Abstract

A point-of-care (POC) immunoassay was established for the sensitive and rapid detection of pathogenic *Escherichia coli* O157:H7, using magnetic Fe₃O₄ organic-inorganic composites (Ab@Fe₃O₄) for immunomagnetic separation, nanozyme platinum nanoparticle (PtNp) organic-inorganic composites (Ap@PtNp) for signal amplification, and thermometer readings. Antibodies and Fe₃O₄ were incubated in Cu²⁺ phosphate buffer to synthesize the magnetic composite Ab@Fe₃O₄ with antibodies, to specifically capture *E. coli* O157:H7. Antimicrobial peptides and PtNp were incubated in Cu²⁺ phosphate buffer to synthesize the signal composites Ap@PtNp with antimicrobial peptides (magainin I), recognizing and labeling *E. coli* O157:H7. In the presence of *E. coli* O157:H7, magnetic microcomposites targeted bacteria and signal microcomposites to form the sandwich structure: Ab@Fe₃O₄-bacteria-Ap@PtNp for magnetic separation. Ap@PtNp of signal composites catalyzed H₂O₂ to generate thermo-signals (temperature rise), which were determined by a thermometer. This point-of-care bioassay detected *E. coli* O157:H7 in the linear range of 10¹–10⁷ CFU mL⁻¹ and with a detection limit of 14 CFU mL⁻¹.

Keywords Foodborne pathogenic bacteria · Point of care · Organic-inorganic composites · Thermal signal

Introduction

Foodborne diseases caused by pathogenic bacteria have become a global public health problem, posing a significant threat to human health [1]. It is widely recognized that the rapid, sensitive, and specific detection of pathogens is becoming more important in controlling illness outbreaks [2]. However, access to laboratory tests remains limited in some poor countries, and also in some developing countries [3]. The rapid, sensitive, and specific point-of-care (POC) detection of foodborne pathogenic bacteria can effectively reduce food- and water-borne outbreaks, especially in resource-limited

settings [4]. Other common methods of detecting pathogenic bacteria use microbiological plating and counting and the polymerase chain reaction (PCR). Although these approaches are specific and sensitive, their applications in such settings are limited as they are easy to contaminate and generate false-positive results [5].

Over recent decades, scientists have successfully developed viable POC bioassays, based on immunoassay to detect foodborne pathogenic bacteria [6]. POC testing has the advantage of greater availability in resource-constrained areas when compared to standard laboratory-based diagnostics. Currently, the main challenge of the POC bioassay is the detection of pathogenic bacteria in food, and the amplification and conversion of associated signals into readable digital outputs on portable devices.

Magnetic nanoparticles (MNPs) have been widely used for the capture and enrichment of pathogenic bacteria in complex food samples [7]. MNPs have unique properties: (1) they are easily manipulated by magnets; (2) they contain rapid solution kinetics and high surface volume ratios to ensure magnetic separation of targets (e.g., pathogenic bacteria); and (3) they have reduced matrix effects [8, 9]. MNPs are excellent candidates for POC immune assays, as they can be developed into

multifunctional bioassay materials, with great potential [10]. To label and enrich for target bacteria, MNPs require biomolecular modifications that recognize targets using complex reagents such as antibodies, aptamers, peptides, carbohydrates, and antibiotics [11]. In recent years, a facile approach for preparing organic-inorganic microcomposites with flower-like construction has been reported; it uses phosphate as an inorganic component and protein as an organic component [12]. Due to its high surface volume ratio, facile synthesis, and outstanding protein compatibility, these organic-inorganic microcomposites have attracted great attention [13]. When compared with traditional protein affixation methods, microcomposites can effectively maintain and even improve protein activity [14]. Spurred on by this facile approach, our research group observed that some nanoparticles (e.g., hemin and MnO_2) could be embedded into organic-inorganic microcomposites, which are capable of biological recognition and signal amplification for the POC detection of foodborne pathogenic bacteria [15, 16]. In this study, the magnetic nanoparticles Fe_3O_4 and pathogenic bacterial antibodies were incubated in Cu^{2+} phosphate buffer to synthesize magnetic organic-inorganic microcomposites for the enrichment and immune-separation of foodborne pathogenic bacteria. To the best of our knowledge, antibody- $\text{Cu}_3(\text{PO}_4)_2$ microcomposites loading Fe_3O_4 nanoparticles (magnetic microcomposites, MMC) have not been reported for the magnetic separation of pathogenic bacteria.

Transducers perform a vital role in the specificity and the signal detection of POC bioassays [17]. Bio-recognition signals from pathogenic bacteria are transformed into quantifiable signals using such transducers [18]. Recently, scientists have developed a variety of transduction methods, applied to the detection of foodborne pathogenic bacteria [19]. Signal transduction modes and physical parameters, such as electrochemical, optical, mass, and pH, are used for signal analysis in bioassays. The development of temperature-sensing technologies has an important practical significance across many fields, such as meteorology, chemistry, pharmacy, biology, and the military [20, 21]. It is encouraging that the emergence of thermo-based bioassays has opened up a new field of bio-sensing systems [22]. Thermometers, as an inexpensive, easy-to-use, fast, and real-time reading independent instrument, provide a powerful, portable, reliable, fast, and cheap detection tool for clinical biomarkers and other analyses [23].

Due to its catalytic efficiencies, excellent stability in harsh environments, ease of production, high efficiencies, and affinity for substrates, nanozyme platinum nanoparticles (PtNp) have been used as substitutes for natural enzymes in immunoassay signal amplification [24]. Our previous research found that PtNp catalyzed the decomposition of H_2O_2 into O_2 , which caused a significant increase in temperature across the reaction system [25]. PtNp can transform target biological identification processes into quantifiable temperature signals. However,

PtNp must be coupled to target biomolecules via a complex process. In this study, the nanozyme, PtNp, and magainin I were incubated in Cu^{2+} phosphate buffer to synthesize a nanozyme Ap@PtNp (signal microcomposites, SMC) as a signal-transforming label for foodborne pathogenic bacteria.

We developed a rapid and portable bioassay for detecting foodborne pathogenic bacteria by used *Escherichia coli* O157:H7 as a model pathogen (Scheme 1). This immunoassay combined magnetic separation using magnetic microcomposites, $\text{Ab@Fe}_3\text{O}_4$, and signal amplification using signal microcomposites Ap@PtNp , with thermo-signal analysis, using a thermometer. In the presence of the target *E. coli* O157:H7, a sandwich structure $\text{Ab@Fe}_3\text{O}_4$ -bacteria- Ap@PtNp was formed (Scheme 1). H_2O_2 decomposition was catalyzed by the nanozyme platinum of SMC to produce thermo. Finally, a thermometer was used to detect temperature changes for the quantitative determination of the target pathogen, *E. coli* O157:H7.

Materials and methods

Reagents and setup

Phosphate-buffered saline (PBS, 0.01 M) (0.01 M NaH_2PO_4 and 0.01 M Na_2HPO_4 , pH 7.4) were procured from Invitrogen, Germany (<https://www.thermofisher.com/us/en/home.html>). Ferro ferric oxide (Fe_3O_4), copper sulfate pentahydrate ($\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$), and the magainin I (GIGKFLHSAGKFGKAFVGEIMKS) peptide were obtained from Sangon Biotech (Shanghai, China, www.sangon.com). PtNp (10 nm) were obtained from Beijing Dk Nanotechnology Co., Ltd. (Beijing, China), and H_2O_2 (30 wt%) was purchased from Shanghai Ling Feng Chemical Regent Co., Ltd. (Shanghai, China, <http://lfhxsj.cn.b2b168.com>). *E. coli* O157:H7 antibodies were supplied by Abcam (ab252713, Shanghai, China, www.abcam.cn). All other chemicals were from Sinopharm Chemical Reagent Beijing Co., Ltd. (Beijing, China, <http://www.crc-bj.com/>) and were analytical grade. Deionized water was used in all experimental procedures and was ultra-filtered using a Millipore Milli-XQ system (18.3 $\text{M}\Omega$ cm, Billerica, MA, USA, www.merckmillipore.com). Bacterial strains of *Salmonella typhimurium*, (Sal, CICC 21484), *Staphylococcus aureus* (Sta, CICC 10384), *Listeria monocytogenes* (Lis, CICC 21635), and *Escherichia coli* O157:H7 (*E. coli* O157:H7, CICC 24187) were purchased from China Center of Industrial Culture Collection (Beijing, China, <http://www.china-cicc.org>). A digital thermometer (model number SJPT302), with a temperature detection range of -50 to $+300$ °C (degree precision = 0.1 °C) was obtained from Sensegene flagship store (Hangzhou, China, <http://www.sensegene.com/>).

Scheme 1 Schematic diagram of the exothermic immunosensor system based on MMC and SMC for the determination of *E. coli* O157:H7 (magnetic microcomposites Ab@Fe₃O₄, MNC; signal microcomposites Ap@PtNp, SMC)

Scanning electron microscopy (SEM) images were obtained using a JEOL JEM-2100 (Tokyo, Japan, <https://www.jeol.co.jp/>). X-ray diffraction (XRD) measurements were determined using an X-ray polycrystal diffractometer (Beijing Purking General Instrument Co., Ltd. XD6, Beijing, China, www.pgeneral.com.cn).

Preparation of Ab@Fe₃O₄ and Ap@PtNp microcomposites

Ab@Fe₃O₄ and Ap@PtNp were prepared according to a previously published report, with a slight modification [26]. Details are also specified in the Supporting Material. The capture efficiency of Ab@Fe₃O₄ was measured by conventional plate method. The capture efficiency (%) = $X/Y \times 100\%$, where X are *E. coli* O157:H7 numbers after magnetic capture, and Y are *E. coli* O157:H7 numbers before magnetic separation.

The detection of *E. coli* O157:H7 using a thermometer

Firstly, 100 μL of different *E. coli* O157:H7 densities (10^1 , 10^2 , 10^3 , 10^4 , 10^5 , 10^6 , 10^7 , 10^8 CFU mL⁻¹) were added to a 5- μL Ab@Fe₃O₄ solution, followed by the addition of 10- μL Ap@PtNp microcomposite, to a final volume of 115 μL . The mixture was incubated for 90 min at 35 °C. The reaction mixture was then washed four times in PBS (0.1 mM, pH 7), using a magnetic separation rack to remove unbound microcomposites. Finally, 600- μL H₂O₂ (30 wt%) was added to generate a decomposition reaction, producing heat. After 7 min, the final reaction temperature was measured. As shown (Fig. S1), the thermo-signal was considerably increased before (left image) and after H₂O₂ decomposition (right image). The temperature was obtained from this mixture. The major advantage of this assay is the

omission of traditional sandwich cleaning steps; a one-step cleaning method is required. When compared with other sandwich methods, our approach had a simpler cleaning procedure and reduced incubation times (Table 1).

Real food assay to determine target *E. coli* O157:H7

The standard addition method was used to calculate recovery [33]. Briefly, 10^3 , 10^4 , and 10^5 CFU mL⁻¹ *E. coli* O157:H7 densities were diluted in PBS (0.1 mM, pH 7). After this, bacteria were added to 1-mL commercial milk, and detected under optimized experimental conditions. Using our linear calibration curves and thermo-signals, target *E. coli* O157:H7 densities were determined from six independent experiments.

Data analysis

The temperature change (ΔT) was represented as the difference between the thermal signals measured by the digital thermometer in the presence and absence of the target bacteria. The experiment data were performed at least three independent experiments (mean \pm standard deviation (SD)) and analyzed by GraphPad PRIME (7.0) software.

Results and discussion

Characterization of Ab@Fe₃O₄ and Ap@PtNp

We report a novel approach that directly synthesizes Ab@Fe₃O₄ that exhibits magnetic properties and hierarchical structures. The morphology of microcomposite of ferrites were characterized by SEM. As shown (Fig. 1a and b), typical

Table 1 Comparison of different sandwich techniques for pathogenic bacteria detection

SEM images show a spherical structure, with a coarse surface and an average spherical diameter of approximately 12 μm . These dimensions and characteristics illustrate that $\text{Ab@Fe}_3\text{O}_4$ morphology was similar to previous hybrid nanoflowers [26]. This was in accordance with our SEM characterization results. These microcomposites not only immobilized Fe_3O_4 , but their high ratio to surface areas, and their good space utilization ratios for efficient antibody entrapment effectively captured the target. In addition, the larger

specific surface areas of $\text{Ab@Fe}_3\text{O}_4$ microcomposites also facilitated the application of related surface reactions. They also provided intrinsic magnetism, allowing the target molecule to be quickly separated from the complex mixture, by a magnetic field in a short time. Similarly, Ap@PtNp had the properties of the catalytic activity of platinum that could be used for the dissociation of H_2O_2 molecules. This catalytic process produced heat which was processed as a final signal output. As shown (Fig. 1c and d), SEM images of Ap@PtNp

Fig. 1 Characterization of microcomposites. SEM images of (a) $\text{Ab@Fe}_3\text{O}_4$ (scale; 20 μm), (b) $\text{Ab@Fe}_3\text{O}_4$ (scale; 2 μm), (c) Ap@PtNp (scale; 10 μm), and (d) Ap@PtNp (scale; 2 μm)

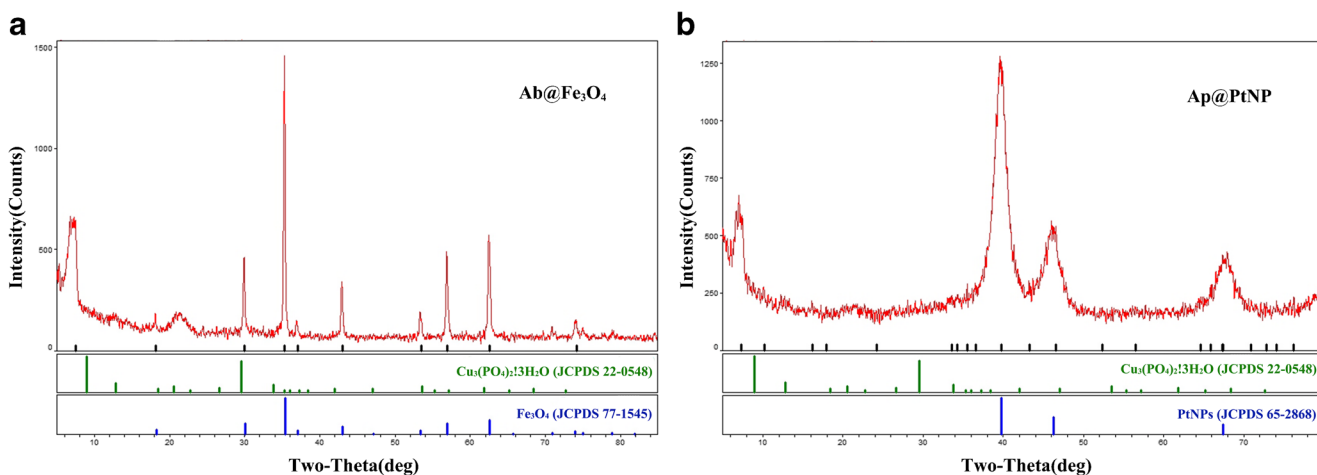

Fig. 2 XRD characterization patterns of (a) Ab@Fe₃O₄ (red line) and Cu₃(PO₄)₂·3H₂O (green line) and Fe₃O₄ (blue line) (b) Ap@PtNP (red line), Cu₃(PO₄)₂·3H₂O (green line), and PtNP (blue line)

displayed a classic form, similar to the morphology of Ab@Fe₃O₄, with an average diameter of approximately 3 μm.

The crystal structure and crystallinity of Ab@Fe₃O₄ and Ap@PtNP were recorded by XRD in the range at 2θ = 5° – 85° on a desktop X-ray diffractometer. Figure 2 a indicates the Ab@Fe₃O₄ fitted well with Cu₃(PO₄)₂·3H₂O (JCPDS file 22-0548) and Fe₃O₄ (JCPDS file 77-1545), revealing the copper phosphate and ferro ferric oxide in the nanoparticles. These characteristic signals appeared for Ab@Fe₃O₄, suggesting that the synthesis of Ab@Fe₃O₄ was crystalline. Similarly, XRD pattern for Ap@PtNP (Fig. 2b) confirmed that microcomposites consisted of crystalline nanoparticles (Cu₃(PO₄)₂·3H₂O (JCPDS file 22-0548 and PtNP JCPDS file 65-2868). In addition, Ab@Fe₃O₄ and Ap@PtNP microcomposite stability was investigated to confirm that the antibody and magainin I still maintained initial activities. As shown (Fig. S2), no thermo-signal changes were observed for *E. coli* O157: H7 detection up to 60 days at 4 °C, thus confirming microcomposite stability up to 2 months. These results suggested that microcomposites had been successfully generated for further studies.

Optimization conditions

Several different parameters were optimized: Fig. S3 A; antibody immobilization on Ab@Fe₃O₄, i.e., 8 μg mL⁻¹; (B) Fe₃O₄ particles in Ab@Fe₃O₄, 1.2 mg mL⁻¹; Fig. S4; the effects of Ab@Fe₃O₄ volume composites on capture efficiency, 5 μL; Fig. S5; (A) the concentration of magainin I, 15 μg mL⁻¹; (B) the concentration of PtNP in Ap@PtNP, 0.5 μg mL⁻¹; Fig. S6; (A) reaction temperature, 35 °C; (B) reaction time, 90 min, and (C) pH 7.

Quantitative detection of *E. coli* O157: H7

Under optimized reaction conditions, *E. coli* O157: H7, at different cell densities, was added to immunoassays to ascertain detection sensitivities. As shown (Fig. 3), a linear relationship was observed between the thermo-signal and the *E. coli* O157: H7 cell density logarithmic scale, in the range 10¹–10⁷ CFU mL⁻¹. A correlation coefficient of 0.975 (Fig. 3b) was also recorded. The linear equation was $Y = 1.631 \cdot X + 0.1000$. We also determined the limit of detection (LOD) using the

Fig. 3 Relationship between ΔT and different target concentrations. **a** 0–10⁸ CFU mL⁻¹ *E. coli* O157:H7 and **b** linear relationship between ΔT and logarithmic *E. coli* O157:H7 concentrations, 10–10⁷ CFU mL⁻¹. Three independent experiments were conducted

Fig. 4 System selectivity. Target bacteria, *E. coli* O157:H7, and other bacteria (*Staphylococcus aureus* (*Sta*); *Listeria monocytogenes* (*Lis*); and *Salmonella typhimurium* (*Sal*)) were used at a cell density of 10^7 CFU mL⁻¹. PBS was used as a control at 0.1 mM (pH = 7). All experimental conditions were optimized and three independent experiments were conducted

following formula: $3\sigma/\text{slope}$ [34] (where σ is the standard deviation of blank samples). The LOD was 14 CFU mL⁻¹, which was superior or comparable to other immunoassay detection limits (Table S1). These materials were easy to bioassay and prepare without any particular molecular interactions that supplies the results compare to other antibody/magainin I-based detection method of pathogenic bacteria [35]. The synthetic processing of this material efficiently eliminated the damage of recognizing element (antibody or magainin I) during immobilization. The main advantage of Ab@Fe₃O₄ and Ap@PtNp materials was that they integrated recognition, separation, and signal release functions to achieve a one-step cleaning detection. Hence, our bioassay had a simpler synthetic procedure and operation steps, when compared with other materials (e.g., metal-organic framework [36]), or common pathogen detection methods (e.g., ELISA [37]). Such sensitive sensing performances may be ascribed to the following: (a) magnetic microcomposites containing millions of Fe₃O₄ particles and target antibody sites, thus achieving significant target accumulation and magnetic separation, allowing thermal signal responses to be efficiently amplified; (b) signal microcomposites also have millions of material binding sites which can be layer-by-layer deposited by PtNp and peptides. Thus, the dual-microcomposite immunoassay structure exhibited great specificity for the sensitive detection of *E. coli* O157: H7.

Bioassay selectivity and reproducibility

To further confirm assay selectivity, several common foodborne pathogens were assessed; *E. coli* O157:H7, *Sal*, *Lis*, *Sta*, and a control (PBS) were investigated. Our data demonstrated that Ab@Fe₃O₄ and Ap@PtNp selectively captured only *E. coli* O157:H7 (Fig. 4). Equally, *E. coli* O157:H7 at densities of 10^2 CFU mL⁻¹, 10^3 CFU mL⁻¹, and 10^4 CFU mL⁻¹ were used to identify bioassay coefficients of variation (CV). Our data indicated that CV of 2.37%, 2.04%, and

2.24%, respectively, were achieved (in quintuplicate), thereby indicating bioassay reproducibility towards target *E. coli* O157:H7 detection.

Detection of *E. coli* O157: H7 in spiked milk samples

To truly evaluate system long-term stability in complex samples, the system was evaluated to detect different *E. coli* O157:H7 cell densities spiked into sterile pure milk. Thermo-signals were obtained and the results summarized (Table S2). These data showed that recoveries of 97.2–115.3% were achieved for milk samples by standard addition methods, with a relative standard deviation (RSD) of 3.9–10.8% ($n = 6$). This method showed an acceptable reproducibility, and has the potential to be used for complex biological samples. These results also demonstrated that the immunoassay possessed improved detection capabilities for pathogenic bacteria, with high sensitivity and accuracy.

Conclusions

In this study, a sensitive, rapid, and portable bioassay was successfully developed for detecting *E. coli* O157:H7 in complex food samples. The system was based on Ab@Fe₃O₄ microcomposite immunomagnetic separation, Ap@PtNp microcomposite signal amplification, and thermometer readings. Utilization of these materials of Ab@Fe₃O₄ and Ap@PtNp efficient guarantee this method's sensitivity and selectivity. These microcomposites need to be simplified the synthetic steps when it is be appropriate for non-professionals. Nevertheless, this POC bioassay has great potential for screening in-field foodborne pathogenic bacteria.
