

*Short communication***Skinned smooth muscle:  
calcium-calmodulin activation independent of myosin phosphorylation**

**ABSTRACT**

In chemically skinned chicken gizzard smooth muscle fibers investigated shortly after preparation, a contraction may be induced by calcium and calmodulin which is independent of myosin phosphorylation at intermediate  $\text{Ca}^{2+}$ -concentrations. However, fibers stored for a prolonged period also contract in the absence of exogenous calmodulin and exhibit a close relationship between force development and myosin phosphorylation.

**KEY WORDS:** Smooth muscle - Skinned fibers - Calmodulin - Myosin phosphorylation

**INTRODUCTION**

In smooth muscle as in skeletal muscle, the contractile proteins are activated by increasing the intracellular free calcium ion concentration, but the calcium sensor is calmodulin rather than troponin. Calmodulin is essential for smooth muscle contraction which is said to be activated by calmodulin dependent phosphorylation of the 20,000 dalton myosin light chain by myosin light chain kinase (MLCK) (1, for review). Here we report that in addition calmodulin may also activate smooth muscle contraction by a different pathway which does not involve the myosin light chain kinase dependent phosphorylation of myosin. The proposed new calmodulin dependent activating mechanism appears to be distinct from other calcium dependent and myosin light chain kinase independent activation mechanisms of smooth muscle contractile proteins (2,3,4,5) as these are not dependent on calmodulin.

**MATERIALS AND METHODS**

Smooth muscle strips from the outer circumferential layer of freshly dissected gizzard obtained immediately after slaughtering the chicken were immersed for 30 min in an ice-cold solution containing (mM): EGTA 5, KCl 50, sucrose 150, imidazole 20 (pH 7.4) and dithioerythrol 2; they were subsequently skinned by the addition of 1% (v/v) Triton X-100 for a further 4 hrs at 4°C (cf. 8, 15). Subsequently the fibers were again immersed into the Triton-free preskinning solution and stored (for less than 1 week) in a solution containing 50% v/v glycerol and 50% relaxing solution pH 7 at -20°C until used. Aged preparations (cf. Table

1b, rows G and H) were obtained after storing the fibers at -20°C for up to 8 weeks. For recording isometric contractions small fiber bundles (about 5 mm in length and 50 to 200  $\mu\text{m}$  in diameter) were glued to an AME 801 force transducer (SensoNor, Horten, Norway) in a nominally calcium-free relaxing solution containing (mM): EGTA 4, KCl 50,  $\text{MgCl}_2$  5, imidazole 25, ATP 1, creatine phosphate 1, creatine phosphokinase (Boehringer Mannheim, FRG) 0.4 mg/ml as well as calmodulin at the concentrations indicated. The pH was adjusted to 7.0,  $T = 20^\circ\text{C}$ . For activation the desired  $\text{Ca}^{2+}$ -concentration was obtained by adjusting the proportion of EGTA and Ca-EGTA and the free  $\text{Ca}^{2+}$ -concentration was calculated by using an apparent binding constant of  $2 \times 10^8 \text{ M}^{-1}$  (cf. 16). Activating solutions also contained calmodulin from bovine testis (17) in varying concentrations, as indicated in the Table. Maximal contractile tension was  $19 \text{ N/cm}^2 \pm 3 \text{ N/cm}^2$  ( $n=5$ ) in 50  $\mu\text{m}$  thick fiber bundles. LC-20 phosphorylation was determined in parallel in other fiber bundles which were subjected to the same experimental protocol except that the fiber bundles were immersed in 15% ice-cold trichloroacetic acid at the desired time (20 min after onset of contraction). Phosphorylated and non-phosphorylated regulatory light chains were quantified by 2D-gel electrophoresis according to (18) and in some experiments according to (19); myosin light chain satellites were never observed.

**RESULTS AND DISCUSSION**

To study the activating effects of calmodulin the cell membrane of chicken gizzard smooth muscle was chemically removed by a Triton X-100 skinning procedure, which renders the contractile structures accessible to exogenous calmodulin and other proteins. In such skinned fibers, suspended in ATP salt solution (see legend to Table 1), contraction-relaxation cycles could be elicited by raising and lowering the free calcium ion concentration in the bathing medium. Freshly prepared skinned fibers of chicken gizzard were fully relaxed at pCa 5.8 if exogenous calmodulin was not present while the extent of myosin phosphorylation was low (cf. Table 1, row B). At pCa 5.8 addition of 0.05  $\mu\text{M}$  calmodulin, however, caused a pronounced contraction (75% maximal) without increase in the extent of light chain-20 phosphorylation (Table 1, rows C, D). Maximal contraction ( $19 \text{ N/cm}^2$ ) was obtained at pCa 5.2 with 3  $\mu\text{M}$  calmodulin which increased the extent of light chain phosphorylation to a level of nearly 50%.

FIGURE 1

Calmodulin activation of skinned chicken gizzard. Time course of force development of skinned fibers from chicken gizzard at constant pCa 5.8 in the absence (x) and in the presence of increasing concentrations of calmodulin (CaM): 0.05  $\mu\text{M}$  (O), 0.1  $\mu\text{M}$  ( $\Delta$ ) and 0.5  $\mu\text{M}$  ( $\square$ ). For composition of solutions cf. Materials and Methods.  $n = 5-7$  fiber bundles for each CaM concentration

As shown in Figure 1, not only the extent, but also the rate of force development was calmodulin-dependent. This slow activation was not due to diffusional limitations, since the skinned fibers were preincubated with calmodulin in relaxing solution for prolonged periods (approximately 15 min) prior to adjusting the pCa to 5.8. The contraction which could be induced by calmodulin and pCa 5.8 at basal levels of myosin phosphorylation was abolished by trifluoperazine ( $10^{-4}\text{M}$ ) and could be restored by addition of 3  $\mu\text{M}$  calmodulin. To obtain further evidence for calcium-calmodulin activation of contraction without an increase in myosin phosphorylation the substrate ATP was replaced by ITP which, like CTP, is no substrate for MLCK, but can be used by the contractile system (cf. 6). In contrast to skinned guinea pig taenia coli (21), in skinned fibers of chicken gizzard dephosphorylated in nucleotide-free salt solutions addition of  $\text{Mg}^{2+}$ -ITP (2 mM) elicited a contraction reaching  $37.8 \pm 2.1\%$  ( $n=8$ ) of the maximal force obtained with  $\text{Mg}^{2+}$ -ATP as substrate at pCa 5.2 and 3  $\mu\text{M}$  calmodulin. No force development occurred with ITP at pCa 5.2 in the absence of exogenous calmodulin.

In conclusion, low concentrations of calcium and calmodulin may activate smooth muscle of freshly prepared skinned gizzard fibers (stored for less than 1 week in glycerol) to produce over 70% of maximal force without noticeable increase in the extent of myosin phosphorylation. On the contrary, phosphorylation-dependent contractions were found in skinned fibers which were aged by prolonged (more than 6 weeks) storing at  $-20^\circ\text{C}$  in glycerol containing relaxing solution. For reasons which are not yet understood the storage of these fibers changed the force-phosphorylation relationship progressively. After about 8 weeks storage they were still relaxed at pCa 8 but produced 62% of maximal tension at pCa 5.8 even in the absence of exogenous calmodulin, while the extent of myosin phosphorylation rose to 42% (cf. Table 1b). Maximal force development occurred at pCa 5.2 in the presence or absence of exogenous calmodulin.

TABLE 1

Effect of calmodulin (CaM) on force development and myosin light chain phosphorylation in freshly skinned fibres (1a) and aged fibers (1b)

1a	pCa	CaM ( $\mu\text{M}$ )	Force (%)	P-LC-20 (%)
A	8	0	0 (6)	$8.7 \pm 1.4$ (6)
B	5.8	0	0 (6)	$8.3 \pm 0.6$ (6)
C	5.8	0.05	$85.7 \pm 3.2$ (7)	$8.7 \pm 1.1$ (7)
D	5.8	0.1	$89.9 \pm 3.2$ (6)	$11.5 \pm 0.9$ (6)
E	5.8	0.5	$96.1 \pm 0.8$ (5)	$29.6 \pm 1.4$ (5)
F	5.2	5	$120.7 \pm 2.3$ (5)	$47.8 \pm 1.2$ (6)

1b	pCa	CaM ( $\mu\text{M}$ )	Force (%)	% LC-phosphorylation
G (aged)	5.8	0	$62.4 \pm 4.9$ (5)	$42.6 \pm 2.6$ (5)
H (aged)	5.2	0	100	$48.2 \pm 2.3$ (5)

Note the variable relation between myosin light chain-20 phosphorylation (in % of total LC 20) and developed force (given as % of force at pCa 5.2 in the absence of exogenous calmodulin). At pCa 8 skinned gizzard fibers are relaxed and the phosphorylation of myosin is basal (0.1  $\mu\text{mole phosphate/mole light chain}$ ), even in the presence of 0.5  $\mu\text{M}$  exogenous calmodulin. If the  $\text{Ca}^{2+}$  concentration is increased to pCa 5.8, there is still no force development and phosphorylation remains at basal levels (cf. rows A and B) provided that no exogenous calmodulin is added. Addition of calmodulin (0.05 or 0.1  $\mu\text{M}$ ) does not increase the extent of light chain phosphorylation, but induces over 70% of the force (rows C and D) obtained at maximum activation (pCa 5.2, 5  $\mu\text{M}$  calmodulin). Note that contraction induced with higher levels of exogenous CaM and  $\text{Ca}^{2+}$  is associated with a significant increase in light chain phosphorylation (rows E and F), as was also the case in aged fibers.

Incidentally, these data on aged fibers agree with earlier experiments reporting a calcium-calmodulin induced contraction in various kinds of skinned smooth muscle including chicken gizzard, which were found to be myosin phosphorylation dependent (6,7,9,10,11). We, therefore, propose two mechanisms by which the calcium-calmodulin complex may activate smooth muscle contraction, one involving activation of MLCK and phosphorylation of a myosin regulatory light chain, and the other one bypassing the MLCK-dependent activating system. The latter calmodulin-dependent regulatory mechanism supports considerable force development without increased myosin phosphorylation and may also be involved in stress maintenance at low LC-20 phosphorylation in skinned (11) and intact (20) preparations of smooth muscle. It will be intriguing to find out whether this new mechanism is thin filament linked (12) and depends on the interaction of calmodulin with caldesmon (13,14), which has also been implicated in the regulation of smooth muscle and non-muscle motility.
