## Abstract

$Y_2O_3$  nanorods were prepared via a hydrothermal method. A series of Sr-modified  $Y_2O_3$  nanorods (Sr- $Y_2O_3$ -NR) with a Sr/Y molar ratio of 0.02–0.06 were synthesized by an impregnation method, and studied with respect to their performance in the oxidative coupling of methane (OCM). The structural and physicochemical properties of these catalysts were characterized by means of XRD,  $N_2$  adsorption, SEM, TEM, XPS,  $O_2$ -TPD and  $CO_2$ -TPD.  $Y_2O_3$  nanorods exhibit higher  $CH_4$  conversion and  $C_2$ – $C_3$  selectivity relative to  $Y_2O_3$  nanoparticles, which could link with the fact that  $Y_2O_3$  nanorods predominantly expose (440) and (222) planes. The addition of a small amount of Sr to  $Y_2O_3$  nanorods enhances the activation of oxygen, the ratio of  $(O^- + O_2^-)/O^{2-}$  and amount of moderate basic sites for the Sr- $Y_2O_3$ -NR catalysts, thus promoting the OCM performance. The best 0.04Sr- $Y_2O_3$ -NR catalyst with a Sr/Y molar ratio of 0.04 can give a 23.0%  $CH_4$  conversion with 50.2%  $C_2$ – $C_3$  selectivity at 650 °C. We found that the  $C_2$ – $C_3$  yield achieved on the  $Y_2O_3$ -based catalysts correlated well with the amount of moderate basic sites present on the catalysts.

## Introduction

Catalytic conversion of methane to value added products has attracted much attention in the past few decades [1–13]. The proven reserve of natural gas, with its major component  $CH_4$ , has increased markedly from 1996 to 2016, and therefore providing

great motivation in methane utilization. There is no doubt that oxidative coupling of methane (OCM) is one of the most prospective directions among the various conversion of methane, since Keller et al. [14] first reported this technology in 1982. The main products of OCM reaction are ethane and ethylene. Ethylene, one of the chemical products with the largest output in the world, has been regarded as one of the important indicators to measure the development level of a country's petrochemical industry [15]. Hence, a wide range of catalysts have been attempted on the OCM reaction [1, 2, 7, 10].

Recently, researchers have shifted the focus of study to the OCM process at relatively low temperatures. It is worth noting that rare earth oxide catalysts with special morphologies (e.g. nanorods, nanobelts and nanowires) such as  $\text{La}_2\text{O}_3$  [16, 17],  $\text{Sm}_2\text{O}_3$  [18] and  $\text{CeO}_2$  [19] can effectively catalyze low-temperature OCM reaction at 500–650 °C. To improve the  $\text{C}_2$  selectivity of OCM reaction, mixed or doped oxides with enhanced basicity such as alkali-rare earth oxides [20] and alkaline earth-rare earth oxides [21–23] were used. In addition to the basicity, introducing the low-valence metal into high-valence metal oxides can produce the surface defects to form electrophilic oxygen species such as  $\text{O}^-$  and  $\text{O}_2^-$  which are conducive to improving the  $\text{C}_2$  selectivity. More recently, we have found that  $\text{Er}_2\text{O}_3$  nanorods,  $\text{Ho}_2\text{O}_3$  nanosheets and their Sr-promoted forms can act as effective catalysts for low-temperature OCM process [24, 25].

Takenaka et al. found that Li-added  $\text{Y}_2\text{O}_3$  was the most effective catalyst for the OCM reaction among various basic metal oxide catalysts ( $\text{MgO}$ ,  $\text{Y}_2\text{O}_3$ ,  $\text{La}_2\text{O}_3$ ,  $\text{Gd}_2\text{O}_3$ ,  $\text{Sm}_2\text{O}_3$ ,  $\text{Eu}_2\text{O}_3$  and  $\text{CeO}_2$ ) modified with Li [20]. Although  $\text{Y}_2\text{O}_3$ -based catalysts used in the OCM reaction were reported, their catalytic performance at relatively low temperature was not satisfactory [20, 26–28]. Inspired by the aforementioned research results [16–19, 24, 25], in the present work we have developed  $\text{Y}_2\text{O}_3$  and Sr-modified  $\text{Y}_2\text{O}_3$  nanorods used as efficient catalysts for low-temperature OCM process. The catalytic performance of these catalysts was correlated with their characterization results.

## Experimental

### Catalyst preparation

$\text{Y}_2\text{O}_3$  nanorods (named as  $\text{Y}_2\text{O}_3$ -NR) were synthesized by a hydrothermal method. In a typical procedure, 3.83 g of  $\text{Y}(\text{NO}_3)_3 \cdot 6\text{H}_2\text{O}$  was dissolved in 100 mL deionized water. 5 mL aqueous ammonia (25–28 wt%) was then added dropwise to  $\text{Y}(\text{NO}_3)_3$  solution under stirring. The resulting suspension was transferred into a Teflon-lined stainless autoclave, followed by being placed in an oven setting at 200 °C for 12 h.  $\text{Y}_2\text{O}_3$  nanoparticles (labelled as  $\text{Y}_2\text{O}_3$ -NP) were synthesized by a conventional precipitate method. 3 mL aqueous ammonia (25–28 wt%) was added dropwise to 100 mL  $\text{Y}(\text{NO}_3)_3$  solution (0.1 M) under stirring. All the obtained precipitates were fully washed with deionized water, dried at 80 °C for 12 h. Finally, the dried  $\text{Y}(\text{OH})_3$  samples were calcined at 750 °C in air for 4 h to obtain  $\text{Y}_2\text{O}_3$  nanorods and nanoparticles.

Sr-modified  $Y_2O_3$  nanorods were synthesized by an incipient wetness impregnation method. Different amounts of  $Sr(NO_3)_2$  were dissolved in deionized water, and then a certain amount of dried  $Y(OH)_3$  nanorods were added. After drying under an infrared lamp, the sample was dried at 80 °C for 12 h, then calcined at 750 °C in air for 4 h. The obtained catalysts were designated as  $xSr-Y_2O_3-NR$ , which  $x$  represents the Sr/Y molar ratio ( $x=0.02, 0.04$  and  $0.06$ ).

### Catalyst characterization

X-ray diffraction (XRD) patterns were recorded on a D2 PHASER X-ray diffractometer using nickel-filtered  $Cu K_\alpha$  radiation at 30 kV and 10 mA. The BET surface areas of the catalysts were measured by  $N_2$  adsorption at  $-196$  °C using a Micromeritics Tristar 3000 instrument. X-ray photoelectron spectroscopy (XPS) analyses were carried out with a Perkin–Elmer PHI 5000C spectrometer. All binding energy values were calibrated using the C 1 s peak at 284.6 eV. Field-emission scanning electron microscopy (FESEM) images were taken using a Hitachi S-4800 instrument. Transmission electron microscopy (TEM) images were recorded on an FEI Tecnai G<sup>2</sup> F20 S-TWIN instrument. Fourier transform infrared (FTIR) spectra were measured on a Nicolet Avatar 360 spectrometer. 20 mg of spent catalyst and 200 mg of KBr were first mixed uniformly. 30 mg of mixture was then pressed into a self-supporting disk.

The amount and strength of basic sites were measured by  $CO_2$  temperature programmed desorption ( $CO_2$ -TPD) using a Micromeritics AutoChem II analyzer. 0.2 g of catalyst (40–60 mesh) was preheated at 750 °C for 1 h under He (30 mL/min), followed by cooling down to 80 °C.  $CO_2$  adsorption was conducted at this temperature, then purged with He (30 mL/min) for 2 h. Finally, the temperature was raised from 80 to 950 °C at a ramping rate of 10 °C/min.  $O_2$  temperature programmed desorption ( $O_2$ -TPD) was measured on the same instrument. 0.2 g of catalyst (40–60 mesh) was preheated at 750 °C for 1 h under He (30 mL/min), followed by cooling down to 50 °C.  $O_2$  adsorption was conducted at this temperature, then purged with He (30 mL/min) for 2 h. Finally, the temperature was then raised from 50 to 700 °C at a ramping rate of 10 °C/min. The desorbed  $CO_2$  and  $O_2$  were detected with a thermal conductivity detector (TCD).

### Oxidative coupling of methane

The oxidative coupling of methane reaction was performed with a fixed-bed quartz tube reactor (internal diameter 6 mm) at atmospheric pressure. 0.2 g of catalyst (40–60 mesh) was loaded in the middle of reactor, with the downstream of the catalyst fixed with quartz wool. The catalytic performance was investigated using a gas mixture of methane and oxygen ( $CH_4/O_2=4/1$  molar ratio). The total flow rate of 60 mL/min, corresponding to a gas hourly space velocity (GHSV) of 18,000 mL/(g h). Prior to the reaction, the catalyst was pretreated at 750 °C in Ar (30 mL/min) for 1 h. The reaction temperature (actually the catalyst bed temperature) was monitored by a thermocouple placed in the middle of the catalyst bed. The reaction products

were analyzed by an on-line GC equipped with a TCD and a 2-m Shincarbon ST packed column (for separation of  $H_2$ ,  $O_2$ ,  $CO$ ,  $CH_4$  and  $CO_2$ ), and by another on-line GC equipped with an FID and a 50-m PoraPLOT Q capillary column (for separation of  $CH_4$ ,  $C_2H_4$ ,  $C_2H_6$ ,  $C_3H_6$  and  $C_3H_8$ ). Before analyzing by TCD, the products were passed through a cold trap at  $-3^\circ C$  to remove most of water generated during the reaction. The  $CH_4$  conversion and  $C_2$ - $C_3$  selectivity were calculated using the standard normalization method based on carbon atom balance.

## Results and discussion

### Catalyst characterization

The XRD patterns of  $Y_2O_3$  nanoparticles, nanorods and Sr-modified nanorods are shown in Fig. 1. All catalysts display similar characteristics of diffraction peaks belonging to the cubic  $Y_2O_3$  phase (PDF #74–1828). The diffraction peaks at ca.  $2\theta = 21^\circ$ ,  $29^\circ$ ,  $34^\circ$ ,  $36.1^\circ$ ,  $40^\circ$ ,  $44^\circ$ ,  $49^\circ$ ,  $54^\circ$ ,  $58^\circ$  and  $59^\circ$  are ascribed to the (211), (222), (400), (411), (332), (134), (440), (611), (622) and (136) planes of cubic  $Y_2O_3$  phase. As the Sr/Y molar ratio is increased to 0.04, a small amount of  $SrCO_3$  phase appeared, which might be produced during the calcination of  $Sr(NO_3)_2 \cdot Y(OH)_3$  through the combination of SrO with  $CO_2$  in air [22, 29]. Table 1 shows that introducing a small amount of Sr into  $Y_2O_3$  nanorods improves the lattice parameter from 1.0546 nm ( $Y_2O_3$ -NR) to 1.0569 nm (0.06Sr- $Y_2O_3$ -NR). Taking into account the larger ionic radius of  $Sr^{2+}$  (0.118 nm) than  $Y^{3+}$  (0.090 nm), this result reveals that Sr is doped into the crystal lattice of  $Y_2O_3$ , albeit Sr was incorporated into  $Y_2O_3$  nanorods via a simple impregnation method [22, 29].

From the SEM images of  $Y_2O_3$ -NR (Fig. 2a) and 0.04Sr- $Y_2O_3$ -NR (Fig. 2b), one can see that both catalysts show the nanorod shape. The average length and width of  $Y_2O_3$ -NR nanorods are 1.11  $\mu m$  and 191 nm, respectively. Obviously, the introduction of a small amount of Sr exerts a bit influence on the nanorod size (Table 1). The TEM image shown in Fig. 3 indicates that  $Y_2O_3$ -NP has irregular particle shape with a mean size of 17 nm. As demonstrated in Figs. S1 and S2, the HR-TEM images

combined with a fast Fourier transform (FFT) analysis disclose that  $Y_2O_3$ -NR and  $0.04Sr-Y_2O_3$ -NR nanorods predominantly expose (440) and (222) planes.

The BET specific surface areas of  $Y_2O_3$  nanoparticles, nanorods and Sr-modified nanorods are between 20.0 and 25.4  $m^2/g$  (Table 1), which are low and typical for the OCM catalysts.  $Y_2O_3$ -NR presents a slightly higher surface area than  $Y_2O_3$ -NP (25.4 vs 20.0  $m^2/g$ ). Modification of  $Y_2O_3$ -NR with a small amount of Sr brings about a slight decrease in surface area.

The XPS spectra of O 1s on the  $Y_2O_3$ -based catalysts are shown in Fig. S3. The O 1s spectrum of each catalyst can be deconvoluted into four peaks associated with three kinds of oxygen species: lattice oxygen ( $O^{2-}$ , ~ 529.4 eV), chemisorbed oxygen species ( $O^-$ , ~ 530.6 eV and  $O_2^-$ , ~ 532.6 eV) and carbonate ( $CO_3^{2-}$ , ~ 531.8 eV) [16, 30–33]. The XPS data are presented in Table 1. It was reported that the chemisorbed oxygen species, i.e. surface electrophilic oxygen species  $O^-$  and  $O_2^-$ , were responsible for the generation of  $C_2$  product in the OCM process, while the lattice oxygen favored deep oxidation of  $CH_4$  to form CO and  $CO_2$  [16, 17, 22, 32, 34]. Hence, the ratio of  $(O^- + O_2^-)/O^{2-}$  was found to correlate positively with  $C_2$  selectivity in the OCM reaction [17, 22, 25, 29, 34]. A comparison of  $Y_2O_3$ -NR with  $Y_2O_3$ -NP indicates that the former catalyst affords a higher ratio of  $(O^- + O_2^-)/O^{2-}$  than the latter one (1.3 vs 1.0). Introducing Sr into  $Y_2O_3$ -NR increases the  $(O^- + O_2^-)/O^{2-}$  ratio, and the  $0.04Sr-Y_2O_3$ -NR catalyst exhibits the highest value (1.8). Apparently, the value of  $(O^- + O_2^-)/O^{2-}$  for all the  $Y_2O_3$ -based catalysts follows the sequence of  $0.04Sr-Y_2O_3$ -NR >  $0.06Sr-Y_2O_3$ -NR >  $0.02Sr-Y_2O_3$ -NR >  $Y_2O_3$ -NR >  $Y_2O_3$ -NP.

A previous theoretical study has revealed that the energy required to produce oxygen vacancies over  $CeO_2$  is lower on the plane of (110) than (111) and (310) [35]. That is to say, oxygen vacancies are more readily to generate on the (110) plane of  $CeO_2$ . Oxygen vacancies can interact with  $O_2$  to form the chemisorbed oxygen species such as  $O^-$  and  $O_2^-$ . Hou et al. pointed out that, among the exposed facets for the  $La_2O_2CO_3$  catalysts, the (110), (1  $\bar{2}$  0) and (2  $\bar{1}$  0) facets had relatively loose atomic configurations, and these facets favored the formation of the chemisorbed oxygen species [33]. Thus, we consider that the higher  $(O^- + O_2^-)/O^{2-}$  ratio for  $Y_2O_3$ -NR than  $Y_2O_3$ -NP could be caused by the fact that the former catalyst predominantly exposes (440) and (222) planes, as revealed by the HR-TEM result.

The activation of oxygen will play an important role in the OCM reaction. To further study the oxygen activation on the  $Y_2O_3$ -based catalysts,  $O_2$ -TPD experiments were performed. The results are given in Fig. 4 and Table 2. The  $Y_2O_3$ -NP catalyst gives two desorption peaks of oxygen, which are located at 93 °C and 526 °C, respectively. The low-temperature and high-temperature peaks are assigned to molecular and chemisorbed oxygen species, respectively [36]. The other  $Y_2O_3$ -based catalysts display only one peak of oxygen desorption located at 370–507 °C, which corresponds to the desorption of chemisorbed oxygen species [36]. These chemisorbed oxygen species originate from the interaction between  $O_2$  and the  $Y_2O_3$ -based catalysts, and may be  $O^-$ ,  $O_2^-$  and  $O^{2-}$  [29, 33]. It is widely accepted that the chemisorbed oxygen species are helpful for  $CH_4$  activation and  $C_2$  selectivity in the OCM reaction [16, 33, 36, 37]. In comparison with  $Y_2O_3$ -NP,  $Y_2O_3$ -NR displays a higher amount of chemisorbed oxygen species (25.8 vs 21.0  $\mu mol/g$ ). Compared with  $Y_2O_3$ -NR, the Sr- $Y_2O_3$ -NR catalysts possess a higher amount of

**Fig. 4** O<sub>2</sub>-TPD profiles of **a** Y<sub>2</sub>O<sub>3</sub>-NP; **b** Y<sub>2</sub>O<sub>3</sub>-NR; **c** 0.02Sr-Y<sub>2</sub>O<sub>3</sub>-NR; **d** 0.04Sr-Y<sub>2</sub>O<sub>3</sub>-NR; **e** 0.06Sr-Y<sub>2</sub>O<sub>3</sub>-NR

**Table 2** O<sub>2</sub>-TPD and CO<sub>2</sub>-TPD data of the Y<sub>2</sub>O<sub>3</sub>-based catalysts

Catalyst	Peak temperature (°C)		Amount of desorbed O <sub>2</sub> (μmol/g)		Amount of basic sites <sup>a</sup> (μmol/g)		
	I	II	I	II	Weak	Moderate	Strong
	Y <sub>2</sub> O <sub>3</sub> -NP	93	526	3.5	21.0	2.3	6.6
Y <sub>2</sub> O <sub>3</sub> -NR	–	507	–	25.8	4.1	22.4	–
0.02Sr-Y <sub>2</sub> O <sub>3</sub> -NR	–	403	–	36.3	3.7	42.6	19.6
0.04Sr-Y <sub>2</sub> O <sub>3</sub> -NR	–	370	–	43.7	3.3	47.9	91.1
0.06Sr-Y <sub>2</sub> O <sub>3</sub> -NR	–	382	–	39.2	3.1	44.9	144.7

<sup>a</sup>The temperature range for weak, intermediate and strong basic sites is 80–200 °C, 200–575 °C and 650–950 °C

chemisorbed oxygen species (36.3–43.7 vs 25.8 μmol/g) and lower peak temperature of the chemisorbed oxygen species desorption (370–403 °C vs 507 °C). The 0.04Sr-Y<sub>2</sub>O<sub>3</sub>-NR catalyst affords the highest amount of chemisorbed oxygen species (43.7 μmol/g). This finding suggests that the incorporation of a small amount of Sr into Y<sub>2</sub>O<sub>3</sub> nanorods enhances the oxygen activation over the catalysts. Doping low-valence Sr into high-valence Y<sub>2</sub>O<sub>3</sub> can improve the number of oxygen vacancies [37–39], thus enhancing the activation of oxygen. Consequently, a higher amount of chemisorbed oxygen species on the Sr-Y<sub>2</sub>O<sub>3</sub>-NR catalysts than Y<sub>2</sub>O<sub>3</sub>-NR can be observed.

Surface basic sites were also considered to play a key role in the OCM reaction [21, 40]. These basic sites could be O<sup>-</sup>, O<sub>2</sub><sup>-</sup> and O<sup>2-</sup> oxygen species [21, 37, 41, 42]. The basic sites with medium strength are considered to be more favorable for forming C<sub>2</sub> product in the OCM reaction [16, 17, 25, 33, 40, 43–46]. The CO<sub>2</sub>-TPD profiles of Y<sub>2</sub>O<sub>3</sub> nanoparticles, nanorods and Sr-modified nanorods are depicted in Fig. 5. There are three peaks of CO<sub>2</sub> desorption from the surfaces of Sr-modified Y<sub>2</sub>O<sub>3</sub> nanorods, which are located at ~150 °C, ~340 °C

**Fig. 5** CO<sub>2</sub>-TPD profiles of **a** Y<sub>2</sub>O<sub>3</sub>-NP; **b** Y<sub>2</sub>O<sub>3</sub>-NR; **c** 0.02Sr–Y<sub>2</sub>O<sub>3</sub>-NR; **d** 0.04Sr–Y<sub>2</sub>O<sub>3</sub>-NR; **e** 0.06Sr–Y<sub>2</sub>O<sub>3</sub>-NR. The signal of each catalyst on the left part was magnified six times

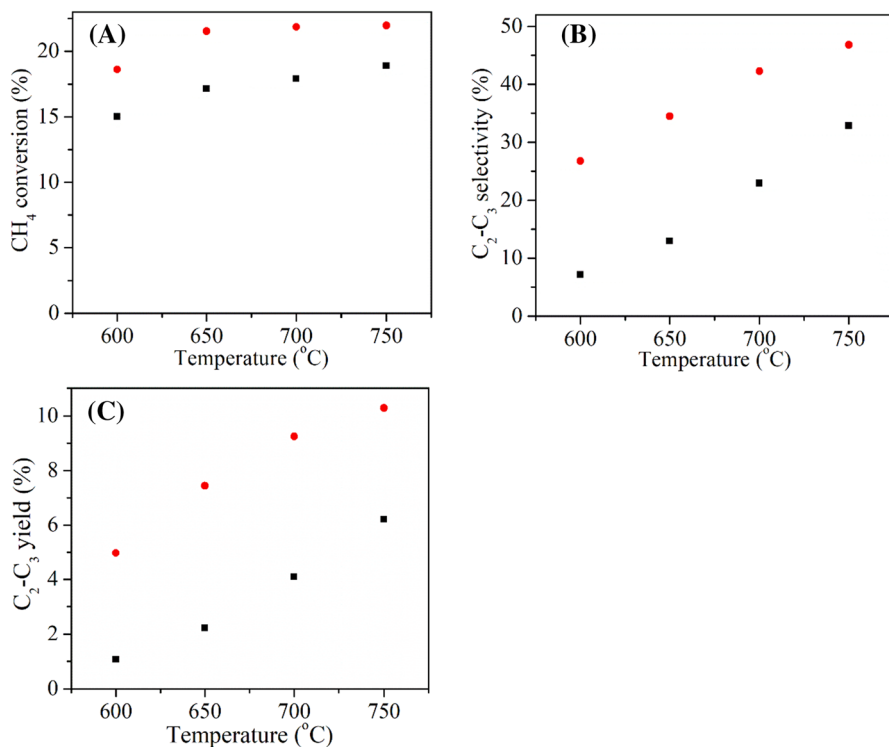

and above 750 °C, corresponding to weak, moderate and strong basic sites of the catalysts [22, 29, 37, 47]. Both Y<sub>2</sub>O<sub>3</sub>-NR and Y<sub>2</sub>O<sub>3</sub>-NP catalysts have only weak and moderate basic sites, giving the peak temperature of CO<sub>2</sub> desorption at ~150 °C and ~340 °C. The CO<sub>2</sub>-TPD data (Table 2) show that the amount of moderate basic sites is higher over Y<sub>2</sub>O<sub>3</sub>-NR than Y<sub>2</sub>O<sub>3</sub>-NP. The Sr–Y<sub>2</sub>O<sub>3</sub>-NR catalysts possess more basic sites with medium strength than Y<sub>2</sub>O<sub>3</sub>-NR, and 0.04Sr–Y<sub>2</sub>O<sub>3</sub>-NR has the greatest amount of moderate basic sites. The amount of moderate basic sites present on all the Y<sub>2</sub>O<sub>3</sub>-based catalysts decreases in the order of 0.04Sr–Y<sub>2</sub>O<sub>3</sub>-NR > 0.06Sr–Sr–Y<sub>2</sub>O<sub>3</sub>-NR > 0.02Sr–Y<sub>2</sub>O<sub>3</sub>-NR > Y<sub>2</sub>O<sub>3</sub>-NR > Y<sub>2</sub>O<sub>3</sub>-NP.

FTIR spectra can provide the information on structure of the catalysts. To gain insight into the impact of introducing excessive Sr on the Sr–Y<sub>2</sub>O<sub>3</sub>-NR catalysts for the OCM process, the used 0.06Sr–Y<sub>2</sub>O<sub>3</sub>-NR and 0.04Sr–Y<sub>2</sub>O<sub>3</sub>-NR catalysts after the OCM reaction at 600 °C for 1 h were recorded and compared in Fig. S4. The peaks located at 3445 and 1637 cm<sup>-1</sup> are attributed to the stretching and bending vibrations of O–H groups in H<sub>2</sub>O [48]. The peaks centered at 1442 and 861 cm<sup>-1</sup> are assigned to the asymmetric stretching and bending vibrations of CO<sub>3</sub><sup>2-</sup> groups [49, 50] which originate from combination of the Sr–Y<sub>2</sub>O<sub>3</sub>-NR catalysts with CO<sub>2</sub> produced in the OCM process. Judging from the peak intensity, there are more surface carbonate species on the spent catalysts of 0.06Sr–Y<sub>2</sub>O<sub>3</sub>-NR than 0.04Sr–Y<sub>2</sub>O<sub>3</sub>-NR.

### Catalytic performance

To explore the morphology effect of the Y<sub>2</sub>O<sub>3</sub> catalysts, we first tested the catalytic performance of Y<sub>2</sub>O<sub>3</sub> nanorods and nanoparticles. With an increase of the reaction temperature from 600 to 750 °C, the CH<sub>4</sub> conversion increases slightly (Fig. 6A), while the selectivity toward C<sub>2</sub>–C<sub>3</sub> (ethylene, ethane, propylene and propane) increases significantly (Fig. 6B). Accordingly, the C<sub>2</sub>–C<sub>3</sub> yield rises with the reaction temperature (Fig. 6C). Whether CH<sub>4</sub> conversion, C<sub>2</sub>–C<sub>3</sub> selectivity or C<sub>2</sub>–C<sub>3</sub> yield, Y<sub>2</sub>O<sub>3</sub>-NR performs better than Y<sub>2</sub>O<sub>3</sub>-NP. For example, Y<sub>2</sub>O<sub>3</sub>-NR affords a 21.9% CH<sub>4</sub> conversion, 42.3% C<sub>2</sub>–C<sub>3</sub> selectivity and 9.3% C<sub>2</sub>–C<sub>3</sub> yield at 700 °C, whereas Y<sub>2</sub>O<sub>3</sub>-NP gives a 17.9% CH<sub>4</sub> conversion, 22.9%

**Fig. 6** CH<sub>4</sub> conversion (A), C<sub>2</sub>-C<sub>3</sub> selectivity (B) and C<sub>2</sub>-C<sub>3</sub> yield (C) as a function of reaction temperature for the Y<sub>2</sub>O<sub>3</sub> catalysts: (filled square) Y<sub>2</sub>O<sub>3</sub>-NP; (filled circle) Y<sub>2</sub>O<sub>3</sub>-NR. Reaction conditions: 0.2 g catalyst, 60 mL/min flow (molar ratio CH<sub>4</sub>/O<sub>2</sub>=4/1)

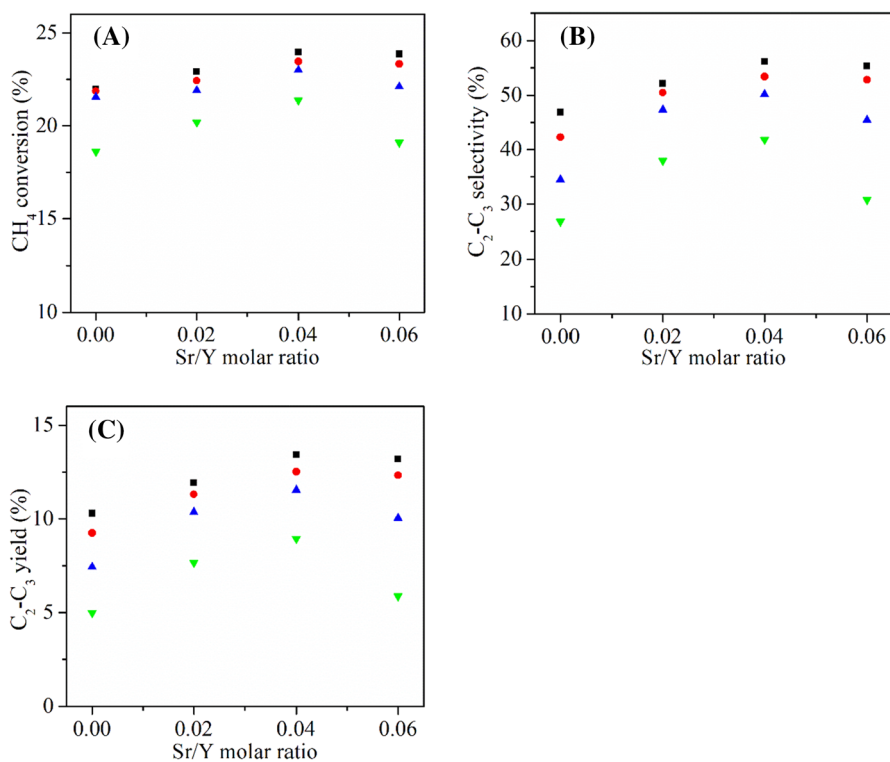

C<sub>2</sub>-C<sub>3</sub> selectivity and 4.1% C<sub>2</sub>-C<sub>3</sub> yield. A higher C<sub>2</sub>-C<sub>3</sub> selectivity achieved on Y<sub>2</sub>O<sub>3</sub>-NR than Y<sub>2</sub>O<sub>3</sub>-NP is caused by a higher (O<sup>-</sup> + O<sub>2</sub><sup>-</sup>)/O<sup>2-</sup> ratio obtained on the former catalyst. The occurrence of more chemisorbed oxygen species and moderate basic sites on Y<sub>2</sub>O<sub>3</sub>-NR than Y<sub>2</sub>O<sub>3</sub>-NP is responsible for a higher CH<sub>4</sub> conversion and C<sub>2</sub>-C<sub>3</sub> yield achieved on the former catalyst. The La<sub>2</sub>O<sub>3</sub>, Sm<sub>2</sub>O<sub>3</sub>, Er<sub>2</sub>O<sub>3</sub> and Ho<sub>2</sub>O<sub>3</sub> rare earth oxide catalysts were also found to display shape effects on the OCM reaction [16–18, 24, 25].

Then we tested the catalytic performance of Sr-Y<sub>2</sub>O<sub>3</sub>-NR catalysts to get a better understanding of the influence of Sr modification. Table 3 shows the typical product distribution over the Y<sub>2</sub>O<sub>3</sub>-NR and Sr-Y<sub>2</sub>O<sub>3</sub>-NR catalysts at 650 °C. In addition to C<sub>2</sub>H<sub>4</sub> and C<sub>2</sub>H<sub>6</sub>, small amounts of C<sub>3</sub>H<sub>6</sub> and C<sub>3</sub>H<sub>8</sub> were also produced. As to the by-products, the selectivity is higher for CO<sub>2</sub> than CO. Compared with the Y<sub>2</sub>O<sub>3</sub>-NR catalyst, the addition of a small amount of Sr slightly improves the CH<sub>4</sub> conversion (Fig. 7A), and obviously enhances the C<sub>2</sub>-C<sub>3</sub> selectivity (Fig. 7B) and yield (Fig. 7C). With an increase of the Sr/Y molar ratio from 0 to 0.06, the CH<sub>4</sub> conversion, C<sub>2</sub>-C<sub>3</sub> selectivity and yield first increase and then decrease. The best catalytic performance is achieved on the 0.04Sr-Y<sub>2</sub>O<sub>3</sub>-NR

**Table 3** Reaction data of the  $Y_2O_3$ -NR and Sr- $Y_2O_3$ -NR catalysts at 650 °C<sup>a</sup>

Catalyst	CH <sub>4</sub> Conv. (%)	Selectivity (%)						C <sub>2</sub> -C <sub>3</sub> Select. (%)	C <sub>2</sub> -C <sub>3</sub> Yield (%)
		C <sub>2</sub> H <sub>4</sub>	C <sub>2</sub> H <sub>6</sub>	C <sub>3</sub> H <sub>6</sub>	C <sub>3</sub> H <sub>8</sub>	CO <sub>2</sub>	CO		
Y <sub>2</sub> O <sub>3</sub> -NR	21.5	16.4	16.4	0.7	1.0	51.1	14.4	34.5	7.4
0.02Sr-Y <sub>2</sub> O <sub>3</sub> -NR	21.9	24.3	20.6	1.1	1.3	42.3	10.4	47.3	10.4
0.04Sr-Y <sub>2</sub> O <sub>3</sub> -NR	23.0	24.5	23.0	1.3	1.4	41.0	8.8	50.2	11.5
0.06Sr-Y <sub>2</sub> O <sub>3</sub> -NR	22.1	21.9	20.8	1.2	1.5	45.0	9.6	45.4	10.0

<sup>a</sup>Reaction conditions: 0.2 g catalyst, 60 mL/min flow (molar ratio CH<sub>4</sub>/O<sub>2</sub> = 4/1)

**Fig. 7** Effect of Sr/Y molar ratio on the catalytic behavior of Sr-modified Y<sub>2</sub>O<sub>3</sub> nanorods at different temperatures: **A** CH<sub>4</sub> conversion, **B** C<sub>2</sub>-C<sub>3</sub> selectivity and **C** C<sub>2</sub>-C<sub>3</sub> yield. (inverted triangle) 600 °C, (triangle) 650 °C, (filled circle) 700 °C, (filled square) 750 °C. Reaction conditions: 0.2 g catalyst, 60 mL/min flow (molar ratio CH<sub>4</sub>/O<sub>2</sub> = 4/1)

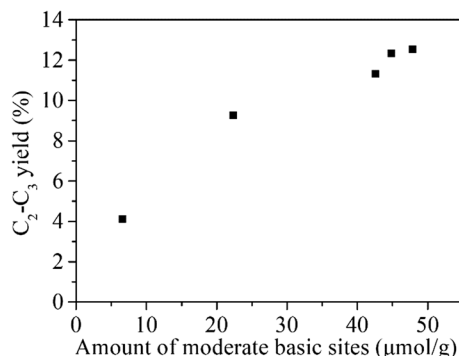

catalyst, which affords a 23.0% CH<sub>4</sub> conversion and 50.2% C<sub>2</sub>-C<sub>3</sub> selectivity at 650 °C. Even at a low temperature of 600 °C, this catalyst still gives a 21.4% CH<sub>4</sub> conversion and 41.8% C<sub>2</sub>-C<sub>3</sub> selectivity. In contrast, the Y<sub>2</sub>O<sub>3</sub>-NR catalyst only affords a 21.5% CH<sub>4</sub> conversion and 34.5% C<sub>2</sub>-C<sub>3</sub> selectivity at 650 °C. In combination with the above XPS, O<sub>2</sub>-TPD and CO<sub>2</sub>-TPD results, the better OCM

performance of the Sr–Y<sub>2</sub>O<sub>3</sub>-NR catalysts than Y<sub>2</sub>O<sub>3</sub>-NR can be attributed to an increased (O<sup>-</sup> + O<sub>2</sub><sup>-</sup>)/O<sup>2-</sup> ratio and number of moderate basic sites, as well as enhanced activation of oxygen. The best 0.04Sr–Y<sub>2</sub>O<sub>3</sub>-NR catalyst display the highest ratio of (O<sup>-</sup> + O<sub>2</sub><sup>-</sup>)/O<sup>2-</sup> as well as the most chemisorbed oxygen species and moderate basic sites. As revealed in Fig. 8, there exists a good correlation between the C<sub>2</sub>–C<sub>3</sub> yield achieved on the Y<sub>2</sub>O<sub>3</sub>-based catalysts at 700 °C and the number of moderate basic sites present on the catalysts. This finding further demonstrates that the presence of moderate basic sites on the OCM catalysts is conducive to improving the C<sub>2</sub> yield [16, 17, 25, 33, 40, 43–46].

A bit lower CH<sub>4</sub> conversion and C<sub>2</sub>–C<sub>3</sub> selectivity can be found on 0.06Sr–Y<sub>2</sub>O<sub>3</sub>-NR than 0.04Sr–Y<sub>2</sub>O<sub>3</sub>-NR at 750 °C and 700 °C, which could link with the blockage of some active sites upon the addition of excessive Sr. An interesting observation is that the former catalyst displays obviously worse OCM performance than the latter one at 650 °C and 600 °C, especially at a low temperature of 600 °C. This can be attributed to the blockage of more active sites by carbonate, since more surface carbonate species are formed on the spent 0.06Sr–Y<sub>2</sub>O<sub>3</sub>-NR catalyst (Fig. S4). Reportedly, there existed the optimal Li and Ba contents for Li–MgO and Ba–La<sub>2</sub>O<sub>3</sub> catalysts used in the OCM process [51, 52].

We chose the best 0.04Sr–Y<sub>2</sub>O<sub>3</sub>-NR catalyst to investigate the lifetime for the OCM reaction performed at 650 °C. As seen in Fig. S5, the 0.04Sr–Y<sub>2</sub>O<sub>3</sub>-NR catalyst displays good stability during 60 h of reaction, maintaining around 23% CH<sub>4</sub> conversion and 50% C<sub>2</sub>–C<sub>3</sub> selectivity. As demonstrated in Fig. S6, the HR-TEM images combined with a fast Fourier transform (FFT) analysis indicate that the predominantly exposed surface facets observed for 0.04Sr–Y<sub>2</sub>O<sub>3</sub>-NR after the stability test are not altered. After the stability test, the SEM image of 0.04Sr–Y<sub>2</sub>O<sub>3</sub>-NR displays the nanorod shape with an average length of 1.10 μm and width of 190 nm (Fig. S7). The 0.04Sr–Y<sub>2</sub>O<sub>3</sub>-NR catalyst possesses a surface area of 19.9 m<sup>2</sup>/g and 43.4 μmol/g of chemisorbed oxygen species. The amount of weak, moderate and strong basic sites of spent 0.04Sr–Y<sub>2</sub>O<sub>3</sub>-NR is 3.3, 47.6 and 90.7 μmol/g. The characterization data obtained for 0.04Sr–Y<sub>2</sub>O<sub>3</sub>-NR after the stability test are equivalent to those of the fresh catalyst, indicating the maintenance of the catalyst structure during the reaction.

**Fig. 8** Relationship between the C<sub>2</sub>–C<sub>3</sub> yield achieved at 700 °C and the amount of moderate basic sites over the Y<sub>2</sub>O<sub>3</sub>-based catalysts. Reaction conditions: 0.2 g catalyst, 60 mL/min flow (molar ratio CH<sub>4</sub>/O<sub>2</sub> = 4/1)

We compared catalytic performance of our catalyst 0.04Sr–Y<sub>2</sub>O<sub>3</sub>-NR and three reference catalysts, i.e. 0.04Ba–Y<sub>2</sub>O<sub>3</sub>-NR nanorods, 0.04Sr–La<sub>2</sub>O<sub>3</sub>-NF nanofibers [22] and 0.04Sr–Sm<sub>2</sub>O<sub>3</sub>-NB nanobelts [18], under our reaction conditions. As shown in Fig. S8. Our catalyst 0.04Sr–Y<sub>2</sub>O<sub>3</sub>-NR displays higher methane conversion than 0.04Sr–La<sub>2</sub>O<sub>3</sub>-NF, and lower conversion than 0.04Ba–Y<sub>2</sub>O<sub>3</sub>-NR and 0.04Sr–Sm<sub>2</sub>O<sub>3</sub>-NB. However, 0.04Sr–Y<sub>2</sub>O<sub>3</sub>-NR nanorods exhibit a bit greater C<sub>2</sub>–C<sub>3</sub> yield than three reference catalysts at 600–750 °C. Recently, Sollier et al. has reported that Sr–La–Ce oxide fibers reached a C<sub>2</sub> yield of 21.7% at 600 °C [53]. In our future work we will study the effect of Ce doping on the Sr–Y<sub>2</sub>O<sub>3</sub>-NR nanorods.

## Conclusions

In this work, we have developed Y<sub>2</sub>O<sub>3</sub> and Sr–Y<sub>2</sub>O<sub>3</sub> nanorods as new catalysts for low-temperature OCM process. The HR-TEM images reveal that Y<sub>2</sub>O<sub>3</sub> and Sr–Y<sub>2</sub>O<sub>3</sub> nanorods preferentially expose (440) and (222) facets. The superior OCM performance of Y<sub>2</sub>O<sub>3</sub> nanorods to their nanoparticles counterpart could be associated with the predominantly exposed (440) and (222) facets on the surface of Y<sub>2</sub>O<sub>3</sub> nanorods. The XPS and CO<sub>2</sub>-TPD results indicate that the addition to a small amount of Sr to Y<sub>2</sub>O<sub>3</sub> nanorods enhances the ratio of (O<sup>-</sup> + O<sub>2</sub><sup>-</sup>)/O<sup>2-</sup> and amount of moderate basic sites. The O<sub>2</sub>-TPD result suggests that the Sr addition promotes the activation of oxygen on the Sr–Y<sub>2</sub>O<sub>3</sub>-NR catalysts. This enhancement and promotion lead to an improved catalytic performance of Y<sub>2</sub>O<sub>3</sub> nanorods upon the introduction of Sr. The optimal 0.04Sr–Y<sub>2</sub>O<sub>3</sub>-NR nanorods with a Sr/Y molar ratio of 0.04 afford a 23.0% CH<sub>4</sub> conversion and 50.2% C<sub>2</sub>–C<sub>3</sub> selectivity at 650 °C. This catalyst displays good stability for 60 h of OCM reaction. We found that there existed a good correlation between the C<sub>2</sub>–C<sub>3</sub> yield achieved on the Y<sub>2</sub>O<sub>3</sub>-based catalysts and the number of moderate basic sites present on the catalysts.
