Key words: papilomavirus, European elk, EEPV genome organization, Sequences, L3 ORF

Abstract

The genome of the European elk papillomavirus (EEPV) was found to be 8,095 base pairs (bp) long and its genetic organization was similar to that of other papillomaviruses. Ten open reading frames (ORFs), designated E1-E7 and L1-L3, were identified in the genome, all located on one strand. The presence of the L3 ORF is rare among the papillomaviruses and to date has only been identified in the genomes of EEPV, the deer papillomavirus (DPV) and the Cottontail papillomavirus (CRPV). The ORF is well conserved between DPV and EEPV with regard to both length and sequence. Potential promoter regions were identified at the 5′-end of the E6 ORF, at the 3′-end of the E1 ORF and downstream of the L1 ORF. Furthermore, two potential polyadenylation signals were found, one located in the long control region (LCR), downstream of the L1 ORF, and another preceding the L2 ORF. The EEVP genome is closely related to the genome of the DPV, the most highly conserved regions being ORFs E1 (70%), E5 (69%), and L1 (74%).

Introduction

Papillomaviruses belong to the Papovaviridae family and consist of a protein capsid surrounding a circular double-stranded DNA of approximately 8,000 base pairs (bp). They have been isolated and characterized from many different animal species (for references, see 1). The papillomaviruses induce proliferation of either the epithelial layer (papillomas), or the fibroblastic layer (fibromas), or both these layers (fibropapillomas). The majority of the papillomaviruses cause papillomas, but a few also cause fibromas or fibropapillomas.

We have focused our attention on viruses from the two latter groups. Warts induced by the European elk papillomavirus (EEPV) and the deer papillomavirus (DPV) are mainly fibromas, while the reindeer papillomavirus (RPV) and the bovine papillomavirus types 1 and 2 (BPV-1 and 2) give rise to fibropapillomas (2-5). EEPV also causes benign lung fibromas in elks (9). All of these viruses transform cultured murine fibroblast cells and induce sacromas in hamsters (2-4,6-8). Moreover, their genomes are more closely related to one another than to other papillomaviruses. Under stringent hybridization conditions EEPV DNA hybridizes to the genomes of DPV and RPV, but not with the BPV-1 genome that is more distantly related to EEPV (4).

The biological properties of EEPV have been described previously (2) and recently the nucleotide sequence of the early (transforming) region of EEPV has been published (10). We report here the complete nucleotide sequence of the EEPV genome. A molecular analysis of the late region made possible a comparison of regions which are equivalent to previously characterized regions in BPV-1, BPV-2, DPV and human papillomavirus type 6 and 16 (HPV-6 and 16) (11-16).

EEPV was isolated from the epithelial layer of a cutaneous fibropapilloma. The viral DNA was cloned into the plasmid vector pBR322 and subclones were constructed to facilitate sequence analysis as described before (2,10). The nucleotide sequence, obtained by the technique of Maxam and Gilbert (17), was analyzed using the University of Wisconsin Genetic Computer Group (UWGCG) software (18). The strategy for sequencing the late region is shown in Fig. 1 and the complete 8,095 bp nucleotide sequence of EEPV starting with the first nucleotide of the *Hpa*1 recognition site is presented in Fig. 2.

The sequence of EEPV DNA revealed that all open reading frames (ORFs) longer than 400 bp are located on one strand (Fig. 3). Ten ORFs were identified, seven in the early region (E1-E7) and three in the late region (L1-L3) (Table 1 and Fig. 3). Three additional potential ORFs were identified, one 309 bp long (ORFX) located between the E5 and L2 ORFs, and two located in the long control region

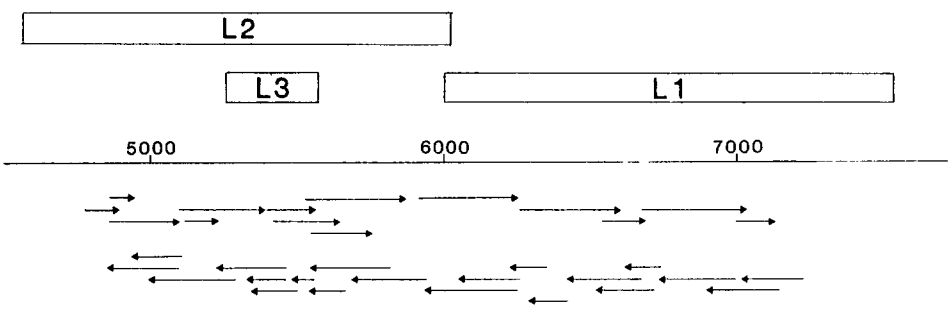

Fig. 1. The strategy for sequencing the late region of EEPV. The arrows show the direction in which the sequence was determined.

Fig. 2. (continued)

(LCR), 263 and 371 bp long respectively (LCR1 and LCR2). The L1 and L2 ORFs in EEPV have their counterparts in all papillomaviruses studied so far, while the L3 ORF has only been identified in the genomes of DPV and the Cottontail rabbit papillomavirus (CRPV) (14,19). The L3 ORF is 321 bp long in both EEPV and DPV, and parts of these two ORFs show a high degree of homology (Fig. 4), whereas no significant homology was found when the L3 ORF of EEPV was compared to that of CRPV. The L1 and L2 ORFs have been shown to code for viral structural proteins (20), but no functional activity has yet been assigned to the L3 ORF.

When compared with other papillomavirus genomes, EEPV shows a higher degree of homology to DPV than to any other papillomaviruses. The ORFs L1 (74%), E1 (70%), and E5 (69%) are best conserved (Table 2a). The extent of homology between the L1 ORF of EEPV and either DPV, BPV-1, BPV-2, HPV-6, or HPV-16 was determined and is shown in Table 2b. The homologies of other ORFs between EEPV, DPV, and BPV-1 are listed in Table 2a. A noteworthy feature of the L1 ORFs in the papillomaviruses sequenced to date is the presence of a conserved postulated splice acceptor site preceding the putative initiator ATG in this ORF

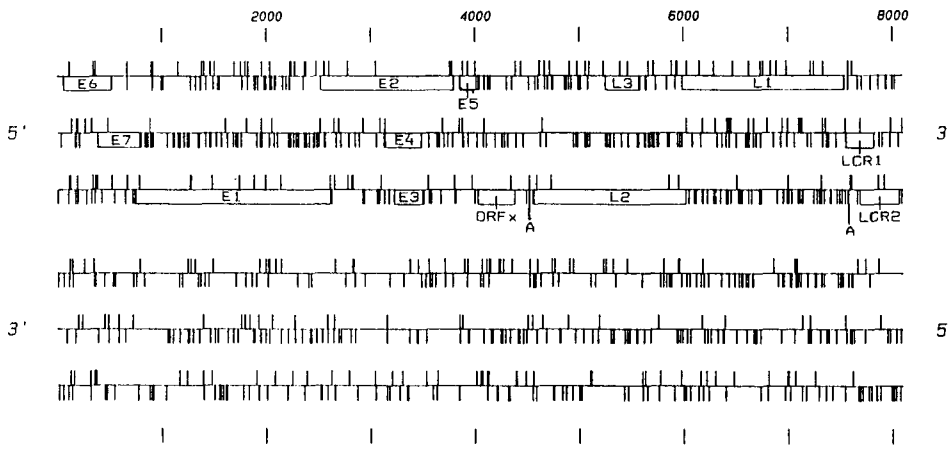

Fig. 3. Genomic organization of EEPV, including all ATG initiation codons (vertical bars above the lines) and termination codons (vertical bars beneath the lines). The ORFs in the genome are boxed. Potential polyadenylatons signals are indicated with A. The sequence data for the early (transforming) region is from Ahola et al. (10).

Table 1. Location and coding capacity of ORFs in the genome of EEPV

ORF	Positions	First ATG	AA* From First ATG	AA*
E1	753–2615	783	611	621
E2	2527–3798	2554	415	424
E3	3231–3497	—	—	89
E4	3143–3484	—	—	114
E5	3865–4014	3886	43	50
E6	64– 522	118	135	153
E7	389– 787	482	102	133
ORFX	4032–4379	4341	13	116
L1	5995–7536	6034	501	514
L2	4566–6020	4590	477	485
L3	5257–5577	5395	61	107
LCR1	7556–7819	7688	88	44
LCR2	7692–8063	7863	124	67

*AA = amino acids

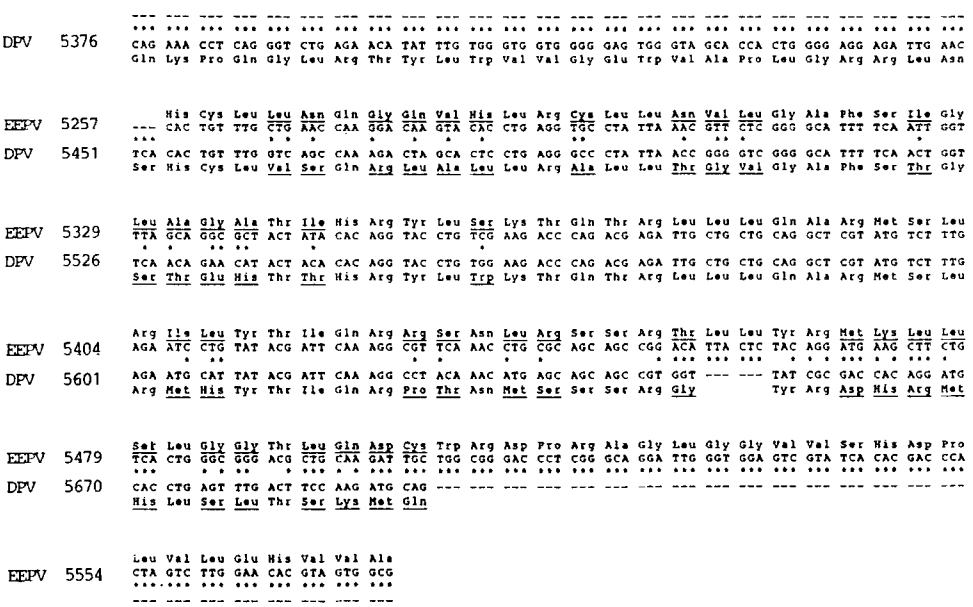

Fig. 4. A comparison between the L3 ORF in DPV and EEPV. Differences at nucleotide sequence level are indicated by asterisks, nonhomologous amino acids are underlined.

Table 2a. Degree of homology at the nucleotide (NT) and amino acid (AA) sequence levels between different ORFs in EEPV, DPV and BPV-1, measured from the first ATG where applicable.

	DPV		BPV-1	
ORF	NT (%)	AA (%)	NT (%)	AA (%)
E1	70	71	57	54
E2	65	56	55	44
E3	—	—	53	28
E4	67	58	52	37
E5	69	72	60	53
E6	58	54	46	43
E7	54	46	46	40
L1	74	73	66	72
L2	60	64	43	37
L3	38	28	—	—

The sequence data was obtained from references 10–12, 14.

Table 2b. The degree of homology between L1 ORFs in EEPV, DPV, BPV-1, BPV-2, HPV-6 and HPV-16, measured from the first ATG in each ORF.

L1	NT (%)	AA (%)
DPV	74	73
BPV-1	66	72
BPV-2	66	71
HPV-6	52	46
HPV-16	56	46

The sequence data was obtained from reference 11–16.

(Table 3). This splice acceptor site has indeed been shown to be used in the case of BPV-1 by S1-analysis (22).

The G + C content of the EEPV genome is 47.7%. However, the bases are not evenly distributed in the genome. For example, the E3 and E4 ORFs (bp 3143–3497) have a G + C content of 62%. In the middle of the genome, including the E5 ORF, there is a T-rich area with a T-content of 35% (bp 3865–4566). A similar T-rich area has been observed in DPV DNA (14).

In the genome of BPV-1, promoter regions have been identified near positions 89 (P_{89}), 2443 (P_{2443}), and 3080 (P_{3080}) (for references see 21). Recently, three additional promoter regions were identified in BPV-1 at positions 7185 (P_{7185}), 7940 (P_{7949}), and within the region 7214–7256, designated the major late promoter (P_L) (21,22). Potential promoter regions were identified in the EEPV genome at positions 87, corresponding to P_{89} in BPV-1 (Fig. 5) and at 2392 corresponding to P_{2443} in BPV-1. A ten base pair repeated sequence (bp 7591–7600 and bp 7606–7615) was identified in EEPV. This has 8 of 10 nucleotides (nt) in common with the

The vertical line preceding the first ATG in the ORFs, indicates potential splice junctions.
*This is the second ATG in the L1 ORF of the HPV-1a, HPV-8 and HPV-16 genomes.
**Base position 1 is the A of the first ATG in the L2 ORF of BPV-2.

Fig. 5. A sequence comparison between the promoter regions P_{7940} and P_{89} in BPV-1 and the corresponding regions of EEPV.

flanking area of P_{7185} (bp 7180–7189) in the BPV-1 genome. Moreover, a similar repeated sequence is present in DPV (bp 7811–7826 and 7836–7851). Upstream of the P_L region in BPV-1 there is a sequence homologous to the simian virus 40 (SV40) late promoter element GGTACCTAACC that has been shown to be important for efficient utilization of the SV40 major late transcriptional start site (21, 23, 24). It is interesting that this sequence homology is present in EEPV at approximately the corresponding location as in BPV-1, whereas no such sequence is found in this part of the genome in DPV. No area similar to the BPV-1 promoter region P_{3080} has been identified in the genome of EEPV.

Two potential polyadenylation (pA) signals (AATAAA) are present in the EEPV genome (Fig. 3). One is located immediately upstream of the L2 ORF (bp 4561) (putative early pA signal) and the other is located downstream of the L1 ORF (bp 7575) (putative late pA signal). Potential pA signals have been found at the corresponding locations in the genomes of DPV and BPV-1 (11, 14).

The repeated motif $ACCGN_4CGGT$ that has recently been shown to be part of two E2-binding regions in BPV-1 (25, 26), is present in five copies in the LCR of EEPV (Table 4).

Taxonomically, elk and deer belong to the Cervidae family, and they show a similar host response to papillomavirus infections, i.e., mainly fibromas develop. Besides the biological similarities between EEPV and DPV, it is interesting that the molecular analysis indicates a higher degree of evolutionary relationship between them than with the bovine fibropapillomaviruses BPV-1 and BPV-2. On the basis of the sequence homolgy and the characteristic host response to infection, EEPV and DPV could be classed as a subgroup of fibromaviruses to distinguish them from the fibropapillomaviruses.

Acknowledgments

We are grateful to Dr. S. Burnett for valuable comments during the preparation of the manuscript. This study was supported by grants from the Swedish Council for Forestry and Agricultural Research, the Swedish Cancer Society and the Swedish National Board for Technical Development.
