Abstract

In this research, molybdenum disulfide (MoS₂) and bismuth trisulfide (Bi₂S₃) particles were synthesized. Bi₂S₃ was loaded on MoS₂ nanosheet and was characterized by several techniques. Degradation of metronidazole (MTZ) and Cefalexin (CFX) were investigated via MoS₂, Bi₂S₃, and MoS₂/Bi₂S₃ particles under near-infrared (NIR) light irradiation. The evaluations of electronic structures and molecular geometries of MoS₂ monolayer, MoS₂/MTZ, and MoS₂/CFX complexes were implemented using the DFT method. According to the electronic density of states (DOS) graphs results, when the MTZ and CFX interact with the monolayer surface, the energy gap (E_g) decreases compared to the MoS₂ nanosheet. In other words, the electronic features of the MoS₂ monolayer were altered after interaction with MTZ and CFX, where a reduction in the E_g value was evaluated (from 1.973 eV in the bare MoS₂ to 0.010 and 1.936 eV in states MTZ and CFX complexes, an alteration of 99.49 and 1.875%, respectively). It can be concluded that the band gap significantly changes when the MTZ interacts with the monolayer surface. The maximum removal efficiencies of MTZ and CFX in 40 min and at pH 7 were obtained by MoS₂/Bi₂S₃ photocatalyst, 91.54 and 73.18%, respectively. The results showed that the particles of Bi₂S₃, MoS₂, and MoS₂/Bi₂S₃ under NIR light irradiation have antibacterial properties, and the highest antibacterial property is related to the MoS₂/Bi₂S₃ particles.

1 Introduction

Pollutants in the pharmaceutical industry wastewater treatment are very complex, non-biodegradable, and very harmful to the environment [1, 2]. The most important effect of antibiotics is low biological biodegradability, high toxicity, specific carcinogenicity, and most importantly their lack of biodegradability, and mutagenic. Their entry into municipal wastewater treatment plants can cause the death of treated organisms and disrupt biological treatment systems [3, 4]. Metronidazole (MTZ) with anti-inflammatory and antibacterial properties is one of the most widely used antibiotics in the world [5]. Its applications include the treatment of infectious diseases caused by anaerobic bacteria and protozoa and its use as an antiparasitic in poultry and fish [6]. This antibiotic is due to its high potency in eliminating infections of the gastrointestinal tract, mouth, teeth, and genitals in the affected organ, and it is one of the most widely used drugs [7, 8].

Cefalexin (CFX) is a cephalosporin antibiotic that is effective in treating many groups of infectious diseases, such as respiratory infections, middle ear infections, skin and soft tissue infections, bone or joint infections, and urinary and genital infections [9]. It is also used for people who have had surgery and other people who are prone to infection for any reason. Therefore, its presence in household effluents, hospitals, and pharmaceutical industries is high. Therefore, these widely used antibiotics must be treated before entering the environment [10]. Various techniques, such as membrane, oxidation, solid phase extraction, sonochemical degradation, nanofiltration, and electrophoresis, have been performed. Advanced oxidation processes (AOPs), including photocatalytic methods [11–20], have shown good potential for the removal of biodegradable organic compounds from municipal and industrial wastewater [21]. Due to the properties of MTZ and CFX antibiotics, it is necessary to control and eliminate this contaminant. In recent years, a family of chemical compounds known as dicalcogen-mediated metals, which have shown interesting properties, have received much attention [22].

MoS_2 is part of the family of dicalcogen intermediate metals. Unlike graphene, these materials offer a variety of electronic properties [23]. As the most famous member of the family of intermediate dicalcogenes, MoS_2 has been extensively used in two-dimensional fields in various fields, such as biomedicine, sensing, catalytic, antibacterial, and field-effect transistors [24]. Recently, the use of MoS_2 nanostructures as an adsorbent in aqueous solution, especially with the nanosheet structure, has received a lot

of attention [25]. MoS_2 as a p-type semiconductor band gap is shown to change from 1.9 to 2.8 eV by the dielectric environment [26, 27]. Meanwhile, the preparation of MoS_2 nanostructures by various methods of preparing nanostructures in parallel with their application has received much attention. One of the most optimal methods for the production of nanostructures is the hydrothermal method [28].

Bismuth trisulfide (Bi_2S_3) as an n-type has gained considerable attention because of its nontoxicity, low cost, direct band gap ($E_g = 1.1$ and 1.6 eV), thermo-chemical stability, and good optoelectronic and thermoelectric properties. Bi_2S_3 is a layered semiconductor with an orthorhombic crystal structure [29, 30]. The applications of Bi_2S_3 include areas, such as solar cells, sensors, photodetectors, photocatalysis, antibacterial, and thermoelectric devices [31]. Bi_2S_3 has different morphologies, such as flower, wire, tube, and sphere [32]. Various methods are used for synthesis such as microwave, hydrothermal, and solvothermal. Semiconductors have conduction between the conductor and the insulator [33].

P-n junctions are very simple bonds with a p-type semiconductor compound on one side of the bond and an n-type semiconductor compound on the other side [34]. In n-type matter, electrons increase, and in p-type, holes predominate. In type n semiconductors, the number of electrons is much more than the number in p-type semiconductors, and also in type p semiconductors, the number of holes is much more than the number in n-type semiconductors. For this reason, when the two types of semiconductors n and p are connected to each other, electrons penetrate into the semiconductor p and holes penetrate into the semiconductor n. The penetration of an electron from the n region to the p region causes the formation of a positive ion in the n-type semiconductor and also similarly, the penetration of a hole causes a negative ion acceptor to form in the p region. It recombines with one of the holes on the p side [35].

Sulfide semiconductors with a small band gap have high photocatalytic activity by starting absorption in the visible and NIR regions. Due to synergy, $\text{MoS}_2/\text{Bi}_2\text{S}_3$ particles have a higher reactive oxidation species (ROS) production capacity and more antibacterial properties [36].

This research aims to investigate the removal of commonly used MTZ and CFX antibiotics using MoS_2 , Bi_2S_3 , and $\text{MoS}_2/\text{Bi}_2\text{S}_3$ photocatalysts under NIR irradiation. Furthermore, the antibacterial activity of MoS_2 , Bi_2S_3 , and $\text{MoS}_2/\text{Bi}_2\text{S}_3$ photocatalysts under NIR irradiation and in the dark has been studied. To compare the experimental and theoretical results, electronic structures and molecular geometries of MoS_2 monolayer, MoS_2/MTZ , and MoS_2/CFX complexes were implemented using the DFT method.

2 Materials and methods

2.1 Material

Ammonium heptamolybdate tetrahydrate ((NH₄)₆Mo₇O₂₄, ≥ 99%), thiourea (CH₄N₂S, > 99%), and bismuth nitrate Bi(NO₃)₃ from Sigma-Aldrich company was prepared. Metronidazole (C₆H₉N₃O₃) and Cefalexin (C₁₆H₁₇N₃O₄S) antibiotics were purchased by Darou Pakhsh Company.

2.2 Synthesis of MoS₂

First, 1.24 g of (NH₄)₆Mo₇O₂₄ and 2.28 g of CH₄N₂S were poured into 36 mL of distilled water and stirred for 30 min. The resulting solution was poured into an autoclave stainless steel for 7 h at a temperature of 170 °C. After performing the synthesis process, a precipitate is obtained which was washed several times with distilled water, and heated in an oven at 150 °C for 2 h to give the MoS₂ product [28].

2.3 Synthesis of Bi₂S₃

0.25 g of CH₄N₂S and 0.61 g of bismuth nitrate Bi(NO₃)₃ were poured in 50 mL of distilled water and stirred for 30 min. Then, 5 mL of HCl was added to the solution. The resulting solution was poured into an autoclave for 20 h at 140 °C. After performing the synthesis process, a precipitate obtained was washed several times with distilled water [37].

2.4 Synthesis of MoS₂/Bi₂S₃

MoS₂/Bi₂S₃ photocatalyst was prepared with a weight ratio of 1:1. In this way, first 0.05 g of MoS₂ and 0.05 g of Bi₂S₃ were poured into 100 mL of distilled water and stirred for 12 h at room temperature. The mixture was washed and dried at 60 °C for 6 h and was placed in a furnace at 400 °C for 3 h.

2.5 Degradation of MTZ and CFX

In this step, MTZ and CFX were prepared at a concentration of 100 mg/L at pH 7. The amount of 0.02 g of MoS₂, Bi₂S₃, and MoS₂/Bi₂S₃ was added to 50 mL of prepared drugs and placed on a magnetic stirrer exposed to NIR light (800 nm, 100 W/cm²) for 5–45 min. Then, the samples were centrifuged at 7500 rpm for 15 min. Finally, the absorption of MTZ and CFX was measured by spectrophotometer at 319 and 261 nm, respectively

$$\text{Efficiency} = \frac{(A_0 - A_t)}{A_0} \times 100, \quad (1)$$

where A_0 is the initial adsorption of the drugs and A_t is its final adsorption on the photocatalytic degradation [20].

2.6 MoS₂/Bi₂S₃ photocatalyst recycling

For this purpose, the MoS₂/Bi₂S₃ photocatalyst used in the degradation process of MTZ and CFX antibiotics was collected by centrifugation and then washed once with ethanol and three times with distilled water. The collected photocatalyst was dried at ambient temperature and then the photocatalyst was reused in the degradation reaction of MTZ and CFX antibiotics.

2.7 Computational details

The evaluations of electronic structures and molecular geometries of MoS₂ monolayer and MTZ/CFX were implemented by means of the DFT method [38, 39] using SIESTA simulation software [40, 41]. Conventional DFT technics do not discuss long-range attractive contributions to van der Waals (vdW) interactions between the adsorbent and adsorbate. Therefore, the dispersion-corrected DFT combined with generalized gradient approximation (GGA-PBE) [42] approaches were employed [43–46]. The PBE function is a good choice for studying MoS₂ material, which is confirmed by the reported DFT work [47]. In the simulation, a two-dimensional periodic boundary condition was utilized for the super-cells with 15.75 × 13.64 × 25 Å for the MoS₂ monolayer. The double zeta polarization (DZP) orbitals have been utilized for the relaxation of the MoS₂ nanosheet in the present study [48]. Furthermore, the interaction between the nuclei and core electrons and the valence electrons was estimated via Troullier–Martin realistic scheme [49, 50]. Further, the complete geometrical optimization was carried out with a conjugate gradient (CG) algorithm until the Hellmann–Feynman force including Pullay-like corrections was converged to 0.01 eV/Å [51]. The mesh cutoff was set to 150 Ry which presents a good accuracy. To better comprehension of physical quantities, a Brillouin zone was sampled using Monkhorst–Pack 5 × 5 × 1 k point sampling for converging geometry, whereas 15 × 15 × 1 for the assessment of the electronic DOS and charge transfer (CT) analysis [52]. The unit cell is allowed to converge in *xy* directions, whereas the *z* path is kept frozen at 25°A, consequently to eschew unwanted interactions between replicas.

To calculate the binding features of MoS₂/Drugs complexes, we computed the interaction energies via pseudopotential approach through van der Waals (vdW) correction suggested by Grimme (DFT-D2) scheme [53] as well applied OpenMX code which is an outstanding DFT code for evaluating the molecular systems [54, 55]. The numerical pseudoatomic orbitals' (PAOs) method was employed as the basis sets for the Kohn–Sham potential and orbitals [56]. PAO basis

functions are specified by C-s2p2d1, H 5.0-s2p2d1, N-s2p2d1, O 7.0-s2p2d1, S 7.0-s2p2d1, and Mo 7.0-s2p2d1. The energy cutoff for MoS₂/Drugs was selected at 200 Ry [57]. In structural optimizations, convergence was assumed around 10⁻⁴ Hartree/Bohr, which offers rational outcomes for under study complexes.

The interaction energy as called E_{int} for the interacting Drugs with the MoS₂ is defined as

$$E_{\text{int}} = E\left(\frac{\text{MoS}_2}{\text{Drugs}}\right) - [E(\text{MoS}_2) + E(\text{Drugs})] - \delta_{\text{BSSE}}, \quad (2)$$

where $E(\text{MoS}_2/\text{Drugs})$, $E(\text{MoS}_2)$, and $E(\text{Drugs})$ are the total energies of the relaxed MoS₂/Drugs complex, the pure MoS₂, and the isolated drugs, respectively.

It is worth mentioning that the basis set superposition error (BSSE) correction was utilized through the counterpoise correction (CC) approach [56]. The δ_{BSSE} statement corresponds to the corrections on the BSSE using the counterpoise technique.

Besides, to clarify the electronic sensitivity of the MoS₂ monolayer toward the adsorption of the drug, the modification in E_g is assessed by

$$\Delta E_g = \left[\frac{(E_{g2} - E_{g1})}{E_{g1}} \right] \times 100\%, \quad (3)$$

where E_{g1} and E_{g2} are the measures of E_g for the pure MoS₂ and the drugs, respectively.

To investigate the nature of the interaction between drugs and MoS₂, the CT was considered through the Mulliken technique [58, 59].

2.8 Antibacterial activities

In this method, each sterilized disk was loaded with a different solution of Bi₂S₃, MoS₂, and MoS₂/Bi₂S₃ particles at a concentration of 1000 mg/μL. The dried disks are then placed

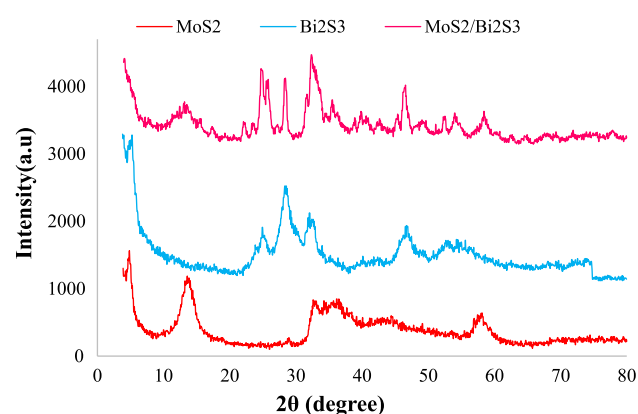

Fig. 1 XRD spectra obtained for MoS₂, Bi₂S₃, and MoS₂/Bi₂S₃

on the surface of the NA agar plates sprayed uniformly by ca 1 × 10⁶ CFU/ml of *Escherichia coli* (*E. coli*) from the culture medium by the applicator and inoculated into the culture medium. Plates with no treatments were used as control. Petri dishes were then irradiated with NIR light (800 nm, 100 W/cm²) for 2 min and also without light and incubated at 37 °C for 12 h in a shaking incubator. After 12 h, the diameters of the growth halos created around the disks were measured in millimeters with a caliper.

3 Results and discussion

3.1 Characterization

XRD technique was used to identify the phase and structure of MoS₂ and Bi₂S₃, MoS₂/Bi₂S₃ photocatalysts. Figure 1 shows the XRD pattern of samples. The XRD of MoS₂ at the angles of 14.39, 32.91, 39.69, and 76.58° corresponds to plates (002), (100), (103), and (110), respectively; which indicates the hexagonal phase by the standard peaks of the characteristic MoS₂ with JCPDS card No. 00-037-1492. The XRD spectrum of the Bi₂S₃ at the angles of 25.01, 28.66, 32.46, and 46.51° corresponds to plates (101), (130), (021), and (431), respectively. The results showed that the Bi₂S₃ were crystallized orthorhombic phase with the value in standard JCPDS card No. 00-017-0320. The peaks of MoS₂/Bi₂S₃ at angles 14.39, 32.91, 39.69, and 76.58° are related to MoS₂, and the peaks at angles of 25.01, 28.66, 32.46, and 46.5°, are related to Bi₂S₃, respectively (Fig. 1).

The average particle size was estimated based on the Debye–Scherrer equation using X’pert Highscore software

$$B = \frac{K\lambda}{L\cos\theta}, \quad (4)$$

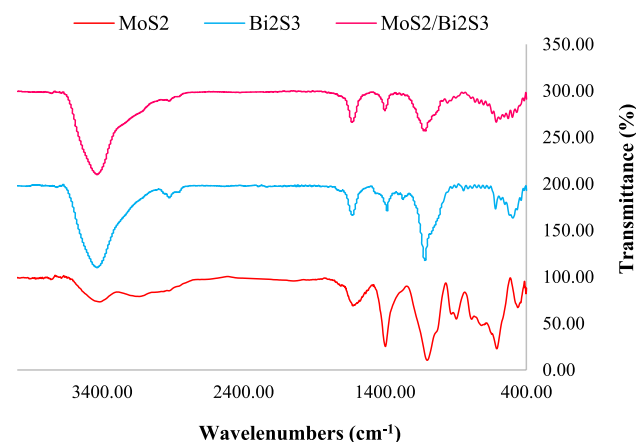

Fig. 2 FTIR spectra obtained for MoS₂, Bi₂S₃, and MoS₂/Bi₂S₃

Table 1 Calculated crystalline and lattice parameters for MoS₂ and Bi₂S₃

Sample	<i>B</i> (nm)	Space group	<i>a</i> (Å)	<i>b</i> (Å)	<i>c</i> (Å)
MoS ₂	52.67	P63/mmc	3.1612	3.1612	12.2985
Bi ₂ S ₃	29.95	Pbnm	11.1490	11.3040	3.9810

where *B* is the particle size, *K* is a constant number equal to 0.9, λ is the applied wavelength in terms of nanometers, and *L* is the peak full width at half maximum (FWHM) in terms

of radians and θ is the angle corresponding to the highest peak [20].

The mean particle sizes calculated by the Debye–Scherrer method were MoS₂, Bi₂S₃, and MoS₂/Bi₂S₃ 52.67 and 29.95, and 64.71 nm, respectively.

For the synthesized particles, the calculated crystal and lattice parameters are displayed in Table 1.

The interaction of infrared radiation with a sample changes the vibrational energy of the bond in its molecules and is a good way to identify functional groups and molecular structures. The FTIR spectra of the MoS₂ in the range

Fig. 3 SEM images, **a, b** MoS₂, **c, d** Bi₂S₃, and **e, f** MoS₂/Bi₂S₃

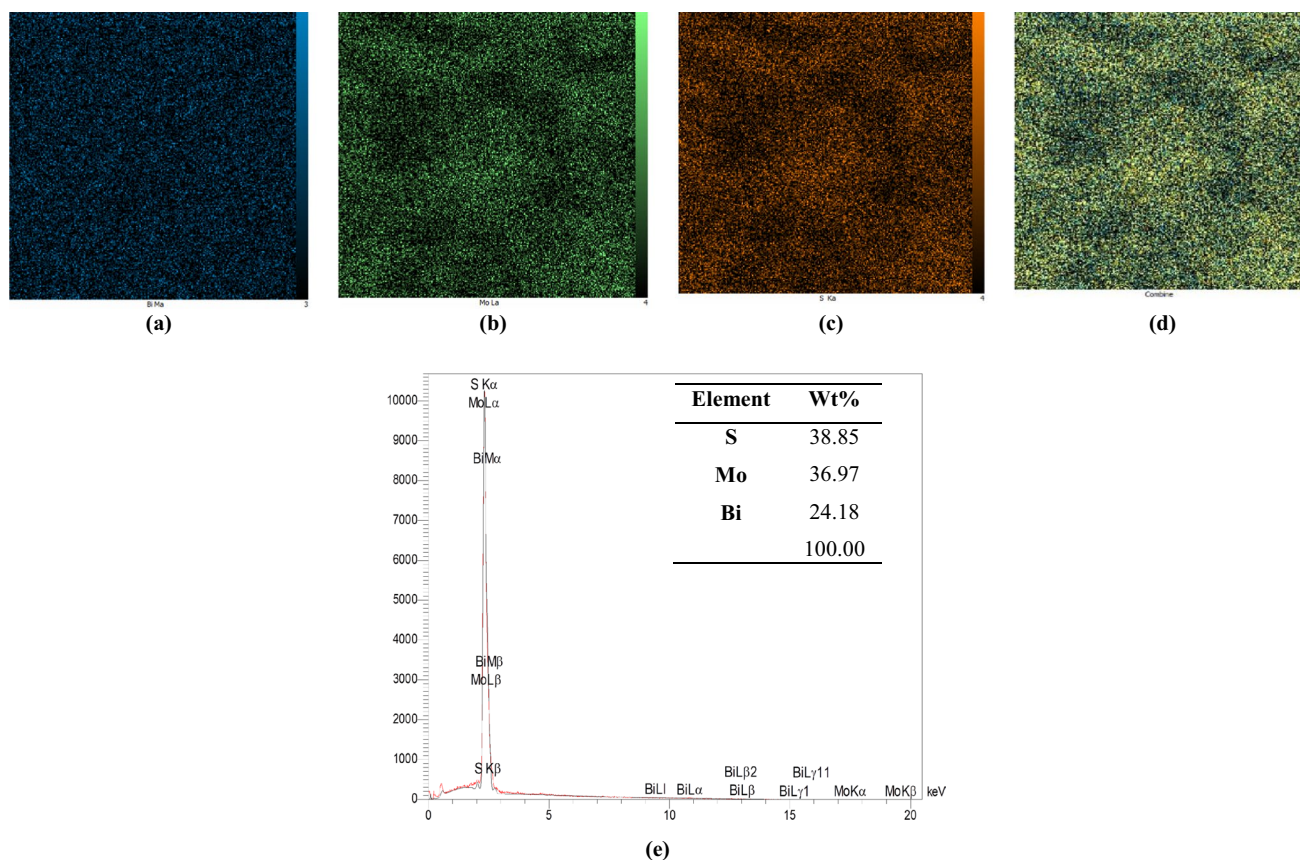

Fig. 4 Map images of **a** Bi, **b** Mo, **c** S, **d** combine and **e** EDS pattern of $\text{MoS}_2/\text{Bi}_2\text{S}_3$

of 476.29 cm^{-1} are related to the Mo–S tensile vibration and in the peak range of 3424.21 cm^{-1} assigned to the O–H tensile vibration. The spectra of FTIR Bi_2S_3 in the range of 495.36 cm^{-1} are related to the tensile vibration of Bi–O, in the range of 618.16 cm^{-1} characteristic to C–S bond, and the peak located at 1117.73 , 1271.87 and 2924.92 cm^{-1} corresponds to the bending vibration C–O, C–O–C, and C–H bond. Also, in the peak range 3436.05 cm^{-1} , it is related to O–H tensile vibration (Fig. 2). In the $\text{MoS}_2/\text{Bi}_2\text{S}_3$, the absorption bands at 467.93 , 499.04 , 528.85 , and 613.33 cm^{-1} are assigned to the Mo–S, Bi–O, C–S, and C–S. The peak located at 1113.29 , 1400.97 , and 1631.65 cm^{-1} corresponds to the bending vibration C–O, C–S, and H–O–H bond. Also, in the peak range of 3436.05 cm^{-1} , it is related to O–H tensile vibration (Fig. 2).

SEM technique was used to determine the surface characteristics and morphology of the synthesized particles. Based on the morphological results, MoS_2 is like flower, Bi_2S_3 is Rod, and Bi_2S_3 particles are well stabilized on MoS_2 (Fig. 3).

Based on the EDS diagram, Mo (36.97%), Bi (24.18%), and S (38.85%) elements are present in $\text{MoS}_2/\text{Bi}_2\text{S}_3$. The Xmap technique examines point-by-point a specific area of

the sample. In this technique, EDS analysis is performed from a large number of points in a specified area and the results of this analysis are displayed as a series of colored dots. Each color represents an element. Where the amount of this element is greater, the number of dots with that particular color is greater. In the Map images for $\text{MoS}_2/\text{Bi}_2\text{S}_3$ the blue, green, and orange dots represent the presence of Bi, Mo, and S, respectively (Fig. 4).

BET/BJH results of MoS_2 , Bi_2S_3 , and $\text{MoS}_2/\text{Bi}_2\text{S}_3$ samples are shown in Fig. 5. Based on the results, by loading the Bi_2S_3 rod on MoS_2 flower surface area and total pore volume increased. However, the average diameter of the average cavities decreased, which shows that Bi_2S_3 is well loaded on MoS_2 (Table 2).

Using the absorption coefficient (α), the band gap of thin layers can be studied with the help of the Tauc equation [16]

$$(\alpha h\nu)^{1/n} = A(h\nu - E_g), \quad (5)$$

where h is the Planck constant, ν is the applied frequency, α is the absorption coefficient, E_g is the band gap, and A is a proportional constant. The band-gap values for MoS_2 , Bi_2S_3 , and $\text{MoS}_2/\text{Bi}_2\text{S}_3$ 1.90, 1.18, and 1.79 (eV) were determined

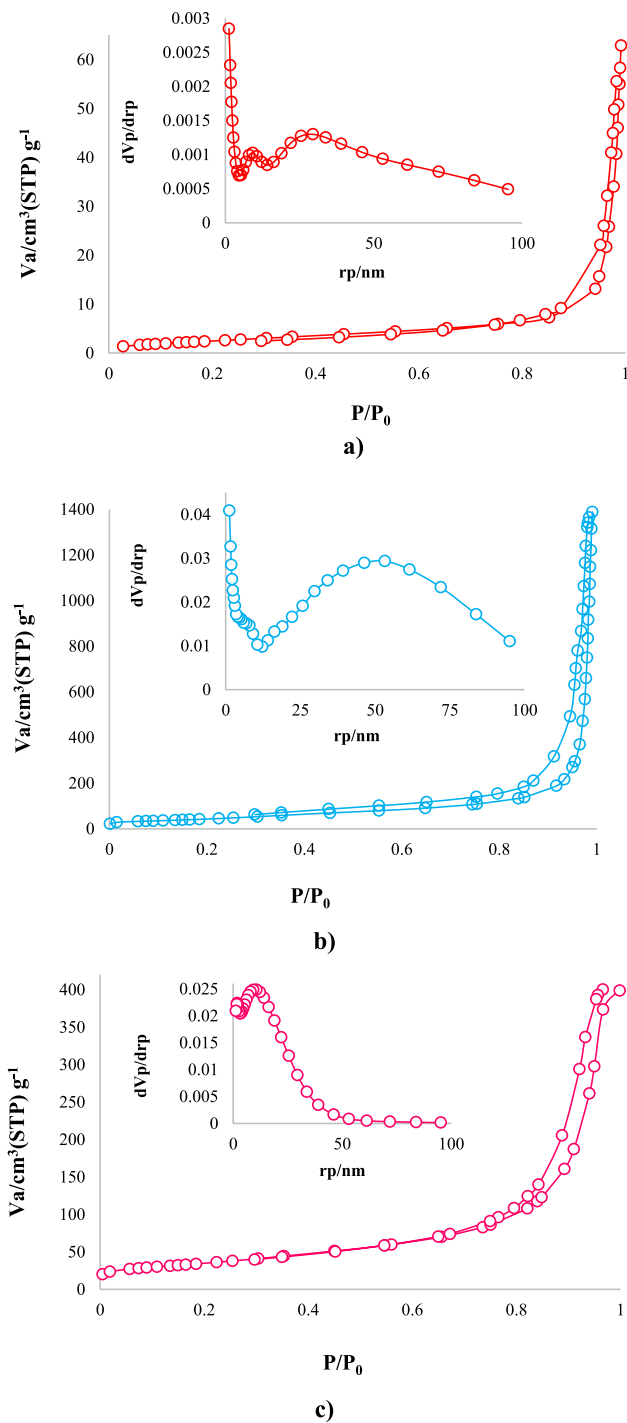

Fig. 5 BET/BJH analysis for **a** MoS₂, **b** Bi₂S₃, and **c** MoS₂/Bi₂S₃

by the Tauc method. The Tauc diagram is shown in Fig. 6. Based on the results as the MoS₂ was bound to Bi₂S₃, the band gap decreased.

Table 2 BET/BJH results for MoS₂, Bi₂S₃, and MoS₂/Bi₂S₃

3.2 Theoretical section

In this section, we examine the interaction between the MoS₂ monolayer and selected drugs in the aqueous environment. In our calculations, MoS₂ monolayer with 17.75 Å × 13.64 Å super-cells has been modeled consisting of 25 and 50 molybdenum and sulfur atoms, respectively. The converged structure of the MoS₂ has a Mo–S bond length of around 2.42 Å. The separation between sulfur layers evaluated as 3.17 Å allows for direct comparison to the experimental data, 3.18 Å, calculated through STM images (Table 3). The obtained results are in good agreement with theoretical outcomes [60–63]. To discover the most stable structure

of MET/CEPH drugs interacting with MoS₂ monolayer, the GGA-PBE approach was implemented for optimization and DFT-D2 for total energies calculations of above-mentioned systems. According to the main goal in this study is the elimination of mentioned drugs in industrial wastewater, we performed the drugs and MoS₂ monolayer interaction in the presence of water molecules as denoted in Fig. 7. After the optimization of the initial structures, the E_{int} were calculated with the DFT–D2 scheme. The E_{int} were assessed around –1.306 and –1.060 eV for MTZ and CFX, respectively, as presented in Table 4. Simultaneously, we considered equilibrium distances in MoS₂/Drugs complex. The obtained results reveal that the distance between the S atom of the MoS₂ monolayer and the H atoms of CFX and MTZ is 2.507 and 2.513 Å, respectively (Fig. 8). Charge analysis is a vital analysis to consider the intermolecular and intra-molecular interactions, and as an appropriate source

Table 5 Computed E_{HOMO} , E_{LUMO} , E_{g} , E_{F} (in eV) and ΔE_{g} is change of E_{g} , for MoS₂/MTZ, MoS₂/CFX complexes and pure MoS₂, Bi₂S₃

Configuration	E_{HOMO}	E_{LUMO}	E_{g}	E_{F}	ΔE_{g} %
MoS ₂	-4.637	-2.664	1.973	-3.926	-
Bi ₂ S ₃	-3.740	-2.606	1.134	-3.186	-
MoS ₂ /MTZ	-2.922	-2.912	0.010	-2.915	99.49
MoS ₂ /CFX	-4.578	-2.642	1.936	-3.502	1.875

for the investigation of the charge transferring in molecular systems. In this stage of the investigation, we calculate the CT between drug molecules and the MoS₂ monolayer. As depicted in Table 5, based on the Mulliken population, 0.01 and 0.010 and 0.121 e have been transferred from CFX and MTZ to MoS₂ monolayer, respectively. The results show also that the MoS₂ sheet gains electrons and drugs molecules lose electrons during the adsorption process. In other words, MoS₂ behaves as an acceptor, and drug molecules act as donor counterpart. There is a negligible CT between the MoS₂ and drug molecules, demonstrating that there is a weak interaction between drugs and MoS₂ nanosheet. To better understand the modification of the electronic structures of the pure MoS₂ monolayer and drug molecules' adsorptions on the MoS₂ monolayer, the electronic DOS diagrams were computed and plotted (Fig. 8).

Fig. 9 The evaluated orbital localized **a** HOMO, **b** LUMO of CFX/MoS₂ complex and **c** HOMO **d** LUMO of MTZ/MoS₂ system. (Red color denotes negative sign and green color indicates the positive sign of the wave function). (0.02 a.u. was employed as the iso-value for the total electron density)

Fig. 10 The obtained total charge density for optimized **a** CFX/MoS₂ and **b** MTZ/MoS₂ systems. (0.05 a.u. was employed as the iso-value for the total electron density)

In electronic DOS plots, the E_g mentions the energy difference between the valence and the conduction levels. The electronic DOS graphs demonstrate that for selected complexes when the drugs interact with the monolayer surface, the band gap decreases compared to pure MoS₂. In other words, the electronic features of the MoS₂ monolayer were altered after adsorption with drugs, where a reduction in the E_g values was evaluated (from 1.973 eV in the pure MoS₂ monolayer to 0.010 and 1.936 eV in states MTZ and CFX complexes, an alteration of 99.49 and 1.875%, respectively) (see Table 5). It can be concluded that the band gap significantly changes when the MTZ interacts with the monolayer surface. Moreover, the difference in the Fermi level of the MoS₂ ($E_F = -3.926$ eV), MoS₂/MTZ ($E_F = -2.915$ eV), and MoS₂/CFX ($E_F = -3.502$ eV) clearly shows a CT between MoS₂ and MoS₂/Drugs in the adsorption process. To further insight into the adsorption process of drugs on the MoS₂ monolayer, frontier molecular orbitals (FMO) including HOMO and LUMO are implemented. The HOMO denotes the ability to donate an electron and the LUMO as an electron acceptor represents the ability to obtain an electron. As shown in Fig. 9, the HOMO level for the MoS₂/CFX

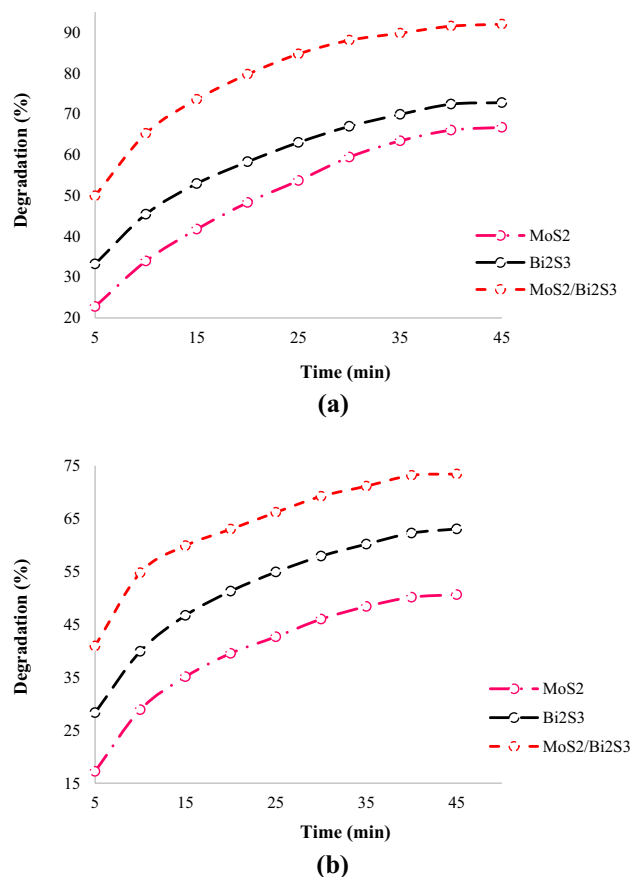

Fig. 11 a Photocatalytic degradation of MTZ by MoS₂, Bi₂S₃, and MoS₂/Bi₂S₃. **b** Photocatalytic degradation of CFX by MoS₂, Bi₂S₃, and MoS₂/Bi₂S₃

complex is mainly located on the CFX drug surface, while the LUMO state is localized on the MoS₂ surface. In the case of the MoS₂/MTZ complex, both the HOMO and LUMO states are only focused on the MoS₂ sheet as represented in Fig. 9. We also assessed the total electron density maps for mentioned complexes. As we can see from Fig. 10, there is an insignificant overlapping of electron clouds between the drug molecules and the MoS₂ monolayer. In other words, there is no evidence for hybridization between two involving molecules.

3.3 Degradation of MTZ and CFX

Sulfide semiconductors with a small band gap have high photocatalytic activity by starting absorption in the visible and NIR regions. NIR photothermic can effectively absorb light energy, resulting in light-to-heat conversion, thereby increasing the reaction temperature. When the temperature increases, the rate of photocatalytic oxidation increases. To investigate the effect of MoS₂, Bi₂S₃, and MoS₂/Bi₂S₃ on the degradation efficiency of antibiotics, MTZ and CFX

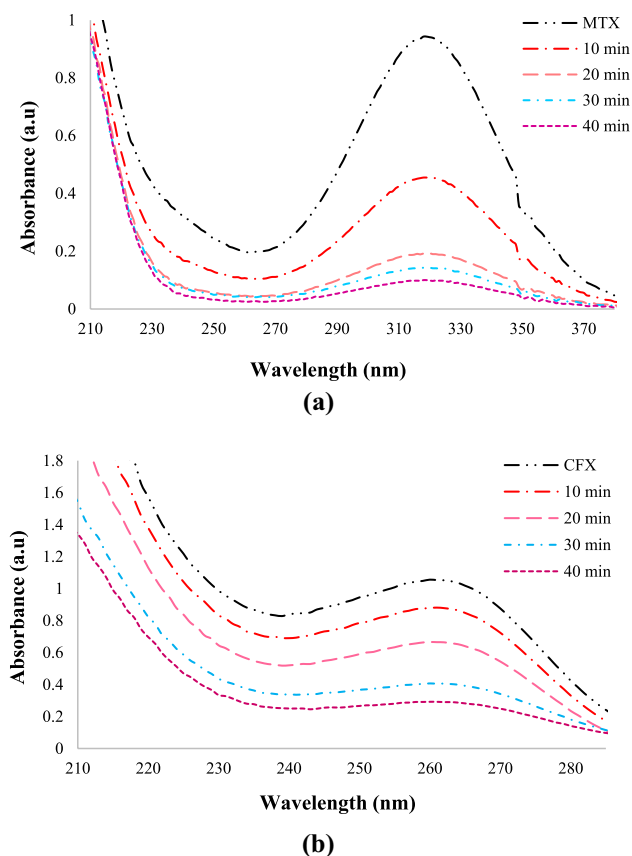

Fig. 12 **a** MTZ UV–Vis spectra before and after degradation. **b** CFX UV–Vis spectra before and after degradation

experiments were performed. According to the results, the performance of the Bi₂S₃ rod is higher than MoS₂ flower, which can be attributed to the high surface area of Bi₂S₃ rod 151.96 (m² g⁻¹) and its small band gap of 1.18 eV. Among all the photocatalysts, the MoS₂/Bi₂S₃ heterostructure had the highest removal efficiency. It can be concluded that MoS₂/Bi₂S₃ heterostructure with a small band gap has high photocatalytic activity with absorption in the NIR region. Experimental results also showed that the degradation efficiency of MTZ is higher than that of CFX. Based on the results, the highest removal efficiencies of MTZ and CFX in 40 min and at pH 7 were obtained by MoS₂ flower/Bi₂S₃ rod photocatalyst, 91.54 and 73.18%, respectively (Fig. 11a, b). The results of optical degradation curves of MTZ ($\lambda = 319$ nm) and CFX ($\lambda = 261$ nm), before and after degradation for 10, 20, 30, and 40 min, are shown in Fig. 12a, b. Based on the results, after 40 min, the absorption of MTZ and CFX has decreased, which can be concluded that MTZ and CFX have been removed from the aqueous media.

3.4 Proposed mechanism of degradation of MTZ and CFX

Several intermediates in the photocatalytic degradation pathways of MTZ and CFX are suggested. Possible photocatalytic degradation pathways for MTZ and CFX are plotted and shown in Fig. 13a, b. For the MTZ photocatalytic degradation pathway, intermediate (I) is related to oxidation and decarboxylation. In addition, N-denitration and hydroxylation lead to the formation of product (III). In CFX, intermediate (I) is created due to ring opening by hydroxylation and demethylation due to OH[•]/O₂^{•-} attack on CFX and methyl exchange with hydroxyl. Decarboxylation and dealkylation can lead to the formation of a product (IV). Intermediate (V) output is due to CFX fragmentation. Deamination and oxidation of intermediate (V) lead to the production of the product (VI). Carboxylation and dealkylation form intermediate (II) and product (III). Previous researchers have suggested similar products for MTZ and CFX [64].

3.5 Recycled MoS₂/Bi₂S₃ photocatalyst

Because the possibility of reusing the synthesized photocatalyst is economically important, therefore, it is necessary to evaluate the efficiency of the MoS₂/Bi₂S₃ photocatalyst during successive recycling. The results obtained after five times recycling and reuse showed that MoS₂/Bi₂S₃ photocatalyst decreased its photocatalytic activity by increasing the recycling frequency, the results of which are shown in Fig. 14a, b.

3.6 Antibacterial activities

In this study, the antibacterial properties of the synthesized particles were investigated. The results showed that disks loaded with a different solution of Bi₂S₃, MoS₂, and MoS₂/Bi₂S₃ particles under NIR light irradiation have antibacterial properties, and the highest antibacterial activity was found in MoS₂/Bi₂S₃ particles under NIR irradiation. Based on the results, the inhibition rate for *E. coli* bacteria by the Bi₂S₃, MoS₂, and MoS₂/Bi₂S₃ particles under NIR light irradiation was recorded 2.6, 3.2, and 6.1 mm, respectively. The inhibition rate for *E. coli* bacteria by the Bi₂S₃, MoS₂, and MoS₂/Bi₂S₃ particles without NIR light irradiation was recorded 1.8, 2.7, and 4.8 mm, respectively (Table 6) [65]. The increase in temperature destroys bacterial membranes and proteins, and as a result, it leads to the inactivation of bacteria. Due to synergy, MoS₂/Bi₂S₃ particles have a higher ROS production capacity and more antibacterial properties (Fig. 15a, b).

Fig. 13 a Proposed degradation pathways for MTZ. **b** Proposed degradation pathways for CFX

Fig. 14 Recycled photocatalytic degradation of **a** MTZ and **b** CFX

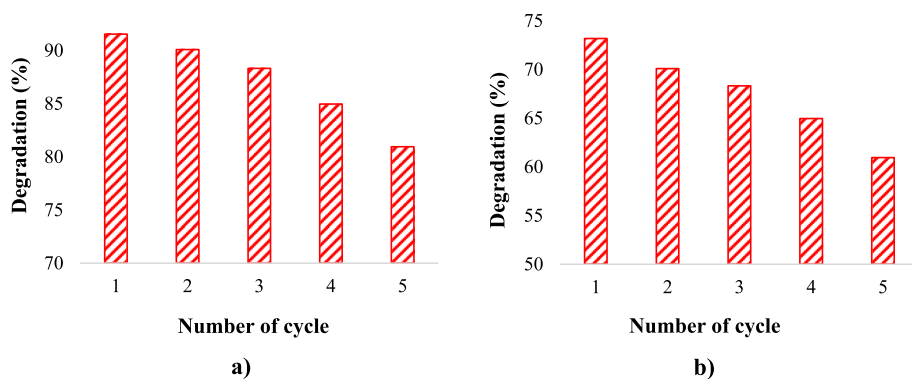

Table 6 Diameter of inhibition zone of Bi₂S₃, MoS₂, and MoS₂/Bi₂S₃ particles under and without NIR light

Sample	Diameter of inhibition zone (mm)
Bi ₂ S ₃ (under NIR light)	2.6
MoS ₂ (under NIR light)	3.2
MoS ₂ /Bi ₂ S ₃ (under NIR light)	6.1
Bi ₂ S ₃ (without NIR light)	1.8
MoS ₂ (without NIR light)	2.7
MoS ₂ /Bi ₂ S ₃ (without NIR light)	4.8

Based on the results obtained from this research, it can be concluded that the photocatalytic degradation of MTZ and CFX drugs under NIR light can be done with the lowest amount of photocatalyst consumed (0.02 g) in 40 min. Also, MoS₂/Bi₂S₃ particles showed acceptable antibacterial properties under NIR light irradiation.

4 Conclusion

MoS₂ flower-like and Bi₂S₃ rod-like were synthesized by hydrothermal method. Then, Bi₂S₃ rod was loaded on the MoS₂ flower. MoS₂, Bi₂S₃, and MoS₂/Bi₂S₃ particles were

Fig. 15 **a** Photographs of colonies of *E. coli* after incubations with Bi₂S₃, MoS₂, and MoS₂/Bi₂S₃ under NIR light. **b** Photographs of colonies of *E. coli* after incubations with Bi₂S₃, MoS₂, and MoS₂/Bi₂S₃ without NIR light

characterized by different techniques. Degradation of MTZ and CFX were investigated onto MoS_2 , Bi_2S_3 , and $\text{MoS}_2/\text{Bi}_2\text{S}_3$ particles under NIR light. Based on the experimental results, the degradation efficiency of MTZ was higher than that of CFX. Also, the highest removal efficiencies of MTZ and CFX in 40 min and at pH 7 were obtained by MoS_2 flower/ Bi_2S_3 rod photocatalyst, 91.54 and 73.18%, respectively. Based on the results, it can be concluded that the $\text{MoS}_2/\text{Bi}_2\text{S}_3$ photocatalyst has an acceptable performance in the removal of antibiotics. Based on the theoretical outcomes, the MoS_2 nanosheet can be used as the appropriate platform for the removal of mentioned antibiotics drugs, especially MTZ. The obtained results reveal that the E_g of MoS_2 was changed after the adsorption of antibiotic drugs. It can be concluded that the E_g significantly changes when the MTZ interacts with the MoS_2 nanosheet. Also, in this study, the antibacterial properties of the synthesized particles were investigated. The results showed that the particles of Bi_2S_3 , MoS_2 , and $\text{MoS}_2/\text{Bi}_2\text{S}_3$ under NIR light irradiation have antibacterial properties, and the highest antibacterial property is related to the $\text{MoS}_2/\text{Bi}_2\text{S}_3$ sample under NIR irradiation. In the present work, $\text{MoS}_2/\text{Bi}_2\text{S}_3$ photocatalyst with antibacterial properties was made for the first time, which is a simple, cost-effective and environmentally friendly technique that has high efficiency for the degradation of antibiotics from aquatic environments.

Author contributions Methodology, data collection, formal analysis, writing—original draft preparation, and writing—review and editing were performed by HP, NEF, and MR. Software and validation were carried out by MR. All authors have read and agreed to the published version of the manuscript.

Availability of data and materials All data will be available if required.
