nut®, and *Artemisia annua* essential oils. Peanuts and Plumpy'nut® led to a decrease in the artemisinin recovered from the liquid digestate fraction. On the other hand, bovine serum albumin led to an increase in artemisinin recovered from liquid simulated digestate fractions, while casein had no effect. The addition of a volume of essential oil equivalent to that found in a high essential oil-producing *A. annua* cultivar also significantly increased the solubility of artemisinin in simulated digestates. Since capsules did not alter the amount of artemisinin extracted from the intestinal liquid, capsules could offer an acceptable alternative to supply *A. annua* dried leaves as a therapeutic source of artemisinin against malaria parasite, and this approach should be tested further in animals and humans.

14.3.4 Laureane and Chamigrane Halosesquiterpenoids

The insertion of halogens such as chlorine and bromine is carried out by haloperoxidases. This seems like a natural response to the abundance of these ions in the marine environment (La Barre et al. 2010). Surprisingly, bromination is more



Farnesyl-pyrophosphate Drimenol Antrocin

Scheme 1 Suggested pathway for the synthesis of antrocin

common than chlorination, even though chlorine is more abundant than bromine in the surroundings. This fact might be due to a bioactivity-related issue, since some brominated compounds seem to be more active as chemical defense agents than those with chlorine.

14.3.5 Drimane-Type Sesquiterpenoids

Antrocin is a sesquiterpene found in *A. camphorata*. To date there is very little available information on how *A. camphorata* synthesizes its metabolites. Lin et al. employed next-generation sequencing (NGS) techniques to study the gene expression of *Antrodia cinnamomea* (Lin et al. 2015), and this served as a first step to provide a better understanding on how terpenoids are synthesized in this species. Although the synthetic pathway of antrocin was not unequivocally elucidated, the authors suggested the pathway shown in Scheme 1 (Lin et al. 2017).

The synthetic route starts with farnesyl pyrophosphate, which is transformed into drimenol by terpene synthases. Different enzymes then modify the structure of drimenol to form a lactone ring through a cyclization.

14.4 Bioactivities (Animal Studies)

14.4.1 Fruits

14.4.1.1 Orange

Valencene is a hydrophobic sesquiterpene with an eremophilane skeleton, and it is found in diverse citrus species. In vivo assays indicate that valencene decreased the melanin content after UVB irradiation in murine B16F10 melanoma. The effect observed was proportional to drug concentration (Nam et al. 2016). These results support the use of this sesquiterpene as a cosmetic against photoaging caused by high skin exposure to UV radiation – the main source of risk of developing skin cancers and precancers.

14.4.1.2 Strawberry

Nerolidol is one of the main components of strawberry essential oils, and a wide range of biological activities have been described for this compound. Growth of

pathogenic or phytopathogenic fungi such as *Candida albicans*, *Microsporum gypseum*, *Fusarium oxysporum*, and *Phytophthora capsici* is susceptible to nerolidol, as supported by numerous in vivo and in vitro studies. This bioactive compound could modify the natural hyphal evolution of the target species (Rahman et al. 2011).

Gastric and duodenal ulcers affect a considerable number of people in the world at least once in their lives. Extrinsic factors such as stress, feeding, smoking, or ingestion of nonsteroidal anti-inflammatory drugs (NSAIDs) induce imbalances in the defensive secretions of the mucosa. All treatments inhibit acid secretions by binding to the proton pump in the gastric parietal cell, thus inhibiting the transport of H^+ to the interior of the gastrointestinal tract or by inhibiting the release of histamine in the mast cells of the gastric mucosa, thus increasing the production of gastric mucus. In any case, side effects such as impotence have encouraged the search for alternative therapies. Nerolidol has exhibited significant in vivo reduction in the ulcerative lesion index and a relevant inhibition in the ulcer formation (Klopell and Lemos 2007). Despite the fact that the mechanism of action requires study, nerolidol is a strong candidate as a component in anti-ulcer or gastroprotective therapies.

Likewise, nerolidol or synergistic combinations with linalool, or tea tree oil, showed repellent activity against several species that damage many vegetables and food crops such as maize, beans, potatoes, peppers, tomatoes, and strawberries (Araújo et al. 2012; Kabugi Mwangi et al. 2013).

Additionally, inflammatory response is mediated by a complex system of small molecules and immune cells. The aim of the system is to eliminate or reduce the main cause of tissular or cell damage and repair all implicated tissue. The therapies used are based on analgesics or NSAIDs. However, the duration of these treatments should be short due to their severe side effects, which can include gastrointestinal injures or hemorrhage. The combination of such treatment with any medication must be taken into account. Essential oils from plants that contain a considerable percentage of nerolidol have shown anti-inflammatory effects in mice and rats. Antinociceptive activity has also been described (Fonsêca et al. 2016; Pinheiro et al. 2011).

Finally, in vivo studies have demonstrated potent cytotoxic effects for this sesquiterpene. The weight of tumor in mice injected with melanoma and fed with nerolidol was reduced by a considerable percentage. Moreover, the incidence of intestinal neoplasia in rats was reduced by feeding rats twice per week with nerolidol (Wattenberg 1991).

14.4.1.3 Grapes

Farnesol could be ingested from grapes, and several types of bioactivity such as anti-inflammatory, anti-allergic, antioxidant, chemopreventive, and anticancer have been described. In vivo studies have shown that the administration of farnesol gives rise to anti-allergic and anti-inflammatory effects in asthmatic mice by decreasing immunoglobulin E total levels (Ku and Lin 2015). Moreover, in vitro and in vivo studies have demonstrated that farnesol inhibits cell proliferation and could initiate apoptosis in HeLa, leukemia, hepatoma melanoma, mammary, pancreatic adenocarcinoma,

or lung carcinoma cells. However, human primary T lymphocytes or monocytes have a high resistance to farnesol-induced apoptosis. The mechanisms involved in this different selectivity are unknown, but they could be linked with the antioxidant activity of farnesol. The mechanism of action and pharmacokinetics require further study (Santhanasabapathy and Sudhandiran 2015).

14.4.1.4 Grapefruit

Grapefruit has been associated with antioxidant, anti-inflammatory, and antibacterial activities (Hamdan et al. 2013). The sesquiterpene nootkatone has shown potent in vitro, ex vivo, and in vivo inhibitory effects on platelet aggregation. The benefits observed on cardiovascular disease through coagulation effects make nootkatone a potential therapeutic alternative to commonly used therapies, where limits in use are recommended due to induced adverse effects and resistance.

14.4.2 Vegetables

14.4.2.1 *Curcuma zedoaria* (Christm.) Roscoe

The rhizomes of *Curcuma zedoaria* are used as a stimulant and for stomachic ailments, anti-diarrhea, and wound healing among other benefits in India and Southeast Asian countries, and it is also used in folk medicine in China and Japan. The extract obtained with acetone/H_2O (8:2) from this plant showed a hepatoprotective effect in mice. An in-depth study of the active constituents was performed (Morikawa 2007). Eight sesquiterpenes, including furanodiene, curdione, neocurdione, dehydrocurdione, germacrone, 13-hydroxygermacrone, curcumenol, and zedoarondiol (Fig. 18), may be promising candidates for the effective treatment of lipopolysaccharide-/D-galactosamine (D-GaIN/LPS)-induced acute liver injury (liver-specific toxin). Protective effects against D-GAIN/LPS toxin and against D-

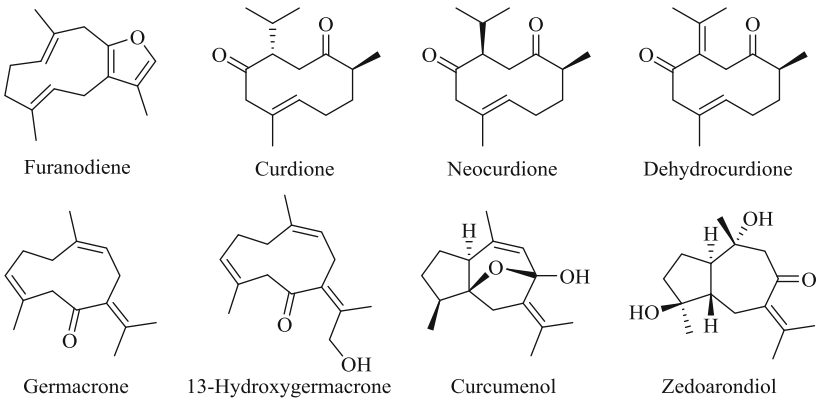


Fig. 18 Active constituents from the rhizomes of *Curcuma zedoaria*

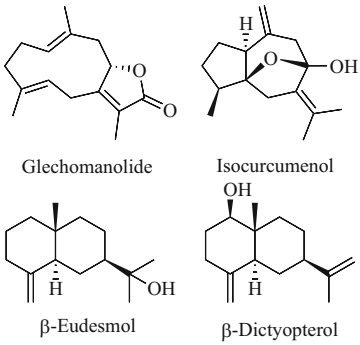

Fig. 19 The most active sesquiterpenes from *Curcuma zedoaria*

GAIN/tumor necrosis factor-α-induced liver injury were observed at 50 mg/Kg upon oral administration. Nevertheless, further studies of the mechanisms of action should be carried out (Morikawa et al. 2002). Likewise, potent vasorelaxant properties have been described for sesquiterpenes derived from this plant. This effect could explain the traditional medicinal value of the rhizomes of *Curcuma zedoaria* for the treatment of "Oketsu" syndrome. Inhibitory effects of the sesquiterpenes on the contractions induced by high K^+ concentration in isolated rat thoracic aorta were evaluated (Matsuda et al. 2001). The following structural requirements were established: the most active compounds were those with germacrane- and eudesmane-type sesquiterpenes; the presence of an *exo*-methylene moiety improved the activity and polyoxygenated sesquiterpenes showed weak activity. The contractions were inhibited by calcium channel-blocking activity. In particular, the most active sesquiterpenes (inhibition >80%, at 100 μM) were germacrone, glechomanolide, isocurcumenol, β-eudesmol, and β-dictyopterol (Fig. 19; Morikawa 2007).

14.4.2.2 *Cichorium intybus* L.

Ether and ethyl acetate extracts of different parts of fresh rhizomes of chicory (hairy roots, inner part, wounded part, neighboring soil, and rhizome skin) were evaluated for their nematicidal activity toward *Globodera rostochiensis* (Nishimura et al. 2000), and the extract from the rhizome skin showed the lowest survival rates with a value of 37.5%.

Two experiments were carried out to study the effect of dietary chicory in cattle against the gastrointestinal nematodes *Ostertagia ostertagi* and *Cooperia oncophora*. In the first experiment, the calves were fed with chicory silage and nutritional complements. In the second experiment, the calves were fed during 7 days with pure forage chicory. *O. ostertagi* counts were reduced by 66% after 22 days on feeding cattle a pure daily dose of chicory (Peña-Espinoza et al. 2016).

Anti-inflammatory effects have been described for chicory extracts. The dried aerial parts of chicory (10 kg) were extracted with ethanol for 1 week. A dose of 500 mg/kg of this extract produced a marked increase in kidney weight when

compared with the control in rats of around 18% and a marked decrease in body weight after the 10th day of treatment (Noori and Mahboob 2009).

14.4.2.3 *Cynara cardunculus* L.

Extracts from artichokes cultivated in Brazil have shown mortality on *Artemia salina.* Artichokes (Noldin et al. 2003) were macerated for 7 days in methanol. The resulting crude product was partitioned in hexane, dichloromethane, ethyl acetate, and butanol. The authors found that the hexane and dichloromethane fractions induced mortality to a significant extent in this shrimp at concentrations of 0.5–2 mg/mL, but the mortality values were not provided. The hexane fraction had an effective concentration of 358 ± 72 μg/mL, which is comparable to that of the positive control quinidine. Although cynaropicrin was the major compound in the dichloromethane fraction, when tested separately, it was not active at 2 mg/mL, thus indicating that another compound could be responsible for the high mortality of microcrustaceans.

Antispasmodic activity has also been reported. In a research project (Emendörfer et al. 2005), the antispasmodic activity of artichoke was evaluated. A crude methanolic extract of leaves was fractionated with hexane, dichloromethane, ethyl acetate, and butanol and then tested for any effect on the guinea pig ileum contractile response elicited by acetylcholine. The ethyl acetate and dichloromethane fractions gave IC_{50} values of 1.22 and 0.93 mg/mL, respectively. The most active fraction from dichloromethane was purified to obtain cynaropicrin. When assayed separately, cynaropicrin had an IC_{50} = 0.065 mg/mL, which is comparable to that of the commercial spasmodic papaverine.

14.4.2.4 Cucurbitaceae Family

Different mixtures of testosterone with pumpkin seed oil (2 and 4 mg/100 g body weight) were administered to rats, and they gave rise to a significant increase in mean prostate size ratio. In this study it was concluded that pumpkin seed oil inhibited testosterone-induced hyperplasia of the rat prostate (Gossell-Williams et al. 2006).

14.4.3 Algae

14.4.3.1 Rhodophyta Algae

The chamigrane elatol (from *Laurencia* spp.) was evaluated in vitro and in vivo for its antitumor properties (Campos et al. 2012). Elatol was able to reduce cell viability with IC_{50} values of 1.1 and 10.1 μM for I.929 and B16F10 cells, respectively. Elatol at a concentration of 50 μM alters the cell cycle progression of B16F10 cells to maintain them in the sub-G_1 phase for up to 48 h in flow cytometry bioassays, and it also causes apoptosis by reduction in the expression of the antiapoptotic protein bcl-xl. Subcutaneous injection in mice of B16F10 cells daily for 10 days caused a

suppression of tumor growth, with a reduction of 71.4% compared with the control and on using the highest tested concentration of 10 mg/kg.

Pacifenol also exerted topical anti-inflammatory effects on the TPA-induced mouse ear edema, with an ID_{50} of 161.1 μg/ear (Gil et al. 1995).

14.4.4 Food with Medicinal Properties

14.4.4.1 Common Butterbur

Butterbur extracts (*Petasites hybridus*) are recommended for the prevention of migraine, and they have been used to treat bronchial asthma and smooth muscle spasms (Schapowal 2002). The pharmacologically active substances of *P. hybridus* are believed to be sesquiterpene esters of the petasin and the furanopetasin chemotype (Chizzola et al. 2006). There is evidence that the extract of the rhizome of *Petasites hybridus* represses leukotriene biosynthesis (Bickel et al. 1994; Thomet et al. 2001), which may be associated with antispasmodic activity and anti-inflammatory action in type I hypersensitivity (Schapowal 2002). This extract also inhibits cyclooxygenase (COX)-2 ($IC_{50} \geq 20$ μg/mL) and COX-1 ($IC_{50} > 400$ μg/mL) activity and ameliorates the activation of p38 mitogen-activated protein kinase stress signaling and IkappaBa in microglial rat cells (Fiebich et al. 2005). Butterbur extracts have also proven to be an effective treatment for hay fever without the sedative effect of the antihistamine cetirizine (Schapowal 2002).

14.4.4.2 *Ginkgo biloba* L.

Standardized *Ginkgo biloba* leaf extract EGb 761® has been used for more than 30 years for cerebral ischemia and dementia due to its neuroprotective effects, as described above. Terpene lactones including ginkgolide B and bilobalide are the most effective constituents. The administration of the sesquiterpene lactone bilobalide (5–20 mg/Kg) injected subcutaneously in mouse model of focal cerebral ischemia demonstrated neuroprotective effects. Administration of this compound 60 min prior to ischemia reduced in a dose-dependent manner the infarct area in mouse brain and in rat brain 2 days after the onset of the injury (Ahlemeyer and Krieglstein 2003). It has also been demonstrated that bilobalide allows mitochondria to maintain their respiratory activity in ischemic conditions by protecting complex I and probably complex III activities. An increase in the respiratory control ratio (RCR) of cerebral mitochondria by 26 and 24% at 8 and 10 mg/Kg, respectively, has been reported by Janssens and co-workers (Janssens et al. 2000).

14.4.4.3 *Chrysanthemum parthenium* (L.) Bernh.

The effects of a chloroform extract of fresh leaves of the herb feverfew on potassium currents in smooth muscle were studied by Barsby et al. (1993b). The extract reduced the inactivating voltage-dependent potassium current in a concentration-related manner, with an IC_{50} value of 56 μg mL^{-1}. Also, feverfew decreased the time

to peak of the current and increased the rate of decay of the current. These results suggest that chloroform extracts of feverfew leaf are capable of producing a selective, open-channel blocking of voltage-dependent potassium channels (Barsby et al. 1993b).

Parthenolide is the main component obtained from the leaves of feverfew (*Tanacetum parthenium*). This plant has been used orally or as an infusion to treat migraine, arthritis, fever, and stomachache. The chemical characteristics of parthenolide (α-methylene-γ-lactone ring and epoxide molecule) enable this moiety to interact with nucleophilic sites of biological molecules. Besides its anti-inflammatory and anti-migraine properties, this sesquiterpene lactone has also shown anticancer effects. An in vivo animal model study carried out by Won et al. demonstrated that this natural product led to a remarkable reduction in the incidence and multiplicity of papilloma. Female SKH-1 hairless mice were employed in this experiment, and they were fed with fresh food pellets containing parthenolide three times a week (1 mg parthenolide/day) for 25 weeks. The results showed a chemopreventive property of parthenolide against UVB-induced skin cancer in mice. The onset of tumor incidence was delayed from week 13 to week 18, the multiplicity of papilloma was reduced by 30%, and a decrease in tumor size was observed (Won et al. 2004).

14.4.4.4 *Taraxacum officinale* (L.) Weber ex F. H. Wigg.

Dandelion is a wild plant that is used as a human food and in folk medicine. Several in vivo studies have been performed on rabbits and mice to evaluate the acute toxicity of this plant. Rabbits were orally administered with dried dandelion plant up to 6 g/Kg body weight for 7 days, while mice were treated with an ethanolic extract, and significant effects or visible toxicity were not observed (Wirngo et al. 2016).

14.4.5 Mushrooms

14.4.5.1 *Antrodia Camphorata*

A. camphorata has traditionally been used as a medicine to protect liver cells. In a study with rats (Dai et al. 2003), oral administration of the mycelia and sporocarps of *A. camphorata* proved to protect the liver against damage induced by ethanol. When rats were administered with ethanol, an increase in the levels of glutamate-pyruvate aminotransferase (GPT) and glutamate-oxaloacetate aminotransferase (GOT) in serum and an increment of the activity of hepatic superoxide dismutase (SOD) were observed. These signals provide proof that hepatic cells are damaged. When liver cells are damaged, the GPT and GOT in the liver are released to serum. SOD is one of the major antioxidant enzymes in liver, and it has been found that damage to liver cells induces the expression of SOD (Zhao et al. 1996). When the rats were administered *A. camphorata* mycelia or sporocarps, the serum levels of GPT and

GOT decreased, and the concentration of SOD was lower than in the control rats, which were only given ethanol. It is suggested that the liver protective activity is associated with the antioxidant activity.

14.5 Benefits (Human Studies)

14.5.1 Fruits

14.5.1.1 Strawberry

Skin irritation and sensitization studies are commonly carried out after occlusive drug applications during 48 h. Edema and erythema were cleared if a negative reaction had occurred after 48 h. Human studies have revealed that nerolidol (4%) in petrolatum causes a negative response after a patch test reaction (Lapczynski et al. 2008). Moreover, a combination of nerolidol and tea tree oil provides an effective alternative for treating pediculosis, an infestation that is now extensive in undeveloped and developed countries (Di Campli et al. 2012).

14.5.2 Food with Medicinal Properties

Artemisinin, parthenolide, and some of their derivatives are lead compounds in clinical trials due to their selectivity toward tumors and cancer stem cells. For example, artemisinin-derived drugs are promising for laryngeal carcinomas (Singh and Verma 2002), uveal melanomas (Berger et al. 2005), and pituitary macroadenomas (Singh and Panwar 2006) and are in phase I–II trials against lupus nephritis and breast, colorectal, and non-small cell lung cancers (Lu 2002; Zhang et al. 2008). Dimethylamino parthenolide is currently in phase I against acute myeloid leukemia, acute lymphoblastic leukemia, and other blood and lymph node cancers (Guzman et al. 2007). One of the most promising characteristics of SLs is their selectivity to target tumor and cancer stem cells while sparing normal ones (Kawasaki et al. 2009). The selectivity shown by sesquiterpene lactones is attributed to their ability to target the sarco-/endoplasmic reticulum calcium ATPase (SERCA) pump, specific proteases secreted by cancer cells, high iron content and cell surface transferrin receptors, nuclear factor-kB (NF-kB) signaling, MDM2 degradation and p53 activation, angiogenesis, metastasis, and epigenetic mechanisms (Ghantous et al. 2010). However, the low amount of these compounds produced by natural sources and their poor bioavailability, in some cases owing to their extensive plasma protein interactions and hydrophobicity, have made their commercialization difficult. Furthermore, it is necessary improve their toxicological profiles, allergenic properties, and off-target effects (Ghantous et al. 2010).

The anticancer activity of the aforementioned compounds is usually attributed to the exocyclic α-methylene-γ-lactone moiety, which can react by Michael-type

addition with biological nucleophiles to form stable adducts. However, this reactivity is also responsible for reducing the bioavailability of SLs because they bind to blood proteins that contain sulfhydryl groups, thus preventing them from achieving concentrations that are crucial to cytotoxicity (Wagner et al. 2004). More recent studies have provided evidence that the number and type of alkylating centers (α-methylene-γ-lactone, α-methylene-δ-lactone, conjugated cyclopentenone, and conjugated side chain ester) are very important for antitumor activities (Maries et al. 1995; Schmidt 1999; Schmidt et al. 1999; Siedle et al. 2003). For example, the presence of the unsaturated carbonyl systems, whether in lactone or cyclopentenone rings or in an ester side chain, increases SL toxicity toward tumor cells. In the cases of carcinosarcomas and chronic adjuvant arthritis, in addition to the α-methylene-γ-lactone and the β-unsubstituted cyclopentenone, it is also a prerequisite to have an α-epoxycyclopentanone for antitumorigenic and anti-inflammatory properties (Ghantous et al. 2010).

Two other important factors involved in the cytotoxic activity of SLs are lipophilicity and molecular geometry. The lipophilicity can be modified by changes in the side chains, usually as ester groups. In general, higher lipophilicity can facilitate penetration through the cell membrane, but this can also decrease beyond a certain size limit, causing steric hindrance on the exocyclic methylene group and preventing the appropriate approach to its target (Guzman et al. 2007). The presence of hydroxyl and methoxyl groups in SLs and their influence on cytotoxicity is not clear, and contradictory results have been published (Bruno et al. 2005; Ghantous et al. 2009; Schmidt and Heilmann 2002). On the other hand, flexible SLs have shown higher cytotoxic activity; for instance, cis-fused lactone rings are more flexible than trans-fused systems, and they have shown higher activity (Beekman et al. 1997; Schmidt et al. 1999). Stereochemistry has also been reported to be an important factor in the anticancer activity of SLs. For instance, parthenin (β-OH isomer at C-1) is more active against ethyl phenylpropiolate-induced mouse ear edema than hymenin (α-OH isomer at C1) (Ghantous et al. 2010).

14.5.2.1 *Ginkgo biloba* L.

Ginkgo biloba extracts have become one of the most popular dietary supplements in America due to their positive effect on memory, their improvement in cognitive function, and their potential beneficial effects in patients with Alzheimer's disease. Janßen et al. reviewed the articles concerning the use of *G. biloba* extracts in the treatment of Alzheimer's disease. It was established that a high dose of *Ginkgo* (240 mg) has a beneficial effect for the cognition outcomes and accompanying psychopathological symptoms. However, data regarding the risk and side effects are still needed as well as a comparison of the benefits in relation to other drugs approved for Alzheimer's disease. For these reasons, long-term studies are necessary to assess the beneficial and adverse effects of long-term therapy with *Ginkgo* (Janßen et al. 2010). Moreover, the standardized leaf extract of *Ginkgo* (EGb 761®) has been used in clinical trials for the treatment of vascular and cognitive disorders. These

extracts contain 24% flavonoids and around 6% terpenoids (bilobalide and ginkgolides among others). The improvement in cognition effects is attributed to the sesquiterpenoid bilobalide, which acts on hippocampal pyramidal neuronal excitability. This sesquiterpenoid acts as an antagonist on the main inhibitory neurotransmitter in the central nervous system (γ-aminobutyric acid (GABA) receptors) acting in the chloride channels (Johnston et al. 2009). Furthermore, a double-blind placebo-controlled pilot study of a standardized *Ginkgo biloba* extract (Seredrin) was performed on patients with primary Raynaud's disease (RD). RD is a common and painful condition characterized by episodic digit ischemia produced by emotion and cold. The treatments available produce high levels of side effects and new alternatives are needed. A total of 22 patients with RD were enrolled in this study, with half receiving a total of 360 mg *Ginkgo biloba* extract per day (divided into three doses of 120 mg) and the other half a matching placebo with a total treatment duration of 10 weeks. A reduction in the number of attacks per day of 56% was observed in the group treated with Seredrin, whereas a reduction of 27% was noted with the placebo. Moreover, significant differences in hemorheology were not observed between the two groups. These preliminary results indicate that *Ginkgo biloba* extract showed positive trends for the treatment of RD. However, in order to confirm its potential, more studies with a larger number of patients should be conducted (Muir et al. 2002).

14.5.2.2 *Artemisia annua* L.

Clinical studies in the late 1970s with patients infected with *P. vivax* or *P. falciparum* demonstrated that artemisinin could kill the malarial parasite, and it was even shown to be completely effective in the treatment of chloroquine-resistant *Falciparum malaria* without obvious side effects. However, the low solubility of artemisinin in both water and oil has limited its therapeutic use. In an effort to improve the pharmacological properties of artemisinin, several semisynthetic derivatives have been tested, with artemether, arteether, and artesunate being the most important, and these showed improved activity when compared to artemisinin and had higher solubility and metabolic and hydrolytic stabilities (Brown 2010).

14.5.2.3 *Taraxacum officinale* (L.) Weber ex F. H. Wigg.

Dandelion is generally considered to be safe, with rare side effects, and it also has been reported to be a weak sensitizer, and allergic reactions have not been ruled out in sensitive people. The allergen in this plant has been identified as taraxinic acid 1′-*O*-β-glucopyranoside. An in vivo study with 235 adults divided into 4 groups (patients with allergic contact dermatitis, patients with atopic dermatitis, nonatopic patients suffering from non-allergic chronic inflammatory illnesses and healthy volunteers) was performed by Jonanovic et al. to evaluate the response of patch testing supplemented with dandelion extract. The results showed that allergic reactions were obtained only in patients with eczema, and irritant reactions were not recorded for dandelion extract. These outcomes reinforce the safety of dandelion consumption (Jovanovic et al. 2004).

14.6 Applications in food

14.6.1 Fruits

14.6.1.1 Apple

α-Farnesene can be used as an artificial flavoring in sour or tart fruits such as kiwi, carambola (star fruit), and green apple.

14.6.1.2 Orange

δ-Cadinene can be used as a flavoring ingredient because the substance, extract, or preparation imparts an agreeable or attractive smell. Likewise, valencene is currently used as a fragrance and flavor in beverages and in chewing gum in particular.

14.6.1.3 Strawberry

Nerolidol is a common flavor intensifier that is widely used in the food industry since it was approved by the US Food and Drug Administration (Weng-Keong et al. 2016).

14.6.1.4 Grapes

The American Food Drug Administration considers farnesol apt for human consumption; however, doses are restricted. They are used in the minimum quantity required to produce their intended effect and otherwise in accordance with all the principles of good manufacturing practice.

14.6.1.5 Grapefruit

Nootkatone is used as a fragrance and as a food additive flavoring agent.

14.6.2 Vegetables

14.6.2.1 *Cichorium intybus* L.

Chicory is an important agricultural crop because its roots and leaves have several uses. For instance, the roots are cooked as a vegetable or roasted as a coffee surrogate, and they are an excellent source of inulin or fructose. The leaves are consumed as a vegetable and are used as livestock forage, especially for ruminants, and the sprouts are consumed raw as admixtures to salads (Barry 1998; Wang and Cui 2011). The bitter taste is generally disliked by consumers, and this is the main reason for the rejection of several foods. Different strategies have been adopted to reduce the content of SLs in chicory. One of these strategies is the breeding of cultivars with very low levels of SLs, but the low content of SLs reduces the resistance against disease or herbivore attack, thus leading to lower crop yields or the increased application of pesticides. Cut chicory was traditionally soaked in cold or warm water to debitter prior to consumption. Wulfkuehler et al. demonstrated that SL levels in freshly cut chicory were markedly lowered by applying warm water (45 °C, 120 s), with SL levels reduced by 60.9–64.5%, and concomitantly the sensory quality and shelf life were improved (Wulfkuehler et al. 2013). However,

the wounds and decompartmentalization of plant cells produced by shredding of freshly cut chicory led to undesired browning, which is catalyzed by oxidative enzymes such as polyphenol oxidase. This browning facilitates microbial growth and accelerates spoilage. In contrast to blade cutting, high-pressure water-jet cutting provides a sterile and permanently renewing cutting medium, thus completely preventing cross-contamination. Wulfkuehler et al. demonstrated that water-jet cutting did not affect the physiological condition, the microbiological quality, or the levels of SLs in freshly cut radicchio when compared to blade cutting using a newly sharpened blade (Wulfkuehler et al. 2015).

14.6.3 Algae

Algae are 80–90% water, and, after drying, they contain 50% carbohydrates, 1–3% lipids, 7–38% minerals, and a highly variable content of proteins (10–47%). The nutritional content varies not only between species but also depending on the date of collection of the algae. For example, *Ulva* sp. contains 57.5 ± 31.1 mg iron/100 g dry weight and 232.28 ± 48.84 mg ascorbic acid/100 g dry weight (Garcia-Casal et al. 2007). However, the selection of edible species with commercial value is based on texture and taste rather than nutritional value (Pereira 2016).

Methods for preparing dishes with algae vary between different countries. In Japan algae are served cold after brief blanching, and different condiments are added such as vinegar, soy sauce, salt, or sugar, while in China they are cooked with pork or noodles and eaten hot (Bangmei and Abbott 1987). In general, algae are consumed with little or no cooking as an accompaniment to raw fish. *Caulerpa* spp. have peppery tastes of different intensities depending on the species (Higa and Kuniyoshi 2000; Vidal et al. 1984), and they can be used for making salads and sauces (Pereira 2015).

14.6.3.1 Chlorophyta Algae

Ulva spp. (Chlorophyta group) that have been studied for their application in the food industry include *U. lactuca*, *U. pertusa*, *U. compressa*, and *U. clathrata*. These are consumed as food condiments and as nutritional supplements in Japan and China. For example, in Japan they are used in salads, soups, cooked meals, and condiments or mixed with other green seaweeds. They are not as widely used in Western countries, but they have been authorized for human consumption in France (Raj et al. 2016).

In order to preserve the phytochemicals, *Ulva* spp. can be dried in a microwave with a very low power (300 W) for 3 min.

14.6.3.2 Cyanophyta Algae

Arthrospira platensis (Cyanophyta) is an edible alga that can be used as an ingredient in flours to add consistency, and it is a source of vitamins and proteins (Zouari et al. 2011).

14.7 Safety, Toxicity, and Side Effects

14.7.1 Fruits

Hazards have not been detected by the European Food Safety Authority for α-farnesene (apple), δ-cadinene (orange), or farnesol (grape).

14.7.1.1 Orange

α-Copaene has been described as being flammable and irritating to skin. During manipulation this compound should be kept out of the reach of children, and skin contact should be avoided by wearing suitable gloves. Moreover, for the sesquiterpene valencene, inhalation or aspiration should be avoided because it could cause lung damage. Otherwise, despite the consumption of fruits and processed foods that contain α-ylangene, its use as flavor or fragrance is not recommended.

14.7.1.2 Strawberry

Safety data for nerolidol have been published. LD_{50} values for oral or parenteral toxicity relative to rat or rabbit are higher than 5000 mg/Kg. In humans tests on a 4% solution of nerolidol did not indicate any irritation or sensitization.

14.7.1.3 Grapefruit

Nootkatone or (+)-nootkatone, the most important and expensive sesquiterpene in grapefruit, is used as a fragrance ingredient, and this should be at least 98% pure, with a melting point of at least 32 °C. Lower purity grades cannot be used as a fragrance ingredient.

14.7.2 Vegetables

14.7.2.1 *Cichorium intybus* L.

Although chicory has been part of the human diet for a long time, the sesquiterpene lactones contained in it might be toxic in large amounts. A 2007 study concerning different toxicological bioassays on the sesquiterpene lactones from chicory roots concluded that chicory root extracts are safe for human consumption and may be used as therapeutic agents (Schmidt et al. 2007).

14.7.2.2 *Cynara cardunculus* L.

Dermatitis cases in humans have been reported after handling artichoke, and it is associated with the presence of cynaropicrin and other related sesquiterpene lactones in this vegetable. A report from 1983 (Meding 1983) indicated that a 44-year-old man with no previous history of allergies had an allergic reaction to eating and handling artichokes, with positive results obtained after 72 h in patch tests carried out on this man using the stem of an artichoke and an ethanol extract of the stem. A recent review (Paulsen 2017), which lists a series of reports of allergic dermatitis suffered after exposure to different sesquiterpene lactones contained in vegetables,

confirms the suspicion that there is a risk of experiencing different allergic reactions such as eruptions on the skin or even respiratory problems. Lettuce, artichoke, and chicory are among the vegetables with reported cases of allergies.

14.7.3 Algae

A remarkable phenomenon related to toxicity in algae is called "red tides" or "harmful algal blooms," when the population of microscopic algae grows by massive amounts. One of the forms of these phenomena is the release of harmful toxins to the water, and these affect fish and other marine organisms (Anderson 1995). *Gymnodinium nagasakiense* is a dynophyte microalga that blooms near Japan (Kajiwara et al. 1992) and produces compounds that alter the growth of other members of the phytoplankton. One of these compounds is the sesquiterpene cubenol, which showed cell-destroying activity at 5 ppm after 30 min against the species *Heterosigma akashiwo*, *Chattonella marina*, *C. antiqua*, and *G. nagasakiense*. This compound is also present in the marine brown algae *Dictyopteris divaricata* and *Undaria pinnatifida*.

14.7.3.1 Chlorophyta Algae

Caulerpa spp. also contain other compounds, including a red-colored alkaloid named caulerpin and caulerpicin, a mixture of sphinganine-derived ceramides (Higa and Kuniyoshi 2000; Nielsen et al. 1982). Together, these compounds have been associated with the toxicity of *Caulerpa* spp., but Vidal et al. indicated that caulerpin and caulerpicin were not responsible for the toxicity of *C. scalpelliformis* (Vidal et al. 1984) because none of the mice died after oral or intraperitoneal administration of up to 2 g/kg or intravenous injection of 0.2 g/kg of caulerpin (Higa and Kuniyoshi 2000).

14.7.4 Food with Medicinal Properties

14.7.4.1 Common Butterbur

Common butterbur, in addition to the beneficial sesquiterpene lactones, contains pyrrolizidine alkaloids (PAs) that are hepatotoxins in animals and humans (Stegelmeier et al. 1999) and have shown carcinogenic and mutagenic potential (Roeder 1995). The highest concentrations are often located in the rhizomes and stalks, with the lowest concentrations in the leaves. The relative concentrations can change depending on where the plants are grown. Therefore, plants intended for use as pharmaceutical ingredients should be low in PAs, and the German Federal Health Bureau established regulations that restrict the oral exposure to pyrrolizidine alkaloids or their *N*-oxides in herbal preparations to 1.0 μg/day (intake restricted to 6 weeks only) or 0.1 μg/day (no restrictions on intake) with the exclusion of pregnant and lactating women, for whom zero exposure is recommended (Stegelmeier et al.

1999). Avula et al. (2012) demonstrated that 7 of 21 dietary supplements analyzed and two species of *Petasites* (*P. hybridus* and *P. frigidus*) contain PAs.

14.7.4.2 *Ginkgo biloba* L.

Although there is a need to study in more depth the risks that *Ginkgo biloba* extract consumption could have, some adverse effects have been reported, including gastrointestinal symptoms, headache, nausea, and allergic skin reactions. Likewise, adverse interactions with common prescription medications have been described (Gornik and Creager 2013). Bleeding reactions have been associated with the combination of *Ginkgo* with aspirin, rofecoxib, or warfarin, and coma has been reported in a patient with Alzheimer's disease who took *Ginkgo* leaf with trazodone (an antidepressant drug) (De Smet 2002).

14.7.4.3 *Ambrosia artemisiifolia* L.

The herb of *A. artemisiifolia* has gained popularity as a medicinal plant and food. Several products are available on the market, and these are typically food supplements (dry ragweed powder, alcoholic extract) or foods (puree made from the fresh buds of the plant). However, the widespread and long-standing folk medicinal application of this plant is not supported by the available data. Furthermore, there are no human studies to support these therapeutic indications, and it is necessary to establish the safety of this herb for human use. With this aim in mind, Kiss et al. studied the repeated dose toxicity of a product containing puree of ragweed herb in a rat model. The results showed some protective effects on the liver and on triglyceride levels during oral ragweed consumption. However, significant changes in the carbamide level and relative organ weights were also found, and these changes are probably indicative of toxic effects on the kidney and brain.

Sesquiterpene lactones may also play a role in some beneficial effects of ragweed, but, on the other hand, these compounds may also have cytotoxic effects. In view of their results, Kiss et al. concluded that the consumption of ragweed is questionable since there are no human toxicological studies, and the results of their animal experiment should be considered as a warning signal (Kiss et al. 2017).

14.7.4.4 *Taraxacum officinale* (L.) Weber ex F. H. Wigg.

Dandelion is used as a salad ingredient, and its roots and extracts are used as a coffee substitute. Rare side effects have been described for this weed, although contact dermatitis, diarrhea, and gastrointestinal upset have been reported. Generally, this plant is not recommended for patients with liver or gallbladder ailments as it has been postulated that dandelion-stimulated bile secretion may occur, although there is no direct scientific evidence for this (Sweeney et al. 2005). The recommended doses for the consumption of this plant have been established by the European Commission and the *British Herbal Pharmacopoeia*. These daily dose recommendations are as follows: fresh or dried leaves (4–10 g), fresh leaf juice (1 teaspoon twice), fluid extract (1–2 teaspoon), fresh roots (2–8 g), and dried powder extract (250–1000 mg four times) (Wirngo et al. 2016). Likewise, dandelion is recognized as a safe food in

the USA with a maximum level of 0.014% for fluid extract and 0.003% for solid extract (Sweeney et al. 2005).

14.8 Marketed Products

14.8.1 Fruits

14.8.1.1 Apple

α-Farnesene is used as a fragrance in rose and other floral compositions. Furthermore, it is used in cosmetics and in perfumes.

14.8.1.2 Orange

There are a number of companies that supply valencene with different levels of purity. Besides, α-ylangene is used for the preparation of fruits, ice creams, yoghurts, and beverages.

14.8.1.3 Strawberry

Nerolidol is frequently found in cosmetics, shampoo, body lotions, and perfumes and as an aroma component of household cleaners and detergents. It has been estimated that the worldwide consumption of nerolidol is in the range from 10 to 100 metric tons (Lapczynski et al. 2008).

14.8.1.4 Grapes

Farnesol is an aromatic constituent in thousands of products such as cosmetics and personal care products, aftershave lotions, cleansing products, colognes, deodorants, eye lotions, face powders, foot powders, fragrances, hair care products, moisturizers, shaving products, and skin care products.

14.8.1.5 Grapefruit

A study of several commercial aromatized vinegars has shown that nootkatone is present in lemon aromatized vinegar, and this imparts its antioxidant activity (Cejudo-bastante et al. 2012).

14.8.2 Vegetables

14.8.2.1 *Cichorium intybus* L.

The commercial part of the chicory plant comprises mainly the innermost leaves, while the outermost leaves are typically removed, and the roots are considered to be waste (Poli et al. 2002). However, chicory roots can be dried and roasted to prepare infusions as coffee substitutes (Schmidt et al. 2007).

14.8.2.2 *Cynara cardunculus* L.

Artichoke leaf extracts are sold as nutraceutical products in pills by different companies, and these can be easily purchased from well-known online stores. Commercial artichoke products include detox preparations in powder (e.g., from Karéléa™ or Artichoke Romarin from Laboratoires Vitarmonyl©), artichoke extracts (Gerlinéa™), drinks to improve digestion in which artichoke is combined with other ingredients such as green tea (AquaLigne™), and artichoke root extracts (Laboratoires Juvamine©), among others.

14.8.2.3 Cucurbitaceae Family

Pumpkin seed oil is sold in pharmacies in the form of a capsule manufactured by the company Good 'N Natural, with each capsule containing 1000 mg of *C. pepo* seed oil (Gossell-Williams et al. 2006). It has been reported that this oil is useful for the treatment of urinary problems related with benign prostatic hyperplasia.

14.8.3 Algae

More than 200 species are processed commercially on the coasts of Korea, Japan, China, the Philippines, Taiwan, Indonesia, Russia, Italy, France, the USA, and Chile. About 60–70% of the 16 million tons of seaweed produced per year was used for human consumption in 2005 (Hudek et al. 2014). Furthermore, the company ALGA^{+} dedicates its commercial activity to the cultivation of macroalgae in Europe (www.algaplus.pt).

14.8.3.1 Cyanophyta Algae

Spirulina is a dietetic supplement obtained from the microalgae of the genus *Arthrospira*. This product is sold under the name spirulina by several companies such as Aldous Labs, Ibornatur, and Nutrex.

14.8.4 Food with Medicinal Properties

14.8.4.1 Common Butterbur

Butterbur extracts are sold by many companies, including Now, Solaray, and Swanson, as different formulations, e.g., capsules, tablets, or softgels. The formulation and the extraction procedure can influence the content of both the beneficial petasins and dangerous PAs, and, for this reason, it is extremely important to know the concentration of these compounds to ensure the safety of the products. Avula et al. (2012) analyzed 21 commercially available petasin products, and they demonstrated that only 7 contained the amount of petasins stated on the package and 7 contained PAs (Avula et al. 2012). For these reasons, more control and better regulation are required to ensure the safety of commercial butterbur extracts.

14.8.4.2 *Ginkgo biloba* L.

Ginkgo biloba extracts are commercialized as tablets, capsules, or softgels by several companies. The standardized commercial extracts of *G. biloba* leaf used in ginkgo supplements contain no less than 6% sesquiterpene lactones and 24% flavonol glycosides, since this concentration has been extensively studied in human clinical trials. While sesquiterpene lactones are only found in ginkgo leaf, the flavonol glycosides are present in many other botanical extracts. However, due to the high production cost and high demand, there is an incentive to adulterate ginkgo extracts with pure flavonols (e.g., rutin, quercetin, kaempferol) or flavonoid-rich materials from less expensive sources to achieve the desired 24% flavonol glycoside content (Avula et al. 2015). The *United States Pharmacopeia 37-National Formulary 32* (USP37-NF32) specified that powdered ginkgo extract should have a flavonoid content of 22–27%, calculated as flavonol glycosides, and a maximum content of 5 ppm of ginkgolic acids, which are known contact allergens. In addition, specifications are also provided for the terpene lactones (bilobalide and ginkgolide A, B, and C), i.e., not less than (NLT) 5.4% and not more than (NMT) 12.0% (Pharmacopeia 2014). Avula et al. (2015) analyzed 25 commercially available *G. biloba* dietary supplements, and 11 of them showed clear evidence of adulteration with *S. japonicum* fruit or flower.

14.8.4.3 *Chrysanthemum parthenium* (L.) Bernh.

In the case of feverfew, preparations of fresh or dried leaves are widely consumed in the UK as a remedy for arthritis and migraine, but the pharmacological basis for this has not been established. Barsby et al. (1993b) determined that there are significant differences in the pharmacology of chloroform extracts of fresh feverfew leaves versus commercially available powdered leaves. For example, the fresh leaves contain an inhibitory principle(s) that causes a time-dependent, non-specific, and irreversible inhibition of the action of smooth muscle agonists and also causes a slow loss of tone of precontracted muscle. In contrast, extracts of powdered leaves did not exert inhibitory effects on the smooth muscle preparations. This difference could be due to the absence of parthenolide and other sesquiterpene lactones in the powdered leaves (Barsby et al. 1993a).

14.8.4.4 *Litsea cubeba* (Lour.) Pers.

Essential oil from the fruits of *Litsea cubeba* L. is rich in citral (around 70%), and prominent bioactivities have been reported. This oil has a very aromatic and lemonlike spicy odor, and it has been approved by the Ministry of Health in China as a food additive in accordance with normative GB 2790–2007 (Si et al. 2012). Commercial essential oils from *Litsea cubeba* L. are marketed under the names May Chang oil and Kangrean oil (from Central Java, Indonesia) (van Hulssen and Koolhaas 2010).

14.8.5 Mushrooms

14.8.5.1 *Antrodia camphorata*

Extracts of *A. camphorata* are sold as functional foods and dietary supplements or as drinks and capsules, mainly due to their hepatoprotective, anticancer, and antioxidant activity. Additionally, *A. camphorata* mycelia extract that is rich in polysaccharides is sold among other fungi extracts as a "mushroom drink," which is a dietary supplement. In many other cases, the extract of this *Antrodia* species is sold as capsules.

14.9 Patents

14.9.1 Fruits

14.9.1.1 Strawberry

A process to retrieve larger quantities of nerolidol from essential oils has been patented. The extraction method of the invention allows a reduction in the loss of volatile oils to give an improved yield of 35% or more and a high active ingredient content – in particular the trans-nerolidol content was significantly increased (Meng et al. 2018).

14.9.1.2 Grapes

Several inventions related to farnesol have been published, including the synthesis of *trans*,*trans*-farnesol (Zeng et al. 2016), the identification of the safe and effective amount of farnesol for the regulation of mammalian keratinous tissue (Lynn Bissett and Jewell-Motz 1999), and its use as a component of an antiplaque oral composition (Nabi et al. 1995).

14.9.1.3 Grapefruit

Diverse patents have been submitted in the past year for nootkatone. These include a composition that provides the release of fragrance over an extended period of time (Goldblum and Warren 2014).

14.9.2 Vegetables

14.9.2.1 *Cichorium intybus* L.

In an effort to reduce the bitterness of chicory plant material or flour, (Peet and Justice 2015) described an invention to make low-bitterness chicory chips and flour food products such as dairy products, yoghurts, ice creams, milk-based drinks, milk-based garnishes, puddings, milkshakes, egg custard, cheeses, nutrition bars, energy bars, breakfast bars, confectionery, bakery products, crackers, cookies, biscuits, cereal chips, snack products, ice tea, fruit juice, diet drinks, sodas, sports drinks, powdered drink mixtures for dietary supplementation, infant and baby food, calcium-

supplemented orange juice, bread, croissants, breakfast cereals, pasta, noodles, spreads, sugar-free biscuits and chocolates, calcium chews, meat products, mayonnaise, salad dressings, nut butter, sauces, and soups. Presently, the removal of the bitter taste is a costly step in the production of inulin from chicory roots, which makes chicory fibers significantly more expensive than cellulose fibers. For these purposes, they considered how chicory plants are cultivated; the procedure for cooking chicory taproots; the drying process of the chicory taproots after cooking to reduce moisture; the concentration of dihydrolactucin, dihydro-8-deoxy-lactucin, lactucin, 8-deoxylactucin, and lactucopicrin; and the milling of chicory taproots (Peet and Justice 2015).

Compositions that can be used to enhance human or animal health and to prevent or treat inflammation that include one or more phytochemical agents derived from a plant source such as chicory are described in another patent (Malnoe et al. 2004). The inventors describe how a chicory extract made with ethyl acetate had a pronounced effect on the inhibition of cyclooxygenase activity by causing a decrease in the amount of PGE2 (95% reduction at 100 μg/mL dose compared with the control).

14.9.2.2 Cyperaceae Family

A patent was filed on the use of extracts of *Cyperus rotundus* in the treatment and prevention of menopausal diseases caused by the decline in estrogen levels or by allergic diseases (Kwak et al. 2015). This patent describes the use of extracts of *C. rotundus* or a series of six sesquiterpenes with high estrogenic activity. The structures of these compounds are provided in Fig. 20. In the patent it is explained that 4α,5α-oxidoeudesm-11-en-3-one, cyper-11-ene-3,4-dione and 3α-methoxyeudesma-4,11-diene showed high estrogenic activity and markedly reduced activities by co-treatment with tamoxifen to work as estrogen supplements.

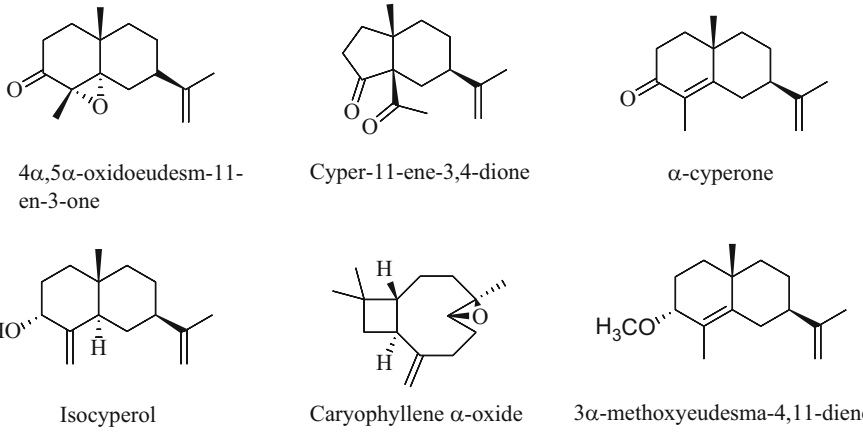

Fig. 20 Sesquiterpenes described as having estrogenic activity

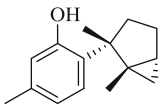

Fig. 21 Structure of the bacteriostatic compound in *L. okamurai*

14.9.3 Algae

There is a patent that concerns hair treatment compositions and methods of manufacturing the compositions for cosmetic use to prevent and reduce alopecia based on brown algae juice (Shim 2001). In this invention, the brown algae juice is mixed with juices of artemisia, pine needle, and other additives in order to obtain different compositions. A typical amount of brown algae juice is in the range of 30–60% of the total weight of the composition. It is hypothesized that the contents of I and Ca in the juice would have an effect on hormone secretion of the thyroid gland related to hair growth. However, none of the secondary metabolites of these algae and their possible effects are mentioned in this invention.

Another patent is related to the application of an algae sesquiterpenoid compound (Fig. 21) to prepare a bacteriostatic agent. This compound is extracted from *L. okamurai*, and it has strong inhibitory effect on *Streptococcus agalactiae* and *Vibrio anguillarum* (Jia et al. 2015).

14.9.4 Mushrooms

14.9.4.1 *Antrodia camphorata*

Antrocin, the main drimane-type sesquiterpenoid from *A. camphorate*, has shown promising anticancer results. A recent patent described medication containing antrocin to inhibit cancer cell growth as well as different bioassays performed to test its activity (Tzeng et al. 2012). It was demonstrated that treatment of breast cancer cells with antrocin would produce a selective inhibition of the cancerous cell proliferation.

14.10 Perspectives

Sesquiterpene lactones have attracted considerable interest since ancient times to treat several illnesses like inflammation, gastric disorders, or infections, and several of the associated metabolites are now in clinical trials, e.g., parthenolide or artemisinin. New efforts should be focused on the search for promising SL-derived drugs with improved physicochemical properties and bioavailability.

Although many sesquiterpenes are bioactive constituents of vegetables that have interesting health-promoting functions, more toxicological studies are required to evaluate accurately the toxicological effects of high quantities of these compounds in humans long-term. Nevertheless, the bitter tastes of these compounds might help to ascertain the appropriate amount of food containing sesquiterpene lactones that should be eaten on a daily basis.

Algae are eaten mainly in Eastern countries where they are integrated in the traditional gastronomy, but over time the consumption of algae is increasing in Western countries. Thanks to their nutritious contents, their use as a food in Europe and America has increased over the last few decades (Domínguez 2013). Given that many studies have highlighted the richness in beneficial secondary metabolites that these plants have, it is expected that their consumption will increase further over time.

Abstract

This chapter provides an in-depth overview of the sesquiterpenes found in cereals and spices. These aliments provide an important source of nutrients for our health, and they are consumed daily. Thus, a knowledge of the constituents is vital to understand the origin of their benefits for human health as well as the possible side effects that can arise upon ingestion. Metabolite routes are detailed, being also provided a deep understanding of their numerous structures and bioactivities, to be used as food supplement or active ingredient in drugs. Among bioactivities found in the literature for these natural compounds, antioxidant, anti-inflammatory, or anticancer is remarkable.

Furthermore, we present a broad study of sesquiterpenes in cereals. We focus on trichothecenes, a family of mycotoxins, which represent a big concern worldwide. A study of their biotransformations in humans and animals, and their toxicity for the organism, is revised. In case of spices and miscellaneous food, a classification of their sesquiterpenes constituents present in the consumable parts was analyzed, showing the relevance of the structure variability in the activity.

Keywords

Dietary sesquiterpenes · Trichothecenes · Sesquiterpenes · Nutritive sesquiterpenes · Spices · Cereals · β-Caryophyllene · Sesquiterpene metabolism · Medicinal sesquiterpenes · Functional food

Abbreviations

15-MAS	15-Monoacetoxyscirpenol
3-ADON	3-Acetyldeoxynivalenol
4-DMAP	4-Dimethylaminopyridine

15.1 Introduction

This chapter provides an in-depth overview of the sesquiterpenes found in cereals and spices. These aliments provide an important source of nutrients for our health, and they are consumed daily. Thus, a knowledge of the constituents is vital to

understand the origin of their benefits for human health as well as the possible side effects that can arise upon ingestion.

Cereals represent one of the most common solid foods (Lawrie 1998); they play an important role in our diet and are an important source of nutrients, particularly for infants. However, there are numerous organisms that can damage or infect cereals both in the field or during storage and this causes many crops to be partially or entirely lost and presents a significant threat to our health. Among these threats it is worth highlighting trichothecenes. These are a family of mycotoxin sesquiterpenoids produced by several fungi from the genera *Fusarium*, *Stachybotrys*, *Myrothecium*, *Cephalosporium*, *Verticimonosporium*, *Trichoderma*, and *Trichothecium* during growth in host plants, food, and other environments (D'Mello et al. 1999; Grove 2007; Rocha et al. 2005). It has been demonstrated that industrial processing of cereal crops prior to their commercialization may decrease the level of these mycotoxins. However, such treatment does not completely eliminate these species (Kushiro 2008; Scudamore et al. 2009), and this results in humans being constantly exposed to these mycotoxins.

A total of 148 trichothecene structures have been isolated from natural sources, as stated by Grove (1986), but this number is increasing steadily. Some of the most important compounds of this family are deoxynivalenol (DON), nivalenol (NIV), diacetoxyscirpenol (DAS), and T-2 and HT-2 toxins. Deoxynivalenol is most frequently detected in small cereal grains, and it is therefore becoming one of the biggest concerns worldwide due to its presence in many countries around the world (Placinta et al. 1999). The European Commission (Regulation 2007) established a regulation for maximum deoxynivalenol levels in different foodstuffs, and the Scientific Committee on Food (SCF) (European Commission 2005) established a Tolerable Daily Intake (TDI) for different mycotoxins produced by *Fusarium* species. Although deoxynivalenol is the most frequently found toxin, it is actually one of the least toxic compounds of this group (Rotter et al. 1996). Different studies on the effects of trichothecenes on animals have shown that other mycotoxins, for example, diacetoxyscirpenol and T-2 toxin, are generally more toxic than deoxynivalenol (Rocha et al. 2005; Thompson and Wannemacher 1986) and these are therefore a threat to humans and animals.

Concerning other foodstuffs, a wide range of plants are used to season different dishes in order to add or promote certain flavors and aromas. The use of spices and condiments in food has been known since ancient times, along with their use in medicinal applications. The development of chemical, physical, and biological technologies has demonstrated many properties of these natural additives, and it is possible to relate some benefits with specific compounds. In some cases, these natural substances are employed in food to provide additional qualities like color (e.g., saffron to give yellowish tones) or as preservatives (e.g., lemon juice to delay microorganism growth).

Most of the spices commonly used in cooking contain natural sesquiterpenes that we ingest and from which we obtain certain benefits. Examples include mint (*Mentha* spp.), pepper (*Piper nigrum*), cinnamon (*Cinnamomum verum*), basil (*Ocimum basilicum*), turmeric (*Curcuma longa*), bay laurel (*Laurus nobilis*), and salvia

(*Salvia officinalis*). The East Indian perennial herb *Curcuma amada* Roxb. is used in culinary applications to provide a raw mango flavor, for which it is commonly known as "mango ginger" (Sarikurkcu et al. 2018). Many medicinal and biological properties have been described for the rhizomes of this species in Indian folk medicine. For example, it is a remarkable appetizer, diuretic, antioxidant, anti-inflammatory, and cure for skin diseases, among other uses, and so it may be noteworthy for pharmacological applications (Policegoudra et al. 2011).

Numerous other examples of condiments used in food that are rich in sesquiterpenes can be found in nature: artemisia (*Artemisia umbelliformis*), mirto (*Myrtus communis*), satureja (*Satureja avromanica*), lemon (*Citrus limon*) and orange peel (*Citrus sinensis)*, mitsuba (*Cryptotaenia japonica* Hassk), and hatsudake (*Lactarius hatsudake*).

Mitsuba is a vegetable that is used as a topping in typical dishes of Eastern Asia, like the Japanese miso soup. This vegetable is characterized by its strong odor and is sometimes related with increased appetite. Sesquiterpenoids are the main components of mitsuba oil (Okuno et al. 2017).

Hatsudake is an edible and somewhat bitter mushroom that is also distributed in eastern areas of Asia like Japan, Korea, and China. This mushroom is employed as a base in Japanese traditional food, and it provides a green color and sweet and spicy flavors (Miyazawa et al. 2010).

15.2 Bioactive Constituents

15.2.1 Sesquiterpenes in Cereals

Trichothecenes are secondary metabolites produced by fungi. The different structures of trichothecenes are derived from a trichothecane (Grove 1986) skeleton (Fig. 1). The core structure of trichothecenes is formed by a fusion of a cyclohexene, tetrahydropyran and cyclopentyl rings, with a double bond at positions C-9 and C-10 and an epoxide group at positions C-12 and C-13, the latter of which is believed to be the cause of the toxicity (Zhou et al. 2008), are the base arrangement of trichothecenes. In this structure there are five positions, denoted as R1 to R5, that can bear different functional groups – most commonly acetyl and hydroxyl groups. Depending on the nature of these substituents trichothecenes are classified into four main groups (A, B, C, and D) (Foroud and Eudes 2009).

Type A trichothecenes stand out from the others due to the absence of a ketone group at C-8. The best known type A trichothecenes produced by the *Fusarium*

Fig. 2 Structures of the best known trichothecenes

species are T-2 and HT-2 toxin, which have an isovalerate group at C-8. Type B trichothecenes have a ketone group in C-8, and this group of compounds includes deoxynivalenol and nivalenol. Type C trichothecenes are characterized by the presence of a second epoxy group at C-7/C-8 or C-9/C-10, and type D trichothecenes possess an ester-linked macrocycle between C-4 and C-16. Trichothecenes from groups A and B are the most widely studied because they are detected in naturally contaminated foods (Côté et al. 1984). The structures of the best known trichothecenes are provided in Fig. 2.

Trichothecenes are nonvolatile and are very resistant to thermal and light degradation, which makes it difficult to remove these compounds during the industrial processes of food elaboration. However, there are several different methods that can be employed to modify their structures to produce less toxic derivatives.

Decontamination of Trichothecenes

Trichothecenes have proven to have high heat resistance (Pronyk et al. 2006) and to resist neutral and acidic pH conditions (Rocha et al. 2005). However, there are several approaches to decontaminate these compounds. The most effective way seems to involve the removal of the epoxy group at C-12/C-13 and/or the double bond at C-9/C-10, both of which are believed to play an important role in the toxicity of these compounds (Fig. 1).

15.2.1.1 Chemical Methods for the Decontamination of Trichothecenes

Oxidation Under Alkaline Conditions

The treatment of deoxynivalenol and nivalenol under alkaline conditions will lead to rupture of the 12,13-epoxy group or the elimination of the C-15 atom as formaldehyde through a retroaldol rearrangement (Bretz et al. 2006).

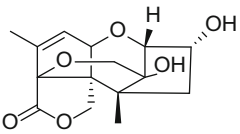

Fig. 3 Structure of Grove's lactone of DON

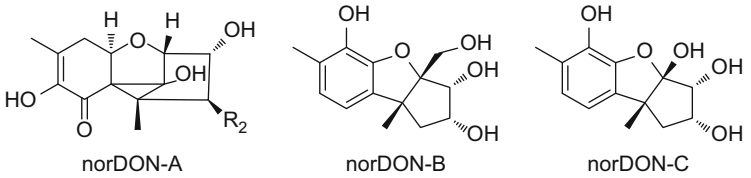

Fig. 4 Structures of the products obtained by treatment of DON under alkaline conditions at 75 °C

Alkaline hydroxylation of deoxynivalenol with 0.1 M methanolic NaOH at room temperature produces a rearrangement in the cyclohexene ring that would lead to the opening of the epoxide group to give a lactone (Fig. 3) (Grove 1985).

Grove et al. carried out the hydroxylation of deoxynivalenol at room temperature, but when the same reaction was carried out by Young et al. at 75 °C, the opening of the epoxy group produced different degradation products (Young 1986). Four new derivatives were detected, namely, norDON-A, norDON-B, norDON-C (Fig. 4), and traces of a compound believed to be the lactone described by Grove.

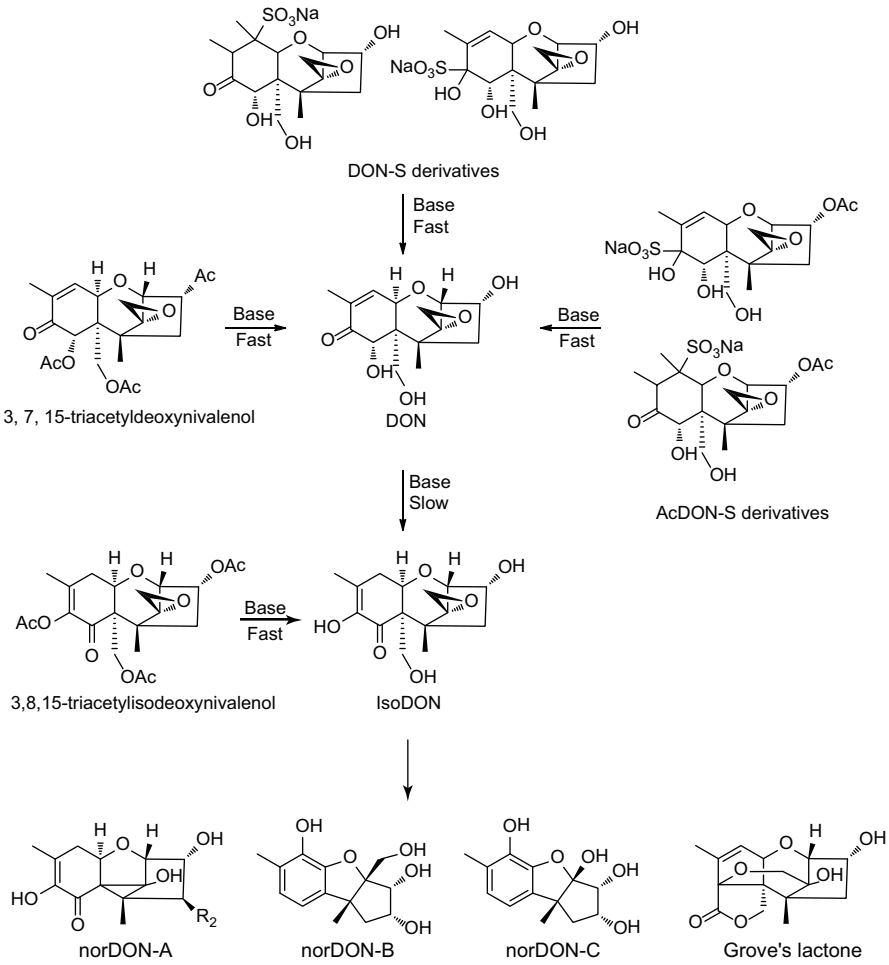
As shown in Scheme 1, alkaline hydroxylation under the same conditions of acetyl and sulfonate derivatives of deoxynivalenol led to rapid hydroxylation to form deoxynivalenol, which is subsequently converted to isodeoxynivalenol (isoDON) and then quickly degraded to the three norDON derivates shown. 3,7,15-Triacetyldeoxynivalenol displayed different behavior and was hydroxylated directly to isodeoxynivalenol (Young 1986). Similar results were obtained when nivalenol was treated under the same conditions, with the equivalent compounds formed for nivalenol of norDON-A, norDON-B, norDON-C, and Grove's lactone.

A process involving heating with *N*-α-acetyl-L-lysine methyl ester would also remove the epoxide group of deoxynivalenol to produce different derivatives (Bretz et al. 2006). In this work five known degradation compounds of deoxynivalenol were observed: isodeoxynivalenol, norDON-A, norDON-B, norDON-C, and Grove's lactone. Four new degradation compounds were observed: 9-hydroxymethyl DON lactone, norDON-D, norDON-E, and norDON-F (Fig. 5).

Oxidation of deoxynivalenol with NaOCl would not open the epoxide in positions C-12 and C-13 but would lead to the formation of another epoxide group at positions C-9 and C-10. An unusual 9α,10α-configuration and a hemiketal in positions C-8 and C-15 were observed (Fig. 6) (Burrows and Szafraniec 1987).

Ozonolysis

Ozonolysis of the trichothecene skeleton takes place at the C-9 and C-10 double bond. The degradation results in the opening of the cyclohexene ring by the mechanism presented in Scheme 2 (Young et al. 2006).



Scheme 1 Alkaline hydrolysis of acetyl and sulfonate derivatives of deoxynivalenol

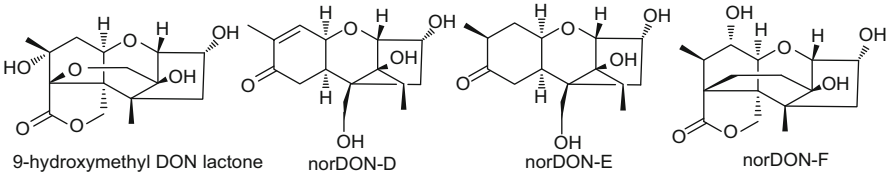


Fig. 5 Structures of 9-hydroxymethyl DON lactone, norDON-D, norDON-E, and norDON-F

Reduction

Reduction of trichothecenes with sodium bisulfite ($NaHSO_3$) and sodium metabisulfite ($Na_2S_2O_5$) produces derivatives with lower toxicity than the original

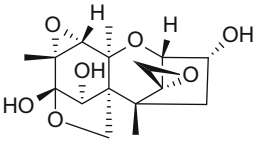

Fig. 6 Structure of the product obtained from the oxidation of DON with NaOCl

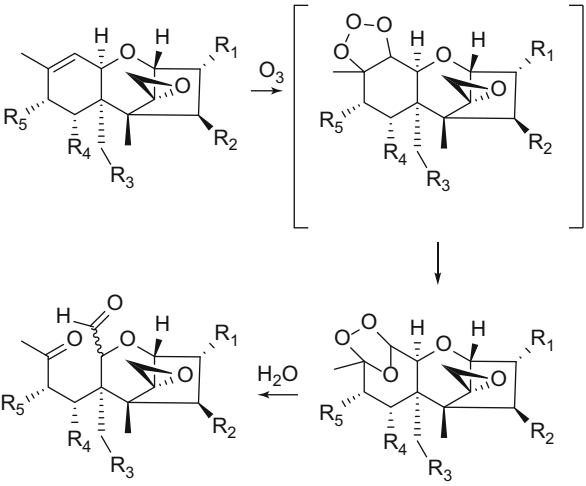

Scheme 2 Mechanism proposed for the opening of the cyclohexene ring during ozonolysis of trichothecenes

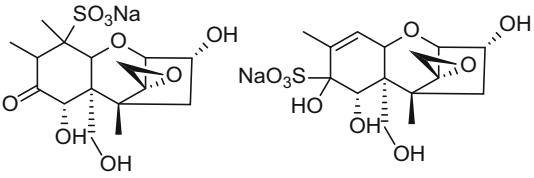

Fig. 7 Structures of deoxynivalenol sulfonate derivatives

trichothecenes. The reactivity of $Na_2S_2O_5$ with different trichothecenes has been studied (Young 1986), and this reaction produces different sulfonate derivatives. Bisulfites usually react with α,β-unsaturated enones in the keto- or β-positions. In the case of deoxynivalenol, the reduction gives sulfonate derivatives in positions 8 and 10 (Fig. 7).

The reaction seems to be influenced by the substituents on adjacent groups, and it is particularly fast in the cases of deoxynivalenol and nivalenol, which bear a hydroxyl group in positions C-7 and C-15, respectively. Nevertheless, the reaction is slower for 3,15-diacetyldeoxynivalenol, which has an acetyl group in position C-15. Isodeoxynivalenol, with an 8-enol-7-one system, reacted very slowly, and 3,8,15-triacetylisodeoxynivalenol did not react at all. These results seem to indicate that steric factors around the ketone group play an important role in the mechanism of the reaction. Similar results were obtained when the same reaction conditions were applied to nivalenol. The chemical environments of the α,β-unsaturated enones of different trichothecenes are shown in Fig. 8.

15.2.1.2 Biological Methods for the Decontamination of Trichothecenes

There are reports concerning biotransformations of trichothecenes by biological systems (Ueno et al. 1983; Westlake et al. 1987), and this offers an interesting and more environmentally friendly alternative for the detoxification of these compounds.

Oxidation

Animals catalyze the hydroxylation of type A trichothecenes produced by the addition of a hydroxyl group to position C-3′ of the substituent in the C-8 position (Corley et al. 1986). Thus, 3′-hydroxy T-2 toxin and 3′-hydroxy HT-2 toxin (Fig. 9) have been identified in different animals such as swine, cow, or rat. This hydroxylation reaction takes place in microsomes. Dihydronicotinamide adenine dinucleotide phosphate (NADPH) is required, and the reaction is catalyzed by cytochrome P450. The presence of a chemical called phenobarbital, which is produced in the liver, enhances the hydroxylation procedure (He et al. 2010).

Deoxynivalenol can also be oxidized by the soil bacterium strain E3-39 (*Agrobacterium-Rhizobium* spp.) to obtain a derivative known as 3-keto-DON

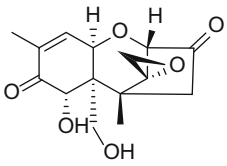

Fig. 10 Structure of 3-keto-DON

(Fig. 10) (Shima et al. 1997). This compound has shown immunosuppressive activity that is ten times lower than that of deoxynivalenol.

Reduction

As mentioned previously, the epoxide group at position C-12 and C-13 is responsible for the toxicity of trichothecenes. It has been shown that the de-epoxy forms of trichothecenes are less toxic than their respective trichothecenes; for example, de-epoxy deoxynivalenol (DOM-1) and de-epoxy nivalenol showed 54 and 55 times lower cytotoxic activity than their epoxy forms (Sundstøl Eriksen et al. 2004).

Many animals can metabolize trichothecenes and remove the epoxide group by reduction to a double bond. However, substitution in position C-4 has been shown to hinder this reaction. This is the case for T-2 toxin, diacetoxyscirpenol, and neosolaniol (NEO), which have an acetyl group in the C-4 position. Hydrolysis of this acetyl group is faster than the de-epoxidation, and this makes it difficult to detect the direct de-epoxy form. Cow rumen microorganisms metabolize deacetoxyscirpenol to give four products: 15-monoacetoxyscirpenol (15-MAS), scirpentriol (SCP), and their de-epoxy forms (DE 15-MAS and DE SCP) (Swanson et al. 1987a). On the other hand, bovine rumen microorganisms have metabolized T-2 toxin into de-epoxy HT-2 toxin (DE HT-2 toxin), de-epoxy T-2 triol (DE T-2 triol), and de-epoxy T-2 tetraol (DE T-2 tetraol), which were also less toxic than their original trichothecenes (Swanson et al. 1987b). The lethal doses to brine shrimp of T-2 toxin and deacetoxyscirpenol, as well as their epoxy and de-epoxy derivatives (Fig. 11) obtained from bovine rumen metabolization, are provided in Table 1 (Swanson et al. 1987b). There are also various nonruminant animals, such as rats, that can also reduce deoxynivalenol into DOM-1 (Yoshizawa et al. 1983).

Hydrolysis

Acetyl groups are common functional groups in the structures of trichothecenes. Their number and position play an important role in the activity of the compounds (Betina 1989). Hydrolysis of these acetyl groups is a common reaction in biochemical pathways involving animals and microorganisms (rumen microflora).

Deoxynivalenol, diacetoxyscirpenol, and T-2 toxin were treated with sheep rumen fluid, and this led to deacetylation of DAS and T-2 Toxin, but DON remained unaltered. As a result, DAS was transformed into 15-monoacetoxyscirpenol and T-2 toxin into HT-2 toxin. Sheep rumen fluid did not have any effect on DON (Kiessling et al. 1984).

Another example of hydrolysis can be found in *Curtobacterium* spp. Strain 114-2. This is a soil bacterium that can hydrolyze T-2 toxin into HT-2 toxin (He

et al. 2010), which is further hydrolyzed to T-2 triol. T-2 triol can subsequently be deacetylated to T-2 tetraol by the rumen bacterium strain BBSH 797 (Fig. 12) (Fuchs 2002).

Different strains of rumen bacteria like *Butyrivibrio fibrisolvens* (cow, deer, and sheep), *Selenomonas ruminantium*, and *Anaerovibrio lipolytica*, which can be isolated from ruminants (cow and sheep), have been tested on T-2 toxin. The results

show that these bacteria can metabolize T-2 toxin into HT-2 toxin, T-2 triol, and neosolaniol with different percentages of transformation (Westlake et al. 1987).

Hydration

In the hydration reaction, a molecule of water is consumed to add a hydroxyl group and a proton to an unsaturated substrate, e.g., an alkene. A strain of *Aspergillus* spp. (*NJA-1*) is able to transform deoxynivalenol into a product that has a mass 18.1 Da higher than DON (Chenghua et al. 2008). The authors suggested that the new molecule would be the result of a hydration reaction, but the chemical structure was not determined.

Conjugation by Glycosylation

In a glycosylation reaction, a glycosyl donor interacts with a glycosyl acceptor to produce a glycoside. Trichothecenes can be conjugated by glycosylation to form glucuronides and glucosides.

Trichothecene glucuronides are molecules formed by the union of a glucuronic acid and a trichothecene through a glycosidic bond, generally with a hydroxyl group located at C-3 of the trichothecene. The glucuronidation derivative seems to be produced by UDP-glucuronosyltransferases. Furthermore, cows are able to metabolize DON and DOM-1 into their glucuronide conjugates (DONGLU and DOM-1GLU) (Côté et al. 1986). On the other hand, swine have proven to be able to metabolize T-2 toxin to give glucuronide conjugates of HT-2 toxin, 3′-OH T-2 toxin, 3′-OH HT-2 toxin, and T-2 toxin among other metabolized products (Corley et al. 1985). Rats are also able to metabolize T-2 toxin and DAS to obtain the glucuronic HT-2 toxin, among other glucuronic derivatives of T-2 toxin. It is believed that a previous deacetylation occurs before the conjugation with glucuronic acid (Gareis et al. 1986), and the glucuronic derivatives of 15-MAS and scirpentriol were obtained from DAS.

Trichothecene glucosides are molecules that result from the union of a trichothecene and the anomeric carbon of a glucose through a glycosidic bond. A UDP-glycotransferase isolated from *Arabidopsis thaliana* catalyzes the transference of glucose from UDP-glucose to the hydroxyl group at C-3 of DON to produce DON-3-glucoside (Poppenberger et al. 2003).

Trichothecene glucuronide and glucoside derivatives of trichothecenes have lower toxicity than their non-derivated counterparts. A methylthiazole tetrazolium (MTS) cell viability assay to study the cytotoxic activity on a human erythroleukemia cell line K562 of DON and DONGLU showed that DON produced 50% inhibition of cell numbers at a concentration of 1.31 μM. In contrast, DONGLU did not show any relevant cytotoxicity up to 270 μM (Wu et al. 2007). The phytotoxic activities of DON and DON-3-glycoside to inhibit protein synthesis of wheat ribosomes was evaluated, and it was shown that DON-3-glycoside was less toxic than DON (Poppenberger et al. 2003).

Combination of Bioprocesses

There are numerous possible biotransformations of trichothecenes, and it is difficult to envisage that when an animal eats food, it will follow only one route of metabolization. On the contrary, the food undergoes different metabolization processes to give a variety of metabolites.

Côté (Côté et al. 1986) analyzed the ability of cow rumen fluid to reduce the epoxy group of DON to obtain DOM-1. However, it was found that cow rumen fluid possesses microorganisms that are capable of transforming 3-acetyldeoxynivalenol (3-ADON) into DOM-1, where DON is an intermediate product (Fig. 13) (King et al. 1984). Thus, deacetylation and de-epoxidation reactions take place in the process.

Eubacterium strain BBSH 797 is the most widely studied bacterium isolated from bovine rumen fluid, and it is responsible for the transformation of DON into DOM-1 (Schatzmayr et al. 2006), which is less toxic than DON. This strain can also transform type A trichothecenes through de-epoxidation and/or deacetylation (Fuchs 2002). T-2 toxin is hydrolyzed to HT-2 toxin in the presence of this strain. HT-2 toxin, T-2 tetraol, and scirpentriol experience a de-epoxidation to give their de-epoxy forms. T-2 triol is metabolized through two different paths: the first one leads to de-epoxy T-2 triol through a de-epoxidation and in the second path T-2 triol is hydrolyzed to T-2 tetraol. Finally, the de-epoxide form is reached.

Incubation of trichothecenes in the presence of fecal and intestinal microflora of different animals was carried out in anaerobic conditions, and this resulted in a diverse range of biotransformations (Swanson 1988). The results showed that rats, swine, and cattle completely transformed DAS into de-epoxy 15-monoacetoxyscirpenol and de-epoxyscirpentriol through a deacetylation and de-epoxidation pathway. Chicken, horses, and dogs managed to produce the deacetylation products (15-MAS and SCP) from DAS but failed to reduce the epoxide group. Rats showed a high metabolization activity to transform T-2 toxin into de-epoxy HT-2 toxin and T-2 triol, in addition to transforming T-2 tetraol and SCP into their de-epoxy forms.

It is important to note that the metabolization of trichothecenes may change markedly between animal varieties of the same species. For example, in contrast to the results obtained by Swanson et al., which were discussed in the last paragraph,

chickens showed an effective de-epoxidation of DON into DOM-1 (He et al. 1992). In another case, swine managed to transform DON into DOM-1 (Kollarczik et al. 1994), whereas metabolization was not observed (He et al. 1992).

The most important metabolization routes found for sesquiterpenes in cereals are summarized in Table 2.

15.2.2 Sesquiterpenes in Spices and Herbs

Among the bioactive compounds that have been identified in food (e.g., glucosides, fatty acids, monoterpenes, or diterpenes), sesquiterpenes are remarkable due to their

	Chicken, horse, and dog	15-MAS and SCP	Hydrolysis	Swanson (1988)

[a]It is important to note that in many cases during metabolization, T-2 toxin transforms into HT-2 toxin through a hydrolysis reaction, and from this point HT-2 toxin follows different metabolization routes. For this reason, even though only one transformation has been listed for HT-2 toxin in the table, more information about its metabolization can be found in the T-2 toxin data in the table.

prominent presence, the role they execute in the plant (and in the environment), and the wide range of activities that they have shown in numerous studies.

When sesquiterpenes are classified according to their skeleton, more than 100 families have been established. The structural variability of these compounds covers a wide range, with differences in the number and size of rings, the presence of aromaticity and/or functional groups, multiplicity of bonds, or isomerism. This

variety of structures provides this family of compounds with a wide range of activities that can provide health benefits when they are consumed in food.

Sesquiterpenoids have been widely studied in herbs and spices over the years because of the profitable properties that these foods show. Among the sesquiterpenoids present, the caryophyllane and humulene skeletons are the most common. Nevertheless, the variety of herbs employed in different cultures means that, within the spices group, there are more than 40 relevant sesquiterpenoids.

Among the sesquiterpenes found in spices and herbs, it is worth highlighting elemanes, cardinanes, drimanes, daucanes, guaianes, eudesmanes, and germacrenes.

15.2.2.1 β-Caryophyllene and Derivatives

β-Caryophyllene is one of the most relevant compounds. This sesquiterpene is related with spiciness in food and this explains its common presence (Jirovetz et al. 2002). The structure of β-caryophyllene contains a cyclobutane ring (Fig. 14), which is very unusual in nature, and only a few compounds such as pentacycloanammoxic acid (Mascitti and Corey 2006; Sinninghe Damste 2002) have this skeleton. In the case of α-humulene, previously known as α-caryophyllene, the morphology is similar to β-caryophyllene, but the cyclobutane ring has been opened (Vedernikov and Roshchin 2011). Other examples of humulene structures include zerumbone, which is obtained from ginger plants, and a relevant group of aziridine derivatives with promising anticancer activity have been synthesized (Gopalan et al. 2017).

Within the zerumbone compounds (Fig. 15), a large number of oxidized derivatives have attracted attention, and many new structures have been defined recently. Triepoxyzerumbol is one such compound and it is synthesized from zerumbone using a lipase catalyst. Another example is (2*R*)-tetrahydrozerumbone, which is prepared in a facile procedure with 5% Pd/C and H_2 from zerumbone. Furthermore, (2*R*)-tetrahydrozerumbone has a powerful balmy fragrance. Finally, 6,7-monoepoxyzerumbone can be obtained by oxidation of monoepoxyzerumbol, which is obtained by epoxidation of zerumbone with MCPBA (3-chloroperbenzoic acid) in ethyl acetate (Kitayama et al. 2007, 2008, 2012).

14-Hydroxy-β-caryophyllene, (*3Z*)-caryophylla-3,8(13)diene-5-ol, and caryophylla-4(12),8(13)diene-5-ol (Fig. 15) are oxygenated β-caryophyllene derivatives present in hops, and these are differentiated by the presence of a hydroxymethyl moiety at the cyclobutane or cyclononane ring (Praet et al. 2016).

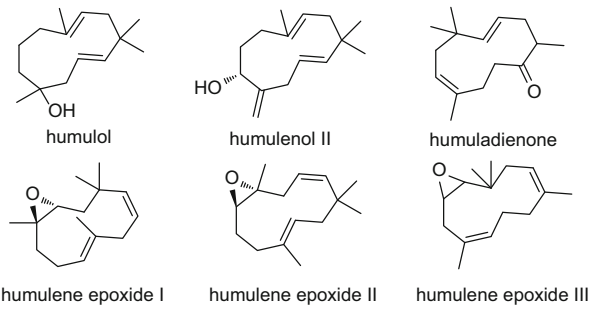

Fig. 16 Structures of humulene derivatives found in beer aroma (stereochemistry is not shown in cases where it is not known)

Hop essential oil also provides two important humulenes for beer aroma: humulenol II and humulene epoxide III. Besides, more humulene-skeleton products have been identified as minor components: humulol, humulene epoxides I and II, and humuladienone (Praet et al. 2016). The structures of these compounds are shown in Fig. 16.

15.2.2.2 Elemanes and Cadinanes

The elemane and cadinane families also cover a large number of spice sesquiterpenoids. The synthetic procedure for these compounds starts with a Cope sigmatropic rearrangement from 1(10),4-germacradienes (Barrero et al. 1999; Akatsuka et al. 1993), with the elemane configuration generally more stable than that of germacranes (Barquera-Lozada and Cuevas 2017). The principal skeleton of these compounds is a cyclohexene unit, like β-elemene and δ-elemene, in which a double bond has been displaced (Fig. 17).

Cadinanes are formed by two fused six-membered rings with an isopropyl group on the carbon next to the fusion point. Cubenol and calamenene are among the main cadinanes present in herbs, such as *Mentha* spp., and they have recently

Oxygenated sesquiterpenes	Spathulenol Caryophyllene oxide Viridiflorol Ledol β-Eudesmol α-Eudesmol α-Cadinol

shown repellent activity against *Curculionidae* Coleoptera (Espinoza et al. 2016) and human benefits that will be discussed later. These cadinanes are also of chemical interest, and some derivatives of natural calamenene have been reported to be formed by an intramolecular Friedel–Crafts-type Michael addition (Sun et al. 2010).

β-Elemene can be found in bay leaf (Table 3), and γ-elemene is present in peppermint essential oil as the second major sesquiterpene after β-caryophyllene (Orav and Kann 2001).

15.2.2.3 Drimanes and Coloratanes

The drimane sesquiterpene skeleton also contains two fused six-membered rings, but it is characterized by a higher number of methyl substituents (Fig. 18). These usually have a highly oxidized structure, as in the case of *Warburgia ugandensis* and *W. stuhlmannii*, from which three dialdehyde drimanes have been isolated. Furthermore, the natural product drimenal, which has antifungal and antibacterial activities, has recently been synthesized (Li et al. 2018a). Muzigadial has also been isolated from *Warbugia* spp. together with polygodial, warbuganal, and ugandensidial, and it has a coloratane carbon sesquiterpene structure (Kubo and Ganjian 1981).

A new derivative of polygodial, 1-(*R*)-hydroxypolygodial, has recently been synthesized, and this has shown relevant results against vanilloid receptors in HEK cells. The different locations of hydroxyl groups in polygodial derivatives were tested, and only the 1-(*R*)-hydroxy derivative showed bioactivity (D'Acunto et al. 2010).

15.2.2.4 Guaianes, Daucanes, and Aromadendranes

Within the sesquiterpenoids, guaiane structures are broadly distributed as secondary metabolites in plants. Sesquiterpene lactones are a specific family of sesquiterpenoids that show wide biological activities in different respects and living organisms (Macías et al. 2007). The skeleton has a five-membered ring fused with a seven-membered ring that has an isopropyl group in the β-position to ring fusion. The presence of double bonds in the cycloheptane ring, along with their number and location, provides a wide variety of guaiane structures (Fig. 19). A good example is α-bulnesene and α-guaiene which have a double bond in different locations. These two molecules are present in black pepper (Nikolic et al. 2015) and also in sweet basil (Nurzyńska-Wierdak 2012). Rotundone is a sesquiterpene derived from the oxidation of α-guaiene, and it is differentiated by the presence of a carbonyl group in

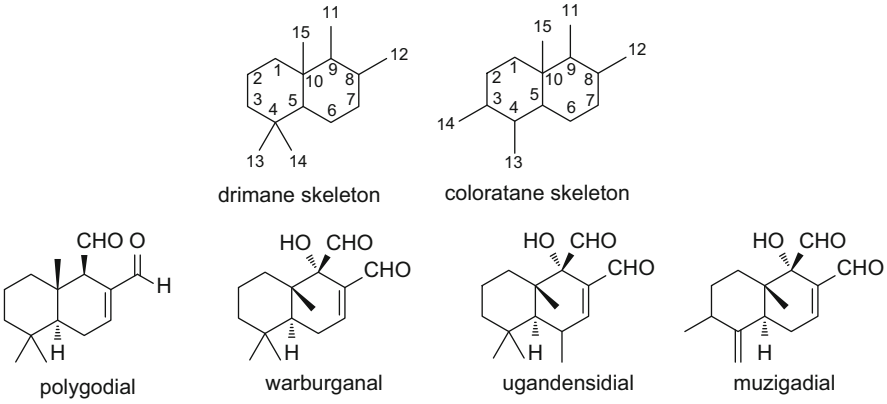

Fig. 18 Drimane skeleton (top left), coloratane sesquiterpene structure (top right), and four relevant drimanes and coloratanes found in ginger plants

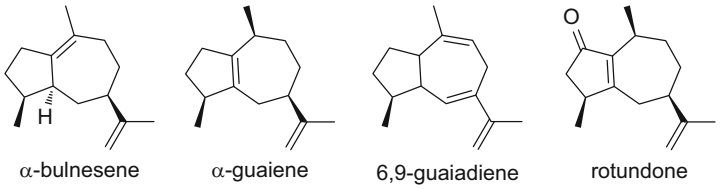

Fig. 19 Numerous structures arise from the variation of the number and location of double bonds in the cycloheptane ring

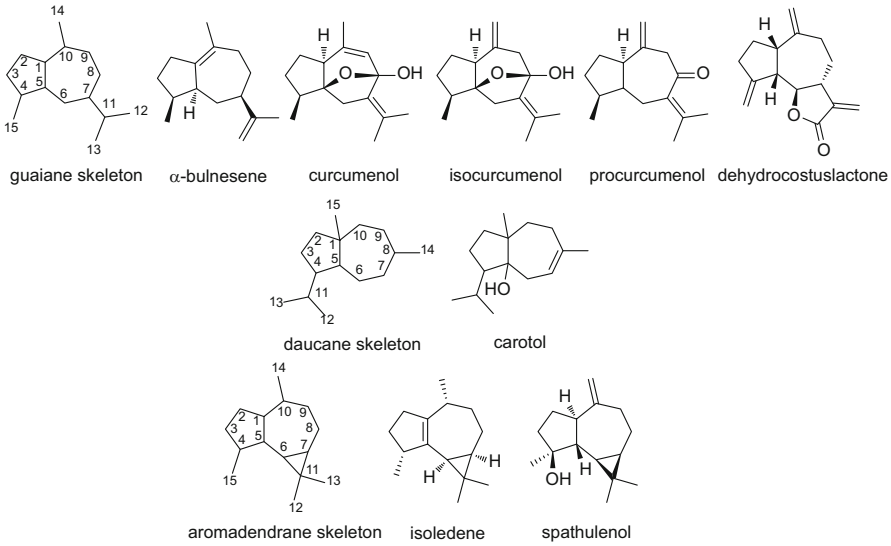

Fig. 20 Guaiane-type sesquiterpene structure (top left) and relevant guaianes isolated from herbs (top right). Daucane skeleton (middle left) and daucanes found in Chinese spice. Aromadendrane skeleton (bottom left) and relevant aromadendrenes isolated from herbs

the pentene ring. Rotundone contributes significantly to pepper aroma, and it also provides characteristic aromas in red wines made from Shiraz grapes. The odor detection threshold of this compound is one of the lowest of all natural products (Wood et al. 2008).

A relevant guaiane sesquiterpene synthesized by holy basil (*Ocimum sanctum*) is α-bulnesene (Suanarunsawat et al. 2009, 2010). Notwithstanding, the highest number of guaianes are isolated from turmeric plants (Zingiberaceae family), which contain curcumenol and related derivatives (Morikawa 2007) (Fig. 20). Daucane-type sesquiterpenoids are very similar to guaiane and differ only in a translocation of the isopropyl group in the five-membered ring and a rearrangement of the positions of the methyl groups. Carotol, isolated from *Alpinia guinanensis* (a food spice in China), is an example of a daucane found in food (Deng et al. 2016).

Aromadendranes have a similar carbon skeleton to guaiane-type compounds, but the most oxidized carbon of the isopropyl group is linked to the seven-membered ring to create a cyclopropane (Fig. 20). These three fused rings (cyclopropane, cycloheptane, and cyclopentane) shape aromadendrane sesquiterpenes. Isoledene is a major aromadendrane in *Mentha* spp. (Park et al. 2016), and spathulenol is the main constituent of the essential oil of *Satureja avromanica* (Iranian spice). Aromadendranes generate guaine sesquiterpenes by a ring opening of the cyclopropane, which leads to the formation of an isopropyl group. This can be easily observed when isoledene is treated with HSO_3F-SO_2FCl or $BF_3{\cdot}Et_2O$ to generate isoguaiene (Moreno-Dorado et al. 2003).

15.2.2.5 Eudesmanes, Secoeudesmanes, and Eremophilanes

Eudesmane-type sesquiterpenoids have a similar skeleton to cadinane, but the isopropyl group is found in the β-position with respect to ring fusion, and these compounds are characterized by a methyl group at C-10.

α-Eudesmol and β-eudesmol (Fig. 21) are two eudesmanolides with a hydroxyl group on the isopropyl group. Both molecules are present in bay leaf, as detailed in

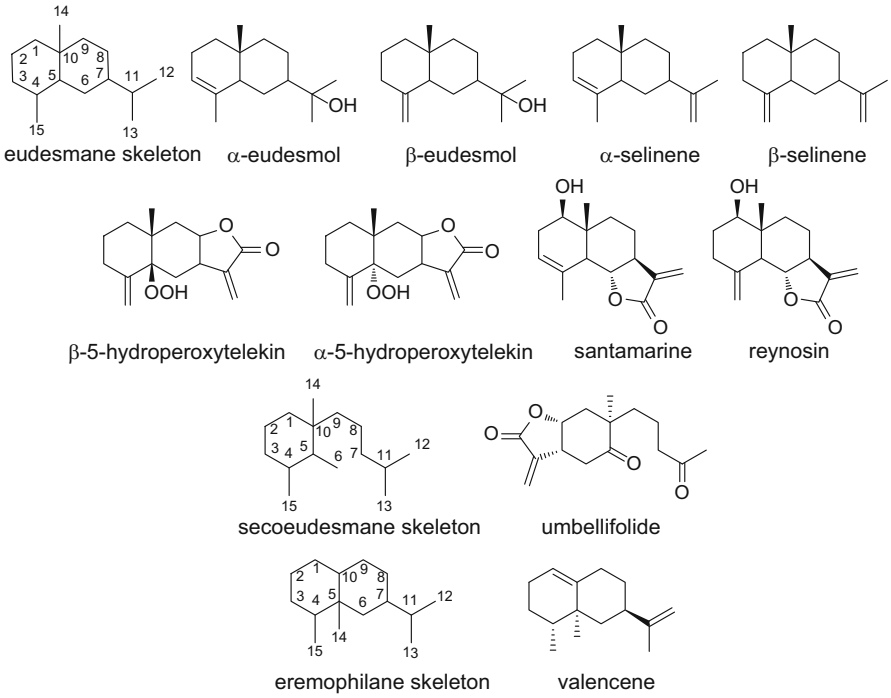

Fig. 21 Eudesmane-type sesquiterpene skeleton (top left) and some interesting eudesmanes found in spices (top right). Secoeudesmane-type sesquiterpene skeleton (middle left) and one of the secoeudesmanes isolated from *A. umbelliformis* (middle right). Eremophilane carbon skeleton (bottom left) and an important compound of this family isolated from herbs (bottom right)

Table 3. β-Eudesmol is also one of the most important compounds in hop (*Humulus lupulus*) used in beer making (Kishimoto et al. 2005). α-Selinene and β-selinene (Fig. 21) are two of the major components of the vegetable mitsuba (Okuno et al. 2017). These compounds are analogous to eudesmol but they lack a hydroxyl group.

Hydroperoxyeudesmanes, such as telekin derivatives, are unusual in nature (Fig. 21). In addition, due to their oxidative nature, they should be avoided in food or drink. Both α- and β-5-hydroperoxytelekins are hydroperoxyeudesmanolides (the -lide suffix indicates a lactone ring fused to the structure) present in *Artemisia umbelliformis*, which is used to generate alcoholic drinks. Apart from these compounds, the secoeudesmane skeleton is also found in *A. umbelliformis*. The seco- prefix indicates a ring aperture in the principal structure (Fig. 21), and a wide variety of natural products have this motif (Cappelletti et al. 1986; Cheng et al. 2014). On the other hand, eremophilanes have the same carbon skeleton as eudesmane, but with a methyl group rearranged. Valencene is a representative compound of this family, and it is commonly isolated from sweet orange. Furthermore, the relevance of this compound as a food flavor has led to an important industrial and biotechnological production (Frohwitter et al. 2014). Valencene is a component of the volatile compounds of citrus fruits, and it is present in orange peel, pulp, and juice (Orav and Kann 2001).

15.2.2.6 Germacranes

Germacranes are the most abundant sesquiterpene-type compounds in herbs. There are different subgroups within the germacrane family, and these include furangermacranes (Chen et al. 2005) and norgermacranes (Nevalainen and Koskinen 2002). Recently, two furan derivatives were isolated from *Curcuma zedoaria* (Matsuda et al. 2001), namely, furanodienone and glechomanolide (Fig. 22). Nevertheless, the most common compounds in this class are simple germacranes. These are characterized by a ten-membered ring with an isopropyl group in C-7 and two methyl

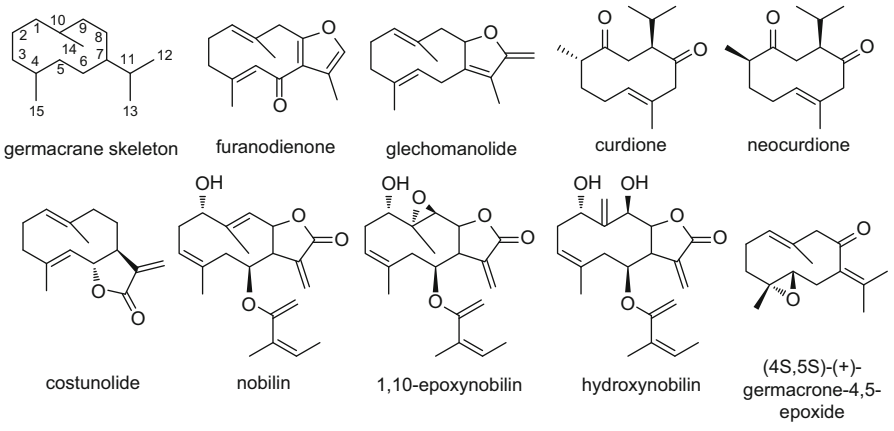

Fig. 22 Germacrane-type sesquiterpenoid (top left) and most relevant germacrenes in herbs

groups. Nobilin and its epoxy and hydroxyl derivatives are important germacrenes with antioxidant activity, and these can be isolated from chamomile extracts by supercritical fluid chromatography (Jones et al. 2014). Curdione and neocurdione (Fig. 22), as well as the previously mentioned curcumenol and isocurcumenol, were isolated from Zingiberaceae plants, and these two germacrenes have medicinal applications in cancer therapy. This kind of anticancer activity is found in costunolide, a well-known sesquiterpene lactone that can be isolated from *Artemisia umbelliformis*, which is used to distill Genepì liquor (Vouillamoz et al. 2015).

15.2.2.7 Other Structures

The sesquiterpenoids discussed above are the most relevant compounds in spices. Nevertheless, there are other sesquiterpenes with different types of carbon skeleton. The spatial arrangement is difficult to envision – for example, α-copaene found in laurel (*Laurus nobilis*) (Fig. 23) is a copaane with two fused six-membered rings and a twisted cyclobutane. This kind of crooked ring seems to be common, and examples include *trans*-α-bergamotene (bisabolane skeleton) found in basil oils or β-bourbonene (sesquiterpene-type bourbonane) found in *Satureja avromanica*, a spice used in Iran, *Mentha piperita*, and milk (Fernandez et al. 2003). More complex arrangements are uncommon, but they have an unexpectedly high stability, e.g., anisatin (Charonnat et al. 1996), a prezizaane found in the Japanese star anise (*Illicium anisatum*) (Ottesen and Magnuson 2010).

The total synthesis of α-copaene was achieved in 1992 by Wenker and co-workers. This synthesis starts with 5-isopropyl-2-methylphenol and involves more than 20 steps to obtain the target copaane (Wenkert et al. 1992). As mentioned

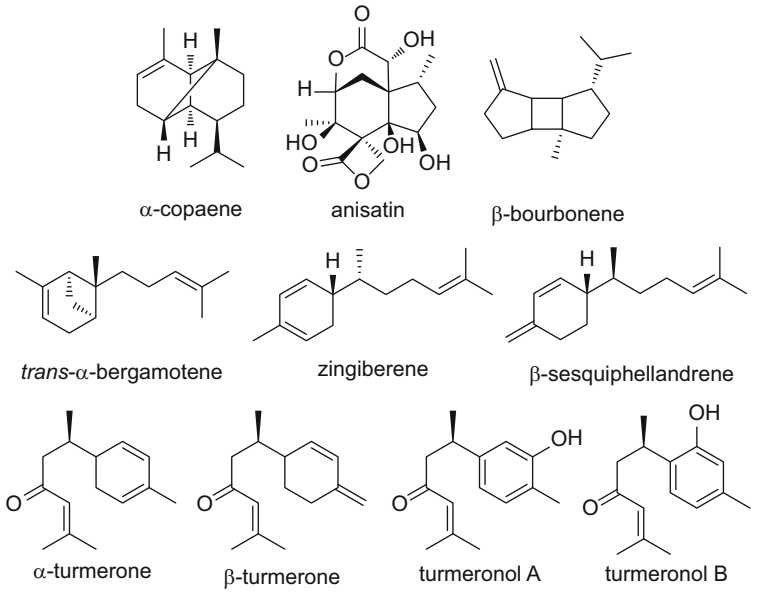

Fig. 23 Less common sesquiterpenoids found in herbs

previously, the syntheses of these natural products are not short or efficient. Another example is the β-bourbonene synthesis. Corbella et al. tried to prepare bourbonane by Beereboom's procedure, but this proved unsuccessful. However, in 1987 Kulkarni and co-workers devised a [2 + 2] photochemical cycloaddition as a key step to obtain the target sesquiterpene (Fig. 23) (Kulkarni et al. 1987).

Zingiberene and β-sesquiphellandrene (Fig. 23), both bisabolanes, are major sesquiterpenes found in ginger (*Zingiber officinale*), and they are important constituents of this spice (Govindarajan and Connell 1983). Some bisabolanes have also been isolated from fruiting bodies of the edible mushroom *Pleurotus eryngii*, which is endemic in Mediterranean areas, Central and Southern Europe, and Central and Western Asia (Kikuchi et al. 2018).

Rhizomes of curcumin are a source of turmeric, one of the most common spices used in cooking. Among turmeric constituents, the major components found in rhizomes are sesquiterpenes, and these impart aromatic properties. Four important sesquiterpenes have been identified: α-turmerone, β-turmerone, turmeronol A, and turmeronol B (Fig. 23) (Gupta et al. 2013).

Cedranes (Fig. 24) are less common sesquiterpenes in food, and their skeleton provides molecules with several types of biological activity (Tajabadi et al. 2018). Traces of cedrene have been identified as the volatile compound of sweet basil (Nurzyńska-Wierdak 2012). α-Cedrene epoxide has been reported as one of the main compounds in the mushroom *L. hatsudake* (Miyazawa et al. 2010).

L. hatsudake also produces a sesquiterpene with some similarity to cedrene, namely, the sesquiterpene-type clovane (Fig. 24) (Miyazawa et al. 2010).

Longifolanes (Fig. 24) are a family of tricyclic sesquiterpenes. Among these sesquiterpenoids, isolongifolanone can be found in certain foods such as mushrooms (*L. hatsudake*), in which is the major compound (Miyazawa et al. 2010). This product, which can be synthesized by oxidation of longifolene, allows the preparation of interesting derivatives that have shown positive fluorescence properties for sensing acidic pH (Wang et al. 2018).

Himachalenes (Fig. 24) contain a cyclohexane linked with a cycloheptane ring in positions 1 and 6. Like cedranes, these compounds are not representative families in food although traces of himachalol have been identified in some species of sweet basil (Nurzyńska-Wierdak 2012).

As shown above, a huge range of structures are present in spices, and it is difficult to envisage that only one kind of sesquiterpene could be present in any spice. On the contrary, it is common that numerous different types of sesquiterpene are present in the same spice.

In sweet basil many sesquiterpenes have been identified and quantified, with *trans*-α-bergamotene, germacrene D, and *epi*-α-cadinol being the major ones (Nurzyńska-Wierdak 2012). Bay leaf (*Laurus nobilis*) has a great wealth of sesquiterpenes (Table 3) (Peris and Blazquez 2015). In some species of sweet basil traces of the cadinenes, *cis*-muurola-4(14),5-diene and *cis*-muurola-3,5-diene (Nurzyńska-Wierdak 2012) have been isolated, and the latter compound has been also identified in the false truffle *Gautieria morchelliformis* (D'Auria et al. 2014).

Peppermint essential oil also provides β-farnesene, δ-cadinene, germacrene D, and germacrene-4-ol. δ-Cadinene is also present in sweet basil, orange juice, and orange soft drinks.

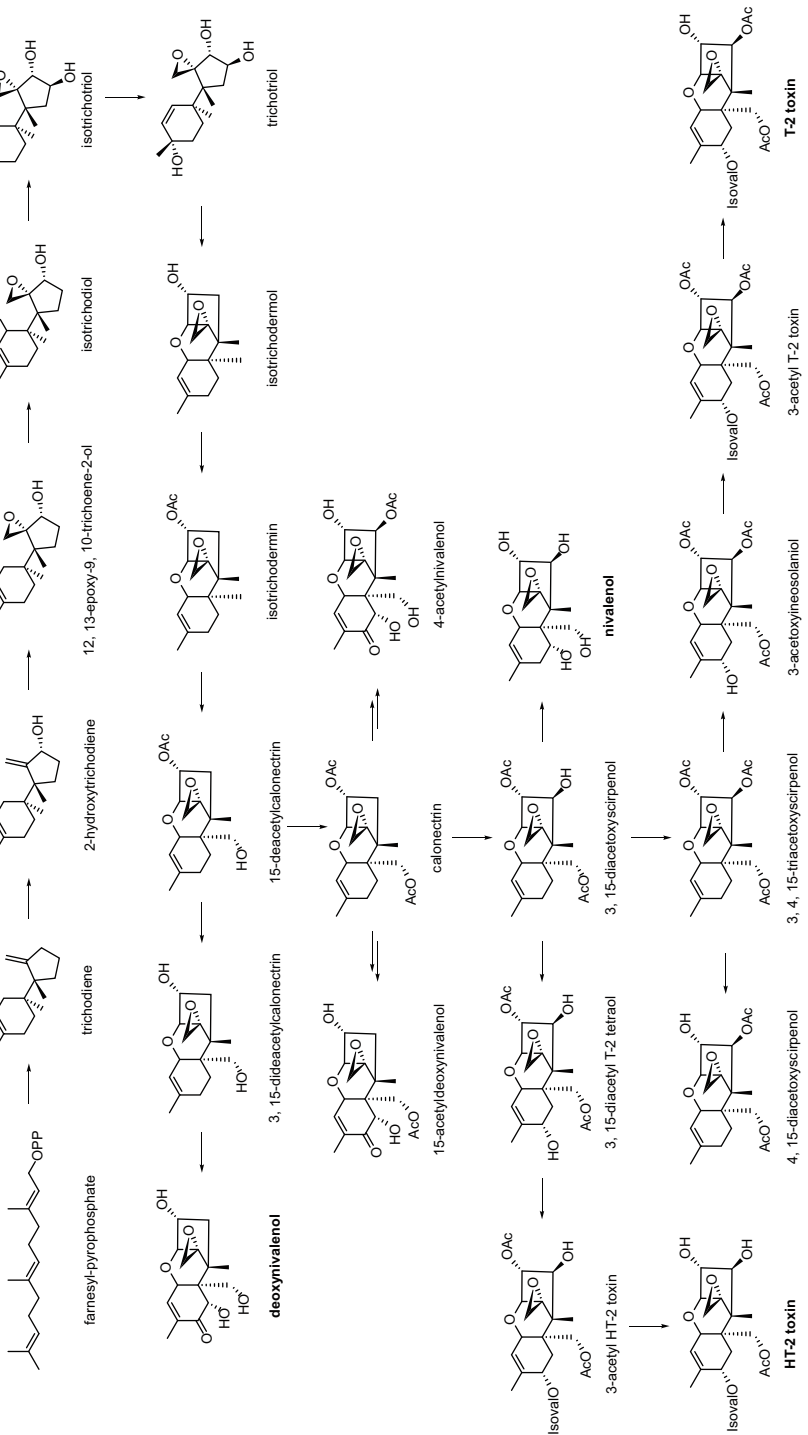
15.2.3 Biosynthetic Route

15.2.3.1 Biosynthetic Route to Trichothecenes

The biosynthesis of trichothecenes (Scheme 3) starts from farnesyl pyrophosphate, which cycles into trichodiene. Trichodiene has been isolated from *Trichothecium roseum*, and different studies have suggested that this molecule is a precursor of the trichothecenes produced by this species. A monooxygenase is responsible for the transformation steps to obtain isotrichotriol from trichodiene.



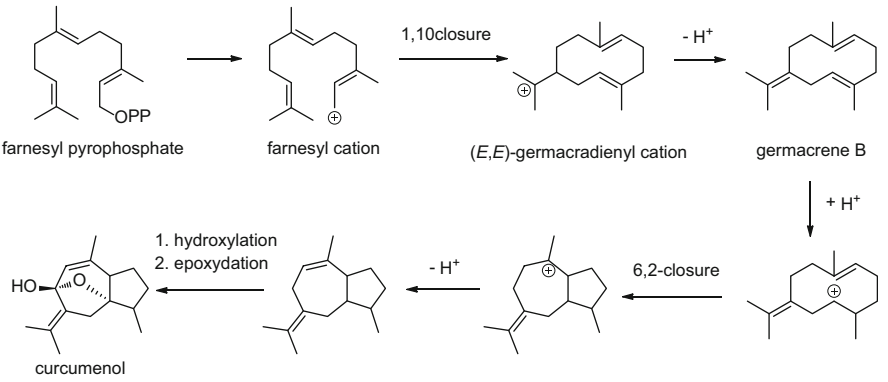
Scheme 3 Trichothecene biosynthesis. The molecules have been identified in different *Fusarium* species. Reproduced with the permission of (Foroud and Eudes 2009)

Numerous studies have been carried out to learn more about the biosynthetic pathway to trichothecenes. Among them, the treatment of strains of *Fusarium sporotrichioides* with oxygenase inhibitors should be highlighted (Desjardins et al. 1988) as this results in the inhibition of trichothecene production and an accumulation of trichodiene. This suggests that trichodiene is, indeed, a precursor of trichothecenes produced by *Fusarium* species. In the next steps, isotrichotriol undergoes two isomerization reactions. The first reaction involves the migration of the hydroxyl group from C-11 to C-9 to give trichotriol. The second reaction is a cyclization that occurs between C-11 and the oxygen atom located at C-2 to give isotrichodermol, which has the trichothecene skeleton structure. Isotrichodermol can also undergo an acetylation at C-3 and a subsequent hydroxylation at C-15 to produce 15-deacetylcalonectrin. From this point, 15-deacetylcalonectrin can follow different transformation pathways to give different trichothecenes. A hydroxylation at positions C-3 and C-7 and a ketone group addition at C-8 would produce DON.

Acetylation of 15-deacetylcalonectrin at C-15 leads to calonectrin, which is a substrate for other trichothecenes. Hydroxylation of calonectrin at C-4 produces 3,15-diacetoxyscirpenol, which can produce nivalenol, T-2 and HT-2 toxins. Nivalenol is produced by different hydroxylations and the addition of a ketone at C-8. T-2 and HT-2 toxin are obtained in different acetylation and hydroxylation reactions at C-3, C-4, and C-8 with subsequent addition of an isovalerate group at C-8. Concurrently, calonectrin and 3,15-diacetoxyscirpenol act as substrates for different deoxynivalenol and nivalenol derivatives.

15.2.3.2 Biosynthetic Route to Sesquiterpenes in Spices and Herbs

In the same way as for all sesquiterpenes, the first step involves farnesyl pyrophosphate, which undergoes two sigmatropic rearrangements to generate the guaiene skeleton (Kumeta and Ito 2010). In the case of curcumenol, a 6,2-closure reaction takes place, and a wide range of synthetic possibilities arise, with the emergence of functional groups. Nevertheless, a 1,10-closure step can give rise to different sesquiterpene skeletons, such as daucane or germacrenes (Scheme 4). Cadinanes are



Scheme 4 Biosynthetic pathway for curcumenol (guaiene)

a special case, and a sesquiterpene synthase has recently been discovered that belongs to the terpene synthase-a (TPS-a) clade and this catalyzes the formation of mainly cadinanes. This discovery was made possible by RNA sequencing to profile the transcriptome of *Laurus nobilis*. This plant, otherwise known as bay laurel, contains a broad range of sesquiterpenes: δ-elemene, β-elemene, β-caryophyllene, germacrene D, and α-bisabolene (Yahyaa et al. 2015).

Labeling experiments conducted with deuterium oxide showed that cadinane sesquiterpenes, such as cadalene, are mainly produced by protonation of the neutral intermediate germacrene D. This finding, which was developed by Garms and co-workers, provides an alternative pathway to the generally accepted one, which involves nerolidyl phosphate (Garms et al. 2010).

15.2.4 Analysis Techniques

15.2.4.1 High-Performance Liquid Chromatography (HPLC)

Trichothecenes can be detected without derivatization. However, the ultraviolet (UV) absorption of these compounds is weak, and detection is therefore difficult. Type B trichothecenes possess a conjugated enone system that enables their detection using a UV detector (Visconti and Bottalico 1983). Type A trichothecenes lack such a chromophore, and it is therefore necessary to use another type of detector, e.g., a refractive index detector (Schmidt and Dose 1984). DON has been detected in contaminated corn at levels of 5–10 ppb (Ehrlich et al. 1983). T-2 and HT-2 toxin were also detected by HPLC on rice samples (Schmidt 1981).

As stated above, in some cases detection of these compounds is difficult, and a derivatization step is required prior to analysis. Trichothecenes contain numerous hydroxyl groups, and these can be transformed into other groups with a strong UV absorption.

Trichothecenes can be treated with *p*-nitrobenzoyl chloride in the presence of 4-dimethylaminopyridine (4-DMAP) to obtain the corresponding trichothecene *p*-nitrobenzoate derivatives, which can be detected at 254 nm (Utley and Maycock 1985). Another procedure involves esterification of the hydroxyl groups using coumarin-3-carbonyl chloride, with the resulting trichothecene derivatives detected using a fluorescence spectrophotometer (Cohen and Boutin-Muma 1992).

Notwithstanding, the analysis of trichothecenes by HPLC is most commonly carried out with a mass detection system, and the most commonly reported are thermospray (Rajakylä et al. 1987) and fast atom bombardment (Kostiainen 1991).

15.2.4.2 Supercritical Fluid Chromatography (SFC)

Supercritical fluid chromatography-tandem mass spectrometry (SFC-MS/MS) allows the detection of trichothecene mixtures using supercritical CO at 100 °C as the mobile phase, without a derivatization step (Kalinoski et al. 1986; Roach et al. 1989; Smith et al. 1985). Both positive chemical ionization and negative ion chemical ionization were studied.

A SFC-MS/MS technique in which ammonia is used for chemical ionization allowed the separation of a DON, DAS, and T-2 toxin mixture with a picogram-range detection limit (Smith et al. 1985). In other studies this technique was used to detect DAS and T-2 toxin at ppm levels in wheat samples (Kalinoski et al. 1986).

Nobilin and 1,10-epoxynobilin have also been separated by supercritical fluid chromatography. Columns with sub-2 μm particles were employed because a smaller particle size stationary phase provides a reduced analysis time and increases the resolution and sensitivity. The column temperature was maintained at 50 °C and the temperature of the sample was 15 °C. The mobile phase employed to separate these two germacranes consisted of CO_2 as solvent A and methanol/isopropanol (1:1) as solvent B (Jones et al. 2014).

15.2.4.3 Gas Chromatography (GC)

The boiling points of sesquiterpenes are relatively low, and a gas chromatograph linked to a mass spectrometer is one of the most common systems used to identify sesquiterpenes (as well as other natural products like alcohols or aldehydes) in volatile oils isolated from different parts of the plant. Identification is achieved by comparison of mass patterns and retention indices (RI) with library data. A flame ionization detector (FID), which provides high sensitivity and low background noise, is the usual detector employed for these analyses.

Gas chromatography is the most widely applied method for the analysis of trichothecenes. Analysis of trichothecenes without derivatization is possible (Stahr et al. 1979), and different detectors can be used, with the electron capture detector (ECD) and mass detection being the most common.

Analysis of non-derivatized trichothecenes using oxygen negative chemical ionization gas chromatography/mass spectroscopy permitted the detection of DON, DAS, T-2 toxin, and HT-2 toxin among other trichothecenes in different food samples. The detection limit reached picogram levels (Miles and Gurprasad 1985).

Despite the fact that direct analysis of trichothecenes without derivatization is possible, most gas chromatography methods for the determination of trichothecenes in food include the derivatization of the hydroxyl groups of the molecules. The derivatization step increases the volatility of the sample and the sensitivity of the analysis.

There are two main derivatization processes used in the analysis of trichothecenes: the first involves silylation of the hydroxyl groups to form the trimethylsilyl (TMS) ethers (Ikediobi et al. 1971) and the other is the formation of fluoroacyl derivatives (Seidel et al. 1993).

Different detectors can be used in the analysis of trichothecenes, but the most common ones are an ECD or a mass detector.

ECD is a very sensitive and selective detector for trichothecenes (Kuroda et al. 1979). The conjugated carbonyl group of type B trichothecenes makes them sensitive to ECD, while for type A trichothecenes, formation of the fluoroacylation derivatives is recommended to obtain a greater sensitivity (Croteau et al. 1994).

Different mass detectors can be used in combination with gas chromatography, and the choice depends on the particular objective. The electron impact detector has

a detection limit of 0.1–1 ng, but the EI spectra provide limited structural information. Positive chemical ionization (PCI) analysis is more useful for qualitative identification (Mirocha et al. 1986) since it provides fewer fragments, and the more distinct ones allow the identification of the different trichothecenes. Negative ion chemical ionization (NICI) has also been applied in the determination of trichothecenes, and a higher sensitivity has been reached with this technique, which allows detection limits of femtograms to be achieved (Krishnamurthyt et al. 1986).

15.2.4.4 Countercurrent Chromatography (CCC)

Elemanes, and particularly β-elemene, have been selectively separated by countercurrent chromatography. The separation was carried out on the crude oil of *Curcumae Rhizoma*. Silver ions were employed to generate coordination complexes, which facilitate a better separation procedure. The selected solvent system was n-hexane/methanol/0.15 M silver nitrate (2:1.5:0.5 v/v/v). The results showed that β-elemene was eluted with other impurities, and silica gel column chromatography was therefore employed to remove them before CCC was applied. A total of 145 mg of β-elemene with >99% purity was obtained from 445 mg of partially purified β-elemene (Lu et al. 2017).

Costunolide has a similar polarity to another sesquiterpene in *Aucklandia lappa* and *Saussurea lappa*, so this compound is difficult to isolate and purify. Nevertheless, Li et al. developed a new method in high-speed countercurrent chromatography techniques to separate these components. The separation conditions provided a difference in retention time of more than 20 minutes between the compounds. 35.7 mg of costunolide and 43.6 mg of dehydrocostuslactone with 100% purity were isolated from 110 mg of crude product on using light petroleum/methanol/water (5:6.5:3.5 v/v/v) as the two-phase solvent system (Li et al. 2005).

15.3 Bioavailability and Metabolism

The incorporation of sesquiterpenoids in the human metabolic system can be difficult due to the solubility and bioavailability of the compounds. These terpenoids must fulfill certain physicochemical requirements before exercising their action, for example, as medicinal or antioxidant agents. Absorption, distribution, metabolism, and excretion (ADME) are the physicochemical aspects in question, and they also encompass solubility, lipophilicity, stability, and acid-base character. When a given sesquiterpene shows acceptable values for these characteristics, then the bioactive action will occur (Durán et al. 2018).

As mentioned above, solubility in water is an important factor in sesquiterpene metabolism. However, due to the wide variety of structures of sesquiterpenes, the presence of different functional groups that enhance solubility is frequent. These groups include hydrogen bond acceptors such as aldehyde or hydroxyl groups. The increase in solubility also improves the bioavailability in aqueous media, which is

the principal medium in the human body. Nevertheless, these groups are responsive to attack by acids in protic media, e.g., the stomach medium.

15.3.1 Bioavailability and Metabolism of Trichothecenes

Several studies have been performed to gain information on the metabolism of trichothecenes in mammals. These compounds are usually metabolized rapidly following different transformation paths. There are four main routes for metabolization. The first three are hydrolysis (Bauer et al. 1985; Corley et al. 1986), conjugation with glucuronic acid (Corley et al. 1985; Gareis et al. 1986), and hydroxylation (Knupp et al. 1987; Yoshizawa et al. 1985). These routes produce a wide variety of metabolites from trichothecenes, and these are less toxic than the original trichothecene.

The fourth metabolization route, and the one believed to represent a true detoxification, is the de-epoxidation of the epoxy group at C-12 and C-13. De-epoxy derivatives of DON and NIV are 54 and 55 times less toxic than DON and NIV, respectively. Some animals, including ruminants and rats, are able to reduce the epoxide group of the trichothecenes and subsequently remove them without suffering damage. Some research results have shown that the rumen microflora is able to reduce the epoxide group of the trichothecenes (Chatterjee et al. 1986; Swanson et al. 1987a) to give de-epoxy derivatives. Other studies have shown that rats excrete a high percentage of orally ingested trichothecenes as their de-epoxy derivatives (Sakamoto et al. 1986; Swanson et al. 1988).

15.3.1.1 T-2 Toxin and HT-2 Toxin

Since T-2 toxin is quickly metabolized into HT-2 toxin and their toxicity is similar, they are discussed together.

After ingestion, T-2 toxin is quickly absorbed and it is evenly transported in the organism. Tritium-labeled T-2 toxin was intravenously injected into swine, and 4 hours later 15–24% of the labeled toxin was found in the gastrointestinal tract. Approximately 5% of the toxins were found in other tissues, mainly the muscle and liver (Corley et al. 1986).

The main metabolization pathway that T-2 toxin follows is a quick deacetylation in position C-4 leading to HT-2 toxin. This reaction takes place mainly in the liver and it is catalyzed by a non-specific carboxyesterase (Johnsen 1988). HT-2 toxin is then further metabolized by different pathways and eliminated. T-2 toxin metabolite products are excreted via urine and feces. Depending on the species, differences in the proportions were observed (Eriksen and Alexander 1998).

15.3.1.2 Deoxynivalenol

DON in plasma is quickly and evenly distributed in the organism. DON was detected in many tissues 30 minutes after its intravenous injection in swine. The highest levels were detected in the liver and kidney, but lower concentrations were also found in many other tissues, including the brain, testes, heart, intestine, and spleen (Prelusky and Trenholm 1991).

DON can follow different metabolization pathways. However, the de-epoxidation to form DOM-1 is the most interesting pathway, as the toxicity of DOM-1 is much lower than that of DON. DOM-1 is a common metabolization product in rats (Yoshizawa et al. 1983). Cow rumen is able to reduce the epoxy group of DON to give DOM-1 (Côté et al. 1986). In this study, most DOM-1 was excreted in urine and feces. It is important to highlight that small residues of DOM-1 were found in the milk produced by cows that were fed with DON contaminated food.

15.3.1.3 Nivalenol

A diet rich in nivalenol was employed to feed swine, and the detection of the toxin in blood was achieved only 20 minutes after ingestion, thus showing a fast absorption. However, this absorption was prolonged, with an absorption from 11% to 43% observed during the first 7.5 hours after feeding. After 16 hours NIV was still being absorbed by the intestine. In the case of excretion, during the first week, NIV was excreted in feces without detecting any metabolization derivates (Hedman et al. 1997). However, in a similar study, 1 week after starting a diet rich in NIV, almost all of the NIV ingested was found in the feces of swine, and this was in the de-epoxy form (Hedman and Pettersson 1997).

Similar results were obtained with rats. A total of 80% of the ingested NIV was excreted in feces as de-epoxy NIV, while only 7% was detected unmetabolized (Onji et al. 1989).

15.3.1.4 Diacetoxyscirpenol

DAS was orally administrated to rats and mice, and the results showed that both species eliminated approximately 90% of the administrated dose through urine and feces during the first day. After 24 hours, low levels of DAS were absorbed in the organism, mainly in the gastrointestinal tract (Wang et al. 1990).

In other studies, rats produced several DAS metabolite derivatives upon ingestion. They were the results of hydroxylation and de-epoxidation reactions of DAS. In urine, 15-MAS, SCP, DE 15-MAS, and DE SCP were found at levels of 3.5%, 4.9%, 9.5%, and 7.2% of the administered dose, respectively. However, in feces only DE 15-MAS and DE SCP were found, with 9.5% and 18.9% of the administered dose, respectively (Sakamoto et al. 1986).

15.3.2 Bioavailability and Metabolism of Sesquiterpenes in Spices and Herbs

Drimane derivatives such as polygodial, warburganal, and ugandensidial (Fig. 18) found in the herb *Warburgia ugandensis* act as –SH acceptors for sulfhydryl groups in chemoreceptor membranes or with L-cysteine to give their usual hot taste. Thus, only the functionality and stereochemistry of these drimanes are necessary for the spicy flavor (Asakawa et al. 2012; Kubo and Ganjian 1981).

Some guaiane-type sesquiterpenoids also show a high level of hydrogen bond acceptor positions due to their multi-hydroxyl functionalization. Curcumenol, isocurcumenol, and procurcumenol (Fig. 20) are the guaianes present in *Curcuma*

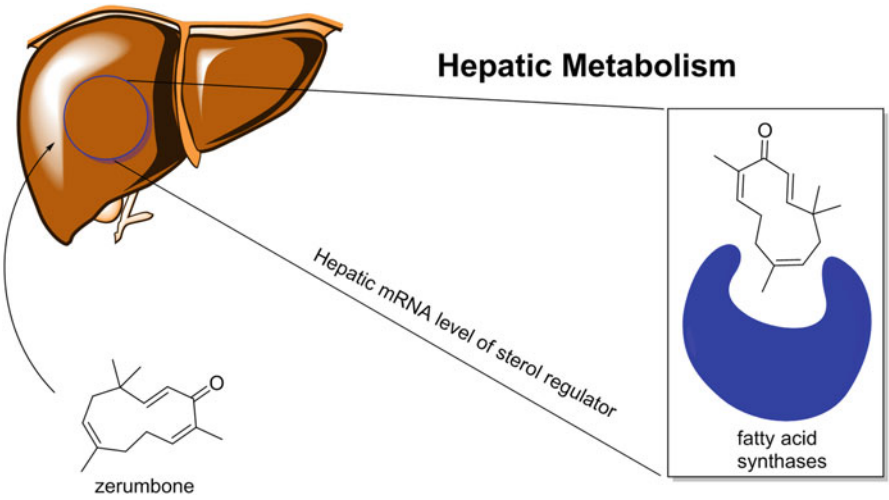


Fig. 25 Mode of action of zerumbone in liver

zedoaria, and they show diuretic and stimulant activity after being eaten (Lo et al. 2015). Curcumenol and its derivatives are nitric oxide (NO) suppressors. This inorganic free radical is produced by oxidation of L-arginine by nitric oxide synthase, which is involved in physiological processes as an inflammatory agent (Lo et al. 2015; Matsuda et al. 2001).

Humulene compounds show a complex metabolism because of their hepatic accumulation. Zerumbone interacts with lipogenic target genes, such as fatty acid synthases, acetyl-CoA carboxylase 1, and stearoyl-CoA desaturase-1. This results in an improvement in insulin resistance and the repression of hepatic lipogenesis (Fig. 25).

The bioavailability of sesquiterpenes and every natural product in the human body is conditioned by pharmacokinetic parameters such as clearance (volume of plasma from which a substance is completely removed per unit time), volume of distribution, or half-life time. Comparison of two usual sesquiterpenes found in food, namely, costunolide and dehydrocostuslactone (Figs. 20 and 22), showed that the bioavailability of costunolide is higher than that of dehydrocostuslactone, with a maximum plasma concentration of >12 μg/mL. Nevertheless, the clearance and the volume of distribution of dehydrocostuslactone are higher than those of costunolide. The persistence of these sesquiterpene lactones in metabolism is very small, with a half-life time of less than 2 minutes, and Peng et al. identified the degradation metabolites in the body, which can be explained by phase I biotransformation and phase II biotransformation (Peng et al. 2014) (Fig. 26).

In addition to metabolism, the way in which sesquiterpenes are consumed is a relevant factor in the degradation of these compounds. Biodegradation of sesquiterpenes in the aqueous environment is limited, and persistence in the human body can be a significant problem. Nevertheless, continuous exposure to aqueous media

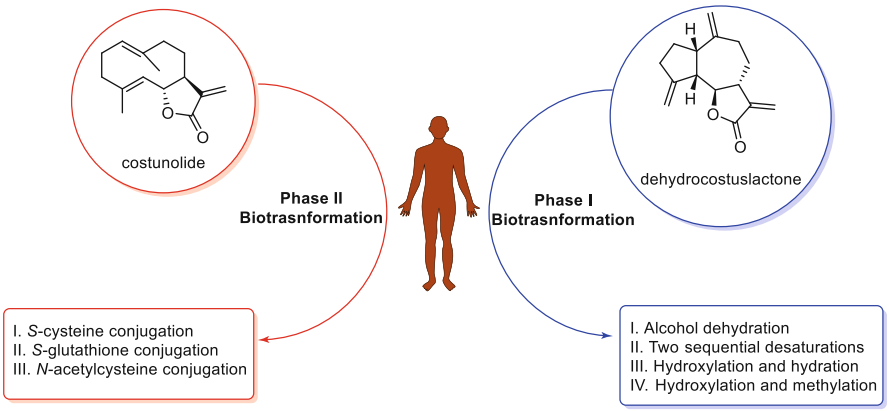

Fig. 26 Metabolism of costunolide and dehydrocostuslactone

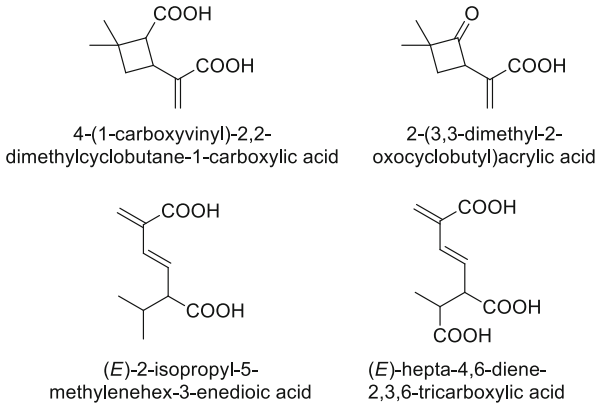

Fig. 27 Potential stable metabolites of β-caryophyllene (top) and germacrene D (bottom)

causes degradation of most sesquiterpenoids. Recent studies on stable metabolites associated with this degradation process have been carried out. β-Caryophyllene is degraded to cyclobutane carboxylic acids, while germacrene D is degraded to two hexadienes (Fig. 27) (Jenner et al. 2011).

It is also worth highlighting the possibility of post-oxidation, which leads to several kinds of oxygenated sesquiterpenes. This is the case for α-guaiene autoxidation derivatives (Fig. 28): α-epoxide and β-epoxide, 7-epi-chabrolidione, corymbolone, and rotundone (Huang et al. 2015).

As stated previously in this section, solubility plays an important role in the metabolism of sesquiterpenes, and this can be improved by different methods, such as encapsulation. It is possible to cover a sparingly soluble compound with a molecular structure that shows higher water solubility. The physicochemical properties of the encapsulated molecule are not altered by intermolecular interaction with the capsule. After being delivered, the encapsulated compound will act in the target

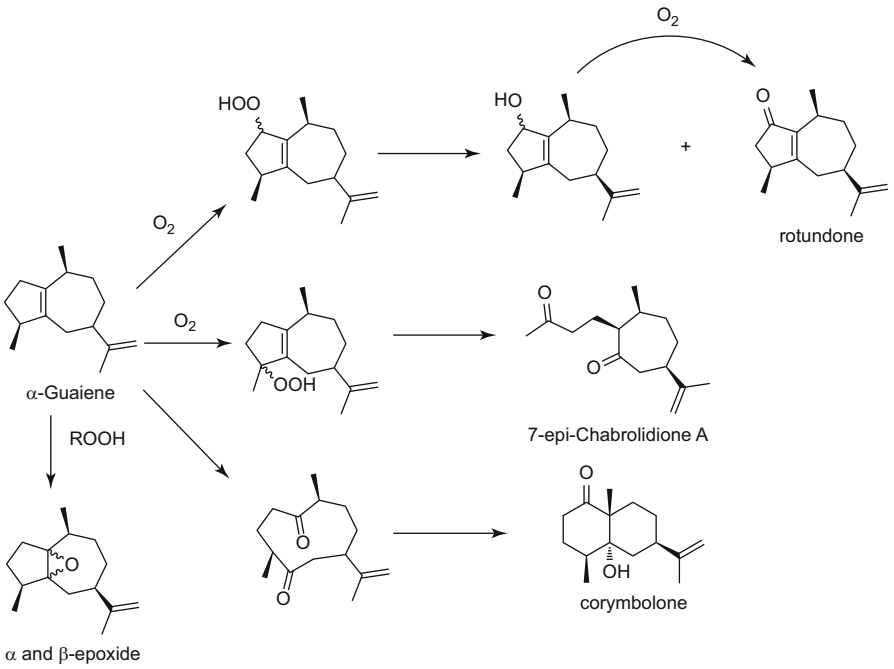

Fig. 28 Mechanistic of autoxidation of α-guaiene. Reproduced (adapted) with permission of Huang et al. (2015). Copyright 2015 American Chemical Society.

without the need to be structurally modified. This technique is usually applied in food, as in the case of β-carotene (vitamin A precursor), by the creation of supramolecular polymer micelles (Mejías et al. 2018a). Furthermore, this approach has been applied recently with sesquiterpene mimics with a polymeric core/shell system, where the solubility was enhanced by more than 27 times (Mejías et al. 2018b).

15.4 Bioactivities

15.4.1 Studies on Animals with Trichothecenes

Trichothecenes are capable of producing a wide range of effects and symptoms that are determined by the dosage of the mycotoxin and the duration of the exposure. Due to their fast metabolization, the symptoms produced by trichothecene poisoning appear quickly.

Several studies have been carried out to research the effect of trichothecenes on animals in their intake or intravascular administration. The authors concluded that these products show counterproductive effects (Côté et al. 1984; D'Mello et al. 1999). The most common effects are diarrhea, emesis, feed refusal, weight loss, gastrointestinal lesions, and, in the most extreme cases, death. However, besides

these common effects, trichothecenes are also responsible for many other dangerous effects. They can inhibit protein synthesis to produce alterations in the circulatory, reproductive, nervous, and immune systems, and they also have carcinogenic and dermal effects and genotoxicity, inhibit the synthesis of DNA and RNA, and produce modifications of the membrane structure (Eriksen and Alexander 1998; Corrier 1991).

15.4.1.1 Inhibition of Protein Synthesis

Some trichothecenes show a potent inhibition of protein synthesis activity (Wei et al. 1974). The mechanism of action starts through binding with the 60S subunit of eukaryotic ribosomes. They are able to inhibit the peptidyl transferase activity and the chain elongation of the protein synthesis process. There are different modes of action: some trichothecenes, like trichodermin and T-2 toxin, seem to reduce the activity of the peptidyl transferase required for the termination step (Warren 1973). On the other hand, other studies have demonstrated that T-2 toxin inhibits the initiation step, probably preventing the second amino acid from joining the first stage of the sequence (Eriksen and Alexander 1998). DON and NIV also showed protein synthesis inhibition. The mechanism of action for DON involves inhibition of the chain elongation (Ehrlich and Daigle 1987), while NIV inhibits initiation (Cundliffe and Davies 1977).

15.4.1.2 Inhibition of DNA/RNA Synthesis

Numerous studies have shown how trichothecenes inhibit the incorporation of thymidine and leucine in the DNA strand. For example, HeLa cells were treated with different concentrations of NIV, and cell proliferation was inhibited at concentration of 0.5 μg/mL. In this study, the incorporation of tritium-labeled thymidine, leucine, and uridine into DNA or RNA was measured. The results showed that at a concentration of 50 μg/mL, thymidine and leucine incorporation was almost completely inhibited. Notwithstanding, uridine incorporation only experienced 10–15% inhibition at the same concentration (Ohtsubo et al. 1968).

T-2 toxin also inhibited the incorporation of thymidine into DNA when it was tested on thymus cell lines (Munsch and Müller 1980). A slight inhibition was observed for concentrations from 0.1 to 1 ng/mL. When the concentration was greater than 10 ng/mL, high levels of inhibition were reached. The effect of T-2 toxin and DAS in human peripheral blood lymphocytes was studied by analyzing the incorporation of labeled tritiated thymidine in DNA synthesis. An inhibition of 50% was reached with concentrations of 1.5 ng/mL of T-2 toxin and 2.7 ng/mL of DAS. Total inhibition was achieved with 8 ng/mL of both toxins (Cooray 1984). Furthermore, DON is able to inhibit completely the incorporation of thymidine and leucine in mice spleen and Peyer's patch cells at a concentration of 1000 ng/mL (Warner et al. 1994).

15.4.1.3 Effects on the Immune System

Trichothecenes have an important and broad immunosuppressive activity. Many studies have shown that T-2 toxin causes necrosis and lymphoid depletion in the

spleen, thymus, and lymphoid nodes in some animals like sheep (Friend et al. 1983), pig (DeNicola et al. 1978), and chicken (Wyatt et al. 1973). Other trichothecenes like DAS and DON have proven to have similar but less marked effects (Côté et al. 1985; Lafarge-Frayssinet 1979).

T-2 toxin (Buening et al. 1982), DAS (Lafarge-Frayssinet 1979), and DON (Atkinson and Miller 1984) reduce the blastogenic response of lymphocytes to mitogens. In the studies performed by Lafarge-Frayssinet and co-workers (Lafarge-Frayssinet 1979), T-2 toxin increased the lymphocyte B and T response at low concentrations. However, it showed a strong inhibition at higher concentrations.

Trichothecenes could also provoke alterations in the immunoglobulin level regulation system. When cows were administered with T-2 toxin, their concentration of immunoglobulins A (IgA) and M (IgM) showed lower levels compared with the control. Immunoglobulin G (IgG) did not show any response to the toxin (Mann 1982). Mice fed with DON showed an increase of IgA levels, but IgM and IgG levels decreased (Pestka et al. 1989).

Besides the aforementioned activities, trichothecenes have many other effects on the immune system. If a living being is intoxicated with trichothecenes, they will have more susceptibility to infectious diseases. T-2 toxin decreases the resistance to salmonellosis (Tai et al. 1988) and tuberculosis (Kanai and Kondo 1984) in mice. In addition, mice intoxicated with DON showed less resistance to *Listeria monocytogenes* infection (Tryphonas 1986) and *Salmonella enteritidis* (Hara-Kudo et al. 1996).

There have also been cases where trichothecenes have increased resistance to bacteria. For example, mice infected with *Staphylococcus hyicus* and *Mycobacterium avium* were given DON and T-2 toxin orally. The results showed a reduction of infection from both bacteria tested (Atroshi et al. 1994).

15.4.2 Studies on Animals with Sesquiterpenes Found in Spices and Herbs

Activities shown by sesquiterpenoids are focused in seven specific types: antioxidant, antibacterial, antihyperlipidemic, antihyperglycemic, anti-inflammatory, neuronal, and circulatory system alterations and anticancer activities. Antioxidant properties are mainly connected with the presence of double bonds and heteroelements with electron acceptor capability. Antibacterial activity is explained as being due to high lipophilicity that allows them to cross the bacteria membrane toward cytosol action. Antihyperlipidemic and antihyperglycemic effects correspond with liver accumulation as a first barrier in the human body. The capability for prostaglandin inhibition allows these compounds to act as anti-inflammatory agents. Their neuronal system effects are believed to be produced by their ability to suppress efferent adrenal sympathetic nerve activity and modifications to intracellular ionic calcium (Ca^{2+}) concentrations. Some studies have also demonstrated that certain sesquiterpenes inhibit the proliferation of cancerous cells.

15.4.2.1 Antioxidant Activity

Antioxidant activity does not seem to have a correlation with compound skeleton type, but a high number of double bonds are present in all of the compounds that show this bioactivity. Spathulenol and α-bulnesene have a similar sesquiterpene structures, with seven-/five-membered rings, and they are the sesquiterpenes in spices with better profiles for this activity. Two experiments to study antioxidant capability have been carried out, namely, the 2,2-diphenyl-1-picrylhydrazyl (DPPH) radical scavenging effect and decreased levels of thiobarbituric acid reactive substances. In terms of reactive oxygen species (ROS) scavenging, β-caryophyllene modulates thermal and oxidative stress, thus decreasing intracellular free radical amounts and maintaining the intracellular ROS equilibrium with redox homeostasis (Pant et al. 2014).

In the case of the 2,2-diphenyl-1-picrylhydrazyl radical, the reaction of this compound with the bioactive agent was studied, and the loss of optical density was evaluated to verify the antioxidant power (Nenov et al. 2011). Spathulenol was tested with this method after being extracted from cinnamon (*Cinnamomum zeylanicum*). α-Bulnesene, isolated from *Ocimum sanctum* – commonly known as holy basil – also shows antioxidant activity. This activity showed a notorious inhibition of the thiobarbituric acid reactive species in mouse blood (Suanarunsawat et al. 2010) (Fig. 29). This kind of bioassay determines the presence of the three antioxidant enzymes: glutathione peroxidase, catalase, and superoxide dismutase. If the cell shows low levels of these enzymes, the oxidative stress is also low, and the compound consumed, α-bulnesene, has antioxidant properties. Low levels of oxidative stress avoid the production of antioxidant enzymes by the cell (Kaur et al. 2012). Furthermore, in vitro studies with sesquiterpenoids showed that β-caryophyllene modulates the lifespan of the soil nematode *Caenorhabditis elegans*. These bacteria are used as a model for aging studies, and the results indicated an increase in the lifespan value by over 22% at a dose of 50 μM.

15.4.2.2 Antibacterial Activity

Despite the antioxidant activity of β-caryophyllene, this molecule stands out due to its antibacterial activity. β-Caryophyllene can be found in mint (*Mentha* spp.) (Park et al. 2016), in savory (*Satureja avromanica*) (Abdali et al. 2017), in lime peel (*Citrus aurantifolia*) (Jafari et al. 2011), and in cinnamon extracts (*C. zeylanicum*) (Nenov et al. 2011). The most common method to evaluate the antimicrobial/antibacterial activity is the disc diffusion assay. Different bacterial cultures, including *Escherichia coli* (*E. coli*), *Aeromonas salmonicida*, *Bacillus subtilis*, and *Staphylococcus aureus*, are swabbed onto agar plates overnight. A solution with a concentration of around 30 μL is then added to the Whatman disc, and the sample is incubated overnight at 37 °C. The inhibition zone is measured and this provides an indication of the antibacterial activity (Balachandran et al. 2015). Cubenol, as an isolated compound, is also strongly active against *E. coli*.

Sesquiterpenes tested in antibacterial tests are usually assayed as extracts, such as β-bourbonene or *trans*-α-bergamotene (Abdali et al. 2017). One problem associated

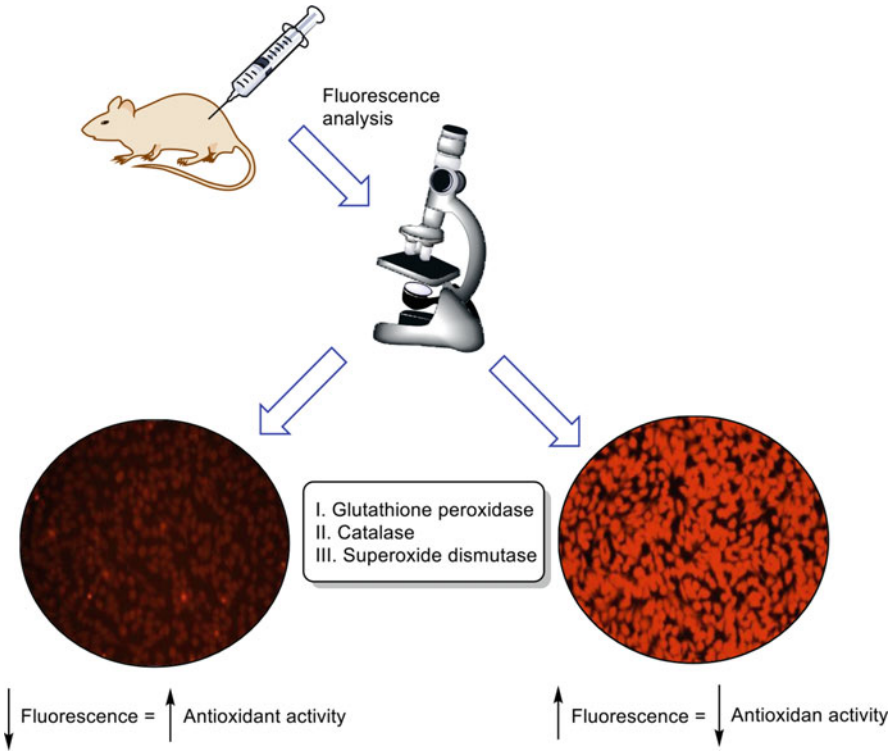

Fig. 29 Scheme of antioxidant assay in mouse blood by quantification of enzymes related with thiobarbituric acid reactive species

with extract tests is the potential for joint action of sesquiterpenes. In industry it is common to apply pure extracts of compounds, but an in-depth analysis of the active ingredients provides information on toxicity and side effects. The removal of unnecessary secondary compounds from the extracts may lead to cost reductions in manufacturing. Synergism can become a complex issue when mixtures are not binary, such as cadinane and caryophyllene sesquiterpenes in *Thymus saturejoides* (Kasrati et al. 2014).

Basil essential oil (*Ocimum basilicum*) has a strong antibacterial activity, as demonstrated by in vitro tests against Gram-positive bacteria *Enterococcus faecalis*, *Micrococcus luteus*, *Sarcina* sp., *Staphylococcus aureus*, *Staphylococcus epidermidis*, and *Staphylococcus mutans* and Gram-negative bacteria *Acinetobacter* sp., *Aeromonas* sp., *Citrobacter freundii*, *E. coli*, *Klebsiella pneumoniae*, *Proteus mirabilis*, *Proteus vulgaris*, *Salmonella choleraesuis*, *Serratia marcescens*, *Shigella flexneri*, and *Yersinia enterocolitica*. Minimum inhibitory concentrations can differ from 0.25 to 1.00 mg per gram for the bacteria listed above. *Pseudomonas aeruginosa* was the only sample tested that did not suffer inhibition (Gaio et al. 2015).

15.4.2.3 Antihyperlipidemic Activity

Antihyperlipidemic effects have been found in sesquiterpenes, and this is mainly due to liver accumulation of these compounds. Predominantly, antihyperlipidemic action is due to suppression of liver lipid synthesis (Suanarunsawat et al. 2010). In the cases of α-bulnesene and β-caryophyllene, their effectiveness is comparable to that of the reference drug simvastatin (Suanarunsawat et al. 2009). Notwithstanding, zerumbone is the sesquiterpene with the highest antihyperlipidemic activity. This humulene is usually isolated from ginger (*Zingiber zerumbet*), and it reduces cholesterol levels in plasma and triglycerides in hepatic tissue of hamsters. The liver of the animal is removed and extracted with chloroform/methanol (1:2) in order to analyze the lipids. After oral administration of zerumbone, fat accumulation in the liver was reduced, and, at the same time, insulin resistance was improved, inflammation was reduced, and hepatic lipogenesis was inhibited by repression of sterol regulatory element-binding protein 1 (SREBP-1c) (Tzeng et al. 2013, 2014). At plasma level, zerumbone has been tested for vasorelaxation on rat aorta, and it showed myorelaxation. Nevertheless, zerumbone does not present positive modulation of L-type Ca^{2+} channel influx, so K^+ channel opening activity may be involved.

15.4.2.4 Antihyperglycemic Activity

Antihyperglycemic studies on sesquiterpenes are carried out in diabetic rats and rabbits. Streptozotocin and alloxan are the compounds used to induce diabetes in animals (Fig. 30) by a single administration of the drug. In the case of rat, different effects were observed after diabetes induction: increased glucose, increased HbA1c, falls in insulin and hemoglobin, falls in liver and skeletal muscle glycogen, and alterations in glycogen synthase and phosphorylase activity. The continuous oral administration of β-caryophyllene significantly decreased the glucose level by

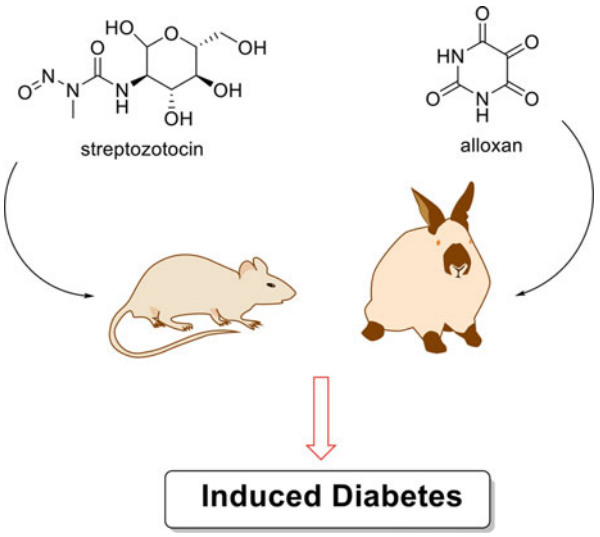

Fig. 30 Compounds used in the diabetic induction process

boosting insulin levels. After 45 days, the sesquiterpenoid restored glucose homeostasis by modulating the activity of enzymes involved in glucose utilization (Basha and Sankaranarayanan 2014). In the case of rabbit, β-caryophyllene was again tested, but it was studied as the extract from *Myrtus communis*, which has a high contribution from α-humulene. The level of glucose was determined by performing a standardized oral glucose tolerance test, and it was verified that sesquiterpenes in the essential oil of this spice influence the intestinal transport mechanism of carbohydrates. In particular, Sepici et al. stated that the extract of *M. communis* inhibits α-glucosidase of the small intestine, so glucose delivery is delayed (Ben Hsouna et al. 2014; Sepici et al. 2004).

15.4.2.5 Anti-inflammatory Activity

Among sesquiterpenes, α-guaiene (Fig. 19) is a promising candidate to replace current nonsteroidal anti-inflammatory drugs (NSAIDs), whose side effects are dangerous, despite their effectiveness in inhibiting prostaglandin synthesis (Tracey 2002). Prostaglandins are compounds that play an important role in the inflammatory response and they are synthesized by catalysis of the enzyme cyclooxygenase (COX) (Lipsky 1999). The results of in vitro bioassays show that α-guaiene inhibits COX-1 and COX-2 with half maximal inhibitory concentration (IC_{50}) values of 43 and 84 μg/mL, respectively. Even better results were obtained when this compound was tested in vitro against 5-lipoxygenase (IC_{50} of 27 μg/mL) and acetylcholinasterase (IC_{50} of 21 μg/mL) (Eldeen et al. 2016). In addition, 5-lipoxygenase works in the biosynthesis of the proinflammatory mediators the leukotrienes in collaboration with acetylcholinasterase, an enzyme that catalyzes the breakdown of acetylcholine, which is a parasympathetic neurotransmitter that inhibits the liberation of proinflammatory mediators (Borovikova et al. 2000).

15.4.2.6 Neuronal System Alterations

β-Eudesmol suppresses efferent adrenal sympathetic nerve activity (ASNA) in rats by intragastric administration. This task is carried out by the afferent vagus nerve and the calcium-permeable nonselective cation channel TRPA1 (expressed in the stomach). Plasma adrenalin levels decrease after the administration of β-eudesmol (Ohara et al. 2018). Mice neuronal outgrowth is also induced by β-eudesmol after increasing the intracellular Ca^{2+} concentration (Obara et al. 2002). More properties have been reported for this compound, and it is worth highlighting the propitious inhibition produced with *in vitro* and *in vivo* tests on angiogenesis, whose disorders contribute to cancer and diabetic retinopathy (Tsuneki et al. 2005). Oral administration of this sesquiterpene also influences the digestive system, as evidenced by the dose-dependent promotion of gastrointestinal motility in mice (Wang et al. 2002).

15.4.2.7 Effects on the Circulatory System

Ginger has been suggested as an alternative antithrombotic drug. Due to its traditional uses, this spice has been tested in human studies. Platelet thromboxane production was evaluated *in vivo*, and when 5 g of raw ginger were consumed daily by humans for 7 days, a significant reduction in mean thromboxane B2 (TxB_2)

to 37% was observed upon taking measurements in serum after blood clotting (Srivastava 1989). The synthesis of the precursor of this product is one of the main targets of aspirin. A subsequent study, in which TxB_2 was measured in human blood after 2 weeks of ginger ingestion, did not provide evidence of antithrombotic activity due to the lack of significant differences with subjects treated with placebo (Janssen et al. 1996). A similar finding was obtained with rats that had consumed ginger daily for 4 weeks, with insignificant reductions of TxB_2 levels. Nonetheless, two other benefits were demonstrated. These were significant changes in the serum prostaglandin-E_2 (PGE_2) at a dose of 50 mg/kg and a significant reduction of serum cholesterol, with the strongest effects obtained at the higher doses tested (500 mg/kg). At lower doses, serum cholesterol reduction was only produced when ginger administration was conducted intraperitoneally (Thomson et al. 2002).

15.4.2.8 Anticancer Activities

Anticancer *in vitro* activity has been suggested for β-caryophyllene and α-humulene, particularly against RAW264.7 (murine macrophage) and HCT-116 (colon cancer) cell line growth. Fractions with α-humulene showed higher activity than fractions rich in β-caryophyllene (El Hadri et al. 2010). Pharmacokinetics of α-humulene have been studied in mice. If this sesquiterpene is orally administered, it will take only 15 minutes to be detected in plasma, with the concentration decreasing thereafter and being undetectable after 12 hours. Upon intravenous administration, this period decreased to 2 hours. The half-lives are 16.8 minutes and 1.8 minutes, respectively. High concentrations of α-humulene were found in the liver, although it was also present in kidneys, heart, lungs, spleen, and brain (Chaves et al. 2008). Turmeric has been shown to have several types of activity. Different human studies have proven its anticancer activity, as well as activity against acne, diabetes, fibrosis, irritable bowel syndrome, and lupus nephritis. Turmeric has also shown potential in animal studies against atherosclerosis, depression, inflammatory processes, neurodegeneration, and obesity (Gupta et al. 2013).

15.5 Benefits

A small amount of research has been carried out in clinical studies on sesquiterpenes found in spices. Horváth et al. reported an interesting analysis concerning the relation between β-caryophyllene and damage reduction in liver after cisplatin anticancer applications.

The anti-inflammatory activity of this caryophyllane is already known, but it has recently been shown to be a natural agonist of endogenous cannabinoid 2 receptors, which are expressed in immune cells. These receptors are damaged after cisplatin treatment and they induce nephron toxicity. Therefore β-caryophyllene liver accumulation has tremendous therapeutic potential in cases involving treatment against cancer (Horvath et al. 2012).

Very little information about the possible benefits of trichothecenes for human health is available, mainly because of the numerous secondary effects. Even so, the diverse range of activities found for trichothecenes suggest that further studies could lead to a way to transform these toxic compounds into therapeutic agents. There are cases where mycotoxins (Shapira and Benhar 2010) are used for therapeutic purposes.

Deacetoxyscirpenol was investigated as a possible molecule to treat cancer in humans (Sudakin 2003). In Phase I clinical trials secondary effects were not found at low doses. Nevertheless, increases in the dose did cause several adverse effects, such as gastrointestinal lesions, among others. As a result, the study was stopped, and the possible medical applications did not go beyond the Phase II stage.

15.6 Application in Food

Food industries have a high demand for natural preservative compounds with additional benefits. Sesquiterpenes have shown this ability, and they have therefore attracted great interest for applications in foodstuffs to provide added value. In this respect it is worth noting the use of sesquiterpenoids as antioxidants, as preservatives (due to their antibacterial activity), and as a source of flavor or aroma.

In some cases, sesquiterpenes are used as natural food additives due to their antioxidant properties, and one example is the use of extracts obtained from eucalyptus leaves. Even though sesquiterpenes are not the strongest antioxidant compounds found in leaves, it is worth highlighting the presence of globulol (Fig. 24), as this is one of the major constituents, and other sesquiterpenes such as aromadendrene (Amakura et al. 2002).

Hydroperoxyeudesmanolides, which were mentioned in a previous section, show antioxidant activity, and they are isolated from *Artemisia umbelliformis*. The application of these compounds in Genepì liquor provides extra value to this drink. Distillation of the raw plant enables the solubilization of hydroperoxide derivatives from plant trichomes (Cappelletti et al. 1986).

During beer brewing, hops are added with the aim of providing bitterness and aromas. β-Eudesmol is a sesquiterpenoid produced by hop species, and it is a contributor to the spicy aroma of beer. In addition, β-caryophyllene, α-humulene, humulene epoxide I, and β-farnesene are compounds that contribute to the sensory properties of beer. Aromatic distinctions can be provided by other types of compound (terpenoids, ketones, acids, etc.), but the levels of many of them decrease during the wort boiling process. This technique is usually applied at the same time as the addition of hops. The previously mentioned sesquiterpenes show a slow linear decrease in concentration when they are subjected to boiling procedures (Kishimoto et al. 2005). Specific aromas are associated with oxygenated sesquiterpenoids from hop, e.g., 14-hydroxy-β-caryophyllene in cedar odor; caryophylla-4(12),8(13)-diene-5-ol (α and β) in lime, herbal, and rubber; (*3Z*)-caryophylla-3,8(13)diene-5-ol (α and β) in lime, herbal, and pine; humulenol II in sagebrush, lime, cedar, and pineapple; and humulene epoxide III in lime and cedar for spicy and rubber aromas (Praet et al. 2016).

However, the main applications of sesquiterpenes from spices are not in drinks but in pastries and cakes. Cream-filled cakes are mainly contaminated with *Staphylococcus epidermis* and *Bacillus subtilis*. The sesquiterpene components of lime essential oil have an antibacterial activity against these bacteria. The reduction in the use of synthetic preservatives such as salt, nitrites, and sulfites is growing due to a demand by consumers for natural products. In the lime extracts employed, β-caryophyllene and *trans*-α-bergamotene are the principal sesquiterpenoids that provide antibacterial action (Jafari et al. 2011).

The antimicrobial activity of black and green pepper essential oils has been tested to inhibit the growth of *Staphylococcus aureus* bacteria in chicken soup. Both peppers showed significant antimicrobial activity, especially the green pepper. As a consequence, these ingredients could be used as natural food preservatives (Nikolic et al. 2015). This is also the case for basil essential oil, which has shown positive effects in controlling *Staphylococcus aureus* proliferation in Italian-type sausage, with the highest activity reported over the first 14 days (Gaio et al. 2015).

Another example is α-cadinol, due to its inhibitory properties on anaerobic bacteria. This sesquiterpene could be included in food, chewing gums or dentifrices to prevent the growth of *Streptococcus mutans* (EP130027A2 1985), a bacterium in the human oral cavity that is associated with tooth decay.

Furthermore, (+)-valencene is another relevant sesquiterpenoid that is a constituent of essential oils of citrus. In this case, (+)-valencene has recently been studied in terms of its biotechnological production from farnesyl pyrophosphate by *Corynebacterium glutamicum*. In author's opinion, the industrial production of this compound with application as anti-proliferative cancer cells and as flavor in food could reduce the costs to be applied as future drug or food supplement (Zhu et al. 2011).

It was shown that simple heterologous expression of a (+)-valencene synthase gene does not allow *C. glutamicum* to produce the sesquiterpene in question. However, when endogenous prenyltransferases were replaced by farnesyl pyrophosphate synthase from *E. coli*, the heterologous expression of (+)-valence synthase genes did result in (+)-valencene production (Frohwitter et al. 2014).

The determination of the best date to initiate grape harvest is a complex task for oenologists. Their efforts are mainly focused on the determination of numerous parameters like acidity or sugar content. However, these parameters do not give sensorial information that is linked to the future organoleptic wine properties. Novel methods are being developed to overcome this problem and these include, for example, focusing on the identification and quantification of particular maturity markers. Thus, some sesquiterpenoids are appropriate for this task, such as bicyclogermacrene, a germacrane employed as a maturity marker for winemaking (Perestrelo et al. 2018).

15.7 Safety

Despite the fact that sesquiterpenes show impressive benefits, they also contain some compounds or derivatives that can be dangerous upon continuous exposure.

15.7.1 Toxicity and Side Effects of Trichothecenes

Very few *in vivo* studies have been carried out on the toxicity of trichothecenes in humans. However, in the last century, many intoxication outbreaks occurred. The most important was in the USSR (Union of Soviet Socialist Republics) in 1932–1947 when, under famine conditions, the population consumed grains contaminated with *Fusarium sporotrichioides* and *Fusarium poae*. Tens of thousands of people were affected and 60% mortality was reported. The intoxication produced alimentary toxic aleukemia (ATA), and four stages were observed in people depending on the exposure and acuity (Joffe 1986). In the first stage, nausea, vomiting, diarrhea, abdominal pain, and lesions in the gastrointestinal tract were detected. When the exposure to the toxins was prolonged, stage two of the disease would produce an improvement of the symptoms observed in the first stage, with the development of anemia, thrombocytopenia, and leukopenia. Continued ingestion of the toxins led to stage three, where necrosis lesions would appear in the gastrointestinal tract and infections and internal hemorrhages occurred.

Besides the aforementioned case, there have been other outbreaks of trichothecene intoxication – mainly in Japan, China, and India (Eriksen and Alexander 1998; Peraica et al. 1999). Nevertheless, the intensity of the symptoms and the impact on the population were much smaller than the case observed in the USSR.

In 1987 the consumption of bread prepared with trichothecene-contaminated wheat from *Fusarium* spp. in India led to the appearance of abdominal pain, throat irritation, diarrhea, and emesis among other symptoms. Studies on the bread demonstrated the presence of DON, NIV, and T-2 toxin among other trichothecene derivatives (Bhat et al. 1989).

The levels of trichothecenes in cereals are a major concern worldwide, and the Scientific Committee on Food established a TDI for some of these compounds. For DON, the TDI is 1 μg/kg of body weight/day. T-2 and HT-2 toxin have a combined temporary daily intake (t-TDI) of 0.06 μg/kg of body weight/day, and a t-TDI of 0.7 μg/kg of body weight/day was established for NIV.

Not many studies have been carried out on humans. However, these compounds seem to have the same effect in humans as in animal assays. DON inhibited both protein and DNA synthesis in human intestinal cells (Kouadio et al. 2005). DNA synthesis was also inhibited by T-2 toxin, DON, and DAS when tested on human lymphocytes. This produced an inhibition of lymphocyte proliferation (Atkinson and Miller 1984; Cooray 1984).

15.7.2 Toxicity and Side Effects of Sesquiterpenes Found in Spices and Herbs

Curcuma aromatica usually shows antioxidant (Dong et al. 2018), anti-angiogenic (Kim et al. 2002), and anticarcinogenic activities (Xiang et al. 2017), and it has recently been introduced as a dietary supplement in Japan. Nevertheless, (4*S*,5*S*)-(+)-germacrone-4,5-epoxide (Fig. 22) is also present in this spice, and this is a germacrane-type sesquiterpene that significantly inhibits human cytochrome P450

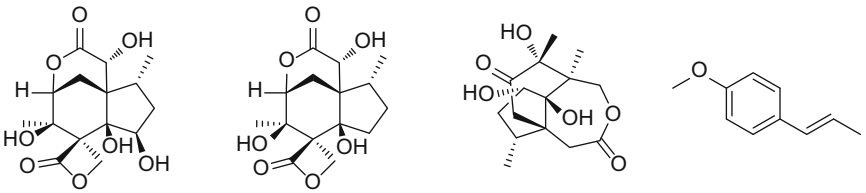

Fig. 31 Principal sesquiterpene toxins in Japanese star anise and the active ingredient in bird flu treatment (right)

(Bamba et al. 2011), which is involved in the oxidative phase of metabolism (Li et al. 2018b), and D_3 vitamin synthesis (Slominski et al. 2018). Furthermore, this effect has been seen with nerolidol and farnesol, which increase the inhibition of cytochromes when administered together (Spicakova et al. 2017).

A review of all previous sections makes clear the relevance of β-caryophyllene within the sesquiterpene groups. The presence of β-caryophyllene at higher levels than other sesquiterpenoids and its multiple bioactivities make it a good candidate for in-depth studies. Oliveira et al. developed an assay in mice with oral administration, and the results indicated an absence of toxicity in all internal organs and hematological aspects (Oliveira et al. 2018).

In relation to toxicity, Japanese star anise has led to controversy in different research investigations related to its benefits and adverse effects. *Illicium anisatum* (Japanese star anise) is usually employed in culinary applications as well as in infusions or tea. One of the sesquiterpene lactones found in this herb is anisatin (Fig. 31), a potent noncompetitive antagonist of γ-aminobutyric acid-dependent neurons in mammals. The receptor mentioned, and also the derivatives (neoanisatin and pseudoanisatin), is a ligand-gated ion channel responsible for important neurotransmission in the brain. The high toxicity of anisatin and its derivatives, like neoanisatin, can result in convulsant activity, hallucination, or epileptic (Ottesen and Magnuson 2010; Schachter 2009; Shen et al. 2012). On the other hand, Japanese star anise contains anethole, which is traditionally employed to cure rheumatism and is also is the active ingredient of bird flu treatment (D'Souza et al. 2017).

According to studies carried out on *I. anisatum*, it is difficult to conclude whether Japanese star anise is really a dangerous food. On analyzing the components present, prolonged exposure to anisatin and derivatives could become unsafe, but a limited administration as a spice is advantageous.

15.8 Marketed Products

15.8.1 Cereal-Based Food

Fusarium infection in cereal crops may occur when they are in the field or in storage. Numerous studies have demonstrated that the industrial processes involved in food preparation and production can reduce the presence of trichothecenes.

Notwithstanding, they cannot be completely removed, and so they are present in many cereal-based foods. Trichothecenes have been detected in soy-based, barley-based, oat-based, rice-based, corn-based cereals, biscuits (wheat based), maize, wheat flour, and other food like bread and beer (wheat beer).

15.8.2 Sesquiterpenes Marketed from Spices and Herbs

Most of the spices discussed in this chapter are marketed products that are available to anyone. Some of them are more accessible than others due to location and production. The principal sesquiterpenes analyzed in herbs that are consumed by humans are shown in Table 4.

Table 4 Marketed spices and their most relevant sesquiterpenes

Spice	Sesquiterpene studied	Spice	Sesquiterpene studied
Citrus sinensis	(+)-Valence	***Polygonum hydropiper***	Polygodial
Citrus aurantifolia	β-Caryophyllene *Trans*-α-bergamotene	***Myrtus communis***	β-Elemene α-Humulene
***Illicium* spp.**	Anethole Anisatin	***Salvia officinalis***	β-Caryophyllene α-Humulene
Cinnamomum zeylanicum	β-Caryophyllene α-Copaene	***Satureja avromanica***	Spathulenol β-Bourbonene
Ocimum sanctum	β-Caryophyllene α-Bulnesene β-Elemene α-Humulene	***Mentha* spp.**	Cubenol β-Caryophyllene Isoledene (-)-Calamene
Matricaria recutita	Matricarin Achillin Acetoxyachillin Leucodin	***Warburgia* spp.**	Polygodial Muzigadial Warburganal Ugandensidial
Curcuma aromatica	(4*S*,5*S*)-(+)-Germacrone-4,5-epoxide	***Alpinia guinanensis***	Carotol
Artemisia umbelliformis	Hydroperoxieudesmanolides Umbellifolide Costunolide Artemorin Santamarine Reynosin	***Laurus nobilis***	δ-Elemene β-Elemene Germacrene D β-Caryophyllene α-Bisabolene
Curcuma zedoaria	Isofuranodienone Glechomanolide Curcumenol Isocurcumenol Procurcumenol Curdione Neocurdione	***Zingiber zerumbet***	Zerumbone

A more detailed study on sesquiterpenes in spices showed that there are more than those listed in Table 4. Nevertheless, it is important to discuss whether the compounds will be absorbed after consumption. The guaianolides matricarin, achillin, acetoxyachillin, and leucodin, which are found in chamomile herb, are only identified in dichloromethane extracts (Tschiggerl and Bucar 2012). In some cases, products are sold after their sesquiterpene properties have been indicated, but this is certainly not always the case. The terpenoids can act in the organism if they are employed in cooking with water. It is therefore important to be cautious about properties described by food developers and when regarding food consumption.

According to Table 4, β-caryophyllene is the main component in spices. In addition, this compound has shown impressive bioactivities against different illness and also as a preventive drug. Degradation of β-caryophyllene, as well as its side effects, was studied, but the results did not show evidence of toxicity to humans. As a consequence, a high-caryophyllene diet should be promoted by the international community.

15.9 Patents

15.9.1 Patents Involving Trichothecenes

There are numerous patents concerning the detection or detoxification process for trichothecenes. This is the case for the combination method involving yeast and different *Bacillus* species as a low cost and environmentally friendly method to detoxify DON. An absorbent composed of a zeolite has been shown to bind specifically with DON, and it is proposed as a method to remove DON from animal feed.

In another case, an enzyme complex containing amidase and esterase is used to remove a group of mycotoxins simultaneously from cereal-based products. The complex is able to remove fumonisins, ochratoxin A, and T-2 toxin efficiently and DON, aflatoxin, and zearalenone partially.

A method has been described to construct a recombinant vector expressing three genes (ADH, AKR6D1, and AKR13B2) involved in the production of proteins to transform DON into a less toxic derivative. It has been proven *in vitro* that these three proteins can jointly transform DON into 3-isomer-deoxynivalenol (3-epi-DON) (Fig. 2), which is much less toxic than DON itself. The first step starts with oxidation, and this transforms DON into 3-oxo-DON, which is subsequently reduced to 3-*epi*-DON.

Another patent concerns extraction methods for different mycotoxins from cereal and other food. This approach involves different steps that allow the toxins to be extracted based on their hydrophilic or hydrophobic properties. The method is able to extract different kinds of aflatoxins, fumonisins, and trichothecenes (DON and T-2 toxin).

15.9.2 Patents Involving Sesquiterpenes Found in Spices and Herbs

There are very few patents related to sesquiterpenes in herbs. One of the most relevant is related to the production of these compounds by cyanobacteria. The gene sequence has been identified, and different sesquiterpenes, such as artemisinin, valence, and bergamotene, can be synthesized as a function of the substrate used to feed them.

Furthermore, the preparation from *Stereum hirsutum* fungus of a novel antidiabetic sesquiterpene has been patented, and the product decreases blood sugar and fructosamine in mice (CN103141300A 2013).

Other patents related to sesquiterpenes are focused on isolation techniques, the development of new extraction methods, or the recovery of volatile compounds. In the cases of ginger, clove, and garlic, an enzymatic process having cellulase, pectinase, protease, and xylanase has been applied to collect the purified spice oil of the herbs, and this oil is rich in sesquiterpenes. The compound zingiber is the subject of the highest number of patents due to its broad application in Asian countries. Bisabolane-type sesquiterpenes isolated from this plant have been patented for use in the pharmaceutical industry and other manufacturing areas. Specifically, an oleoresin is employed to catch the bisabolane.

Finally, separation methods for enriched oil have been patented. A novel distillation device with a dual function of extraction and separation has been employed to collect low-boiling point and high-boiling point components of essential oils in herbs. This system is characterized by a reflux extractor formed by a condenser, a cooler, a high-level oil-water separator, and a water return pipe connected to each other by steam pipes. Furthermore, a countercurrent chromatography method has been patented to isolate chloranthalactone A from *Chloranthus spicatus* by using a mixture of solvents composed of hexane/ethyl acetate/methanol/water (1–3:5–15:2–7:4–15).

15.10 Perspectives

As stated in this chapter, the main problem associated with trichothecenes is their toxicity and the inability to completely remove them in industrial processes. Many studies have shown that a feasible way to decrease greatly their toxicity is the reduction of the epoxy group. This reduction has been achieved at laboratory scale and in biological systems, but it has not been studied on an industrial scale. The authors believe that it would be of interest to carry out an in-depth study in this matter, as cereals play a fundamental role in diet worldwide and there is a continuous exposure of humans to these toxins.

As mentioned in the section on toxicity, a detailed study of star anise should be carried out to determine the maximum safe quantity that can be consumed. The duality aspect of profitable antibiotic activity and the adverse effects of anisatin have not been studied in detail. Furthermore, other plants employed as culinary herbs – such as laurel, which contains ledol – have similar problems that must be analyzed. In the authors' opinion, future efforts on sesquiterpenes related with food with high

levels of consumption have to be focused on determining just how dangerous these kinds of foodstuffs are.

According to clinical studies, it is clear that the potential use of sesquiterpenes as nutraceutical compounds in food has been poorly studied. The last stage of a bioassay in chemistry is difficult, but the sesquiterpenoids analyzed in herbs and cereals are abundant, and they have contrasting benefits in humans. As a consequence, clinical studies related to different illnesses should be performed and not just preventive uses or laboratory tests.

15.11 Cross-References

- ▶ Antioxidants in Diets and Food
- ▶ Curcumin in Food
- ▶ Sesquiterpenes in Fresh Food

Dietary Monoterpenoids

16

Yoshinori Asakawa

Contents

Abstract

A great number of foods, vegetables, fruits, and beverages contain various types of monoterpenoids and their related compounds. This chapter summarizes the distribution of monoterpenoids in dietary foods, vegetables, fruits, beverages, and processed foods, and their biological activity, effects, and application to our health, as well as metabolic pathways of several monoterpenoids in mammals.

16.1 Introduction

Since human being's ancestors began bipedal locomotion, they understood which foods are safe, poisonous, or toxic, and which foods are important to keep their health, and obtained their knowledges of conservation methods of foods, to make processed foods, like cheese, butter, as well as beverages, such as red and white wine, and beer, and succeeded in the production of essential oils including many kinds of monoterpenoids which have been used not only in food preservation but also as some drugs and food additives and in aromatherapy. Now we have many kinds of different foods and processed foods, sports and alcoholic, and non-alcoholic drinks and their supplements in food courts, supermarkets, and department stores. Almost all of edible fruits, mushrooms, sea algae, bryophytes, lichens, pteridophytes, and vegetables and processed foods contain secondary metabolites; mono-, sesqui-, di-, tri-, and tetraterpernoids (carotenoids); phytosterols; pigment components (anthocyanins, flavonoids, stilbenoids); vitamins; hormones; etc. We unconsciously take those foods as breakfast, lunch, and dinner with beverages including green, Oolong, and many kinds of herbal tea as well as alcoholic beverage.

In this chapter, the distribution of monoterpenoids and related compounds in the representative foods, fruits, vegetables, and beverages and their biological activity and metabolism in mammalian body and application are summarized.

16.2 Distribution of Monoterpenoids and Related Compounds in Foods, Fruits, Vegetables, and Beverages

In Table 1, a number of different kinds of foods, fruits, vegetables, and beverages have alphabetically been listed, and the distribution of monoterpenoids and their related compounds as well as their biological effects and application have also been briefly described (Awano et al. 2002; El-Zaeddi et al. 2016; Gottardi et al. 2016; Lasekan and Azeez 2014; Maarse 1991; Kotan et al. 2007; Umemoto et al. 1994; Williams 2011; http://botanicallove.com; https://essentialoils.co.za/essential-oils/citronella.htm; https://www.healthline.com/health/essential-oils-find-the-right-one-for-you#12; http://www.tipdisease.com/2014/11/benefits-and-nutrition-of-chives-allium.html; http://tropical.theferns.info/viewtropical.php; https://www.economie.gouv.fr/files/files/directions_services/dgccrf/imgs/breve/2014/documents/harmonized_list_Section_A.pdf; https://www.5amtag.ch/en/wissen-en/phytochemicals/).

Each monoterpene is listed according to the retention times appeared in gas chromatography (GC) and/or GC-mass spectrometry (GC/MS).

Monoterpenoids are composed of two isoprene units and therefore contain ten carbon atoms (C10), except for the presence nor- (C9) (**67-69**, **131**, and **301**), homomonoterpene (C11) (**74**, **111**, and **242**), and dihomo-monoterpenoids (C12) (**93** and **115**) which are rare natural products. Up to now, over 1,500 monoterpenoids are

Table 1 The dietary plant and fungi used as foods, beverages, and herbal medicines including monoterpenoids and their related compounds and application, benefits, and effects

Abelmoschus esculentus	β-Cyclocitral (**73**)	Vegetable, beverages (herbal tea) Anticancer, antidiabetes, antioxidant For constipation, leucorrhea, spermatorrhea, jaundice, gastritis, gastric ulcers
Averrhoa carambola (Star fruit)	Cumene (**68**), α-terpineol (**312**), carvomenthone (**41**), geraniol (**97**), β-damascenone (**84**), β-ionol (**116**), 4-hydroxy-β-ionone (**123**)	Fruit, beverages Antidiarrheal, antiinflammatory, antioxidant For digestion and immune system booster, promoting healthy hair, nails, and skin
Abies firma	α-Pinene, camphene, Δ^3-carene, bornyl acetate	Beverages (herbal tea) Antidiabetes, antifungal, antimicrobial
Abies sachalinensis var. *mayriana* (Abies oil)	Santene (**301**), tricyclene (**336**), α-pinene (**254**), camphene (**23**), (*Z*)-sabinene (**294**), β-pinene (**255**), myrcene (**191**), Δ^3-carene (**31**), limonene (**152**), *p*-cymene (**79**), β-phellandrene (**255**), α-phellandrene (**254**), terpinolene, (**316**), linalool (**158**), fenchyl acetate (**92a**), pinocarveol (**258a**), bornyl acetate (**15**)	Foods, flavor source (soap, bath additive, deodorant) Antifungal, antioxidant
Acacia decurrens var. *dealbata* (Mimosa oil)	α-Pinene, β-pinene, β-sabinene (**295**), α-phellandrene, myrcene, α-terpinene (**308**), γ-terpinene (**309**), terpinolene (**316**), α-fenchyl alcohol (**89**), linalool, terpinen-4-ol (**307a**), α-terpineol, nerol (**234b**), geraniol, geranyl acetate (**99**)	High-grade compound, flagrance, perfume retention agent Antidepressant, antistress, hypersensitivity, uplifting For anxiety, depressed mood, emetic, skin nourishment, urinary tract infection
Acacia farnesiana (Cassie oil)	*p*-Menth-1-ene (**221a**), limonene, (*E*)-β-ocimene, linalool, camphor (**29**), β-cyclocitral (**73**), nerol, geraniol, α-terpineol, geranial (**94**), thymol (**333**), methyl geranate (**96**), citronellyl acetate (**59**), neryl acetate (**236**), geranyl acetate, (*E*)-α-ionone, dihydro-β-ionone (**125**), geranyl acetone (**111**), β-ionone (**122**)	High-grade fragrance, food flavor (for raspberry) Antipyretic, antispasmodic, aphrodisiac, stimulant For conjunctivitis, dysentery, skin inflammation, tuberculosis

(continued)

Table 1 (continued)

Achillea millefolium (Yarrow oil, Milfoil oil)	Tricyclene, α-thujene (**329**), α-pinene, camphene, β-sabinene, β-pinene, myrcene, α-terpinene, *p*-cymene, limonene, 1,8-cineol (**52**), camphor, γ-terpinene, terpinolene, chrysanthenone (**50**), (*E*)-pinocarveol (**258a**), borneol, terpinen-4-ol, α-terpineol, (*Z*)-piperitol (**263**), carvotanacetone (**46**), piperitone (**81**), (*Z*)-chrysanthenyl acetate (**49b**), bornyl acetate	Beverages Antibacterial, antidepressant, antiinfectious, antifungal, antiinflammatory, antimicrobial, antioxidant, antiphlogistic, antirheumatic, antisclerotic, antiseptic, antispasmodic, astringent, balsamic, calmative cicatrizing circulatory, cytophylactic decongestant, deodorant, digestive, disinfectant, diuretic, emollient, expectorant, febrifuge, hemostatic, hypotensive, immunostimulant, laxative, regenerative, restorative, spasmolytic, stimulant, stomachic, thermogenic, tonic, vasodilatory, vulnerary For emmenagogue
Acorus calamus (Calamus oil)	α-Pinene, camphene, sabinene, myrcene, Δ^3-carene, *p*-cymene, limonene, (*Z*)-β-ocimene, (*E*)-β-ocimene, γ-terpinene, terpinolene, linalool, camphor, (*Z*)-β-terpineol (**310**), borneol, terpinene-4-ol (**307a**), α-terpineol (*E*)-carveol, citronellol (**58**), geraniol, methyl citronellate (**57**), bornyl acetate	Foods, beverage industry (for beer, liquor, tonics, tooth powders) Anesthetic, antibacterial, anticancer, anticholinesterase, anticonvulsive, antidiabetes, antidiarrheal, antifungal, antigastrointestinal, antihyperlipidemic, antiinflammatory, antioxidant, antiproliferative, antispasmodic antitoxic, myoelectric action, immunomodulatory For appetite, colic, earache, headache, hemorrhoids, memory problems, neuralgia, poor circulation, rheumatoid arthritis, strokes, skin disorders, ulcers, upset stomach
Acorus gramineus	α-Pinene, camphene, β-pinene, limonene, 1,8-cineole (**52**), *p*-cymene, linalool, camphor, borneol	Foods, beverages Antibacterial, antifungal, antimicrobial, antiperiodic, antirheumatic, antispasmodic, diuretic, sedative, stimulant, stomachic, tonic, vermifuge For anodyne, cardiac carminative, diaphoretic, depression, digestive, emmenagogue, epilepsy, expectorant, febrifuge, sudorific

(continued)

Table 1 (continued)

Actinidia arguta (= *A. japonica*)	α-Pinene, β-pinene, sabinene, myrcene, (*Z*)-β-ocimene, (*E*)-β-ocimene, limonene, 1,8-cineole, terpinolene, linalool, camphor, (7*E*)-8-hydroxylinalool (**159a**), geranyl acetone, (7*Z*)-8-hydroxyllinalool (**159b**), lilac alcohol a-d (**142-145**), lilac alcohol formate 1 (**151**), lilac alcohol formate 2 (**151**), lilac aldehyde 1-4 (**146-149**), (*E*)-linalool oxide (**164a**), (*Z*)-linalool oxide (**164b**), β-ionone	Fruit, beverages Anticancer, antifatigue, antihypercholesterolemia, antiinflammatory, antioxidant, tonic, felis attractant For digestion
Actinidia kiwi	*Fruits*: α-pinene, β-pinene, Δ^3-carene, myrcene, limonene, 1,8-cineole, (*Z*)-β-ocimene, (*E*)-β-ocimene, *p*-cymene, linalool, α-terpineol, geraniol, carvone (**42**), geranyl acetone *Fruits: by acid and enzymatic hydrolysis*: 1,4-Cineole (**51**), 1,8-cineole, *p*-cymene, isophorone (**131**), (*E*)-linalool oxide, (*Z*)-linalool oxide, terpinen-1-ol (**306**), carvenone (**36**), phellandral (**265**), geraniol, *p*-cymenol (**83**), cumin alcohol (**70**), 3-oxo-β-ionone (**118**)	Foods, beverages Antiallergenic, anticancer, antidiabetes, antihypercholesterolemia, antihypertension, antiinflammatory, antioxidant For bone, tooth, vision strengthen, brain development, infant growth, immunity booster, skin health
Actinidia polygama	Actinidin (**1**), iridomyrmecin (**128**), matatabilactone (**18**), pulegone (**267**), *neo*-matatabiol (**175b**), 5-hydroxymatatabidiether (**176**), 7-hydroxymatatabi-diether (**177**), actinidiolide (**2**), actinidol (**4**), *allo*-matatabiol (**175a**), dehydroiridodial (**127b**), dihydroactinidiolide (**3**), dehydroiridodiol (**127a**), *iso*-dihydronepetalactone (**227**), *iso*-iridomyrmecin (**129**), matatabi ether (**179**), matatabiether (**178**), *neo*-nepetalactone (**225**), nepetalic acid (**230**)	Beverages, medicinal liquor Antiseptic, CNS-paralytic, insecticide, pesticide, proteolytic

(continued)

Table 1 (continued)

Aesculus hippocastanum	1,8-Cineole, (*Z*)-linalool oxide, (*E*)-linalool oxide	Tonic as foods Anesthesia, antiinflammatory, antioxidant, antipyretic, astringent, promoting blood circulation For arthritis, cough, dysentery, diarrhea, enlarged prostate, fever, hemorrhoids, menstrual pain, phlebitis, soft tissue swelling from bone fracture, sprains, skin lupus, skin ulcers, varicose veins
Agaricus bisporus	α-Terpineol	Vegetable Anticancer, anticholesterolemic, antidiabetes, antihypoglycemic, antihypolipidemic, antiinflammatory, antimicrobial, antinociceptive, antioxidant, immunomodulatory
Agastache rugosa (Korean mint) (Agastache oil)	α-Pinene, myrcene, limonene, menthone (**189**), pulegone, *iso*-pulegone (**268**)	Flavoring (for salad), beverages Antibacterial, anticancer, antifungal, aromatic, carminative, diaphoretic, febrifuge, stomachic For abdominal bloating, angina pain, chest congestion, cold symptom, diarrhea, dietary indiscretion, headaches, nausea, vomiting
Akebia quinata	Limonene, *p*-cymene terpinolene, linalool, borneol, (*Z*)-sabinene hydrate (**297**), terpnen-4-ol, bornyl acetate, (*E*)-carveol	Foods For stomach and menstrual pain, cystitis, inflammation, stomachache, ulcer, uretic
Allium chinense (Baker's garlic)	Linalool	Vegetable (garnish on salads) Astringent, carminative, expectorant For stuffiness sensation, chest pain, angina pectoris, pleurisy, bronchitis, diarrhea, tenesmus in cases of dysentery
Allium schoenoprasum (Chive)	Linalool, thymol	Vegetable Antibacterial, anticancer, antifungal, antiinflammatory, antihypertension For acne, Alzheimer's disease, arthritis, eye sight, insect repellent, digestion, rheumatoid

(continued)

Table 1 (continued)

Allium tuberosum (Chinese chives)	*Fresh leaves:* α-terpineol, nerol, geraniol *Stoked 30 days*: β-pinene, linalool	Vegetable Anticancer, antiinflammatory, antimicrobial, antioxidant For anemia, atherosclerosis, coronary heart disease, bone booster, digestion, detoxification immunity, skin, vision health
Aloe arborescens	Limonene, carvone (**42**),	Foods, beverages Analgesic, antibiotic, antifungal, antimicrobial, antiinflammatory, antioxidant, antiseptic, antitumor, antiviral, cicatrizing, cytotoxic, depurative, diuretic, eupeptic, gastroprotective, laxative, toning
Aloe ferox	α-Pinene, camphene, β-pinene, Δ^3-carene, limonene, 1,8-cineole, α-terpinene, α-terpinolene, *o*-cymene (**77**), bornylene (**22**), theaspirane (**319**), bornyl acetate	Foods, beverages Antiinflammatory, hypoglycemic, laxative For asthma, dermatitis, diabetes, dry skin, genital herpes, hepatitis, immune system booster, psoriasis, seborrheic, stomachache, ulcer, sunburns
Alpinia japonica (Alpinia oil)	Tricyclene, α-pinene, camphene, α-phellandrene, limonene, α-fenchene (**88**), (*E*)-β-ocimene, *p*-cymene, 1,8-cineol, fenchone (**92a**), camphor, borneol, myrtenol (**196a**), terpinene-4-ol, pinocarvone (**260**), α-terpineol, α-fenchyl alcohol, β-fenchyl alcohol (**91**), β-fenchyl acetate	Beverages Antiinflammatory, antitumor For diarrhea, hematemesis, menoxenia, muscle pain, stomachache
Alpinia speciosa	*Leaves:* tricyclene, α-thujene, α-pinene, camphene, sabinene, β-pinene, myrcene, α-phellandrene, α-terpinene, *p*-cymene, limonene, γ-terpinene, 1,8-cineole, (*Z*)-β-ocimene, (*Z*)-sabinene hydrate, terpinolene, linalool, camphor, (*E*)-*p*-menth-2-en-1-ol (**211a**), (*Z*)-*p*-menth-2-en-1-ol (**211b**), terpinen-4-ol, α-terpineol, β-terpineol (**310**), borneol, (*E*)-piperitol (**262**), myrtenal, (*Z*)-carveol, (*E*)-carveol, cumin aldehyde, α-	Foods, food additives (cookies, sponge cakes, noodles), beverages Antiaging antiallergenic, antibacterial, antifungal, antihypertension, antiinflammatory, antimicrobial, antioxidative, diuretic, spasmolytic, insecticide, sedative For cardiovascular disease, menstrual cramps, muscle pain

(continued)

Table 1 (continued)

	phellandral (**265**), thymol, linalyl *iso*-valerate (**172**), terpinyl pentanoate (**314b**) *Flowers:*α-thujene (**329**), α-pinene, camphene, sabinene, myrcene, α-phellandrene, α-terpinene, 1,8-cineole, (*E*)-β-ocimene, γ-terpinene, (*Z*)-sabinene hydrate, terpinolene, linalool, (*Z*)-*p*-menth-2-en-1-ol, (*E*)-*p*-menth-2-en-1-ol, camphor, terpinen-4-ol, α-terpineol, (*E*)-piperitol (**262**), bornyl acetate *Seeds:* α-pinene, camphene, sabinene, β-pinene, myrcene, α-phellandrene, 1,8-cineole, (*Z*)-β-ocimene, γ-terpinene, terpinolene, linalool, fenchyl alcohol, (*E*)-*p*-menth-2-en-1-ol, camphor, β-terpineol, pinocarvone (**260**), pinocamphone (**261**), terpinen-4-ol, α-terpineol, borneol, (*E*)-piperitol (**262**), myrtenal, (*Z*)-carveol, (*E*)-carveol, cumin aldehyde, thymol, geranyl acetate, linalyl *iso*-valerate (**172**) *Whole plant*: fenchene, (*E*)-pinocarveol (**258a**), *iso*-borneol (**19a**), ascaridole (**9**), nerol, myrtenol, geraniol, fenchyl alcohol, *p*-cymene-8-ol (**80**), thymol, carvacrol, (*E*)-*p*-mentha-1(7),8-dien-2-ol (**203a**)	
Alpinia zerumbet	α-Thujene, α-pinene, camphene, sabinene, β-pinene, myrcene, α-terpinene, limonene, β-phellandrene, 1,8-cineole, (*Z*)-β-ocimene, γ-terpinene, *p*-cymene, terpinolene, linalool, (*Z*)-pinocarveol (**258b**), camphor, terpinene-4-ol, dill ether (**86**), α-terpineol, carvone, *p*-menth-1-en-9-ol (**206**)	Beverages Anticancer, antidiabetes, antihypertension, antiinflammatory, antimalarial, antimicrobial, antinociceptive, antioxidant, antipyretic, antispasmodic, antiulcerogenic, diuretic, neuropsychiatric syndrome For cardiovascular disorders, cold
Amanita rubescens	α-Pinene, β-pinene, limonene, 1,8-cineole, linalool, menthol	Foods

(continued)

Table 1 (continued)

Amygdalus persica (= *Prunus persica*)	Sabinene, limonene, *p*-cymene, linalool, linalyl formate (**167**), linalyl acetate (**168**), linalyl pentanoate (**171**), linalyl hexanoate (**174**), β-ionone	Fruit Antiaging, anticancer For healthy bones and teeth, strengthening the immune system, preventing nervous system, cancer prevention, healthy brain, blood pressure control
Amygdalus dulcis (Almond)	α-Thujene, α-pinene, camphene, sabinene, myrcene, limonene, 1,8-cineol, linalool, borneol, *p*-cymene-9-ol, (*E*)-verbenol (**342a**), myrtenol, α-terpineol, carvacrol	Foods Antiaging, antiarteriosclerosis, anticancer, antioxidant, hypocholesterolemia
Ananas comosus	α-Pinene, β-pinene, myrcene, limonene, (*E*)-β-ocimene, (*Z*)-β-ocimene, linalool, terpinen-4-ol, α-terpineol, geraniol	Fruit, beverages Anticancer, antiinflammatory, antioxidant, antiscorbutic diuretic For arthritis, diaphoretic, digestion, gastric irritability, jaundice, laxative
Angelica archangelica	α-Pinene, camphene, β-pinene, sabinene, myrcene, Δ^3-carene, limonene, β-phellandrene, α-phellandrene, *p*-cymene, (*E*)-β-ocimene, (*Z*)-β-ocimene, terpinolene, cryptone (**67**), carvone	Beverages, flavoring agent Antibacterial, anticancer, antifungal, antiinflammatory For acne control, appetizer, blood circulation, digestion, flatulence, hepatoprotective, improving recovery, menstrual and respiratory disorders, rheumatism, relaxant, mouth and skin health, ureter infections
Angelica keiskei	α-Thujene, tricyclene, sabinene, Δ^3-carene, myrcene, β-phellandrene, γ-terpinene, *p*-cymene, α-terpinolene, linalool, *p*-cymen-9-ol, terpinen-4-ol, bornyl acetate, (*E*)-β-ionone, citronellyl butanoate (**61**)	Beverages Antiaging, antibacterial, anticancer, antifungal antihypertension antiinflammatory, antimicrobial, antioxidant, antiparasitic, tonic For anemia, constipation, detoxification, diabetes, gastrointestinal disorder, joint and muscular pain, nerve degeneration, premenstrual syndrome, immune system booster, weight loss

(continued)

Table 1 (continued)

Angelica sylvestris	α-Pinene, camphene, sabinene, β-pinene, myrcene, α-phellandrene, *p*-cymene, limonene, terpinolene, cryptone, carvone, bornyl acetate	Candies, beverages (herbal tea) Antifungal, antimicrobial, antiparasitic, diuretic, expectorant For anorexia, anxiety, arthritis, circulation problems, cold, coughs, cystitis, dementia, dyspepsia, fever, headaches, indigestion, insomnia, muscular cramps, nervousness and plague, nocturia, respiratory catarrh, rheumatic pain, runny nose, stroke, sore throat flatulence, urinary antiseptic
Aniba rosaeodora (Bois de Rose oil)	Limonene, 1,8-cineole, linalool, α-terpineol, nerol, geraniol, linalyl acetate	Flavoring, perfumes, cosmetics Analgesic, antibiotic, antiseizure, antiseptic, aphrodisiac, cephalic, deodorant, insecticide For protecting the health of skin, relieving stress and pain, sexual health, sore muscle, source of linalool, spiritual and mediation
Anthemis nobilis (Roman chamomile oil)	α-Pinene, sabinene, myrcene, *p*-cymene, 1,8-cineole, limonene, (*E*)-β-ocimene, artemisia ketone (**5**), α-terpinene, terpinolene, terpinen-4-ol, α-terpineol, carvone	Beverages, deodorant for liquor, flavor reinforcing agent Anticancer, antiinflammatory, antimicrobial, sedative
Anthriscus cerefolium (Chervil)	β-Pinene	Vegetables, beverages (herbal tea) Antifungal, antihypertension, antiinflammatory, antioxidant, diuretic, mild stimulant, negative inotropic, spasmolytic For digestion
Anthriscus cerefolium (Wild chervil)	α-Pinene, sabinene, myrcene, β-phellandrene, (*Z*)-β-ocimene	Vegetables, beverages (herbal tea) Analgesic, antiinflammatory, antiplatelet aggregation, antiproliferative, antipyretic, antitussive, antitumor, antiviral, diuretic For cough remedy

(continued)

Table 1 (continued)

Apium graveolens var. *dulce* (Celery)	α-Thujene, α-pinene, camphene, β-pinene, sabinene, myrcene, cumene (**68**), α-terpinene, limonene, β-phellandrene, *p*-cymene, γ-terpinene, (*E*)-β-ocimene, terpinolene, *p*-mentha-1,3,8-triene (**204**), borneol, terpinene-4-ol, carveol	Vegetable (salad, cooked vegetable, in soup, stews) Antibacterial, anticancer, antihypertension, antiinflammatory, antimicrobial, antioxidant, antiulcerogenic For bladder and liver disorders, stomach digestion, urinary tract infections
Apium graveolens var. *dulce* (Celery)	*Seed oil*: α-pinene, β-pinene, myrcene, limonene, (*E*)-β-ocimene, γ-terpinene, *p*-cymene, linalool, (*E*)-limonene 1,2-oxide (**154a**), dihydrocarvone (**43**), *p*-mentha-6,8-dien-2-ol, α-terpineol, (*E*)-carveol, carvone, (*E*)-sabinyl acetate (**299**), (*Z*)-carveyl acetate (**39b**), (*Z*)-*p*-mentha-2,8-dien-1-ol (**209b**) *Leaves*: α-pinene, β-pinene, myrcene, limonene, γ-terpinene, *p*-cymene, (*E*)-limonene-1,2-oxide (**154a**), (*Z*)-limonene-1,2-oxide (**154b**), α-terpineol, dihydrocarveol (**37**), (*E*)-*p*-mentha-2,8-dien-1-ol (**209a**), (*Z*)-p-metha-2,8-dien-1-ol (**209b**), (*Z*)-*p*-mentha-1(7),8-diene-2-ol (**203b**), (*E*)-*p*-mentha-1(7),8-dien-2-ol (**203a**), (*Z*)-carveol (**39a**), (*E*)-carveol (**38a**), *p*-mentha-8-en-1,2-diol, dihydrocarvone, carvone, (*Z*)-*p*-mentha-1(7),8-dien-2-yl acetate (**203c**), (*E*)-carveyl acetate (**38b**), pinocarveyl acetate (**259**)	Vegetable Analgesic, antiarteriosclerosis, anticancer, antihypertension, analgesic, diuretic, platelet condensation For constipation, whole intestine
Apium graveolens var. *rapaceum*	α-Pinene, sabinene, myrcene, α-terpinene, limonene, β-phellandrene, γ-terpinene, (*E*)-β-ocimene, *p*-cymene, linalool, terpinen-4-ol, α-terpineol	Vegetable Antiosteoporosis, antipneumonia, antitumor, diuretic For brain and muscle function, digestion, gout, immunity system booster, digestion, Parkinson's disease, brain and muscle, function, rheumatism, skin health, wounds

(continued)

Table 1 (continued)

Arachis hypogaea	Myrcene, limonene, β-terpinenyl acetate (**311**)	Foods Antiaging, anti-Alzheimer disease's, antidiabetes, antihypertension, antiinfluenza, antioxidant
Aralia cachemirica	α-Pinene, camphene, β-pinene, sabinene, myrcene, α-phellandrene, α-terpinene, limonene, 1,8-cineolol, (*Z*)-β-ocimene, linalool	Anticancer, antibacterial, antiinflammatory For arthritis, diabetes mellitus, gastritis, hypoglycemia, nephritis, rheumatic lumbago, lameness
Aralia cordata	α-Pinene, camphene, β-pinene, sabinene, Δ^3-carene, myrcene, α-phellandrene, limonene, terpinolene, (*Z*)-*allo*-ocimene (**245**), (*E*)-*allo*-ocimene (**246**), *p*-cymene, camphor, borneol, *p*-cymen-8-ol, terpinen-4-ol, carvone, α-terpineol, (*E*)-sabinene hydrate (**296**), (*E*)-carveol, β-citronellol, (*E*)-pinocamphone (**261**), α-thujone (**331a**), verbenone, (*E*)-pinocarveol, lavandulol (**136**), *p*-methadien-2-ol, thymol	Vegetable Antipyretic, diaphoresis, sedative For cold, sensitive constitution
Aralia elata (Angelica tree)	α-Pinene, camphene, β-pinene, (*E*)-β-sabinene (**294**), myrcene, α-phellandrene, α-terpinene, limonene, β-phellandrene, (*Z*)-β-ocimene, γ-terpinene, (*E*)-β-ocimene, *p*-cymene, α-terpinolene, (*Z*)-linalool oxide, (*E*)-linalool oxide, myrtenol, linalool, camphor, borneol, myrtenal (**195**), *p*-cymen-9-ol, terpinen-4-ol, α-terpineol, nerol (**234b**), geraniol, geranial, bornyl acetate, geranyl formate (**98**), geranyl butanoate (**101**), geranyl hexanoate (**107**), geranyl octanoate (**109**), geranyl benzoate (**110**), neryl *iso*-valerate (**237b**), neryl hexanoate (**239**), bornyl hexanoate (**18**), citronellyl hexanoate (**65**), citronellic acid (**56**), geranic acid (**95**), β-ionone, (*Z*)-jasmone (**133**)	Vegetable Antidiabetes, antimicrobial, antioxidant, sterilization For blood improvement, immune system booster

(continued)

Table 1 (continued)

Arctium lappa	Neral, geranial, geraniol	Beverages (detoxifying herb) Antibacterial, anticancer, antifungal, antihepatotoxic, antiinflammatory, antimicrobial, antimutagenic, antioxidant, antitumor, antiulcer, diaphoretic, diuretic, hypoglycemic For carminative, cholagogue, depurative, eczema, ringworm, stomachic, skin disease
Arctostaphylos uva-ursi	α-Thujene, β-thujene (**330**), limonene, *p*-cymene, linalool, camphor, (*Z*)-linalool oxide, (*E*)-linalool oxide, borneol, *p*-cymene-9-ol, myrcenol (**192**), α-campholenal (**28**), (*E*)-pinocarveol, lilac aldehyde B (**147**), lilac aldehyde A (**146**), nerol oxide (**242**), (*Z*)-β-ocimenol (**247**), menthol (**183**), lilac aldehyde C (**148**), α-phellandren-8-ol, (**270**), *p*-mentha-1,5-dien-8-ol,(**217**), *iso*-menthol (**186a**), terpinen-4-ol, *iso*-verbanol (**340a**), *neo*-isomenthol (**188**), α-terpineol, myrtenol, γ-terpineol, verbenone, (*E*)-carveol, *p*-menth-1-en-9-al (**221d**), perilla alcohol (**271**), nerol, geraniol, β-cyclocitral, carvone, perilla ketone, (**273**), pulegone, carvacrol methyl ether (**35**), piperitone, (**281**), perillaldehyde (**274**), *iso*-menthyl acetate (**186b**), thymol methyl ether (**334**), thymol, carvacrol, (*E*)-β-damascenone (**85**), (*Z*)-jasmone (**133**), (*E*)-geranyl acetone, dihydroactinidiolide, (*Z*)-β-ocimenone (**249**)	Foods For bladder and kidney disorders, bronchitis, constipation, inflammatory diseases of the urinary tract, urethritis, cystitis, strengthening and imparting tone to the urinary passages, swelling of the bladder, urethra, constipation, urethritis

(continued)

Table 1 (continued)

Artemisia absinthium (Worm wood)	α-Thujene, α-pinene, verbenene, sabinene, β-pinene, myrcene, α-phellandrene, α-terpinene, (*E*)-sabinene hydrate, linalyl acetate, camphor, (*E*)-verbenol, thujone, α-campholenal, sabinaketone, pinocarvone, umbellulone, terpinen-4-ol, myrtenal, verbenone, β-terpinyl acetate (**311**), (*Z*)-chrysanthenyl acetate (**49**), neryl isobutanoate (**237a**), geranyl isobutanoate (**102**), neryl isovalerate (**237b**)	Beverages (herbal tea) Anthelmintic, antioxidant, antiseptic, cardials, insecticidal, narcotic, diaphoretic For Crohn's disease, loss of appetite, indigestion, gallbladder disorders, low sexual desire, spasms, sweating stimulant, worm infestations, wounds
Artemisia annua	α-Pinene, camphene *p*-cymene, camphor, 1,8-cineole, 3(10)-caren-4-ol (**32**), α-terpineol, carvone, artemisia ketone (**5**), artemisyl acetate (**7**), (*Z*)-chrysanthenyl acetate (**49**), yomogi alcohol (**345**)	Beverages Anthelminthic, anticancer, antimalarial, antipyretic, antiseptic, antispasmodic, antiviral For carminative, cold, cough, diarrhea, nervous diseases, stimulant, tonic, stomachic
Artemisia capillaris	α-Pinene, β-pinene, Δ^3-carene, limonene, γ-terpinene, *p*-cymene, α-terpineol, bornyl acetate	Beverages Antifibrotic, antiinflammatory, antioxidant, antisteatotic, antiviral, cholagogue, choleretic, vermicide
Artemisia dracunculus (Tarragon oil or estragon oil)	α-Pinene, camphene, sabinene, β-pinene, myrcene, *p*-cymene, limonene, α-phellandrene, (*Z*)-β-ocimene, (*E*)-β-ocimene, *allo*-ocimene (**246**), γ-terpinene, α-terpinene, (*Z*)-sabinene hydrate (**297**), linalool, β-thujone (**331b**), camphor, terpinen-4-ol, *iso*-menthol (**186a**), bornyl acetate, carvacrol, α-terpinyl acetate (**313**)	Flavoring and fragrance, beverages, source, vine flavor Analgesic, antidiabetes, antiinflammatory, antimicrobial, sedative For osteoarthritis, sleep aid
Artemisia indica var. *maximowiczii*	α-Pinene, camphene, sabinene, myrcene, limonene, 1,8-cineol, *p*-cymene, camphor, (*E*)-sabinene hydrate, verbenol, borneol, chrysanthenone, (*E*)-chrysanthenyl acetate, (**48a**), verbenol, 2-pinen-4-ol [(=(Z)-verbenol)] (**343**), terpinen-4-ol, thujone, *p*-menth-1-en-8-ol (**205**), bornyl acetate, lavandulyl acetate (**137**)	Foods, food additives, food flavor for Japanese cookies, Mochi (sticky rice boll) Antipyretic For abdominal pain, anemia, back pain, diarrhea, hemostatic, poor circulation, stomachic

(continued)

Table 1 (continued)

Artemisia indicium var. *indicum*	α-Pinene, myrcene, limonene, 1,8-cienole, (*Z*)-β-ocimene, chrysanthenone (**50**), camphor, borneol, bornyl acetate	Foods (leaves for Japanese cuisine) Antimicrobial
Artemisia princeps (Japanese mugwort)	α-Thujene, α-pinene, camphene, β-pinene, sabinene, myrcene, α-phellandrene, α-terpinene, limonene, 1,8-cineole, β-phellandrene, (*Z*)-β-ocimene, γ-terpinene, (*E*)-β-ocimene, *p*-cymene, terpinolene, *o*-cymene, dehydro-*p*-cymene (**75**), 2,3-dehydro-1,8-cineole (**53**), artemisia ketone, yomogi alcohol, terpinen-4-ol, α-thujone, artemisyl acetate (**7**), β-thujone (**331b**), camphor, (*E*)-verbenol, borneol, (*E*)-sabinene hydrate, chrysanthenone, artemisia alcohol (**8**), thujanol acetate (**325b**), (*Z*)-sabinene hydrate, pinocarvone, myrtenal (**195**), *p*-cymen-9-ol, citronellol, (*E*)-myrtenol, (*Z*)-myrtenol, α-terpineol, carvone, thujyl alcohol (**326**), α-terpinyl acetate, carveyl acetate,, verbenone (**344**), (*Z*)-carveol, (*E*)-carveol, neral (**234a**), geranial, geraniol, piperitol, chrysanthenol (**47**), bornyl acetate (**15**), lavandulyl acetate (**137**), bornyl propanoate (**16a**), bornyl isobutyrate (**16b**), bornyl angelate (**16c**), (*Z*)-myrtenol (**194b**), (*E*)-myrtanol (**194a**), perilla alcohol (**271**), perillaldehyde, *p*-mentha-1(7),8-triendien-2-ol, *iso*-piperitenone (**276**), piperityl acetate (**264**)	Foods, beverages Analgesic, anticancer, expectorant, hemostatic For anemia prevention, blood circulation, cerebral infarction prevention, constipation, hematogenesis, menstrual regulation, myocardial
Artemisia tridentata	Artemisia triene (**6b**), santolina triene (**301b**), α-thujene, α-pinene, camphene, 1,8-cineol, chrysanthenone, camphor, pinocarvone, geranyl *iso*-butanoate (**102**), geranyl butanoate (**101**), neryl *iso*-valerate (**237b**), geranyl *iso*-valerate (**104**)	Perfume, beverages (herbal tea) Antibacterial, antirheumatic, antiseptic, digestive, disinfectant, febrifuge, ophthalmic, poultice, sedative For bronchitis pneumonia, bad colds, coughs, sore throats

(continued)

Table 1 (continued)

Asparagus officinalis	Geranyl acetone, β-ionone	Vegetable (raw or pickled, cooked) Anticancer, antidiabetes, antimicrobial, antioxidant, antitussive, diuretic, expectorant, fatigue recovery, porcelain skin, hypolipidemic, vermicide For lung heat, convulsions, mange
Atractylodes japonica	Δ^3-Carene, sabinene, *p*-cymene, verbenol	Herbal medicines. Antiosteoporosis For allergies, bloating, diarrhea, dust mites, dialysis, edema, fluid retention, indigestion, joint pain, rheumatism, stomachache, weight loss
Basella rubra	Limonene, 2-menthene (**181**), pulegone, myrcenol, piperitone (**281**), piperitenone (**275**), β-damascenone	Vegetable, beverages (herbal tea) Androgenic, anticancer, antifungal, antihypoglycemic, antimicrobial, antioxidant, cytotoxic, antibacterial, antiinflammatory, antiulcer, antiviral, central nervous system depressant, hypocholesterolemic, immunomodulatory, nephroprotective, gastroprotective For wound healing
Bassia scoparia (Kochia, Mexican fireweed)	Camphenilone (**26**), damascenone, bornyl angelate (**16c**)	Vegetable Antifungal, antimicrobial, antiphlogistic astringent, cardiotonic, diuretic, restorative For colds, diarrhea, dysentery, dyspepsia, eczema, fevers, hernia, incontinence of urine, intercostal neuralgia, hernia
Beta vulgaris var. *rapa* (Table beet, red beet, yellow beet)	Carvone, γ-irone (**130c**)	Vegetable, beverage (juices) Antioxidant
Betula pendula	*p*-Cymene, (*E*)-linalool oxide, (*Z*)-linalool oxide	Foods, alcoholic beverages, aroma, and flavor Anticholesterolemic, antifungal, antiinflammatory, diuretic, germicides, laxative tonic For eczema, intermittent fevers, psoriasis

(continued)

Table 1 (continued)

Boletopsis leucomelas	α-Pinene, *o*-cymene (**77**), (*E*)-pinocarveol (**258a**), menthol (**183**), terpinen-4-ol, *p*-cymen-8-ol (**81**), cryptone (**67**)	Foods Apoptosis induction
Boletus edulis	α-Pinene, limonene, 1,8-cineole, linalool, menthol, (*E*)-geranyl acetone, β-ionone	Foods
Boswellia carterii (Olibanum oil)	α-Pinene, camphene, α-phellandrene, *p*-cymene, verbenol, verbenone, bornyl esters	Beverages Arthritis, anticancer, antiinflammatory For asthma, Parkinson's disease, rheumatoid arthritis
Brassica campestris	Cumene	Vegetable
Brassica oleracea var. *capitata* (Cabbage)	1,8-Cineole, β-cyclocitral, geranyl acetone	Vegetable
Brassica juncea (Leaf mustard)	Linalool, citronellol, nerol, geraniol	Vegetable Antitumor, anodyne, diuretic For abscesses, aperitif, emetic, cold, lumbago, rheumatism, rubefacient, stomach disorders
Brassica juncea var. *integrifolia* (Mustard vegetable)	Pulegone, lavandulol (**136**)	Vegetable, pungent spice Anticancer, antimicrobial, diuretic, expectorants, stimulant
Brassica napus (= *B. napa* var. *amplexicaulis*)	α-Pinene, β-pinene, sabinene, myrcene, limonene, 1,8-cineole, perillene (**277**), linalool, β-ionone	Vegetable Antigout, antiinflammatory, antiscurvy, diuretic
Brassica oleracea var. *acephala* (Kale)	1,8-Cineole, geranyl acetone	Vegetable, beverages Anticancer, antidiabetes, antioxidant For hot flashes, high cholesterol, heart disease, colitis, constipation, loss of vision, wound healing
Brassica oleracea var. *italica* (Broccoli)	Limonene	Vegetable Antiinflammatory, laxative For glaucoma, pneumonia
Callicarpa americana	β-Pinene, α-terpinene, *p*-cymene limonene, 1,8-cineolle, γ-terpinene, *(Z)*-linalool oxide, terpinolene, linalool, β-fenchyl alcohol, (*Z*)-*p*-ment-2-en-ol, α-campholenal, (*E*)-sabinol, pinocarvone, borneol, α-terpineol, myrtenal, myrtenol	Fruit, beverages (herbal tea) Diuretic For dysentery, colic, fever, malaria, rheumatism, stomachaches

(continued)

Table 1 (continued)

Callicarpa japonica	α-Pinene, β-pinene, linalool	Antibacterial, antiviral, hemostatic, insecticidal For intestinal and uterine bleeding
Camellia sinensis	Myrcene, limonene, linalool, *p*-cymene, (*E*)-linalool oxide (furanoid) (**164a**), (*Z*)-linalool oxide (furanoid) (**164b**), linalool oxide (pyranoid), (**165a,b**), jasmone, terpinen-4-ol, α-terpineol, citral, nerol, geraniol, menthol, geranic acid, neryl acetone (**241**), actinidiolide	Beverages Antiarteriosclerosis, anticancer, antiinflammatory, antimicrobial, antioxidant, antiviral, diuretic, hypoglycemic, suppressing blood sugar rise, hypotensive, hypolipidemic, hypocholesterolemia, skin secretion regulating action
Cananga odorata f. *genuine* (Ylang-ylang oil)	α-Pinene, limonene, linalool, geraniol, geranyl acetate	Foods to avoid with arthritis, luxury compounded fragrance Antiaging, antiinflammatory, antioxidant, anxiety, carminative, insect repellent, NO production inhibition For athlete's foot, arthritis, asthma, colds, cough, depression, diarrhea, fever, headaches, insomnia, irregular menstrual period, malaria, joint, menstrual and muscle pain, nervous fatigue, sinus infections, wound healing
Cananga odorata f. *macrophylla* (Cananga oil)	α-Pinene, limonene, linalool, geranyl acetate	Flavoring agent in gelatins, puddings, and beverages, cosmetics for soap Antiinflammatory, antimicrobial For cold, hypertension, insect bites, menopausal disorders, nervous fatigue, skin care
Canavalia gladiata	*	Vegetables, beverages Antiinflammatory For ache, asthma, atopic dermatitis, dysentery, kidney disease, obesity, stomachache, vomiting

(continued)

Table 1 (continued)

Cannabis sativa	*Seed*: α-thujene, α-pinene, camphene, β-pinene, α-terpinene, sabinene, limonene, 1,8-cineol, γ-terpinene, (*E*)-β-ocimene, fenchene	For amyotrophic lateral sclerosis, cachexia or dramatic weight loss, muscle atrophy, cancer, constipation, glaucoma, HIV/AIDS, Huntington's disease, inflammatory bowel, injury with spasticity, multiple sclerosis, muscle spasms, nausea, neuropathy, Parkinson's disease, spinal cord post-traumatic stress disorder, seizures
Cantharellus cibarius	α-Pinene, limonene, 1,8-cineol, menthol	Foods
Capsicum annuum var. *grossum* (Bell pepper, sweet pepper)	*Green, turning, and red stage*: α-pinene, β-pinene, Δ^3-carene, myrcene limonene, (*Z*)-β-ocimene, (*E*)-β-ocimene, *p*-mentha-1,3,8-triene, linalool, fenchyl alcohol	Vegetable Anticancer, antimicrobial, antioxidant, antiseptic For appetite stimulator, cough, counter immunomodulatory, headache, irritant, parasitic infection, rheumatism, sore throat, toothache, wound healing
Capsicum frutescens (= *C. annum*) (Red pepper, chili pepper)	*Oleoresin*: β-pinene, Δ^3-carene, myrcene, limonene, α-phellandrene, 1,8-cineole, linalool, terpinen-4-ol, α-terpineol, thujone, β-cyclocitral, carvone, dihydro-α-ionone (**121**), dihydro-β-ionone (**125**), α-ionone, β-ionone, geranyl acetone, dihydroactinidiolide *Sweet chili*: α-thujene, α-pinene, camphene, β-pinene, sabinene, Δ^3-carene, myrcene, limonene, α-phellandrene, γ-terpinene, *p*-cymene, terpinolene, linalool, terpinen-4-ol *Fresh Jalapenos*: linalool, α-terpineol, β-ionone	Vegetable, flavoring, food preservatives Antimicrobial, antifungal, antihemorrhoidal, antiobesity, antirheumatic, antiseptic, carminative, circulation and alters temperature regulation, diaphoretic, detoxifiers, digestive, gastrointestinal circulation, sialagogue, stomachic For cardiovascular disease, metabolic syndrome
Carica papaya	α-Pinene, β-pinene, Δ^3-carene, myrcene, limonene, (*E*)-β-ocimene, (*Z*)-β-ocimene, *o*-cymene, linalool, (*E*)-linalool oxide, (*Z*)-linalool oxide, verbenone	Foods, flavoring used in candies, jellies, preserves, ice cream, meat tenderizers, chewing gum Antidiabetes, antihypertension, antiinflammatory, antimicrobial, antiparasitic, antiseptic, diuretic, hypocholesterolemic

(continued)

Table 1 (continued)

Carthamus tinctorius	*Flower:* α-phellandrene, α-terpinene, limonene, γ-terpinene, *p*-cymene, 1,8-cineole, camphor, terpinen-4-ol, α-phellandrene oxide (**278**), β-damascenone	Beverages For angina, arteriosclerosis prevention, breast cancer, cataract arteriosclerosis, eye strain, poor blood circulation promotion, uterine fibroids, whole intestine
Carum carvi (Caraway oil)	Limonene, dihydrocarvone (**43**), carvone, carveol, dihydrocarveol (**37**), perilla alcohol, carvacrol	Beverages, canned food flavor, liquor of seasoning, sausage, meat, confectionary flavor, spice Antigriping agent, antiinflammatory, antimicrobial, antioxidant, carminative, pediculicide, mild CNS depressant, immunomodulatory, stomachic
Carum copticum (Ajowan oil)	α-Thujene, α-pinene sabinene, myrcene, α-terpinene, limonene, β-phellandrene, γ-terpinene, *p*-cymene, β-fenchyl alcohol (**92a**), (*Z*)-limonene oxide, terpinolene, terpinen-4-ol, thymol, carvacrol	Foods, spice in curries, cosmetics (lotion, ointment) Abortifacient, abortion potential, amebiasis, antiarthritic, antibacterial, anticarcinogenic, antidyspnea, antilithiasis, antimicrobial, antiparasitic, antiplatelet-aggregatory, antiseptic, antitussive, bronchodilatory, carminative, diuretic, expectorant, genotoxicity, galactagogic For acute pharyngitis, cold, diarrhea, digestive, dysentery, gastrointestinal, inflectional respiratory disorders, indigestion, rheumatic pain
Celosia argentea	α-Pinene, camphene, limonene, *p*-menth-3-en-8-ol, β-cyclocitral, pulegone, carvanacetone, geranyl acetone, (*E*)-β-ionone	Beverages (herbal tea) Astringent, hemostatic, ophthalmic, parasiticide, poultice For bloody stool, dysentery diarrhea, hemorrhoid, uterine bleeding, leucorrhoea, menstrual dysfunction
Centaurea cyanus	β-Thujene, α-terpinene, γ-terpinene, *p*-cymene, α-terpinolene, (*E*)-linalool oxide, *p*-cymene-9-ol, terpinen-4-ol, verbenone	Beverages Astringents, skin conditioning

(continued)

Table 1 (continued)

Centella asiatica	α-Pinene, camphene, sabinene, β-pinene, myrcene, α-phellandrene, Δ^3-carene, Δ^2-carene, α-terpinene, *p*-cymene, limonene, *p*-menth-3,8-diene (**221b**), 1,8-cineole, (*E*)-*allo*-ocimene (**245a**), γ-terpinene, terpinolene, linalool, *m*-cymen-9-ol, terpinene-4-ol, (Z)-dihydrocarvone, verbenone, (*E*)-carveol, carvone, (*E*)-myrtenol, *p*-cymene-7-ol (=cumin alcohol) (**70**), *p*-cymene-9-ol, α-terpineol, geraniol, myrtenyl acetate	Beverages (herbal tea) Antischistosomiasis For anxiety, cold, flu, diarrhea, fatigue, hepatitis, indigestion, jaundice, sunstroke, tonsillitis, urinary tract infection, wound healing
Chaenomeles japonica	α-Pinene, β-pinene, sabinene, Δ^3-carene, myrcene α-phellandrene, α-terpinene, limonene, γ-terpinene, terpinolene, geraniol, carveol, terpinen-4-ol, citronellal, neral, geranial, perillaldehyde, carvone, linalyl acetate, citronellyl acetate, neryl acetate (**237**), α-terpinyl acetate	Beverages, juice wine, puree, aroma extracts, syrup liquor, carbonated soft drink, marmalades, flavored sweet, ice cream included fruit sugar extracts, nourishing tonic Anticonvulsant, antitussive, expectorant For gastrospasm, muscle ache
Chamaecyparis formosensis (Benihi oil)	α-Pinene, camphene, sabinene, myrcene, limonene, 1,8-cineole, γ-terpinene, camphor, borneol, α-terpineol, myrtenol, myrtenal, bornyl acetate, geranyl acetone, dihydromyrtenol (**199**), myrtenyl acetate (**197**)	Compound flavor Antifungal, antimicrobial, larvicidal (mosquito), nitric oxide production inhibitory
Chamaecyparis obtusa (Hinoki oil)	α-Pinene, camphene, β-pinene, limonene, borneol, α-terpineol, bornyl acetate	Compound flavor, soap flavor, bath additives Bactericidal, insecticide
Chamaecyparis obtusa var. *formosana* (Formosan hinoki oil)	α-Pinene, camphene, β-pinene, sabinene, γ-terpinene, *p*-cymene, linalool, α-terpineol, α-thujaplicin (**327**), β-thujaplicin (=hinokitiol) (**328a**)	Compound flavor, soap flavor, bath additives Bactericidal, insecticide
Chenopodium album	α-Pinene, limonene, *p*-cymene, α-terpinene, ascaridole (**9**), pinane-2-ol (=pinene hydrate) (**286** or **287**), α-terpineol, α-terpinyl acetate	Foods, vegetable, herbal medicines Antioxidant, anthelmintic, antiinflammatory, antifungal, antinociceptive, antipruritic, hypotensive, laxative For hepatic disorders, spleen enlargement, intestinal ulcers

(continued)

Table 1 (continued)

Chenopodium ambrosioides (Mexican tea)	α-Pinene, myrcene, Δ^3-carene, α-terpinene, *p*-cymene, limonene, γ-terpinene, pinocarvone, dihydroascaridole (**10**), ascaridole (**9**), (*Z*)-isoascaridole (**11b**), (*E*)-isoascaridole (**11a**), α-terpinyl acetate, thymol	Beverage (herbal tea), vegetable Analgesic, antifungal, antimicrobial, antiinflammatory
Chrysanthemum coronarium (Garland chrysanthemum)	α-Pinene, camphene, β-pinene, myrcene, *p*-cymene, linalool	Beverages, vegetable Anticancer, antiinflammatory
Chrysanthemum indicum	Tricyclene, α-pinene, α-thujene, camphene, β-pinene, sabinene, myrcene, α-terpinene, limonene, α-phellandrene, (*Z*)-β-ocimene, γ-terpinene, (*E*)-β-ocimene, *p*-cymene, terpinolene, 1,8-cineole, linalool, α-thujone, (*E*)-sabinene hydrate, α-terpinyl acetate, chrysanthenone, camphor, pinocarvone, (*Z*)-chrysanthenyl acetate (**49**), bornyl acetate, terpinen-4-ol, umbellulone (**337**), (*E*)-chrysanthenyl acetate (**48**), (*E*)-piperitol, α-terpineol, borneol, piperitone, carvone, (*E*)-chrysanthenol (**47**), myrtenol, (*E*)-carveol (**38a**), *p*-cymen-9-ol, (*Z*)-carveol (**39a**)	Beverages (herbal tea, alcoholic), food additives Antiphlogistic, antimicrobial, blood tonic, hypocholesterolemic, hypotensive For blood stasis, depurative, detoxifying, dissipating blood stasis, dissipating heat, febrifuge, migraine stomachic, vasodilator, vulnerary
Chrysanthemum morifolium	α-Thujene, α-pinene, camphene, β-pinene, sabinene, myrcene, limonene, *p*-cymene, α-ocimene, γ-terpinene, terpinolene, camphor, 2-pinene-4-ol [=(*Z*)-verbenol)], (**343**), α-terpineol, *p*-menth-1-en-8-ol, (*E*)-verbenol (**342a**), bornyl acetate, chrysanthenyl acetate (**48** or **49**)	Foods, beverages Antibacterial, antifungal, antiphlogistic, antiinflammatory, antipyretic, carminative, lower chest pain, depurative, diaphoretic, digestive, enema, febrifuge, heat rash symptoms,. hypocholesterolemic, ophthalmic, refrigerant, sedative, stomachache
Cicer arietinum (Chick pea)	*Seeds*: α-pinene, camphene, β-pinene, Δ^3-carene, myrcene, α-terpinene, limonene, β-phellandrene, γ-terpinene, *p*-cymene, terpinolene	Foods Antibilious, anticancer, anticonvulsant, antidiabetes, antidiarrheal, antiinflammatory, antinephrolithiasic, antioxidant, aphrodisiac, diuretic, estrogenic, hepatoprotective, hypocholesterolemic, hypolipidemic

(continued)

Table 1 (continued)

Cichorium endivia (Endive)	β-Pinene, *p*-cymene, (*Z*)-linalool oxide, (*E*)-linalool oxide, myrtenol, α-terpineol, carvone, dihydrocarvone, dihydroactinidiolide (**10**), actinidiolide (**2**), β-ionone, geranyl acetone	Vegetable Astringent For constipation, dyspepsia, snake bite
Cichorium intybus	1,8-Cineole, camphor, linalool, α-terpineol, thymol, carvacrol, geranyl acetone, β-ionone	Vegetable, food additives, beverages. *Root*: coffee substitute Antibacterial, antifungal, hypoglycemic For appetite loss, blood purifier, gall stones, gout, lowering blood sugar valance, maintaining hormonal swelling and skin irritation, premenstrual syndromes, rheumatism
Cinnamomum rivulorum	*Leaf oil*: α-pinene, geraniol, cumin aldehyde (**71**) *Bark oil*: geraniol, cumin aldehyde	Beverages
Cinnamomum camphora (Camphor oil)	α-Pinene, camphene, β-pinene, myrcene, α-phellandrene, limonene, camphor *Seed*: α-pinene, β-pinene, myrcene, limonene terpinolene, linalool, camphor, α-terpineol	Foods (young shoots and leaves cooked). Old leaves for flavoring in baked goods, candy, spice Anesthetic, anthelmintic, antifungal, antiinflammatory, antimicrobial, antineurotic, antioxidant, antirheumatic, antiseptic, antispasmodic, cardiotonic, carminative, diaphoretic, germicide, insecticide, sedative, stimulant, tonic, vermicide For digestive complaints and depression, decongestant, disinfectant For diarrhea, hysteria, nervousness
Cinnamomum camphora var. *glaucescens* (Apopino oil)	α-Pinene camphene, limonene, 1,8-cineole, linalool, camphor, α-terpineol, geraniol	Mosquito larvicidal, nematocidal
Cinnamomum cappru-corende	*Leaf oil*: linalool, geraniol, cumin aldehyde, cumin alcohol (**70**)	Beverages

(continued)

Table 1 (continued)

Cinnamomum cassia (Cassia oil)	*Cassia oil*: α-pinene, borneol, α-terpineol	Food flavor, beverages (herbal tea), cookies, bread, chewing gum, crude drug Analgesic, antibiotic, antiinfectious, antiinflammatory, antineuralgic, antiseptic, antispasmodic, antiviral, aphrodisiac, bactericidal, cholagogue, cicatrisant, decongestant, expectorant, digestive, emmenagogue, febrifuge, hepatic, hypotensive, insecticide, muscle relaxant, nervine, sedative, stimulant, stomachic, sudorific, tonic, vermifuge
Cinnamomum cassia	*Leaf/bark oil*: α-pinene, camphene, β-pinene, Δ^3-carene, myrcene, limonene, 1,8-cineol, (*E*)-β-ocimene, *p*-cymene, camphor, *iso*-borneol (**19a**), borneol, α-terpineol, geraniol, carvone, bornyl acetate	Beverages, flavoring agent Antiseptic For headache, neuralgia, stomach ulcer, diabetes, obesity
Cinnamomum citriodorum	α-Pinene, α-phellandrene, limonene, 1,8-cineol, linalool, (*E*)-rose oxide (**291**), *iso*-pulegol (**283**), citronellol, neral (**234a**), geraniol, geranial (**94**), α-terpinyl acetate, cumin aldehyde, cumin alcohol	Spice, beverages Stomach ailments
Cinnamomum dubium	*Leaf oil:* α-pinene, geraniol, cumin alcohol *Bark oil:* geraniol, cumin alcohol	Beverages
Cinnamomum loureirii (Japanese cassia oil)	α-Pinene, camphene, β-pinene, Δ^3-carene, limonene, 1,8-cineole, linalool, *p*-cymene, camphor, α-terpineol, citral	Food flavor for cookies, bread, chewing gum, spice, beverages

(continued)

Table 1 (continued)

Cinnamomum zeylanicum (Ceylon cinnamon oil)	α-Pinene, myrcene, limonene, *p*-cymene, α-phellandrene, 1,8-cineole, linalool, camphor, terpinen-4-ol, α-terpineol, geranyl acetate	Beverages, food flavor, spice, and flavor and aroma enhancer for beverage, cookies, bread, chewing gum, source Analgesic, anti-Alzheimer's disease, antiaging, antibiotic, antidiabetes, antifungal, antioxidant, antiparasitic, antiseptic, antispasmodic, aphrodisiac, astringent, bactericide, cardiac, carminative, emmenagogue, insecticide, nephropathy, stimulant, stimulating appetite, stomachic, tonic, vermifuge For diarrhea, cold, headaches, respiratory complaint, muscular aches and pain, stomach upset
Cinnamosma fragrans	1,8-Cineol, linalool, geraniol, nerol, geranic acid	Antimicrobial, anti-leishmania, antimultidrug resistant For malarial symptoms, fatigue, muscular aches
Cinnamosma macrocarpa	β-Pinene, limonene, γ-terpinene, terpinolene	Antiaging, anticancer, fatigue, isogenic, malarial symptoms, muscular aches
Cinnamosma madagascariensis	α-Thujene, α-pinene, camphene, sabinene, verbenene (**341**), myrcene, p-mentha-1(7),8-diene, limonene, α-phellandrene, β-phellandrene, α-terpinene, 1,8-cineole, (*Z*)-β-ocimene, γ-terpinene, (*E*)-β-ocimene, p-cymene, terpinolene, linalool, (*Z*)-linalool oxide, (*E*)-β-linalool oxide (**166**), α-campholenal (**28**), (*E*)-pinocarveol (**258a**), pinocarvone (**260**), borneol, α-phellandren-8-ol (=*p*-mentha-1,5-den-8-ol) (**270**), terpinen-4-ol, myrtenal, *p*-cymen-9-ol, myrtenol, verbenone, α-terpineol, cryptone, thymol methyl ether (**334**), carvacrol methyl ether (**35**), bornyl acetate, linalyl acetate (**168**), *iso*-bornyl acetate (**20**), myrtenyl acetate (**197**), α-terpinyl acetate (**311**)	For dementia, dental decay, elephantiasis, epilepsy, fatigue, filariasis, gastrointestinal, malarial symptoms, muscular aches, respiratory, parasitic infections

(continued)

Table 1 (continued)

Citrullus lanatus (= *C. vulgaris)* (Watermelon)	Limonene, neral, geranial, geraniol, geranyl acetone	Foods Anticancer, antiinflammatory, antioxidant For digestion, hair care, heart health, macular degeneration, muscle soreness
Citrus aurantifolia (Mexican lime oil)	α-Thujene, α-pinene, camphene, sabinene, β-pinene, myrcene, α-phellandrene, α-terpinene, *o*-cymene, limonene, β-ocimene, γ-terpinene, α-terpinolene, linalool, fenchyl alcohol, *p*-menth-2-en-1-ol (**211a**), camphor, terpinen-1-ol (**306**), camphene hydrate (**24**), β-citronellal, borneol, isopulegone (**268**), terpinen-4-ol, geranial, neral, nerol, geraniol, bornyl acetate, citronellyl acetate, neryl acetate, geranyl acetate	Foods, cosmetic flavor. Antibacterial, anticancer, antidiabetes, antifungal, antihypertensive, antiinflammatory, antilipidemia, antioxidant For bone, heart, liver, urinary protection
Citrus aurantium ssp. *amara* (Bitter orange oil)	α-Pinene, β-pinene, myrcene, α-phellandrene, limonene, (*E*)-β-ocimene, α-terpinolene, linalool, neral, geranial, perillaldehyde, terpinen-4-ol, α-terpineol, linalyl acetate, geranyl acetate	Foods, beverages, cosmetics, crude drug (dried peel) Adrenergic, antibacterial, antiinflammatory, antiviral, cardiovascular and neurologic effects (dried peel)
Citrus aurantium subsp. *amara* (Petitgrain oil)	β-Pinene, camphene, limonene, linalool, geraniol, linalyl acetate	Flavor for soap, cosmetics Antimicrobial, antioxidant, antispasmodic
Citrus aurantium subsp. *amara* (Neroli oil)	α-Pinene, camphene, limonene, β-ocimene, (−)-linalool, α-terpineol, geraniol, linalyl acetate, geranyl acetate	Food flavor, beverages, flavor for cosmetics, compound flavor, bath additives, crude drug (dried peel) Antiinflammatory, antioxidant For anxiety, better sleep, depression, stress, stomachic, bitter stomachs

(continued)

Table 1 (continued)

Citrus aurantium subsp. *bergamia* (Bergamot oil)	α-Pinene, camphene, β-pinene, sabinene, myrcene, α-phellandrene, α-terpinene, limonene, β-phellandrene, 1,8-cineole, (*Z*)-β-ocimene, γ-terpinene, *p*-cymene, terpinolene, (*E*)-linalool oxide (**164a**, **165a**), (*Z*)-linalool oxide (**164b**, **165b**), (*E*)-limonene 1,2-oxide (**154a**), (*Z*)-limonene 1,2-oxide (**154b**), (*E*)-sabinene hydrate, terpinen-4-ol, citronellyl acetate, neral, α-terpinyl acetate, α-terpineol, neryl acetate, geranial, carvone, geranyl acetate, nerol, geraniol, perillyl acetate (**272**)	Foods. For many cosmetics: (eau de cologne, lotion, cream, soap) Antimicrobial, antiinflammatory For alleviates tension, anxiety, depression, digestion, hypotension
Citrus flaviculpus	α-Pinene, α-fenchene, camphene, β-pinene, sabinene, myrcene, α-phellandrene, α-terpinene, limonene, (*Z*)-β-ocimene, β-phellandrene, α-terpinene, *p*-cymene, γ-terpinene, terpinolene, α-thujone, (*Z*)-limonene oxide, menthone, (*E*)-linalool oxide, citronellal, camphor, terpinyl acetate, α-terpineol, neryl acetate, carvone, geranyl acetate, citronellol, perillaldehyde, carvone oxide (**44**), geranyl propanoate (**100**), *p*-menth-1-en-9-yl acetate, (**207**), nerol, (*E*)-carveol, *p*-menth-1-en-9-ol (**206**), *p*-menth-1,8-dien-9-ol or 10-ol (**218b**), limonene diol (**155**), neryl oxide (**241**)	Fruit, beverages, flavor, and fragrance
Citrus japonica	*Peel essential oil*: α-pinene, myrcene, limonene, β-phellandrene, carvone, geranyl acetate *Leaf essential oil*: 1,8-cineole, (*Z*)-linalool oxide, (*E*)-linalool oxide, linalool, camphor, borneol, δ-terpineol, menthol, terpinen-4-ol, (*E*)-*iso*-citral (**113a+232**), α-terpineol, citronellol, nerol, geranial, geraniol, bornyl acetate, geranyl formate, citronellyl acetate	Foods, fruit, beverages, jam, syrup, marmalade Antiphlogistic, antiviral, carminative, deodorant, expectorant

(continued)

Table 1 (continued)

Citrus junos (Yuzu)	α-Pinene, camphene, β-pinene, sabinene, myrcene, α-phellandrene, *p*-mentha-1(7),8-diene (**201**), α-terpinene, limonene, β-phellandrene, γ-terpinene, *p*-cymene, terpinolene, *p*-mentha-1,4,8-triene (**216**), (*Z*)-β-ocimene, linalool, α-terpineol, (*Z*)-carveol, nerol, geraniol, perillyl alcohol, *p*-mentha-1,8-dien-10-ol (=limonene 10-ol) (**156**), (*Z*)-limonene oxide, (*E*)-limonene oxide, dehydro-*p*-cymene (**75**), (*E*)-sabinene-hydrate, thymol methyl ether, terpinen-4-ol, *p*-mentha-1(7),2-dien-8-ol (**213**),(7*E*)-8-hydroxy-linalool (**159a**)	Fruit, foods, beverages (herbal tea, liquor, wine), flavor, food additives, vinegar, flavoring many snack products, marmalade, cake, syrup, spicy Japanese sauce with green or red chili pepper, citrus bath (yuzu bath) Antihypercholesterolemia, antiobesity, antioxidant, α-amylase and lipase inhibitory
Citrus lemon (Lemon oil)	α-Thujene, α-pinene, camphene, β-pinene, sabinene, myrcene, α-terpinene, γ-terpinene, limonene, linalool, neral, geranial, geraniol, neryl acetate, methyl geranate	Foods and food flavor, beverages. For many cosmetics; soap, eau de cologne, cosmetic water Bactericidal, stomachic
Citrus medica var. *sarcodactylis*	*Fruits/leaves*: α-pinene, β-pinene, myrcene, limonene, γ-terpinene, linalool, citronellal, neral, geranial, nerol, geraniol	Foods, beverages, sweets, Kampo medicines
Citrus medica var. *corsican*	α-Thujene, α-pinene, sabinene, β-pinene, myrcene, α-terpinene, *p*-cymene, limonene, (*E*)-β-ocimene, (*Z*)-β-ocimene, γ-terpinene, terpinolene, linalool, citronellal, *iso*-neral (**233**), *iso*-geranial, terpinen-4-ol, nerol, neral, geraniol, geranial, neryl acetate, geranyl acetate *Fruits/leaves*: α-pinene, β-pinene, myrcene, limonene, γ-terpinene, linalool, citronellal, neral, geranial, nerol, geraniol	Foods, beverages, sweets, Kampo medicines Analgesic, anthelmintic, antiinflammatory, antioxidant For cardiovascular health, constipation, diarrhea
Citrus paradisi (Grapefruit oil)	α-Pinene, β-pinene, sabinene, myrcene, α-phellandrene, limonene, (*E*)-ocimene, β-phellandrene, γ-terpinene, β-ocimene, linalool, (*Z*)-linalool oxide, (*E*)-linalool oxide, terpinen-4-ol, α-terpineol, neral, carvone, geranial, geraniol, geranyl acetate, perillaldehyde	Food flavor, beverage aroma Antiinflammatory, antiobesity, antistress, hypotension For acne, cold, depression, digestion, hangovers, headaches, jet lag

(continued)

Table 1 (continued)

Citrus reticulata var. *mandarin* (Mandarin oil)	α-Pinene, camphene, β-pinene, sabinene, myrcene, α-phellandrene, α-terpinene, limonene, β-phellandrene, (*Z*)-β-ocimene, γ-terpinene, *p*-cymene, terpinolene, (*E*)-sabinene hydrate, linalool, citronellal, terpinen-4-ol, neral, α-terpineol, nerol, geraniol, geranial, citronellal, geranyl acetate, citronellol, perillaldehyde, thymol, (*E*)-*p*-mentha-2,8-diol	Food flavor: soft drink, liquor, candy, compound fragrance Antiarteriosclerosis, antifungal, antiinflammatory, antioxidant For appetite, bilious diarrhea, carminative, catarrh, ear ache, fever, laxative, stomachic, tonic, toothache
Citrus sinensis (Orange oil)	α-Thujene, α-pinene, β-pinene, myrcene, limonene, α-terpinene, (+)-linalool, α-terpineol, geranial, neral, geraniol, nerol, citronellol, perillaldehyde	Foods, beverages, perfume, fragrances, cosmetics, crude drug (dried peel) Anticancer, antimicrobial, antioxidant, anxiety, depression, insecticide
Citrus sphaerocarpa	α-Thujene, α-pinene, β-pinene, sabinene, Δ^3-carene, myrcene, α-phellandrene, α-terpinene, limonene, β-phellandrene, γ-terpinene, *p*-cymene, terpinolene, dihydro-*p*-cymene, terpinene-4-ol, (*E*)-*p*-mentha-2,8-dien-1-ol, (*E*)-verbenol (**342**), (*E*)-piperitol (**262**), limonene-4-ol (**157**), terpinolene, γ-terpineol, piperitone, geranial, neryl acetate, geranyl acetate (**99**), β-citronellol, nerol	Fruit, beverages (juices, non-alcoholic and alcoholic), foods (frozen desserts, snack foods), flavor for cooked fish, Sashimi, soup, noodles), vinegar
Citrus sudachi	α-Thujene, α-pinene, camphene, sabinene, β-pinene, myrcene, Δ^3-carene, limonene, α-phellandrene, *p*-mentha-1,(7) 8-diene (**202**), α-terpinene, *p*-cymene, ocimene, α-terpinene, terpinolene, 1,8-cineole, β-phellandrene, (*Z*)-β-ocimene, (*E*)-β-ocimene, linalool, (*E*)-sabinene hydrate (**296**), (*Z*)-linalool oxide, (*E*)-linalool oxide, β-terpineol, citronellal, pinocarveol, terpinen-4-ol, terpinolene-4,8-oxide (**318**), α-terpineol, dihydrocarvone, dihydrocarveol (**37**), (*Z*)-carveol, (*E*)-limonene-1,2-	Fruit, beverages (herbal tea, liqueur), food additives, flavor (cooked fish, Sashimi, soup, noodles), vinegar (Sushi, Tempura, Tofu) Antiinflammatory, antioxidant, hypocholesterolemic, antihypertension

(continued)

Table 1 (continued)

	oxide, (*Z*)-limonene-1,2-oxide, citronellol, (*E*)-carveol, (*E*)-*p*-mentha-2,8-dien-1-ol, cryptone, limonene-4-ol, cumin aldehyde (**71**), carvone, piperitone, *p*-menth-3-en-2-one (=*iso*-piperitone) (**282**), geranial, geraniol, perillaldehyde, perilla alcohol, citronellyl acetate, neryl acetate, piperitone, (*Z*)-*iso*-piperitenol (**280**), (*E*)-*iso*-piperitenol (**279**), β-*iso*-geraniol (**113b**), myrtenol, (*Z*)-*p*-mentha-1(7),8-dien-2-ol (**203b**), nerol, *iso*-piperitenone (**276**), *p*-cymen-9-ol, *p*-mentha-1,3-dien-7-ol (**215**), limonen-10-ol (**156**), cumin alcohol (**70**), thymol, carvacrol, geranyl acetone	
Citrus tamurana	α-Pinene, α-fenchene, camphene, β-pinene, sabinene, myrcene, α-phellandrene, α-terpinene, limonene, β-phellandrene, (Z)-β-ocimene, α-terpinene, *p*-cymene, terpinolene, α-thujone, (*Z*)-limonene oxide, menthone, (*E*)-linalool oxide, citronellal, camphor, terpinyl acetate, α-terpineol, neryl acetate, carvone, geranyl acetate, citronellol, perillaldehyde, carvone oxide (**44**), geranyl propanoate, *p*-menth-1-en-9-yl acetate (**207**), isopiperitone (**282**), nerol, (*E*)-carveol, *p*-menth-1-en-9-ol (**206**), *p*-menth-1,8-dien-10-ol (=limonene-10-ol) (**156**), limonene diol (**155**), nerol oxide (**241**)	Fruits, beverages
Citrus unshiu	Limonene, γ-terpinene, linalool, myrcene, *o*-cymene	Fruit, beverages (herbal tea), food additives Antimicrobial, antioxidant
Citrus yuko	*αγ*-Pinene, camphene, β-pinene, limonene, 1,8-cineole, terpinolene, α-terpineol, terpinen-4-ol	Foods, fruit, beverages, food additives, vinegar Antibacterial, antidiabetes, anticancer, antihypertension, antiobesity, antioxidant

(continued)

Table 1 (continued)

Clerodendrum trichotomum	Linalool	Foods (leaves) Analgesic, antihypertensive, antiinflammatory, antioxidant, antirheumatic, sedative
Clitocybe odora	Limonene, linalool	Foods
Coix lacryma-jobi	*	Foods, herbal medicines. Antiallergic, anticancer, antidiabetes, antiinflammatory, hypoglycemic, hypolipidemic, gastroprotective
Colchicum autumnale	*	For familiar Mediterranean fever, gout, narrow therapeutic index
Colocasia esculenta (rhizome) (Taro)	(*E*)-Linalool oxide, linalool, α-terpineol, nerol, geraniol, geranyl acetone, β-damascenone	Vegetable Anticancer, antihypertension For anemia, blood, bone and eye health, immune system booster
Conocephalum conicum	α-Pinene, camphene, β-pinene, limonene, terpinolene, camphor, linalool, bornyl acetate	Foods Antifungal, antimicrobial
Copaifera reticulata (Copaiba oil)	α-Pinene, β-pinene, Δ^3-carene, α-terpinene, *p*-cymene, limonene, 1,8-cineole, γ-terpinene	Fragrance, perfume retention agent Analgesic, antibacterial, anticancer, antifungal, antihistamine, antiinflammatory, antimicrobial, antioxidant, antirheumatic, antitussive, antiviral, COX-inhibitor, depurative, febrifuge, hypocholesterolemia, insecticidal, modulator, pediculicide, purgative, tonic, vermifuge For immune system booster
Coptis japonica	α-Pinene, 1,8-cineol, citral	Beverages (Kampo medicine) For angina, bacterial bloody bowel discharge, diarrhea, hematemesis, mental anxiety, stomachache, stomatitis
Coriandrum sativum	α-Pinene, β-pinene, myrcene, *p*-cymene, limonene, camphene, α-terpinene, linalool, (*E*)-linalool oxide, *iso*-borneol, α-terpineol, cumin aldehyde, β-citral, geraniol, linalool, terpineol, citronellol, geraniol, geranyl acetate	Vegetable, flavoring of sources, liquor, spice for soup, curries Antianxiety symptoms, antimicrobial, antiglycemic, hypotension, increasing HDL cholesterol For digestive symptoms, reduce blood sugar

(continued)

Table 1 (continued)

	Seed essential oil: α-pinene, camphene, sabinene, *p*-cymene, linalyl acetate, limonene, γ-terpinene, (*E*)-β-ocimene, terpinolene, linalool, (*Z*)-β-sabinene hydrate, camphor, terpinen-4-ol, geraniol, geranyl acetate, α-terpineol, citronellol, nerol, myrtenyl acetate	Flavor for various commercial foods, as liquor, teas, meat products, and pickles Antibacterial, antifungal, antioxidant, antispoilage, hypoglycemic For joint pain, influence on carbohydrate metabolism
Coriandrum sativum	Linalool	Culinary herb Antifungal, antimicrobial For bowel spasms, digestion problems, diarrhea, hernia, hemorrhoids, intestinal gas, joint pain, toothaches, worms
Crataegus cuneata	α-Pinene, camphene, β-b-pinene, myrcene, Δ^3-carene, α-terpinene, *p*-cymene, limonene, 1,8-cineole, β-ocimene, γ-terpinene, terpinolene, α-terpineol, *p*-menth-1-en-8-ol, linalool	Foods, beverages ACE inhibitory, antiarrhythmic, anti-HIV, antihyperlipidemic, antihypertensive, antiinflammatory, antimicrobial, antioxidant, cytotoxic, gastroprotective, hepatoprotective, hypoglycemic, radioprotective For cardiovascular disorders, central nervous and immune system, myocardial infarction, myocardial ischemia, congestive heart failure, eyes health
Crocus sativa (Saffron oil)	α-Pinene, β-pinene, 1,8-cineole	Fruit essence, spice, coloration for foods, deodorant Analgesic, sedative
Cryptotaenia japonica (Mitsuba)	α-Pinene, sabinene, β-pinene, myrcene, α-terpinene, limonene, γ-terpinene	Vegetable, flavor, for soup, pickles, stir fried Hemorrhages For cold, fevers, medicinal strengthened tonic, benefit in women
Cucumis melo	β-Pinene, 1,8-cineole, limonene, γ-terpinene, *p*-menth-1-en-8-ol (**205**), verbenone, β-cyclocitral, terpinyl acetate, geranyl acetone, β-ionone, dihydroactinidiolide	Fruit Antidiabetes, antihypertension For bone health, digestive disorders, eye health, immune function

(continued)

Table 1 (continued)

Cucumis sativus	Sabinene, β-pinene, limonene, (*E*)-β-ocimene, linalool, *p*-menth-1-en-3-one (**220**), α-terpinolene	Vegetable Antiaging, antidiabetes, antioxidant, blood protection, dyslipidemia
Cucurbita pepo (Pepo pumpkin)	α-Pinene, β-pinene, sabinene, myrcene, limonene, α-phellandrene, Δ^3-carene, α-terpinene, *p*-cymene, limonene, 1,8-cineole,. linalool, γ-terpinene, terpinen-4-ol, α-terpineol, β-cyclocitral, carvone, linalyl acetate, terpinyl acetate, β-ionone	Foods, beverages Antihypertension, antiinflammatory, anthelmintic For benign prostatic, erysipelas, headache, hyperplasia, irritable bladder, lower urinary tract symptoms, micturition disorders, neuralgia
Cucurbita maxima (Pumpkin)	α-Pinene, sabinene, β-pinene, myrcene, α-phellandrene, Δ^3-carene, limonene, α-terpinene, 1,8-cineole γ-terpinene, α-terpineol, linalool, geraniol, β-cyclocitral, carvone, linalyl acetate, α-terpinyl acetate, α-ionone, β-ionone	Vegetable Anticancer, antioxidant For cardiovascular and heart health, strengthening bone, improving vision
Cucurbita pepo var. *melopepo* (Zucchinis)	α-Pinene, myrcene, ocimene, limonene, 1,8-cineole, linalool, camphor	Beverages (herbal tea) vegetable Antiandrogen, antiinflammatory, reduction in prostate growth, detrusor activity
Curcuma aeruginosa	α-Pinene, camphene, β-pinene, 1,8-cineole, camphor, *iso*-borneol, borneol	Vegetable, food appetizers, dye, spice, food flavoring, coloring agent Antiasthma, antibronchitis, antifungal, antiinflammatory, antimicrobial, antinociceptive, antioxidant, antipyretic, antitumor, antiulcerogenic, cytotoxicity, dyspepsia, nitric oxide production, inhibitory, uterine relaxant For axillary, blood booster, cough, diarrhea, dysentery, fertilize the womb, flatulence, gastritis, hair growth stimulant, hemorrhoids, increase appetite, intestinal worms, etic infections, menstruation pain, parasitic infections, postpartum problem, skin penetration enhancer

(continued)

Table 1 (continued)

Curcuma amada	α-Pinene, β-pinene, (*Z*)-dihydroocimene (**253**), myrcene, (*E*)-dihydroocimene (**252**), α-phellandrene, *p*-cymene, carvomenthone (**41**), (*Z*)-β-ocimene (**250**), β-phellandrene, limonene, 1,8-cineole, (*E*)-β-ocimene (**251**), Δ^3-carene, α-terpinene, γ-terpinene, linalool, dihydromyrtenol (**199**), *p*-menth-4(8)-en-9-ol (**212**), *p*-menth-1-en-9-ol (**221d**), *p*-mentha-1,8-dien-9-ol (**218b**), bornyl acetate, citronellal (**55**), *p*-cymene-9-ol, camphor, camphene hydrate, β-terpineol, borneol, lavandulol, α-terpineol, geranial, neral, α-terpinyl acetate, thymol, α-ionone	Foods, flavor and spice, beverages Analgesic, antifungal, antiinflammatory, antimicrobial, antioxidant, antiplatelet, antipyretic, antitubercular, antitumor, antiulcer, CNS depressant, cytotoxic, expectorant, hepatoprotective, hypotriglyceridemia, insecticidal, insect repellent, larvicidal For aphrodisiac, appetizer, asthma, bronchitis, contusions, bruises diuretic, emollient, itching, laxative, rheumatic pain, skin diseases, sprains
Curcuma angustifolia	α-Pinene, camphene, myrcene, limonene, 1,8-cineole, (*E*)-linalool oxide, (*Z*)-linalool oxide, (*E*)-*p*-menth-2-en-1-ol (**211a**), camphor, camphene hydrate, *iso*-borneol, borneol, terpinen-4-ol, *p*-cymen-9-ol, myrtenal, α-terpineol, myrtenol, (*E*)-carvotanacetol (**45**), nerol, piperitone, geranial, *iso*-bornyl acetate (**20**), thymol, carvacrol, sabinyl acetate (**299**)	Food supplements, vegetable, food appetizers, cosmetic ingredient Analgesic, antifungal, antimicrobial, antioxidant, antiparasitic For asthma, body and gastrointestinal pain, dysentery, fevers, fungal infections, muscle relaxant, skin protecting
Curcuma aromatica	α-Pinene, camphene, β-pinene, myrcene, limonene, α-phellandrene, α-terpinene, 1,8-cineole, (*Z*)-β-ocimene, *p*-cymene, terpinolene, linalool, camphor, borneol, terpinen-4-ol, myrtenol, (*E*)-pinocarveol (**258a**), *iso*-borneol, α-terpineol, piperitenone (**275**)	Food supplements, beverages, flavoring, coloring agents, food appetizers Antiaging antiangiogenic, antibacterial, antidiabetes, antifibrotic, antifungal, antiinflammatory, antioxidant, antiplatelet, antiproliferative, antitumor, cardioprotective, carminative, cytotoxic, insecticidal, tonic For alleviating pain, blood stasis and circulation, complexion, chronic depression, liver diseases, infections, easing bruises, relieving sprains, skin eruptions, snake bites

(continued)

Table 1 (continued)

Curcuma australasica	*	Antiinflammatory, cytotoxic, nitric oxide and prostaglandin production inhibitory
Curcuma caesia	1,8-Cineol, camphor	Functional foods Antihepatotoxicity, antiinflammatory, antimicrobial, antioxidant, antitumor, antiulcer, muscle relaxant, carminative, dysentery, CNS depressant For asthma, bruises, constipation, cough, diarrhea, digestive problems, dysentery, epilepsy, jaundice, kidney disorders, leukoderma, piles, rheumatic pain, sprains, stimulant, skin and wound infection, tonsillitis, toothaches, urination
Curcuma domestica (=*C. longa*) (Curcuma oil or turmeric oil)	α-Pinene β-pinene, sabinene, myrcene, α-phellandrene, Δ^3-carene, limonene, α-terpinene, β-phellandrene, 1,8-cineole, (*Z*)-β-ocimene, γ-terpinene, (*E*)-β-ocimene, terpinolene, linalool, *p*-mentha-1,3, 8-triene, camphor, *iso*-borneol, borneol, *p*-cymen-8-ol, α-terpineol, terpinen-4-ol, verbenone, cumene, thymol, carvacrol, geranyl acetate	Food flavor, beverages, a dye, cosmetics α-Amylase and α-glucosidase inhibitor, anesthetic, anxiolytic, antiaflatoxigenic, antiallergic, anti-Alzheimer's disease, antiarthritic, antiatherosclerotic, antibacterial, anticarcinogenic, anticonvulsant, antidiabetes, antifatty liver, antifungal, antigenic, antihepatotoxic, antiinflammatory, antimutagenic, antiobesity, antioxidant, antiplatelet, antiproliferative, antithrombotic, antivasoconstrictive, antiulcerogenic, chemopreventive, cytotoxic, gastroprotective, hepatoprotective, hypoglycemic, hypothermic, hypolipidemic, immunomodulatory, insecticidal, insect repellent joint-protective, larvicidal, mosquitocidal (against *Aedes aegypti* and *Anopheles*), neuroprotective, neurotoxin-inhibitory, phytotoxic, scolicidal, sedative, spasmolytic, tonic

(continued)

Table 1 (continued)

		For anthelmintic, appetizer, carminative, chest congestion, cough, diabetic wounds, digestive aid, dysentery, infections, fever, gastritis, hypercholesterolemia, hypertension, jaundice, laxative, liver gall, bladder problems, menstrual discomfort, rheumatoid, skin diseases, stomachic, urinary tract infections
Curcuma glans	α-Pinene, β-pinene, limonene, 1,8-cineole, camphor, borneol, *iso*-borneol, *iso*-pinocamphone (**269**), terpinen-4-ol	Beverages Antibacterial, antiviral 4. For the herpes simplex virus, sore throat, tonsillitis, wounds or abscesses in the mouth, throat, nose
Curcuma haritha	Camphene, β-pinene 1,8-cineole, *iso*-borneol, camphor	Beverages
Curcuma harmandii	1,8-Cineol	Beverages
Curcuma harmandii	β-Pinene, 1,8-cineole	Beverages
Curcuma heyneana	α-Pinene, camphene, β-pinene, camphor, *iso*-borneol	Accelerating wound healing, antiinflammatory, antimicrobial, antioxidant For anthelmintic in skin scrub, body sliming, cancer prevention, diarrhea
Curcuma inodora	1,8-Cineole	Beverages
Curcuma kwangsiensis	1,8-Cineole, linalool, terpinen-4-ol, camphor, α-terpineol, *iso*-borneol	Food additives, herbal medicines Cytotoxic, antiinflammatory, antimicrobial, antioxidant
Curcuma leucorrhiza	1,8-Cineole, camphor, linalool, *iso*-borneol	Foods Antifungal, antimicrobial, antioxidant For cancer, cough, diabetes, treatment of enlarged liver and spleen, stomach ulcer
Curcuma mangga	β-Pinene, myrcene, *p*-menth-2-en-1-ol (**211a**), *p*-menth-1-en-9-ol, *iso*-pulegol	Foods Analgesic, antiallergic, anticoagulant, antifungal, antimicrobial, antioxidant, antiplatelet, antiproliferative, antitumor, antiulcerogenic, cytotoxic, nitric oxide production inhibition For ornamental, blood purifier, treatment swellings

(continued)

Table 1 (continued)

Curcuma phaeocaulis	α-Pinene, camphene, β-pinene, 1,8-cineole, linalool camphor *iso*-borneol, borneol, terpinen-4-ol, α-terpineol, verbenone, carvone, carveol	Food additives, beverages, herbal medicines Analgesic, antifungal, antiinflammatory, antimicrobial, antioxidant, antithrombotic, antiviral, cytotoxic For alleviating pain, hepatoprotective, gastritis, reducing blood stasis, tumor therapy
Curcuma pierreana	α-Pinene, camphene, 1,8-cineole, camphor, *iso*-borneol, bornyl acetate, *iso*-bornyl acetate	Food flavoring, vegetable, spice, dye, coloring agent, appetizers Antifungal, antimicrobial
Curcuma purpurascens	1,8-Cineol, camphor	Angiogenesis, antifungal, antioxidant, antiproliferative, apoptogenic, cytotoxic, gastroprotective
Curcuma rhabdota	Camphor	Beverages
Curcuma rubescens	Camphor	Beverages
Curcuma singularis	Camphor, fenchone	Antibacterial
Curcuma sylvatica	α-Fenchene	Beverages
Curcuma wenyuji	1,8-Cineole, linalool, terpinen-4-ol, α-terpineol, *iso*-borneol	Food additives. Antiinflammatory, antimicrobial, antioxidative, cytotoxic
Curcuma xanthorrhiza	α-Pinene, camphene, β-pinene, α-phellandrene, α-terpinolene, β-phellandrene, terpinolene, 1,8-cineole, γ-terpinene, terpinolene, camphor, *p*-cymen-8-ol (**80**), borneol, *iso*-borneol, *iso*-carveol (**40**), *iso*-pinocamphone (**269**), citronellyl pentanoate (**64**)	Foods, food additives, food coloring, spice, dye, cosmetics Analgesic, antiaflatoxigenic, antibacterial, anticancer, anticandidal, antihepatotoxic, antihyperglycemic, antihyperlipidemic, antiinflammatory, antimetastatic, antimicrobial, antimycotic, antinociceptive, antiobesogenic, antioxidant, antiulcerogenic, antispasmodic, antitumor, diuretic, estrogenic, hepatoprotective, hypotensive, gastroprotective, larvicidal, neuroprotective For gallstones, arthritis, Alzheimer's disease, dysentery, bloody diarrhea, bursitis, carpal tunnel syndrome, cataracts, chemopreventive, children's fevers, constipation, diabetes, eczema, endometriosis, gastric

(continued)

Table 1 (continued)

		problem, osteoporosis, halitosis, heart diseases, high blood pressure, hemorrhoids, hypertension, hypotriglyceridemia, liver cirrhosis, rheumatism, skin and stomach diseases, tendinitis, and skin eruptions
Curcuma zedoaria	1,8-Cineole, *p*-cymene, α-phellandrene, camphor, α-terpinyl acetate, *iso*-borneol, borneol	Foods, food additives, beverages Aggregation analgesic, antiallergic, antiangiogenic antifungal, antigingivitis, antihypertensive, antiinflammatory, antimicrobial, antimutagenic, antinociceptive, antiplatelet antiproliferative, antioxidant, antitumor antiulcerogenic, carminative, cytotoxic, diuretic, demulcent, expectorant, hemagglutinating, hypoglycemic, insecticidal, larvicidal, piscicidal, rubefacient, stimulant
Cydonia oblonga (Marmelo)	β-Phellandrene, 1,8-cineole, (*Z*)-linalyl oxide, camphor, α-terpineol, β-cyclocitral, (*E*)-damascone, *iso*-citral [= *iso*-geranial (**113a**) + *iso*-neral (**232**)]	Foods, fruit, beverage (cider, wine fruit in liquor), jam, jelly, marmalades, pastes, pudding Antiallergenic, anticancer, antidiabetes, antiinflammatory, antioxidant, antivinous, astringent, cardiac, carminative, digestive, diuretic, emollient, expectorant, sedative, tonic For cardiovascular reproductive, gastric ulcers, gastrointestinal and coronary diseases, hair health, heart attacks, immune system booster, peptic, rectral, respiratory disorders, refrigerant, restorative, skin care, smooth muscle contraction, stimulant, stroke, treatment of dysentery, weight loss aid
Cymbopogon citratus	Myrcene, limonene, (*E*)-β-ocimene, (*Z*)-β-ocimene, α-terpinolene, citronellol, (*Z*)-verbenol, nerol, neral, geraniol, carveol, geranyl acetate	Flavoring agent in foods, drinks, and desserts Analgesic, antibiotic, antiinflammatory, antimutagenic, sedative For circulation, immunity booster, mosquito repellent

(continued)

Table 1 (continued)

Cymbopogon citratus	Citronellal	Incense, pesticide, perfume, carminative
Cymbopogon flexuosus (Lemongrass oil)	α-Pinene, camphene, β-pinene, myrcene, *p*-cymene, limonene, linalool, β-ocimene, γ-terpinene, α-terpineol, citral, citronellal, geraniol, geranyl acetate, geranic acid	Flavoring agent in foods Antibiofilm, anticancer, antifungal, antimicrobial, cytotoxicity
Cymbopogon nardus (Ceylon *Citronera* oil)	Camphene, (−)-borneol, citronellal, geraniol, citral, citronellal, (+)-citronellol, geranyl acetate	Food flavoring, perfume, beverages Analgesic, antimicrobial, antiparasitic, diuretic, insecticide For strengthening muscle spasms, increasing appetite
Cymbopogon winterianus (Java *Citronera* oil)	Limonene, linalool, isopulegol, citronellal, neral, geraniol, geranial, citronellyl acetate, neryl acetate	Flavor ingredient Antimicrobial, antiseptic, antispasmodic, febrifuge
Cynanchum rostellatum (=*Metaplexis japonica*)	Linalool, α-terpineol	Beverages (herbal tea), tonic For mental fatigue
Cynara scolymus (Artichoke)	Limonene, myrtenal. verbanol (**339a**), carvone, thymol	Vegetable Antiulcer For hypercholesterolemia, regulating blood pressure, improving liver and digestive health, lowering blood sugar, symptoms of irritable bowel syndrome
Cupressus sempervirens var. *stricta* (Cypress oil)	α-Pinene, camphene, sabinene, β-pinene, myrcene, Δ^3-carene, limonene, terpinolene, α-terpineol, bornyl acetate, α-terpinyl acetate	Compound flavor. Antispasmodic For regulating blood flow, aiding the respiratory system, relieving stress
Daucus carota (Carrot)	Thujene, α-pinene, camphene, β-pinene, sabinene, myrcene, limonene, α-phellandrene, β-phellandrene, (*E*)-α-ocimene, γ-terpinene, α-terpinolene, *p*-mentha-1,3,8-triene, *p*-cymene, terpinen-4-ol, α-terpineol, camphor, borneol, *p*-cymen-9-ol, thymol methyl ether, β-citral, carvone, bornyl acetate, geranyl acetate, geranyl acetone, linalyl 3-methylbutanoate (=isovalerate) (**172**), *iso*-bornyl acetate, geranyl acetone, geranyl butanoate (**101**), geranyl isobutanoate (**102**), geranyl 2-methylbutanoate (**104**)	Vegetable Anticancer, antifungal, antimicrobial, antioxidant antiviral For blood circulation, stimulating nutraceutical, promoting hair growth, strengthening hair, follicle hair roots

(continued)

Table 1 (continued)

Dendrobium moniliforme	1,8-Cineole, terpinolene, linalool, terpinen-4-ol	Beverages Antiatopic dermatitis, anticancer, antifatigue, anticonstipation, antihypertension, antioxidant, antiproliferative, gastric hypoglycemic, hypolipidemic, immune enhancement, tonic For cure throat inflammatory, secretion of saliva, ulcer protective
Dianthus caryophyllus (Carnation oil)	Limonene, β-ocimene	Beverages (herbal tea), perfume, tonic for fevers For calming the nervous system, congestion, heart health, lowering fever and pain, mosquito repellent, nervousness and stress, skin health, sweat production, skin benefits
Dimocarpus longan	β-Myrcene, Δ^3-carene, α-phellandrene, *p*-cymene, *p*-menth-1,3,8-triene, *allo*-ocimene (**245**, or **246**), (*E*)-β-ocimene, camphor	Fruit Anticancer, antidote, antifungal, antiinflammatory, antioxidant, febrifuge, as a tonic for insomnia, neurasthenic, stomachic, vermifuge For anemia, anxiety, iron deficiency, insomnia stress, stomachic, febrifuge
Dioscorea alata (Water yam, greater yam) (cooked)	α-Pinene, β-pinene, myrcene, limonene, terpinolene, linalool, terpinen-4-ol, α-terpineol	Foods Laxative, vermifuge For fever, gonorrhea, inflamed hemorrhoids, leprosy, tumors
Dioscorea japonica (Japanese yam)	Camphor, menthol, borneol, terpein-4-ol, geraniol, geranyl acetone	Foods Hypercholesterolemia
Diospyros kaki (Persimmon)	β-Ionone, geranyl acetone	Foods, fruit, for salad, jam, dried fruit Acaricidal, anticancer, antihypertension, antifungal, antiinflammatory, antimicrobial, antioxidant, antitumor, hypocholesterolemic For boosting asthma, cough with phlegm, defecate, diarrhea, digestion, dysentery, eye disorders, health of lungs, spleen, heart, smooth up blood circulation, blood pressure, heart health

(continued)

Table 1 (continued)

Elettaria cardamomum var. *minus* (Cardamom oil)	α-Pinene, camphene, β-pinene, sabinene, myrcene, α-terpinene, limonene, 1,8-cineole, *p*-cymene, (*Z*)-β-ocimene, (*E*)-β-ocimene, linalool, *p*-cymen-9-ol, fenchene (**88**), fenchone (**92b**), limonene-1,2-epoxide, linalool oxide, borneol, α-terpineol, cryptone, camphor, pinocarvone, β-fenchyl alcohol (**91**), terpinen-4-ol, carvone, myrtenol, phellandral (**265**), thujyl alcohol (**326**), nerol, geraniol, citronellol, (*E*)-pinocarveol, linalyl acetate, *iso*-borneol, α-terpinyl acetate, α-fenchyl acetate, (**90**), β-fenchyl acetate (**92a**)	Food flavor, cookies, source, liqueurs, luxury spices Antifungal, antimicrobial, antiviral, carminative, stomachic, tonic For asthma, colic, constipation, diarrhea, diuretic, dyspepsia, epilepsy, hypertension, muscle pain
Eleutherococcus senticosus (=Acanthopanax senticosus)	α-Pinene, β-pinene, myrcene, *p*-cymene, β-phellandrene, linalool epoxide, terpinen-4-ol, cryptone, α-terpineol	For angina pectoris, cold, coronary heart disease, diabetes, Helpes simplex, inflammation, treatment of combined neurosis, lowering blood sugar, cold, coronary stress-induced pathophysiologic changes, menopausal syndrome, strengthening the spleen and kidney, nourishing the kidney
Enteromorpha prolifera (Green laver)	α-Pinene, limonene, terpinolene, linalool, 1,8-cineole, carvone, geraniol, β-ionol (**116**), dihydroactinidiolide	Sea vegetable (for snacks) Antioxidant
Equisetum arvense	Linalool, α-ionone (**120**), dihydroactinidiolide (**3**), 3-oxo-α-ionone (**117**), 4-oxo-α-ionone (**119**)	Food (sporophytes) Antibacterial, antiinflammatory, antimicrobial, antioxidant, astringent, coagulant, demulcent, diuretic

(continued)

Table 1 (continued)

Eriobotrya japonica (Loquat)	Cumene, α-thujene, α-pinene, camphene, β-pinene, limonene, 1,8-cineole (*Z*)-β-ocimene γ-terpinene, α-terpineol, linalool, (*Z*)-β-terpineol (**310**), terpinen-4-ol, *p*-cymen-8-ol (**81**), α-terpineol, geraniol, (*E*)-β-ionone	Fruit, beverages, allaying vomiting and thirst, expectorant, sedative *Leaves*: Analgesic, antibacterial, antiemetic, antitussive, antiviral, astringent, coughs, feverish colds, diuretic, expectorant, intestinal astringent, mouthwash bronchitis *Flower*: Expectorants *Fruit*: Allaying vomiting and thirst, expectorant, sedative
Eucalyptus citriodora (*E. citriodora* oil)	α-Phellandrene, 1,8-cineole, citronellal, citronellol, citronellyl acetate, geranyl acetate, *iso*-pulegol (**283**), *neoiso*-pulegol (**284**)	Disinfectant, compound fragrance, perfumery Insect repellent
Eucalyptus dives (Piperitone-phellandrene-eucalyptus oil)	α-Thujene, camphene, α-phellandrene, limonene, 1,8-cineol, *p*-cymene, piperitone (**281**)	Disinfectant, deodorant Antifungal, antiinflammatory, antimicrobial For allergies, cough, earaches, headaches, improving respiratory conditions, boosting mental clarity, and aiding wound care
Eucalyptus globulus (Eucalyptus oil)	α-Pinene, camphene, 1,8-cineole, pinocarveol, pinocarvone, myrtenol, verbenone, carvone	Deodorant Bactericide, insecticide For disinfectant, oral care drugs
Eucalyptus macarthurii (Geranyl acetate-eucalyptus oil)	Geraniol, linalool, geranyl acetate	Flavoring, backed goods, confectionary, meat products, beverages, compound fragrance
Eucommia ulmoides	β-Cyclocitral, geraniol, β-damascone, α-ionone, geranyl acetone	Anticancer, antihypertension, antisenescence For debasing fattiness, diuretics, enhancing the strength, preventing miscarriage
Eugenia caryophyllus (Clove oil)	α-Thujene, α-pinene, β-pinene, myrcene, α-terpinene, fenchone, geranial (**94**), cumin aldehyde, α-terpinyl acetate	Food flavor, spice, high-grade cosmetics, oral care drugs, digestive ailments Antifungal, antimicrobial For diarrhea, intestinal worms
Eupatorium japonica	α-Pinene, camphene, β-pinene, myrcene, (*Z*)-β-ocimene, (*E*)-β-ocimene, bornyl acetate	Antipyretic, diuretic, hematemesis, neuralgia For edema

(continued)

Table 1 (continued)

Evernia prunastri (Oak moss oil)	(−)-α-Pinene, (−)-camphene, (−)-β-pinene, myrcene, limonene, *p*-cymene, 1,8-cineol, linalool, camphor, (−)-carvone, (+)-α-thujone, (−)-β-thujone, (+)-terpinen-4-ol, (+)-α-terpineol, (−)-borneol, α-fenchyl alcohol, β-fenchyl alcohol, geraniol, citronellol	Perfume fixative Antiinflammatory, antiirritant, antimicrobial, antiseptic, expectorant
Fagopyrum esculentum (Buckwheat)	*Boiled powder*: α-pinene, camphene, β-pinene, sabinene, myrcene, limonene, linalool, β-cyclocitral, menthone, *p*-cymene, camphor, α-terpinyl acetate, linalool oxide, terpinen-4-ol, nerol, geraniol, bornyl acetate, geranyl acetone, thymol, methyl geranate, dihydroactinidiolide	Foods, raw or cooked, noodles, pancakes, breads Capillary tonic For eczema, erysipelas, high blood pressure, gout, liver disorders, strengthening blood vessel, radiation damage, varicose veins
Fallopia japonica	α-Pinene, β-pinene, linalool, β-ionone epoxide	Anticancer, antihypertension, antiinflammatory, antitussive, diuretic For cognitive problems, gastrointestinal health, heart ailments, hemostatic improvement of cystitis, irregular menstrual periods
Farfugium japonicum (=*Ligularia tussilaginea*)	α-Pinene, sabinene	Vegetable, salads, soups, beverages (seed) Anticancer, antiinflammatory, antimicrobial, antioxidant
Ferula assa-foetida	α-Pinene, camphene, sabinene, β-pinene, myrcene, *p*-cymene, limonene, (*Z*)-β-ocimene, (*E*)-β-ocimene	Foods, candies Antispasmodic, carminative, expectorant, laxative, sedative Stimulant, emmenagogue, vermifuge, blood, and lowers blood pressure For asthma, bronchitis, flatulent, colic, hysteria, infantile pneumonia, whooping cough
Ficus carica	α-Pinene, camphene, β-pinene, Δ^3-carene, limonene, (*Z*)-β-ocimene, (*E*)-β-ocimene, linalool, (*Z*)-menth-2-en-1-ol, (*E*)-menth-2-en-1-ol, (*E*)-verbenol, terpinen-4-ol, α-terpineol, (*Z*)-piperitol,	Foods Abortifacient, analgesic, antiarthritic, diuretic, emetic, febrifuge, stimulant, tonic, vermifuge

(continued)

Table 1 (continued)

	verbenone, carvacrol methyl ether, linalyl acetate, bornyl acetate, terpinen-4-yl acetate, (*E*)-piperityl acetate (**264**), α-terpinyl acetate, geranyl acetate, β-cyclocitral, (*E*)-β-damascenone (**84**), (*E*)-β-damascone	
Fistulina hepatica	α-Pinene, β-pinene, limonene, 1,8-cineole, linalool, menthol, α-terpinene, (*E*)-geranyl acetone	Foods
Flammulina velutipes	β-Pinene, α-terpinene, dihydrocarveol	Foods
Flammulina velutipes (Winter mushroom)	α-Pinene, sabinene, limonene, α-terpinene, *p*-cymene, camphor, menthofuran (**182a**), *p*-menthen-3,9-epoxide (**182b**) *Heated material*: limonene, sabinene, α-terpinene	Foods Anti-Alzheimer's disease, anticancer, anticholesterolemic, antiinflammatory, hypolipidemic For cholesterol and lipid reduction, dementia, gastric ulcers, hypertension, liver disorders, thrombosis
Foeniculum vulgare	α-Phellandrene, fenchone, thymol, carvacrol	Foods, flavorings in baked goods, meat and fish dishes, ice cream, alcoholic beverages, and herb mixtures Acaricidal, antidiabetes, antifungal, antihirsutism, antiinflammatory, antimicrobial, antioxidant, antithrombotic, antitumor, cytochrome inhibitory, cytoprotection, estrogenic, hepatoprotective, uterine contraction
Fragaria elatior (Strawberry oil)	Verbenone, citronellol, α-terpineol, myrtenol, carveyl acetate	Foods, concentrated juice Antiallergic antiasthma, antidiabetes, antihypertension For enhancing cognitive function, heart protection, improving eye sight, strengthening immune system, treating arthritis and gout
Garcinia mangostana	Linalool, α-terpineol, limonene, (*E*)-β-ocimene, (*Z*)-β-ocimene, linalool oxide, linalool, neral, nerol, geraniol	Antimicrobial, antiobesitic, antioxidant For eczema, burn, sores, thirst for one's mouth

(continued)

Table 1 (continued)

Gardenia jasminoides	Linalool, terpineol, linalyl acetate	Natural yellow dye. Analgesic, antioxidant, antiseptic, antispasmodic, diuretic, hypotensive, sedative For abdominal pain, carminative, cold, cough, dyspepsia, fever, flatulence, hepatitis, lymph node, menorrhagia, tuberculosis
Gaultheria miqueliana (Wintergreen oil)	α-Thujene, α-pinene, sabinene, myrcene, ocimene, carene, α-phellandrene, limonene, *p*-mentha-1(7),2-diene (**214**), *p*-mentha-1,8(9)-diene, 1,8-cineole, 1inalool, bornyl acetate, neral, geraniol, citronellol, methyl geranate, fenchone, menthone	Flavor, candy, chewing gum, soft drink Antiinflammatory, antiseptic For cold, detoxification, digestion, fever, flu, headache, infections, muscle relaxation
Ginkgo biloba	α-Pinene, limonene, α-ionone, β-ionone (**122**)	Food (seed), beverage. Alzheimer's disease, antiaging, anticancer, antihypertension, antiinflammatory For anxiety, asthma, cancer prevention, dementia, depression, fibromyalgia, hemorrhoids, heart health, hypertension, multiple sclerosis, tinnitus, vertigo
Glechoma hederacea	α-Pinene, β-pinene, sabinene, myrcene, 1,8-cineol, (*E*)-β-ocimene, (*Z*)-β-ocimene, *p*-mentha-2,4(8)-diene (**208**), *allo*-ocimene, pinocamphone (**261**), *iso*-pinocamphone (**269**), myrtenal	Beverages Antiphlogistic, antimutagenic, antioxidant, expectorant For anodyne, digestive, stimulant
Glehnia littoralis	α-Pinene, β-phellandrene, geraniol	Beverages (herbal tea) Aphrodisiac, antitussive, expectorant For asthma, cough
Glycine max (Soybeans)	Linalool, (*Z*)-jasmone	Foods, beverages Anticancer, antiinflammatory For birth defects, bone health, diabetes, digestion, heart health, healthy weight gain, metabolic alleviation of menopausal symptoms, obesity, sleep disorders

(continued)

Table 1 (continued)

Glycyrrhiza echinata	Tetrahydrolavandulol (**141**)	Beverages (herbal tea), sweet ingredients Expectorant, tonic
Glycyrrhiza glabra	(*Z*)-Pinene hydrate (**287**), tetrahydrolavandulol, terpinen-4-ol, (*E*)-linalool oxide, *p*-cymen-9-ol, α-terpineol, cumin aldehyde (**71**), piperitone, thymol, carvacrol	Food Antiinflammatory For arthritis, congestion, diabetes, fatigues, infertility, menopause, menstrual disorder, mucous nausea, poor circulation, respiratory infection, rheumatoid, tonsillitis, ulcer
Glycyrrhiza inflata	Tetrahydrolavandulol, cumin aldehyde, carvacrol	Cosmetics
Glycyrrhiza uralensis	Thujene, linalool, α-terpineol, carvacrol, *p*-cymene, fenchone, lavandulol, *p*-cymenol (**83**), linalool oxide	Natural sweeter, candies
Grifola frondosa	(*E*)-Sabinene hydrate, (*Z*)-sabinene hydrate	Foods
Guaiacum officinale (Guaiac wood oil)	*	Flavor, compound flavor materials, chewing gum and cakes Antimicrobial For arteriosclerosis, chronic, cold, cough, cutaneous diseases, dysmenorrhea, flu, poor circulation, respiratory complaints, rheumatism, toothache
Gymnema sylvestre	1,8-Cineole	Dietary supplements. Antiinflammatory, antimicrobial, antioxidant, diuretic For anemia, arthritis, asthma, cardiopathy, constipation, diabetes, hypercholesterolemia, indigestion, microbial infections, osteoporosis
Gynostemma pentaphyllum	1,8-Cineole	Beverages (herbal tea) Antioxidant, appetite enhancement
Hamamelis virginiana	Linalool, (*Z*)-linalool oxide, (*E*)-linalool oxide, myrtenol, (*E*)-pinocarveol, nerol oxide, *iso*-borneol, terpinen-4-ol, *p*-cymen-9-ol, α-terpineol, myrtenol, nerol, *iso*-bornyl formate (**19b**), geraniol, geranyl formate (**98**), geranyl acetate, (*E*)-β-damascenone	Beverages Antiinflammatory, antiviral For bruise, gastric ulcer, hematemesis, hemorrhages, hemorrhoids, prostration, sore throats, stool, traumatic conjunctivitis

(continued)

Table 1 (continued)

Helianthus annuus (Sunflower)	Roasted seed: carvacrol, thymol, sabinene hydrate	Foods Antioxidant
Heliotropium peruvianum	α-Pinene, camphene, Δ^3-carene, limonene, (*E*)-β-ocimene, *p*-cymene, linalool, thujone	Beverages, high-grade fragrance, food flavor; cookies, candy Antiphlogistic, diuretic For curative vulnerary, malaria, wound healing
Hordeum vulgare (Barley)	(*E*)-Damascenone	Food grain, natural sweeter, brewing beer, alcoholic beverages Antidigestion, antihypertension, antiinflammatory, hypocholesterolemic, hypoglycemic, weight loss promotion For bronchitis, diabetes, febrifuge, indigestion
Houttuynia cordata	α-Pinene, camphene, β-sabinene, β-pinene, myrcene, 1,8-cineol, *p*-cymene, linalool, α-terpinene, limonene, (*E*)-β-ocimene, geraniol, bornyl acetate, geranyl acetate, α-cyclogeranyl acetate (**114**), thymol	Foods, nutrient, beverages Antibacterial, anticancer, antiinflammatory, antimutagenic, antiviral (HSV-1, HIV-1), immunologic function
Hygrophorus agathosmus	α-Pinene, β-pinene, 1,4-cineole (**51**), limonene, 1,8-cineole, *p*-cymene, linalool, α-terpineol, geranyl acetone, β-ionone	Foods
Hypericum perforatum (St. John's wort)	α-Pinene, β-pinene, α-fenchene, myrcene, α-phellandrene, *p*-cymene, limonene, (*E*)-β-ocimene, α-terpinene, (*Z*)-thujone, β-fenchyl alcohol, (*Z*)-*p*-menth-2-en-1-ol (**211b**), α-campholenal (**28**), (*E*)-pinocarveol (**258a**), camphor, *iso*-pulegol, *iso*-borneol, (*E*)-pinocamphone, pinocarvone, *p*-cymen-9-ol, α-terpineol, myrtenol, verbenone, (*E*)-carveol, carvone, geranial, geranyl acetone	Beverages (herbal tea) Antibacterial, antifungal, sedative, analgesic, diuretic, antimalarial, vulnerary For burns, contusions, depression, gastroenteritis, hemorrhoids, hysteria, neuralgia, sprains, rheumatism, trauma, ulcers

(continued)

Table 1 (continued)

Hyssopus officinalis	α-Thujene, α-pinene, camphene, β-pinene, sabinene, myrcene, limonene, β-phellandrene, (*Z*)-β-ocimene, α-thujene, β-thujene, pinocamphone, *iso*-pinocamphone, linalool, pinocarvone, myrtenol	Pungent spice Diaphoretic, expectorant, mild stimulant, vulnerary poultice
Illicium verum (Star anise oil)	α-Pinene, β-pinene, limonene, phellandrene, 1,8-cineole, linalool	Spice, fragrant oil for cooking, perfumery, soaps Liqueur brandy, cookie flavor attached, crude drugs Carminative, mild stimulant For carminative, toothpastes, mouthwashers, skin cream, stomachic
Ipomoea batatas (Sweet potato)	*Grilled:* linalool, geraniol, β-ionone *Head space*: linalool, β-ionone *Alcohol beverage (Imo Shochu)*: α-terpineol, citronellol, nerol, geraniol	Vegetable, alcoholic beverages Antiinflammatory For arthritis, asthma, bronchitis, diabetes, digestion, cancer, immunity booster, stomach ulcer
Iris germanica (= *I. florentina*) (*Iris* resinoid)	α-Pinene, β-pinene, linalool, geraniol	Beverages, deodorant for liquor, whiskey, wine Expectorant For breath freshener, bronchitis, congestion, cough, decongestant, dropsy, sore throat
Jasminum officinale *Jasminum officinale* var. *grandiflorum* (Jasmine oil)	(+)-Linalool, linalyl acetate, nerol, geraniol, jasmone (**133**), methyl jasmonate (**134**), jasmine lactone (**132**)	Beverages, food flavor, high-grade compound fragrance Antioxidant, antifertility, antiviral, dermatological, emmenagogue, insecticidal, sedative For aphrodisiac, cough, insomnia, skin care
Jasminum sambac	Linalool, linalyl acetate	Beverage, flavoring ingredients in jasmine tea Antifungal, antimicrobial, antioxidant
Juglans mandshurica	α-Pinene, sabinene, β-pinene, (*E*)-β-ocimene, terpinolene, linalool, pinocarvone, pinocarveol, myrtenal, myrtenol, verbenone, verbenol	Foods Antiinflammatory, anticancer For diabetes, cardiovascular disease, bone metabolism, sleep cycle health
Juglans mandshurica var. *sachalinensis*	α-Pinene, sabinene, β-pinene, (*E*)-β-ocimene, terpinolene, linalool, pinocarvone, pinocarveol, myrtenal, myrtenol, verbenone, verbenol	Foods Antiinflammatory, anticancer For diabetes, cardiovascular disease, bone metabolism, sleep cycle health

(continued)

Table 1 (continued)

Juniperus utilis	α-Pinene, myrcene, Δ^3-carene, β-pinene, α-terpineol, borneol citronellol, bornyl acetate, α-terpinyl acetate, citronellyl acetate	Foods, condiments, beverages, flavoring ingredients, source of gin and medicinal liquor Antimicrobial, digestion, removal of kidney and bladder stones
Juniperus virginiana (Cedar wood oil)	Tricyclene, α-pinene, camphene, fenchene, thuya-2,4 (10)-diene (**323**), β-pinene, sabinene, β-phellandrene, α-terpinene, *p*-cymene, limonene, (*Z*)-β-ocimene, γ-terpinene, terpinolene, (*Z*)-sabinene hydrate (**297**), (*Z*)-linalool oxide, (*Z*)-rose oxide (**292**), (*Z*)-*p*-menth-2-en-1-ol, α-campholenal (**28**), geijerene (**93**) (*E*)-pinocarveol, camphor, (*Z*)-verbenol (**343**), (*E*)-verbenol (**342a**), (*E*)-pinocamphone (**261**), terpinene-4-ol, α-terpineol, myrtenal, verbenone, (*E*)-carveol, carvacrol methyl ether, bornyl acetate, carvacrol, citronellyl acetate, (*E*)-myrtenyl acetate (**197**)	Compound flavor, soap flavor, inner aroma Antiseborrheic, antiseptic, antispasmodic, astringent, diuretic, emmenagogue, expectorant, insecticide sedative, tonic
Lagenaria siceraria var. *gourda* (Bottle gourd)	Limonene, Δ^3-carene, *p*-menth-1-en-3-one (**221b**), terpinolene, geranyl acetone	Foods, vegetable Adenopathy, alexiteric, alopecia, anticancer, antitumor, diuretic, dropsy, emetic, insanity, laxative, lithontripic, purgative, rheumatic For ache, bilious, burn, convulsion, fever, wound
Laminaria japonica (=*Saccharina japonica*) (Kelp)	α-Terpineol, β-cyclocitral, β-homocyclocitral (**74**), β-ionone	Foods, beverages Anticancer, antiinflammatory, antioxidant, hypocholesterolemic, hypoglycemic, lower cholesterol, immunity booster For digestion, menstruation symptoms

(continued)

Table 1 (continued)

Laurus nobilis (Laurel leaf oil)	α-Thujene, α-pinene, camphene, sabinene, β-pinene, α-phellandrene, Δ^2-carene, α-terpinene, o-cymene (**30**), 1,8-cineole, (*Z*)-β-ocimene, (*E*)-β-ocimene, γ-terpinene, (*Z*)-sabinene hydrate, *p*-mentha-3,8-diene (**221b**), (*E*)-sabinene hydrate, linalool, *allo*-ocimene, (*E*)-sabinol, (**298**), camphor, β-pinene oxide (**288**), *iso*-borneol, *iso*-pulegol (**283**), *neoiso*-pulegol (**284**), α-terpineol, (*Z*)-carveol, (*Z*)-*p*-mentha-1(7),8-dien-1-ol, (*E*)-sabinene hydrate, sabinyl acetate (**299**), *neo*-3-thuyanol acetate (**325b**), *iso*-verbanol acetate (**340b**), α-terpinyl acetate	Flavor for meat products, soup, cookies, source, spice, beverages Antibiotic, antimicrobial, antineuralgic, antispasmodic, astringent, insecticide, sedative, tonic For bronchitis, flu
Lavandula angustifolia (=*L. vera*)	α-Pinene, camphene, myrcene, α-terpinene, *p*-cymene, 1,8-cineole, ocimene, γ-terpinene, sabinene hydrate, terpinolene, linalool, *iso*-pulegol, (*E*)-pinocarveol, camphor, borneol, linalool oxide, terpinene-4-ol, *m*-cymen-9-ol (**81**), α-terpineol, (*Z*)-verbenone, eucarvone (**87c**), camphor, (**87c**), nerol, linalool hydrate (**163**), carvone, linalyl acetate, geraniol, lavandulyl acetate (**137**), 8-hydroxylinalool (**159a** or **159b**), neryl acetate	Beverages (herbal tea), perfume ingredients handmade soap Antifungal, antiinflammatory, antioxidative For anxiety disorders, calm, relaxant, eye strain
Lavandula hybrid (Lavandin oil)	Camphor, (+)-borneol, (−)-lavandulol, lavandulyl acetate	Flavor Antiseptic antimicrobial, expectorant For Alzheimer's and Parkinson's diseases, bronchitis, chest congestion, cold, flu, mental strengthen
Lavandula officinalis (Lavender oil)	α-Pinene, β-pinene, limonene, 1,8-cineole, linalool, linalyl acetate, lavandulol, lavandulyl acetate, citronellal	Flavor (skin lotion, soap perfume), beverages Antifungal For bronchitis, cold, coughs, cramps, dementia, eczema, flu, insomnia, menstrual disorders, pneumonia, ulcers

(continued)

Table 1 (continued)

Lens culinaris	Limonene, *o*-cymene, linalool, γ-terpinene, terpinen-4-ol, α-terpinyl acetate, *p*-cymen-7-ol, menthol	Foods Mucilaginous, laxative For constipation, intestinal affections, cleansing in foul, indolent ulcers
Lentinus edodes (Chinese mushroom)	*Fresh fruiting body*: camphene, β-pinene, limonene, linalool *Dried fruiting body*: β-pinene, sabinene, limonene, geraniol	Foods, beverages (herbal tea) Anticancer, hypocholesterolemia For cardiovascular, lower cholesterol, immunity booster
Leonurus japonicus (Chinese motherwort)	α-Pinene, camphene, fenchene, *p*-mentha-1,5,8-triene, menthone, *p*-menth-4-en-3-one, menthol, β-terpineol, perillyl acetate (**272**)	Beverages (herbal tea) For amenorrhea, blood circulation, blood stasis, dysmenorrhea, diuretics, dispelling edema, menstrual disturbance, postpartum hemorrhage, removing blood stasis
Ligustrum japonicum	α-Pinene, β-pinene, myrcene, limonene, borneol, α-terpineol	Beverages (herbal tea) Acaricidal for acaridae and pyroglyphid mites, antiinflammatory, antimicrobial, antiviral For dizziness, improving vision, menopause symptoms, soreness. tinnitus, vertigo
Lilium auratum (Golden-banded lily)	(*E*)-α-Ocimene, *p*-menthen-1-en-9-al (**221d**), linalool, (*Z*)-linalool oxide, (*E*)-linalool oxide, α-terpineol	Vegetable For mental and emotional health, reducing insomnia, healing burn, scars, wounds
Lilium lancifolium	Linalool	Vegetable, cosmetic For chronic bronchitis, skin care, up lighting, refreshing
Lilium leichtlinii	Linalool	Vegetable, cosmetic For chronic bronchitis, skin care, up lighting, refreshing
Lilium speciosum	Linalool	Vegetable, cosmetic For chronic bronchitis, skin care, up lighting, refreshing
Lindera strychnifolia (Lindera oil)	α-Pinene, camphene, β-pinene, myrcene, limonene, (*Z*)-β-ocimene, 1,8-cineole, *p*-cymene, terpinolene, fenchyl alcohol, fenchyl acetate, terpinen-4-ol, borneol, bornyl acetate	Beverages (herbal tea), aromatic Antifungal, antiphlogistic, antispasmodic, diuretic, tonic, vermicide For anodyne, abdominal, astringent, carminative, decongestant, diaphoretic, distension, dysuria, edema, enuresis febrifuge, menstrual cramps, scabies, stomach chills, stomachic

(continued)

Table 1 (continued)

Lindera umbellata	α-Pinene, Δ^3-carene, limonene, 1,8-cineole, linalool, geraniol, geranyl acetate, carvone	Beverages (herbal tea), cosmetics Antibacterial, anticancer, antifungal, antiinflammatory, antiobesity, expectorant For acute gastrointestinal, back pain, eczema, neuralgia, stiff neck
Liquidambar orientalis (Asiatic styrax)	α-Pinene, camphene, sabinene, β-pinene, α-phellandrene, α-terpinene, terpinolene, terpinen-4-yl acetate (**307b**), menthol, terpinen-4-ol, α-terpineol, (*E*)-piperitol, (*E*)-carveol, nerol, (*Z*)-myrtanol (**194b**), (*E*)-myrtenol, (*E*)-carveyl acetate	Oriental compounding flavor Bronchial catarrh
Liquidambar styraciflua (American styraciflua)	Tricyclene, α-thujene, α-pinene, camphene, sabinene, β-pinene, *p*-menth-1(7),8-diene, α-phellandrene, α-terpinene, *o*-cymene, limonene, (*Z*)-β-ocimene, (*E*)-β-ocimene, γ-terpinene, β-fenchyl alcohol, terpinolene, pinocarveol, (*E*)-verbenol, pinocarvone (**260**), borneol, terpinen-4-ol, *p*-cymen-9-ol, α-terpineol, (*Z*)-piperitol, verbenone, (*E*)-carveol, carvone	Natural perfumery incents. Antifungal, antiinflammatory, antimicrobial, antiseptic For alleviating pain
Litchi chinensis	Sabinene, linalool	Fruit Analgesic antibacterial, anticancer, antihyperlipidemic, antiplatelet, antitussive, antiviral, diuretic, hemostatic, hypoglycemic For cough, diabetes, epigastric, flatulence, hernia-like conditions, neuralgic pains, obesity, stomach ulcers, testicular swelling
Lonicera japonica	*p*-Cymene, (*Z*)-linalool oxide, (*E*)-linalool oxide, 1,8-cineole, linalool, (*Z*)-jasmine lactone (**132**), (*Z*)-jasmone (**133**), methyl *epi*-jasmonate, limonene, α-terpineol, geraniol	Beverages (herbal tea) For *Alveolar pyorrhea*, stomatitis, tonsillitis
Luffa cylindrica	Limonene, *p*-cymene, linalool, β-terpineol, camphor, cumin aldehyde (**71**), bornyl acetate	Vegetable Anthelmintic, antipyretic, tonic For emollient, galactagogic, jaundice, leprosy, lung complaints, nephritis, purgative, splenopathy, stomachic, syphilis, tumors

(continued)

Table 1 (continued)

Lycium chinense (Chinese wolfberry)	*Fruits/leaves*: limonene, terpinen-4-ol, menthol, linalool, geraniol, β-ionone, (*E*)-β-ionone-5,6-epoxide, dihydro-β-ionone, ionol	Fruit Antipyretic, diuretic, hypotensive, tonic
Lyophyllum shimeji	*p*-Cymen-9-ol	Foods
Magnolia obovata (=*M. hypoleuca*)	Tricyclene, α-pinene, camphene, β-pinene, myrcene, limonene, *m*-menth-1(7),8-diene (**202**), α-terpinene, *p*-cymene, linalool, 1,8-cineole, γ-terpinene, (4*Z*)-thujanol (**324**), terpinolene, fenchyl alcohol, pinocampheol [=(*E*)-3-pinanol] (**258c**), camphor, 3-methyl-camphenillol (**25**), terpinen-4-ol, α-terpineol, borneol, citronellol, neral, geraniol, geranial, bornyl acetate, geranyl acetate, methyl geranate	Food additives Antispasmodic, sedative For good sleep, detoxify, respiratory disorders
Mangifera indica (Mango oil)	α-Pinene, camphene, β-pinene, Δ^3-carene, limonene, sylvestrene, (**305**), β-phellandrene, α-phellandrene, β-ocimene, γ-terpinene, terpinolene, *p*-cymene, (*E*)-pinocarveol, terpinen-4-ol, cryptone, α-terpineol	Fruit Aphrodisiac, anticancer, antidiabetes, antiobesity, antioxidant, antistomachis, hypocholesterolemia, lower cholesterol, tonic For alkalize body, digestion, eye care, heart stroke, immunity system stimulate, removal of kidney stone, skin cleanser
Matricaria chamomilla (German chamomile oil)	α-Pinene, camphene, sabinene, yomogi alcohol, *p*-cymene, limonene, 1,8-cinecole (*E*)-β-ocimene, γ-terpinene, artemisia ketone (**5**), artemisia alcohol (**8**), linalool, terpinen-4-ol	Beverages (herbal tea), flavoring, cosmetics, soaps, mouthwashes Antiphlogistic antiinflammatory, antiseptic, antispasmodic, promoting relaxation For anxiety, chickenpox, diarrhea, eczema, hemorrhoids, indigestion, insomnia, mouth sores, stomach cramps, stomach ulcer
Matricaria recutita	α-Pinene, sabinene, myrcene, limonene, *p*-cymene, 1,8-cineole, (*E*)-β-ocimene, artemisia ketone, γ-terpinene, terpinen-4-ol, α-terpineol, carvone	Beverages (herb tea) Antimicrobial, antispasmodic

(continued)

Table 1 (continued)

Melaleuca quinquenervia	α-Pinene, α-fenchene, β-pinene, myrcene, limonene, α-terpinene, 1,8-cineole, γ-terpinene, (*E*)-β-ocimene, *p*-cymene, terpinolene, (*Z*)-linalool oxide (furanoid), (*E*)-linalool oxide (furanoid), linalool, terpinen-4-ol, *p*-menth-2-en-1-ol (**211b**), neral, terpinyl acetate, α-terpineol, geraniol	Beverages (herbal tea) Antispasmodic, antiseptic, antihelmintic, diaphoretic, expectorant
Melissa officinalis (Lemon balm)	α-Pinene, sabinene, β-pinene, myrcene, α-phellandrene, Δ^3-carene, *p*-cymene, *o*-cymene, limonene, β-phellandrene, γ-terpinene, terpinolene, linalool, (*E*)-thujene, camphor, *iso*-pulegol, citronellal, lavandulal (**135**), lavandulol (**136**), citronellol, neral, geranial, α-citral, neryl acetate, geraniol, geranyl acetate, geranic acid methyl ester (**96**), (*Z*)-carveol (**39b**), carvacrol	Foods, beverages, cosmetics Spice, fragrance Analgesic, antiaging, antibronchitis, antidepressant, antihypertensive, antimicrobial, antiviral, diaphoretic, insecticide, insect repellant, sedative, tranquilizer For headache
Mentha arvensis (Japanese mint oil)	Camphene, limonene, menthol (**183**), menthone (**189**), menthyl acetate (**184**), *neo*-menthol (**187**), piperitone, thymol	Food flavor (chewing gam, tobacco, cookies), crude drug Antifungal, antimicrobial
Mentha piperita (Peppermint oil)	α-Thujene, α-pinene, camphene, sabinene, β-pinene, myrcene, Δ^3-carene, α-terpinene, *p*-cymene, 1,8-cineole, limonene, (*Z*)-β-ocimene, (*E*)-β-ocimene, γ-terpinene, (*E*)-sabinene hydrate, terpinolene, (*Z*)-sabinene hydrate, linalool, (*Z*)-sabinol, menthone, *iso*-menthone, menthol, *iso*-menthol, *neoiso*-menthol (**188a**), myrtenol, pulegone, *iso*-pulegone, *neoiso*-menthyl acetate (**188b**), perillyl alcohol, thymol, menthyl acetate (**184**)	Beverages (peppermint tea, herbal tea, alcoholic drinks), spice, and for flavoring candy, ice cream, chewing gum and fruit preserves, toothpaste, shampoos, soaps Antispasmodic, carminative For anxiety, cold, flatulence, cold, indigestion

(continued)

Table 1 (continued)

Mentha piperita var. *vulgaris*	(−)-Menthol, menthyl acetate, menthone, menthofuran (**182a**)	Various food flavors Antiseptic, antiinfectious action For catarrhal congestion, clearing, colds, colic, coughs, diarrhea, digestive disorders, general fatigue, hay fever, headaches, impatience, indecision, indigestion, irritable bowel syndrome, jet lag, mental exhaustion, migraine, nausea, poor memory, sinus, stomach pains, vomiting
Mentha pulegium	α-Pinene, β-pinene, myrcene, limonene, 1,8-cineole, ocimene, *p*-cymene, *p*-mentha-1,3,8-triene (**204**), isophorone (**131**) *p*-menth-2-en-1-ol, (*E*)-sabinene hydrate, (*Z*)-sabinene hydrate, linalool, α-terpineol, (*Z*)-verbenol, menthone, neomenthol, menthofuran, menthol, menthyl acetate, borneol, *iso*-pulegone, (Z)-citral, α-terpinyl acetate, (*Z*)-piperitenone oxide, carveol, piperitone, carvone, thymol, linalyl butanoate (**170**), carvacrol, (*E*)-mentha-7(8)-dien-2-ol (**203a**), pulegone	Fragrance, flavoring, beverages (herbal tea) Antiseptic, antispasmodic, bowel disorders, carminative, diaphoretic, emmenagogue, flea-killing bath, insect repellent, pediculicide For mouth sores, mild CNS depressant, pneumonia, respiratory ailments, rubefacient, skin eruptions, stimulant, stomach pains, weakness
Mentha pulegium var. *eriantha* (Pennyroyal oil)	(+)-Pulegone, (−)-menthone, (+)-*iso*-menthone (**190**), piperitone, piperitenone (**275**), *iso*-piperitenone (**276**)	Soap flavor, source for menthol Antimicrobial, antioxidant
Mentha spicata (Spearmint oil)	α-Pinene, camphene, sabinene, β-pinene, myrcene, limonene, 1,8-cineole, (*Z*)-β-ocimene, (*Z*)-sabinene hydrate, linalool, (Z)-*p*-menth-2-en-1-ol, (*Z*)-limonene oxide, (*E*)-limonene oxide, δ-terpineol, terpinen-4-ol, borneol, dihydrocarveol (**37**), (*Z*)-dihydrocarvone (**43**), (*E*)-carveol (**38a**), (*Z*)-carveol (**39a**), pulegone, carvone, *iso*-bornyl acetate, *iso*-dihydrocarveyl acetate, (−)-carvone, menthone, pulegone, carvomenthone (**41**), dihydrocumin aldehyde (**72**)	Foods flavor (chewing gum), beverages (herbal remedy) For ailments, antiemetic, antioxidant, antispasmodic, carminative, diuretic, stimulant, stomachic For digestive disorders, fevers, headaches, restorative

(continued)

Table 1 (continued)

Mentha viridis	α-Pinene, myrcene, limonene, (*E*)-β-ocimene, α-terpineol, (*E*)-carveol, carvone, (*E*)-carveyl acetate (**38b**)	Beverages (herbal tea) Antiemetic, antimicrobial, antioxidant, antispasmodic, carminative, cytotoxicity, diaphoretic, diuretic, restorative, stimulant, stomachic For ailments, fevers, headaches, digestive disorder
Mercurialis leiocarpa	Myrtenol (**196**), myrtanal (**193**), geranial, myrtenal (**195**), citronellol, myrtanol (**194a** or **194b**)	Foods, beverages, dye
Momordica charantia	Linalool, (*E*)-linalool oxide, (*Z*)-linalool oxide, α-terpinolene, nerol, geraniol α-ionone, β-ionone, β-ionone-5,6-epoxide	Foods, beverages (herbal tea) Antidiabetes, antiinflammatory, antimicrobial, antioxidant, antitumor, antiviral, hypolipidemic For Hodgkin's disease, wound healing
Monarda citriodora (Lemon bee balm)	α-Pinene, camphene, sabinene, β-pinene, myrcene, α-phellandrene, Δ^3-carene, α-terpinene, *p*-cymene, 1,8-cineole, (*Z*)-β-ocimene, γ-terpinene, linalool, α-terpineol, geraniol, citral, thymol, carvacrol	Beverages (herbal tea), fragrance Carminative, insect repellent For colds, coughs, fevers, and respiratory problems
Monostroma nitidum	β-Cyclocitral, α-ionone, β-ionone, β-ionone 5,6-epoxide	Foods, food additives, beverages Antiinflammatory, antioxidant, hypolipidemic
Morella rubra (=Myrica rubra)	Tricyclene, α-pinene, α-thujene, sabinene, myrcene, α-phellandrene, 1,4-cineole, 1,8-cineole, (Z)-β-ocimene, *iso*-limonene (**153**), linalool, (*E*)-linalool oxide, (*Z*)-linalool oxide, α-camphelenol (**27**), terpinen-4-ol, α-terpineol	Fruit Antiallergic, anticancer antiinflammatory, antimicrobial For cold, diarrhea, fever, joint pain, vomiting
Morinda citrifolia (Noni)	α-Pinene, sabinene, limonene, (*Z*)-β-ocimene, γ-terpinene, terpinolene, linalool, α-terpinolene	Foods, juice Analgesic, antiarthritic, anticancer, antidiabetes, antiemetic, antifungal, antiinflammatory, antimicrobial, antioxidant, antiparasitic, antiseptic, antituberculosis, antiviral, anxiolytic, sedative For immunity enhancing, memory enhancing, osteoporotic, otoscopy enhancer, wound healing

(continued)

Table 1 (continued)

Morus alba (Mulberry)	α-Pinene, α-thujene, camphene, Δ^3-carene limonene, *allo*-ocimene, (*Z*)-β-damascenone, geranyl acetone	Foods, beverages Analgesic, antibacterial, anticancer, antidiabetes, antihypertensive, antityrosinase, diaphoretic, gallstones dissolving, gastric acid neutralizing, hepatoprotective, sedative
Myristica fragrans (Nutmeg oil)	α-Pinene, β-pinene, sabinene, camphene, limonene, *p*-cymene, linalool, α-terpineol, borneol	Flavor food products, (cakes, cocky source, ketchup), spice Antiinflammatory, insecticide For cold, cough, digestion, fever, gastritis, nausea, pain, rheumatic, vomiting
Myroxylon balsamum var. *genuinum* (=*Toluifera balsamum, Myoxylon touiferu*) (Tolu balsam)	α-Pinene, β-pinene, linalool, carvone, geraniol, menthol, citronellal	Food aromatizer, beverages, flavoring (soft drinks, confectionaries, ice cream chewing gums), flavor for soap, cosmetics Antibacterial, antimicrobial, antiparasitic, antiseptic, bronchitis, catarrh, colds, expectorant, headache For asthma, flu, lung ailments, external wounds, rheumatism sores, sprains, tuberculosis, venereal diseases
Myroxylon pereirae (=*M. balsamum)* (Peru balsam)	α-Pinene, limonene, terpinolene	Food additives (gum, mucilage), food flavor, beverages (coffee, flavored beer, gin, liquor, tea, wine), cosmetics Antifungal, antimicrobial, antiseptic, expectorant For asthma, bronchitis, catarrh, chapped skin, cold, cough, eczema, external wounds, flu, poor circulation, rashes, rheumatism, sensitive skin, stress
Myrtus communis	α-Pinene, 1.8-cineole	Fragrance, infusion gargle
Myristica fragrans	α-Pinene, sabinene, β-pinene, myrcene, α-phellandrene, Δ^3-carene, *iso*-terpinolene (317), *o*-cymene, γ-terpinene, terpinolene, (*Z*)-4-thunanol (324), linalool, β-terpinyl acetate, (*E*)-*p*-menth-2-en-1-ol (211a), terpinen-4-ol, α-terpineol, (*Z*)-piperitol (263)	Spice Antibacterial, antiinflammatory, antioxidant

(continued)

Table 1 (continued)

Nandina domestica	Linalool, β-cyclocitral, *p*-cymen-9-ol	Beverages (herbal tea) Antipyretic, antitussive, tonic For asthma, flu, impotence, whooping cough, tired eyes
Narcissus jonquilla (Jonquil oil)	Linalool, α-terpineol	Flavoring agents, compound flavor Aphrodisiac, antispasmodic, narcotic
Nasturtium officinale (Water cress)	*Flower/stem*: α-pinene, β-pinene, myrcene, limonene, (*E*)-β-ocimene, α-terpinolene, α-terpineol, *p*-cymene-9-ol, pulegone *Leaf/ stem*: limonene, pulegone, *p*-cymen-9-ol, α-terpinolene	Vegetable Anticancer, antidiabetes, antimicrobial, antioxidant, antiscorbutic, antituberculosis, cardioprotective, dentalgia, depurative, diuretic, expectorant, hepatoprotective, hypoglycemic, purgative, stimulant, stomachic
Nelumbo nucifera (Lotus)	α-Pinene, 3,6,6-trimethyl-2-norpinene (**243**), sabinene, β-pinene, 1,4-cineole, terpinolene, *iso*-terpinolene (**313**), terpinen-4-ol, α-terpineol, (*E*)-*p*-menth-2-en-7-ol (**200**)	Foods (seeds), beverages (herbal tea) Analgesic, antimicrobial, antiinflammatory, antioxidant, gastrointestinal regulation, hypoglycemic, immunomodulatory
Nepeta cataria (Nepeta oil, Catnip oil)	α-Thujene, α-pinene, (*E*)-sabinene, β-pinene, Δ^3-carene, myrcene, limonene, γ-terpinene, linalool, 1,8-cineol, ascaridole (**9**), camphor, α-citral, δ-terpineol (**315**), iso-dihydronepetalactone (**227**), (*E*, *Z*)-nepetalactone (**228**), isopulegol, (*Z*,*E*)-nepetalactone (**229**), dihydronepetalactone (**226**), citronellal, citronellol, geranial, geraniol, neral, nerol, geranyl acetate, citronellyl acetate, thymol, nepetalic acid (**230**), nepetalic anhydride (**231**)	Foods, beverages, for making sauce, soup, herbal medicine Anticonvulsant, antiinflammatory, antimicrobial, antioxidant, antispasmodic, carminative, diuretic, insecticidal soporific, stimulant, sedative, tonic For anxiety, diarrhea. digestive, gastrointestinal and respiratory disorders such as asthma, bronchitis, colic, cough, headaches, hysteria, insanity, menstruating pain, nausea prevention, nervousness, relieve fevers, restlessness, sleeplessness, stress, sweating Felis attractant
Nepeta cataria	β-Pinene, ascaridole, limonene, citral, geraniol, citronellol, nerol, neo-nepetalactone (**225**), (*E*,*Z*)-nepetalactone (**228**), (*Z*, *E*)-nepetalactone (**229**)	Beverages (herbal tea) Antispasmodic, intestinal cramps, mild CNS stimulant, nervine For cancer, cold, colic, diarrhea, increase appetite, indigestion, menstruation disorders, sweating

(continued)

Table 1 (continued)

Nephelium lappaceum (Rambutan)	α-Pinene, limonene, (*E*)-geranyl acetone, β-damascenone	Fruit Antiallergic, antidiabetes, antioxidant, antiviral For coronary heart disease, diarrhea, dysentery, sperm health, strengthening bones
Ocimum basilicum (Basil oil)	α-Pinene, α-terpinene, γ-terpinene, *p*-cymene, 1,8-cineole, terpinolene, linalool, (*Z*)-linalool oxide. (*E*)-linalool oxide, (*E*)-sabinene hydrate, camphor, terpinen-4-ol, linalyl acetate (*E*)-*p*-menth-2-en-1-ol, bornyl acetate, carvacrol methyl ether, 3-methyl-camphenillol (**25**), (*Z*)-dihydrocarvone, terpinen-1-ol (**306**), menthol, (*E*)-pinocarveol, δ-terpineol, lavandulol, (*E*)-verbenol, α-terpinyl formate α-terpineol, borneol, dihydrocarveol, α-citral. verbenone, (*E*)-linalool oxide (pyranoid), (*Z*)-linalool oxide (pyranoid), (*Z*)-piperitol, citronellol, myrtenol, nerol, (*E*)-carveol, *p*-cymen-8-ol, geraniol, piperitenone, perillyl alcohol, cumin alcohol *Methyl chavicol type*: (methyl chavicol), linalool *Methyl cinnamate type*: (methyl cinnamate), linalool, methyl chavicol, 1,8-cineole *Camphor type*: camphor, camphene, limonene, borneol *Citral type*: citral, linalool, citronellol, citronellol *Thymol type*: thymol, carvacrol	Food flavor, spice, Italian, Indonesian, Vietnamese, Thai cuisine. Anthelmintic, antiaging, antibacterial, anticancer, antihyperglycemic, antiinflammatory, antifungal, antimicrobial, antioxidant, antiplasmodial, antitubercular, bronchitis, carminative, expectorant, insecticide, mild stimulant For cancer, cardiovascular diseases, constipation, coughs, diabetes diarrhea, headaches, kidney malfunction, mental health booster, rheumatoid arthritis,. warts, worms
Oenanthe javanica (Water dropwort)	α-Pinene, camphene, sabinene, β-pinene, myrcene, limonene, (*Z*)-β-ocimene, *p*-cymene, α-terpinene, γ-terpinene, α-terpinolene, linalool, bornyl acetate, carvacrol, borneol, γ-terpineol, linalool oxide, *p*-cymen-9-ol, terpinen-4-ol,	Vegetable, beverages (herbal tea), salad, seasoning in soups stews Analgesic, anticancer, anticoagulant, antifatigue, antiinflammatory, antinociceptive, antimutagenic, antioxidant, antithrombotic, antiviral, cardiovascular

(continued)

Table 1 (continued)

	thymol methyl ether, carvacrol methyl ether, geranyl acetone	protection, ethanol elimination, hepatoprotective, immune enhancement, insecticidal, hypoglycemic, neuroprotective For cough, depurative, discomfort, febrifuge, epidemic fever, headache, hematuria, influenza, jaundice, metrorrhagia, styptic
Olea europaea	Tricyclene, α-pinene, camphene, sabinene, β-pinene, myrcene, 2,3-dehydro-1,8-cineole (**53**), Δ^3-carene, *p*-cymene, limonene, 1,8-cineole, (*E*)-β-ocimene, γ-terpinene, (*Z*)-linalool oxide, linalool, (*Z*)-*p*-mentha-2,8-dien-1-ol (**209b**), camphor, menthone, umbellulone (**337**), menthol, terpinen-4-ol, α-terpineol, carvacrol methyl ether, *iso*-bornyl acetate, (*E*)-β-damascenone	Foods, beverages Antihypertensive, antioxidant, hypoglycemic, hypocholesterolemic, diuretic For asthma, bronchitis, cholagogue, diarrhea, emollient, febrifuge, gallstones, laxative, skin cleanser, urinary infections
Ophiocordyceps sinensis	*p*-Menth-4(8)-en-9-ol (**212**)	Beverages Antitumor, tonic For alcohol hepatitis, appetite, arthritis, bronchitis, chronic pain, coronary heart disease, longevity, diabetes, dizziness, erectile dysfunction, endurance, female aphrodisiac, general weakness, infertility, jaundice, malignant, liver and kidney diseases, longevity, malignant, prostate enlargement, rheumatism, sciatica and backache, sleeping patterns, tuberculosis
Origanum majorana (Origanum majorana leaf oil)	β-Phellandrene, *p*-cymene, β-thujene, linalool, (*E*)-2-menthen-1-ol (**211a**), (*Z*)-2-menthen-1-ol (**211b**), terpinen-4-ol, *p*-cymen-8-ol, α-terpineol, (*Z*)-piperitol (**263**), linalyl acetate, terpinyl acetate, dihydroumbellulone (**338**), terpinyl propanoate (**314**), geranyl acetone, carvacrol	Vegetables, curry powder, cooking food, fragrant Antimicrobial, antioxidant

(continued)

Table 1 (continued)

Origanum vulgare	Thujene, α-pinene, camphene, sabinene, β-pinene, myrcene, limonene, α-terpinene, *p*-cymene, γ-terpinene, terpinolene, 1,8-cineol, linalool, β-ocimene, (*Z*)-linalool oxide, *p*-cymen-9-ol, borneol, thymol, carvacrol	Foods, spice Antibacterial, anticancer, antidiabetes mellitus, antifungal, antiinflammatory, antioxidant, carminative, digestive aid For bronchitis, cold sores, diarrhea, headache, menstrual pain, vomiting
Orthosiphon aristatus	β-Pinene, camphene, limonene, linalool, cyclocitral, carvone, camphor, borneol, bornyl acetate	Beverages Antidiabetes, antihepatitis, antihypertensive For edema, jaundice, kidney stone, rheumatism
Oryza sativa (Rice)	Limonene, *p*-cymene, linalool, geranyl acetone	Foods *Brown and germinated brown rice*: Anticancer, antidiabetes mellitus, antidiarrheal, antioxidant, reduction of cardiovascular risk
Osmanthus fragrans var. *aurantiacus* (Osmanthus oil)	Linalool, linalyl oxide, α-ionone, β-ionone, γ-decalactone, δ-dihydro-β-ionone (**126**)	Cosmetic fragrance Tea flavor attached
Paeonia lactiflora (Peony)	Perilla alcohol, thymol, carvacrol	Beverages (herbal tea) Atherosclerosis For chronic fatigue, syndrome (CFS), dysfunction, epilepsy, headache, liver cirrhosis, menstrual disorders, migraine, muscle cramps, nausea, neuralgia, sperms, upset stomach, viral hepatitis, whooping cough (pertussis)
Panax ginseng	β-Pinene, myrcene, *p*-cymene, β-phellandrene, limonene, α-terpineol	Foods, beverages, Kampo medicines. Aphrodisiac, antidepressant For improving both mental and performance, increasing resistance
Panax notoginseng	Camphene, β-pinene, limonene, β-phellandrene, α-terpinolene α-phellandrene	Beverages Antihypertensive For angina, intracranial hemorrhage, liver disorders, osteoarthritis, pain, stroke, swelling

(continued)

Table 1 (continued)

Panax quinquefolius (North American ginseng)	α-Pinene, camphene, β-pinene, limonene	Beverages Anti-Alzheimer's disease, anticancer, antidiabetes, antiinflammatory, antimicrobial, antiobesitic, antioxidant, anxiolytic, hypertrophy, improve cognitive, neuroprotective
Papaver somniferum (Poppy)	*Seeds*: α-pinene, *o*-cymene	Food additives, flavor, for cookies, bread, egg, grilled fishes Antibacterial, antiflu, antiinflammatory, anticancer, antiobesity, antitumor, detoxicant, expectorant, fungicide, herbicide, immunomodulatory, insecticide, nematocidal, pesticide, photo sensitizer, sedative
Pastinata sativa (Parsnip)	Terpinolene	Vegetable Antioxidant For psoriasis, vitiligo
Paxillus involutus	1,8-Cineole	Foods (cooked)
Pelargonium denticulatum	Geraniol, citronellol	Antibacterial, antifungal
Pelargonium graveolens	α-Pinene, myrcene, *p*-cymene, limonene, γ-terpinene, linalool, (*Z*)-linalool oxide, (*E*)-rose oxide (**291**), (*E*)-linalool oxide, (*Z*)-rose oxide (**292**), *neoiso*-pulegol (**284**), menthone, *iso*-menthone (**190**), *iso*-menthol (**186a**), α-terpineol, citronellol, neral, geraniol, neryl formate (**235**), citronellic acid (**56**), geranic acid methyl ester, 8-hydroxy-*neo*-menthol (**185**), citronellyl acetate (**59**), citronellyl propionate (**60b**), citronellyl isobutanoate (**62**), citronellyl butanoate (**61**), citronellyl 2-methylbutanoate (**63**), citronellyl pentanoate (**64**), citronellyl heptanoate (**65**), lavandulyl 2-methylbutanoate (**139**), lavandulyl tiglate (**140**),	Beverages, cosmetic, soap, fragrance, lotions Antianxiety, antiaging, antibacterial, antifungal for food spoilage pathogens, antiinflammatory, antioxidant, antiviral For anxiety, aiding, depression, burns, calming nerves, digestive, ulcers, abscesses, cold sores, creating a relaxing, uplifting feeling, nerve pain relief, premenstrual tension, respiratory ailments, sore throats, ulcers, abscesses, wounds

(continued)

Table 1 (continued)

	geranyl formate (**98**), geranyl propanoate (**100**), geranyl isobutanoate (**102**), geranyl butanoate (**101**), geranyl 2-methylbutanoate (**105**), geranyl pentanoate (**103**), geranyl tiglate (**106**), geranyl hexanoate (**107**), geranyl heptanoate (**108**), geranyl octanoate (**109**)	
Pelargonium odoratissimum	Thujene, α-pinene, sabinene, β-pinene, myrcene, α-terpinene, *p*-cymene, limonene, 1,8-cineole, ocimene, γ-terpinene, linalool, fenchone, fenchyl alcohol, camphor, menthone, *iso*-menthone (**190**), *iso*-borneol, terpinen-4-ol, α-terpineol, citronellol, (*E*)-carveol, (*Z*)-carveol, piperitone	Beverages, apple aroma Antiseptic, astringent, tonic For aromatherapy, debility, gastroenteritis, hemorrhage, injuries, mouthwash, neuralgia, ointment, skin complaints, throat infections
Pelargonium radula (Geranium oil)	Geraniol, citronellol, *iso*-menthone, citronellol, citronellyl formate (**60a**), geranyl formate (**98**), geranyl acetate (**97**)	Food flavoring (jellies), food additives, beverages (herbal tea) Antibacterial, antifungal
Pelargonium roseum	α-Pinene, linalool, geraniol, menthone, citronellol, citronellyl formate, geranyl acetone (**111**)	Analgesic, antibacterial, antifungal. antiinflammatory, antiseptic, astringent
Perilla frutescens (=*P. frutescens* var. *frutescens*, *P. frutescens* var. *japonica*) (Egoma)	*Leaves:* α-pinene, β-pinene, limonene, *p*-cymene, linalool, linalyl acetate, linalyl senecioate (**173**), geraniol, elsholtzia ketone (**87b**), naginata ketone (**224**), perilla ketone (**273**), *iso*-egomaketone (**87a**) *Seeds:* (Himalaya): 1,8-cineole, γ-terpinene, linalool, perilla ketone, *iso*-perilla ketone (**290**)	Vegetable, food additives, flavor Anticancer, antiinflammatory, antimicrobial, antispasmodic, inducing sweating For allergies, asthma, heart diseases, colitis/Crohn's disease, heart diseases, nausea, sunstroke
Perilla frutescens var. *crispa* f. *purpurea* (Akajiso)	Linalool, perillaldehyde, shisool	Vegetable, beverages, food additive, flavor, species Leaf: food as Japanese cuisines (Tempura, Sushi)
Perilla frutescens var. *crispa* f. *viridis* (Aojiso) (*Perilla* oil)	α-Pinene, camphene, β-pinene, myrcene, limonene, *p*-cymene, (*E*)-linalool oxide, (*Z*)-linalool oxide, linalool, (−)-menthol, α-terpineol, carvone, (−)-perillaldehyde, (*E*)-carveol (**38a**), (Z)-carveol (**39a**), (*E*)-	Vegetable, food additives Flavor *Leaves*: food as Japanese cuisines (Tempura, Sushi) Analgesic, antiallergenic, antibacterial, antibiotic, anticorrosion, antifungal,

(continued)

Table 1 (continued)

	shisool (**303**), (*Z*)-shisool (**304**), (−)-perilla alcohol (**271**), perilla ketone, *iso*-egomaketone (**87a**), shisofuran (**302**), (*Z*)-jasmone, thymoquinone (**335**), carvone	antiinflammatory, antioxidant, antipyretic, antitumor, antitussive, apoptosis inducing, insecticidal, sedative, stomachic For asthma, constipation, back and muscle pain, cold, intestinal disorders
Perilla frutescent var. *crispa* f. *crispa* (leaf) (Chirimenjiso)	(*E*)-Linalool oxide, (*Z*)-linalool oxide, linalool, pinanol, α-terpineol, perillaldehyde, 10-pinanol [=(*E*)-myrtanol)] (**194a**), perilla alcohol, geraniol	Vegetable, beverages, food additives, flavor, species *Leaves*: food as Japanese cuisines (Tempura, Sushi) Antiinflammatory, antimicrobial
Persea americana (Avocado oil)	α-Pinene, camphene, sabinene, β-pinene, myrcene, limonene, β-ocimene, α-phellandrene, α-terpinene, 1,8-cineole, γ-terpinene, carvone, neryl acetate	Foods, food flavor Antihypertensive, antioxidant, hypocholesterolemia For aphrodisiac, coughs, diarrhea, dysentery, gout, hair growth, liver disorders, smooth skin
Persicaria tinctoria	Limonene	Vegetable, beverages, cookies Antidote, antiinflammatory, antiphlogistic, antipyretic, depurative For epidemic proctitis, erysipelas, freckles, infantile convulsions and high febrile conditions of children, mumps, pimples, thrush
Petasites japonicus	α-Pinene, camphene, β-pinene, myrcene, limonene, α-phellandrene, Δ^3-carene, p-cymene, perillaldehyde, linalool, γ-terpinene, *p*-menth-1-en-9-ol, thymol methyl ether, linalyl propanoate (**169**)	Vegetable, beverages (herbal tea) Antitussive, tonsillitis For headache, discomfort of gastrointestinal system, menstrual wellness
Petroselinum crispum (Parsley)	α-Thujene, α-pinene, camphene, β-pinene, sabinene, myrcene, Δ^3-carene, α-phellandrene, α-terpinene, limonene, β-phellandrene, (*E*)-β-ocimene, (*Z*)-β-ocimene, γ-terpinene, *p*-cymene, α-terpinolene, *p*-mentha-1,3,8-triene, α-terpineol, *p*-cymen-8-ol, cryptone, α-campholenal (**28**), (*E*)-pinocarveol (**258a**), pinocarvone, myrtenal, myrtenyl acetate (**197**)	Vegetable, beverage (herbal tea), tonic Antihypertensive, antimicrobial, antiseptic, antispasmodic, diuretic, stimulant For abortifacient, amenorrhea, anemia, diabetes, dysmenorrhea, gastrointestinal disorders, halitosis, insect bite, kidney stones

(continued)

Table 1 (continued)

Peucedanum japonicum	α-Thujene (**329**), α-pinene, α-fenchene, camphene, β-pinene, myrcene, Δ^3-carene, α-phellandrene, α-terpinene, *p*-cymene, limonene, β-phellandrene, (*Z*)-β-ocimene, (*E*)-β-ocimene, γ-terpinene, terpinolene, *allo*-ocimene, (*E*)-limonene oxide, (*E*)-pinocarveol, lavandulol, terpinen-4-ol, verbenol, α-terpineol, β-citronellol, pinocarvone, cryptone, piperitone, thymol, nerol, campholenal (**28**), neral, geranial, linalyl acetate, isobornyl acetate, bornyl acetate, sabinyl acetate, α-fenchyl acetate, citronellyl acetate, thymol methyl ether, carvacrol methyl ether	Vegetable juice, beverages Antiasthmatic, antiinflammatory For allergic, lung inflammation, cold, cough, headache, liver, lung, kidney, spleen stomach meridians, rental disorder, typhoid fever
Phaseolus vulgaris	α-Pinene, Δ^3-carene, limonene, geranyl acetone	Vegetable For diabetes, obesity, weight loss
Phellodendron amurense	*Leaves*: α-pinene, camphene, sabinene, myrcene, α-phellandrene, Δ^3-carene, limonene, (Z)-β-ocimene, γ-terpinene, limonene oxide, camphor, piperitone oxide *Seeds*: tricyclene, α-pinene, myrcene, β-citronellol, geranyl acetone	Beverages (herbal tea) Antiinflammatory, bitter stomach medicine For anemia, anorexia, convergence, diarrhea, gastric spasm, pneumonia, pulmonary tuberculosis, sterilization
Phyllostachys heterocycla cv. *pubescens*	Menthone, geranyl acetone, α-ionone, damascenone, β-ionone	Food, beverages Antimicrobial
Phyllostachys nigra	Citronellyl isovalerate *Fermented:* limonene, linalool	Foods (young shoots), beverages (herbal tea). Antiemetic, antipyretic, antitussive, astringent, depurative, diuretic, expectorant, hemostasis, sedative, tonic For asthma, cough, fevers, nose bleeds, phlegm, pneumonia, rabies, styptic, vomiting

(continued)

Table 1 (continued)

Physalis peruviana (Cape gooseberry)	α-Pinene, camphene, verbenene, dehydrosabinene (**293**), myrcene, α-terpinene, limonene, 1,8-cineole, (*E*)-β-ocimene, *p*-cymene, α-terpinolene, rose oxide, linalool oxide, isopulegol, α-fenchyl alcohol, terpinen-4-ol, β-cyclocitral, (*Z*)-citral, limonene 4-ol (=mentha-1,8-dien-4-ol) (**157**), α-terpineol, borneol, myrtenal, verbenone, geranial, β-citronellol, nopol (**242**), (*Z*)-*p*-menta-1(7),8-dien-2-ol (**203b**) geraniol, *p*-cymen-9-ol, geranyl acetone, (*Z*)-myrtanol (**194b**), carvacrol, neric acid (**233**), dihydroactinidiolide (**3**)	Fruit, jam, pies, puddings, chutneys, salad, cocktail Anticancer, antimycobacterial, antioxidant, antipyretic, diuretic, eye sight improving, immunomodulatory, liver and kidney against fibrosis protecting For arthritis pain, asthma, dermatitis, hepatitis, malaria, leukemia, rheumatism
Pimenta dioica (Allspice)	α-Pinene, sabinene, myrcene, limonene, α-phellandrene, Δ^3-carene, α-terpinene, *p*-cymene, 1,8-cineole, (*Z*)-β-ocimene, γ-terpinene, terpinolene, linalool, *p*-menth-2-en-1-ol, terpinen-4-ol, *p*-cymen-8-ol, α-terpineol, α-phellandrene epoxide, (*E*)-piperitol	Foods, beverages, flavor, perfumery, soup. Mulled wine, sider Anesthetic, antiseptic, fungicide, pesticide For ailments, flatulence, muscle pain, upset stomachic
Pimenta officinalis (Pimenta oil, allspice oil)	α-Phellandrene, 1,8-cineole	Food flavor (meats, source, pickles, cookies), spice Anticancer, antidiabetes, antifungal, antimicrobial, antioxidant, carminative, nematocidal
Pimenta racemosa (Bay oil)	α-Pinene, β-pinene myrcene, α-terpinene, *p*-cymene, limonene, 1,8-cineole, α-phellandrene, (*E*)-β-ocimene, γ-terpinene, terpinolene, linalool, terpnen-4-ol, α-terpineol, citral	Food flavor, table source, cosmetic water flavor, hair cosmetic product Acaricidal, antifungal antiinflammatory, antimicrobial, antioxidant
Pine nut from *Pinus cembroides* *P. geradiana* *P. koraiensis* *P. monophylla* *P. odules* *P. pinea*	α-Pinene, camphene, β-pinene, Δ^3-carene, limonene, *p*-menth-1-en-8-ol, terpinen-4-ol, verbenone, borneol, bornyl acetate	Beverages Antitussive, insulation, sedative, brain and stomachic activation
Pinellia ternata	*o*-Cymene, limonene, linalool, menthone, borneol, menthol, terpinen-4-ol, citronellol, pulegone, *iso*-pulegone, (*E*)-*p*-menth-2-en-7-ol, cumin alcohol	Beverages (herbal tea) For sore throat

(continued)

Table 1 (continued)

Pinus densiflora (Turpentine oil)	α-Pinene, β-pinene, camphene, sabinene, myrcene, α-ocimene, α-terpinene, terpinolene α-terpineol	Foods (seed), production of pinene For bladder, kidney, skin complaints, cough, cold, influenza, rheumatic, rubefacient
Pinus palustris (Pine oil)	Terpineol, α-fenchyl alcohol, borneol	Flavor Antiseptic, bactericides, disinfectant, diuretic, vermifuge For cough, chronic, cold, colic, diarrhea, worms
Piper betel	*Betel leaf oil*: *p*-cymene, 1,8-cineole, (Z)-sabinene hydrate (**297**), carvacrol	Foods, beverages, flavor. Anticancer, antimalarial, antimicrobial, expectorant, hypocholesterolemic For asthma, diabetes, good stomachic, healing wounds, luxury, oral health
Piper nigrum	*Pepper oil*: α-thujene, α-pinene, sabinene, β-pinene, myrcene, Δ^3-carene, limonene, α-phellandrene, β-phellandrene, γ-terpinene, cryptone, terpinolene, α-terpinene, *p*-cymene, dihydrocarveol (**37**)	Spice (black and white pepper), food additives (sausage, soup, source, cans
Piptoporus betulinus (Polypore)	Limonene	Foods, beverages (herbal tea) Antiseptic, antifungal, tonic for the immune system For parasitic worms, wound healing
Pittosporum tobira	α-Pinene, β-pinene, myrcene, limonene, (*E*)-β-ocimene	Beverages (herbal tea) Anticancer, antifungal, antiinflammatory, antioxidant, antiproliferative
Pleurotus ostreatus (Oyster mushroom)	α-Pinene, *p*-cymene, linalool, (*E*)-linalool oxide	Foods Anticancer, atherosclerosis, antioxidant, hypolipidemic For diabetes, immune system booster, respiratory tract infection
Pogostemon cablin (Patchouli oil)	α-Pinene, β-pinene, camphene, limonene, myrtenol, α-terpineol, camphor, cumin aldehyde	Breath fresheners, incent agent, soap perfume
Polianthes tuberosa (Tuberose oil)	Geraniol, nerol, geranyl acetate, neryl acetate	Luxury compounded fragrance

(continued)

Table 1 (continued)

Polygonatum odoratum	Citronellol	Adaptogenic, allergic, antibacterial, antimicrobial, antioxidant, antiperiodic, antitussive, cardiotonic, demulcent, diuretic, energizer, hypoglycemic, ophthalmic, resolvent, sedative, tonic For dry throat, dry coughs, coronary heart disease, skin toner
Polygonum minus (Kesum oil)	α-Thujene, α-pinene, limonene, β-ocimene, myrtenol, myrtenol, borneol, geraniol, geranyl acetone	Vegetable Aggregation, antifungal, antiinflammatory antimicrobial, antioxidant, antiplatelet, antiproliferative, antiulcer, cytotoxicity, cognitive and digestive enhancing, gastroprotective, genotoxicity, immunomodulatory For body aches, digestive disorders, stomachic
Polygonum hydropiper (Water pepper)	α-Pinene, myrcene, dihydro-α-ionone (**121**)	Vegetable, spice, beverages (tea) For diarrhea, dyspepsia, itching skin, menstrual bleeding, hemorrhoids, poultice for swollen and inflamed areas
Porphyra tenera	Piperitone oxide (**281b**), β-cyclocitral, α-ionone, neryl acetone (**240**), β-ionone	Foods, food additives Antiinflammatory, antioxidant
Prunella vulgaris	Limonene, linalool, (*E*)-linalyl oxide, (*Z*)-linalyl oxide, β-cyclocitral, geranyl acetone	Herbal medicine. Antiinflammatory
Prunella vulgaris var. *lilacina*	Limonene, camphor, linalool, linalool oxide, β-cyclocitral, geranyl acetone	Antiallergic, anticancer, antiinflammatory, antimicrobial, antioxidant, antiviral, diuretic, tonic, astringent For beriberi, cystitis, hemostasis, sore throat, stomatitis, tonsillitis
Prunus amygdalus var. *amara* (Bitter almond oil)	*	Food flavor (cakes, wine)
Prunus armeniaca (Apricot oil)	Limonene, (*E*)-β-ocimene, linalool, dihydro-β-ionone (**125**), dihydroactinidiolide, damascone, β-ionone, (*E*)-rose oxide (**291**)	Fruit, flavor, crude drugs

(continued)

Table 1 (continued)

Prunus mume (Ume oil)	*Fruit: p*-cymene, (*E*)-linalool oxide, (*Z*)-linalool oxide	Fruit, food flavor (fruit oil)
Prunus persica (Peach oil)	Linalool	Fruit Anticancer, antidiabetes, antiinflammatory, antioxidant, hypocholesterolemic For bone and kidney disorders, cardiovascular, skin health, eye vision
Pseudocydonia sinensis	Linalool, terpinen-4-ol, α-terpineol, neral, geranial	Beverages, alcoholic beverage Anticancer, antimicrobial, antioxidant, diuretic, expectorant For cough, diarrhea, pharyngitis
Pseudocydonia sinensis (Chinese quince) (=*Cydonia sinensis*)	Limonene, (*E*)-theaspirane (**319**), (*Z*)-theaspirane (**320**), carvone, (*E*)-linalyl oxide, (*Z*)-linalyl oxide	Candied fruit, fruit liquor Antiinflammatory, antioxidant For cough, diuretic
Psidium guajava	*White fruit* (*head space*): α-pinene, 1,8-cinenole, borneol, cumin alcohol *Essential oils (leaf/fruits):* α-pinene, β-pinene, Δ^2-carene (**30**), α-phellandrene, α-terpinene, *p*-cymene, limonene, 1,8-cineol, (*Z*)-β-ocimene, (*E*)-β-ocimene, γ-terpinene, terpinolene, *allo*-ocimene, α-terpineol, carvone	Fruit Antibacterial, anticough, antidiabetes, antihelmintic, antimicrobial, antioxidant, antiproliferation, antispasmodic, cooling, laxative, tonic For diarrhea in children, pulmonary disorders, relief of cough, ulcers, wounds
Psidium guajava	*Fruits/leaves:* camphene, sabinene, limonene, *(Z)*-β-ocimene, 1,8-cineole, α-terpineol, citral, β-ionone	Fruit Antiatopic, antidiabetes, antihypertension, dermatitis For cerebral infection, intestinal regulation lightening, stomachic
Pteridium aquilinum	α-Thujene, α-pinene, sabinene, β-pinene, myrcene, limonene, α-terpinene, 1,8-cineole, (*Z*)-β-ocimene, *allo*-ocimene, γ-terpinene, terpinolene, fenchone, neral, geranial, *iso*-artemisia ketone (**6a**), nerol, geraniol	Foods, source of starch, herbal medicine Antimicrobial, antioxidant, antiparasitic, jaundices

(continued)

Table 1 (continued)

Pueraria montana var. *lobata*	α-Thujene, α-pinene, sabinene, β-pinene, myrcene, γ-terpinene, limonene, α-terpinene 1,8-cineole, (*Z*)-β-ocimene, *allo*-ocimene, γ-terpinene, linalool, fenchone, neral, geranial, *iso*-artemisia ketone (**6a**)	Foods, source of starch, beverages (herbal tea) Antihypertension For alcoholism, angina, angioplasty, cold, diabetic, hay fever, headache, flu, heart failure, dizziness, ischemic stroke, nephropathy, retinopathy, upset stomach, sinus infections, swine flu, vomiting
Punica granatum	α-Thujene, α-pinene, sabinene, β-pinene, camphene, limonene, Δ^3-carene, α-phellandrene, γ-terpinene, *p*-cymene, β-phellandrene, camphor, α-terpineol	Foods, beverages (juice), food seasoning, cosmetics Anticancer, antidiabetes, antihelmintic, antiinflammatory, antimicrobial, antiobesity, antioxidant, antiswelling, diarrhea, dysentery, stomachache, suppression for melanin
Pyropia tenera	Limonene, α-terpineol, α-ionone, β-ionone, dihydroactinidiolide	Foods Anticancer, antiinflammatory For immune system booster
Raphanus sativus (Red radish)	Δ^3-Carene	Foods, vegetable For appetite, bronchitis, chronic diarrhea, colds, cough, fever, intestinal, liver and stomach disorders, gallstones, high cholesterol
Raphanus sativus var. *longipinnatus*	Camphene, myrcene, α-terpinene, limonene, 1,8-cineole, *m*-cymene (**76**), terpinene-4-ol, *p*-menth-6-en-3-one (**221e**), piperitone, carvone, camphor, *neoiso*-menthol, dihydrocarveol, α-terpineol, menthol, menthyl acetate, nerol, bornyl acetate, carvacrol, geranyl acetone	Foods, vegetable Antidiabetes, antimicrobial, antiobesity
Rheum rhaponticum (Rhubarb, garden rhubarb)	Limonene, linalool, β-ionone, α-terpineol, (*E*)-geranyl acetone	Foods, beverages, syrups, liqueurs, jam, compote, juice, ingredients in ice cream, yogurt, candies Antidiarrheal, laxative
Rosa damascena f. *trigintipetala* (Rose oil)	Linalool, (−)-citronellol, geraniol, nerol, geraniol, (*E*- or *Z*-rose oxide (**291** or **292**)	Food flavor, beverages (rose water) Antispasmodic, relaxant, stomachic

(continued)

Table 1 (continued)

Rosa rugosa (Hamanasu oil)	α-Pinene, β-pinene, myrcene, limonene, 3-carene, (*E*)-β-ocimene, linalool, (*E*)-rose oxide (**291**), citronellal, geraniol, citronellol, α-citral, nerol, geranyl acetate, neryl acetate, citronellyl acetate	Foods, perfume, cosmetics, spices
Rosmarinus officinalis (Rosemary oil)	α-Pinene, camphene, β-pinene, limonene, thyuja-2,4(10)-diene (**323**), α-phellandrene, α-terpinene, *p*-cymene, 1,8-cineole, γ-terpinene, *p*-mentha-2,4(8)-diene (**208**), terpinolene, linalool, chrysanthenone, camphor, pinocarvone, menthol, borneol, terpinen-4-ol, α-terpineol, verbenone, bornyl acetate	Flavoring food, cosmetic, perfume, spice, spray, crude drug, beverages (herb tea) Antiinflammatory, antimicrobial, antioxidant, antispasmodic, carminative, GI irritant For hair growth, hepatic, intestinal renal, respiratory affections, skin health
Rubus idaeus	α-Pinene, camphene, sabinene, β-pinene, myrcene, limonene, Δ^3-carene, *p*-cymene α-phellandrene, (*E*)-β-ocimene, terpinolene, (*Z*)-β-ocimene, 1,8-cineole, α-terpinene, β-phellandrene, γ-terpinene, linalool, (*E*)-linalool oxide (furanoid), (*E*)-linalool oxide (pyranoid), (*Z*)-linalool oxide (pyranoid), linalyl acetate, terpinen-4-ol, (*Z*)-piperitol (**263**), (*Z*)-sabinol (**300**), α-terpineol, camphor, menthone, menthol, menthyl acetate, myrtenol, *neo-allo*-ocimene (**244**), *p*-cymen-9-ol, 8-hydroxylinalool, neral, nerol, cyclocitral, verbenone, dihydrolinalool, geranial, geraniol, *iso*-piperitenone, (*Z*)-jasmone, theaspirane A (**319**), theaspirane B (**320**), theaspirane I, theaspirane II, dihydroactinidiolide, α-ionone, β-ionone, damascenone, dihydro-α-ionone (**121**), dihydro-β-ionone (**125**)	Foods, fruit Anticancer, antidiabetes, antifungal, antihypertension, antiinflammatory, antiobesity, antioxidant For Alzheimer's and Parkinson's diseases, chronic diseases, digestion, eye and heart health

(continued)

Table 1 (continued)

Russula cyanoxantha	α-Pinene, 1,4-cineole, limonene, 1,8-cineole, linalool, α-terpineol, geranyl acetone	Foods
Ruta graveolens	Geijerene (**93**), geyrene (**115**), piperitenone (**275**), (*E*)-piperitenone oxide (**285**), (*Z*)-piperitone oxide (**289**), (*Z*)-*iso*-pulegone (**268**)	Beverages Antidiabetes, antidiarrhetic, antifebrile, antimicrobial, antiinflammatory, antiparasitic, antirheumatic, antiulcer, healing, vermicide For cramps, earache, headache, diabetes, menstrual disorders
Salvia officinalis (Sage oil)	α-Thujene, tricyclene, α-pinene, camphene, sabinene, β-pinene, α-phellandrene, α-terpinene, *p*-cymene, limonene, 1,8-cineol, γ-terpinene, terpinolene, camphor, terpinen-4-ol, α-terpineol, borneol, bornyl acetate, α-thujone (**331a**), β-thujone (**331b**)	Foods, food flavor (sausage, pickles, soup, canes, vine), beverages, crude drugs, spice Antiinflammatory, antioxidant, anthelmintic, antisecretary, astringent, diuretic, emmenagogue, insect repellent, nitric oxide production and NF-kB transcription factor inhibitory, strengthen bones and immune system For asthma, gastroenteritis, cognitive disorder, digestion, mouthwashes, wound healing
Salvia sclarea (Clary sage oil)	α-Pinene, sabinene, β-pinene, myrcene, limonene, 1,8-cineol, (*Z*)-β-ocimene, linalool, (*E*)-β-ocimene, *allo*-ocimene, α-terpinene, γ-terpinene, terpinolene, α-phellandrene, β-phellandrene, (*E*)-linalool oxide (furanoid), (*Z*)-linalool oxide (furanoid), linalyl acetate, camphor, *p*-cymen-8-ol, *iso*-borneol, linalyl formate, terpinen-4-ol, neral, lavandulol, geranyl formate, geranial, geranyl acetate, α-terpineol, α-terpinyl acetate, neryl acetate, damascenone, nerol, nerol oxide, cumenol (**68b**), geraniol, thymol, carvacrol, carvacrol methyl ether	Food flavor beverages (herbal tea) Antibacterial, antidepressant, antiinflammatory, antispasmodic, tonic For indigestion, circulation, stress relief, pain, and premenstrual problems

(continued)

Table 1 (continued)

Sambucus nigra (Elderberry)	Limonene, linalool, bornyl acetate, (*E*)-β-damascenone, carvacrol	Foods, jam, marmalade, pies, beverages (wine, liqueurs, juice, tea) Antiinflammatory, diuretic, diaphoretic, laxative For flu, stimulating immune system, well-being
Santalum album (Sandalwood oil)	Camphene, α-terpinene	Food products, macadamia nut, bush food preparation, oriental flavor, cosmetics, soap flavor, aroma retaining agents For cold, liver, digestive gallbladder, hemorrhoids, muscle problems, mental disorders, scabies, urinary tract infections
Saposhnikovia divaricata	α-Pinene, β-pinene, myrcene, *o*-cymene	Vegetable Analgesic, anticancer, antiinflammatory, antioxidative, antiproliferative, immunoregulatory
Sasa veitchii	Linalool, α-terpineol, geranyl acetone	Beverages (herbal tea) Antihypertension, anticancer, antiinflammatory, antimicrobial, cardiotonic For constipation, diabetes mellitus, stomachic, ulcer
Sassafras albidum (=*Sassafras variifolium*) (Sassafras oil)	α-Pinene, myrcene, α-phellandrene, β-phellandrene, linalool, camphor, citral, geraniol, geraniol esters	Foods, food additives, beverages (herbal tea), perfume Analgesic, anticancer, antifungal, antimicrobial, antipyretic, antiseptic, carminative, diaphoresis For acne, bronchitis, dentifrice, diaphoretic, dysentery, menstrual disorders, kidney problem, rheumatism, rubefacient, skin sores, sudorific, swelling, trauma, urinary disorders
Satureja hortensis	α-Pinene, myrcene, camphene, β-pinene, myrcene, α-phellandrene,, α-terpinene, *p*-cymene, *o*-cymene, γ-terpinene, thymol, carvacrol	Flavor, garnish, beverages (herbal tea) Sedative For cramps, diarrhea
Satureja montana (Winter savory)	p-Cymene, γ-terpinene, borneol, geraniol, thymol, carvacrol, thymol methyl ether, carvacrol methyl ether	Flavoring for cooked foods, garnish for salads, beverages (herbal tea), liquors

(continued)

Table 1 (continued)

Saxifraga stolonifera	α-Pinene, cumene, *p*-cymene, terpinolene, linalool, α-terpineol, geraniol geranyl acetate, citronellol	Vegetable Antiaging, anticancer, antioxidant
Sechium edule (=*Chayota edulis*)	Limonene, *p*-cymene	Vegetable Antidiabetes mellitus, antineoplastic, antioxidant
Sesamum indicum	α-Pinene, myrcene, linalool, carvomenthone, geraniol, geranial, neral, fenchyl alcohol, *iso*-pulegol, thymol	Foods Antiaging, antihyperlipidemic, antihypertension For AIDS-related wasting, bowel obstruction, burns, cough, diabetes, gingivitis, lower blood pressure, serum lipid
Solanum lycopersicum (=Lycopersicon esculentum)	*Fresh tomato head space*: β-phellandrene, linalool, geranial, neral, β-cyclocitral, 5,6-epoxy-β-ionone *Leaves (essential oils):* α-thujene, α-pinene, Δ^2-carene, β-pinene, myrcene, limonene, α-phellandrene, α-terpinene, *p*-cymene, γ-terpinene, (*Z*)-β-ocimene, (*E*)-β-ocimene, β-phellandrene, terpinolene, 1,8-dineole, Δ^2-carene epoxide (**32**), limonene epoxide, linalool, neral, geranial, geraniol *Whole, pulp, fluid*: linalool, nerol, geranial, β-cyclocitral, geranyl acetone	Foods, processed foods (ketchup, paste), vegetable, beverages Anticancer, antidiabetes, antiosteoporosis, antioxidant, immunity booster, detoxification For cardiovascular disease, fatigue, liver health, sleepiness, strengthening bone Food flavor
Solanum melongena (Eggplant, aubergine)	Δ^3-Carene, linalool	Vegetable For asthenia, bronchitis, cholera, diabetes, dysentery, dysuria, hemorrhoids, otitis, skin infections, toothache
Solanum tuberosum (Potato)	Tricyclene, α-pinene, sabinene, limonene, myrcene, linalool, 1,8-cineole	Vegetable (salad, bug, soup, gratin), source of starch, alcoholic beverages (vodka, poitin, or akvavit)
Spinacia oleracea (Spinach)	β-Cyclocitral, geranyl acetone, β-ionone epoxide	Vegetable For stomach and intestinal complaints, fatigue, stimulating growth in children, recovery from illness

(continued)

Table 1 (continued)

Stevia rebaudiana	α-Pinene, sabinene, β-pinene, limonene, (*E*)-β-ocimene, bornylene (**22**), linalool, (*Z*)-linalool oxide, (*E*)-linalool oxide, terpnen-4-ol, α-terpineol, myrtenol, *p*-menth-1-en-9-ol (**206**), β-cyclocitral, neral, nerol, geraniol, carvacrol	Food additive (sweetener). Antimicrobial, contraceptive, hypoglycemic, hypotension regulation
Suillus bellinii	α-Pinene, β-pinene, 1,4-cineole, limonene, 1,8-cineole, linalool, menthol, geranyl acetone, β-ionone	Foods
Suillus granulatus	α-Pinene, β-pinene, 1,4-cineole, limonene, 1,8-cineole, linalool, menthol, α-terpineol, geranyl acetone, β-ionone	Foods
Suillus grevillei	Limonene, geranyl acetone	Foods
Suillus luteus	α-Pinene, β-pinene, 1,4-cineole, limonene, linalool, menthol, α-terpineol, geranyl acetone, β-ionone	Foods
Syzygium aromaticum (=*Eugenia aromatica*)	(*E*)-β-Ocimene, linalool, terpinen-4-ol, nerol	Food, beverages, spice (meat, curry) Analgesic, anticancer, antimicrobial, antioxidant, antiseptic, hypoglycemic, lower blood sugar For stomach ulcers
Taraxacum officinale	Carvacrol, dihydrocitronellal (**54**), geranyl acetone	Foods, beverages Antiinflammatory, antioxidant, antiviral, blood and lipid regulatory, diuretic, hepatoprotective For breast and gallbladder problems, infections, pneumonia, swelling, stimulating bile flow, water retention
Taxus cuspidata	Linalool, α-terpineol, myrtenal, geraniol, nerol, bornyl acetate, *p*-cymen-9-ol	Beverages (herbal tea) Antihypertension For heart, kidney and liver disorders, paralysis, neuralgia rheumatism

(continued)

Table 1 (continued)

Thea sinensis (Green tea oil)	Linalool, geraniol	Beverages, food additives (ice cream, noodle) Antihypertension, antiobesity, antioxidant, antiviral, hypocholesterolemia For blood clots, blood sugar control, cavities, colds, flu, gum and heart disease, immunity system booster, osteoporosis, ulcers
Thujopsis dolabrata var. *hondai* (Hiba oil)	α-Pinene, sabinene, β-pinene, limonene, myrcene, borneol, sabinol, sabinyl acetate, terpinyl acetate carvacrol, α-thujaplicin (**327**), β-thujaplicin (**328a**), γ-thujaplicin (=hinokitiol) (**328b**)	Soap flavor, aroma retaining agents Antibacterial, antifungal, antiinflammatory, antiproliferative, antiviral For hypertension, liver and kidney disorders, jaundice rheumatoid
Thymus quinquecostatus	Tricyclene, thujene, α-pinene, camphene, myrcene, limonene, terpinolene, Δ^2-carene, *p*-cymene, (*E*)-β-ocimene, γ-terpinene, linalool, terpinen-4-ol, nerol, geraniol, (*Z*)-piperitol (**263**), borneol, bornyl acetate, camphor, dihydrocarvone, carvone, thymol, carvacrol, thymol methyl ether, linalyl butanoate (**170**)	Foods, beverages, cosmetics, pharmaceutics Antimicrobial, antitumor Insecticide, mosquito repellent
Thymus vulgaris (Thyme oil)	α-Thujene, α-pinene, β-pinene, camphene, verbenene (**341**), sabinene, myrcene, α-phellandrene, Δ^3-carene, limonene, α-terpinene, *p*-cymene, 1,8-cineol, (*E*)-β-ocimene, γ-terpinene, camphor, linalool, terpinen-4-ol, α-terpineol, (*E*)-sabinene hydrate (**296**), (*Z*)-linalool oxide, (*E*)-linalool oxide, (*E*)-verbenol, borneol, geraniol, *p*-cymen-9-ol, verbenone, thymol methyl ether, linalyl acetate, fenchone, thymol, carvacrol	Food flavor (source, dressing), dried leaf seasoning, crude drugs Anticancer, anticonvulsant, antifungal, antioxidant, antiseptic, antitussive, carminative, expectorant, rubefacient
Tragopogon porrifolius (Salsify)	Limonene, geranial, geranyl acetone	Foods, for soups and stews
Tricholoma equestre	α-Pinene, limonene, 1,8-cineol, linalool, geranyl acetone, β-ionone	Foods
Tricholoma matsutake (Matsutake fungus)	α-Pinene, limonene, linalool, α-terpineol, bornyl acetate	Foods, for soups Anticancer, antimicrobial

(continued)

Table 1 (continued)

Tricholomopsis rutilans	α-Pinene, β-pinene, 1,4-cineole, limonene, 1,8-cineol, linalool, geranyl acetone, β-ionone	Foods
Trigonella foenum-graecum (Fenugreek)	*Dried seeds*: α-thujene, α-pinene, sabinene, limonene, 1,8-cineole, linalool, borneol, terpinen-4-ol	Foods, vegetable, curry powder Analgesic, antiobesity, antipyretic, diuretic, gastroenteritis, hypocholesterolemia, oral diseases, stomachic
Trigonella torbatjamensis	α-Pinene, sabinene, limonene, 1,8-cineole, α-thujone, borneol, terpinen-4-ol, α-terpineol, carvone, bornyl acetate	Vegetable Antipyretic, diuretic For anorexia, bronchitis, chronic, colitis, cough, dropsy, hernia supportive, heart disease, impotence, vomiting
Triticum aestivum (Bread wheat)	Limonene, (*E*)-β-ocimene, (*Z*)-β-ocimene, linalool, linalool oxide	Foods, beverages Anticancer, antiinflammatory For childhood asthma, preventing gallstones, post-menopausal symptoms, reducing chronic inflammation
Ulva pertusa (Sea lettuce, green laver)	α-Pinene, limonene, *p*-cymene, *m*-cymene, linalool, perilla alcohol, perillaldehyde, carveol, β-cyclocitral, α-ionone, β-ionone, geranyl acetone	Foods, food additives, beverages
Undaria pinnatifida	β-Cyclocitral, α-ionone, β-ionone	Foods, food additives, beverages Antiangiogenic, anticancer, antiinflammatory, antiobesity, antioxidant, neuroprotective For cerebrovascular diseases
Urtica dioica	Camphor, borneol, menthol, β-cyclocitral, β-homocyclocitral (**74**), bornyl acetate, thymol, carvacrol	Foods, vegetable Antiasthmatic, antidandruff, antifungal, antioxidant, antiviral, astringent, depurative, diuretic, galactagogic, hemostatic, hypoglycemic, immunomodulatory, tonic For anemia, arthritis, eczema, excessive menstruation, hematuria, hemorrhoids, jaundice, menorrhagia, nephritis, rheumatism

(continued)

Table 1 (continued)

Valeriana hardwickii	α-Pinene, camphene, γ-terpinene, α-terpinyl acetate, bornyl acetate	Beverages Analeptic, antidiarrheal, antispasmodic, carminative, diuretic, expectorant, hypotension, nervine, nerve tonic, sedative, stimulant For epilepsy, hysteria, rheumatic
Valeriana officinalis (Valerian oil)	Tricyclene, α-thujene, α-pinene, α-fenchene, camphene, sabinene, β-pinene, *p*-cymene, limonene, β-phellandrene, γ-terpinene, camphor, terpinene-4-ol, α-terpineol, myrtenol, (*E*)-carvacrol, borneol, bornyl acetate, (*E*)-pinocarveyl acetate (**259**), myrtenyl acetate, terpinyl acetate, (*Z*)-carveyl acetate (**39b**), linalyl *iso*valerate (**172**), β-ionone, bornyl *iso*valerate (**17**), myrtenyl isovalerate (**198**), neryl *iso*valerate (**237b**), geranyl isovalerate (**104**), perillaldehyde, geranyl pentanoate (**103**)	Food flavor, beverages Anodyne, antiasthma, anticonvulsant, antihypertension, antispasmodic, antitussive, carminative, hypnotic, sedative, diuretic For cramp, excitability, hypochondriasis, hysterical states, intestinal colic, insomnia, migraine
Valeriana officinalis var. *latifolia*	Tricyclene, α-pinene, Δ^3-carene, α-fenchene, camphene, β-pinene, β-terpinene, myrcene, *p*-cymene, limonene, β-phellandrene, γ-terpinene, terpinolene, linalool, (*E*)-*p*-mentha-2,8-dien-1-ol, limonene, camphor, terpinen-4-ol, α-terpineol, *p*-menth-1-en-8-ol, borneol, myrtenol (=2-pinen-10-ol) (**196**), perillaldehyde, bornyl acetate, myrtenyl acetate, terpinyl acetate, *iso*-bornyl isovalerate (**21**), (*E*)-verbenyl acetate (**339b**)	Food flavor Antiasthma, anticonvulsant, antitussive, diuretic, sedative, uretic
Verbena officinalis	Limonene, 1,8-cineole linalool, verbenone, geranial	Beverages (herbal tea) For menstrual dysfunction
Vicia faba (Broad bean)	3-Thujen-2-ol (**332**), β-damascone	Foods Antioxidant, bone strengthening For anemia

(continued)

Table 1 (continued)

Vigna angularis (Azuki)	Linalool, linalool oxide, (*Z*)-jasmone (**133**), α-ionone, β-ionone, damascone	Foods Antiadipogenic, antioxidant
Vitis vinifera	Linalool, nerol, citronellol, α-terpineol, (*E*)-linalyl oxide, (*Z*)-linalyl oxide, geranial, geraniol, 8-hydroxydihydrolinalool (**161**), hydroxynerol (**239**), (7*E*)-8-hydroxylinalool (**159a**), hydroxygeraniol (**112**), geranic acid	Foods, fruit, jams, juice, beverages (wine) Antiinflammatory *Seed extract:* anticancer, increase HDL cholesterol For allergy symptom, arteriosclerosis, diabetes, endometriosis, fibromyalgia, heart disease, hemorrhoids, psoriasis, retinopathy
Xanthium strumarium	Limonene, borneol	Beverages (herbal tea) Analgesics, anodyne, anthelmintic, antipyretic, antirheumatic, sedative, tonic For appetizer, complexion cooling, diaphoretic, digestive, diuretic, emollient fattening, improving appetite, laxative, neuralgia, sweating
Xerocomus subtomentosus	Limonene	Foods
Zanthoxylum piperitum (Japanese pepper oil)	α-Pinene, β-pinene, sabinene, myrcene, limonene, α-phellandrene, (*Z*)-β-ocimene, (*E*)-β-ocimene, Δ^2-carene, β-phellandrene, 1,8-cineol, α-terpinene, terpinolene, *p*-cymene, linalool, citronellol, citronellal, *iso*-pulegol, β-terpineol, α-terpineol, nerol, geraniol, terpinen-4-ol, cryptone, citronellol, cumin aldehyde, geranyl acetate, neryl acetate, citronellyl acetate, piperitone, *iso*-pulegol, (*E*)-*p*-mentha-2,8(9)-diol (**219**), myrtenol, (*Z*)-carveol, (*E*)-carveol, 18-hydroxylinalool, linalyl acetate, linalool 8-acetate (**160**), α-terpinyl acetate	Foods, food additives, spice (young leaf, seed) Anthelmintic, antibacterial, antifungal, antiinflammatory, antimicrobial, antioxidant, antiperiodic, antiseptic, antispasmodic, antitumor, antitussive, astringent, carminative, digestive, disinfectant, diuretic, expectorant, immunity booster, parasiticide, stimulant, stomachic, tonic For poor circulation, sweating
Zea mays (Maize, corn)	Myrcene, limonene, thymol, carvacrol, geranyl acetone	Foods
Zingiber mioga (Mioga ginger)	α-Pinene, camphene, sabinene, β-pinene, myrcene, α-phellandrene, limonene, β-phellandrene, 1,8-cineole, (*E*)-ocimene, (*Z*)-ocimene, *p*-cymene, γ-terpinene, (*E*)-	Foods, food additives Anticancer, antihypertensive, antiinflammatory, antiviral For abnormal and irregular digestion, fever, hematemesis, menstruation, skin health

(continued)

Table 1 (continued)

	sabinene hydrate, linalool, (*Z*)-sabinene hydrate, terpinen-1-ol (**306**), α-fenchyl alcohol, β-terpinene (**307c**), *neoiso*-menthol, pinocarveol, α-terpineol, borneol, myrtenol, (*E*)-carveol, *p*-cymen-9-ol, *p*-menth-3-en-7-ol (**223**), β-cyclocitral, camphor, linalyl acetate, limonene-1,2-epoxide, perillaldehyde, carvenone (**36**), piperitone, carvone, bornyl acetate, methyl geranate, myrtenyl acetate, β-cyclocitral, myrtenal, citral, fenchone, thymol, geranyl acetone, β-ionone	
Zingiber officinale	*Fresh rhizome*: β-pinene, camphene, myrcene, β-phellandrene, (*Z*)-β-ocimene, *p*-cymene, 1,8-cineol, (*Z*)-sabinol *p*-cymen-9-ol, camphor, α-phellandrene, terpinolene, α-terpineol, linalool, *iso*-borneol, neral, geranial, geranyl acetate, *iso*-bornyl formate (**19b**) *Steam distilled*: tricyclene, α-pinene, camphene, sabinene, myrcene, β-pinene, γ-terpinolene, linalool, camphor, camphene hydrate (**24**), terpinen-4-ol, citronellal, borneol, α-terpineol, citronellol, neral, geraniol, geranial, citronellyl acetate, geranyl acetate, geranic acid	Foods, food additive (bread, cookies, source, liqueurs, candied food), spice, beverages (ginger ale) Analgesic, anticancer, antifungal, antimicrobial, antiinflammatory, antioxidant, carminative, diaphoretic, diuretic, GI irritant, insecticidal, mild stimulant For back pain, cold, gastrointestinal and respiratory disease, detoxification, nausea, nephroprotective, relaxant, stomachic, sweating, warming
Zingiber zerumbet	α-Pinene, camphene, sabinene, myrcene, limonene, l,8-cineole, linalool, γ-terpinene, geranial	Foods, food additives, beverage Antiallergic, analgesic, antimicrobial, antinociceptive, immunomodulatory
Ziziphus jujuba	(*E*)-β-Ocimene, perillene (**277**), γ-terpinene, linalool, *(Z)*-sabinene hydrate, (*E*)-sabinene hydrate, terpinen-4-ol, citronellol	Foods, fruit, beverages, for Kampo medicine Anticancer, antiinflammatory, antiobesity, antioxidant, hepato- and gastrointestinal protective, immunostimulating, inhibition of foam cell, formation in macrophages

known, and these constitute acyclic, monocyclic, and bicyclic monoterpenoids. Monoterpenoids occur in nature as hydrocarbons, alcohols, aldehydes, ketones, oxides, carboxylic acids, and their esters including lactones.

As seen in Table 1, almost all of the listed foods and beverages contain monocyclic monoterpenoids with *para*-menthane skeleton. Acyclic and bicyclic monoterpenoids have been found in foods as secondary major components. Many *Citrus* species belonging to the Rutaceae, *Curcuma* and *Zingiber* to the Zingiberaceae, and *Cinnamomum* to the Lauraceae families contain a large number of monoterpenoids in their peels, rhizomes, leaves, and/or roots. Foods belonging to the Lamiaceae also include many monoterpenoids. 170 edible species of the Lamiaceae and their medicinal properties due to biological activity were reviewed including the references (Carovic-Stanko et al. 2016). Many of them have also been listed in Table 1. They are *Acinos* (2 species), *Ajuga* (2), *Anisochilus* (2), *Anisomeles* (1), *Agastache* (1), *Calamintha* (3), *Cedronella* (1), *Clerodendrum* (1), *Coleus* (4), *Dracocephalum* (1), *Elsholtzia* (4), *Glechoma* (1), *Gmelina* (1), *Gomphostemma* (2), *Hyptis* (5), *Isodon* (3), *Lallemantia* (1), *Lamium* (4), *Lavandula* (8), *Leucas* (4), *Leonotis* (1), *Lycopus* (2), *Meehania* (1), *Melittis* (1), *Mentha* (13), *Micromeria* (3), *Monarda* (4), *Mosla* (2), *Nepeta* (4), *Ocimum* (4), *Origanum* (5), *Perovskia* (1), *Phlomis* (4), *Plectranthus* (1), *Pogostemon* (1), *Salvia* (16), *Satureja* (5), *Scutellaria* (1), *Sideritis* (3), *Stachys* (23), *Teucrium* (2), *Thymra* (1), *Thymus* (14), and *Ziziphora* (1).

Over 200 herbs and species including foods and medicinal uses with beautiful illustration of each plant species have been demonstrated by Ravindran (2017).

The most common monoterpene hydrocarbons are α-pinene (**254**), β-pinene (**255**), camphene (**23**), myrcene (**191**), limonene (**152**), terpinolene (**316**), α- (**256**) and β-phellandrene (**257**), *p*-cymene (**79**), and (*E*)- (**248**) and (*Z*)-β-ocimene (**249**), of which limonene is a ubiquitous component in various *Citrus* fruits. α-Terpinene (**308**) and γ-terpinene (**309**) are often found in vegetable and fruits. α- (**329**) and β-thujenes (**330**), fenchene (**88**), sabinenes (**294** & **295**), and tricyclene (**336**) are rare monoterpene hydrocarbons in foods and fruits. The monoterpene ketones, camphor (**29**), carvone (**42**), piperitenone (**275**), and piperitone (**281**), are often seen in foods as minor components. The presence of monoterpene alcohol, menthol (**183**), is limited in the genus *Mentha* as the major compounds, together with its stereoisomers, *iso*-menthol (**186a**), *neo*-menthol (**187**), and *neoiso*-menthol (**188**) and menthone (**189**). Borneol (**13**), geraniol (**97**), linalool (**158**), nerol (**234b**), terpinen-4-ol (**307a**), and α-terpineol (**312**) are widely distributed monoterpene alcohols in many foods. In *Citrus* group, a few monoterpene aldehydes, citronellal (**55**), geranial (**94**), and neral (**294a**), have been found as the major components to contribute to their characteristic aroma. The *Perilla* genus produces perillaldehyde (**274**) and its dihydro derivative such as *(Z)*- (**303**) and *(E)*-shisools (**304**) (Almed 2019). The most predominant monoterpene ethers are 1,8-cieole (**52**) and linalool oxides (**164,a**, **164b**, **165a** & **165b**). As the monoterpene esters, bornyl (**15**), citronellyl (**59**), geranyl (**99**), and terpinyl acetates (**313**), have been found in

many different foods and vegetables, only several aromatic monoterpenoids, such as carvacrol (**34**) and thymol (**333**), and their methyl ethers (**35**, **334**), cumin alcohol (**70**), and cumin aldehyde (**72**) as well as cymene derivatives (**76-78** & **80-83**) have been isolated from or detected in the *Thymus* and the other Lamiaceae species as the main phenolic monoterpenoids. There are many characteristic fruits and vegetables including totally different monoterpenoids from the other edible plant groups. They are *Actinidia polygama* which included actinidin (**1**), actinidiolide (**2**), matatabiether derivatives (**176-179**), and *neo*-matatabi lactone (**238**). *Aralia elata*, *Daucus carota*, *Pelargonium graveolens*, and *Valerian officinalis* produce many alkynyl esters of borneol (**14-21**), citronellol (**59-66**), geraniol (**98-110**), linalool (**167-174**), lavandulol (**137-140**), and nerol (**235-238**), respectively. *Nepeta cataria* is also very specific medicinal plant biosynthesizing monoterpene with δ-lactone skeletons, such as nepetalactone derivatives (**226-229**, **231**). The chemical profiles of *Perilla* species used as the vegetable in the Far East are also very characteristic because they produce not only perillaldehyde (**274**) and its monodihydro derivatives, shisools (**303** & **304**), mentioned above but also different types of monoterpene ketones from the other ones, such as *iso*-egomaketone (**87a**), elsholtzia ketone (**87b**), naginata ketone (**224**), and perilla ketone (**273**). Theaspirane (**319**) and its derivatives (**319-320**), having unique spiro skeletal structures, were detected in *Pseudocydonia sinensis* and *Rubus idaeus*. *Chenopodium ambrosioides* elaborates a few unique endoperoxides, ascaridole (**9**) and its dihydro derivative (**10**), as well as two *p*-menthane diepoxides (**11a** & **11b**).

Zingiber officinale is one of the most widely used as foods, food additives, spice, and beverage (ginger ale and herbal tea) in the world. In Japan sliced fresh ginger with vinegar is important diet for Sushi, and its dried powder with sugar has been used as antitussive and warm protection of the body, and a great number of the references of phytochemicals and their benefits of *Z. officinale* are in many journals (Sharifi-R et al. 2017). Its essential oils contain not only pungent substances, gingerols and shogaol, but also a number of different monoterpenoids are identified.

One of the most widely used spices is the *Curcuma* species, of which *C. longa* (=*C. domestica*) is the most popular food in the world, and curcumin, yellow pigment in its rhizome, has been used for Cali in particular. There are so many *Curcuma* species in Asia, and they have traditionally been used as folk medicines and foods as well as beverages as shown in Table 1 (Dosoky and Setzer 2018, Dosoky et al. 2019; Zhang et al. 2017; Rajkumari and Sanatombi 2017; Widyowati and Agil 2018; Zachariah and Leela 2006; https://www.newdirectionsaromatics.com/blog/products/).

The *Cinnamomum* species are also widely used as herbal tea as well as Kampo medicine for cold, flu, etc. (Liyanage et al. 2017; Zachariah and Leela 2006). One of the most widely used fruits as foods, desserts, and beverages is the *Citrus* species which contained monoterpenoids as major volatiles (Gonzalez-Mas et al. 2019; Njorogo et al. 1994; Tomiyama et al. 2012). There are so many biodiversity of *Citrus*, of which *Citrus lemon* in Europe, *C. aurantium* (Mexican lime), *C. sinensis* (Valencia orange), and *C. paradisi* (grapefruit) are well-known species and so important for diet. *C. sudachi* which is endemic in Tokushima Pref. in Japan;

C. junos (Yuzu) in Kochi, Tokushima, and Kyoto; and *C. sphaerocarpa* (Kabosu) in Oita, Japan, are very well-known fruits, for application to many Japanese cuisines, especially to Sushi, Tempura, and noodles. Recently there are also many hybrids of *Citrus* fruits which are often much more tasty or aromatic than each mother *Citrus* species.

One of the most widely used dietary monoterpenoids is (−)-menthol (**183**) which has been obtained by steam distillation of several *Mentha* species as the natural products; however, environment-friendly green or clean chemistry is emphasized in the field of organic and natural product chemistry. Noyori's high efficient production of (−)-menthol using (S)-BINAP-Rh catalyst is one of the most important green chemistries (Tani et al. 1982; Otsuka and Tani 1991), and 1,000 ton of (−)-menthol has been produced by this method for 1 year and used as food additives, ice cream, candies, chewing gums, cosmetics, toothpaste, shampoo, etc.

The benefits including the application of foods and food additives as well as the medicinal uses of the representative volatile oils from basil, bergamot, camphor, carrot, cedar wood, citronella, clary, eucalyptus, frankincense, geranium, ginger root, lavender, lemon, lemongrass, myrrh, orange, patchouli, pine, rose geranium, rosemary, sage, spearmint, tea tree, turmeric, vetiver, wintergreen, and ylang-ylang are summarized in the website (https://www.newdirectionsaromatics.com/blog/products/). The top 12 healthful fruits are also shown in the website (http://medicalnewstoday.com), and 11 best low-sugar fruits, 10 low-glycemic fruits for diabetes, 11 best fruits for weight loss, 20 top healthy salad topping, 20 healthiest fruits on the planet, and 10 low-carb smoothies preparation related to the dietary monoterpenoids are reported in the website (http://healthline.com). The Useful Tropical Plants Database (http://tropical.theferns.info/viewtropical.php) contains the information on the edible, medicinal, and many other uses of several thousand plants that can be grown in tropical regions.

16.3 Distribution of Monoterpenoids and Related Compounds in Spore-Forming Plants and Fungi

Sea Algae: Seaweeds have been used for centuries for both food and medicinal purposes (Santos et al. 2018). It has been long believed that they possess antiaging properties and help to keep good health. As a great number of chemical researches have been carried out on various types of seaweeds over the years, the abundance of antioxidants has been found in many sea algae. There have also been some important discoveries of antiinflammatory and immune system booster properties from sea algae. Scientists have studied the three main varieties of sea algae, green (Chlorophyceae), brown (Phaeophyceae), and red species (Rhodophyceae). Several sea algae, green alga, *Ulva pertusa*; brown algae, *Undaria pinnatifida* and *Saccharina japonica* (= *Laminaria japonica*); and red alga, *Pyropia tenera*, have been used as foods and processed foods in the Far East, especially in Japan, almost every day; however, the presence of monoterpenoids in algae is very rare. *U. pertusa* contains several monoterpene hydrocarbons, α-pinene, limonene, and *p*- and *m*-

cymenes, as well as perilla alcohol (**271**) and its aldehyde (**274**) which have been found in the terrestrial vegetables, such as *Perilla* species. *Saccharina* and *Pyropia* species produce *a*-terpineol (**312**).

Bryophytes: More than 20000 species of bryophytes (mosses, liverworts, and hornworts) are known. However, neither references of dietary monoterpenoids nor those who ate such a small plant group have been seen since a long time ago. Only liverworts contain oil bodies in organelle cell, and a large amount of mono-, sesqui-, and diterpenoids, as well as aromatic compounds and polyketides, have been found (Asakawa 1982, 1995; Asakawa et al. 2013). Recently one of the thalloid liverworts, *Conocephalum conicum*, which contains several monoterpene hydrocarbons and alcohol has been served as toping to hamburger and to consommé soup in Japan.

***Pteridophytes*:** There are a great biodiversity of ferns. Generally the leaves and stems of ferns are very solid, and they are not edible except for several species. In Japan three species of young shoots of a few ferns, *Equisetum arvense*, *Pteridium aquilinum*, and *Osmunda japonica*, are served as foods and vegetables; however, the presence of ubiquitous monoterpene hydrocarbons and alcohols is seen in the former two species as shown in Table 1.

***Lichens*:** This group is also large biodiversity. Since very early times, many lichens have been used to cure diarrhea, epilepsy, fever, hydrophobia, jaundice, and skin disorders. Some lichens have been known to have anticancer and spasmolytic activity. One of the most economical lichens is *Evernia prunastri* from which essential oils are obtained as the preparation of cosmetics and perfumery goods. This lichen also possesses antiinflammatory, antiirritant, antiseptic, and expectorant properties and is treated for intestine and skin disorders. It contains ubiquitous monoterpenoids as seen in Table 1. However, no records as a food of this species have been seen in the references. On the other hand, *Cetraria islandica* and *Bryoria fremontii* were important sources of food for humans in Northern Europe and North America in the past, respectively. *Umbilicaria* and *Lasallia* have frequently been used as foods in North America; *Umbilicaria esculenta* is used in a variety of traditional Korean and Japanese foods. However, the above lichens do not contain any monoterpenoids.

***Fungi and Mushrooms*:** The phytochemicals of fungi and mushrooms are also a great biodiversity and very complex (Pavel 2016). There are three kinds of mushrooms, edible, inedible, and poisonous species, of which 8 million tons of edible and nutritional mushrooms are consumed as foods for 1 year in the world. Several edible mushrooms *Boletopsis leucomelas*, *Clitocye odora*, *Flammulina velutipes*, *Grifola frondosa*, *Lentinus edodes*, *Pleurotus ostreatus*, *Pholiota microspora*, and the other species contain monoterpenoids with n-octane derivatives (Kalac 2016; Parior et al. 1996a, b). However, only several edible mushrooms containing monoterpenoids are served for European, Chinese, and Japanese cuisine. For example, black fungus, *L. edodes*, has been used as many foods and processed foods; however, the content of the monoterpenoids, both the fresh and dried fruit bodies, is faint. The most expensive mushroom in Japan is *Tricholoma matsutake* which is used for consommé soup. It produces 1-octen-3-ol and methyl cinnamate which are important aroma of this mushroom with a few monoterpenes, limonene, linalool, and α-terpineol, as the

minor components. Essential oil derived from the fungus, *Ceratocystis virescens*, contains α-terpineol, linalool, geranial, geraniol, geranyl acetate, neral, citronellol, and citronellyl acetate. *Trametes odorata* has been reported to have citronellol, nerol, and geraniol. Some *Phellinus* species produced linalool. The volatile oil of the rust fungus, *Cronartium fusiforme*, includes α-pinene, β-pinene, camphene, 3-carene, limonene, β-phellandrene, and terpinen-4-ol; however, these fungi have not been used as foods. Several edible and nutritional mushrooms including monoterpenoids are listed in Table 1.

16.4 Biological Activity of Monoterpenoids

Aerial parts, leaves, fruits, and flowers of the listed plants and spore-forming plants and fungi are edible. Tubers and roots of many plants are also edible. Almost all of the listed plants and fungi in Table 1 show various bio- and pharmacological activities, antimicrobial, anodyne, antiseptic, antiinflammatory, antiproliferative, anesthetic, antimalarial, antifungal, antirheumatic, excitant, laxative, anticholinesterase, diaphoretic, antiseptic, antiepileptic, febrifuge, anticancer, antitussive, hyaluronidase inhibitory, antimycobacterial, antioxidant, antipyretic, diaphoretic, gastroprotective, stomachic, anxiolytic, refrigerant, emmenagogue, cytotoxic, antispasmodic, analgesic, antidysentery, antihypertensive, antidepressant, ulcer healing, sedative, carminative, hypoglycemic, diuretic, astringent, cardiotonic, and tonic, and are used to treat colic, menstrual disorder, indigestion, flatulence, pulmonary and urinary infections, fever, cough, colds, cardiovascular and immunological diseases, chronic bronchitis, asthma, headache, fever, epilepsy, and dyspepsia. The most frequently cited activities in the listed medicinal plants are antimicrobial and antioxidant. Alcohol derivatives of oxygenated monoterpenoids had greater antimicrobial activities than those of ketone derivatives. For example, menthol inhibited the growth of 24 bacterial strains, whereas menthone showed antifungal activity against only 4 bacteria. The similar phenomenon was also found for fenchyl alcohol and fenchone. Borneol, linalool, and nerol were more active than their acetate derivatives (Kotan et al. 2007).

Cancer is the second largest single cause of death climbing over six million lives every year worldwide. Colorectal cancer is one of the most common cancers in the world, and about 90% of this cancer is caused by metastasis, not by solid tumor. In spite of the recent chemotherapy development, survival times of cancer patients are very limited. Natural products including essential oils are the most successful strategy to find novel anticancer drugs and more than two thirds of the drugs used in cancer therapy.

Many diets including monoterpenoids show chemoprevention against cancer. Especially essential oils which are a mixture of volatile lipophilic constituents, monoterpenoids, and phenyl propanoids have potential anticancer and antitumor activities. More than several hundred papers have been published on anticancer and antitumor activity of essential oils and crude extracts from foods and fruits from

Table 2 Benefits and pharmacological activity of monoterpenoids included in foods, vegetables, and beverages

Monoterpenoids	Benefits and pharmacological activity
Ascaridole (**9**)	Anticancer (breast), anti-leishmanial, antimalarial, antinociceptive, antioxidant, antiparasitic, antitrypanosomal, antiviral, strengthen immune system
Borneol (**13**)	Anticancer, anesthetic, antispasmodic, antimicrobial, antiosteoporosis, sedative, skin tonic
Bornyl acetate (**15**)	Anticancer (gastric), analgesic, antifungal, antimicrobial, antiosteoporosis
Camphor (**29**)	Anticancer (colon), absorbent, anesthetic, antiarthritic, antifungal, antiinflammatory, antimicrobial, antineuralgic, antioxidant, antiosteoporosis, antiphlogistic, antirheumatic, antiseptic, antispasmodic, aphrodisiac, carminative, cooling, decongestant, diaphoretic, disinfectant, germicide, hypotension, narcotic, insecticide, nervous pacifier, treat cold, cough. For neurodermatitis, stimulant, warming
Carvacrol (**34**)	Anticancer (colon, lung), antibacterial, antifungal, antiinflammatory, antioxidant, antiparasitic, antiviral, strengthen immune system
Carveol (**39a** & **39b**)	Anticancer (breast), flavor additive
Carvone (**42**)	Anticancer (forestomach, lung), anesthetic, antiacetylcholinesterase, antiallergic, antifungal, antihyperglycemic, antioxidant, antiseptic, insecticidal, piscicidal, relaxant, expectorant, carminative, diuretic, sedative, stimulant, vermicide, perfume, flavoring
1,4-Cineole (**51**)	Antifungal
1,8-Cineole (**52**)	Anticancer (colon), analgesic, anthelmintic, antiacetylcholinesterase, antibacterial, anticaries, anticatarrhal, antifatigue, antifungal, antiinflammatory, antioxidant, antiosteoporosis, antiplaque modifiers halitosis, antirheumatic, antiseptic, antispasmodic, antitussive, antiulcer, antiviral, choleretic, convulsant, cough suppressant, decongestant, expectorant, headaches, hepatotonic, herbicidal, gastro protective, hypotension, increase cerebral blood flow, insecticidal, muscle relaxant, neurotoxin, pesticidal, sedative, skin absorption, stimulant, transdermal
Citral (**94** & **234b**)	Anticancer (breast), antibacterial, antifungal, antiviral, antiseptic, antioxidant. For physical or psychological stress, sedative
Citronellal (**55**)	Analgesic, antibacterial, antidepressant, antifungal, antiinflammatory, antimicrobial, antiseptic, antispasmodic, antiviral, diuretic, expectorant, febrifuge, hypertensive, pesticidal, insecticidal, sedative, stimulant, stomachic, tonic, vermifuge, flavor, fragrance
Citronellol (**58**)	Anticancer, analgesic, antifungal, antimicrobial, antiinflammatory, antiseptic, antispasmodic, anticonvulsant, hypotension, insecticidal, pesticidal, sedative, vasorelaxant

(continued)

Table 2 (continued)

Monoterpenoids	Benefits and pharmacological activity
p-Cymene (**79**)	Analgesic, antiacetylcholinesterase, antianxiety, antifungal, antimicrobial, antioxidant, neuroprotective, antiinflammatory, antirheumatic, antiviral, antiinfluenza, fragrance, herbicidal, laxative, pesticides, sedative, soothing
Dihydrocarvone (**43**)	Antimicrobial
Fenchone (**92b**)	Anticancer (breast, liver), antimicrobial, antifungal. For digestive discomfort
Fenchyl alcohol (**89** & **91**)	Antimicrobial, fragrance, flavoring agents
Geranial (**94**)	Rose-like scent: insecticidal, antioxidant
Geraniol (**97**)	Anticancer (colon, hepatoma, kidney, liver, lung, melanoma, pancreas, prostate, skin), analgesic, antibacterial, antioxidant, antiseptic
Geranyl acetate (**99**)	Antifungal, antimicrobial, antiinflammatory
Iso-menthol (**186a**)	Antimicrobial
Limonene (**152**)	Anticancer (breast, colon, forestomach, liver, lung, ovarian, prostate, skin), antiasthmatic, antifungal, antibacterial antihyperglycemic, antiinflammatory, antimutagenic, antiseptic, antispasmodic, antioxidant, antiviral, digestive, appetite suppressant, detoxicant, expectorant, herbicidal, immunomodulatory, muscle relaxant, pesticidal, transdermal absorption For physical or psychological, sedative, stress
Limonene 1,2-oxide (**154a** & **154b**)	Antimicrobial, antifungal, flavor
Linalool (**158**)	Anticancer, anesthetic, antiallergic, antiasthmatic, antispasmodic, antianaphylactic, anticonvulsant, antidepressant, antifungal, antiacetylcholinesterase, antileukemic, antimicrobial, antiinflammatory, antifungal, antimicrobial, antiseptic, antispasmodic, broncho relaxant, expectorant, narcotic, insecticidal, sedative
Linalyl acetate (**168**)	Anticancer (colon), antiinflammatory, antimicrobial, antiseptic, astringent, hypotensive, insecticidal
p-Mentha-2,8-dien-1-ol (**209a** & **209b**)	Anticancer (colon)
p-Mentha-8(9)-en-1,2-diol (=lemon diol) (**155**)	Anticancer (colon)
Menthol (**183**)	Anticancer (breast, colon), antiacetylcholinesterase, anesthetic, analgesic, antiallergic antiasthmatic, antibacterial, antihalitosis, antihistamic antimicrobial, antiinflammatory, antineuralgic, antirheumatic, antiosteoporosis, antipruritic, antipyretic, antiseptic, antispasmodic, bradycardic, carminative, cooling, decongestant, depressant, diaphoretic, expectorant, gastric sedative, modify dental pain, muscle relaxant, perfumery and flavoring, pesticidal, stimulant, refrigerant, respiratory
Menthone (**189**)	Antimicrobial
Myrcene (**191**)	Antiinflammatory, analgesic, antibiotic, antimutagenic, sedative

(continued)

Table 2 (continued)

Monoterpenoids	Benefits and pharmacological activity
Myrtenyl acetate (**197**)	Insecticidal
Nerol (**234b**)	Analgesic, antimicrobial, hypotension, tonic
Neryl acetate (**236**)	Antimicrobial, antiinflammatory, heal wound, healthy aging
Perilla alcohol (**271**)	Antiangiogenic, anticancer (breast, colon, liver, malignant brain, murine leukemia, ovarian, pancreas), antioxidant
Perillaldehyde (**274**)	Anticancer (colon)
Perillyl acetate (**272**)	Insecticidal, flavor, fragrance, insecticide
α-Phellandrene (**256**)	Antibacterial, antifungal, antimicrobial, diarrheal, emetic, hyperthermic, ingestion, laxative, pesticides, flavoring, perfumery
β-Phellandrene (**257**)	antifungal, antiviral, bactericidal, decongestant Expectorant, fragrance, perfumery, antiseptic
α-Pinene (**254**)	Anticancer, antibacterial, antiinfluenza, antiviral, antiinflammatory, antiosteoporosis, antiseptic, bronchodilator, expectorant, insecticide sedative, tranquillizer
β-Pinene (**255**)	Anticandidal
Piperitone (**281**)	Antiasthmatic, herbicidal, decongestant, flavoring, pesticidal. For synthesis of menthol
Sabinene (**294** & **295**)	Antifungal, antimicrobial, antiinflammatory, antioxidant
Terpinen-4-ol (**307a**)	Anticancer (colon), antiallergenic, antiasthmatic, antifungal, antimicrobial, antioxidant, antiseptic, antispasmodic, antitussive, antiacetylcholinesterase, antiulcer, diuretic, herbicidal, insecticidal, pesticidal, vulnerary
γ-Terpinene (**309**)	Anticancer (colon), antibacterial. Antifungal, antiinsomnia, antiproliferative, antioxidant, cytotoxic. For physical or psychological stress
α-Terpineol (**312**)	Anticancer, analgesic, antiesthetic, antiallergenic, antiasthmatic, antispasmodic, antitussive, antibiotic, antibronchitis, anticancer (colon), anticarcinogenic, anticonvulsant, antifungal, antihypertensive, antiinflammatory, antimicrobial, antinociceptive, antioxidant, antiulcer, cardiovascular disease, cholagogues, expectorant, insecticidal, perfumery, pesticides, skin penetration enhancing, sedative, vulnerary
Thujone (**331a** & **331b**)	Antiosteoporosis, insecticidal, convulsant
Thymol (**333**)	Anticancer (colon), antibacterial, antiobesity, antiosteoporosis, insecticidal, hypotension, immunity booster, pesticides, skin disorders
Thymoquinol	Anticancer (colon), insecticidal
Thymoquinone (**335**)	Anticancer (colon, myeloblast, leukemia HL-60, neuroblastoma), antiinflammatory, antioxidant, hepatoprotective, insecticidal
α-Thujaplicin (**327**) and β-Thujaplicin (**328a**)	Anticancer (colon), antiaging, antibacterial, antiinflammatory, antioxidant
Verbenone (**344**)	Anticancer, antimicrobial, antifungal, antioxidant, insecticidal, perfumery

which each monoterpene hydrocarbon and oxygenated monoterpene possessing antitumor and anticancer activity are listed in Table 2.

Bayala et al. (2014), Crowell (1999), and Sobral et al. (2014) reported the significant review articles of anticancer and antitumor active monoterpenoids from essential oils and solvent extracts. 1.8-Cineole (**52**), geraniol (**97**), limonene (**152**), perilla alcohol (**271**), perillaldehyde (**274**), and α-terpineol (**312**) showed effective for colorectal cancer in vitro and animal experiments. At present, the effect of chemoprevention against cancer and antitumor of essential oils have been investigated on breast, colon, brain, liver, skin, prostate, lung, leukemia, kidney, oral cervix, ovary, pancreas, mouth epidermal carcinoma, nasopharyngeal, neuroblastoma, stomach, and uterus, among which the breasts are the research target against anticancer of essential oils. One of the most treated monoterpenoids against cancer chemotherapy is geraniol (**97**) (Cho et al. 2016).

Many reviews concerning the cancer chemotherapy using essential oils and dietary monoterpenoids have been reported. Crowell (1999) summarized dietary monoterpene biochemistry, monoterpene metabolism and disposition, antitumor activity of monoterpenes, and mechanism of action of monoterpenes, referred by many recent papers. Biological property of α-terpineol was reviewed by Khaleel et al. (2018) in detail.

16.5 Microbial and Mammalian Biotransformation of Monoterpenoids and Their Related Compounds

As described in the former paragraph, not only fruits, vegetables, food, and products but also many herbal beverages contain many varieties of monoterpenoids, and we take these foods into our body, almost every day; however, the fetal of those volatile components in our body remained to be clarified. The entire major biochemical event taking place in an organism is controlled by enzymes which display major types of chemoselectivity, regio- and diastereoselectivity, and enantioselectivity. Enzymes of microorganisms and mammals are able to transform a huge variety of secondary metabolites, such as mono-, sesqui-, and diterpenoids, alkaloids, steroids, antibiotics, and amino acids, from foods, vegetables, and fruits as well as spore-forming green plants with the three major nutrients, carbohydrates, fats, and proteins, to produce pharmacologically and medicinally valuable substances. There are a great number of reports concerning biotransformation of essential oils, terpenoids, steroids, alkaloids, and acetogenins using bacteria, fungi, and mammals. Mikami (1988) reported the review article of biotransformation of terpenoids entitled "Microbial Conversion of Terpenoids." Noma and Asakawa (2010a, b) reported the biotransformation of a number of natural and synthetic acyclic and cyclic mono-, sesqui-, and diterpenoids, ionones, α-damascone, adamantanes, and aromatic compounds,

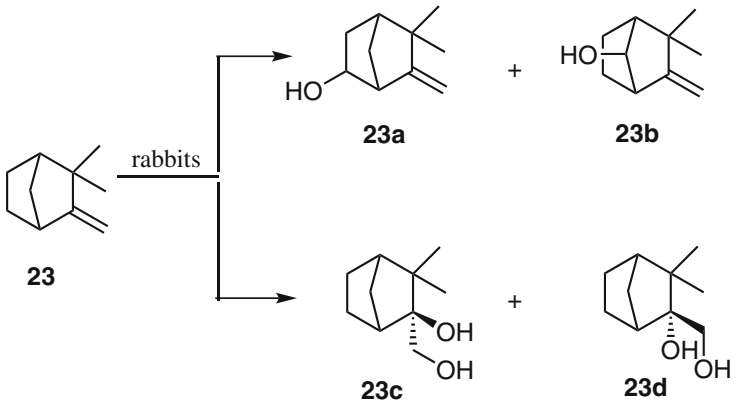

Fig. 1 Biotransformation of racemic camphene (**23**) by rabbits (Noma and Asakawa 2010a, b)

using mammals (rats and rabbits) and human enzymes. Biotransformation pathways of some representative monoterpenoids included in diets are shown in Figs. 1, 2, 3, 4, 5, 6, 7, 8, 9, and 10 (Noma and Asakawa 2010a, b).

Camphene (**23**), Δ^3-carene (**31**), limonene (**152**), and (+)-α-pinene (**254**) and its enantiomer (**254**)′ were orally administered to rabbits, and after 1 day, urine was collected and then enzymatically hydrolyzed, followed by extraction with ether to obtain the biotransformed products. Rabbits converted camphene to two secondary alcohols (**23a** and **23b**) and two diols (**23c** and **23d**) (Fig. 1). Limonene (**152**) was biotransformed by rat CYP enzymes to give two natural products, (*E*)-carveol (**38b**) and limonene-10 (**156**) (Fig. 2).

Eight biotransformed compounds (**31a–31h**) were obtained from rabbits' urine after Δ3-carene (**31**) was orally administered. In this bioconversion, a three-membered ring was cleaved to give 2,2-dimethyl carbinol (**31a** & **31b**). Furthermore, one of 1,1-dimethyl group on a cyclopropane ring was oxidized to form primary alcohols (**31c**) and **31h.** The allylic methyl group at C-10 of **31** was also oxidized to give primary alcohol (**31f**), then to carboxylic acid (**31g**), followed by the further oxidation to afford **31h** (Fig. 3).

Both (+)- (**254**) and (−)-pinene (**254**)′ were independently administered to rabbits. From the latter substrate, an insect pheromone, (*E*)-verbenol (**342**′), was obtained in high yield. The human microsomal enzyme also converted to (−)-pinene to (*E*)-verbenol (**342a**′). Rabbits and human enzyme also converted both (+)- and (−)-pinene (**254** and **245**′) to myrtenol (**196**) and its enantiomer (**196**′) (Fig. 4). Terpinolene (**316**) was converted to two allylic primary alcohols (**316a**) and **316b** (Fig. 5).

Four monoterpene ketones, camphor (**29**), fenchone (**92**), menthone (**189**), and (−)-verbenone (**344**′), were treated with rat and human CYP enzymes, respectively. From (−)-camphor, (*Z*)-4-hydroxycamphor (**29a**) was obtained. On the other hand, three new hydroxycamphors (**29b**′**-29d**′) and an enantiomer (**29a**′) of **29a** were obtained (Fig. 6).

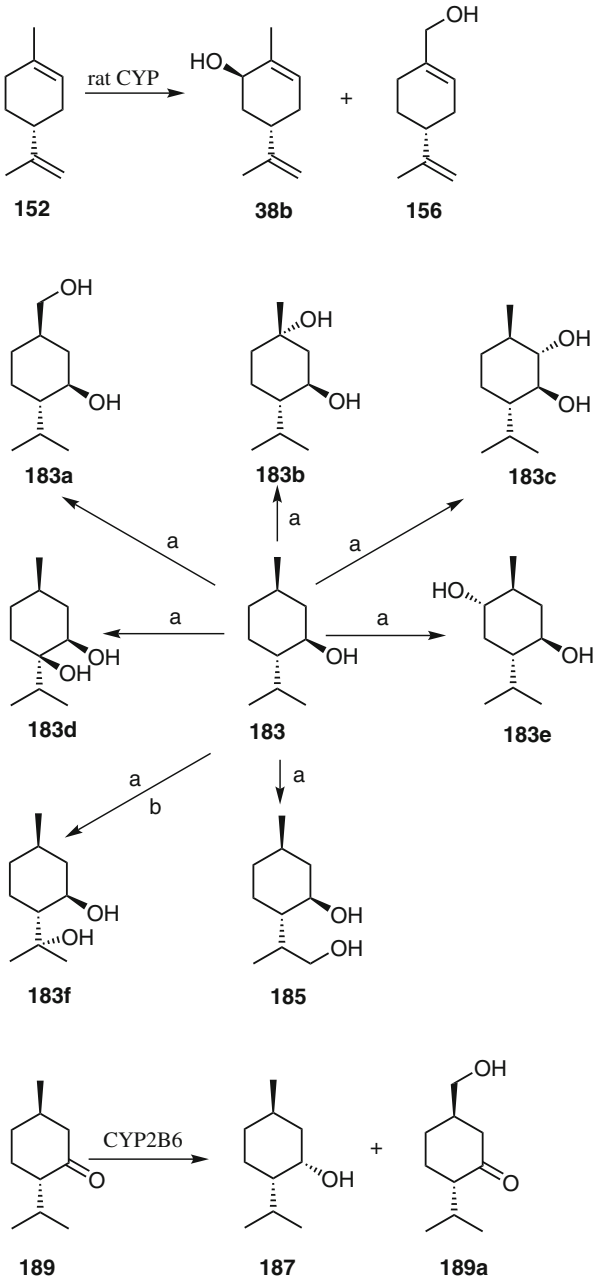

Fig. 2 Microbial biotransformation of (+)-limonene (**152**) by rat CYP2c11/CYP2B21, (−)-menthol (**183**) by *Aspergillus niger* (**a**) and human CYP 2A6 (**b**), and menthone (**189**) by CYP2B6 (Noma and Asakawa 2010a, b)

(+)-Fenchone (**92**) and its enantiomer (**92′**) were also treated with human CYP 450 to give two secondary alcohols (**92ba**, **92bb**) and one primary alcohol (**92bc**) and their enantiomers (**92ba′-92bc′**). In this case, enantioselectivity has not been observed (Fig. 7).

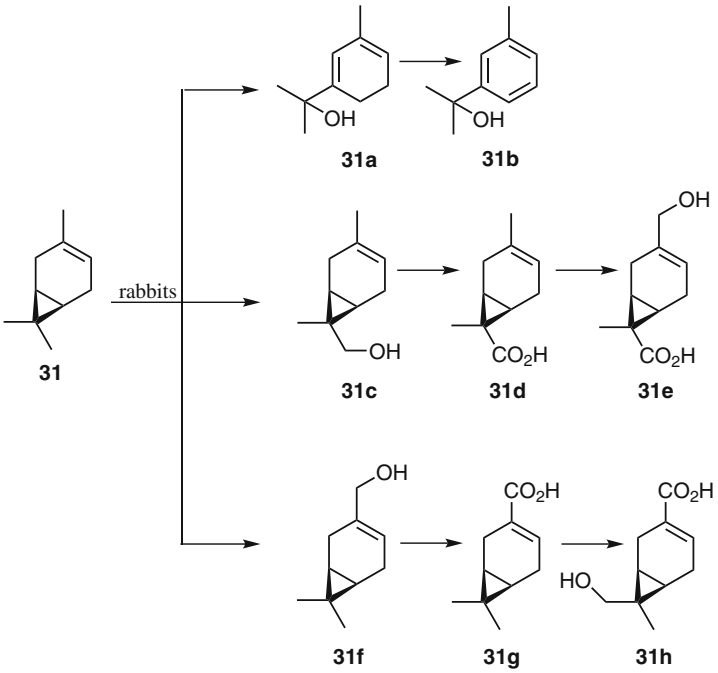

Fig. 3 Biotransformation of (+)-Δ^3-carene (**31**) by rabbits (Noma and Asakawa 2010a, b)

Treatment of menthone (**189**) with CYP2B6 enzyme gave 10-hydroxymenthone (**189a**) and (+)-*neo*-menthol (**187**). In this case, oxidation and reduction reactions occurred (Fig. 2). Treatment of (−)-verbenone (**344**) with human or rat CYP enzymes gave 10-hydroxyverbenone (**344a′**) and dihydroverbenone (**344b′**), respectively (Fig. 4).

(−)-Menthol (**183**) which is one of the most important dietary monoterpene alcohols was treated with human CYP enzyme or the black fungus, *Aspergillus niger*. The former enzyme biotransformed **183** only to 8-hydoxymenthol (**183f**) which possesses potent mosquito repellent activity. On the other hand, treatment of **183** with *A. niger* gave 6 hydroxymenthols (**183a-e**) and the same tertiary alcohol (**183f**) (Fig. 2).

Two monoterpene aldehydes, (−)-myrtenal (**195′**) and (*S*)-(−)-perillaldehyde (**274**), were orally administered to rabbits. Rabbit converted **195′** to myrtenic acid (**196c′**) and (−)-myrtenol (**196′**) which was further reduced to give two myrtanol isomers (**194a′** and **194b′**) (Fig. 4). From the latter compound, (*E*)-shisool (**303**) was obtained together with the carboxylic acid (**274a**) (Fig. 5).

Two monoterpene ethers, 1,4-cineol (**51a**) and 1,8-cineol (**52**), were also administered to rabbits. From the former urine, two tertiary alcohols (**51b** and **51c**), three primary alcohols (**51d–51g**), and a carboxylic acid (**51e**) which might be formed from the primary alcohol (**51d**) were isolated. 1.4-Cineol (**51**) was biotransformed by human and rat CYP enzyme to convert to (**2Z**)-hydroxy-1,4-cineole (**51a**)

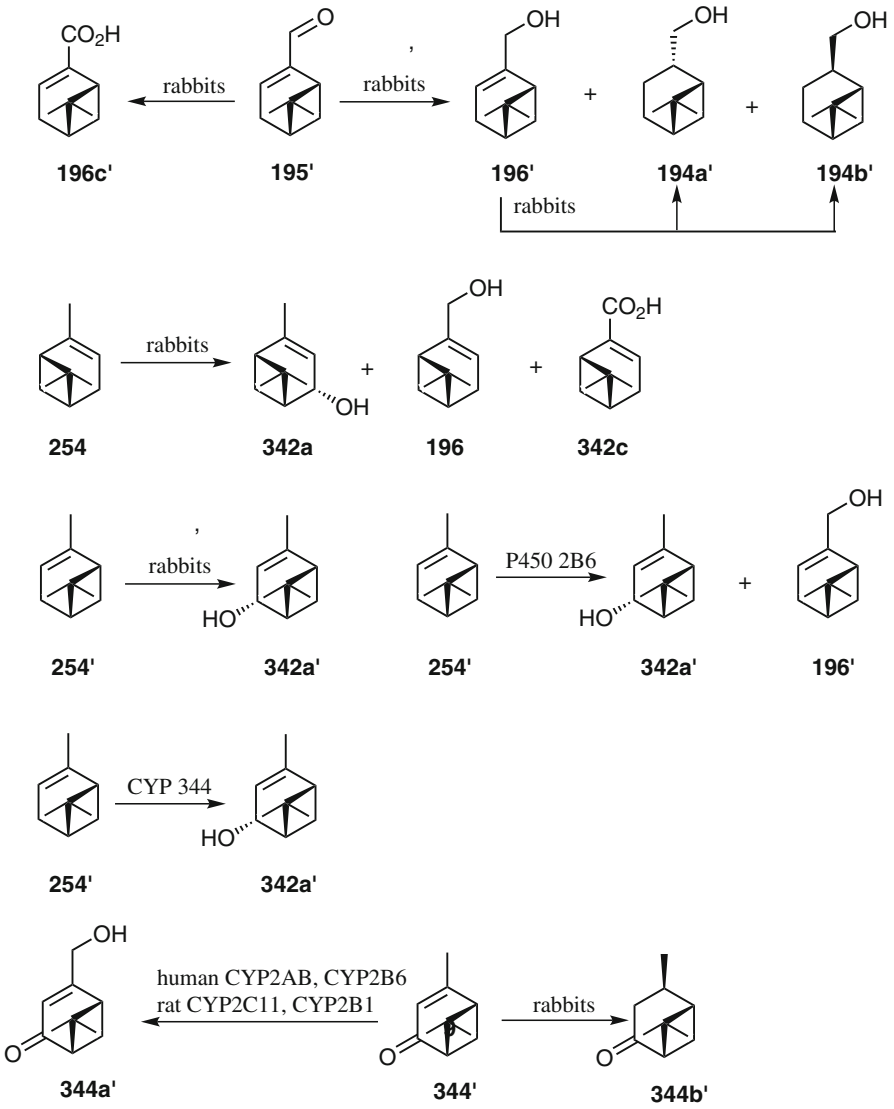

Fig. 4 Biotransformation of (−)-myrtenal (**195′**), (−)-mytenol (**196′**), (+)-α-pinene (**254**) and (−)-α-pinene (**254′**), and (−)-verbenone (**344′**) by rabbits and human liver microsomones (Noma and Asakawa 2010a, b)

(Fig. 8). On the other hand, rabbit converted 1,8-cineole (**52**) to four diastereoisomeric secondary alcohol (**51-52d**) but not to primary alcohol. In case of bioconversion of **52** using human enzyme and rats, three optical isomers (**52a′**, **52b′**, & **52d′**) of **52a**, **52b**, and **52d** were obtained in pure forms (Fig. 9). In this biotransformation,

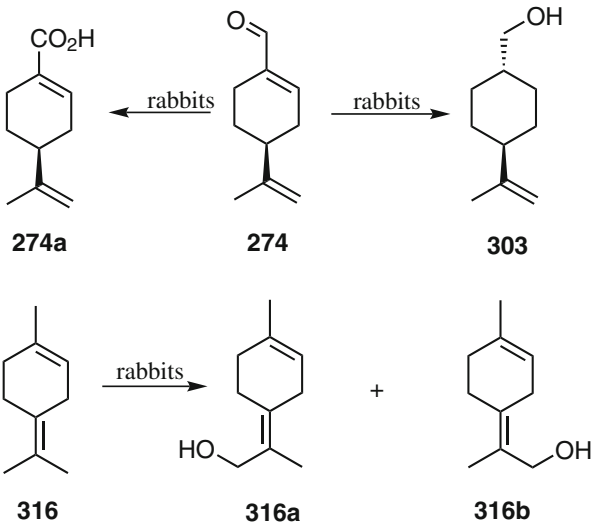

Fig. 5 Biotransformation of (*S*)-(−)-perillaldehyde (**274**) and terpinolene (**316**) by rabbits (Noma and Asakawa 2010a, b)

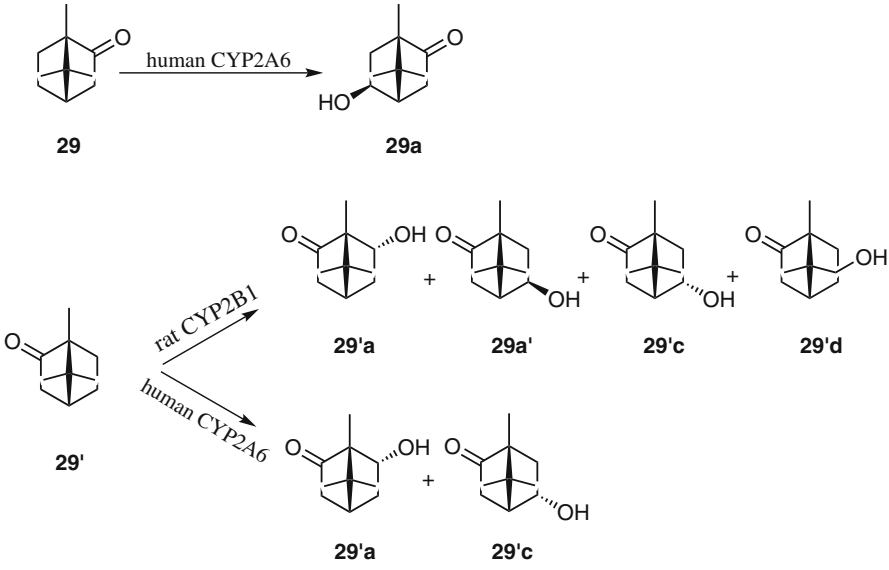

Fig. 6 Biotransformation of (−)-camphor (**29**) and (+)-(**29′**) by rat CYP 2B1 and human CYP2A6 rabbits (Noma and Asakawa 2010a, b)

the regiospecific introduction of oxygen function was observed by two enzymatic systems (rabbit and human/rat enzymes).

Two aromatic monoterpenoids, *p*-cymene (**79**) and carvacrol (**34**), were administered to rabbits or rats. From *p*-cymene, two natural products, 8-hydroxy-*p*-cymene

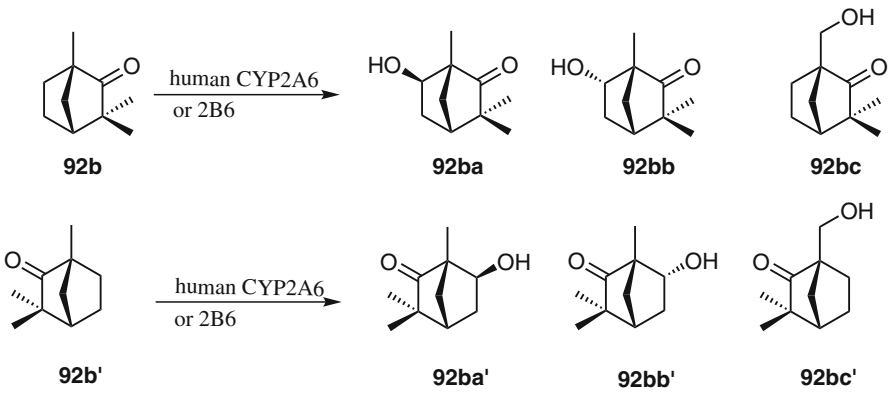

Fig. 7 Biotransformation of (+)-(**92b**) and (−)-fenchone (**92b′**) by human CYP2A6 or CYP2B6 (Noma and Asakawa 2010a, b)

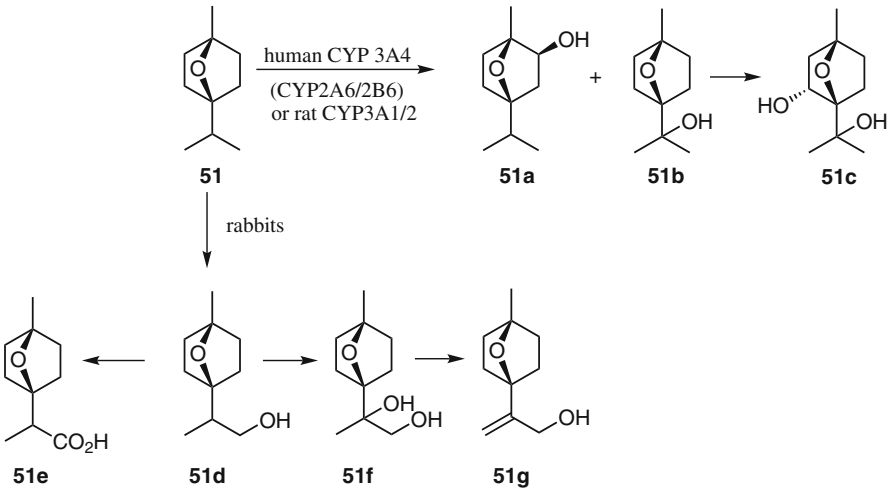

Fig. 8 Biotransformation of 1,4-cineole (**51**) by rabbits, human and rat P-450 enzymes (Noma and Asakawa 2010a, b)

(**80**) and 9-hydroxy-*p*-cymene (**81**), were obtained (Fig. 10). On the other hand, carvacrol (=2-hydroxy-p-cymene) (**34**) was administered to rat to give 8 metabolites (**14a-34h**), of which **34b** and **24e** possess the similar structures of **80** and **81** obtained from p-cymene (Fig. 10). The direct introductions of oxygen function on benzene ring and oxidation reaction of aryl methyl group have been observed in case of bioconversion of carvacrol (**34**). Thus almost all of monoterpenoids mentioned above were biotransformed by human enzymes and their direct administration by

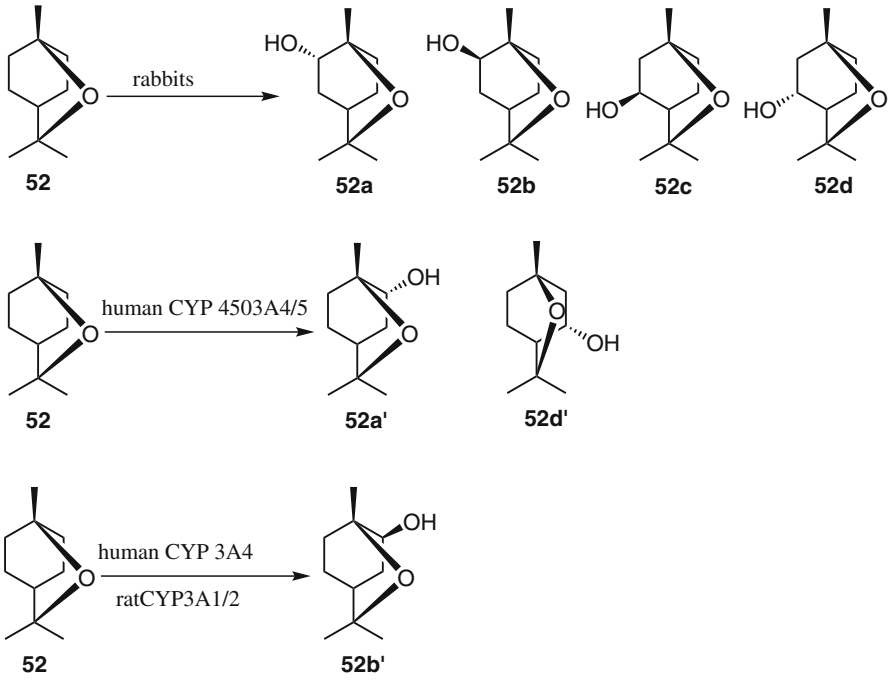

Fig. 9 Biotransformation of 1,8-cineole (**52**) by rabbits, human CYP 4503A/4/5, human CYP3A4 and rat CYP 3A1/2 (Noma and Asakawa 2010a, b)

mammals (rats and rabbits) to give oxidative metabolites, mainly primary, secondary, and tertiary alcohols. Such enzymes and mammals detoxify secondary metabolites, such as monoterpenoids, including foods, vegetables, fruits, and beverages, as well as processed foods and supplements.

16.6 Conclusion

As seen in Table 1, almost all of foods, vegetables, food additives, and beverage contain various types of monoterpene hydrocarbons, alcohols, ketones, and oxides. The presence of monoterpene aldehydes is restricted to be perillaldehyde, geranial, neral, and citronellal and cumin aldehyde. The presence of aromatic terpenoids is also limited to be *p*-cymene and its derivatives as well as carvacrol and thymol and their methyl ethers. The volatile components and essential oils are composed of a mixture of mainly monoterpenoids, and almost all of essential oils containing monoterpenoids show antimicrobial and antifungal activity. Such essential oils play an important role in the preserve of each fresh or dried food,

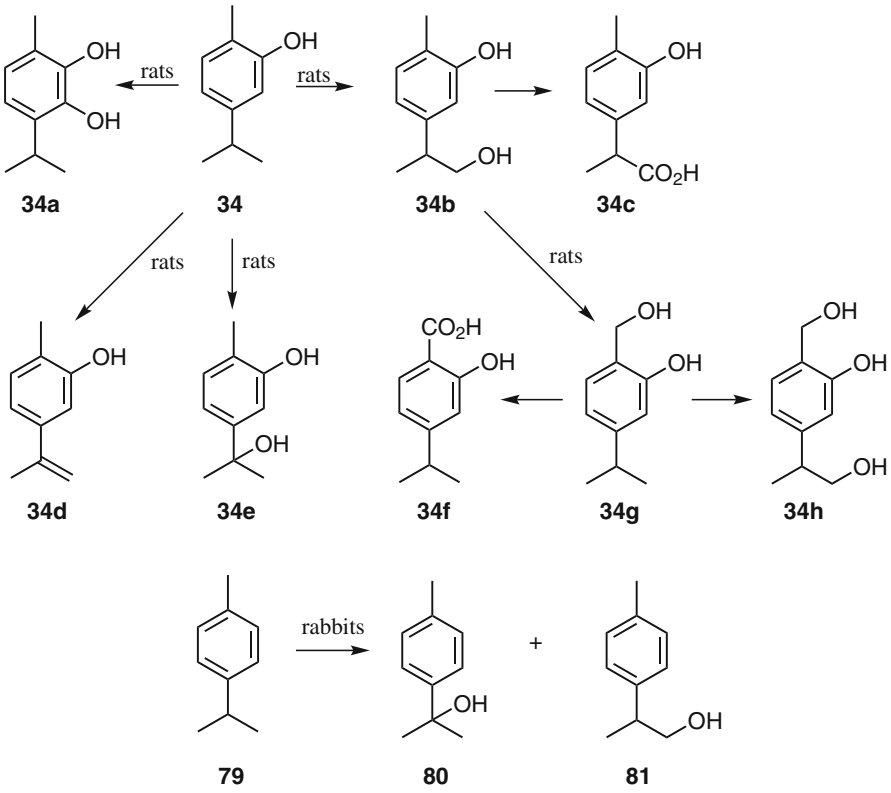

Fig. 10 Biotransformation of carvacrol (**34**) by rats and *p*-cymene (**79**) by rabbits (Noma and Asakawa 2010a, b)

vegetable, and beverage. Dietary monoterpenoids show not only antimicrobial activity but also much different activity against our body, especially antioxidant, antiinflammatory, anticancer, antiseptic, antihypertension, hypoglycemic, hypocholesterolemic, sedative, and carminative effects as seen in many foods, vegetables, and beverage to maintain our body comfortably and healthfully. Many monoterpenoids have been tested against cancer cell lines and the other human organisms, and each pure monoterpenoid possesses anticancer properties and aforementioned pharmacological activity in relatively low concentration as shown in Table 2. It is absolutely difficult for the author to gather all of foods, vegetables, processed foods, and beverages including herbal tea and alcoholic beverages from the world and to tabulate the distribution of monoterpenoids and their benefits, uses, and pharmacological activity. However, the author believes that these tables are useful for future dietary monoterpene research and hope that many significant and valuable effects for our body will be found in the known and

unknown edible plants, fungi, bryophytes, lichen, and algae and a lot of safe and healthy supplements and food additives as well as processed foods will be created.
