Abstract This article is concerned with the propagation of guided type-Lamb waves in a magneto-electro-elastic composite plate. As a numerical method, the ordinary differential equation with the Thomson Haskell parameterization of Stroh formalism is employed to determine the wave characteristics in the composite plate by imposing the traction-free boundary condition on the top and bottom surfaces. Multiple crossing appears in the dispersion curves between the symmetric and the antisymmetric Lamb modes, which makes the dispersion curves more complicated and interesting to study. We are trying in this research to find, are these modes really coupled and why? For that, a set of numerical results are presented like the dispersion curves, the non-dimensional frequency, bulk waves slowness curve as well as the mechanical displacement U_1 and U_3 versus the non-dimensional thickness. These results could be interesting for the analysis and design of new acoustic devices based on magneto-electro-elastic material as well as a good candidate for nondestructive testing technology.

1 Introduction

Due to the vast applications of smart materials in aerospace, sensors and actuators transport vehicles, medical instruments, supersonic airplanes and so on. Intelligent structures made of piezoelectric and magnetostrictive materials (MEE) are nowadays widely utilized in engineering fields. In 1990s, a strong magneto-electrical coupling effect was found in two-phase structure composed of piezoelectric and piezomagnetic materials, which has wide practical application in many scientific fields [1, 2] and reported that this coupling effect cannot be found in a single-phase material. Moreover, MEE material shows important properties that the electrical polarization could be produced directly by the application of magnetic field, or indirectly the modification of the magnetic state is induced by an electric field. For these advantages, MEE have received wide applications in modern industries such as nondestructive testing, aircraft structure and vibration control. Lamb waves have been extensively studied in laboratory as in industry for many years because he has the ability to propagate through the entire thickness of the plate [3, 4]. Understanding Lamb wave behavior in composite magneto-electro-elastic material is important because it is directly related to the application in actuator/sensor technology, the nondestructive testing technology, etc.

We studied in this paper the propagation behavior of guided type Lamb wave in composite $\text{BaTiO}_3\text{-CoFe}_2\text{O}_4$ with different volume fraction of BaTiO_3 (25%, 50% and 75%). Multiple crossing was found between symmetric and antisymmetric Lamb modes. Many researchers have studied the reason of crossing in dispersion curve. Chuanwen and Yang [5] studied Lamb wave in PMN-xPT piezoelectric plate with different anisotropies. Multiple crossings was found in dispersion curves in [001]c and [011]c polarized PMN-PT crystals plates. They attribute the multiple crossing to the multivalued slowness curves. Tomáš Grabec and al [6] apply the Ritz–Rayleigh method for the calculation of Lamb waves in extremely anisotropic media, interesting dispersion curve was found in Ni–Mn–Ga [100]-direction Plate and Ni–Mn–Ga in [110]-direction plate. Chuanwen Rui and Wenwu [7] studied Lamb and SH wave in PMN-xPT ($x = 0.29, 0.33$) single crystal plates. Multiple mode couplings appear in the dispersion curves for both the symmetric and the antisymmetric Lamb and SH wave. Solie and Auld [8] presented dispersion curves in a [001] cut cubic plate, and they have linked the splitting mode between the antisymmetric and symmetric mode to the slowness curves of bulk wave specifically on the concavity of the quasi-shear slowness curves. Chuanwen, Rui, Hui and Wenwu [9] studied the guided wave behavior in the [100] and [110] directions of $0.67\text{Pb}(\text{Mg}_{1/3}\text{Nb}_{2/3})\text{O}_3\text{-}0.33\text{PbTiO}_3$ piezoelectric plate, they attribute the multiple crossing in the dispersion curve to the moderate anisotropy of the crystal. Several other researchers have studied theoretically and experimentally the presence of crossing points in anisotropic [10, 11] and isotropic plate [12]. Understanding the dispersion behavior of Lamb waves in composite magneto-electro-elastic plates is valuable for developing new Lamb wave devices. As mentioned above, the present study is concerned with the propagation behavior of Lamb wave in magneto-electro-elastic composite material. Using the state vector approach a set of dispersion curves was plotted. Interesting phenomena found in these types of materials were the antisymmetric and symmetric guided modes coupling each other several times as wave-number increases. This paper is organized as follows: First, in Sect. 2, the ordinary differential equation is developed in case of decoupled Lamb wave, in Sect. 3 we present some numerical results: The dispersion curve plotting routines used by the MATLAB is explained. The bulk slowness curve was shown to explain the intertwining between modes. Some mechanical displacement profiles that visualize the differences between the mode families are plotted and discussed.

2 Theoretical background

Consider a transversal isotropic homogenous magneto-electro-elastic plate with thickness $h = 1$ mm, which is infinite in the (x_1, x_2) plane but finite in the vertical direction x_3 . All the mechanical, piezoelectric and piezomagnetic constants are taken from the reference [13] (see Table 1). The coordinate system used in this work is shown in Fig. 1.

2.1 Formulation of the ordinary differential equation

The propagation of elastic waves in a magneto-electro-elastic (MEE) material will therefore be studied in the quasi-static approximation, that is to say that the magnetic energy which accompanies elastic deformation is negligible compared to electric energy. The useful equations are, then the following:

$$\begin{aligned}
 S_{ij} &= \frac{1}{2} \left(\frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i} \right) \\
 E_k &= -\frac{\partial \varphi}{\partial x_k} \\
 H_k &= -\frac{\partial \psi}{\partial x_k}
 \end{aligned} \tag{1}$$

where φ is the electrical potential and H the magnetic potential.

For the magneto-electro-elastic medium, the generalized constitutive relations are given as [14, 15]:

$$\begin{aligned}
 T_{ij} &= C_{ijkl} \frac{\partial u_l}{\partial x_k} + e_{kij} \frac{\partial \varphi}{\partial x_k} + f_{kij} \frac{\partial \psi}{\partial x_k} \\
 D_i &= e_{ikl} \frac{\partial u_l}{\partial x_k} - \varepsilon_{ik} \frac{\partial \varphi}{\partial x_k} - d_{ik} \frac{\partial \psi}{\partial x_k} \\
 B_i &= f_{ikl} \frac{\partial u_l}{\partial x_k} - d_{ki} \frac{\partial \varphi}{\partial x_k} - \mu_{ik} \frac{\partial \psi}{\partial x_k}
 \end{aligned} \tag{2}$$

where C_{ijkl} , ε_{ik} and μ_{ik} are the elastic, the dielectric and the magnetic permeability coefficients, respectively; e_{ikl} , f_{ikl} and d_{ik} are the piezoelectric, piezomagnetic and magneto-electric coefficients, respectively. To describe the propagation behavior of guided Lamb wave in magneto-electro-elastic (MEE) material, we use the ordinary differential equation as a method [16]. The Hooke law and the dynamic relation equation (RFD) are therefore written as a system of ordinary differential equations of the first order with non-constant coefficients of eight ranks.

$$\frac{\partial \xi}{\partial x_3} = i\omega Q\xi \text{ where } \xi = \begin{bmatrix} i\omega U_1 \\ i\omega U_3 \\ i\omega \varphi \\ i\omega \psi \\ T_{13} \\ T_{33} \\ D_3 \\ B_3 \end{bmatrix} \tag{3}$$

where Q is the fundamental acoustic tensor, a square matrix dimensioned (8×8) , which depends mainly on the physical properties and the guiding slowness component S_1 , Q can be written as [17]:

$$Q = \begin{bmatrix} S_1 \Gamma_{33}^{-1} \Gamma_{31} & \Gamma_{33}^{-1} \\ S_1^2 (\Gamma_{13} \Gamma_{33}^{-1} \Gamma_{31} - \Gamma_{11}) + \rho I_4 & S_1 \Gamma_{13} \Gamma_{33}^{-1} \end{bmatrix} \tag{4}$$

I_4 Is the (4×4) identity matrix, S_1 denoting the first component of the slowness vector. The parameter ρ is the density of the material and Γ_{ik} are the (4×4) matrices formed from the elastic constants C_{ijkl} , piezoelectric constant e_{kij} , piezomagnetic constants f_{kij} , dielectric permittivity ϵ_{ik} , magnetic permeability constants μ_{ik} and magneto-electric coupling coefficient d_{ik} .

$$\Gamma_{ik} = \begin{bmatrix} C_{1i1k} & C_{1i3k} & e_{kli} & f_{kli} \\ C_{3i1k} & C_{3i3k} & e_{k3i} & f_{k3i} \\ f_{i1k} & f_{i3k} & -\epsilon_{ik} & -\mu_{ik} \\ f_{i1k} & f_{i3k} & -d_{ik} & -\mu_{ik} \end{bmatrix} \tag{5}$$

The solution of this differential equation is a transfer matrix M which relates the state vector at $x_3 = 0$ and $x_3 = -h$.

$$\xi(x_3 = 0) = M \xi(x_3 = -h), \quad M = e^{iQh} \tag{6}$$

To solve the system of differential equations for a particular direction is in fact to find the eigenvalues and the eigenvectors of the matrix Q . This routine is done numerically by the “**eig**” function of the MATLAB software. There are eight of these which correspond to eight partial waves. Four waves propagate to the positive x_3 . Their eigenvalues represent the third component of the wave vector k_3^{+j} and their corresponding eigenvector matrix denoted $V^+ = \begin{bmatrix} P_j^+ \\ D_j^+ \end{bmatrix}$, or P_j^+ correspond to the polarization of these waves and D_j^+ represent the stresses. The other four waves propagating toward the negative x_3 , their eigenvalues k_3^{-j} and the matrix of the corresponding eigenvectors is denoted by $V^- = \begin{bmatrix} P_j^- \\ D_j^- \end{bmatrix}$ ($j = 1, 2, 3$ and 4). Indeed, the diagonalized form of the matrix Q is represented by:

$$Q = V \beta_{x_3}^+ V^{-1} = \begin{bmatrix} P_j^- & P_j^+ \\ D_j^- & D_j^+ \end{bmatrix} \begin{bmatrix} \beta_z^- & 0 \\ 0 & \beta_z^+ \end{bmatrix} \begin{bmatrix} P_j^- & P_j^+ \\ D_j^- & D_j^+ \end{bmatrix}^{-1} \tag{7}$$

where $\beta_{x_3}^+ = I \text{diag}(k_{x_3}^{1+}, k_{x_3}^{2+}, k_{x_3}^{3+}, k_{x_3}^{4+})$.

From (3) and (6)

$$\begin{aligned} \Rightarrow M &= V e^{iQ\beta_{x_3}} V^{-1} \\ \Rightarrow M &= \begin{bmatrix} P_j^- & P_j^+ H_j^+ \\ D_j^- & D_j^+ H_j^+ \end{bmatrix} \begin{bmatrix} P_j^- H_j^- & P_j^+ \\ D_j^- H_j^- & D_j^+ \end{bmatrix}^{-1} \end{aligned} \tag{8}$$

From Eq. (6) we obtain:

$$\begin{bmatrix} i\omega U(x_3 = -h) \\ T(x_3 = -h) \end{bmatrix} = M \begin{bmatrix} i\omega U(x_3 = 0) \\ T(x_3 = 0) \end{bmatrix} \tag{9}$$

2.2 Boundary conditions

The boundary conditions for the propagation of Lamb waves in homogeneous magneto-electro-elastic plate requires that the normal and tangential component of the stress, electric and magnetic displacement, magnetic and electric potential should vanish at the upper and lower surfaces.

Electrically open and magnetically close conditions (denoted by “os”): [18, 19]

$$\begin{aligned}
 &\text{At } x_3 = 0 \\
 &\quad \tau_{13} = \tau_{33} = D_3 = B_3 = 0 \\
 &\text{At } x_3 = -h \\
 &\quad \tau_{13} = \tau_{33} = D_3 = B_3 = 0
 \end{aligned} \tag{10}$$

Electrically shorted and magnetically open conditions (denoted by “so”): [18, 19]

$$\begin{aligned}
 &\text{At } x_3 = 0 \\
 &\quad \tau_{13} = \tau_{33} = \varphi = \psi = 0 \\
 &\text{At } x_3 = -h \\
 &\quad \tau_{13} = \tau_{33} = \varphi = \psi = 0
 \end{aligned} \tag{11}$$

2.3 Solution

By developing Eq. (9) we obtain: [20]

$$\begin{pmatrix} i\omega U_1 \\ i\omega U_3 \\ i\omega\varphi \\ i\omega\psi \\ T_{13} \\ T_{33} \\ D_3 \\ B_3 \end{pmatrix}_0 = \begin{pmatrix} Q_{11}^{os} & Q_{12}^{os} \\ Q_{21}^{os} & Q_{22}^{os} \end{pmatrix} \begin{pmatrix} i\omega U_1 \\ i\omega U_3 \\ i\omega\varphi \\ i\omega\psi \\ T_{13} \\ T_{33} \\ D_3 \\ B_3 \end{pmatrix}_{-h} \tag{12}$$

$$\begin{pmatrix} i\omega U_1 \\ i\omega U_3 \\ D_3 \\ B_3 \\ T_{13} \\ T_{33} \\ i\omega\varphi \\ i\omega\psi \end{pmatrix}_0 = \begin{pmatrix} Q_{11}^{so} & Q_{12}^{so} \\ Q_{21}^{so} & Q_{22}^{so} \end{pmatrix} \begin{pmatrix} i\omega U_1 \\ i\omega U_3 \\ D \\ B_3 \\ T_{13} \\ T_{33} \\ i\omega\varphi \\ i\omega\psi \end{pmatrix}_{-h} \tag{13}$$

Developing Eqs. (12) and (13) as well as introducing the boundary conditions we obtain:

$$0 = Q_{21}^{os} \begin{pmatrix} i\omega u_1 \\ i\omega u_3 \\ i\omega\varphi \end{pmatrix} \tag{14}$$

$$0 = Q_{21}^{so} \begin{pmatrix} i\omega u_1 \\ i\omega u_3 \\ D_3 \\ B_3 \end{pmatrix} \tag{15}$$

We obtain a homogeneous system of Eqs. (14, 15). In order to obtain the nontrivial solutions of the above equations (Eqs. 14–15), the determinant of $Q_{21}^{os,so}$ must vanish. So, the dispersive behaviors for the magneto-electrical open and shorted case can be investigated.

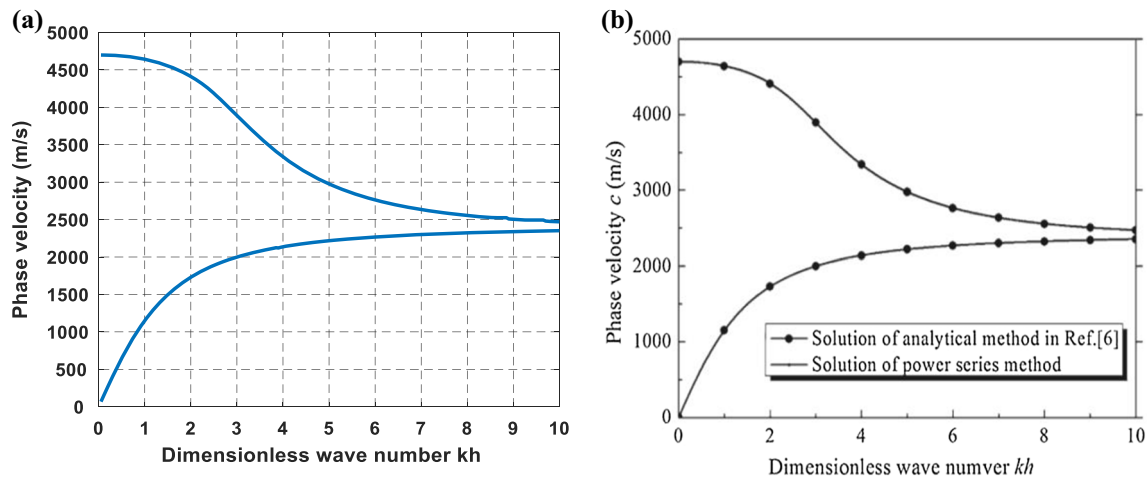

Fig. 2 Dispersion curves of S_0 and A_0 modes of homogeneous composite material, for magneto-electrically open case: **a** author result, **b** result from [21]

3 Results and discussion

3.1 Validation of the formulation

The authors of this research confirm that the unusual behavior of the dispersion curve found for the first time in these types of magneto-electro-elastic composite materials requires a validation of our calculation programs.

So, the dispersion curves of S_0 and A_0 modes of homogeneous composite material from reference [21] were plotted. Indeed, by comparing the result obtained by our method with this obtained by the power series method used by Cao et al. [21], we find that the two dispersion diagrams perfectly agree as shown in Fig. 2.

3.2 Results and discussion

In this section, the numerical evaluation is carried out using MATLAB software to assess the dispersion curves of the Lamb wave in homogenous BaTiO_3 piezoelectric material, CoFe_2O_4 piezomagnetic material and composite magneto-electro-elastic BaTiO_3 – CoFe_2O_4 with the different volume fraction of BaTiO_3 ($\delta = 25\%$, 50% and 75%). In this section, we represent the phase velocity and the non-dimensional frequency versus the non-dimensional wave-number. The non-dimensional frequency is defined as follows: $\Omega = \omega h \sqrt{C_{\max}/\rho}$, with C_{\max} is the highest value of the elastic matrix.

The velocities of the most Lamb wave's modes decrease rapidly with frequency, then after passing a minimum tend to the shear wave velocity. As shown in Fig. 3a–d the dispersion nature in the piezoelectric BaTiO_3 homogenous plate and CoFe_2O_4 piezomagnetic homogenous plate are regular. Contrariwise multiple mode coupling appears in the dispersion curves for both the dilatational and flexural Lamb mode as they approach the surface wave limit for the BaTiO_3 – CoFe_2O_4 composite with volume fraction $\delta = 25\%$, 50% , 75% . We are trying in this research to answer two important questions:

- Is there a relationship between the nature of the material (piezoelectric/piezomagnetic/magneto-electric) and the intersection between the symmetric and antisymmetric modes?
- “Are these modes really coupled or no”?

To answer the first question we presented in Fig. 4 the dispersion curves for CoFe_2O_4 – BaTiO_3 composite plates with volume fraction ($\delta = 25\%$, 50% , 75%) with and without the magneto-electric coefficient. It is found that the vanish of the piezoelectric and piezomagnetic coefficients decreases the phase velocity of all Lamb modes, whereas the crossing between the modes remains unchanged except for the higher modes for the composite $75\% \text{ BaTiO}_3$ – $25\% \text{ CoFe}_2\text{O}_4$ or the number of crossing points between the modes decreases. So the splitting between A_n and S_n mode cannot be attributed to the piezoelectric and piezomagnetic nature of composite material. Solie and Auld [8] attribute the splitting between the antisymmetric and symmetric

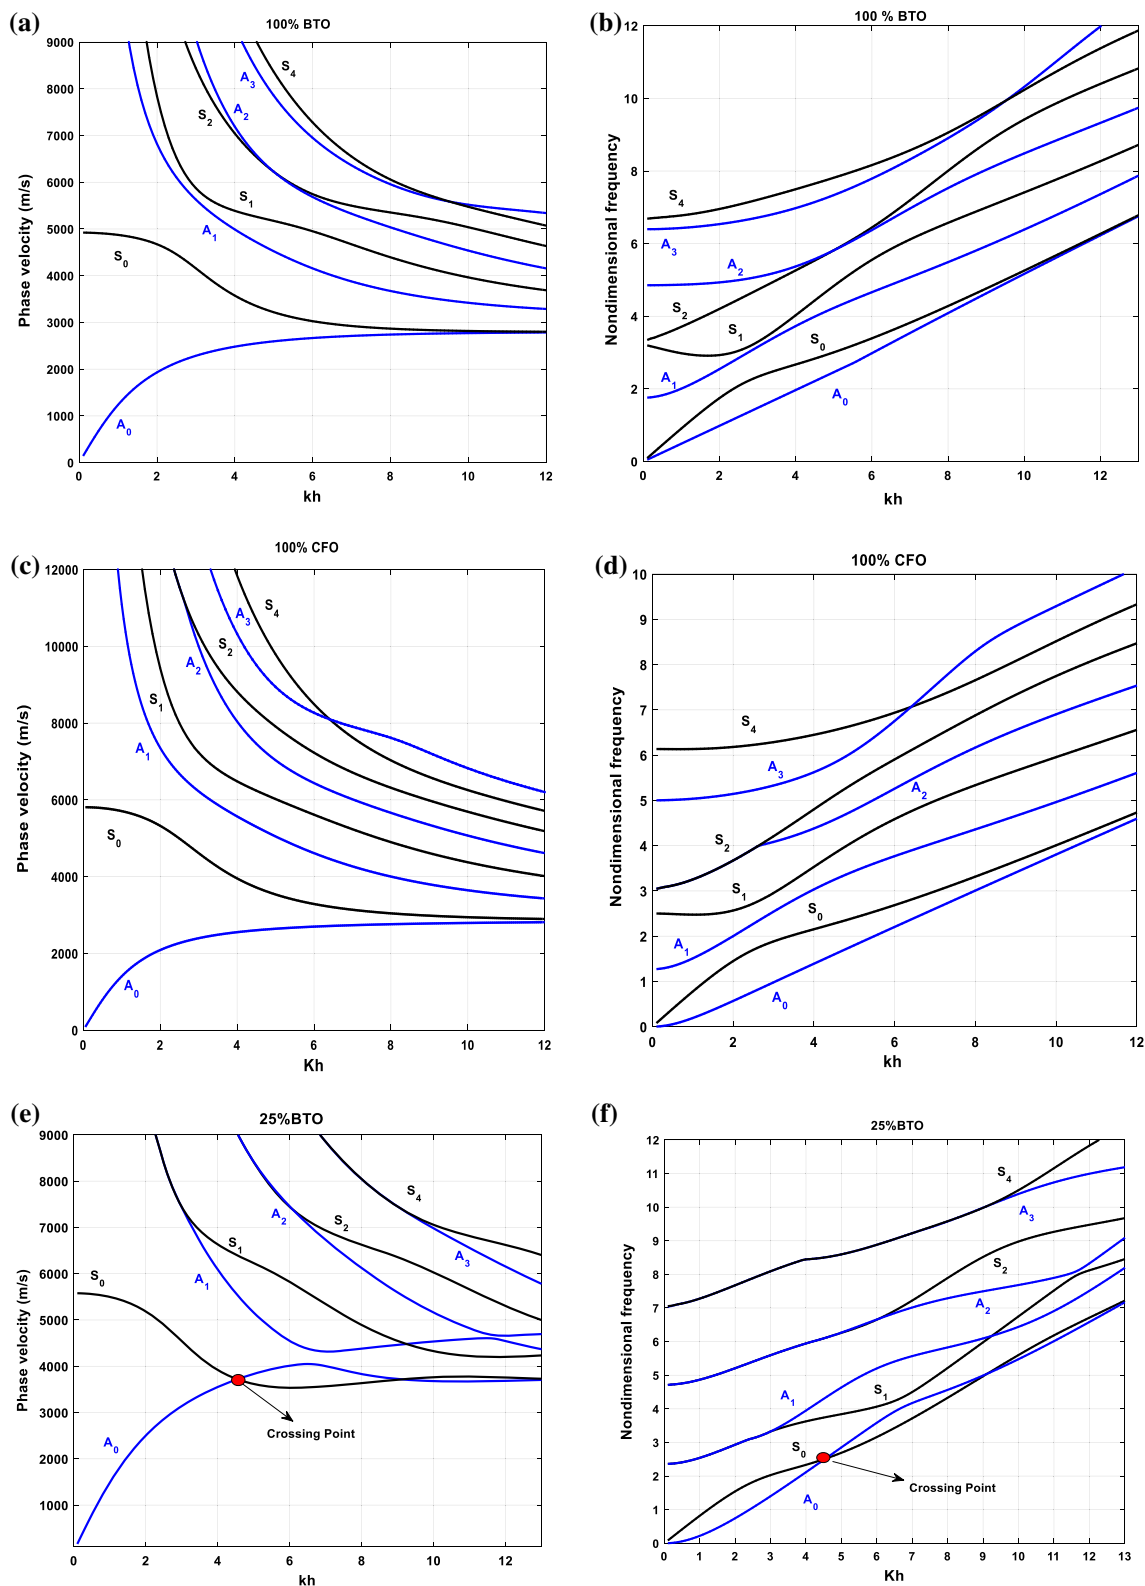

Fig. 3 a–j Dispersion curves for CoFe₂O₄–BaTiO₃ plates with different volume fraction of BaTiO₃ ($\delta = 0\%$, 25%, 50%, 75% and 100%)

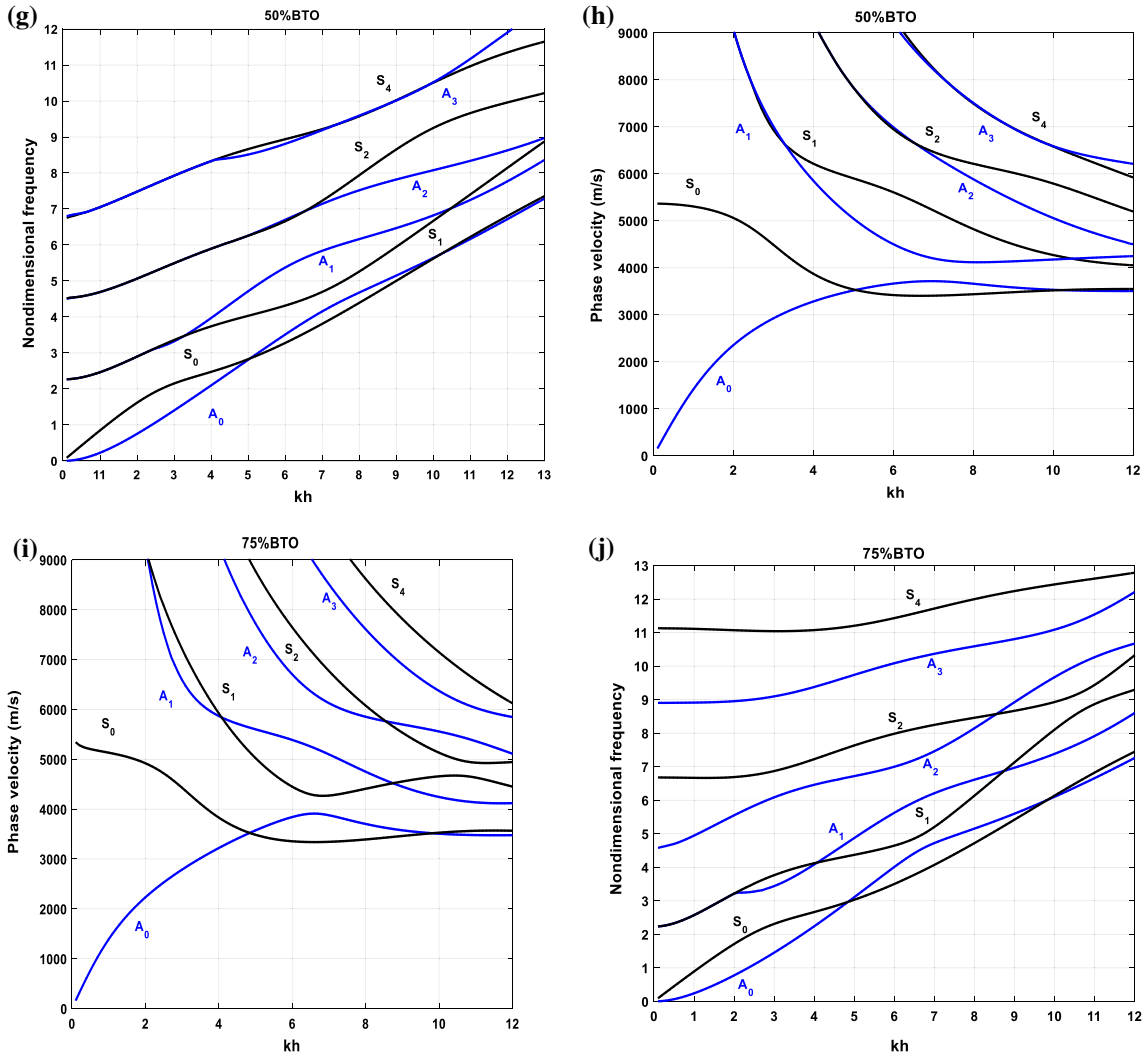

Fig. 3 continued

mode to the behavior of the slowness curve, precisely to the concavity of the quasi-shear slowness curves for “non-piezoelectric” material.

Under MATLAB R 2016a software a computational program was written to plot the slowness curves in YZ [0 1 0; -1 0 0; 0 0 1] sagittal plane. Figures 5 show the slowness curves for all materials with different volume fraction δ . The slowness surface noted “m” (inverse of the phase velocity) characterizes the free propagation of the elastic waves in a solid and indicates the direction of propagation of the energy. It is the place of the ends of the vector $\vec{m} = \vec{n} / V$ where n is the direction of propagation. The slowness surface generally consists of three tablecloths relating to a quasi-longitudinal mode and two quasi-shears ones. The slowness curves of BaTiO₃ material are all circles, indicating that the slowness (and hence phase velocity) is independent of propagation direction of waves polarized in this plane, for the CoFe₂O₄ material we have little anisotropy in the quasi-shear partial wave. By cons the magneto-electro-elastic composite materials are strongly anisotropic (particularly in the quasi-shear partial wave). The concavity of quasi-shear velocity curves indicate high anisotropy of the material and can be an explanation of the oscillation of symmetric and antisymmetric modes as they approach their asymptotic limit. To the author’s knowledge few researchers answer the question “are these modes really coupled or not?”. To explain the phenomenon in Fig. 6, a succession of mechanical displacement profile u_1 and u_3 through the non-dimensional thickness has been presented.

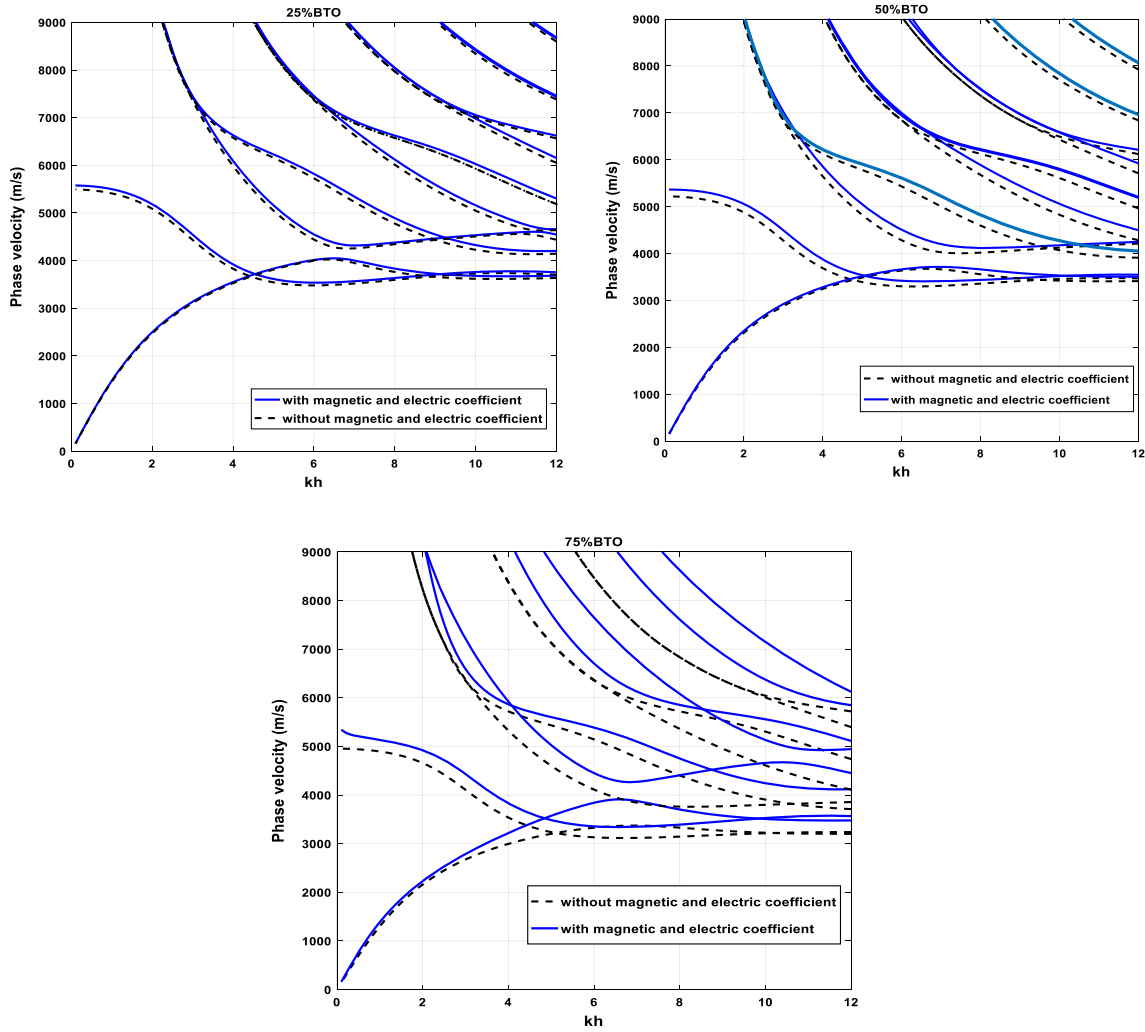

Fig. 4 Dispersion curves for $\text{CoFe}_2\text{O}_4\text{-BaTiO}_3$ plates with volume fraction of BaTiO_3 ($\delta = 25\%, 50\%, 75\%$) with magnetic and electric coefficient and without magnetic and electric coefficient

The classification of the symmetric and antisymmetric Lamb modes is deduced from the symmetries of the displacements u_1 and u_3 with respect to the median plane of the plate. The displacements of the antisymmetric modes are of the type:

$$\begin{cases} U_1(x_3) = -U_1(-x_3) \\ U_3(x_3) = U_3(-x_3) \end{cases} \quad (16)$$

The displacements of the symmetric modes are of the type:

$$\begin{cases} U_1(x_3) = U_1(-x_3) \\ U_3(x_3) = -U_3(-x_3) \end{cases} \quad (17)$$

Figure 7 shows that the displacement profiles u_1 and u_3 of A_0 mode before the crossing point at $kh = 4$ and after the crossing point at $kh = 6$ retains its antisymmetrical nature, which proves the intersection phenomenon between these two modes.

As for the A_0 mode, Fig. 8 shows that the displacement profiles u_1 and u_3 of the S_0 mode before the crossing point at $kh = 4$ and after the crossing point at $kh = 6$ retain its symmetrical nature, which proves the intersection phenomenon of the A_0 and S_0 modes.

4 Conclusion

In this research, we analyze in detail the problem of propagation of Lamb wave in magneto-electro-elastic composite plate. The dispersion curves (phase velocity and non-dimensional frequency versus non-dimensional wave-number) were plotted. Multiple intertwining modes were found in the dispersion curve which makes it both complex and important. The crossing between acoustic modes is awarded to the moderate anisotropy of the magneto-electro-elastic (MEE) composite explained by the bulk slowness curve. Finally, a succession of mechanical displacement profiles was shown to prove the crossing between the A_n and S_n mode.
