Abstract–In this paper, the CO<sub>2</sub> absorption rates into aqueous solutions of Methydiethanolamine (MDEA) at various oncentrations of 1, 2, 3 and 4 M and temperatures varying from 293 to 323 K were measured by using a labor concentrations of 1, 2, 3 and 4 M and temperatures varying from 293 to 323 K were measured by using a laboratory stirred reactor. The kinetics experiments were conducted under a pseudo first order regime. The data were analyzed by means of chemical absorption theory and the kinetic parameters associated with the reaction, such as the reaction order and the reaction rate constants, were evaluated. The effect of temperature on the reaction rate constant was assessed and the activation energy was evaluated at about 44.12 kJoule/mol.

Key words: Reaction, Methyldiethanolamine, Carbon Dioxide, Kinetics, Absorption

# **INTRODUCTION**

The removal of acid gases such as  $CO<sub>2</sub>$  and  $H<sub>2</sub>S$  from natural and refinery gases is an important industrial process. The use of alkanolamine-based solvents such as MEA, DEA, and MDEA is still the choice in gas treating technology. The design and analysis of separation processes involving aqueous solutions of such species require accurate knowledge of the kinetics of the reactions involved.

**EXECUTE 10** School of Chemica<br> **School of Chemica**<br> **School of Chemica**<br> **School of Chemica**<br> **SCHORT COMMUNICATION**<br> **SCHORT CONTIFICATION**<br> **SCHORT CONTIFICATION**<br> **SCHORT CONTIFICATION**<br> **SCHORT CONTIFICATION**<br> **CONTI** The use of aqueous solutions of methyldiethanolamine (MDEA) for the removal of acid gases is a well-known process in gas treating technology. Due to its instantaneous reaction with  $H_2S$  as compared to the slower one with  $CO<sub>2</sub>$ , aqueous solutions of MDEA are usually used for the selective removal of  $H_2S$  from sour gases containing both  $CO<sub>2</sub>$  and  $H<sub>2</sub>S$  [Kohl and Riesenfeld, 1985]. Owing to its higher loading capacity and lower heat of reaction compared to DEA, which implies less energy of regeneration, MDEA is still the choice for the removal of  $CO<sub>2</sub>$  from gas streams. The reaction between carbon dioxide and aqueous and non-aqueous solutions of methyldiethanolamine (MDEA) has been frequently studied in the last two decades. There appear to be no discrepancies among investigators with regard to the overall reaction order of two. However, there are still variations in the observed reaction rate constant. Versteeg et al. [1996] correlated most of the available data for the second order reaction rate constant in the following form:

$$
x_2 = 3.1 \times 10^5 \exp\left(-\frac{5080}{T}\right) m^3 \cdot mol^{-1} \cdot s^{-1}
$$
 (1)

However, this equation does not agree well with many other published works. For example, the reaction rate at  $20^{\circ}$ C varies from 1.35 [Haimour et al., 1987] to  $4.7 \text{ m}^3 \cdot \text{kmol}^{-1} \cdot \text{s}^{-1}$  [Rinker et al., 1995]. 1.35 [Haimour et al., 1987] to 4.7 m<sup>3</sup>·kmol<sup>-1</sup>·s<sup>-1</sup> [Rinker et al., 1995]. The work of Yu et al. [1985] deviates by about a factor of two from the above equation, even though the activation energy is well in The work of Yu et al. [1985] deviates by about a factor of two from line with the values reported by others.  $k_2 = 3.1 \times 10^5 \text{exp}(-\theta)$ <br>wever, this equationed works. For example of the summer of al., 1<br>5 [Haimour et al., 1<br>e work of Yu et al., above equation, e<br>e with the values re<br>whom correspondential: mk\_aroua@un

The observed discrepancies may be attributed to the different experimental techniques used in collecting the data and/or the inconsistency of the physical data such as solubility and diffusivity used in the analysis. Versteeg and Van Swaaij [1988a] attributed the major part of these discrepancies to the influence of primary and secondary amine contaminants on the absorption rate.

In this work, additional data on the kinetics of the reaction between CO<sub>2</sub> and aqueous solutions of methyldiethnolamine (MDEA) are reported at 293, 303, 313, and 323 K. Carbon dioxide partial pressure was varied over a wide range and the order of each reaction with respect to the reacting gas was assessed. The amine concentrations were varied from 1 M to 4 M leading to the evaluation of the order of the reaction with respect to the amine concentration.

# **REACTION SCHEME**

### 1. Reaction Mechanism

A general agreement exists among investigators concerning the reaction mechanism between CO<sub>2</sub> and tertiary amines. Except for a few, most investigators have indicated that tertiary amines such as MDEA could not react directly with  $CO<sub>2</sub>$ . Jensen et al. [1954] studied the reaction of  $CO<sub>2</sub>$  with triethanolamine (TEA) at high pH values (pH≅13) and concluded the formation of monoalkylcarbonate according to the following reaction:

(2)

However, the contribution of this reaction at low pH values can be neglected. Generally, the accepted mechanism for the reaction between CO<sub>2</sub> and tertiary amine such as MDEA is the one proposed by Donaldson and Nguyen [1980]. In this case, the reaction can be described as a base catalyzed hydration of  $CO$ , according to the reaction

<sup>†</sup> To whom correspondence should be addressed. E-mail: mk\_aroua@um.edu.my

$$
CO2 + R1R2R3N + H2O \xrightarrow{\alpha_2} R1R2R3NH+ + HCO3 (3)
$$

Based on this mechanism, the amine is assumed to be initially associated with H<sub>2</sub>O molecules and weakens the H-O bond. As a result, an increase in the nucleophilic reactivity of the water toward CO2 is observed. Versteeg and Van Swaaij [1988a] and Benitez Garcia et al.  $[1990]$  studied the absorption of  $CO<sub>2</sub>$  into aqueous solution of triethylamine and demonstrated that it was identical to that of alkanolamines. They concluded that the reaction of  $CO<sub>2</sub>$  at low pH values could not be attributed to the formation of monoalkylcarbonate. Furthermore, experimental studies for the absorption of  $CO<sub>2</sub>$  in non-aqueous solutions of MDEA conducted among others by Versteeg and Van Swaaij [1988a] showed that this type of reaction could be satisfactorily described as physical absorption. These results uphold the validity of the mechanism given by reaction (3).  $R_1R_2R_3NH^* + HCO_3$ <br>the amine is assumed t<br>es and weakens the H-O-<br>leophilic reactivity of the H-O-<br>leophilic reactivity of the dependence of CO<sub>2</sub> internonstrated that it was<br>neluded that the reaction<br>ributed to the form

# 2. Reaction Rate

The reaction of  $CO<sub>2</sub>$  with MDEA as given by Eq. (3) is mostly assumed to be a pseudo first-order reaction. By neglecting the effect of the reverse reaction, its reaction rate is given by

$$
R_{CO_2 \text{ MDEA}} = k_{2,\text{ MDEA}} [CO_2] [MDEA]
$$
\n
$$
(4)
$$

Besides reaction (3), the bicarbonate formation reaction must also be considered, since its contribution to the overall reaction rate is very important.

$$
CO2 + OH2 \longleftrightarrow HCO33
$$
 (5)

This reaction can enhance mass transfer even at lower concentrations of hydroxyl ion as was shown by Blauwhoff et al. [1984]. The forward rate of reaction first given by Pinsent et al. [1956] can be described as follows:  $R_{CO_2 \text{ MDEA}} = k_{2, \text{ MDEA}} [CO_2][\text{MDEA}]$ <br>sides reaction (3), the bicarbona<br>considered, since its contributio<br>y important.<br> $CO_2 + OH^- \longleftrightarrow HCO_3^-$ <br>is reaction can enhance mass trans of hydroxyl ion as was shown<br>ward rate of reaction

$$
\mathbf{R}_{co_2 \cdot OH} = -\dot{\mathbf{k}}_{OH} \begin{bmatrix} \mathbf{CO}_2 \end{bmatrix} \begin{bmatrix} \mathbf{OH}^{\top} \end{bmatrix} \tag{6}
$$

Where,

$$
Log_{10}k_{OH}^* = 13.635 - 2895/T \text{ m}^3 \cdot \text{kmol}^{-1} \cdot \text{s}^{-1}
$$
 (7)

Thus, the effect of this reaction on the overall reaction rate should be carefully assessed. Accurate estimation of the hydroxyl ion concentration in the solution is very important in order to generate a reliable value for the reaction rate constant. Versteeg et al. [1996]  $R_{CO_2 \cdot OH} = -k_{OH}$ <br>here,<br>Log<sub>10</sub> $k_{OH} = 13.0$ <br>us, the effect constration in the iable value for Log<sub>10</sub>k<sub>oH</sub><br>us, the ef<br>carefully<br>tration in<br>iable valu

concluded that, in a large number of studies, especially those for tertiary amines performed by using absorption techniques, the influence of OH<sup>−</sup><br>the presence<br>The latter spo ence of OH $\bar{ }$  on the reaction with  $CO<sub>2</sub>$  was overestimated due to the presence of other negative charged ions such  $HCO<sub>3</sub><sup>-</sup>$  and  $CO<sub>3</sub><sup>-</sup>$ . 3<br>T  $\frac{1}{2}$ n The latter species are produced by the reaction between bicarbonate ion and hydroxyl ion as follows:

$$
HCO3- + OH- \longleftrightarrow CO32 + H2O
$$
 (8)

Another parallel reaction taking place in the aqueous medium is the  $CO<sub>2</sub>$  hydration reaction according to the following scheme:

$$
CO_2 + H_2O \longleftrightarrow HCO_3^- + H^+ \tag{8a}
$$

The contribution of reaction (9) to the overall reaction rate is insignificant in the case of MDEA solutions and is usually neglected. Thus, from Eqs. (4) and (6), the overall reaction rate can be expressed as

$$
R_{ov} = R_{CO_2 \cdot MDEA} + R_{CO_2 \cdot OH} = k_{ov} [CO_2]
$$
\n(9)

$$
\mathbf{R}_{ov} = \mathbf{k}_{ov}[\mathbf{CO}_2] = \mathbf{k}_{2, \text{MDEA}}[\mathbf{CO}_2][\mathbf{MDEA}] + \mathbf{k}_{\text{OH}}^*[\mathbf{CO}_2][\mathbf{OH}^*]
$$
 (10)

$$
R_{\omega} = R_{CO_2 \cdot MDE4} + R_{CO_2 \cdot OH} = k_{\omega} [CO_2]
$$
(9)  
ance, the overall reaction rate  $R_{\omega}$  can be written as  

$$
R_{\omega} = k_{\omega} [CO_2] = k_{2, MDE4} [CO_2] [MDEA] + k_{OH}^* [CO_2] [OH^*]
$$
(10)  
here the overall reaction rate constant  $k_{\omega}$  becomes  

$$
k_{\omega} = k_{2, MDE4} [MDEA] + k_{OH}^* [OH^*]
$$
(11)  
e apparent reaction rate constant is defined as follows:  

$$
k_{\omega p} = k_{\omega} - k_{OH}^* [OH^*] = k_{2, MDE4} [MDEA]
$$
(12)  
**THEORY**

The apparent reaction rate constant is defined as follows:

$$
\mathbf{k}_{\text{app}} = \mathbf{k}_{\text{ov}} - \mathbf{k}_{\text{OH}}^* [\mathbf{OH}^-] = \mathbf{k}_{2,\text{MDEA}} [\mathbf{MDEA}] \tag{12}
$$

# **THEORY**

Hence, the overall reaction rate R<sub>ov</sub> can be written as<br>  $R_{\infty} = k_{\infty} [CO_2] = k_{2, MDEA} [CO_2] [MDEA] + k_{off}^* [CO_2]$ <br>
Where the overall reaction rate constant  $k_{\infty}$  becomes<br>  $k_{\infty} = k_{2, MDEA} [MDEA] + k_{off}^* [OH^-]$ <br>
The apparent rea Where the overall reaction rate constant k<sub>ov</sub> becomes<br>  $k_{\infty} = k_{2, MDEA}[MDEA] + k_{off}^{*}[OH^{-}]$ <br>
The apparent reaction rate constant is defined as folle<br>  $k_{\infty p} = k_{\infty} - k_{off}^{*}[OH^{-}] = k_{2, MDEA}[MDEA]$ <br> **THEORY**<br>
The theory of gas-liqu The theory of gas-liquid absorption with chemical reaction is well established [Danckwerts, 1970] and will not be discussed in this paper. Only the relevant points that are necessary to analyze the experimental results will be highlighted. For a chemical reaction between a gaseous constituent A and a liquid reactant B in an aqueous solution to yield a product P,  $R_{\infty} = k_{\infty} [CO_2] = k_{2, MDE4} [CO_2] [MDEA] + k_{off}^*$ <br>

$$
k_1 = R_A / (C_A' - C_A^{\circ}), \tag{16}
$$

In this case,  $C_A^i$ ,  $C_A^b$  are the concentrations of A at the interface and in the liquid bulk, respectively.

Danckwerts [1970] analyzed the relationship between the enhancement factor, E, and the Hatta number [1928], Ha, which is defined as

$$
k_1 = R_A / (C_A^i - C_A^i),
$$
\n(16)

\nthis case,  $C_A^i$ ,  $C_A^b$  are the concentrations of A at the interface and the liquid bulk, respectively.

\nDanckwerts [1970] analyzed the relationship between the enhancement factor, E, and the Hatta number [1928], Ha, which is defined as

\n
$$
Ha = \left(\frac{2}{m+1} D_a k_{mn} (C_A^*)^{m-1} C_B^n\right)^{1/2} / + k_1
$$
\n(17)

\nhere  $C_A^*$  is the concentration of the gas at interface and is given

\n
$$
C_A^* = \frac{P_A}{H_A}
$$
\n(18)

\nand  $C_B$  is the concentration of the liquid reactant able to participate the chemical reaction. He concluded that three different reaction

• Third zone corresponds to the instantaneous reaction regime. In this case the instantaneous enhancement factor is given by

$$
E_i = \left(\frac{D_A}{D_B}\right)^{1/2} + \left(\frac{D_B}{D_A}\right)^{1/2} \frac{C_B}{zC_A^*}
$$
\n(19)

condition [Alvarez-Fuster et al., 1980]:

 $3 \leq E = H_a \leq E_i$  (20)

In this region, the specific absorption rate can be expressed as

$$
E_i = \left(\frac{D_A}{D_B}\right)^{1/2} + \left(\frac{D_B}{D_A}\right)^{1/2} \frac{C_B}{zC_A^*}
$$
 (19)  
The region of pseudo m-n<sup>th</sup> order is characterized as satisfying the  
condition [Alvarez-Fuster et al., 1980]:  
 $3 \leq E = H_a \leq E_i$  (20)  
In this region, the specific absorption rate can be expressed as  

$$
R_A = \left(\frac{P_A}{H_A}\right)^{\frac{m+1}{2}} \left(\frac{2}{m+1}D_A k_{mn}C_B^n\right)^{1/2}
$$
 (21)  
**January, 2007**

January, 2007

If the resistance in the gas phase is not negligible, the specific absorption rate is given as follows:

$$
\frac{P_A}{R_A} = \frac{1}{k} + \frac{H_A}{\sqrt{\frac{2}{m+1}k_{mn}C_i^{m+1}C_B^n}}
$$
(22)

Using Eq. (21) the overall reaction rate can be calculated as follows:

$$
k_{\infty} = k_{mn} = \left(R_A H_A^{\frac{m+1}{2}} / P_A^{\frac{m+1}{2}} D_A^{\ 0.5}\right)^2
$$
 (23)

# PHYSICO-CHEMICAL PROPERTIES

The use of Eq. (21) to determine the different kinetic constants associated with CO<sub>2</sub>-alkanolamine reactions requires knowledge of the values of several parameters. Among the important parameters are the solubility and the diffusivity of  $CO<sub>2</sub>$  as well as the diffusivity of the alkanolamine in the aqueous solutions. Carbon dioxide reacts with alkanolamine and therefore it is not possible to determine directly its solubility and diffusivity. Based on the similarity in molecular configuration, molecular volume and electronic structure, the  $CO<sub>2</sub>/N<sub>2</sub>O$  analogy has been used to estimate the required physical properties [Laddha et al., 1979]. Thus the solubility of  $CO<sub>2</sub>$ is given by:  $\frac{P_A}{R_A}$  ing k<sub>o</sub>  $R_{\scriptscriptstyle{A}}$ ing $k_{\scriptscriptstyle{ow}}$ <br>Thoc  $\frac{1}{R_A} =$ <br>ing E<br> $k_{\infty} =$ <br>The vociat  $\frac{1}{k}$  +  $\frac{H_A}{\sqrt{\frac{2}{m+1}}k_{mn}}$ <br>  $k_{mn} = (R_A H_A^{\frac{m+1}{2}})$ <br> **PHYSIC**<br>

### Table 1. Published data on the solubility of  $N, O$  in MDEA aqueous solutions

An experimental investigation on the rate of  $CO<sub>2</sub>$  absorption into aqueous methyldiethanolamine solutions 19

Amine	Temperature K	Concentration mol/liter	Reference
<b>MDEA</b>	293-333	0-2.865	Versteeg and Van Swaaij [1988b]
	288-323	$0-8.806$	Al-Ghawas et al. [1989]
	298-347.7	$0-3.350$	Tomcej and Otto [1989]
	288-308	0.3.200	Haimour and Sandall [1984]
	293.15-368.15	0.84-4.27	Tamimi et al. [1994]
	303-313	2.55	Li and Lai $[1995]$

Table 2. Published data on the diffusion coefficient of  $N_2O$  aqueous MDEA solutions

Similarly to the work of Snijder et al. [1993], the available solubility data of  $N_2O$  in aqueous MDEA solutions summarized in Table 1 were compiled in a single relationship that takes into account the effects

$$
H_{N, O \text{-} MDEA} = \exp\left(14.964814 - \frac{1977.4}{T} + 0.03989 C_{MDEA}\right) \tag{31}
$$

of both temperature and amine concentration,  $C_{MDEA}$ , as follows:<br>  $H_{N,O-MDEA} = \exp\left(14.964814 - \frac{1977.4}{T} + 0.03989 C_{MDEA}\right)$  (<br>
The range of validity of this equation is 288<T<333 K and 0.34<br>  $C_{MDEA}$ <4.35 mol/l with an ov The range of validity of this equation is 288<T<333 K and 0.348< and a maximum deviation of 13.6%.  $H_{N,O-MDEA} = \exp\left(14.964814 - \frac{1}{2} \right)$ <br>e range of validity of this equested a maximum deviation of 1.<br>The available data in the open<br>neous MDEA summarized in<br> $D_{N,O-MDEA} = 10^{-9} \cdot \exp\left(8.16161 - \frac{1}{2} \right)$ <br>th an overall average  $\exp\left(14.964814 - \frac{1977.4}{T} + 0.03989C_{MDEA}\right)$ <br>validity of this equation is 288<T<333 K<br>ol/l with an overall average absolute devia<br>um deviation of 13.6%.<br>le data in the open literature on the diffusivi<br>EA summarized in Ta

The available data in the open literature on the diffusivity of  $N_2O$  in aqueous MDEA summarized in Table 2 were correlated as follows:

$$
D_{N_1O\text{-}MDEA} = 10^{-9} \cdot \exp\left(8.161613 - \frac{2252.944}{T} - 0.300062 \cdot C_{MDEA}\right) (32)
$$

C<sub>MDEA</sub><4.35 mol/l with an overall average absolute deviation of 0.2%<br>and a maximum deviation of 13.6%.<br>The available data in the open literature on the diffusivity of N<sub>2</sub>O in<br>aqueous MDEA summarized in Table 2 were corr with an overall average absolute deviation of 3.54% and a maximum deviation of 22.6%. The range of validity of this relationship is specified as follows: D<sub>N,O-MDEA</sub>=10<sup>-9</sup> · exp(8.161613–<br>th an overall average absolute<br>um deviation of 22.6%. The ran<br>specified as follows:<br>288<T<342.1 K and 0<C<sub>MDEA</sub><4.3<br>r the diffusivity of MDEA in l<br>Snijder et al. [1993] was used a<br>ln(D)  $\exp\left(8.161613 - \frac{2232.944}{T} - 0.300062 \cdot C_{MDEA}\right)$ <br>verage absolute deviation of 3.54% and a n<br>f 22.6%. The range of validity of this relation<br>lows:<br>and 0<C<sub>MDEA</sub> <4.35 mol/l<br>y of MDEA in MDEA solutions, the correl:<br>993] wa

$$
288 < T < 342.1 \text{ K}
$$
 and  $0 < C_{MDEA} < 4.35 \text{ mol/l}$ 

For the diffusivity of MDEA in MDEA solutions, the correlation of Snijder et al. [1993] was used as follows:

$$
\ln(D) = -13.088 - \frac{2360.7}{T} - 24.727 \times 10^{-5} C_{MDEA}
$$
 (33)

The range of validity of this relationship with respect to amine concentration and temperature is 0.9<C<4.01 mol/l and 298<T<348 K, respectively.

To estimate the viscosity of the amine solution, the correlation developed by Glasscock et al. [1991], which originally proposed mixtures of DEA, MDEA, and MEA with water, was found to be valid even for single solutions of MDEA with water and is used in this work as follows: ln(D) = −13.088 −<br>
e range of validity<br>
tration and temper<br>
pectively.<br>
To estimate the vi<br>
veloped by Glasse<br>
xtures of DEA, M<br>
id even for single<br>
s work as follows:<br>
Ln $\mu$ =B<sub>1</sub>+B<sub>2</sub>/T+B<sub>3</sub>T<br>
e viscosity of water  $\frac{2360.7}{T}$  - 24.727 × 10<sup>-3</sup> C<sub>MDEA</sub><br>of this relationship with restature is 0.9 < C < 4.01 mol/l a<br>scosity of the amine solutions of the amine solutions<br>ock et al. [1991], which of<br>DEA, and MEA with wate<br>solutions of

$$
Ln \mu = B_1 + B_2 / T + B_3 T \tag{34}
$$

The viscosity of water at different temperatures was taken from Handbook of Chemistry and Physics [2002].

For the density of the MDEA solution, the following relationship was used:

$$
d = \frac{1055.3 + 0.7663 \cdot (T - 273.15)}{1000}
$$
 (35)  
EXPERIMENTAL  
Material

### **EXPERIMENTAL**

1. Material

The chemicals used in the investigation were 98.5% assay Methyldiethanolamine obtained from Riedel deHaën, commercially available carbon dioxide and nitrogen with purity of 99.99% and 99.999%, respectively, and Reagecon standard 1.0 M aqueous NaOH and 0.1 M HCl solutions. All of these chemicals were used as received. Distilled water was used as the solvent throughout the experiment.

# 2. Experimental Set Up and Procedure

The experimental setup used in this work is somewhat similar to that described by Laddha and Danckwerts [1981]. The experiments were carried out in a 10 cm internal diameter double jacketed stirred cell reactor with a total volume of the about  $1,800 \text{ cm}^3$ . The gas and liquid were stirred separately with individual stirrers

with separate variable gearboxes. The liquid stirrer speed was maintained during all experiment at 35 rpm, while that of the gas was set at about 1,200 rpm. Temperature in the reactor was measured with a J type thermocouple and was controlled by an RC20 LAUDA water circulator. A pressure transducer was used to record the total pressure in the reactor. Another accessory fitted to the reactor was a pH probe that was linked to a data acquisition system. In a typical experiment, 600 ml of freshly prepared solution was initially charged into the reactor and stirred at a constant speed. The system was then purged with nitrogen for a few minutes to remove any possible gas contaminants that might have been present before switching to the reaction gas containing  $CO<sub>2</sub>$  and  $N<sub>2</sub>$  mixed in the desired proportion. The total flowrate of the reaction gas was controlled by using Brooks Mass Flow Controllers. The exhaust leaving the reactor was sent to an infrared Rosemount® model 880A CO<sub>2</sub> analyzer. The outlet  $CO<sub>2</sub>$  concentration was monitored through a computerized data acquisition system. At the end of each experiment, the total CO<sub>2</sub> in the liquid was determined by precipitation method. There was no significant difference between the results obtained by using the physical technique and that from the wet chemistry analytical method. However, the results discussed in this work are those obtained by using the physical method.

# **RESULTS AND DISCUSSION**

The CO<sub>2</sub> absorption data into aqueous solutions of methyldiethanolamine were analyzed by means of chemical absorption theory,

Table 6. Experimental data for the reaction  $CO<sub>2</sub> \text{MDEA}$  4.0 M at different temperatures

and are summarized in Tables 3-6. An evaluation of the data reproducibility revealed that the estimated error in the overall analysis was less than 5% except for less than 2 kPa where the error could be as

high as 7%.<br>The concentration of amine in the solution,  $C_{MDE4}$ , was checked at the beginning and the end of each experiment by titrating an aliquot sample with a standard solution of 1 N HCl. In all cases, the discrepancy between the initial and the final amine concentration was found to be less than 3%. Thus the assumption of constant total amine concentration throughout the experiment was justified.

### 1. Mass Transfer Coefficient

The concentration of amine in the solution,  $C_{\text{MDEt}}$ , was checked<br>the beginning and the end of each experiment by titrating an aliquot<br>nple with a standard solution of 1 N HCl. In all cases, the discrep-<br>cy between the Absorption data of pure  $CO<sub>2</sub>$  in water at 293 K were used to calculate  $k_1$ . The mixing speed of the liquid was varied substantially from low values to moderate values without affecting the smoothness of the gas-liquid interface. The values of  $k_1$  were calculated by using Eq. (15). The results are presented in Fig. 2 as a plot of  $\ln(Sh/\sqrt{Sc})$ and Reynolds numbers in the form of Sh=0.1217R<sup> $0.6949$ </sup>Sc<sup>0.5</sup> is obtained. Since the Sc range for the experiment was not large, the exponent on Sc was assumed to be 0.5 in accordance with the penetra-

Fig. 7. Reaction order with respect to MDEA concentration at different temperatures.

0.5. Thus, the order of the reaction with respect to amine concentration is equal to unity, which is in agreement with the value reported in the literature.

### 2. Reaction Rate Constant

The overall rate of the reaction between CO<sub>2</sub> and the amine solution with the contribution of the reaction of  $CO<sub>2</sub>$  with the hydroxyl ion was calculated according to Eq. (23). The second order reaction rate,  $k_{app}$ , was obtained from the overall reaction rate and the amine concentration according to Eq. (12) by neglecting the contribution of the hydroxyl ion to the reaction. Solubility of CO<sub>2</sub> in aque-<br>ous solutio amine concentration according to Eq. (12) by neglecting the contribution of the hydroxyl ion to the reaction. Solubility of  $CO_2$  in aque-<br>ous solutions of MDEA required for the evaluation of  $k_m$  was estious solutions of MDEA required for the evaluation of  $k_{\nu}$ , was esti-<br>mated by using Eq. (23). The solubility of CO<sub>2</sub> and N<sub>2</sub>O in water is<br>given by Eqs. (29) and (30), respectively; the solubility of N<sub>2</sub>O in<br>amine so mated by using Eq. (23). The solubility of  $CO<sub>2</sub>$  and  $N<sub>2</sub>O$  in water is given by Eqs.  $(29)$  and  $(30)$ , respectively; the solubility of N<sub>2</sub>O in amine solution is given by Eq.  $(31)$ . The diffusivity of CO<sub>2</sub> in MDEA solutions was calculated in the same way as for the solubility by using Eqs. (25), (27), (28) and (32); the effect of the temperature on the viscosity and density of the solution is considered in Eqs. (34) and (35), respectively. Final results are summarized in Table 7. It is

Fig. 8. Arrhenius plot for the reaction  $CO<sub>2</sub>$ -MDEA.

Table 7. Second order reaction rate constant at different temperatures

Temp $(K)$		am average			
	1 M	2 M	3 M	4 M	$l/mol$ s <sup>-1</sup>
293	4.57	4.62	5.40	7.02	5.40
303	7.16	737	10.33	11.61	9.12
313	15.99	13 71	16.25	18.39	16.08
323	27.33	22.24	33.28	33.28	29.03

worth noticing here that the results summarized in the previous table verify the condition stated in Eq. (20).

Good agreement between the generated  $k<sub>2</sub>$  values presented in Table 7 and those published by Versteeg et al. [1996] has been observed where the effects of temperature have been extensively studied. Fig. 4 shows the Arrhenius plot for  $k_2$  at 20, 30 and 40 °C. From this plot the activation energy has been found to be 44.12 k Joule/ mol, which is in line with the literature data. The temperature dependence of the rate constant was correlated as follows:

 $k_{\text{cm}}$ =3.82×10<sup>8</sup>·exp(-5308.6/T)

Which is in excellent agreement with the correlation given in Eq. (1).

# **CONCLUSION**

The reaction between  $CO<sub>2</sub>$  and tertiary amine MDEA in aqueous solutions was analyzed by using the base catalysis of the  $CO<sub>2</sub>$ hydration proposed by Donaldson and Nguyen [1980]. The reaction is overall second order, first order with respect to free amine concentration. The contribution of the reaction between  $CO<sub>2</sub>$  and hydroxyl ion is insignificant and could be neglected in the analysis. The activation energy for the second order reaction rate constant,  $k<sub>2</sub>$ , is evaluated at about 44.12 kJ/mol, while the temperature dependency of the rate constant,  $k_2$ , can be estimated from the following relationship:  $k_{cm} = 3.82 \times 10^8 \exp(-5308.6/T)$
