Abstract Molecular differentiation in 24 accessions representing 19 taxa of Indian *Citrus* has been examined through sequence analysis of Internal Transcribed Spacer (ITS) region of nrDNA. Sequence length in the 24 accessions of *Citrus* taxa ranged from 512 to 665 bp (ITS1 & ITS2 partial and 5.8S complete sequence). The ITS sequences were very rich in G+C content ranging from 61.40 to 66.60% with an average of 64.2%. Genetic distance within *Citrus* group ranged from 0 to 13.4% with an average of 4.6%, showing

moderate rate of nucleotide divergence. The phylogeny was inferred using the Maximum parsimony (MP) and Neighbor-Joining (NJ) methods. Both MP and NJ trees separated all the 24 accessions of *Citrus* into six distinct clusters. The disposition of all the accessions of *Citrus* in separate clusters in ITS-derived dendrograms was partly in accordance with the morpho-taxonomic affinities of the target taxa. This study supports the concept of *Citrus medica* (citron), *C. reticulata* (mandarin), and *C. maxima* (pummelo) as the basic species of the genus. However, ITS marker could not find any clear cut differentiation between subgenera *Citrus* and *Papeda* as proposed in Swingle's *Citrus* classification system. The present study also supports the distinctiveness of *C. indica* (Indian wild orange), *C. latipes* (Khasi papeda) and *C. hystrix* (Melanesian papeda) as true species, besides elucidating the probable hybrid origin and relationships among the cultivated species/biotypes, such as *Citrus × aurantiifolia* (sour lime) *C. × limon* (lemon), *C. × taitensis* (Indian rough lemon), *C. limettioides* (sweet lime), *C. × aurantium* (including sour and sweet oranges and grapefruit), and other indigenous varieties of Indian origin: *C. megaloxycarpa* (sour pummelo), *C. karna* (karna orange), *C. pseudolimon* (Hill lemon), 'Memang athur', 'Pummelo-lemon' and 'Kathairi nimbu'.

Keywords *Citrus* · Internal Transcribed Spacer (ITS) · Maximum parsimony · Neighbour-joining · Phylogeny

Introduction

The genus *Citrus* L. belongs to the subfamily Aurantioideae of the family Rutaceae (Swingle and Reece 1967). It includes some of the major fruit crops of the world, such as the citrons, lemons, limes, mandarins, sour oranges, sweet oranges, pummelos, grapefruits, kumquats, etc. (Mabberley 2008). Citrus fruits are well known for their dietary, nutritional, medicinal and cosmetic properties and are also good sources of citric acid, flavonoids, phenolics, pectins, limonoids, etc. (Dugo and Di Giacomo 2002). Recent studies support the traditional uses of citrus fruits in several diseases like scurvy, cancer, HIV/AIDS, contraception, cough, and reducing blood pressure (Mabberley 2004).

Citrus is believed to have its primary centre of origin in south and south-east Asia, particularly in the region extending from northeast India, eastward through the Malayan Archipelago to China and Japan, and southward to Australia (Nicolosi 2007; Pfeil and Crisp 2008). Citrus fruits are widely cultivated throughout the tropical and subtropical regions of the world (Webber 1943). Citrus is the third most important fruit crop grown in India after mango and banana with an estimated production of 8,608,000 MT in a total area of 9,23,000 HA (Anonymous 2010).

Despite its manifold economic importance and increasing demands in the global citrus industry, the taxonomy of *Citrus* is still controversial, mainly due to the sexual compatibility between *Citrus* and its related genera, apomixis (adventive nucellar polyembryony), high frequency of bud mutations, long history of cultivation, and wide dispersion (Moore 2001). Consequently, there has been no consensus among the taxonomists as to the actual number of species that constitute the genus *Citrus*. Among the two principal *Citrus* classification systems in current practice, Swingle (1943; revised by Swingle and Reece 1967) included 16 species (10 spp. in subgenus *Citrus* and 6 spp. in subgenus *Papeda*) while that of Tanaka (1954, 1977) recognized up to 162 species in two subgenera: *Archicitrus* and *Metacitrus*. Advanced studies, based on the biochemical and morphological characterization, suggest that there are only three basic species, i.e. citron (*C. medica* L.), mandarin (*C. reticulata* Blanco), and pummelo [*C. maxima* (Burm.) Merr.] within the subgenus *Citrus* whereas the other edible citrus (e.g. lemon, lime, sour orange, sweet orange, grapefruit,

etc.) have been considered as apomictically perpetuated biotypes of probable hybrid origin (Barrett and Rhodes 1976; Scora 1988). The concept of basic species was well-supported by Moore (2001) and Mabberley (1997, 2004).

Taxonomic characterization leading to unambiguous identification of *Citrus* species and their genetic resources are essential requisites for citrus breeding, citriculture and citrus industry. Since morphological characters are only of limited use, alternate approaches, including application of appropriate molecular markers, have now been increasingly adopted to address the problems in *Citrus* taxonomy. Several workers have revisited the taxonomy and phylogeny of *Citrus* and related genera using molecular markers such as isozymes (Herrero et al. 1996), RAPD & PCR-RFLP (Federici et al. 1998; Abkenar et al. 2004), RAPD, SCAR & PCR-RFLP (Nicolosi et al. 2000; Jena et al. 2009), AFLP (Liang et al. 2007; Pang et al. 2007), SSR (Barkley et al. 2006), ISSR (Fang et al. 1998; Shahsavari et al. 2007) and sequence data analysis of ITS region of nrDNA (Xu et al. 2006; Kyndt et al. 2010; Pessina et al. 2011) and non-coding chloroplast DNA (cpDNA) regions (Chase et al. 1999; Araujo et al. 2003; Morton et al. 2003; Lu et al. 2011). Bayer et al. (2009), in a recent molecular analysis based on nine cpDNA sequences, broadened the circumscription of *Citrus* to include seven other closely related genera of the orange subfamily, such as *Clymenia* Swingle, *Fortunella* Swingle, *Poncirus* Raf., *Microcitrus* Swingle, *Eremocitrus* Swingle, *Oxanthera* Montrouz., and *Feroniella* Swingle.

India is rich in *Citrus* genetic resources, both in cultivation and wild. In a systematic account on Indian *Citrus*, Nair and Nayar (1997) followed primarily Swingle and Reece (1967) and partly Tanaka (1977) and included 18 taxa, comprising of eight species under subgenus *Citrus*, three under subgenus *Papeda*, and seven other indigenous *Citrus* varieties with a suspected hybrid origin and uncertain taxonomic affinities. In an earlier study (Jena et al. 2009), the present authors examined the molecular phylogeny of Indian *Citrus* using PCR-RFLP of the *trnD-trnT* and *rbcL-ORF 106* regions as well as sequence data analysis of the *trnL-trnF* intergenic spacer region of cpDNA. In the present study, we have revisited the phylogenetic relationships among the Indian *Citrus* species/varieties using sequence variation in ITS (internal transcribed spacer) region of nuclear ribosomal DNA.

Materials and methods

Plant samples

Fifty accessions of 19 *Citrus* taxa or biotypes (species/cultivars/hybrids) and one out-group taxon [*Atalantia monophylla* (L.) DC.] were collected from wild as well as domesticated stocks from different parts of India. Young fresh leaf tissues from all the sample materials were collected and stored in silica gel (20–60 mesh) and were used subsequently for genomic DNA isolation. Details of accessions used for morphometric and ITS sequence analyses are given in Table 1. Voucher specimens of all the accessions were deposited in the Herbarium of the National Botanical Research Institute (LWG), Lucknow, India.

Morphological characterization

Fifty accessions of *Citrus* (Table 1) were used for morpho-metric analysis. Seventy-six discrete morphological characters (33 quantitative and 43 qualitative characters) were selected from taxonomic literature (Barrett and Rhodes 1976; IPGRI 1999; Nair and Nayar 1997) and by examination of living plants and herbarium collections of Indian *Citrus* (ESM_1.pdf). The characters were converted into bi-states and multi-states (interval) code (ESM_2.pdf). Standardization of morphological data was done based on YBAR option with the software NTSYS ver. 2.10e (Rohlf 2000). A pair wise similarity matrix was generated using Simple Matching coefficient and a dendrogram was constructed based on UPGMA (Unweighted Pair Group Method by Arithmetic averages) with the same software. Principal Coordinate Analysis (PCOA) was performed to analyse non-hierarchical relationship among the accessions (Gower 1966). This analysis was executed by calculating the eigenvectors and eigenvalues from Eigen programme in the NTSYS software, which resulted in a two-dimensional plot.

DNA extraction

Total genomic DNA was isolated from a final set of 25 representative accessions through Cetyl Trimethyl Ammonium Bromide (CTAB) method (Rogstad 1993). Quantitation of isolated DNA was done spectrophotometrically and its quality checked by electrophoresis on 0.8% agarose gel.

ITS-PCR amplification, Sequencing and Sequence analysis

Entire ITS region (ITS1, 5.8S, ITS2) of *Citrus* and outgroup accessions was amplified using a pair of universal primers, i.e. ITSP4—TCCTCCGCTTATTGATATGC (White et al. 1990) and ITSP5—AAGTCGTAACAAGGTTTCCGTAG (Kollipara et al. 1997). The concentration of PCR components was optimized for amplification of ITS region: 10 mM Tris (pH 8.9), 50 mM KCl, 0.2 mM dNTP each, 1.5 mM MgCl₂, 1 U *Taq* DNA polymerase, 10 pmol primer each (ITSP4 and ITSP5) and 50 ng genomic DNA in 50 µl final reaction volume. PCR was programmed as pre-denaturation at 94°C for 3 min, 35 cycles of denaturation at 94°C for 1 min, annealing at 50°C for 1 min, extension at 72°C for 1.5 min and final extension at 72°C for 5 min.

Total ITS-PCR products were electrophoresed in 0.8% low melting agarose gel (Bangalore Genei) at 80 V for 3 h, and bands were visualized in UVITec Gel Documentation System. The bands were excised and purified using Clean Genei kit (Bangalore Genei). The yield of purified DNA was quantified using UV spectrophotometer. Eluted PCR products were sequenced using an Applied Biosystems Automated Sequencer (Model 3730, version 3.1) using both forward and reverse primer. Sequences of 25 accessions of *Citrus* including one outgroup were annotated and submitted to the NCBI GenBank (accessions nos. GQ225843—GQ225867).

The identity of sequences was confirmed through a BLASTn search in NCBI data base (Altschul et al. 1997) for determining their homology with sequences of related taxa available in EMBL/GenBank Data bases. The sequences were aligned using Clustal-W program (Higgins et al. 1994) with the default settings. Phylogenetic analysis was carried out in MEGA 4 software (Tamura et al. 2007). Pair-wise sequence divergence rates between accessions were calculated using Maximum Composite Likelihood method (Tamura et al. 2004). Phylogeny reconstruction was carried out using Maximum Parsimony (MP) and Neighbor Joining (NJ) methods. MP tree was constructed using the Close-Neighbor-Interchange algorithm with search level 3 in which the initial trees were obtained with the random addition of sequences (10 replicates), while NJ tree was obtained using the Maximum Composite Likelihood criterion. In MP analysis all the

* Indicates samples used for ITS analysis

characters were assigned equal weights at all nucleotide positions (Fitch 1971). In the MP and NJ analyses, all positions containing gaps and missing data were eliminated from the dataset (Complete Deletion option). Support values of the internal branches of MP and NJ trees were evaluated through boot strap method (500 replicates) (Felsenstein 1985).

Results

Morpho-metric analysis

Similarity values of all the fifty accessions of *Citrus* ranged from 0.18 to 1.00 with an average of 0.39 (ESM_3.pdf). *C. megaloxycarpa* Lush. (CMEG-S1)

showed minimum similarity value of 0.18 with all accessions of *C. reticulata* (CRET-B1, CRET-S2 and CRET-L3). Maximum similarity at interspecific level was observed between *C. pseudolimon* Tanaka (CPSE-L4) and *C. ×limon* (L.) Burm. f. (CLIM-L1 and CLIM-L2).

The UPGMA dendrogram (Fig. 1) resolved four main clusters and eight groups as shown below:

Cluster I: Group I: *C. megaloxycarpa* Lush. (Sour Pommelo) and *C. sp.* (Pummelo-lemon); Group II: *C. maxima* (Burm.) Merr. (Sweet pummelo), *C. sp.* (Kathairi nimbu) and *C. ×aurantium* L. (Grapefruit),

Cluster II: Group I: *C. ×aurantium* L., (Sour orange), *C. ×aurantium* L. (Sweet orange); Group

10	71.6680	11.9483	2.0314	89.4942

II: *C. latipes* (Swingle) Tanaka (Khasi papeda), *C. hystrix* DC. (Melanesian papeda),

Cluster III: Group I: *C. ×aurantiifolia* (Christm.) Swingle (Sour lime), *C. limettioides* Tanaka (Sweet lime); Group II: *C. medica* L. (Citron), *C. ×limon* (L.) Burm. f. (Lemon), *C. pseudolimon* Tanaka (Hill lemon), *C. karna* Raf. (Karna orange), *C. ×taitensis* Lush. (Indian rough lemon),

Cluster IV: Group I: *C. reticulata* Blanco (Mandarin); Group II: *C. indica* Tanaka (Indian wild orange), and *C. sp.* (Memang athur).

Mantel test was carried out for comparing the UPGMA cluster analysis and similarity matrix. A correlation value ($r = 0.93$) showed very good fit of UPGMA clustering pattern to the data. PCOA was used for identifying multi-dimensional relationships among characters for the definition of groups. In this analysis, 1st and 2nd principal co-ordinates accounted for 28.01 and 19.13% of the total variation, respectively (Table 2). 2-D plot (Fig. 2) generated through PCOA also showed the same grouping pattern as the UPGMA dendrogram.

ITS sequence data

The BLASTn search helped determine that the new sequences were from ITS region and maximum homology was obtained from ITS sequences of *Citrus* and related taxa of Rutaceae. On the basis of the angiosperm consensus motif determined by Jobes and Thien (1997), the putative start and end points of 5.8 S regions in the aligned sequences were identified. The aligned ITS sequences are shown in Fig. 3. Sequence

length in the 24 *Citrus* accessions ranged from 512 to 665 bp (ITS1 & ITS2 partial and 5.8S complete sequence) and 564 bp in *A. monophylla*. In *Citrus*, the length of ITS1 ranged from 118 to 269, ITS2 from 150 to 276 and 5.8S from 162 to 165. The data set including alignment gaps and missing data comprised 741 bp aligned nucleotide positions, which included 388 conserved sites, 320 variable sites and 144 parsimony informative sites. When missing data were excluded, the sequence length was 463 bp, including 293 conserved, 159 variable and 82 parsimony informative sites. The ITS sequences were very rich in G+C content ranging from 61.40% (*C. ×aurantiifolia*) to 66.60% (*C. maxima*) with an average of 64.2%. The nucleotide frequencies were found as 0.208 (A), 0.316 (C), 0.304 (G), and 0.171 (T). The transition/transversion rate ratios were $k1 = 1.167$ (purines) and $k2 = 2.796$ (pyrimidines). Transition/transversion bias (R) was 1.158. Summary of ITS sequence data is given in Table 3 and 4.

ITS sequence analysis showed moderate rate of nucleotide divergence within and among the *Citrus* taxa and *A. monophylla* (Table 5). Genetic divergence within *Citrus* group ranged from 0 to 13.4% with an average of 4.6%. *C. megaloxycarpa* showed 0% nucleotide divergence with *C. ×limon*, while maximum distance (13.4%) was found between *C. indica* (CIND-D08) and *C. ×aurantiifolia*. Sequence divergence within *C. indica* accessions ranged from 0.8% (CIND-N25 and CIND-K26) to 4.1% (CIND-D08 and CIND-D18) with an average of 2.5%. Nucleotide divergence between the basic species of *Citrus* was 3.6% (*C. medica* and *C. maxima*), 2.1% (*C. maxima* and *C. reticulata*), and 2.5% (*C. medica* and *C. reticulata*).

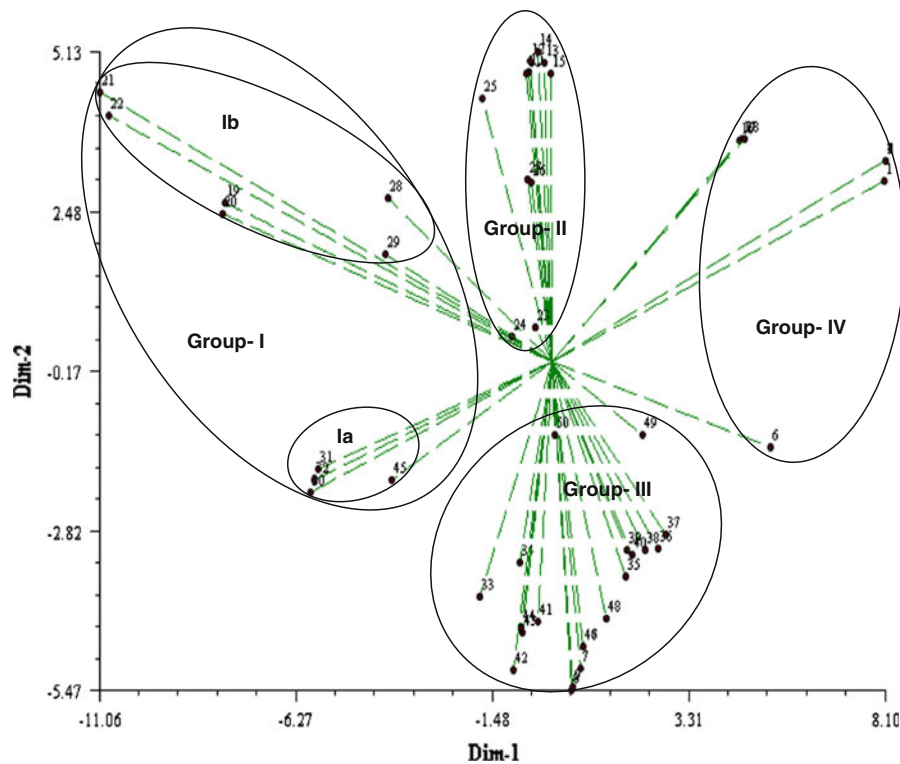

Fig. 2 2-D plot of the first and second co-ordinate axes, derived from principal coordinate analysis of 50 accessions of *Citrus* using morpho-metric data. The 1st and 2nd co-ordinates are

28.01 and 19.13% respectively (*Note:* Numbers are equivalent to those listed in Table 1)

In the aligned sequence, three substitutions were recorded only in *C. indica* and ‘Memang athur’ at coordinate 265 (C→T), 316 (C→T) and 459 (A→T) (Fig. 3). One substitution (coordinate 26, G→A) was observed only in citron group (*C. medica*, *C. ×taitensis*, *C. ×limon*, *C. ×aurantiifolia*, *C. limettioides*) and ‘Memang athur’. Similarly, one substitution occurred at coordinate 390 (A→G) only in *C. ×taitensis* and ‘Memang athur’. Two substitutions occurred at coordinate 10 (C→T) and 353 (C→T) in *C. maxima*, *C. ×aurantium* (Sour orange) and *C. ×aurantium* (Grapefruit).

Maximum Parsimony (MP) analysis resulted in 63 most parsimonious trees (length = 154), out of which a single fully resolved consensus tree is shown in Fig. 4, with consistency index (CI—0.6804) and retention index (RI- 0.7350). The percentage of replicate trees in which the associated taxa clustered together in the bootstrap test (500 replicates) is shown at the nodes. There were a total of 380 positions in the final dataset, out of which 50 were parsimony

informative. Maximum parsimony tree (Fig. 4 and 5) placed all accessions in the following six clusters:

- Cluster I: *C. pseudolimon* and ‘Pummelo-lemon’; ‘Kathairi nimbu’ and *C. ×aurantiifolia*;
- Cluster II: *C. medica* –W and *C. medica*-D;
- Cluster III: *C. reticulata*, *C. ×aurantium* (Grapefruit), and *C. ×aurantium* (Sour orange);
- Cluster IV: *C. ×taitensis*, *C. limettioides*, *C. ×limon*, *C. megaloxycarpa*, and *C. karna*;
- Cluster V: *C. latipes*, *C. hystrix*, *C. maxima* and *C. ×aurantium* (Sweet orange);
- Cluster VI: *C. indica*, and ‘Memang athur’.

Atalantia monophylla was separately attached at the base of tree as the diverging *Citrus* relative’s lineage. The phylogeny was also inferred using the Neighbor-Joining method, which resulted in an optimal tree with the SBL (sum of branch length) of 0.3911. There were a total of 380 positions in the final dataset. The optimal NJ tree (Fig. 6) separated all the 24 accessions in the six clusters as similar to MP tree.

Discussion

All major morphology-based classification of *Citrus* (Swingle 1943; Swingle and Reece 1967; Tanaka 1954, 1977; Bhattacharya and Dutta 1956; Hodgson 1965; Singh 1967; Singh and Nath 1969) relied on combination of a few special characters of the foliage (size and shape of the petiole wings and the ratio between length/breadth of petiole and lamina), flower (number of flowers per inflorescence, colour of buds and petals, cohesion of stamens), fruits (size, shape, texture and colour of epicarp, presence or absence of mamillate apex, thickness and texture of mesocarp, taste of juice) and seed (size, shape, colour of cotyledon and chalazal cap). Frequent hybridization, introgression, bud mutations and polyploidy have created innumerable hybrids and mutant varieties of

Citrus throughout the Citrus belt of the world. This in turn created confusion among taxonomists in comprehending the species and generic limits within *Citrus* and closely related genera within the orange subfamily. Those who followed the biological species concept did not accord true species status to natural or human-made hybrids and bud sports of Citrus fruits (Swingle and Reece 1967; Mabberley 1998, 2004, 2008), whereas others like Tanaka (1977), who followed an horticultural concept, gave true species status to any notable variants of Citrus fruits, irrespective of their actual mode of origin and taxonomic affinities. While both the above approaches have their own merits and demerits, a proper circumscription and classification of *Citrus* at global, regional and national scale is still awaited. In the present study we have analysed the resolving power of morphological and molecular (nr

Table 4 Results of ITS sequence analysis

Parameters	ITS
Length range (In-group) (bp)	512–665
Length (Out-group) (bp)	564
Aligned length (bp) including missing data	741
No. of conserved sites (%)	388 (52.36)
No. of variable sites (%)	320 (43.18)
No. of Informative sites (%)	144 (19.43)
Aligned length (bp) excluding missing data	463
No. of conserved sites (%)	293 (63.28)
No. of variable sites (%)	159 (34.34)
No. of Informative sites (%)	82 (17.71)
G+C content range (%)	61.4–66.6
G+C content mean (%)	64.2
Sequence divergence (%)	0–13.4
Nucleotide frequencies of	
Adenine	0.208
Thymine	0.171
Cytosine	0.316
Guanine	0.304
Transition/transversion rate ratios for	
Purines (K1)	1.167
Pyrimidines (K2)	2.796
Overall transition/transversion bias (R)	1.158
No. of MP trees	63
Branch length	154
Consistency Index (CI)	0.6804
Retention Index (RI)	0.7350

DNA ITS) markers in discriminating the true basal species, probable hybrids and varieties of Indian *Citrus*. The main results of morpho-metric and ITS sequence analyses are discussed to elucidate the taxonomic identity, origin and phylogeny of 19 biotypes of Indian *Citrus* studied.

ITS sequence variations

ITS analysis carried out in Indian taxa of *Citrus* was useful in differentiating all the true species and species/varieties of probable hybrid origin in distinct clusters or groups. Range of ITS sequence length (512–665 bp) of *Citrus* was almost similar to that of ITS sequence length (565–634 bp) of *Phebalium* group (Rutaceae: Boronieae) (Mole et al. 2004). ITS1 sequence length in *Citrus* species ranged from 118 (including partial sequences) to 269 bp, while

ITS2 region ranged from 150 (including partial sequences) to 276 bp. Similar length variation was also reported in several angiosperms (Baldwin 1993; Baldwin et al. 1995). GC content of ITS region was also found very high (61.40–66.60%) in *Citrus*, which is slightly higher (50–67%) than that reported in *Cucurbita*, *Cucumis* and other genera of Cucurbitaceae (Jobst et al. 1998). Similar case was also observed in the plants of Poaceae, in which higher GC content was reported in arid region than the plants from temperate region (Salinas et al. 1988).

In *Citrus*, 293 conserved, 159 variable and 82 parsimony informative sites were found in the aligned ITS sequences (463 bp, excluding missing data). Maximum conserved regions were observed in 5.8S and ITS2 regions. Maximum variable sites were found in ITS1 region. Similar results were also reported in *Citrus* by Xu et al. (2006), who observed that the ITS1 region in *Citrus* taxa showed maximum nucleotide variations due to high rate of point mutation. Interspecific sequence divergence in *Citrus* ranged from 0 to 13.4%, which was comparatively lower than that of reported nucleotide sequence divergence in *Coffea* (Rubiaceae; 1.5–39%; Lashermes et al. 1997). However, low sequence divergence (0.0–4.86%) was also observed in *Cistus* (Cistaceae) (Guzmán and Vargas 2005).

Phylogenetic relationships among Indian *Citrus*

The UPGMA dendrogram based on morpho-metric analysis (Fig. 1) and the MP and NJ trees (Fig. 4, 5 and 6) generated through nr DNA ITS sequence analysis segregated *C. maxima*, *C. medica* and *C. reticulata* in separate clusters. The clear separation of these three species in three distinct clusters supports the concept of basic species within *Citrus*.

Citrus medica (citron) is believed to have acted as male parent in the origin of several hybrids/cultivars of *Citrus* (Federici et al. 1998; Nicolosi et al. 2000; Moore 2001; Mabberley 2004). In our morpho-metric study, all the accessions of *C. ×limon*, *C. pseudolimon*, *C. karna*, *C. ×taitensis*, *C. ×aurantifolia* and *C. limettioides* grouped along with *C. medica* in cluster III. Our ITS data recognized *C. medica* as a true basic species as both wild and domesticated accessions of the species grouped in the cluster II with a very high bootstrap value of 95% (NJ tree) and 86% (MP tree). One substitution (coordinate 26, G→A)

Table 5 Pairwise genetic divergence of 24 accessions of *Citrus* species and the outgroup, *Atalantia monophylla* from ITS sequence data using Maximum Composite Likelihood method

1. *Citrus indica* (CIND-D07)-W, 2. *C. indica* (CIND-D08)-W, 3. *C. indica* (CIND-D18)-D, 4. *C. indica* (CIND-N25)-W, 5. *C. indica* (CIND-K26)-W, 6. *C. sp.* (Memang-athur), 7. *C. medica*-W, 8. *C. medica*-D, 9. *C. latipes*, 10. *C. hystrix*, 11. *C. maxima*, 12. *C. reticulata*, 13. *C. ×aurantium* (sweet orange), 14. *C. ×aurantium* (grapefruit), 15. *C. ×aurantium* (sour orange), 16. *C. megaloxycarpa*, 17. *C. sp.* (Kathairi nimbu), 18. *C. ×tattensis* (rough lemon), 19. *C. karna*, 20. *C. ×limon*, 21. *C. pseudolimon*, 22. *C. sp.* (Pummelo-lemon), 23. *C. ×aurantifolia*, 24. *C. ×aurantifolia*, 25. *Atalantia monophylla*

Bold represents minimum and maximum value of sequence divergence

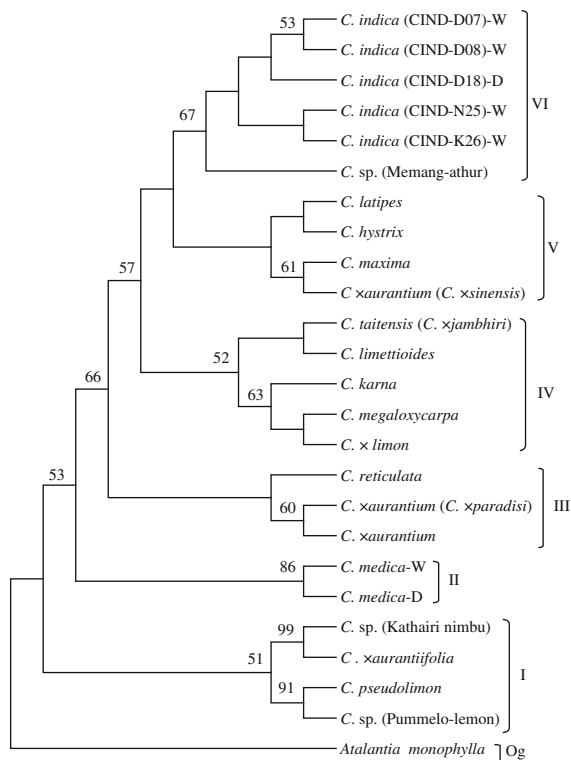

Fig. 4 MP bootstrap consensus tree of 24 accessions of *Citrus* and the outgroup, *Atalantia monophylla* from ITS sequence data analysis. Numbers are bootstrap values based on 500 resampling

was observed only in citron group (*C. medica*, *C. x taitensis*, *C. x limon*, *C. x aaurantiifolia*, *C. limettioides*) and ‘Memang athur’. This substitution indicates involvement of *C. medica* as one of parents in the hybrid origin of lemons and limes. *C. x taitensis*, *C. limettioides*, *C. megaloxycarpa*, and *C. karna* grouped in the same cluster in both NJ and MP trees, with a robust bootstrap value of 85%, indicative of their common lineage. Based on morphology all these species (except *C. limettioides*) are characterized by having mammillate fruit apex, which is characteristic of *C. medica*. So the involvement of citron as one of the parents in the origin of *C. x taitensis*, *C. megaloxycarpa* and *C. karna* could not be ruled out. This result also indicates that one of the species of citron group may be acted as putative parent in the origin of ‘Memang athur’. This inference further gained support by substitution occurred at coordinate 390 (A→G) only in *C. x taitensis* and ‘Memang athur’, as both are morphologically most similar in fruit characters.

Citrus maxima and *C. reticulata* are believed to have contributed to the development of several

Fig. 5 MP bootstrap condensed tree of 24 accessions of *Citrus* and the outgroup, *Atalantia monophylla* from ITS sequence data analysis. Numbers are bootstrap values based on 500 resampling. Branches with <50% bootstrap values are collapsed

commercial *Citrus* fruits, such as sour orange (*C. x aaurantium*, a cross between mandarin and pummelo), sweet orange (*C. x aaurantium*; *syn. C. sinensis* (L.) Osbeck (a backcross between pummelo and mandarin), grapefruit (*C. x aaurantium*; *syn. C. paradisi* (a backcross between pummelo and sweet orange) (Moore 2001; Mabberley 2004). In UPGMA tree, the sour and sweet oranges were grouped together in a separate cluster along with the Khasi papeda and Melanesian papeda, while in the MP and NJ trees the grapefruit and sour orange formed a separate cluster along with *C. reticulata*, and the sweet orange grouped with *C. maxima* along with the Khasi papeda and Melanesian papeda. Our previous study, based on cpDNA data, also elucidated the involvement of *C. reticulata* as a maternal parent in the origin of sweet orange (Jena et al. 2009). The consistent grouping of sweet orange with *C. maxima* in the ITS-derived trees indicates the role of *C. maxima* as a male parent in the

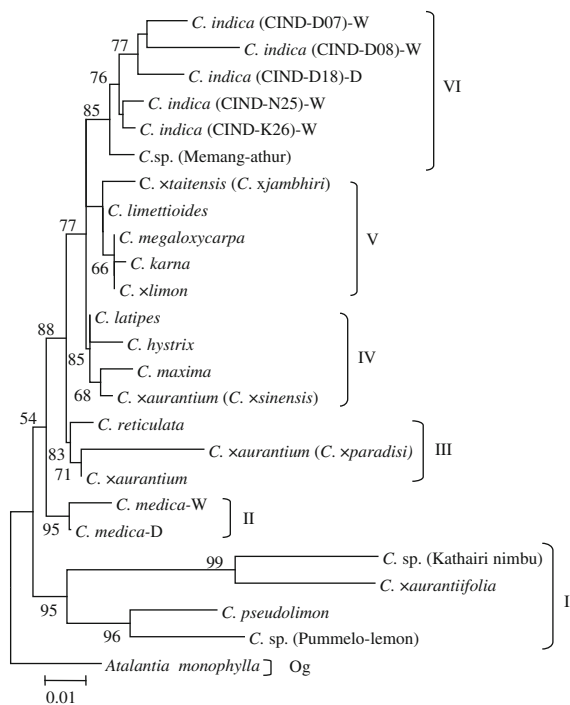

Fig. 6 NJ bootstrap consensus tree of 24 accessions of *Citrus* and the outgroup, *Atalantia monophylla* from ITS sequence data analysis. Numbers are bootstrap values based on 500 resampling

origin of sweet oranges. Moreover, two substitutions at coordinate 10 (C→T) and 353 (C→T) in *C. maxima*, *C. xaurantium* (sour orange) and *C. xaurantium* (grapefruit) support a common genetic lineage of the three species. These results support that involvement of both *C. maxima* and *C. reticulata* in the hybrid origin of the sour orange, sweet orange and grapefruit.

Swingle and Reece (1967) divided *Citrus* into two subgenera: *Citrus* and *Papeda*. The wild species including *C. latipes* and *C. hystrix* were classified under subgenus *Papeda* of the genus *Citrus* by Swingle (1943). Tanaka (1954) also classified the wild species of *Citrus* under *Archicitrus*, which also included other cultivated species like citrons, lemons, limes, oranges and pummelos. Our ITS data analysis, however, could not find any clear cut differentiation between subgenera *Citrus* and *Papeda* according to Swingle's system. This supports the earlier findings of Nicolosi et al. (2000) and Pang et al. (2007). In NJ and MP trees, based on ITS sequence data, *C. latipes* and *C. hystrix* were grouped with *C. maxima* and *C. xaur-*

antium (sweet orange) in the same cluster with a robust bootstrap value (85%). This grouping showed close genetic affinity of the Papedas with the Pummelos as supported by earlier studies based on RAPD and RFLP (Federici et al. 1998), cpDNA (Nicolosi et al. 2000), and AFLP (Pang et al. 2007).

Citrus indica is a true wild species endemic to the Garo Hills in Meghalaya. Tanaka (1928) was the first to describe it as a new species. He (Tanaka 1977) placed *C. indica* in section *Acrumen* of the Subgenus *Metacitrus*. Cluster IV in our UPGMA tree included *C. indica*, 'Memang athur' and *C. reticulata*, which diverged from other clusters with similarity value of 0.34. 'Memang athur' consistently grouped with *C. indica* with maximum similarity (0.56), indicating closer relationship among the two. All accessions of *C. indica* and 'Memang athur' diverged from *C. reticulata* group with similarity value of 0.43, showing maximum similarity with *C. reticulata* based on morphology. This grouping supports Tanaka's placement of *C. indica* with the mandarins. Swingle and Reece (1967) suspected *C. indica* to be of hybrid origin involving a wild species of *Citrus* (*C. latipes*?) and one of the cultivated species of *Citrus* as putative parents. Maberley (2004) also subscribed Swingle's view in treating *C. indica* as a species of suspected hybrid origin. Based on RAPD and PCR-RFLP data, Federici et al. (1998) argued against the hybrid origin of *C. indica*. In our ITS analysis, *C. indica* was independently grouped with its close variant 'Memang athur' in the cluster VI in both MP and NJ trees. This result, therefore, does not support the hybrid origin of *C. indica* as it consistently separated out as a distinct cluster with good boot strap support (67 and 77%). Similar result was also found in our previous study based on sequence analysis of *trnL-trnF* region cpDNA (Jena et al. 2009).

'Memang athur' is a hitherto unidentified *Citrus* fruit, which we could locate in one of the Garo tribal settlements in Daribokgre in NBR and its vicinity. Morphologically, 'Memang athur' looks more similar to *C. indica* in the leaf shape, small and scarlet red fruits, and medium to large sized plumpy seeds. Some characters, like petiole size, serrations on leaf margin, flowers with thick fleshy, 4 or 5 purplish tinged petals, mammiform fruit apex, longitudinal furrow and ridge on the surface, and reddish chalazal cap bring 'Memang athur' much closer to *C. medica*. Based on

the morphological characters and partial seed sterility, ‘Memang athur’ appears to be a probable hybrid. Malik et al. (2006) suspected it to be a hybrid between *C. indica* and one of the cultivated *Citrus* species. In the aligned sequence, three substitutions at coordinate 265 (C→T), 316 (C→T) and 459 (A→T) in *C. indica* and ‘Memang athur’ and grouping together in the same cluster of MP and NJ trees support our previous study in *Citrus* based on ISSR markers (Kumar et al. 2010) that *C. indica* is perhaps one of the putative parents involved in the hybrid origin of Memang athur. This gained further support from phylogenetic trees that ‘Memang athur’ consistently grouped along with *C. indica* in all the trees. ‘Memang athur’ clearly separated from *C. indica* with a robust bootstrap value of 85% (NJ tree) and 67% (MP tree), within the cluster VI of ITS derived trees, which showed close similarity with *C. indica*. The results support that ‘Memang athur’ is closely related to *C. indica* genetically.

Citrus megaloxycarpa (sour pummelo) is suspected to be a probable hybrid between *C. maxima* and *C. ×limon* (Nair and Nayar 1997). It is morphologically close to *C. maxima*, except difference in some characters like presence of marginate or narrowly winged petiole, purplish tinged petal, sour juice and purple chalazal cap. Lushington (1910) established it as a valid species. Bhattacharya and Dutta (1956) and Tanaka (1977) also accepted it as a valid species, while Swingle and Reece (1967) and Nair and Nayar (1997) considered it as a probable hybrid. The present morpho-metric data support that *C. megaloxycarpa* is very close to *C. maxima*, while our ITS data show the placement of *C. megaloxycarpa* in the *C. ×limon* cluster in both MP and NJ trees. The genetic identity (100% similarity) between *C. megaloxycarpa* and *C. ×limon* as shown in the nucleotide divergence rate (0%; Table 5) is indicative of the probable hybrid origin and close phylogenetic affinity of sour pummelo with the lemon group.

C. pseudolimon (the ‘Hill-lemon or ‘Gulgal’ or ‘Kumaon lemon’) has been considered as a variety of lemon. Morpho-metric data placed the ‘Hill lemon’ in the citron cluster along with lemon and lime groups. ITS analysis, on the other hand supported its placement in the sour lime group along with ‘pummelo-lemon’ and ‘Kathairi nimbu’. ‘Kathairi nimbu’ is an unusually interesting citrus fruit characterized by prominently bumpy-warty epicarp, broadly mammillae or

depressed apex and a prominently collared neck at base. It is a seedless form, clonally propagated through suckers or stem cuttings. Morpho-metric results showed close morphological affinity of ‘Kathairi nimbu’ to *C. maxima*, whereas in ITS analysis it consistently grouped with the sour lime (*C. ×aurantiifolia*) cluster. ‘Pummelo-lemon’ is another interesting variety/hybrid, showing intermediate characters of pummelo and lemon. Based on ITS data, it clustered along with Hill lemon and lime group while morphological data supported the close relationship of Pummelo-lemon with pummelo (*C. maxima*).

Conclusions

ITS analysis carried out in Indian taxa of *Citrus* was useful in differentiating all the true species and species/varieties of probable hybrid origin in distinct clusters or groups. The disposition of all the accessions of *Citrus* in distinct clusters based on ITS sequence data was partly in accordance with the morpho-taxonomic affinities of different taxa. The separation of *Citrus maxima*, *C. medica* and *C. reticulata* in distinct clusters or subclusters supports their distinctiveness as the basic species of edible *Citrus*. ITS sequence analysis could not find any clear cut differentiation between subgenera *Citrus* and *Papeda* according to Swingle’s system. The study also supported the distinctiveness of *C. indica*, *C. latipes* and *C. hystrix* as true species, besides elucidating the hybrid origin and relationships among the cultivated species/biotypes, such as *C. ×aurantiifolia*, *C. ×limon*, *C. ×taitensis*, *C. limettioides*, *C. ×aurantium* (including sour and sweet oranges and grapefruit), *C. megaloxycarpa*, *C. karna*, *C. pseudolimon*, ‘Memang athur’, ‘Pummelo-lemon’ and ‘Kathairi nimbu’. The outcomes of this study will be useful for correct taxonomic identification, documentation, characterization and evaluation of Indian *Citrus* and its genetic resources.

Acknowledgments The authors wish to thank the Director, CSIR-National Botanical Research Institute (NBRI) for providing facilities to carry out this work, and the officers & staff of Nokrek Biosphere Reserve (NBR), Tura, Meghalaya for their help and support during exploration trips to NBR. The financial support received from the Department of Biotechnology, New Delhi and the Council of Scientific and Industrial Research (CSIR), New Delhi to carry out this work is gratefully acknowledged.
