Abstract Difenoconazole was a triazole fungicide with proven bio-efficacy which leads to morphological and functional changes in the fungal cell membrane. In this work, field trials were conducted in three apple orchards. Sampling methods were improved in both the terminal residual and dissipation experiments. Residual data were analyzed and results showed that, at both recommended rates with 3 times applications and 1.5-folds of recommended rates with 4 times applications, the preharvest intervals (PHIs) of difenoconazole in apples were 6–7 days. The DT₅₀ of difenoconazole in apples and soils were 6.3–10.2 and 9.6–68.4 days, respectively. The DT₉₀ them were 26.2–40.6 and 45.6–216.3 days, respectively.

Keywords Difenoconazole · Residual · PHI · Apple · Soil

The complex factors such as pH, temperature, meteorological, microorganism of soil and ground water are different from place to place (Walker et al. 2001). It is not sufficient to evaluate a pesticide environment safety on just one kind of a crop or in just one single field place. Especially for the large area countries such as China, Canada and USA, the national standards of a pesticide usage such as the maximum residue limit (MRL) regulations and the preharvest intervals (PHIs) should take full account of the dietary habits of their people,

the climate of food production area (Philippe et al. 2007) and the length of growth cycle of crops.

Belonging to 14 α -demethylation inhibitors, difenoconazole is a systemic triazole fungicide that controls a broad spectrum of foliar, seed and soil-borne diseases caused by *Ascomycetes*, *Basidiomycetes* and *Deuteromycetes* in cereals, soya, rice, grapes, pome fruit, stone fruit, potatoes, sugar beet and several vegetable and ornamental crops (Ellen et al. 1997). In some previous studies, the dissipation behavior of difenoconazole in apple leaves, grass, apple orchard soils, Chinese cabbage and its growth soil were examined (Jacob and Werner 1996; Ellen et al. 1997; Wang et al. 2008). It was found that in apple orchard, difenoconazole in soil was most derived from falling leaves and centered in the soil layer of 0–10 cm. It was also found that difenoconazole followed sigmoidal degradation kinetics in a silt loam soil and its residue had a long persistence. However, those studies were not comprehensive and representative; more studies were needed to evaluated environmental safety of difenoconazole.

In this study, field experiments were conducted in three places, namely Xiaoxian (Anhui province), Daxing (Beijing) and Hangzhou (Zhejiang province). These places were the representative production areas of apples in China. The physicochemical properties of the three soils were qualitatively and quantitatively analyzed, the meteorological conditions in the experimental period had been recorded. The terminal residual experiments were conducted on apples to detect the PHIs of difenoconazole on apples; the residual experiments were conducted both on apples and soils to research the dissipations of difenoconazole. Coupled with an improvement on the sampling method and the soil physicochemical properties test, the residual data were fitted with the simple first-order (SFO) kinetics model to depict the dissipation behaviors of difenoconazole.

Materials and Methods

Difenoconazole (CAS No. 119446-68-3, purity: 97.5%) and its commercial formulation (10% Wettable Powder (WP) of difenoconazole) were got from Beijing organic agriculture technology center (China). HPLC grade ethyl acetate, florisil columns were purchased from Dikma (Dikma, China). All other chemicals were of analytical grade were purchased from Beijing Chemical Works (China).

Regulated by Institute for the Control of Agrochemicals, Ministry of Agriculture (ICAMA), PHI was the time period (in days) required for dissipation of the initial deposits after several times spraying at some intervals of time to below the MRL. Specifically, the residues of the three continuous samples after PHI should below the MRL. In this study, the terminal residue experiments were conducted in three places (Xiaoxian, Daxing and Hangzhou) to evaluate the PHIs of difenoconazole in apples.

The spraying action should stop once the medicated solution saturated and dropped from the trees (ICAMA), therefore, the application dosage measured not by the active ingredient per hectare (a.i./ha) but by active ingredient weight per liter (mg/kg). In this study, difenoconazole 10% WP was applied at 66.7 and 100 mg/kg water solutions at 24, 16, 8 and 0 days (4 times) before harvest, 16, 8 and 0 days (3 times) before harvest, respectively. Each treatment including the untreated control had three replications in the randomized separate plots.

Xiaoxian, Daxing and Hangzhou were apple production region; the field trials were conducted in June of 2008. There was no history of difenocloazole application in these experiment areas. Three replicates and one control plots with a total area of 400 m² (about 36 trees) were set in each trial.

Application was conducted by hand with a manual knapsack sprayer (Jacto HD400) at 4 kilogram-force (kgf)/cm² working pressure. Difenocloazole 10% WP was applied in crops and soils at the dosage of 100 mg/kg, which was 1.5 times higher than the recommended dosage. The physicochemical properties of the six soils were analyzed and listed in Table 1.

For the sample cleanup, a florisil solid-phase extraction (SPE) cartridge (1 g, Dikma, China) was preconditioned with 5 mL of acetone followed by 5 mL of hexane. Acetonitrile (50 mL) extract was evaporated to near dryness (at 43°C), redissolved with 2 × 3 mL hexane, residue was loaded into the cartridge and the effluent was discarded. The cartridge was eluted with 6 mL acetone-hexane (1:2) and dried under a gentle stream of nitrogen. The residue was re-constituted in 2 mL ethyl acetate and filtered through a 0.45 mm filter before GC analysis.

Table 1 Physicochemical characterisation of the three soils

Origin of the soil	Xiaoxian	Daxing	Hangzhou
Longitude	116°56'9"E	116°24'49"E	120°4'38"E
Latitude	34°9'52"N	39°37'9"N	30°17'56"N
pH (suspended 2:5 in water)	7.78	8.01	5.73
Total organic C content (%)	1.1	1.3	1.4
Clay (%) $D < 0.002$ mm	11.1	21.4	9.2
Silt (%) $0.002 < D < 0.05$ mm	37.2	16.1	37.9
Sand (%) $0.05 < D < 2$ mm	51.7	62.5	52.9
CEC (meq per 100 g)	7.9	20.3	12.6

K (mg kg ⁻¹)	160.8	91.2	134.5
Mean CFU per g dry soil (SD)	1.20E+06	5.70E+05	2.90E+06

Gas chromatographic (GC) analysis was carried out on a Varian 3800 gas chromatograph (Walnut Creek, CA, USA) equipped with a PFPD and capillary column (DB-17, 15.0 m × 0.25 mm ID, 0.25-μm film thickness), using nitrogen carrier gas at a flow rate of 1.5 mL min⁻¹. The GC temperature program was initially held at 150°C for 2 min, ramped to 280°C at a rate of 15°C min⁻¹, and held for 20 min. The GC injector was set to 270°C. The 1-μL extracts were injected onto the GC column in a pulsed splitless mode.

The method validation followed the Ministry of Agriculture, People's Republic of China guidelines on quality control procedures for pesticide residues analysis. All validation experiments were performed using blank samples of untreated watermelon, apple and soil.

Linearity was performed by analyzing spiked difenoconazole at six concentration levels between 0.01 and 10 mg/kg. The method was assessed with recovery experiments for watermelon, apple and soil ($n = 5$) at three spiking concentrations (0.001, 0.01, and 0.1 mg/kg). The limits of detection (LOD) and quantification (LOQ) were calculated as the concentration of each analyte that produce a chromatographic peak with signal/noise ratio of 3 and 10, respectively. All the calculations for statistical analysis were performed by using the Matlab 7.0.

Simple first-order kinetics (SFO) model was used to analyze residual data. This model assumes that the change in chemical concentration over time (dC_t/dt) is related to its concentration at that time and a rate constant k.

$$\frac{dC_t}{dt} = -kt \quad (1)$$

Thus, integrating the equation, the concentration at time t after spiking, C_t can be expressed as:

$$C_t = C_0 e^{-kt} \quad (2)$$

where C_0 is the initial concentration. According to OECD guideline 307, the first-order model is to be favoured for interpretation of the data unless its determination coefficient, r^2 , is below 0.7 (OECD 2002). The time at which the concentration reaches half of the initial concentration is referred to DT₅₀ (Eq. 3), while the time for 90% dissipation of ivermectin (DT₉₀) was calculated as given in Eq. 4.

$$DT_{50} = \frac{\ln 2}{k} \quad (3)$$

$$DT_{90} = \frac{\ln 10}{k} \quad (4)$$

Results and Discussions

Standard calibration curve of difenoconazole was constructed by plotting the analyte concentration against peak areas (0.01–10 mg/kg, n = 5). The standard curve equation was $y = 607750x - 55094$ ($R^2 = 0.9996$).

Recoveries of difenoconazole in apples and soils were 88.7%–104.1% and 91.9%–97.4%, respectively. LOD and LOQ of difenoconazole were 0.0002 and 0.001 mg/kg, respectively.

The experiment errors include random and system errors, they related to many phases, such as the adhesion ability of different crop species, human factors, sampling methods and meteorological conditions, etc.

In this study, the adhesion ability of difenoconazole in different apple species was tested. Four kinds of apples, namely *Changfu4*, *Red fuji*, *Golden delicious* and *Red star*, which were the common apple species in Chinese market were used. The four kind's apples were immersed in same concentration of pesticide water solutions at about 3 s, and then hang them to dry. Residues of such treatments were analyzed; results showed that RSD% between them was higher than 5%. The differences which caused by human elements was tested as well. In Daxing (Beijing), four people were randomly selected from our laboratory with different sex, height and weight. A same concentration of pesticide water solution was applied on the same species of apple trees with the same type of apparatuses (Jacto HD400). Although spraying was done as uniformly as possible, the RSD% of residues between all eight apple trees (two trees for each person) was as high as 10–34.7%, while RSD% of residues on a bunch to bunch basis within a single apple tree was as high as 208.7%. Recommended in “Standard operating procedures on pesticide registration residue field trials”, which edited by Institute for the Control of Agrochemicals, Ministry of Agriculture (ICAMA), the sampling amount of apples was 2 kg. In our

test, increasing the sampling amount from 12 (more than 2 kg for all) to 30 apples (more than 5 kg for all), the RSD% in a single apple tree was significantly decreased to less than 5%; however, the RSD% between apple trees was still kept above 10%.

MRL of difenoconazole for apples differed from country to country. It is 1.0 mg/kg in Japan and Korea, but 0.5 mg/kg in China. For this study, considering the factors of the food safety, 0.5 mg/kg was chosen as the MRL value in the terminal residue experiments.

As shown in Table 2, the PHIs at different dosages and frequencies of application were similar in one place, but different from places to places. Considering the possibilities that the different species, different application frequencies and different application dosages could induce different residues, we recommend the PHI for apples is 7 days.

The dissipation behavior of difenoconazole in watermelons and apples in six cities of China over time period of 2008 were shown in Fig. 1. It was found that the dissipation was faster initially and slowed down with the passage of time. Similar kinetics of difenoconazole had been observed in grapes by Banerjee (2008).

Considering the analysis of experiment errors which mentioned above, it was not surprised that difenoconazole showed mutative initial deposits in different places (C_0 in Tables 3, 4), which was 0.29 mg/kg in Xiaoxian, 0.38 mg/kg in Daxing and 0.26 mg/kg in Hangzhou. DT₅₀ and DT₉₀

DT_{90}	108.7	45.6	216.3

**Fig. 2** Mean temperature of experiment plots during field trial process of the three places

of apples in different regions were in the range of 4.6–11.4 and 26.2–81.7 days, respectively.

Temperatures and rainfalls of the three places during the experiment time were recorded and shown in Figs. 2 and 3. Residual data of difenoconazole in soils were shown in Fig. 4.

In this study, the pesticide was applied at the same dosage (100 g a.i./ha) and by the same apparatuses (Jacto HD400) in all three places, however, different initial concentrations of difenoconazole appeared in different soils. In the reports of Fredlund (1994), Terry and Hutson (1999), the higher permeability of sand soils and the translaminar movement of difenoconazole decreased the initial concentration of difenoconazole in soils. In this paper, the similar situation was detected in Daxing (sand content rate

**Fig. 3** Monthly rainfall of experiment plots during field trial process of the three places**Fig. 4** Residual data of difenoconazole in soil

was 62.5% and the initial concentration was 0.755 mg/kg) and Hangzhou (sand content rate was 52.9% and the initial concentration was 0.718 mg/kg), the initial concentration decreased with the increasing of sand content rate.

In our test, we found that higher temperatures possessed higher dissipation rate (Fig. 2; Tables 3, 4). Similar reports about the relationships between the temperatures and the dissipation rates of pesticide were also observed by many authors (Maria and Lennart 2007; José et al. 2009).
