**Abstract** The  $\text{MgB}_2$  superconductor was doped with electroluminescent  $\text{Y}_2\text{O}_3:\text{Eu}$ , to synthesise a superconducting metamaterial. The temperature dependence of the resistivity of the superconductor indicates that the critical temperature ( $T_C$ ) of samples decreases when increasing the amount of doped  $\text{Y}_2\text{O}_3$  nanorods, due to impurity ( $\text{Y}_2\text{O}_3$ ,  $\text{MgO}$  and  $\text{YB}_4$ ). However, the  $T_C$  of the samples increase with increasing amount of doped  $\text{Y}_2\text{O}_3:\text{Eu}^{3+}$  nanorods, which are opposite to doped  $\text{Y}_2\text{O}_3$  nanorods. Moreover, the transition temperature of the sample doped with 8 wt %  $\text{Y}_2\text{O}_3:\text{Eu}^{3+}$  nanorods is higher than those of doped and pure  $\text{MgB}_2$ . The  $T_C$  of the sample doped with 8 wt %  $\text{Y}_2\text{O}_3:\text{Eu}^{3+}$  nanorods is 1.15 K higher than that of the sample doped with 8 wt %  $\text{Y}_2\text{O}_3$ . The  $T_C$  of sample doped with 8 wt %  $\text{Y}_2\text{O}_3:\text{Eu}^{3+}$  is 0.4 K higher than that of pure  $\text{MgB}_2$ . Results indicate that doping electroluminescent materials into  $\text{MgB}_2$  increases the transition temperature; this novel strategy may also be applicable to other superconductors.

**Keywords**  $\text{Y}_2\text{O}_3:\text{Eu}^{3+}$  nanorods ·  $\text{MgB}_2$  superconductor · Solid-state method ·  $T_C$

## 1 Introduction

The binary metal boride superconductor  $\text{MgB}_2$  has attracted considerable attention in theoretical studies and applications

[1–6].  $\text{MgB}_2$  presents a great potential in superconductive device applications because of its advantages, namely, relatively high critical temperature ( $T_C$  nearly 40 K) [1], large superconducting correlation length [7], high critical current density, wide energy gap [8] and facile preparation.

$\text{MgB}_2$  is an inexpensive type II superconductor with a simple structure and can be easily synthesised [3]. However, the application of  $\text{MgB}_2$  is restricted by its lower  $T_C$  compared with those of high-temperature superconductors. Several studies attempted to increase  $T_C$  by using doping agents. Results indicated that dopants decrease the  $T_C$  of the  $\text{MgB}_2$  superconductor [9] and affect its physical properties, such as carrier concentration, lattice constant and crystallinity [10]. For example, doping aluminium (or carbon) in place of Mg (or B) in  $\text{MgB}_2$  significantly decreases the  $T_C$  of  $\text{MgB}_2$  [11]. Recently, Ma et al. increased the  $T_C$  of commercial  $\text{MgB}_2$  from 33.0 to 37.8 K through nonsubstitutional hole-doping of the  $\text{MgB}_2$  structure with small, single-wall carbon nanotube inclusions [12].

Metamaterials have gained increased attention because of their special properties and application potential [13–17]. In 2007, our group proposed that combining inorganic electroluminescent (EL) materials with metamaterials can induce a substantial change in superconducting materials, left-handed materials, photonic crystals and so on [18]. In the same year, Jang et al. studied the effects of ZnO doping on the superconductivity and crystal structure of the (Bi, Pb)-2233 superconductor [19]. Light-induced superconductivity has recently been considered as a research hotspot. In 2011, Cavalleri et al. used mid-infrared femtosecond pulses to transform a stripe-ordered compound, namely, nonsuperconducting  $\text{La}_{1.675}\text{Eu}_{0.2}\text{Sr}_{0.125}\text{CuO}_4$ , into a transient three-dimensional superconductor [20]. In 2013, Cavalleri et al. experimentally demonstrated the excitation of Josephson plasma in  $\text{La}_{1.84}\text{Sr}_{0.16}\text{CuO}_4$ , by using intense

narrowband radiation from infrared free-electron laser tuned to the 2-THz Josephson plasma resonance [21]. The group believed that laser pulse led to deformed crystal structures and induced superconductivity [22].

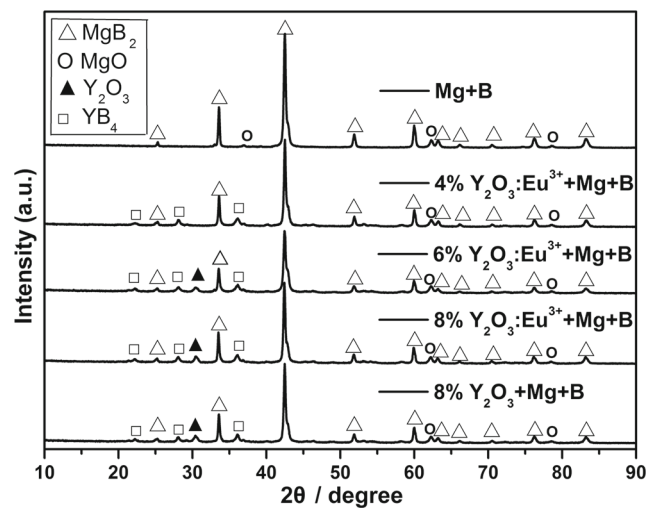

$\text{Y}_2\text{O}_3:\text{Eu}^{3+}$  phosphor is a well-known red phosphor used in fluorescent light, field emission displays and cathode ray tubes, because of its excellent luminescence efficiency, narrow spectra, high brightness and environmental and chemical stability [23, 24]. In this paper, we examined the effect of electroluminescence on  $T_C$  by doping  $\text{Y}_2\text{O}_3$ ,  $\text{Y}_2\text{O}_3:\text{Sm}^{3+}$  and  $\text{Y}_2\text{O}_3:\text{Eu}^{3+}$  nanorods into the  $\text{MgB}_2$  superconductor to produce a superconducting metamaterial. The appropriate doping content for increasing the  $T_C$  of the  $\text{MgB}_2$  superconducting metamaterial was demonstrated by controlling the concentration of  $\text{Y}_2\text{O}_3:\text{Eu}^{3+}$  nanorods.

## 2 Experimental Section

Bulk  $\text{MgB}_2$  sample was synthesised with  $\text{Y}_2\text{O}_3:\text{Eu}^{3+}$  nanorods by traditional solid-state sintering [25]. Briefly, 0.22 g of magnesium (Mg, 97 % purity, 10  $\mu\text{m}$  in size), 0.18 g of boron (B, 99.99 % purity, 1  $\mu\text{m}$  in size) and  $\text{Y}_2\text{O}_3:\text{Eu}^{3+}$  (nanorods, 1–2  $\mu\text{m}$  in length, 150–200 nm in diameter) were uniformly mixed at different mass ratios and ground for 20 min in an agate mortar. The mixture was transferred into a mould and pressed into cylindrical tablets at 20 MPa for 30 min. The samples were then sintered at 850 °C for 2 h under flowing high-purity Ar gas (99.99 % purity) at a heating rate of 5 °C  $\text{min}^{-1}$ . These procedures were also used to prepare  $\text{MgB}_2$  doped with  $\text{Y}_2\text{O}_3$  or  $\text{Y}_2\text{O}_3:\text{Sm}$  nanorods. Afterwards, the crystal structure was investigated through X-ray diffraction (XRD) by using a BRUKER D8 Advanced X-ray diffractometer with Cu  $K\alpha$  irradiation. Resistivity was measured using the four-probe technique. Electric field was imported through the electrodes. The measuring current was 100 mA.

## 3 Results and Discussion

The image in Fig. 1 shows the X-ray diffraction patterns of the series of  $\text{MgB}_2$  doped with different amounts of  $\text{Y}_2\text{O}_3$  and  $\text{Y}_2\text{O}_3:\text{Eu}^{3+}$  nanorods. Similar with other reports, the XRD results of pure  $\text{MgB}_2$  indicate that the  $\text{MgO}$  phase exists in  $\text{MgB}_2$ . In comparison, the XRD results of the doping samples show that  $\text{YB}_4$  phase, which is generated from the reaction of B and  $\text{Y}_2\text{O}_3$ , appears in the other samples. Surplus  $\text{Y}_2\text{O}_3$  presents in XRD patterns with increasing amount of doping material. The XRD patterns also indicate that samples doped with  $\text{Y}_2\text{O}_3$  nanorods are similar to those

**Fig. 1** X-ray diffraction patterns of  $\text{Y}_2\text{O}_3$ - and  $\text{Y}_2\text{O}_3:\text{Eu}^{3+}$ -doped  $\text{MgB}_2$  samples after sintering

doped with  $\text{Y}_2\text{O}_3:\text{Eu}$  nanorods, because of the effective incorporation of Eu into the lattice of  $\text{Y}_2\text{O}_3$ .

This study aims to prepare a composite superconducting metamaterial consisting of  $\text{MgB}_2$  superconductor and  $\text{Y}_2\text{O}_3:\text{Eu}$  electroluminescent material. Firstly, we synthesised  $\text{Y}_2\text{O}_3:\text{Eu}$  nanorods on the basis of relevant research about  $\text{Y}_2\text{O}_3:\text{Eu}$  powders [26]. Figure 2 shows the EL spectrum of  $\text{Y}_2\text{O}_3:\text{Eu}$  nanorods. The spectrum indicates that the strongest peak centred at 613 nm corresponds to  $\text{Eu}^{3+}$  ions typical of transition from  $^5\text{D}_0$  to  $^7\text{F}_2$ . Moreover, the full width at half maximum of the main emission peak is only 7 nm, suggesting superior monochromaticity, which is

**Fig. 2** Electroluminescence spectrum of  $\text{Y}_2\text{O}_3:\text{Eu}$  nanorods and  $\text{Y}_2\text{O}_3:\text{Sm}$  nanorods

**Fig. 3** Temperature dependence of resistivity of the undoped and 4, 6, and 8 wt% doped MgB<sub>2</sub> samples. **a** Doped Y<sub>2</sub>O<sub>3</sub> nanorods; **b** doped Y<sub>2</sub>O<sub>3</sub>:Eu<sup>3+</sup> nanorods

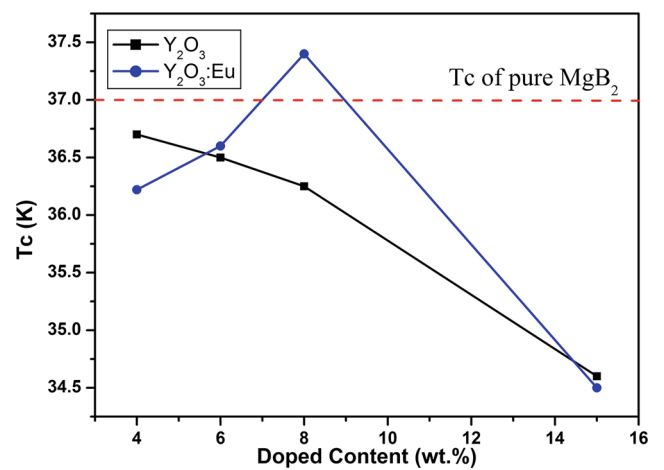

consistent with other reports. Secondly, the superconducting metamaterials were prepared by doping Y<sub>2</sub>O<sub>3</sub>:Eu nanorods into MgB<sub>2</sub>. Electric field in bulk MgB<sub>2</sub> stimulates the electroluminescence of Y<sub>2</sub>O<sub>3</sub>:Eu. To further demonstrate the effect of electroluminescence in MgB<sub>2</sub>, we synthesised Y<sub>2</sub>O<sub>3</sub>:Sm nanorods whose electroluminescence intensity is much lower than that of Y<sub>2</sub>O<sub>3</sub>:Eu (Fig. 2).

Figure 3 presents the temperature dependence of the resistivity of the series of MgB<sub>2</sub> samples doped with different amounts of Y<sub>2</sub>O<sub>3</sub> or Y<sub>2</sub>O<sub>3</sub>:Eu<sup>3+</sup> nanorods. As is observed in Fig. 3a, the superconducting T<sub>c</sub> of pure MgB<sub>2</sub> is 37 K, which is higher than those of other doped samples. The transition width of pure MgB<sub>2</sub> is only 0.4 K, which is also the minimum value in all samples. The superconducting T<sub>c</sub> decreases, whereas the width of transition increases with increasing doping amount. For instance, the T<sub>c</sub> of the sample doped with 8 wt% Y<sub>2</sub>O<sub>3</sub> is 36.25 K, which is lower than that of pure samples. The presence of impurities, such as Y<sub>2</sub>O<sub>3</sub>, MgO and YB<sub>4</sub>, induced the deterioration of intercrystalline connectivity [27, 28].

The image in Fig. 3b shows that the T<sub>c</sub> of samples doped with 4 or 6 wt % Y<sub>2</sub>O<sub>3</sub>:Eu<sup>3+</sup> nanorods is lower than that of pure MgB<sub>2</sub>, which is consistent with those of samples doped with Y<sub>2</sub>O<sub>3</sub>. However, the T<sub>c</sub> of sample doped with 8 wt % Y<sub>2</sub>O<sub>3</sub>:Eu<sup>3+</sup> nanorods is the highest among all samples, including pure MgB<sub>2</sub>. The T<sub>c</sub> of sample doped with 8 wt % Y<sub>2</sub>O<sub>3</sub>:Eu<sup>3+</sup> nanorods is 1.15 K higher than that of the sample doped with 8 wt % Y<sub>2</sub>O<sub>3</sub> nanorods. It is peculiar that the T<sub>c</sub> of sample doped with 8 wt % Y<sub>2</sub>O<sub>3</sub>:Eu<sup>3+</sup> nanorods is 0.4 K higher than that of pure MgB<sub>2</sub>. The curve of MgB<sub>2</sub> doped with 8 wt % Y<sub>2</sub>O<sub>3</sub>:Sm is also shown in Fig. 3b to confirm whether electroluminescence or rare earth element affects the transition temperature. The transition temperature of MgB<sub>2</sub> doped with 8 wt % Y<sub>2</sub>O<sub>3</sub>:Sm is 0.9 K lower

than that of MgB<sub>2</sub> doped with 8 wt % Y<sub>2</sub>O<sub>3</sub>:Eu (Fig. 3b). Europium, which results in bright red light, is critical for T<sub>c</sub>.

The images in Fig. 4 presents the T<sub>c</sub> of the series of MgB<sub>2</sub> samples doped with different amounts of Y<sub>2</sub>O<sub>3</sub> or Y<sub>2</sub>O<sub>3</sub>:Eu<sup>3+</sup> nanorods. The T<sub>c</sub> values of samples decrease with increasing amount of doped Y<sub>2</sub>O<sub>3</sub> nanorods, which is consistent with previous reports. However, it is fantastic that the T<sub>c</sub> values of samples increase with the amount of doped Y<sub>2</sub>O<sub>3</sub>:Eu<sup>3+</sup> nanorods. Additionally, the T<sub>c</sub> of sample doped with 8 wt% Y<sub>2</sub>O<sub>3</sub>:Eu<sup>3+</sup> nanorods is 0.4 K higher than that of pure MgB<sub>2</sub>. However, the transition temperature decreases rapidly when the doping percentage of Y<sub>2</sub>O<sub>3</sub>:Eu is larger than 8. The phenomenon cannot be explained by existing theories. The mechanism of increasing superconducting T<sub>c</sub> still needs further studies. The transition temperature is one of the most crucial factors that limits

**Fig. 4** The T<sub>c</sub> of the series MgB<sub>2</sub> samples doped different contents of Y<sub>2</sub>O<sub>3</sub> or Y<sub>2</sub>O<sub>3</sub>:Eu<sup>3+</sup> nanorods

the application of superconductors. As such, increasing the transition temperature of superconductors is of great interest. Hence, doping EL materials in  $\text{MgB}_2$  is a novel strategy for increasing the transition temperature and may also be applicable to other superconductors.

#### 4 Conclusion

We synthesised a composite material,  $\text{MgB}_2$  superconductor doped with the EL materials  $\text{Y}_2\text{O}_3:\text{Eu}$ , which is called a superconducting metamaterial. The XRD results indicate that the crystallinity and the purity of  $\text{MgB}_2$  decrease with increasing the doping content. However, more  $\text{Y}_2\text{O}_3:\text{Eu}^{3+}$  would remain in the samples at a high doping content. The temperature dependence of resistivity indicates that the  $T_C$  values of samples decrease with increasing amount of doped  $\text{Y}_2\text{O}_3$  nanorods; this finding is consistent with previous reports. However, it is remarkable that the  $T_C$  values of samples increase with increasing amount of doped  $\text{Y}_2\text{O}_3:\text{Eu}^{3+}$  nanorods. The  $T_C$  of the sample doped with 8 wt%  $\text{Y}_2\text{O}_3:\text{Eu}^{3+}$  is 1.15 K higher than that of sample doped with 8 wt%  $\text{Y}_2\text{O}_3$ . It is remarkable that the  $T_C$  of the sample doped with 8 wt%  $\text{Y}_2\text{O}_3:\text{Eu}^{3+}$  is 0.4 K higher than that of pure  $\text{MgB}_2$ . However, the transition temperature of the sample doped with 8 wt%  $\text{Y}_2\text{O}_3:\text{Sm}$  nanorods is 0.9 K lower than that of the sample doped with 8 wt%  $\text{Y}_2\text{O}_3:\text{Eu}$  nanorods. Transition temperature is one of the most crucial factors that limits the application of superconductors. Doping EL materials in  $\text{MgB}_2$  is a novel strategy for increasing the transition temperature and may also be applicable to other superconductors.
