## Abstract

A new integration strategy of transition metal sulfide with carbon-based materials is used to boost its catalytic property and electrochemical performances in supercapacitor application. Herein, crystalline reduced graphene oxide (rGO) wrapped ternary metal sulfide nanorod composites with different rGO ratios are synthesized using hydrothermal technique and are compared for their physical, chemical, and electrochemical performances. It is found that their properties are tuned by the weight ratios of rGO. The electrochemical investigations reveal that  $\beta$ -NiCu<sub>2</sub>S/rGO nanocomposite electrode with 0.15 wt.% of rGO is found to possess maximum specific capacitance of 1583 F g<sup>-1</sup> at current density of 15 mA g<sup>-1</sup> in aqueous electrolyte medium. The same electrode shows excellent cycling stability with capacitance retention of 89% after 5000 charging/discharging cycles. The reproducibility test performed on NiCu<sub>2</sub>S/rGO nanocomposite electrode with 0.15 wt.% of rGO indicates that it has high reproducible capacitive response and rate capability. Thus, the present work demonstrates that the  $\beta$ -NiCu<sub>2</sub>S/rGO nanocomposite can serve as a potential electrode material for developing supercapacitor energy storage system.

## Introduction

Supercapacitors have attracted major attention as an energy storage device because of their ability to deliver excellent power density, fast charging rates with slow discharging time, and superior cycling stability (Ghosh and Pumera 2021; Lin et al. 2021), thus making it a suitable choice to combat the increasing demand for portable devices and electric vehicles. The properties of materials being used as the electrodes highly influence the performance of a supercapacitor. Various materials in the form of oxides (Zhai et al. 2020), nitrides (Maity et al. 2020), hydroxides, sulfides (Wang et al. 2020a, b), phosphates (Iqbal et al. 2021c), polymers (Khanam et al. 2020), etc. have been studied for their supercapacitor performances (Hsu et al. 2021; Kang et al. 2022). Among them, binary sulfide materials based on transition metals (Lin et al. 2021) such as NiS, Ni<sub>3</sub>S<sub>4</sub> (Guan et al. 2017; Gou et al. 2017), CoS (Liu et al. 2015; Aloqayli et al. 2017), MnS (Pujari et al. 2016; Tang et al. 2015a), MoS<sub>2</sub> (Karade et al. 2016; Ghosh et al. 2021), Cu<sub>2</sub>S, and Cu<sub>7</sub>S<sub>4</sub> (Yue et al. 2021; Gao et al. 2021; Zhang et al. 2021d) have been shown to possess enhanced supercapacitor performances. However, these

binary sulfides offer low energy density, which hinders its practical application. In order to improve energy density as well as to obtain superior supercapacitor performances, ternary metal sulfides are preferred over binary sulfides due to their excellent optical property, high catalytic efficiency, and superior electrical conductivity (Liu et al. 2018). Unlike transition metal oxides, the reports on the discussion of supercapacitor performances of ternary metal sulfides are limited. Recently, it has been observed that, compared with transition metal oxides, transition metal sulfides offer unique stoichiometric compositions, enhanced redox reaction, and higher specific capacitance due to different valence states and crystal structure (Niu et al. 2021; Wang et al. 2018). Particularly, nickel-copper-sulfide nanomaterials have drawn increasing interest as a result of their superior redox characteristics and high theoretical specific capacitance arising as a result of Cu atom offering different oxidation states when combined with high electrochemically active Ni element (Li et al. 2021a). They are also cost-effective and least polluting. Thus, integrating Ni and Cu results in high electrochemical properties (Shinde et al. 2021; Kiey and Hasanin 2021) and, when combined with sulfur, the material Ni-Cu-S gives rise to high conductivity, narrow band gap, better ionic diffusivity, and large anion polarizability, contributing largely towards enhanced supercapacitor performances (Iqbal et al. 2021b). Apart from the above-mentioned advantages, metal sulfides in general suffer from poor long-term cycling stability due to the insulating nature of sulfur. Also, the volume expansions of sulfides and thermodynamically unstable and oxidizing nature of sulfides are the most common problems when dealing with metal sulfides in supercapacitor application (Iqbal et al. 2021a).

On the other hand, carbon materials derivatives such as graphene, graphene oxide, reduced graphene oxide, carbon nanotubes, and nanocarbon have been synthesized in different routes (Gurzęda et al. 2017; Trikkaliotis et al. 2020; Deng et al. 2022; Peng et al. 2022; Ghosh et al. 2021; Ojha et al. 2021) and extensively studied for various energy and environmental applications such as batteries (Liu et al. 2022; Alidoost et al. 2022; Xu et al. 2022a), solar cell (Bandara et al. 2022; Murugadoss et al. 2016; Murugadoss et al. 2015), supercapacitors (Arora et al. 2022; Chen et al. 2022; Shokry et al. 2022; Reina et al. 2022; Yibowei et al. 2021), oxygen reduction reaction (Xu et al. 2022b; Karanfil et al. 2022; Singla et al. 2021), photocatalytic/electrocatalytic water splitting (Antony et al. 2015; Shah et al. 2022; Zhu et al. 2022; Purabgola et al. 2022; Truong et al. 2022), and pollutant removal (Oliveira et al. 2019; Tan et al. 2016). Especially, carbon-based materials (Zhang et al. 2021c) as electrodes for supercapacitor have acquired potential attraction due to their excellent electrochemical properties, high active surface area, and good conductivity resulting in efficient charge storage with high power density though

energy density is limited (Iqbal et al. 2021a; González and Colet 2019). In order to overcome the shortcomings of metal sulfides in supercapacitor application, metal sulfides have been made composites with carbon-based materials and studied for their supercapacitor performances. Recently, cobalt sulfide was made composite with nitrogen doped carbon derived from zeolitic imidazolate frameworks-67 using chemical vapor deposition technique (Wang et al. 2022) which were proposed to have advanced electrode performances in supercapacitor application. The composite electrode exhibited specific capacitance of  $789 \text{ F g}^{-1}$  at current density of  $1 \text{ A g}^{-1}$  with a rate capacity of 80.2% under a current density of  $20 \text{ A g}^{-1}$ . The fabricated capacitor with the CoS-carbon composite obtained a high energy density of  $32.8 \text{ Wh kg}^{-1}$  with the power density of  $620 \text{ W kg}^{-1}$  and possessed 89.2% of capacity retention after 10,000 charge-discharge cycles at current density of  $5 \text{ A g}^{-1}$ . On the other hand,  $\text{Mn}^{2+}$  doped  $\text{CoS}_2$ -carbon nanotube composites synthesized by wet-chemical approach (Agboola et al. 2022) were found to have excellent electrical conductivity ( $0.063 \text{ S cm}^{-1}$ ) with specific capacitance of  $603 \text{ F g}^{-1}$  at  $5 \text{ mV s}^{-1}$  and 82.2% capacitance retention. It was proposed that the CNT support increased the electrical conductivity of  $\text{Mn-CoS}_2$ , reduced its aggregation which facilitated the ease transfer of ions during electrochemical reactions. Similarly, Ramesh et al. (2022) fabricated  $\text{NiCo}_2\text{S}_4$ -metal organic framework nanostructured multiwalled carbon nanotube composites which were found to possess a specific capacitance of  $455 \text{ F g}^{-1}$  at  $1 \text{ A g}^{-1}$  with excellent capacitance retention of 98.43% after 10,000 cycles. Recently, Rana et al. (2022) studied the electrochemical behavior of rGO wrapped chromium sulfide nanoplates on nickel foam for supercapacitor application. They found that the robust and porous structure of the electrode facilitated the electrolyte diffusion and thus showcased outstanding electrochemical performance by exhibiting a specific capacitance of  $2563.12 \text{ F g}^{-1}$  at  $5 \text{ mV s}^{-1}$  with energy density of  $87.50 \text{ Wh kg}^{-1}$  and power density of  $1607 \text{ W kg}^{-1}$  at  $2.0 \text{ mA cm}^{-2}$ . The fabricated electrode also obtained a stability up to 1000 cycles which was attributed to the outstanding electrical conduction provided by rGO between the nickel foam and  $\text{Cr}_2\text{S}_3$ . Further, the ternary composite such as  $\text{Ti}_3\text{C}_2/\text{carbon nanotubes}/\text{MnCo}_2\text{S}_4$  electrodes designed by Dang et al. (2022) which showed gravimetric capacitance of  $823 \text{ F g}^{-1}$  at a current density of  $1 \text{ A g}^{-1}$  with 63.5% specific capacity retention at  $5 \text{ A g}^{-1}$  and had excellent cycling stability of 94.09% after 5000 cycles. The high performance of this electrode is due to the conductive network provided by  $\text{Ti}_3\text{C}_2/\text{CNT}$  hybrid sheets which efficiently accommodate the volume swelling of  $\text{MnCo}_2\text{S}_4$ . Thus because of extraordinary electrochemical behavior, facile synthesis, economical, and low toxicity of carbon materials, they are made composite with other materials to obtain the desired supercapacitor performance.

Likewise, it has been found that ternary metal compounds offer the best supercapacitor performances when made composites with different carbon materials due to high surface area offered by carbon materials that improves the redox reactions (Li et al. 2021b; Liu et al. 2021), thus enhancing the conductivity, stability, and electrochemical activity (Tang et al. 2015b; Zhang et al. 2021a). Among different carbon materials, rGO has been widely studied and found to be one of the most promising supports for nanomaterials in supercapacitor applications (Patil et al. 2021). For example, Hoa et al. (2021) exhibited the electrochemical supercapacitor performances of needle-like RGO/NiCo<sub>2</sub>S<sub>4</sub> aerogel synthesized using hydrothermal technique. The prepared aerogel electrode showed a high specific capacity of 813 F g<sup>-1</sup> in the 3 M KOH aqueous electrolyte at a current rate of 1.5 A g<sup>-1</sup>, due to its high porosity and conductive nature. The asymmetric supercapacitor of RGO/NiCo<sub>2</sub>S<sub>4</sub>//RGO delivered a specific capacitance of 45.3 F g<sup>-1</sup> at 1 A g<sup>-1</sup> and capacitance retention of 84.3% after 2000 cycles. It also delivered high energy density of 40.3 Wh kg<sup>-1</sup> at 375 W kg<sup>-1</sup> and a power density of 26.2 kW kg<sup>-1</sup> at 3.7 kWh kg<sup>-1</sup>. Similarly, Xu et al. (2020) synthesized NiMoS<sub>4</sub>/RGO lamella structure by a hydrothermal approach and got a specific capacity of 124 mAh g<sup>-1</sup> at 1 A g<sup>-1</sup>. The fabricated NiMoS<sub>4</sub>/RGO//activated carbon device possessed an excellent energy density of 63 Wh kg<sup>-1</sup> at power density 1125 W kg<sup>-1</sup> with stable capacitance retention of 81% after 5000 cycles, owing to the high chemical activity of Ni with better conductive support provided by Mo and RGO. Another study reported the synthesis of sandwich-like NiCo<sub>2</sub>S<sub>4</sub>/RGO using vacuum filtration method (Wu et al. 2018), exhibiting specific capacity of 1000.5 F g<sup>-1</sup> at 1 A g<sup>-1</sup> and the asymmetric supercapacitor (ASC) fabricated with NiCo<sub>2</sub>S<sub>4</sub>/RGO//AC hybrid electrode delivered high energy density of 15.4 Wh kg<sup>-1</sup> and power density 2227.3 W kg<sup>-1</sup> with cycling stability of 80.5% over 5000 cycles, due to the increase in interlayer spacing, thus aiding the efficient penetration and diffusion of ions. Recently, manganese cobalt sulfide/rGO nanocomposites synthesized through dispersion method by Tung et al. (2022) were found to exhibit specific capacitance of 3812.5 F g<sup>-1</sup> at 2 A g<sup>-1</sup> and 1780.8 F g<sup>-1</sup> at a high current density of 50 A g<sup>-1</sup> with the capacitance retention over 92% after 22,000 cycles at 50 A g<sup>-1</sup>. It was observed that the presence of rGO decreased the charge transfer resistance and enhanced ion exchange during the electrochemical studies. To the best of our knowledge, there are no reports which demonstrate the electrochemical performances of ternary Ni-Cu sulfide/rGO nanocomposites. Due to the unique supercapacitor properties of NiCuS and rGO materials, fabricating β-NiCuS/rGO composites and using them for supercapacitors application could be a promising strategy for improving the performances of energy storage devices (Zhang et al. 2020).

In order to understand the performances of β-NiCuS/rGO composites for supercapacitor application, herein we synthesized β-NiCu<sub>2</sub>S (NC) and β-NiCu<sub>2</sub>S/0.05 wt.% of rGO (NCR-1), β-NiCu<sub>2</sub>S/0.1 wt.% of rGO (NCR-2), and β-NiCu<sub>2</sub>S/0.15 wt.% of rGO (NCR-3) nanocomposites via one-step hydrothermal approach. The structure, morphology, composition, and chemical state of synthesized pristine β-NiCu<sub>2</sub>S and composites are characterized using X-ray diffraction (XRD), Fourier transform infrared (FTIR) spectroscopy, Raman spectroscopy, field emission scanning electron microscope (FESEM), and X-ray photoelectron spectroscopy (XPS). Electrochemical studies are carried out with three-electrode cell configuration. The fabricated β-NiCu<sub>2</sub>S (NC) and different composites NCR-1, NCR-2, and NCR-3 are also evaluated in detail for their supercapacitor performances.

## Experimental procedure

### Materials

All chemicals used here are analytical grade and used without further purification. Nickel chloride (NiCl<sub>2</sub>·6H<sub>2</sub>O), copper chloride (CuCl<sub>2</sub>·6H<sub>2</sub>O), thiourea (NH<sub>2</sub>CSNH<sub>2</sub>), polyvinylidene difluoride (PVDF), carbon black, nickel foam (NF) and hydrazine hydrate (N<sub>2</sub>H<sub>2</sub>·H<sub>2</sub>O) were procured from Sigma Aldrich. N-methyl-2-pyrrolidone (NMP) was obtained from SDFCL, India. Potassium hydroxide (KOH), hydrochloric acid (HCl), deionized (DI) water, acetone, and ethanol were purchased from SRL chemicals, India.

### Sample preparation

#### Preparation of NC nanorods

In order to prepare NC nanorods, 0.48 g NiCl<sub>2</sub>·6H<sub>2</sub>O, 0.54 g CuCl<sub>2</sub>·6H<sub>2</sub>O, and 1.52 g NH<sub>2</sub>CSNH<sub>2</sub> were added into 40 mL DI water and continuously stirred for 30 min. After this, 20 mL of N<sub>2</sub>H<sub>2</sub>·H<sub>2</sub>O was added dropwise into the above mixture and stirred for other 30 min to obtain black precipitate. The obtained transparent black precipitate was further transferred into a 100-mL autoclave and hydrothermally treated at 160 °C for 20 h. Once reaching room temperature, the sample was centrifuged with DI water and ethanol several times. The obtained final product was dried at 80 °C for 12 h. This is labeled as NC. The same procedure was repeated for the preparation of NCR-1, NCR-2 and NCR-3 composites where the stipulated amount of graphene oxide (synthesis procedure of GO is given below) was added into the black precipitate mentioned above, stirred for 30 min, and transferred to autoclave for hydrothermal treatment at 160 °C for 20 h. The GO is reduced to rGO due to the presence of hydrazine

hydrate present in the reaction mixture and hence leads to the formation of NC-rGO composites.

### Preparation of graphene oxide

Modified Hummers method was followed for the synthesis of graphene oxide (GO). Graphite (10 g) and sodium nitrate ( $\text{NaNO}_3$ ) (4 g) were mixed into 185 mL of concentrated sulfuric acid ( $\text{H}_2\text{SO}_4$ ) and the reaction mixture was magnetically stirred in an ice bath for 1 h. Later, potassium permanganate ( $\text{KMnO}_4$ ) (32 g) was added slowly into the reaction mixture while maintaining its temperature below  $5^\circ\text{C}$  and the suspension was continuously stirred for 1 h. After vigorous stirring, ice bath was removed, which resulted in dark brown color solution to which deionized water was added until suspension volume reaches 500 mL, followed by addition of hydrogen peroxide ( $\text{H}_2\text{O}_2$ ) (15 mL). Finally, the obtained suspension was centrifuged and washed repeatedly with water and hydrochloric acid (HCl). The product was dried at  $80^\circ\text{C}$  for 24 h to obtain GO, the pH of which was found to be 5.7 after washing.

### Electrode fabrication

The working electrode was fabricated using the synthesized materials by mixing them with carbon black (super P) and polyvinylidene fluoride (PVDF) (binder) in the weight ratio of 80:10:10. The above mixer was well ground and N-methyl-2-pyrrolidone (NMP) solvent was added to make it slurry. Then, the obtained black color slurry was uniformly coated on pure Ni foam (NF) and dried at  $60^\circ\text{C}$  for 5 h. The dried NF was used as working electrode for supercapacitor studies. The weight of the electrode materials, coated on the Ni foam, is calculated by finding the difference of weight of Ni foam before and after slurry coating. Prior to the electrode preparation, the NF was washed with 3 M HCl, acetone, ethanol, and DI water, respectively, in an ultrasonic bath for each 10 min to eliminate NiO layer on the NF surface. The cleaned NF was dried in a vacuum oven at  $60^\circ\text{C}$  for 2 h.

### Material characterization

Crystalline nature and phase identifications of the as-prepared samples are carried out using powder XRD with Cu  $K\alpha$  radiation (D8, Bruker). The functional groups of prepared samples were investigated by FTIR spectroscopy (PerkinElmer-1600). The morphology analysis of NC and different weight ratio of rGO NCR (1–3) samples is performed by FE-SEM (JEOL 6360). A Raman spectroscopic study of the synthesized samples was carried out using Renishaw Raman spectrometer coupled with

laser source of wavelength 514 nm. XPS was performed using hemispherical analyzer EA 15 (PREVAC) equipped with dual anode non-monochromatic X-ray source RS 40B1 (PREVAC). The measurements were performed using Al  $K\alpha$  (1486.6 eV) radiation and analyzer pass energy of 100 eV. The electron binding energy (BE) scale was calibrated at the maximum of C 1s core excitation at 285 eV.

### Electrochemical studies

The electrochemical measurements were carried out on Bio-Logic (SP-300) electrochemical workstation in a three-cell electrode configuration. The as-fabricated NF electrode was used as working electrode; saturated calomel electrode (SCE) and Pt-wire were utilized as reference and counter electrode, respectively. The electrochemical activities of the as-prepared pristine NC and ternary material composites (NCR-1, NCR-2 and NCR-3) were evaluated using cyclic voltammetry (CV), galvanostatic charge–discharge (GCD), and electrochemical impedance spectroscopic (EIS) techniques. The electrochemical performance was measured within the potential range of 0 to 0.6 V in 3 M KOH aqueous electrolyte. The specific capacitance ( $SC$ ) of the fabricated electrode materials was estimated from the CV profiles using the following Eq. 1:

$$SC = \frac{1}{v \times m \times (\Delta V)} \int_{v_i}^{v_f} I(V) dV \quad (1)$$

where  $SC$  represents the specific capacitance (F/g),  $v$  denotes the scan rate (mV/s),  $m$  is the mass loading of the active material,  $\Delta V$  represents the potential window (V), and  $\int_{v_i}^{v_f} I(V) dV$  denotes the integral area under the CV curve. The specific capacitance ( $SC$ ) of the fabricated electrode was calculated from the GCD curves by the following Eq. 2:

$$SC = \frac{I \times \Delta t}{m \times \Delta v} \quad (2)$$

where  $SC$  represents the specific capacitance (F/g),  $I$  denotes the current density (A),  $\Delta t$  is the discharge time (s),  $\Delta v$  represents the potential window (V), and  $m$  denotes the mass (g) of the active material (Narathana et al. 2021; Gholami and Arvand 2021).

To understand the reproducibility of NCR composites, four similar electrodes were fabricated using the best sample. The reproducibility of the electrodes of the best sample was conducted by analyzing CV measurements carried out at  $20\text{ mV s}^{-1}$  and GCD measurements carried out at a current density of  $15\text{ mA g}^{-1}$  in 3 M KOH electrolyte using electrochemical work station. The

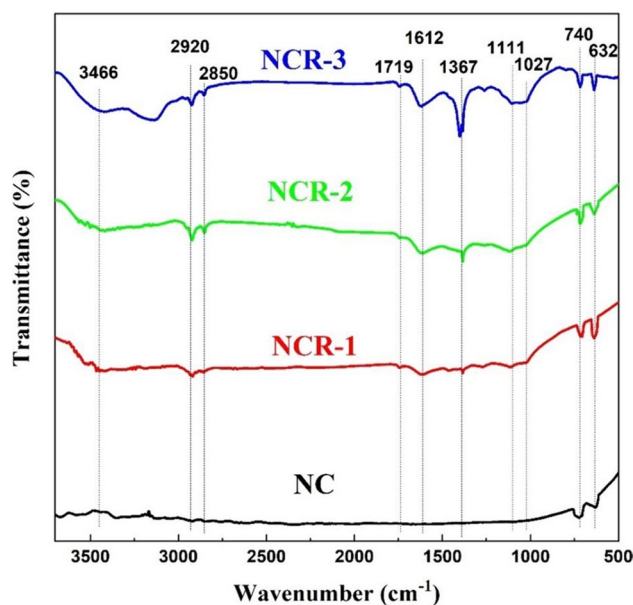

**Fig. 1** XRD pattern of (a) GO, (b) NC, (c) NCR-1, (d) NCR-2 and (e) NCR-3

reproducibility of the samples was also tested by comparing GCD measurements obtained at 15, 16, 17, 18 and 20 mA g<sup>-1</sup> current densities for all the four electrodes. The electrodes were thoroughly cleaned with distilled water several times, dried it and placed inside the vacuum desiccator before every measurement.

## Results and discussion

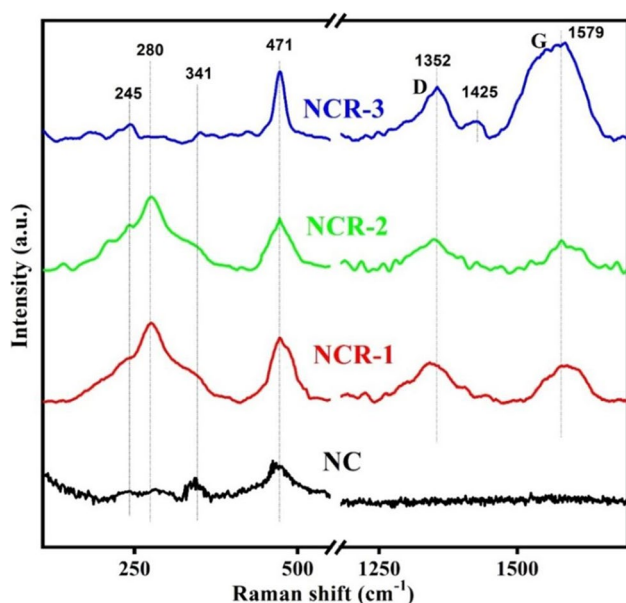

The crystal phase purity of the prepared samples was evaluated by powder X-ray diffraction (PXRD) experiment, depicted in Fig. 1. The XRD spectra of all the samples (Fig. 1a, b, c, d) exhibit the diffraction peaks at  $2\theta$  angles of 18.44°, 30.33°, 32.68°, 35.73°, 37.39°, 40.49°, 48.87°, 50.17°, 52.68°, 56.29°, 57.48° and 59.76°, which can be indexed to the planes (110), (101), (300), (021), (220), (211), (131), (410), (401), (321), (330) and (012) of rhombohedral phase of  $\beta$ -NiS (JCPDS: 12–0041), respectively (Xie et al. 2021; Bhagwan et al. 2020). Similarly, they exhibit the diffraction peaks at  $2\theta$  angles of 27.89°, 28.09°, 29.38° and 46.63°, which can be indexed to the planes of (024), (262), (342) and (076) of orthorhombic  $\text{Cu}_2\text{S}$ , respectively (JCPDS: 12–0227) (Rahaman et al. 2020). In addition to the above diffraction planes, the XRD patterns of NCR-1, NCR-2 and NCR-3 also exhibit newer diffraction peaks at  $2\theta = 27.85^\circ$  and  $29.27^\circ$ , corresponding to (024) and (342) planes of  $\text{Cu}_2\text{S}$ , the intensity of which increases as we increase the concentration of rGO. This clearly indicates that the increased rGO concentration in NCR-2

**Fig. 2** FTIR spectrum of (a) NC, (b) NCR-1, (c) NCR-2 and (d) NCR-3

and NCR-3 nanocomposites induced a phase change in  $\text{Cu}_2\text{S}$ . The XRD of all samples possesses distinct peaks at  $44^\circ$  and  $51.2^\circ$ , which correspond to (111) and (200) peaks of Ni-Cu (JCPDS: 65–7246). Thus, from the characteristic XRD, peaks analysis indicates the formation of  $\beta$ -NiCu<sub>2</sub>S.

The XRD graph of as synthesized graphene oxide is given in Fig. 1a. A strong peak at  $2\theta = 11.9^\circ$  corresponding to (001) plane of GO clearly indicates that the synthesized GO is of high quality and good crystallinity (Sibirian et al. 2018). There is also a weak peak present at  $2\theta = 26.49^\circ$  that can be ascribed to the disordered character of graphitic structure caused by oxidation process and also indicates the traces of unoxidized graphite (Gurzęda et al. 2017). Whereas in Fig. 1b, c, d, the signature peak of GO ( $2\theta = 11.9^\circ$ ) is totally absent and whereas the peak at  $2\theta = 26.3^\circ$  which corresponds to the  $\pi$ -conjugated structure of graphene is of high intensity which clearly indicates that the added GO into the  $\beta$ -NiCu<sub>2</sub>S reaction mixture was completely reduced to reduced graphene oxide (rGO) after hydrothermal treatment due to the presence of hydrazine hydrate (Shoeb et al. 2021; Hu et al. 2020; Hidayah et al. 2017). In Fig. 1b, c, d, there are weak intensity peaks present at approximately  $2\theta = 26.32^\circ$ ,  $42.63^\circ$ , and  $54.97^\circ$ , which correspond to the (002), (100) and (004) reflection planes of rGO, respectively (Singh et al. 2021). It is clearly evident that the added GO into the  $\beta$ -NiCu<sub>2</sub>S reaction mixture is completely reduced to reduced graphene oxide (rGO) after hydrothermal treatment due to the presence of hydrazine hydrate (Shoeb

**Fig. 3** Raman spectrum of (a) NC, (b) NCR-1, (c) NCR-2 and (d) NCR-3

et al. 2021; Hu et al. 2020). It can be seen that the XRD patterns of prepared nanocomposite peak has no other impurity peaks. Also, it is noticed that the intensity of the peaks increases with respect to increase in rGO composition, as evident from Fig. 1. This clearly indicates that the synthesized samples are highly pure and crystallinity increases with increase in rGO concentration. Pure and

high crystalline sample can provide a fast diffusion channel for ions and promote the electrochemical reaction in supercapacitor application (Wang et al. 2019).

The FTIR spectra of the as-synthesized materials such as pristine NC and their rGO nanocomposites (NCR-1, NCR-2 and NCR-3) are shown in Fig. 2. All the samples exhibit stronger absorption bands around  $632\text{ cm}^{-1}$  and  $740\text{ cm}^{-1}$ , which can be ascribed to Ni–S bond vibration in c (Jansi et al. 2019) and Cu–S vibration in  $\text{Cu}_2\text{S}$  (Yu et al. 2016). The appearance of peak at  $1612\text{ cm}^{-1}$  metal–OH stretching vibration in NCR-1 to NCR-3 samples indicates the formation of NC-rGO composites (Kamalanathan and Gopalakrishnan 2015). The peak at  $3466\text{ cm}^{-1}$  is ascribed to the stretching vibration of O–H bonds due to the presence of moisture in all the composite samples. The absorption bands at 1738, 1367 and  $1111\text{ cm}^{-1}$  observed in NCR-1 to NCR-3 samples can be ascribed to the stretching vibrations of C=O from carbonyl groups, carboxyl stretching C–OH of  $\text{O}=\text{C}-\text{OH}$ , and C–O alkoxy groups present in the rGO, respectively. Similarly, the characteristics rGO absorption peaks at 2920 and  $2850\text{ cm}^{-1}$ , corresponding to C–H stretching in asymmetric and symmetric vibrations, respectively, are found to be absent in NC. As it is noticed that these characteristics rGO peaks are less in intensity in NCR-1 to NCR3 samples. This indicates the maximum reduction of GO to rGO during the hydrothermal synthesis. Among NCR samples, NCR-3 possesses slightly higher intensity characteristic peaks of rGO, which can be due to the presence of high rGO concentration. The additional peak

**Fig. 4** FE-SEM images of (a) NC, (b) NCR-1, (c) NCR-2 and (d) NCR-3

**Fig. 5** XPS spectra of NCR-3 nanocomposite: (a) Ni 2p, (b) Cu 2p, (c) S 2p and (d) C1s level spectra

present at  $1027\text{ cm}^{-1}$  corresponds to C–O stretching mode that arises from the adsorbed carbon and oxygen atom in the samples from the atmosphere (Narthana et al. 2021).

The Raman spectra of all the synthesized samples have been analyzed and presented in Fig. 3. The Raman peaks around  $245$  and  $280\text{ cm}^{-1}$  correspond to  $\beta$ -NiS vibration (Bishop et al. 1998). These peaks are weakly present in NC and NC-3, whereas these peaks are intense in NCR-1 and NCR-2. A weak vibrational mode observed around  $341\text{ cm}^{-1}$  present in all the samples belongs to  $\beta$ -NiS vibration (Li et al. 2007). On the other hand, the vibrational mode at  $472\text{ cm}^{-1}$  corresponds to  $\text{Cu}_2\text{S}$  (Lai et al. 2010), which is present in all the samples. The difference in the characteristic bands of Raman spectra among different samples is thought to be caused by the change in the coordination state of metal ion and/or the microstructure of the NiS or  $\text{Cu}_2\text{S}$  nanoparticles, which is evident from the FESEM images in Fig. 4. Thus, the Raman analysis of all the samples confirms the presence of  $\beta$ -NiCu<sub>2</sub>S, which is in agreement with the XRD results. The presence of rGO in the samples is analyzed using D and G bands in Raman spectra. All the composite samples have their D and G band present at  $1352\text{ cm}^{-1}$  and  $1580\text{ cm}^{-1}$ , whereas these peaks are absent in pristine NC sample, thus confirming the presence of rGO in composites. The D band observed at around  $1352\text{ cm}^{-1}$  indicates the features of  $\text{sp}^3$  defects

in carbon, while the G band observed around  $1579\text{ cm}^{-1}$  represents the in-plane vibrations of  $\text{sp}^2$  bonded carbons (Perera et al. 2012; Rao et al. 2011). The intensity ratio of the D band to the G band ( $I_D/I_G$ ) is calculated in general to study the order of defects in rGO or graphene (Perera et al. 2012). The  $I_D/I_G$  values are calculated to be 1.1, 0.95, and 0.6 for NCR-1, NCR-2 and NCR-3, respectively. It is observed that the  $I_D/I_G$  value decreases with increase in rGO concentration in the composite samples. The high  $I_D/I_G$  ratio of NCR-3 implies that the sample has lower density of defects present in rGO compared to NCR-1 and NCR-2 composites. Also, the decrease in the  $I_D/I_G$  ratio denotes the increase in the number of rGO layers (Yoon et al. 2009). This can be attributed to the increase in rGO composition in NCR-3. It is also noted that, in NCR-3, the G band is broadened, while the intensity of the D band increases slightly when compared to NCR-1 and NCR-2, which can be attributed to the significant decrease in size of the in-plane  $\text{sp}^2$  domains (Shen et al. 2011). A weak peak at  $1430\text{ cm}^{-1}$  in NCR-3 could be attributed to  $\text{sp}^3$  hybridization-rich phase of amorphous carbons (Chadha et al. 2021), which may be present due to the high concentration of rGO. The results from Raman spectra analysis demonstrate the successful reduction of GO to rGO during hydrothermal treatment as well as the formation of  $\beta$ -NiCu<sub>2</sub>S/rGO composites.

Fig. 6 CV profile of (a) NC, (b) NCR-1, (c) NCR-2 and (d) NCR-3

The morphology of as prepared pristine NC and NCR-1, NCR-2 and NCR-3 composites was analyzed using FE-SEM (Fig. 4). The SEM image of pristine NC (Fig. 4a) exhibited distinct rod like structure. Thereby in Fig. 4b, c, d, it is noticed that the  $\beta$ -NiCu<sub>2</sub>S nanorods are wrapped with rGO nanosheet on their surface. The rGO nanosheet wraps around  $\beta$ -NiCu<sub>2</sub>S nanorods increase their contact surface area, which paves way for efficient redox reaction due to enhanced charge transfer and conductivity of the composite samples. The nanorods are less visible and rGO sheet morphology is more prominent with increase in rGO weight percent as in NCR-3, indicating a dense wrap of rGO nanosheets over NiCu<sub>2</sub>S nanorods compared to NCR-2 and NCR-1 (Hu et al. 2021; Huang et al. 2021).

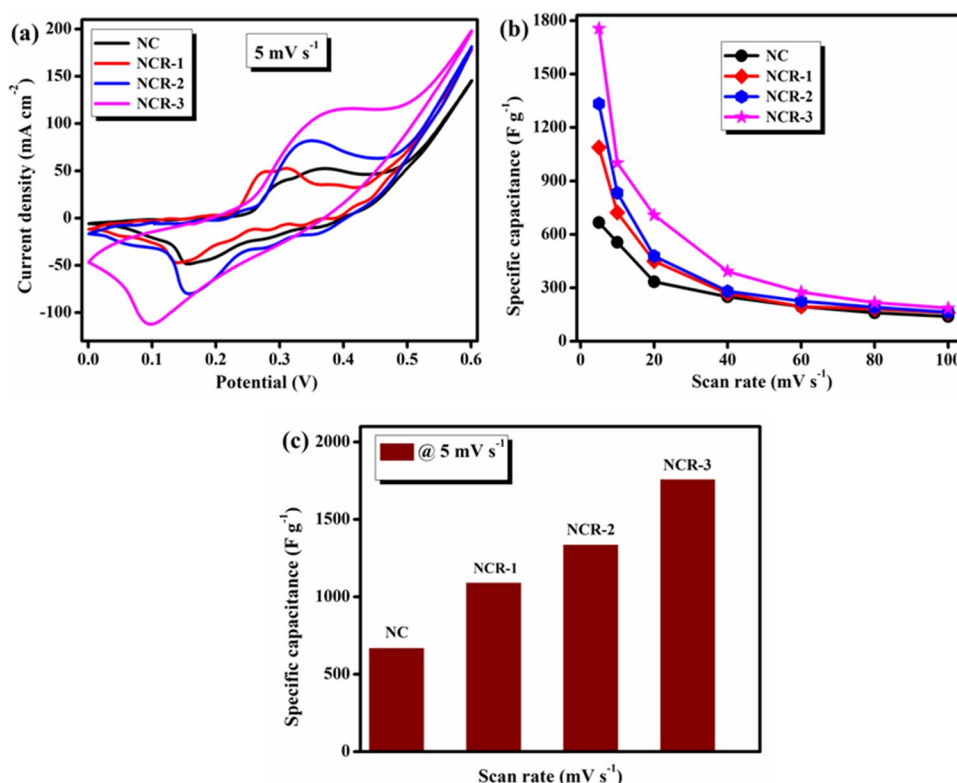

The wrapping of rGO nanosheets over  $\beta$ -NiCu<sub>2</sub>S nanorods increases their contact surface area, which paves the way for efficient redox reaction due to enhanced charge transfer and conductivity (Xu et al. 2020). The protective layers of rGO also aid in improving

the material conductivity and also avert the aggregation of  $\beta$ -NiCu<sub>2</sub>S nanoparticles (Wang et al. 2020a). The average length and diameter of the nanorods are calculated to be 270 and 100 nm for NC, 220 and 75 nm for NCR-1, 250 and 60 nm for NCR-2 and 230 and 63 nm for NCR-3.

The chemical composition and the oxidation state of NiCuS/rGO are studied using XPS. The Ni 2p spectra of NiCuS/rGO are deconvoluted, as shown in Fig. 5a. The peaks located at 873.5 eV and 855.9 eV represent Ni 2p<sub>1/2</sub> and Ni 2p<sub>3/2</sub>, respectively, with their satellite peaks present at 883.6, 864.7 and 860.8 eV (Beigbaghlou et al. 2018). This indicates that Ni is present in the form of Ni<sup>2+</sup>. The peak at 852.9 eV is due to the presence of metallic Ni (Ni<sup>0</sup>) on the surface (Hengne et al. 2018; Cao and Cheng 2019) due to NiCu alloy phase. The Cu spectra of the sample have Cu 2p<sub>3/2</sub> peak at 932.8 eV and Cu 2p<sub>1/2</sub> peak at 952.8 eV, which suggest that Cu is in the form of Cu<sub>2</sub>S (Kar et al. 2014), which is evident from the XRD, Raman, and FTIR spectra results. The

**Fig. 7** (a) Comparison of CV profile for all fabricated samples of NC, NCR-1, NCR-2 and NCR-3 at  $5 \text{ mV s}^{-1}$ ; (b) scan rate vs specific capacitance; and (c) comparison of specific capacitance of the fabricated electrodes at the scan rate of  $5 \text{ mV s}^{-1}$ .

deconvolution of Cu 2p spectra is presented in Fig. 5b, in which the peaks centered at 954.6 eV and 952.2 eV correspond to Cu  $2p_{1/2}$ , whereas the peaks centered at 934.8 eV and 932.7 eV correspond to Cu  $2p_{3/2}$ . The peaks centered at 962.1 eV and 942 eV are the satellite peaks of Cu 2p (Cao and Cheng 2019). In Fig. 5c, the deconvolution of S 2p spectra gives rise to three peaks, in which the peaks centered at 163.8 eV and 162.1 eV correspond to S  $2p_{1/2}$  and S  $2p_{3/2}$ , respectively. The shake-up satellite peak present at 168.2 eV can be attributed to the presence of surface adsorbed sulfur species, such as  $\text{SO}_4^{2-}$  and  $\text{HSO}_4^-$  (Khani and Wipf 2017; Justin et al. 2019). From Fig. 5d, the presence of rGO is confirmed by analyzing the C 1s spectra of the sample. The deconvolution of C 1s spectra gives rise to four peaks centered at 284.5, 286, 287.6 and 290 eV, which correspond to the graphitic  $\text{sp}^2$  hybridized graphitic carbon (C=C), the graphitic  $\text{sp}^2$  carbon atom (C–O), the carbonyl (C=O),

and the carboxyl carbon (HO–C=O), respectively, which confirm the presence of rGO in the sample (Zhang et al. 2021b).

### Electrochemical performance

The electrochemical performance of electrodes prepared with NC, NCR-1, NCR-2 and NCR-3 is evaluated by CV, GCD and EIS measurements via 3-electrode cell configuration in 3 M KOH aqueous electrolyte. Figure 6 displays the cyclic voltammograms of NC, NCR-1, NCR-2 and NCR-3 electrodes performed at a scan rate of 5 to  $100 \text{ mV s}^{-1}$  in the potential range from 0.0 to 0.6 V. The CV profiles of all the fabricated electrodes exhibited a pair of redox peaks, which confirm that the charges are stored in a Faradic manner under redox reactions (Xu et al. 2020). The observed pair of oxidation and reduction peaks in Fig. 6 resulted from  $\text{Ni}^{2+}/\text{Ni}^{3+}$  and  $\text{Cu}^+/\text{Cu}^{2+}$  redox reactions (Wu et al. 2018). From Fig. 6a, b, c, d, it is observed that the area under the CV curves of all pristine and nanocomposite samples are increasing with increase in the sweep rate over 5 to  $100 \text{ mV s}^{-1}$  which is attributed to the minimal internal resistance at the electrode–electrolyte interface (Xie et al. 2021).

It is noticed, from the CV of NCR composite samples, that as the scan rate increases, the oxidation and reduction peaks were shifted to the higher and lower potentials, respectively. Among all the electrodes, NCR-3 shows the

**Table 1** Calculated specific capacitance at the scan rate of  $5 \text{ mV s}^{-1}$

Electrode materials	Scan rate ( $\text{mV s}^{-1}$ )	Specific capacitance ( $\text{F g}^{-1}$ )
NC	5	666.7
NCR-1	5	1088.9
NCR-2	5	1333.4
NCR-3	5	1755.6

**Fig. 8** GCD curves of (a) NC, (b) NCR-1, (c) NCR-2 and (d) NCR-3

largest CV area (Fig. 6d), hinting that the incorporation of rGO (0.15 wt.%) has improved the electrochemical performance of the NiCu<sub>2</sub>S/rGO composite (Sabeeh et al. 2021; Ndambakuwa et al. 2021). This electrode also possessed high stability during the electrochemical process. The redox peaks of NCR-3 are observed to be high due to the high amount of rGO present in the sample compared to NCR-1 and NCR-2 (Darsara et al. 2021; Miao et al. 2020). The CV profiles of all the electrodes at 5 mV s<sup>-1</sup> (Fig. 7a) are compared and it is noticed that NCR-3 exhibits larger area compared to other composite samples. The overall specific capacitances (*SC*) are calculated using Eq. 1 from Fig. 7a and displayed in Table 1.

From Table 1, it is noted that the fabricated NCR-3 electrode delivers maximum *SC* of 1755.6 F g<sup>-1</sup> at 5 mV s<sup>-1</sup>, which is attributed to the enhanced surface to volume ratio and efficient electron transport property due to the presence of large amount of rGO and its efficient interface with NiCu<sub>2</sub>S. The *SC* values are calculated with respect to different scan rates and are plotted in Fig. 7b. It is noticed that the *SC* values are decreased when the scan rate is increased, which is because of the deficient time for the electrolyte ions to diffuse into electrode inner pores at higher scan rates (He et al. 2020). Also, it is noticed that the specific capacitance value is dependent on the rGO concentration in the samples. Among all samples, it is noticed that NCR-3 has higher specific capacitance in all scan rates compared to other

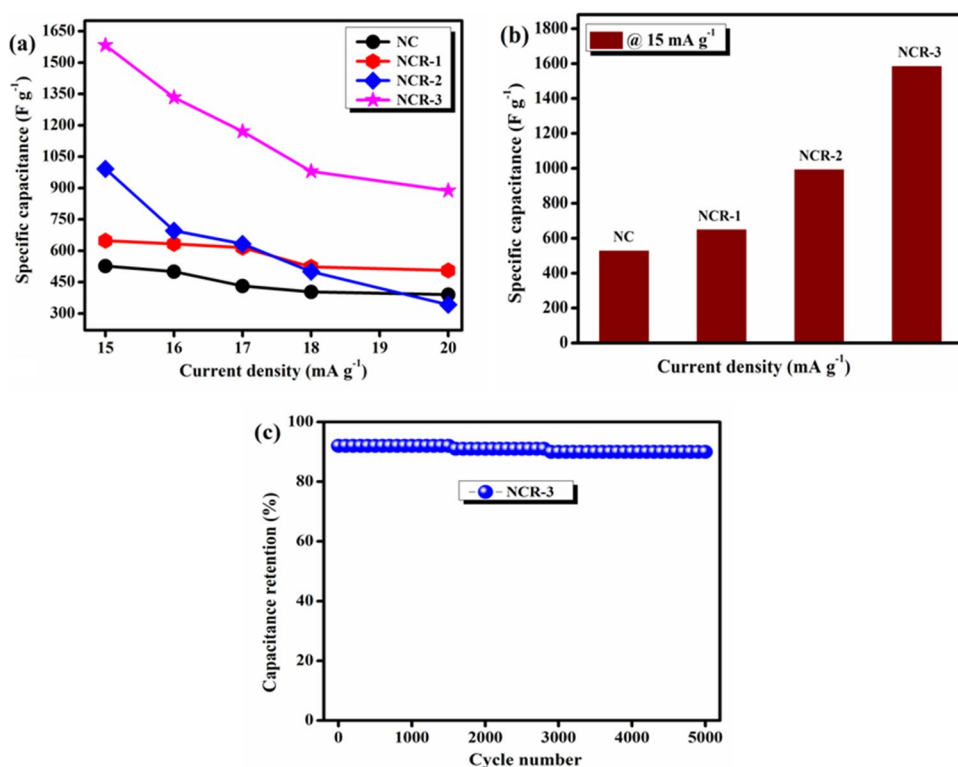

composites (NCR-1 and NCR-2) and pristine NC owing to the higher rGO concentration. Also, the CV profile of NCR-3 electrode shows high specific surface-active area compared to pristine NC, NCR-1 and NCR-2, respectively, at same scan rate of 5 mV s<sup>-1</sup>, as shown in Fig. 7c.

The galvanostatic charge/discharge studies are carried out for pristine NC and composite NCR-1, NCR-2 and NCR-3 electrodes in 3 M KOH electrolyte with potential window from 0.0 to 0.6 V for different current densities of 15, 16, 17, 18 and 20 mA g<sup>-1</sup>, which are depicted in Fig. 8a, b, c, d. The distinct voltage plateaus in the GCD curves exhibit the battery-supercapacitor hybrid characteristics, which is consistent with the results of CV curves in Fig. 6a, b, c, d. Figure 8 shows typical supercapacitor characteristics with excellent electrochemical capacitive nature and superior electrochemical

**Table 2** Calculated specific capacitance at the current density of 15 mA g<sup>-1</sup>

Electrode materials	Current density (mA g <sup>-1</sup> )	Specific capacitance (F g <sup>-1</sup> )
NC	15	527
NCR-1	15	648
NCR-2	15	991
NCR-3	15	1583

**Fig. 9** GCD analysis of (a) and (b) specific capacitance of fabricated electrodes NC, NCR-1, NCR-2 and NCR-3 and (c) represent capacitance retention of NCR-3 electrode at 5000 cycles

reversibility (Gholami and Arvand 2021). Compared to pristine NC electrode (Fig. 8a), the nanocomposite NCR-1, NCR-2 and NCR-3 electrodes in Fig. 8b, c, d shows the longest charge–discharge time and highest specific capacitance, which is in good agreement with the CV results discussed above. The SCs are calculated from discharge time in corresponding GCD curves using Eq. 2, which are displayed in Table 2.

**Fig. 10** EIS profile of (a) NC, NCR-1, NCR-2 and NCR-3

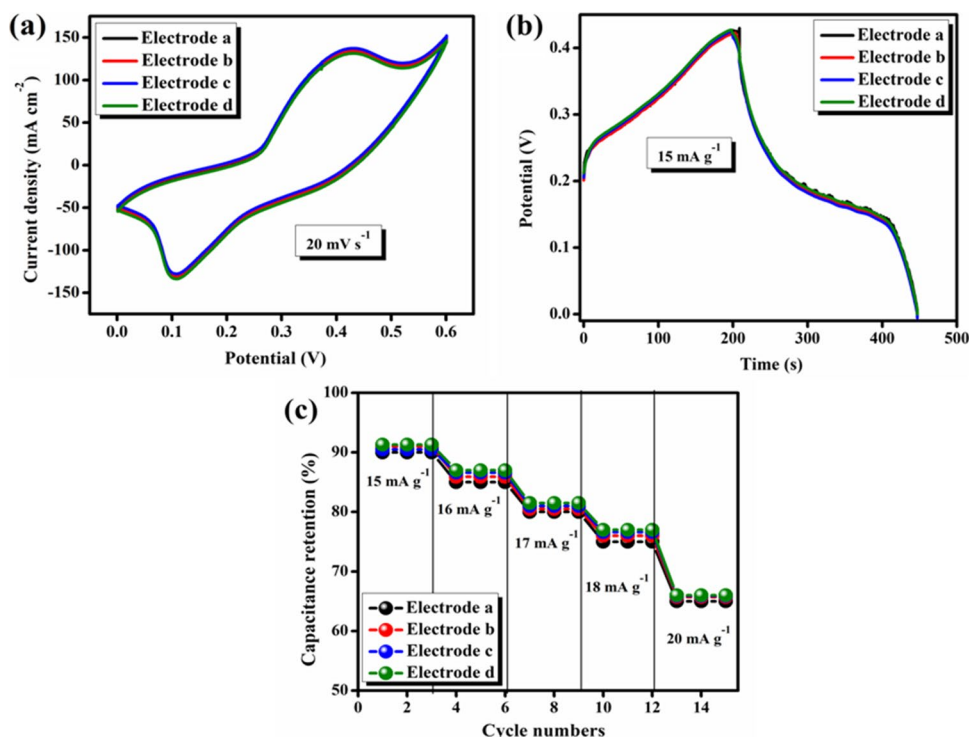

Among the electrodes, NCR-3 exhibited higher specific capacitance values, as shown in Fig. 9a, b, which is in agreement with the CV results. The stability is tested for NCR-3 electrode, which is the best performing sample, the results of which are presented in Fig. 9c. It suggests that NCR-3 retained about 89% of its initial capacitance after 5000 cycles at 18 mA g<sup>-1</sup>. The cycling stability results show remarkable rate capability of composites owing to its high electrochemical stability. This is because of the increase in concentration of rGO, leading to the increase in high surface to volume ratio resulting in efficient ion transfer in the electrode/electrolyte interface (Nandhini and Muralidharan 2021; Boopathiraja et al. 2020).

The interfacial charge transport resistance of the electrolyte/electrode material interface for all the pristine and composite samples is measured using EIS-Nyquist plot

**Table 3** The charge transfer resistance of synthesized samples

Electrode materials	Charge transfer resistance, R <sub>ct</sub> (Ω cm <sup>-1</sup> )
NC	28
NCR-1	19
NCR-2	15
NCR-3	12

**Fig. 11** Reproducibility test of (a) CV graphs of four electrodes taken at a scan rate of  $20 \text{ mV s}^{-1}$ , (b) GCD graphs of four electrodes at  $15 \text{ mA g}^{-1}$  current density, and (c) rate capability of the four electrodes at 15, 16, 17, 18 and  $20 \text{ mA g}^{-1}$  current density for three consecutive GCD cycles

analysis done in the frequency range from 100 kHz to 0.1 Hz depicted in Fig. 10 using three electrode systems. The Nyquist plots of all the sample electrodes possessed a small semicircle in high frequency region ( $R_{ct}$ ), which indicates lower charge-transfer resistance at the interface between the electrode/electrolyte. Also, a straight line nearer to the imaginary axis ( $R_s$ ) with shorter length frequency, observed in the low frequency region, suggests low ion diffusion resistance from the electrolyte to the surface of the electrode (Ma et al. 2020). The calculated  $R_{ct}$  values are displayed in Table 3.

### Reproducibility analysis

The reproducibility of the performance of the best sample (NCR-3) was analyzed to evaluate the practical application of a supercapacitor. The as-fabricated four similar NCR-3 electrodes were named as electrode a, electrode b, electrode c and electrode d. The obtained CV at  $20 \text{ mV s}^{-1}$  scan rate and GCD curves at  $15 \text{ mA g}^{-1}$  current density of the four fabricated electrodes are depicted in Fig. 11a, b. The shape of the CV curves remains quasi-rectangular pattern for all the four prepared electrodes with least variation in the geometric area. The GCD curves remain almost similar in shape for all the four electrodes and possess excellent specific capacitance of  $1597 \text{ F g}^{-1}$ ,  $1590 \text{ F g}^{-1}$ ,  $1583 \text{ F g}^{-1}$  and  $1575 \text{ F g}^{-1}$  for electrode a, electrode b, electrode c, and electrode d, respectively, at current density of  $15 \text{ mA g}^{-1}$ . The slight variation in specific capacitance value might be

due to the minor change in the loaded mass of each of the electrode samples as specific capacitance is inversely proportional to mass loading. The rate capability for the four NCR-3 electrodes is evaluated for three consecutive cycles at each current density of 15, 16, 17, 18 and  $20 \text{ mA g}^{-1}$  whose variation is depicted in Fig. 11c. Similar patterns are observed in the graph for three consecutive cycles for all the current densities. It is also found that the rate of change of capacitive response for all the four electrodes is almost same. These results indicate that the synthesized NCR-3 composite has good stability with high reproducibility (Sarmah and Kumar 2019; Li et al. 2011; Li et al. 2022).

Compared with pristine NC, the performance of rGO wrapped NCR-1, NCR-2 and NCR-3 samples possessed unique structure and morphology, which provides abundant electroactive sites. The higher rGO concentration helps in improving better stability, high contact area, and high electrochemical activity. The overall results illustrate that NCR-3 is a promising electrode material for supercapacitor applications, which exhibits satisfactory electrochemical behaviors, including high specific capacitance, good cycle stability, and high reproducibility.

### Conclusion

The novel electrodes of pristine nickel copper sulfide and their composites with different concentrations of rGO nanosheets are synthesized using facile hydrothermal

technique. The synthesis procedure gives rise to rGO sheets wrapped  $\beta$ -phase NiCu<sub>2</sub>S nanorods, which is clear from XRD, FTIR, Raman, FESEM and XPS analysis. It is noted that GO is completely reduced to rGO during the synthesis of NiCu<sub>2</sub>S/rGO composites. The electrochemical investigation states that the NiCu<sub>2</sub>S/rGO composites perform better than pristine NiCu<sub>2</sub>S nanorods. Among different rGO composites, the NiCu<sub>2</sub>S nanorod composite with 0.15 wt.% of rGO exhibited high specific capacitance of 1583 F g<sup>-1</sup> at 15 mA g<sup>-1</sup> with excellent stability having capacitance retention of 89% after 5000 cycles possessing high reproducibility and rate capability.
