ABSTRACT: We investigate the simplest gauge theory for spontaneous R-parity breaking and its testability at the LHC. This theory, based on a local B-L gauge symmetry, can be considered as the simplest framework for understanding the origin of the R-parity violating interactions, giving rise to potential lepton number violating signals and suppressed baryon number violating operators. The full spectrum of the theory and the constraints coming from neutrino masses are analyzed in detail. We discuss the proton decay issue and the possible dark matter candidates. In order to assess the testability of the theory we study the properties of the new gauge boson, the neutralino decays and the main production channels for the charged sleptons at the LHC. We find that final states with four charged leptons, three of them with the same-sign, and four jets are the most striking signals for the testability of the lepton number violation associated with spontaneous R-parity violation at the LHC.

1 Introduction

The Large Hadron Collider (LHC) will hopefully soon discover the underlying theory for the TeV scale and might allow us to understand a more fundamental law of nature. For more than three decades the idea of Supersymmetry has attracted the attention of many experts in the particle physics community and the minimal supersymmetric extension of the

Standard Model [1–3] (MSSM) is still considered one of the most appealing candidates for the theory of particle physics at the TeV scale. It is well known that the MSSM provides an understanding of why the SM-like Higgs boson is light, contains a cold dark matter candidate, allows for the unification of the gauge couplings and allows for the mechanism of electroweak baryogenesis to explain the baryon asymmetry in the universe.

There are several open issues in the MSSM, one of them being the origin of the discrete symmetry R-parity [4, 5]. This symmetry plays a major role in the MSSM and it is defined as $R = (-1)^{3(B-L)+2S}$, where B , L and S stand for baryon number, lepton number and spin, respectively. In many MSSM studies it is assumed that R-parity is conserved or explicitly broken without understanding the origin of this symmetry. However, the fate of R-parity is crucial for the discovery of supersymmetry since, as is well known, R-parity conservation give rise to channels with multi-jets, multi-leptons and missing energy at the LHC, while signatures of broken R-parity are multi-leptons, multi-jets, and missing energy due to the SM neutrinos only.

The simplest and most elegant framework for the origin of R-parity is based on local B-L symmetry. This connection was explored for the first time in ref. [6], and in ref. [7] a simpler scenario was studied. See also ref. [8] for a complete discussion of how to gauge R-parity.¹ Recently, we have investigated the simplest B-L models in refs. [14–17] and found the following main result

*The simplest theories based on local B-L make the following prediction:
R-parity must be spontaneously broken at the TeV scale and
one expects to observe lepton number violation at the LHC!*

In this letter we study in detail the theory proposed in ref. [15] which can be considered as the simplest gauge theory for R-parity violation. In this context the only way to break local B-L and obtain the MSSM after symmetry breaking is to give a vacuum expectation value to one of the right-handed sneutrino required by anomaly cancellation. One of the most important features of this theory is that the B-L and R-parity breaking scales are determined by the soft supersymmetric breaking scale. This idea was studied for the first time in ref. [14] which defined the simplest left-right symmetric model.

We review the theory and symmetry breaking mechanism in sections II and III. The full spectrum of the theory [15] is discussed in section IV and the constraints coming from neutrino masses in section VI. We discuss the proton decay issue and the possible dark matter candidates in section V. In order to understand the testability of the theory we study the properties of the new gauge boson, the neutralino decays in section VII and in section VIII the main production channels for the charged sleptons at the Large Hadron Collider. We find that the channels with four charged leptons (three with the same electric charge) and four jets give us the most striking signals for the testability of lepton number violation at the LHC.

¹It is important to mention that the breaking of B-L in the context of the MSSM was studied for the first time in ref. [9]. See also refs. [10–13] for the study of R-parity in other models.

2 The minimal gauge theory for spontaneous R-parity violation

The simplest gauge theory for spontaneous R-parity breaking was proposed in ref. [15]. In this context one can understand dynamically the origin of the R-parity violating terms in the MSSM. Here we discuss the structure of the theory and the full spectrum.

- *Gauge symmetry and matter fields*: this theory is based on the gauge group

$$\text{SU}(3)_C \otimes \text{SU}(2)_L \otimes \text{U}(1)_Y \otimes \text{U}(1)_{B-L},$$

and the different matter chiral superfields are given by

$$\hat{Q} = \begin{pmatrix} \hat{u} \\ \hat{d} \end{pmatrix} \sim (2, 1/3, 1/3), \quad \hat{L} = \begin{pmatrix} \hat{\nu} \\ \hat{e} \end{pmatrix} \sim (2, -1, -1), \quad (2.1)$$

$$\hat{u}^c \sim (1, -4/3, -1/3), \quad \hat{d}^c \sim (1, 2/3, -1/3), \quad \hat{e}^c \sim (1, 2, 1). \quad (2.2)$$

In order to cancel the $B-L$ anomalies one introduces three chiral superfields for the right-handed neutrinos:

$$\hat{\nu}^c \sim (1, 0, 1). \quad (2.3)$$

- *Higgs sector*: the Higgs sector is composed of two Higgs chiral superfields as in the MSSM

$$\hat{H}_u = \begin{pmatrix} \hat{H}_u^+ \\ \hat{H}_u^0 \end{pmatrix} \sim (2, 1, 0), \quad \hat{H}_d = \begin{pmatrix} \hat{H}_d^0 \\ \hat{H}_d^- \end{pmatrix} \sim (2, -1, 0). \quad (2.4)$$

- *Interactions*: with this field content the superpotential reads as

$$\mathcal{W}_{\text{BL}} = \mathcal{W}_{\text{MSSM}} + Y_\nu \hat{L}^T i\sigma_2 \hat{H}_u \hat{\nu}^c, \quad (2.5)$$

where

$$\begin{aligned} \mathcal{W}_{\text{MSSM}} = & Y_u \hat{Q}^T i\sigma_2 \hat{H}_u \hat{u}^c + Y_d \hat{Q}^T i\sigma_2 \hat{H}_d \hat{d}^c \\ & + Y_e \hat{L}^T i\sigma_2 \hat{H}_d \hat{e}^c + \mu \hat{H}_u^T i\sigma_2 \hat{H}_d. \end{aligned} \quad (2.6)$$

In addition to the superpotential, the model is also specified by the soft terms:

$$\begin{aligned} V_{\text{soft}} = & m_{\tilde{\nu}^c}^2 |\tilde{\nu}^c|^2 + m_{\tilde{L}}^2 |\tilde{L}|^2 + m_{\tilde{e}^c}^2 |\tilde{e}^c|^2 + m_{H_u}^2 |H_u|^2 + m_{H_d}^2 |H_d|^2 \\ & + \left(\frac{1}{2} M_{\text{BL}} \tilde{B}' \tilde{B}' + A_\nu \tilde{L}^T i\sigma_2 H_u \tilde{\nu}^c + B\mu H_u^T i\sigma_2 H_d + \text{h.c.} \right) + V_{\text{soft}}^{\text{MSSM}}, \end{aligned} \quad (2.7)$$

where the terms not shown here correspond to terms in the soft MSSM potential.

Since we have a new gauge symmetry in the theory we need to modify the kinetic terms for all MSSM matter superfields, and include the kinetic term for right-handed neutrino superfields

$$\mathcal{L}_{\text{Kin}}(\nu^c) = \int d^2\theta d^2\bar{\theta} (\hat{\nu}^c)^\dagger e^{g_{\text{BL}} \hat{V}_{\text{BL}}} \hat{\nu}^c. \quad (2.8)$$

Here \hat{V}_{BL} is the B-L vector superfield. Using these interactions we can study the full spectrum of the theory.

3 Electroweak and B-L symmetry breaking

As in the MSSM, electroweak symmetry is broken by the vevs of H_u^0 and H_d^0 , while $U(1)_{B-L}$ is broken due to the vev of right-handed sneutrinos. Notice that this is the only field which can break local $B-L$ and give mass to the new neutral gauge boson in the theory. Therefore, the theory predicts spontaneous R-parity violation. It is important to mention that the $B-L$ and R-parity breaking scales are determined by the soft supersymmetric breaking scale, and one must expect lepton number violation at the LHC.

The neutral fields are defined as

$$H_u^0 = \frac{1}{\sqrt{2}}(v_u + h_u) + \frac{i}{\sqrt{2}}A_u, \quad (3.1)$$

$$H_d^0 = \frac{1}{\sqrt{2}}(v_d + h_d) + \frac{i}{\sqrt{2}}A_d, \quad (3.2)$$

$$\tilde{\nu}^i = \frac{1}{\sqrt{2}}(v_L^i + h_L^i) + \frac{i}{\sqrt{2}}A_L^i, \quad (3.3)$$

$$\tilde{\nu}_i^c = \frac{1}{\sqrt{2}}(v_R^i + h_R^i) + \frac{i}{\sqrt{2}}A_R^i, \quad (3.4)$$

and the relevant scalar potential reads as

$$V = V_F + V_D + V_{\text{soft}}, \quad (3.5)$$

$$V_F = |\mu|^2 |H_u^0|^2 + |-\mu H_d^0 + \tilde{\nu}_i Y_\nu^{ij} \tilde{\nu}_j^c|^2 + \sum_i |Y_\nu^{ij} \tilde{\nu}_j^c|^2 |H_u^0|^2 + \sum_j |\tilde{\nu}_i Y_\nu^{ij}|^2 |H_u^0|^2, \quad (3.6)$$

$$V_D = \frac{(g_1^2 + g_2^2)}{8} \left(|H_u^0|^2 - |H_d^0|^2 - \sum_i |\tilde{\nu}_i|^2 \right)^2 + \frac{g_{\text{BL}}^2}{8} \left(\sum_i (|\tilde{\nu}_i^c|^2 - |\tilde{\nu}_i|^2) \right)^2, \quad (3.7)$$

$$V_{\text{soft}} = (\tilde{\nu}_i^c)^\dagger m_{\tilde{\nu}_i^c}^2 \tilde{\nu}_j^c + \tilde{\nu}_i^\dagger m_{\tilde{\nu}_i}^2 \tilde{\nu}_j + m_{H_u}^2 |H_u^0|^2 + m_{H_d}^2 |H_d^0|^2 \\ + (\tilde{\nu}_i a_\nu^{ij} \tilde{\nu}_j^c H_u^0 - B\mu H_u^0 H_d^0 + \text{h.c.}). \quad (3.8)$$

Using the above scalar potential and assuming that all parameters are real we can find the minimization conditions

$$v_u \left[\mu^2 + \frac{1}{2} Y_\nu^{ij} v_R^j Y_\nu^{ik} v_R^k + \frac{1}{2} v_L^i Y_\nu^{ij} v_L^k Y_\nu^{kj} + \frac{g_1^2 + g_2^2}{8} (v_u^2 - v_d^2 - v_L^i v_L^i) + m_{H_u}^2 \right] \\ + \frac{1}{\sqrt{2}} v_L^i a_\nu^{ij} v_R^j - B\mu v_d = 0, \quad (3.9)$$

$$v_d \left[\mu^2 - \frac{(g_1^2 + g_2^2)}{8} (v_u^2 - v_d^2 - v_L^i v_L^i) + m_{H_d}^2 \right] - \frac{1}{\sqrt{2}} \mu v_L^i Y_\nu^{ij} v_R^j - B\mu v_u = 0, \quad (3.10)$$

$$\frac{1}{2} v_L^i Y_\nu^{ij} v_R^j v_L^m Y_\nu^{mk} - \frac{1}{\sqrt{2}} \mu v d v_L^i Y_\nu^{ik} + \frac{1}{2} v_u^2 Y_\nu^{ij} v_R^j Y_\nu^{ik} + \frac{g_{\text{BL}}^2}{8} (v_R^i v_R^i - v_L^i v_L^i) v_R^k \\ + \frac{1}{2} v_R^i [(m_{\tilde{\nu}^c}^2)_{ki} + (m_{\tilde{\nu}^c}^2)_{ik}] + \frac{1}{\sqrt{2}} v_L^i a_\nu^{ik} v_u = 0, \quad (3.11)$$

$$\begin{aligned} & \frac{1}{2} v_L^i Y_\nu^{ij} v_R^j Y_\nu^{km} v_R^m - \frac{1}{\sqrt{2}} \mu v_d Y_\nu^{kj} v_R^j + \frac{1}{2} v_u^2 v_L^i Y_\nu^{ij} Y_\nu^{kj} - \frac{(g_1^2 + g_2^2)}{8} (v_u^2 - v_d^2 - v_L^i v_L^i) v_L^k \\ & - \frac{g_{\text{BL}}^2}{8} (v_R^i v_R^i - v_L^i v_L^i) v_L^k + \frac{1}{2} v_L^i \left[(m_L^2)_{ki} + (m_L^2)_{ik} \right] + \frac{1}{\sqrt{2}} a_\nu^{kj} v_R^j v_u = 0. \end{aligned} \tag{3.12}$$

In order to have phenomenological allowed solutions the v_L^i have to be small, and the v_R^i have to be much larger than v_u, v_d and v_L^i . Up to negligibly small terms² the right-handed sneutrino acquire a vev in only one family. A possible solution and the one used throughout this paper is $v_R^i = (0, 0, v_R)$. In this case:

$$v_R^2 \approx -\frac{8(m_{\tilde{\nu}^c}^2)_{33}}{g_{\text{BL}}^2}, \tag{3.13}$$

$$v_L^k \approx \frac{v_R}{\sqrt{2}} \frac{(\mu v_d Y_\nu^{k3} - a_\nu^{k3} v_u)}{\left[(m_L^2)_{kk} - \frac{(g_1^2 + g_2^2)}{8} (v_u^2 - v_d^2) - \frac{g_{\text{BL}}^2}{8} v_R^2 \right]}. \tag{3.14}$$

Notice that the minimization conditions for v_u , eq. (3.9), and v_d , eq. (3.10) are not greatly altered from their MSSM equivalents since the extra terms are very small.

3.1 Radiative symmetry breaking

In the MSSM, the large top Yukawa coupling drives the up-type soft Higgs mass squared parameter to negative values for generic boundary conditions leading to radiative electroweak symmetry breaking [18, 19]; a celebrated success of the MSSM. A valid question is then if the same success is possible in achieving a tachyonic right-handed sneutrino mass in this $B - L$ model as required by eq. (3.13). Unfortunately, this is not possible through a large Yukawa coupling since the Yukawa couplings of the right-handed neutrino are all dictated to be small by neutrino masses. However, there is an alternate possibility whereby a positive mass squared parameter for the right-handed sneutrino at the high scale will run to a tachyonic value at the low scale. This is due to the presence of the so-called S -term (due to D -term contributions to the RGE) in the soft mass RGE, as discussed for this $B - L$ model in [20–22]. A short outline of the mechanism follows.

The RGE for the right-handed sneutrino soft mass squared parameter is

$$16\pi^2 \frac{dm_{\tilde{\nu}^c}^2}{dt} = -3g_{\text{BL}}^2 |M_{\text{BL}}|^2 + \frac{3}{4} g_{\text{BL}}^2 S_{\text{BL}}, \tag{3.15}$$

with

$$S_{\text{BL}} = \text{Tr} \left(2m_{\tilde{Q}}^2 - m_{\tilde{u}^c}^2 - m_{\tilde{d}^c}^2 - 2m_L^2 + m_{\tilde{e}^c}^2 + m_{\tilde{\nu}^c}^2 \right), \tag{3.16}$$

where the trace is over the three generations of the fermions and the soft mass parameters in the trace are for the squark doublet, right-handed up squark, right-handed down squark, slepton doublet, right-handed charged slepton and right-handed sneutrino, respectively. The gaugino mass term always drives the sneutrino mass parameter positive at the low

²The size would go as $\frac{Y_\nu \mu v_d v_L}{m_{\tilde{\nu}^c}^2} < 10^{-10}$. The maximum values for Y_ν and v_L are about 10^{-6} and 10^{-2} GeV, respectively, see figure 4.

scale but if the overall sign of the S -term is positive, it could lead to the opposite effect. Such an effect would require a non-zero S -term at the high scale, which is not possible if the soft masses are universal across the generations of each flavor. An example of a suitable boundary condition with minimal variation from the popular MSUGRA Ansatz is universal boundary conditions for all sfermions except for the right-handed sneutrinos, which might have the boundary conditions

$$m_{\tilde{\nu}_1^c}^2 = m_{\tilde{\nu}_2^c}^2 = P m_0^2, \quad m_{\tilde{\nu}_3^c}^2 = Q m_0^2, \quad (3.17)$$

where m_0 is the universal mass and $P > 1$ and $Q < 1$. The boundary condition for S_{BL} is then

$$S_{BL} = (2P + Q - 1)m_0^2, \quad (3.18)$$

having the necessary sign to contribute negatively to the sneutrino soft mass parameter as it is evolved from the high scale down. The necessary sizes of P and Q depend on the size of the gaugino mass parameter which has the opposite effect, see [20–22] for more details. So while, the traditional radiative symmetry breaking from universal boundary conditions is not possible in these models, it is possible to radiatively break $B - L$ through this S -term starting from a positive value. For the implementation of the radiative mechanism in the non-minimal model see ref. [23].

4 Mass spectrum and lepton number violation

4.1 R-parity violating interactions

After symmetry breaking lepton number is spontaneously broken in the form of bilinear R-parity violating interactions. There are no trilinear R-parity violating interactions at the renormalizable level. These bilinear interactions mix the leptons with the Higgsinos and gauginos:

$$\begin{aligned} & \frac{1}{2}g_{BL}v_R(\nu_3^c\tilde{B}'), \quad \frac{1}{2}g_2v_L^i(\nu_i\tilde{W}^0), \quad \frac{1}{\sqrt{2}}g_2v_L^i(e_i\tilde{W}^+), \\ & \frac{1}{2}g_1v_L^i(\nu_i\tilde{B}), \quad \frac{1}{\sqrt{2}}Y_\nu^{i3}v_R(L_i^T i\sigma_2 \tilde{H}_u), \quad \frac{1}{\sqrt{2}}Y_\nu^{i3}v_L^i(\tilde{H}_u^0 \nu_3^c), \quad \frac{1}{\sqrt{2}}Y_e^i v_L^i(\tilde{H}_d^- e_i^c). \end{aligned}$$

The first term is new and is the only term not suppressed by neutrino masses. The fifth term corresponds to the so-called ϵ term, and second, third and fourth terms are small but important for the decay of neutralinos and charginos. See section V for the discussion of the baryon number violating operators.

There are also lepton number violating interactions coming from the soft terms and the B-L D-term. From V_{soft} one gets

$$A_\nu^{i3} \frac{v_R}{\sqrt{2}} \tilde{L}_i^T i\sigma_2 H_u,$$

while from the D-term one finds

$$g_{BL}^2 v_R \tilde{\nu}^c \left(\tilde{q}^\dagger \frac{1}{6} \tilde{q} - \tilde{l}^\dagger \frac{1}{2} \tilde{l} \right).$$

As one can expect these terms are important to understand the scalar sector of the theory.

4.2 Mass spectrum

Gauge boson: the neutral gauge boson associated to the $B - L$ gauge group is Z_{BL} . Using the covariant derivative for the right-handed sneutrinos, $D_\mu \tilde{\nu}^c = \partial_\mu \tilde{\nu}^c + i \frac{g_{BL}}{2} B'_\mu \tilde{\nu}^c$, the mass term for Z_{BL} is:

$$M_{Z_{BL}} = \frac{g_{BL}}{2} v_R. \quad (4.1)$$

Now, using the experimental collider constraint [24]:

$$\frac{M_{Z_{BL}}}{g_{BL}} \geq 3 \text{ TeV}, \quad (4.2)$$

and eq. (3.13) one finds the condition

$$|(m_{\tilde{\nu}^c})_{33}| > 2.12 g_{BL} \text{ TeV}. \quad (4.3)$$

Then, if $g_{BL} = 0.1$ the soft mass above has to be larger than 200 GeV. This condition can be easily satisfied without assuming a very heavy spectrum for the supersymmetric particles.

Neutralinos and neutrinos: as in any supersymmetric theory where R -parity is broken all the fermions with the same quantum numbers mix and form physical states which are linear combinations of the original fields. The neutralinos in this theory are a linear combination of the fields, $(\nu_i, \nu_j^c, \tilde{B}', \tilde{B}, \tilde{W}^0, \tilde{H}_d^0, \tilde{H}_u^0)$. Then, the neutralino mass matrix is given by

$$\mathcal{M}_N = \begin{pmatrix} 0 & \frac{1}{\sqrt{2}} Y_\nu^{ij} v_u & -\frac{1}{2} g_{BL} v_L^i & -\frac{1}{2} g_1 v_L^i & \frac{1}{2} g_2 v_L^i & 0 & \frac{1}{\sqrt{2}} Y_\nu^{ij} v_R^j & 0 \\ \frac{1}{\sqrt{2}} Y_\nu^{ij} v_u & 0 & \frac{1}{2} g_{BL} v_R^j & 0 & 0 & 0 & \frac{1}{\sqrt{2}} Y_\nu^{ij} v_L^i & 0 \\ -\frac{1}{2} g_{BL} v_L^i & \frac{1}{2} g_{BL} v_R^j & M_{BL} & 0 & 0 & 0 & 0 & 0 \\ -\frac{1}{2} g_1 v_L^i & 0 & 0 & M_1 & 0 & -\frac{1}{2} g_1 v_d & \frac{1}{2} g_1 v_u & 0 \\ \frac{1}{2} g_2 v_L^i & 0 & 0 & 0 & M_2 & \frac{1}{2} g_2 v_d & -\frac{1}{2} g_2 v_u & 0 \\ 0 & 0 & 0 & -\frac{1}{2} g_1 v_d & \frac{1}{2} g_2 v_d & 0 & -\mu & 0 \\ \frac{1}{\sqrt{2}} Y_\nu^{ij} v_R^j & \frac{1}{\sqrt{2}} Y_\nu^{ij} v_L^i & 0 & \frac{1}{2} g_1 v_u & -\frac{1}{2} g_2 v_u & -\mu & 0 & 0 \end{pmatrix}. \quad (4.4)$$

We have discussed above that only one right-handed sneutrinos get a vev, $v_R^i = (0, 0, v_R)$. Now, integrating out the neutralinos one can find the mass matrix for the light neutrinos. In this case one has three active neutrinos and two sterile neutrinos, and the mass matrix in the basis $(\nu_e, \nu_\mu, \nu_\tau, \nu_e^c, \nu_\mu^c)$ is given by

$$M_\nu = \begin{pmatrix} A v_L^i v_L^j + B \left[Y_\nu^{i3} v_L^j + Y_\nu^{j3} v_L^i \right] + C Y_\nu^{i3} Y_\nu^{j3} \frac{1}{\sqrt{2}} v_u Y_\nu^{i\beta} & \\ & \frac{1}{\sqrt{2}} v_u Y_\nu^{\alpha j} & \\ & & O_{2 \times 2} \end{pmatrix}, \quad (4.5)$$

where

$$A = \frac{2\mu^2}{\tilde{m}^3}, \quad B = \left(\frac{v_u}{\sqrt{2} v_R} + \frac{\sqrt{2} \mu v_d v_R}{\tilde{m}^3} \right), \quad C = \left(\frac{2 M_{BL} v_u^2}{g_{BL}^2 v_R^2} + \frac{v_d^2 v_R^2}{\tilde{m}^3} \right), \quad (4.6)$$

$$\tilde{m}^3 = \frac{4 [\mu v_u v_d (g_1^2 M_2 + g_2^2 M_1) - 2 M_1 M_2 \mu^2]}{g_1^2 M_2 + g_2^2 M_1}. \quad (4.7)$$

Figure 1. Sample spectra for neutrino masses in the normal and inverted hierarchies.

Here α and β take only the values 1 and 2. From the experimental limits on active neutrino masses we obtain $(Y_\nu)_{i\alpha} \lesssim 10^{-12}$. This can be compared to $(Y_\nu)_{i3} \lesssim 10^{-5}$, which is less constrained because of the TeV scale seesaw suppression. It has been pointed out in ref. [25, 26] (and earlier in a different context [7]) that this theory predicts the existence of two light sterile neutrinos which are degenerate or lighter than the active neutrinos, a so-called 3 + 2 neutrino model. A sample possible spectrum is displayed in figure 1.

Recently, it has been shown in [27] that precision cosmology and big-bang nucleosynthesis mildly favor extra radiation in the universe beyond photons and ordinary neutrinos, lending support to the existence of sub-eV sterile neutrinos.

Charginos and charged leptons: in this theory the chargino mass matrix, in the basis $(e_j^c, \tilde{W}^+, \tilde{H}_u^+)$ and $(e_i, \tilde{W}^-, \tilde{H}_d^-)$, is given by

$$\mathcal{M}_{\tilde{\chi}^\pm} = \begin{pmatrix} 0 & M_C \\ M_C^T & 0 \end{pmatrix}, \quad (4.8)$$

with

$$M_C = \begin{pmatrix} -\frac{1}{\sqrt{2}} Y_e^{ij} v_d & 0 & \frac{1}{\sqrt{2}} Y_e^{ij} v_L^j \\ \frac{1}{\sqrt{2}} g_2 v_L^i & M_2 & \frac{1}{\sqrt{2}} g_2 v_d \\ -\frac{1}{\sqrt{2}} Y_\nu^{ij} v_R^j & \frac{1}{\sqrt{2}} g_2 v_u & \mu \end{pmatrix}. \quad (4.9)$$

Squarks and sleptons: in the sfermion sector, the mass matrices \mathcal{M}_u^2 , and \mathcal{M}_d^2 for squarks, and \mathcal{M}_e^2 for charged sleptons, in the basis $(\tilde{f}, \tilde{f}^{c*})$, are given by

$$\mathcal{M}_u^2 = \begin{pmatrix} m_{\tilde{Q}}^2 + m_u^2 + \left(\frac{1}{2} - \frac{2}{3} s_W^2\right) M_Z^2 c_{2\beta} + \frac{1}{3} D_{\text{BL}} & \frac{1}{\sqrt{2}} (a_u v_u - Y_u \mu v_d) \\ \frac{1}{\sqrt{2}} (a_u v_u - Y_u \mu v_d) & m_{\tilde{u}^c}^2 + m_u^2 + \frac{2}{3} M_Z^2 c_{2\beta} s_W^2 - \frac{1}{3} D_{\text{BL}} \end{pmatrix}, \quad (4.10)$$

$$\mathcal{M}_d^2 = \begin{pmatrix} m_{\tilde{Q}}^2 + m_d^2 - \left(\frac{1}{2} - \frac{1}{3} s_W^2\right) M_Z^2 c_{2\beta} + \frac{1}{3} D_{\text{BL}} & \frac{1}{\sqrt{2}} (Y_d \mu v_u - a_d v_d) \\ \frac{1}{\sqrt{2}} (Y_d \mu v_u - a_d v_d) & m_{\tilde{d}^c}^2 + m_d^2 - \frac{1}{3} M_Z^2 c_{2\beta} s_W^2 - \frac{1}{3} D_{\text{BL}} \end{pmatrix}, \quad (4.11)$$

$$\mathcal{M}_e^2 = \begin{pmatrix} m_{\tilde{L}}^2 + m_e^2 - \left(\frac{1}{2} - s_W^2\right) M_Z^2 c_{2\beta} - D_{\text{BL}} & \frac{1}{\sqrt{2}} (Y_e \mu v_u - a_e v_d) \\ \frac{1}{\sqrt{2}} (Y_e \mu v_u - a_e v_d) & m_{\tilde{e}^c}^2 + m_e^2 - M_Z^2 c_{2\beta} s_W^2 + D_{\text{BL}} \end{pmatrix}, \quad (4.12)$$

where $c_{2\beta} = \cos 2\beta$, $s_W = \sin \theta_W$ and

$$D_{\text{BL}} \equiv \frac{1}{8} g_{\text{BL}}^2 v_R^2 = \frac{1}{2} M_{Z_{\text{BL}}}^2. \quad (4.13)$$

m_u , m_d and m_e are the respective fermion masses and a_u , a_d and a_e are the trilinear a -terms corresponding to the Yukawa couplings Y_u , Y_d and Y_e . Typically, it is assumed that substantial left-right mixing occurs only in the third generation. Regardless, the physical states are related to the gauge states by

$$\begin{pmatrix} \tilde{f}_1 \\ \tilde{f}_2 \end{pmatrix} = \begin{pmatrix} \cos \theta_{\tilde{f}} & \sin \theta_{\tilde{f}} \\ -\sin \theta_{\tilde{f}} & \cos \theta_{\tilde{f}} \end{pmatrix} \begin{pmatrix} \tilde{f} \\ \tilde{f}^{c*} \end{pmatrix}. \quad (4.14)$$

The masses in the sneutrino sector are given by

$$M_{\tilde{\nu}_i}^2 = m_{\tilde{L}_i}^2 + \frac{1}{2} M_Z^2 \cos 2\beta - \frac{1}{2} M_{Z_{\text{BL}}}^2, \quad (4.15)$$

$$M_{\tilde{\nu}_3^c}^2 = M_{Z_{\text{BL}}}^2, \quad (4.16)$$

$$M_{\tilde{\nu}_\alpha^c}^2 = m_{\tilde{\nu}_\alpha^c}^2 + D_{\text{BL}}, \quad (4.17)$$

and $\alpha = 1 \dots 2$. For simplicity we listed the mass matrices in the limit $v_L^i, a_\nu, Y_\nu \rightarrow 0$. For the most general expressions see appendix A. It is important to mention that all sfermion masses are modified due to the existence of the B-L D-term.

In order to understand the properties of the spectrum we assume a simplified spectrum for the superpartners. In the case of the sfermions we will assume for simplicity the same value for all soft masses. In this case if we neglect the left-right mixing the full spectrum of sfermions will be defined by M_{SUSY} (the universal soft supersymmetry breaking mass), $\tan \beta$ and the mass of the B-L gauge boson. Using this simplified spectrum we show in figure 2 the values for the sfermion masses for different values of $M_{Z_{\text{BL}}}$. Notice that the condition that left-handed slepton masses have to be positive impose a bound on the $M_{Z_{\text{BL}}}$ for a given value of M_{SUSY} , i.e. $M_{Z_{\text{BL}}} < \sqrt{2} M_{\tilde{L}}$. In this way, we can appreciate that the spectrum can be very constrained. As it is well-known, in the general case one cannot predict the spectrum since the soft masses are unknown.

5 Nucleon stability and dark matter

It is well-known that when R-parity is broken in a supersymmetric theory one has to understand the possible constraints coming from proton decay [28]. In the MSSM one has several interactions which could mediate proton decay at tree level and one-loop level. At the renormalizable level one has the lepton and baryon number violating interactions

$$\mathcal{W}_{RpV} = \epsilon \hat{L} \hat{H}_u + \lambda \hat{L} \hat{L} \hat{e}^c + \lambda' \hat{Q} \hat{L} \hat{d}^c + \lambda'' \hat{u}^c \hat{d}^c \hat{d}^c, \quad (5.1)$$

which are not allowed in our theory before B-L breaking, and in general one has the dimension five operators

$$\mathcal{W}_{RpC}^5 = \frac{\lambda_\nu}{\Lambda} \hat{L} \hat{L} \hat{H}_u \hat{H}_u + \frac{\lambda_L}{\Lambda} \hat{Q} \hat{Q} \hat{Q} \hat{L} + \frac{\lambda_R}{\Lambda} \hat{u}^c \hat{d}^c \hat{u}^c \hat{e}^c + \frac{\lambda_{\nu^c}}{\Lambda} \hat{u}^c \hat{d}^c \hat{d}^c \hat{\nu}^c. \quad (5.2)$$

Figure 2. Spectrum for sfermion masses assuming the same value for all soft masses, $M_{\text{SUSY}} = 1 \text{ TeV}$ and $\tan \beta = 5$.

Notice that the first term in the above equation is not allowed in our theory, but the last terms can mediate proton decay. The operators $QQQL$ and $u^c d^c u^c e^c$ mediate proton decay at one-loop level and typically the scale Λ should be larger than 10^{17} GeV in order to satisfy the experimental bounds on proton decay. For a detailed discussion see ref. [28]. Once B-L is broken by the vev of the right-handed sneutrinos one finds new contributions to proton decay at tree level. From the Yukawa coupling $Y_\nu \hat{L} \hat{H}_u \hat{\nu}^c$ one gets the lepton number violating interaction $L \tilde{H}_u$ and from the last term, $\hat{u}^c \hat{d}^c \hat{d}^c \hat{\nu}^c$, in the above equation one gets the interaction $\tilde{u}^c d^c s^c$. Using these interactions and integrating out the neutralinos and squarks we find the following constraint

$$\frac{\lambda_{\nu^c}^{1123} Y_u Y_\nu^{i3} v_R^2}{\Lambda M_{\tilde{u}}^2 2M_{\tilde{\chi}^0}} < 10^{-30} \text{ GeV}^{-2}, \tag{5.3}$$

from the channel $p \rightarrow K^+ \nu$. Then, assuming that $\lambda_{\nu^c}^{1123} \sim 1$, and $Y_\nu^{i3} \sim 10^{-6}$ (see figure 4) one gets $\Lambda > 10^{17} \text{ GeV}$. This constrain is similar to the one we get from the dimension five operators. Therefore, one can say that if the above couplings are order one the cutoff of the theory has to be large. Also one can think about possible scenarios where the couplings are small, see for example [29].

At first glance, finding a dark matter in R -parity violating theories seems hopeless. But while the traditional neutralino LSP case is no longer valid, the situation is not lost. As first discussed in [30, 31], such models can have an unstable LSP gravitino, with a lifetime longer than the age of the universe. The strong suppression on its lifetime is due to both the planck mass (M_P) suppression associated with its interaction strength and bilinear R -parity violation which is small due to neutrino masses and must facilitate the decay of the LSP. In the mass insertion approximation, this can be understood as the gravitino going

Figure 3. Gravitino decay into a photon and a neutrino.

into a photon and neutralino which then has some small mixing with the neutrino due to R -parity violation ($m_{\chi\nu}$), thereby allowing $\tilde{G} \rightarrow \gamma\nu$ as in figure 3. Adopting approximations made in [30, 31], the lifetime for the gravitino decaying into a photon and neutrino (in years) is about

$$\tau(\tilde{G} \rightarrow \gamma\nu) \sim 2 \times 10^{10} \left(\frac{m_{3/2}}{100 \text{ GeV}} \right)^{-3} \left(\frac{m_{\chi\nu}/m_\chi}{10^{-6}} \right)^{-2} \text{ years}, \quad (5.4)$$

which for appropriate values of the gravitino mass leads to a long enough life time. Unlike in R -parity conserving models with a gravitino LSP, there are no issues with big bang nucleosynthesis from slow NLSP decay since the NLSP decays more promptly through R -parity violating interactions. Several interesting studies have been conducted on the signatures and constraints of unstable gravitino dark matter, see for example [30–33].

6 Experimental constraints

In order to understand the different lepton number violating decays in the theory we need to understand which are the main constraints from neutrino experiments. Today, we know well the numerical values for two of the neutrino mixings and the mass squared differences. The neutrino mixing matrix V_{PMNS} is defined as

$$V_{PMNS} = \begin{pmatrix} c_{12} c_{13} & c_{13} s_{12} & s_{13} \\ -c_{23} s_{12} - c_{12} s_{13} s_{23} & c_{12} c_{23} - s_{12} s_{13} s_{23} & c_{13} s_{23} \\ s_{12} s_{23} - c_{12} c_{23} s_{13} & -c_{12} s_{23} - c_{23} s_{12} s_{13} & c_{13} c_{23} \end{pmatrix}, \quad (6.1)$$

where $c_{ij} = \cos \theta_{ij}$ and $s_{ij} = \sin \theta_{ij}$ with $0 \leq \theta_{ij} \leq \pi/2$. The physical neutrino masses are contained in $m_\nu = \text{diag}(m_{\nu_1}, m_{\nu_2}, m_{\nu_3})$. As it is well-known, there are two possible neutrino spectra:

$$\text{Normal Hierarchy (NH): } m_{\nu_1}, m_{\nu_2} = \sqrt{m_{\nu_1}^2 + \Delta m_{21}^2}, m_{\nu_3} = \sqrt{m_{\nu_1}^2 + |\Delta m_{31}^2|}, \quad (6.2)$$

$$\text{Inverted Hierarchy (IH): } m_{\nu_1} = \sqrt{m_{\nu_3}^2 + |\Delta m_{31}^2|}, m_{\nu_2} = \sqrt{m_{\nu_1}^2 + \Delta m_{21}^2}, m_{\nu_3},$$

where [34]

$$7.27 \times 10^{-5} \text{ eV}^2 \leq \Delta m_{21}^2 \leq 8.03 \times 10^{-5} \text{ eV}^2, \quad (6.3)$$

$$2.17 \times 10^{-3} \text{ eV}^2 < |\Delta m_{31}^2| < 2.54 \times 10^{-3} \text{ eV}^2, \quad (6.4)$$

are the solar and atmospheric mass squared differences, respectively.

In order to understand the allowed values for the vevs of the left-handed sneutrinos and the Dirac Yukawa couplings we assume for simplicity that the off-diagonal block matrices in eq. (4.5) are zero, hence decoupling the two light sterile neutrinos from the active ones. In this case, all neutrino masses and mixing originate from the upper-left block matrix in eq. (4.5), which we label m_ν . The flavor pattern, and hence the rank of this matrix, dictates that one neutrino will be massless. This matrix is diagonalized by the PMNS matrix

$$m_\nu = V_{\text{PMNS}}^T M_\nu V_{\text{PMNS}}, \quad (6.5)$$

where $m_\nu = \text{diag}(0, \sqrt{\Delta m_{21}^2}, \sqrt{|\Delta m_{31}^2|})$ in the Normal Hierarchy and $m_\nu = \text{diag}(\sqrt{|\Delta m_{31}^2|}, \sqrt{|\Delta m_{31}^2| + \Delta m_{21}^2}, 0)$ in the Inverted Hierarchy. This yields a system of six equations quadratic in the vevs of the right-handed sneutrinos and Yukawa couplings, although solving for these is not the most efficient way to proceed. Instead, notice that the product above yields the following six terms

$$\begin{aligned} V^j &\equiv v_L^i V_{\text{PMNS}}^{ij}, \\ Y^j &\equiv Y_\nu^{i3} V_{\text{PMNS}}^{ij}. \end{aligned} \quad (6.6)$$

- Normal Hierarchy

In the Normal Hierarchy one obtains the following six equations

$$AV_1^2 + 2BV_1Y_1 + CY_1^2 = 0, \quad (6.7)$$

$$AV_1V_2 + B(V_1Y_2 + V_2Y_1) + CY_1Y_2 = 0, \quad (6.8)$$

$$AV_1V_3 + B(V_1Y_3 + V_3Y_1) + CY_1Y_3 = 0, \quad (6.9)$$

$$AV_2V_3 + B(V_2Y_3 + V_3Y_2) + CY_2Y_3 = 0, \quad (6.10)$$

$$AV_2^2 + 2BV_2Y_2 + CY_2^2 = m_2, \quad (6.11)$$

$$AV_3^2 + 2BV_3Y_3 + CY_3^2 = m_3. \quad (6.12)$$

In order for these equations to be consistent, $V_1 = Y_1 = 0$. While this condition represents some fine-tuning between parameters, it is a result of the simplifying assumption that the sterile and active light states decouple. In a more general scenario, this condition would not be necessary.

The remaining system of equations, the last three, is underdetermined with three equations and four unknowns. Solving with respect to Y_3 yields

$$Y_2 = \epsilon_1 \sqrt{\frac{m_2}{m_3}} \sqrt{\frac{-Y_3^2 R - Am_3}{R}}, \quad (6.13)$$

$$V_3 = \frac{-BY_3 + \epsilon_3 \sqrt{Y_3^2 R + Am_3}}{A}, \quad (6.14)$$

$$V_2 = \frac{-BY_2 + \epsilon_2 \sqrt{Y_2^2 R + Am_2}}{A}, \quad (6.15)$$

with

$$R \equiv B^2 - AC, \quad \epsilon_1 = \pm 1, \quad \epsilon_2 = \pm 1, \quad \epsilon_3 = \frac{\epsilon_1}{\epsilon_2} \frac{RY_3}{\sqrt{R^2 Y_3^2}}. \quad (6.16)$$

Parameter	Range
M_1	100–1200 GeV
M_2	100–1200 GeV
$ \mu $	100–1200 GeV
$\tan \beta$	3–50
$ Y_3 $	10^{-7} – 10^{-5}
M_{BL}	100–1200 GeV
$M_{Z_{\text{BL}}}$	1000 GeV
g_{BL}	0.33

Table 1. Parameters and ranges scanned for the plots in figures 4, 8–13.

Inverting eq. (6.6) one translates these solutions to the variables of interest. The result being that specifying the SUSY spectrum and B-L parameters ($M_{Z_{\text{BL}}}$ and g_{BL}) as well as Y_3 specifies all the values for v_L^i and Y_ν^{i3} .

- Inverted Hierarchy

In the case of the inverted spectrum one can use the same procedure. However, one needs to make the following replacements: $m_1 \leftrightarrow m_3$, $Y_1 \leftrightarrow Y_3$, $V_1 \leftrightarrow V_3$. In this way when we solve the equations for V_i and Y_i , one obtains $V_3 = 0$, $Y_3 = 0$ and the solutions above where we have made the previous substitutions.

In figure 4 we show the allowed values for the vevs of the left-handed sneutrinos and the Dirac Yukawa couplings for a scan over the parameters listed in table 1. As one can appreciate the allowed values for v_L^i are in the range $(10^{-2} - 10)$ MeV while the Yukawa couplings change between 10^{-7} and 10^{-5} . Now, using these results we are ready to discuss all R-parity violating decays.

7 Lepton number violation and decays

At this point, the relevant pieces of this model have been laid out and the question of interesting signals can now be tackled. Since lepton number is violated, same-sign dileptons and multijet are possible final states. Such signatures are interesting since they have no SM background. However, the final states depend critically on the nature of the LSP and since R-parity is violated the possibilities are more numerous than normal, *i.e.* colored and charged fields.

These possibilities are briefly discussed in appendix D. We find that the most clear single of lepton number violation (and therefore the most interesting for us) results from the decays of a neutralino LSP through the process (see figure 5):³

$$pp \rightarrow \gamma^*, Z^*, Z_{\text{BL}}^* \rightarrow \tilde{e}_i^* \tilde{e}_i \rightarrow e_i^\pm e_i^\mp e_j^\mp e_k^\mp 4j.$$

³Throughout this paper, shorthand such as $pp \rightarrow \tilde{e}^* \tilde{e}$ represents the process $pp \rightarrow \tilde{e}^* \tilde{e} + X$, where the activity associated with X has low transverse momentum and is not associated with the relevant physics of interest. Alternatively, this notation represents all possible production methods of $\tilde{e}^* \tilde{e}$ from the partons inside the proton taking their respective parton distribution functions into account.

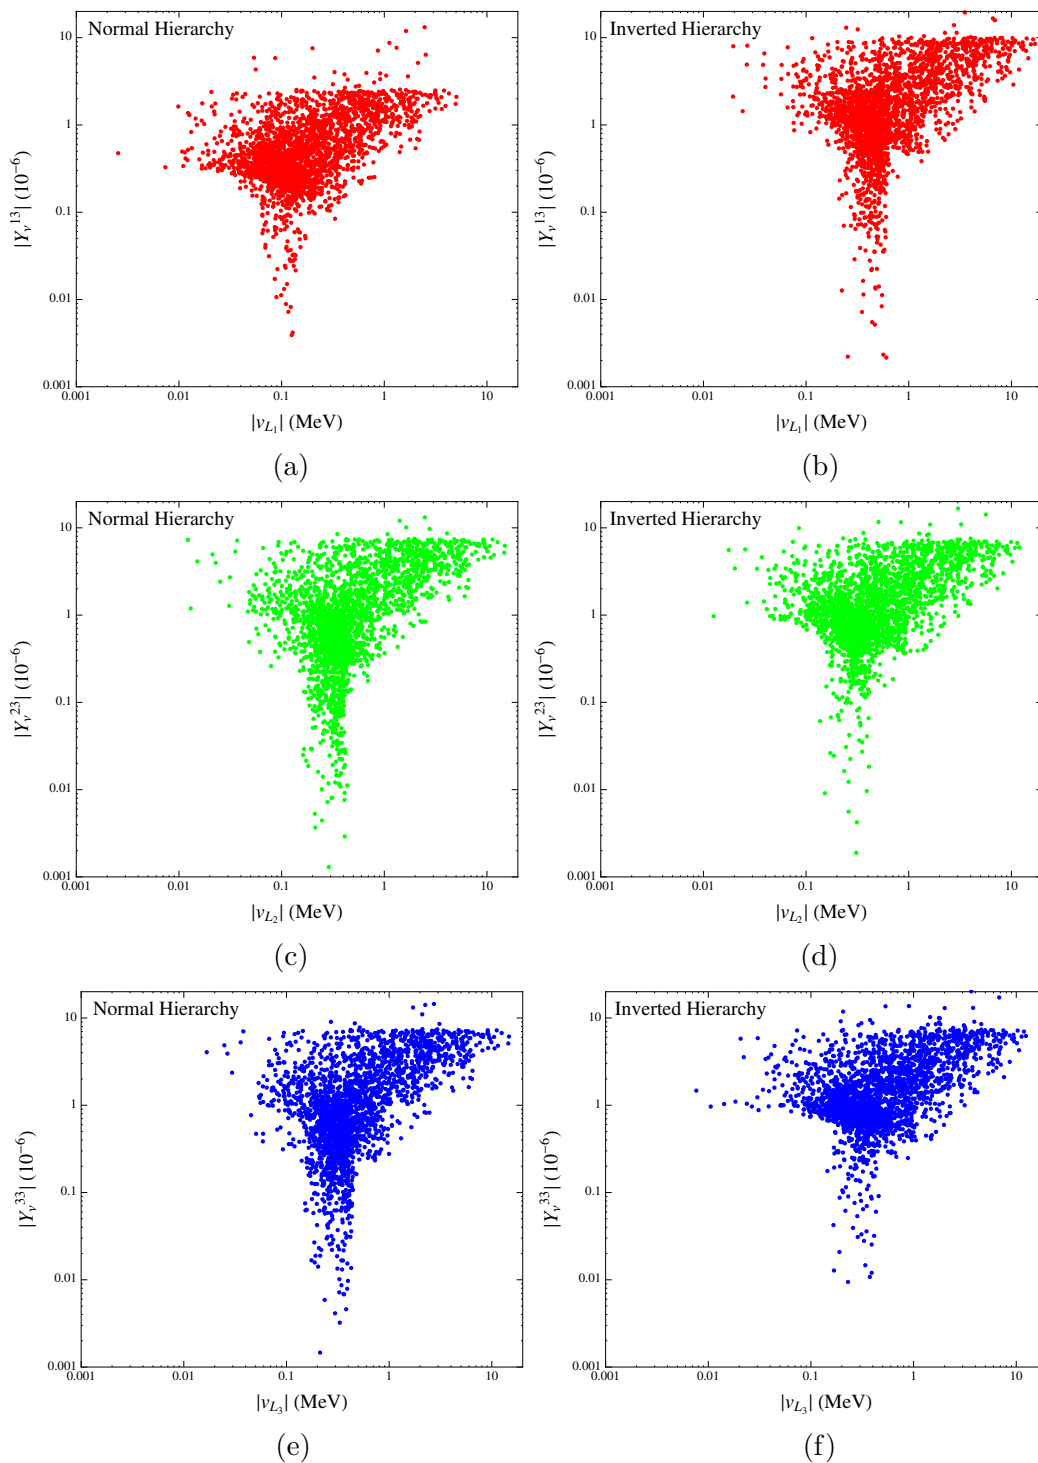

Figure 4. Allowed values for the v_L^i versus $(Y_{\nu})_{i3}$ in agreement with the neutrino masses and mixings constraints in the NH (IH) in a,c and e (b,d and f) for a scan over the parameters listed in table 1.

Figure 5. Topology of the signals with multi-leptons.

In order to quantify this signal we will continue by investigating the decays of the Z_{BL} gauge boson, the charged slepton and the neutralino and in the next section, the production mechanism for the charged sleptons at the LHC.

7.1 B-L gauge boson decays

The Z_{BL} boson can decay into a pair of charged fermions, light neutrinos, and into two sfermions. The partial widths for the decay into particles P_1, P_2 of masses m_1, m_2 are given by

$$\Gamma(Z_{BL} \rightarrow P_1 P_2) = \frac{1}{16\pi M_{Z_{BL}}} |\overline{\mathcal{M}}(Z_{BL} \rightarrow P_1 P_2)|^2 \times \sqrt{\left(1 - \frac{(m_1 + m_2)^2}{M_{Z_{BL}}^2}\right) \left(1 - \frac{(m_1 - m_2)^2}{M_{Z_{BL}}^2}\right)}, \quad (7.1)$$

where the squared matrix elements for specific final states are in appendix B. The Z_{BL} branching ratios are plotted in figure 6 for a fixed soft universal mass for all sfermions, $M_{SUSY} = 1$ TeV, versus the Z_{BL} mass. Decay channels into SUSY particles only open up for a Z_{BL} mass of around 1.2 TeV and at much 1.4 TeV, the sleptons become tachyonic. As can be appreciated from figure 2, tachyonic sleptons are reached before decay channels into the squarks can open. The branching ratios for the sleptons are divided up into sneutrinos, smuons plus selectrons and staus in anticipation of the associated signals. However, each individual slepton pair has the same branching ratio, about 2.5% at $m_{Z_{BL}} = 1.4$ TeV. In figure 7 we show the predictions for the total decay width and the invisible decays of the Z_{BL} gauge boson. Since the new gauge boson can decay into five light neutrinos the invisible decay can be large, a few GeV when the mass is above 1 TeV. These properties of the Z_{BL} are very important in order to discover this theory at the LHC. In summary, one

Figure 6. Z_{BL} branching ratios versus Z_{BL} mass for a universal soft mass for all sfermions, $M_{\text{SUSY}} = 1 \text{ TeV}$. Here the subscript one refers to the lightest eigenstate in each family and this case corresponds to the purely left-handed slepton (zero mixing angle is assumed). Given the universal soft mass for the sfermions, only the left-handed slepton channels can be open. Right-handed squark channels can open for larger values of $M_{Z_{\text{BL}}}$ but only at the cost of unphysical tachyonic slepton masses.

can say that the new neutral gauge boson is B-L like with branching ratios

$$\begin{aligned} \text{Br}(Z_{\text{BL}} \rightarrow e_1^+ e_1^-) &\sim 40\%, & \text{Br}(Z_{\text{BL}} \rightarrow \nu\nu) &\sim 35\%, \\ \text{Br}(Z_{\text{BL}} \rightarrow jj) &\sim 20\%, & \text{and } \text{Br}(Z_{\text{BL}} \rightarrow \bar{t}t) &\sim 5\%, \end{aligned} \quad (7.2)$$

since the branching ratios for the SUSY decays are small and the invisible decay can be large. For example when $M_{Z_{\text{BL}}} = 1.2 \text{ TeV}$ the invisible decay width is $\Gamma_{Z_{\text{BL}}}(\text{invisible}) \sim 3 \text{ GeV}$.

7.2 Charged slepton decays

The leading decay channels for the charged left-handed sleptons, \tilde{e}_i^\pm , are the decays into neutralinos and charginos

$$\tilde{e}_i^\pm \rightarrow e_i^\pm \tilde{\chi}_a^0, \quad \tilde{e}_i^\pm \rightarrow \nu \tilde{\chi}_A^\pm, \quad \tilde{e}_i^\pm \rightarrow \tilde{\nu}_j W^\pm,$$

where i, j are lepton generational indices, a labels the neutralinos from lightest to heaviest and A labels the charginos from lightest to heaviest. In addition to these decay modes there are various R -parity violating decays which only dominate when the slepton is the LSP. The last channel above usually involves an off-shell product particle (a three-body decay)

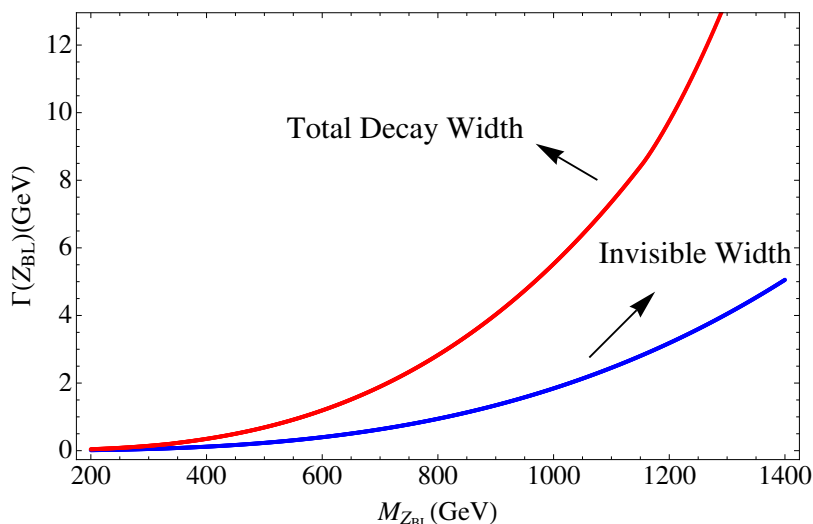

Figure 7. The total decay width, $\Gamma(Z_{BL})$, versus Z_{BL} mass for a universal soft mass for all sfermions, $M_{SUSY} = 1$ TeV.

and is therefore suppressed. The decay widths for the remaining two relevant channels are given by

$$\Gamma(\tilde{e}_i^\pm \rightarrow e_i^\pm \tilde{\chi}_a^0) = \frac{m_{\tilde{e}_i}}{32\pi} \left(|g_{BL}N_{2a} + g_1N_{3a} + g_2N_{4a}|^2 + \left| \frac{2\sqrt{2}m_{e_i}}{v_d} N_{5a} \right|^2 \right) \left(1 - \frac{m_{\tilde{\chi}_a^0}^2}{m_{\tilde{e}_i}^2} \right)^2, \quad (7.3)$$

$$\Gamma(\tilde{e}_i^\pm \rightarrow \nu_j \tilde{\chi}_A^\pm) = \frac{m_{\tilde{e}_i}}{16\pi} |g_2V_{1A}^-|^2 \left(1 - \frac{m_{\tilde{\chi}_A^\pm}^2}{m_{\tilde{e}_i}^2} \right)^2, \quad (7.4)$$

where N_{ab} diagonalizes the neutralino mass matrix and in the chargino sector one has $V^-XV^+ = \text{diag}(m_{\tilde{\chi}_1}, m_{\tilde{\chi}_2})$. Due to the presence of the right-handed neutrino and \tilde{B}' , position 2, 3, 4 and 5 in the N refer to \tilde{B}' , \tilde{B} , \tilde{W} and, \tilde{H}_d , respectively. While it is hard to make predictions for the branching ratios of the charged sleptons decaying into a charged lepton and LSP without knowing the details of the spectrum, we briefly outline the best case scenario. Our final results will be given both with this best case scenario in mind and with arbitrary $\text{Br}(\tilde{e}_i \rightarrow e_i \tilde{\chi}_1^0)$.

For a mostly bino LSP, it is possible that charged selectrons decay one hundred percent into the LSP since the charginos and other neutralinos could be heavier. For a wino LSP however, the lightest chargino channel is very likely to be open. Because of the factor of 2 difference between eq. (7.3), and eq. (7.4) if all other neutralinos and charginos are kinematically disallowed, one can expect

$$\frac{\Gamma(\tilde{e}_i^\pm \rightarrow e_i^\pm \tilde{\chi}_1^0)}{\Gamma(\tilde{e}_i^\pm \rightarrow \nu_j \tilde{\chi}_1^\pm)} \sim \frac{1}{2}, \quad (7.5)$$

meaning a 33% branching ratio for a charged slepton into a wino LSP. Meanwhile, the left-handed selectron does not couple to the charged Higgsino. Therefore, in the same limit

where all other neutralinos and charginos are out of kinematic range, the charged sleptons decays one hundred percent into the LSP for a Higgsino LSP.

7.3 Neutralino decays

The leading decay channels for the lightest neutralino, $\tilde{\chi}_1^0$, include

$$\tilde{\chi}_1^0 \rightarrow e_i^\pm W^\mp, \quad \tilde{\chi}_1^0 \rightarrow \nu_i Z, \quad \tilde{\chi}_1^0 \rightarrow \nu_i h_k, \quad \tilde{\chi}_1^0 \rightarrow e_i^\pm H^\mp. \quad (7.6)$$

The amplitude for the two first channels are proportional to the mixing between the leptons and neutralinos, while the last one is proportional to the Dirac-like Yukawa terms. While decays to all the MSSM Higgses are possible, typically, only the lightest MSSM Higgs, h ($k = 1$), is light enough for the scenario we consider here and so we will only take it into account.

A naive estimation of the decay width yields

$$\Gamma(\tilde{\chi}_1^0) \sim \frac{g_2^2}{32\pi} |V_{\nu\chi}|^2 M_\chi, \quad (7.7)$$

where $V_{\chi\nu}$ is the mixing between the neutralino and neutrino which is proportional to $\sqrt{m_\nu/M_\chi}$. Assuming that $m_\nu < 0.1$ eV the decay length one finds $L(\tilde{\chi}_1^0) \gg 0.6$ mm. Therefore, even without making a detailed analysis of the decays of the lightest neutralino one expects signals with lepton number violation and displaced vertices in part of the parameter space. For a recent analysis of the neutralino decays in R-parity violating models see ref. [35, 36].

The specific decay width expressions are

$$\Gamma^{e_i W_L} \equiv \Gamma(\tilde{\chi}_a \rightarrow e_i^\pm W_L^\mp) = \frac{g_2^2}{64\pi M_W^2} |V_{ia}|^2 m_{\tilde{\chi}_a}^3 \left(1 - \frac{m_W^2}{m_{\tilde{\chi}_a}^2}\right)^2, \quad (7.8)$$

$$\Gamma^{e_i W_T} \equiv \Gamma(\tilde{\chi}_a \rightarrow e_i^\pm W_T^\mp) = \frac{g_2^2}{32\pi} |V_{ia}|^2 m_{\tilde{\chi}_a} \left(1 - \frac{m_W^2}{m_{\tilde{\chi}_a}^2}\right)^2, \quad (7.9)$$

$$\Gamma^{\nu_i Z_L} \equiv \Gamma(\tilde{\chi}_a \rightarrow \nu_i Z_L) = \frac{g_2^2}{64\pi M_W^2} |V_{ia}|^2 m_{\tilde{\chi}_a}^3 \left(1 - \frac{m_Z^2}{m_{\tilde{\chi}_a}^2}\right)^2, \quad (7.10)$$

$$\Gamma^{\nu_i Z_T} \equiv \Gamma(\tilde{\chi}_a \rightarrow \nu_i Z_T) = \frac{g_2^2}{32\pi c_W^2} |V_{ia}|^2 m_{\tilde{\chi}_a} \left(1 - \frac{m_Z^2}{m_{\tilde{\chi}_a}^2}\right)^2, \quad (7.11)$$

$$\Gamma^{\nu_i h} \equiv \Gamma(\tilde{\chi}_a \rightarrow \nu_i h) = \frac{g_2^2}{64\pi M_W^2} |V_{ia}|^2 \cos^2 \alpha m_{\tilde{\chi}_a}^3 \left(1 - \frac{m_h^2}{m_{\tilde{\chi}_a}^2}\right)^2. \quad (7.12)$$

Here α is the mixing angle in the Higgs sector and in the decoupling limit, $M_A^2 \gg M_Z^2$, which we assume: $\cos \alpha = \sin \beta$. The index i indicates the generation of lepton and a the neutralino with $a = 6$ is the heaviest and $a = 1$ is the lightest. These expressions depend on the mixing between the light neutrinos and the neutralinos, V_{ia} , which is derived in appendix C. Of course, only the decays of the LSP are relevant since the decays of the other neutralinos will be dominated by R-parity conserving decays, hence $a = 1$ for our

Hierarchy	LSP Personality	Bino	Wino	Higgsino
NH	Decay Length	1.1 mm	0.03 mm	1×10^{-4} mm

Table 2. Values of interest for a sample point in parameter space: $\epsilon_1 = \epsilon_2 = 1, Y_3 = Y_1 = 10^{-6}, M_{Z_{BL}} = M_{\tilde{B}'} = 1$ TeV, $\tan\beta = 5$ and $m_h = 125$ GeV. Here M_1, M_2 and μ are 100 GeV, 500 GeV and 500 GeV for the bino LSP case, 500 GeV, 150 GeV and 500 GeV for the wino LSP case and 500 GeV, 500 GeV and 100 GeV for the Higgsino LSP case respectively.

purposes. Table 2 displays the values of interest for a specific point in parameter space to gain an appreciation for possible values. Notice that in these scenarios the branching ratios for the channels with charged leptons can be large.

In figures 8–10 are the decay lengths versus LSP mass resulting from a scan over all the possible values of ϵ_1 and ϵ_2 and over the parameters and ranges specified in table 1. The points are divided according to the largest component of the LSP and the neutrino hierarchy with a dominantly bino, wino and Higgsino LSP in the NH shown in (a) and for an IH in (b), respectively. The relevant decay lengths can be understood by studying the mixings in eq. (4.4). Since the higgsino-neutrino decay strength is the largest, $\sim Y_\nu v_R$, the Higgsino LSP has the shortest decay length. It is followed by the wino LSP with mixing $\sim g_2 v_L$ and finally the bino with coupling $\sim g_1 v_L$ and therefore the largest possible decay lengths. Displaced vertices associated with the lifetime of the LSP will only be discernible in a very limited part of the parameter space.

The LSP branching ratios into the various possible channels versus the LSP mass are displayed in figures 11–13 scanning over the parameters in table 1 and plotting the dominantly bino, wino and Higgsino LSP in (a) for a NH and in (b) for an IH. The lack of variance with scanned parameters displayed in the νZ and νh channels are due to the sum over all three flavors of neutrinos and also exists for the sum over the three charged lepton plus W^\pm channels which total about 50% (or more if the other channels hadn't fully turned on yet). Although it is not obvious from the figures 11–13, the branching ratio to the electron W^\pm channel is always smaller than either the $\mu^\mp W^\pm$ or the $\tau^\mp W^\pm$ in the NH. Since we now know the properties of the neutralinos and selectrons decays we are ready to study the production channels.

Figure 8. Decay length in millimeters versus LSP mass for a dominantly bino LSP in (a) for a NH and in (b) for an IH. Parameters are scanned according to the ranges specified in table 1 and over all values of ϵ_1 and ϵ_2 .

Figure 9. Decay length in millimeters versus LSP mass for a dominantly wino LSP in (a) for a NH and in (b) for an IH. Parameters are scanned according to the ranges specified in table 1 and over all values of ϵ_1 and ϵ_2 .

8 Production and signals

The lepton number violating signal discussed in the beginning of the previous section proceeds from the pair production of charged sleptons. While the MSSM contributions to this production drop rapidly with charged slepton mass (since that mass must be above the Z threshold), in this model further contributions due to the Z' resonance can significantly increase the cross section. These enhancement are discussed first followed by a study of the expected number of events at the LHC.

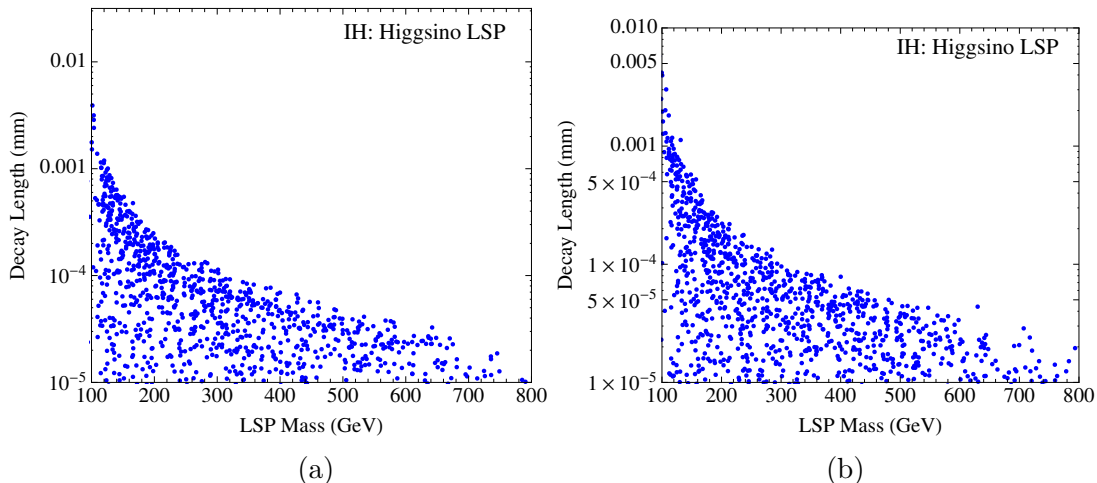

Figure 10. Decay length in millimeters versus LSP mass for a dominantly Higgsino LSP in (a) for a NH and in (b) for an IH. Parameters are scanned according to the ranges specified in table 1 and over all values of ϵ_1 and ϵ_2 .

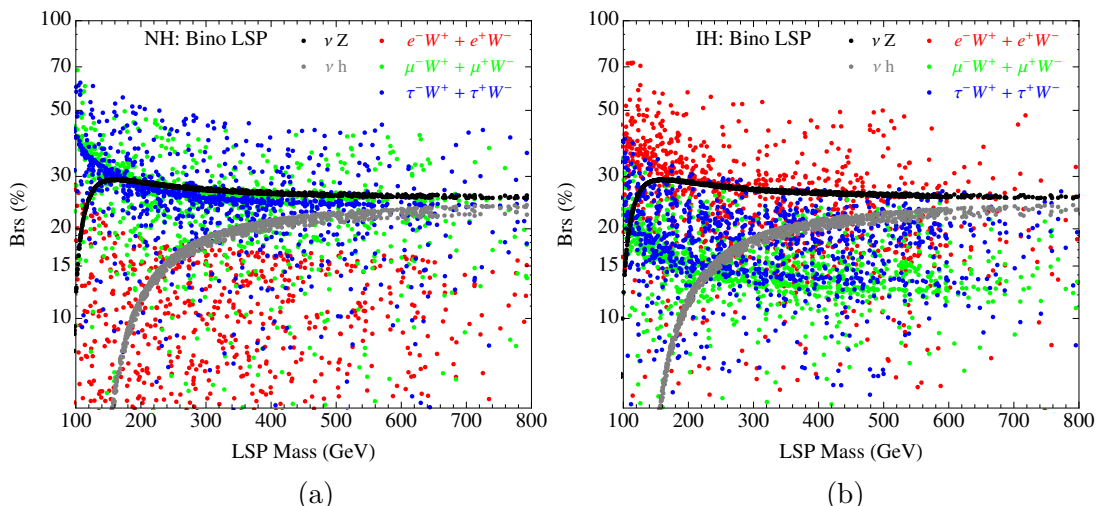

Figure 11. LSP branching ratios versus LSP mass for a dominantly bino LSP in (a) for a NH and in (b) for an IH. Parameters are scanned according to the ranges specified in table 1 and over all values of ϵ_1 and ϵ_2 .

8.1 Sleptons production mechanisms

The main production channel for the charged sleptons is through the photon, the Z gauge boson and the Z_{BL} boson

$$q(p_1)\bar{q}(p_2) \rightarrow \gamma, Z^*, Z_{BL}^* \rightarrow \tilde{e}^*(p_3)\tilde{e}(p_4).$$

The hadronic cross section is given by

$$d\sigma_{pp \rightarrow \tilde{e}^* \tilde{e}}(s) = \sum_{q=u,d,c,s} \int_{\tau_0}^1 d\tau \frac{d\mathcal{L}_{q\bar{q}}^{pp}}{d\tau} d\hat{\sigma}_{q\bar{q} \rightarrow \tilde{e}^* \tilde{e}}(\hat{s}), \tag{8.1}$$

Figure 12. LSP branching ratios versus LSP mass for a dominantly wino LSP in (a) for a NH and in (b) for an IH. Parameters are scanned according to the ranges specified in table 1 and over all values of ϵ_1 and ϵ_2 .

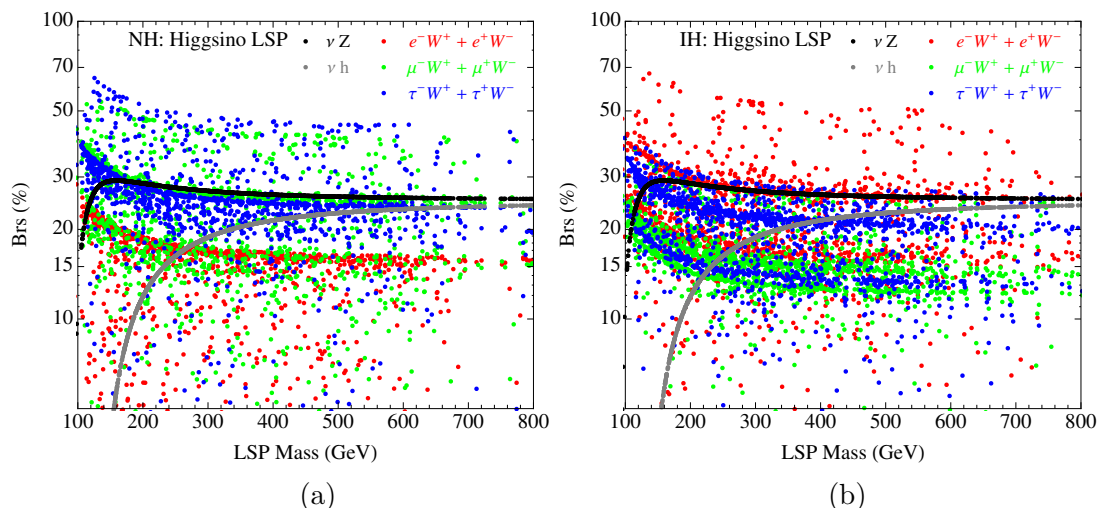

Figure 13. LSP branching ratios versus LSP mass for a dominantly Higgsino LSP in (a) for a NH and in (b) for an IH. Parameters are scanned according to the ranges specified in table 1 and over all values of ϵ_1 and ϵ_2 .

where $\tau_0 = 4M_{\tilde{e}}^2/s$ and the differential partonic cross section is

$$d\hat{\sigma}_{q\bar{q} \rightarrow \tilde{e}^* \tilde{e}}(\hat{s}) = |\overline{\mathcal{M}}_{q\bar{q} \rightarrow \tilde{e}^* \tilde{e}}(\hat{s})|^2 \frac{d\text{PS}^{(2)}}{2\hat{s}}. \quad (8.2)$$

Here $d\text{PS}^{(2)} = d\hat{t}/8\pi\hat{s}$ is the two particle phase-space element and $\hat{s} = \tau s$, where s is the hadronic center-of-mass energy squared. As it is well-known the parton luminosities are given by

$$\frac{d\mathcal{L}_{ab}^{\text{AB}}}{d\tau} = \frac{1}{1 + \delta_{ab}} \int_{\tau}^1 \left(f_{a/A}(x, \mu) f_{b/B}\left(\frac{\tau}{x}, \mu\right) + f_{a/B}\left(\frac{\tau}{x}, \mu\right) f_{b/A}(x, \mu) \right), \quad (8.3)$$

where the functions $f_{a/A}(x, \mu)$ are the particle distribution functions (PDFs). The amplitude squared for these processes can be written as

$$|\overline{\mathcal{M}}_{q\bar{q} \rightarrow \tilde{e}^* \tilde{e}}(\hat{s})|^2 = \frac{2}{3} (\hat{u}\hat{t} - M_{\tilde{e}}^4) |\mathcal{A}_{q\bar{q} \rightarrow \tilde{e}^* \tilde{e}}(\hat{s})|^2, \quad (8.4)$$

with $\hat{s} = (p_1 + p_2)^2$, $\hat{t} = (p_1 - p_3)^2$, $\hat{u} = (p_1 - p_4)^2$ and

$$\mathcal{A}_{q\bar{q} \rightarrow \tilde{e}^* \tilde{e}}(\hat{s}) = \frac{C_{q\bar{q}\gamma} C_{\gamma\tilde{e}^* \tilde{e}}}{\hat{s}} + \frac{2C_{q\bar{q}Z} C_{Z\tilde{e}^* \tilde{e}}}{\hat{s} - M_Z^2 + iM_Z\Gamma_Z} + \frac{C_{q\bar{q}Z_{BL}} C_{Z_{BL}\tilde{e}^* \tilde{e}}}{\hat{s} - M_{Z_{BL}}^2 + iM_{Z_{BL}}\Gamma_{Z_{BL}}}, \quad (8.5)$$

where

$$\begin{aligned} C_{q\bar{q}\gamma} &= e_q e, & C_{\gamma\tilde{e}_L^* \tilde{e}_L} &= e_l e, & C_{Z\tilde{e}_L^* \tilde{e}_L} &= \frac{e}{\sin 2\theta_W} L_e, & (8.6) \\ C_{q_L q_L Z} &= \frac{eL_q}{\sin 2\theta_W}, & C_{q_R q_R Z} &= \frac{eR_q}{\sin 2\theta_W}, & C_{f\bar{f}Z_{BL}} &= g_{BL} \frac{n_{BL}^f}{2}, & C_{\tilde{f}^* \tilde{f}Z_{BL}} &= g_{BL} \frac{n_{BL}^f}{2}. & (8.7) \end{aligned}$$

Here $L_f = I_f^3 - e_f \sin^2 \theta_W$ and $R_f = -e_f \sin^2 \theta_W$, where I_f^3 is the isospin of the fermion f . Now, using the equations

$$\hat{u} = 2M_{\tilde{e}}^2 - \hat{t} - \hat{s}, \quad (8.8)$$

$$\hat{t} = M_{\tilde{e}}^2 - \frac{\hat{s}}{2} + y \sqrt{\hat{s} \left(\frac{\hat{s}}{4} - M_{\tilde{e}}^2 \right)}, \quad (8.9)$$

we can compute the cross section

$$\sigma_{pp \rightarrow \tilde{e}_L^* \tilde{e}_L}(s) = \sum_{q=u,d,s} \int_{-1}^1 dy \int_{\tau_0}^1 d\tau \frac{d\mathcal{L}_{q\bar{q}}^{pp}}{d\tau} \sigma(M_{\tilde{e}}, y, \tau, s). \quad (8.10)$$

The numerical results for the selectron production cross sections are shown in figure 14 for different scenarios, with g_{BL} assumed to be the maximum value allowed by the experimental constraints: eq. (4.2). We have compared our analytical results for the cross section with the results in ref. [38] and found the same result in the case of the MSSM. In figure 14 we can see that even in the MSSM the cross section can be large and when the Z_{BL} is included the cross section can be even larger due to the resonance enhancement. For example when the $M_{Z_{BL}} = 1$ TeV one can have a cross section above 1 fb where the selectron mass is below 450 GeV and $\sqrt{s} = 7$ TeV.

8.2 Signals with multi-leptons

In this paper we wish to investigate the most promising signals associated with lepton number violation, through the process

$$q\bar{q} \rightarrow \gamma, Z^*, Z_{BL}^* \rightarrow \tilde{e}_i^* \tilde{e}_i \rightarrow e_i^+ e_i^- \tilde{\chi}_1^0 \tilde{\chi}_1^0 \rightarrow e_i^+ e_i^- e_j^\pm e_k^\pm 4j, \quad (8.11)$$

where $i, j, k = 1 \dots 3$ are generational indices. See figure 5 for the illustration of these signals. However, we will focus on the electron and muon channels since hadronic activity

Figure 14. Drell-Yan production cross sections for the charged sleptons in our model. The dashed line corresponds to the prediction in the MSSM and the solid lines show the results in our model for different values of the Z_{BL} mass. The gauge coupling g_{BL} is assumed to be at the maximum value allowed by the experimental constraints: eq. (4.2).

associated with the tau would blemish the signal of lepton number violation, namely three same-sign leptons, one lepton with opposite sign, four jets and no missing energy. Taking a cue from eq. (4.12), which shows that the left-handed (right-handed) sleptons receive a negative (positive) contribution to their mass from the $B-L$ D -term, we assume that only the left-handed sleptons are producible through this process.

We begin by giving an estimate for the number of events in the limit of mostly bino, wino and Higgsino LSP. We present results for a 7 TeV LHC with 10 fb^{-1} of data. The combinatorics factor for the channels of interest are given by

$$\begin{aligned} \mathcal{F}_{jk} = & 2(2 - \delta_{jk}) \text{Br}(\tilde{e}_i^\pm \rightarrow e_i^\pm \tilde{\chi}_1^0)^2 \times \text{Br}(\tilde{\chi}_1^0 \rightarrow e_j^\pm W^\mp) \\ & \times \text{Br}(\tilde{\chi}_1^0 \rightarrow e_k^\pm W^\mp) \times \text{Br}(W^\pm \rightarrow jj)^2, \end{aligned} \quad (8.12)$$

so that the final states are

$$\begin{aligned} e^\pm e^\mp e^\mp e^\mp 4j, & \quad e^\pm e^\mp e^\mp \mu^\mp 4j, & \quad e^\pm e^\mp \mu^\mp \mu^\mp 4j, \\ \mu^\pm \mu^\mp e^\mp e^\mp 4j, & \quad \mu^\pm \mu^\mp e^\mp \mu^\mp 4j, & \quad \mu^\pm \mu^\mp \mu^\mp \mu^\mp 4j. \end{aligned}$$

We assume that $\text{Br}(\tilde{e}_i^\pm \rightarrow e_i^\pm \tilde{\chi}_1^0) \sim 100\%, 33\%, 100\%$ for a bino, wino and Higgsino LSP respectively, following the discussion in section 7.2. The branching ratio of the W boson into jets is about 67%. For the RPV neutralino decays we pick the most prominent regions from figures 11–13 and display these values along with \mathcal{F}_{jk} in table 3. Values are shown for both the normal and inverted hierarchies.

To calculate the number of events expected after 10 fb^{-1} of data, we convolute the combinatorics in table 3 with the cross sections for a 1 TeV Z_{BL} shown in figure 14 and

Hierarchy	LSP	$\text{Br}(\tilde{\chi}_1^0 \rightarrow e^\pm W^\mp)$	$\text{Br}(\tilde{\chi}_1^0 \rightarrow \mu^\pm W^\mp)$	\mathcal{F}_{ee}	$\mathcal{F}_{e\mu}$	$\mathcal{F}_{\mu\mu}$
NH	Bino	1–20%	10–50%	0.0001–0.036	0.002–0.18	0.01–0.22
NH	Wino	1–20 %	10–50%	0.00001–0.004	0.0002–0.02	0.001–0.024
NH	Higgsino	2–25 %	10–50%	0.0004–0.056	0.004–0.22	0.008–0.24
IH	Bino	10–60%	10–30 %	0.009–0.32	0.018–0.32	0.009–0.08
IH	Wino	10–60%	13–30%	0.001–0.035	0.003–0.034	0.002–0.009
IH	Higgsino	10–60%	13–35%	0.008–0.32	0.024–0.37	0.016–0.11

Table 3. Ranges for the branching ratios of the LSP to charge lepton and W boson taken from the corresponding dense regions in figures 11–13. These are used to calculate the overall combinatorics factor, \mathcal{F}_{jk} for the final state $e_i^\pm e_i^\mp e_j^\pm e_k^\pm 4j$. Values are separated by the composition of the LSP: mostly bino, wino and Higgsino and for both the normal and inverted hierarchies.

Figure 15. Number of $e_i^\pm e_i^\mp e_j^\pm e_k^\pm 4j$ at a 7 TeV LHC for 10 fb^{-1} of data for a bino LSP. Branching ratio values are shown in table 3, while cross section values are taken from figure 14. Data is divided into (a) for the NH, and (b) for the IH.

multiply by ten; the results are displayed in figures 15–17. Notice that in most of the scenarios one can have several events which are basically background free. The main backgrounds coming from $t\bar{t}WZ$ and $jjjjW^\pm Z$ are very suppressed.

In order to understand the testability of the model at the LHC we show curves of constant number of $e_i^\pm e_j^\mp e_j^\pm e_k^\pm 4j$ events per 10 fb^{-1} of data in figure 18 in the $\text{Br}(\tilde{\chi}_1^0 \rightarrow e_j^\pm W^\mp) - \text{Br}(\tilde{e}_i^\pm \rightarrow e_i^\pm \tilde{\chi}_1^0)$ plane. Values are shown for a seven TeV LHC, with a 1 TeV Z_{BL} and $m_{\tilde{e}_i} = 200 \text{ GeV}$. In the case of the observation of such events at the LHC, the Z_{BL} mass can be reconstructed from electron-electron and muon-muon events and the selectron mass may be reconstructible from its decay into two leptons and two jets. Therefore allowing the calculation of the cross section for charged slepton pair-production. A plot such as figure 18 can be used to get a better handle on the two unknown branching ratios and shed further light on the model.

Figure 16. Number of $e_i^\pm e_i^\mp e_j^\pm e_k^\pm 4j$ at a 7 TeV LHC for 10 fb^{-1} of data for a wino LSP. Branching ratio values are shown in table 3, while cross section values are taken from figure 14. Data is divided into (a) for the NH, and (b) for the IH.

Figure 17. Number of $e_i^\pm e_i^\mp e_j^\pm e_k^\pm 4j$ at a 7 TeV LHC for 10 fb^{-1} of data for a Higgsino LSP. Branching ratio values are shown in table 3, while cross section values are taken from figure 14. Data is divided into (a) for the NH, and (b) for the IH.

In order to estimate the reach of the LHC we also present curves of constant number of $e_i^\pm e_i^\mp e_j^\pm e_k^\pm 4j$ events per 10 fb^{-1} of data in the $\text{Br}(\tilde{e}_i^\pm \rightarrow e_i^\pm \tilde{\chi}_1^0) - m_{\tilde{e}_i}$ plane in figure 19. This is again for a seven TeV LHC, with a 1 TeV Z_{BL} and we show two possible values for $\text{Br}(\tilde{\chi}_1^0 \rightarrow e_j^\pm W^\mp)$, representing the upper (lower) part of that range in blue (green). One can see that even if the slepton mass is around 450 GeV one could observe a few events with multileptons and four jets. It is important to mention we satisfy the recent bounds coming from ATLAS [39, 40].

Figure 18. Curves of constant number of events for the final state $e_i^\pm e_i^\mp e_j^\pm e_j^\mp 4j$ in the $\text{Br}(\tilde{\chi}_1^0 \rightarrow e_j^\pm W^\mp) - \text{Br}(\tilde{e}_i^\pm \rightarrow e_i^\pm \tilde{\chi}_1^0)$ plane. Values are shown for a seven TeV LHC, $M_{Z_{BL}} = 1 \text{ TeV}$ and $m_{\tilde{e}_i} = 200 \text{ GeV}$.

Figure 19. Curves of constant number of events for the final state $e_i^\pm e_i^\mp e_j^\pm e_j^\mp 4j$ in the $\text{Br}(\tilde{e}_i^\pm \rightarrow e_i^\pm \tilde{\chi}_1^0) - m_{\tilde{e}_i}$ plane. Values are shown for a seven TeV LHC, $M_{Z_{BL}} = 1 \text{ TeV}$ and for two different values of $\text{Br}(\tilde{\chi}_1^0 \rightarrow e_j^\pm W^\mp)$, representing the upper (lower) part of that range in blue (green).

9 Summary and outlook

In this article we have studied in detail the theory proposed in ref. [15] which we consider the simplest gauge theory for R-parity violation. This theory makes a prediction for the LHC since in order to break the B-L gauge symmetry the right-handed sneutrino must get a vacuum expectation value and one should observe lepton number violation at colliders. We have found the following results:

- In figure 2 we have illustrated in a simple way that one can have a realistic scenario for all sfermion masses even if some of the sfermion masses have a negative and large contribution from the B-L D-term in the theory. We have shown that in order to avoid tachyonic masses one should satisfy the condition $M_{Z_{BL}} < \sqrt{2}m_{\tilde{L}}$. This is a simple result which helps us to understand the constraints on the spectrum.
- The full spectrum of the theory and the constraints coming from neutrino masses were analyzed in detail. The spectrum for neutrinos is interesting since it contains five light neutrinos: three active neutrinos and two sterile neutrinos. Using the experimental constraints on the masses and mixing for the active neutrinos we show in figure 4 the allowed values for the vacuum expectations of the left-handed neutrinos and the Yukawa couplings. As we have discussed in the text, these results are crucial to understand the decays of the lightest supersymmetric particle in the theory.
- In figures 6 and 7 we have shown the properties of the new neutral gauge boson in the theory, the B-L gauge boson. Since one has two extra light neutrinos in the theory the invisible decay width is larger in this case. The contributions of the supersymmetric particle to the decay width are small and so the Z_{BL} is like the B-L gauge boson in the non-SUSY scenarios.
- We have investigated the neutralinos decays in great detail. In figures 8–10 we have shown the results for the decay length in the different cases. As one can appreciate in figures 8–10 there are some scenarios in the Bino limit where one could expect displaced vertices. The branching ratios have been investigated in figures 11–13 and we can summarize the results in the following way

$$\text{Br}(\tilde{\chi}_1^0 \rightarrow \tau W), \text{Br}(\tilde{\chi}_1^0 \rightarrow \mu W) > \text{Br}(\tilde{\chi}_1^0 \rightarrow e W),$$

in the Normal Hierarchy and

$$\text{Br}(\tilde{\chi}_1^0 \rightarrow e W), \text{Br}(\tilde{\chi}_1^0 \rightarrow \mu W) > \text{Br}(\tilde{\chi}_1^0 \rightarrow \tau W),$$

in the Inverted Hierarchy, in majority of the parameter space.

- We have studied the main production channels for the charged sleptons at the LHC. In this case one can produce the charged sleptons through the photon and the Z as in the MSSM, and through the new neutral gauge boson, Z_{BL} , in our model. As we have shown in figure 14 the production cross section can be large and thanks to the

presence of the Z_{BL} one can have even larger values for the cross section due to the resonance enhancement. We should point out that this production channel (through the photon and Z) is very important to understand the signals in any model for R-parity violation.

- The most striking signals for lepton number violation in this context are the channels with three leptons with the same electric charge and four jets. In figure 15–19 we have shown that one can have a large number of events at the LHC with only 10 fb^{-1} . The background for these channels is suppressed, therefore there is a hope to test or rule out this theory in the near future.

A Mass matrices

In the case of the CP-odd neutral scalars, in the basis (A_L, A_R, A_d, A_u) , one finds that the mass matrix reads as

$$\mathcal{M}_{odd}^2 = \begin{pmatrix} \frac{v_R}{v_L} B_\nu & B_\nu & -\frac{1}{\sqrt{2}} Y_\nu \mu v_R & -\frac{1}{\sqrt{2}} a_\nu v_R \\ B_\nu & \frac{v_L}{v_R} B_\nu & -\frac{1}{\sqrt{2}} Y_\nu \mu v_L & -\frac{1}{\sqrt{2}} a_\nu v_L \\ -\frac{1}{\sqrt{2}} Y_\nu \mu v_R & -\frac{1}{\sqrt{2}} Y_\nu \mu v_L & \frac{v_u}{v_d} B\mu + \frac{Y_\nu \mu v_L v_R}{\sqrt{2} v_d} & B\mu \\ -\frac{1}{\sqrt{2}} a_\nu v_R & -\frac{1}{\sqrt{2}} a_\nu v_L & B\mu & \frac{v_d}{v_u} B\mu - \frac{a_\nu \mu v_L v_R}{\sqrt{2} v_u} \end{pmatrix}, \quad (\text{A.1})$$

while for the CP-even scalars, in the basis (h_L, h_R, h_d, h_u) , one finds:

$$\mathcal{M}_S^2 = \begin{pmatrix} S_\nu^2 & S_{\nu H}^2 \\ (S_{\nu H}^2)^T & S_H^2 \end{pmatrix}, \quad (\text{A.2})$$

where

$$S_\nu^2 \equiv \begin{pmatrix} \frac{1}{4} (g_1^2 + g_2^2 + g_{BL}^2) v_L^2 + \frac{v_R}{v_L} B_\nu - \frac{1}{4} (g_{BL}^2 - 2Y_\nu^2) v_L v_R - B_\nu & \\ -\frac{1}{4} (g_{BL}^2 - 2Y_\nu^2) v_L v_R - B_\nu & \frac{1}{4} g_{BL}^2 v_R^2 + \frac{v_L}{v_R} B_\nu \end{pmatrix}, \quad (\text{A.3})$$

$$S_{\nu H}^2 \equiv \begin{pmatrix} \frac{1}{4} (g_1^2 + g_2^2) v_L v_d - \frac{1}{\sqrt{2}} Y_\nu \mu v_R & -\frac{1}{4} (g_1^2 + g_2^2 - 4Y_\nu^2) v_L v_u + \frac{1}{\sqrt{2}} a_\nu v_R \\ -\frac{1}{\sqrt{2}} Y_\nu \mu v_L & Y_\nu^2 v_R v_u + \frac{1}{\sqrt{2}} a_e v_L \end{pmatrix}, \quad (\text{A.4})$$

$$S_H^2 \equiv \begin{pmatrix} \frac{1}{4} (g_1^2 + g_2^2) v_d^2 + \frac{v_u}{v_d} B\mu + \frac{Y_\nu \mu v_R v_L}{\sqrt{2} v_d} & -\frac{1}{4} (g_1^2 + g_2^2) v_u v_d - B\mu \\ -\frac{1}{4} (g_1^2 + g_2^2) v_u v_d - B\mu & \frac{1}{4} (g_1^2 + g_2^2) v_u^2 + \frac{v_d}{v_u} B\mu - \frac{a_\nu v_L v_R}{\sqrt{2} v_u} \end{pmatrix}. \quad (\text{A.5})$$

In the case of the charged scalars, in the basis $(\tilde{e}, (\tilde{e}^c)^*, H_u^-, H_d^-)$ the mass matrix reads as:

$$M_C^2 = \begin{pmatrix} C_e^2 & C_{eC}^2 \\ (C_{eH}^2)^T & C_H^2 \end{pmatrix}, \quad (\text{A.6})$$

with

$$C_e^2 \equiv \begin{pmatrix} C_{11}^2 & B_e \\ B_e & C_{22}^2 \end{pmatrix}, \quad (\text{A.7})$$

$$C_{eH}^2 \equiv \begin{pmatrix} \frac{1}{4}g_2^2 v_L v_d - \frac{1}{2}Y_e^2 v_L v_d - \frac{1}{\sqrt{2}}Y_\nu \mu v_R & \frac{1}{4}g_2^2 v_L v_u - \frac{1}{2}Y_\nu^2 v_L v_u - \frac{1}{\sqrt{2}}a_\nu v_R \\ \frac{1}{2}Y_e Y_\nu v_R v_u + \frac{1}{\sqrt{2}}a_e v_L & \frac{1}{2}Y_e Y_\nu v_R v_d + \frac{1}{\sqrt{2}}Y_e \mu v_L \end{pmatrix}, \quad (\text{A.8})$$

$$C_H^2 \equiv \begin{pmatrix} \frac{1}{4}g_2^2 (v_u^2 - v_L^2) + B\mu \frac{v_u}{v_d} + \frac{1}{2}Y_e^2 v_L^2 + \frac{Y_\nu \mu v_R v_L}{\sqrt{2}v_d} & B\mu + \frac{1}{4}g_2^2 v_u v_d \\ B\mu + \frac{1}{4}g_2^2 v_u v_d & \frac{1}{4}g_2^2 (v_d^2 + v_L^2) + \frac{v_d}{v_u} B\mu - \frac{1}{2}Y_\nu^2 v_L^2 - \frac{a_\nu v_L v_R}{\sqrt{2}v_u} \end{pmatrix}. \quad (\text{A.9})$$

In the above equations C_{11}^2 and C_{22}^2 are given by

$$C_{11}^2 = \frac{1}{4}g_2^2 (v_u^2 - v_d^2) + \frac{1}{2}Y_e^2 v_d^2 - \frac{1}{2}Y_\nu^2 v_u^2 + \frac{v_R}{v_L} B_e, \quad (\text{A.10})$$

and

$$C_{22}^2 = M_{\tilde{e}c}^2 + \frac{1}{4}g_1^2 (v_u^2 - v_d^2 - v_L^2) + \frac{1}{8}g_{\text{BL}}^2 (v_R^2 - v_L^2) + \frac{1}{2}Y_e^2 (v_d^2 + v_L^2). \quad (\text{A.11})$$

We also define for convenience: $B_\nu = \frac{1}{\sqrt{2}}(Y_\nu \mu v_d - a_\nu v_u)$ and $B_e = \frac{1}{\sqrt{2}}(Y_e \mu v_u - a_e v_d)$.

B Decay amplitude

The amplitude for Z_{BL} are

$$|\overline{\mathcal{M}}(Z_{\text{BL}} \rightarrow f_i \bar{f}_i)|^2 = \frac{4}{3}c_f \left(\frac{g_{\text{BL}}}{2} n_{\text{BL}}^f \right)^2 m_{Z_{\text{BL}}}^2 \left(1 + \frac{2m_{f_i}^2}{m_{Z_{\text{BL}}}^2} \right), \quad f_i = u, d, c, s, b, t, e, \mu, \tau; \quad (\text{B.1})$$

$$|\overline{\mathcal{M}}(Z_{\text{BL}} \rightarrow \nu_i \bar{\nu}_i)|^2 = \frac{2}{3} \left(\frac{g_{\text{BL}}}{2} n_{\text{BL}}^\nu \right)^2 m_{Z_{\text{BL}}}^2, \quad (\text{B.2})$$

$$|\overline{\mathcal{M}}(Z_{\text{BL}} \rightarrow \bar{N} N)|^2 = \frac{2}{3} \left(\frac{g_{\text{BL}}}{2} n_{\text{BL}}^{\nu_R} \right)^2 m_{Z_{\text{BL}}}^2 \left(1 - 4 \frac{m_N^2}{m_{Z_{\text{BL}}}^2} \right), \quad (\text{B.3})$$

$$\begin{aligned} |\overline{\mathcal{M}}(Z_{\text{BL}} \rightarrow \tilde{f}_\alpha \tilde{f}_\beta^*)|^2 &= \frac{1}{3}c_{\tilde{f}} \left(\frac{g_{\text{BL}}}{2} n_{\text{BL}}^{\tilde{f}} \right)^2 m_{Z_{\text{BL}}}^2 \left(1 - \frac{2m_{\tilde{f}_\alpha}^2 + 2m_{\tilde{f}_\beta}^2}{m_{Z_{\text{BL}}}^2} + \frac{(m_{\tilde{f}_\alpha}^2 - m_{\tilde{f}_\beta}^2)^2}{m_{Z_{\text{BL}}}^4} \right) \\ &\quad \times \left(U_{\alpha 1}^{\tilde{f}} U_{\beta 1}^{\tilde{f}} + U_{\alpha 2}^{\tilde{f}} U_{\beta 2}^{\tilde{f}} \right)^2, \quad \tilde{f}_\alpha \tilde{f}_\beta^* = \tilde{q}_{i\alpha} \tilde{q}_{i\beta}^*, \tilde{l}_{i\alpha} \tilde{l}_{i\beta}^*, \tilde{\nu}_i \tilde{\nu}_i^*, \tilde{\nu}_{Ri} \tilde{\nu}_{Ri}^*. \end{aligned} \quad (\text{B.4})$$

Here, i is a generation index, c_f are color factors ($c_{q_i} = 3$, $c_{l_i} = 1$) and $U^{\tilde{f}}$ are the unitary sfermion mixing matrices.

C Neutrino-neutralino mixing matrix

In the basis $\psi^T = (\nu, \chi)$, the mass matrix has the general form

$$\mathcal{M} = \begin{pmatrix} 0_{3 \times 3} & m_D \\ m_D^T & M_\chi \end{pmatrix}, \quad (\text{C.1})$$

where \mathcal{M} is diagonalized by \mathcal{N}

$$\mathcal{N}^\dagger \mathcal{M} \mathcal{N}^* = \begin{pmatrix} m_\nu^D & 0 \\ 0 & M_\chi^D \end{pmatrix}, \quad (\text{C.2})$$

m_ν^D is the diagonal mass matrix for the light neutrinos, M_χ^D is the diagonal mass matrix for the neutralinos and

$$\mathcal{N} = \begin{pmatrix} U & V \\ V_c & U_c \end{pmatrix}. \quad (\text{C.3})$$

Eq. (C.2) yields

$$m_\nu^D = U^\dagger m_D V_c^* + V_c^\dagger m_D^T U^* + V_c^\dagger M_\chi V_c, \quad (\text{C.4})$$

$$M_\chi^D = V^\dagger m_D^T V_c^* + U_c^\dagger M_\chi U_c^* + U_c^\dagger m_D^T V^*, \quad (\text{C.5})$$

$$0 = U^\dagger m_D U_c^* + V_c^\dagger M_\chi U_c^* + V_c^\dagger m_D^T V^*, \quad (\text{C.6})$$

and

$$U \sim U_c \sim \mathcal{O}(1); \quad V \sim V_c \sim \mathcal{O}\left(\frac{m_\nu^D}{m_D}\right). \quad (\text{C.7})$$

The unitarity condition yields the following expressions

$$UU^\dagger + VV^\dagger = U^\dagger U + V_c^\dagger V_c = V_c V_c^\dagger + U_c U_c^\dagger = V^\dagger V + U_c^\dagger U_c = I, \quad (\text{C.8})$$

$$UV_c^\dagger + VU_c^\dagger = U^\dagger V + V_c^\dagger U_c = 0.$$

In eq. C.6, the $V_c^\dagger m_D^T V^*$ is negligible whereas in eq. C.5 the M_χ term dominates. Therefore

$$U^\dagger m_D + V_c^\dagger M_\chi = 0, \quad (\text{C.9})$$

$$U_c^\dagger M_\chi U_c = M_\chi^D, \quad (\text{C.10})$$

$$m_D U_c^* = V M, \quad (\text{C.11})$$

where the last expression is a result of inverting eq. C.10, substituting it into eq. C.9 and making use of the unitarity conditions. Substituted eq. C.9 into eq. C.4 yields

$$V_c^\dagger m_D^T = m_\nu^D U^T. \quad (\text{C.12})$$

These results can be use to manipulate the seesaw relation:

$$m_\nu = U m_\nu^D U^T = m_D M_\chi^{-1} m_D^T, \quad (\text{C.13})$$

where m_ν is the nondiagonal light neutrino mass matrix diagonalized by U . Substituting eq. (C.12) for $m_\nu^D U^T$, rearranging using the unitarity condition yields and solving for V yields

$$V = m_D M_\chi^{-1} U_c \tag{C.14}$$

This can be rewritten by inverting eq. (C.5):

$$V = m_D U_c^* (M_\chi^D)^{-1}. \tag{C.15}$$

Where V can be identified with V_{ia} , the matrix that describes the mixing between the neutrinos and the neutralinos and is necessary for computing the neutralino decay properties. This result agrees with the naive expectation from the mass insertion approximation. While in the decay widths, eqs. (7.8)–(7.12), factors of U and E (the matrix that diagonalizes the charged lepton mass matrix) appear, they do so as sums of unitarity quantities and therefore are either zeroes or ones.

D LSP candidates and their final states

The violation of R-parity increases the space of possible LSPs, which is now no longer restricted to chargeless fields. We therefore take the time here to make a quick survey of the possible final states in this model. For each possible LSP, we consider its production, if lepton number violation is observable in principle and if there are any obstruction to this observation. Finally, we judge which LSP leads to the most interesting signals. For us, these are the signals where lepton number violation is explicit: same-sign leptons with no missing energy (which might be due to neutrinos thereby confounding the counting of lepton number). Of course this can only arise from neutral LSPs.

- Gluino (\tilde{g}) LSP:

Gluino pairs are produced through strong cross sections at the LHC. Their possible decays are

$$\begin{aligned} pp &\rightarrow \tilde{g}\tilde{g} \rightarrow tt \bar{b}b e_i^- e_j^-, t\bar{t} \bar{t}t \nu\nu, \\ pp &\rightarrow \tilde{g}\tilde{g} \rightarrow 4j e_i^\pm e_j^\pm, 4j \nu\nu, \end{aligned}$$

where the former is favored if the third generation squarks are lighter than the first two. The gluino decay width can be estimated as

$$\Gamma(\tilde{g} \rightarrow f' \bar{f} e_i^\pm) \sim \alpha_s \frac{M_{\tilde{g}}^5 (v_L^i)^2}{M_{\tilde{q}}^4 M_{\tilde{\chi}^+}^2 64\pi^2}.$$

For $M_{\tilde{g}} = 100 \text{ GeV}$, $M_{\tilde{q}} = 500 \text{ GeV}$, $M_{\tilde{\chi}^+} = 500 \text{ GeV}$ and $v_L^i = 10 \text{ MeV}$, one finds that the decay width is smaller than 10^{-13} GeV : a long enough lifetime for the gluino to form bound states but short enough so that it decays within the detector.

In principle, these channels can yield spectacular signals at the LHC. However a recent inclusive analysis in the search for isolated same-sign muons published by the

ATLAS collaboration has placed a model independent upper bound on the gluino pair production cross section of 58 fb [37]. Imposing this bound translate into a lower bound on the gluino mass of around 1 TeV indicating a heavy SUSY spectrum. Since we are interested in the scenarios with low energy supersymmetry we do not pursue this scenario further.

- Squark (\tilde{q}) LSP:

A stop LSP allows for final states with two third generation quarks of the same type and two leptons:

$$pp \rightarrow \tilde{t}^* \tilde{t} \rightarrow \bar{b} b e_i^\pm e_j^\mp, \text{ or } \bar{t} t \nu \nu,$$

while a first or second generation squark LSP has channels with two jets and two leptons:

$$pp \rightarrow \tilde{q}^* \tilde{q} \rightarrow 2j e_i^\pm e_j^\mp, 2j \nu \nu.$$

These channels have strong cross sections but do not provide information on the violation of the total lepton number. Since squarks in this case act as leptoquarks (each decaying into a quark and lepton) bounds on this scenario can be derived from leptoquark searches.

- Charged slepton (\tilde{e}_i) LSP:

Charged sleptons can be pair produced through the Z and Z_{BL} , with signals

$$pp \rightarrow \tilde{e}_i^* \tilde{e}_i \rightarrow \bar{t} t \bar{b} b, e_i^+ e_i^- \nu \nu,$$

where once more, lepton number violation is not discernible. The $\bar{t} b$ final state is due to the mixing of the charged sleptons with the charged Higgs boson which typically decays in this way. The leptonic channel arises due to the R-parity violating mixing between the charged leptons (neutrinos) and the charginos (neutralinos).

- Sneutrino ($\tilde{\nu}_i$) LSP:

Sneutrino pair production also proceeds through the Z and Z_{BL} with the following possible final states:

$$pp \rightarrow \tilde{\nu}^* \tilde{\nu} \rightarrow \bar{b} b \bar{b} b, \nu \nu \nu \nu, e_i^+ e_j^- e_i^+ e_k^-$$

The first final state results from the R-parity violating mixing of the sneutrino with the Higgs boson, while the latter two states are due to the R-parity violating mixing between the charged leptons (neutrinos) and the charginos (neutralinos).

- Chargino ($\tilde{\chi}^\pm$) LSP:

Charginos pair production is possible through the Z and leads to channels with two charged leptons due to the R-parity violating mixing between the charged leptons (neutrinos) and the charginos (neutralinos).

$$pp \rightarrow \tilde{\chi}^+ \tilde{\chi}^- \rightarrow e_i^+ e_j^- Z Z, \nu \nu W^+ W^-.$$

While in this case lepton flavor violation is observable, total lepton number cannot be probed.

- Neutralino ($\tilde{\chi}_1^0$) LSP:

This scenario allows for several interesting channels with lepton number violation. If the neutralino is Higgsino-like the pair production (See section 7.3 for information on neutralino decays):

$$pp \rightarrow \tilde{\chi}_1^0 \tilde{\chi}_1^0 \rightarrow 4j e_i^\pm e_j^\pm,$$

is possible through the Z , as well as associated production which gives rise to channels with three charged leptons:

$$pp \rightarrow \tilde{\chi}_1^0 \tilde{\chi}_1^\pm \rightarrow 4j \nu e_i^\pm e_j^\pm e_k^\pm.$$

Unfortunately, these channels are interesting only in the Higgsino-like neutralino scenario and in general the cross sections can be small. However, striking channels with three same-sign charged leptons, multijets and no missing energy through the pair production of selectrons are generally present:

$$pp \rightarrow \tilde{e}_i^* \tilde{e}_i \rightarrow e_i^\pm e_i^\mp e_j^\mp e_k^\mp 4j.$$

Such striking signals maybe the signatures that help test this model at the LHC. As we show above, the production cross section can be large and there are no relevant backgrounds.
