PACS. 03.65. – Quantum theory; quantum mechanics.

Summary. – When a state of a physical system dynamically changes to another state, it is important to know the correlation existing between the initial state and the final state. This correlation is described by a compound state (measure) in classical systems. In this note, we show a way how to construct such a compound state in quantum systems which is an extension of the classical compound state.

It is rather important in many physical sciences to study the dynamical change of states of a system. One of the most general description of this state change for classical systems is suggested in the communication theory of Shannon.

A state of a classical dynamical system is expressed by a probability measure on that system and its dynamical change is generally considered as follows (1): let X, Hbe compact Hausdorff spaces and  $\mathscr{F}_X, \mathscr{F}_Y$  be their Borel fields, respectively. We denote the set of all regular probability measures (states) on  $(X, \mathscr{F}_X)$  by P(X) and on  $(Y, \mathscr{F}_Y)$ by P(Y). A mapping  $\lambda: X \times \mathscr{F}_Y \to R^+$  satisfying the following two conditions is called a channel: i)  $\lambda(x, \cdot) \in P(Y)$  for each fixed  $x \in X$  and ii)  $\lambda(\cdot, Q)$  is a continuous measurable function on X for each fixed  $Q \in \mathscr{F}_Y$ . This mapping is often called a transition (or Markov) kernel and is useful to study, for instance, information transmission and stochastic processes. A channel so defined provides a mechanism of state change. Namely, a state  $\varphi \in P(X)$  is transferred to a state  $\psi \in P(Y)$  under a channel  $\lambda$  such as

(1) 
$$\psi(Q) = \int_{\mathbf{x}} \lambda(x, Q) \varphi(\mathrm{d}x) , \qquad Q \in \mathscr{F}_{\mathbf{y}} .$$

Moreover, in order to study the process of state change and the property of a channel itself, we need a compound state (joint probability) indicating the correlation existing

<sup>(1)</sup> H. UMEGAKI: J. Math. Anal. Appl., 25, 41 (1969).

between the initial state  $\varphi$  and the final state  $\psi$ . The compound state  $\Phi$  is given by

(2) 
$$\Phi(Q_1, Q_2) = \int_{Q_1} \lambda(x, Q_2) \varphi(\mathrm{d}x)$$

for any  $Q_1 \in \mathscr{F}_X$  and  $Q_2 \in \mathscr{F}_Y$ .

In quantum dynamics, we take two  $C^*$ -systems  $(\mathscr{A}, \mathfrak{S}(\mathscr{A}))$  and  $(\mathscr{B}, \mathfrak{S}(\Lambda))$ , one of which describes an initial (input) system corresponding to  $(X, \mathscr{F}_X, P(X))$  above and another describes a final (output) system corresponding to  $(Y, \mathscr{F}_X, P(X))$ . Here  $\mathscr{A}$ (respectively,  $\mathscr{B}$ ) is a  $C^*$ -algebra with unity  $I_{\mathscr{A}}$  (respectively,  $I_{\mathscr{B}}$ ) and  $\mathfrak{S}(\mathscr{A})$  (respectively,  $\mathfrak{S}(\mathscr{B})$ ) is the set of all states (*i.e.* normalized positive linear functionals) on  $\mathscr{A}$  (respectively,  $\mathscr{B})$  (<sup>2</sup>). Then let us consider a mapping  $\Lambda^*$  from  $\mathfrak{S}(\mathscr{A})$  to  $\mathfrak{S}(\mathscr{B})$  such that its dual map  $\Lambda$ :  $:\mathscr{B} \to \mathscr{A}$  is completely positive (<sup>2</sup>) with  $\Lambda I_{\mathscr{B}} = I_{\mathscr{A}}$ . This mapping  $\Lambda^*$  is called a channel between two quantum-dynamical systems (<sup>3</sup>). In particular, when  $\mathscr{A} = C(X)$ , the set of all continuous functions on X, and  $\mathscr{B} = C(Y)$ , the formula (1) defines a channel  $\Lambda^*$  from P(X) to P(Y) (*i.e.*  $\psi = \Lambda^* \varphi$ ) because every probability measure  $\varphi$  on  $(X, \mathscr{F}_X)$  can be regarded as a state on C(X) by the Riesz-Markov-Kakutani theorem. We meet several channels in several fields of physics. For example, time evolution automorphism group, dynamical semi-group and conditional expectation on a certain algebra are typical channels.

Now it is well known (4) that the joint probability measure does not generally exist in quantum systems. Hence it has been difficult to define a compound state describing the correlation existing between an initial state  $\varphi \in \mathfrak{S}(\mathscr{A})$  and its final state  $\Lambda^* \varphi \in \mathfrak{S}(\mathscr{A})$ . The aim of this note is to construct such a compound state and to show that our compound state is an extension of the classical one given by (2).

For an initial state  $\varphi$  and the final state  $\Lambda^*\varphi$ , a compound state  $\Phi$  on  $\mathscr{A} \otimes \mathscr{B}$ of  $\varphi$  and  $\Lambda^*\varphi$  should satisfy the following two conditions: i)  $\Phi(A \otimes I_{\mathscr{B}}) = \varphi(A)$  for any  $A \in \mathscr{A}$  and ii)  $\varphi(I_{\mathscr{A}} \otimes B) = \Lambda^*\varphi(B)$  for any  $B \in \mathscr{B}$ . There exist many states satisfying these conditions, for instance,  $\Phi_0 = \varphi \otimes \Lambda^*\varphi$  is such a state. But this state does not carry any correlation between  $\varphi$  and  $\Lambda^*\varphi$ .

For any weak \*-compact convex subset  $\mathscr{S}$  of  $\mathfrak{S}(\mathscr{A})$ , there exists a maximal measure  $\mu$  such that  $\varphi$  is the barycentre of  $\mu$  and  $\mu$  is pseudosupported by the set  $e \times \mathscr{S}$  of all extreme points of  $\mathscr{S}$  in the sense that  $\mu(Q) = 1$  for every Baire subset Q of  $\mathscr{S}$  with  $Q \supset e \times \mathscr{S}$ <sup>(5)</sup>. In this case, we write

(3) 
$$\varphi = \int_{\langle \mathbf{a} \times \mathscr{S} \rangle} \omega \, \mathrm{d} \mu \, .$$

Note that the above maximal measure  $\mu$  is not always unique, and we denote the set of all such measures by  $M_{w}(\mathscr{S})$ .

We now construct a «true» compound state of  $\varphi$  and  $\Lambda^*\varphi$ . For each  $\mu \in M_{\varphi}(\mathscr{S})$ , define

(4) 
$$\varphi_{\mu} = \int_{\omega} \omega \otimes \Lambda^* \omega \, \mathrm{d}\mu$$

It is easy to see that this state  $\Phi_{\mu}$  satisfies the conditions i) and ii) mentioned above. Let us now show that the compound state defined by (4) is indeed an extension of the

classical one. When  $\mathscr{S} = P(X)$ , the extremal decomposition of a state  $\varphi \in P(X)$  is unique and given by

(5) 
$$\varphi = \int_{\mathbf{x}} \delta_{\mathbf{x}} \varphi(\mathrm{d}\mathbf{x}) \, ,$$

where  $\delta_x$  is the Dirac measure concentrated at a point  $x \in X$ . Since  $(\Lambda^* \delta_x)(Q_2) = \lambda(x, Q_2)$  for any  $Q_2 \in \mathcal{F}_Y$ , we have

$$\varPhi_{\varphi}(Q_1 \times Q_2) = \int_{\mathbf{x}} \delta_x(Q_1) \Lambda^* \, \delta_x(Q_2) \varphi(\mathrm{d}x) = \int_{\mathbf{x}} l_{Q_1}(x) \, \lambda(x, Q_2) \varphi(\mathrm{d}x) = \int_{Q_1} \lambda(x, Q_2) \varphi(\mathrm{d}x) + \int_{Q_2} \lambda(x, Q_2) \varphi(\mathrm{d}x) = \int_{Q_2} \lambda(x, Q_2) \varphi(\mathrm{d}x) + \int_{Q_2} \lambda(x, Q_2) \varphi(\mathrm{d}x) = \int_{Q_2} \lambda(x, Q_2) \varphi(\mathrm{d}x) = \int_{Q_2} \lambda(x, Q_2) \varphi(\mathrm{d}x) + \int_{Q_2} \lambda(x, Q_2) \varphi(\mathrm{d}x) = \int_{Q_2} \lambda(x, Q_2) \varphi(\mathrm{d}x) = \int_{Q_2} \lambda(x, Q_2) \varphi(\mathrm{d}x) + \int_{Q_2} \lambda(x, Q_2) \varphi(\mathrm{d}x) = \int_{Q_2} \lambda(x, Q_2) \varphi(\mathrm{d}x) + \int_{Q_2} \lambda(x, Q_2) \varphi(\mathrm{d}x) = \int_{Q_2} \lambda(x, Q_2) \varphi(\mathrm{d}x) = \int_{Q_2} \lambda(x, Q_2) \varphi(\mathrm{d}x) + \int_{Q_2} \lambda(x, Q_2) \varphi(\mathrm{d}x) = \int_{Q_2} \lambda(x, Q_2) \varphi(\mathrm{d}x) = \int_{Q_2} \lambda(x, Q_2) \varphi(\mathrm{d}x) + \int_{Q_2} \lambda(x, Q_2) \varphi(\mathrm{d}x) = \int_{Q_2} \lambda(x, Q_2) \varphi(\mathrm{d}x) + \int_{Q_2} \lambda(x, Q_2) \varphi(\mathrm{d}$$

for any  $Q_1 \in \mathscr{F}_X$  and  $Q_2 \in \mathscr{F}_Y$ .

We finally consider the case of  $\mathscr{A} = C(\mathscr{H}_1) = C(\mathscr{H}_1) + CI$ , where  $C(\mathscr{H})$  is the set of all compact operators on a separable Hilbert space  $\mathscr{H}$ . Then  $\mathfrak{S}(\mathscr{A})$  contains the set  $T(\mathscr{H}_1)_{\pm,1}$  of all positive trace class operators on  $\mathscr{H}_1$  with unit trace and so does  $\mathfrak{S}(\mathscr{B})$ . Moreover, a channel  $\Lambda^*$  is a trace-preserving completely positive map from  $T(\mathscr{H}_1)_{\pm,1}$ to  $T(\mathscr{H}_2)_{\pm,1}$ . In this case, if an extremal decomposition of a state  $\varrho \in T(\mathscr{H}_1)_{\pm,1}$  is given by  $\varrho = \sum_{i=1}^{i} \lambda_n \varrho_n$ , then our compound state is

$$\sigma := \sum_{n} \lambda_n \varrho_n \otimes \Lambda^* \varrho_n \, .$$

Among these compound states, the following is the most important:

(6) 
$$\sigma_{\boldsymbol{g}} = \sum_{\boldsymbol{n}} \lambda_{\boldsymbol{n}} E_{\boldsymbol{n}} \otimes A^* E_{\boldsymbol{n}} \,.$$

The symbols appearing in (6) mean the following: a)  $\lambda_n$  is the eigenvalue of  $\varrho$ , and the eigenvalue of multiplicity m is repeated precisely m times. b)  $E_n = |x_n\rangle\langle x_n|$  in Dirac's notation, where  $x_n$  is an eigenvector associated with  $\lambda_n$  and it is unique if and only if  $\lambda_n$  is nondegenerate (5). c) E represents  $\{E_n\}$ . The compound state  $\sigma_E$  depends on E, hence on the choice of the eigenvectors  $\{x_n\}$ . This compound state is first introduced in (<sup>2</sup>), but it is a special case of our compound state  $\Phi_{\mu}$  as just discussed.

The compound state constructed for quantum systems plays a similar role as the joint probability measure for classical systems, so that it is useful to formulate quantum communication theory ( $^{6}$ ) and to study the dynamics of state change ( $^{7}$ ).
